yarn.nodemanager.log-dirs	*Default Value*: `/opt/mapr/hadoop/hadoop-<version>/logs/userlogs/<applicationID>/<containerID>/<filename>.log` *Description*: The location to store container logs on the node. An application's log directory is `${yarn.nodemanager.log-dirs}/application_${appid}`. Individual containers' log directories are named `container_{$contid}`. Each container directory will contain the files *stderr*, *stdin*, and *syslog* generated by that container. **NOTE:** You can find the application ID associated with your job in the Control System.
yarn.log-aggregation-enable	*Default Value*: `false` *Description*: Indicates whether the logs are aggregated.
yarn.nodemanager.log.retain-seconds	*Default Value*: `10800 (3 hours)` *Description*: Specifies the duration for which user logs are maintained, when log aggregation is disabled.
yarn.log-aggregation.retain-seconds	*Default Value*: `-1` *Description*: Specifies the number of seconds to retain logs, when log aggregation is enabled. The default value of *-1*, disables the deletion of logs.
yarn.log-aggregation.retain-check-interval-seconds	*Default Value*: `-1` *Description*: The interval between aggregated log retention checks. If set to *0* or a negative value, then the value is computed as one-tenth of the aggregated log retention time. **NOTE:** Setting this to a low value may cause unnecessary log retention checks.
yarn.nodemanager.remote-app-log-dir	*Default Value*: `/tmp/logs` *Description*: The location on the filesystem where the logs are aggregated.
yarn.nodemanager.remote-app-log-dir-suffix	*Default Value*: `logs` *Description*: The suffix for the directory that stores the aggregated logs for each user.

Configuration for Apache Shuffle

You can disable Direct Shuffle and enable Apache Shuffle for MapReduce applications through the following setting:

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

yarn.nodemanager.aux-services *Value*: `mapreduce_shuffle`

zoo.cfg
Lists the ZooKeeper configuration file.

Example zoo.cfg File

The file `/opt/mapr/zookeeper/zookeeper-$version/conf/zoo.cfg` specifies ZooKeeper configuration parameters.

```
# The number of milliseconds of each tick
tickTime=2000
# The number of ticks that the initial
# synchronization phase can take
initLimit=20
# The number of ticks that can pass between
# sending a request and getting an acknowledgement
syncLimit=10
# the directory where the snapshot is stored.
dataDir=/opt/mapr/zkdata
# the port at which the clients will connect
clientPort=5181
# max number of client connections
maxClientCnxns=1000
#autopurge interval - 24 hours
autopurge.purgeInterval=24
#superuser to allow zk nodes delete
superUser=mapr
#readuser to allow read zk info for authenticated clients
readUser=anyone
# cldb key location
mapr.cldbkeyfile.location=/opt/mapr/conf/cldb.key
#security provider name
authMech=MAPR-SECURITY
# security auth provider
authProvider.1=org.apache.zookeeper.server.auth.SASLAuthenticationProvider
# use maprserverticket not userticket for auth
mapr.usemaprserverticket=true
#
# Added for 3.4.11-mapr
#
# ZK-to-ZK server authentication using MAPR-SASL
# Set quorum.auth.enableSasl=false for insecure cluster, =true for secure
cluster
quorum.auth.enableSasl=true
quorum.auth.learnerRequireSasl=true
quorum.auth.serverRequireSasl=true
quorum.auth.learner.loginContext=QuorumLearner
quorum.auth.server.loginContext=QuorumServer
quorum.cnxn.threads.size=20
#
# Added for 3.5.6-mapr
#
# ZK server-to-server SSL encryption
#
sslQuorum=true
serverCnxnFactory=org.apache.zookeeper.server.NettyServerCnxnFactory

```
ssl.quorum.enabledProtocols=TLSv1.2
# MapR uses the cluster name in the certificates, no host names
ssl.quorum.hostnameVerification=false
#
#  The Jetty Admin Server allows ZK access via a URL
#  Like  http://localhost:8080/commands/stat
#  Default port 8080 may cause conflicts; thus server disabled by default
# admin.serverPort=8080
admin.enableServer=false
#
# For upgrade from an existing 3.4.11 or older that had no snapshots
snapshot.trust.empty=true
#
```

WARNING: `maxClientCnxns` limits the number of concurrent ZooKeeper connections that a single client machine may make. This value does not set a limit for the whole cluster. The default is 100. If you plan to run more than 100 jobs from a single node, increase this value.

ATTENTION: By default, only **authenticated** users (users with a valid ticket) are allowed to execute ZooKeeper related commands. To allow **all** users to execute ZooKeeper related commands, add the entry `sessionRequireClientSASLAuth=false` to this file and restart ZooKeeper.

Enable Encrypted Quorum Communication

Perform the following steps to enable encrypted quorum communication between ZooKeeper nodes:

1. Copy all `*.p12` certificates from the master CLDB node to all the ZooKeeper nodes.
2. Set the user and group of all the `*.p12` certificates to `mapr` on all the ZooKeeper nodes.
3. Set `sslQuorum=true` in the `zoo.cfg` file.
4. Restart ZooKeeper and Warden:

   ```
   service mapr-zookeeper restart
   service mapr-warden restart
   ```

Related tasks

Enabling Security on a Configured Cluster on page 1762
Describes how to enable security for the cluster, platform, ecosystem components, and network-based connections.

zookeeper-env.sh
Use this file to load or unload JMX parameters for ZooKeeper.

By default, in all Data Fabric versions, the ZooKeeper JMX parameters are not loaded.

To load ZooKeeper JMX parameters, set the JMXDISABLE parameter to `false` in the `zookeeper-env.sh` file within the `/opt/mapr/zookeeper/zookeeper-$version/conf` directory.

```
JMXDISABLE=false
```

Restart the ZooKeeper process: `service mapr-zookeeper restart`.

To unload ZooKeeper JMX parameters, set:

```
JMXDISABLE=true
```

in `zookeeper-env.sh`. Restart the ZooKeeper process: `service mapr-zookeeper restart`.

Alarms Reference

The pages in this section provide details about all of the types of alarms.

User/Group Alarms

User/group alarms indicate problems with user or group quotas. The following tables describe the Data Fabric user/group alarms.

- Entity Advisory Quota Alarm
- Entity Quota Alarm

Entity Advisory Quota Alarm

UI Column	User Advisory Quota Alarm
Logged As	AE_ALARM_AEADVISORY_QUOTA_EXCEEDED
Meaning	A user or group has exceeded its advisory quota. See Setting Quota Defaults for Users and Groups on page 1063 for more information about user/group quotas.
Resolution	No immediate action is required. To avoid exceeding the hard quota, clear space on volumes created by the user or group, or stop further data writes to those volumes.
Configuration	Configurable when setting/modifying entity properties. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

Entity Quota Alarm

UI Column	User Quota Alarm
Logged As	AE_ALARM_AEQUOTA_EXCEEDED
Meaning	A user or group has exceeded its quota. Further writes by the user or group will fail. See Setting Quota Defaults for Users and Groups on page 1063 and Set or Modify Quotas for Users and/or Groups on page 1258 for more information about user/group quotas.
Resolution	Free some space on the volumes created by the user or group, or increase the user or group quota.
Configuration	Configurable when setting/modifying entity properties. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

Cluster Alarms

Cluster alarms indicate problems that affect the cluster as a whole. The following sections describe the Data Fabric cluster alarms.

CLDB Low Memory Alarm

UI Column	Cluster freespace above CLDB heapsize
Logged As	CLUSTER_ALARM_CLDB_HEAPSIZE

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Meaning	The CLDB process needs more memory to cache containers.

Resolution	The CLDB heap size is no longer sufficient for the CLDB to cache containers. The solution is to increase the CLDB memory settings on all CLDB nodes, using the same value for the minimum and maximum heap sizes. The text the alarm code provides will include the minimum amount of memory required to be sufficient; however, to accommodate future growth, you should set these values to a somewhat higher number. For example, if the alarm indicates that the CLDB needs 4000 MB, you should set the minimum and maximum heap sizes to a larger value such as 4400 MB.
	The CLDB memory settings are controlled by the following parameters in the `warden.conf` file located in `$MAPR_HOME/conf/`:
	`service.command.cldb.heapsize.max=<max heap size>`
	`service.command.cldb.heapsize.min=<min heap size>`
	Restart the Warden service on each CLDB node after you edit the `warden.conf file`.

License Near Expiration

UI Column	License Near Expiration Alarm
Logged As	CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION
Meaning	The Enterprise Edition license associated with the cluster is within 30 days of expiration.
Resolution	Renew the Enterprise Edition license.
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

License Expired

UI Column	License Expiration Alarm
Logged As	CLUSTER_ALARM_LICENSE_EXPIRED
Meaning	The Enterprise Edition license associated with the cluster has expired. Enterprise Edition features have been disabled.
Resolution	Renew the Enterprise Edition license.

Cluster Almost Full

UI Column	Cluster Almost Full
Logged As	CLUSTER_ALARM_CLUSTER_ALMOST_FULL
Meaning	The cluster storage is almost full. The percentage of storage used before this alarm is triggered is 90% by default, and is controlled by the configuration parameter `cldb.cluster.almost.full.percentage`.
Resolution	Reduce the amount of data stored in the cluster. If the cluster storage is less than 90% full, check

©Copyright 2024 Hewlett Packard Enterprise Development LP

	the `cldb.cluster.almost.full.percentage` parameter via the `config load` command, and adjust it if necessary via the `config save` command.
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

Cluster Full

UI Column	Cluster Full
Logged As	CLUSTER_ALARM_CLUSTER_FULL
Meaning	The cluster storage is full. MapReduce operations have been halted.
Resolution	Free up some space on the cluster.

Maximum Licensed Nodes Exceeded alarm

UI Column	Licensed Nodes Exceeded Alarm
Logged As	CLUSTER_ALARM_LICENSE_MAXNODES_EXCEEDED
Meaning	The cluster has exceeded the number of nodes specified in the license.
Resolution	Remove some nodes, or upgrade the license to accommodate the added nodes.

New Cluster Features Disabled

UI Column	New Cluster Features Disabled
Logged As	CLUSTER_ALARM_NEW_FEATURES_DISABLED
Meaning	Features added in version 2.0 or 3.0 are not enabled on the cluster.
Resolution	Enable the latest features for the data-fabric version that you are currently running.

Upgrade in Progress

UI Column	Software Installation & Upgrades
Logged As	CLUSTER_ALARM_UPGRADE_IN_PROGRESS
Meaning	A rolling upgrade of the cluster is in progress.
Resolution	No action is required. Performance may be affected during the upgrade, but the cluster should still function normally. After the upgrade is complete, the alarm is cleared.

VIPAssignment Failure

UI Column	VIP Assignment Alarm
Logged As	CLUSTER_ALARM_UNASSIGNED_VIRTUAL_IPS
Meaning	Core software was unable to assign a VIP to any NFS servers.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Resolution	Check the VIP configuration, and make sure at least one of the NFS servers in the VIP pool are up and running. See Setting Up VIPs for NFS. This alarm can also indicate that a VIP's hostname exceeds the maximum allowed length of 16. Check the log file `/opt/mapr/logs/nfsmon.log` for additional information.

DARE Enabled

UI Column	DARE Enabled Alarm
Logged As	CLUSTER_ALARM_DARE_COPY_MASTER_KEY
Meaning	Data-at-rest encryption (DARE) is enabled on the cluster.
Resolution	When DARE is enabled on the cluster, a data-at-rest encryption master key file is generated and stored in the `/opt/mapr/conf/tokens` folder on the CLDB node. Before dismissing the alarm, make a backup of the `/opt/mapr/conf/tokens` folder. For an upgraded cluster, you must also back up the `dare.master.key` stored in `/opt/mapr/conf/`. Loss of the master key file or the `/opt/mapr/conf/tokens` folder can be catastrophic and irreversible and might result in loss of data.

DARE Incompatible

UI Column	DARE Incompatible Alarm
Logged As	CLUSTER_ALARM_DARE_INCOMPATIBLE
Meaning	Not all nodes on the cluster are enabled for data-at-rest encryption (DARE).
Resolution	When DARE is enabled on certain nodes in the cluster, there may still be some nodes that are not (yet) enabled for DARE. Enable DARE on all the nodes before dismissing the alarm.

Too Many Snapshots

UI Column	Too Many Snapshots
Logged As	CLUSTER_ALARM_TOO_MANY_SNAPSHOT_CONTAINERS
Meaning	There are too many snapshots on this cluster.
Resolution	Delete snapshots from the cluster before dismissing the alarm.

Service Endpoints changed

UI Column	Either of the following: • API Server endpoints changed for <cluster-name> • API Server endpoints changed for <cluster-name>. Added cluster <cluster-name>.

©Copyright 2024 Hewlett Packard Enterprise Development LP

	• API endpoints changed. Updated from Cluster Group primary. • API Server endpoints changed by updating ClusterGroup Primary. • API Server endpoints changed. Removed cluster <cluster-name> • API Server endpoints changed by resetTable.
Logged As	CLUSTER_ALARM_CLUSTERGROUP_ENDPOINTS_UPDATED
Meaning	This alarm is an information alarm. The alarm indicates a change in API server endpoint(s), that is, IP address(es). **NOTE:** The API server endpoints/IP addresses may be required by Data Fabric for high availability. API server endpoints would change if one of the following occurs: • A new cluster is added to the cluster group/global namespace • An existing cluster is removed from the cluster group/global namespace • The primary cluster for the cluster group/global namespace changes • An API server is added to or removed from any of the member clusters of the cluster group
Resolution	Download the updated API server endpoints from the UI by following the instructions given on Viewing the Fabric Endpoint or by using the clustergroup get cgtable on page 2064 command. Dismiss the alarm manually on the UI to turn the alarm off.

Insights running in trial mode

UI Column	Insights running in trial mode
Logged As	CLUSTER_ALARM_INSIGHTS_TRIAL_MODE
Meaning	The insights feature that is enabled on the cluster is running in trial mode with Hive Metastore using the Derby RDBMS to store insights table metadata.
Resolution	Associate the Hive metastore with a production grade RDBMS such as PostgreSQL or MySQL. The alarm will be cleared once this is done.

Node Alarms

Node alarms indicate problems in individual nodes. The following tables describe the MapR node alarms.

CLDB Service Alarm

UI Column	CLDB Alarm
Logged As	NODE_ALARM_SERVICE_CLDB_DOWN

©Copyright 2024 Hewlett Packard Enterprise Development LP

Meaning	The CLDB service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the CLDB service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3027. If the warden successfully restarts the CLDB service, the alarm is cleared. If the warden is unable to restart the CLDB service, see more troubleshooting information.

Core Present Alarm

UI Column	Core Present
Logged As	NODE_ALARM_CORE_PRESENT
Meaning	A service on the node has crashed and created a core dump file. When all core files are removed, the alarm is cleared.
Resolution	See troubleshooting information.

Debug Logging Active

UI Column	Excess Logs Alarm
Logged As	NODE_ALARM_DEBUG_LOGGING
Meaning	Debug logging is enabled on the node.
Resolution	Debug logging generates enormous amounts of data, and can fill up disk space. If debug logging is not absolutely necessary, turn it off: use the `setloglevel` on page 2364 command. If it is absolutely necessary, make sure that the logs in `/opt/mapr/logs` are not in danger of filling the entire disk.

Disk Failure

UI Column	Disk Failure Alarm
Logged As	NODE_ALARM_DISK_FAILURE
Meaning	A disk has failed on the node.
Resolution	Check the disk health log (`/opt/mapr/logs/faileddisk.log`) to determine which disk failed and view any SMART data provided by the disk. See Managing Disks on page 1125.

Duplicate Host ID

UI Column	Duplicate Host Id
Logged As	NODE_ALARM_DUPLICATE_HOSTID

©Copyright 2024 Hewlett Packard Enterprise Development LP

Meaning	Two or more nodes in the cluster have the same host ID.
Resolution	Multiple nodes with the same host ID are prevented from joining the cluster, in order to prevent addressing problems that can lead to data loss. To correct the problem and clear the alarm, make sure all host IDs are unique and use the `maprcli node allow-into-cluster` command to un-ban the affected host IDs.

FileServer Service Alarm

UI Column	FileServer Alarm
Logged As	NODE_ALARM_SERVICE_FILESERVER_DOWN
Meaning	The FileServer service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the FileServer service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3027 file. If the warden successfully restarts the FileServer service, the alarm is cleared. If the warden is unable to restart the FileServer service, see more troubleshooting information.

Gateway Service Alarm

Label for Alarm on MCS UI	Gateway Service Down
Text for Alarm on Log File	NODE_ALARM_SERVICE_GATEWAY_DOWN
Meaning	The gateway service has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the gateway service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3027. If the warden successfully restarts the gateway service, the alarm is cleared. If the warden is unable to restart the gateway service, see more troubleshooting information.

Beeswax Service Alarm

Label for Alarm on MCS UI	NODE_ALARM_SERVICE_BEESWAX_DOWN
Text for Alarm on Log File	NODE_ALARM_SERVICE_BEESWAX_DOWN
Meaning	The Beeswax service has stopped running.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Resolution	Go to the node information page or the **Services** page in the Control System to check if the Beeswax service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3027. If the warden successfully restarts the Beeswax service, the alarm is cleared. If the warden is unable to restart the Beeswax service, see more troubleshooting information.

S3 Server Alarm

Label for Alarm on MCS UI	S3 Server Down
Text for Alarm on Log File	NODE_ALARM_SERVICE_S3SERVER_DOWN
Meaning	The S3 server has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the S3 server is running. The warden will try three times to restart the S3 server automatically. After an interval (30 minutes by default) the warden will again try three times to restart the S3 server. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3027. If the warden successfully restarts the S3 server, the alarm is cleared. If the warden is unable to restart the S3 server, see more troubleshooting information.

Heartbeat Processing Slow

UI Column	Heartbeat Processing Slow Alarm
Logged As	NODE_ALARM_HB_PROCESSING_SLOW
Meaning	The time that has elapsed since the CLDB processed the previous heartbeat from the file system node has exceeded 5 seconds.
Resolution	When the CLDB is processing a heartbeat from a node, it will compare the current time to the time at which the previous heartbeat from that node was processed. If the elapsed time exceeds 5 seconds then this alarm is raised. If this alarm occurs frequently, investigate what might be causing the relevant node or nodes to be busy, or whether the CLDB nodes have enough resources to handle their load.

HBMaster Service Alarm

UI Column	HBase Master Alarm
Logged As	NODE_ALARM_SERVICE_HBMASTER_DOWN
Meaning	The HBMaster service on the node has stopped running.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Resolution	To check whether the HBMaster service is running, go to the node information page or the **Services** page in the Control System. Warden will try three times to restart the service automatically. After an interval (30 minutes by default), Warden will again try three times to restart the service. The interval can be configured using the `services.retryinterval.time.sec` parameter in the `warden.conf` file. If Warden successfully restarts the HBMaster service, the alarm is cleared. If Warden is unable to restart the HBMaster service, it might be necessary to contact technical support.

HBRegion Service Alarm

UI Column	Hbase RegionServer Alarm
Logged As	NODE_ALARM_SERVICE_HBREGION_DOWN
Meaning	The HBRegion service on the node has stopped running.
Resolution	To check whether the HBRegion service is running, go to the node information page or the **Services** page in the Control System. Warden will try three times to restart the service automatically. After an interval (30 minutes by default), Warden will again try three times to restart the service. The interval can be configured using the `services.retryinterval.time.sec` parameter in the `warden.conf` file. If Warden successfully restarts the HBRegion service, the alarm is cleared. If Warden is unable to restart the HBRegion service, it might be necessary to contact technical support.

High MAST Gateway Memory Alarm

UI Column	High Memory Usage
Logged As	NODE_ALARM_HIGH_MASTGATEWAY_MEMORY
Meaning	Memory consumption of MAST Gateway exceeds the memory allocated for MAST Gateway.
Resolution	Tune the percentage of node memory allocated for MAST Gateway in the `/opt/mapr/conf/conf.d/warden.mastgateway.conf` file. See Configuring MAST Gateway for more information. If core is generated for this error, contact HPE support.

HistoryServer Alarm

UI Column	HistoryServer Alarm
Logged As	NODE_ALARM_SERVICE_HISTORYSERVER_DOWN
Meaning	The HistoryServer on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether HistoryServer is running. Warden will try three times to restart the service automatically ever 30 minutes (by default).

©Copyright 2024 Hewlett Packard Enterprise Development LP

	This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 3027 file. If warden successfully restarts the HistoryServer, the alarm is cleared. If Warden is unable to restart the HistoryServer, see more troubleshooting information.

HiveMeta Alarm

UI Column	HiveMeta Alarm
Logged As	NODE_ALARM_SERVICE_HIVEMETA_DOWN
Meaning	The HiveMeta service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether Hive Metastore is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 3027 file. If Warden successfully restarts the Hive Metastore service, the alarm is cleared. If Warden is unable to restart the Hive Metastore service, see more troubleshooting information.

HiveServer 2 Alarm

UI Column	HiveServer 2 Alarm
Logged As	NODE_ALARM_SERVICE_HS2_DOWN
Meaning	The HiveServer 2 service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether HiveServer 2 is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 3027 file. If Warden successfully restarts the HiveServer 2 service, the alarm is cleared. If Warden is unable to restart the HiveServer 2 service, see more troubleshooting information.

Hoststats Alarm

UI Column	HostStats
Logged As	NODE_ALARM_SERVICE_HOSTSTATS_DOWN
Meaning	The Hoststats service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the

©Copyright 2024 Hewlett Packard Enterprise Development LP

	Hoststats service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3027 file. If the warden successfully restarts the service, the alarm is cleared. If the warden is unable to restart the service, review more troubleshooting information.

Incorrect Topology Alarm

UI Column	CLDB Alarm
Logged As	NODE_ALARM_INCORRECT_TOPOLOGY_ALARM
Meaning	The `mapr.cldb.internal` volume's topology (normally `/cldb`) must include all CLDB nodes. This alarm signifies that one or more CLDB nodes are outside the CLDB volume's topology.
Resolution	There are two ways to resolve this alarm: • Move any stray CLDB nodes into the topology in which `mapr.cldb.internal` resides. See Setting Up Volume Topology on page 1212 for more information. • Change the volume topology of `mapr.cldb.internal` to include the stray CLDB nodes. See Administering Volumes on page 1149 for more information.

Installation Directory Full Alarm

UI Column	Installation Directory Full
Logged As	NODE_ALARM_OPT_MAPR_FULL
Meaning	The partition `/opt/mapr` on the node is running out of space (95% full).
Resolution	Free up some space in `/opt/mapr` on the node.

Instance Mismatch Alarm

UI Column	Instance Mismatch Alarm
Logged As	NODE_ALARM_NUM_INSTANCES_MISMATCH
Meaning	The number of file system instances is not as configured.
Resolution	Restart warden on the node by running the following command: `service mapr-warden restart`

High FileServer Memory Alarm

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

UI Column	High FileServer Memory Alarm
Logged As	NODE_ALARM_HIGH_MFS_MEMORY
Meaning	Memory consumed by **fileserver** service on the node is in excess of the allotted amount.
Resolution	Log on as root to the node for which the alarm is raised, and restart the Warden: `service mapr-warden restart`
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

MapR User Mismatch

UI Column	MapR User Mismatch Alarm
Logged As	NODE_ALARM_MAPRUSER_MISMATCH
Meaning	The cluster nodes are not all set up to run MapR services as the same user (for example, some nodes are running MapR as `root` while others are running as `mapr_user`.
Resolution	For the nodes on which the User Mismatch alarm is raised, follow the steps in Changing the User for Data Fabric Services from the Command-Line on page 1123.

Memory Allocation Alarm

UI Column	Memory Allocation Alarm
Logged As	NODE_ALARM_MEMORY_ALLOCATION_EXCEEDED
Meaning	The percentage of system memory required to run services on the node exceeds the set threshold and could potentially overload the node. If you installed a service on the node that causes the sum of memory used by the services on the node to exceed the threshold set, the system raises the alarm.
Resolution	To clear the alarm, you can add more memory to the node, stop a service from running on the node, or remove a service from the node. You can run the `service list` command to see the memory allocated to each service on the node. See service list for more information. The `services.memoryallocation.alarm.threshold` property in `warden.conf` defines the maximum amount of system memory that services running on the node can use before triggering the alarm. The default setting for this property is 95 percent: `services.memoryallocation.alarm.threshold=95` The percentage of system memory that services can use on the node should not exceed 95. Restart

©Copyright 2024 Hewlett Packard Enterprise Development LP

	the Warden service on the node after you edit the `warden.conf` file.

Memory Usage Alarm

UI Column	Memory Usage Alarm
Logged As	NODE_ALARM_MEMORY_SWAPPING
Meaning	The HostStats service raises this alarm for swap space when the delta of swap in memory and the delta of swap out memory exceeds the threshold set over a specific time period.
Resolution	To clear the alarm, you can increase the physical memory or reduce the load running on the node. You can run the `service list` command to see the memory allocated to each service on the node. See `service list` for more information. The memory swapping alarm is controlled by the following properties in `/opt/mapr/conf/hoststats.conf`: • `alarm.swapping.threshold` • `alarm.swapping.counter` The memory threshold for swap in and swap out is defined by the `alarm.swapping.threshold` property, which is set to 100MB by default. The duration over which HostStats checks the delta of the memory is defined by the `alarm.swapping.counter`, which is set to 100 seconds by default.

High NFS4 Memory Alarm

UI Column	High NFS4 Process Memory Consumption
Logged As	NODE_ALARM_HIGH_NFS4_MEMORY
Meaning	Memory consumed by **NFS4** service on the node is in excess of the allotted amount.
Resolution	Log on as root to the node for which the alarm is raised, and restart the NFS4 service or Warden: `service mapr-warden restart`
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

NFS Gateway Alarm

UI Column	NFS Service Down
Logged As	NODE_ALARM_SERVICE_NFS_DOWN
Meaning	The NFS service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether

©Copyright 2024 Hewlett Packard Enterprise Development LP

	the NFS service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3027 file. If the warden successfully restarts the NFS service, the alarm is cleared. If the warden is unable to restart the NFS service, see more troubleshooting information.

NFSv4 Service Alarm

UI Column	NFSv4 Service Down
Logged As	NODE_ALARM_SERVICE_NFS4_DOWN
Meaning	The NFSv4 service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the NFS service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3027 file. If the warden successfully restarts the NFS service, the alarm is cleared. If the warden is unable to restart the NFS service, refer to NFSv4 Troubleshooting on page 1576 to restart the service.

NodeManager Alarm

Explains how to resolve the issue with the Node Manager service stopping on the node.

UI Column	NodeManager Alarm
Logged As	NODE_ALARM_SERVICE_NODEMANAGER_DOWN
Meaning	The NodeManager service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether NodeManager is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 3027 file. If warden successfully restarts the NodeManager, the alarm is cleared. If warden is unable to restart the NodeManager, see more troubleshooting information.

No Disk Attached Alarm

UI Column	No Disk Attached Alarm
Logged As	NODE_ALARM_NO_DISK_ATTACHED
Meaning	There are one or more file system instances on a node with no SP assigned to them.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Resolution	To clear the alarm, assign at least one SP per file system.

No Heartbeat Alarm

Describes the NODE_ALARM_NO_HEARTBEAT alarm.

UI Column	No Heartbeat Alarm
Logged As	NODE_ALARM_NO_HEARTBEAT
Meaning	Node is not undergoing maintenance, and no heartbeat detected for over 5 minutes.
Resolution	Check the status of the node manually.
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

This alarm is raised when a node is down for more than 5 minutes. By default, this alarm is not raised if an edge node is down. To raise an alarm for edge nodes as well, set the CLDB parameter `cldb.ignore.posix.only.hb.alarm` to `0` using the command:

```
/opt/mapr/bin/maprcli config save -values
'{cldb.ignore.posix.only.hb.alarm:"0"}'
```

Security Certificate Expiry Alarm

Describes the NODE_ALARM_CERTIFICATE_NEAR_EXPIRATION alarm.

UI Column	SSL Certificate Expiry
Logged As	NODE_ALARM_CERTIFICATE_NEAR_EXPIRATION
Meaning	SSL certificates are expiring within the number of days denoted by the CLDB setting `cldb.ssl.cert.expiring.alarm.days`. See cldb.conf on page 3006 for more information.
Resolution	Renew the SSL certificates. See Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster for more information.
Configuration	None.
Specification	This alarm is raised when any of the first ten security certificates in `/opt/mapr/conf/ssl_keystore` or in `/opt/mapr/conf/ssl_truststore` are set to expire within the number of days denoted by the CLDB setting `cldb.ssl.cert.expiring.alarm.days`. Once the alarm is raised, the administrator needs to find out the certificates that are expiring, and renew them. To find out the certificates that are expiring, use the `/opt/mapr/server/getSSLExpiryCerts.py` Python script. For example: `python /opt/mapr/server/ getSSLExpiryCerts.py -print Below certificates expiring in the next 120 days Truststore: Alias: 100day valid`

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
until: Mon Jul 13 04:04:15 PDT 2020
            Alias: 65day valid
until: Mon Jun 08 03:45:44 PDT 2020
            Alias: 70day valid
until: Sat Jun 13 03:46:00 PDT 2020
            Alias: 80day valid
until: Tue Jun 23 03:46:14 PDT 2020
            Alias: 90day valid
until: Fri Jul 03 04:03:57 PDT 2020
            Keystore:
            Alias: 3daymay17 valid
until: Thu May 21 04:20:26 PDT 2020
```

Related reference

cldb.conf on page 3006
Contains the configuration for CLDB nodes.

Node Too Many Containers

UI Column	Too Many Containers Alarm
Logged As	NODE_ALARM_TOO_MANY_CONTAINERS
Meaning	Number of containers on this node reached the maximum limit.
Resolution	Delete unused volumes or Snapshots. You can reset the maximum with: `maprcli config save -values {"pernode.numcntrs.alarm.thr":"<number>"}`
Configuration	Configurable at cluster level. This alarm is also raised when total number of containers (including snap containers) exceed 10 times the value of `pernode.numcntrs.alarm.thr`. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

PAM Misconfigured Alarm

UI Column	Pam Misconfigured Alarm
Logged As	NODE_ALARM_PAM_MISCONFIGURED
Meaning	The PAM authentication on the node is configured incorrectly.
Resolution	See PAM Configuration.

ResourceManager Alarm

UI Column	ResourceManager Alarm
Logged As	NODE_ALARM_SERVICE_RESOURCEMANAGER_DOWN
Meaning	The ResourceManager service on the node has stopped running.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Resolution	Go to the node information page or the **Services** page in the Control System to check whether ResourceManager is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 3027 file. If warden successfully restarts the ResourceManager, the alarm is cleared. If warden is unable to restart the ResourceManager, see more troubleshooting information.

Root Partition Full Alarm

UI Column	Root Partition Full
Logged As	NODE_ALARM_ROOT_PARTITION_FULL
Meaning	The root partition ('/') on the node is running out of space (99% full).
Resolution	Free up some space in the root partition of the node.

Tiny Buckets Flush Alarm

UI Column	Lot of Tiny Buckets Flushed
Logged As	NODE_ALARM_TINY_BUCKET_FLUSH
Meaning	Indicates lot of small buckets (<= 8mb) are getting flushed in DB resulting in performance degradation. You may see put operation performance going down during this phase and will need to take corrective actions to fix it. This will not bring down the cluster and data is still accessible.
Resolution	Increase memory for file system as number of active tablets is very high.

Time Skew Alarm

UI Column	Time Skew Alarm
Logged As	NODE_ALARM_TIME_SKEW
Meaning	The clock on the node is out of sync with the master CLDB by more than 20 seconds.
Resolution	Use NTP to synchronize the time on all the nodes in the cluster.

Version Alarm

UI Column	Version Alarm
Logged As	NODE_ALARM_VERSION_MISMATCH
Meaning	One or more services on the node are running an unexpected version or there is a mismatch in the file system patch versions on the nodes.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Resolution	Stop the node, Restore the correct version of any services you have modified, and re-start the node. See Administering Nodes on page 1082.

WebServer Service Alarm

UI Column	Webserver Alarm
Logged As	NODE_ALARM_SERVICE_WEBSERVER_DOWN
Meaning	The WebServer service on the node has stopped running.
Resolution	Go to the node information page or the **Services** page in the Control System to check whether the WebServer service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3027. If the warden successfully restarts the WebServer service, the alarm is cleared. If the warden is unable to restart the WebServer service, see more troubleshooting information.

Table-Replication Alarms

You can view table-replication alarms using the Control System and the CLI. See Viewing Active Table Replication Alarms on page 1675 for more information.

Table Replication Errors

Explains the alarm that is raised when there are table replication errors.

Logged As	VOLUME_ALARM_TABLE_REPL_ERROR
Meaning	This alarm displays the paths and names of the source tables for which the alarms were issued. Up to ten (10) source tables, that have encountered an error, are displayed.

Diagnostics

To identify the cause of the alarm, run the maprcli table replica list command. This command displays an `errors` field with additional information about the error.

```
maprcli table replica list -path <table path>
```

The `errors` field provides the following information:

- Code - table replication error code:
- Host - host that the error occurred on
- Msg - error message information

For additional information about possible causes of the error, see the following log files (located in the **/opt/mapr/logs** directory):

- mfs.log-5 - for the nameserver node of the source table

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- mfs.log-5 - for the nameserver node of the destination table
- gateway.log

Error Conditions

Possible Error Conditions	Description
A missing table or column family on the destination cluster	If a column family no longer exists in the replica, pause replication with the `maprcli table replica pause` command, recreate the column family with the `maprcli table cf create`command, run the CopyTable utility to copy data from the source table into the column family, and then resume replication with the `maprcli table replica resume` command.
A mismatch in column family names for the table on the destination cluster	If the column family still exists in the replica but the name of the column family was changed, run the `maprcli table cf edit` command with the parameter `-newcfname` set to the correct name. Replication will resume automatically.
Unreachable gateways on the destination cluster	This error occurs only if none of the gateways on the cluster are reachable.
Autosetup with directcopy has failed while copying data from the source to the replica	This error could be raised under the following conditions: • If this error occurs due to a connection failure, this alarm should get resolved once the connection is restored. • If this error occurs due to other error conditions such as missing tables, mis-matched column families, or an unreachable gateway, the error condition may not get resolved on its own and may need administration action. For example, if a PUT operation fails on destination cluster due to an Out-Of-Space condition, the administrator will need to add more storage before the PUT retry succeeds.

Table Replication Lag High

Logged As	VOLUME_ALARM_TABLE_REPL_LAG_HIGH
Meaning	These alarms display the paths and names of the source tables for which the replication lag is high. High lag times might be caused by these conditions: • High load on the source or replica • Low network bandwidth between the source and replicas • Miscellaneous error conditions that prevent replication from proceeding • Replication explicitly paused on the source cluster
Configuration	Configurable at the volume level. See volume create on page 2592 for more information.

Table Replication Asynchronous

Logged As	VOLUME_ALARM_TABLE_REPL_ASYNC

©Copyright 2024 Hewlett Packard Enterprise Development LP

Meaning	These alarms display the pathnames of the source tables that are involved. If HPE Ezmeral Data Fabric Database is replicating synchronously and it judges the latency of the replication stream to be too high, it will switch to asynchronous replication temporarily. After a new gateway is created, an existing gateway is restarted, or after latency is sufficiently reduced, HPE Ezmeral Data Fabric Database switches the mode of replication back to synchronous. You can also check whether a source table is being replicated synchronously or asynchronously by running the command `table replica list` on page 2517 .

Elasticsearch Formatting Alarm

Logged As	NODE_ALARM_SERVICE_ELASTICSEARCH_EXCP
Meaning	The put of primary table cannot be converted/ formatted for pushing to ElasticSearch. If the primary table has ElasticSearch as one of its replicas, that may miss updates on some rows as they could not be converted to a supported format for ElasticSearch.
Resolution	Check for rows that could not be formatted for pushing to ElasticSearch in file system logs and insert row with data that can be pushed to ElasticSearch.

Secondary Index Alarms

Secondary index alarms indicate issues that HPE Ezmeral Data Fabric Database might encounter while updating secondary indexes. It is important that you understand what the alarms indicate, and how to resolve the issue causing them.

Secondary Index Update Lag High

Logged As	VOLUME_ALARM_TABLE_INDEX_LAG_HIGH
Meaning	This alarm displays the paths and names of the source tables for which replication lag is high. High lag times might be caused by these conditions: • High load on the source or replica • Low network bandwidth between the source and replicas • Miscellaneous error conditions that prevent replication from proceeding • Replication explicitly paused on the source cluster
Resolution	If you have configured the threshold for this alarm too low, you can increase the theshhold. You configure this lag at the volume level by specifying the `dbindexlagsecalarmthresh` parameter. See volume modify on page 2681 for more information.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Secondary Index Update Error

Logged As	VOLUME_ALARM_TABLE_INDEX_ERROR
Meaning	This alarm occurs if the JSON table regions cannot connect to any of the internal gateways used to update fields in a secondary index. This might be caused by these conditions: • The replication gateway failed. • You have configured too few replication gateway instances.
Resolution	If the gateway failed, restart it. Otherwise, add more gateways. See Managing Gateways on page 1511 for further information.

Secondary Index Encoding Error

Logged As	VOLUME_ALARM_TABLE_INDEX_ENCODING_ERROR
Meaning	This alarm occurs when any of the following encoding errors occur during index updates: • The indexed rowkey size is too big (> 32 Kb). • The indexed field contains a CAST function, and a failure occurs evaluating the CAST function.
Resolution	You must either correct your underlying data or redefine the index to avoid missing rows. See Troubleshooting Secondary Index Encoding Errors on page 1451 for details about how to identify these errors and possible corrective actions. You also must manually clear this alarm, even if you drop the index or the table.

Volume Alarms

Volume alarms indicate problems in individual volumes. The following sections describe the data-fabric volume alarms.

Compaction Failed

UI Column	Volume Compaction Failed
Logged As	VOLUME_ALARM_COMPACTION_FAILURE
Meaning	Data could not be purged as the compactor did not complete the run.
Resolution	Wait for the compactor to run again or manually trigger the compactor using the `volume compact` on page 2588 command.

Compaction Skipped Large Container Volume Alarm

Compaction is skipped due to large container with garbage below the garbage threshold in the container.

Label for Alarm on MCS UI	Compaction Skipped Large Container

©Copyright 2024 Hewlett Packard Enterprise Development LP

Text for Alarm on Log File	VOLUME_ALARM_COMPACTION_SKIPPED_LARGE_CONTAINER
Meaning	Compaction has been skipped for the container because container size is large, but the amount of garbage to be reclaimed from the container is not large enough. When the amount of garbage to reclaim is less than the value specified for `mastgateway.ctc.opt.largenuminodes.thresh mb` (default is 2GB), compaction is skipped. Refer to Data Compaction and Recall Criteria on page 502 for details on data compaction and recall criteria. Compaction is skipped for some large containers having garbage beyond configured threshold. This happens when the value of the configuration variable, `mastgateway.ctc.opt.largenuminodes.skipq ualifiedctrs.enabled`, is set to 1. **NOTE:** Refer to config on page 2090 for the detailed description of the configuration variables.
Resolution	Use one of the following ways as suitable. • Increase the garbage threshold high enough so that when compaction runs, the actual amount of garbage goes below this higher threshold. The variable, `mastgateway.ctc.opt.largenuminodes.thr eshmb`, represents the garbage threshold. • Run compaction manually with a lower overhead threshold. This causes compactor to free up more space. However, this option causes compaction to run longer. Default overhead threshold is 30%. Refer to Running the Compactor Using the CLI and REST API on page 1244 for details on running compaction manually. The alarm goes away when compaction frees up enough space in the container. The alarm continues to display if the garbage in the container after compaction is above the garbage threshold.

Data Unavailable

UI Column	Data Alarm
Logged As	VOLUME_ALARM_DATA_UNAVAILABLE
Meaning	This is a potentially very serious alarm that may indicate data loss. Some of the data on the volume cannot be located. This alarm indicates that enough nodes have failed to bring the replication factor of part or all of the volume to zero. For example, if the volume is stored on a single node and has a replication factor of one, the Data Unavailable alarm will be raised if that volume fails or is taken out of service unexpectedly. If a volume is replicated properly (and therefore is stored on multiple nodes) then the Data Unavailable alarm can indicate that a significant number of nodes is down.
Resolution	Investigate any nodes that have failed or are out of service.

©Copyright 2024 Hewlett Packard Enterprise Development LP

- You can see which nodes have failed by looking at the Node Health pane in the **Overview** page in the Control System.
- Check the cluster(s) for any snapshots or mirrors that can be used to re-create the volume.

For additional troubleshooting information, see how to handle this alarm.

Data Under-Replicated
Describe the alarm that is triggered when a volume is under replicated.

UI Column	Replication Alarm
Logged As	VOLUME_ALARM_DATA_UNDER_REPLICATED
Meaning	The volume replication factor is lower than the desired replication factor set for the volume. This can be caused by failing disks or nodes, or the cluster may be running out of storage space.
Resolution	Investigate any nodes that are failing. You can see which nodes have failed by looking at the Node Health pane in the **Overview** page on the Control System. Determine whether it is necessary to add disks or nodes to the cluster. This alarm is generally raised when the nodes that store the volumes or replicas have not sent a heartbeat for five minutes. To prevent re-replication during normal maintenance procedures, Data Fabric waits a specified interval (by default, one hour) before considering the node dead and re-replicating its data. You can control this interval by setting the `cldb.fs.mark.rereplicate.sec` parameter using the `config save` command. For additional troubleshooting information, see how to handle this alarm.

Warm-Tier Data Node Down
Provides the resolution for the Warm-Tier Data Node Down alarm.

UI Column	Warm-Tier Data Node Down
Logged As	VOLUME_ALARM_DEGRADED_EC_STRIPES
Meaning	One of the nodes or SPs, on which either the data or parity fragments associated with the tiering enabled volume resides, is offline or down.
Resolution	Data Fabric tolerates failure of nodes equal to the number of parity fragments. However, to ensure the availability of data, add nodes to the topology or cluster.

Data Under-Encoded

UI Column	Volume Data Under-Encoded
Logged As	VOLUME_ALARM_CRITICALLY_DEGRADED_EC_STRIPES
Meaning	The number of nodes that are down is equal to the number of parity fragments.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Resolution	Data Fabric tolerates failure of nodes equal to the number of parity fragments. However, to ensure the availability of data, add nodes to the topology or cluster.

Data Below-Parity

UI Column	Volume Data Below-Parity
Logged As	VOLUME_ALARM_EC_DATA_UNAVAILABLE
Meaning	The number of SPs or nodes that are offline or down exceed the number of parity fragments set for the tiering-enabled volume. Data Fabric only tolerates failure of nodes equal to the number of parity fragments set for the tiering-enabled volume.
Resolution	Add more nodes to the topology or cluster.

Offload/Recall Failed

UI Column	Volume Offload/Recall Failed
Logged As	VOLUME_ALARM_OFFLOAD_RECALL_FAILURE
Meaning	The volume data could not be offloaded or could not be recalled.
Resolution	Check the log file for more information on the error. For some errors, CLDB tries to offload the data again after a brief wait. For more information, see Retrying Failed Operation on page 1241.

Inodes Limit Exceeded

UI Column	Inodes Exceeded Alarm
Logged As	VOLUME_ALARM_INODES_EXCEEDED
Meaning	The volume contains too many files or the size of the namespace container size has exceeded the configured limit.
Resolution	This alarm indicates that not enough volumes are set up to handle the number of files stored in the cluster or the size of the name container exceeds the limit. Typically, each user or project should have a separate volume. To resolve the name container issue, investigate the cause for the alarm. After careful consideration, create one or more volumes and move data into the new volumes. See How to handle the VOLUME_ALARM_INODES_EXCEEDED alarm for more information on resolving this alarm.
Configuration	Configurable at cluster and volume level. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

Large Row

UI Label	Large Row

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Logged As	VOLUME_ALARM_TABLE_LARGE_ROW_WARNING
Meaning	A row in a table within the specified volume has reached 75% of the maximum supported row size of 2 GB. The alarm provides the rowkey and the name of the table. If the rowsize exceeds 2 GB, subsequent HPE Ezmeral Data Fabric Database operations on the corresponding table region will fail with an I/O error.
Resolution	Ensure that client applications that access the table are managing row data correctly, so that no row exceeds 2 GB. The method of resolving the alarm depends on the way in which client applications were managing row data. For example, if client applications allowed too many versions of cell data, delete excess versions. If client applications neglected to remove old columns or column families, remove those manually.

Mirror Failure

UI Column	Mirror Alarm
Logged As	VOLUME_ALARM_MIRROR_FAILURE
Meaning	A mirror operation failed.
Resolution	Make sure the CLDB is running on both the source cluster and the destination cluster. Look at the CLDB log (`/opt/mapr/logs/cldb.log`) and the filesystem log (`/opt/mapr/logs/mfs.log`) on both clusters for more information. If the attempted mirror operation was between two clusters, make sure that both clusters are reachable over the network. Make sure the source volume is available and reachable from the cluster that is performing the mirror operation. For more troubleshooting information, see how to handle this alarm.

No Nodes in Topology

UI Column	No Nodes in Vol Topo
Logged As	VOLUME_ALARM_NO_NODES_IN_TOPOLOGY
Meaning	The path specified in the volume's topology no longer corresponds to a physical topology that contains any nodes, either due to node failures or changes to node topology settings. While this alarm is raised, MapR places data for the volume on nodes outside the volume's topology to prevent write failures.
Resolution	Add nodes to the specified volume topology, either by moving existing nodes or adding nodes to the cluster. See Understanding Topology on page 474.

Snapshot Failure

UI Column	Snapshot Alarm
Logged As	VOLUME_ALARM_SNAPSHOT_FAILURE

©Copyright 2024 Hewlett Packard Enterprise Development LP

Meaning	A snapshot operation failed.
Resolution	Make sure the CLDB is running. Look at the CLDB log (`/opt/mapr/logs/cldb.log`) and the Data Fabric file system log (`/opt/mapr/logs/mfs.log`) on both clusters for more information. If the attempted snapshot was a scheduled snapshot that was running in the background, try a manual snapshot. For more troubleshooting information, see how to handle thi alarm.

Snapshot Restore Failure

Describes the alarm that is triggered when the Snapshot Restore operation fails repeatedly.

UI Column	Snapshot Restore Failure Alarm
Logged As	VOLUME_ALARM_SNAPRESTORE_MAXRETRIES_EXCEEDED
Meaning	The snapshot restore operation failed and is retried for more than five (5) times for a single container.
Resolution	View MFS and CLDB logs to determine the cause of failure. Ensure that the master containers for all nodes are up and running.

Related concepts

Restoring a Volume From a Snapshot on page 504
Provides a synopsis of restoring a volume from a snapshot. Describes the implications, and the prerequisites.

Topology Almost Full

UI Column	Vol Topo Almost Full
Logged As	VOLUME_ALARM_TOPOLOGY_ALMOST_FULL
Meaning	The nodes in the specified topology are running out of storage space.
Resolution	Move volumes to another topology, enlarge the specified topology by adding more nodes, or add disks to the nodes in the specified topology.
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

Label Almost Full

The alarm that is triggered when Storage Pools/Nodes with the specified label are running out of space.

UI Column	Vol Label Almost Full
Logged As	VOLUME_ALARM_LABEL_ALMOST_FULL
Meaning	The free storage space on Storage Pools/Nodes with the specified label is lesser than the threshold value. This can disrupt creation/replication of containers with the specified label.
Resolution	Move volumes to another topology with sufficient free storage space on nodes with the specified label,

©Copyright 2024 Hewlett Packard Enterprise Development LP

	enlarge the current topology by adding more nodes with the specified label, or add disks with the specified label to the nodes in the current topology.
Configuration	Configurable at cluster level. See Configuring the VOLUME_ALARM_LABEL_ALMOST_FULL alarm for more information.

Topology Full Alarm

UI Column	Vol Topo Full
Logged As	VOLUME_ALARM_TOPOLOGY_FULL
Meaning	The nodes in the specified topology have out of storage space.
Resolution	Move volumes to another topology, enlarge the specified topology by adding more nodes, or add disks to the nodes in the specified topology.

Label Full Alarm

The alarm that is triggered when Storage Pools/Nodes with the specified label are completely out of space.

UI Column	Vol Label Full
Logged As	VOLUME_ALARM_LABEL_FULL
Meaning	There is no more free storage space on Storage Pools/Nodes with the specified label. This will definitely disrupt creation/replication of containers with the specified label.
Resolution	Move volumes to another topology with sufficient free storage space on nodes with the specified label, enlarge the current topology by adding more nodes with the specified label, or add disks with the specified label to the nodes in the current topology. **NOTE:** There is a Label Almost Full on page 3065 alarm that is raised when the available storage space goes below the configured threshold.

Volume Advisory Quota Alarm

UI Column	Vol Advisory Quota Alarm
Logged As	VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED
Meaning	A volume has exceeded its advisory quota.
Resolution	No immediate action is required. To avoid exceeding the hard quota, clear space on the volume or stop further data writes.
Configuration	Configurable in volume properties. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

Volume Become Master Stuck

UI Column	VOLUME BECOME MASTER STUCK

©Copyright 2024 Hewlett Packard Enterprise Development LP

Logged As	VOLUME_ALARM_BECOME_MASTER_STUCK
Meaning	This means that there are some containers (associated with the volume) that don't have Master role. The alarm description displays the containers on which Master role is not assigned.
Resolution	Run `dump containerinfo` on page 2139 command to determine the node on which role is not assigned and restart that node. If you see the alarm after the node is restarted, contact HPE support.

Volume CGs Violating Reliability Alarm

UI Column	Vol CGs Vilolating Reliability Alarm
Logged As	VOLUME_ALARM_CGS_VIOLATING_RACK_RELIABILITY
Meaning	A volume has violated rack reliability constraints. This alarm is raised after more parity containers of a CG are allocated and located in a rack of the volume ectopology. This might occur when nodes in the backend EC volume are moved across racks of ectopology.
Resolution	CGs are properly moved to another rack. The software triggers internal actions that move CG containers across racks to ensure that they conform to `honorrackreliability` requirements. After required containers are moved, the software clears the alarm.
Configuration	Configurable in volume properties. See the `honorrackreliability ec rack reliability` parameter in Volume Modify or volume create on page 2592 for more information.

Volume with Non-Local Containers

UI Column	Local Volume containers non-local
Logged As	VOLUME_ALARM_DATA_CONTAINERS_NONLOCAL
Meaning	This is a local volume and its containers should all reside on the same node. Some containers were created on another node, which may cause performance issues in MapReduce applications.
Resolution	Recreate the local volume or review information on how to handle this alarm.

Volume Quota Alarm

UI Column	Vol Quota Alarm
Logged As	VOLUME_ALARM_QUOTA_EXCEEDED
Meaning	A volume has exceeded its quota. Further writes to the volume will fail.
Resolution	Free some space on the volume or increase the volume hard quota.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Configuration	Configurable in volume properties. See Configuring the Alarm Threshold Using the CLI on page 1068 for more information.

HPE Ezmeral Data Fabric Environment

This section provides information associated with the Data Fabric environment.

HPE Ezmeral Data Fabric Parameters

Describes Data Fabric parameters and their default values.

The following table lists user-configurable parameters and their default values. These default values reflect those in the default configuration files, plus any overrides shipped out-of-the-box in `core-site.xml`, `mapred-site.xml` or other configuration files. You can override these values by editing or adding them in `mapred-site.xml` or `core-site.xml` using the `-D` option to the `hadoop jar` command whenever you submit a job or set values explicitly in your code.

Parameter	Default
fs.mapr.bailout.on.library.mismatch	true
fs.mapr.bind.retries	false

Parameter	Default
mapreduce.heartbeat.1000	10000
mapreduce.job.complete.cancel.delegation.tokens	TRUE
mapreduce.maprfs.use.compression	TRUE
mapreduce.reduce.input.limit	-1
mapreduce.task.classpath.user.precedence	FALSE
maprfs.openfid2.prefetch.bytes	0
tasktracker.http.threads	2
topology.node.switch.mapping.impl	

Default HPE Ezmeral Data Fabric Configurations
Lists sources from which default Data Fabric configuration parameters are derived.

The default values for configuration parameters can come from various sources:

- marpred-default.xml
- core-default.xml
- yarn-default.xml
- Data Fabric code
- Hadoop code

The topics in this section include the default values for each parameter and the source of the default.

NOTE: For each parameter, an entry in the <name>-site.xml file overrides the default.

Default Core Parameters

Property	Description
dfs.bytes-per-checksum	Default value: 512 Default source: code
dfs.ha.fencing.ssh.connect-timeout	Default value: 30000 Default source: core-default.xml
dfs.namenode.checkpoint.dir	Default value:${hadoop.tmp.dir}/dfs/namesecondary Default source: code
dfs.namenode.checkpoint.edits.dir	Default value: ${fs.checkpoint.dir} Default source: code
dfs.namenode.checkpoint.period	Default value: 3600 Default source: code
file.blocksize	Default value: 67108864 Default source: core-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

file.bytes-per-checksum	Default value: 512 Default source: core-default.xml
file.client-write-packet-size	Default value: 65536 Default source: core-default.xml
file.replication	Default value: 1 Default source: core-default.xml
file.stream-buffer-size	Default value: 4096 Default source: core-default.xml
fs.AbstractFileSystem.file.impl	Default value: org.apache.hadoop.fs.local.LocalFs Default source: core-default.xml
fs.AbstractFileSystem.ftp.impl	Default value: org.apache.hadoop.fs.ftp.FtpFs Default source: core-default.xml
fs.AbstractFileSystem.har.impl	Default value: org.apache.hadoop.fs.HarFs Default source: core-default.xml
fs.AbstractFileSystem.hdfs.impl	Default value: com.mapr.fs.MFS Default source: code
fs.AbstractFileSystem.maprfs.impl	Default value: com.mapr.fs.MFS Default source: code
fs.AbstractFileSystem.viewfs.impl	Default value: org.apache.hadoop.fs.viewfs.ViewFs Default source: core-default.xml
fs.automatic.close	Default value: TRUE Default source: core-default.xml
fs.checkpoint.size	Default value: 67108864 Default source: code
fs.client.resolve.remote.symlinks	Default value: TRUE Default source: core-default.xml
fs.defaultFS	Default value: maprfs:/// Default source: code
fs.df.interval	Default value: 60000 Default source: core-default.xml
fs.du.interval	Default value: 600000 Default source: core-default.xml
fs.file.impl	Default value: org.apache.hadoop.fs.LocalFileSystem Default source: code

Default YARN Parameters

Parameter	Description
mapreduce.job.hdfs-servers	Default value: ${fs.defaultFS} Default source: yarn-default.xml
yarn.acl.enable	Indicates whether ACLs are enabled. Default value: FALSE Default source: yarn-default.xml
yarn.admin.acl	ACL of who can be admin of the YARN cluster. Default value: * Default source: yarn-default.xml
yarn.am.liveness-monitor.expiry-interval-ms	The expiry interval for application master reporting. Default value: 600000 Default source: yarn-default.xml
yarn.app.mapreduce.job.update-status-max-retries	The number of job status update retries. Default value: 0 (retried only 1 time) For a value N, the update is retried 1+N times.
yarn.app.mapreduce.job.update-status-retry-interval	The interval in milliseconds for job status update retries. Default value: 2000 (2000 millisecond or 2 seconds delay is observed before each retry attempt)
yarn.client.application-client-protocol.poll-interval-ms	The interval that the yarn client library uses to poll the completion status of the asynchronous API of application client protocol. Default value: 200 Default source: yarn-default.xml
yarn.client.failover-proxy-provider	When HA is enabled, the class to be used by Clients, AMs and NMs to failover to the Active RM. It should extend org.apache.hadoop.yarn.client.RMFailoverProxyProvider. Default value: org.apache.hadoop.yarn.client.ConfiguredRMFailoverProxyProvider Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties.
yarn.client.failover-retries	When HA is enabled, the number of retries per attempt to connect to a ResourceManager. In other words, it is the ipc.client.connect.max.retries to be used during failover attempts. Default value: 0 Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

yarn.client.failover-retries-on-socket-timeouts	When HA is enabled, the number of retries per attempt to connect to a ResourceManager on socket timeouts. In other words, it is the ipc.client.connect.max.retries.on.timeouts to be used during failover attempts. Default value: 0 Default source: yarn-default.xml
yarn.client.max-nodemanagers-proxies	Maximum number of proxy connections for node manager. It should always be more than 1. NMClient and MRAppMaster will use this to cache connection with node manager. There will be at max one connection per node manager. Ex. configuring it to a value of 5 will make sure that client will at max have 5 connections cached with 5 different node managers. These connections will be timed out if idle for more than system wide idle timeout period. The token if used for authentication then it will be used only at connection creation time. If new token is received then earlier connection should be closed in order to use newer token. This and (yarn.client.nodemanager-client-async.thread-pool-max-size) are related and should be sync (no need for them to be equal). Default value: 0 Default source: yarn-default.xml
yarn.client.nodemanager-client-async.thread-pool-max-size	Max number of threads in NMClientAsync to process container management events. Default value: 500 Default source: yarn-default.xml
yarn.client.nodemanager-connect.max-wait-ms	Default value: 900000 Default source: yarn-default.xml
yarn.client.nodemanager-connect.retry-interval-ms	Default value: 10000 Default source: yarn-default.xml
yarn.dfs-logging.dir-glob	Default value: maprfs:////var/mapr/local/*/logs/yarn/userlogs Default source: Code
yarn.dfs-logging.handler-class	Default value: com.mapr.hadoop.yarn.util.MapRFSLoggingHandler Default source: Code
yarn.external.token.manager	Default value: com.mapr.hadoop.yarn.security.MapRTicketManager Default source: Code
yarn.http.policy	Configures the HTTP endpoint for YARN Daemons.The following values are supported: -HTTP_ONLY : Service is provided only on http -HTTPS_ONLY : Service is provided only on https Default value: HTTP_ONLY Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

yarn.ipc.rpc.class	RPC class implementation. Default value: org.apache.hadoop.yarn.ipc.HadoopYarnProtoRPC Default source: yarn-default.xml
yarn.log-aggregation.retain-check-interval-seconds	How long to wait between aggregated log retention checks. If set to 0 or a negative value, then the value is computed as one-tenth of the aggregated log retention time. Default value: -1 Default source: yarn-default.xml See YARN Log Aggregation.
yarn.log-aggregation.retain-seconds	How long to keep aggregation logs before deleting them. -1 disables. Default value: 2592000 Default source: code See YARN Log Aggregation.
yarn.log-aggregation-enable	Whether to enable log aggregation. Default value: FALSE Default source: yarn-default.xml See YARN Log Aggregation.
yarn.mapr.ticket.expiration	Default value: 604800000 Default source: code
yarn.nm.liveness-monitor.expiry-interval-ms	How long to wait until a NodeManager is considered dead. Default value: 600000 Default source: yarn-default.xml
yarn.nodemanager.container-localizer.log.level	Configuring container localizer logs Default value: INFO Default source: code
yarn.nodemanager.address	The address of the container manager in the NM. Default value: ${yarn.nodemanager.hostname}:0 Default source: yarn-default.xml
yarn.nodemanager.admin-env	Environment variables that should be forwarded from the NodeManager's environment to the container's environment. Default value: MALLOC_ARENA_MAX=$MALLOC_ARENA_MAX Default source: yarn-default.xml

last-updated: Nov 14, 2024

yarn.nodemanager.aux-services	The valid service name should only contain a-zA-Z0-9_ and can not start with numbers. Default value: mapreduce_shuffle, mapr_direct_shuffle Default source: code
yarn.nodemanager.aux-services.mapr_direct_shuffle.class	Default value: com.mapr.hadoop.mapred.LocalVolumeAuxService Default source: code
yarn.nodemanager.aux-services.mapreduce_shuffle.class	Default value: org.apache.hadoop.mapred.ShuffleHandler Default source: yarn-default.xml
yarn.nodemanager.check-interval-localizing-container.ms	The frequency at which the ApplicationMaster checks the running time of the localizing container. Specified in milliseconds. Default value: -1 Default source: YarnConfiguration
yarn.nodemanager.container-executor.class	Identifies who will execute (launch) the containers. Default value: org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor Default source: code
yarn.nodemanager.container-manager.thread-count	Number of threads the container manager uses. Default value: 20 Default source:yarn-default.xml
yarn.nodemanager.container-monitor.interval-ms	How often to monitor containers. Default value: 3000 Default source: yarn-default.xml
yarn.nodemanager.container-monitor.procfs-tree.smaps-based-rss.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.nodemanager.delete.debug-delay-sec	Number of seconds after an application finishes before the NodeManager's DeletionService will delete the application's localized file directory and log directory. To diagnose Yarn application problems, set this property's value large enough (for example, to 600 = 10 minutes) to permit examination of these directories. After changing the property's value, you must restart the NodeManager in order for it to have an effect. The roots of Yarn applications' work directories are configurable with the yarn.nodemanager.local-dirs property (see below), and the roots of the Yarn applications' log directories is configurable with the yarn.nodemanager.log-dirs property (see also below). Default value: 0 Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

yarn.nodemanager.delete.thread-count	Number of threads used in cleanup. Default value: 4 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.interval-ms	Frequency of running disk health checker code. Default value: 1200000 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.max-disk-utilization-per-disk-percentage	Default value: 90 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.min-free-space-per-disk-mb	Default value: 0 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.min-healthy-disks	The minimum fraction of number of disks to be healthy for the nodemanager to launch new containers. This correspond to both yarn-nodemanager.local-dirs and yarn.nodemanager.log-dirs. i.e. If there are less number of healthy local-dirs (or log-dirs) available, then new containers will not be launched on this node. Default value: 0.25 Default source: yarn-default.xml
yarn.nodemanager.docker-container-executor.exec-name	Default value: /usr/bin/docker Default source: yarn-default.xml
yarn.nodemanager.env-whitelist	Environment variables that containers may override rather than use NodeManager's default. Default value: JAVA_HOME,HADOOP_COMMON_HOME,HADOOP_HDFS_HOME,HADOOP_CONF_DIR,HADOOP_YARN_HOME Default source: yarn-default.xml
yarn.nodemanager.external.token.localizer	Default value: com.mapr.hadoop.yarn.nodemanager.MapRTicketLocalizer Default source: code
yarn.nodemanager.health-checker.interval-ms	Frequency of running node health script. Default value: 600000 Default source: yarn-default.xml
yarn.nodemanager.health-checker.script.timeout-ms	Script time out period. Default value: 1200000 Default source: yarn-default.xml
yarn.nodemanager.hostname	The hostname of the NM. Default value: 0.0.0.0 Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

yarn.nodemanager.keytab	Keytab for NM. Default value: /etc/krb5.keytab Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.cgroups.hierarchy	The cgroups hierarchy under which to place YARN proccesses (cannot contain commas). If yarn.nodemanager.linux-container-executor.cgroups.mount is false (that is, if cgroups have been pre-configured), then this cgroups hierarchy must already exist and be writable by the NodeManager user, otherwise the NodeManager may fail. Only used when the LCE resources handler is set to the CgroupsLCEResourcesHandler. Default value: /hadoop-yarn Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.cgroups.mount	Whether the LCE should attempt to mount cgroups if not found. Only used when the LCE resources handler is set to the CgroupsLCEResourcesHandler. Default value: false Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.cgroups.strict-resource-usage	Default value: FALSE Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.nonsecure-mode.limit-users	Default value: TRUE Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user	Default value: nobody Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.nonsecure-mode.user-pattern	The allowed pattern for UNIX user names enforced by Linux-container-executor when used in nonsecure mode (use case for this is using cgroups). The default value is taken from /usr/sbin/adduser. Default value: ^[_.A-Za-z0-9][-@_.A-Za-z0-9]{0,255}?[$]?$ Default source: yarn-default.xml
yarn.nodemanager.linux-container-executor.resources-handler.class	The class which should help the LCE handle resources. Default value: org.apache.hadoop.yarn.server.nodemanager.util.DefaultLCEResourcesHandler Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

yarn.nodemanager.local-cache.max-files-per-directory	It limits the maximum number of files which will be localized in a single local directory. If the limit is reached then sub-directories will be created and new files will be localized in them. If it is set to a value less than or equal to 36 [which are sub-directories (0-9 and then a-z)] then NodeManager will fail to start. For example; [for public cache] if this is configured with a value of 40 (4 files + 36 sub-directories) and the local-dir is /tmp/local-dir1, then it will allow 4 files to be created directly inside /tmp/local-dir1/filecache. For files that are localized further, it will create a sub-directory "0" inside /tmp/local-dir1/filecache and will localize files inside it until it becomes full. If a file is removed from a sub-directory that is marked full, then that sub-directory will be used back again to localize files. Default value: 8192 Default source: yarn-default.xml
yarn.nodemanager.local-dirs	List of directories to store localized files in. An application's localized file directory will be found in: ${yarn.nodemanager.local-dirs}/usercache/${user}/appcache/application_${appid}. Individual containers' work directories, called container_${contid}, will be subdirectories of this. Default value: ${hadoop.tmp.dir}/nm-local-dir Default source: yarn-default.xml
yarn.nodemanager.localizer.address	Address where the localizer IPC is. Default value: ${yarn.nodemanager.hostname}:8040
yarn.nodemanager.localizer.cache.cleanup.interval-ms	Interval in between cache cleanups. Default value: 60000 Default source: yarn-default.xml
yarn.nodemanager.localizer.cache.target-size-mb	Target size of localizer cache in MB, per local directory. Default value: 10240 Default source: yarn-default.xml
yarn.nodemanager.localizer.client.thread-count	Number of threads to handle localization requests. Default value: 5 Default source: yarn-default.xml
yarn.nodemanager.localizer.fetch.thread-count	Number of threads to use for localization fetching. Default value: 4 Default source: yarn-default.xml
yarn.nodemanager.log.retain-seconds	Time in seconds to retain user logs. Only applicable if log aggregation is disabled. Default value: 10800 Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

yarn.nodemanager.log-aggregation.compression-type	T-file compression types used to compress aggregated logs. Default value: none Default source: yarn-default.xml
yarn.nodemanager.log-aggregation.roll-monitoring-interval-seconds	Default value: -1 Default source: yarn-default.xml
yarn.nodemanager.log-dirs	Where to store container logs. An application's localized log directory will be found in ${yarn.nodemanager.log-dirs}/application_${appid}. Individual containers' log directories will be below this, in directories named container_{$contid}. Each container directory will contain the files stderr, stdin, and syslog generated by that container. Default value: ${yarn.log.dir}/userlogs Default source: yarn-default.xml
yarn.nodemanager.pmem-check-enabled	Whether physical memory limits will be enforced for containers. Default value: true Default source: yarn-default.xml
yarn.nodemanager.process-kill-wait.ms	Max time to wait for a process to come up when trying to cleanup a container. Default value: 2000 Default source: yarn-default.xml
yarn.nodemanager.recovery.enabled	Default value: TRUE Default source: yarn-default.xml
yarn.nodemanager.remote-app-log-dir	Where to aggregate logs to. Default value: /tmp/logs Default source: yarn-default.xml
yarn.nodemanager.remote-app-log-dir-suffix	The remote log dir will be created at {yarn.nodemanager.remote-app-log-dir}/${user}/{thisParam} Default value: logs Default source: yarn-default.xml
yarn.nodemanager.resource.cpu-vcores	Number of CPU cores that can be allocated for containers. Default value: ${nodemanager.resource.cpu-vcores} Default source: code
yarn.nodemanager.resource.io-spindles	Default value: ${nodemanager.resource.io-spindles} Default source: code

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

yarn.nodemanager.resource.memory-mb	Amount of physical memory, in MB, that can be allocated for containers. Default value: ${nodemanager.resource.memory-mb} Default source: code
yarn.nodemanager.resource.percentage-physical-cpu-limit	Default value: 100 Default source: yarn-default.xml
yarn.nodemanager.resourcemanager.minimum.version	The minimum allowed version of a resourcemanager that a nodemanager will connect to. The valid values are NONE (no version checking), EqualToNM (the resourcemanager's version is equal to or greater than the NM version), or a Version String. Default value: NONE Default source: yarn-default.xml
yarn.nodemanager.sleep-delay-before-sigkill.ms	Number of ms to wait between sending a SIGTERM and SIGKILL to a container. Default value: 250 Default source: yarn-default.xml
yarn.nodemanager.vmem-check-enabled	Whether virtual memory limits will be enforced for containers. Default value: false Default source: yarn-default.xml
yarn.nodemanager.vmem-pmem-ratio	Ratio between virtual memory to physical memory when setting memory limits for containers. Container allocations are expressed in terms of physical memory, and virtual memory usage is allowed to exceed this allocation by this ratio. Default value: 2.1 Default source: yarn-default.xml
yarn.nodemanager.webapp.address	NM Webapp address. Default value: ${yarn.nodemanager.hostname}:8042 Default source: yarn-default.xml
yarn.nodemanager.windows-container.cpu-limit.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.nodemanager.windows-container.memory-limit.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.resourcemanager.address	The address of the applications manager interface in the ResourceManager. Default value: ${yarn.resourcemanager.hostname}:8032 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1974.

©Copyright 2024 Hewlett Packard Enterprise Development LP

yarn.resourcemanager.admin.address	The address of the ResourceManager admin interface. Default value: ${yarn.resourcemanager.hostname}:8033 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1974.
yarn.resourcemanager.admin.client.thread-count	Number of threads used to handle the ResourceManager admin interface. Default value: 1 Default source: yarn-default.xml
yarn.resourcemanager.am.max-attempts	The maximum number of application attempts. This is a global setting for all ApplicationMasters. Each ApplicationMaster can specify its individual maximum number of application attempts via the API, but the individual number cannot be more than the global upper bound. If it is, the ResourceManager will override it. The default number is set to 2, to allow at least one retry for the ApplicationMaster. Default value: 2 Default source: yarn-default.xml
yarn.resourcemanager.application-tokens.master-key-rolling-interval-secs	Interval for the roll over for the master key used to generate application tokens. Default value: 86400 Default source: yarn-default.xml
yarn.resourcemanager.aux-services	Default value: RMVolumeManager Default source: code
yarn.resourcemanager.aux-services.HSVolumeManager.class	Default value: com.mapr.hadoop.yarn.resourcemanager.RMVolumeManager Default source: code
yarn.resourcemanager.aux-services.RMVolumeManager.class	Default value: com.mapr.hadoop.yarn.resourcemanager.RMVolumeManager Default source: code
yarn.resourcemanager.client.thread-count	The number of threads used to handle applications manager requests. Default value: 50 Default source: yarn-default.xml
yarn.resourcemanager.configuration.provider-class	Default value: org.apache.hadoop.yarn.LocalConfigurationProvider Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

yarn.resourcemanager.connect.max-wait.ms	Maximum time to wait to establish connection to the ResourceManager. Default value: 900000 Default source: yarn-default.xml
yarn.resourcemanager.connect.retry-interval.ms	How often to retry connecting to the ResourceManager. Default value: 30000 Default source: yarn-default.xml
yarn.resourcemanager.container.liveness-monitor.interval-ms	How often to check that containers are still alive. Default value: 600000 Default source: yarn-default.xml
yarn.resourcemanager.container-tokens.master-key-rolling-interval-secs	Interval for the roll over for the master key used to generate container tokens. It is expected to be much greater than yarn.nm.liveness-monitor.expiry-interval-ms and yarn.rm.container-allocation.expiry-interval-ms. Otherwise the behavior is undefined. Default value: 86400 Default source: yarn-default.xml
yarn.resourcemanager.delayed.delegation-token.removal-interval-ms	Interval at which the delayed token removal thread runs. Default value: 30000 Default source: yarn-default.xml
yarn.resourcemanager.dir	Default value: /var/mapr/cluster/yarn/rm Default source: code
yarn.resourcemanager.fs.state-store.num-retries	Default value: 0 Default source: yarn-default.xml
yarn.resourcemanager.fs.state-store.retry-interval-ms	Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.fs.state-store.retry-policy-spec	hdfs client retry policy specification. hdfs client retry is always enabled. Specified in pairs of sleep-time and number-of-retries and (t0, n0), (t1, n1), ..., the first n0 retries sleep t0 milliseconds on average, the following n1 retries sleep t1 milliseconds on average, and so on. Default value: 2000, 500 Default source: yarn-default.xml
yarn.resourcemanager.fs.state-store.uri	URI pointing to the location of the FileSystem path where RM state will be stored. This must be supplied when using org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore as the value for yarn.resourcemanager.store.class Default value: /var/mapr/cluster/yarn/rm/system Default source: code

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

yarn.resourcemanager.ha.automatic-failover.embedded	Enable embedded automatic failover. The embedded elector relies on the RM state store to handle fencing, and is primarily intended to be used in conjunction with ZKRMStateStore. Default value: TRUE Default source: yarn-default.xml
yarn.resourcemanager.ha.automatic-failover.enabled	Enable automatic failover. Default value: TRUE Default source: yarn-default.xml
yarn.resourcemanager.ha.automatic-failover.zk-base-path	The base znode path to use for storing leader information, when using ZooKeeper based leader election. Default value: /yarn-leader-election Default source: yarn-default.xml
yarn.resourcemanager.ha.custom-ha-rmaddressfinder	Default value: org.apache.hadoop.yarn.client.MapRZKBasedRMAddressFinder Default source: code
yarn.resourcemanager.ha.enabled	Enable RM high-availability. If enabled: **1.** The RM starts in the Standby mode by default and transitions to the Active mode after it is prompted to do so. **2.** The nodes in the RM ensemble are listed in yarn.resourcemanager.ha.rm-ids. **3.** The id of each RM comes from yarn.resourcemanager.ha.id, **4.** The actual physical addresses come from the configs of the pattern: {rpc-config}.{id}. Default value: false Default source: yarn-default.xml
yarn.resourcemanager.hostname	The hostname of the ResourceManager. Default value: 0.0.0.0 Default source: yarn-default.xml
yarn.resourcemanager.keytab	The keytab for the ResourceManager. Default value: /etc/krb5.keytab Default source: yarn-default.xml
yarn.resourcemanager.leveldb-state-store.path	Default value: ${hadoop.tmp.dir}/yarn/system/rmstore Default source: yarn-default.xml
yarn.resourcemanager.max-completed-applications	The maximum number of completed applications RM keeps. Default value: 10000 Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

yarn.resourcemanager.nodemanager.minimum.version	The minimum allowed version of a connecting nodemanager. The valid values are NONE (no version checking), EqualToRM (the nodemanager's version is equal to or greater than the RM version), or a Version String. Default value: NONE Default source: yarn-default.xml
yarn.resourcemanager.nodemanagers.heartbeat-interval-ms	The heart-beat interval in milliseconds for every NodeManager in the cluster. Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.principal	The Kerberos principal for the ResourceManager. Default value:mapr Default source: code
yarn.resourcemanager.proxy-user-privileges.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.resourcemanager.recovery.enabled	Enable RM to recover state after starting. If true, then yarn.resourcemanager.store.class must be specified. Default value: false When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1974.
yarn.resourcemanager.resource-tracker.address	Default value: ${yarn.resourcemanager.hostname}:8031 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1974.
yarn.resourcemanager.resource-tracker.client.thread-count	Number of threads to handle resource tracker calls. Default value: 50 Default source: yarn-default.xml
yarn.resourcemanager.scheduler.address	The address of the scheduler interface. Default value: ${yarn.resourcemanager.hostname}:8030 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1974.

©Copyright 2024 Hewlett Packard Enterprise Development LP

yarn.resourcemanager.scheduler.class	The class to use as the resource scheduler. Default value: org.apache.hadoop.yarn.server.resourcemanager.scheduler.fair.FairScheduler Default source: code
yarn.resourcemanager.scheduler.client.thread-count	Number of threads to handle scheduler interface. Default value: 50 Default source: yarn-default.xml
yarn.resourcemanager.scheduler.monitor.enable	Enable a set of periodic monitors (specified in yarn.resourcemanager.scheduler.monitor.policies) that affect the scheduler. Default value: false Default source: yarn-default.xml
yarn.resourcemanager.scheduler.monitor.policies	The list of SchedulingEditPolicy classes that interact with the scheduler. A particular module may be incompatible with the scheduler, other policies, or a configuration of either. Default value: org.apache.hadoop.yarn.server.resourcemanager.monitor.capacity.ProportionalCapacityPreemptionPolicy Default source: yarn-default.xml
yarn.resourcemanager.staging	Default value: /var/mapr/cluster/yarn/rm/staging Default source: code
yarn.resourcemanager.state-store.max-completed-applications	The maximum number of completed applications RM state store keeps, less than or equals to ${yarn.resourcemanager.max-completed-applications}. By default, it equals to ${yarn.resourcemanager.max-completed-applications}. This ensures that the applications kept in the state store are consistent with the applications remembered in RM memory. Any values larger than ${yarn.resourcemanager.max-completed-applications} will be reset to ${yarn.resourcemanager.max-completed-applications}. Note that this value impacts the RM recovery performance.Typically, a smaller value indicates better performance on RM recovery. Default value: ${yarn.resourcemanager.max-completed-applications} Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

yarn.resourcemanager.store.class	The class to use as the persistent store. If org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore is used, the store is implicitly fenced; meaning a single ResourceManager is able to use the store at any point in time. More details on this implicit fencing, along with setting up appropriate ACLs is discussed under yarn.resourcemanager.zk-state-store.root-node.acl. Default value: org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore Default source: yarn-default.xml
yarn.resourcemanager.system	Default value: /var/mapr/cluster/yarn/rm/system Default source: code
yarn.resourcemanager.system-metrics-publisher.dispatcher.pool-size	Default value: 10 Default source: yarn-default.xml
yarn.resourcemanager.system-metrics-publisher.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.resourcemanager.webapp.address	The http address of the ResourceManager web application. Default value: ${yarn.resourcemanager.hostname}:8088 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1974.
yarn.resourcemanager.webapp.delegation-token-auth-filter.enabled	Default value: TRUE Default source: yarn-default.xml
yarn.resourcemanager.webapp.https.address	The https adddress of the ResourceManager web application. Default value: ${yarn.resourcemanager.hostname}:8090 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 1974.
yarn.resourcemanager.work-preserving-recovery.enabled	Default value: TRUE Default source: yarn-default.xml
yarn.resourcemanager.work-preserving-recovery.scheduling-wait-ms	Default value: 10000 Default source: yarn-default.xml
yarn.resourcemanager.zk-acl	ACL's to be used for ZooKeeper znodes. Default value: world:anyone:rwcda Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

yarn.resourcemanager.zk-num-retries	Number of times RM tries to connect to ZooKeeper. Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.zk-retry-interval-ms	Retry interval in milliseconds when connecting to ZooKeeper. Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.zk-state-store.parent-path	Full path of the ZooKeeper znode where RM state will be stored. This must be supplied when using org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore as the value for yarn.resourcemanager.store.class Default value: /rmstore Default source: yarn-default.xml
yarn.resourcemanager.zk-timeout-ms	ZooKeeper session timeout in milliseconds. Session expiration is managed by the ZooKeeper cluster itself, not by the client. This value is used by the cluster to determine when the client's session expires. Expirations happens when the cluster does not hear from the client within the specified session timeout period (i.e. no heartbeat). Default value: 10000 Default source: yarn-default.xml
yarn.scheduler.maximum-allocation-mb	The maximum allocation for every container request at the RM, in MBs. Memory requests higher than this won't take effect, and will get capped to this value. Default value: 8192 Default source: yarn-default.xml
yarn.scheduler.maximum-allocation-vcores	The maximum allocation for every container request at the RM, in terms of virtual CPU cores. Requests higher than this won't take effect, and will get capped to this value. Default value: 4 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-mb	The minimum allocation for every container request at the RM, in MBs. Memory requests lower than this won't take effect, and the specified value will get allocated at minimum. Default value: 1024 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-vcores	The minimum allocation for every container request at the RM, in terms of virtual CPU cores. Requests lower than this won't take effect, and the specified value will get allocated the minimum. Default value: 1 Default source: yarn-default.xml

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

yarn.resourcemanager.zk-timeout-ms	Default value: 10000 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-mb	Default value: 1024 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-vcores	Default value: 1 Default source: yarn-default.xml

Environment Variables
Describes the environment variables specific to the HPE Ezmeral Data Fabric.

For core release 6.0 and later, environment variables should be set in `/opt/mapr/conf/env_override.sh`. Editing `/opt/mapr/conf/env.sh` is no longer recommended. For more information, see About env_override.sh on page 3113.

Variable	Example Values	Description
`CLDB_EXTERNAL_RPC_PORT`	`5000`	If clients outside the cluster cannot reach CLDB on the default port, use the `CLDB_EXTERNAL_RPC_PORT` environment variable to specify the port on which CLDB can be reached.
`JAVA_HOME`	`/usr/lib/jvm/java-7-sun`	The directory where the correct version of Java is installed.
`MAPR_ECOSYSTEM_LOGIN_OPTS`	`*hybrid*`	Specifies the JAAS configuration to use with installed open source components.
`MAPR_EXTERNAL`	`10.10.123.25,10.10.123.30`	If your cluster nodes have multiple NICs, use the MAPR_EXTERNAL environment variable to grant external clients access to a cluster node on specific IP addresses. The value of the MAPR_EXTERNAL environment variable on a node is a comma-separated list of up to four IP addresses with no spaces.
`MAPR_HOME`	`/opt/mapr` (default)	The directory in which the core software is installed. **CAUTION:** Specifying a `MAPR_HOME` directory other than `/opt/mapr` is not supported and can cause installation errors.
`MAPR_JWT_TOKEN_LOCATION`	`/tmp/jwt`	If SSO is configured, you can use this environment variable to set the location of the JWT token. Doing so removes the need to provide a ticket when issuing `maprcli` commands. It also removes the need to provide an AccessKey and SecretKey when issuing MinIO (`mc`) commands for the Object Store.
`MAPR_SUBNETS`	`10.10.123.0/24,10.10.124.0/24`	`MAPR_SUBNETS` is used for Data Fabric RPC to RPC communication. The MFS, CLDB, NFS, and LOOPBACKNFS modules use this environment variable. The NFS and LOOPBACKNFS modules use this environment variable when registering with CLDB. If you do not want Data Fabric to use all NICs on each node, use this environment variable to restrict Data Fabric traffic to specific NICs. Set `MAPR_SUBNETS` to a comma-separated list of up to four subnets in CIDR notation with no spaces. If you do not set `MAPR_SUBNETS`, Data Fabric uses all NICs present on the node. If `MAPR_SUBNETS` is set, make sure that the node can reach all nodes in the cluster (servers and clients) using the specified subnets.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Variable	Example Values	Description
MAPR_USER	mapr (default)	Used with configure.sh on page 2825 to specify the user under which Data Fabric runs its services. If not explicitly set, it defaults to the user mapr. After configure.sh is run, the value is stored in daemon.conf on page 3011 .

About env_override.sh
Describes the purpose of the env_override.sh file.

The env_override.sh file allows you to create to store custom settings for environment variables. By default, /opt/mapr/conf/env.sh contains environment variables for a HPE Ezmeral Data Fabric cluster, but upgrading to a new Data Fabric release causes the env.sh file to be replaced. (A backup is stored as /opt/mapr/conf/env.sh<timestemp>.) After env.sh is replaced, any custom settings are removed.

For Data Fabric 6.0 and later, keep any custom settings in /opt/mapr/conf/env_override.sh. It is no longer necessary to modify env.sh.

Upgrading a cluster does not remove or modify env_override.sh. /opt/mapr/conf/env.sh reads the env_override.sh file at the end of its execution. If the same parameter is listed in both env.sh and env_override.sh, the value specified in env_override.sh is used. If env_override.sh is not present, the values in env.sh are used.

You create env_override.sh from a blank file and insert export statements into the file. For example:

Sample env_override.sh File

```
export CLDB_EXTERNAL_RPC_PORT=5000
export JAVA_HOME=/usr/lib/jvm/java-11-openjdk-11.0.8.10-0.el8_2.x86_64
export MAPR_HOME=/opt/mapr
export MAPR_EXTERNAL=10.10.123.25,10.10.123.30
export MAPR_SUBNETS=10.10.123.0/24,10.10.124.0/24
export MAPR_USER=mapr
export MAPR_ECOSYSTEM_LOGIN_OPTS=*hybrid*
```

Controlling Access to JMX Metrics
Environment variables and configure.sh options introduced in release 6.2.0 let you control how metrics are collected and who can access the metrics from JMX-enabled services.

JMX is a technology for monitoring system services. In the HPE Ezmeral Data Fabric, you can use environment variables or configure.sh options to enable or disable access to JMX metrics. The JMX-enabled services are:

- CLDB
- Drill
- Hive
- NodeManager
- Oozie
- ResourceManager
- Spark

©Copyright 2024 Hewlett Packard Enterprise Development LP

Understanding the MAPR_JMX Variables

The following table describes the environment variables. For release 6.2.0, JMX is enabled by default, and local binding is enabled by default:

Environment Variable	Default Value		Description
	Secure Cluster	Non-Secure Cluster	
MAPR_JMXAUTH*	true	false	Enables or disables authentication for JMX metrics for a node. JMXAUTH is only used in conjunction with MAPR_JMXLOCALHOST or MAPR_JMXREMOTEHOST. JMXAUTH is ignored if MAPR_JMXRLOCALBINDING is set to true.
MAPR_JMXDISABLE*	false	false	If set to true, disables JMX for the entire node. In this scenario, Collectd does not receive JMX metrics.
MAPR_JMXLOCALBINDING*	true	true	If set to true, disables TCP/IP listening on the the local JMX port. There is no TCP/IP listener at all after you turn on local binding. In this scenario, you can only get JMX metrics from the node itself by configuring a process that attaches to the Java process, such as a debugger tool. You can connect only to processes that you own.
MAPR_JMXLOCALHOST	false	false	Enables the JMX server in the Java processes to listen on the local host and on the JMX port number. The local host is a TCP/IP listener that listens on the local host only. It does not let you connect remotely.
MAPR_JMXREMOTEHOST	false	false	Enables the JMX server to listen on the JMX port and allows users from outside the cluster to connect to that port. You can turn on REMOTEHOST if you want to have a cluster with both LOCALBINDING and REMOTEHOST. Turning on REMOTEHOST allows you to use JConsole, Virtual VM, or any of these other tools to log in and look at what the Java processes is doing. If MAPR_JMXREMOTEHOST is set to true, the system always uses SSL and authentication.
MAPR_JMXSSL*	false	false	Enables or disables SSL for JMX metrics for a node. This variable is ignored if MAPR_JMXREMOTEHOST is set to true.

*For internal use only. Manually changing the the value of this environment variable is not recommended.

Changing the MAPR_JMX Environment Variables

Suppose you want to change the value of MAPR_JMXREMOTEHOST to true. Doing so allows you to use a tool, such as JConsole, to log in remotely and monitor the Java processes. To change the MAPR_JMXREMOTEHOST setting:

1. Export the new value of MAPR_JMXREMOTEHOST in /opt/mapr/conf/env_override.sh:

```
export MAPR_JMXREMOTEHOST=true
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

2. Run `/opt/mapr/server/configure.sh -R`, and restart all services. For example:
   a. Stop Warden by using the `systemctl stop mapr-warden` command.
   b. Stop ZooKeeper by using the `systemctl stop mapr-zookeeper` command.
   c. Restart ZooKeeper by using the `systemctl start mapr-zookeeper` command.
   d. Restart Warden by using the `systemctl start mapr-warden` command.

Using the JMX Options for `configure.sh`

The following `configure.sh` options are supported for managing JMX on individual nodes:

Option	Description
`-JMXEnable`	Enables JMX support for every service on the node where JMX is configured to be enabled. JMX is enabled by default.
`-JMXDisable`	Globally disables JMX support for all JMX-enabled services on the node.
`-JMXLocalBindingEnable`	Enables local binding for JMX connections. Local binding is enabled by default.
`-JMXLocalBindingDisable`	Disables local binding for JMX connections.
`-JMXLocalHostEnable`	Enables the local-host TCP port for JMX. This setting is mutually exclusive with `JMXRemoteHostEnable`.
`-JMXLocalHostDisable`	Disables the local-host TCP port for JMX.
`-JMXRemoteHostEnable`	Enables the remote TCP port for JMX. This setting is mutually exclusive with `JMXLocalHostEnable`.
`-JMXRemoteHostDisable`	Disables the remote TCP port for JMX.

To use `-JMX` options, run `configure.sh -R` with the `-JMX` option on the desired node. For example:

```
/opt/mapr/server/configure.sh -R -JMXRemoteHostEnable
```

Ports Used by HPE Ezmeral Data Fabric Software
Lists the ports used by Data Fabric services.

Avoiding Port Conflicts

To avoid trouble with port conflicts on your Data Fabric clusters, try these tips:

- Remap the ports for the HBaseMaster and HBaseRegionServer services to ports below `32768`.
- Set the ephemeral port range to stop at `50029` by changing the value in the file `/proc/sys/net/ipv4/ip_local_port_range`. Note that this setting changes the available number of ephemeral ports from the default of `28233` ports to `17233`.

Ports Needed for POSIX Clients and File System to Communicate With Each Other

POSIX clients communicate with the CLDB and server components of the Data Fabric filesystem. You need to open the relevant ports for TCP connectivity from POSIX clients to the Data Fabric file-system cluster nodes. Open the CLDB, file-system server, and file-system server instances ports, as detailed in the following section.

Services and Ports Quick Reference

The following list defines the ports used by a Data Fabric cluster, along with the default port numbers. All the ports used by Data Fabric software are **TCP** ports.

Airflow Webserver	*Source IP*: Nodes/clients accessing Airflow webserver *Destination IP*: Nodes running Airflow webserver *Ports*: 8780 *Purpose*: Used by Airflow webserver clients to access the Airflow webserver *Parameter and File where Port is Configured*: Not Applicable
Airflow Scheduler	*Source IP*: Airflow webserver *Destination IP*: Nodes running Airflow scheduler *Ports*: 8793 *Purpose*: Used by Airflow webserver to access the Airflow scheduler *Parameter and File where Port is Configured*: Not Applicable
API Server (apiserver)	*Source IP*: Cluster nodes running apiserver *Destination IP*: Cluster nodes running apiserver *Ports*: • 5701 • 5702 *Purpose*:Clustering support *Parameter and File where Port is Configured*: Not Applicable
CLDB	*Source IP*: Nodes running any Data Fabric services, clients interacting with the file system *Destination IP*: Cluster nodes running CLDB services *Ports*: 7222 A client reads CLDB IP and port number from the `/opt/mapr/conf/mapr-clusters.conf` file. The client initially tries to communicate with CLDB on port `7222`. Once it establishes the connection, it fetches the additional CLDB IPs and ports from the connected CLDB. By default, CLDB listens on ports `7222` and `7223`. For performance reasons, additional ports may be opened, depending on the configuration parameter `cldb.num.rpc.threads` in the `/opt/mapr/conf/cldb.conf` file. For example, setting `cldb.num.rpc.threads=3`, opens up ports `7222`, `7223` and `7224`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

	NOTE: The `cldb.num.rpc.threads` parameter is hard-coded with a default value of 3. To change this value, add this parameter with the new value to the `/opt/mapr/conf/cldb.conf` file. **NOTE:** If you upgrade from Core 5.2.x or Core 6 to Core 6.1 and above, the value of `cldb.num.rpc.threads` is not changed. The default remains as 3, which means three ports are open for each CLDB node. The client tries connecting to the CLDBs till timeout occurs in the case of soft mount, while the client indefinitely retries in the case of hard mount. If a client cannot connect to a CLDB port, the CLDB is marked unreachable. For example, assume a CLDB with IP 10.10.10.10 and 3 ports `7222`, `7223` and `7224`. If a client fails to connect to the CLDB say on port `7223`, the CLDB 10.10.10.10 is marked unreachable, and the client will not try the two other ports for the next few minutes. It tries to connect with the next CLDB entry in the list. For load balancing at CLDB, a client will always pick a random port among the available CLDB ports. *Purpose*: file system API calls *Parameter and File where Port is Configured*: • `/opt/mapr/conf/cldb.conf` • `/opt/mapr/conf/warden.conf` • `/opt/mapr/conf/mapr-clusters.conf`
CLDB JMX Monitor Port	*Source IP*: Nodes running CLDB services *Destination IP*: CLDB JMX monitor port *Ports*: 7220 *Purpose*: The port on which `Collectd` gathers CLDB metrics through JMX. *Parameter and File where Port is Configured*: Not Applicable
CLDB web port	*Source IP*: Nodes/clients connecting to the CLDB GUI *Destination IP*: Cluster nodes running CLDB services *Ports*: 7221 *Purpose*: CLDB GUI for a cluster with security disabled. For a secure cluster, the port is `7443` as defined by the `maprlogin` utility. *Parameter and File where Port is Configured*: `/opt/mapr/conf/cldb.conf`
maprlogin utility	*Source IP*: Connections using the maprlogin utility *Destination IP*: Cluster nodes running CLDB services *Ports*: 7443 *Purpose*: When security is enabled for a cluster, the CLDB listens for connections on port 7443. If security is disabled, the `maprlogin` utility is unable to reach the CLDB.

	Parameter and File where Port is Configured: Not Applicable
Data Access Gateway	*Source IP*: Clients using the HPE Ezmeral Data Fabric Database JSON REST API with HTTPS *Destination IP*:Not Applicable *Ports*: 8243 *Purpose*: The port used to connect to the Data Access Gateway using HTTPS *Parameter and File where Port is Configured*: `rest.https.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: Node.js OJAI client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678 *Purpose*: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: Python OJAI client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678 *Purpose*: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: Go OJAI client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678 *Purpose*: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: C# OJAI client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678 *Purpose*: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Data Access Gateway	*Source IP*: Java OJAI thin client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 5678

©Copyright 2024 Hewlett Packard Enterprise Development LP

	Purpose: The port used to connect the OJAI client to the Data Access Gateway *Parameter and File where Port is Configured*: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`
Apache Kafka Wire Protocol Service	*Source IP*: Apache Kafka Client *Destination IP*: Cluster nodes running the Data Access Gateway service *Ports*: 9092 *Purpose*: The port used by Apache Kafka Wire Protocol Service to connect the Kafka client to the Data Access Gateway service. *Parameter and File where Port is Configured*: `port` in `/opt/mapr/data-access-gateway/conf/kafka-server.conf`
Drill JMX Port	*Source IP*: Nodes running the Drillbit service *Destination IP*: Drill JMX Port *Ports*: 6090 *Purpose*: The port on which `Collectd` gathers Drill metrics via JMX. *Parameter and File where Port is Configured*: Not Applicable
Drill Web UI	*Source IP*: Nodes running the Drillbit service *Destination IP*: Nodes running the Drillbit service *Ports*: 8047 *Purpose*: TCP port needed for the Drill Web UI and clients using REST API and nodes running the Drillbit service. *Parameter and File where Port is Configured*: `drill.exec.http.port` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`
Drill (User Port)	*Source IP*: Nodes running the Drillbit service and clients using JDBC/ODBC *Destination IP*: Nodes running the Drillbit service *Ports*: 31010 *Purpose*: TCP user port address. Used between nodes in a Drill cluster. Needed for an external client, such as Tableau, to connect into the cluster nodes. Also needed for the Drill Web UI. You can also use this port to connect directly to a Drillbit. *Parameter and File where Port is Configured*: `drill.exec.rpc.user.server.port` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`
Drill (Control Port)	*Source IP*: Nodes running the Drillbit service *Destination IP*: Nodes running the Drillbit service *Ports*: 31011 *Purpose*: TCP port that controls the port address. Used between nodes in a Drill cluster. Needed for multi-node installation of Drill. *Parameter and File where Port is Configured*: `drill.exec.rpc.bit.server.port`

©Copyright 2024 Hewlett Packard Enterprise Development LP

	in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`
Drill (Data Port)	*Source IP*: Nodes running the Drillbit service *Destination IP*: Nodes running the Drillbit service *Ports*: 31012 *Purpose*: TCP data port address. Used between nodes in a Drill cluster. Needed for multi-node installation of Drill. *Parameter and File where Port is Configured*: `drill.exec.rpc.bit.server.port + 1` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`
Drill (ZooKeeper Port)	*Source IP*: Clients using JDBC/ODBC and nodes running ZooKeeper services *Destination IP*: Nodes running the Drillbit service *Ports*: 5181 *Purpose*: ZooKeeper port used to connect to Drill through the JDBC driver. *Parameter and File where Port is Configured*: `See the ZooKeeper entry in this list.`
Elasticsearch (Components Communication Port)	*Source IP*: Non-Elasticsearch components, such a web browser, curl, and Kibana, that connect to Elasticsearch. *Destination IP*: Nodes running Elasticsearch for monitoring use cases *Ports*: 9200 *Purpose*: Non-Elasticsearch components use this port when communicating with Elasticsearch. *Parameter and File where Port is Configured*: You can configure a different port for monitoring use cases when you run the configure.sh on page 2825 script with the `-ES` parameter.
Elasticsearch (Daemons Communication Port)	*Source IP*: Nodes running Elasticsearch *Destination IP*: Nodes running Elasticsearch for monitoring use cases *Ports*: 9300 *Purpose*: Elasticsearch uses this port for communications between Elasticsearch daemons. *Parameter and File where Port is Configured*: Not Applicable
Gateway	*Source IP*: Nodes sending operations to replicate *Destination IP*: Nodes running the gateway service *Ports*: 7660 *Purpose*: The port used by gateway services to listen for incoming replication operations. *Parameter and File where Port is Configured*: Not Applicable
Grafana	*Source IP*: Web Browsers *Destination IP*: Nodes running Grafana for monitoring *Ports*: 3000

©Copyright 2024 Hewlett Packard Enterprise Development LP

	Purpose: Web browsers use this port when connecting to Grafana. *Parameter and File where Port is Configured*: Not Applicable
HBase Master	*Source IP*: HBase Clients *Destination IP*: Nodes running HBase Master services *Ports*: 16000 *Purpose*: HBase API and HBase shell use this port to connect to HBase Master *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase Master Web UI	*Source IP*: HBase Master Web UI clients *Destination IP*: Nodes running HBase Master services *Ports*: 16010 *Purpose*: Information Web UI of HBase Master *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase Thrift Server	*Source IP*: HBase Thrift Server clients *Destination IP*: Nodes running HBase Thrift Server *Ports*: 9090 *Purpose*: The HBase client uses this port to connect to HBase, using the Thrift protocol *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase Thrift Web UI	*Source IP*: HBase Thrift Web UI clients *Destination IP*: Nodes running HBase Thrift *Ports*: 9095 *Purpose*: Information Web UI of HBase Thrift *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase REST Server	*Source IP*: HBase REST Server clients *Destination IP*: Nodes running HBase REST Server *Ports*: 8080 *Purpose*: The HBase client uses this port to connect to HBase using the HTTP protocol *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase REST Web UI	*Source IP*: HBase REST Web UI clients *Destination IP*: Nodes running HBase REST *Ports*: 8086 *Purpose*: Information Web UI of HBase REST *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`

last-updated: Nov 14, 2024

HBase Regionserver	*Source IP*: HBase Clients *Destination IP*: Nodes running HBase Regionserver services *Ports*: 16020 *Purpose*: HBase API and HBase shell use this port to connect to HBase RegionServer *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HBase Regionserver UI	*Source IP*: HBase Regionserver Web UI clients *Destination IP*: Nodes running HBase Regionserver *Ports*: 16030 *Purpose*: Information Web UI of HBase Regionserver *Parameter and File where Port is Configured*: `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml`
HistoryServer RPC	*Source IP*: Not Applicable *Destination IP*: Nodes running MapReduce JobHistory Server *Ports*: 10020 *Purpose*: Not Applicable *Parameter and File where Port is Configured*: Not Applicable
HistoryServer Web UI and REST APIs	*Source IP*: Clients that access Job History Server UI in a *non-secure* cluster *Destination IP*: Secure nodes running MapReduce JobHistory Server in a non-secure cluster *Ports*: 19888 *Purpose*: Non-secure HistoryServer Web UI and REST APIs *Parameter and File where Port is Configured*: See mapred-site.xml on page 3019
HistoryServer Web UI and REST APIs	*Source IP*: Clients that access Job History Server UI in a *secure* cluster *Destination IP*: Secure nodes running MapReduce JobHistory Server in a secure cluster *Ports*: 19890 *Purpose*: Secure HistoryServer Web UI and REST APIs *Parameter and File where Port is Configured*: See mapred-site.xml on page 3019
Hive Metastore	*Source IP*: Nodes/clients performing Hive queries/operations *Destination IP*: Nodes running the Hive metastore services *Ports*: 9083 *Purpose*: Used by Hive clients to query/access the Hive metastore *Parameter and File where Port is Configured*: `/opt/mapr/hive/hive-<version>/conf/hive-site.xml`

©Copyright 2024 Hewlett Packard Enterprise Development LP

Hiveserver2	*Source IP*: Nodes or clients performing hive queries using JDBC/ODBC *Destination IP*: Nodes running Hiveserver2 *Ports*: 10000 *Purpose*: Port through which clients perform hive queries *Parameter and File where Port is Configured*: Not Applicable
Hiveserver2 Web UI	*Source IP*: Not Applicable *Destination IP*: Nodes running Hiverserver2 Web UI *Ports*: 10002 *Purpose*: Provides access to Hive configuration settings, local logs, metrics, and information about active sessions and queries. *Parameter and File where Port is Configured*: Not Applicable
Hoststats	See `hoststats.port` and `hs.port` in the Warden configuration file.
Httpfs	*Source IP*: Nodes/clients accessing httpfs services *Destination IP*: Nodes running httpfs services *Ports*: 14000 *Purpose*: Used by httpfs file clients to access the httpfs server *Parameter and File where Port is Configured*: • `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/httpfs-env.sh`
Hue Webserver	*Source IP*: Nodes/clients accessing Hue web services *Destination IP*: Nodes running Hue web services *Ports*: 8888 *Purpose*: Used by Hue webserver clients to access the Hue webserver *Parameter and File where Port is Configured*: `/opt/mapr/hue/hue*/desktop/conf/hue.ini`
KSQL	*Source IP*: All cluster nodes *Destination IP*: Nodes running KSQL *Ports*: 8084 *Purpose*: KSQL *Parameter and File where Port is Configured*: `$KSQL_INSTALL_DIR/etc/ksql/ksqlserver.properties`
Kafka Connect	*Source IP*: All cluster nodes *Destination IP*: Nodes running Kafka Connect *Ports*: 8083 *Purpose*: Kafka Connect REST API calls *Parameter and File where Port is Configured*: `/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Kafka REST	*Source IP*: All cluster nodes *Destination IP*: Nodes running Kafka REST *Ports*: 8082 *Purpose*: Kafka Connect REST API calls *Parameter and File where Port is Configured*: `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties`
Kafka Schema Registry	*Source IP*: All cluster nodes *Destination IP*: Nodes running Kafka Schema Registry *Ports*: 8087 *Purpose*: Kafka Schema Registry API calls *Parameter and File where Port is Configured*: `/opt/mapr/schema-registry/schema-registry-<version>/config/schema-registry.properties`
Kibana	*Source IP*: Web browsers *Destination IP*: Nodes running Kibana for monitoring use cases *Ports*: 5601 *Purpose*: Web browsers use this port when connecting to Grafana. *Parameter and File where Port is Configured*: Not Applicable
MAST Gateway	*Source IP*: Nodes running MAST Gateway service *Destination IP*: Nodes running MAST Gateway service *Ports*: 8660 *Purpose*: Data Fabric clients use this port to connect to the MAST Gateway *Parameter and File where Port is Configured*: `/opt/mapr/conf/mastgateway.conf`
file system server	*Source IP*: Nodes running any Data Fabric services, clients interacting with the file system *Destination IP*: Nodes running FileServer services *Ports*: 5660, 5692, 5724, and 5756 *Purpose*: The filesystem is a random read-write distributed filesystem that allows applications to concurrently read and write directly to disk. Clients use these ports to access the file-system server. *Parameter and File where Port is Configured*: Not Applicable
file system server	*Source IP*: Nodes running the gateway service *Destination IP*: Nodes running the file system *Ports*: 6660 *Purpose*: The port on which gateway nodes send replicated operations to nodes in destination clusters. *Parameter and File where Port is Configured*: Not Applicable
file system server instances	*Source IP*: Not Applicable *Destination IP*: Not Applicable

	Ports: See Working with Multiple Instances of the File System on page 1075 *Purpose*: Multiple file system instances *Parameter and File where Port is Configured*: Not Applicable
Object Store	*Source IP*: Nodes accessing MOSS *Destination IP*: Nodes running MOSS *Ports*: 9000 *Purpose*: Port for MOSS *Parameter and File where Port is Configured*: The *moss.port* option in `/opt/mapr/conf/moss.conf`. **CAUTION:** The default port for S3 Gateway is also 9000. If you run S3 Gateway and Object Store, change one of the ports to avoid conflicts.
S3 Gateway	*Source IP*: Nodes accessing the S3 Gateway server *Destination IP*: Nodes running the S3 Gateway server *Ports*: 9000 *Purpose*: Port for the S3 Gateway server *Parameter and File where Port is Configured*: The *ports* option in `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json`
NFS	*Source IP*: Nodes/clients accessing the filesystem via the NFS protocol *Destination IP*: Nodes running Data Fabric NFS Services *Ports*: 2049 *Purpose*: NFSv3 or NFSv4 access to the file system *Parameter and File where Port is Configured*: Not Applicable
NFS	*Source IP*: Nodes running NFS services *Destination IP*: Nodes running NFS services *Ports*: 9997, 9998 *Purpose*: NFS VIP Management *Parameter and File where Port is Configured*: `/opt/mapr/conf/nfsserver.conf`
NodeManager JMX Port	*Source IP*: Nodes running NodeManager *Destination IP*: NodeManager JMX Port *Ports*: 8027 *Purpose*: The port on which Collectd gathers metrics from NodeManager nodes via JMX. *Parameter and File where Port is Configured*:Not Applicable
NodeManager	*Source IP*: Not Applicable *Destination IP*: Nodes running NodeManager *Ports*: 8099

last-updated: Nov 14, 2024

	Purpose: The node manager manages the health of each node in the cluster. *Parameter and File where Port is Configured*:`yarn.nodemanager.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
NodeManager Localizer RPC	*Source IP*: Not Applicable *Destination IP*: Nodes running NodeManager *Ports*: 8040 *Purpose*: The port that node manager uses to localize resources for a node. With localization, remote resources are downloaded to the local filesystem for access. *Parameter and File where Port is Configured*: `yarn.nodemanager.localizer.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
NodeManager Web UI and REST APIs	*Source IP*: External Web browsers and REST clients accessing NodeManager services in a non-secure cluster *Destination IP*: Nodes running NodeManager services in a non-secure cluster *Ports*: 8042 *Purpose*: NodeManager HTTP port *Parameter and File where Port is Configured*: `yarn.nodemanager.webapp.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
NodeManager Web UI and REST APIs	*Source IP*: External Web browsers and REST clients accessing NodeManager services in a secure cluster *Destination IP*: Nodes running NodeManager services in a secure cluster *Ports*: 8044 *Purpose*: NodeManager HTTPS port *Parameter and File where Port is Configured*: `yarn.nodemanager.webapp.https.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`
OpenTSDB	*Source IP*: OpenTSDB clients, such as `Collectd`. *Destination IP*: Nodes running OpenTSDB for monitoring use cases. *Ports*: 4242 *Purpose*: `Collectd` uses this port to write metrics to OpenTSDB. *Parameter and File where Port is Configured*: You can configure a different port for monitoring use cases when you run configure.sh on page 2825 script with the `-OT` parameter.
Port Mapper	*Source IP*: Nodes running Data Fabric NFS Services *Destination IP*: Nodes/clients accessing the filesystem using the NFS protocol *Ports*: 111

Shuffle HTTP	*Source IP*: Not Applicable *Destination IP*: Shuffle HTTP *Ports*: 13562 *Purpose*: The port that MapReduce Shuffle uses. Transferring the map outputs to reducer inputs in sorted form is the shuffle operation. *Parameter and File where Port is Configured*: Not Applicable
Spark Standalone Master (RPC)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 7077 *Purpose*: The port on which to submit jobs in a Spark standalone cluster. *Parameter and File where Port is Configured*: `SPARK_MASTER_PORT` in `SPARK_HOME/conf/spark-env.sh`
Spark Standalone Master (Web UI)	*Source IP*: Nodes/clients accessing Spark services in a *non-secure* cluster *Destination IP*: Nodes running Spark services in a non-secure cluster *Ports*: 8580 *Purpose*: The port on which browsers connect to Spark master in a non-secure Spark standalone cluster. *Parameter and File where Port is Configured*: `SPARK_MASTER_WEBUI_PORT` in `SPARK_HOME/conf/spark-env.sh`
Spark Standalone Master (Web UI)	*Source IP*: Nodes/clients accessing Spark services in a *secure* cluster *Destination IP*: Nodes running Spark services in a secure cluster *Ports*: 8980 *Purpose*: The port on which browsers connect to a Spark master in a secure Spark standalone cluster. *Parameter and File where Port is Configured*: `SPARK_MASTER_WEBUI_PORT` in `SPARK_HOME/conf/spark-env.sh`
Spark Standalone Worker	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 8081 *Purpose*: The port on which browsers connect to Spark workers in a Spark standalone cluster. *Parameter and File where Port is Configured*: `SPARK_WORKER_WEBUI_PORT` in `SPARK_HOME/conf/spark-env.sh`
Spark Thrift Server (if start and stop server using Spark scripts)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 10000 *Purpose*: The port on which JDBC clients connect to Spark Thrift server.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	Parameter and File where Port is Configured: `hive.server2.thrift.port` in `SPARK_HOME/conf/hive-site.xml`
Spark Thrift Server (if start and stop server through Warden, starting in EEP 4.0)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 2304 *Purpose*: The port on which JDBC clients connect to Spark Thrift server. *Parameter and File where Port is Configured*: `hive.server2.thrift.port` in `SPARK_HOME/conf/hive-site.xml`
Spark History Server	*Source IP*: Clients that access Spark Job History in a *non-secure* cluster *Destination IP*: Nodes running Spark History Server in a non-secure cluster *Ports*: 18080 *Purpose*: The port on which browsers connect to a non-secure Spark history server. *Parameter and File where Port is Configured*: `spark.history.ui.port` in `SPARK_HOME/conf/spark-default.conf"`
Spark History Server	*Source IP*: Clients that access Spark Job History in a *secure* cluster *Destination IP*: Nodes running Spark History Server in a secure cluster *Ports*: 18480 *Purpose*: The port on which browsers connect to a secure Spark history server. *Parameter and File where Port is Configured*: `spark.ssl.historyServer.port` in `SPARK_HOME/conf/spark-defaults.conf (starting from Spark-2.2.1)`
Spark External Shuffle Service	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 7337 *Purpose*: The port on which Spark jobs connect to External Shuffle server. *Parameter and File where Port is Configured*: `spark.shuffle.service.port` in `SPARK_HOME/conf/spark-default.conf`
Tez Shuffle	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 13563 *Purpose*: Port to communicate with the Tez Shuffler. A Tez specific shuffle handler allows data to be shuffled in a way that takes advantage of the new features in Tez *Parameter and File where Port is Configured*: Not Applicable
Timeline Server	*Source IP*: Not Applicable *Destination IP*: Not Applicable

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	Ports: 10200 *Purpose*: Hadoop IPC port used for internal communication in Hadoop *Parameter and File where Port is Configured*: Not Applicable
Timeline Server Web Interface (HTTP)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 8188 *Purpose*: Non-secure web access for the Timeline Server. The Timeline Server allows storage and retrieval of an application's current and historic information in a generic fashion. *Parameter and File where Port is Configured*: Not Applicable
Timeline Server Web Interface (HTTPS)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 8190 *Purpose*: Secure web access for the Timeline Server *Parameter and File where Port is Configured*: Not Applicable
Tomcat Port (Hive-on-Tez UI)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 9383 *Purpose*: The non-secure port to access the Tez UI. Hive-on-Tez speeds up execution of Hive queries. *Parameter and File where Port is Configured*: Not Applicable
Tomcat SSL Port (Hive-on-Tez UI)	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 9393 *Purpose*: The secure port to access the Tez UI. *Parameter and File where Port is Configured*: Not Applicable
Web UI	*Source IP*: External web browser accessing either a *non-secure* or a *secure* cluster *Destination IP*: Nodes running the Control System Web UI in a non-secure or a secure cluster *Ports*: 8443 *Purpose*: Control System Web UI *Parameter and File where Port is Configured*: `/opt/mapr/apiserver/conf/properties.cfg`
Zeppelin	*Source IP*: Not Applicable *Destination IP*: Not Applicable *Ports*: 9995 *Purpose*: The port to connect to the Zeppelin Docker container *Parameter and File where Port is Configured*: Configurable by setting `ZEPPELIN_SSL_PORT` when running the Zeppelin Docker image

last-updated: Nov 14, 2024

ZooKeeper	*Source IP*: Nodes running ZooKeeper services, clients executing ZooKeeper API calls *Destination IP*: Nodes running ZooKeeper services *Ports*: 5181 *Purpose*: ZooKeeper API calls *Parameter and File where Port is Configured*: • `/opt/mapr/zookeeper/zookeeper-<version>/conf/zoo.cfg` • `/opt/mapr/conf/warden.conf, /opt/mapr/conf/cldb.conf` • `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` • `/opt/mapr/hive/hive-<version>/conf/hive-site.xml`
ZooKeeper follower-to-leader Communication	*Source IP*: Nodes running ZooKeeper services *Destination IP*: Nodes running ZooKeeper services *Ports*: 2888 *Purpose*: ZooKeeper Server > Server Communication *Parameter and File where Port is Configured*: `/opt/mapr/zookeeper/zookeeper-<version>/conf/zoo.cfg`
ZooKeeper Leader Election	*Source IP*: Nodes running ZooKeeper services *Destination IP*: Nodes running ZooKeeper services *Ports*: 3888 *Purpose*: ZooKeeper Server > Server Communication *Parameter and File where Port is Configured*: `/opt/mapr/zookeeper/zookeeper-<version>/conf/zoo.cfg`

Log Files

Lists the log files for each HPE Ezmeral Data Fabric component.

The table below provides information on the log files for the components.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Component	Type of Log	Log File	Configuration File	Rotation	Maximum File Size	# of Backups	Expiration Period
CLDB	Main	/opt/mapr/logs/cldb.log	/opt/mapr/conf/log4j.cldb.properties	By Size	100MB	9	-
	Disk Balancer	/opt/mapr/logs/cldbdiskbalancer.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Role Balancer	/opt/mapr/logs/cldbrolebalancer.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Time Skew	/opt/mapr/logs/timeskew.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Data Fabric filesystem Summary	/opt/mapr/logs/cldbfssummary.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Audit	/opt/mapr/logs/cldbaudit.log.json	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	-
	Guts	/opt/mapr/logs/cldbguts.log	/opt/mapr/conf/log4j.properties	-	-	-	10 days
	Proxy	/opt/mapr/logs/cldbproxy.log	/opt/mapr/conf/log4j.properties	-	-	-	10 days

Increasing Log Retention

To increase log retention for specific component, you can modify the configuration file and reset the value of the properties.

Increasing Log Retention for file system

In the `/opt/mapr/conf/mfs.conf` file, increase the value for the `mfs.max.logfile.size.in.mb` property. The value for this property is computed using the following formula:

```
maxSizePerLogFile = maxLogSize / MAX_NUM_OF_LOG_FILES
```

Here:

- `maxLogSize` specifies the total amount of space that file system log files can consume.
- `MAX_NUM_OF_LOG_FILES` specifies the total number of file system log files (5 hard coded).

For example, for a value of 10 GB, there will be 5 log files (`mfs.log-3` to `mfs.log-3.4`) of 2GB each.

Increasing Log Retention for CLDB

NOTE: This setting does not impact audit logging.

In the `/opt/mapr/conf/log4j2.cldb.xml` file, modify the `SizeBasedTriggeringPolicy` and `DefaultRolloverStrategy` properties.

- Modify the `size` attribute for `SizeBasedTriggeringPolicy` that specifies the size of each `cldb.log` before rolling over to write to a new log file. For example,

  ```
  <SizeBasedTriggeringPolicy size="1024MB"/>
  ```

- Modify the `max` attribute for `DefaultRolloverStrategy` that specifies the number of `cldb.log*` files to be retained before the oldest one is deleted. For example,

  ```
  <DefaultRolloverStrategy max="20" fileIndex="min"/>
  ```

With the aforementioned values for `SizeBasedTriggeringPolicy` and `DefaultRolloverStrategy`, the CLDB log files can grow to 20GB (1024*20), before they are purged.

IMPORTANT: You must restart CLDB on all nodes for the change in the values of CLDB log retention properties to take effect. Restart the passive CLDB nodes first, followed by restarting of the active CLDB node, so that the active CLDB node fails over to a passive CLDB node with the new values for CLDB log retention properties. Run the following command to restart a CLDB node.

```
maprcli node services -cldb restart -nodes $(hostname)
```

Increasing Log Retention for Hadoop Services

You can increase log retention for ResourceManager, NodeManager, HistoryServer, and TimelineServer by modifying the following properties in the `/opt/mapr/hadoop/hadoop-<Version>/etc/hadoop/log4j.properties` file:

- `hadoop.log.maxfilesize` — specifies the size of each `<service-name>-hostname>.log` before rolling over.
- `hadoop.log.maxbackupindex` — specifies the number of `<service-name>-<hostname>.log*` before the oldest one is deleted.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

For example, suppose the following configuration:

- `hadoop.log.maxfilesize` = 1024Mb
- `hadoop.log.maxbackupindex` = 10

There will be 10 GB of total service-specific logs (1GB per file) before the oldest file is purged.

Setting the Tracing Level

To check all the modules and their current logging levels, run the following command:

```
maprcli trace info
```

To set the tracing level for a module, run the `maprcli trace setlevel` command. For example:

```
maprcli trace setlevel -module FuseMonitor -level DEBUG
```

Configuring Profiling for Operations

To check the amount of time it took to complete each operation (from the time of submission), enable profiling for client RPC and file system operations. To enable profiling for:

- Client RPC, run the following command:

  ```
  fcdebug -s <shmid> -m ClntProfileRpc -1 DEBUG
  ```

  TIP: For more information, see `fcdebug`.

  Enabling profiling for the client RPC will allow you to determine, for each RPC, the amount of time it took to receive a response after submitting the request.

- file system operations, run the following command:

  ```
  maprcli trace setlevel -module FSProfile -level debug
  ```

  TIP: For more information, see `maprcli`.

  Enabling profiling for file system operations will allow you to determine the amount of time it took file system to process each operation.

By default, profiling is disabled for both client RPC and file system operations. Once enabled, the log for:

- Client RPC should look similar to the following:

  ```
  2016-06-16 10:58:04,6404 DEBUG ClntProfileRpc
  fs/client/fileclient/cc/client.cc:3483 Thread: 32188 Profile: CltRpcDone:
  server 10.10.100.196:5692 took 1 msec error 0 FID 2125.34.262486  Getattr

  2016-06-16 11:13:55,7480 DEBUG ClntProfileRpc

elapsedTm
28 client 10.10.100.196 err 0 FID: 2121.16.2 Isplus true
```

For example, to check the time it took for a read RPC, run the following command:

```
# cat /opt/mapr/logs/ffs.log* | grep -nrui "CltRpcDone" | grep -nrui "read"
| less
1009:1014:2016-06-16 11:21:51,8203 DEBUG ClntProfileRpc

2182.32.131232
off 7143424 len 131072 name 2125.34.262486
```

Archiving CLDB Logs

The CLDB logs can be archived by setting the value for the configuration parameter, `cldb.logarchiver.enabled`, using the maprcli config save command. The value can be:

- 0 — disable
- 1 — enable

To:

- Enable archiving, run the following command:

```
maprcli config save -values '{"cldb.logarchiver.enabled":"1"}'
```

- Disable archiving, run the following command:

```
maprcli config save -values '{"cldb.logarchiver.enabled":"0"}'
```

The default value for this parameter is 2, which indicates that the CLDB log archiving is disabled; but on clusters with 50 or more file system nodes, the CLDB log archiving will be automatically enabled unless the value is explicitly set to 0.

If/when archiving is enabled:

- All static CLDB log files, except the active `cldb.log` file, are periodically scanned and archived in `/var/mapr/cldblog/<hostname>` directory.

©Copyright 2024 Hewlett Packard Enterprise Development LP

- The filename for the archived log file is autogenerated based on the date and timestamp on the first log line in the file chosen for archival.

  For example, suppose a log file with the following first line:

  ```
  2017-04-06 12:42:16,020 INFO CLDB [main]: Loading properties file : /opt/
  mapr/conf/cldb.conf
  ```

  The archived log filename in `/var/mapr/cldblog/<hostname>` directory will be:
  `2017-04-06_12.42.16.020`

Enabling Runtime Logging

To enable logging at runtime for the file client (`libfsalmapr.so` library), run the `fcdebug` utility:

```
/opt/mapr/server/tools/fcdebug -s <shmid> -m <module> [-l <level>]
/opt/mapr/server/tools/fcdebug -i -s <shmid>
```

Before running this command, make a note of the following:

- If necessary, run `maprcli trace info` to retrieve the list of modules.

  The default value for module is all.

- Level should be one of FATAL, ERROR, WARN, INFO, DEBUG.

  If level is not specified, default level is applied for the module.

- The `-i` lists the current debug level of all modules.

- The `shmid` is available in the `fsal.log-*` files when `libMapRClient` is loaded.

  For example, the first line in the log file is something similar to the following:

  ```
  2017-02-13 11:56:32,6809 ERROR FuseAPI fs/client/fileclient/cc/
  fuse_api.cc:1371
  Thread: 428 Shmid to be used by fcdebug 512720897
  ```

  This `shmid` can be used with `fcdebug`.

NOTE: Run `fcdebug` once for every library (every library has a separate shared memory). The `shmids` can be found in the respective `fsal` log files.

Viewing Audit Logs

The following sections describe audit logs for execution of any maprcli command, REST API call, or action in Control System, and audit logs for cluster administration, file system, table, and stream operations.

Viewing Log Entries for Audited maprcli Command Executions
Describes where audit records of operations performed using the CLI are stored and how to view them.

The execution of any `maprcli` command on the cluster is logged in the local filesystem on the node on which the execution happened. The log file is `/opt/mapr/mapr-cli-audit-log/audit.log.json`. Auditing of CLI operations is always enabled, whether or not auditing is enabled for cluster-level operations with the `maprcli audit cluster` command.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Typical log entries provide a timestamp of the execution, the UID of the user who ran the command, the IP address from which the user ran the command, the command itself, and the status of the execution. Status codes are 0 for success and 1 for failure. The error messages field provides the reasons for failures.

Below are some typical log entries:

```
{"timestamp":
{"$date":"2015-06-15T11:45:56.434Z"},"uid":2147483632,"ipAddress":
"10.10.20.12","command":"volume info","arguments":
{"name":"mapr.opt"},"status":
1,"errors": ["Volume lookup of mapr.opt failed, No such volume"]}
{"timestamp":
{"$date":"2015-06-15T11:49:34.434Z"},"uid":2147483632,"ipAddress":
"10.10.20.12","command":"alarm add","arguments":{"baseService":"1","alarm":
"NODE_ALARM_SERVICE_GATEWAY_DOWN","service":"gateway","displayName":"Gateway
ServiceDown",
"serviceName":"GatewayService","terse":"nagwsd"},"status":1,"errors":
["Terse name of
nagwsd already exists in the system.","Alarm
NODE_ALARM_SERVICE_GATEWAY_DOWN already
exists in the system."]}
{"timestamp":
{"$date":"2015-06-15T11:49:52.598Z"},"uid":2147483632,"ipAddress":
"10.10.20.12","command":"volume create","arguments":
{"name":"mapr.hbase","path":"/hbase",
"replicationtype":"low_latency"},"status":1,"errors":["Volume Name
mapr.hbase, Already In Use"]}
```

Viewing Audit Logs for Cluster Administration
Describes where audit records of cluster administration operations are stored and how to view them.

Entries for audit logs are initially held in memory until 128 operations have been logged or 10 seconds have elapsed, whichever happens first. At that point, the new log entries are flushed to disk.

Audit logs are in JSON format, so they can be queried by Drill or processed by other third-party tools or your own scripts.

Audit logs are readable only by the `mapr` and `root` users on the cluster where the logs are located. These users can also copy and delete audit logs.

The `status` field in every log entry shows the status of the attempted operation. The status codes are taken from the Linux `errno.h` file. For a list of these codes, see Status Codes That Can Appear in Audit Logs.

Audit logs use Coordinated Universal Time (UTC) in the records of audited operations.

The cleanup of old audit log files is handled by Warden either when they are older than 10 days (the default retention time) or when they are older than the number of days set for the `log.retention.time` parameter in the `/opt/mapr/conf/warden.conf` file. To prevent Warden from removing the log files, by default, `cldbaudit*` and `authaudit*` are listed under the `log.retention.exceptions` parameter in the `warden.conf` file.

To enable Warden to automatically cleanup log files, remove `cldbaudit*` and `authaudit*` from the `log.retention.exceptions` parameter in the `warden.conf` file and, if you want a shorter cleanup time, set the value for `log.retention.time` parameter in the `warden.conf` file. The value for `log.retention.time` must be specified in milliseconds.

To disable all exceptions, comment out the `log.retention.exceptions` parameter, that is, `#log.retention.exceptions`. When this parameter is null, that is, `log.retention.exceptions=`, no files are picked for log cleanup.

Viewing Audit Logs for File System, Table, and Stream Operations
Describes where file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Streams audit logs are stored and how to view them.

Operations on the HPE Ezmeral Data Fabric file, database, and event data are captured and recorded in the audit logs. The operations take place within volumes and have effects at the level of the file system.

These audit logs are stored in a system volume created specifically to store them. This volume is created automatically during cluster installations and upgrades. Operations are logged on the nodes on which the operations are executed, which could differ from the nodes where operations are initiated. Logs are stored in the file system at `/var/mapr/local/<node_name>/audit/`. By default, only root and the cluster administrator (typically `mapr`) can read the log files. To allow other users to read the logs, set ACEs on the directory granting `readfile` (`rf`), `readdir` (`rd`), and `lookupdir` (`ld`) permissions to the users. For example:

```
~# hadoop mfs -setace -R -aces "rf:u:root|u:mapr|u:m7user1,rd:u:root|u:mapr|
u:m7user1,ld:u:root|u:mapr|u:m7user1" /var/mapr/local/sample.qa.lab/audit/
```

NOTE: For more information, see Enabling Volume, Directory, and File Authorizations with ACEs on page 1845.

Audit logs for operations on directories and files

Operations on directories and files, as well as the deletion of HPE Ezmeral Data Fabric Database tables, are logged in files that have this naming convention: `FSAudit.log.json-dd-mm-yyyy-<001-999>`

To see what information is recorded in typical log entries, see Example Log Entries for Audited File System Operations.

Audit logs for operations on HPE Ezmeral Data Fabric Database tables and HPE Ezmeral Data Fabric Streams

All operations on HPE Ezmeral Data Fabric Database tables and HPE Ezmeral Data Fabric Streams are logged in files that have this naming convention: `DBAudit.log.json-dd-mm-yyy-<001-999>`

Operations that result from maprcli commands, REST calls, or activity in MCS are also logged in `/opt/mapr/mapr-cli-audit-log/audit.log.json` on the local file system of the nodes where the operations are processed.

To see what information is recorded in typical log entries, see Example Log Entries for Audited Operations on HPE Ezmeral Data Fabric Database Binary and JSON Tables on page 3156.

NOTE: Due to how the creation of tables is processed internally, sometimes the creation of tables is logged in `FSAudit.log.json`, rather than in `DBAudit.log.json`.

Common Features of Audit Logs for File System, Table, and Stream Operations

Entries for audit logs are initially held in memory until 128 operations have been logged or 10 seconds have elapsed, whichever happens first. At that point, the new log entries are flushed to disk, depending on the *coalesce* interval.

The coalesce interval represents the interval of time during which READ, WRITE, or GETATTR operations on one file from one client IP address and UID/GID are logged only once for a particular operation, if auditing is enabled.

For example, suppose that a client application reads a single file three times in 6 minutes, so that there is one read at 0 minutes, another at 3 minutes, and a final read at 6 minutes. If the coalesce interval is at least 6 minutes, then only the first read operation is logged. However, if the interval is between 4 minutes, then only the first and third read operations are logged. If the interval is 2 minutes, all three read operations are logged.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Now however, if the client was also writing to the file, irrespective of the coalesce interval for the read operation in the example stated previously, the write operation is logged, as it is a different operation from reading.

The default value is 60 minutes. Setting this field to a larger number helps prevent audit logs from growing quickly. To change the coalesce interval, see volume audit on page 2583.

Audit logs are in JSON format, so they can be queried by Drill or processed by other third-party tools or your own scripts.

Audit logs are readable only by the `mapr` and `root` users on the cluster where the logs are located. These users can also copy and delete audit logs.

The status field in every log entry shows the status of the attempted operation. The status codes are taken from the Linux `errno.h` file. For a list of these codes, see Status Codes That Can Appear in Audit Logs.

Audit logs use Coordinated Universal Time (UTC) in the records of audited operations.

When operations are performed on directories, files, or tables that are being audited, the full names for those objects, as well as the current volume and the name of the user performing the operation, are not immediately available to the auditing feature. What are immediately available are IDs for those objects and users. Converting IDs to names at run-time would be costly for performance. Therefore, audit logs contain file identifiers (FIDs) for directories, files, and tables; volume identifiers for volume; and user identifiers (UIDs) for users.

You can resolve identifiers into names by using the expandaudit utility. This utility creates a copy of the log files for a specified volume, and in that copy are the names of the file system objects, users, and volumes that are in the audit log records. You can then query or process the copy.

A sample of the logs is as follows:

```
{"timestamp":
{"$date":"2021-07-14T13:05:01.506Z"},"resource":"test-audit-logs","operation
":"volumeMirrorPermCheck","username":"root","uid":0,"clientip":"10.163.167.2
14","status":0}
{"timestamp":
{"$date":"2021-07-14T08:44:01.553Z"},"resource":"255","operation":"volumeLoo
kup","username":"root","uid":0,"clientip":"10.163.167.214","status":2}
```

NOTE: There will be an entry in the audit log for each IP address on a node. For example, suppose there is a node with multiple IP addresses. The audit log on this node may show multiple entries of the same operation, each associated with a different IP address.

NOTE: The number of bytes read or written is not recorded.

Example Log Entries for Audited File System Operations

When auditing of file system operations is enabled at the cluster level, volume level, and file system level, each operation on a directory or file is logged on the node on which the operation was initiated.

Typical log entries provide a timestamp of the operation, the type of operation, the UID of the user who ran the command, the IP address from which the user ran the command, identifiers of the affected resources, the volume identifier, and the status of the operation. Status codes come from the Linux `errno.h` file. For a list of these codes, see Status Codes That Can Appear in Audit Logs.

NOTE: Due to the way that the creation of tables is processed internally, sometimes the creation of tables is logged in `FSAudit.log.json`, rather than in `DBAudit.log.json`.

Below are some typical log entries:

```
{"timestamp":
{"$date":"2015-06-06T10:44:22.800Z"},"operation":"MKDIR","uid":0,"ipAddress"
:
```

"volumeId":"68048396","status":"0"}
```

Example Log Entries for Audited Operations on HPE Ezmeral Data Fabric Database Binary and JSON Tables

When auditing of table operations is enabled at the cluster level, volume level, and file system level, each operation on a table is logged on the node where the operation was executed, which could differ from the node where the operation was initiated.

Typical log entries provide a timestamp of the operation, the type of operation, the UID of the user who ran the command, the IP address from which the user ran the command, identifiers of the affected resources,

©Copyright 2024 Hewlett Packard Enterprise Development LP

and the status of the operation. Fields such as “ColumnFamily” and “Column” for some operations are also included when applicable. Row keys are not included. Status codes come from the Linux `errno.h` file. For a list of these codes, see Status Codes That Can Appear in Audit Logs.

NOTE: Due to the way that the creation of tables is processed internally, sometimes the creation of tables is logged in `FSAudit.log.json`, rather than in `DBAudit.log.json`.

NOTE: Audit logs do not display the indices of array elements when there are put or update operations on arrays that are in documents within JSON tables.

Below are some typical log entries:

```
{"timestamp":
{"$date":"2015-06-06T11:31:02.621Z"},"operation":"DB_GET","uid":0,"ipAddress
":
"10.10.105.51","volumeId":48210891,"tableFid":"2751.77.131402","status":0}
{"timestamp":
{"$date":"2015-06-06T11:31:02.623Z"},"operation":"DB_SCAN","uid":0,"ipAddres
s":
"10.10.104.51","volumeId":48210891,"tableFid":"2751.77.131402","status":0}
{"timestamp":
{"$date":"2015-06-06T11:31:02.624Z"},"operation":"DB_PUT","uid":0,"ipAddress
":
"10.10.104.51","volumeId":48210891,"columnFamily":"cf0","columnQualifier":"c
0","tableFid":
"2751.77.131402","status":0}
```

To convert the user IDs to usernames, file identifiers to pathnames, and volume IDs to volume names, run the expandaudit utility. For example, here are the same audit records after they were processed by this utility:

```
{"timestamp":
{"$date":"2015-06-06T11:31:02.621Z"},"operation":"DB_GET","uid":0,"ipAddress
":
"10.10.105.51","VolumeName":"mapr.cluster.root","volumeId":48210891,"tablePa
th":
"/ycsb1433588330006/ycsbTable0","status":0}
{"timestamp":"{$date=2015-06-06T11:03:16.721Z}","operation":"DB_SCAN","user"
:"root","uid":
"0","ipAddress":"10.10.105.51","VolumeName":"mapr.cluster.root","volumeId":"

amily":"cf0",
"columnQualifier":"c0","tablePath":"/ycsb1433588330006/
ycsbTable0","status":0}
```

Managing Audit Logs for File System and Table Operations

There are three parameters that you can use to manage audit logs for file system and table operations:

- `-maxSize`
- `-retention`
- `-coalesce`

You can set the first two parameters with the maprcli audit data command. You can set the third parameter with the maprcli volume audit command.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Effects of the -maxSize parameter

When you enable auditing with the audit data on page 2024`maprcli audit data` command, you can use the `-maxSize` parameter to specify the size at which an alarm is raised concerning the size of the audit volume. The alarm is displayed on the dashboard in the Control System and in the output of the alarm list on page 2011`maprcli alarm list` command. This alarm simply means that the threshold size has been reached. Audited operations are still logged to the audit volume in question.

There are three actions that you can take:

- If you decide that you want to be notified when the audit volume reaches a smaller or larger size, you can change the threshold by running the `maprcli audit data` command and changing the value of the `-maxSize` parameter.
- If you want to try preventing audit log files from growing as quickly as they are, you can change the number of identical operations that are logged within a number of minutes. Run the `maprcli audit data` command and increase the value of the `-coalesce` parameter. This parameter is described subsequently.
- If you are concerned about longer-term space requirements for storing audit log files, you can change the number of days to keep old log files before they are deleted. Run the `maprcli audit data` command and decrease the value of the `-retention` parameter. This parameter is also described below.

Effects of the -retention parameter

When you enable auditing with the `maprcli audit data` command, you can use the `-retention` parameter to specify how many days to keep old log files.

Audit logs are rotated every night at midnight UTC time . The saved audit logs are kept until the retention period expires.

For example, suppose the retention period is 30 days. The node 192.168.10.15 in the volume `/myVolume` contains 30 days of saved log files for file-system operations and the current date is March 30, 2016. The directory `/var/mapr/local/102.168.10.15/audit/` contains these log files:

```
FSAudit.log.json-30-03-2016-001
FSAudit.log.json-29-03-2016-001
FSAudit.log.json-28-03-2016-001
...
FSAudit.log.json-01-03-2016-001
```

NOTE: If MFS is restarted on the same day, audit logs gets rotated, and new files with convention -002, -003, and so on are created with each restart.

If there is no more disk space for new entries in audit logs, audit logging stops.

If the size of the audit log volume exceeds its quota, an alarm is raised, though logging continues. The alarm is `VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED`. You can view alarms in the Control System or by running the command `maprcli alarm list`. The default quota is 32 GB.

Effects of the -coalesce parameter

The coalesce on page 6520parameter represents the interval of time during which READ, WRITE, or GETATTR operations on one file from one client IP address and UID/GID are logged only once for a particular operation, if auditing is enabled.

For example, suppose that a client application reads a single file three times in 6 minutes, so that there is one read at 0 minutes, another at 3 minutes, and a final read at 6 minutes. If the coalesce interval is at

©Copyright 2024 Hewlett Packard Enterprise Development LP

least 6 minutes, then only the first read operation is logged. However, if the interval is between 4 minutes, then only the first and third read operations are logged. If the interval is 2 minutes, all three read operations are logged.

Now however, if the client was also writing to the file, irrespective of the coalesce interval for the read operation in the example stated previously, the write operation is logged, as it is a different operation from reading.

The default value is 60 minutes. Setting this field to a larger number helps prevent audit logs from growing quickly.

Status Codes That Can Appear in Audit Logs

In the `status` field in entries in audit logs, numeric codes other than 0 for success can appear. For the list of possible codes, their keyword equivalents, and descriptions, refer to the standard Linux `errno-base.h` and `errno.h` files. The `authaudit.log.json` file contains HTTP status codes. See HTTP Status Codes for more information.

Viewing Application Logs

You can use logs to view the status and analyze the execution of applications in a cluster.

To view the status or to access logs for running applications, you can use the user interface associated with the YARN framework.

- For MapReduce version 2 or non-MapReduce applications, access the ResourceManager user interface from the Control System to view the status and logs for a particular application.

For completed applications, the distributed nature of YARN frameworks can make analyzing the execution of applications difficult because tasks and containers are scattered throughout the cluster. Without centralized or aggregated logging, you must manually access all the log files for a completed application by merging the log details for a particular application across multiple nodes in the cluster. With centralized or aggregated logging, you can can access all the logs for a completed application in a centralized location. However, the steps to access logs for completed applications differ based on the configured logging option.

Logging Options

In a HPE Ezmeral Data Fabric cluster, the logging option that you configure defines how the logs are stored and accessed:

- **Centralized logging.** The logs are written to local volumes on the file system.
- **YARN log aggregation.** The logs are written to the local file system, and then the container logs from each node are aggregated and stored on the file system.
- **Local logging.** The log files for each job or application are written to the local file system. This method is the default behavior for MapReduce version 2 (MRv2) applications and non-MapReduce applications.
  - For MRv2 or other applications that run on YARN, the logs are written to the following directory on the local file system: `/opt/mapr/hadoop/hadoop-2.x.x/logs/userlogs/`

The logging options that you can choose from are determined by the type of jobs or applications that you run:

Type of Job or Application	Available Logging Options
MRv2	• Centralized logging • YARN log aggregation • Local logging (default)

©Copyright 2024 Hewlett Packard Enterprise Development LP

Type of Job or Application	Available Logging Options
YARN applications (non-MapReduce)	• YARN log aggregation • Local logging (default)

If you enable centralized logging for MRv2, the MapReduce applications uses centralized logging, while the other YARN applications in the cluster use local logging.

NOTE: Select a logging option that stores the logs on the file system for the following reasons:

- Prevent job or application failures due to a lack of space on the local file system for logs.
- Prevent the loss or inaccessibility of logs due to node failure. Logs stored in a local volume are two-way replicated.

YARN Log Aggregation

The YARN Log Aggregation option aggregates and moves log files for completed applications from the local file system to the HPE Ezmeral Data Fabric . This allows users to view the entire set of logs for a particular application using the HistoryServer UI or by running the `yarn logs` command.

By default, YARN container logs are not aggregated on the Data Fabric . Instead, the logs are retained for 3 hours on the local file system before they are deleted. To enable YARN log aggregation or to edit the configuration of YARN log aggregation, you must edit the `yarn-site.xml` file in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/`

Enabling YARN Log Aggregation

To enable YARN log aggregation, add or edit the following properties in `yarn-site.xml`:

- Set the value of the `yarn.log-aggregation-enable` to `true`.
- Configure the `yarn.log.server.url` property to contain the URL of the YARN HistoryServer, which should look like the following:

secure cluster	`https://<historyserver-host>:19890/jobhistory/logs`

- Optional: Set the `yarn.nodemanager.remote-app-log-dir` value to a location in the HPE Ezmeral Data Fabric file system. By default, the location is `maprfs:///tmp/logs`.
- Optional: Set the `yarn.nodemanager.remote-app-log-dir-suffix` value to the name of the folder that should contain the logs for each user. By default, the folder name is `logs`.

Aggregated logs are owned by the user who runs the job. For example, if user **`admin`** runs a job, the logs are stored to `maprfs:///tmp/logs/admin`. If user **`analyst`** runs a job, the logs are stored to `maprfs:///tmp/logs/analyst`. If these two users do not share the same UNIX group, they will be unable to see each other's logs.

NOTE: If centralized logging and YARN log aggregation are enabled, the logs for MapReduce version 2 applications are managed by Centralized Logging while the logs for non-MapReduce applications are managed by YARN log aggregation.

Enabling YARN Local-Node Log Aggregation

The steps in this procedure configure log aggregation for NodeManager processes, enabling you to store the logs on nodes (node-local volumes) where the YARN containers are launched.

©Copyright 2024 Hewlett Packard Enterprise Development LP

To enable YARN local-node log aggregation, add or edit the following properties in the `yarn-site.xml` file:

1. Set the `yarn.node-local-log-aggregation.enable` value to `true`.

   NOTE: The default setting for YARN Log Aggregation (`yarn.log-aggregation-enable`) should be removed or set to `false` in the `yarn-site.xml` file.

2. Optional: Set the `yarn.node-local-log-aggregation.metadata-path` value to a location in the system. By default the location is `maprfs:///NM_REMOTE_APP_LOG_DIR/<user>/logsMeta`. `NM_REMOTE_APP_LOG_DIR` should match the `yarn.nodemanager.remote-app-log-dir` property.

   NOTE: The location should not be an absolute path (the location begins from `/`). In the file system (`maprfs`), the default setting for NM_REMOTE_APP_LOG_DIR is `/tmp/logs`.

3. Optional: Set the `node-local-log-aggregation.metadata-filename` value to the name of the metafile that should contain the information about containers for each node. By default, the file name is `containers.seq`. If you use default paths, the file is stored at `/tmp/logs/${user}/logsMeta/<appId>/<nodeName>/containers.seq`.

4. Restart NodeManager and HistoryServer services.

Aggregated logs are owned by the user who runs the job.

Different users cannot see each other's logs. For example, if the HPE Ezmeral Data Fabric user **`admin`** runs a job, the logs are stored in `maprfs:///var/mapr/local/<nodeNames>/mapred/nodeManager/logs/admin/<appId>`. If a user **`analyst`** runs a job, the logs are stored in `maprfs:///var/mapr/local/<nodeNames>/mapred/nodeManager/logs/analyst/<appId>`.

Viewing Logs for Completed Applications

With YARN log aggregation, you can use yarn commands or the HistoryServer UI to access logs for completed applications.

View Application Logs from the Command Line

About this task

Get the application ID and then view log files for the application.

Get the Application ID

To get the application ID for an application that is in a "running" state, you can run the following command:

```
yarn application -list
```

However, if you run `yarn application -list` after a job completes, the command will not return any information.

To get the application ID for an application in any state (submitted, accepted, or running), run the following command:

```
yarn application -list -appStates ALL
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

The `yarn appication -list` command returns information similar to the following, including the application ID:

```
20/10/19 14:57:51 INFO
client.MapRZKBasedRMFailoverProxyProvi
der: Updated RM address to
node1.cluster.com/192.168.33.11:8032
Total number of applications
(application-types: [] and states:
[SUBMITTED, ACCEPTED, RUNNING]):1
Application-Id Application-Name
Application-Type User Queue State
Final-State Progress Tracking-URL
application_1603118361219_0002
QuasiMonteCarlo MAPREDUCE mapr
root.mapr ACCEPTED UNDEFINED 0% N/A
```

View Application Logs

Run the following command to view log files for an application:

```
yarn logs -applicationId
<application-ID>

//Example: yarn logs -applicationId
application_1603118361219_0002
```

Using UI to View Logs for Completed Applications

Explains how to view HistoryServer logs using the graphical interface.

About this task

You can view the logs for completed applications through the Control System and by directly accessing the HistoryServer UI.

Using the Control System to View the HistoryServer Logs for Completed Applications

Procedure

1. Log on to the Control System and click **Services** to display the list of services.

   NOTE: The **Services** menu is not available on the Kubernetes version of the Control System.

2. Click the **History Server** link in the list of services to display the **JobHistory** page in a new tab.
3. Click the job ID link for the job you want to view the logs for.
4. Click the logs link in the **Logs** column of the **Application Master** section.

Using the HistoryServer UI to View Logs for Completed Applications

Procedure

1. Open a browser and go to the following URL to open the JobHistory page:

   Non-secure cluster

   ```
   http://<IP address of HistoryServer
   node>:19888
   ```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Secure cluster	`https://<IP address of HistoryServer node>:19890`

2. Click the job ID link for the job for which you want to view the logs.
3. Click the logs link in the **Logs** column of the **Application Master** section.

Editing the Retention Settings of Aggregated Logs

About this task

By default, aggregate logs are stored on the HPE Ezmeral Data Fabric file system for 30 days. The retention time for aggregated logs also applies to centralized logs.

To edit the retention settings, add or edit the following properties in the *yarn-site.xml* file:

Procedure

1. Set the value of `yarn.log-aggregation.retain-seconds` to the duration that the logs are maintained. If you set a negative value for `yarn.log-aggregation.retain-seconds`, logs arre not deleted.

   NOTE: The duration specified by `yarn.log-aggregation.retain-seconds` starts from the time that the application starts running. Therefore, if you configure the duration, be sure to consider how long you want the log to remain in addition to the amount of time that the application will take to run. For example, if you expect most applications to take 20 seconds to run, do not set the value of this property to 20 seconds because the log might be deleted as soon as the applications completes.

2. Optionally, set the `yarn.log-aggregation.retain-check-interval-seconds` to specify how often the log retention check should be run. By default, it is one-tenth of the log retention time.

Results

For more details about the properties that impact the YARN container logs and the aggregation option, see yarn-site.xml.

Centralized Logging

Describes the centralized logging feature of HPE Ezmeral Data Fabric.

Data Fabric's Centralized Logging feature provides a job-centric or application-centric view of all log files generated by a MapReduce program. With centralized logging, the log files are written to local volumes in the Data Fabric filesystem. You can run the `maprcli job linklogs` command for running or completed jobs to create a centralized log directory populated with symbolic links to all log files pertaining to the specified jobs or to the application.

Managing Centralized Logs for MapReduce Version 2 Applications

To manage centralized logs for MapReduce Version 2 applications, enable centralized logging, configure log retention, and view application logs.

Enabling Centralized Logging for MapReduce Version 2

Describes how to enable central logging for MapReduce version 2 applications.

About this task

As of MapR version 4.0.2, you can use centralized logging for MapReduce version 2 applications. However, this feature is disabled by default. In MapR version 4.0.1, centralized logging is not supported for MapReduce version 2 applications.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Procedure

- Configure the `yarn.use-central-logging-for-mapreduce-only` property in the `yarn-site.xml` file to enable or disable centralized logging.

  The `yarn-site.xml` file is located in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/`.

  - To disable centralized logging, remove the property `yarn.use-central-logging-for-mapreduce-only` from the `yarn-site.xml` file, or set the value of `yarn.use-central-logging-for-mapreduce-only` to `false` in the `yarn-site.xml` file.
  - To enable centralized logging, set the value of `yarn.use-central-logging-for-mapreduce-only` to `true` in the `yarn-site.xml` file. If you enable centralized logging while applications are running, restart all ResourceManagers. In a production cluster, restart ResoureManagers one at a time to prevent interruption to the running applications. The applications running during this process may not have centralized logging enabled.

Configuring Log Retention Time for MapReduce Version 2 Applications

Lists the parameter that controls the log retention time for MapReduce applications.

Procedure

- Set the value of `yarn.log-aggregation.retain-seconds` to the number of seconds you want to retain the logs once the application starts in the `yarn-site.xml` file.

  The value defaults to 30 days. The value that you set for this property also applies to the retention of aggregated YARN logs.

  The `yarn-site.xml` file is in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`.

Viewing Logs for Completed MapReduce Version 2 Applications

With centralized logging, you can use maprcli or the HistoryServer user interface to access completed logs.

Using the Command Line to View Logs for Completed Applications

Describes how to view logs from the CLI.

Procedure

1. Use the `maprcli job linklogs` command to create centralized logs for completed applications. For example, you can run the following `maprcli job linklogs` command to create centralized logs for `application_1434605941718_0001:`

   ```
   maprcli job linklogs -jobid application_1434605941718_0001 -todir /logsdir
   ```

   The centralized log directory contains symbolic links that are organized by hostname and containerID.

©Copyright 2024 Hewlett Packard Enterprise Development LP

2. To determine where the logs are located, run the following command on the directory that contains the symlinks to the log files for a specific container:

   ```
   hadoop mfs -ls <todir>/<applicationID>/hosts/<hostName>/<containerID>
   ```

   For example, if you specified `logsdir` as the directory, you might issue a command similar to the following example. The system then displays the location of the log files:

   ```
   hadoop mfs -ls /logsdir/application_1434605941718_0001/hosts/
   qa-node178.qa.lab/container_e02_1434605941718_0001_01_000003

   Found 1 items
   lrwxrwxrwx U U U 3 root root 138 2015-06-18 05:50 0
   /logsdir/application_1434605941718_0001/hosts/qa-node178.qa.lab/
   container_e02_1434605941718_0001_01_000003
   ->
   ../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/userlogs/
   application_1434605941718_0001/container_e02_1434605941718_0001_01_000003
   p 2068.40.262432 qa-node178.qa.lab:5660 qa-node175.qa.lab:5660
   ```

   The link location appears after the arrow.

3. To determine the types of log files that are available for this container and the path to each available log file, run the following command:

   ```
   hadoop fs -ls <link location>
   ```

   For example:

   ```
   hadoop fs -ls ../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/
   userlogs/application_1434605941718_0001/
   container_e02_1434605941718_0001_01_000003

   -rw-r-----   2 root root       2337 2015-06-18 05:48
   ../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/userlogs/
   application_1434605941718_0001/
   container_e02_1434605941718_0001_01_000003/syslog
   ```

   In this example, the path to the syslog is the only one that is displayed in the output. However, the stdout or stderr may also be available depending on what is generated by the application.

4. Run one of the following options to view the contents of a log file:
   a) To view the end of the log file, run `hadoop fs -tail <path to log file>`.

      ```
      hadoop fs -tail ../../../../var/mapr/local/
      qa-node178.qa.lab/logs/yarn/userlogs/application_1434605941718_0001/
      container_e02_1434605941718_0001_01_000003/syslog
      ```

   b) To view the entire log file, run `hadoop fs- cat <path to log file>`.

      ```
      hadoop fs- cat ../../../../var/mapr/local/
      qa-node178.qa.lab/logs/yarn/userlogs/application_1434605941718_0001/
      container_e02_1434605941718_0001_01_000003/syslog
      ```

Using the HistoryServer UI to View Logs for Completed Applications
: Describes how to view logs using the HistoryServer interface.

©Copyright 2024 Hewlett Packard Enterprise Development LP

About this task

You can view the logs in the HistoryServer interface.

View Logs in the HistoryServer Interface Launched Using the Control System

Procedure

1. Log on to the Control System and click **Services** to display the list of services installed on the cluster.
2. Click the HistoryServer link in the list of services to open the **Job History** page in a new tab.
3. Click the Job ID link for the job for which you want to view the logs.
4. Click the logs link in the **Logs** column of the **Application Master** section.

View Logs Using the HistoryServer Interface

Procedure

1. Go the URL similar to the following example, to open the Job History page:

   ```
   <IP address of HistoryServer node>:19888
   ```

2. Click the Job ID link for the job for which you want to view the logs.
3. Click the logs link in the **Logs** column of the **Application Master** section.

Viewing the Service Log

Esplains how to view service logs using Kibana.

About this task

If Kibana is installed on the node, you can view the service log in the Kibana UI from the Control System. To view the log in the Kibana UI from the Control System:

Procedure

1. Log in to the Control System and do one of the following:
   - Click **Services** to display the list of services installed on the cluster.
   - Go to the **Summary** tab in the service information page for the service.
2. Click in the **Log Viewer** column to view the log for the associated service in the Kibana UI.
   See Kibana User Guide for more information.

Cluster Maintenance Schedule

Lists a sample maintenance schedule for the cluster.

A maintenance schedule shows which tasks a cluster administrator should perform daily, weekly, monthly, and quarterly, along with the initial setup tasks. This sample schedule is offered as a template that you can customize to suit your needs.

Initial Setup	Daily	Weekly	Monthly	Quarterly
Perform hardware checks	Check alarms	Check logs (cluster and job logs)	Clean up logs	Audit storage use
Check Prerequisites	Onboard new users	Check for zombie jobs	Reevaluate node and volume topology	Perform security audit

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Initial Setup	Daily	Weekly	Monthly	Quarterly
Verify Installation	Offboard users	Perform simple performance test	Check performance (jobs, I/O)	Upgrade core, Hive, HCatalog
High Availability planning	Check cluster health	Verify snapshots	Verify mirrors	
Set up VIPs for NFS for the HPE Ezmeral Data Fabric	Perform hardware maintenance (disks)	Remove old snapshots	Clean up data	
Benchmark and tuning		Failbacks to restore service layout	file system balancing	
Set up node and volume topologies				
Capacity planning			Upgrade ecosystem components (other than Hive and HCatalog, which are done quarterly)	
Set up user permissions (ACLs, directory permissions, users, home directories)				
Set up quotas				
Set up compression				
Configure cluster queues for MapReduce jobs				
Set up schedules (fair scheduler, capacity scheduler, job placement)				
Set up snapshots and mirrors				
Configure NICs				
Set up monitoring tools				
Set up security				
Create a disaster recovery plan				

Language Support for HPE Ezmeral Data Fabric Database Tables

This section lists the human languages that HPE Ezmeral Data Fabric tables can store, retrieve, and process.

Data Fabric tables can store, retrieve, and process data in the following languages:

A

Abaza Abkhazian Achinese Acoli Adangme Adyghe Afar Afrikaans Aghem Ainu Akan Akkadian Akoose Albanian Aleut Amharic Amo Ancient Egyptian Ancient Greek Angika Arabic Aragonese Aramaic Arapaho Arawak Armenian Aromanian Assamese Assyrian Neo-Aramaic Asturian Asu Atikamekw Atsam Avaric Avestan Awadhi Aymara Azerbaijani

Troubleshooting Cluster Administration

Lists the common errors and their solutions.

The following list identifies how to address several cluster administration issues:

The URL reported by YARN for tracking job details does not load.	This URL uses the output of the `hostname -f` command, which must be the fully qualified domain name (FQDN) for the node. On Ubuntu, make sure that the */etc/hostname* file is configured with the node's FQDN. On CentOS/Redhat, make sure that the */etc/sysconfig/network* file is configured with the node's FQDN, then restart the node.
The ResourceManager does not start.	If the ResourceManager does not come up, check the following: • Check that you supplied the correct ResourceManager hostname or IP address in the `-RM` parameter when running configure.sh on each node at installation time. If you are not sure, you can re-run configure.sh to correct the problem. • Do not specify a ResourceManager port with the hostname or IP address in the `-RM` parameter; there is no `<port>` option. • Make sure that you specified the same ResourceManager hostname or IP address on all nodes when running configure.sh. • For more information about what might be causing a problem, check the ResourceManager logs:*/opt/mapr/hadoop/hadoop-<version>/logs*
The NodeManager does not start.	If the NodeManager does not come up, check the following: • Make sure that the fileserver role is installed on the node by looking in the */opt/mapr/roles* directory. • Make sure that the fileserver service is running, using either the service list command or the Control System. • For more information about what might be causing a problem, check the NodeManager logs:*/opt/mapr/hadoop/hadoop-2.3.0/logs*
Job history is not available.	If job history is not recorded, check the following: • Make sure that the HistoryServer role is installed on the desired node by looking in the */opt/mapr/roles* directory. Note that only one node in the cluster can have the HistoryServer role.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- Make sure the HistoryServer is running on the desired node, using either the service list command or the Control System.
- Check that you supplied the correct HistoryServer hostname or IP address in the `-HS` parameter when running configure.sh on each node at installation time. If you are not sure, you can re-run configure.sh to correct the problem.

Submitted applications do not show up in the ResourceManager.

If you submit an application and it does not appear in the ResourceManager, check the following:

- Make sure the application is running in YARN and not as a local application (check for *app_local* or *job_local* in the application output).
- Check the class path on which the application was invoked, and make sure that */opt/mapr/hadoop/hadoop-<version>/etc/hadoop* includes the class paths.
- Make sure that you are running the correct version of Hadoop. Example:

```
ls -l /usr/bin/hadooplrwxrwxrwx 1
root root 40
   Mar
4 11:38 /usr/bin/hadoop -> /opt/
mapr/hadoop/hadoop-2.3.0/bin/hadoop
```

The application throws a ClassNotFound exception at job submission time.

If you submit an application and it throws the ClassNotFound exception, check the following:

- Check that the application jar is correctly packaged with the required class.
- Make sure that you are running the correct version of Hadoop. Example:

```
ls -l /usr/bin/hadooplrwxrwxrwx 1
root root 40
   Mar
4 11:38 /usr/bin/hadoop -> /opt/
mapr/hadoop/hadoop-2.3.0/bin/hadoop
```

I want to move the HistoryServer and ResourceManager to different nodes.

If you have installed the HistoryServer and the ResourceManager on the same node (when you initially ran configure.sh you did not specify the `-HS` parameter, or you specified the same IP address or hostname for both the `-RM` and `-HS` parameters), you can use configure.sh to move one or both services to different nodes. Make sure to specify both the `-HS` parameter and the `-RM` parameter, because if you only specify the `-RM` parameter the HistoryServer will move to the ResourceManager node.

Timing issue prevents services from starting on a secure cluster.

If your cluster has security features enabled, you may encounter a timing issue that results in services failing to start during initial configuration with the `-F` option. (This issue does not arise if you are bringing up a cluster that has already been installed and configured.)

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

When you run the configure.sh script with the `-F` option, the ZooKeeper and Warden services start up on the primary node first, then as other nodes are installed, services are automatically started on those nodes. However, because of this timing issue, Warden may fail to communicate with ZooKeeper, and the cluster may fail to come up.

If you encounter this problem, do not use the `-F` option. Instead, stop all ZooKeeper and Warden services on all nodes, then start the ZooKeeper services on all of the ZooKeeper nodes (that is, the nodes where the ZooKeeper packages are installed). Finally, start the Warden services on all nodes.

How to find a node's serverid.

Some `maprcli` commands take an argument `serverid`, which is an unique identifier for each node in a cluster. This id is also sometimes referred to as the *node id*.

To find the `serverid`, use the maprcli node list command, which lists information about all nodes in a cluster. The `id` field is the value to use for `serverid`.

For example:

```
maprcli node list -columns hostname,id
   id                   hostname
ip
   4800813424089433352  node-28.lab
10.10.20.28
   6881304915421260685  node-29.lab
10.10.20.29
   4760082258256890484  node-31.lab
10.10.20.31
   8350853798092330580  node-32.lab
10.10.20.32
   2618757635770228881  node-33.lab
10.10.20.33
```

You can also get this listing as a JSON object by using the `-json` option. For example:

```
maprcli node list -columns
id,hostname -json
   {
        "timestamp":1358537735777,
        "status":"OK",
        "total":5,
        "data":[
                {

"id":"4800813424089433352",

"ip":"10.10.20.28",

"hostname":"node-28.lab"
                },
                {

"id":"6881304915421260685",

"ip":"10.10.20.29",
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
"hostname":"node-29.lab"
                },
                {

"id":"4760082258256890484",

"ip":"10.10.20.31",

"hostname":"node-31.lab"
                },
                {

"id":"8350853798092330580",

"ip":"10.10.20.32",

"hostname":"node-32.lab"
                },
                {

"id":"2618757635770228881",

"ip":"10.10.20.33",

"hostname":"node-33.lab"
                }
        ]
   }
```

Error 'mv Failed to rename maprfs...' when moving files across volumes.

Prior to version 2.1, you cannot move files across volume boundaries in the HPE Ezmeral Data Fabric Platform. You can move files within a volume using the `hadoop fs -mv` command, but attempting to move files to a different volume results in an error of the form "`mv: Failed to rename maprfs://<source path> to <destination path>`".

As a workaround, you can copy the file(s) from source volume to destination volume, and then remove the source files.

The example below shows the failure occurring. In this example directories `/a` and `/b` are mount-points for two distinct volumes.

```
hadoop fs -ls /
   Found 2 items
   drwxrwxrwx   - root root
0 2011-12-02 15:14 /a
   drwxrwxrwx   - root root
0 2011-12-02 15:09 /b

hadoop fs -put testfile /a
hadoop fs -ls /a
   Found 1 items
   -rwxrwxrwx   3 root root
2048000 2011-12-02 15:18 /a/testfile

root@node1:~# hadoop fs -mv /a/
testfile /b
   mv: Failed to rename maprfs://
10.10.80.71:7222/a/testfile to /b
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

The following example shows the work-around, moving a file `/a/testfile` to directory `/b`, and then removing the source file.

```
hadoop fs -cp /a/testfile /b/testfile
hadoop fs -ls /b
   Found 1 items
   -rwxrwxrwx   3 root root
2048000 2011-12-02 15:19 /b/testfile

hadoop fs -rmr /a/testfile
   Deleted maprfs://
10.10.80.71:7222/a/testfile

hadoop fs -ls /a
```

This workaround is only necessary if `/a` and `/b` correspond to different volumes.

'ERROR com.mapr.baseutils.cldbutils.CLDBRpcCommonUtils' in cldb.log, caused by mixed-case cluster name in mapr-clusters.conf.

HPE Ezmeral Data Fabric cluster names are case sensitive. However, some versions of MapR v1.2.x have a bug in which the cluster names specified in `/opt/mapr/conf/mapr-clusters.conf` are not treated as case sensitive. If you have a cluster with a mixed-case name, after upgrading from v1.2 to v2.0+, you may experience CLDB errors (in particular for mirror volumes) which generate messages like the following in `cldb.log`:

```
2012-07-31 04:43:50,716 ERROR
com.mapr.baseutils.cldbutils.CLDBRpcCo
mmonUtils
[VolumeMirrorThread]: Unable to reach
cluster with name: qacluster1.2.9. No
entry found in file /conf/
mapr-clusters.conf for cluster
qacluster1.2.9.
Failing the CLDB RPC with status 133
```

(The path given in this message is relative to `/opt/mapr/`, which might be misleading.)

As a work-around after upgrading, to continue working with mirror volumes created in v1.2, duplicate any lines with upper-case letters in `mapr-clusters.conf`, converting all letters to lower case.

Mirror volumes created in v2.0+ do not exhibit this behavior.

HPE Ezmeral Data Fabric Control System does not display on Internet Explorer.

The HPE Ezmeral Data Fabric Control System supports Internet Explorer version 9 and above. In IE9, **Compatibility View** under the **Tools** menu must be turned off, or else the user interface will not display correctly.

Unable to kill a job using the Metrics UI.

The following error displays when the root user tries to kill a job using the Metrics UI: `Failed to get Job information for job_x, Error: mapr is not allowed to impersonate root`

©Copyright 2024 Hewlett Packard Enterprise Development LP

To resolve this issue, add the following properties to core-site.xml in directory `/opt/mapr/hadoop/hadoop-0.20.2/etc/` :

```
<property>
<name>hadoop.proxyuser.mapr.groups</
name>
<value>*</value>
<description>Allow the superuser mapr
to impersonate any member of any
group</description>
</property>

<property>
<name>hadoop.proxyuser.mapr.hosts</
name>
<value>*</value>
<description>The superuser can
connect from any host to impersonate a
user</description>
</property>
```

YARN logs are deleted before the application completes.

The duration that YARN container logs are maintained starts from the time that the application starts running.

When YARN container logs are not aggregated, the YARN container logs are retained for 3 hours on each node. To update the duration, edit the value of `yarn.nodemanager.log.retain-seconds` in the yarn-site.xml file.

When YARN container log aggregation is enabled, by default, the aggregated logs are not deleted. However, this setting can be overridden in yarn-site.xml file. To update the duration, edit the value of `log-aggregation.retain-seconds` in the yarn-site.xml file.

You must consider how long you want the log to remain past the amount of time that the application will take to run. For example, if you expect most applications to take 20 seconds to run, do not set the value of this property to 20 seconds because the log may be deleted before the applications competes.

YARN applications fail because /tmp subdirectories have been deleted.

Some RHEL and CentOS platforms include the `tmpwatch` service by default. This service cleans up the `/tmp` directory on a regular basis. However, this operation causes the deletion of directories that are needed for applications to run (for example, `nm-local-dir` for YARN). The running NodeManager process does not re-create these missing directories, causing applications to fail.

Jobs fail when the timeline server is down

The timeline server for the Hive-on-Tez user interface does not support high availability. Jobs fail when the resource manager cannot connect to the timeline server. However, you can change the `yarn.timeline-service.client.best-effort` property to TRUE in the yarn-site.xml file to allow applications to run successfully even when the timeline server is down.

last-updated: Nov 14, 2024

Best Practices for Backing Up HPE Ezmeral Data Fabric Information

Lists the best practices and performance considerations to follow when backing up HPE Ezmeral Data Fabric information.

To back up configuration information and data from your HPE Ezmeral Data Fabric cluster, you must install the appropriate Linux backup client from your backup software provider on your servers in your HPE Ezmeral Data Fabric cluster. Your backup client user must have the proper filesystem, and volume permissions. For details on how to configure HPE Ezmeral Data Fabric volume permissions see Creating Volume-level ACLs on page 1840 and Managing Access Controls on page 1838.

Backup Configuration Data

By default, all installation files on the cluster, for each server in the cluster, are stored in a single directory on each server in the HPE Ezmeral Data Fabric cluster. To ensure that you backup all the configuration files, HPE Ezmeral Data Fabric supported applications, as well as log files, back up the `/opt/mapr` directory for all servers in the cluster.

Note that the `/opt/mapr` location includes all log files. Log files can add a significant amount of data to your backup environment, so evaluate if they are needed for your business continuity requirements. To backup just the configuration files for the cluster, backup the `/opt/mapr/conf` directory from all servers in the cluster.

Backup Volume Data

HPE Ezmeral Data Fabric's recommended way to backup and restore data, is to enable and configure snapshots and volume mirroring for your data, to another HPE Ezmeral Data Fabric cluster. This step ensures that your business continuity and disaster recovery needs are met.

See the following links for setting up Snapshots, Mirroring, Table and Streams replications.

- Snapshots: Managing Snapshots on page 1250
- Mirrors: Mirror Volumes on page 476
- Data Fabric DB Table Replication: Managing Table Replication on page 1411
- Data Fabric Streams Replication: Stream Replication on page 774

If you do not have a secondary cluster to mirror your data, back up your volumes by specifying the following path in your Linux backup agent: `/mapr/cluster_name/` - For example: `/mapr/my.cluster.com/`.

Performance Considerations When Backing Large Data Sets

You could run into bandwidth and performance limitations when you specify only one path to your HPE Ezmeral Data Fabric cluster, where your data in your volumes is stored on only one Linux host agent. The bottleneck can occur due to the size of that data you are backing up (large file sizes), or due to the number of files you have in your directory structure (millions of files in one directory).

To mitigate performance issues, break up the volumes across multiple Linux backup agents, with specific mount paths. For example:

```
HPE Ezmeral Data Fabric Linux Host 1 (hostname1):
          /mapr/my.cluster.com/volume1
          /mapr/my.cluster.com/volume2
          /mapr/my.cluster.com/volume3
```

```
HPE Ezmeral Data Fabric Linux Host 2 (hostname2):
          /mapr/my.cluster.com/volume4
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
          /mapr/my.cluster.com/volume5
          /mapr/my.cluster.com/volume6
```

```
HPE Ezmeral Data Fabric Linux Host 3 (hostname3):
          /mapr/my.cluster.com/volume7
          /mapr/my.cluster.com/volume8
          /mapr/my.cluster.com/volume9
```

Preserve Metadata About the Volumes
To preserve metadata such as permissions and *ACE* rules, run a pre-script process as the `mapr` user, in your backup agent. For example in your pre-script configuration for your host agent for your cluster, you would run:

```
maprcli volume dump create
        -name volume1 -dumpfile volume1_fulldump1 -e statefile1
```

Some backup software may need "stderr" or "stdout" codes to run pre or post processing scripts within their product. In that case, you may need to write a bash script to dump the file to a location of your choice, and ensure that your backup agent is configured to backup that directory. Consult your backup software provider's documentation. For information on creating volume dumps, see Create and Maintain Volume Dump File on page 2627.

IPv6 Support in Data Fabric

Describes the IPv6 support feature for Data Fabric.

IMPORTANT: HPE Ezmeral Ecosystem Pack (EEP) components do not support IPv6.

Data Fabric can be installed on hosts with IPv6 addresses. In other words, external endpoints for Data Fabric can have IPv6 addresses. Data Fabric can communicate with clients over IPv6 addressing. Inter-cluster traffic and intra-cluster traffic over IPv6 connections is supported with IPv4 compatibility.

Data Fabric deployment over IPv6 addresses is possible when both the hardware hosting Data Fabric and the Data Fabric software are able to detect and support IPv6 addresses.

The underlying hardware that hosts Data Fabric must have a network interface card (NIC) that supports IPv6 addressing.

An application that wishes to communicate with Data Fabric over IPv6 can do so, when Data Fabric is installed on IPv6-compatible hardware and IPv6 support is enabled on Data Fabric.

NOTE: When you have a network interface card (NIC) that supports both IPv4 and IPv6 addressing, each IP address must be identifiable by a distinct hostname. In other words, a single hostname must NOT map to both the IPv4 and IPv6 addresses.

The following table describes the terminology related to IPv6 client/server nodes.

Term	Description
IPv6-aware	The term denotes readiness of the underlying hardware. It indicates that the NIC associated with a node that hosts Data Fabric is IPv6 compatible, and can communicate with other nodes with IPv6 and IPv4 addresses.
IPv6-unaware	The term denotes readiness of the underlying hardware. It indicates that the NIC associated with a node that hosts Data Fabric is incompatible to handle IPv6 traffic, and can handle IPv4 traffic only.
IPv6-enabled	The term denotes that IPv6 is enabled on Data Fabric software. The Data Fabric node on which IPv6 is enabled is able to communicate with IPv6 addresses. The node is able to communicate with IPv4 addresses.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Term	Description
IPv6-only	The term denotes that IPv6 is enabled on Data Fabric software. The Data Fabric node on which IPv6 is enabled is able to communicate exclusively with IPv6 addresses only. Communication with IPv4 addresses is not supported on this node.

The following matrix explains in detail the communication between a client node and a Data Fabric node for various IP address type combinations.

Type of application (Type of client node)	IPv6-unaware server (IPv4 -only server node)	IPv6-unaware server (IPv6-enabled server node	IPv6-aware server (IPv6-only server node)	IPv6-aware server (IPv6-enabled server node)
IPv6-unaware client (IPv4-only node)	client-server communication takes place over IPv4	client-server communication takes place over IPv4	no communication	client-server communication takes place over IPv4
IPv6-unaware client (IPv6-enabled node)	client-server communication takes place over IPv4	client-server communication takes place over IPv4	no communication	client-server communication takes place over IPv4
IPv6-aware client (IPv6-only node)	no communication	no communication	client-server communication takes place over IPv6	client-server communication takes place over IPv6
IPv6-aware client (IPv6-enabled node)	client-server communication takes place over IPv4	client-server communication takes place over IPv4	client-server communication takes place over IPv6	client-server communication takes place over IPv6

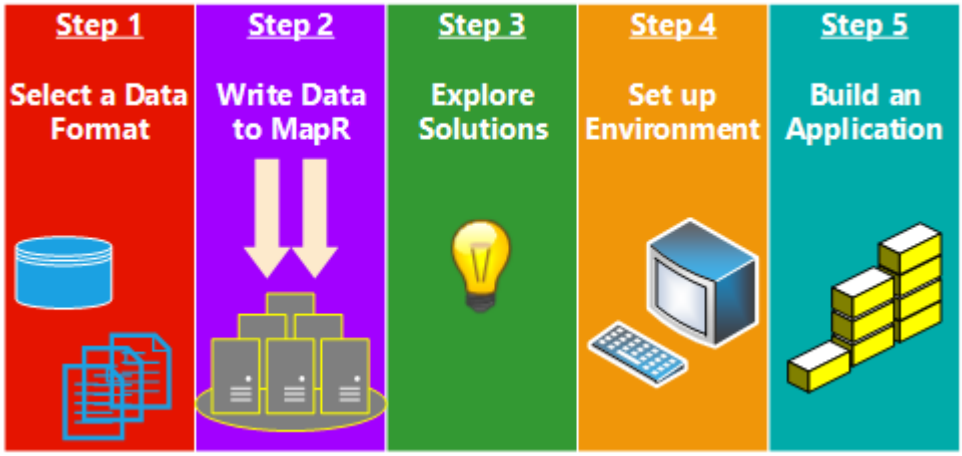
7.9.0 Development

This section contains information related to application development for Ezmeral ecosystem components and HPE Ezmeral Data Fabric products, including the file system, Database (Key-Value and JSON), and Event Streams.

Application Development Process

Before you start developing applications on the HPE Ezmeral Data Fabric platform, consider how you will get the data into the platform, the storage format of the data, the type of processing or modeling that is required, and how the data will be accessed.

At a high-level, building an application comes down to the following steps:



©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

1. Step 1: Select a Data Storage Format on page 3179
2. Step 2: Write Data to HPE Ezmeral Data Fabric on page 3182
3. Step 3: Explore Ways to Work With the Data on page 3182
4. Step 4: Set Up the Development Environment on page 3185
5. Step 5: Build the Application on page 3193

Step 1: Select a Data Storage Format

Consider the data format options and determine how you want to use to store your data.

Keep in mind that a single application can access data from a variety of data formats. The following data formats are available.

HPE Ezmeral Data Fabric File Store

HPE Ezmeral Data Fabric File Store is a random read-write distributed file system that allows applications to concurrently read and write directly to files. This data store is great for storing and scanning large data sets of historical data, and for sharing files between various services and applications. Any node with access to the file system can access files on it.

Consider the following examples:

- Write large amounts of user click-stream data for a web site in a simple directory structure based on the date, and then process that data using tools like Spark, Drill, Hive or another MapReduce application.
- Store various types of images, audio files, and video files in one shared directory so that web or mobile applications can render the content as required.
- Share configuration files or internationalized resources among various applications by storing these files in a shared directory.
- Simplify the deployment of new applications by adding java libraries (.jar files) to a shared directory and then including the directory in the classpath of one or more applications.
- Store the Docker files and images in a shared location which can be accessed by various servers. This provides a single, shared location from which users can launch containers.

When you store large data sets, use a file format in which the data can be consumed efficiently. For example, Parquet, ORC, sequence files are good for storing and scanning. Parquet is great for storing data on the file system because it stores data in columnar format, which can be partitioned. Parquet also works well for use cases where you query the data with Drill or process the data with Spark applications. Note that you can use CSV or JSON formats, but they scanning these formats is less efficient.

For more information about the file system, see File System on page 469.

HPE Ezmeral Data Fabric Database

HPE Ezmeral Data Fabric Database is an enterprise-grade, high performance, NoSQL database management system that supports both binary and JSON tables. Consider using HPE Ezmeral Data Fabric Database tables when you want to query and organize large amounts data. It also integrates with Drill, Apache Spark, Hive and other MapReduce tools to provide applications the ability to scan or query large data sets in an efficient, distributed way.

HPE Ezmeral Data Fabric Database provides the following features:

- **A flexible schema.** Each row or document can have its own set of attributes.

©Copyright 2024 Hewlett Packard Enterprise Development LP

- **Efficient random access.** Applications can quickly access one or more records using a row key, document ID, or a conditional queries.
- **Easy and efficient data mutation.** Applications can insert, update, and delete rows or documents.

HPE Ezmeral Data Fabric Database Binary Tables	HPE Ezmeral Data Fabric Database binary tables consist of rows that are identified by primary keys and row data is identified by key/value pairs. HPE Ezmeral Data Fabric Database tables are similar to HBase tables in that HPE Ezmeral Data Fabric Database does not determine or store the datatype of each value in the table. But, HPE Ezmeral Data Fabric Database tables perform operations more efficiently than HBase table. You might want to use binary tables when you want to create or use an existing HBase application. However, on the Converged Data Platform, JSON tables are usually preferred due to their flexibility.
HPE Ezmeral Data Fabric Database JSON Tables	A HPE Ezmeral Data Fabric Database JSON tables provide a flexible, powerful schema that you can customize based on the data that you want to represent. Each row in a JSON table corresponds to an JSON document with an unique _id and each JSON document can have a different set of columns. HPE Ezmeral Data Fabric Database JSON tables determine the datatype of each value based on the type of data written to the document. The following example lists three JSON documents from a single JSON table. Note that the attributes associated with each document varies.

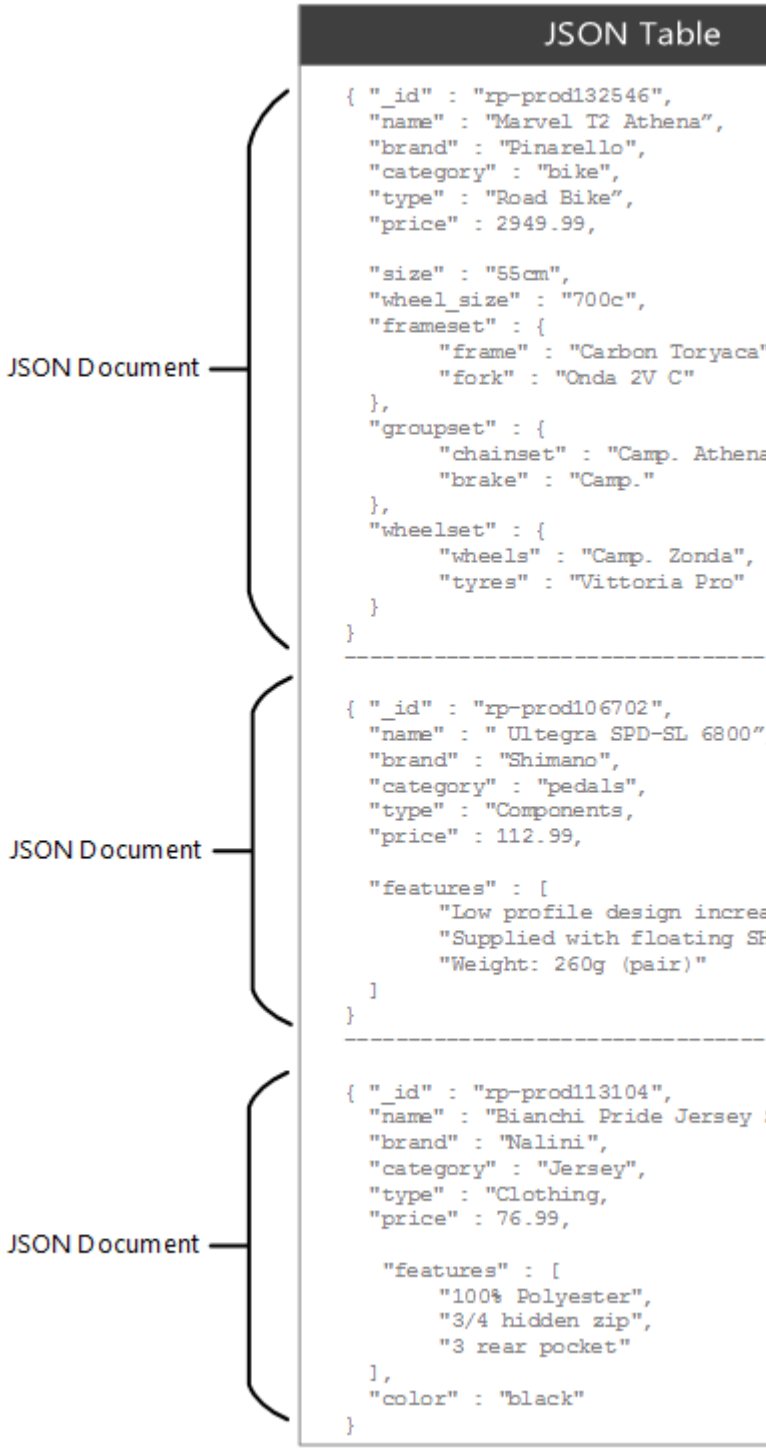
last-updated: Nov 14, 2024



For more information, see HPE Ezmeral Data Fabric Database on page 610.

HPE Ezmeral Data Fabric Streams

HPE Ezmeral Data Fabric Streams is a publish/subscribe messaging solution that uses the Apache Kafka API. HPE Ezmeral Data Fabric Streams writes events as messages in a topic and topics are part of a stream. Producer applications can publish events to a stream and consumer applications can read all or a subset of the messages in a stream. By default, messages are stored in a topic for 7 days and then automatically purged. However, you can shorten or extend the time-to-live (ttl) for messages in a stream based on your use case.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

For more information, see HPE Ezmeral Data Fabric Streams on page 745.

Step 2: Write Data to HPE Ezmeral Data Fabric

Depending on your use case, move existing data onto the HPE Ezmeral Data Fabric platform or write data directly to the platform.

You can write batch data or streaming data to HPE Ezmeral Data Fabric. Batch data refers to data that is already in a data-store while streaming data refers to the continuous flow of real-time messages that have yet to be written to a data-store. Streaming data is generally processed as it is received while batch data is processed after a set of data is written to the datastore. There are many ways to write batch and streaming data to the platform, the following sections provide a few examples.

Write Batch Data to the Platform

You can use an NFS client, hadoop command, or ecosystem components to write batch data to file system. Basic POSIX file system operations can be used to move data to file system. For example, you can use NFS clients, POSIX clients, or applications that utilize libraries such as java.io to access the file system. Hadoop commands and hdfs APIs can be used to add or update files on the file system. For example, you can use the hadoop `distcp` command to copy data from HDFS to file system. Hadoop Ecosystem components, such as Apache Flume, can also be used to push log files to file system.

You can also write, update, or delete batch data to HPE Ezmeral Data Fabric Database tables. Applications can use the OJAI API to write to JSON tables or the HBase API to write to binary tables.

Write Streaming Data to the Platform

Write streaming event data as messages in HPE Ezmeral Data Fabric Event Data Streams topics using Kafka APIs or a REST client application. C, Java, or Python applications can produce messages to one or more topics in event streams. Additionally, applications written in any language can use the REST Proxy to produce messages to one or more topics in an event stream. For example, a financial service application, written in Java, could produce messages about stock market activity to an event stream topic.

Step 3: Explore Ways to Work With the Data

Once the data is in the HPE Ezmeral Data Fabric platform, explore the various features and components available on the platform and determine your path. You may want to access data in its initial format or perform some data modeling or processing prior to accessing the data.

The following sections provide some examples to help you determine which approach will work for your particular use case.

Process Data

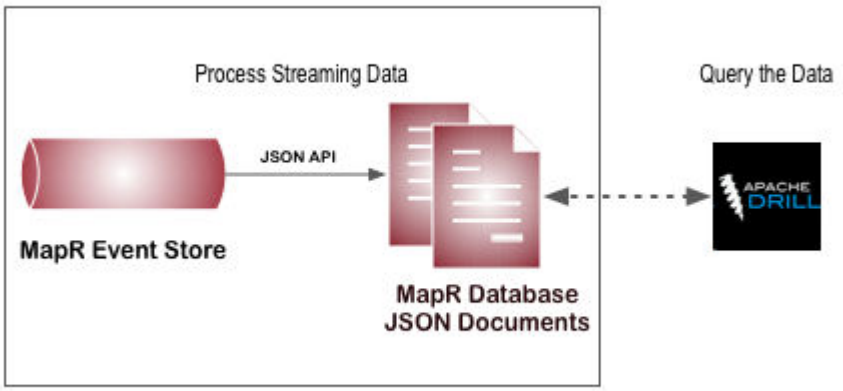
When developing applications that ingest data, consider if the data requires some processing before the data can be consumed or stored.

Consider the following scenarios:

- **Process the Data Before Querying the Data**

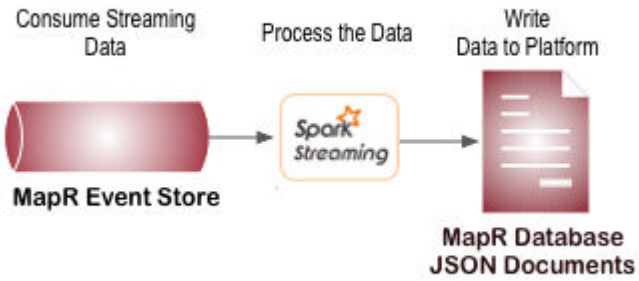
  To efficiently query data, you may want to convert the data into a different format. For example, if you want to use Drill to query event data, you can convert streaming data from topics to a JSON table to enable more efficient querying. To do this, ingest event data using HPE Ezmeral Data Fabric Streams, use the HPE Ezmeral Data Fabric Streams API to read the data from topics and the JSON API to store the data in a JSON table, then use Drill to query the JSON tables.

©Copyright 2024 Hewlett Packard Enterprise Development LP



- **Process Data before Storing the Data**

  You may also want to process the data based on business needs to perform some pre-processing before long term storage. For example, you can consume streaming data from a HPE Ezmeral Data Fabric Streams topic with a Spark Streaming application which performs calculations or adds additional data before storing the data in a different data-store such as a HPE Ezmeral Data Fabric Database JSON table.



- **Perform Calculations as the Data is Stored**

  You may want to modify a single row in a table and then incrementally aggregate data. For example, you can use HPE Ezmeral Data Fabric Database tables to store large amounts of customer information or product catalog data and then read and write to a subset of that data. Then, modify a single row in a table to incrementally aggregate data. For example, to aggregate the number of clicks on a page, you can have a row key for each date and page. Internally, you can design the table to increment based on timestamp. The following example shows a row of data for the info page on 2017-02-22:

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
2017-01-22-info.html => key
Total : 1230 +1
H00 :   100
M1:1
M2: 5
...
M30 : 10
...
H20 : 50 +1
M1:1
...
M25: 1
```

- **Process Large Sets of Data**

  There are also many methods to process files in their initial state. To process large sets of data on the HPE Ezmeral Data Fabric File Store, it is common to use Spark or MapReduce applications. MapReduce applications perform parallel,distributed processing of data in batches and are therefore a great way to process large datasets. Spark applications can be used to iteratively process large sets of data with machine learning algorithms. For an example of using a machine learning algorithm with a Spark application, see Building a Recommendation Engine with Spark.

Access Data

There are many use cases for why you might want to access data and many methods to access the data. Operational applications or E-commerce services may want to access data on the HPE Ezmeral Data Fabric platform to provide customers a view of transactional data. Business users may want to view user profile data or submit queries through a BI tool to visually analyze the data.

The following sections will provide some examples for how to access the data so that you can envision that will work for your use case.

- **Access Data in HPE Ezmeral Data Fabric File Store**

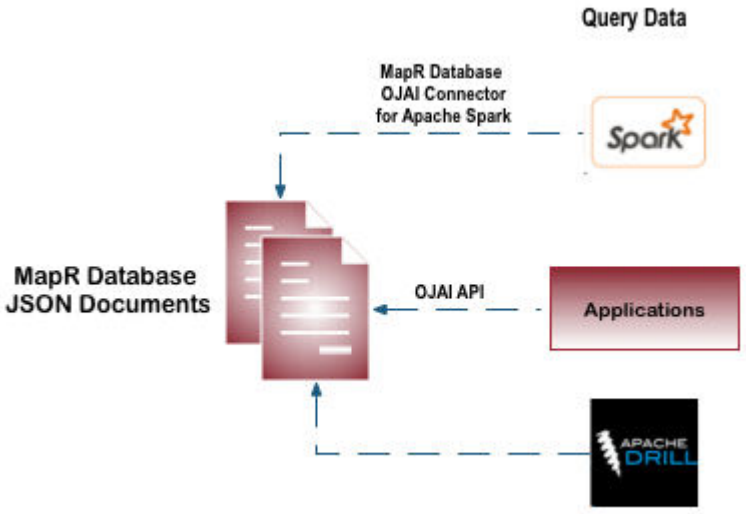
  The most common way to access data in the HPE Ezmeral Data Fabric File Store is via a NFS mount point that is remote or local to the cluster. You can use HDFS commands as well but they are generally only used for migrating hadoop applications to the HPE Ezmeral Data Fabric platform. If you require high throughput, security, and scalability, consider installing the POSIX client as this provides a more efficient way to access data in the HPE Ezmeral Data Fabric File Store. You can also query the data directly using Drill.

- **Access Data in HPE Ezmeral Data Fabric Database**

  The methods that you can use to access HPE Ezmeral Data Fabric Database table data differs based on the table type. You can access HPE Ezmeral Data Fabric Database binary table data with the HBase shell and applications that use the HBase API. You can access HPE Ezmeral Data Fabric Database JSON table data with the dbshell, and java applications that use the OJAI API. You can also use Drill or Spark to query HPE Ezmeral Data Fabric Database binary and JSON table data directly.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024



- **Access Data in HPE Ezmeral Data Fabric Streams**

  Data in HPE Ezmeral Data Fabric Streams can be accessed by one or more stream consumers and the number of consumers can change over time depending on business needs.

  Similar to the various ways you can write data to topics a stream, data in stream topics can be accessed by applications that utilize the Kafka API or a REST interface. You can also use Spark to query streams for new messages at a given interval and access any new messages that are available.

  HPE Ezmeral Data Fabric Streams provides flexibility to add new consumers without making changes to the producer application. For example, you have a HPE Ezmeral Data Fabric Streams producer that writes all twitter feeds to a stream. Today, this stream is accessed by a single consumer application that provides access to twitter feeds with content related to IOT. The next week, there may be a request check for how many tweets originate from a specific account. Providing access to different data in an existing stream can be achieved by creating a new consumer which reads from the same stream.

Step 4: Set Up the Development Environment

Before you start building the application, figure out how your the application will connect to the cluster and what the library dependencies and installation requirements are.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Applications are often run on edge nodes which are nodes that are not part of the cluster. Setting up an edge node so that it can be used to develop and run applications consists of the following steps:

- Selecting a client that you will use to connect to the cluster.
- Installing additional clients required for your use case.
- Determining the application dependencies.

NOTE: The dependencies to build and run applications differ based on your use case and the various types of data or tools that are part of an application.

The following sub-topics include the various methods to connect to the cluster, and minimal requirements to build and run applications.

Connect to the Cluster

Application are often run on nodes that are not part of the Data Fabric cluster. There are many methods to connect to a Data Fabric cluster; this section briefly describes each option.

Data Fabric Client	The Data Fabric client includes the libraries and utilities required on an edge node to perform the following: connect to the cluster, submit MapReduce applications, submit YARN applications, run hadoop fs commands, and run hadoop mfs commands. However, to run applications that access data from HPE Ezmeral Data Fabric Database or HPE Ezmeral Data Fabric Streams, you must configure additional dependencies. For more information about the Data Fabric client, see HPE Ezmeral Data Fabric Client on page 383 and How Data Fabric Clients Connect to the Cluster on page 999. **NOTE:** Although it is not recommended, you can include the file system JAR file in the application instead of installing the Data Fabric client. However, there are caveats and specific requirements to make this work. For information, see Using the File System JAR to Connect to the Cluster on page 3186.
Data Fabric POSIX Clients	Data Fabric POSIX clients enable app servers, web servers, and other client nodes and applications to read and write directly and securely to the file system. For more information about the POSIX clients, see POSIX Clients on page 516 and POSIX Clients on page 410.
Data Fabric NFS Clients	You can mount the cluster itself via NFS so that your applications can read and write data directly. For more information, see Managing the HPE Ezmeral Data Fabric NFS Service on page 1530.

Using the File System JAR to Connect to the Cluster

The file system JAR file includes the Data Fabric client libraries required to connect to the cluster. While this is strongly discouraged, application developers can bundle the file system JAR file in Data Fabric file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Streams applications instead of installing the Data Fabric client on the edge node (node that runs the application). Applications should not bundle the file system JAR file unless the application meets certain requirements.

IMPORTANT: When bundling the file system JAR file, if there is a binary mismatch between the bundled JAR file and the version that the cluster expects, this can result in failures. In release 5.2.2 and later, the system detects the mismatch and prevents the application from starting. In releases earlier than 5.2.2, nodes running applications may run out of memory or shut down unexpectedly.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Requirements

You can bundle the file system JAR (`maprfs-<version>-mapr.jar`) with applications that meet all of the following requirements:

- The application communicates directly with the file system, HPE Ezmeral Data Fabric Database, or HPE Ezmeral Data Fabric Streams
- The application does not run as a MapReduce or YARN job/application on the cluster.
- The application does not include file system JARs on the local machine in its classpath.
- The application accesses a cluster that is not secure.

Configuring the Cluster Connection

When you include the file system JAR in an application instead of installing the Data Fabric client on the edge node, you must create and configure a `mapr-clusters.conf` file on node that runs the application.

1. Set a `MAPR_HOME` environment variable to a location such as `/opt/mapr`.
2. Create the `mapr-clusters.conf` file in the `$MAPR_HOME/conf` directory.
3. Configure the `mapr-clusters.conf` file with the cluster name and the list of CLDB nodes.

   For example, the `mapr-clusters.conf` on an edge node would contain the following content if it was connecting to a cluster named `my.cluster` with CLDB nodes on centos765, centos234, and centos123:

   ```
   my.cluster secure=false centos765 centos234 centos123
   ```

   For more information about how to configure `mapr-clusters.conf`, see mapr-clusters.conf on page 3018.

For more information about how the Data Fabric client connects to the cluster, see How Data Fabric Clients Connect to the Cluster on page 999.

Using Maven to Include file system JAR as a Dependency

If you use Maven to bundle the file system JAR file with an application and you plan to run the application on a Data Fabric cluster where a patch has been applied, ensure that you specify both a system scope and a local system path to the file.

For example, to bundle the file system JAR file, the `pom.xml` file may include the following:

```
...
 <groupId>com.mapr.hadoop</groupId>
        <artifactId>maprfs</artifactId>
        <version>${mapr.core.version}</version>
        <scope>system</scope>
        <systemPath>/opt/mapr/lib/maprfs-5.2.0-mapr.jar</systemPath>
...
```

By default, the Data Fabric Maven repository includes JAR files from https://repository.mapr.com/maven/. This default Maven repository includes JAR files associated with the GA packages for each Data Fabric release. Therefore, when a patch has been applied to the cluster, failure to specify a system scope may result in errors due to a binary mismatch between the file system JAR files used by the application and the cluster.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Known Issues

Nodes running applications with a bundled file system JAR file may run out of memory or shut down unexpectedly in the following scenarios:

The version of the file system JAR included in the application differs from the version that is available on the cluster.	This may occur when a patch was applied to some, but not all the nodes in the cluster. It can also occur when Maven is bundling the GA version of the JAR file when the cluster expects a newer, patched version.
Two versions of the JAR are available on the node.	For YARN applications, the NodeManager nodes that run the tasks or containers store local versions of the dependencies included with the application. In this scenario, since both the cluster's file system JAR and the version included in the application are available on the node, it is unknown which JAR will be used when processing the application.

HPE Ezmeral Data Fabric Database JSON Application Requirements

The following tables include the minimal node requirements for building and running HPE Ezmeral Data Fabric Database JSON table applications.

Java Applications

Node Requirements	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	Select one of the following options: • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. For more information, see Connect to the Cluster on page 3186.
The OJAI Query Service is installed	To use secondary indexes, you may need to enable this service. See Preparing Clusters for Querying using Secondary Indexes on JSON Tables on page 1438 for more information.
HPE Ezmeral Data Fabric Database libraries are configured as a dependency.	When you build an application, use the Maven Repository to determine the dependencies. The POM file should include the Data Fabric Repository and the OJAI Driver project. When you run the application, provide the dependencies in the application's classpath. For more information, see Compiling and Running Java OJAI Applications on page 3481
Other items to consider.	If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file. For example, to use the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, see Configuring the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark on page 4836

HPE Ezmeral Data Fabric Database Binary Application Requirements

The following tables include the minimal node requirements for building and running HPE Ezmeral Data Fabric Database binary table applications.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Java Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	Select one of the following options: • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. For more information, see Connect to the Cluster on page 3186.
The HBase client is installed.	Install the HBase client. The HBase client is as part of the EEP installation. For more information, see 7.9.0 Installation on page 66. **NOTE:** The HBase client is include when you install PACC.
HBase client library files are configured as an application dependency.	When you build the application, use the Maven Repository to determine the dependencies. The POM file should include the Data Fabric Repository and the HBase client dependency. When you run an application, include the `hbase classpath` script and additional dependencies in the application's classpath. For more information, see Compiling and Running HPE Ezmeral Data Fabric Database Binary Applications on page 3298
Other Items	If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file.

C Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	Select one of the following options: • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. For more information, see Connect to the Cluster on page 3186.
The HBase Client is installed.	Install the HBase client. The HBase client is as part of the EEP installation. For more information, see 7.9.0 Installation on page 66. **NOTE:** The HBase client is include when you install PACC.
The `libMapRClient` library and `libjvm` shared libraries are in the application's library search path and the `libMapRClient` header files are in this directory:`/opt/mapr/include/hbase`	For more information, see Building and Launching C Applications on page 3292.

last-updated: Nov 14, 2024

HPE Ezmeral Data Fabric Streams Application Requirements

The following tables include the minimal node requirements for building and running HPE Ezmeral Data Fabric Streams consumer and producer applications.

Java Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	Select one of the following options: • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. For more information, see Connect to the Cluster on page 3186.
The Streams Java Client is installed.	Install the HPE Ezmeral Data Fabric Streams Java Client. The HPE Ezmeral Data Fabric Streams Java client (`mapr-kafka`) is available as part of the EEP installation. For more information, see 7.9.0 Installation on page 66. **NOTE:** The Streams Java Client is included when you install PACC.
Streams Java client and the Data Fabric Streams project library files are configured as an application dependency.	When you build the application, use the Maven Repository to determine the dependencies. The POM file should include the Data Fabric Repository, the HPE Ezmeral Data Fabric Streams Java Client dependency, and the HPE Ezmeral Data Fabric Streams project dependency. When you run an application, include the dependencies in the application's classpath. For more information, see Compiling and Running HPE Ezmeral Data Fabric Streams Java Apps on page 3605
Other Items	If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file.

File System Application Requirements

The following tables include the minimal node requirements for building and running file system applications.

Java Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	Select one of the following options: • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. For more information, see Connect to the Cluster on page 3186.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Node Requirement	Method(s) to Meet Requirement

Include hadoop-common libraries as a dependency.	When you compile the application, use the Maven Repository to determine the dependencies.The POM file should include the Data Fabric Repository and the hadoop-common dependency:
	
	`<repositories>`
	`<repository> <id>mapr-releases</id>`
	`<url>https://repository.mapr.com/maven/</url>`
	`<snapshots><enabled>false</enabled></snapshots> <releases><enabled>true</enabled></releases>`
	`</repository>`
	`</repositories>`
	
	`<dependencies>`
	`<dependency>`
	`<groupId>org.apache.hadoop</groupId>`
	`<artifactId>hadoop-common</artifactId>`
	`<version>${hadoop.version}</version>`
	`</dependency>`
	`</dependencies>`
	
	When you run the application, include the following in the application's classpath: `` `hadoop classpath` ``
	
	For more information, see Compiling and Running a Java Application on page 3256.

NOTE:

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 3186.

C Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	Select one of the following options: • Install and configure the Data Fabric client. • Install the PACC and run an application container. For more information, see Connect to the Cluster on page 3186.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Node Requirement	Method(s) to Meet Requirement
Include the libhdfs libraries and Data Fabric libraries when you compile the application.	The Data Fabric libraries are available in the following location: `/opt/mapr/lib` Link to the libhdfs libraries in the following location: `MAPR_HOME/hadoop/hadoop-2.x/` For more information, see Compiling and Running C Applications on File System Clients on page 3198

YARN Application Requirements

The following tables include the minimal node requirements for building and running YARN applications.

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	Select one of the following options: • Install and configure the Data Fabric client. • Install the PACC and run an application container. For more information, see Connect to the Cluster on page 3186.

Hadoop libraries are configured as an application dependency.	When you compile the application, use the Maven Repository to determine the dependencies. The POM file should include the Data Fabric Repository and the hadoop-common dependency:
	`<repositories> <repository> <id>mapr-releases</id> <url>https://repository.mapr.com/maven/</url> <snapshots><enabled>false</enabled></snapshots> <releases><enabled>true</enabled></releases> </repository> </repositories>`
	`<dependencies> <dependency> <groupId>org.apache.hadoop</groupId> <artifactId>hadoop-common</artifactId> <version>${hadoop.version}</version> </dependency> </dependencies>`
	When you run the application, include the following in the application's classpath: `` `hadoop classpath` ``
	Note: Based on how you submit the application, the classpath locations and requirements differ. See External Applications and Classpath on page 4013 and Classpath Construction on page 4014.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Node Requirement	Method(s) to Meet Requirement
Other Items	• If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file. • Any third-party library that is required by a MapReduce program must be accessible to this node and the data node that processes the job or application. For more information, see Managing Third-Party Libraries on page 4014.

Step 5: Build the Application

Start building an application! This section lists a few of the sample applications available in HPE Ezmeral Data Fabric.

NOTE: When building and running your application, you may want to use a classpath for printing to standard output. The following classpaths are available:

mapr classpath	Prints CLASSPATH to standard output. This classpath could be used to build your application classpath to runHPE Ezmeral Data Fabric applications for YARN and other components.
mapr clientclasspath	Prints CLASSPATH for HPE Ezmeral Data Fabric Database clients to standard output. The clientclasspath could be used to build the classpath to run your HPE Ezmeral Data Fabric Database (binary and JSON) and HPE Ezmeral Data Fabric Streams applications.

HPE Ezmeral Data Fabric Database JSON

Managing JSON Tables on page 3337	This section describes how to create, list, and delete JSON tables as well as set permissions and manage column families using either the Data Fabric Java API library or the HPE Ezmeral Data Fabric Database Shell commands.
Creating JSON Documents in Java OJAI on page 3360	This section provides several Java examples of creating a document.
Examples: Inserting JSON Documents on page 3369	This section shows how to insert a document or data into a document store (HPE Ezmeral Data Fabric Database JSON table) with Java and dbshell.
Examples: Querying JSON Documents on page 3440	This section provides several examples of querying documents.
HPE Ezmeral Data Fabric Database JSON MapReduce: Sample App on page 3532	This sample Java application extends the Apache Hadoop MapReduce framework to read records (JSON documents) from a JSON table and inserts new documents into another JSON table. This API library allows you to write your own MapReduce applications to write data from one JSON table to another.

HPE Ezmeral Data Fabric Database Binary

C API Examples on page 3275	This section provides examples using the HPE Ezmeral Data Fabric Database libMapRClient C API to operate on HPE Ezmeral Data Fabric Database binary tables.

last-updated: Nov 14, 2024

HPE Ezmeral Data Fabric Database Sample C Application on page 3279	This section provides additional sample C applications that accesses and performs operations on HPE Ezmeral Data Fabric Database binary tables.

HPE Ezmeral Data Fabric Streams Streams

Sample Java Consumer on page 3548	This sample Java consumer application iterates through the returned records, extracts the value of each message, and prints the value to standard output.
Sample Java Producer on page 3550	This sample Java producer application publishes messages to a stream topic.
Developing a HPE Ezmeral Data Fabric Streams C Application on page 3626	These sample C applications publish messages to a stream topic and consumes the messages.
Developing HPE Ezmeral Data Fabric Streams Python Applications on page 3983	These sample Python applications publish messages to a stream topic and consumes the messages.

file system

Sample Applications on page 3260	This sample Java application demonstrates how to set, get, modify, and delete ACEs on files using the Java APIs.
hdfs_write_revised.c on page 3203	This C application demonstrates how to write to files by using the hdfsWrite() and hdfsPwrite() APIs.
hdfs_read_revised.c on page 3211	This C application demonstrates how to read from files by using the hdfsRead() and hdfsPread() APIs.
hdfs_connect_as_user.c on page 3218	This C application demonstrates how to create and write to files impersonating another user by using the hdfsConnectAsUser() API.

Github Repo

You can find additional sample code on the MapR Demos Github repository.

File Store and Apps

The following sections provide information about accessing the File Store with C and Java applications.

Copying Data from Apache Hadoop to a Data Fabric Cluster

Describes the procedure to copy data from an Apache Hadoop to a Data Fabric cluster.

You can use the hdfs protocol, webhdfs protocol, or NFS for the HPE Ezmeral Data Fabric to copy data from Apache Hadoop to a Data Fabric cluster.

The following table describes these methods:

Method	Description
hdfs:// protocol	Use the `hadoop distcp` command with the `hdfs://` protocol to copy data from an HDFS cluster into a Data Fabric cluster if the HDFS cluster and the Data Fabric cluster use the same RPC protocol version. For all other scenarios, use the `webhdfs://` protocol or NFS for the HPE Ezmeral Data Fabric gateway to copy data to a Data Fabric cluster.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Method	Description
webhdfs:// protocol	Use the `hadoop distcp` command with the `webhdfs://` protocol to copy data from an HDFS cluster into a Data Fabric cluster.
NFS	Mount a Data Fabric cluster to an HDFS cluster using NFS for the HPE Ezmeral Data Fabric mount. Then use the `hadoop distcp` command to copy data between the two clusters.

Copy Data Using the hdfs:// Protocol
Describes the procedure to copy data from a HDFS cluster to a HPE Ezmeral Data Fabric cluster using the `hdfs://` protocol.

Before you can copy data from an HDFS cluster to a HPE Ezmeral Data Fabric cluster using the `hdfs://` protocol, you must configure the HPE Ezmeral Data Fabric cluster to access the HDFS cluster. To do this, complete the steps listed in Configuring a HPE Ezmeral Data Fabric Cluster to Access an HDFS Cluster for the security scenario that best describes your HDFS and HPE Ezmeral Data Fabric clusters, and then complete the steps listed under Verifying Access to an HDFS Cluster.

You also need the following information:

- `<NameNode>` - the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>` - the port for connecting to the NameNode in the HDFS cluster
- `<HDFS path>` - the path to the HDFS directory from which you plan to copy data
- `<Data Fabric File system path>` - the path in the HPE Ezmeral Data Fabric cluster to which you plan to copy HDFS data
- `<file>` - a file in the HDFS path

To copy data from HDFS to HPE Ezmeral Data Fabric file system using the `hdfs://` protocol, complete the following steps:

1. Run the following Hadoop command to determine if the HPE Ezmeral Data Fabric cluster can read the contents of a file in a specified directory on the HDFS cluster:

   ```
   hadoop fs -cat <NameNode>:<NameNode port>/<HDFS path>/<file>
   ```

   Example

   ```
   hadoop fs -cat hdfs://nn1:8020/user/sara/contents.xml
   ```

2. If the HPE Ezmeral Data Fabric cluster can read the contents of the file, run the `distcp` command to copy the data from the HDFS cluster to the HPE Ezmeral Data Fabric cluster:

   ```
   hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> maprfs://
   <Data Fabric File system path>
   ```

   Example

   ```
   hadoop distcp hdfs://nn1:8020/user/sara maprfs:///user/sara
   ```

Copying Data Using the webhdfs:// Protocol
Describes how to copy data from a HDFS cluster to a HPE Ezmeral Data Fabric cluster using the `webhdfs://` protocol.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Before you can copy data from an HDFS cluster to a HPE Ezmeral Data Fabric cluster using the `webhdfs://` protocol, you must configure the HPE Ezmeral Data Fabric cluster to access the HDFS cluster. To do this, complete the steps listed in Configuring a HPE Ezmeral Data Fabric Cluster to Access an HDFS Cluster for the security scenario that best describes your HDFS and HPE Ezmeral Data Fabric clusters, and then complete the steps listed under Verifying Access to an HDFS Cluster.

The HDFS cluster must have WebHDFS enabled. Verify that the following parameter exists in the `hdfs-site.xml` file and that the value is set to `true`.

```
<property>
<name>dfs.webhdfs.enabled</name>
<value>true</value>
</property>
```

You also need the following information:

- `<NameNode>` - the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode HTTP Port>` - the HTTP port on the NameNode in the HDFS cluster
- `<HDFS path>` - the path to the HDFS directory from which you plan to copy data
- `<Data Fabricfilesystem path>` - the path in the HPE Ezmeral Data Fabric cluster to which you plan to copy HDFS data

To copy data from the HDFS to the HPE Ezmeral Data Fabric file system using the `webhdfs://` protocol, complete the following step:

Run the following command from a node in the HPE Ezmeral Data Fabric cluster:

```
hadoop distcp webhdfs://<NameNode>:<NameNode HTTP Port>/<HDFS path>
maprfs:///<Data Fabric filesystem path>
```

Example

```
hadoop distcp webhdfs://nn2:50070/user/sara maprfs:///user/sara
```

NOTE: The triple slashes in `maprfs:///...` are required.

Copying Data Using NFS for the HPE Ezmeral Data Fabric
Describes how to copy files from one data-fabric cluster to another using NFS for the HPE Ezmeral Data Fabric.

If NFS for the HPE Ezmeral Data Fabric is installed on the Data Fabric cluster, you can mount the Data Fabric cluster to the HDFS cluster and then copy files from one cluster to the other using `hadoop distcp`. If you do not have NFS for the HPE Ezmeral Data Fabric installed and a mount point configured, see Accessing Data with NFS v3 on page 1538 and Managing the HPE Ezmeral Data Fabric NFS Service on page 1530.

To perform a copy using distcp via NFS for the HPE Ezmeral Data Fabric, you need the following information:

- `<Data Fabric NFS Server>` - the IP address or hostname of the NFS server in the data-fabric cluster
- `<maprfs_nfs_mount>` - the NFS export mount point configured on the data-fabric cluster; default is `/mapr`
- `<hdfs_nfs_mount>` - the NFS for the HPE Ezmeral Data Fabric mount point configured on the HDFS cluster

©Copyright 2024 Hewlett Packard Enterprise Development LP

- `<NameNode>` - the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>` - the port on the NameNode in the HDFS cluster
- `<HDFS path>` - the path to the HDFS directory from which you plan to copy data
- `<Data Fabric file system path>` - the path in the Data Fabric cluster to which you plan to copy HDFS data

To copy data from HDFS to the Data Fabric file system using NFS for the HPE Ezmeral Data Fabric, complete the following steps:

1. **Mount HDFS.**

   Issue the following command to mount the Data Fabric cluster to the HDFS NFS for the HPE Ezmeral Data Fabric mount point:

   ```
   mount <Data Fabric NFS Server>:/<maprfs_nfs_mount> /<hdfs_nfs_mount>
   ```

   Example

   ```
   mount 10.10.100.175:/mapr /hdfsmount
   ```

2. **Copy data.**

   a. Issue the following command to copy data from the HDFS cluster to the Data Fabric cluster:

   ```
   hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> file:///
   <hdfs_nfs_mount>/<MapR file system path>
   ```

   Example

   ```
   hadoop distcp hdfs://nn1:8020/user/sara/file.txt file:///hdfsmount/
   user/sara
   ```

   b. Issue the following command from the Data Fabric cluster to verify that the file was copied to the Data Fabric cluster:

   ```
   hadoop fs -ls /<MapR file system path>
   ```

   Example

   ```
   hadoop fs -ls /user/sara
   ```

Accessing the File System with C Applications

HPE Ezmeral Data Fabric provides a modified version of `libhdfs` that supports access to the data-fabric file system. You can develop applications with C that read files, write to files, change file permissions and file ownership, create and delete files and directories, rename files, and change the access and modification times of files and directories.

`libMapRClient` supports and makes modifications to the hadoop-<version> version of `libhdfs`. The API reference notes which APIs are supported by hadoop-<version>.

`libMapRClient`'s version of `libhdfs` contains the following changes and additions:

- There are no calls to a JVM, so applications run faster and more efficiently.
- Changes to APIs

©Copyright 2024 Hewlett Packard Enterprise Development LP

- *hadoop-<version>:* Support for `hdfsBuilder` structures for connections to HDFS is limited. Some of the parameters are ignored.
- *hadoop-<version>:* `hdfsGetDefaultBlockSize()`: If the file system that the client is connected to is an instance of file system, the returned value is 256 MB, regardless of the actual setting.
- *hadoop-<version>:* `hdfsCreateDirectory()`: The parameters for buffer size, replication, and block size are ignored for connections to the data-fabric file system.
- *hadoop-<version>:* `hdfsGetDefaultBlockSizeAtPath()`: If the file system that the client is connected to is an instance of file system, the returned value is 256 MB, regardless of the actual setting.
- *hadoop-<version>:* `hdfsOpenFile()`: The parameters for buffer size and replication are ignored for connections to the data-fabric file system.

- APIs that are unique to `libMapRClient` for hadoop-<version>
  - `hdfsCreateDirectory2()`
  - `hdfsGetNameContainerSizeBytes()`
  - `hdfsOpenFile2()`
  - `hdfsSetRpcTimeout()`
  - `hdfsSetThreads()`

Installing and Configuring File System C Clients

Install the `mapr-client` package on the nodes on which you plan to build and run client applications. This package installs the `libMapRClient` library. See Setting Up the Client.

NOTE: The `mapr-core` package contains the files that are in the `mapr-client` package. If you have installed the `mapr-core` package, you do not need to install the `mapr-client` package.

The modified versions of `libhdfs` are installed in this directory:

`MAPR_HOME/hadoop/hadoop-<version>/`

Compiling and Running C Applications on File System Clients

The HPE Ezmeral Data Fabric file system exposes the HDFS API. If you already have a client program built to use `libhdfs`, you do not have to relink your program just to access the file system. However, re-linking to the Data Fabric-specific shared library `libMapRClient.so` will give you better performance on the file system. Unlike `libhdfs.so`, `libMapRClient.so` does not make Java calls to access the file system.

The following script sets environment variables to necessary values and compiles one of the sample applications. Use this script as an example for building and launching your own applications.

When you set HADOOP_HOME for your own client applications, set it to the path for the version of `libhdfs` that your application uses. The path is:

`MAPR_HOME/hadoop/hadoop-<version>/`

Also, set the path to your application in the `gcc` command, of course.

This script assumes that `MAPR_HOME` is set to the default value of `/opt/mapr`.

```
#!/bin/bash
#Setup environment
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
export HADOOP_HOME=${MAPR_HOME}/hadoop/hadoop-<version>/
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:${MAPR_HOME}/lib/
export LD_RUN_PATH=${LD_RUN_PATH}:${MAPR_HOME}/lib
GCC_OPTS="-Wl,--allow-shlib-undefined -I. -I{$HADOOP_HOME}/include/"

#Compile and Link
gcc ${GCC_OPTS} ${HADOOP_HOME}src/c++/libhdfs/hdfs_read.c -o hdfs_read -L$
{MAPR_HOME}/lib -lMapRClient

#Launch the application
./hdfs_read
```

NOTE:

- The compiled `libMapRClient` is statically linked to the following third-party libraries:
  - Crypto++: `libcryptoapp.a` (v5.6.2)
  - Protobuf: `libprotobuf-lite.a` (v2.5.0)
- If a client application connects to the local fileserver, before launching the application you can set the MAPR_CLIENT_SHMEM environment variable to control how much of the local system memory should be devoted to the resources and buffers used for communication between the client application and the local fileserver. By default, the size of the shared memory is 20 MB. If you want to change this value, specify it as a number of pages. For example, to set the shared memory at 128 MB, multiply 128 by 10242 bytes and then divide the product by 8192 bytes. In this case, the value would be 16384 pages.

Overview of the File System C APIs in libMapRClient

Although you can use the file system C APIs to perform other tasks, the most common use of the file system C APIs is to write to and read from files.

Review the following information for an overview of the steps required to use file system C APIs in libMapRClient:

1. Create a connection to the MapR file system running on a MapR cluster. For information about connections, see Establishing Connections to Filesystems.
2. Create or open a file. You can create explicitly or by calling one of the `hdfsOpen()` APIs and specifying a file that doesn't exist. Opening a file sets the current offset to 0, the first byte in the file. You can move file offset explicitly with the `hdfsSeek()` API. Writes done by `hdfsWrite()` and reads done by `hdfsRead()` increment the offset by the number of bytes written or read.

   Use `hdfsTell()` to find out what the current offset is.

   For information about how to specify the location of a file to create or open, see Specifying Paths to Files and Directories.
3. Write to or read from the file. When you write to a file, you pass a buffer that contains the data that you want to write. Writes can be done from the default offset, which is 0 when the file is opened, appended to the end of the file, or done from an offset that you specify. Write buffers are flushed to the server periodically. For more information about writes, seeWriting to Files.

   When you read from a file, you pass a pointer to a buffer for storing the data that is read. Reads can be done from the default offset or from an offset that you specify. For more information about reads, see Reading from Files.

©Copyright 2024 Hewlett Packard Enterprise Development LP

4. Close the file.

   Closing a file implicitly flushes any remaining write buffers to the server. It also frees resources that are associated with the file.

5. Disconnect from the file system.

For more detailed information about these steps, see:

Establishing Connections to the File System

The APIs for establishing connections to the file system and returning file-system handles are:

- hadoop-<version>: `hdfsConnect()`
- hadoop-<version>: `hdfsConnectAsUser()`

  NOTE: This API ignores the impersonation request and is therefore equivalent to `hdfsConnect()`.

- hadoop-<version>: `hdfsConnectNewInstance()`

The `hdfsConnectAsNewUserInstance()` API is not supported for connections to file system fileservers.

These APIs behave in the same way:

- If `default` is specified for the `host` parameter, the APIs connect to the first cluster listed in the file `MAPR_HOME/conf/mapr-clusters.conf`. (`MAPR_HOME` defaults to `/opt/mapr`.)
- If a hostname or IP address is specified for the `host` parameter:
  1. Look in `MAPR_HOME/conf/mapr-clusters.conf` on the client node to match the specified hostname or IP address to a CLDB host and port.
  2. If they find a match, they try to connect to the cluster, and all standard features for connections to Data Fabric clusters are available. These features include high availability across CLDBs and secure connections.
  3. If they do not find a match or if they cannot locate a `mapr-clusters.conf` file, they try to connect to the CLDB host specified in the call to create the connection. However, the standard features for connections to Data Fabric clusters are not available. For example, if the cluster is secured, the connection will fail.

It is possible to have more than one open connection at a time. For each connection, simply return the file-system handle to a different instance of `hdfsFS`, as in this example:

```
    //Connect to Cluster 1 (picked up from /opt/mapr/conf/
mapr-clusters.conf)
        hdfsFS fs1 = hdfsConnectNewInstance("default", 7222);
    //Connect to Cluster 2
        hdfsFS fs2 = hdfsConnectNewInstance("n1c", 7222);
    //Connect to Cluster 3
        hdfsFS fs3 = hdfsConnectNewInstance("n1d", 7222);
```

You can then obtain file handles for files in each connected cluster, as in this example. For each cluster, this example code calls `hdfsOpenFile()`, passing in the handle to the file system, the absolute path to a file (and the file is created before being opened, if it doesn't already exist) and a file-access flag that specifies to open the file in write-only mode. This mode truncates existing files to offset 0, deleting their content.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Ignore the last three parameters for this example. `hdfsOpenFile()` returns a handle to the file or an error message, if the open operation fails.

```
     //Create files for write operations on all clusters
        const char* writePath = "/tmp/write-file1.txt";
        hdfsFile writeFile1 = hdfsOpenFile(fs1, writePath, O_WRONLY, 0, 0,
0);
        if (!writeFile1) {
        fprintf(stderr, "Failed to open %s for writing on Cluster 1!\n",
writePath);
            exit(-2);
     }
        hdfsFile writeFile2 = hdfsOpenFile(fs2, writePath, O_WRONLY, 0, 0,
0);
        if (!writeFile2) {
        fprintf(stderr, "Failed to open %s for writing on Cluster 2!\n",
writePath);
            exit(-2);
     }
         hdfsFile writeFile3 = hdfsOpenFile(fs3, writePath, O_WRONLY, 0, 0,
0);
     if (!writeFile3) {
        fprintf(stderr, "Failed to open %s for writing on Cluster 3!\n",
writePath);
            exit(-2);
     }
         fprintf(stderr, "Opened %s for writing successfully on all 3
clusters...\n", writePath);
```

After working with the files, close them and disconnect from the file system, as in this example:

```
// Close all files
if (writeFile1)
        hdfsCloseFile(fs1, writeFile1);
if (writeFile2)
        hdfsCloseFile(fs2, writeFile2);
if (writeFile3)
        hdfsCloseFile(fs3, writeFile3);

// Disconnect from all clusters
hdfsDisconnect(fs1);
hdfsDisconnect(fs3);
hdfsDisconnect(fs3);
```

Specifying Paths to Files and Directories

Many of the APIs require clients to pass a path to a file or directory. You can specify absolute paths or relative paths. Absolute paths must begin with a forward slash. Relative paths are relative to the working directory, which you can set by calling `hdfsSetWorkingDirectory()` and find out by calling `hdfsGetWorkingDirectory()`. Any path that does not begin with a forward slash is considered to be relative to the working directory.

The maximum length of paths is 4096 bytes.

You cannot specify paths to a cluster other than the cluster for the current connection. All paths are local to the cluster connected to. You can, however, explicitly connect to multiple clusters, as described in Establishing Connections to the File System on page 3200.

Writing to Files

There are two APIs for writing to files: `hdfsWrite()` and `hdfsPwrite()`. With both APIs, you pass a buffer that contains the data to write. You also pass the length of the buffer in bytes. There maximum length

©Copyright 2024 Hewlett Packard Enterprise Development LP

of the buffer is the maximum size of the datatype that is used to specify the buffer length. The datatype is a custom datatype: `tSize`, a signed 32-bit integer.

Both APIs return the number of bytes that were written. Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

For an example of both APIs in action, see `hdfs_write_revised.c`.

NOTE: The `core-site.xml` flags:

- `fs.mapr.flush.unaligned` default setting (`false`) enables flushes to the server in 8K boundaries. Unaligned flushes can happen only if idle flusher (`fs.mapr.write.idleflush.timeout`) is triggered. If this behavior is not desired, set the value for `fs.mapr.flush.unaligned` to `true`, which will enable flushing of unaligned write buffers (so that even small writes can be flushed on every subsequent write call).
- `fs.mapr.write.idleflush.timeout` automatically flushes the buffer, by default, after 3 seconds for all the open files. This can be disabled by setting the value to `0`. If value is specified, buffer is flushed automatically between *n* to *n*+1 seconds. For example, if value is 3 seconds, the write buffer is not cached after 4 seconds.

See also: Default core Parameters.

Using hdfsWrite()

When a file is opened in write-only mode or read-write mode, the file is truncated from offset 0, effectively deleting the content of the file. Therefore, the initial write to the file begins at offset 0. You can start subsequent writes anywhere in the file after first calling `hdfsSeek()` to move to the desired offset. After a write operation, the offset is located at the last written byte.

If the file is opened in append mode, data is appended to the end of the file only.

If a call to `hdfsSeek()` moves the offset past the end of the file before a call to `hdfsWrite()`, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo`.()

On error, pending write buffers are flushed to the server.

Using hdfsPwrite()

Whereas `hdfsWrite()` increments the current offset by the amount of bytes returned by the API (except in case of error), `hdfsPwrite()` does not change the value of current offset. If the current offset before the call to `hdfsPwrite()` is 0 and you specify the offset 10 for the write operation, after the write the current offset remains 0.

If a call to `hdfsPwrite()` specifies an offset that is past the end of the file, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

On error, pending write buffers are flushed to the server.

Reading from Files

There are two APIs for reading from files: `hdfsRead()` and `hdfsPread()`. With both `hdfsRead()` and `hdfsPRead()`, you pass a pointer to a buffer for the runtime to read bytes into and the length of the buffer. There maximum length of the buffer is the maximum size of the datatype that is used to specify the buffer length. The datatype is a custom datatype: `tSize`, a signed 32-bit integer.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Both functions return the number of bytes that are actually read.

For an example of both APIs in action, see `hdfs_read_revised.c`.

Using hdfsRead()

Whenever you open a file, the file pointer is placed at offset 0. If you want to start reading at an offset other than 0, call `hdfsSeek()` to move the file pointer forward to that offset before you call `hdfsRead()`.

When you call `hdfsSeek()`, you specify the offset as a value of type `tOffset`, which is a fixed-width, signed 64-byte integer type for storing offsets. `tOffset` is defined in `hdfs.h`.

If a file is already open and you are not sure what the current offset is, you can find out by calling `hdfsTell()`.

After `hdfsRead()` finishes a read operation, the current offset is set to the last byte read plus one.

Using hdfsPread()

With `hdfsPread()`, you specify the offset at which you want to start reading, so you don't first have to call `hdfsSeek()` to move to that offset.

However, the offset that you specify does not change the current offset in the file. After `hdfsPread()` finishes the read operation, the current offset is not set to the last byte read plus one. Instead, the current offset remains as it was before the read operation.

Sample Applications

The following applications demonstrate how to write to and read from files using the APIs:

hdfs_write_revised.c

Sample Application

This application demonstrates how to write to files by using the APIs `hdfsWrite()` and `hdfsPwrite()`: `hdfs_write_revised.c`

Before running this application:

- Ensure that you have access either to a cluster running file system.
- Ensure that a text-based file that you have access to exists on the cluster. Note the path to the file and the size of the file in bytes.
- The content of the file will be deleted before the first write is performed by the application.
- Decide on the length in bytes of a string to write to the file.

To build and run it, download it from this page to a Data Fabric client or to a system with the `mapr-core` package installed. Then, modify the `run.sh` script in Building and Running C Applications on file system Clients to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `errno.h`
- `fcntl.h`

The APIs are defined in `hdfs.h`. The file `fcntl.h` defines the file-access flags.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

The application performs the actions that are described in the following sections.

Takes a filename, file size, and buffer size as input

When you launch the application, provide the path and name of the file, the size of the file, and the number of bytes to write.

```
hdfs_write <filename> <filesize>
<buffersize>
```

Sets an RPC timeout

`hdfsSetRpcTimeout()` is specific to the `libMapRClient` version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.

```
int err = hdfsSetRpcTimeout(30);
if (err) {
  fprintf(stderr, "Failed to set rpc
timeout!\n");
  exit(-1);
}
```

Connects to a file system, using an API that is supported in the hadoop-2.x version of libhdfs

The application tries to connect to the first file system cluster that is specified in the `mapr-clusters.conf` file in the `MAPR_HOME/conf` directory on the client. After connecting to the file system, the application returns a handle to the file system.

```
hdfsFS fs = hdfsConnect("default", 0);
if (!fs) {
  fprintf(stderr, "Oops! Failed to
connect to hdfs!\n");
  exit(-1);
}
```

Stores the values of the arguments

The application stores the values of the arguments in a character array and in two variables of type `tSize`. This datatype is defined in `hdfs.h` and is a fixed-width, signed 32-byte integer type for storing the size of data for read or write operations.

```
const char* rfile = argv[1];
tSize fileSize = strtoul(argv[2],
NULL, 10);
tSize bufferSize = strtoul(argv[3],
NULL, 10);
```

Opens the file that you specified

The application opens the specified file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the file system
- The name of the file, which you supplied when you launched the application.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- A flag to indicate the mode in which to open the file. In this case, the flag is `O_WRONLY`. This flag creates the file if the file does not exist and truncates the file if the file does exist. If the file existed and you wanted to preserve the content of the file, you would specify `O_WRONLY | O_APPEND` for flag. These flags are defined in the header file `fcntl.h`.
- The default chunk size for the directory in which the file is either located or will be created. This value is specified by the 0 in the last parameter.

Although there are two other parameters in the `hdfsOpenFile()` function – the fourth and fifth, the `libMapRClient` version of `libhdfs` ignores them.

```
hdfsFile writeFile = hdfsOpenFile(fs,
rfile, O_WRONLY, 0, 0, 0);
if (!writeFile) {
   fprintf(stderr, "Failed to open %s
for writing!\n", rfile);
   exit(-2);
}
```

Creates a buffer of the size that you specified and populates the buffer

At this point that the application, creates a string to populate the buffer. This is the data that the application will write.

```
char* buffer = malloc(sizeof(char) *
bufferSize);
if(buffer == NULL) {
  fprintf(stderr, "Failed to allocate
memory!\n");
  return -2;
}
int i;
  for (i=0; i<bufferSize; i++) {
  buffer[i] = 'a' + i%26;
}
```

Writes an entire file with hdfsWrite()

The application calls the function `writeLength()`:

```
int ret = writeLength(fs, writeFile,
buffer, bufferSize, fileSize);
if (ret < 0) {
  goto done;
}
```

This function writes the content of the buffer to the file, starting at offset 0.

```
int
writeLength(hdfsFS fs, hdfsFile
writeFile, char *buffer, tSize
bufferSize, tSize writeSize)
{
  tSize writeBytes = 0;
  tSize ret = 0;
  uint64_t totalWrite = 0;
  if (fs == NULL || writeFile == NULL
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
|| buffer == NULL) {
    return -1;
  }
  if (writeSize == 0) {
    return 0;
  }
  for
(writeBytes=0; writeBytes<writeSize;
writeBytes+=bufferSize) {
    ret = hdfsWrite(fs, writeFile,
(void*)buffer, bufferSize);
    if (ret > 0) {
      totalWrite += ret;
    } else {
      fprintf(stderr, "hdfsWrite
failed with error %d \n", errno);
      hdfsCloseFile(fs, writeFile);
      return -1;
    }
  }
  return 0;
}
```

Seeks an offset and writes from that offset with hdfsWrite()

The application next calls the function `writeAtOffse()`:

```
  tSize writeBytes =
writeAtOffset(fs, writeFile, 0,
buffer, bufferSize);
if (writeBytes < 0) {
  goto done;
}
```

This function writes the content of the buffer to the file, starting at the specified offset. If the file already exists, the file is first truncated to this offset before the write operation begins. In this case, the specified offset is 0.

The difference between this function and the previous function is that, before writing, it calls `hdfsSeek()` to move to the specified offset in the file.

```
tSize
writeAtOffset(hdfsFS fs, hdfsFile
writeFile, tOffset offset,
                char *buffer, tSize
bufferSize)
{
  tSize ret = 0;
  if (fs == NULL || writeFile == NULL
|| buffer == NULL) {
    return -1;
  }
  ret = hdfsSeek(fs, writeFile,
offset);
  if (!ret) {
    //hdfsWrite will return -1 if
ret != number of bytes asked to
    //be written.
    ret = hdfsWrite(fs, writeFile,
buffer, bufferSize);
    if (ret < 0) {
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
      fprintf(stderr, "hdfsWrite
failed with error %d \n", errno);
    }
  } else {
    fprintf(stderr, "hdfsSeek failed
with error %d \n", errno);
  }
  if (ret < 0) {
    //hdfsWrite does a flush in case
of an error, explicit flush
    //is not required.
    hdfsCloseFile(fs, writeFile);
  }
  //Current offset within the file
will be positioned at (offset +
writeBytes)th byte.
  return ret;
}
```

Performs a positional write with hdfsPwrite()

The application next calls the function `positionalWrite()`:

```
writeBytes = positionalWrite(fs,
writeFile, 20, buffer, bufferSize);
if (writeBytes < 0) {
  goto done;
}
```

This function writes the content of the buffer to the file, starting at the offset that you specify.

```
tSize
positionalWrite(hdfsFS fs, hdfsFile
writeFile, tOffset offset,
               char *buffer, tSize
bufferSize)
{
  tSize writeBytes = 0;
  if (fs == NULL || writeFile == NULL
|| buffer == NULL) {
    return -1;
  }
  writeBytes = hdfsPwrite(fs,
writeFile, offset, buffer,
bufferSize);
  if (writeBytes < 0) {
    fprintf(stderr, "hdfsPwrite
failed with error %d \n", errno);
    hdfsCloseFile(fs, writeFile);
  }
  //Current offset within the file
will not be advanced if hdfsPwrite is
used
  return writeBytes;
}
```

Closes the file

```
hdfsCloseFile(fs, writeFile);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Frees the buffer	`free(buffer);`
Disconnects from the file system	`hdfsDisconnect(fs);`

hdfs_read_revised.c

Sample Application

This application demonstrates how to read from files by using the APIs `hdfsRead()` and `hdfsPread()`: `hdfs_read_revised.c`

Before running this application:

- Ensure that you have access to a cluster running file system.
- Ensure that a text-based file that you have access to exists on the cluster. Note the path to the file.
- Decide on the number of bytes to read from the file.

To build and run it, download it from this page and copy it to a Data Fabric client. Then, modify the `run.sh` script in Building and Running C Applications on file system Clients to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `errno.h`
- `fcntl.h`

The APIs are defined in `hdfs.h`. The file `fcntl.h` defines the file-access flags.

The application performs the actions that are described in the following sections.

Takes a filename and buffer size as input	After compiling the application, type the following command to launch the application and pass in the path and name of the file, as well as the size of the buffer to read data into: `hdfs_read <filename> <buffer size>`

Sets an RPC timeout	`hdfsSetRpcTimeout()` is specific to the `libMapRClient` version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.
	`int err = hdfsSetRpcTimeout(30);`
	`if (err) {`
	`  fprintf(stderr, "Failed to set rpc timeout!\n");`
	`  exit(-1);`
	`}`

Connects to a file system, using an API that is supported in the hadoop-2.x version of libhdfs	The application tries to connect to the first file system cluster that is specified in the `mapr-clusters.conf` file in the `MAPR_HOME/conf` directory on the client.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

After connecting to the file system, the application returns a handle to the file system.

```
hdfsFS fs = hdfsConnect("default", 0);
if (!fs) {
  fprintf(stderr, "Oops! Failed to
connect to hdfs!\n");
  exit(-1);
}
```

Stores the values of the arguments

The application stores them in a character array and in a variable of type `tSize`. This datatype is defined in `hdfs.h` and is a fixed-width, signed 32-byte integer type for storing the size of data for read or write operations.

```
const char* rfile = argv[1];
tSize bufferSize = strtoul(argv[2],
NULL, 10);
```

Opens the file that you specified

The application opens the specified file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the file system
- The name of the file, which you supplied when you launched the application.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_RDONLY`, which specifies read-only mode.
- The default chunk size for the directory in which the file is either located or will be created. This value is specified by the 0 in the last parameter.

Although there are two other parameters in the `hdfsOpenFile()` function – the fourth and fifth, the `libMapRClient` version of `libhdfs`ignores them.

```
hdfsFile readFile = hdfsOpenFile(fs,
rfile, O_RDONLY, 0, 0, 0);
if (!readFile) {
  fprintf(stderr, "Failed to open %s
for reading!\n", rfile);
  exit(-2);
}
```

Creates a buffer of the size that you specified

This is the buffer that the application will read data into.

```
  char* buffer = malloc(sizeof(char)
* bufferSize);
if(buffer == NULL) {
  fprintf(stderr, "Failed to allocate
memory!\n");
  return -2;
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Reads an entire file with hdfsRead

The application calls the function `readEntireFile()`:

```
//Read entire file from the beginning
int ret = readEntireFile(fs,
readFile, buffer, bufferSize);
if (ret < 0) {
  goto done;
}
```

This function uses a WHILE loop. In each loop iteration, the function reads an amount of data that is equal to the size of the buffer. When the amount of bytes read is less than the size of the buffer, the end of the file has been reached and the function breaks the loop. The number of bytes read is added to a total in each iteration.

```
int
readEntireFile(hdfsFS fs, hdfsFile
readFile, char *buffer, tSize
bufferSize)
{
  tSize readBytes = bufferSize;
  uint64_t totalRead = 0;
  if (fs == NULL || readFile == NULL
|| buffer == NULL) {
    return -1;
  }
  while (readBytes == bufferSize) {
    readBytes = hdfsRead(fs,
readFile, (void*)buffer, bufferSize);
    if (readBytes > 0) {
      totalRead += readBytes;
    } else {
      if (readBytes < 0) {
        fprintf(stderr, "hdfsRead
failed with error %d \n", errno);
        hdfsCloseFile(fs, readFile);
        return -1;
      }
      break;
    }
  }
  return 0;
}
```

Seeks an offset and reads from that offset with hdfsRead()

The application next calls the function `readAtOffset()`, passing in 0 as the offset from which to start reading the file.

```
//Read file at a particular offset
//In this case, we are reading from
offset 0
tSize readBytes = readAtOffset(fs,
readFile, 0, buffer, bufferSize);
if (readBytes < 0) {
  goto done;
}
```

This function calls `hdfsSeek()` to move to the specified offset in the file.

©Copyright 2024 Hewlett Packard Enterprise Development LP

If the seek is successful, the function reads from that offset until the buffer is full. The function then returns the number of bytes that were read.

If the seek or the read is not successful (meaning `hdfsSeek()` or `hdfsRead()` returned -1), the function closes the file and returns -1.

The offset in the file is the next byte after the end of the data that was read.

```
tSize
readFromOffset(hdfsFS fs, hdfsFile
readFile, tOffset offset,
               char *buffer, tSize
bufferSize)
{
  tSize ret = 0;
  if (fs == NULL || readFile == NULL
|| buffer == NULL) {
    return -1;
  }
  ret = hdfsSeek(fs, readFile,
offset);
  if (!ret) {
    ret = hdfsRead(fs, readFile,
buffer, bufferSize);
    if (ret < 0) {
      fprintf(stderr, "hdfsRead
failed with error %d \n", errno);
    }
  } else {
    fprintf(stderr, "hdfsSeek failed
with error %d \n", errno);
  }
  if (ret < 0) {
    hdfsCloseFile(fs, readFile);
  }
  //Current offset within the file
will be positioned at (offset +
readBytes)th byte.
  return ret;
}
```

Performs a positional read with hdfsPread()

The application calls `positionalRead()`, passing 100 as the offset from which to start the read.

```
  readBytes = positionalRead(fs,
readFile, 100, buffer, bufferSize);
if (readBytes < 0) {
  goto done;
}
```

The function reads data into the buffer, starting at offset 100, without first calling `hdfsSeek()` to move the offset to that position. The offset is not moved to 100 before the read begins. The offset stays where it is, the read begins at offset 100, and (after the read) the offset remains where it was before the read. The offset in the file is ignored by the positional read.

```
tSize
positionalRead(hdfsFS fs, hdfsFile
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
readFile, tOffset offset,
                char *buffer, tSize
bufferSize)
{
  tSize readBytes = 0;
  if (fs == NULL || readFile == NULL
|| buffer == NULL) {
    return -1;
  }
  readBytes = hdfsPread(fs, readFile,
offset, buffer, bufferSize);
  if (readBytes < 0) {
    fprintf(stderr, "hdfsPread failed
with error %d \n", errno);
    hdfsCloseFile(fs, readFile);
  }
  //Current offset within the file
will not be advanced if hdfsPread is
used
  return readBytes;
}
```

Closes the file

```
hdfsCloseFile(fs, readFile);
```

Frees the buffer

```
free(buffer);
```

Disconnects from the file system

```
hdfsDisconnect(fs);
```

hdfs_connect_as_user.c

Sample Application

This application demonstrates how to create and write to files impersonating another user by using the API `hdfsConnectAsUser()`.

Before running this application, ensure that you have access to a cluster running Data Fabric file system.

To build and run it, download it from this page and copy it to a Data Fabric client or to a system with the mapr-core package installed. Then, modify the `run.sh` script in Building and Running C Applications on file system Clients to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `stdlib.h`
- `string.h`

NOTE: The impersonation APIs are defined in `hdfs.h`.

The application performs the actions that are described in the following sections.

Takes two usernames and a hostname as input

After compiling the application, type the following command to launch the application and pass in the two usernames (to impersonate) and host name:

```
hdfs_connect_as_user <username1>
<username2> <hostname>if (argc < 4) {
  fprintf (stderr, "Provide two
usernames to impersonate and the host
name\n");
  printf ("USAGE: ./
hdfs_connect_as_user mapruser1
mapruser2 10.10.xx.xxx\n");
  exit(EXIT_FAILURE);
}
```

Stores the values of the arguments

The application stores the values of the arguments in character arrays. The application uses the port, 7222, to connect to the given host, and uses character arrays for user directory and file path.

```
char *impersonate_user1 = argv[1];
char *impersonate_user2 = argv[2];
char *host_addr = argv[3];
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
int port_num = 7222;
char user1_dir[100];
char writePath[100];
int ret_val;
```

Populates the directory path and file path

The application creates a default path for the user directory and file.

```
sprintf(user1_dir, "/tmp/%s_dir",
impersonate_user1);
sprintf(writePath, "%s/test_file",
user1_dir);
```

Sets an RPC timeout

The `hdfsSetRpcTimeout()` is specific to the libMapRClient version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.

```
int err = hdfsSetRpcTimeout(30);
if (err) {
  fprintf(stderr, "Failed to set rpc
timeout!\n");
  exit(-1);
}
```

Connects to the file system as the impersonated user

The application connects to the file system as the impersonated user (<username1>) using `hdfsConnectAsUser()`. If successful, this operation returns a handle to the file system.

```
printf("Impersonate user: %s\n",
impersonate_user1);
printf("Connecting using
hdfsConnectAsUser() as user %s\n",
impersonate_user1);
hdfsFS fs_handle =
hdfsConnectAsUser(host_addr,
port_num, impersonate_user1);
if (fs_handle == NULL) {
    printf("hdfsConnectAsUser()
failed.\n");
    exit(EXIT_FAILURE);
}
```

Creates a directory as the impersonated user

The application creates a directory under `/tmp` as the impersonated user (<username1>).

```
printf("User1: Create a directory :
%s\n", user1_dir);
ret_val =
hdfsCreateDirectory(fs_handle,
user1_dir);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsCreateDirectory()
failed.\n");
  exit(EXIT_FAILURE);
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Creates and opens a file

The application creates a file and opens the file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the file system.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_WRONLY|O_CREAT`. This flag creates the file and opens it for writing.

For more details, see `hdfsOpenFile()` documentation.

```
printf("User1: Create and write to
the file as user1 : %s\n", writePath);
hdfsFile writeFile =
hdfsOpenFile(fs_handle, writePath,
O_WRONLY|O_CREAT, 0, 0, 0);
if(!writeFile) {
  printf("hdfsOpenFile() failed.\n");
  exit(EXIT_FAILURE);
}
```

Writes to the open file

The application writes to the open file as the impersonated user (<username1>).

```
char* buffer = "Hello, from user 1!";
tSize num_written_bytes =
hdfsWrite(fs_handle, writeFile,
(void*)buffer, strlen(buffer)+1);
if (hdfsFlush(fs_handle, writeFile)) {
  printf("failed to flush %s\n",
writePath);
  exit(EXIT_FAILURE);
}
```

Closes the file

The application closes the file after successfully writing to the file as the impersonated user (<username1>).

```
printf("User1: Close file %s.\n",
writePath);
hdfsCloseFile(fs_handle, writeFile);
```

Connects to the file system as the impersonating user

The application connects to the file system as the second user (<username2>) using `hdfsConnectAsUser()` and returns a handle to the file system.

```
printf("Impersonate user: %s\n",
impersonate_user2);
printf("Connecting using
hdfsConnectAsUser() as user %s\n",
impersonate_user2);
hdfsFS fs_handle2 =
hdfsConnectAsUser(host_addr,
port_num, impersonate_user2);
if (fs_handle2 == NULL) {
  printf("hdfsConnectAsUser()
failed.\n");
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
  exit(EXIT_FAILURE);
}
```

Tries to write to the file as the impersonating user

The application tries to open the file created by the impersonated user (<username1>) and write to the file as the impersonating user (<username2>). This operation fails as the impersonating user (<username2>) is denied access to the file created by the impersonated user (<username1>) and the application returns error EACCES.

```
printf("User2: Try opening file
created by user1 for writing : %s\n",
writePath);
hdfsFile writeFile2 =
hdfsOpenFile(fs_handle2, writePath,
O_WRONLY, 0, 0, 0);
int errNum = errno;
if(writeFile2) {
    printf("User2: hdfsOpenFile()
should have failed for %s.\n",
impersonate_user2);
    exit(EXIT_FAILURE);
} else {
    if (errNum == EACCES) {
        printf("User2: As expected
hdfsOpenFile() with EACCES.\n");
    } else {
        printf("User2: hdfsOpenFile()
failed with errno:%d expected %d.\n",
errNum, EACCES);
        exit(EXIT_FAILURE);
    }
}
```

Deletes a directory

The application deletes a directory as the impersonated user (<username1>) using the file system handle created for this user.

```
printf("Delete directory : %s\n",
user1_dir);
ret_val = hdfsDelete(fs_handle,
user1_dir, 1);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsDelete() failed.\n");
  exit(EXIT_FAILURE);
}
```

Disconnects the impersonating user

The application disconnect the impersonating user (<username2>) from the file system.

```
printf("Disconnect the impersonation
user2.\n");
ret_val = hdfsDisconnect(fs_handle2);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsDisconnect()
failed.\n");
  exit(EXIT_FAILURE);
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Disconnects the impersonated user	The application disconnect the impersonated user (<username1>) from the file system.

```
printf("Disconnect the impersonation
user1.\n");
ret_val = hdfsDisconnect(fs_handle);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsDisconnect()
failed.\n");
  exit(EXIT_FAILURE);
}
```

Reference for the file system C APIs

The following sections describe the custom datatypes, structures, and APIs in the `libMapRClient` version of `libhdfs`:

Type Definitions

`libhdfs` defines the following custom data types, which are supported by `libMapRClient`:

tObjectKind

An enumeration, the values of which are ‘F’ for file and ‘D’ for directory. Used to specify whether an object is a file or directory.

tOffset

A signed 64-bit integer that is used to specify an offset within a file and the size of a file.

tPort

An unsigned 16-bit integer that is used to specify a port to use in connections to filesystems.

tSize

A signed 32-bit integer that is used to specify the size of data in bytes to read or write.

©Copyright 2024 Hewlett Packard Enterprise Development LP

tTime

A data type of `time_t` that is used to specify a time in seconds.

Structures

`libhdfs` defines these structures, which are supported by `libMapRClient`.

hdfsBuilder

Supported by libhdfs for hadoop-2.x

This structure can be passed to `hdfsBuilderConnect()` for creating connections to file system clusters. In the `libMapRClient`, four of the parameters are ignored. `forceNewInstance` is ignored, though the header file does not indicate this.

```
struct hdfsBuilder {
    int forceNewInstance;
    const char *nn;
    tPort port;
    const char *kerbTicketCachePath; // Ignored
    const char *userName;            // Ignored
    struct hdfsBuilderConfOpt *opts; // Ignored
};
```

Parameters

`nn`

Specifies the CLDB node to connect to when `hdfsBuilderConnect()` is called. This value is set by `hdfsBuilderSetNameNode()`.

- If `default` is specified for the `host` parameter, `hdfsBuilderConnect()` will connect to the first cluster listed in the file `MAPR_HOME/conf/mapr-clusters.conf`. (`MAPR_HOME` defaults to `/opt/mapr`.)
- If a hostname or IP address is specified for the `host` parameter, `hdfsBuilderConnect()`, look in `MAPR_HOME/conf/mapr-clusters.conf` on the client node to match the specified hostname or IP address to a CLDB host and port.
  - If they find a match, they try to connect to the cluster and all standard features for connections to Data Fabric clusters are available. These features include high availability across CLDBs and secure connections.
  - If they do not find a match or if they cannot locate a `mapr-clusters.conf` file, they try to connect to the CLDB host specified in the call to create the connection. However, the standard features for connections to Data Fabric clusters are not available. For example, if the cluster is secured, the connection will fail.

`port`

Specifies the port to connect to on the CLDB node. This value is set by `hdfsBuilderSetNameNodePort()`.

hdfsFileInfo

Supported by libhdfs for hadoop-2.x

This structure is returned by `hdfsGetPathInfo()` and deleted by `hdfsFreeFileInfo()`. It contains information about the file or directory that is specified in the call to `hdfsGetPathInfo()`.

`ParameterstObjectKind mKind`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Specifies whether the object is a file or directory.

`char *mName`

Specifies the name of the object.

`tTime mLastMod`

Specifies the epoch time in milliseconds of the last modification to the object.

`tOffset mSize`

Specifies the size of the object in bytes.

`short mReplication`

Specifies the count of replicas of the object.

`tOffset mBlockSize`

Specifies the block size for the object.

`char *mOwner`

Specifies the owner of the object.

`char *mGroup`

Specifies the group that is associated with the object.

`short mPermissions`

Specifies the permissions on the object.

`tTime mLastAccess`

Specifies the epoch time in milliseconds at which the object was created.

APIs

The following sections provide information about the hdfs APIs:

hdfsAvailable()

Supported by `libMapRClient` for hadoop-2.x

Returns the number of bytes that can be read from an input stream without blocking. This number is simply the size of the file in bytes.

Signature

```
int hdfsAvailable(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns the size of the file in bytes, -1 on error.

Check errno for error codes and meanings.

©Copyright 2024 Hewlett Packard Enterprise Development LP

errno is set to EINVAL if the arguments provided are invalid.

hdfsBuilderConnect()

Supported by `libMapRClient` for hadoop-2.x

Connects to a Data Fabric file system using the parameters that are specified in an `hdfsBuilder` structure.

Signature

```
hdfsFS hdfsBuilderConnect(struct hdfsBuilder *bld)
```

Parameters

Parameter	Description
bld	The builder to use for the connection. This value cannot be NULL.

Return Value

Returns the handle to the file system or NULL on error.

hdfsBuilderSetForceNewInstance()

Not supported for file system

This API is ignored.

hdfsBuilderSetKerbTicketCachePath()

Not supported for file system

This API is ignored.

hdfsBuilderSetNameNode()

Supported by `libMapRClient` for hadoop-2.x

Specifies a CLDB node for an `hdfsBuilder` structure.

Signature

```
void hdfsBuilderSetNameNode(struct hdfsBuilder *bld, const char *nn)
```

Parameters

Parameter	Description
bld	An `hdfsBuilder` structure. This value cannot be NULL.
nn	The hostname or IP address of a name node. Use NULL to connect to the local file system. Use `default` to connect to the first file system cluster that is listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

hdfsBuilderSetNameNodePort()

Supported by `libMapRClient` for hadoop-2.x

Sets the port in an `hdfsBuilder` structure.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Signature

```
void hdfsBuilderSetNameNodePort(struct hdfsBuilder *bld, tPort port)
```

Parameters

Parameter	Description
bld	An `hdfsBuilder` structure. This value cannot be NULL.
port	The port to use for connections. If the CLDB node is set to NULL or `default`, use 0.

hdfsBuilderSetUserName()

Not supported for file system

This API is ignored.

hdfsChmod()

Supported by `libMapRClient` for hadoop-2.x

Changes permissions on a file or directory in the manner of the `chmod` command.

Signature

```
int hdfsChmod(hdfsFS fs, const char* path, short mode)
```

Parameters

Parameter	Description
fs	The handle to the file system. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path to the file or directory.
mode	The bitmask for the new permissions.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

errno is set to EPERM if the process does not have enough privileges to perform the operation.

hdfsChown()

Supported by `libMaprClient` for hadoop-2.x

Changes ownership of a file or directory in the manner of the `chown` command.

©Copyright 2024 Hewlett Packard Enterprise Development LP

ATTENTION:

- To permit a client to resolve user or group from a server, set the `fs.mapr.server.resolve.user` parameter to `true` in `core-site.xml`, for both secure and non secure clusters. Setting this is essential when the client does not belong to the same domain as the mapr cluster nodes, and does not have any knowledge of users present in that domain.
- To permit CLDB to resolve user or group, set the `cldb.security.resolve.user` configuration parameter to `1` on a non-secure cluster as follows:

  ```
  maprcli config save -values {"cldb.security.resolve.user":1}
  ```

  You do not have to set this parameter for a secure cluster, as it is already set to `1`.

Signature

```
int hdfsChown(hdfsFS fs, const char* path, const char *owner, const char
*group)
```

Parameters

Parameter	Description
fs	The handle to the file system. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path to the file or directory
owner	The user to own the file or directory. Set to NULL to keep the owner as is.
group	The group to own the file or directory. Set to NULL to keep the owner as is.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

errno is set to EPERM if the process does not have enough privileges to perform the operation.

hdfsCloseFile()

Supported by `libMapRClient` for hadoop-2.x

Closes an open file. Flushes all pending write buffers for the file and releases resources that are associated with the file.

Signature

```
int hdfsCloseFile(hdfsFS fs, hdfsFile file)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsConnect()

Supported by `libMapRClient` for hadoop-2.x

Connects to a file system cluster.

If a connection to the cluster in which the remote host is located already exists, the functions return a handle to this existing connection.

If a connection to the cluster does not already exist, the functions return a handle to a new connection instance.

Note that if `default` is used for the `host` parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to file system.

Signature

```
hdfsFS hdfsConnect(const char* host, tPort port)
```

Parameters

Parameter	Description
host	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value `default` and use the port number 0. This parameter does not accept NULL as a value.
port	The port on which the host is listening.

Return Value

Returns a handle to the connected file system, or NULL on error.

Check errno for error codes and meanings.

hdfsConnectAsUser()

Supported by `libMapRClient` for hadoop-2.x

Connects to a file system cluster as specified user.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

If a connection to the cluster in which the remote host is located already exists, the functions return a handle to this existing connection.

If a connection to the cluster does not already exist, the functions return a unique handle to a connection instance for each user.

NOTE: If `default` is used for the host parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to file system.

Signature

```
hdfsFS hdfsConnectAsUser(const char* host, tPort port, const char* user)
```

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.
`user`	The user connected to the cluster.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsConnectAsUid()
Connects to a file system cluster as specified user ID.

Supported by `libMapRClient` for hadoop-2.x

If a connection to the cluster in which the remote host is located already exists, the function returns a handle to this existing connection.

If a connection to the cluster does not already exist, the function returns a unique handle to a connection instance for the specified user ID.

NOTE: To connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client, use `default` as the value for the `host` parameter.

For more information about connections, see Establishing Connections to the File System on page 3200.

Signature

```
hdfsFS hdfsConnectAsUid(const char* host, tPort port, uid_t uid)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.
`user ID`	The ID of the user connected to the cluster.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsConnectAsUserNewInstance()

Supported by libMapRClient for hadoop-2.x

Connects to a file system cluster as specified user.

The function returns a handle to a new connection instance.

NOTE: If default is used for the host parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to file system.

Signature

```
hdfsFS hdfsConnectAsUserNewInstance(const char* host, tPort port, const
char* user)
```

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsConnectNewInstance()

Supported by `libMapRClient` for hadoop-2.x

Connects to a file system cluster.

The function returns a handle to a new connection instance.

©Copyright 2024 Hewlett Packard Enterprise Development LP

NOTE: If `default` is used for the host parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to file system.

Signature

```
hdfsFS hdfsConnectNewInstance(const char* host, tPort port)
```

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.
`user`	The user connected to the cluster.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsCopy()

This API is not supported.

hdfsCreateDirectory()

Supported by `libMapRClient` for hadoop-2.x

Creates a file or directory at the specified path. Intermediate directories in the path that do not exist are created.

Signature

```
int hdfsCreateDirectory(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The handle of the file system in which to create the file or directory. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the directory.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

errno is set to EINVAL if the input arguments are not valid, EEXIST if the directory already exists, or EACCES if the parent directory does not allow the user write permission.

hdfsCreateDirectory2()

Supported by `libMapRClient` for hadoop-2.x

Makes the given file and all non-existent parents into directories. Stores the size of the name container in a location that you pass a pointer into, so that you can keep track of this size. The size is in bytes.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Signature

```
int hdfsCreateDirectory2(hdfsFS fs, const char* path, tSize
*nameSizeInBytes)
```

Parameters

Parameter	Description
fs	The handle of the file system in which to create the file or directory. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the directory.
nameSizeInBytes	A pointer to a memory buffer that can store the size in bytes of the name container.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsDelete()

Supported by `libMapRClient` for hadoop-2.x

Deletes the specified directory or file.

Signature

```
int hdfsDelete(hdfsFS fs, const char* path, int recursive)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file or directory to delete is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the file.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameter	Description
recursive	A value of 0 deletes the specified directory, if the directory is empty. If the directory is not empty, an error is returned. A non-zero value deletes the specified directory and all of its subdirectories. If the specified object is a file, not a directory, this parameter is ignored.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings. Some of the key errors are ESTALE, EACCES, and EPERM.

hdfsDisconnect()

Supported by `libMapRClient` for hadoop-2.x

Disconnects from the specified file system.

Even if there is an error, the resources that are associated with the file system handle are freed.

Signature

```
int hdfsDisconnect(hdfsFS fs)
```

Parameter

Parameter	Description
fs	The handle of the file system to disconnect from. Obtain this handle with one of the `hdfsConnect()` APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsExists()

Supported by `libMapRClient` for hadoop-2.x

Checks whether a given directory or file exists on the file system.

Signature

```
int hdfsExists(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The directory or file to check the existence of.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Return Value

Returns 0 if the directory or file exists, -1 on error.

Check errno for error codes and meanings.

hdfsExists2()

Supported by `libMapRClient` for hadoop-2.x

Checks the file system directly (avoiding a client cache) to determine whether a given file or directory exists.

Signature

```
int hdfsExists2(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The directory or file to check the existence of.

Return Value

Returns 0 if the directory or file exists, -1 on error.

Check errno for error codes and meanings.

hdfsFileFreeReadStatistics()

This API is not supported.

hdfsFileGetReadStatistics()

This API is not supported.

hdfsFileIsOpenForRead()

This API is not supported.

hdfsFileIsOpenForWrite()

This API is not supported.

hdfsFlush()

Supported by `libMapRClient` for hadoop-2.x

Flushes the write buffer for the specified file to the server

Signature

```
int hdfsFlush(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle with one of the `hdfsConnect()` APIs.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameter	Description
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

hdfsFreeBuilder()

Supported by `libMapRClient` for hadoop-2.x

Frees the memory that was used by an `hdfsBuilder` structure and its parameter values.

Signature

```
void hdfsFreeBuilder(struct hdfsBuilder *bld)
```

Parameters

Parameter	Description
bld	An `hdfsBuilder` structure. The value cannot be NULL.

hdfsFreeFileInfo()

Supported by `libMapRClient` for hadoop-2.x

Frees up the array of `hdfsFileInfo` structures that is returned by `hdfsListDirectory()`, including allocated fields.

Signature

```
void hdfsFreeFileInfo(hdfsFileInfo *hdfsInfo, int numEntries)
```

Parameters

Parameter	Description
hdfsInfo	The array of dynamically-allocated `hdfsFileInfo` structures.
numEntries	The size of the array.

hdfsFreeHosts()

Supported by `libMapRClient` for hadoop-2.x

Frees an array that was returned by `hdfsGetHosts()`.

Signature

```
void hdfsFreeHosts(char ***blockHosts)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameters

Parameter	Description
blockHosts	The two-dimensional array that was returned by `hdfsGetHosts()`.

hdfsGetCapacity()

Supported by `libMapRClient` for hadoop-2.x

Returns the capacity in bytes of the connected file system.

Signature

```
tOffset hdfsGetCapacity(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle by calling one of the `hdfsConnect()` APIs.

Return Value

Returns the capacity in bytes of the connected file system, -1 on error.

Check errno for error codes and meanings.

errno can be set to EINVAL in case of error.

hdfsGetDefaultBlockSize()

Supported by libMapRClient for hadoop-2.x

Gets the default size of blocks for the connected file system.

Signature

```
tOffset hdfsGetDefaultBlockSize(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The handle of file system. Obtain this handle with one of the `hdfsConnect()` APIs.

Return Value

Returns 256 MB.

Returns -1 on error.

Check errno for error codes and meanings.

hdfsGetDefaultBlockSizeAtPath()

Supported by `libMapRClient` for hadoop-2.x

Gets the block size of a file at the specified path.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Signature

```
tOffset hdfsGetDefaultBlockSizeAtPath(hdfsFS fs, const char *path)
```

Parameters

Parameter	Description
fs	The handle of the file system. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The location and name of the file.

Return Value

Returns 256 MB.

Check errno for error codes and meanings.

hdfsGetHosts()

Supported by `libMapRClient` for hadoop-2.x

Gets hostnames where a particular block, as determined by the offset and block size, is stored. Due to replication, a single block could be present on multiple hosts.

This function can be useful for understanding the performance implications of file access, and to validate or verify changes to the replication factor.

Signature

```
char*** hdfsGetHosts(hdfsFS fs, const char* path, tOffset start, tOffset
length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the file.
start	The start of the block.
length	The length of the block.

Return Value

If successful, returns a dynamically-allocated two-dimensional array of hostnames. The last element in the array is NULL.

Returns NULL on error.

Check errno for error codes and meanings.

hdfsGetNameContainerSizeBytes()

Unique to libMapRClient

Get the size of the container hosting the path.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Signature

```
int tSize hdfsGetNameContainerSizeBytes(hdfsFS fs, const char *path)
```

Parameters

Parameter	Description
path	Path of the file or directory residing on the container.

Return Value

Returns size of the container on success; -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

hdfsGetPathInfo()

Supported by libMapRClient for hadoop-2.x

Returns a dynamically-allocated `hdfsFileInfo` structure that contains information about the given path.

Call `hdfsFreeFileInfo()` when the structure is no longer needed.

See `hdfsFileInfo()` for information about the information that this object contains.

Signature

```
hdfsFileInfo * hdfsGetPathInfo(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this by calling one of the `hdfsConnect()` APIs.
path	The path of the file.

Return Value

Returns a dynamically-allocated `hdfsFileInfo` structure on success, and NULL on error.

errno is set to EINVAL for invalid arguments and to EACCES for invalid access.

hdfsGetUsed()

Supported by libMapRClient for hadoop-2.x

Returns the total number of bytes bytes that are being used by all of the files in the file system.

Signature

```
tOffset hdfsGetUsed(hdfsFS fs)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameters

Parameter	Description
fs	The file system handle.

Return Value

Returns the total size in bytes or -1 on error.

Check errno for error codes and meanings.

hdfsGetWorkingDirectory()

Supported by libMapRClient for hadoop-2.x

Gets the current working directory for the file system. Before calling this method, the application must have called `hdfsSetWorkingDirectory()`.

Signature

```
char* hdfsGetWorkingDirectory(hdfsFS fs, char *buffer, size_t bufferSize)
```

Parameters

Parameter	Description
fs	The file system handle.
buffer	The buffer in which to copy path of current working directory.
bufferSize	The length of user-buffer.

Return Value

Returns the buffer on success, NULL on error.

errno is set to EINVAL for invalid arguments.

hdfsGetXattr()

Supported by libMapRClient for hadoop-2.x

Gets extended attribute values from a file.

Signature

```
int hdfsGetXattr(hdfsFS fs, const char* path, const char *name, char
*value,  size_t size);
```

Parameters

Parameter	Description
`fs`	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
`name`	The name of the extended attribute.
`path`	The path to the file.
`size`	The size of the buffer.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameter	Description
`value`	The value for the extended attribute that is read from the system and written to the buffer.

Return Value

Returns:

- Current size of the value of the extended attribute on success
- -1 on error

  Check `errno` for error codes and meanings.

hdfsListDirectory()

Supported by `libMapRClient` for hadoop-2.x

Gets list of files and directories for a given path. Returns the information in a dynamically allocated array of `hdfsFileInfo` structures.

`hdfsFreeFileInfo()` should be called to deallocate memory when this structure is no longer needed.

This method is the equivalent of the `ls -l` command.

Signature

```
hdfsFileInfo *hdfsListDirectory(hdfsFS fs, const char* path, int
*numEntries)
```

Parameters

Parameter	Description
fs	The handle of the file system. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the directory.
numEntries	Set to the number of files/directories in path. Cannot be 0 or NULL.

Return Value

Returns a dynamically-allocated array of `hdfsFileInfo` structures on success and NULL on error.

Check errno for error codes and meanings.

hdfsMove()

This API is not supported.

hdfsNewBuilder()

Supported by `libMapRClient` for hadoop-2.x

Returns an `hdfsBuilder` structure. You can set values for its parameters and then pass it to `hdfsBuilderConnect()`.

Signature

```
struct hdfsBuilder *hdfsNewBuilder(void)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Return Value

Returns a new `hdfsBuilder` structure.

Returns ENOMEM if unable to allocate memory for a new `hdfsBuilder` structure.

hdfsOpenFile()

Supported by `libMapRClient` for hadoop-2.x

Opens a file in the specified mode. Creates the file and intermediate directories if they do not exist.

Requires a valid file system handle, which one of the `hdfsConnect()` APIs can provide.

Before the call to `hdfsOpenFile()`, `hdfsExists()` can check that the file exists, if a check is needed.

After finishing work on a file, call `hdfsCloseFile()` to free the memory that is associated with the file.

Signature

```
hdfsFile hdfsOpenFile(hdfsFS fs, const char* path, int flags, int
bufferSize, short replication, tSize blocksize)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The full path to the file.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameter	Description
flags	One of the following values. These flags are included in the fcntl.h header file. **O_RDONLY** — Opens the file in read-only mode with the current offset at 0. **O_RDWR** — Opens the file in read-write mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file to offset 0. **O_RDWR** | **O_APPEND** — Opens the file in read-write mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API. **O_WRONLY** — Opens the file in write-only mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file. **O_WRONLY** | **O_APPEND** — Opens the file in write-only mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API.
bufferSize	*Ignored for files on Data Fabric file system*
replication	*Ignored for files on Data Fabric file system*
blocksize	The size of chunks for the file in bytes. Specify 0 if you want to use the value that is specified for the `fs.mapr.block.size` parameter in the `/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml` file on the client (if the client is using the libMapRClient version of hadoop-2.x). If this parameter is not set in `core-site.xml`, the default value is taken from the directory's `.dfs_attrributes` file.

Return Value

Returns the handle to the open file or NULL on error.

Check errno for error codes and meanings.

©Copyright 2024 Hewlett Packard Enterprise Development LP

hdfsOpenFile2()

Supported by `libMapRClient` for hadoop-2.x

Opens a file in a given mode. Creates the file if the file does not exist.

If `hdfsOpenFile2()` creates a file, it stores the size of the name container in a location that you pass a pointer into, so that you can keep track of this size. The size is in bytes.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Before the call to `hdfsOpenFile2()`, `hdfsExists()` can check that the file exists, if a check is needed.

After finishing work on a file, call `hdfsCloseFile()` to free the resources that are associated with the file.

Signature

```
hdfsFile hdfsOpenFile2(hdfsFS fs, const char* path, int flags, int
bufferSize, short replication, tSize blocksize, tSize *nameSizeInBytes)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The full path to the file.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameter	Description
flags	One of the following values. These flags are included in the fcntl.h header file. **O_RDONLY** — Opens the file in read-only mode with the current offset at 0. **O_RDWR** — Opens the file in read-write mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file. **O_RDWR** | **O_APPEND** — Opens the file in read-write mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API. **O_WRONLY** — Opens the file in write-only mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file. **O_WRONLY** | **O_APPEND** — Opens the file in write-only mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API.
bufferSize	*Ignored for files on Data Fabric file system*
replication	*Ignored for files on Data Fabric file system*
blocksize	The size of chunks for the file in bytes. Use 0 if you want to use the value that is specified for the `fs.mapr.block.size` parameter in the `/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml` file on the client (if the client is using the libMapRClient version of hadoop-2.x). If this parameter is not set in `core-site.xml`, the default value is taken from the directory's `.dfs_attrributes` file.
nameSizeInBytes	A pointer to a memory buffer that can store the size in bytes of the name container. The value is returned only if `hdfsOpenFile2()` creates the specified file because the file does not already exist.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Return Value

Returns the handle to the open file or NULL on error.

Check errno for error codes and meanings.

hdfsPread()

Supported by libMapRClient for hadoop-2.x

Reads an open file from a specified offset.

Whereas `hdfsRead()` increments the current offset in the file by the number of bytes that are read, `hdfsPread()` does not change the current offset. For example, if the current offset is 0 and `hdfsPread()` starts reading from offset 100, after the read the current offset is still 0.

Signature

```
tSize  hdfsPread(hdfsFS fs, hdfsFile file, tOffset position, void* buffer,
tSize length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.
position	Offset from which to read.
buffer	The buffer to copy read bytes into.
length	The length of the buffer. The maximum size of `tSize` is the maximum buffer length.

Return Value

Returns the number of bytes actually read, which can be less than than the length of the buffer if the end of the file is reached during the read. Returns -1 on error.

On error, errno is set to one of the following values:

- EACCES if the access permissions are violated.
- ESTALE if the file doesn't exist on the server.
- EINVAL if the arguments are invalid or if the file type doesn't support read operations.

To recover from errors, close the file by calling `hdfsCloseFile()`.

hdfsPwrite()

Supported by libMapRClient for hadoop-2.x

Writes starting at a specified position in an open file.

Whereas `hdfsWrite()` increments the current offset by the amount of bytes returned by the API (except in case of error), `hdfsPwrite()` does not change the value of current offset. If the current offset before the call to `hdfsPwrite()` is 0 and you specify the offset 10 for the write operation, after the write the current offset remains 0.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

If a call to `hdfsPwrite()` specifies an offset that is past the end of the file, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

On error, pending write buffers are flushed to the server.

Signature

```
tSize hdfsPwrite(hdfsFS fs, hdfsFile file, tOffset position, const void*
buffer, tSize length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The handle of the file. Obtain this handle with one of the `hdfsOpenFile()` APIs.
position	The offset at which to start writing.
buffer	The data to write.
length	The number of bytes to write. The maximum length is the maximum size of `tSize`.

Return Value

Returns the number of bytes written, -1 on error.

Check errno for error codes and meanings.

hdfsRead()

Supported by libMapRClient for hadoop-2.x

Reads data from the current offset in an open file. After the read, the current offset is incremented by the number of bytes read.

To read from a specific offset, first call `hdfsSeek()` to move to that offset in the file. Then, call `hdfsRead()`.

Alternatively, call `hdfsPread()`, specifying an offset in the call. `hdfsPread()` does not increment the current offset in the file. The offset that you specify in the call is used only for the read.

Signature

```
tSize hdfsRead(hdfsFS fs, hdfsFile file, void* buffer, tSize length)
```

Parameters

Parameter	Description
fs	The file system handle. File system handle can be obtained using one of the `hdfsConnect()` APIs.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameter	Description
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.
buffer	The buffer to copy bytes into during the read.
length	The length of the buffer. The maximum length of the buffer is the maximum size of `tSize`.

Returned Value

Returns the number of bytes actually read, which can be less than than the length of the buffer if the end of the file is reached during the read. Returns -1 on error.

Check errno for error codes and meanings.

hdfsReadStatisticsGetRemoteBytesRead()

This API is not supported.

hdfsRename()

Supported by libMapRCient for hadoop-2.x

Renames the specified file. For information about the format to use for paths, see Specifying Paths to Files and Directories.

Signature

```
int hdfsRename(hdfsFS fs, const char* oldPath, const char* newPath)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
oldPath	The path of the source file.
newPath	The path of the destination file.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSeek()

Supported by `libMapRClient` for hadoop-2.x

Moves the current offset to another offset in the specified file.

Signature

```
int hdfsSeek(hdfsFS fs, hdfsFile file, tOffset desiredPos)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameters

Parameter	Description
fs	The handle for the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The handle to the file. Obtain this handle with one of the `hdfsConnect()` APIs.
desiredPos	The offset to move forward to.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetTicketAndKeyFile()
Dynamically loads a ticket file

Supported by `libMapRClient` for hadoop-2.x

Use this API to dynamically load a ticket file to connect to newly added clusters and nodes, without restarting your application.

Signature

```
int hdfsSetTicketAndKeyFile(const char *fname)
```

Parameters

Parameter	Description
fname	The name of the ticket file to reload.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetReplication()

This API is not supported.

hdfsSetRpcTimeout()

Unique to libMapRClient

Sets the RPC timeout in seconds. Before creating a connection to a file system cluster, you can set an RPC timeout for your connections to CLDB nodes and fileservers, passing the number of seconds for the timeout as an integer.

Signature

```
int hdfsSetRpcTimeout(int seconds)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameters

Parameter	Description
seconds	The time in seconds to wait before timing out. The default is 99 seconds. If you change the value, set it either to 0 or to greater than 30 seconds. If RPC timeout is set to 0, remote procedure calls will continue to be retried until they are successful.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetThreads()

Unique to libMapRClient

Configures the number of threads for flushing write buffers. This number is specific to individual clients. The default number is 8.

The number of threads must be positive. If it isn't, EINVAL is returned.

Signature

```
int hdfsSetThreads(int threads)
```

Parameters

Parameter	Description
threads	The number of threads for flushing write buffers.

Return Value

Returns the current number of flush threads for the client, -1 on error. Check errno for error codes and meanings.

hdfsSetWorkingDirectory()

Supported by libMapRClient for hadoop-2.x

Set the working directory. All relative paths will be resolved relative to it.

For example, if you call this API to set the working directory to `/mycluster/myvolume` and subsequently call `hdfsOpenFile()` with the path `/temp/tmp.txt`, the full path to the file to open is assumed to be `/mycluster/myvolume/temp/tmp.txt`.

Signature

```
int hdfsSetWorkingDirectory(hdfsFS fs, const char* path)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameters

Parameter	Description
fs	The handle of the file system where the directory is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the new working directory.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL for invalid arguments.

hdfsSetXattr()

Supported by libMapRClient for hadoop-2.x

Sets extended attribute on a file.

Signature

```
int hdfsSetXattr(hdfsFS fs, const char* path, const char *name, int
nameLen, char *value, int valueLen);
```

Parameters

Parameter	Description
`fs`	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
`name`	The name of the extended attribute.
`nameLen`	The length of the name of the extended attribute.
`path`	The path to the file.
`value`	The value for the extended attribute.
`valueLen`	The length of the value of the extended attribute.

Return Value

Returns `0` on success, `-1` on error.

Check `errno` for error codes and meanings.

hdfsTell()

Supported by libMapRClient for hadoop-2.x

Gets the current offset in the file in bytes.

Signature

```
tOffset hdfsTell(hdfsFS fs, hdfsFile file)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns the current offset in bytes, or -1 on error.

Check errno for error codes and meanings.

hdfsUtime()
Changes the access and modification times of a file or directory.

Supported by libMapRClient for hadoop-2.x

Signature

```
int hdfsUtime(hdfsFS fs, const char* path, tTime mtime, tTime atime)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file or directory is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path to the file or directory.
mtime	The new modification time or 0 (if you want to set only the access time) in seconds.
atime	The new access time or 0 (if you want to set only the modification time) in seconds. For more information, see the `atimeUpdateTimeInterval` entry in volume create on page 2592.

Return Value

Returns 0 on success, -1 on error.

errno is set to EINVAL if the input arguments are invalid.

errno is set to EPERM if the process does not have enough privileges to perform the operation.

hdfsWrite()

Supported by libMapRClient for hadoop-2.x

Writes to the specified open file.

If the file is opened in write-only mode, writes start at offset 0 because write-only mode causes the content of the file to be truncated when the file is opened.

If the file is opened in append mode, data is appended to the end of the file.

If there are concurrent writes that start at the same offset, only the last write to finish persists.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

If a call to `hdfsSeek()` moves the offset past the end of the file before a call to `hdfsWrite()`, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

On error, pending write buffers are flushed to the server.

Signature

```
tsize hdfsWrite(hdfsFS fs, hdfsFile file, const void* buffer, tSize length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The handle of the file. Obtain this handle with one of the `hdfsOpenFile()` APIs.
buffer	The buffer containing the data to be written.
length	The number of bytes to write. This value cannot be zero. The maximum length of the buffer is the maximum size of the `tSize` data type.

Return Value

Returns the number of bytes written, -1 on error.

Check errno for error codes and meanings.

Accessing HPE Ezmeral Data Fabric File Store in Java Applications

As a high-performance file system, portions of the HPE Ezmeral Data Fabric File Store file client are based on a native maprfs library. When developing an application, specifying dependence on the JAR file that includes the maprfs library enables you to build applications without having to manage platform-specific dependencies.

The following sections describe how to access the HPE Ezmeral Data Fabric File Store in a Java program.

Writing a Java Application

In your Java application, you will use a Configuration object to interface with the file system. When you instantiate a Configuration object, it is created with values from Hadoop configuration files.

If the program is built with JAR files from the Data Fabric installation, the Hadoop 1 configuration files are in the `$MAPR_HOME/hadoop/hadoop-<version>/conf` directory, and the Hadoop 2 configuration files are in the `$HADOOP_HOME/etc/hadoop` directory. This Hadoop configuration directory is in the hadoop classpath that you include when you compile and run the Java program.

If the program is built through maven using mapr maven artifacts, the default Hadoop configuration files are included in the maven artifacts. The user needs to programmatically update the Hadoop configuration to match the Hadoop configuration files on the Data Fabric cluster.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Sample Code

The following sample code shows how to interface with Data Fabric file system using Java. The example creates a directory, writes a file, then reads the contents of the file.

```
/* Copyright (c) 2009 & onwards. MapR
Tech, Inc., All rights reserved */

//package com.mapr.fs;

import java.net.*;
import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;

/**
* Assumes mapr installed in /opt/mapr
*
* Compilation:
* javac -cp $(hadoop classpath)
MapRTest.java
*
* Run:
* java -cp .:$(hadoop classpath)
MapRTest /test
*/

        int bb = istr.readInt();
        istr.close();
        System.out.println( "Read
ok");
        }
}
```

Compiling and Running a Java Application

You can compile and run the Java application using JAR files from the mapr maven repository or from the Data Fabric installation.

Using JARs from the Maven Repository

Maven artifacts from version 2.1.2 onward are published to https://repository.mapr.com/maven/. When compiling for Data Fabric core version 6.1, add the following dependency to the `pom.xml` file for your project:

```
<dependency>
   <groupId>org.apache.hadoop</
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
groupId>
  <artifactId>hadoop-common</
artifactId>
  <version>2.7.0-mapr-1808</version>
</dependency>
```

This dependency adds the dependencies from the mapr maven repository the next time you do a `mvn clean install`. The JAR that includes the `maprfs` library is a dependency for the `hadoop-common` artifact.

For a complete list of artifacts and further details, see Maven Artifacts for the HPE Ezmeral Data Fabric on page 4946.

Using JARs from the Data Fabric Installation

The `maprfs` library is included in the hadoop classpath. Add the hadoop classpath to the JAVA classpath when you compile and run the Java application.

- To compile the sample code, use the following command:

```
javac -cp $(hadoop classpath)
MapRTest.java
```

- To run the sample code, use the following command:

```
java -cp .:$(hadoop classpath)
MapRTest /test
```

Loading the Data Fabric Native Library

By default, the root class loader will load the native library to allow all children to see and access it. If the native library is loaded by a child class, other classes will not be able to access the library. To allow applications and associated child classes to access the symbols and variables in the native library, we recommend loading the native library via the root loader.

The loading of the native library via the root class loader is accomplished by injecting code into the root loader. If Data Fabric runs on top of applications (such as Tomcat) where it does not have access to the root class loader, the native library will not be loaded. Child classes that try to access the symbols under the assumption that the root class loader successfully loaded the native library will fail.

The parameter `-Dmapr.library.flatclass`, when specified with Java, disables the injection of code via the root class loader, thus disabling the loading of the native library using the root class loader. Instead, the application trying to access the symbols can load the native library themselves. However, since the native library can be loaded only once and can only be seen by the application loading it, ensure that only one application within the JVM attempts to load and access the native library.

Garbage Collection in Data Fabric

The garbage collection (GC) algorithms in Java provide opportunities for performance optimizations for your application. Java provides the following GC algorithms:

- *Serial* GC. This algorithm is typically used in client-style applications that don't require low pause times. Specify `-XX:+UseSerialGC` to use this algorithm.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- *Parallel* GC, which is optimized to maximize throughput. Specify `-XX:+UseParNewGC` to use this algorithm.
- *Mostly-Concurrent* or *Concurrent Mark-Sweep* GC, which is optimized to minimize latency. Specify `-XX:+UseConcMarkSweepGC` to use this algorithm.
- *Garbage First* GC, a new GC algorithm intended to replace Concurrent Mark-Sweep GC. Specify `-XX:+UseG1GC` to use this algorithm.

Consider testing your application with different GC algorithms to determine their effects on performance.

Flags for GC Debugging

Set the following flags in Java to log the GC algorithm's behavior for later analysis:

```
-verbose:gc
-Xloggc:<filename>
-XX:+PrintGCDetails
-XX:+PrintGCDateStamps
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
```

For more information, see the Java Garbage Collection Tuning document or the Java Garbage Collection links.

Converting fid and volid

The following file system APIs are available in `com.mapr.fs.MapRFileSystem` for converting fid to file path and volid to volume name:

- `public String getMountPathFidCached(String fidStr) throws IOException`
- `public String getVolumeNameCached(int volId) throws IOException`
- `public String getVolumeName(int volId) throws IOException`
- `public String getMountPathFid(String fidStr) throws IOException`

Converting fid to File Path

The `getMountPathFid(string)` and `getMountPathFidCached(string)` APIs can be used for converting file ID to the full path to the file. The `getMountPathFid()` API makes a call to CLDB and file system to get the file path from the fid. Because this API does not cache or store this information locally, it might make repeated requests to CLDB and file system for the same fid and this might result in many RPCs to both CLDB and file system. The `getMountPathFidCached()` API makes a call the CLDB and file system one time and stores the information locally in the shared library of the client. For subsequent calls, it uses the locally stored information to retrieve the file path from the fid. However, if there are many files in the volume, there might still be a large number of calls to CLDB and file system to determine the file path for each fid in the volume. The caching is useful if the API attempts to determine the file path for the same fid repeatedly. The cache is purged after 15 seconds. If the file name changes before the cache is purged, you will see the old name for the file until the cache expires. You can use these APIs to convert the fid to the file path.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

For example, the sample consumer application and the sample uncached consumer application for consuming audit logs as stream messages use these methods as shown below.

- **Sample Cached Consumer**

```
{
     String token =
st1.nextToken();
     /* If the field has fid,
expand it using Cached API */
     if (token.endsWith("Fid")) {
       String lfidStr =
st1.nextToken();
       String path= null;
       try {
           path =
fs.getMountPathFidCached(lfidStr);
// Expand FID to path
       } catch (IOException e){
     }
     lfidPath =
"\"FidPath\":\""+path+"\",";
     // System.out.println("\nPAth
for fid " + lfidStr +  "is " +
path);
}
```

- **Sample Uncached Consumer**

```
{
     String token =
st1.nextToken();
     if (token.endsWith("Fid")) {
         String lfidStr =
st1.nextToken();
         String path= null;
         try {
           path =
fs.getMountPathFid(lfidStr);//
Expand FID to path
         } catch (IOException e){
         }
     lfidPath =
"\"FidPath\":\""+path+"\",";
     // System.out.println("\nPAth
for fid " + lfidStr +  "is " +
path);
}
```

Converting volid to Volume Name

The `getVolumeName()` and `getVolumeNameCached()` APIs can be used for converting volume IDs to volume name. The `getVolumeName()` API makes a call to the CLDB every time to get the volume name from the volid and this may result in too many RPCs to CLDB. The `getVolumeNameCached()` API makes a call to the CLDB one time and stores the information locally in the shared library of the client. For subsequent calls, it uses the locally stored information to retrieve the

©Copyright 2024 Hewlett Packard Enterprise Development LP

volume name from the volid. The cache is purged after 15 seconds. You can use these APIs to convert the volid to volume name.

For example, the sample consumer application and the sample uncached consumer application for consuming audit logs as stream messages uses these methods as shown below.

- **Sample Cached Consumer**

```
if (token.endsWith("volumeId")) {
       String volid =
st1.nextToken();
       String name= null;
       try {
         int volumeId =
Integer.parseInt(volid);
           // Cached API to
convert volume Id to volume Name
           name =
fs.getVolumeNameCached(volumeId);
         }
       catch (IOException e){
       }
       lvolName =
"\"VolumeName\":\""+name+"\",";
       //
System.out.println("\nVolume Name
for volid " + volid +  "is " +
name);
}
```

- **Sample Uncached Consumer**

```
if (token.endsWith("volumeId")) {
       String volid =
st1.nextToken();
       String name= null;
       try {
         int volumeId =
Integer.parseInt(volid);
           // API to convert
volume Id to volume Name
           name =
fs.getVolumeName(volumeId);
         }
       catch (IOException e){
       }
       lvolName =
"\"VolumeName\":\""+name+"\",";
       //
System.out.println("\nVolume Name
for volid " + volid +  "is " +
name);
}
```

Sample Applications
Demonstrates how to set ACEs using the Java APIs.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Sample Application

The sample application demonstrates how to set, get, modify, and delete ACES on files using the Java APIs.

Before running this application, verify that you have access to a cluster running file system. To build and run this application:

1. Set the classpath:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the java file:

```
javac FileAceTest.java
```

3. Run the final `FileAceTest.class` file.

The application imports the following libraries:

- `java.io.*`
- `java.net.*`
- `java.util.*`

The application performs the actions described in the following sections.

Connects to a file system

The application tries to connect to the first file system cluster that is specified in the `mapr-clusters.conf` file in the `$MAPR_HOME/conf` directory on the client. After connecting to the file system, the application returns a handle to the file system.

```
Configuration conf = new
Configuration();
FileSystem fs = FileSystem.get(conf);
//MapRFileSystem fs =
getMapRFileSystem();
```

Creates a new directory and a new file in the directory

The application creates a new directory and a file in the directory.

```
Path testDir = new Path(rootDir +
"FileAceTest");
mkDir(fs, testDir);

Path testFile = new Path(testDir + "/
testFile");
createFile(fs, testFile);
```

Sets ACEs on the new directory and the file

The application then sets ACEs to grant m7user1 user or the root user permissions to list the contents of the directory, which is required for the user to write and/or execute files in the directory. In addition, the

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

application sets ACEs on the file in the directory to grant the m7user1 user read access on the file.

```
MapRFileAce ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DFILE);
ace.setBooleanExpression("u:m7user1");
aces.add(ace);
ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DDIR);
ace.setBooleanExpression("u:m7user1|
u:root");
aces.add(ace);
((MapRFileSystem)fs).setAces(testDir,
aces);
((MapRFileSystem)fs).setAces(testFile,
 aces);
```

Verifies the ACEs set on the directory and file

The application then prints the ACEs set on the directory and file.

```
List<MapRFileAce> newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
for (int i = 0; i <
newDirAces.size(); ++i) {

System.out.println(newDirAces.get(i).g
etAccessType() + ": " +

newDirAces.get(i).getBooleanExpressio
n());
}

List<MapRFileAce> newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
for (int i = 0; i <
newFileAces.size(); ++i) {

System.out.println(newFileAces.get(i).
getAccessType() + ": " +

newFileAces.get(i).getBooleanExpressio
n());
}
```

Modifies the ACEs on the directory and file

The application modifies the ACEs on the directory to grant m7user2 user also permissions to list the contents of the directory, which is required for the users to write and/or execute files in the directory. It also modifies the ACEs on the file to grant write access on the file to m7user2 user. Please note that when modifying ACEs on the file to grant write access

©Copyright 2024 Hewlett Packard Enterprise Development LP

to m7user2 user, the application does not change read access, which was granted to m7user1 user.

```
aces = new ArrayList<MapRFileAce>();
ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DDIR);
ace.setBooleanExpression("u:m7user1|
u:root|u:m7user2");
aces.add(ace);
ace = new
MapRFileAce(MapRFileAce.AccessType.WRI
TEFILE);
ace.setBooleanExpression("u:m7user2");
aces.add(ace);
((MapRFileSystem)fs).modifyAces(testDi
r, aces);
((MapRFileSystem)fs).modifyAces(testFi
le, aces);
```

Verifies the changes to ACEs on the directory and file

The application prints the changes in ACEs on the directory and the file.

```
newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
for (int i = 0; i <
newDirAces.size(); ++i) {

System.out.println(newDirAces.get(i).g
etAccessType() + ": " +

newDirAces.get(i).getBooleanExpressio
n());
}

newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
for (int i = 0; i <
newFileAces.size(); ++i) {

System.out.println(newFileAces.get(i).
getAccessType() + ": " +

newFileAces.get(i).getBooleanExpressio
n());
}
```

Deletes ACEs on directory and file

The application deletes all ACEs on the directory and the file.

```
((MapRFileSystem)fs).deleteAces(testDi
r);
((MapRFileSystem)fs).deleteAces(testFi
le);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Verifies the ACEs on the directory and the file	The application prints the ACEs on the directory and the file after they are deleted.

```
newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
if (newDirAces == null ||
newDirAces.size() == 0)
  System.out.println("AceCount: 0");
else
  System.out.println("AceCount: " +
newDirAces.size());
System.out.println("");
newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
if (newFileAces == null ||
newFileAces.size() == 0)
  System.out.println("AceCount: 0");
else
  System.out.println("AceCount: " +
newFileAces.size());
```

Example FileAceTest.java File

```
import java.io.*;
import java.net.*;

      System.out.println(newFileAces.get(i).getAccessType() + ": " +
                         newFileAces.get(i).getBooleanExpression());
    }

    // Remove path
    rmR(fs, testDir);
  }
}
```

Troubleshooting

My application that includes maprfs-0.1.jar is now missing dependencies and fails to link.

As of version 2.1.2 , the contents of `maprfs-0.1.jar` are now in two JAR files:

- `maprfs-<version>.jar`

©Copyright 2024 Hewlett Packard Enterprise Development LP

- `maprfs-jni-<version>.jar`

The `<version>` refers to the version of the distribution. For example, if you have an existing application written for `maprfs-0.1.jar` and you update it to load `maprfs-2.1.2.jar`, you must also include `maprfs-jni-2.1.2.jar`. This change was made to enable loading on distributed class-loader environments that use the `maprfs` libraries to access the filesystem from multiple contexts.

These JAR files are installed in the `/opt/mapr/hadoop/hadoop<version>/lib/` directory, or can be accessed via the Maven Central Repository.

HPE Ezmeral Data Fabric Database and Apps

This section contains information about developing client applications for JSON and key-value tables.

Why use HPE Ezmeral Data Fabric Database?

From a developer's point-of-view, HPE Ezmeral Data Fabric Database provides the following capabilities:

- **Extreme scale for CRUD operations**: Enabled by the integration of HPE Ezmeral Data Fabric Database with the HPE Ezmeral Data Fabric Filesystem, CRUD operations are extremely fast and efficient.
- **Flexible data model**: HPE Ezmeral Data Fabric Database can be used as both a document database and a column-oriented database. So if the content structure changes, the applications do not need to be re-written.
- **Rich query**: Integration with Apache Drill on page 4116 for HPE Ezmeral Data Fabric Database provides a low-latency distributed query engine for large-scale datasets, including structured and semi-structured/nested data.
- **Integration with Apache Spark**: HPE Ezmeral Data Fabric Database provides HPE Ezmeral Data Fabric Database Connectors for Apache Spark on page 4834 that allow you to access HPE Ezmeral Data Fabric Database tables through Spark applications.
- **Strong data consistency**: Consistently fast response with strong data consistency with row/document level ACID transactions and in-memory database options for faster speeds.

HPE Ezmeral Data Fabric Database JSON provides additional benefits:

- **High performance via Secondary Indexes on page 661**: No memory copying. No need to retrieve the full document to make updates due the log-based database architecture. No application changes needed to leverage secondary indexes for efficient query execution.
- **Easy application development**: JSON constructs such as maps, arrays, and data types are supported natively.
- **Language-specific client APIs:** Java, Python, and Node.js client APIs

NOTE: HPE Ezmeral Data Fabric has a universal namespace which means that the same namespace is used for files, tables, and streams. A universal namespace streamlines application development for different operations.

How Do I Get Started with HPE Ezmeral Data Fabric Database JSON?

The following diagram illustrates an end-to-end flow associated with getting started with HPE Ezmeral Data Fabric Database JSON.

NOTE: *This flow is not the only way to get started!*

You can also run through end-to-end examples using preconfigured, single node HPE Ezmeral Data Fabric clusters. The following table describes an option:

Container for Developers	Development Environment for HPE Ezmeral Data Fabric on page 57 is a Docker container that runs a single node cluster. Using HPE Ezmeral Data Fabric Database JSON: Getting Started, you can do the following: • Set up the Docker container • Import data into HPE Ezmeral Data Fabric Database JSON tables • Use HPE Ezmeral Data Fabric Database Shell to query, insert, and update JSON documents in HPE Ezmeral Data Fabric Database JSON tables • Use Drill to query HPE Ezmeral Data Fabric Database JSON tables • Run sample Java OJAI applications • Run a sample Spark application using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark

Installing the mapr-client Package

The `mapr-client` package must be installed on each node where you will be building and running your applications. This package installs all of the MapR Libraries needed for application development regardless of programming language or type of HPE Ezmeral Data Fabric Database table (binary or JSON).

About this task

NOTE: The `mapr-core` package contains the files that are in the `mapr-client` package. If you have installed the `mapr-core` package, you do not need to install the `mapr-client` package.

Complete the following steps to install the `mapr-client` package from a repository:

Procedure

1. Configure the repository to point to `https://package.ezmeral.hpe.com/releases/<release version>/<operating system>`

   For example, if your VM has a CentOS operating system, edit the **/etc/yum.repos.d/mapr_core.repo** file to add the location.

2. Based on your operating system, run one of the following commands to install the package:
   - On RHEL/Centos: `yum install mapr-client`
   - On Ubuntu: `apt-get install mapr-client`
   - On SLES: `zypper install mapr-client`

last-updated: Nov 14, 2024

Passing the HPE Ezmeral Data Fabric Database Table Path

This topic describes the methods for passing a HPE Ezmeral Data Fabric Database table name. Binary table names can be passed by either specifying the table path in the API or by setting the table path in the **core-site.xml** file. JSON table names are passed by specifying the table path in the API.

Specifying the Table Path in the API

With this method, you provide the complete path to the table using the following format: `/mapr/<cluster>/<volume>/<table>`

NOTE: This format is independent of the programming language. This method is used for both HPE Ezmeral Data Fabric Database binary and JSON tables.

For example, if you were adding a new column family to a table and you had the following information:

- Cluster name: `newyork`
- Volume name: `vol1`
- Table name: `table1`

The table path would be `/mapr/newyork/vol1/table1`

Specifying the Table Path in the core-site.xml File

With this method, you specify the table path with `hbase.table.namespace.mappings` property in the **/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/core-site.xml** file.

NOTE: This method is specific to HPE Ezmeral Data Fabric Database binary tables only. This method is independent of the programming language.

In the following example, all tables that you create and access via the API, will be in the `/tables_dir1` directory. If you specified the table name `table1` in the API, the full path to the table would be `/tables_dir1/table1`.

```
<property>
   <name>hbase.table.namespace.mappings</name>
   <value>*:/tables_dir1</value>
</property>
```

Tuning Parameters for Client Apps

Though tuning client applications is generally not necessary, Data Fabric does offer tuning parameters to change the behavior of client-side caching.

Client application cache pending puts in buffers that are unique to each tablet (*region*, in HBase terminology). Individual put buffers are flushed when they are full or idle. As a result of this architecture and behavior, client applications tend to send RPCs of 128KB when flushing puts to disk, which results in better performance than flushing a single global buffer would, as that could result in a large number of small RPCs.

You can change the values of parameters that affect how put buffers are flushed. Set values for them in the `hbase-site.xml` file or `core-site.xml` file in your Data Fabric installation. If a non-default value for a parameter is set in both files, the value in the `hbase-site.xml` file is used.

db.mapr.putbuffer.threshold.mb	Specifies the size of the cumulative put buffer for all tablets in the client application. When this threshold is reached, the put buffer that is most full is flushed to its tablet.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	The default value is 32MB. Increasing this value can improve performance when an application performs operations on very large tables or on a very large number of tables.
db.mapr.putbuffer.threshold.sec	Specifies the number of seconds that HPE Ezmeral Data Fabric Database should wait before flushing an idle put buffer. The default value is 3. This parameter has no effect if automatic flushing is enabled.
fs.mapr.tabletlru.size.kb	Specifies the size of the metadata cache for all tables in a client application.. The metadata for each tablet is 128 bytes. The default value of this parameter is 512KB, which allows for the caching of the metadata of 4,096 tablets. When this metadata cache is full, any operation on a tablet for which the metadata is not cached requires an RPC to fetch that tablet's metadata. Moreover, caching the newly retrieved metadata removes from the cache the metadata of a different tablet. Increasing this value can improve performance when an application performs operations on very large tables or on a very large number of tables.
fs.mapr.threads	Specifies the number of threads to use when flushing put buffers. Each thread makes synchronous RPCs when flushing. The default value is 64.

Developing Applications for Binary Tables

HPE Ezmeral Data Fabric Database provides a C API, `libMapRClient` and partially supports the Apache HBase 1.1 Java APIs for performing operation on HPE Ezmeral Data Fabric Database binary tables.

The HPE Ezmeral Data Fabric Database C API, `libMapRClient`, runs more efficiently on HPE Ezmeral Data Fabric Database and performs faster against HPE Ezmeral Data Fabric Database tables than the open source library of C APIs, `libhbase`, that is used to create and access Apache HBase tables. The `libMapRClient` header files are in this directory: **/opt/mapr/include/hbase**

HPE Ezmeral Data Fabric Database also supports all of the Apache HBase 1.1 Java APIs, except where noted in this documentation. For a number of critical Java APIs, for filters, and for comparators, this documentation explicitly lists what is supported, rather than what is not supported.

You can easily port existing applications that use the open-source version of `libhbase` or the HBase Java APIs to use HPE Ezmeral Data Fabric Database binary tables.

Current Limitations

- Custom HBase filters are not supported.
- HBase co-processors are not supported.

©Copyright 2024 Hewlett Packard Enterprise Development LP

NOTE: Filters used with Scan operations support regular expressions. When you filter scans on HPE Ezmeral Data Fabric Database tables, you can use regular expressions that comprise the Perl Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in java.util.regex.pattern. See HBase Java Regular Expressions Support on page 3327 for a list of supported regular expressions.

Creating C Apps - Binary Tables

Data Fabric provides a library of C APIs – `libMapRClient` – for performing operations on HPE Ezmeral Data Fabric Database binary tables.

The HPE Ezmeral Data Fabric Database `libMapRClient` C API library is Data Fabric's extension of the `libhbase` C API library. The `libMapRClient` header files are in this directory: **/opt/mapr/include/hbase**

`libMapRClient` uses the following conventions:

- All data types are prefixed with 'hb_'.
- All exported functions are annotated with HBASE_API, prefixed with 'hb_' and named using the following convention: `'hb_<subject>_<operation>_[<object>|<property>]'`
- All asynchronous APIs take a callback which is triggered when a request completes. This callback can be triggered in the caller's thread or in another thread. To avoid any potential deadlock or starvation, applications should not block in the callback routine.
- All callbacks take a void pointer for application developers to supply their own data. This void pointer is passed when callback is triggered.

NOTE: No explicit batching is supported for asynchronous APIs.

WARNING: It is the responsibility of applications to free up all backing data buffers. However, for asynchronous APIs, applications must wait before freeing buffers until after receiving callbacks or manipulating results. For better performance of asynchronous APIs, `libMapRClient` does not copy data buffers that are allocated for mutations, gets, and scans. These buffers hold table names, name space identifiers, row keys, column-family names, and column names or qualifiers. Instead, libMaprClient temporarily takes ownership of the buffers and references them with pointers until the callback is triggered. Therefore, applications should not free memory buffers before receiving callbacks for mutations. Applications also should not free memory buffers before receiving results for gets and scans. If applications must read results, the applications should not free memory buffers until the results are destroyed.

©Copyright 2024 Hewlett Packard Enterprise Development LP

NOTE: When one of these asynchronous APIs is invoked, a work item is created and queued for processing on the client:

- `hb_client_destroy()`
- `hb_get_send()`
- `hb_mutation_send()`
- `hb_scanner_destroy()`
- `hb_scanner_next()`

The work item is picked up as soon as possible by a thread in a thread pool.

Client applications can often call these asynchronous APIs faster than the work items are processed. To ensure that the queue of work items does not grow without bound, the configuration parameter `fs.mapr.pool.queue.max_size` is set by default to 10,000. You can modify this parameter in the `/opt/mapr/conf/dbclient.conf` file for a client.

Whenever the number of work items in the queue reaches this limit, `libMapRClient` returns the `ENOBUFS` error for each asynchronous call. Client applications are expected to handle this error, and can try the call again later.

libMapRClient C APIs

This section provides the HPE Ezmeral Data Fabric Database `libMapRClient` C API library. This library is MapR's extension of the `libhbase` C API library. The `libMapRClient` header files are in the directory: **/opt/mapr/include/hbase**.

The `libMapRClient` API implements functions in addition to the functions in the `libhbase` API.

NOTE: Your applications need include only the `hbase.h` header file. The header files are provided for display purposes.

admin.h	Describes the APIs for Apache HBase table administration operations such as creating and enabling tables, checking if tables exist, and deleting tables, to name a few .
client.h	Describes the APIs for Apache HBase client side operations such as creating and terminating client connections, and flushing buffered client-side writes to Apache HBase.
coldesc.h	Describes the APIs for performing operations such as creation, deletion, and setting the maximum and minimum number of cell versions to be retained for each Apache HBase column family.
connection.h	`libMapRClient` includes a function in the `connection.h` header file: `hb_connection_create_as_user()`. This function provides support for impersonation, so that you can connect to a HPE Ezmeral Data Fabric cluster and access HPE Ezmeral Data Fabric Database tables by using a specific username. The user that is passed with the `hb_connection_create_as_user()` API must have permissions on the tables that the application accesses. For example, to read from a table, the user must have the `readperm` permission. To write to a

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	table, the user must have the `writeperm` permission. See Enabling Table and Stream Authorizations with ACEs on page 1343. For `hb_connection_create()` and `hb_connection_create_as_user()`, the standard C APIs for Apache HBase require a list of ZooKeeper nodes. For HPE Ezmeral Data Fabric Database, this list is interpreted as a list of CLDB nodes. The `zk_root` parameter is ignored. If `zk_quorum` is NULL, then the connection is created to the default cluster that is listed in the `mapr-clusters.conf` file.
get.h	Describes the APIs to query and fetch data from Apache HBase tables.
hbase.h	Describes the APIs and data structures of a C client for Apache HBase.
log.h	Describes the APIs to manage Apache HBase logs.
macros.h	Defines internal macros that Apache HBase uses for its operations.
multiget.h	Describes the APIs to queue and manage multiple GET requests to fetch data from Apache HBase tables.
mutations.h	Describes the APIs for row and column mutations on Apache HBase tables.
result.h	Describes the buffers for internal temporary storage of results.
scanner.h	Describes the APIs for the client side scanner to scan and request rows from the Apache HBase server.
types.h	Defines the data types and error codes that Apache HBase uses.

C API Examples

This section provides examples using the HPE Ezmeral Data Fabric Database `libMapRClient` C API to operate on HPE Ezmeral Data Fabric Database binary tables.

The HPE Ezmeral Data Fabric Database `libMapRClient` C API library is Data Fabric's extension of the `libhbase` C API library. The libMapRClient header files are in this directory: `/opt/mapr/include/hbase`

Filtering SCAN Operation Results Example

This example shows filtering on the results of a SCAN operation.

```
for (uint32_t i = 0; i < num_filters; ++i) {
    hb_scanner_t scanner = NULL;
    hb_scanner_create(client, &scanner);
    hb_scanner_set_table(scanner, table_name, table_name_len);
    hb_scanner_set_num_max_rows(scanner, 3);  // maximum 3 rows at a time
    hb_scanner_set_num_versions(scanner, 10); // up to 10 versions of the
cell
    hb_scanner_set_filter(scanner, (byte_t *)filters[i],
strlen(filters[i]));
    hb_scanner_next(scanner, scan_callback, NULL); // dispatch the call
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    wait_for_scan();
 }
```

This example uses the following array of filters:

```
static char filters[][200] = {"RandomRowFilter(0.5)",
       "ColumnCountGetFilter(2)",
       "ColumnPaginationFilter(1)",
       "ColumnPrefixFilter('column-a')",
       "FamilyFilter(=,'binaryprefix:f')",
       "PrefixFilter('row_') AND QualifierFilter(<,'binaryprefix:g')",
       "SKIP TimestampsFilter(1392222222222)",
       "WHILE ValueFilter(=,'binaryprefix:cell2_value_v1')",
       "FuzzyRowFilter('row00','00001')",
       "TimestampsFilter(1430937732000,1431024132000)"};
       }
```

NOTE: For more information about suppport for HBase Java Filters by the HPE Ezmeral Data Fabric Database C API, see HBase Java Filters Support on page 3293

Filtering GET Operation Results Example
This example shows filtering on the results of a GET operation.

```
{
    bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
    hb_get_t get = NULL;
    hb_get_create(rowKey->buffer, rowKey->length, &get);
    hb_get_add_column(get, FAMILIES[0], 1, NULL, 0);
    hb_get_add_column(get, FAMILIES[1], 1, NULL, 0);
    hb_get_set_table(get, table_name, table_name_len);
    hb_get_set_num_versions(get, 10); // up to ten versions of each column
    hb_get_set_filter(get, (byte_t *)filters[9], strlen(filters[9]));
    get_done = false;
    hb_get_send(client, get, get_callback, rowKey);
    wait_for_get();
 }
```

This example uses the following array of filters:

```
static char filters[][200] = {"RandomRowFilter(0.5)",
       "ColumnCountGetFilter(2)",
       "ColumnPaginationFilter(1)",
       "ColumnPrefixFilter('column-a')",
       "FamilyFilter(=,'binaryprefix:f')",
       "PrefixFilter('row_') AND QualifierFilter(<,'binaryprefix:g')",
       "SKIP TimestampsFilter(1392222222222)",
       "WHILE ValueFilter(=,'binaryprefix:cell2_value_v1')",
       "FuzzyRowFilter('row00','00001')",
       "TimestampsFilter(1430937732000,1431024132000)"};
       }
```

NOTE: For more information about suppport for HBase Java Filters by the HPE Ezmeral Data Fabric Database C API, see HBase Java Filters Support on page 3293

Impersonation Example
This sample application demonstrates the capabilities of the new C API for impersonation.

The sample also shows how to use the API in your own programs. The application is located in the `/opt/mapr/examples/interactive` directory.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Prerequisite for compiling and running this sample application

Install the `mapr-client` package on the node where you will build the application. See Installing the Data Fabric Client (Non-FIPS) on page 383. If the `mapr-core` package is already installed, you do not need to install the `mapr-client` package.

Compiling this sample application

To compile and run this sample application, set the `MAPR_IMPERSONATION_ENABLED` environment variable to `true` and then read the instructions in the `README` file in the `/opt/mapr/examples/interactive` directory.

Though the application links against `libjvm`, a Java virtual machine (JVM) is not spawned. However, the `libMapRClient` does have Java dependencies.

Set Time Range Example
This example scans HPE Ezmeral Data Fabric Database binary tables and sets the time range.

```
int32_t scanWithTimeranges( std::string table_name, int32_t num_versions,
uint64_t max_num_rows, std::string start_row_key,
                std::string end_row_key, int64_t min_ts, int64_t max_ts,
std::string name_space, std::string column_name) {
        hb_scanner_t scanner = NULL;
        int32_t retCode;

        scan_num_rows = 0;
        scan_cell_count = 0;
        scan_done = false;
        // scanner object create
        hb_scanner_create(client, &scanner);

        scan_data_t *scan_data = (scan_data_t *) calloc(1,
sizeof(scan_data_t));

        // set the table to scan
        scan_data->table_name_ = bytebuffer_printf("%s",
table_name.c_str());
        hb_scanner_set_table(scanner, (char *)
scan_data->table_name_->buffer, scan_data->table_name_->length));

        // start and end row - optional
        scan_data->start_row_key_ = bytebuffer_printf("%s",
start_row_key.c_str());
        hb_scanner_set_start_row(scanner, scan_data->start_row_key_->buffer,
                        scan_data->start_row_key_->length);

        scan_data->end_row_key_ = bytebuffer_printf("%s",
end_row_key.c_str());
        hb_scanner_set_end_row(scanner, scan_data->end_row_key_->buffer,
                        scan_data->end_row_key_->length);

        // add columns
        bytebuffer cfName   = bytebuffer_printf("%s",
data_qualifier[0].c_str());
        bytebuffer columnName   = bytebuffer_printf("%s",
data_qualifier[1].c_str());
        retCode=hb_scanner_add_column(scanner,(byte_t
*)cfName->buffer,cfName->length,columnName->buffer,columnName->length);

        // set versions
        hb_scanner_set_num_versions(scanner, num_versions);

        // set timerange
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
        hb_scanner_set_timerange(scanner, min_ts, max_ts);

        // scan data
        retCode = hb_scanner_next(scanner, scan_callback, scan_data);
        return retCode;
}
```

Set Time Stamp Example

This example scans HPE Ezmeral Data Fabric Database binary tables and sets the time stamp.

```
int32_t scanWithTimestamp( std::string table_name, int32_t num_versions,
uint64_t max_num_rows, std::string start_row_key,
                std::string end_row_key, int64_t ts, std::string
name_space, std::string column_name) {
        hb_scanner_t scanner = NULL;
        int32_t retCode;

        scan_num_rows = 0;
        scan_cell_count = 0;
        scan_done = false;

        // scanner object create
        hb_scanner_create(client, &scanner);

        scan_data_t *scan_data = (scan_data_t *) calloc(1,
sizeof(scan_data_t));

        // set the table to scan
        scan_data->table_name_ = bytebuffer_printf("%s",
table_name.c_str());
        hb_scanner_set_table(scanner, (char *)
scan_data->table_name_->buffer, scan_data->table_name_->length));

        // start and end row - optional
        scan_data->start_row_key_ = bytebuffer_printf("%s",
start_row_key.c_str());
        hb_scanner_set_start_row(scanner, scan_data->start_row_key_->buffer,
                        scan_data->start_row_key_->length);

        scan_data->end_row_key_ = bytebuffer_printf("%s",
end_row_key.c_str());
        hb_scanner_set_end_row(scanner, scan_data->end_row_key_->buffer,
                        scan_data->end_row_key_->length);

        // add columns
        bytebuffer cfName   = bytebuffer_printf("%s",
data_qualifier[0].c_str());
        bytebuffer columnName   = bytebuffer_printf("%s",
data_qualifier[1].c_str());
        retCode=hb_scanner_add_column(scanner,(byte_t
*)cfName->buffer,cfName->length,columnName->buffer,columnName->length);

        // set versions
        hb_scanner_set_num_versions(scanner, num_versions);

        // set timestamp
        hb_scanner_set_timestamp(scanner, ts);

        // scan data
        retCode = hb_scanner_next(scanner, scan_callback, scan_data);
        return retCode;
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Delete Specific Cells Example
This example deletes specific cells that correspond to a specific timestamp.

```
nt32_t deleteRowExactTS(std::string table_name, std::string row_key,
        std::vector<std::string> data, int64_t ts) {

        int32_t retCode = 0;
        // initialize delete object
        hb_delete_t del = NULL;

        row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
        row_data->key = bytebuffer_printf("%s", row_key.c_str());
        row_data->tablename = bytebuffer_printf("%s",table_name.c_str());

        // create delete object
        hb_delete_create(row_data->key->buffer, row_data->key->length,
&del);

        cell_data_t *prevCell=NULL;
        // add cells that needs to be deleted
        for(int t=0; t < (int)data.size(); t++) {
             vector<string> data_qualifier = split(data.at(t),':');
             cell_data_t *cell_data= new_cell_data();
             if(t==0)
                row_data->first_cell = cell_data;
             else
                prevCell->next_cell = cell_data;

             cell_data->columnFamily =
bytebuffer_printf("%s",data_qualifier[0].c_str());
             cell_data->columnName =
bytebuffer_printf("%s",data_qualifier[1].c_str());

             //add column, fam/column/ts to delete the exact version
             retCode=hb_delete_add_column_exact(del,
cell_data->columnFamily->buffer, cell_data->columnFamily->length,

cell_data->columnName->buffer,cell_data->columnName->length,ts);
             prevCell = cell_data;
        }

        // set the table name in delete mutation object
        hb_mutation_set_table(del, (const char
*)row_data->tablename->buffer,row_data->tablename->length);

        //send the delete request
        retCode = hb_mutation_send(client, del, delete_callback, row_data);
        return retCode;
}
```

HPE Ezmeral Data Fabric Database Sample C Application
Data Fabric provides a sample C application that accesses and performs operations on HPE Ezmeral Data Fabric Database binary tables. This section describes the various operation performed by the application.

The sample C application is located in the `/opt/mapr/examples/sample` directory.

Prerequisites

In order to compile and run the sample application, install the `mapr-client` package on the node where you will build the application. See Impersonation Example on page 3276. If the `mapr-core` package is already installed, you do not need to install the `mapr-client` package.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Compiling

To compile and run the sample application, read the instructions in the `README` file in the `/opt/mapr/examples/sample` directory.

Set the log level and specify the log stream

APIs used

These two APIs are defined in the header file `log.h`:

- `hb_log_set_level()`: Sets the log output level. The levels are defined in the header file types.h.
- `hb_log_set_stream()`: Sets the location of the log output. By default, log messages are sent to stderr.

Code

```
hb_log_set_level(HBASE_LOG_LEVEL_DEBUG); // defaults to INFO
const char *logFilePath = getenv("HBASE_LOG_FILE");
if (logFilePath != NULL) {
  FILE* logFile = fopen(logFilePath, "a");
  if (!logFile) {
    retCode = errno;
    fprintf(stderr, "Unable to open log file \"%s\"", logFilePath);
    perror(NULL);
    goto cleanup;
  }
  hb_log_set_stream(logFile); // defaults to stderr
}
```

Log levels are specified in the header file `types.h`.

```
/**
 *  Log levels
 */
typedef enum {
  HBASE_LOG_LEVEL_INVALID = 0,
  HBASE_LOG_LEVEL_FATAL   = 1,
  HBASE_LOG_LEVEL_ERROR   = 2,
  HBASE_LOG_LEVEL_WARN    = 3,
  HBASE_LOG_LEVEL_INFO    = 4,
  HBASE_LOG_LEVEL_DEBUG   = 5,
  HBASE_LOG_LEVEL_TRACE   = 6
} HBaseLogLevel;
```

Create a connection

API used: `hb_connection_create()`

Use this function to connect to the Data Fabric cluster.

This API takes three parameters:

```
const char *zk_ensemble,     /* [in] NULL terminated, comma separated
                                     *   string of CLDB servers. e.g.
                                     *   "<server1[:port]>,...".
const char *zk_root,              /* [in] Ignored for MapR-DB. */
hb_connection_t *connection_ptr); /* [out] pointer to hb_connection_t */
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

There are two methods by which you can use the `zk_ensemble` parameter to determine how the Data Fabric client connection locates the Data Fabric cluster to connect to:

Set `zk_ensemble` to NULL to connect to the default cluster that is defined in the `mapr-clusters.conf` file.	HPE recommends this method, which uses the configuration information that is listed for the cluster in the `mapr-clusters.conf` file.
Set `zk_ensemble` to a string that includes hostnames or IP addresses.	With this method, the client application can connect to a non-default cluster explicitly. The client application searches through the `mapr-clusters.conf` file to find a cluster entry with a matching hostname/IP address. The first entry that is found to contain a matching hostname[:port]/IP address[:port} is used for the connection, as is the configuration information for that entry. If none of the hostnames or IP addresses specified for `zk_ensemble` are located in entries in `mapr-clusters.conf`, or if `mapr-clusters.conf` does not exist, the client application tries to connect to the first specified hostname[:port]/IP address[:port]. If the client application cannot make a connection, it moves to the next specified hostname[:port]/IP address[:port]. **WARNING:** Because no `mapr-clusters.conf` file is involved, no additional configuration information is used for connections. For example, connections made in this way cannot be secure because no security parameters are provided.

Examples

```
//connect to default cluster specified in mapr-clusters.conf (preferred)
if ((err = hb_connection_create(NULL,
                                NULL,
                                &connection)) != 0) {
  HBASE_LOG_ERROR("Could not create MapR-DB connection : errorCode = %d.",
err);
  goto cleanup;
}

//Connect directly to cluster with these specified IP addresses.
//Typically this means there is no mapr-clusters.conf and security not used.
if ((err = hb_connection_create("192.168.1.1:7222,192.168.1.2:7222",
                                NULL /* ignored */,
                                &connection)) != 0) {
  HBASE_LOG_ERROR("Could not create MapR-DB connection : errorCode = %d.",
err);
  goto cleanup;
}
```

Code in the sample application

```
if ((retCode = hb_connection_create(zk_ensemble,
                                    zk_root_znode,
                                    &connection)) != 0) {
  HBASE_LOG_ERROR("Could not create HBase connection : errorCode = %d.",
retCode);
  goto cleanup;
}
```

last-updated: Nov 14, 2024

This API is defined in the header file `connection.h`:

Create a table

The sample application creates a table by calling a function named ensureTable.

APIs used

The definition of this function uses these APIs:

APIs defined in the header file `admin.h`.

- `hb_admin_table_create()`: Creates a table. Returns 0 on success or an error code.
- `hb_admin_table_delete()`: Deletes a table. Returns 0 on success or an error code.
- `hb_admin_destroy()`: Disconnects the hb_admin object, releasing any internal objects or connections that were created in the background.
- `hb_admin_table_disable()`: Disables an HBase table. Returns 0 on success or an error code. Only sets a flag in memory to say that the table is disabled.

  NOTE: Tables never need to be disabled or enabled in HPE Ezmeral Data Fabric Database, which has no notion of disabling or enabling tables. However, applications ported from HBase to HPE Ezmeral Data Fabric Database will attempt to disable and enable tables. By placing a flag in memory, HPE Ezmeral Data Fabric Database allows those applications to proceed without error when performing admin functions on tables.
- `hb_admin_table_enable()`: Enables an HBase table. Returns 0 on success or an error code. As with hb_admin_table_enable, this function sets a flag in memory and performs no other operation.
- `hb_admin_table_enabled()`: Checks whether an HBase table is enabled. Returns 0 if the table is enabled. If the table is disabled, returns either the error message HBASE_TABLE_DISABLED or an error code, if an error occurs. In HPE Ezmeral Data Fabric Database, this API only checks for the existence of an in-memory flag that indicates whether to consider a table as disabled or enabled.
- `hb_admin_table_exists()`: Checks whether a table exists. Returns 0 on success or an error code.

APIs defined in the header file `coldesc.h`.

- `hb_coldesc_create()`: Creates a column-family descriptor. Returns a handle to an hb_columndesc object or NULL, if unsuccessful.
- `hb_coldesc_set_maxversions()`: Sets the maximum number of cell versions to be retained for the column family. The default is 3.
- `hb_coldesc_set_minversions()`: Sets the minimum number of cell versions to be retained for the column family. The default is 0.
- `hb_coldesc_set_ttl()`: Sets the time-to-live value in seconds for data in column cells. The default is forever.

©Copyright 2024 Hewlett Packard Enterprise Development LP

- `hb_coldesc_set_inmemory()`: Boolean. Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.

  For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if its `inmemory` parameter is set to `false`, but preference will be given to column families where this parameter is set to `true`. A column family can have more than 32 bytes stored inline if its `inmemory` parameter is set to `true`.

  If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have the `inmemory` parameter set to `true`. All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data at all will be stored in-line for that column family.

  The default value for the `inmemory` parameter is `false`.

- `hb_coldesc_destroy()`: Releases resources that are held by a column-family descriptor.

Sequence of steps in the ensureTable function

1. Create an admin handle from the connection.
2. Using the admin handle, check whether the specified table exists.
3. If the table exists, delete it.
4. Specify columns and column families for the table.
5. Create the table.
6. Check whether the table is enabled. If it isn't enabled, enable it.
7. Disable the table and then enable it again.
8. Destroy the column descriptors.
9. Destroy the `hb_admin` structure.

Code for the ensureTable function at line 325

```
static int
ensureTable(hb_connection_t connection, const char *table_name) {
  int32_t retCode = 0;
  hb_admin_t admin = NULL;

  if ((retCode = hb_admin_create(connection, &admin)) != 0) {
    HBASE_LOG_ERROR("Could not create HBase admin : errorCode = %d.",
retCode);
    goto cleanup;
  }

  if ((retCode = hb_admin_table_exists(admin, NULL, table_name)) == 0) {
    HBASE_LOG_INFO("Table '%s' exists, deleting...", table_name);
    if ((retCode = hb_admin_table_delete(admin, NULL, table_name)) != 0) {
      HBASE_LOG_ERROR("Could not delete table %s[%d].", table_name,
retCode);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
      goto cleanup;
    }
  } else if (retCode != ENOENT) {
    HBASE_LOG_ERROR("Error while checking if the table exists: errorCode =
%d.", retCode);
    goto cleanup;
  }

  hb_coldesc_create(FAMILIES[0], 1, &HCD[0]);
  hb_coldesc_set_maxversions(HCD[0], 2);
  hb_coldesc_set_minversions(HCD[0], 1);
  hb_coldesc_set_ttl(HCD[0], 2147480000);
  hb_coldesc_set_inmemory(HCD[0], 1);

  hb_coldesc_create(FAMILIES[1], 1, &HCD[1]);

  HBASE_LOG_INFO("Creating table '%s'...", table_name);
  if ((retCode = hb_admin_table_create(admin, NULL, table_name, HCD, 2)) ==
0) {
    HBASE_LOG_INFO("Table '%s' created, verifying if enabled.", table_name);
    retCode = hb_admin_table_enabled(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Table '%s' is %senabled, result %d.", table_name, retCode?"not
":"");
    retCode = hb_admin_table_disable(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Attempted to disable table '%s', result %d.", table_name);
    retCode = hb_admin_table_disable(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Attempted to disable table '%s' again, result %d.", table_name);
    retCode = hb_admin_table_enable(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Attempted to enable table '%s', result %d.", table_name);
    retCode = hb_admin_table_enable(admin, NULL, table_name);
    CHECK_API_ERROR(retCode,
        "Attempted to enable table '%s' again, result %d.", table_name);
  }
  hb_coldesc_destroy(HCD[0]);
  hb_coldesc_destroy(HCD[1]);

cleanup:
  if (admin) {
    hb_admin_destroy(admin, NULL, NULL);
  }
  return retCode;
}
```

Code to call the ensureTable function

```
if ((retCode = ensureTable(connection, table_name)) != 0) {
  HBASE_LOG_ERROR("Failed to ensure table %s : errorCode = %d", table_name,
retCode);
  goto cleanup;
}
```

Create a client

API used

`hb_client_create()`: Initializes a handle to `hb_client_t` object that can be passed to other APIs. You need to use this method only once per cluster. The returned handle is thread-safe. This API is defined in the `client.h` header file.

Code

```
if ((retCode = hb_client_create(connection, &client)) != 0) {
  HBASE_LOG_ERROR("Could not connect to HBase cluster : errorCode = %d.",
retCode);
  goto cleanup;
}
```

Asynchronously put ten rows of one cell each

APIs used in this operation

The first 6 APIs are defined in the header file `mutations.h`:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the name of the table for the put operation.
- `hb_mutation_set_bufferable()`: Sets whether or not the RPC call for the put operation can be buffered on the client side.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

The last API is defined in the header file `client.h`:

- `hb_client_flush()`: Flushes any buffered client-side write operations to the server. The callback is invoked after everything that was buffered at the time of the call is flushed. Invocation of the callback is a guarantee that all outstanding RPC calls are complete.

Sequence of steps in this code extract

1. Create a row object named row_data.
2. Create a put object.
3. Specify the name of the table.
4. Set whether or not the RPC call for the put operation can be buffered on the client side.
5. Create cell data.
6. Create a cell.
7. Add the cell to the row.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

8. Queue the put.
9. After following the steps above 10 times, flush the puts to the server.
10. Wait for the RPC calls to complete.

Code

```
// let's send a batch of 10 puts with single cell asynchronously
outstanding_puts_count += num_puts;
for (int i = 0; i < num_puts; ++i) {
  row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
  row_data->key   = bytebuffer_printf("%s%02d", rowkey_prefix, i);
  hb_put_create(row_data->key->buffer, row_data->key->length, &put);
  hb_mutation_set_table(put, table_name, table_name_len);
  hb_mutation_set_durability(put, DURABILITY_SKIP_WAL);
  hb_mutation_set_bufferable(put, false);

  cell_data_t *cell_data = new_cell_data();
  row_data->first_cell = cell_data;
  cell_data->value = bytebuffer_printf("%s%02d", value_prefix, i);

  hb_cell_t *cell = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
  cell_data->hb_cell = cell;

  cell->row = row_data->key->buffer;
  cell->row_len = row_data->key->length;
  cell->family = FAMILIES[rand() % 2];
  cell->family_len = 1;
  cell->qualifier = column_a->buffer;
  cell->qualifier_len = column_a->length;
  cell->value = cell_data->value->buffer;
  cell->value_len = cell_data->value->length;
  cell->ts = HBASE_LATEST_TIMESTAMP;

  hb_put_add_cell(put, cell);
  HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                 cell->row_len, cell->row);
  hb_mutation_send(client, put, put_callback, row_data);
}
hb_client_flush(client, client_flush_callback, NULL);
wait_for_flush();

wait_for_puts(); // outside the loop, wait for 10 puts to complete
```

Asynchronously put two cells in a single row

APIs used

These APIs are defined in the header file `mutations.h`:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

last-updated: Nov 14, 2024

Sequence of steps

1. Create a row object named row_data.
2. Create a put object.
3. Specify the name of the table.
4. Create cell data for the first cell.
5. Create the first cell.
6. Add the data to the first cell.
7. Add the first cell to the row.
8. Create cell data for the second cell.
9. Create the second cell.
10. Add the data to the second cell.
11. Add the second cell to the row.
12. Queue the put.
13. Wait 3 seconds, flush the queue, and wait for the RPC calls to complete.

`wait_for_puts()` without `hb_client_flush()`: Waits for all outstanding put requests to be flushed. If hb_client_flush() is not called before wait_for_puts(), it can take up to three seconds for outstanding put requests to be flushed.

Code

```
  // now, let's put two cells in a single row
  outstanding_puts_count++;
  {
    row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
    row_data->key = bytebuffer_printf("row_with_two_cells");
    hb_put_create(row_data->key->buffer, row_data->key->length, &put);
    hb_mutation_set_table(put, table_name, table_name_len);
    hb_mutation_set_durability(put, DURABILITY_SYNC_WAL);

    // first cell
    cell_data_t *cell1_data = new_cell_data();
    row_data->first_cell = cell1_data;
    cell1_data->value = bytebuffer_printf("cell1_value_v1");

    hb_cell_t *cell1 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
    cell1_data->hb_cell = cell1;

    cell1->row = row_data->key->buffer;
    cell1->row_len = row_data->key->length;
    cell1->family = FAMILIES[0];
    cell1->family_len = 1;
    cell1->qualifier = column_a->buffer;
    cell1->qualifier_len = column_a->length;
    cell1->value = cell1_data->value->buffer;
    cell1->value_len = cell1_data->value->length;
    cell1->ts = 1391111111111L;
    hb_put_add_cell(put, cell1);
```

last-updated: Nov 14, 2024

```
    // second cell
    cell_data_t *cell2_data = new_cell_data();
    cell1_data->next_cell = cell2_data;
    cell2_data->value = bytebuffer_printf("cell2_value_v1");

    hb_cell_t *cell2 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
    cell2_data->hb_cell = cell2;

    cell2->row = row_data->key->buffer;
    cell2->row_len = row_data->key->length;
    cell2->family = FAMILIES[1];
    cell2->family_len = 1;
    cell2->qualifier = column_b->buffer;
    cell2->qualifier_len = column_b->length;
    cell2->value = cell2_data->value->buffer;
    cell2->value_len = cell2_data->value->length;
    cell2->ts = 1391111111111L;
    hb_put_add_cell(put, cell2);

    HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                   cell1->row_len, cell1->row);
    hb_mutation_send(client, put, put_callback, row_data);
    wait_for_puts();
  }
```

Asynchronously put a second version in one column of one row

APIs used

These APIs are defined in the header file mutations.h:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a row object named row_data.
2. Create a put object.
3. Specify the name of the table.
4. Create cell data for the first cell.
5. Create the first cell.
6. Add the data to the cell, using a later timestamp than in the previous operation.
7. Add the first cell to the row.
8. Queue the put.

©Copyright 2024 Hewlett Packard Enterprise Development LP

9. Wait 3 seconds, flush the queue, and wait for the RPC calls to complete.

Code

```
// now, let's put second version in one column
outstanding_puts_count++;
{
  row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
  row_data->key = bytebuffer_printf("row_with_two_cells");
  hb_put_create(row_data->key->buffer, row_data->key->length, &put);
  hb_mutation_set_table(put, table_name, table_name_len);
  hb_mutation_set_durability(put, DURABILITY_SYNC_WAL);

  // first cell
  cell_data_t *cell1_data = new_cell_data();
  row_data->first_cell = cell1_data;
  cell1_data->value = bytebuffer_printf("cell1_value_v2");

  hb_cell_t *cell1 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
  cell1_data->hb_cell = cell1;

  cell1->row = row_data->key->buffer;
  cell1->row_len = row_data->key->length;
  cell1->family = FAMILIES[0];
  cell1->family_len = 1;
  cell1->qualifier = column_a->buffer;
  cell1->qualifier_len = column_a->length;
  cell1->value = cell1_data->value->buffer;
  cell1->value_len = cell1_data->value->length;
  cell1->ts = 1392222222222L;
  hb_put_add_cell(put, cell1);

  HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                 cell1->row_len, cell1->row);
  hb_mutation_send(client, put, put_callback, row_data);
  wait_for_puts();
}
```

Scan the entire table

APIs used

These APIs and more are defined in the header file `scanner.h`:

- `hb_scanner_create()`: Creates a client side row scanner. The returned scanner is not thread safe. No RPC will be invoked until the call to fetch the next set of rows is made. You can set the various attributes of this scanner until that point. @returns 0 on success, non-zero error code in case of failure.
- `hb_scanner_next()`: Request the next set of results from the server. You can set the maximum number of rows returned by this call using hb_scanner_set_num_max_rows().
- `hb_scanner_num_max_rows()`: Sets the maximum number of rows to scan per call to hb_scanner_next().
- `hb_scanner_num_versions()`: Sets the maximum versions of a column to fetch.
- `hb_scanner_set_table()`: Sets the name of the table to scan.

Sequence of steps

1. Create the scanner object.

©Copyright 2024 Hewlett Packard Enterprise Development LP

2. Set the name of the table to scan.
3. Set the number of rows to scan at a time.
4. Set the number of versions to scan.
5. Request the next set of results from the server.
6. `wait_for_scan()`: wait for the rpc call to complete.

Code

```
  // now, scan the entire table
  {
    hb_scanner_t scanner = NULL;
    hb_scanner_create(client, &scanner);
    hb_scanner_set_table(scanner, table_name, table_name_len);
    hb_scanner_set_num_max_rows(scanner, 3);  // maximum 3 rows at a time
    hb_scanner_set_num_versions(scanner, 10); // up to 10 versions of the
cell
    hb_scanner_next(scanner, scan_callback, NULL); // dispatch the call
    wait_for_scan();
  }
```

Fetch a row that has two cells

APIs used

- `hb_get_add_column()`: Adds a column family and optionally a column qualifier to an hb_get_t object.
- `hb_get_create()`: Creates an `hb_get_t` object and populates the handle `get_ptr`.
- `hb_get_send()`: Queues the get request. The callback specified by `cb` is called on completion. Any buffers attached to the get object can be reclaimed only after the callback is received.
- `hb_get_set_num_versions()`: Sets maximum number of latest values of each column to be fetched. This API is optional.
- `hb_get_set_table()`: Sets the name of the table to get data from.

Sequence of steps

1. Create a row object named `rowKey`.
2. Create a get object.
3. Specify the column families and optional column qualifiers to get values from.
4. Specify the name of the table.
5. Specify the number of versions of the column values to get.
6. Queue the get request.
7. Wait for the get to complete.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Code

```
// fetch a row with row-key="row_with_two_cells"
{
  bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
  hb_get_t get = NULL;
  hb_get_create(rowKey->buffer, rowKey->length, &get);
  hb_get_add_column(get, FAMILIES[0], 1, NULL, 0);
  hb_get_add_column(get, FAMILIES[1], 1, NULL, 0);
  hb_get_set_table(get, table_name, table_name_len);
  hb_get_set_num_versions(get, 10); // up to ten versions of each column
  get_done = false;
  hb_get_send(client, get, get_callback, rowKey);
  wait_for_get();
}
```

Delete a specific version of a column in the row that was fetched

APIs used

The APIs that are used are defined in the header file `mutations.h`.

- `hb_delete_add_column()`: Set the column criteria for hb_delete_t object. Set the qualifier to NULL to delete all columns of a family. Only the cells with timestamp less than or equal to the specified timestamp are deleted. Set the timestamp to `INT64_MAX` to delete all versions of the column. This API is optional for deletes.
- `hb_delete_create()`: Creates a structure for delete operation and return its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a delete object for a row with a particular row key.
2. Add a column to the delete object.
3. Specify the name of the table from which to delete the cell version.
4. Queue the delete.
5. Wait three seconds for the delete to be flushed, then wait for the RPC call to complete.

Code

```
// delete a specific version of a column
{
  bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
  hb_delete_t del = NULL;
  hb_delete_create(rowKey->buffer, rowKey->length, &del);
  hb_delete_add_column(del, FAMILIES[0], 1,
      column_a->buffer, column_a->length, 1391111111112L);
  hb_mutation_set_table(del, table_name, table_name_len);
  delete_done = false;
  hb_mutation_send(client, del, delete_callback, rowKey);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    wait_for_delete();
  }
```

Destroy the client and the connection

APIs used

- `hb_client_destroy()`: Cleans up `hb_client_t` handle and releases any held resources. The callback is called after the connections are closed, but just before the client is freed. This API is defined in the header file `client.h`.
- `hb_connection_destroy()`: Destroys the connection and frees all resources allocated at creation time. This API is defined in the header file `connection.h`.

Sequence of steps

1. Destroy the client.
2. Destroy the connection.

Code

```
  if (client) {
    HBASE_LOG_INFO("Disconnecting client.");
    hb_client_destroy(client, client_disconnection_callback, NULL);
    wait_client_disconnection();
  }
  if (connection) {
    hb_connection_destroy(connection);
  }
```

Building and Launching C Applications

This topic describes basic setup for building and launching C application using the `libMapRClient` C API library

Prerequisites

The HPE Ezmeral Data Fabric Database `libMapRClient` C API library is Data Fabric's extension of the `libhbase` C API library). The libMapRClient header files are in this directory: **/opt/mapr/include/hbase**

- Verify that the `mapr-client` package is installed on the node. The `mapr-client` package must be installed on each node that builds an application. The `libMapRClient` header files are in this directory: `/opt/mapr/include/hbase`.
- Verify that both the `libMapRClient` library and `libjvm` shared libraries are in the application's library search path.

Building Applications

When building applications that use `libMapRClient`, run this command:

```
gcc -o <application_name> <source_file> -I/opt/mapr/include/hbase -L/opt/
mapr/lib/ -lMapRClient -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

For example, the following command builds the `hello_hbase` application with the `hello_hbase.c` source code:

```
gcc -o hello_hbase hello_hbase.c -I/opt/mapr/include/hbase -L/opt/
mapr/lib/ -lMapRClient -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

NOTE:

- The compiled libMapRClient is statically linked to the following third-party libraries: Crypto++: libcryptoapp.a (v5.6.2)Protobuf: libprotobuf-lite.a (v2.5.0)
- The `libMapRClient` library has dependencies on `libjvm`, though a JVM is not instantiated. In general, the `libjvm` library is located within the JDK/JRE installation directory.

Launching Applications

Before launching an application, set this value for the environment variable `LD_LIBRARY_PATH`:

```
/opt/mapr/lib:/usr/lib/jvm/java-6-openjdk-amd64/jre/lib/amd64/server
```

If the client is on Windows, append the following directories to the `PATH` environment variable:

- `$MAPR_HOME/lib`
- `$JAVA_HOME/bin/server`

If the application uses the `hb_connection_create_as_user` API for impersonation, set the `MAPR_IMPERSONATION_ENABLED` environment variable to `true`.

What To Do Next

Launch the application!

HBase Java Filters Support
The hb_get_set_filter() and hb_scanner_set_filter() C APIs are used to filter the results of GET and SCAN operations. These APIs are in the **get.h** and **scanner.h** header files.

They both take filters that are passed as strings, as well as the length of these strings. HPE Ezmeral Data Fabric Database parses the strings to construct filters.

Their signatures are:

```
int32_t hb_get_set_filter(hb_get_t get, const byte_t *filter, const int32_t
filterLen);
int32_t hb_scanner_set_filter(hb_scanner_t scanner, const byte_t *filter,
const int32_t filterLen);
```

For examples, see Filtering GET Operation Results Example on page 3276 and Filtering SCAN Operation Results Example on page 3275.

Filter Format and Arguments
Filters are specified in the Thrift Filter Language and are in this format: `FilterName (argument, argument,... , argument)`. Arguments that represent strings are enclosed in single quotation marks (‘). Arguments that represent booleans, integers, or comparison operators (<, <=, =, !=, >, >=) are not enclosed in single quotation marks.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Binary Operators

You can combine filters by using the binary operators `AND` and `OR`. For example, `PrefixFilter ('Row') AND PageFilter (1) AND FirstKeyOnlyFilter ()` returns all key-value pairs that match the following conditions:

- The row containing the key-value must start with the prefix "Row".
- The key-value must be located in the first row of the table.
- The key-value must be the first key-value pair in the row.

For another example, `(RowFilter (=, 'binary:Row 1') AND TimeStampsFilter (74689, 89734)) OR ColumnRangeFilter ('abc', true, 'xyz', false))` returns all key-value pairs that

Match both of the following conditions:

- The key-value is in a row for which the row key is "Row 1".
- The key-value has a timestamp of either 74689 or 89734.

Or match this condition:

- The key-value is located in a column that is lexicographically greater than or equal to "abc" and less than "xyz".

Unary Operators

You can also use the following unary operators with filters:

- SKIP

  For a particular row, if any of the key-values don't pass the filter condition, the entire row is skipped. For example, `SKIP ValueFilter (0)` omits rows in which any values are not 0.

- WHILE

  Rows are tested in order against the filter condition. Rows that meed the condition are included in the result set. When a row fails to meet the condition, filter processing stops and no more rows are tested.

Evaluation of Filters

When filters are combined with the binary operators, unary operators, or both, they are evaluated according to these rules:

1. First, evaluate the contents of parentheses.
2. Next, evaluate filters that use unary operators. Both SKIP and WHILE operators have the same precedence.
3. Finally, evaluate filters that use the binary operators. AND has higher precedence than OR.

For example, in a filter of the form `Filter1 AND Filter2 OR Filter`, `Filter1 AND Filter2` is evaluated and the result is *X*. Then, *X* `OR Filter3` is evaluated.

For another example, a filter of the form `Filter1 AND SKIP Filter2 OR Filter3` is evaluated in these steps:

1. Evaluate `SKIP Filter2` with the result being *X*.
2. Evaluate `Filter1 AND` *X* with the result being *Y*.
3. Evaluate *Y* `OR Filter3`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Compare Operators and Comparators
This topic describesthe compare operators and comparators for comparison filters.

The comparison filters DependentColumnFilter, FamilyFilter, QualifierFilter, RowFilter, and ValueFilter use the following syntax:

```
filter(<compareOperator>, <comparatorType:Value>)
```

Compare Operators

The following compare operators are supported: <,<=, =, !=, >, >=

Comparators

There are four comparators:

Comparator	Description
BinaryComparator	This comparator lexicographically compares against the specified byte array . Values are byte arrays. For example, `binary:abc` matches values that are lexicographically greater than "abc”.
BinaryPrefixComparator	This comparator lexicographically compares against a specified byte array. It only compares up to the length of this byte array. Values are byte arrays. For example, `binaryprefix:abc` matches values in which the first 3 characters are lexicographically equal to "abc"
RegexStringComparator	This comparator compares against the specified byte array using the given regular expression. You can use only the = and != compare operators with this comparator. Values are regular expressions. For example, `regexstring:ab*yz` matches values that begin with "ab" and end with "yz”.
SubStringComparator	This comparator tests whether the given substring appears in a specified byte array. The comparison is case insensitive. You can use only the = and != compare operators with this comparator. Values are strings. For example, `substring:abc123` matches values that contains the substring "abc123”.

Supported Filters

Filter	Format	Description
ColumnCountGetFilter	`ColumnCountGetFilter(`*x*`)`	Returns the first x columns in a row. Used for GET operations.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Filter	Format	Description
ColumnPaginationFilter	`ColumnPaginationFilter(x,y)`	Returns the first x columns after the number y of columns that is specified for the offset.
ColumnPrefixFilter	`ColumnPrefixFilter('prefix')`	Returns only those key-values in columns that have names that start with the specified prefix. The column prefix must be of the form “qualifier”.
ColumnRangeFilter	`ColumnRangFilter('minColumn','maxColumn',boolean,boolean)`	Returns only those key-values that are in columns that have names between minColumn and maxColumn. For example, if minColumn is 'an', and maxColumn is 'be', the filter returns key-values from columns named 'ana', 'bad', but not from columns named 'bed' or'eye' If minColumn is null, there is no lower bound. If maxColumn is null, there is no upper bound. This filter also takes two boolean variables to indicate whether to include the minColumn and maxColumn.
DependentColumnFilter	`DependentColumnFilter('family','qualifier')`	Tries to locate the specified column in each row and returns all key-values that have the same timestamp in that column. If a row does not contain the specified column, none of the key-values in that row are returned.
FamilyFilter	`FamilyFilter(compareOperator,'comparator:value')`	Filters by column family. If the comparison returns true, the filter returns all of the key-values in the matching column family.
FirstKeyOnlyFilter	`FirstKeyOnlyFilter()`	Returns the first key-value from each row.
FirstKeyValueMatchingQualifiersFilter	`FirstKeyValueMatchingQualifier('qualifier_1','qualifier_2',...'qualifier_n')`	Serially compares each qualifier in a row with the given qualifiers. If the current qualifier matches any of the given qualifiers, the filter stops and includes the current row (up to the current qualifier) in the result set.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Filter	Format	Description
FuzzyRowFilter	`FuzzyRowFilter('rowkey','fuzzy_info')`	Filters data based on fuzzy row key. Performs fast-forwards during scanning. It takes pairs (row key, fuzzy info) to match row keys. Where fuzzy info is a byte array with 0 or 1 as its values: 0 - means that this byte in provided row key is fixed, i.e. row key's byte at same position must match 1 - means that this byte in provided row key is NOT fixed, i.e. row key's byte at this position can be different from the one in provided row key Example: Let's assume row key format is userId_actionId_year_month. Length of userId is fixed and is 4, length of actionId is 2 and year and month are 4 and 2 bytes long respectively. Let's assume that we need to fetch all users that performed certain action (encoded as "99") in Jan of any year. Then the pair (row key, fuzzy info) would be the following: row key = "????_99_????_01" (one can use any value instead of "?") fuzzy info = "\x01\x01\x01\x01\x00\x00\x00\x00\x01\x01\x01\x01\x00\x00\x00" I.e. fuzzy info tells the matching mask is "????_99_????_01", where at ? can be any value.
InclusiveStopFilter	`InclusiveStopFilter('rowKey')`	Returns all key-values that are in the rows up to and including the specified row that has the specified row key.
KeyOnlyFilter	`KeyOnlyFilter()`	Returns the key component of each key-value.
MultipleColumnPrefixFilter	`MultipleColumnPrefixFilter('prefix_1','prefix_2',...,'prefix_n')`	Returns the key-values from columns that have names that begin with any of the specified prefixes.
PageFilter	`PageFilter(pageSize)`	Returns the number of rows that is equivalent to the specified page size..
PrefixFilter	`PrefixFilter('rowKey_prefix')`	Returns the key-values from a row that has a key which starts with the specified row-key prefix.
QualifierFilter	`QualifierFilter(compareOperator,'comparator:value')`	Filters by column. If the comparison returns true, the filter returns all of the key-values in the matching column.
RandomRowFilter	`RandomRowFilter(probability)`	Filters by probability. For example, RandomRowFilter(0.25) means that there is a 1 in 4 chance that the filter will pick the first row, a 1 in 4 chance that the filter will pick the next row, and so on until all rows in the table have been processed in this way.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Filter	Format	Description
RowFilter	`RowFilter(compareOperator,'comparator:value')`	Filters by row key. If the comparison returns true, the filter returns all of the key-values in the matching row.
SingleColumnValueExcludeFilter	`SingleColumnValueExcludeFilter('columnFamily','qualifier', compareOperator,'comparator:value')`	This filter takes the same arguments and behaves the same as SingleColumnValueFilter: however, if the column is found and the condition passes, all of the columns of the row will be returned except for the tested column value.
SingleColumnValueFilter	`SingleColumnValueFilter('columnFamily','qualifier', compareOperator,'comparator:value')`	This filter takes a column family, a qualifier, a compare operator and a comparator. If the specified column is not found: all of the columns of that row will be emitted. If the column is found and the comparison with the comparator returns true, all of the columns of the row will be emitted. If the condition fails, the row will not be returned.
SkipFilter	`SKIP filter`	See the description of the SKIP unary operator above .
TimeStampsFilter	`TimeStampsFilter('timestamp_1','timestamp_2',..., 'timestamp_n')`	Returns the key-values that have timestamps that match any of the specified timestamps.
ValueFilter	`ValueFilter(compareOperator,'comparator:value')`	Filters by key-value. If the comparison returns true, the filter returns the matching key-value.
WhileMatchFilter	`WHILE filter`	See the description of the WHILE unary operator above .

Creating Java Apps - Binary Tables

This topics describes the supported Apache HBase Java APIs used for CRUD operations on HPE Ezmeral Data Fabric Database binary tables.

HPE Ezmeral Data Fabric Database supports all of the Apache HBase 1.0 Java APIs, except where noted in this documentation. For a number of critical Java APIs, for filters, and for comparators, this documentation explicitly lists what is supported, rather than what is not supported.

Code written for Apache HBase can be easily ported to use HPE Ezmeral Data Fabric Database binary tables.

HPE Ezmeral Data Fabric Database binary tables do not support low-level HBase API calls that are used to manipulate the state of an Apache HBase cluster. HBase API calls that are not supported by HPE Ezmeral Data Fabric Database tables report successful completion to allow legacy code written for Apache HBase to continue executing, but do not perform any actual operations.

NOTE: For the list of supported HBase v0.98 APIs, refer to the HBase Java API Support on page 3300.

Compiling and Running HPE Ezmeral Data Fabric Database Binary Applications

For applications that use the HPE Ezmeral Data Fabric Database Java API for binary tables, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Compile and Determine Dependencies

1. Add the Data Fabric maven repository to the list of repositories in your application's `pom.xml`, if it is not there already:

```
<repository>
      <id>mapr-releases</id>
      <url>https://repository.mapr.com/maven/</url>
      <snapshots><enabled>true</enabled></snapshots>
      <releases><enabled>true</enabled></releases>
</repository>
```

   For more information, see Maven Artifacts for the HPE Ezmeral Data Fabric on page 4946.

2. Add a dependency to the HBase client project:

```
<dependencies>
<dependency>
  <groupId>org.apache.hbase</groupId>
  <artifactId>hbase-client</artifactId>
  <version><version selected from the repository></version>
</dependency>
<dependencies>
```

   NOTE:

   - The hbase-client version mentioned above is an example. The actual version that your application requires is based on the current EEP and Data Fabric core version that you are running. The file versions are listed in the following location: https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/hbase/hbase-client/ Ensure that the version tags include reference to m7-<maprversion>. Otherwise, your applications will not be able to access HPE Ezmeral Data Fabric Database binary tables.
   - If your application uses both the HPE Ezmeral Data Fabric Database JSON and HPE Ezmeral Data Fabric Database Binary APIs, you may encounter a conflict in the netty library used by each API. To avoid this, exclude the netty library from your `hbase-client` dependency as follows:

```
<dependency>
   <groupId>org.apache.hbase</groupId>
   <artifactId>hbase-client</artifactId>
   <version><version selected from the repository></version>
   <exclusions>
     <exclusion>
        <artifactId>netty-all</artifactId>
           <groupId>io.netty</groupId>
     </exclusion>
   </exclusions>
</dependency>
```

3. Use Maven to compile the application and resolve dependencies. For example, you can run `mvn clean package`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Running Applications

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 3186.

If the cluster is secure, the node must also have a Data Fabric ticket configured for the user that runs the application. See Managing Tickets on page 1815.

You can use the following command to launch HPE Ezmeral Data Fabric Database binary applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

NOTE: The classpath should include items that are part of the 'hbase classpath' script plus any other required dependencies.

HBase Java API Support

This topic describes the methods in the Apache HBase Java API library that are supported for HPE Ezmeral Data Fabric Database tables.

Admin Method Support

This topic lists the methods that the HPE Ezmeral Data Fabric Database supports in the HBase interface `Admin`.

The HPE Ezmeral Data Fabric Database tables support the following HBase methods, except where noted.

`abort(String why, Throwable e)`	*Modifier and Type*: `void` *Purpose*: Aborts the server or client *Supported*: No
`addColumn(TableName tableName, HColumnDescriptor column)`	*Modifier and Type*: `void` *Purpose*: Adds a column to an existing table *Supported*: Yes
`assign(byte[] regionName)`	*Modifier and Type*: `void` *Purpose*: Assigns a region *Supported*: No
`balancer()`	*Modifier and Type*: `boolean` *Purpose*: Invokes the balancer **NOTE:** The HPE Ezmeral Data Fabric Database does not require balancing. Therefore, the method is ignored. *Supported*: No
`cloneSnapshot(byte[] snapshotName, TableName tableName)`	*Modifier and Type*: `void` *Purpose*: Creates a new table by cloning the snapshot content *Supported*: No

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

cloneSnapshot(String snapshotName, TableName tableName)	*Modifier and Type*: `void` *Purpose*: Creates a new table by cloning the snapshot content *Supported*: No
close()	*Modifier and Type*: `void` *Purpose*: Releases any resources held *Supported*: Yes
closeRegion(byte[] regionname, String serverName)	*Modifier and Type*: `void` *Purpose*: Closes a region *Supported*: No
closeRegion(ServerName sn, HRegionInfo hri)	*Modifier and Type*: `void` *Purpose*: Closes a region *Supported*: No
closeRegion(String regionname, String serverName)	*Modifier and Type*: `void` *Purpose*: Closes a region *Supported*: No
closeRegionWithEncodedRegionName(String encodedRegionName, String serverName)	*Modifier and Type*: `boolean` *Purpose*: For expert administrators. *Supported*: No
compact(TableName tableName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a table *Supported*: No
compact(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Compacts a table *Supported*: No
compactRegion(byte[] regionName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a region *Supported*: No
compactRegion(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Compacts an individual region *Supported*: No
compactRegionServer(ServerName sn, boolean major)	*Modifier and Type*: `void` *Purpose*: Compacts all regions on the region server *Supported*: No
coprocessorService()	*Modifier and Type*: `CoprocessorRpcChannel` *Purpose*: Creates and returns a RpcChannel instance connected to the active master *Supported*: No
coprocessorService(ServerName sn)	*Modifier and Type*: `CoprocessorRpcChannel` *Purpose*: Creates and returns a RpcChannel instance connected to the active master *Supported*: No
createNamespace(NamespaceDescriptor descriptor)	*Modifier and Type*: `void`

©Copyright 2024 Hewlett Packard Enterprise Development LP

	Purpose: Creates a new namespace *Supported*: No
createTable(HTableDescriptor desc, byte[] startKey, byte[] endKey, int numRegions)	*Modifier and Type*: `void` *Purpose*: Creates a new table with the specified number of regions *Supported*: Yes
createTable(HTableDescriptor desc, byte[][] splitKeys)	*Modifier and Type*: `void` *Purpose*: Creates a new table with an initial set of empty regions defined by the specified split keys *Supported*: Yes
createTable(HTableDescriptor desc)	*Modifier and Type*: `void` *Purpose*: Creates a new table *Supported*: Yes
createTableAsync(HTableDescriptor desc, byte[][] splitKeys)	*Modifier and Type*: `void` *Purpose*: Creates a new table but does not block and wait for it to come online **NOTE:** The HPE Ezmeral Data Fabric Database treats this method as synchronous and returns null when the table is created. *Supported*: Yes
deleteColumn(String tableName, String columnName)	*Modifier and Type*: `void` *Purpose*: Deletes a column from a table *Supported*: Yes
deleteColumn(TableName tableName, byte[] columnName)	*Modifier and Type*: `void` *Purpose*: Deletes a column from a table *Supported*: Yes
deleteNamespace(String name)	*Modifier and Type*: `void` *Purpose*: Deletes an existing namespace. *Supported*: No
deleteSnapshot(byte[] snapshotName)	*Modifier and Type*: `void` *Purpose*: Deletes an existing snapshot *Supported*: No
deleteSnapshot(String snapshotName)	*Modifier and Type*: `void` *Purpose*: Deletes an existing snapshot *Supported*: No
deleteSnapshots(Pattern pattern)	*Modifier and Type*: `void` *Purpose*: Deletes existing snapshots whose names match the specified pattern *Supported*: No
deleteSnapshots(String regex)	*Modifier and Type*: `void` *Purpose*: Deletes existing snapshots whose names match the specified pattern *Supported*: No
deleteTable(String tableName)	*Modifier and Type*: `void`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	Purpose: Deletes a table *Supported*: Yes
`deleteTable(byte[] tableName)`	*Modifier and Type*: `void` *Purpose*: Deletes a table *Supported*: Yes
`deleteTable(TableName tableName)`	*Modifier and Type*: `void` *Purpose*: Deletes a table *Supported*: Yes
`deleteTables(Pattern pattern)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Delete tables that match the passed-in pattern, and waits on completion *Supported*: Yes
`deleteTables(String regex)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Delete tables that match the passed-in regular expression, and waits on completion *Supported*: Yes
`disableTable (String tableName)`	*Modifier and Type*: `void` *Purpose*: Disables table, and waits for completion **NOTE:** The HPE Ezmeral Data Fabric Database does not require disabling of tables. Therefore, although it supports these methods, it only flags the table as disabled, and does not perform any other operation. *Supported*: Yes
`disableTable(TableName tableName)`	*Modifier and Type*: `void` *Purpose*: Disables table, and waits for completion **NOTE:** The HPE Ezmeral Data Fabric Database does not require disabling of tables. Therefore, although it supports these methods, it only flags the table as disabled, and does not perform any other operation. *Supported*: Yes
`disableTableAsync (String tableName)`	*Modifier and Type*: `void` *Purpose*: Disables the table, but does not block and wait for it be completely disabled *Supported*: Yes
`disableTableAsync(TableName tableName)`	*Modifier and Type*: `void` *Purpose*: Disables the table, but does not block and wait for it be completely disabled *Supported*: Yes
`disableTables(Pattern pattern)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Disables tables that match the passed-in pattern, and waits on completion *Supported*: Yes
`disableTables(String regex)`	*Modifier and Type*: `HTableDescriptor[]`

©Copyright 2024 Hewlett Packard Enterprise Development LP

	Purpose: Disable tables that match the passed-in regular expression, and waits on completion *Supported*: Yes
enableCatalogJanitor(boolean enable)	*Modifier and Type*: `boolean` *Purpose*: Enables/Disables the catalog janitor *Supported*: No
enableTable(String tableName)	*Modifier and Type*: `void` *Purpose*: Enables a table **NOTE:** The HPE Ezmeral Data Fabric Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation. *Supported*: Yes
enableTable(bye[] tableName)	*Modifier and Type*: `void` *Purpose*: Enables a table **NOTE:** The HPE Ezmeral Data Fabric Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation. *Supported*: Yes
enableTable(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Enables a table **NOTE:** The HPE Ezmeral Data Fabric Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation. *Supported*: Yes
enableTableAsync (String tableName)	*Modifier and Type*: `void` *Purpose*: Enables the table, but does not block and wait for it be completely enabled *Supported*: Yes
enableTableAsync(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Enables the table, but does not block and wait for it be completely enabled *Supported*: Yes
enableTables(Pattern pattern)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Enable tables that match the passed-in pattern, and waits on completion *Supported*: Yes
enableTables(String regex)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Enable tables that match the passed-in regular expression. and waits on completion *Supported*: Yes
execProcedure(String signature, String instance, Map<String,String> props)	*Modifier and Type*: `void`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	Purpose: Executes a distributed procedure on a cluster *Supported*: No
execProcedureWithRet(String signature, String instance, Map<String,String> props)	*Modifier and Type*: `>byte[]` *Purpose*: Executes a distributed procedure on a cluster. *Supported*: No
flush(TableName tableName)	*Modifier and Type*: `>void` *Purpose*: Flushes a table *Supported*: Yes
flush(byte[] tableNameOrRegionName)	*Modifier and Type*: `>void` *Purpose*: Flushes a table *Supported*: Yes
flush(String tableNameOrRegionName)	*Modifier and Type*: `>void` *Purpose*: Flushes a table *Supported*: Yes
flushRegion(byte[] regionName)	*Modifier and Type*: `>void` *Purpose*: Flushes an individual region *Supported*: Yes
getAlterStatus(byte[] tableName)	*Modifier and Type*: `Pair<Integer,Integer>` *Purpose*: Gets the status of the alter command - indicates the number of regions that have received the updated schema Asynchronous operation **NOTE:** The HPE Ezmeral Data Fabric Database always returns (0,0). *Supported*: No
getAlterStatus(TableName tableName)	*Modifier and Type*: `Pair<Integer,Integer>` *Purpose*: Gets the status of the alter command - indicates the number of regions that have received the updated schema Asynchronous operation **NOTE:** The HPE Ezmeral Data Fabric Database always returns (0,0). *Supported*: No
getClusterStatus()	*Modifier and Type*: `ClusterStatus` *Purpose*: Gets the status of the cluster *Supported*: No
getCompactionState(String tableNameOrRegionName)	*Modifier and Type*: `CompactionState` *Purpose*: Get the current compaction state of a table *Supported*: No
getCompactionState(TableName tableName)	*Modifier and Type*: `org.apache.hadoop.hbase.protobuf.generated.AdminProtos.GetRegionInfoResponse.CompactionState` *Purpose*: Gets the current compaction state of a table *Supported*: No

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

getCompactionStateForRegion(byte[] regionName)	*Modifier and Type*: `org.apache.hadoop.hbase.protobuf.generated.AdminProtos.GetRegionInfoResponse.CompactionState` *Purpose*: Gets the current compaction state of a region *Supported*: No
getConfiguration()	*Modifier and Type*: `org.apache.hadoop.conf.Configuration` *Purpose*: Gets the configuration used by the instance *Supported*: Yes
getConnection()	*Modifier and Type*: `Connection` *Purpose*: Gets the connection used by this object *Supported*: Yes
getMasterCoprocessors()	*Modifier and Type*: `String[]` *Purpose*: Helper delegate to getClusterStatus().getMasterCoprocessors() *Supported*: No
getMasterInfoPort()	*Modifier and Type*: `int` *Purpose*: Gets the information port of the current master, if one is available *Supported*: No
getNamespaceDescriptor(String name)	*Modifier and Type*: `NamespaceDescriptor` *Purpose*: Gets a namespace descriptor by name *Supported*: No
getOnlineRegions(ServerName sn)	*Modifier and Type*: `List<HRegionInfo>` *Purpose*: Gets all the online regions on a region server *Supported*: No
getOperationTimeout()	*Modifier and Type*: `int` *Purpose*: The HPE Ezmeral Data Fabric Database never uses the timeout value **NOTE:** If you use the v1.1 API with the HPE Ezmeral Data Fabric Database, the method is ignored. *Supported*: No
getQuotaRetriever(QuotaFilter filter)	*Modifier and Type*: `QuotaRetriever` *Purpose*: Returns a QuotaRetriever to list the quotas based on the filter *Supported*: No
getTableDescriptor (byte[] tableName)	*Modifier and Type*: `HTableDescriptor` *Purpose*: Gets the table descriptor *Supported*: Yes
getTableDescriptor(TableName tableName)	*Modifier and Type*: `HTableDescriptor` *Purpose*: Gets the table descriptor *Supported*: Yes
getTableDescriptors(List<String> names)	*Modifier and Type*: `HTableDescriptor[]`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	Purpose: Gets table descriptors *Supported*: Yes
getTableDescriptorsByTableName(List<TableName> tableNames)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Gets table descriptors *Supported*: Yes
getTableRegions (byte[] tableName)	*Modifier and Type*: `List<HRegionInfo>` *Purpose*: Gets the regions of a given table *Supported*: Yes
getTableRegions(TableName tableName)	*Modifier and Type*: `List<HRegionInfo>` *Purpose*: Gets the regions of a given table *Supported*: Yes
isAborted()	*Modifier and Type*: `boolean` *Purpose*: Queries on the catalog janitor state. The HPE Ezmeral Data Fabric Database always returns false. *Supported*: No
isCatalogJanitorEnabled()	*Modifier and Type*: `boolean` *Purpose*: Queries on the catalog janitor state. The HPE Ezmeral Data Fabric Database always returns false. *Supported*: No
isProcedureFinished(String signature, String instance, Map<String,String> props)	*Modifier and Type*: `boolean` *Purpose*: Checks the current state of the specified procedure *Supported*: No
isSnapshotFinished(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	*Modifier and Type*: `boolean` *Purpose*: Checks the current state of the passed snapshot *Supported*: No
isTableAvailable(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if all regions of the table are available *Supported*: Yes
isTableAvailable(TableName tableName, byte[][] splitKeys)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table has been created with the specified number of splitkeys that was used while creating the given table *Supported*: No
isTableAvailable(TableName tableName)>	*Modifier and Type*: `boolean` *Purpose*: Returns true if all regions of the table are available *Supported*: Yes
isTableDisabled(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is offline

©Copyright 2024 Hewlett Packard Enterprise Development LP

	NOTE: Although the HPE Ezmeral Data Fabric Database supports this method, it only checks the flag. *Supported*: Yes
isTableDisabled(TableName tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is offline **NOTE:** Although the HPE Ezmeral Data Fabric Database supports this method, it only checks the flag. *Supported*: Yes
isTableEnabled(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is online **NOTE:** Although the HPE Ezmeral Data Fabric Database supports this method, it only checks the flag, and does not change the flag. *Supported*: Yes
isTableEnabled(TableName tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is online **NOTE:** Although the HPE Ezmeral Data Fabric Database supports this method, it only checks the flag, and does not change the flag. *Supported*: Yes
listNamespaceDescriptors()	*Modifier and Type*: `NamespaceDescriptor[]` *Purpose*: Lists available namespace descriptors *Supported*: No
listSnapshots()	*Modifier and Type*: `List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>` *Purpose*: Lists completed snapshots *Supported*: No
listSnapshots(Pattern pattern)	*Modifier and Type*: `List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>` *Purpose*: Lists all the completed snapshots that match the given pattern *Supported*: No
listSnapshots(String regex)	*Modifier and Type*: `List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>` *Purpose*: Lists all the completed snapshots that match the given regular expression *Supported*: No
listTableDescriptorsByNamespace(String name)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Gets the list of table descriptors by namespace *Supported*: No
listTableNames()	*Modifier and Type*: `TableName[]`

©Copyright 2024 Hewlett Packard Enterprise Development LP

	Purpose: Lists all the names of userspace tables *Supported*: Yes
`listTableNames(Pattern pattern, boolean includeSysTables)`	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified pattern *Supported*: Yes
`listTableNames(Pattern pattern)`	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified pattern *Supported*: Yes
`listTableNames(String regex, boolean includeSysTables)`	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified regular expression *Supported*: Yes
`listTableNames(String regex)`	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified regular expression *Supported*: Yes
`listTableNamesByNamespace(String name)`	*Modifier and Type*: `TableName[]` *Purpose*: Gets the list of table names by namespace *Supported*: Yes
`listTables()`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the userspace tables *Supported*: Yes
`listTables(Pattern pattern, boolean includeSysTables)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the tables that match the given pattern. **NOTE:** The HPE Ezmeral Data Fabric Database does not have system tables and therefore, the boolean value is ignored. *Supported*: Yes
`listTables(Pattern pattern)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the userspace tables matching the given pattern. *Supported*: Yes
`listTables(String regex, boolean includeSysTables)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the tables matching the given pattern. **NOTE:** The HPE Ezmeral Data Fabric Database does not have system tables and therefore, the boolean value is ignored. *Supported*: Yes
`listTables(String regex)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the userspace tables that match the given regular expression. *Supported*: Yes

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

majorCompact(byte[] tableNameOrRegionName)	*Modifier and Type*: `void` *Purpose*: Compacts a table, or an individual region. *Supported*: Deprecated
majorCompact(String tableNameOrRegionName)	*Modifier and Type*: `void` *Purpose*: Compacts a table, or an individual region. *Supported*: Deprecated
majorCompact(byte[] tableNameOrRegionName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a table, or a region *Supported*: Deprecated
majorCompact(String tableNameOrRegionName, String columnFamily)	*Modifier and Type*: `void` *Purpose*: Compact a column family within a table, or a region *Supported*: Deprecated
majorCompactRegion(byte[] regionName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a region *Supported*: No
majorCompactRegion(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Compacts a table, or an individual region *Supported*: No
mergeRegions(byte[] nameOfRegionA, byte[] nameOfRegionB, boolean forcible)	*Modifier and Type*: `void` *Purpose*: Merges two regions *Supported*: No
modifyColumn(TableName tableName, HColumnDescriptor columnFamily)	*Modifier and Type*: `void` *Purpose*: Modifies an existing column family on a table *Supported*: Yes
modifyColumn(TableName tableName, HColumnDescriptor columnFamily)	*Modifier and Type*: `void` *Purpose*: Modifies an existing column family on a table *Supported*: Yes
modifyNamespace(NamespaceDescriptor descriptor)	*Modifier and Type*: `void` *Purpose*: Modifies an existing namespace *Supported*: No
modifyTable (byte[] tableName, HTableDescriptor htd)	*Modifier and Type*: `void` *Purpose*: Modifies an existing table *Supported*: Yes
modifyTable(final String tableName, final HTableDescriptor htd)	*Modifier and Type*: `void` *Purpose*: Modifies an existing table *Supported*: Yes
modifyTable(TableName tableName, HTableDescriptor htd)	*Modifier and Type*: `void` *Purpose*: Modifies an existing table. This method is the more IRB friendly version. *Supported*: Yes
move(byte[] encodedRegionName, byte[] destServerName)	*Modifier and Type*: `void`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	Purpose: Moves the region to the destination *Supported*: No
offline(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Offlines specified region from master's in-memory state *Supported*: No
restoreSnapshot(byte[] snapshotName, boolean takeFailSafeSnapshot)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
restoreSnapshot(byte[] snapshotName)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
restoreSnapshot(String snapshotName, boolean takeFailSafeSnapshot)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
restoreSnapshot(String snapshotName)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
rollWALWriter(ServerName serverName)	*Modifier and Type*: `void` *Purpose*: Rolls the log writer. *Supported*: No
runCatalogScan()	*Modifier and Type*: `int` *Purpose*: Requests a scan of the catalog table *Supported*: No
setBalancerRunning(boolean on, boolean synchronous)	*Modifier and Type*: `boolean` *Purpose*: Turns the load balancer on or off **NOTE:** The HPE Ezmeral Data Fabric Database does not require balancing. Therefore, the method just sets a flag. There is no impact on the Data Fabric table. *Supported*: No
setQuota(QuotaSettings quota)	*Modifier and Type*: `void` *Purpose*: Applies the new quota settings *Supported*: No
shutdown()	*Modifier and Type*: `void` *Purpose*: Shuts down the HBase cluster *Supported*: No
snapshot(byte[] snapshotName, TableName tableName)	*Modifier and Type*: `void` *Purpose*: Creates a timestamp consistent snapshot for the given table *Supported*: No

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

snapshot(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	*Modifier and Type*: `void` *Purpose*: Takes a snapshot, and waits for the server to complete that snapshot (blocking). *Supported*: No
snapshot(String snapshotName, TableName tableName, org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription.Type type)	*Modifier and Type*: `void` *Purpose*: Creates a typed snapshot of the table *Supported*: No
snapshot(String snapshotName, TableName tableName)	*Modifier and Type*: `void` *Purpose*: Takes a snapshot for the given table *Supported*: No
split(byte[] tableNameOrRegionName)	*Modifier and Type*: `void` *Purpose*: Splits a table **NOTE:** The tableNameOrRegionName parameter has a different format when used with Data Fabric tables than with Apache HBase tables. With Data Fabric tables, specify both the table path and the FID as a comma-separated list. *Supported*: Yes
split(TableName tableName, byte[] splitPoint)	*Modifier and Type*: `void` *Purpose*: Splits a table. **NOTE:** The tableNameOrRegionName parameter has a different format when used with Data Fabric tables than with Apache HBase tables. With Data Fabric tables, specify both the table path and the FID as a comma-separated list. *Supported*: No
split(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Splits a table. **NOTE:** The tableNameOrRegionName parameter has a different format when used with Data Fabric tables than with Apache HBase tables. With Data Fabric tables, specify both the table path and the FID as a comma-separated list. *Supported*: Yes
splitRegion(byte[] regionName, byte[] splitPoint)	*Modifier and Type*: `void` *Purpose*: Splits an individual region. *Supported*: No
splitRegion(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Splits an individual region *Supported*: Yes
stopMaster()	*Modifier and Type*: `void` *Purpose*: Shuts down the current HBase master only *Supported*: No

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

stopRegionServer(String hostnamePort)	*Modifier and Type*: `void` *Purpose*: Stops the designated region server *Supported*: No
tableExists(TableName tableName)	*Modifier and Type*: `boolean` *Purpose*: Returns whether a table with the specified name exists *Supported*: Yes
tableExists(byte[] tableName)	*Modifier and Type*: `boolean` *Purpose*: Returns whether a table with the specified name exists *Supported*: Yes
tableExists(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Returns whether a table with the specified name exists *Supported*: Yes
takeSnapshotAsync(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	*Modifier and Type*: `org.apache.hadoop.hbase.protobuf.generated.MasterProtos.SnapshotResponse` *Purpose*: Takes a snapshot without waiting for the server to complete that snapshot (asynchronous). Ensure that you take only a single snapshot at a time, or the results may be undefined. *Supported*: No
truncateTable(TableName tableName, boolean preserveSplits)	*Modifier and Type*: `void` *Purpose*: Truncates a table *Supported*: Yes
unassign(byte[] regionName, boolean force)	*Modifier and Type*: `void` *Purpose*: Unassigns a region from the current hosting region server *Supported*: No
updateConfiguration()	*Modifier and Type*: `void` *Purpose*: Updates the configuration, and triggers an online configuration change on all the region servers *Supported*: No
updateConfiguration(ServerName server)	*Modifier and Type*: `void` *Purpose*: Updates the configuration, and triggers an online configuration change on all the region servers *Supported*: No

BufferedMutator Method Support

This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase interface `BufferedMutator`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted.

Method Name	Modifier and Type	Description	Supported?
`close()`	void	Performs a flush() and releases any resources held.	Yes

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Method Name	Modifier and Type	Description	Supported?
`flush()`	void	Executes all the buffered, asynchronous Mutation operations and waits until they are done.	Yes
`getConfiguration()`	org.apache.hadoop.conf.Configuration	Returns the Configuration object used by this instance.	Yes
`getName()`	TableName	Gets the fully qualified table name instance of the table that this BufferedMutator writes to.	Yes
`getWriteBuffer()`	long	Get the internal write buffer.	No
`getWriteBufferSize()`	long	Returns the maximum size in bytes of the write buffer for this HTable.	No
`mutate(List<? extends Mutation> mutations)`	void	Send some Mutation objects to the table.	Yes
`mutate(Mutation mutation)`	void	Sends a Mutation to the table.	Yes
`setWriteBufferSize()`	long	Sets the maximum size (in bytes) of the write buffer for this HTable	No

Connection Method Support
This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase interface `Connection`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted. For full details about this interface, see `Interface Connection`.

Method Name	Modifier and Type	Description	Supported?
`close()`	void	Close this connection.	Yes
`getAdmin()`	Admin	Retrieve an Admin implementation to administer an HBase cluster.	Yes
`getBufferedMutator(BufferedMutatorParams params)`	BufferedMutator	Retrieve a BufferedMutator for performing client-side buffering of writes.	Yes
`getBufferedMutator(TableName tableName)`	BufferedMutator		Yes
`getConfiguration()`	org.apache.hadoop.conf.Configuration	Retrieve the Configuration object used by this connection.	Yes
`getRegionLocator(TableName tableName)`	RegionLocator	Retrieve a RegionLocator implementation to inspect region information on a table.	Yes

©Copyright 2024 Hewlett Packard Enterprise Development LP

Method Name	Modifier and Type	Description	Supported?
`getTable(TableName tableName)`	Table	Retrieve a Table implementation for accessing a table.	Yes
`getTable(TableName tableName, ExecutorService pool)`	Table		Yes
`isClosed()`	boolean	Returns whether the connection is closed or not.	Yes

ConnectionFactory Method Support
This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase class `ConnectionFactory`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted. For full details about this class, see the `ConnectionFactory` class in the Client package..

Method Name	Modifier and Type	Description	Supported?
`createConnection()`	static Connection	Create a new Connection instance using default HBaseConfiguration.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf, ExecutorService pool)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf, ExecutorService pool, User user)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf, User user)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes

RegionLocator Method Support
This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase interface `RegionLocator`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted. For full details about this interface, see `Interface RegionLocator` interface in the Client package.

Method Name	Modifier and Type	Description	Supported?
`close()`	void	Close this connection.	Yes
`getAllRegionLocations()`	List<HRegionLocation>	Retrieves all of the regions associated with this table.	Yes
`getConfiguration()`	Configuration	Retrieve the Configuration Object used by this RegionLocator.	Yes

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Method Name	Modifier and Type	Description	Supported?
`getEndKeys()`	byte[][]	Gets the ending row key for every region in the currently open table.	Yes
`getName()`	TableName	Gets the fully qualified table name instance of this table.	Yes
`getRegionLocation(byte[] row)`	HRegionLocation	Finds the region on which the given row is being served.	Yes
`getRegionLocation(byte[] row, boolean reload)`	HRegionLocation		Yes
`getStartEndKeys()`	Pair<byte[][],byte[][]>	Gets the starting and ending row keys for every region in the currently open table.	Yes
`getStartKeys()`	byte[][]	Gets the starting row key for every region in the currently open table.	Yes

Table Method Support
This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase interface `Table`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted. For full details about this interface, see `Interface Table` in the Client package.

Method Name	Modifier and Type	Description	Supported?
`append(Append append)`	Result	Appends values to one or more columns within a single row.	Yes
`batch(List<? extends Row> actions)`	Object[]	A batch call on Deletes, Gets, Puts, Increments, Appends and RowMutations.	Deprecated
`batch(List<? extends Row> actions, Object[] results)`	void	Method that does a batch call on Deletes, Gets, Puts, Increments and Appends.	Yes
`batchCallback(List<? extends Row> actions, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	Object[]	Method that does a batch call on Deletes, Gets, Puts, Increments and Appends with a callback.	YesFootnote.

[1] Not fully supported. When used with HPE Ezmeral Data Fabric Database, the callback is ignored.
[2] Not fully supported. When used with HPE Ezmeral Data Fabric Database, the durability is ignored.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Method Name	Modifier and Type	Description	Supported?
`batchCallback(List<? extends Row> actions, Object[] results, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	<R> void	Same as batch(List, Object[]), but with a callback. HPE Ezmeral Data Fabric Database ignores the callback.	YesFootnote.
`batchCoprocessorService(com.google.protobuf.Descriptors.MethodDescriptor methodDescriptor, com.google.protobuf.Message request, byte[] startKey, byte[] endKey, R responsePrototype, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	<R extends com.google.protobuf.Message> void	Creates an instance of the given Service subclass for each table region spanning the range from the startKey row to endKey row (inclusive), all the invocations to the same region server will be batched into one call.	No
`batchCoprocessorService(com.google.protobuf.Descriptors.MethodDescriptor methodDescriptor, com.google.protobuf.Message request, byte[] startKey, byte[] endKey, R responsePrototype)`	<R extends com.google.protobuf.Message> Map<byte[],R>		No

©Copyright 2024 Hewlett Packard Enterprise Development LP

Method Name	Modifier and Type	Description	Supported?
`checkAndDelete(byte[] row, byte[] family, byte[] qualifier, byte[] value, Delete delete)`	boolean	Atomically checks if a row/family/qualifier value matches the expected value.	Yes
`checkAndDelete(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, Delete delete)`	boolean		Yes
`checkAndMutate(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, RowMutations mutation)`	boolean		Yes
`checkAndPut(byte[] row, byte[] family, byte[] qualifier, byte[] value, Put put)`	boolean		Yes
`checkAndPut(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, Put put)`	boolean		Yes
`close()`	void	Releases any resources held or pending changes in internal buffers.	Yes
`coprocessorService(byte[] row)`	CoprocessorRpcChannel	Creates and returns a RpcChannel instance connected to the table region containing the specified row.	No

©Copyright 2024 Hewlett Packard Enterprise Development LP

Method Name	Modifier and Type	Description	Supported?
`coprocessorService(Class<T> service, byte[] startKey, byte[] endKey, org.apache.hadoop.hbase.client.coprocessor.Batch.Call<T,R> callable, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	<T extends com.google.protobuf.Service,R> void	Creates an instance of the given Service subclass for each table region spanning the range from the startKey row to endKey row (inclusive), and invokes the passed Batch.Call.call(T) method with each Service instance.	No
`coprocessorService(Class<T> service, byte[] startKey, byte[] endKey, org.apache.hadoop.hbase.client.coprocessor.Batch.Call<T,R> callable)`	<T extends com.google.protobuf.Service,R> Map<byte[],R>		No
`delete(Delete delete)`	void	Deletes the specified cells/row.	Yes
`delete(List<Delete> deletes)`	void	Deletes the specified cells/rows in bulk.	Yes
`exists(Get get)`	boolean	Test for the existence of columns in the table, as specified by the Get.	Yes
`existsAll(List<Get> gets)`	boolean[]	Test for the existence of columns in the table, as specified by the Gets, in batch.	Yes
`get(Get get)`	Result	Extracts certain cells from a given row.	Yes
`get(List<Get> gets)`	Result[]	Extracts certain cells from the given rows, in batch.	Yes
`getConfiguration()`	org.apache.hadoop.conf.Configuration	Returns the Configuration object used by this instance.	Yes
`getName()`	TableName	Gets the fully qualified table name instance of this table.	Yes
`getScanner(byte[] family, byte[] qualifier)`	ResultScanner	Gets a scanner on the current table for the given family and qualifier.	Yes
`getScanner(byte[] family)`	ResultScanner	Gets a scanner on the current table for the given family.	Yes
`getScanner(Scan scan)`	ResultScanner	Returns a scanner on the current table as specified by the Scan object.	Yes
`getTableDescriptor()`	HTableDescriptor	Gets the table descriptor for this table.	Yes
`getWriteBufferSize()`	long	Returns the maximum size in bytes of the write buffer for this HTable.	No

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Method Name	Modifier and Type	Description	Supported?
`increment(Increment increment)`	Result	Increments one or more columns within a single row.	Yes
`incrementColumnValue(byte[] row, byte[] family, byte[] qualifier, long amount, Durability durability)`	long	Atomically increments a column value.	YesFootnote.
`incrementColumnValue(byte[] row, byte[] family, byte[] qualifier, long amount)`	long	See incrementColumnValue(byte[], byte[], byte[], long, Durability).	Yes
`mutateRow(RowMutations rm)`	void	Performs multiple mutations atomically on a single row.	Yes
`put(List<Put> puts)`	void	Puts some data in the table, in batch.	Yes
`put(Put put)`	void	Puts some data in the table.	Yes
`setWriteBufferSize(long writeBufferSize)`	void	Sets the size of the buffer in bytes.	No

HColumnDescriptor and HTableDescriptor Support
This section describes the supported fields in the HColumnDescriptor and the HTableDescriptor classes.

HPE Ezmeral Data Fabric Database supports all of the methods that are in these classes. However, it supports only a subset of their fields.

HColumnDescriptor Class

Field	Description
BLOCKSIZE	Size of blocks in files stored to the filesytem (hfiles).
BLOOMFILTER	Whether or not to use bloomfilters.
COMPRESSION	Compression type.
IN_MEMORY	Whether to serve from memory or not.
MIN_VERSIONS	Minimum number of versions to keep.
NAME	Name of the column family.
TTL	Time to live of cell contents.
VERSIONS	Number of versions to keep.

HTableDescriptor Class

Field	Description
AUTOSPLIT	Specifies whether to split the table into regions automatically as the table grows. The average size of each region is determined by the`regionsizemb` parameter. The default value is `true`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Field	Description
BULKLOAD	Boolean. Specifies whether to perform a full bulk load of the table. The default is `false`. For more information, see Bulk Loading and Data Fabric Tables.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Field	Description
DELETE_TTL	Used for multi-master replication. Normally, delete operations are purged after the affected table cells are updated. Whereas the result of an update is saved in a table until another change overwrites or deletes it, the result of a delete is not saved. In multi-master replication, this difference can lead to tables being unsynchronized. Example Suppose that you have set up multi-master replication between table `customers` in the cluster `sanfrancisco` and table `customers` in the cluster `newyork`. Client applications then make these two changes: **1.** On `/mapr/sanfrancisco/customers`, put row A at 10:00:00 AM. **2.** On `/mapr/newyork/customers`, delete row A at 10:00:01 AM. On `/mapr/sanfrancisco/customers`, the order of operations is: **1.** Put row A with a timestamp of 10:00:00 AM **2.** Delete row A with a timestamp of 10:00:01 AM (This operation is repllicated from `/mapr/newyork/customers`.) On `/mapr/newyork/customers`, the order of operations is: **1.** Delete row A with a timestamp of 10:00:01 AM **2.** Put row A with a timestamp of 10:00:00 AM (This operation is replicated from `/mapr/sanfrancisco/customers`.) Now, though the put happened on `/mapr/sanfrancisco/customers` at 10:00:00 AM, the put reaches `/mapr/newyork/customers` several seconds after that. Suppose that the actual time that the put arrives at `/mapr/newyork/customers` is 10:00:03 AM. To ensure that both tables stay synchronized, `/mapr/newyork/customers` should preserve the delete until after the put is replicated. Then, the delete can be applied after the put. Therefore, the time-to-live for the delete should be at least long enough for the put to arrive at `/mapr/newyork/customers`. In this case, the time-to-live should be at least 3 seconds. In general, the time-to-live for deletes should be greater than the amount of time that it takes replicated operations to reach replicas. By default, the value is 24 hours. For example, suppose (to extend the scenario above) that you pause replication during weekdays and resume it on weekends. The put takes place on Monday morning `/mapr/sanfrancisco/customers` at 10:00:00 AM and the delete takes place at `/mapr/newyork/customers` at 10:00:01 AM. Replication does not resume until 12:00:00 AM Saturday morning. Given the volume of operations to be replicated and the potential for network problems, it is possible that these operations will not be replicated until Sunday. In this scenario, a value of 7 days for DELETE_TTL (7 multiplied by 24 hours) should provide sufficient margin.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Field	Description
NAME	Name of the table.

Support for HBase Java Filters Support

HPE Ezmeral Data Fabric Database supports the following Java filters, which work identically to their Apache HBase versions. See the Apache HBase API for more information, specifically, the Apache HBase Filter package.

Filter	Description
`ColumnCountGetFilter`	Simple filter that returns first N columns on row only. This filter was written to test filters in Get and as soon as it gets its quota of columns, `filterAllRemaining()` returns true. This makes this filter unsuitable as a Scan filter.
`ColumnPaginationFilter`	A filter, based on the `ColumnCountGetFilter`, takes two arguments: limit and offset. This filter can be used for row-based indexing, where references to other tables are stored across many columns, in order to efficient lookups and paginated results for end users. Only most recent versions are considered for pagination.
`ColumnPrefixFilter`	This filter is used for selecting only those keys with columns that matches a particular prefix. For example, if prefix is 'an', it will pass keys with columns like 'and', 'anti' but not keys with columns like 'ball', 'act'.
`ColumnRangeFilter`	This filter is used for selecting only those keys with columns that are between minColumn to maxColumn. For example, if minColumn is 'an', and maxColumn is 'be', it will pass keys with columns like 'ana', 'bad', but not keys with columns like 'bed', 'eye' If minColumn is null, there is no lower bound. If maxColumn is null, there is no upper bound. minColumnInclusive and maxColumnInclusive specify if the ranges are inclusive or not.
`DependentColumnFilter`	A filter for adding inter-column timestamp matching Only cells with a correspondingly timestamped entry in the target column will be retained Not compatible with Scan.setBatch as operations need full rows for correct filtering
`FamilyFilter`	This filter is used to filter based on the column family. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the column family portion of a key. This filter can be wrapped with `WhileMatchFilter` and `SkipFilter` to add more control. Multiple filters can be combined using `FilterList` . If an already known column family is looked for, use `Get.addFamily(byte[])` directly rather than a filter.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Filter	Description
`FilterList`	Implementation of `Filter` that represents an ordered List of Filters which will be evaluated with a specified boolean operator `FilterList.Operator.MUST_PASS_ALL` (`AND`) or `FilterList.Operator.MUST_PASS_ONE` (`OR`). Since you can use Filter Lists as children of Filter Lists, you can create a hierarchy of filters to be evaluated. `FilterList.Operator.MUST_PASS_ALL` evaluates lazily: evaluation stops as soon as one filter does not include the KeyValue. `FilterList.Operator.MUST_PASS_ONE` evaluates non-lazily: all filters are always evaluated. Defaults to `FilterList.Operator.MUST_PASS_ALL` .
`FirstKeyOnlyFilter`	A filter that will only return the first KV from each row. This filter can be used to more efficiently perform row count operations.
`FirstKeyValueMatchingQualifiersFilter`	The filter looks for the given columns in KeyValue. Once there is a match for any one of the columns, it returns ReturnCode.NEXT_ROW for remaining KeyValues in the row. **Note**: It may emit KVs which do not have the given columns in them, if these KVs happen to occur before a KV which does have a match. Given this caveat, this filter is only useful for special cases like `RowCounter` .
`FuzzyRowFilter`	Filters data based on fuzzy row key. Performs fast-forwards during scanning. It takes pairs (row key, fuzzy info) to match row keys. Where fuzzy info is a byte array with 0 or 1 as its values: • 0 - means that this byte in provided row key is fixed, i.e. row key's byte at same position must match • 1 - means that this byte in provided row key is NOT fixed, i.e. row key's byte at this position can be different from the one in provided row key Example: Let's assume row key format is userId_actionId_year_month. Length of userId is fixed and is 4, length of actionId is 2 and year and month are 4 and 2 bytes long respectively. Let's assume that we need to fetch all users that performed certain action (encoded as "99") in Jan of any year. Then the pair (row key, fuzzy info) would be the following: row key = "????_99_????_01" (one can use any value instead of "?") fuzzy info = "\x01\x01\x01\x01\x00\x00\x00\x00\x01\x01\x01\x01\x00\x00\x00" I.e. fuzzy info tells the matching mask is "????_99_????_01", where at ? can be any value.
`InclusiveStopFilter`	A Filter that stops after the given row. There is no "RowStopFilter" because the Scan spec allows you to specify a stop row. Use this filter to include the stop row, eg: [A,Z].
`KeyOnlyFilter`	A filter that will only return the key component of each KV (the value will be rewritten as empty). This filter can be used to grab all of the keys without having to also grab the values.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Filter	Description
`MultipleColumnPrefixFilter`	This filter is used for selecting only those keys with columns that matches a particular prefix. For example, if prefix is 'an', it will pass keys will columns like 'and', 'anti' but not keys with columns like 'ball', 'act'.
`PageFilter`	Implementation of Filter interface that limits results to a specific page size. It terminates scanning once the number of filter-passed rows is > the given page size. Note that this filter cannot guarantee that the number of results returned to a client are <= page size. This is because the filter is applied separately on different region servers. It does however optimize the scan of individual HRegions by making sure that the page size is never exceeded locally.
`PrefixFilter`	Pass results that have same row prefix.
`QualifierFilter`	This filter is used to filter based on the column qualifier. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the column qualifier portion of a key. This filter can be wrapped with `WhileMatchFilter` and `SkipFilter` to add more control. Multiple filters can be combined using `FilterList` . If an already known column qualifier is looked for, use `Get.addColumn(byte[], byte[])` directly rather than a filter.
`RandomRowFilter`	A filter that includes rows based on a chance.
`RowFilter`	This filter is used to filter based on the key. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the row, and column qualifier portions of a key. This filter can be wrapped with `WhileMatchFilter` to add more control. Multiple filters can be combined using `FilterList`. If an already known row range needs to be scanned, use `CellScanner` start and stop rows directly rather than a filter.
`SingleColumnValueExcludeFilter`	A `Filter` that checks a single column value, but does not emit the tested column. This will enable a performance boost over `SingleColumnValueFilter` , if the tested column value is not actually needed as input (besides for the filtering itself).

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Filter	Description
`SingleColumnValueFilter`	This filter is used to filter cells based on value. It takes a `CompareFilter.CompareOp` operator (equal, greater, not equal, etc), and either a byte [] value or a ByteArrayComparable. If we have a byte [] value then we just do a lexicographic compare. For example, if passed value is 'b' and cell has 'a' and the compare operator is LESS, then we will filter out this cell (return true). If this is not sufficient (eg you want to deserialize a long and then compare it to a fixed long value), then you can pass in your own comparator instead. You must also specify a family and qualifier. Only the value of this column will be tested. When using this filter on a `CellScanner` with specified inputs, the column to be tested should also be added as input (otherwise the filter will regard the column as missing). To prevent the entire row from being emitted if the column is not found on a row, use `setFilterIfMissing(boolean)` . Otherwise, if the column is found, the entire row will be emitted only if the value passes. If the value fails, the row will be filtered out. In order to test values of previous versions (timestamps), set `setLatestVersionOnly(boolean)` to false. The default is true, meaning that only the latest version's value is tested and all previous versions are ignored. To filter based on the value of all scanned columns, use `ValueFilter`.
`SkipFilter`	A wrapper filter that filters an entire row if any of the Cell checks do not pass. For example, if all columns in a row represent weights of different things, with the values being the actual weights, and we want to filter out the entire row if any of its weights are zero. In this case, we want to prevent rows from being emitted if a single key is filtered. Combine this filter with a `ValueFilter`: `scan.setFilter(new SkipFilter(new ValueFilter(CompareOp.NOT_EQUAL, new BinaryComparator(Bytes.toBytes(0))));` Any row which contained a column whose value was 0 will be filtered out (since ValueFilter will not pass that Cell). Without this filter, the other non-zero valued columns in the row would still be emitted.
`TimestampsFilter`	Filter that returns only cells whose timestamp (version) is in the specified list of timestamps (versions). Note: Use of this filter overrides any time range/time stamp options specified using `Get.setTimeRange(long, long)`, `Scan.setTimeRange(long, long)`, or `Scan.setTimeStamp(long)`. See the Apache HBase API, Client package for detailed information.

last-updated: Nov 14, 2024

Filter	Description
`ValueFilter`	This filter is used to filter based on column value. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the cell value. This filter can be wrapped with `WhileMatchFilter` and `SkipFilter` to add more control. Multiple filters can be combined using `FilterList`. To test the value of a single qualifier when scanning multiple qualifiers, use `SingleColumnValueFilter`.
`WhileMatchFilter`	A wrapper filter that returns true from `filterAllRemaining()` as soon as the wrapped filters `Filter.filterRowKey(byte[], int, int)`, `Filter.filterKeyValue(org.apache.hadoop.hbase.Cell)`, `Filter.filterRow()` or `Filter.filterAllRemaining()` methods returns true.

HBase Java Regular Expressions Support

This topics defines the subset of Java regular expressions that are supported for HPE Ezmeral Data Fabric Database tables.

Filters used with Scan operations support regular expressions. When you filter scans on HPE Ezmeral Data Fabric Database tables, you can use regular expressions that comprise the Perl-Compatible Regular Expressions library, as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`.

Characters

Pattern	Description
x	The character x
\\	The backslash character
\0n	The character with octal value 0n (0 <= n <= 7)
\0nn	The character with octal value 0nn (0 <= n <= 7)
\xhh	The character with hexadecimal value 0xhh
\t	The tab character ('\u0009')
\n	The newline (line feed) character ('\u000A')
\r	The carriage-return character ('\u000D')
\f	The form-feed character ('\u000C')
\a	The alert (bell) character ('\u0007')
\e	The escape character ('\u001B')
\cx	The control character corresponding to x

last-updated: Nov 14, 2024

Character Classes

Pattern	Description
[abc]	a, b, or c (simple class)
[Supported Regular Expressions in HPE Ezmeral Data Fabric Database Tables^abc]	Any character except a, b, or c (negation)
[a-zA-Z]	a through z or A through Z, inclusive (range)

Predefined Character Classes

Pattern	Description
.	Any character (may or may not match line terminators)
\d	A digit: [0-9]
\D	A non-digit: [Supported Regular Expressions in HPE Ezmeral Data Fabric Database Tables^0-9]
\s	A whitespace character: [\t\n\x0B\f\r]
\S	A non-whitespace character: [Supported Regular Expressions in HPE Ezmeral Data Fabric Database Tables^\s]
\w	A word character: [a-zA-Z_0-9]
\W	A non-word character: [Supported Regular Expressions in HPE Ezmeral Data Fabric Database Tables^\w]

Classes for Unicode Blocks and Categories

Pattern	Description
\p{Lu}	An uppercase letter (simple category)
\p{Sc}	A currency symbol

Boundaries

Pattern	Description
^	The beginning of a line
$	The end of a line
\b	A word boundary
\B	A non-word boundary
\A	The beginning of the input
\G	The end of the previous match

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Pattern	Description
\Z	The end of the input but for the final terminator, if any
\z	The end of the input

Greedy Quantifiers

Pattern	Description
X?	X, once or not at all
X*	X, zero or more times
X+	X, one or more times
X{n}	X, exactly n times
X{n,}	X, at least n times
X{n,m}	X, at least n but not more than m times

Reluctant Quantifiers

Pattern	Description
X??	X, once or not at all
X*?	X, zero or more times
X+?	X, one or more times
X{n}?	X, exactly n times
X{n,}?	X, at least n times
X{n,m}?	X, at least n but not more than m times

Possessive Quantifiers

Pattern	Description
X?+	X, once or not at all
X*+	X, zero or more times
X++	X, one or more times
X{n}+	X, exactly n times
X{n,}+	X, at least n times
X{n,m}+	X, at least n but not more than m times

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Logical Operators

Pattern	Description
XY	X followed by Y
X|Y	Either X or Y
(X)	X, as a capturing group

Back References

Pattern	Description
\n	Whatever the nth capturing group matches

Quotation

Pattern	Description
\	Nothing, but quotes the following character
\Q	Nothing, but quotes all characters until \E
\E	Nothing, but ends quoting started by \Q

Special Constructs

Pattern	Description
(?:X)	X, as a non-capturing group
(?=X)	X, via zero-width positive lookahead
(?!X)	X, via zero-width negative lookahead
(?<=X)	X, via zero-width positive lookbehind
(?<!X)	X, via zero-width negative lookbehind
(?>X)	X, as an independent, non-capturing group

HBase Java Comparators Support

HPE Ezmeral Data Fabric Database supports the following Java filters, which work identically to their Apache HBase versions. See the Apache HBase API for more information, specifically, the Apache HBase Filter package.

Comparator	Description
`>BinaryComparator`	A binary comparator which lexicographically compares against the specified byte array using `Bytes.compareTo(byte[], byte[])`.
`BinaryPrefixComparator`	A comparator which compares against a specified byte array, but only compares up to the length of this byte array. For the rest it is similar to BinaryComparator.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Comparator	Description
`BitComparator`	A bit comparator which performs the specified bitwise operation on each of the bytes with the specified byte array. Then returns whether the result is non-zero.
`NullComparator`	A binary comparator which lexicographically compares against the specified byte array using `Bytes.compareTo(byte[], byte[])`.
`RegexStringComparator`	This comparator is for use with `CompareFilter` implementations, such as `RowFilter` , `QualifierFilter` , and `ValueFilter` , for filtering based on the value of a given column. Use it to test if a given regular expression matches a cell value in the column. Only EQUAL or NOT_EQUAL comparisons are valid with this comparator. For example: `ValueFilter vf = new ValueFilter(CompareOp.EQUAL, new RegexStringComparator(// v4 IP address "(((25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?)\\.){3,3}" + "(25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?))(\\/[0-9]+)?" + "|" + // v6 IP address "((([\\dA-Fa-f]{1,4}:){7}[\\dA-Fa-f]{1,4})(:([\\d]{1,3}.)" + "{3}[\\d]{1,3})?)(\\/[0-9]+)?"));`
`SubstringComparator`	This comparator is for use with SingleColumnValueFilter, for filtering based on the value of a given column. Use it to test if a given substring appears in a cell value in the column. The comparison is case insensitive. Only EQUAL or NOT_EQUAL tests are valid with this comparator. For example: `SingleColumnValueFilter scvf = new SingleColumnValueFilter("col", CompareOp.EQUAL, new SubstringComparator("substr"));`

Unsupported HBase Java Methods

This topic identifies the HBase Java methods that are not supported for HPE Ezmeral Data Fabric Database tables. Attempts to call any of these methods results in an `UnsupportedOperationException` exception.

Methods for ACLs for cells:

- `Put.setACL(String user, org.apache.hadoop.hbase.security.access.Permission perms)`

©Copyright 2024 Hewlett Packard Enterprise Development LP

- `Append.setACL(Map<String,org.apache.hadoop.hbase.security.access.Permission> perms)`
- `Delete.setACL(Map<String,org.apache.hadoop.hbase.security.access.Permission> perms)`
- `Increment.setACL(Map<String,org.apache.hadoop.hbase.security.access.Permission> perms)`

Methods for cell visibility:

- `Put.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Append.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Delete.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Increment.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`

Methods for time-to-live for cell values:

- `Put.setTTL(long ttl)`
- `Append.setTTL(long ttl)`
- `Delete.setTTL(long ttl)`
- `Increment.setTTL(long ttl)`

Other methods

- `Delete.deleteFamilyVersion(byte[] family, long timestamp)`
- `Scan.setReversed(boolean reversed)`
- `Scan.setBatch()`
- `Scan.setCaching()`
- `Scanner.next(int nbRows)`

Impersonation through the HBase REST Gateway
Impersonation enables access to tables via user IDs other than the user that runs the Gateway.

You can enable user impersonation to access HPE Ezmeral Data Fabric Database tables via the HBase REST Gateway. This feature is not supported in earlier combinations of Data Fabric and HBase packages.

Impersonation is only supported if the REST Gateway is running as the mapr user (MAPR_USER).

You can enable impersonation via the Gateway on both non-secure and secure Data Fabric clusters (secured using either MapR SASL or Kerberos). HPE Ezmeral Data Fabric Database does not support gateway impersonation using a Thrift interface.

NOTE: Impersonation for HBase REST Gateway is enabled by default on secure clusters.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Enabling Impersonation on a Non-Secure Cluster

About this task
To enable impersonation on a non-secure cluster, follow these steps:

Procedure

1. Install the `mapr-hbase` package on a cluster that is running version 4.0.2 or later. This package contains all of the HBase binaries. For installation details, see HBase Client and HPE Ezmeral Data Fabric Database.
2. Enable simple authentication via the REST Gateway by appending the following property to the `hbase-site.xml` file (`/opt/mapr/hbase/hbase<hbase_version>/conf/hbase-site.xml`): The simple authentication protocol is a Hadoop pseudo authenticator that serves as an example and is part of the hadoop-common package.

   ```
   <property>
   <name>hbase.rest.authentication.type</name>
   <value>simple</value>
   </property>
   ```

3. Set the following environment variable to enable impersonation:

   ```
   export MAPR_IMPERSONATION_ENABLED=1
   ```

4. Start the REST Gateway server as the MAPR_USER.

   ```
   /opt/mapr/hbase/hbase<hbase_version>/bin/hbase-daemon.sh start rest -p
   port
   ```

Using Custom Authentication
This section describes how to use Hadoop pseudo authentication for custom authentication.

About this task
Editing the `hbase-site.xml` file is the procedure to follow if you want to use Hadoop pseudo authentication. Alternatively, you can write and use your own authenticator to substitute for the "simple" configuration by implementing the Hadoop AuthenticationHandler interface. If you are using custom authentication, place your authenticator jar in the following directory:

```
/opt/mapr/hbase/hbase-<hbase_version>/lib/
```

Then start the REST Gateway.

Mapping to HBase Table Namespaces
This section describes mapping table namespaces between Apache HBase tables and HPE Ezmeral Data Fabric Database binary tables.

The HPE Ezmeral Data Fabric implementations of the HBase Java API and libhbase differentiate between Apache HBase tables and HPE Ezmeral Data Fabric Database tables according to table names. In certain cases, such as migrating code from Apache HBase tables to HPE Ezmeral Data Fabric Database tables, users need to force the API they are using to access a HPE Ezmeral Data Fabric Database table, even though the table name could map to an Apache HBase table. The `hbase.table.namespace.mappings` property allows you to map Apache HBase table names to HPE Ezmeral Data Fabric Database tables. This property is typically set in the configuration file `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

In general, if a table name includes a slash (`/`), the name is assumed to be a path to a HPE Ezmeral Data Fabric Database table, because slash is not a valid character for Apache HBase table names. In the case of "flat" table names without a slash, namespace conflict is possible, and you might need to use table mappings.

Table Mapping Naming Conventions

A table mapping takes the form *`name`*`:`*`map`*, where *`name`* is the table name to redirect and *`map`* is the modification made to the name. The value in *`name`* can be a literal string or contain the `*` wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

Mappings and Table Listing Behaviors

When you use the `list` command without specifying a directory, the command's behavior depends on two factors:

- Whether a table mapping exists
- Whether Apache HBase is installed and running

Here are three different scenarios and the resulting `list` command behavior for each.

- There is a table mapping for *, as in `*:/tables`. In this case, the `list` command lists the tables in the mapped directory.
- There is no mapping for *, and Apache HBase is installed and running. In this case, the `list` command lists the HBase tables.
- There is no mapping for *, and Apache HBase is not installed or is not running.
  - For HBase 0.98.12, the shell will try to connect to an HBase cluster but it will return an error instead.
  - For HBase 1.1 or above, if the `mapr.hbase.default.db` property in the hbase-site.xml is set to `hbase`, the list command will return an error stating that HBase is not available. If the `mapr.hbase.default.db` property is set to `maprdb`, list command will list the HPE Ezmeral Data Fabric Database tables under the user's home directory.

Example 1: Map all HBase tables to HPE Ezmeral Data Fabric Database tables in a directory

In this example, any flat table name `foo` is treated as a HPE Ezmeral Data Fabric Database table in the directory `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>*:/tables_dir</value>
        </property>
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Example 2: Map specific Apache HBase tables to specific HPE Ezmeral Data Fabric Database tables

In this example, the Apache HBase table name `mytable1` is treated as a HPE Ezmeral Data Fabric Database table at `/user/aaa/mytable1`. The Apache Hbase table name `mytable2` is treated as a HPE Ezmeral Data Fabric Database table at `/user/bbb/mytable2`. All other Apache HBase table names are treated as stock Apache HBase tables.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/</value>
        </property>
```

Example 3: Combination of specific table names and wildcards

Mappings are evaluated in order. In this example, the flat table name `mytable1` is treated as a HPE Ezmeral Data Fabric Database table at `/user/aaa/mytable1`. The flat table name `mytable2` is treated as a HPE Ezmeral Data Fabric Database table at `/user/bbb/mytable2`. Any other flat table name `foo` is treated as a HPE Ezmeral Data Fabric Database table at `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/,*:/tables_dir</value>
        </property>
```

Thread-pool Settings for Performance

The HPE Ezmeral Data Fabric Database C APIs internally have one thread pool per client. Threads work on the async tasks enqueued by a client application. There are two thread-pool parameters that you can modify in the `/opt/mapr/conf/dbclient.conf` file for better application performance.

fs.mapr.pool.threads

This parameter controls the number of connections that a client application makes with HPE Ezmeral Data Fabric Database for append, increment, read, and scan requests. For a higher rate of throughput to HPE Ezmeral Data Fabric Database, you can increase this value. The default value is 10.

fs.mapr.highpri.pool.threads

This parameter controls the number of threads that invoke application-provided callbacks. If an application's callbacks are not lightweight but instead perform complex calculations that require significant processing, increase this value to avoid delays in invoking callbacks. The default value is 2.

Building MapReduce Applications

This section provides information about building and running custom MapReduce application that access HPE Ezmeral Data Fabric Database binary tables.

The steps for building and running custom MapReduce applications that run against HPE Ezmeral Data Fabric Database are the same as the steps for building and running custom MapReduce applications that run against Apache HBase. The steps are documented in the Apache HBase Reference Guide at http://hbase.apache.org/book.html#mapreduce.

However, you must use an HBase JAR file from MapR's Maven repository at https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/hbase/hbase-server/. The name of the JAR file that you use must contain the version of HBase and the version of MapR that you are using.

For example, if you are using HBase 1.1 and MapR version 5.1, you would use the file `hbase-server-1.1.1-mapr-1602.jar`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Performing Bulkloads with MapReduce

This section describes custom MapReduce applications used to perform bulkloads for HPE Ezmeral Data Fabric Database binary tables.

You can use the `HFileOutputFormat configureIncrementalLoad()` method for writing custom MapReduce applications to perform bulk loads. Although the name of the method implies that you can use it only for incremental bulk loads, the method also works for full bulk loads, provided that the `-bulkload`, `BULKLOAD`, or `Bulkload` parameter for a table is set to true, as described in Bulk Loading and HPE Ezmeral Data Fabric Database Tables.

If you have a custom MapReduce applications that does not use `HFileOutputFormat.configureIncrementalLoad()`, simply use the path to the HPE Ezmeral Data Fabric Database table that you want to load. Using `HFileOutputFormat.configureIncrementalLoad()` provides at least two advantages:

This method performs a number of tasks that your application would otherwise need to do explicitly:

1. Inspects the table to configure a total order partitioner
2. Uploads the partitions file to the cluster and adds it to the DistributedCache
3. Sets the number of reduce tasks to match the current number of regions
4. Sets the output key/value class to match `HFileOutputFormat`'s requirements
5. Sets the reducer up to perform the appropriate sorting (either `KeyValueSortReducer` or `PutSortReducer`)

This method turns off Speculative Execution automatically. For details, see the note below.

WARNING: Turning off Speculative Execution

Speculative Execution of MapReduce tasks is on by default. For custom applications that load HPE Ezmeral Data Fabric Database binary tables, it is recommended to turn Speculative Execution off. When it is on, the tasks that import data might run multiple times. Multiple tasks for an incremental bulkload could insert one or more versions of a record into a table. Multiple tasks for a full bulkload could cause loss of data if the source data continues to be updated during the load.

If your custom MapReduce application uses `HFileOutputFormat.configureIncrementalLoad()`, you do not have to turn off Speculative Execution manually. `HFileOutputFormat.configureIncrementalLoad()` turns it off automatically. Speculative Execution is automatically turned off for MapReduce utilities such as `CopyTable` and `ImportTsv`.

If you are writing a custom MapReduce application that does not use the `HFileOutputFormat configureIncrementalLoad()` method for bulk loading, you must turn off Speculative Execution manually.

Turn off Speculative Execution by setting the following MapReduce version 2 parameter to false: `mapreduce.map.speculative`

If the job is programmatically written, you can turn off Speculative Execution at the code level: `job.setSpeculativeExecution(false);`

Setting for OJAI Applications to Use Data Fabric Client Features

Describes how to set the classpath for OJAI applications to use data-fabric client features.

When you launch an OJAI application that needs to submit MapReduce or YARN applications, or to run `hadoop fs` or `hadoop mfs` commands, ensure that you prefix the classpath with `/opt/mapr/conf:/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop`. Alternatively, copy the `core-site.xml` file to the `/src/main/resources/` folder.

Developing Applications for JSON Tables

As part of its support for JSON tables, HPE Ezmeral Data Fabric Database implements the OJAI API. The OJAI API provides methods for creating, reading, updating, and deleting JSON documents in HPE Ezmeral Data Fabric Database JSON tables. It is available in Java, and starting in EEP 6.0, also available in Node.js, Python, C#, and Go. HPE Ezmeral Data Fabric Database also provides a HPE Ezmeral Data Fabric Database JSON Client API for managing JSON tables and a HPE Ezmeral Data Fabric Database JSON REST API for performing basic operations using HTTP calls.

The following shows the general flow for developing an OJAI client application that accesses HPE Ezmeral Data Fabric Database JSON tables:

1. Make a connection to HPE Ezmeral Data Fabric Database using the OJAI Connection and Driver interfaces.
2. Request a HPE Ezmeral Data Fabric Database JSON table using the JSON DocumentStore.
3. Specify the table, document, or column family operation.
4. Perform the operation on the table.
5. Return the results.

For additional information about OJAI, refer to the following:

- OJAI wiki page
- OJAI github repository - The README file provides an introduction to OJAI

The HPE Ezmeral Data Fabric Database JSON Client API, implemented in Java, enables you to create, drop, and alter HPE Ezmeral Data Fabric Database JSON tables and column families.

You can also use HTTP calls to create, delete, and query HPE Ezmeral Data Fabric Database JSON tables Using the HPE Ezmeral Data Fabric Database JSON REST API on page 3513.

API Documentation

The following are links to the detailed API pages:

- Java OJAI Client API
- Node.js OJAI Client API
- Python OJAI Client API
- C# OJAI Client API
- Go OJAI Client API
- HPE Ezmeral Data Fabric Database JSON Client API

NOTE: Beginning with MapR version 6.0, the HPE Ezmeral Data Fabric Database `Table` interface in the HPE Ezmeral Data Fabric Database JSON Client API is deprecated and replaced by the `DocumentStore` interface in the OJAI API.

Managing JSON Tables

This section describes how to create, list, and delete JSON tables, alter JSON table attributes, set permissions, and manage column families. You can perform these operations using either the HPE Ezmeral Data Fabric Database JSON Client API library or HPE Ezmeral Data Fabric Database Shell commands.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

HPE Ezmeral Data Fabric Database JSON Client API

The HPE Ezmeral Data Fabric Database JSON Client API is a Java library. There is not a Python implementation of the library, but you can create and drop HPE Ezmeral Data Fabric Database JSON tables in the Python OJAI client.

Admin API

Use the methods in this interface to perform these tasks:

- Create JSON tables
- Alter JSON tables
- Delete JSON tables
- List JSON tables in a folder
- See if a JSON table exists

For a full list of methods, see the Admin interface

TableDescriptor API

Use the methods in this interface to perform these tasks:

- Create tables with non-default values for one or more of their parameters
- Alter tables

For a full list of interfaces and methods, see the TableDescriptor interface.

HPE Ezmeral Data Fabric Database Shell

The mapr dbshell is a tool for the creation and lightweight manipulation of JSON tables and documents. To run dbshell, enter `mapr dbshell` on the command line after logging into a node in a cluster. See HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5728 for more information.

Creating JSON Tables

This topic describes how to create HPE Ezmeral Data Fabric Database JSON tables using either programmatic APIs or dbshell.

NOTE: Before creating a table, you typically create a directory and Data Fabric volume. This is not required; however, it is a good practice. For example, assuming both the directory and volume names are `sample`, the command would be:

```
// Create directories with hadoop
hadoop fs -mkdir /sample

// Create a Data Fabric volume using maprcli create volume
maprcli volume create -name sample -path /sample -type rw
```

Java

The following Java code examples show you how to create a table in the following ways:

- By using the default values for the table attributes,
- By setting specific values for the table attributes.

See the Admin and TableDescriptor APIs for more information.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

The following example shows how to create a table by calling an `Admin` object's `createTable()` `method` and passing, as an argument, the path that you want to use for the new table:

```
public void createJSONTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tablePath);
         }
    }
}
```

Tables created with this version of the `createTable()` method use the default values for their attributes.

Alternatively, the following example how to create a table by passing a `TableDescriptor` object as an argument to the `createTable() method`:

```
/* Create a TableDescriptor for the table to create,
 * passing in the path of the table.
 */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Pass the TableDescriptor object and the path to the table
 * to the Admin.createTable() method.
 */
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tableDescriptor);
        }
    }
}
```

This alternative allows you to set values for some of the table's attributes.

Node.js

To create a table in the Node.js OJAI client, call the `Connection.createStore()` method:

```
connection.createStore(table_path)
    .then((store) => {
        // Process result
        ...
    });
```

The method returns a `DocumentStore` object.

Python

To create a table in the Python OJAI client, call the `Connection.create_store()` method:

```
store = connection.create_store(store_path=table_path)
```

The method returns a `DocumentStore` object.

©Copyright 2024 Hewlett Packard Enterprise Development LP

dbshell

The following **dbshell** command shows code syntax for creating a table:

```
# mapr dbshell
maprdb root:> create /<tablePath>/<tableName>
```

C#

To create a table in the C# OJAI client, call the `connection.CreateStore(string storePath)` method:

```
var store = connection.CreateStore(string storePath);
```

The method returns a `DocumentStore` object.

Go

To create a table in the Go OJAI client, call the `connection.CreateStore()` function:

```
store, error := connection.CreateStore("/store_path")
```

The function returns a new `DocumentStore` and an error.

Listing JSON Tables

This topic describes how to list the JSON tables by using either the HPE Ezmeral Data Fabric Database JSON Client API or HPE Ezmeral Data Fabric Database Shell.

Permission Required

The `readAce` permission on the volumes where the JSON tables are located. Setting Whole Volume ACEs on page 1346

Java

The table is listed by calling HPE Ezmeral Data Fabric Database JSON Client API `Admin` object's `listTables()` method and passing, as an argument, the path of the folder.

Use a conditional loop to iterate through the returned list and retrieve the names of the tables.

```
public void listTables(String parentFolder) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        for(Path tablePath : admin.listTables(parentFolder)) {
            System.out.println(tablePath);
        }
    }
}
```

NOTE: The parameter `parentFolder` provides a path to a folder that is in the filesystem. See "**Table Paths**" in HPE Ezmeral Data Fabric Database JSON Tables for examples.

dbshell

```
# mapr dbshell
maprdb root:> list /demo
/demo/user
/demo/checkin
/demo/review
/demo/business
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
/demo/tip
5 table(s) found.
```

See dbshell list on page 5746 for further details.

Altering JSON Table Attributes
This topic describes how to change the values of table attributes by using the HPE Ezmeral Data Fabric Database JSON Client API.

In this example, the code turns off the `bulkload` flag on the table. Applications will typically need to turn off this flag after a bulk load of the table with the `import`, `importJSON`, or `copytable` utility.

Create a `TableDescriptor` object for an existing table by passing the path of the table to the `Admin` interface's `getTableDescriptor()` method.

Permissions Required

The `readAce` and `writeAce` permissions on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1346.

Example

Tables are altered a by using the `TableDescriptor` object and then passing that object to the `Admin` interface's `altertable()` method.

```
public void alterTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        TableDescriptor tableDesc = admin.getTableDescriptor(tablePath);
        // set bulk load to false
        tableDesc.setBulkLoad(false);
        admin.alterTable(tableDesc);
    }
}
```

Deleting JSON Tables
This topic describes how to delete HPE Ezmeral Data Fabric Database JSON tables using either programmatic APIs or dbshell.

Java

To delete a table in the Java OJAI client, call an `Admin` object's `deleteTable()` method and pass, as an argument, the path of the table to delete:

```
public void deleteTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (admin.tableExists(tablePath)) {
            admin.deleteTable(tablePath);
        }
    }
}
```

Node.js

To delete a table in the Node.js OJAI client, call the `Connection.deleteStore()` method:

```
connection.deleteStore(table_path)
    then((deleteResponse) => {
        // Process deleteReponse
        ...
    });
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Python

To delete a table in the Python OJAI client, call the `Connection.delete_store()` method:

```
rc = connection.delete_store(store_path=table_path)
```

dbshell

```
# mapr dbshell
maprdb root:> drop <table path>
```

See dbshell drop on page 5732 for additional details.

C#

To delete a table in the C# OJAI client, call the `connection.DeleteStore(string storePath)` method:

```
connection.DeleteStore(string storePath);
```

Go

To delete a table in the Go OJAI client, call the `connection.DeleteStore()` function:

```
err := connection.DeleteStore("/store_path")
```

Permissions Required

You must have both the `readAce` and `writeAce` permissions on the volumes where the JSON tables are located to delete it. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1346.

Permission Types for Fields and Column Families in JSON Tables
By using ACEs, you can grant or deny access to fields and column families that are in JSON tables.

There are three types of permission:

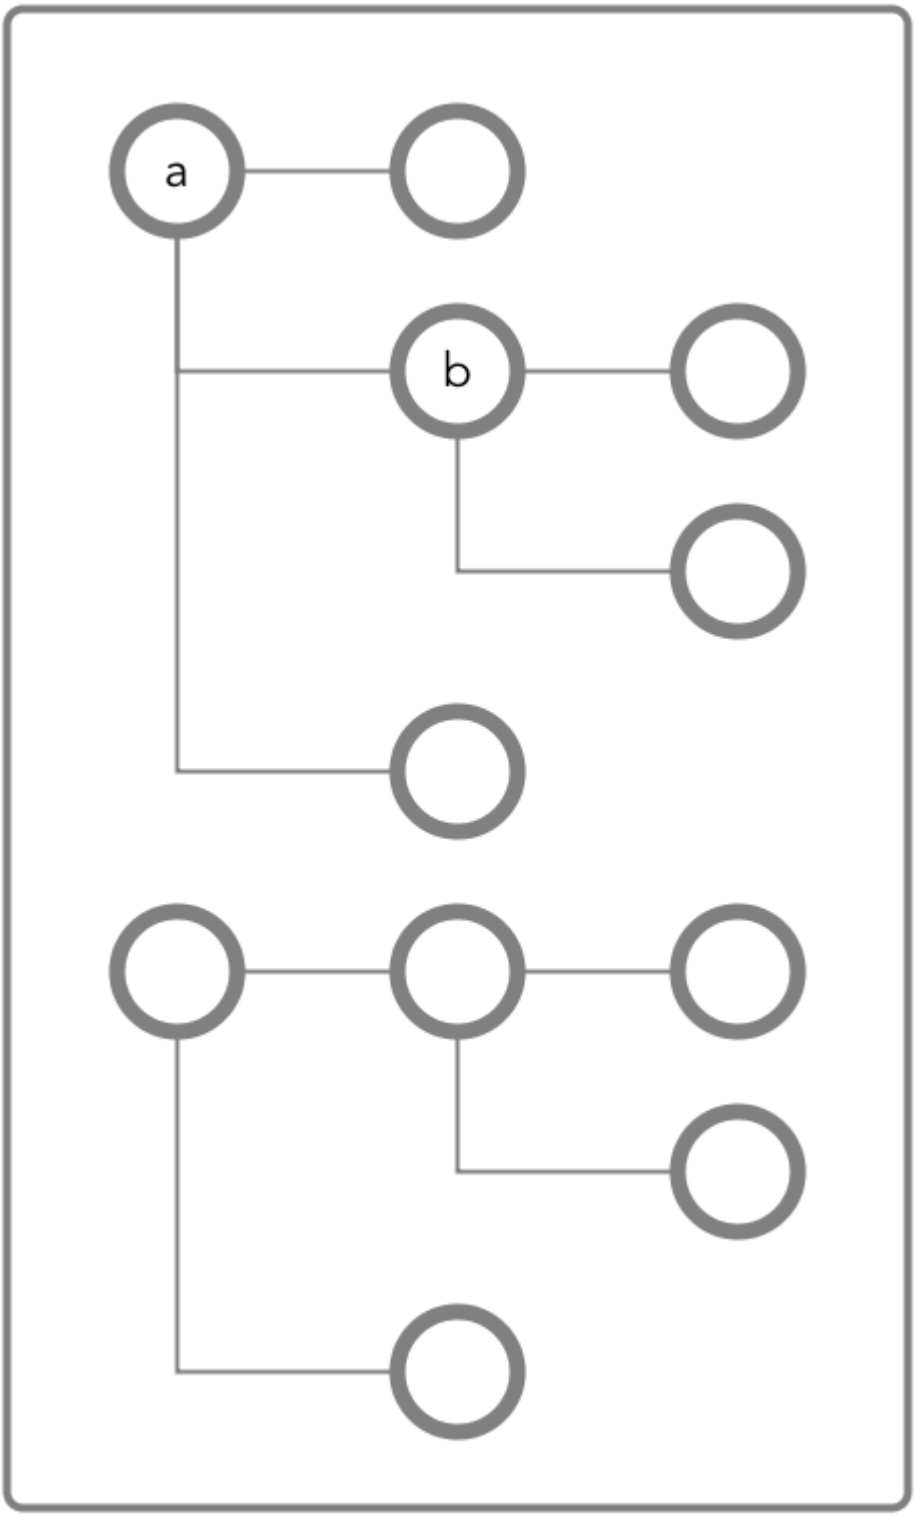
- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access fields on which the grantee has write or read permission.

For example, suppose that a user has read and write access to only field b below.

©Copyright 2024 Hewlett Packard Enterprise Development LP



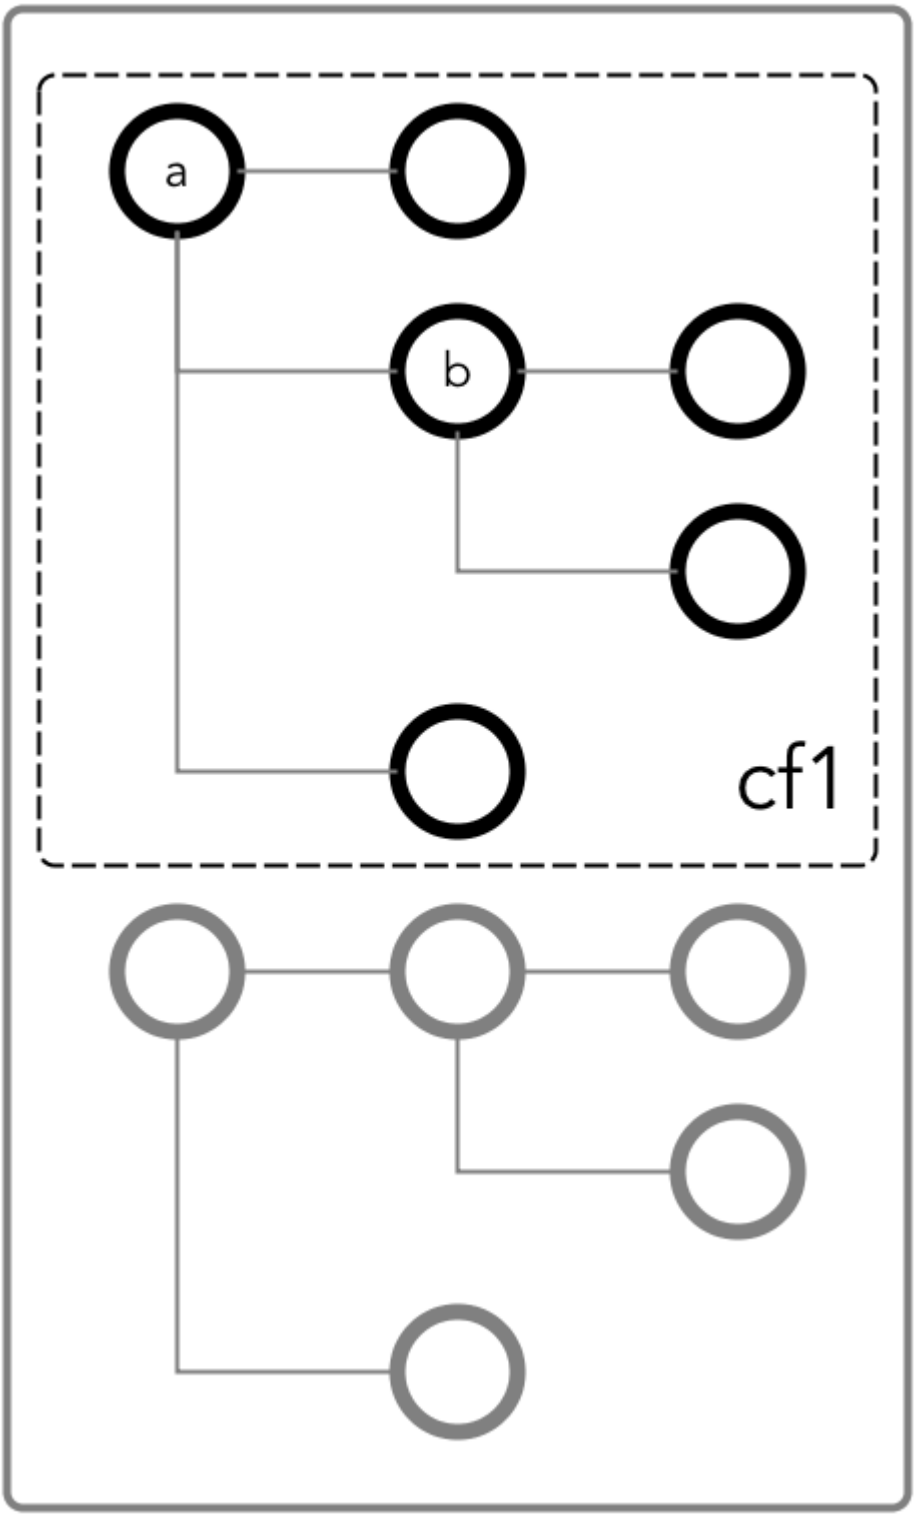
To access field b, the user would need to be able to traverse (pass through) field a. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If a user was denied traverse permission on the default column family, the user would not be able to access field b. Granting traverse permission on field a in this case would have no effect.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

In the example below, field a is part of the `cf1` column family.



To be able to read and write at field b, the user could be granted the traverse permission on the column family.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Read (`readperm`)

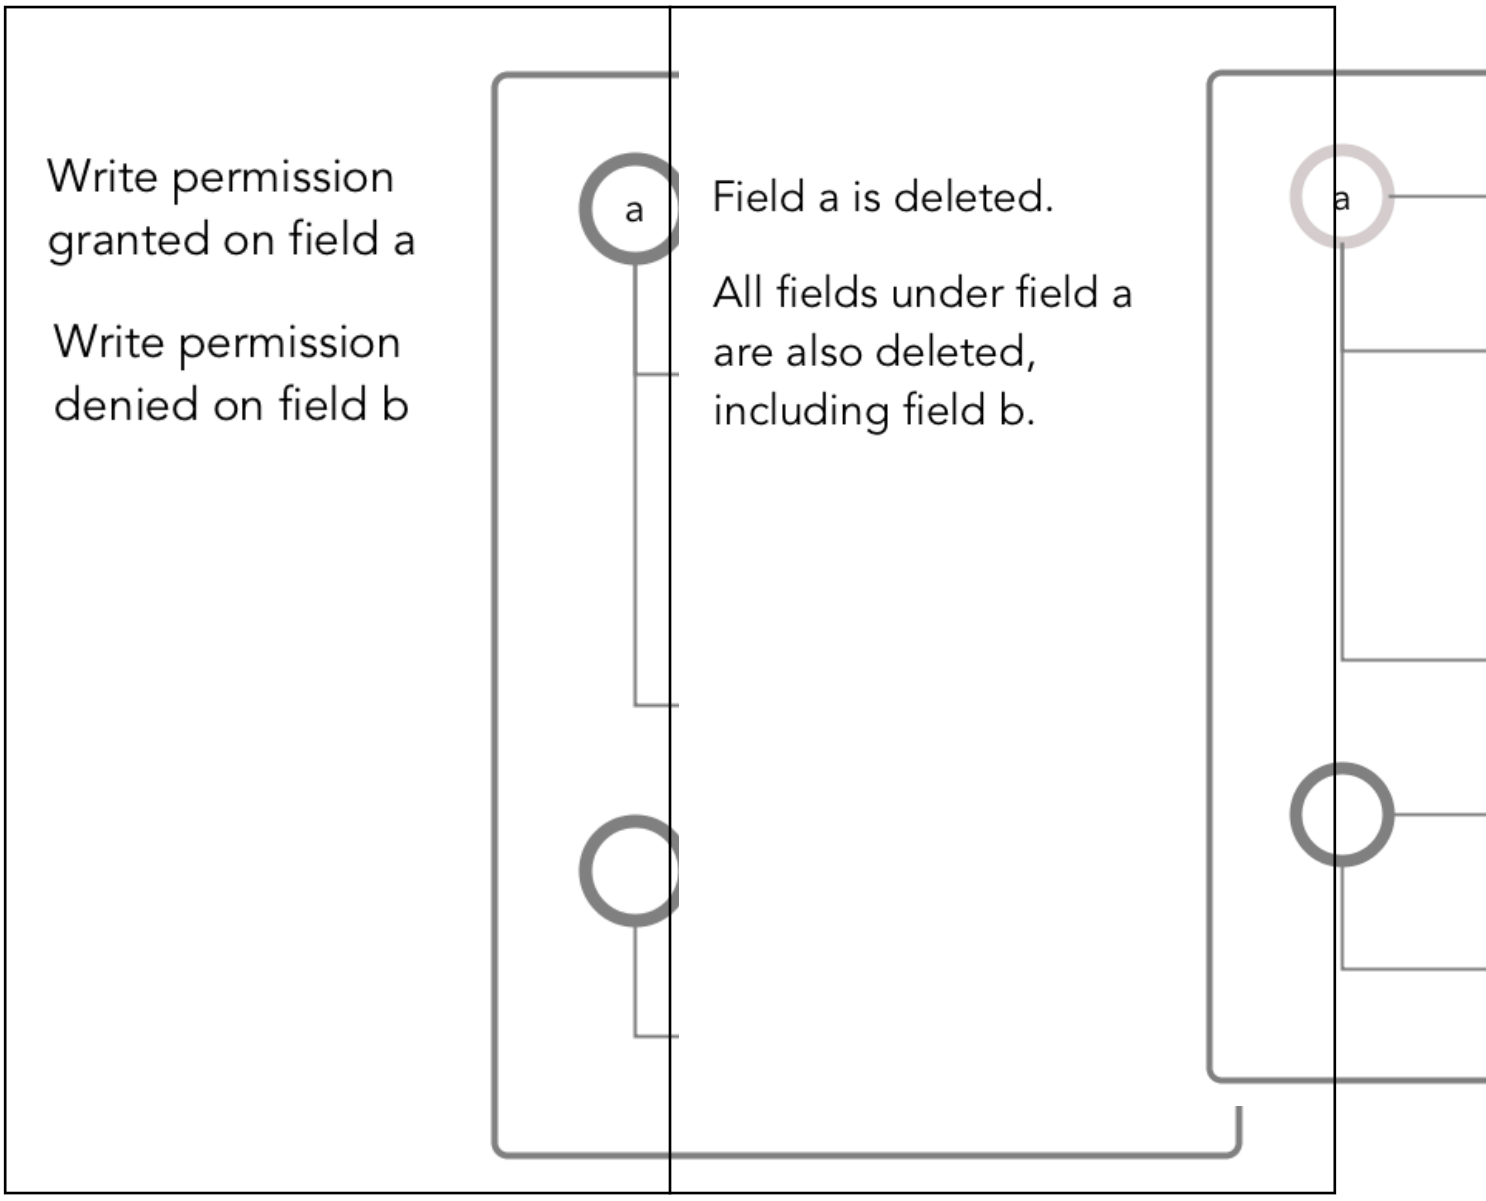
The read permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field on which the permission was granted. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (`writeperm`)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite field value.

As illustrated in the two diagrams below, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.



Obtaining `readperm` and `writeperm` on Fields
In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

If the field is in the default column family

In the document below, you want to perform an operation on field c, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field c.

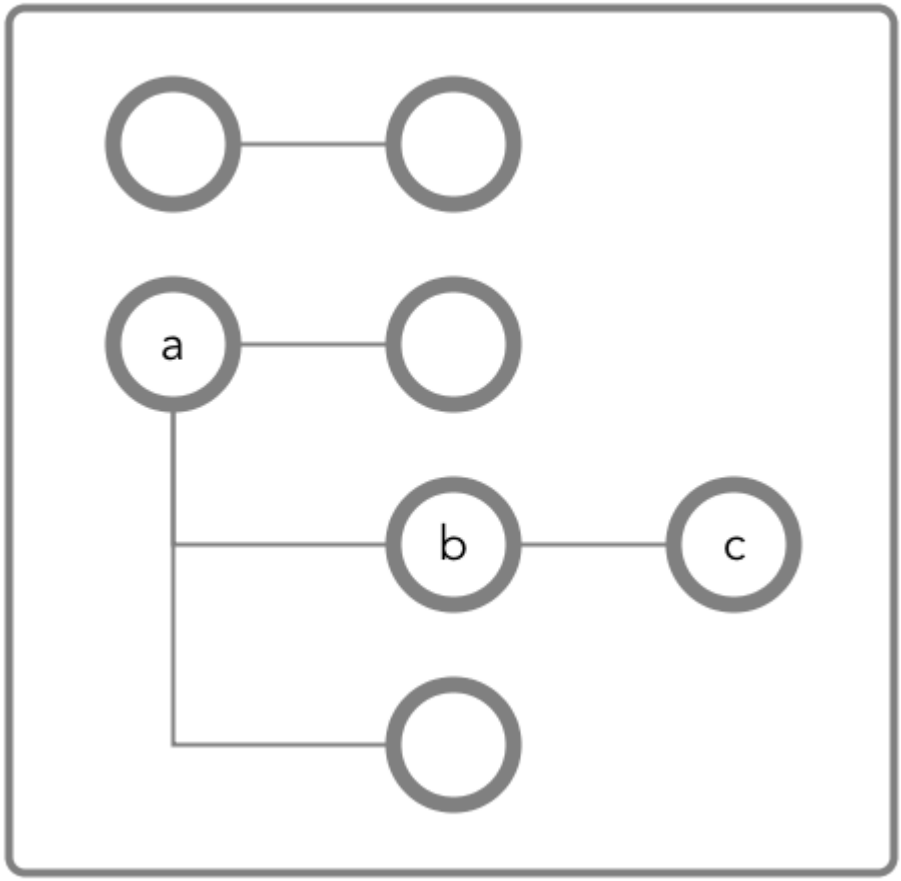


Figure 28: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field c inherits these permissions, assuming that the permissions were not denied on field a or b.

If you do not have `readperm` and `writeperm` on field a or b, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field c. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```
maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have `readperm` and `writeperm` on the default column family

In this case, you need the `traverseperm` permission on the default column family. Fields a and b inherit this permission. You also need `readperm` and `writeperm` on field `c`.

You could be granted these permissions with commands similar to these:

```
maprcli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see Column Families in JSON table.

In the following document, you want to perform an operation on field `c`, which is in the column family `cf1` that is defined at field b with the path `a.b`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

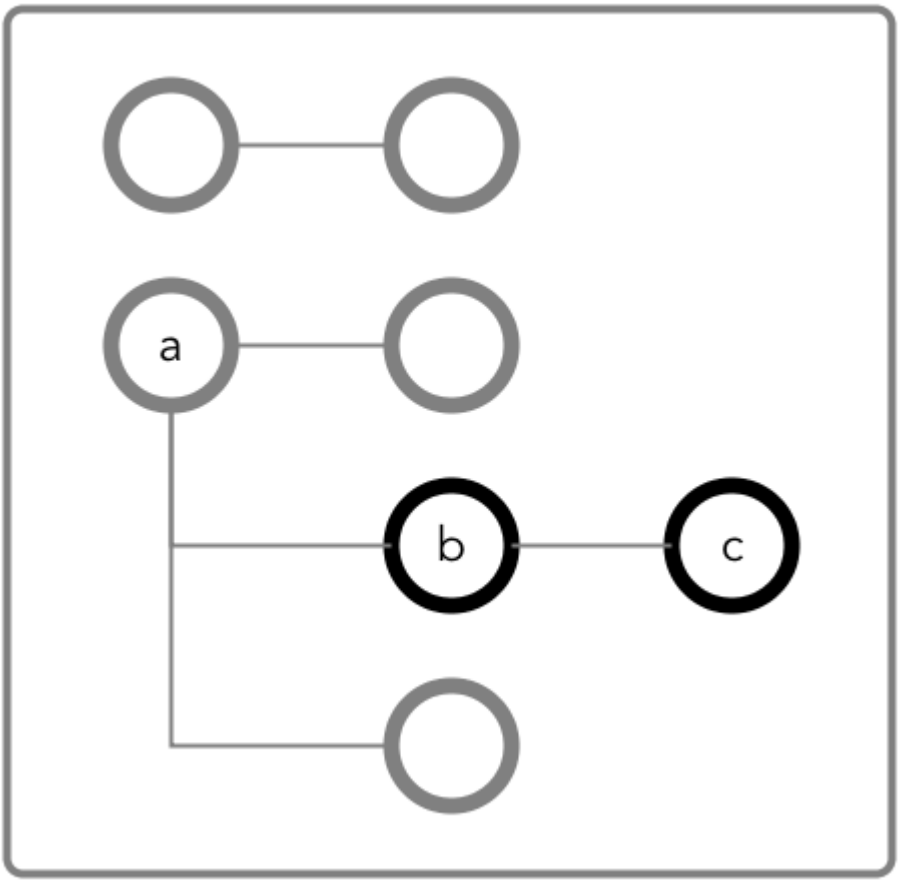

Figure 29: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have `readperm` and `writeperm` on field `b`	You need `traverseperm` on field b and both `readperm` and `writeperm` on field c. You can be granted these permissions with commands similar to these:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field> -writeperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have `readperm` and `writeperm` on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Obtaining `readperm` or `writeperm` on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm or writeperm permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

If the field is in the default column family

In the following document, you want to perform an operation on field `c,` which is in the default column family. The operation requires you to have `readperm` or `writeperm` on field `c`.

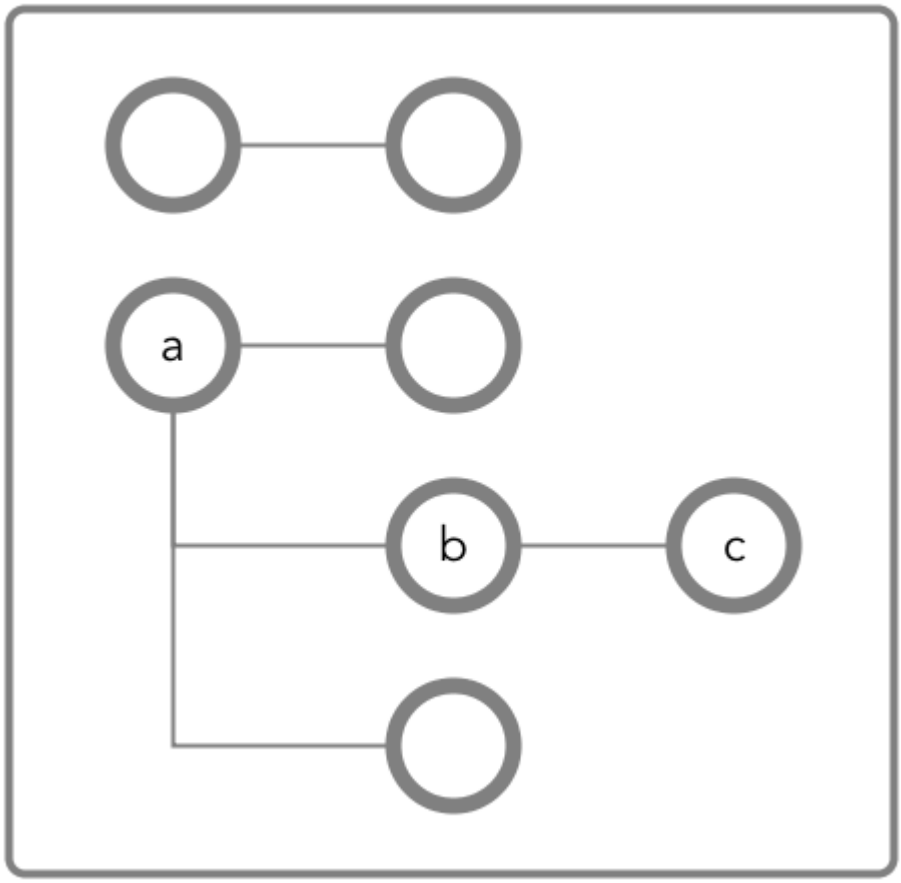

Figure 30: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (`readperm` or `writeperm`) on the default column family	In this case, field `c` inherits the permission, assuming that the permission was not denied on field `a` or `b`. If you do not have `readperm` or `writeperm` on field `a` or `b`, you need `traverseperm` on the field that denied you the permission that you need. You also need `readperm` or `writeperm` explicitly granted to you on field `c`. Example commands to grant these permissions: `/opt/mapr/bin/maprcli table cf colperm set -path <path to JSON table> -cfname`

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
default -name a.b -traverseperm
u:<user ID> | <existing ACE for this
field>
```

The next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (`readperm` or `writeperm`) on the default column family

In this case, you need the `traverseperm` permission on the default column family. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see Column Families in JSON Tables.

In the following document, you want to perform an operation on field `c`, which is in the column family that is defined at field b with the path `a.b`. The operation requires you to have `readperm` or `writeperm` on field `c`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

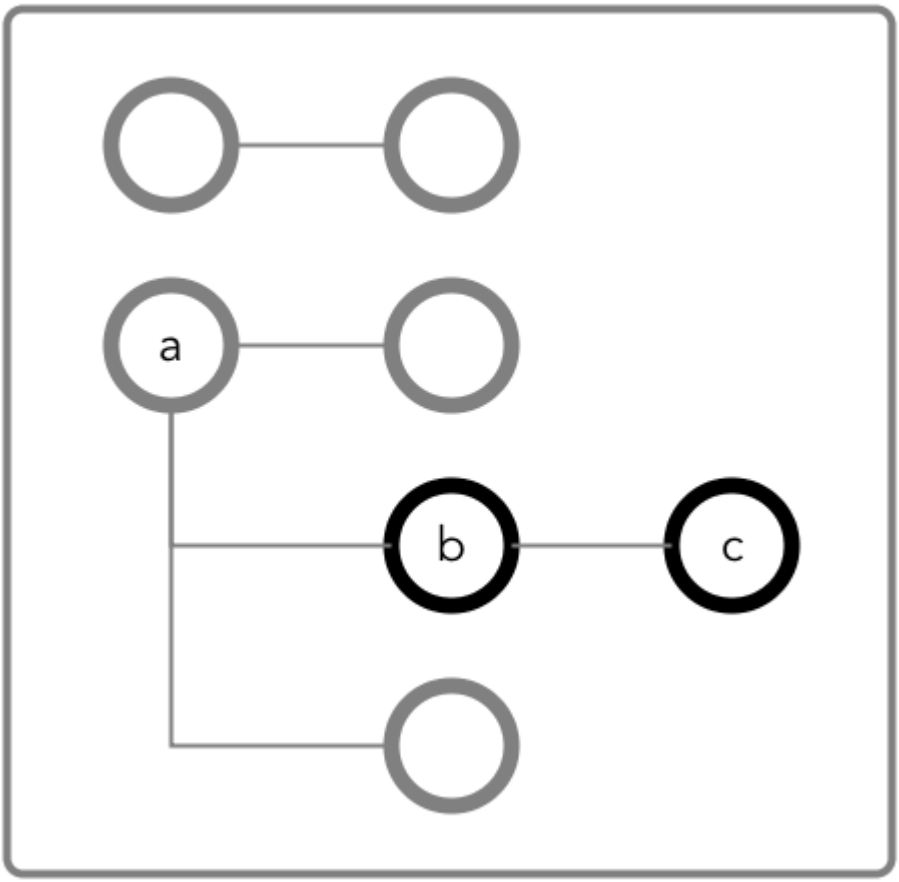

Figure 31: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have the permission you need (`readperm` or `writeperm`) on field `b`	You need `traverseperm` on field b, and you need `readperm` or `writeperm` granted to you explicitly on field c.
	Example commands to grant these permissions:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have the permission you need (`readperm` or `writeperm`) on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Setting Permissions on Arrays

If you are granting permissions on a field and the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and

©Copyright 2024 Hewlett Packard Enterprise Development LP

scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

NOTE: This topic describes the behavior of permissions in HPE Ezmeral Data Fabric Database version 6.1 and later, regardless of the data-fabric version you used to grant the permissions.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
    "_id" : "id001",
    "person" : [
        {"name" : {"last" : "Smith", "first" : "John"}},
        {"name" : {"last" : "Subramanium", "first" : "Ananya"}}
    ]
}
{
    "_id" : "id002",
    "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
    "_id" : "id003",
    "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person` to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables
Summarizes the default ACEs for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

Action	Method	Permissions	Default Access-Control Expressions
Set default permissions on new column families when creating a JSON table.	Java API	`-defaultreadperm -defaulttraverseperm -defaultwriteperm`	`u:<ID of the process>`
	`maprcli table create`		`u:<user ID of table creator>`
	mapr dbshell		
	Control System		
Set default permissions on new column families when editing a JSON table.	`maprcli table edit`		Current ACEs
	Control System		
Set permissions on a column family when creating the column family.	`maprcli table cf create`	`-readperm -traverseperm -writeperm -indexperm`	ACEs for `-defaultreadperm`, `-defaulttraverseperm`, and `-defaultwriteperm`
	Control System		
Set permissions on a column family when editing the column family.	`maprcli table cf edit`		Current ACEs
	Control System		
Set permissions on individual fields.	`maprcli table cf colperm set`		Inherited from column family or parent field
	Control System		
Set the dynamic mask	`maprcli table cf column datamask set`	`-defaultunmaskedreadperm -unmaskedreadperm`	Set to the table creator
	`maprcli table cf colperm set`		
	`maprcli table create`		
	`maprcli table edit`		
	`maprcli table cf create`		
	`maprcli table cf edit`		
	`maprcli table cf colperm set`		
	Control System

last-updated: Nov 14, 2024

Managing Column Families

JSON tables store data in column families, which are collections of fields that are stored together on disk.

Each table has a default column family, which is default storage for all fields in the documents of a table. You can create additional column families to store data for a collection of fields in a separate location on disk. Queries that operate only on data that is stored in a column family are more efficient and better performing than queries on the same data when that data is stored with other data in a table. You can also cache values from a column family in memory.

Applications do not need to be aware of the existence of column families. They perform CRUD operations by using the paths of fields in a document. For example, to update any of the fields below `a.c`, an application does not need to be aware that the field is in the column family at the path `a.c`. The application simply moves through the document along the path to the field.

For more information, see Column Families in JSON Tables on page 641.

Creating Column Families

You can create column families with the HPE Ezmeral Data Fabric Database JSON Java API library by using the `Admin.createTable(TableDescriptor tableDescriptor)` method.

Add a column family to the `TableDescriptor` object before passing that object to the `createTable()` method.

Restriction

If any existing column family in a JSON table, including the default column family, uses a time-to-live that is greater than 0, you cannot create any additional column families in that table. See Setting TTL for Data.

Permissions Required

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `createrenamefamilyperm` on the table

Example

Here is an example of using the API to create two column families -- the default column family and a custom column family -- during the creation of a table:

```
/* Create a TableDescriptor for the table to create,
   passing in the path of the table. */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Create a FamilyDescriptor for the default column family.
   When you create a table with the API, you must also create
   the default column family.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor defaultfamilyDesc = MapRDB.newDefaultFamilyDescriptor();
tableDescriptor.addFamily(defaultfamilyDesc);

/* Create a FamilyDescriptor for the custom column family
   to create. The setJsonFieldPath() method specifies the field
   at which to create the column family.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor familyDescriptor = MapRDB.newFamilyDescriptor()
  .setName("CF1")
  .setJsonFieldPath("a.b");
tableDescriptor.addFamily(familyDescriptor);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
// Pass the TableDescriptor to the Admin.createTable() method.
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
  try (Admin admin = MapRDB.newAdmin()) {
    if (!admin.tableExists(tablePath)) {
      admin.createTable(tableDescriptor);
    }
  }
}
```

Alternative Method

You can also create column families in JSON tables by running the command `table cf create`.

Altering Column Families
You can alter column families, including the default column family for a table, by using the `Admin.alterFamily()` method in the HPE Ezmeral Data Fabric Database JSON Java API library.

Permissions Required

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `createrenamefamilyperm` on the table

Example

Here is an example of using the API to change the name of a column family:

```
public void alterColumnFamily(String tablePath, String familyName,
  String newFamilyName) throws DBException {
  try (Admin admin = MapRDB.newAdmin()) {

    /* Get a TableDescriptor object for the table. This object
       gives access to the column families that are in the table. */
    TableDescriptor tableDesc = admin.getTableDescriptor(tablePath);

    /* Get a FamilyDescriptor object for the column family to
       change the name of. /
    FamilyDescriptor familyDesc = tableDesc.getFamily(familyName);

    // Rename the column family.
    familyDesc.setName(newFamilyName);

    /* Call alterFamily(), passing in the path of the table,
       the original name of the column family, and the
       FamilyDescriptor in which the new name was set. */
    admin.alterFamily(tablePath, familyName, familyDesc);
  }
}
```

Alternative Method

You can also edit column families in JSON tables by running the command `table cf edit`.

Deleting Column Families
You can delete a column family (except for the default column family) in a JSON table with the `Admin.deleteFamily()` Java method.

©Copyright 2024 Hewlett Packard Enterprise Development LP

IMPORTANT: Starting in the 6.0 release, you cannot delete a column family from a JSON table.

Permissions Required

The `readAce` and `writeAce` permissions on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1346.

Behavior

The data that is in the specified column family is deleted. If the column family is followed by one or more column families in a hierarchy, the other column families in the hierarchy are unaffected and still accessible. For example, if column family `CF1` at path `a.c` is followed by column family `CF2` at path `a.c.f`, `CF2` remains accessible and only the data in `CF1` is deleted.

Before deleting the column family `CF1` at `a.c`	After deleting the column family `CF1` at `a.c`
`{ "a" : { "b" : "value_b", "c" : { "d" : "value_d", "e" : "value_e", "f" : { "g" : "value_g", "h" : "value_h" } } } }`	`{ "a" : { "b" : "value_b", "c" : { "d" : "", "e" : "", "f" : { "g" : "value_g", "h" : "value_h" } } } }`

Example of using the `Admin.deleteFamily()` method

```
public void deleteColumnFamily(String tablePath, String familyName) throws
DBException {
    try (Admin admin = MapRDB.newAdmin()) {
      if (admin.tableExists(tablePath)) {
        admin.deleteFamily(tablePath, familyName);
      }
    }
}
```

Parameter	Description
`tablePath`	The path of the table in the filesystem. See the "Table Paths" section in HPE Ezmeral Data Fabric Database JSON Tables on page 638.
`familyName`	The name of the column family to delete. You cannot delete the default column family. If familyName is equal to "default", the API returns an exception.

Setting TTL for Data

You can delete stale JSON documents in JSON tables automatically by setting a time-to-live (TTL) value on the column family.

TTL is set only on the default column family in a JSON table. The duration that you set applies to each entire JSON document in the JSON table.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

NOTE: Only the default column family can exist in order to set TTL; no other column families can exist in the JSON table. You also cannot set the TTL for a JSON table if it has secondary indexes.

Data can become stale. If the data in an JSON document has not been updated within a certain period of time, you might want to delete the document. In the case of a large amount of JSON documents, applications should not have to track the time between updates and then delete the expired documents.

Because the time-to-live that is set on a column family affects an entire JSON table, only the default column family is allowed to have a non-default time-to-live value. In addition, to prevent multiple column families from having non-default time-to-live values, additional column families can not be created in a table if the default column family has a non-default value. This is because if more than one column family had a non-default TTL value, fragments of documents would expire at different times, leading to inconsistent views of data.

Permission Required

The `writeAce` permission on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1346.

Example: Setting the default column family to a non-default time-to-live value

If you set the time-to-live parameter for the default column family to 864,000 seconds, JSON documents in that table are considered to be stale if the document's data has not been updated within 10 days and are automatically deleted.

The following code example creates a JSON table, the default column family and sets the TTL to a non-default value of 10 days (864,000 seconds).

```
/* Create a TableDescriptor for the table to create,
   passing in the path of the table. */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Create a FamilyDescriptor for the default column family.
   When you create a table with the API, you must also create
   the default column family.
   Set the TTL to 10 days.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor defaultfamilyDesc = MapRDB.newDefaultFamilyDescriptor()
   .setTTL(864000);
tableDescriptor.addFamily(defaultfamilyDesc);

// Pass the TableDescriptor to the Admin.createTable() method.
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
  try (Admin admin = MapRDB.newAdmin()) {
    if (!admin.tableExists(tablePath)) {
      admin.createTable(tableDescriptor);
    }
  }
}
```

Managing JSON Documents

To perform CRUD operations (create, read, update, and delete) on JSON documents in HPE Ezmeral Data Fabric Database JSON tables using the OJAI API, you use `Document`, `DocumentStore`, and `DocumentMutation` objects.

You can also perform these operations using HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5728.

©Copyright 2024 Hewlett Packard Enterprise Development LP

`Document`

To create a JSON document, you must create a `Document` object. See the following for information specific to each language:

Java	To create a JSON document in Java OJAI, use the Document interface. See Creating JSON Documents in Java OJAI on page 3360 to learn about the different ways to create `Document` objects in Java.
Node.js	To create a `Document` object in Node.js OJAI, simply create a JSON object. See Sample OJAI Code for Creating JSON Documents on page 3365 for an example of how to do this.
Python	The preferred approach is to create a `Document` object in Python is to create a Python dictionary. You can also use the Document interface. See Creating JSON Documents in Python OJAI on page 3364 to learn about these two ways to create JSON documents in Python.
C#	To create a `Document` object in C# OJAI, create a C# object. See Sample OJAI Code for Creating JSON Documents on page 3365 for an example of how to do this. For C# OJAI examples, see this Github page.
Go	To create a `Document` object in Go OJAI, create a Go structure. See Sample OJAI Code for Creating JSON Documents on page 3365 for an example of how to do this.

`DocumentStore`

After you create a `Document` object, you can pass it to the `DocumentStore` interface. The interface has methods to perform the following tasks:

- Delete documents from tables
- Insert documents into tables
- Replace documents in tables

See the following for API links to the `DocumentStore` interface in each language:

Java	DocumentStore

©Copyright 2024 Hewlett Packard Enterprise Development LP

NOTE: By default, OJAI implements non-buffered writes. If you want buffered writes instead, use the `ojai.mapr.documentstore.buffer-writes` option and with the `Document` object. This option is available only in the Java OJAI API. See Enabling Buffered Writes in Java OJAI on page 3485 for more information.

Node.js	DocumentStore
Python	DocumentStore
C#	DocumentStore For C# OJAI examples, see this Github page.
Go	DocumentStore

`DocumentMutation`

To make changes to JSON documents, create a `DocumentMutation` object. A `DocumentMutation` enables you to perform OJAI mutations, which includes replacing, updating, combining, and deleting fields in a JSON document. For a list of available mutations, see Using OJAI Mutation Syntax on page 3377.

Java	To create a `DocumentMutation` object, call the methods in the `DocumentMutation` class corresponding to the mutation operations you want to perform. See DocumentMutation for a list of available methods. Pass the `DocumentMutation` object to either the DocumentStore.checkAndUpdate or DocumentStore.update method to apply the changes to the document. The first method accepts a QueryCondition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.
Node.js	To create a `DocumentMutation` object, create a JSON object Using OJAI Mutation Syntax on page 3377. Pass the `DocumentMutation` object to either the DocumentStore.checkAndUpdate or DocumentStore.update method to apply the changes to the document. The `DocumentStore.checkAndUpdate()` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.
Python	To create a `DocumentMutation` object, create a Python dictionary object Using OJAI Mutation Syntax on page 3377. Pass the `DocumentMutation` object to either the DocumentStore.check_and_update or DocumentStore.update method to apply the changes to the document. The `DocumentStore.check_and_update()` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both

©Copyright 2024 Hewlett Packard Enterprise Development LP

	methods have an `_id` parameter corresponding to the document to be updated.
C#	To create a `DocumentMutation` object, create a C# object Using OJAI Mutation Syntax on page 3377. Pass the `DocumentMutation` object to either the `DocumentStore.CheckAndUpdate` or `DocumentStore.Update` method to apply the changes to the document. The `DocumentStore.CheckAndUpdate` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated. For C# OJAI examples, see this Github page.
Go	To create a `DocumentMutation` object, create a Go structure Using OJAI Mutation Syntax on page 3377. Pass the `DocumentMutation` structure to either the `DocumentStore.CheckAndUpdate` or `DocumentStore.Update` method to apply the changes to the document. The `DocumentStore.CheckAndUpdate` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.

By default, the default maximum size of a JSON document is 32 MB. A `DocumentMutation` does not enforce this limit. HPE Ezmeral Data Fabric Database enforces the limit when you pass your `DocumentMutation` object to the `DocumentStore` method. See JSON Document Size on page 624 for information about how to increase this limit.

See Examples: Updating JSON Documents on page 3385 for examples that use mutations.

Creating JSON Documents in OJAI

The way you create a JSON document in your OJAI application depends on the language you use.

Creating JSON Documents in Java OJAI

There are several ways to create JSON documents in your Java OJAI application. They all require you to call the `Connection.newDocument` method to create a `Document` object.

More information

Connection

Document

Create a Document Using a Document Object in Java OJAI

You can create a new JSON document in your Java OJAI client by first calling the `Connection.newDocument()` method to create a `Document` object, and then calling methods on the object to specify document fields and values.

The following shows the detailed sequence of steps:

1. Create a new JSON document by calling the `newDocument()` method in the `Connection` class.
2. Specify the ID of the document with the `setId()` method.
3. Specify field names and their values with the `set()` or `setArray()` method.
4. Return the results in a `Document` object.

©Copyright 2024 Hewlett Packard Enterprise Development LP

For example, suppose you want to create the following JSON document:

```
{
    "_id" : "movie0000001",
    "title" : "OJAI -- The Documentary",
    "studio" : "MapR Technologies, Inc.",
    "release_date" : "2015-09-29",
    "trailers" : {
        "teaser" : "https://10.10.21.90/trailers/teaser",
        "theatrical" : "https://10.10.21.90/trailers/theatrical"
    },
    "characters" : [
        "Heroic Developer",
        "Evil Release Manager",
        "Mad Development Manager"
    ],
    "box_office_gross" : 1000000000L
}
```

The following method creates the document:

```
public Document buildDocument() {
    return connection.newDocument()
        .setId("movie0000001")
        .set("title", "OJAI -- The Documentary")
        .set("studio", "MapR Technologies, Inc.")
        .set("release_date", Values.parseDate("2015-09-29"))
        .set("trailers.teaser", "https://10.10.21.90/trailers/teaser")
        .set("trailers.theatrical", "https://10.10.21.90/trailers/
theatrical")
        .setArray("characters",
            ImmutableList.of(
                "Heroic Developer", "Evil Release Manager", "Mad
Development Manager"))
        .set("box_office_gross", 1000000000L);
}
```

Create a Document from a JSON String in Java OJAI

You can create a new JSON document in your Java OJAI client by passing a JSON string to the `Connection.newDocument()` method.

To create the following JSON document:

```
{
    "_id":"id001",
    "a":1,
    "b":"aString",
    "array":[
        1,
        2,
        "arrStr",
        {
            "c":"arrMapStr"
        }
    ]
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Call `Connection.newDocument()`, passing in a JSON string with escaped quotes:

```
Document pojoDoc = connection.newDocument(
    "{\"_id\":\"id001\",\"a\":1,\"b\":\"aString\",\"array\":[1,2,\"arrStr\",
{\"c\":\"arrMapStr\"}]}");
```

Create a Document from a JavaBean

You can create a new JSON document in your Java OJAI client by passing a JavaBean to the `Connection.newDocument(Object bean)` method. Through an example, the content shows you a sample JavaBean class, how to create a bean for that class, how to create a JSON document from the bean, and how to convert a JSON document back to a bean.

Sample JavaBean Class

Suppose that you are using a JavaBean class named `ExampleJson`:

```
package com.example;

import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import javax.annotation.Generated;
import com.fasterxml.jackson.annotation.JsonAnyGetter;
import com.fasterxml.jackson.annotation.JsonAnySetter;
import com.fasterxml.jackson.annotation.JsonIgnore;
import com.fasterxml.jackson.annotation.JsonInclude;
import com.fasterxml.jackson.annotation.JsonProperty;
import com.fasterxml.jackson.annotation.JsonPropertyOrder;

@JsonInclude(JsonInclude.Include.NON_NULL)
@Generated("org.jsonschema2pojo")
@JsonPropertyOrder({
    "a",
    "b",
    "array"
})

public class ExampleJson {

    @JsonProperty("a")
    private Double a;
    @JsonProperty("b")
    private String b;
    @JsonProperty("array")
    private List<Object> array = new ArrayList<Double>();
    @JsonIgnore
    private Map<String, Object> additionalProperties = new HashMap<String,
Object>();

    /**
      *
      * @return
      * The a
      */
    @JsonProperty("a")
    public Double getA() {
        return a;
    }

    /**
      *
```

```
      * @param a
      * The a
      */
    @JsonProperty("a")
    public void setA(Double a) {
        this.a = a;
    }

    /**
      *
      * @return
      * The b
      */
    @JsonProperty("b")
    public String getB() {
        return b;
    }

    /**
      *
      * @param b
      * The b
      */
    @JsonProperty("b")
    public void setB(String b) {
        this.b = b;
    }

    /**
      *
      * @return
      * The array
      */
    @JsonProperty("array")
    public List<Object> getArray() {
        return array;
    }

    /**
      *
      * @param array
      * The array
      */
    @JsonProperty("array")
    public void setArray(List<Object> array) {
        this.array = array;
    }

    @JsonAnyGetter
    public Map<String, Object> getAdditionalProperties() {
        return this.additionalProperties;
    }

    @JsonAnySetter
    public void setAdditionalProperty(String name, Object value) {
        this.additionalProperties.put(name, value);
    }
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Create a Bean

You can create a bean for the `ExampleJson` class with the following code:

```
ExampleJson bean = new ExampleJson();

bean.setA(1);
bean.setB("aString");

List arrList = new ArrayList();
arrList.add(1);
arrList.add(2);
arrList.add("arrStr");

Map arrMap = new HashMap();
arrMap.put("c","arrMapStr");
arrList.add(arrMap);
bean.setArray(arrList);
```

Create a New Document from a Bean

After creating the `ExampleJson` bean, you can create a JSON document using the bean with the following call:

```
Document pojoDoc = connection.newDocument(bean);
```

The document will have the following structure:

```
{
    "a":1,
    "b":"aString",
    "array":[
        1,
        2,
        "arrStr",
        {
            "c":"arrMapStr"
        }
    ]
}
```

Create a JavaBean from a JSON Document

You can also create a JavaBean from a JSON document. For example, suppose you modify the document that you created earlier:

```
pojoDoc.set("d","10");
```

The following converts the modified document back into an `ExampleJson` bean:

```
ExampleJson bean = pojoDoc.toJavaBean(ExampleJson.class);
```

Creating JSON Documents in Python OJAI
There are two ways to create JSON documents in your Python OJAI application, one of which is the preferred approach.

©Copyright 2024 Hewlett Packard Enterprise Development LP

The preferred way to create a Python dictionary object and then pass it to the `Connection.new_document()` method:

```
json_dict = {
    "_id" : "movie0000001",
    "title" : "OJAI -- The Documentary",
    "studio" : "MapR Technologies, Inc.",
    "release_date" : "2015-09-29",
    "trailers" : {
        "teaser" : "https://10.10.21.90/trailers/teaser",
        "theatrical" : "https://10.10.21.90/trailers/theatrical"
    },
    "characters" : [
        "Heroic Developer",
        "Evil Release Manager",
        "Mad Development Manager"
    ],
    "box_office_gross" : 1000000000L
}
new_document = connection.new_document(dictionary=json_dict)
```

Alternatively, you can call `Document` interface methods to set fields and values:

```
doc = connection.new_document()
        .set_id("movie0000001")
        .set('title', 'OJAI - The Documentary')
        .set('studio', 'MapR Technologies, Inc.')
        .set('release_date', ODate.parse(date_str='2015-09-29'))
        .set('trailers.teaser', 'https://10.10.21.90/trailers/teaser')
        .set('trailers.theatrical', 'https://10.10.21.90/trailers/
theatrical')
        .set('characters', ['Heroic Developer', 'Evil Release Manager',
'Mad Development Manager'])
        .set('box_office_gross', 1000000000)
```

See the following for more details about the APIs:

- Connection
- Document

Sample OJAI Code for Creating JSON Documents
The sample code in this section shows you how to create a JSON document.

Java

The code is available at OJAI_001_GetConnectionCreateDocument.java.

```

        "sslTargetNameOverride=node1.cluster.com"

    // Create a connection to data access server
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Json string or map from which the Document will be created
    newMap := map[string]interface{}{
        "_id":  "id001",
        "name": "Joe",
        "age":  50,
        "address": map[string]interface{}{
            "street": "555 Moon Way",
            "city":   "Gotham",
        },
    }

    // Create new document from json_document
    newDocument := connection.CreateDocumentFromMap(newMap)

    // Print the new OJAI Document
    fmt.Println(newDocument.AsJsonString())

    // Close connection
    connection.Close()
}
```

Examples: Inserting JSON Documents

This section contains sample code that inserts a JSON document into a HPE Ezmeral Data Fabric Database JSON table. It also shows the HPE Ezmeral Data Fabric Database Shell syntax for inserting documents.

Java

The following code is available at OJAI_002_GetStoreAndInsertDocuments.java.

After you create the JSON document, call the DocumentStore.insertOrReplace method to insert the document into HPE Ezmeral Data Fabric Database.

```
/**

 */
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

import com.mapr.ojai.examples.data.Dataset;
import com.mapr.ojai.examples.data.User;

public class OJAI_002_GetStoreAndInsertDocuments {

  public static void main(String[] args) {

    System.out.println("==== Start Application ===");

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI
    final DocumentStore store = connection.getStore("/demo_table");

    for (final User someUser : Dataset.users) {
      // Create an OJAI Document form the Java bean (there are other ways
too)
      final Document userDocument = connection.newDocument(someUser);

      System.out.println("\t inserting "+ userDocument.getId());

      // insert the OJAI Document into the DocumentStore
      store.insertOrReplace(userDocument);
    }

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Node.js

The following code is available at OJAI_002_GetStoreAndInsertDocuments.js.

The following code creates a list of JSON objects and then calls the DocumentStore.insertOrReplace method to insert the document into HPE Ezmeral Data Fabric Database.

```
/*

                        'state': 'CA',
                        'zipCode': 95142
                    },
                    'phoneNumbers': [
                        {'areaCode': 555, 'number': 5425639},
                        {'areaCode': '555', 'number': '542-5656'}]
                    }
                   ]

for doc_dict in document_list:
    # Create new document from json_document
    new_document = connection.new_document(dictionary=doc_dict)
    # Print the OJAI Document
    print(new_document.as_json_str())

    # Insert the OJAI Document into the DocumentStore
    store.insert_or_replace(new_document)

# close the OJAI connection
connection.close()
```

dbshell

The following shows the syntax to insert a document with HPE Ezmeral Data Fabric Database Shell. See dbshell insert on page 5744 for more information and examples.

```
# mapr dbshell
maprdb root:>

// Syntax for inserting a document using the document ID
maprdb root:> insert <table path> --value '{"_id": "<row-key", < table
field >}'

// Syntax for inserting a document using document value
maprdb root:> insert <table path> --id <row-key> --value '{"_id":
"<row-key", < table field >}'
```

C#

The following code is available at 002_GetStoreAndInsertDocuments.cs.

©Copyright 2024 Hewlett Packard Enterprise Development LP

The following code creates a list of JSON strings, creates Documents from the list, and calls the `DocumentStore.InsertOrReplace` method to insert the documents into the HPE Ezmeral Data Fabric Database.

            store.InsertOrReplace(document);
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The following code is available at 002_get_store_and_insert_documents.go.

The following code creates a list of JSON dictionary objects, creates Document objects, and calls the DocumentStore.InsertOrReplaceDocument function to insert the documents into HPE Ezmeral Data Fabric Database.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    isExists, err := connection.IsStoreExists(storeName)
    if err != nil {
        panic(err)
    }
    var store *client.DocumentStore
    if isExists {
        store, err = connection.GetStore(storeName)
        if err != nil {
            panic(err)
        }
    } else {
        store, err = connection.CreateStore(storeName)
        if err != nil {
            panic(err)
        }
    }

    // Slice of maps from which the Document will be created
    documentArray := []map[string]interface{}{
        {
            "_id":       "user0000",
            "age":       35,
            "firstName": "John",

        // Print the new OJAI Document
        fmt.Println(newDocument.AsJsonString())
        //Insert the OJAI Document into the DocumentStore
        store.InsertOrReplaceDocument(newDocument)
    }

    // Close connection
    connection.Close()
}
```

Using OJAI Mutation Syntax

To perform updates using OJAI, you specify the document you want to update using its `_id` field, create *mutations* for that document, and then update it in your document store. OJAI defines a syntax for specifying mutations. Mutations allow you to append, decrement, delete, increment, combine, replace, and update fields in a document. This topic describes the syntax for the supported mutation operations and provides examples.

The following table lists the mutations OJAI supports. Each entry in the table contains a brief description of the mutation and a link to a section in this topic that describes the mutation in more detail.

Mutation Operation	Description
Append	Appends values to binary, string, and array fields
Decrement	Decrements field values
Delete	Deletes fields
Increment	Increments field values
Merge	Combines a nested document with an existing document
Put	Replaces field values or adds new fields
Set	Updates field values or adds new fields

The examples in this topic use the following sample JSON document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 10,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

last-updated: Nov 14, 2024

OJAI Append Mutations

Syntax

```
{"$append":{"fieldpath":value}}
```

```
{"$append":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The `$append` mutation is a read-modify-write operation. Use it to append specified values to existing binary, string, or array type fields. If there is type mismatch in any intermediate field specified in a *fieldpath* for the document, the mutation fails with an error. For example, an append mutation on field path `a.b.c` fails if the field `a` is a scalar.

To append multiple field paths, use an array notation to list the field paths.

Example

The following mutation appends an element to the array `a.b` and appends the string `" MapR"` to the end of the string already in the field path `a.c.e`:

```
{"$append":[{"a.b":{"appd":1}},
{"a.c.e":" MapR"}]}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 }, { "appd" :
1 } ],
    "c" : {
      "d" : 10,
      "e" : "Hello MapR"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Decrement Mutations

Syntax

```
{"$decrement":"fieldpath"}
```

```
{"$decrement":
{"fieldpath":decrementValue}}
```

```
{"$decrement":
[{"fieldpath1":decrementValue1},
{"fieldpath2":decrementValue2},...]}
```

Description

The `$decrement` mutation decrements the value in the *fieldpath*. To decrement multiple field paths, use an array notation to list the field paths.

©Copyright 2024 Hewlett Packard Enterprise Development LP

If the *fieldpath* does not exist, the mutation adds a new field to the document with the value *decrementValue*.

The *decrementValue* is optional and defaults to -1.

The mutation fails if there is a type mismatch in the field.

Example

The following updates the value 10 in `a.c.d` to 5 by using the decrement mutation:

```
{"$decrement":{"a.c.d":5}}
```

The mutation results in the following document, with the field update highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 5,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Delete Mutations

Syntax

```
{"$delete":"fieldpath"}
```

```
{"$delete":
["fieldpath1","fieldpath2",...]}
```

Description

The `$delete` mutation removes either a single field or a list of fields from a document. If the field does not exist, the delete ignores that field.

Example

The following mutation removes two fields from the document:

```
{"$delete":["a.b[1]","a.c.e"]}
```

The mutation results in the following document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false } ],
    "c" : {
      "d" : 10
    }
  },
  "m" : "MapR wins"
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

OJAI Increment Mutations

Syntax

```
{"$increment":"fieldpath"}
```

```
{"$increment":
{"fieldpath":incrementValue}}
```

```
{"$increment":
[{"fieldpath1":incrementValue1},
{"fieldpath2":decrementValue2},...]}
```

Description

The `$increment` mutation increments the value in the *fieldpath*. To increment multiple field paths, use an array notation to list the field paths.

If the *fieldpath* does not exist, the mutation adds a new field to the document with the value *incrementValue*.

The *incrementValue* is optional and defaults to 1.

The mutation fails if there is a type mismatch in the field.

Example

The following updates the value 10 in `a.c.d` to 15 by using the increment mutation:

```
{"$increment":{"a.c.d":5}}
```

The mutation results in the following document, with the field update highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 15,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Merge Mutations

Syntax

```
{"$merge":
{"fieldpath":nestedDocument}}
```

Description

The `$merge` mutation combines a *nestedDocument* with an existing document at a specified *fieldpath*. If the original document already contains subfields specified in the *nestedDocument*, then the mutation replaces the values for those subfields. Otherwise, it adds new subfields to the document.

NOTE: The `$merge` mutation does not support the array notation that other mutation operations provide.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

To specify more than one merge operation in a single mutation, use the syntax described at either Specifying Multiple Mutation Operations on page 3383 or OJAI Mutations Without Explicit Mutation Operation Names on page 3384. When using these syntax variations, avoid specifying overlapping field paths. HPE Ezmeral Data Fabric Database treats these as conflicting mutations and discards conflicts.

Examples

The following mutation replaces the pre-existing field path `a.c.d` with the value 11. It adds a new subfield y to the nested document `a.c`.

```
{"$merge":{"a.c":{"d":11,"y":"yo"}}}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello",
      "y" : "yo"
    }
  },
  "m" : "MapR wins"
}
```

The following mutation replaces the value in the field path `a.b` and adds a new subfield `a.d`:

```
{"$merge":{"a":{"b":1,"d":"MapR"}}}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : 1,
    "c" : {
      "d" : 10,
      "e" : "Hello"
    },
    "d" : "MapR"
  },
  "m" : "MapR wins"
}
```

OJAI Put Mutations

Syntax

```
{"$put":{"fieldpath":value}}
```

```
{"$put":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Description

The `$put` mutation is a replace operation. It is not a read-modify-write operation; it does no validation on the data. If the specified *fieldpath* exists, the mutation replaces the *fieldpath*'s value with the new *value,* regardless of the type of the original value. For example, you can update a field `a.b` from an array to a nested document. If the *fieldpath* does not exist, the mutation creates a new field with the given *value*. Because the operation does no data validation, it is significantly faster than the set operation.

To replace multiple field paths, use an array notation to list the field paths.

Example

The following example replaces the pre-existing fields `a.b` and `a.c.d` with values whose types differ from the original types. It also adds a new field `a.x`.

```
{"$put":[{"a.b":{"boolean":true}},
{"a.c.d":"eureka"},{"a.x":1}]}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : { "boolean" : true },
    "c" : {
      "d" : "eureka",
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

The mutation behaves as follows for the pre-existing fields:

- For `a.b`, the mutation replaces the original array of nested documents with a single nested document.
- For `a.c.d`, the mutation changes the field from an integer to a string.

OJAI Set Mutations

Syntax

```
{"$set":{"fieldpath":value}}
```

```
{"$set":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The `$set` mutation updates one or more fields in a document. It is a read-modify-write operation. It validates the type of the existing value before applying the mutation. If the specified *fieldpath* does not exist in a document, the mutation creates a new field. If the *fieldpath* exists but is not of the same type as the type of new *value*, then the entire mutation fails.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

To update multiple field paths, use an array notation to list the field paths.

Example

The following example updates the pre-existing fields `a.b.[0]` and `a.c.d`. It also adds a new field `a.x`.

```
{"$set":[{"a.b[0].boolean":true},
{"a.c.d":11},{"a.x":1}]}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : true },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

Specifying Multiple Mutation Operations

You can specify more than one operation in a single mutation by specifying each operation separated by a comma.

The following is a mutation with six operations:

```
{
   "$set":{"x":[1,2,3]},
   "$put":{"a.c.e":{"$binary":"AAAADg=="}},
   "$increment":"a.b[1].decimal",
   "$delete":"a.b[0]",
   "$merge":{"newDoc":{"k":"MapR DBShell rocks!!"}},
   "$append":{"m":"!!!"}
}
```

It results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "decimal" : 124.456 } ],
    "c" : {
      "d" : 10,
      "e" : { "$binary" : "AAAADg==" }
    }
  },
  "m" : "MapR wins!!!",
  "newDoc" : { "k" : "MapR DBShell rocks!!" },
  "x" : [ 1, 2, 3 ]
}
```

The mutation applies the updates in the following manner:

- The `$set` mutation adds a new array field `x` with the value `[1, 2, 3]`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- The `$put` mutation replaces the string `"Hello"` with the nested document `{"$binary":"AAAADg=="}`.
- The `$increment` mutation increments the value `123.456` in the second element of the array `a.b`.
- The `$delete` mutation deletes the field path `a.b[0]`, resulting in a single element array `a.b`.
- The `$merge` mutation adds a new field `newDoc` with the nested document `{"k":"MapR DBShell rocks!!"}` as its value.
- The `$append` mutation appends the string `"!!!"` to the end of the string `"MapR wins"`.

Conflicting Mutations

When you specify a mutation with field paths that are overlapping, HPE Ezmeral Data Fabric Database detects the conflict, discards the previous conflicting operation, and proceeds with the next operation.

For example, suppose you have the following document:

```
{"_id":"id1", "a":{"b":{"c":5}}}
```

The following mutation has two operations with overlapping fields `a.b`:

```
{"$delete":"a.b","$set":{"a.b.d":10}}
```

You may have intended for the mutation to first delete `a.b` and then to replace it with `a.b.d` as follows:

```
{"_id":"id1", "a":{"b":{"d":"10"}}}
```

But the *actual* result is the following:

```
{"_id":"id1", "a":{"b":{"c":5,"d":"10"}}}
```

In this case, the set operation on **`a.b.d`** causes the delete operation on **`a.b`** to be discarded.

NOTE: In the earlier example in this section, the `$increment` and `$delete` operations are not conflicting because one operates on `a.b[1]`, while the other operates on `a.b[0]`. On the other hand, the following are conflicting operations:

```
{"$increment":"a.b[1].decimal","$delete":"a.b"}
```

OJAI Mutations Without Explicit Mutation Operation Names

You can specify a mutation without using an explicit mutation name. These mutations run as merge operations.

For example, the following mutation merges the fields `k` and `a.c.d` to the document by adding a new field `k` and updating `a.c.d`:

```
{"k":"eureka","a":{"c":{"d":1234}}}
```

The mutation results in the following document, with updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
      "d" : 1234,
      "e" : "Hello"
    }
  },
  "k" : "eureka",
  "m" : "MapR wins"
}
```

Examples: Updating JSON Documents
This section contains sample code that updates a JSON document in a HPE Ezmeral Data Fabric Database JSON table using an OJAI mutation. It also shows the HPE Ezmeral Data Fabric Database Shell syntax for updating documents.

See Using OJAI Mutation Syntax on page 3377 for more details about OJAI mutations.

Java

The following code is available at OJAI_012_UpdateDocument.java. It does the following:

- Finds a document using the DocumentStore.findById method
- Creates a DocumentMutation that updates a field
- Updates the document by calling the DocumentStore.update method

```
/**

package com.mapr.ojai.examples;

import org.ojai.store.Connection;
import org.ojai.store.DocumentMutation;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

public class OJAI_012_UpdateDocument {

  public static void main(String[] args) {

    System.out.println("==== Start Application ===");

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI DocumentStore
    final DocumentStore store = connection.getStore("/demo_table");

    String docId = "user0002";

    // Print the document before update
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    System.out.println( "\t"+
store.findById(docId).getMap("address").toString() );

    // Create a DocumentMutation to update the zipCode field
    DocumentMutation mutation = connection.newMutation()
        .set("address.zipCode", 95196L);

    System.out.println("\tUpdating document "+ docId);

    // Update the Document with '_id' = "user0002"
    store.update(docId, mutation);

    // Print the document after update
    System.out.println( "\t"+
store.findById(docId).getMap("address").toString() );

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Node.js - Update

The following code is available at OJAI_011_UpdateDocument.js. It does the following:

- Finds a document using the DocumentStore.findById method
- Creates an OJAI mutation that updates a field
- Updates the document by calling the DocumentStore.update method

```
/*
 * Copyright (c) 2018 MapR, Inc.
 *

    return store.findById(docId);
  })
  .then((docBeforeUpdate) => {
    // Print the document before update
    console.log(`Document with id ${docId} before update`)
    console.log(docBeforeUpdate);

    const mutation = {'$put': {'address.zipCode': 95196}};
    const condition = {'$eq': {'address.street': '320 Blossom Hill Road'}}
    return store.checkAndUpdate(docId, mutation, condition);
  })
  .then((updateResult) => {
    console.log(updateResult);
    // Find the document after update
    return store.findById(docId);
  })
  .then((docAfterUpdate) => {
    // Print the document after update
    console.log(`Document with id ${docId} before update`)
    console.log(docAfterUpdate);
  });
```

Python - Update

The following code is available at 012_update_document.py. It does the following:

- Finds a document using the DocumentStore.find_by_id method
- Creates an OJAI mutation that updates a field

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- Updates the document by calling the DocumentStore.update method

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

doc_id = 'user0002'

# Print the document before update
document_before_update = store.find_by_id(doc_id)
print("Document with id {0} before update".format(doc_id))
print(document_before_update)

# Create mutation to update the zipCode field
mutation = {'$set': {'address.zipCode': 95196}}

# Execute update
store.update(_id=doc_id, mutation=mutation)

document_after_update = store.find_by_id(doc_id)
print('Document with id {0} after update'.format(doc_id))
print(document_after_update)
```

Python - Check and Update

The following code is available at 013_check_and_update_document.py. It does the following:

- Finds a document using the DocumentStore.find_by_id method
- Creates an OJAI mutation that updates a field
- Creates an OJAI condition to apply in the check and update
- Performs the check and update on the document by calling the DocumentStore.check_and_update method

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
                 "ssl=true;" \
                 "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
                 "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

doc_id = 'user0001'

# Print the document before update
document_before_update = store.find_by_id(doc_id)
print("Document with id {0} before update".format(doc_id))
print(document_before_update)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
# Create mutation to update the zipCode field
mutation = {'$put': {'address.zipCode': 99999}}

# Create condition
condition = {'$eq': {'address.street': '320 Blossom Hill Road'}}

# Execute check_and_update.
# Returns True if condition True and document was updated.
update_result = store.check_and_update(_id=doc_id,
                                       mutation=mutation,
                                       query_condition=condition)

print(update_result)

document_after_update = store.find_by_id(doc_id)
print('Document with id {0} after update'.format(doc_id))
print(document_after_update)
```

dbshell

The following dbshell command is equivalent to the code examples. See dbshell update on page 5747 for more information and examples.

```
# mapr dbshell
maprdb root:> update /demo_table --id user002 --m {"$set":
{"address.zipCode":95196}}
```

C# - Update

The following code is available at 012_UpdateDocument.cs. It does the following:

- Finds a document using the `DocumentStore.FindById` method to print the document before update.
- Creates an OJAI mutation that updates a field.
- Updates the document by calling the `DocumentStore.Update` method.

```
using System;
using MapRDB.Driver;

public class UpdateDocument
{
    public void UpdateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        var docId = "user0002";

        // Print the document before update
        var documentBeforeUpdate = store.FindById(docId);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
        Console.WriteLine($"Document with id {docId} before update:");
        Console.WriteLine(documentBeforeUpdate);

        // Create mutation to update the zipCode field
        var mutation =
connection.NewDocumentMutation().Set("address.zipCode", (long)95196);

        // Execute update
        store.Update(docId, mutation);

        // Print the document after update
        var documentAfterUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} after update:");
        Console.WriteLine(documentAfterUpdate);

        // Close the OJAI connection
        connection.Close();
    }
}
```

C# - Check and Update

The following code is available at 013_CheckAndUpdateDocument.cs. It does the following:

- Finds a document using the `DocumentStore.FindById` method to print the document before update.
- Creates an OJAI mutation that updates a field.
- Creates an OJAI condition to apply in the check and update.
- Performs the check and update on the document by calling the `DocumentStore.CheckAndUpdate` method.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class CheckAndUpdateDocument
{
    public void CheckAndUpdateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        var docId = "user0001";

        // Print the document before update
        var documentBeforeUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} before update:");
        Console.WriteLine(documentBeforeUpdate);

        // Create mutation to update the zipCode field
        var mutation =
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
connection.NewDocumentMutation().SetOrReplace("address.zipCode", 99999);

        // Create condition
        var condition = connection
            .NewQueryCondition()
                .Is("address.street", QueryOp.EQUAL, "320 Blossom Hill
Road")
                .Close()
            .Build();

        // Execute CheckAndUpdate.
        // Returns True if condition True and document was updated
        var updateResult = store.CheckAndUpdate(docId, condition, mutation);

        Console.WriteLine(updateResult);

        // Print the document after update
        var documentAfterUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} after update:");
        Console.WriteLine(documentAfterUpdate);

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - Update

The following code is available at 012_update_document.go. It does the following:

- Finds a document using the `DocumentStore.FindByIdString` function to print the document before update
- Creates an OJAI mutation that updates a field
- Updates the document by calling the `DocumentStore.Update` function

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"
    documentId := "user0002"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Print the document before update
    documentBeforeUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Document with id %v before update.\n %v", documentId,
documentBeforeUpdate.AsJsonString())

    // Create mutation to update the zipCode field
    mutation := map[string]interface{}{"$set": map[string]interface{}
{"address.zipCode": 95196}}

    // Execute update
    err = store.Update(client.BosiFromString(documentId),
client.MosmFromMap(mutation))
    if err != nil {
        panic(err)
    }

    // Print the document after update
    documentAfterUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Document with id %v after update.\n %v", documentId,
documentAfterUpdate.AsJsonString())

    // Close connection
    connection.Close()
}
```

Go - Check and Update

The following code is available at 013_check_and_update_document.go. It does the following:

- Finds a document using the DocumentStore.FindByIdString function to print the document before update
- Creates an OJAI mutation that updates a field
- Creates an OJAI condition to apply in the check and update
- Performs the check and update on the document by calling the `DocumentStore.CheckAndUpdate` function

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
```

Querying JSON Documents

This section describes how to query JSON documents in HPE Ezmeral Data Fabric Database JSON tables using the OJAI API library and HPE Ezmeral Data Fabric Database Shell. It includes sample programs using the OJAI API library and shows how to run the same queries in HPE Ezmeral Data Fabric Database Shell.

Querying in OJAI Applications

To query HPE Ezmeral Data Fabric Database JSON tables in your OJAI applications, you use the OJAI `Query` interface. The typical flow of your application involves creating a connection, obtaining a handle to the HPE Ezmeral Data Fabric Database JSON table you want to query, constructing the query, performing the query, and then processing the results.

NOTE: The Node.js, Python, C#, and Go OJAI clients are supported starting in EEP 6.0.

Description

The `DocumentStore` interface includes a `Query` interface. The `Query` interface allows you to build a query programmatically.

Java

To construct an OJAI query, call the following methods in the `Query` interface:

- Query.select
- Query.where
- Query.orderBy
- Query.offset
- Query.limit

To run the query, pass the `Query` object to the DocumentStore.find method.

Node.js

To construct an OJAI query, create a Node.js JSON object using OJAI Query Syntax on page 3419.

To run the query, pass the `Query` object to the DocumentStore.find method.

Python

To construct an OJAI query, create a Python dictionary object using OJAI Query Syntax on page 3419.

To run the query, pass the `Query` object to the DocumentStore.find method.

NOTE: The following `Query` methods are available in the Python OJAI API, but creating a Python dictionary is the preferred approach:

- Query.select
- Query.where
- Query.order_by
- Query.offset
- Query.limit

C#

To construct an OJAI query, create a C# object.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

To run the query, pass the `Query` object to the `DocumentStore.Find` method.

NOTE: The following `Query` methods are available in the C# OJAI API:

- Query.Select
- Query.Where
- Query.OrderBy
- Query.Offset
- Query.Limit

Go

To construct an OJAI query, create a Go object.

To run the query, pass the `Query` object to the `DocumentStore.FindQuery` function.

NOTE: The following `Query` functions are available in the Go OJAI API:

- `Query.Select`
- `Query.WhereCondition`
- `Query.OrderBy`
- `Query.Offset`
- `Query.Limit`

Basic Application Flow

The following steps describe the basics in developing client applications that query HPE Ezmeral Data Fabric Database JSON tables using the OJAI API.

Java

1. Create a Connection instance to your Data Fabric cluster using the DriverManager class:

```
Connection connection =
DriverManager.getConnection("ojai:m
apr:");
```

NOTE: Do not omit the ending colon in the connection string.

2. Obtain a DocumentStore handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
DocumentStore store =
connection.getStore(tablePath);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

3. Create a Query object using the connection object:

```
Query query =
connection.newQuery();
```

4. Perform the query operation on the table:

```
QueryResult result =
store.find(query);
```

5. Process the results.

   The following code snippet iterates through the QueryResult and prints each document as a JSON string:

```
for (final Document userDocument :
result) {
    // Print the OJAI Document

System.out.println(userDocument.asJ
sonString());
}
```

   To process individual fields within a document, use the DocumentReader interface. The following code snippet iterates through the fields in a document and prints the fields that are strings:

```
Iterable it =
result.documentReaders();
for (DocumentReader reader : it) {
    EventType et = null;
    while ((et = reader.next()) !=
null) {
        if (et ==
EventType.STRING) {

System.out.println("Value of field
" + reader.getFieldName() + ": " +
reader.getString());
        }
    }
}
```

6. Close the result stream, the connection to the document store, and the connection to Data Fabric:

```
result.close();
store.close;
connection.close();
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Node.js

1. Create a connection:

```
ConnectionManager.getConnection('lo
calhost:5678?;user=mapr;password=ma
pr;ssl=false')
    .then((connection) => {
        // Process connection
        ...
    });
```

2. Obtain a handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
connection.getStore(tablePath)
    .then((store) => {
        // Process store
        ...
    });
```

3. Create a query object:

```
const query = {};
```

4. Perform the query operation on the table:

```
const stream = store.find(query)
```

5. Process the results:

```
stream.on('data', (document) =>
console.log(document));
```

6. Close the connection to Data Fabric:

```
stream.on('end', () => {
  console.log('end');
  connection.close();
});
```

Python

1. Create a Connection instance to your Data Fabric cluster using the `ConnectionFactory` class:

```
connection_str =
'localhost:5678?;user=mapr;password
=mapr;ssl=false'
connection =
ConnectionFactory.get_connection(co
nnection_str=connection_str)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

2. Obtain a DocumentStore handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
store =
connection.get_store(table_path)
```

3. Create a Query object using the connection object:

```
query =
connection.new_query().build()
```

4. Perform the query operation on the table:

```
query_result = store.find(query)
```

5. Process the results.

   The following code snippet iterates through the QueryResult and prints each document as a Python dictionary:

```
for doc in query_result:
    print(doc)
```

6. Close the connection to Data Fabric:

```
connection.close()
```

C#

1. Create a `Connection` instance to your Data Fabric cluster using the `ConnectionFactory` class:

```
var connectionStr =
$"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/
ssl_truststore.pem;" +

$"sslTargetNameOverride=node1.mapr.
com";
var connection =
ConnectionFactory.CreateConnection(
connectionStr);
```

2. Obtain a `DocumentStore` handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
var store =
connection.GetStore(storePath);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

3. Create a `Query` object using the connection object:

```
var query =
connection.NewQuery().Build();
```

4. Perform the query operation on the table:

```
var queryResult =
store.Find(query);
```

5. Process the results.

   The following code snippet iterates through the `QueryResult` and prints each document as a JSON:

```
var documentStream = await
queryResult.GetDocumentAsyncStream(
).GetAllDocuments();
foreach (var document in
documentStream)
{

Console.WriteLine(document.ToJsonSt
ring());
}
```

6. Close the connection to Data Fabric:

```
connection.Close();
```

Go

1. Create a `Connection` instance to your Data Fabric cluster:

```
connectionString :=
"localhost:5678?
auth=basic;user=mapr;password=mapr;
ssl=false"
connection, error :=
client.MakeConnection(connectionStr
ing)
```

2. Obtain a `DocumentStore` handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
store,
error := connection.CreateStore("/
store_path")
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

3. Create a Query object:

```
query, err := client.MakeQuery()
query.Build()
```

4. Perform the query operation on the table:

```
queryResult, err :=
store.FindQuery(query,
&client.FindOptions{})
```

5. Process the results.

   The following code snippet iterates through the QueryResult and prints each document as a JSON:

```
    for _, doc := range
queryResult.DocumentList() {
        fmt.Println(doc)
    }
```

6. Close the connection to Data Fabric:

```
connection.Close()
```

See Examples: Querying JSON Documents on page 3440 for complete code examples.

Related concepts

OJAI Distributed Query Service on page 619
OJAI queries either directly access HPE Ezmeral Data Fabric Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for HPE Ezmeral Data Fabric Database JSON, powered by Apache Drill. The Data Fabric client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of Drill.

Comparisons and Sorts in OJAI Queries

When running OJAI queries with comparisons and sorts, you need to be aware of how different data types behave. You also need to understand how sorting works in Data Fabric DB queries. Depending on the component that runs the sort, you may encounter unexpected behavior.

OJAI supports comparisons using the `QueryCondition` interface. For information about how to use this interface, see Query Conditions in OJAI Applications on page 3405.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

When using the OJAI `Query` `where` and `orderby`, and comparing and sorting across different data types, there are subtleties you should take into consideration. See Using Comparable JSON Document Data Types in Comparisons and Sorts on page 628 and Using Non-comparable JSON Document Data Types in Comparisons and Sorts on page 629 for more information.

If you do not have a secondary index defined that can generate your query's specified `orderby`, then your query requires an explicit sort. If you have installed the OJAI Distributed Query Service on page 619, the service performs the sort. If you have not, the Data Fabric client performs the sort, but restricts the amount of data it can sort. The default sort limit is 5000 documents. For example, if your query returns 10,000 documents, and you specify a query result `limit` of 5000 documents, the Data Fabric client can perform the sort.

IMPORTANT: The Data Fabric client returns an error if your query result size exceeds the client's sort limit.

You can avoid errors due to the client sort limitation by adhering to the following guidelines:

- If you know the largest possible query result size when your queries specify an `order by`, you can increase the sort limit of your client to that maximum size by setting the `ojai.mapr.query.max-client-sort-limit` parameter.

  The following code snippets increase the limit to 6000:

Java

```
query.setOption("ojai.mapr.query.ma
x-client-sort-limit", 6000);
```

NOTE: This option is not applicable to the Java OJAI Thin Client.

Node.js

```
const query
= {"$select":"col","$options":
{"ojai":{"mapr":{"query":
{"max-client-sort:6000}}}}
const stream = store.find(query)
```

Python

```
query = {"$select":"col","$options":
{"ojai":{"mapr":{"query":
{"max-client-sort:6000}}}}
query_result = store.find(query)
```

C#

```
            var query =
connection.NewQuery()
                .Select("col")
                .SetMaxClientSortLimi
t(6000)
                .Build();

            var queryResult =
store.Find(query);
```

Go

```
query := map[string]interface{}{
    "$select":"col",
    "$options":map[string]interface{}
{
        "ojai":map[string]interface{}
{
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
"mapr":map[string]interface{}{

"query":map[string]interface{}{

"max-client-sort":6000}}}}
queryResult, err :=
store.FindQueryMap(query,
&client.FindOptions{})
```

You can also set this option across all your OJAI clients by modifying a data access gateway property. See Administering the Data Access Gateway - Application Properties for details.

- If you do not know the largest possible query result size, specify a `limit` in your queries. If your query result size exceeds that `limit`, the client sorts the entire result set but returns only a subset of the rows up to the specified limit. This avoids the error, but may result in unintended behavior if your application is not expecting a truncated result. You should take corrective action if necessary.

  See Querying with Order By on page 3470 for an example of how to set a query `limit`.

Permissions and OJAI Queries
You need to understand permission requirements because they affect filter conditions in your OJAI queries.

HPE Ezmeral Data Fabric Database enforces permissions when your application processes the query result. In the basic application flow shown in the previous section, this corresponds to step 5. In an application, if user1 performs the query while user2 processes the result, then the result corresponds to user2's permissions.

You should create a separate OJAI connection for each unique user. Sharing a connection across users can result in non-optimal queries or invalid permission errors.

The following permissions are required to query documents:

- The `readAce` permission on the volumes where the JSON tables that contain the documents are located. See Setting Whole Volume ACEs on page 1346.
- The `readperm` permission on the JSON table's column families containing fields being queried. See Enabling Table and Stream Authorizations with ACEs on page 1343.

If the user does not have the `readperm` permission on a field, HPE Ezmeral Data Fabric Database treats the field as non-existent for that user. When a query selects a non-existent field, HPE Ezmeral Data Fabric Database ignores the field. If a query filters on a non-existent field, the query behaves as follows:

Filter Condition on Non-existent Field	Behavior
Filter for specific values in the field	No documents qualify the filter because a non-existent field does not match any value.
Filter for non-matches in the field	All documents qualify the filter because a non-match on a non-existent field is a no-op.

The exception is the rowkey field. Access control on the rowkey is not available. Users can always select and filter on rowkey.

For information about setting permissions, see Permission Types for Fields and Column Families in JSON Tables on page 1381.

OJAI Query Options
OJAI supports query options that enable you to modify the behavior of your queries. This includes an option to force secondary index usage and options to influence the behavior of sorts.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Available Query Options

The following table lists available query options. Some options may or may not apply, depending on whether your query uses the OJAI Distributed Query Service. The detailed descriptions make a note of this.

Option Name	Description	Details
`ojai.mapr.query.hint-using-index`	Forces the Data Fabric client to use a particular index, regardless of cost considerations	Forcing Secondary Index Usage in OJAI on page 3404
`ojai.mapr.query.force-noncovering-sort`	Enables sort behavior to avoid partial sorts due to secondary index lags	Avoiding Partial Sorts with Secondary Indexes in OJAI on page 3404
`ojai.mapr.query.max-client-sort-limit`	Sets the Data Fabric client sort limit	Comparisons and Sorts in OJAI Queries on page 3401
`ojai.mapr.query.force-drill`	When set to `true`, forces the Data Fabric client to use the OJAI Distributed Query Service	Forcing Usage of the OJAI Distributed Query Service on page 3405
`ojai.mapr.drill.<OJAI Distributed Query Service Property Name>`	Sets options for the OJAI Distributed Query Service	Setting OJAI Distributed Query Service Properties on page 3405

Setting Query Options

To set these options in your OJAI application, see the following topics:

Java	Setting Query Options in Java OJAI on page 3485
Node.js	Setting Query Options in Node.js Using OJAI Query Syntax on page 3493
Python	Setting Query Options in Python Using OJAI Query Syntax on page 3503
C#	Setting Query Options in C# OJAI on page 3507
Go	Setting Query Options in Go OJAI on page 3511

Forcing Secondary Index Usage in OJAI

To force the Data Fabric client to use an index, specify the name of the index with the `ojai.mapr.query.hint-using-index` option.

Regardless of cost considerations, the Data Fabric client attempts to use the specified index. To use the index, the index must benefit filter conditions, the order by, or projections in the query as described at Queries that Benefit from Secondary Indexes on page 687. Otherwise, the Data Fabric client ignores the option.

To force the Data Fabric client to *not* use any indexes, specify the table name without the full path as the second parameter in the calls shown earlier. For example, if the full path of your table is `/mapr/sanfrancisco/volume1/customer`, pass the name `customer` as the second parameter.

NOTE: Setting this option in your OJAI application has no effect if you are using the OJAI Distributed Query Service.

Avoiding Partial Sorts with Secondary Indexes in OJAI

Partial sorts can occur due to secondary index lags. To avoid these lags, set the `ojai.mapr.query.force-noncovering-sort` option to TRUE.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

This option forces the OJAI Distributed Query Service to explicitly sort the data. Do not set this option if you do not expect to encounter index lags. Otherwise, you lose the ordering advantage that secondary indexes provide.

For more information about why partial sorts occur, see Partial Sorts with Non-Covering Indexes on page 697.

Forcing Usage of the OJAI Distributed Query Service

When set to `true`, the Data Fabric client uses the OJAI Distributed Query Service execution path, rather than selecting an execution path that it determines to be most optimal. See OJAI Distributed Query Service on page 619 for more information about the different query execution paths.

Setting OJAI Distributed Query Service Properties

OJAI queries may leverage the OJAI Distributed Query Service. To modify OJAI Distributed Query Service property settings in your OJAI application, prefix the OJAI Distributed Query Service property name with `ojai.mapr.drill`.

For example, the option `ojai.mapr.drill.planner.enable_index_planning` disables using secondary indexes when queries use the Query Service.

See Index Planning and Execution Configuration Options on page 4303 for the list of available OJAI Distributed Query Service properties.

Related concepts

OJAI Distributed Query Service on page 619
OJAI queries either directly access HPE Ezmeral Data Fabric Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for HPE Ezmeral Data Fabric Database JSON, powered by Apache Drill. The Data Fabric client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of Drill.

Query Conditions in OJAI Applications

You can create a query condition in an OJAI application in either of two ways. One way is to create an OJAI `QueryCondition` object and call methods in the class to construct your query condition. Another way is to create an OJAI query condition in a JSON format.

Creating an OJAI QueryCondition Object

The Java and Python OJAI clients support a `QueryCondition` interface. After you create a `QueryCondition` object, call methods in the class to construct your query condition.

Creating a `QueryCondition` Object

Java

Java OJAI provides a `QueryCondition.is()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryCondition.Op`
- The value to compare the field path against

The field path is either a field in a JSON document, a subfield within a nested document, or an array element.

Depending on the type of the field path, you specify the comparison value as follows:

©Copyright 2024 Hewlett Packard Enterprise Development LP

Scalar Data	You can specify the value using either a Java typed value (for example, `int`, `float`, or `String`) or a Java OJAI object. The API supports the following OJAI types: • `ODate` • `OInterval` • `OTime` • `OTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Java `Map` object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a Java `List` object. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.is()`, `QueryCondition` also supports the following methods:

`QueryCondition` Method	**Description**
`equals()` `notequals()`	Match for equality or non-equality on nested documents and arrays
`in()`	Search for individual elements in an array
`like()`	Search for string values using SQL LIKE expressions

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

QueryCondition Method	Description
`matches()`	Search for string values using regular expressions. You can use regular expressions that compose the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See HBase Java Regular Expressions Support on page 3327 for a list of supported regular expressions.
`and()`	Begins a new AND condition block
`or()`	Begins a new OR condition block
`elementAnd()`	Begins a new `elementAnd` block. See OJAI Query Condition Operators on page 3422 for a detailed description of this operator.
`close()`	Closes a compound condition block
`build()`	Builds the condition

NOTE: The material described in this section is a subset of the `QueryCondition` API. It introduces you to the basics of the API. For the complete API, see the QueryCondition interface.

Python

Python OJAI provides a `QueryCondition.is_()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryConditionOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. See OJAI Query Conditions Using Container Field Paths on page 3431 for details.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data

You can specify the value using either a Python scalar value (for example, `int`, `float`, or `str`) or a Python OJAI object.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	The API supports the following OJAI types: • `ODate` • `OInterval` • `OTime` • `OTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Python `dictionary` object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a Python `list` object. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.is_()`, `QueryCondition` also supports the following methods:

`QueryCondition` Method	**Description**
`equals_()` `not_equals_()`	Match for equality or non-equality on nested documents and arrays
`in_()`	Search for individual elements in an array
`like_()`	Search for string values using SQL LIKE expressions
`matches_()`	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See HBase Java Regular Expressions Support on page 3327 for a list of supported regular expressions.

last-updated: Nov 14, 2024

QueryCondition Method	Description
`and_()`	Begins a new `AND` condition block
`or_()`	Begins a new `OR` condition block
`element_and()`	Begins a new `elementAnd` block. See OJAI Query Condition Operators on page 3422 for a detailed description of this operator.
`close()`	Closes a compound condition block
`build()`	Builds the condition

NOTE:

- The material described in this section is a subset of the `QueryCondition` API. It introduces you to the basics of the API. For the complete API, see the QueryCondition interface.
- The preferred approach for creating query conditions in Python is to create the condition in a JSON format. See Creating an OJAI Query Condition Using a JSON String on page 3417

C#

C# OJAI provides a `QueryCondition.ls()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. For details, see OJAI Query Conditions Using Container Field Paths on page 3431.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data	You can specify the value using either a C# scalar value (for example, `int`, `float`, or `string`) or a C# OJAI object. The API supports the following OJAI types: • `OjaiDate` • `OjaiInterval`

©Copyright 2024 Hewlett Packard Enterprise Development LP

	• `OjaiTime` • `OjaiTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a C# object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a C# `list` of values of the specified type. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.ls()`, `QueryCondition` also supports the following methods:

`QueryCondition` Method	**Description**
`Condition()`	Search for values using a specific condition.
`Equals()` `NotEquals()`	Match for equality or non-equality on nested documents and arrays.
`Exists()` `NotExists()`	Search for a field if the given field path exists, or verify that a field path does not exist.
`In()` `NotIn()`	Search for individual elements in an array or verify their absence.
`Like()` `NotLike()`	Search for string values using SQL LIKE expressions or verify they do not match the specified SQL LIKE expression.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

QueryCondition Method	Description
`Matches()` `NotMatches()`	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library, as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. For a list of supported regular expressions, see HBase Java Regular Expressions Support on page 3327.
`SizeOf()`	Search for a value of the specified size. The value must be one of the following types: • `string` • `binary` • `iDictionary` • `iList`
`TypeOf()` `NotTypeOf()`	Search for value of the specified Type or verify its absence.
`And()`	Begins a new `AND` condition block.
`Or()`	Begins a new `OR` condition block.
`ElementAnd()`	Begins a new `ElementAnd` block. For a detailed description of this operator, see OJAI Query Condition Operators on page 3422.
`Close()`	Closes a compound condition block.
`Build()`	Builds the condition.

NOTE:

- The material described in this section is a subset of the QueryCondition API. It introduces you to the basics of the API. For the complete API, see the QueryCondition interface.
- The preferred approach for creating query conditions in C# is to create the condition in a JSON format. See 009_FindQueryWithSelectAndCondition.cs or Example: Creating a QueryCondition Object on page 3414.

Go

Go OJAI provides a `QueryCondition.ls()` function for specifying query conditions. The function takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. For details, see OJAI Query Conditions Using Container Field Paths on page 3431.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data	You can specify the value using either a Go scalar value (for example, `int`, `float64`, or `string`) or a Go OJAI object. The API supports the following OJAI types: • `OjaiDate` • `OjaiTime` • `OjaiTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Go object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a Go `list` of values of the specified type. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.ls()`, `QueryCondition` also supports the following functions:

`QueryCondition` Function	**Description**
`AddCondition()`	Search for values using a specific condition.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

QueryCondition Function	Description
`Equals()` `NotEquals()`	Match for equality or non-equality on nested documents and arrays.
`Exists()` `NotExists()`	Search for a field if the given field path exists, or verify that it does not exist.
`In()` `NotIn()`	Search for individual elements in an array or verify their absence.
`Like()` `NotLike()`	Search for string values using SQL LIKE expressions or verify they do not match the specified SQL LIKE expression.
`Matches()` `NotMatches()`	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library, as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. For a list of supported regular expressions, see HBase Java Regular Expressions Support on page 3327.
`TypeOf()` `NotTypeOf()`	Search for value of the specified Type or verify its absence.
`And()`	Begins a new `AND` condition block.
`Or()`	Begins a new `OR` condition block.
`ElementAnd()`	Begins a new `ElementAnd` block. For a detailed description of this operator, see OJAI Query Condition Operators on page 3422.
`Close()`	Closes a compound condition block.
`Build()`	Builds the condition.

©Copyright 2024 Hewlett Packard Enterprise Development LP

NOTE:

- The material described in this section is a subset of the `Query` API. It introduces you to the basics of the API. For the complete API, see the Query interface.
- The preferred approach for creating query conditions in Go is to create the condition in a JSON format. See 009_find_query_with_select_and_condition.go or Example: Creating a QueryCondition Object on page 3414.

Example: Creating a `QueryCondition` Object

The following example shows how to define a `QueryCondition` object for this query condition:

```
(a.b.[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

Java

```
QueryCondition qc =
connection.newCondition()
    .and()
        .is("a.b[0].boolean",
Op.EQUAL, false)
        .or()
            .is("a.c.d",
Op.NOT_EQUAL, 5)
            .is("a.b[1].decimal",
Op.GREATER, 1)
            .is("a.b[1].decimal",
Op.LESS, 10)
            .close()
    .close()
    .build();
```

Pass the `QueryCondition` object to the Query.where method. For a complete Java code example, see the *Java - OJAI QueryCondition Object* example at Querying with Conditions on page 3457.

Python

```
qc = connection.new_condition()
    .and_()
        .is_('a.b[0].boolean',
QueryConditionOp.EQUAL, False)
        .or_()
            .is_('a.c.d',
QueryConditionOp.NOT_EQUAL, 5)
            .is_('a.b[1].decimal',
QueryConditionOp.GREATER, 1)
            .is_('a.b[1].decimal',
QueryConditionOp.LESS, 10)
            .close()
    .close()
    .build()
```

Pass the `QueryCondition` object to the Query.where method. For a complete Python code example, see

©Copyright 2024 Hewlett Packard Enterprise Development LP

the *Python - OJAI QueryCondition Object* example at Querying with Conditions on page 3457.

C#

```
var condition =
connection.NewQueryCondition()
    .And()
        .Is("a.b[0].boolean",
QueryOp.EQUAL, false)
        .Or()
            .Is("a.c.d",
QueryOp.NOT_EQUAL, 5)
            .Is("a.b[1].decimal",
QueryOp.GREATER, 1)
            .Is("a.b[1].decimal",
QueryOp.LESS, 10)
            .Close()
    .Close()
    .Build();
```

Pass the `Condition` object to the `Query.Where` method. For a complete C# code example, see the *C# - OJAI QueryCondition Object* example at Querying with Conditions on page 3457.

Go

```
    condition, err :=
client.MakeCondition(
        client.And(),

client.Is("a.b[0].boolean",
client.EQUAL, false),
            client.Or(),
                client.Is("a.c.d",
client.NOT_EQUAL, 5),

client.Is("a.b[1].decimal",
client.GREATER, 1),

client.Is("a.b[1].decimal",
client.LESS, 10),
            client.Close(),
        client.Close())
    condition.Build()
```

Pass the `Condition` object to the `Query.WhereCondition` function. For a complete Go code example, see the *Go - OJAI QueryCondition Object* example at Querying with Conditions on page 3457.

Examples: Using the `QueryCondition.elementAnd` Method

The following example shows how to write the `elementAnd` condition described at Using elementAnd with Nested Documents on page 3434, using a `QueryCondition` object:

Java

```
QueryCondition qc =
connection.newCondition()
    .elementAnd("grades[]")
        .is("course",
QueryConditionOp.EQUALS, "history")
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
        .is("score",
QueryConditionOp.EQUALS, 12)
        .close()
    .build();
```

Python

```
qc = connection.new_condition()
    .element_and("grades[]")
        .is_("course",
QueryConditionOp.EQUALS, "history")
        .is_("score",
QueryConditionOp.EQUALS, 12)
        .close()
    .build()
```

C#

```
var condition =
connection.NewQueryCondition()
    .ElementAnd("grades[]")
        .Is("course", QueryOp.EQUALS,
"history")
        .Is("score", QueryOp.EQUALS,
12)
        .Close()
    .Build();
```

Go

```
    condition, err :=
client.MakeCondition(
        client.ElementAnd("grades[]"),
            client.Is("course",
client.EQUAL, "history"),
            client.Is("score",
client.EQUAL, 12),
        client.Close())
    condition.Build()
```

The following code corresponds to the example described at Using elementAnd with Scalar Values on page 3436 using a `QueryCondition` object:

Java

```
QueryCondition qc =
connection.newCondition()
    .elementAnd("values[]")
        .is("$",
QueryConditionOp.GREATER, 7)
        .is("$",
QueryConditionOp.LESS, 14)
        .close()
    .build();
```

Python

```
qc = connection.new_condition()
    .element_and("values[]")
        .is_("$",
QueryConditionOp.GREATER, 7)
        .is_("$",
QueryConditionOp.LESS, 14)
        .close()
    .build()
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

C#

```
var condition =
connection.NewQueryCondition()
    .EementAnd("values[]")
        .Is("$", QueryOp.GREATER, 7)
        .Is("$", QueryOp.LESS, 14)
        .Close()
    .Build();
```

Go

```
    condition, err :=
client.MakeCondition(
        client.ElementAnd("values[]"),
            client.Is("$",
client.EQUAL, 7),
            client.Is("$",
client.EQUAL, 14),
        client.Close())
    condition.Build()
```

Creating an OJAI Query Condition Using a JSON String
You can create a query condition using OJAI syntax to specify the condition in JSON format. This is the preferred approach for the Node.js, Python, C#, and Go OJAI clients.

The following example shows you how to create the following query condition using the syntax:

```
(a.b.[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

Java

This is a Java string for the condition:

```
String jc = new String(
    '{ \
        "$and":[ \
            {"$eq":
{"a.b[0].boolean":false}}, \
            {"$or":[ \
                {"$ne":{"a.c.d":5}}, \
                {"$gt":
{"a.b[1].decimal":1}}, \
                {"$lt":
{"a.b[1].decimal":10}} \
            ]} \
        ]} \
    )';
```

Pass the string to the Query.where method. See the *Java - OJAI Query Condition in JSON Format* example at Querying with Conditions on page 3457 for a complete Java code example.

Node.js

This is a Node.js JSON object for the condition:

```
query =
    {"$where":
        {"$and":[
            {"$eq":
{"a.b[0].boolean":false}},
            {"$or":[
                {"$ne":{"a.c.d":5}},
                {"$gt":
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
{"a.b[1].decimal":1}},
                {"$lt":
{"a.b[1].decimal":10}}
            ]}
        ]}
    };
```

See the *Node.js - OJAI Query Condition in JSON Format* example at Querying with Conditions on page 3457 for a complete Node.js code example.

Python

This is a Python dictionary for the condition:

```
query =
    {"$where":
        {"$and":[
            {"$eq":
{"a.b[0].boolean":false}},
            {"$or":[
                {"$ne":{"a.c.d":5}},
                {"$gt":
{"a.b[1].decimal":1}},
                {"$lt":
{"a.b[1].decimal":10}}
            ]}
        ]}
    }
```

See the *Python - OJAI Query Condition in JSON Format* example at Querying with Conditions on page 3457 for a complete Python code example.

C#

This is a JSON string for the condition:

```
var query =
    @"{""$where"":" +
        @"{""$and"":[" +
            @"{""$eq"":
{""a.b[0].boolean"":false}}," +
            @"{""$or"":["
+
                @"{""$ne"":{""a.c.d"":
{""$numberInt"":""5""}}}," +

@"{""$gt"":{""a.b[1].decimal"":
{""$decimal"":""1""}}}," +

@"{""$lt"":{""a.b[1].decimal"":
{""$decimal"":""10""}}}" +
            @"]}" +
        @"]" +
   @"}";
```

Go

This is a JSON string for the condition:

```
query := "{\"$where\": +
                "{\"$and\":[" +
                    "{\"$eq\":
{\"a.b[0].boolean\":false}}," +
                    "{\"$or\":[" +
                        "{\"$ne\":
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
{\"a.c.d\":5}}," +
                                "{\"$gt\":
{\"a.b[1].decimal\":1}}," +
                                "{\"$lt\":
{\"a.b[1].decimal\":10}}" +
                              "]}" +
                    "]}" +
               "}"
```

To learn about the complete OJAI syntax for query conditions, see OJAI Query Condition Syntax on page 3422.

NOTE: The OJAI clients are supported starting in EEP 6.0.0.

OJAI Query Syntax
OJAI defines a syntax for specifying queries on JSON documents. You can use this syntax in Node.js and Python OJAI client applications and HPE Ezmeral Data Fabric Database shell.

See Query with --query on page 5735 to learn about how to use this syntax in HPE Ezmeral Data Fabric Database shell.

An OJAI query can include the following components:

- Projection
- Condition
- Order by
- Limit
- Offset
- Options

You can specify some or all these components in a query, separating each component with a comma.

OJAI Query Projection

Syntax	`"$select":"fieldpath"`
	
	`"$select":`
	`["fieldpath1","fieldpath2",...]`

Description	The projection is the list of field paths to select in your query. You can specify a single field path or multiple. When specifying multiple, use an array notation to list the field paths. See JSON Document Field Paths on page 630 for more information about the syntax of different JSON document field paths.
Examples	Single field path: `"$select":"a.c.d"`

©Copyright 2024 Hewlett Packard Enterprise Development LP

Multiple field paths:

```
"$select":["a.c.d", "a.c.e", "m[0]"]
```

OJAI Query Condition

Syntax

```
"$where":OJAIQueryCondition
```

Description

The condition filters your query result. See OJAI Query Condition Syntax on page 3422 for more information about the syntax of an *OJAIQueryCondition*.

Example

If you have the following condition:

```
(a.b.[0].boolean == false && (a.c.d !
= 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

This is the OJAI JSON syntax for the condition:

```
"$where":{
    "$and":[
        {"$eq":
{"a.b[0].boolean":false}},
        {"$or":[
            {"$ne":{"a.c.d":5}},
            {"$gt":
{"a.b[1].decimal":1}},
            {"$lt":
{"a.b[1].decimal":10}}
            ]
        }
    ]
}
```

OJAI Query Order By

Syntax

```
"$orderby":"fieldpath"
```

```
"$orderby":{"fieldpath":"order"}
```

```
"$orderby":[fieldpath1,fieldpath2,...]
```

```
"$orderby":[{"fieldpath1":"order"},
{"fieldpath2":"order"},...]
```

Description

The order by specifies the field paths on which to sort your query result. You can specify a single field path or multiple. When specifying multiple, use an array notation to list the field paths. For each field path, you can optionally specify an *order* of either `asc` or `desc`. Both *order* keywords are case insensitive. The default is `asc`. When specifying an *order*, enclose the *fieldpath* and *order* with curly braces.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Examples

Order on a single field path in the default `asc` order:

```
"$orderby":"a.c.e"
```

Order on a single field path in the `desc` order:

```
"$orderby":{"a.c.e":"desc"}
```

Order on two field paths, where the second specifies a `desc` order:

```
"$orderby":["a.c.d",{"a.c.e":"desc"}]
```

OJAI Query Limit

Syntax

```
"$limit":positive-integer
```

Description

The number of documents to return from the query.

Example

Return only ten documents:

```
"$limit:10
```

OJAI Query Offset

Syntax

```
"$offset":positive-integer
```

Description

The number of documents to skip before returning results to the client. The offset value has a direct effect on query time; as the offset value increases, query time also increases.

Example

Process the query and skip the first five documents in the result set before returning the results to the client.

```
"$offset":5
```

OJAI Query Options

Syntax

```
"$options":{optionName:optionValue}
```

```
"$options":
[{optionName1:optionValue1},
{optionName2:optionValue2},...]
```

Description

Settings that influence a query's execution path. See OJAI Query Options on page 3403 for a list of available options.

When specifying the *optionName*, you must separate the components of the option name, replacing the dots with curly braces and colons and enclosing each component in quotes.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Example

Force the query to use the OJAI Distributed Query Service by setting the `ojai.mapr.query.force-drill` option:

```
"$options":{"ojai":{"mapr":{"query":
{"force-drill":true}}}}
```

OJAI Query Condition Syntax

OJAI defines a syntax for specifying query conditions that allows you to express query conditions in a JSON format. This topic describes the supported operators and provides examples of these query conditions.

When writing an OJAI application, you can also apply query conditions by calling OJAI API methods, corresponding to specific operators. This section does not discuss this alternative. For details on that alternative, see Query Conditions in OJAI Applications on page 3405.

NOTE: Using the JSON format is the preferred approach for Python and Node.js OJAI clients.

OJAI Query Condition Operators

OJAI supports comparison, existence, between, match, like, type of, size of, in, and logical operators.

Click the name in the following box to navigate to the section that provides details on each operator.

- Equals
- Greater Than
- Greater Than or Equals
- Less Than
- Less Than or Equals
- Not Equals
- Exists
- Not Exists
- Between on page 3423
- Matches
- Not Matches
- Like
- Not Like
- Type Of
- Not Type Of
- Size Of on page 3426
- In
- Not In
- And
- Or
- Element And

Comparison Operators

Operators

Operator	Syntax
Equals	`{"$eq": {"fieldpath":value}}`
Greater Than	`{"$gt": {"fieldpath":value}}`
Greater Than or Equals	`{"$ge": {"fieldpath":value}}`
Less Than	`{"$lt": {"fieldpath":value}}`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Operator	Syntax
Less Than or Equals	`{"$le": {"fieldpath":value}}`
Not Equals	`{"$ne": {"fieldpath":value}}`

Description

Compares the data in *fieldpath* against *value* for the specified operator.

Float and double data are approximate representations of decimal values. They may not return true in equality comparisons against their equivalent decimal values.

You can specify only equality and non-equality conditions on nested documents and arrays.

In the case of equality on nested documents, all of the fields in the nested document must match. The order of the fields is not relevant.

In the case of equality on arrays, both the order of the elements and the element values must match.

Existence Operators

Exists

Syntax

```
{"$exists":"fieldpath"}
```

Description

Checks for existence of *fieldpath*.

Not Exists

Syntax

```
{"$notexists":"fieldpath"}
```

Description

Checks for non-existence of *fieldpath*.

See Existence Conditions with Container Field Paths on page 3432 for details about how these operators behave when you use them with container field paths.

Between

Syntax

```
{"$between":{"fieldpath":
[startValue,endValue]}}
```

Description

Checks if the value in *fieldpath* is in the range specified by *startValue* and *endValue*, where the values are inclusive.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Matches Operators

Operators

Operator	Syntax
Matches	`{"$matches": {"fieldpath":matchValue}}`
Not Matches	`{"$notmatches": {"fieldpath":matchValue}}`

Description

Performs a regular expression match on *`fieldPath`* using *`matchValue`*.

You can use regular expressions that compose the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See HBase Java Regular Expressions Support for a list of supported regular expressions.

Like Operators

Operators

Operator	Syntax
Like	`{"$like": {"fieldpath":likeValue}}`
Not Like	`{"$notlike": {"fieldpath":likeValue}}`

Description

Performs a SQL LIKE comparison on `fieldPath` where *`likeValue`* is a string with wildcard characters '%' and '_'.

Special-Purpose Characters for the Like Operators

The OJAI API allows you to use four special-purpose characters or patterns with `$like` operator expressions:

Special-Purpose Character	Description	Example
%	Matches any string of zero or more characters.	`"abc%"` matches `"abc"`, `"abcd"`, `"abcde232136"`, etc. `"%abc"` matches `"abc"`, `"pqrabc"`, etc.
_	Matches a single character.	`"_am"` matches `"ram"`, `"sam"`, `"Sam"`, `"cam"`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Special-Purpose Character	Description	Example
`[]`	Matches a single character in the specified set or range.	`"[r-t]am"` matches `"ram"`, `"sam"`, and `"tam"` but not `"Sam"` or `"cam"`.
`[^]`	Matches a single character **not** in the specified set or range.	`"[^r-t]am"` matches `"Sam"`, `"pam"`, `"jam"`, or `"cam"` but not `"ram"`, `"sam"` and `"tam"`.

When any of these special characters is used as a literal, the character can be enclosed within `[]`:

Literal	Corresponding Like Expression
`"[a]"`	`"[[]a]"`
`"a%"`	`"a[%]"`
`"a_c"`	`"a[_]c"`

Note that `"^"` and `"]"` need not be escaped.

Type of Operators

Type Of

Syntax

```
{"$typeof":{"fieldpath":"typeValue"}}
```

Description

Checks whether *`fieldpath`* is of type *`typeValue`*.

Not Type Of

Syntax

```
{"$nottypeof":{"fieldpath":"typeValue"}}
```

Description

Checks whether *`fieldpath`* is not of type *`typeValue`*.

`typeValue` can be any of `map`, `array`, `binary`, `date`, `time`,

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

`timestamp`, `interval`, `double`, `float`, `long`, `int`, `short`, `byte`, `string`, `boolean`, or `null`.

Size Of

Syntax

```
{"$sizeof":{"fieldpath":{"comparisonOp":intValue}}}
```

Description

Compares the size of the data in *`fieldpath`* against *`intValue`*, using *`comparisonOp`* . The size varies depending on the type of *`fieldPath`*:

String	Length of string
Array	Number of elements in the array
Nested document	Number of subfields in the nested document

`comparisonOp` can be any of `$eq`, `$lt`, `$le`, `$gt`, `$ge`, or `$ne`.

In Operators

In

Syntax

```
{"$in":{"fieldpath":inOpValues}}
```

Description

Checks whether the data in *`fieldpath`* is in the list specified by *`inOpValues`*.

Not In

Syntax

```
{"$notin":{"fieldpath":inOpValues}}
```

Description

Checks whether the data in *`fieldpath`* is not in the list specified by *`inOpValues`*

Logical Operators

And

Syntax

```
{"$and":[OJAIQueryConditions]}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Description

Applies logical AND on a list of conditions. *`OJAIQueryConditions`* is a comma-separated list of OJAI query conditions.

Or

Syntax

```
{"$or":
[OJAIQueryConditi
ons]}
```

Description

Applies logical OR on a list of conditions. *`OJAIQueryConditions`* is a comma-separated list of OJAI query conditions.

Element And

Syntax

```
{

"$elementAnd":{

"containerFieldPa
th":

[OJAIQueryConditi
ons]
    }
}
```

NOTE: Supported starting in MapR 6.1.

Description

Applies multiple conditions as part of a group. All conditions must be true for a common array element.

`OJAIQueryConditions` is the comma-separated list of the OJAI query conditions.

`containerFieldPath` exhibits the following behaviors:

- *`containerFieldPa th`* specifies the container path prefix of the common container element.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- If *containerFieldPath* refers to a container of nested documents, then you must use field paths relative to the common prefix in your *OJAIQueryConditions* .
- If the *containerFieldPath* refers to a container of scalar values, then you use the $ symbol to refer to individual elements in your *OJAIQueryConditions*.

NOTE: There is no `elementOr` operator because it is semantically equivalent to an OR operator.

Related concepts

OJAI Query Condition Examples on page 3428
This section contains examples that show you how to use different OJAI query condition operators in combination with different field references and data types.

OJAI Query Conditions Using Container Field Paths on page 3431
Starting in MapR 6.1, HPE Ezmeral Data Fabric Database supports the notion of a *container field path*. A container field path enables you to perform comparisons on a field path that is either a single value or an arbitrary array element. You can use container field paths with arrays and nested documents, including nested documents with multiple levels of nesting and multidimensional arrays.

OJAI Query Conditions Using elementAnd on page 3434
The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

OJAI Query Condition Examples

This section contains examples that show you how to use different OJAI query condition operators in combination with different field references and data types.

The examples in this section use the following JSON documents:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "003", "name" : "Ipod 003", "tags" : 10 }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

Example	Documents Returned
`{"$exists":"tags.v"}` Matches documents where `tags` is a nested document that has a `v` subfield.	008
`{"$eq":{"tags":10}}` Matches documents where `tags` equals the scalar value 10.	003
`{"$eq":{"tags.t":"ipod"}}` Matches documents where `tags` is a nested document with a subfield `t` equal to "ipod".	005, 008
`{"$eq":{"tags":{"t":"ipod"}}}` Matches documents where `tags` is a nested document with a single subfield `t` equal to "ipod".	005
`{"$eq":{"tags":{"v":10,"t":"ipod"}}}` Matches documents where `tags` is a nested document with two subfields, `v` and `t`. `v` is equal to 10, and `t` is equal to "ipod". The order of subfields in the condition does not matter.	008
`{"$eq":{"tags":["electronics","ipod","apple"]}}` Matches documents where `tags` is an array with the three elements listed.	001
`{"$eq":{"tags":["ipod","electronics","apple"]}}` This example does not match any document, whereas the previous does, because the order of the elements in this example does not match the order in document 001.	None
`{"$between":{"tags":[5,15]}}` Matches documents where `tags` is a scalar value between 5 and 15.	003
`{"$like":{"tags[1]":"ip%"}}` Matches documents where the first array element in `tags` qualifies the wildcard string `"ip%"`	001, 004
`{"$typeof":{"tags":"map"}}` Matches documents where `tags` is a nested document.	005, 008
`{"$typeof":{"tags":"array"}}` Matches documents where `tags` is an array.	001, 004, 006, 007

©Copyright 2024 Hewlett Packard Enterprise Development LP

Example	Documents Returned
`{"$sizeof":{"tags":{"$ge":3}}}` Matches documents where the size of the data in `tags` is greater than or equal to three. • 001 matches because the array has three elements • 002 matches because the string is of length four • 004 matches because the nested document has three subfields	001, 002, 004
`{"$in":{"tags":["ipod", 10, {"t":"ipod"}]}}` Matches documents where `tags` equals any of the values listed. Note that the values can be of different types.	002, 003, 005
`{ "$and":[ {"$lt":{"tags[1].v":10}}, {"$matches":{"tags[1].t":"ap{2}"}} ] }` Matches documents where the first array element in `tags` has a nested document with a subfield `v` less than one, and the same nested document also matches the regular expression `"ap{2}"`.	007
`{ "$or":[ {"$exists":"tags.v"}, {"$typeof":{"tags":"string"}} ] }` Matches documents where either `tags` is a nested document with a subfield `v`, or `tags` is a scalar string.	002, 008

NOTE: You can improve the performance of queries with conditions by using secondary indexes. See Queries that Benefit from Secondary Indexes on page 687 for more details.

OJAI Query Conditions Using Container Field Paths
Starting in MapR 6.1, HPE Ezmeral Data Fabric Database supports the notion of a *container field path*. A container field path enables you to perform comparisons on a field path that is either a single value or an arbitrary array element. You can use container field paths with arrays and nested documents, including nested documents with multiple levels of nesting and multidimensional arrays.

Conditions with Container Field Paths on Arrays

If you have a field that has a single value rather than an array of values, when using the container notation, HPE Ezmeral Data Fabric Database treats the single value as an array with one element. This enables you to use a container field path to access a field that has both array elements and scalar values. The array elements and scalar values can be of any type.

Suppose you have the following set of documents:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "003", "name" : "Ipod 003", "tags" : 10 }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

To find all documents that contain the tag named `"ipod"`, you can use the following OJAI query condition, where you reference `tags` using a container field path:

```
{"$eq":{"tags[]":"ipod"}}
```

The expression matches the following documents, with the matching condition highlighted in bold:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
```

Note that the matching documents have the following characteristics:

- In 001 and 004, `tags` are array fields.
- In 002, `tags` is a scalar value.
- In 001 and 004, the `tags` arrays have elements in addition to `"ipod"`.

You can also use the `AND` operator to match multiple container field path conditions.

For example, the following condition finds all documents that have both `"ipod"` and `"apple"` tags:

```
{
    "$and":[
        {"$eq":{"tags[]":"ipod"}},
        {"$eq":{"tags[]":"apple"}}
    ]
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

The expression matches the following document, with the matching conditions highlighted in bold:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ]
```

Conditions with Container Field Paths on Nested Documents

You can also use the container field path in combination with a nested document subfield reference.

For example, using the same set of documents shown earlier, the following OJAI query condition finds all documents in which `"ipod"` is specified in the subfield named `t` within the `tags` nested document:

```
{"$eq":{"tags[].t":"ipod"}}
```

This expression returns the following documents, with the matching condition highlighted in bold:

```
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" : "ipod"
} ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

Note that the matching documents have the following characteristics:

- In 005 and 008, `tags` is a single nested document.
- In 006 and 007, `tags` is an array of nested documents.
- In 004, the `tags` array has both scalar data and a nested document.
- In 004 and 006, the `tags` array have other array elements that do not match the nested document subfield `t`.

Existence Conditions with Container Field Paths

Existence Operators on page 3423 check for the existence and non-existence of a specified field path. When you use `$exists` with a container field path, the specified field path can be any element in an array.

Using the same set of documents shown earlier, the following OJAI query condition finds all documents where the `tags` array has a nested document with a subfield `t`:

```
{"$exists":"tags[].t"}
```

The expression matches the following documents with the matching condition highlighted in bold:

```
{"_id":"004","name":"Ipod 004","tags":[10,"ipod",{"t":"ipod"}]}
{"_id":"005","name":"Ipod 005","tags":{"t":"ipod"}}
{"_id":"006","name":"Ipod 006","tags":[{"t":"ipod"},{"t":"apple"}]}
{"_id":"007","name":"Ipod 007","tags":[{"t":"ipod","v":10},
{"t":"apple","v":9}]}
```

When you use `$notexists` with a container field path, it matches *any* element in the array that does not meet the existence condition:

```
{"$notexists":"tags[].t"}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

The expression returns the following documents with the matching condition highlighted in bold:

```
{"_id":"001","name":"Ipod 001","tags":[**"electronics","ipod","apple"**]}
{"_id":"002","name":"Ipod 002","tags":**"ipod"**}
{"_id":"003","name":"Ipod 003","tags":**10**}
{"_id":"004","name":"Ipod 004","tags":[**10,"ipod"**,{"t":"ipod"}]}
```

Even document `004` has a `tags[].t` element, the other elements in that document's `tags` array do not; therefore, the document qualifies the condition.

Conditions with Container Field Paths Across Multiple Levels of Nested Documents

The following are examples of query conditions that match the sample document shown at Container Field Paths Across Multiple Levels of Nested Documents:

```
{"$eq":{"projects[].customer.contacts[].emails[].value":"jdoe@gmail.com"}}
```

```
{"$eq":{"projects[].customer.contacts[].role":"CEO"}}
```

Conditions with Container Field Paths on Multidimensional Arrays

The following examples reference documents that store the high and low temperatures for each day in a week. They use a two-dimensional array to store this data. The first element of each nested array element is the high temperature for a day, and the second element is the low. Typically, the two-dimensional array has seven array pairs, one for each day of the week. But in cases where data is unavailable, the document has only the days available.

For example, document 002 has a single dimensional array because it has data for only one day that week.

```
{
   "_id" : "001",
   "temps" : [[61,49],[74,51],[75,51],[74,52],[78,54],[75,53],[75,54]],
   "weekOf" : "4/29/2018"
}
{
   "_id" : "002",
   "temps" : [81,60],
   "weekOf" : "5/12/2018"
}
{
   "_id" : "003",
   "temps" : [[80,55],[78,54],[79,54],[77,53],[79,54],[77,54],[78,54]],
   "weekOf" : "5/13/2018"
}
```

As described at Container Field Paths with Multidimensional Arrays, you can specify a container field path in a dimension only if it does not precede a dimension that specifies an explicit element. For example, the following condition is not allowed because the first dimension specifies a container field path and precedes element 1 in the second dimension:

```
// Invalid condition
{"$ge":{"temps[][1]":60}}
```

The following table shows examples of conditions on multidimensional arrays that HPE Ezmeral Data Fabric Database supports:

©Copyright 2024 Hewlett Packard Enterprise Development LP

Example	Documents Returned
`{"$ge":{"temps[][]":60}}` Matches documents that have any temperature greater than 60. • Documents 001 and 003 match because all days have high temperatures above 60. • Document 002 matches because day 1 has a low temperature of 60. Although `temps` in this document is a one-dimensional array, the container notation treats it as a two-dimensional array.	001, 002, 003
`{"$ge":{"temps[1][]":75}}` Matches documents that have any temperature greater than 75 on the second day of the week	003
`{"$eq":{"temps[]":[78,54]}}` Matches documents that have a high and low temperature of 78 and 54 on the same day. • Day 5 from document 001 matches this condition. • Days 2 and 7 from document 003 match this condition.	001, 003

Related concepts

OJAI Query Conditions Using elementAnd on page 3434
The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

OJAI Query Conditions Using `elementAnd`

The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

Using `elementAnd` with Nested Documents

Assume that you have the following set of documents that reflect student scores on courses. Each document has an array of `grades`. `Grades` is a nested document that reflects how the students scored on each course they took.

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"score":12,"course":"history"},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"course":"history","score":12,"cmts":"..."},
{"course":"english","score":18}]}
{"_id":"003","grades":[{"course":"math","score":11},
{"course":"history","score":15},{"course":"english","score":12},
{"course":"sports","score":4}]}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
{"_id":"005","grades":[{"course":"math","score":15.5},
{"course":"history","score":10},{"course":"physics","score":11}]}
```

If you want to find the students who scored 12 in history, you use the following `elementAnd` condition:

```
{
    "$elementAnd":{
        "grades[]":[
            {"$eq":{"course":"history"}},
            {"$eq":{"score":12}}
        ]
    }
}
```

The condition matches the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"course":"history","score":12,"cmts":"..."},
{"course":"english","score":18}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

The example illustrates the following behavior:

- The positions of the subfields in the nested document are not significant.
- In document 002, there are other subfields in the nested document that do not match the specified conditions.

In contrast, the following example expresses a different condition, using `and` instead of `elementAnd`:

```
{
    "$and":[
        {"$eq":{"grades[].course":"history"}},
        {"$eq":{"grades[].score":12}}
    ]
}
```

This condition returns documents corresponding to students who have taken history and scored 12 on *any* course. The following are the matching documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"course":"history","score":12,"cmts":"..."},
{"course":"english","score":18}]}
{"_id":"003","grades":[{"course":"math","score":11},
{"course":"history","score":15},{"course":"english","score":12},
{"course":"sports","score":4}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

The example illustrates the following behavior:

- Besides returning the same documents as the previous `elementAnd` example, this condition also returns document 003.

©Copyright 2024 Hewlett Packard Enterprise Development LP

- Document 003 matches because that student took history and scored 12 on english, rather than history.
- Document 005 does not match because although the student took history, the student did not score 12 on any courses.

Using `elementAnd` with Scalar Values

If you apply `elementAnd` to a container of scalar values, you use the $ symbol to denote an unspecified container element.

Suppose you have the following documents:

```
{"_id" : "001", "name" : "a", "values" : [1, 2, 3, 6, 15] }
{"_id" : "002", "name" : "b", "values" : [3, 6, 9, 10, 15] }
{"_id" : "003", "name" : "c", "values" : [14] }
{"_id" : "004", "name" : "c", "values" : 11 }
```

To find all documents where `values[]` contains a number between 7 and 11 (inclusive), you can use the following condition:

```
{
    "$elementAnd":{
        "values[]":[
            {"$ge":{"$":7}},
            {"$le":{"$":11}}
        ]
    }
}
```

The condition returns the following documents, with the matching numbers highlighted in bold:

```
{"_id":"002","name":"b","values":[3,6,9,10,15]}
{"_id":"004","name":"c","values":11}
```

The example illustrates the following behavior:

- In document 002, multiple elements in the array match the condition.
- In document 004, `values` is a scalar value.

Suppose you apply the following condition that uses `and` instead of `elementAnd`:

```
{
    "$and":[
        {"$ge":{"values[]":7}},
        {"$le":{"values[]":11}}
    ]
}
```

All documents except 003 match this `and` condition because in the matching documents, `values[]` contains *some* number greater than or equal to 7 and *some* number less than or equal to 11. The difference is that the same number does not need to match both conditions, which is the case for document 001.

Using `between` with `elementAnd`

You cannot use a container field path in a `between` condition. To use the `between` operator to match against an arbitrary array element, you must include the `between` condition in an `elementAnd` condition.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

The following table shows the proper way to specify a `between` condition that is equivalent to the `elementAnd` example from the previous section:

Correct Condition	Incorrect Condition
`{ "$elementAnd":{ "values[]":[ {"$between":{"$":[7,11]}} ] } }`	`{"$between":{"values[]":[7,11]}}`

This example uses `between` to match against an arbitrary scalar array element. You can also use `between` to match against a subfield in a nested document, in which the nested document is an arbitrary array element.

For example, using the sample documents shown earlier, the following table shows the correct way to apply the `between` operator on the subfield `score` in the nested documents that are elements in the `grades` array:

Correct Condition	Incorrect Condition
`{ "$elementAnd":{ "grades[]":[ {"$between":{"score": [15.5,20]}} ] } }`	`{"$between":{"grades[].score": [15.5,20]}}`

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"cmts":"...","course":"history","score":12},
{"course":"english","score":18}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","details":{"info":"..."},"score":12}]}
{"_id":"005","grades":[{"course":"math","score":15.5},
{"course":"history","score":10},{"course":"physics","score":11}]}
```

Using Other Operators in `elementAnd` Conditions

You can also use operators like `or` in `elementAnd`'s query condition list.

For example, the following condition finds all students who scored 12 in either history or english:

```
{
    "$elementAnd":{
        "grades[]":[
            {"$or":[
                {"$eq":{"course":"history"}},
                {"$eq":{"course":"english"}}
            ]},
            {"$eq":{"score":12}}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
        ]
    }
}
```

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"cmts":"...","course":"history","score":12},
{"course":"english","score":18}]}
{"_id":"003","grades":[{"course":"math","score":11},
{"course":"history","score":15},{"course":"english","score":12},
{"course":"sports","score":4}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

Combining `elementAnd` with Other Operators

You can combine `elementAnd` with other operators like `and`.

For example, using the sample documents shown earlier, suppose you want to find all students who scored 12 in history as well scored 15.5 in math. The following condition expresses this criteria:

```
{
   "$and":[
      {
         "$elementAnd":{
            "grades[]":[
               {"$eq":{"course":"history"}},
               {"$eq":{"score":12}}
            ]
         }
      },
      {
         "$elementAnd":{
            "grades[]":[
               {"$eq":{"course":"math"}},
               {"$eq":{"score":15.5}}
            ]
         }
      }
   ]
}
```

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

Querying with HPE Ezmeral Data Fabric Database Shell

This section describes how to query JSON documents using either the `find` or `findbyid` command in HPE Ezmeral Data Fabric Database Shell (dbshell). It introduces the functionality the `find` command supports and describes the two ways to specify your queries. It also provides links to reference pages and examples.

The `findbyid` command allows you to retrieve a single document with a specified id from a HPE Ezmeral Data Fabric Database JSON table.

The `find` command allows you to specify projections and filter conditions (using JSON strings) to retrieve specific documents. It also allows you to specify the following options:

- Range of document IDs to retrieve
- Offset from which to start retrieval
- Order by to sort fields in the document
- Limit on the number of documents to retrieve

To invoke HPE Ezmeral Data Fabric Database shell, run the following command on a Data Fabric cluster node:

```
% mapr dbshell
```

For a complete list and description of options available, see dbshell find or findbyid on page 5732.

Alternatives for Writing Dbshell Query Commands

You can construct your dbshell queries in one of two ways:

- Use individual options in the `find` command
- Use the `--query` option in the `find` command and specify keywords as arguments to `--query`

The following example illustrates the differences between the two alternatives.

Suppose you want to query the table `/apps/tab` with the following criteria:

- Select fields `f1` and `f2`
- Limit the result to ten documents
- Skip the first two documents
- Filter documents where the field `f3` equals 15
- Sorts on field `f1`

Click on each of the following tabs to see the syntax for each alternative:

Use Individual Options in `find`

```
find /apps/tab --fields f1,f2 --limit
10 --offset 2 --where {"$eq":
{"f3":15}} --orderby f1
```

Use the `--query` Option in `find`

```
find /apps/tab --query {"$select":
["f1","f2"],"$limit":10,"$offset":2,"$
where":{"$eq":
{"f3":15}},"$orderby":"f1"}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

For more examples on how to use the two query alternatives, see the following links:

Use Individual Options in `find`	Use the `--query` Option in `find`
Query Examples with Other Options on page 5740	• Query with --query on page 5735 • Query with --orderby on page 5739

NOTE: With both options, you need to specify the query condition using OJAI Query Condition Syntax on page 3422.

Examples: Querying JSON Documents
This section provides query examples using the OJAI API. The examples include querying by document ID, retrieving all documents in a store, selecting individual fields, specifying query conditions, and ordering your query result. For reference, the examples also include the equivalent HPE Ezmeral Data Fabric Database Shell (dbshell) commands.

If you hover over the right hand side of all code examples, you can use the 
icon to copy and paste the code.

You can also download the code examples from github at https://github.com/mapr-demos/ojai-examples.git.

Querying By ID
The examples in this section show you how to query for a single document ID.

Java

This example retrieves a single document identified by the ID `user001`.

NOTE: To query for a range of document IDs, you must specify an OJAI QueryCondition. See Querying with Conditions on page 3457 for examples of the syntax.

        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Fetch the OJAI Document by its '_id' field
        var document = store.FindById("user0001");

        // Print the OJAI Document
        Console.WriteLine(document);

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

This example retrieves a single document identified by the ID `user0001`.

NOTE: To query for a range of document IDs, you must specify an OJAI Condition. See Querying with Conditions on page 3457 for examples of the syntax.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
        panic(err)
    }

    // Fetch the OJAI Document by its '_id' field
    doc, err := store.FindByIdString("id0001")
    if err != nil {
        panic(err)
    }

    // Print the OJAI Document
    fmt.Println(doc.AsJsonString())

    // Close connection
    connection.Close()
}
```

Querying and Returning All Documents
The examples in this section show you two ways of retrieving all documents from a document store.

Java - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.find method.

```
/**
 * Copyright (c) 2017 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License");
 * you may not use this file except in compliance with the License.
 * You may obtain a copy of the License at

    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following is the equivalent of the code examples using dbshell. See dbshell find or findbyid on page 5732 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> find /demo_table
```

C# - Example 1

The following example queries a document store and returns all documents by using the `GetAllDocuments` method.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindAllDocuments
{
    public async void FindAllDocuments()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Fetch all OJAI Documents from table
        var queryResult = store.Find();
        var documentStream = await queryResult.GetAllDocuments();

        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
        // Close the OJAI connection
        connection.Close();
    }
}
```

C# - Example 2

The following example queries a document store and returns all documents. It creates a `Query` object and passes that to the `DocumentStore.Find` method.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindAllQuery
{
    public async void FindAllQuery()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Build an OJAI query
        var query = connection.NewQuery().Build();

        // Options for find request
        var options = new QueryOptions()
        {
            IncludeQueryPlan = true,
            Timeout = 1000
        };

        // Fetch all OJAI Documents from table
        var queryResult = store.Find(query, options);

        // Get query plan
        Console.WriteLine(queryResult.GetQueryPlan());

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.FindAll function.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Fetch all OJAI Documents from table
    findResult, err := store.FindAll(&client.FindOptions{IncludeQueryPlan:
false, ResultAsDocument: true})

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Go - Example 2

The following example queries a document store and returns all documents. It creates a Query object and passes that to the DocumentStore.FindQuery function.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{IncludeQueryPlan: true,
ResultAsDocument: true}

    // Build an OJAI query
    query, err := client.MakeQuery()
    if err != nil {
        panic(err)
    }

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQuery(query, options)

    // Get query plan
    fmt.Println(findResult.QueryPlan())

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Paginating Your Result

An alternative to returning all documents from a store is to specify a limit in the query. Another alternative is to paginate the result using offset and limit. Querying with Order By on page 3470 contains an example that shows you how to use offset and limit. Although the example also uses order by, you can use offset and limit independent of order by.

Querying with Select

The examples in this section query a document store and retrieve specific fields from the documents.

NOTE: Selecting a specific field is also known as a *projection*. You can improve the performance of projection queries by using secondary indexes. See Using Indexes to Optimize Projections in Queries on page 698 for more details.

Python

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using an OJAI query.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$select": ["_id", "address.zipCode"]}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
    }

# fetch OJAI Documents by query
query_result = store.find(query, options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following two dbshell commands are equivalent to the code examples. See dbshell find or findbyid on page 5732 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> find /demo_table --query {"$select":["_id","address.zipcode"]}

maprdb root:> find /demo_table --fields _id,address.zipcode
```

C#

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using an OJAI query.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"_id",
"address.zipCode"}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Querying with Conditions

The examples in this section query a document store and return documents that have specific conditions.

For more information about how to specify query conditions in OJAI, see Query Conditions in OJAI Applications on page 3405.

NOTE: You can improve the performance of queries with conditions by using secondary indexes. See Queries that Benefit from Secondary Indexes on page 687 for more details.

Java - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the Query.where method. It uses an OJAI QueryCondition to specify the condition.

```
maprdb root:> find /demo_table --where {"$eq":
{"address.zipCode":95196}}
```

C# - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the `Query.Where` method. It uses an OJAI QueryCondition to specify the condition.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithCondition
{
    public async void FindQueryWithCondition()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        //Create an OJAI query
        var query = connection
            .NewQuery()
                .Where(connection
                        .NewQueryCondition()
                            .Is("address.zipCode", QueryOp.EQUAL, 95196)
                            .Close()
                        .Build())
                 .Build();

        // Fetch the OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document);
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

C# - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithConditionJson
{
    public async void FindQueryWithConditionJson()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI query
        var query =
            @"{" +
                @"""$where"":" +
                    @"{" +
                        @"""$eq"":{""address.zipCode"":
{""$numberLong"":""95196""}}" +
                    @"}" +
            @"}";

        // Fetch OJAI Documents by query
        var queryResult = store.FindQuery(query);

        var documentStream = await queryResult.GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the `Query.WhereCondition` function. It uses an OJAI Condition to specify the condition.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create a condition
    condition, err := client.MakeCondition(client.Is("address.zipCode",
client.EQUAL, 95196), client.Close())
    if err != nil {
        panic(err)
    }
    condition.Build()

    // Create an OJAI query
    query, err := client.MakeQuery(client.WhereCondition(condition))
    if err != nil {
        panic(err)
    }
    query.Build()

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQuery(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Go - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
package main

import (
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

NOTE: The commands are shown split across multiple lines for readability. When using dbshell, you must enter them in a single line.

C#

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses an OJAI query and condition.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithSelectAndCondition
{
    public async void FindQueryWithSelectAndCondition()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI condition
        var condition = connection
            .NewQueryCondition()
                .Is("address.zipCode", QueryOp.EQUAL, 95196)
                .Close()
            .Build();

        // Create an OJAI query
        var query = connection
            .NewQuery()
                .Select("name", "adress.zipCode", "age", "phoneNumbers[0]")
                .Where(condition)
            .Build();

        // Fetch OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses an OJAI query and condition.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"firstName",
"address.zipCode", "age", "phoneNumbers[0]"},
        "$where": map[string]interface{}{
            "$eq": map[string]interface{}{"address.zipCode": 95196}}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Querying with Order By

The examples in this section query a document store and return specific fields from the documents, sorted in a specific order. One of the examples also uses offset and limit.

©Copyright 2024 Hewlett Packard Enterprise Development LP

NOTE: You can improve the performance of order by queries by using secondary indexes. See Using Indexes to Optimize ORDER BY Queries on page 695 for more information.

Java - Order By

The following example shows how to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sorting the documents by `_id`. It uses the Query.select and Query.orderBy methods.

NOTE: The example sorts in the default ascending order. To sort in descending order, modify the `orderby` method call as follows:

```
orderBy("_id", SortOrder.DESC)
```

```

        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"_id",
"firstName", "lastName", "address.zipCode"},
        "$offset":  2,
        "$limit":   1,
        "$orderby": map[string]interface{}{"_id": "asc"}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Using the Java OJAI Client
This topic describes HPE Ezmeral Data Fabric Database functionality that is applicable to only the Java OJAI client. This includes instructions on how to compile your Java OJAI application, enable buffered writes, use the read your own writes feature, and enable available query options.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/java/src/main/java/com/mapr/ojai/examples

Compiling and Running Java OJAI Applications
For applications that use the Java OJAI API, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

Compile and Determine Dependencies

Use Maven to compile and determine the application dependencies.

1. Add MapR's Maven repository to your `pom.xml` file, if it is not already added:

```
<repositories>
    <repository>
        <id>mapr-releases</id>
        <url>https://repository.mapr.com/nexus/content/repositories/
releases</url>
        <snapshots><enabled>true</enabled></snapshots>
        <releases><enabled>true</enabled></releases>
    </repository>
</repositories>
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

2. Add a dependency to the MapR OJAI driver project:

```
<dependencies>
    <dependency>
        <groupId>com.mapr.ojai</groupId>
        <artifactId>mapr-ojai-driver</artifactId>
        <version>6.0.0-mapr</version>
    </dependency>
</dependencies>
```

   NOTE: Replace the `<version>` property with the HPE Ezmeral Data Fabric Database version that you are using.

3. Use Maven to compile the application and resolve dependencies.

Run the Application

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 3186.

When the cluster is secure, the node must also have a MapR ticket configured for the user that runs the application.

You can use the following command to launch HPE Ezmeral Data Fabric Database JSON applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

Enable OJAI Tracing

To help debug your Java OJAI application, you can enable OJAI tracing. MapR uses the `log4j` API to log tracing messages. To enable writing these messages to standard output, follow these steps:

1. Set the following property in your `/opt/mapr/conf/log4j.properties` file:

```
log4j.logger.com.mapr.ojai.store.impl=TRACE, stdout
```

2. Add the following to your `java` launch command:
   - In your java classpath, add the library that includes custom MapR `log4j` classes:

```
-cp /opt/mapr/lib/central-logging-7.9.0-mapr.jar:<other classpaths>:.
```

   - Define the location of the `log4j.properties` file:

```
-Dlog4j.configuration=file:/opt/mapr/conf/log4j.properties
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Reading Your Own Writes in Java OJAI

The Java OJAI `DocumentStore` and `Query` APIs provide the ability to track writes to JSON tables. Use these APIs to ensure your application reads recent writes on JSON tables with secondary indexes.

Description

You should use this feature if it is important for your query results to reflect synchronized data between a JSON table and its secondary indexes. Because HPE Ezmeral Data Fabric Database updates secondary indexes asynchronously, it is possible for a JSON table and its secondary indexes to become out-of-sync while the index update is in progress.

For example, consider the following scenario:

- Your application updates a JSON table.
- The JSON table includes an `address` field that is a nested document with a `zipCode` subfield.
- You have a secondary index on `zipCode`.
- Later in your application, you query the JSON table filtering on `zipCode`.

You want your query result to reflect the updates from earlier in your application. To achieve this, use the `DocumentStore` and `Query` APIs that enable you to retrieve up-to-date information from the index. The APIs synchronize write operations on the JSON table with read operations on a secondary index.

See Asynchronous Secondary Index Updates on page 705 for more information about index updates.

NOTE: The Python and Node.js OJAI APIs do not support this feature.

API Details

The OJAI `DocumentStore` and `Query` interfaces provide the following methods to support this functionality.

`DocumentStore.beginTrackingWrites`	Begins tracking the write operations performed through this instance of `DocumentStore`. The method takes an optional `previousWritesContext` parameter. If you specify this parameter, the tracking uses that context as the base state.
`DocumentStore.endTrackingWrites`	Flushes any buffered writes operations for this `DocumentStore` and returns a `writesContext`. Use this context to ensure that writes are visible to later queries. You can use the context across `DocumentStore` objects in the same, as well as different, client processes, when the stores refer to the same JSON table. For example, you can pass the `writesContext` returned by one `DocumentStore` to a second `DocumentStore`, to begin write tracking on the second store.
`DocumentStore.clearTrackedWrites`	Stops the write tracking and clears any state on this `DocumentStore` instance.
`Query.waitForTrackedWrites`	Sets the `writesContext` parameter for this query. A `writesContext` allows this query to "see" all the writes that happened inside the `writesContext` of a `DocumentStore`.

For the complete API, see Java OJAI Client API.

last-updated: Nov 14, 2024

Read Your Own Writes Example

A complete code example is available on github at OJAI_013_ReadYourOwnWrite.java. The following are code snippets from that example. Each step contains links to corresponding lines of code in the github example:

1. Call beginWriteTracking to set the starting point for the commit context on the JSON table `/demo_table`:

```
// Create an OJAI connection to MapR cluster
final Connection connectionNode1 =
DriverManager.getConnection("ojai:mapr:");

// Get an instance of OJAI DocumentStore
final DocumentStore storeNode1 = connectionNode1.getStore("/demo_table");

// initiate tracking of commit-context
storeNode1.beginTrackingWrites();
```

2. Update the `zipCode` of an existing user and insert a new user in `/demo_table`:

```
// issue a set of mutations/insert/delete/etc
storeNode1.update("user0000",
connectionNode1.newMutation().set("address.zipCode", 95110L));
storeNode1.insertOrReplace(connectionNode1.newDocument(
    "{\"_id\": \"user0004\", \"firstName\": \"Joel\",
\"lastName\": \"Smith\", \"age\": 56, \"address\": {\"zipCode\":
{\"$numberLong\":95110}}}"));
```

3. Call endWriteTracking to flush the write operations after step 1, including updates to the secondary index:

```
final String commitContext = storeNode1.endTrackingWrites();
```

   The call also returns a `commitContext`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

4. Issue a query that calls waitForTrackedWrites with the `commitContext` from step 3:

```
/*
 * Next section of the code can run on the same or on a different node,
 * the `commitContext` obtained earlier needs to be propagated to that
node.
 */

// Create an OJAI connection to MapR cluster
final Connection connectionNode2 =
DriverManager.getConnection("ojai:mapr:");

// Get an instance of OJAI DocumentStore
final DocumentStore storeNode2 = connectionNode2.getStore("/demo_table");

// Build an OJAI query and set its commit context with timeout of 2
seconds
final Query query = connectionNode2.newQuery()
    .select("_id", "firstName", "lastName", "address.zipCode")
    .where("{\"$gt\": {\"address.zipCode\": 95110}}")
    .waitForTrackedWrites(commitContext)
    .build();
```

   The query filters on the indexed subfield `address.zipCode`. The `commitContext` ensures that the query result includes the changes made in step 2.

Setting Query Options in Java OJAI
This topic describes how to set query options in your Java OJAI application.

See OJAI Query Options on page 3403 for a list of available query options.

To set an option, pass the option name as the first parameter to the Query.setOption method:

```
query.setOption("ojai.mapr.query.hint-using-index", indexName);
```

Enabling Buffered Writes in Java OJAI
By default, HPE Ezmeral Data Fabric Database JSON does not buffer writes. You can improve performance by enabling buffered writes in your Java OJAI application.

Description

The buffered writes option can be set in the Connection.getStore method. You pass the option setting through a `Document` object in the second parameter to the method. The `Document` object sets `ojai.mapr.documentstore.buffer-writes` to either `true` or `false`. The default value is `false`, which means that writes are not buffered.

Example Code Snippet

The following code sample enables buffered writes:

```
final DocumentStore store =
    connection.getStore(
        "/demo_table",

connection.newDocument().set("ojai.mapr.documentstore.buffer-writes",
true));
```

Using the Java OJAI Thin Client
Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write HPE Ezmeral Data Fabric Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the

©Copyright 2024 Hewlett Packard Enterprise Development LP

OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Java OJAI Thin Client Benefits

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface
- An OJAI interface that is tailored to Java developers
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

Comparing the Java OJAI Client and the Java OJAI Thin Client

Note these considerations when deciding whether to use the Java OJAI Client or the Java OJAI Thin Client:

- Both the Java OJAI client and Java OJAI Thin Client use the same API (Java OJAI Client API).
- The Java OJAI client is more scalable, more performant, and more fault tolerant, but also more complicated to deploy. See Using the Java OJAI Client on page 3481.
- The Java OJAI Thin Client requires you to specify the service (Data Fabric Data Access Gateway) to which you will connect.
- The Java OJAI Thin Client is a pure Java client, while the Java OJAI client requires a JNI library.

Installing the Data Fabric Data Access Gateway

To use the Java OJAI Thin Client, you must install the Data Fabric Data Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the Java OJAI Thin Client and the HPE Ezmeral Data Fabric cluster. To administer the gateway and configure load balancing, see Administering the Data Access Gateway on page 1948.

Java OJAI Thin Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Java OJAI Thin Client Connection String

The string you use to connect your OJAI client to a HPE Ezmeral Data Fabric cluster must have the following format:

```
"ojai:mapr:thin:@<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

<hostname>	Name of the HPE Ezmeral Data Fabric Data Access Gateway host
<port>	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3115) that gRPC clients use to connect to the HPE Ezmeral Data Fabric Data Access Gateway

©Copyright 2024 Hewlett Packard Enterprise Development LP

	Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only `basic`
user=<username>	The user name for `basic` authentication
password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and cluster security settings. The default for this option is `true`, which is the required setting if connecting to a secure HPE Ezmeral Data Fabric cluster. If connecting to a nonsecure HPE Ezmeral Data Fabric cluster, set it to `false`. If set to `false`, the other SSL parameters are ignored.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3512. Must be set if the `ssl` option is `true`.

Here is an example of a connection string:

```
"ojai:mapr:thin:@localhost:5678?
auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
```

Advanced Parameters

Advanced parameters such as `maxmsgsize` are optional for the Java OJAI Thin Client connection string:

maxmsgsize	If you use thin-client version `1.0.2-mapr` and later, `maxmsgsize` sets the maximum message size that the gRPC client accepts. The default is set to 32 MB, as this is the default maximum document size for HPE Ezmeral Data Fabric Database JSON tables. The value specified in the connection string should be less than or equal to the value set in the Data Access Gateway configuration on the server side (see Administering the Data Access Gateway on page 1948).

Maven Coordinates

The Maven coordinates are:

```
<dependency>
    <groupId>com.mapr.ojai</groupId>
    <artifactId>mapr-ojai-driver-thin</artifactId>
    <version>1.0.3-mapr</version>
</dependency>
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Additional Resources

The Java OJAI Client examples at the following location also apply to the Java OJAI Thin Client. Only the connection string and the Maven artifact name will be different for the thin client: https://github.com/mapr-demos/ojai-examples/tree/master/java/src/main/java/com/mapr/ojai/examples

Using the Node.js OJAI Client

Starting with EEP 6.0, you can use the Node.js OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON from middleware components, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface in Node.js
- An OJAI interface that is tailored to Node.js developers
- Support for Callback and Promise/Async Node.js asynchronous programming models
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing
- Use of JavaScript to manipulate HPE Ezmeral Data Fabric Database JSON documents

To use the Node.js OJAI client, you must install the Data Fabric Data Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the Node.js client and the HPE Ezmeral Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. See Administering the Data Access Gateway on page 1948 for information about how to administer the gateway and configure load balancing.

IMPORTANT: HPE Ezmeral Data Fabric does not support running the Node.js OJAI client in a web browser.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/nodejs

Source Code: https://github.com/mapr/maprdb-node-client

Getting Started with the Node.js OJAI Client

This section describes the software required to run the Node.js OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Node.js OJAI applications.

The Node.js OJAI client is available starting in the EEP 6.0 release.

Software Requirements

You must have the following software installed to run the client:

©Copyright 2024 Hewlett Packard Enterprise Development LP

Client Software	Installation Notes
Node.js	Supported versions: • 6.x • 8.x • 9.x • 10.x
Node.js OJAI client	Install the client by using the following command: `npm install node-maprdb`

You also must have access to the following software:

- MapR/Data Fabric cluster 6.1 or later
- Data Access Gateway 2.0 or later

To run a Node.js OJAI application, you simply need to install and configure the Data Access Gateway:

- Installing the Data Access Gateway Service on page 1948
- Modifying Configuration Settings for the Data Access Gateway Service on page 1949

Node.js OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Node.js OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

`<hostname>`	Name of the Data Access Gateway host. For information about the host name, see Configuring SSL for OJAI Clients on page 3512.
`<port>`	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3115) that gRPC clients use to connect to the Data Access Gateway Default: 5678
`auth=<scheme_name>`	The authentication scheme for the current connection; currently, only `basic`
`user=<username>`	The user name for `basic` authentication

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a non-secure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 1948.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3512. Required when the `ssl` option is set to `true`.

sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string.
	
	For example, imagine that you are using the following:
	• Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`.
	• Internal DNS is `node1.mydomain.com`.
	• CA signed certificate is issued to `node1.mydomain.com`.
	
	Using these names, you must specify the following connection string:
	
	`"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;`**`sslTargetNameOverride=node1.mydomain.com`**`"`
	
	Other examples of connection strings are the following:
	
	`"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"`
	`"localhost:5678?ssl=false;auth=basic;user=fred;password=george"`

Node.js OJAI Connection Retry Options

If your OJAI client cannot connect to your cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Connection Option Parameter	Description	Default Value
`ojai.mapr.rpc.wait-multiplier`	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
`ojai.mapr.rpc.wait-max-attempt`	Maximum wait time between attempts regardless of the multiplier parameter	18000 ms
`ojai.mapr.rpc.max-retries`	Maximum number of retry attempts	7

The following examples demonstrate how these parameters work, including the default case:

Attempt #	Wait Time (in ms) for each Retry Attempt	
	Default Parameters: `{ 'ojai.mapr.rpc.wait-multiplier': 1000, 'ojai.mapr.rpc.wait-max-attempt': 18000, 'ojai.mapr.rpc.max-retries': 7 }`	`{ 'ojai.mapr.rpc.wait-multiplier': 2, 'ojai.mapr.rpc.wait-max-attempt': 90, 'ojai.mapr.rpc.max-retries': 5 }`
1	10	10
2	10*1000 = 10000	10*2 = 20
3	18000 10000*1000 = 10,000,000, which exceeds 18000	20*2 = 40
4	18000	40*2 = 80
5	18000	90 80*2 = 160, which exceeds 90
6	18000	Error
7	18000	N/A
8	Error	N/A

To set these retry options, you must pass them in the `ConnectionManager.getConnection` call:

```
const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';
const options = {
  'ojai.mapr.rpc.wait-multiplier': 5,
  'ojai.mapr.rpc.wait-max-attempt': 50,
  'ojai.mapr.rpc.max-retries': 3
}

let connection;
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
ConnectionManager.getConnection(connectionString,options)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
```

Writing Node.js OJAI Applications

For information about writing a Node.js OJAI application, see the Node.js sections in the following topics:

Querying in OJAI Applications on page 3395	Provides an introduction to the basic flow of an OJAI application that queries a HPE Ezmeral Data Fabric Database JSON table
Examples: Querying JSON Documents on page 3440	Contains code samples of OJAI applications that query HPE Ezmeral Data Fabric Database JSON tables
Managing JSON Documents on page 3357	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Ezmeral Data Fabric Database JSON tables

Node.js OJAI Client Classes and Methods

This topic lists and describes the classes supported by the Node.js OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
`ConnectionManager`	Manages connections to HPE Ezmeral Data Fabric Database JSON.
`Connection`	Provides a logical connection to an OJAI data source: for example, HPE Ezmeral Data Fabric Database JSON.
`DocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Ezmeral Data Fabric Database JSON tables.
`QueryResult`	Encapsulates the stream of result sets for an OJAI query.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.

See Node.js OJAI Client API for details about each class, including the methods available in each class.

Setting Query Options in Node.js OJAI

There are two categories of options you can set in your Node.js OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a Node.js OJAI Method Call

Option Name	Description
`ojai.mapr.query.include-query-plan`	Enables or disables availability of the query plan for retrieval Value: `true|false` Default: `false`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Option Name	Description
`ojai.mapr.query.timeout-milliseconds`	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.find` method.

The following code snippet sets the query timeout to 3000 milliseconds:

```
const docStream = store.find(
    query,
    { 'ojai.mapr.query.timeout-milliseconds': 3000 }
);
```

Setting Query Options in Node.js Using OJAI Query Syntax

OJAI Query Options on page 3403 describes query options that are available in all OJAI clients. To use these options in Node.js OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the Python OJAI Client

Starting with EEP 6.0, you can use the Python OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface in Python
- An OJAI interface that is tailored to Python developers
- Use of Python types to manipulate HPE Ezmeral Data Fabric Database JSON documents
- Support for Python multiprocessing and multithreading modules
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the Python OJAI client, you must install the Data FabricData Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the Python client and the HPE Ezmeral Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. See Administering the Data Access Gateway on page 1948 for information about how to administer the gateway and configure load balancing.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/python

Source Code: https://github.com/mapr/maprdb-python-client

Getting Started with the Python OJAI Client

This section describes the software required to run the Python OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Python OJAI applications.

The Python OJAI client is available starting with the EEP 6.0 release.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Python	Use Python 2.7 or later
pip	See https://pip.pypa.io/en/stable/installing/ for instructions specific to your environment.
Python OJAI client	Install the client by using the following command: `pip install maprdb-python-client`

You also must have access to the following software:

- MapR/Data Fabric cluster 6.1 or later
- MapR Data Access Gateway 2.0 or later

To run a Python OJAI application, you simply need to install and configure the Data Access Gateway:

- Installing the Data Access Gateway Service on page 1948
- Modifying Configuration Settings for the Data Access Gateway Service on page 1949

Python OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Python OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

`<hostname>`	Name of the Data Access Gateway host. For information about the host name, see Configuring SSL for OJAI Clients on page 3512.
`<port>`	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3115) that gRPC clients use to connect to the Data Access Gateway Default: 5678
`auth=<scheme_name>`	The authentication scheme for the current connection; currently, only `basic`
`user=<username>`	The user name for `basic` authentication
`password=<password>`	The password for `basic` authentication

©Copyright 2024 Hewlett Packard Enterprise Development LP

ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a non-secure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 1948.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3512. Required when the `ssl` option is set to `true`.

sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string.
	
	For example, imagine that you are using the following:
	• Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`.
	• Internal DNS is `node1.mydomain.com`.
	• CA signed certificate is issued to `node1.mydomain.com`.
	
	Using these names, you must specify the following connection string:
	`"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;`**`sslTargetNameOverride=node1.mydomain.com`**`"`
	
	Other examples of connection strings are the following:
	`"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"`
	`"localhost:5678?ssl=false;auth=basic;user=fred;password=george"`

Python OJAI Connection Retry Options

If your OJAI client cannot connect to your cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

©Copyright 2024 Hewlett Packard Enterprise Development LP

Connection Option Parameter	Description	Default Value
`ojai.mapr.rpc.wait-multiplier`	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
`ojai.mapr.rpc.wait-max-attempt`	Maximum wait time between attempts regardless of the multiplier parameter	18000 ms
`ojai.mapr.rpc.max-retries`	Maximum number of retry attempts	7

The following examples demonstrate how these parameters work, including the default case:

Attempt #	Wait Time (in ms) for each Retry Attempt	

	Default Parameters:
	`{`
	`'ojai.mapr.rpc.wait-multiplier': 1000,`
	`'ojai.mapr.rpc.wait-max-attempt': 18000,`
	`'ojai.mapr.rpc.max-retries': 7`
	`}`
		`{`
		`'ojai.mapr.rpc.wait-multiplier': 2,`
		`'ojai.mapr.rpc.wait-max-attempt': 90,`
		`'ojai.mapr.rpc.max-retries': 5`
		`}`

1	10	10
2	10*1000 = 10000	10*2 = 20
3	18000 10000*1000 = 10,000,000, which exceeds 18000	20*2 = 40
4	18000	40*2 = 80
5	18000	90 80*2 = 160, which exceeds 90
6	18000	Error
7	18000	N/A
8	Error	N/A

To set these retry options, you must pass them in the `ConnectionFactory.get_connection` call:

```
connection_str = 'localhost:5678?auth=basic;user=mapr;password=mapr;' \
    'ssl=true;' \
    'sslCA=/opt/mapr/conf/ssl_truststore.pem;' \
    'sslTargetNameOverride=node1.mapr.com'
options = {
    'ojai.mapr.rpc.wait-multiplier': 5,
    'ojai.mapr.rpc.wait-max-attempt': 50,
    'ojai.mapr.rpc.max-retries': 3
}
connection =
ConnectionFactory.get_connection(connection_str=connection_str,options=optio
ns)
```

Writing a Python OJAI Application

For information about writing a Python OJAI application, see the Python sections in the following topics:

Querying in OJAI Applications on page 3395	Provides an introduction to the basic flow of an OJAI application that queries a HPE Ezmeral Data Fabric Database JSON table
Examples: Querying JSON Documents on page 3440	Contains code samples of OJAI applications that query HPE Ezmeral Data Fabric Database JSON tables
Managing JSON Documents on page 3357	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Ezmeral Data Fabric Database JSON tables

Python OJAI Client Classes and Methods

This topic lists and describes the classes supported by the Python OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
`Connection`	Provides a logical connection to an OJAI data source: for example, HPE Ezmeral Data Fabric Database JSON.
`ConnectionDriver`	Provides a connection handler, which enables you to get and check connections
`ConnectionManager`	Manages connections to HPE Ezmeral Data Fabric Database JSON.
`Document`	Provides the primary, DOM-based interface for inspecting OJAI documents.
`DocumentMutation`	Encapsulates a mutation to an existing OJAI document in a store.
`DocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Ezmeral Data Fabric Database JSON tables.
`DocumentStream`	Encapsulates the result set of an OJAI query.
`QueryResult`	Encapsulates the result set of an OJAI query.
`Query`	Encapsulates an OJAI query.
`QueryCondition`	Encapsulates a query condition; similar to a SQL `where` clause.
`Value`	Encapsulates the value of a field, scalar, or complex type in an OJAI document.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.
`OInterval`	Encapsulates the OJAI `INTERVAL` type.

See Python OJAI Client API for details about each class, including the methods available in each class.

Multiprocessing and Multithreading in Python OJAI Applications

Python supports multiprocessing and multithreading modules that enable you to spawn either multiple processes or multiple threads in a Python program. This section contains examples that show you how to use these modules in your Python OJAI application.

Multiprocessing in Python OJAI Applications

The following code example spawns multiple processes using the Python `multiprocessing` module. When you use the module, you must create a separate OJAI connection for each process.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

The code example is available at 014_multiprocessing_example.py.

```
"""Following example works with Python Client"""

import multiprocessing
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

"""Create a connection, get store, insert_or_replace/update document in
 store via multiprocessing"""

# Create a connection string using path:user@password
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"

# Create method which will be used for multiprocessing
def sample():
    # Create connection from connection_url
    # Cannot share connection for processes,
    # so need to create connection for each process.
    connection =
ConnectionFactory().get_connection(connection_str=connection_str)

    # Get a store and assign it as a DocumentStore object
    store = connection.get_or_create_store('/tmp/store_name')

    # Insert 15 documents, represented as Python dictionaries,
    # into DocumentStore
    for i in range(15):
        store.insert_or_replace(doc={'_id': str(i), 'name': 'Greg'})

    # Create DocumentMutation object using the OJAIConnection object
    mutation = connection.new_mutation()

    # Set mutation value
    mutation.set_or_replace(field_path='name', value='T')

    # Update 15 Document in store
    for i in range(15):
        store.update(_id=str(i), mutation=mutation)

# Create simple method for run process from Pool
def run(unused_var):
    pass

# Create data for multiprocessing
proces_count = 7
map_iterable = [1]  # simple iterator

# Create Pool object using the function and process_count value
p = multiprocessing.Pool(proces_count, initializer=sample)

# Run processes from the Pool
p.map(run, map_iterable)
```

last-updated: Nov 14, 2024

Multithreading in Python OJAI Applications

You can use either the Python `thread` or `threading` module to spawn multiple threads in your Python application. When you use these modules, you can share an OJAI connection across threads.

Thread Module

The following code example uses the `thread` module. It is available at 015_thread_example.py.

```
"""Following example works with
Python Client"""
import thread
import time
from
mapr.ojai.storage.ConnectionFactory
import ConnectionFactory

"""Create a connection, get store,
insert_or_replace/update document in
 store via thread using same
connection"""

# Create method which will be used
for threads
def run_thread(name, conn):
    # Print that thread started with
threadName
    print('\n Start thread ', name)

    # Get a store and assign it as a
DocumentStore object
    store =
conn.get_or_create_store('/tmp/
store_name')

    # Insert 15 documents,
represented as Python dictionaries,
    # into DocumentStore
    for index in range(15):

store.insert_or_replace(doc={'_id':
str(index), 'name': 'Greg'})

    # Create DocumentMutation object
using the OJAIConnection object
    mutation = conn.new_mutation()

    # Set mutation value

mutation.set_or_replace(field_path='na
me', value='T')

    # Update 15 Document in store
    for index in range(15):
        store.update(_id=str(index),
mutation=mutation)

    # Print that thread done with
threadName
    print('\n Done thread ', name)

# Create a connection string using
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
path:user@password
connection_str = "localhost:5678?
auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/
ssl_truststore.pem;" \

"sslTargetNameOverride=node1.mapr.com"

# Create connection from
connection_url
# Can share connection for processes,
# so need to only one connection
instance for all threads
connection =
ConnectionFactory.get_connection(conne
ction_str)

# Create 10 threads using the same
connection instance
for i in range(10):
    thread_name =
'Thread-{}'.format(str(i))

thread.start_new_thread(run_thread,
(thread_name, connection,))

# This thread implementation doesn't
return thread object
# so thread status cannot be checked
# Wait 10 seconds
time.sleep(10)

# Close connection
connection.close()
```

Threading Module

The following code example uses the `threading` module. It is available at 016_threading_example.py.

```
"""Following example works with
Python Client"""
import threading
import time

from
mapr.ojai.storage.ConnectionFactory
import ConnectionFactory

"""Create a connection, get store,
insert_or_replace/update document in
 store via thread using same
connection"""

# Create a connection string using
path:user@password
connection_str = "localhost:5678?
auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/
ssl_truststore.pem;" \
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
"sslTargetNameOverride=node1.mapr.com"

# Create connection from
connection_url
# Can share connection for processes,
# so need to only one connection
instance for all threads
connection =
ConnectionFactory.get_connection(conne
ction_str)

# Create child for sample threading
implementation
class MyThread(threading.Thread):
    # Implement __init__() method,
which takes thread name and
    # connection object
    def __init__(self, name,
connection):

threading.Thread.__init__(self)
        self.name = name
        self.connection = connection

    # Implement run() method
    def run(self):
        # Print that thread started
with threadName
        print('\n Start thread ',
self.name)

        # Get a store and assign it
as a DocumentStore object
        store =
connection.get_or_create_store('/tmp/
store_name')

        # Insert 15 documents,
represented as Python dictionaries,
        # into DocumentStore
        for index in range(15):

store.insert_or_replace(doc={'_id':
str(index), 'name': 'Greg'})

        # Create DocumentMutation
object using the OJAIConnection object
        mutation =
connection.new_mutation()

        # Set mutation value

mutation.set_or_replace(field_path='na
me', value='T')

        # Update 15 Document in store
        for index in range(15):

store.update(_id=str(index),
mutation=mutation)
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
        # Print that thread done with
threadName
        print('\n Done thread ',
self.name)

# This thread implementation return
thread object
# so thread status can be checked via
native methods
# Simple thread waiter for thread
list:
def waiter(threads):
    for my_thread in threads:
        # Check that current thread
is alive
        if my_thread.is_alive():
            time.sleep(1)
            # Wait until current
thread finished
            waiter(threads)
        # Move to the next thread if
this is not alive
        elif not my_thread.is_alive():
            pass

# Create list instance for storing
created threads objects
thread_list = []

# Create and run 10 threads
for i in range(10):
    # Create thread instance using
MyThread and OJAIConnection object
    thread =
MyThread(name='Thread-{0}'.format(str(
i)),

connection=connection)

    # Start current thread
    thread.start()

    # Append thread object into
thread_list
    thread_list.append(thread)

# Wait until all threads will finished
waiter(thread_list)

# Close connection
connection.close()
```

Setting Query Options in Python OJAI

There are two categories of options you can set in your Python OJAI application. This topic describes both and shows you how to set each.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Setting Query Options Using a Python OJAI Method Call

Option Name	Description
`ojai.mapr.query.include-query-plan`	Enables or disables availability of the query plan for retrieval Value: `True`|`False` Default: `False`
`ojai.mapr.query.result-as-document`	Enables or disables returning the query result as an OJAI `Document` class object versus a Python dictionary Value: `True`|`False` Default: `False`; returns query result as a Python dictionary
`ojai.mapr.query.timeout-milliseconds`	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the DocumentStore.find method.

The following code snippet sets the option to return the query result as a Document object:

```
options = {'ojai.mapr.query.result-as-document': True}
query_result = store.find(query, options=options)
```

Setting Query Options in Python Using OJAI Query Syntax

OJAI Query Options on page 3403 describes query options that are available in all OJAI clients. To use these options in Python OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the C# OJAI Client

Starting with EEP 6.1.0, you can use the C# OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface in C#
- An OJAI interface that is tailored to C# developers
- Use of C# types to manipulate HPE Ezmeral Data Fabric Database JSON documents
- Support for C# asynchronous programming and threading mechanism
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the C# OJAI client, you must install the Data Fabric Data Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the C# client and the HPE Ezmeral Data Fabric cluster. The gateway also performs data processing to keep the client

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

lightweight. See Administering the Data Access Gateway on page 1948 for information about how to administer the gateway and configure load balancing.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/csharp

Getting Started with the C# OJAI Client

This section describes the software required to run the C# OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write C# OJAI applications.

The C# OJAI client is available starting in the EEP 6.0.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Visual Studio 2017	https://visualstudio.microsoft.com/vs/

C# OJAI client	• Install the client by using the NuGet Command Line Interface (CLI).
	• Install the `MapRDB.Driver` using the NuGet Package Manager Console:
	`Install-Package MapRDB.Driver -Version 1.0.0`
	• Use the dotnet command line interface:
	`dotnet add package MapRDB.Driver`
	• Use the NuGet Package Manager UI. For instructions, follow this link.

You also must have access to the following software:

- MapR cluster 6.1 or later
- MapR Data Access Gateway 2.0 or later

To run a C# OJAI application, you simply need to install and configure the MapR Data Access Gateway:

- Installing the Data Access Gateway Service on page 1948
- Modifying Configuration Settings for the Data Access Gateway Service on page 1949

C# OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

©Copyright 2024 Hewlett Packard Enterprise Development LP

C# OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

<hostname>	Name of the Data Access Gateway host. For information about the host name, see Configuring SSL for OJAI Clients on page 3512.
<port>	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3115) that gRPC clients use to connect to the Data Access Gateway Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only `basic`
user=<username>	The user name for `basic` authentication
password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a non-secure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 1948.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3512. Required when the `ssl` option is set to `true`.
sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string. For example, imagine that you are using the following: • Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`. • Internal DNS is `node1.mydomain.com`. • CA signed certificate is issued to `node1.mydomain.com`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Using these names, you must specify the following connection string:

```
"ec2-203-0-113-25.compute-1.amazonaws.
com:5678?ssl=true;sslCA=/opt/app/conf/
rootca.pem;sslTargetNameOverride=node1
.mydomain.com"
```

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?
auth=basic;user=fred;password=george;s
slCA=/opt/app/conf/rootca.pem"
"localhost:5678?
ssl=false;auth=basic;user=fred;passwor
d=george"
```

C# OJAI Connection Retry Options

If your OJAI client cannot connect to your MapR cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
`retryExponentialMultiplier`	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
`retryCount`	Maximum number of retry attempts	7

To set these retry options, you must pass them in the `ConnectionFactory.CreateConnection` call:

```
var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
var connection = ConnectionFactory.CreateConnection(connectionStr, 3, 5);
```

Writing a C# OJAI Application

For information about writing a C# OJAI application, see the C# sections in the following topics:

Querying in OJAI Applications on page 3395	Provides an introduction to the basic flow of an OJAI application that queries a HPE Ezmeral Data Fabric Database JSON table
Examples: Querying JSON Documents on page 3440	Contains code samples of OJAI applications that query HPE Ezmeral Data Fabric Database JSON tables
Managing JSON Documents on page 3357	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Ezmeral Data Fabric Database JSON tables

©Copyright 2024 Hewlett Packard Enterprise Development LP

C# OJAI Client Classes and Methods

This topic lists and describes the classes supported by the C# OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
`Value`	Encapsulates the value of a field, scalar, or complex in an OJAI document.
`OjaiDocument`	Provides the primary, DOM-based interface for inspecting OJAI documents
`OjaiDocumentStream`/ `QueryResult`	Encapsulates the result set of an OJAI query.
`OjaiDocumentMutation`	Encapsulates a mutation to an existing OJAI document in a store.
`Query`	Encapsulates an OJAI query.
`QueryCondition`	Encapsulates a query condition; similar to a SQL `where` clause.
`ConnectionFactory`	Provides a logical connection to an OJAI data source: for example, HPE Ezmeral Data Fabric Database JSON.
`MapRDBConnection`	Provides a connection handler, which enables you to get and check connections.
`OjaiDocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Ezmeral Data Fabric Database JSON tables.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.
`OInterval`	Encapsulates the OJAI `INTERVAL` type.

See the C# OJAI Client API for details about each class, including the methods available in each class.

Setting Query Options in C# OJAI

There are two categories of options you can set in your C# OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a C# OJAI Method Call

Option Name	Description
`IncludeQueryPlan`	Enables or disables availability of the query plan for retrieval Value: `true|false` Default: `false`
`Timeout`	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.Find` method.

The following code snippet sets the query timeout to 3000 milliseconds:

```
var queryResult = store.Find(query, new QueryOptions() { Timeout = 3000 });

var queryResult = store.Find(query, new QueryOptions(3000));
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Setting Query Options in C# Using OJAI Query Syntax

OJAI Query Options on page 3403 describes query options that are available in all OJAI clients. To use these options in C# OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the Go OJAI Client

Starting with EEP 6.0.0, you can use the Go OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface in Go
- An OJAI interface that is tailored to Go developers
- Use of Go types to manipulate HPE Ezmeral Data Fabric Database JSON documents
- Support for Go multithreading using Goroutines
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the Go OJAI client, you must install the Data Fabric Data Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the Go client and the HPE Ezmeral Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. To administer the gateway and configure load balancing, see Administering the Data Access Gateway on page 1948.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/golang

Source Code: https://github.com/mapr/maprdb-go-client

Getting Started with the Go OJAI Client

This section describes the software required to run the Go OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Go OJAI applications.

The Go OJAI client is available starting in the EEP 6.0.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Golang 1.10 (or later)	
Go OJAI client	Install the client using the following command: `go get github.com/mapr/maprdb-go-client`

You also must have access to the following software:

- MapR cluster 6.1 or cluster from later versions of Data Fabric
- Data Access Gateway 2.0 or later

©Copyright 2024 Hewlett Packard Enterprise Development LP

To run a Go OJAI application, you must install and configure the Data Access Gateway:

- Installing the Data Access Gateway Service on page 1948
- Modifying Configuration Settings for the Data Access Gateway Service on page 1949

For some sample code, see https://github.com/magpierre/mapr_go_client_mqtt. `main.go` shows a simple Go client that reads from an MQTT messaging protocol and writes to a data-fabric JSON database.

Go OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Go OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

<hostname>	Name of the Data Access Gateway host
<port>	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3115) that gRPC clients use to connect to the Data Access Gateway Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only `basic`
user=<username>	The user name for `basic` authentication
password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a nonsecure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 1948.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3512.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Must be set if the `ssl` option is `true`.

`sslTargetNameOverride=<CA certificate common name>`

Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string.

For example, imagine that you are using the following:

- Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`.
- Internal DNS is `node1.mydomain.com`.
- CA signed certificate is issued to `node1.mydomain.com`.

Using these names, you must specify the following connection string:

```
"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;sslTargetNameOverride=node1.mydomain.com"
```

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
"localhost:5678?ssl=false;auth=basic;user=fred;password=george"
```

`sslValidate=true|false`

When `ssl=true`, indicates whether or not the client should validate the server certificate against a list of CA certificates. The default is `true`.

Go OJAI Connection Retry Options

If your OJAI client cannot connect to your data-fabric cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
`MaxAttempt`	Maximum number of retry attempts	9
`WaitBetweenSeconds`	Maximum wait time between attempts	12 s
`CallTimeoutSeconds`	Maximum call timeout	60 s

To set these retry options, you must pass them in the `client.MakeConnectionWithRetryOptions` call:

```
    connectionString := "localhost:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
        "sslTargetNameOverride=node1.cluster.com"
    options := &client.ConnectionOptions{MaxAttempt:3,
WaitBetweenSeconds:10, CallTimeoutSeconds:60}
    connection, _ :=
client.MakeConnectionWithRetryOptions(connectionString, options)
```

Writing a Go OJAI Application

For information about writing a Go OJAI application, see the Go sections in the following topics:

Querying in OJAI Applications on page 3395	Provides an introduction to the basic flow of an OJAI application that queries a HPE Ezmeral Data Fabric Database JSON table
Examples: Querying JSON Documents on page 3440	Contains code samples of OJAI applications that query HPE Ezmeral Data Fabric Database JSON tables
Managing JSON Documents on page 3357	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Ezmeral Data Fabric Database JSON tables

Go OJAI Client Structures and Functions

This topic lists and describes the structures supported by the Go OJAI client and provides a link to document pages that describe the functions in each structure.

Structure Name	Description
`Document`	Provides the primary, DOM-based interface for inspecting OJAI documents.
`QueryResult`	Encapsulates the result set of an OJAI query.
`DocumentMutation`	Encapsulates a mutation to an existing OJAI document in a store.
`Query`	Encapsulates an OJAI query.
`Condition`	Encapsulates a query condition; similar to a SQL `where` clause.
`Connection`	Provides a logical connection to an OJAI data source: for example, HPE Ezmeral Data Fabric Database JSON.
`DocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Ezmeral Data Fabric Database JSON tables.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.

For details about each structure, including the functions available in each structure, see the Go OJAI Client API.

Setting Query Options in Go OJAI

There are two categories of options you can set in your Go OJAI application. This topic describes both and shows you how to set each.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Setting Query Options Using a Go OJAI Function Call

Option Name	Description
`IncludeQueryPlan`	Enables or disables availability of the query plan for retrieval. Value: `true|false` Default: `false`
`ResultAsDocument`	Enables or disables returning the query result as an OJAI `Document` object list versus a Go map list. Value: `True|False` Default: `False`: returns query result as a Go map list
`Timeout`	Query timeout in milliseconds. Maximum allowed value is 2147483647 Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.FindQueryWithContext` function.

The following code snippet sets the query timeout to 3000 milliseconds:

```
timeoutCtx, cancel := context.WithTimeout(context.Background(),
time.Duration(3*time.Second))
result, err := suite.store.FindQueryWithContext(query, findOptions,
timeoutCtx)
cancel()
```

Setting Query Options in Go Using OJAI Query Syntax

OJAI Query Options on page 3403 describes query options that are available in all OJAI clients. To use these options in Go OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Configuring SSL for OJAI Clients
Describes certificates and how to configure SSL for OJAI clients, including which PEM file to point to and how to determine which DAG host name to use.

The process of installing Data Fabric with security enabled automatically generates default `ssl_keystore` and `ssl_truststore` files on the first CLDB server used by all clients and servers. Data Access Gateway (DAG) and other cluster services use these certificates to perform authentication and encryption for websites that use the HTTPS protocol.

The certificates are generated in the `/opt/mapr/conf` directory under `ssl_truststore.*` and `ssl_keystore.*`. The `ssl_truststore.*` files contain the client side certificates (signer for the certificate in the `ssl_keystore`). The `ssl_keystore.*` files contain the server side certificates (a single self-signed certificate with a wildcard SubjectDN).

When you configure a client to connect to a cluster, you create a connection string. If the connection is SSL enabled, you must include the path to the certificate of trust. You can either configure the client to use the default certificates or you can point to custom certificates. However, if the certificate on the server side is signed using a real certificate signing authority, you do not need to include an `ssl_truststore` in the connection string because the default `ssl_truststore` will recognize the signed certificate.

For additional information, see SSL Certificates on page 817.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Using the Default Certificates Generated by Data Fabric

For an application running on a cluster node, provide the path to the PEM file, as shown in the following example:

```
sslCA=/opt/mapr/conf/ssl_truststore.pem
```

For an application that is not running on a cluster node, copy the `ssl_truststore.pem` file from `/opt/mapr/conf/` to a location on the non-cluster node and then specify the path to the `ssl_truststore.pem` file:

```
sslCA=/path/to/certificate/ssl_truststore.pem
```

Using Custom Certificates

If an administrator created custom certificates for the cluster (as described in SSL Certificates on page 817), the certificates must have an equivalent truststore in PEM format. Create a PEM version of the truststore file and use that PEM file with the clients. For example, `sslCA=/path/to/custom/certificates/ssl_truststore.pem`.

For additional information, see Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a Cluster.

Determining which DAG Host Name to Use

Open the `ssl_truststore.pem` file and locate the certificate with `Subject = C`. The certificate with `Subject = C` also has a CN host name. Use this CN host name.

If you see a wildcard character (*) instead of a file name, you can use any host that is running DAG and suffix it with `.ec2.internal`, as shown:

```
*.ec2.internal
```

Using the HPE Ezmeral Data Fabric Database JSON REST API

Starting in the EEP 5.0 release, you can use a REST API to access HPE Ezmeral Data Fabric Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on HPE Ezmeral Data Fabric Database JSON tables.

The API supports the following operations:

- Create and delete HPE Ezmeral Data Fabric Database JSON tables
- Insert, update, and delete documents from a table
- Retrieve documents while specifying filter conditions and projections

The REST API has the following characteristics:

- Operations are stateless
- Operations are synchronous
- Request responses are not buffered
- Web connections are secure when connecting to secure MapR clusters
- Supports the following methods of authentication:
  - Basic authentication

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

  - Token-based authentication using JSON Web Tokens (JWT)
- Supports user impersonation - All data access calls are run on behalf of the authenticated user
- Returns HTTP error codes and detailed error responses in the response message body

When connecting to a MapR cluster, you must use HTTPS in your requests.

With basic authentication, you pass a username and password in your Web client. With token based authentication, you generate a token and then pass the token in the header of subsequent API requests.

The MapR Data Access Gateway is the service that supports this web API. You should configure multiple instances of this service across your MapR cluster to distribute request processing. To achieve load balancing, you must install an external load balancer. Using token based authentication and an external load balancer, you can achieve high availability and failover. Because the REST API is stateless, you do not have to regenerate your authentication token when different service instances process your API request. This applies even in the event of failovers and service restart. You must regenerate your token when it expires.

The API does not support the following features:

- HPE Ezmeral Data Fabric Database JSON administrative commands, except the commands noted earlier
- Read Your Own Writes

To modify properties that the HPE Ezmeral Data Fabric Database JSON REST API uses, see Application Properties.

Related concepts

Understanding the HPE Ezmeral Data Fabric Data Access Gateway on page 1003
The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster.

Administering the Data Access Gateway on page 1948
The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Getting Started with the HPE Ezmeral Data Fabric Database JSON REST API

A simple way to invoke the HPE Ezmeral Data Fabric Database JSON REST API is to use cURL commands. This section contains a sequence cURL commands that demonstrate the basic functionality of the API.

NOTE: The HPE Ezmeral Data Fabric Database JSON REST API is available starting in the EEP 5.0 release.

The operations shown are the following:

- Create a HPE Ezmeral Data Fabric Database JSON table
- Insert documents into the table
- Retrieve documents from the table, including retrievals that contain field projections and conditions
- Update individual documents and fields within a document

To learn about the complete API, see the reference material at Understanding the HPE Ezmeral Data Fabric Database JSON REST API on page 3520.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

The examples in this section assume that you installed the Data Fabric Data Access Gateway on the host `10.10.100.42`. The examples use HTTPS with the default HTTPS port of `8243`. For information about installing the Data Access Gateway, see Installing the Data Access Gateway Service on page 1948.

NOTE: The examples URL encode the slashes in the table path (%2F) to differentiate them from the slashes in the command API.

Using Basic Authentication

The commands in this section use basic authentication. To use this form of authentication, you must pass the username and password in all commands, using the `-u` option.

1. Create a HPE Ezmeral Data Fabric Database JSON table in the path `/apps/employees`:

```
curl -X PUT \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

2. Insert 3 documents into the table:

```
curl -X POST \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr \
  -H 'Content-Type: application/json' \
  -d '[{"_id":"user001","first_name":"John","last_name":"Doe"},
 {"_id":"user002","first_name":"Jane","last_name":"Doe"},
 {"_id":"user003","first_name":"Simon","last_name":"Davis"}]'
```

3. Retrieve all of the documents:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F' \
  -u root:mapr
```

   The command returns the following:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        },
        {
            "_id": "user003",
            "first_name": "Simon",
            "last_name": "Davis"
        }
    ]
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

4. Limit the GET request to 2 documents starting at offset 1:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F?
offset=1&limit=2' \
  -u root:mapr
```

The command returns the following:

```
{
    "DocumentStream": [
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        },
        {
            "_id": "user003",
            "first_name": "Simon",
            "last_name": "Davis"
        }
    ]
}
```

5. Retrieve only the first names in the documents:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
fields=first_name' \
  -u root:mapr
```

The command returns the following:

```
{
    "DocumentStream": [
        {
            "first_name": "John"
        },
        {
            "first_name": "Jane"
        },
        {
            "first_name": "Simon"
        }
    ]
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

6. Retrieve all documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}' \
  -u root:mapr
```

NOTE: You must pass `'-g'` in the cURL command due to the nested braces in the condition.

The command returns 2 documents:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        }
    ]
}
```

7. Retrieve the id and first name of documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}&fields=_id,first_name' \
  -u root:mapr
```

NOTE: You must pass `'-g'` in the cURL command due to the nested braces in the condition.

The command returns the following:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John"
        },
        {
            "_id": "user002",
            "first_name": "Jane"
        }
    ]
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

8. Run the same command, also retrieving the query plan:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":
{"last_name":"Doe"}}&fields=_id,first_name&getPlan=true' \
  -u root:mapr
```

   The output includes the query plan:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John"
        },
        {
            "_id": "user002",
            "first_name": "Jane"
        }
    ],
    "QueryPlan": [
        [
            {
                "streamName": "DBDocumentStream",
                "parameters": {
                    "queryConditionPath": true,
                    "projectionPath": [
                        "_id",
                        "first_name"
                    ],
                    "primaryTable": "/apps/employees"
                }
            }
        ]
    ]
}
```

9. Update the first name in one of the documents, specifying the `id` in the command:

```
curl -X POST \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"$set":{"first_name":"Jay"}}'
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

10. Retrieve the updated document, specifying the `id` in the command:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -u root:mapr
```

The document contains an updated first name:

```
{
    "_id": "user001",
    "first_name": "Jay",
    "last_name": "Doe"
}
```

11. Replace the same document, but this time with a user who has only a first name:

```
curl -X PUT \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"_id":"user001","first_name":"Jonathan"}'
```

12. Retrieve the new document by passing the `id` in the request:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -u root:mapr
```

The document contains only a first name:

```
{
    "_id": "user001",
    "first_name": "Jonathan"
}
```

Using Token-Based Authentication

To use token-based authentication, you first create a token, authenticating with a username and password. You then pass the generated token in all subsequent commands.

1. Generate a token using the following command:

```
curl -X POST \
  'https://10.10.100.42:8243/auth/v2/token' \
  -u root:mapr
```

The command returns the following token:

```
{
    "token":
"eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJyb290IiwiYXVkIjoid2ViIiwiZXhwIjoxNTIwMjY
5MTQwLCJpYXQiOjE1MjAyNjczNDB9.NT8L2deiA6v55bfbU_opiG1XXGPP0IwfSex3jW5A1Zs
oI1ar09it7-XwNtRqfL_I29IHLyfmuHcT5eSIpwq6ng"
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

2. Pass the token in your cURL command, as shown in the following GET:

```
curl -X GET \
  https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees \
  -H 'Authorization:
Bearer
eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJyb290IiwiYXVkIjoid2ViIiwiZXhwIjoxNTIwMjY5MTQwLCJpYXQiOjE1MjAyNjczNDB9.NT8L2deiA6v55bfbU_opiG1XXGPP0IwfSex3jW5A1Zso
I1ar09it7-XwNtRqfL_I29IHLyfmuHcT5eSIpwq6ng'
```

Understanding the HPE Ezmeral Data Fabric Database JSON REST API
The section describes the details of the HPE Ezmeral Data Fabric Database JSON REST API.

The following table summarizes the commands the API supports. Click on the command for details about the command parameters and examples.

Category	REST API Command	Description
Authentication	POST /auth/v2/token on page 3520	Creates an authentication token
Table Operations	PUT /api/v2/table/{path} on page 3521	Creates a HPE Ezmeral Data Fabric Database JSON table
	DELETE /api/v2/table/{path} on page 3521	Drops a HPE Ezmeral Data Fabric Database JSON table
Table Document Operations	POST /api/v2/table/{path} on page 3522	Adds one or more documents to a HPE Ezmeral Data Fabric Database JSON table
	PUT /api/v2/table/{path}/document/{id} on page 3522	Updates a document by id in a HPE Ezmeral Data Fabric Database JSON table
	POST /api/v2/table/{path}/document/{id} on page 3523	Updates a partial document by id in a HPE Ezmeral Data Fabric Database JSON table using mutations
	DELETE /api/v2/table/{path}/document/{id} on page 3524	Deletes a single document by id in a HPE Ezmeral Data Fabric Database JSON table
	GET /api/v2/table/{path} on page 3525	Retrieves one or more documents from a HPE Ezmeral Data Fabric Database JSON table
	GET /api/v2/table/{path}/document/{id} on page 3528	Retrieves a single document by id from a HPE Ezmeral Data Fabric Database JSON table

POST /auth/v2/token
Authenticates a user. If successful, creates an authentication token that you use in subsequent API requests. By default, the token expires in 30 minutes. After a token expires, you must rerun this command to generate a new token.

Request Example

The following creates an authentication token for user `root`:

```
curl -X POST \
  'https://10.10.100.42:8243/auth/v2/token' \
  -u root:mapr
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Response Example

```
200 OK

{
  "token":
"eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJtYXByIiwiYXVkIjoid2ViIiwiZXhwIjoxNTE2NzQ2MD
c4LCJpYXQiOjE1MTY3NDQyNzh9.6YXWX72UP9_U9DPmT8c-_DQRDwY_TL0DEdsBaBqoaLf8iK0qH
NctyBTbFO5ktUJMTubVOj6D7pFOEyEuV8lhjA"
}
```

For an example that shows how to use the token returned by this API call in a subsequent `GET` command, see Using Token-Based Authentication on page 3519.

PUT /api/v2/table/{path}
Creates a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the new HPE Ezmeral Data Fabric Database JSON table

Request Example

The following creates a table with the path `/apps/employees`:

```
curl -X PUT \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps/employees' \
  -u root:mapr
```

Response Example

```
201 Created
```

DELETE /api/v2/table/{path}
Drops a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table

Request Example

The following drops a table with the path `/apps/employees`:

```
curl -X DELETE \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u <username>:<password>
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Response Example

```
200 OK
```

POST /api/v2/table/{path}
Adds or replaces one or more documents in a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
fieldAsKey `string` *(query)*	The name of the field that serves as the key in the JSON document
mode `string` *(query)*	Defines the behavior of the operation. The following are the possible values: • `insertOrReplace` - Inserts new document if specified document ID does not exist; otherwise, replaces existing document specified by the ID. • `insert` - Inserts new document; if the specified document ID already exists, returns an error. • `replace` - Replaces document with specified ID; returns an error if document does not exist. Default: `insertOrReplace`
body *(body)*	The body of the documents to add or replace

Request Example

The following inserts 3 documents into `/apps/employees`:

```
curl -X POST \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr \
  -H 'Content-Type: application/json' \
  -d '[{"_id":"user001","first_name":"John","last_name":"Doe"},
 {"_id":"user002","first_name":"Jane","last_name":"Doe"},
 {"_id":"user003","first_name":"Simon","last_name":"Davis"}]'
```

Response Example

```
200 OK
```

PUT /api/v2/table/{path}/document/{id}
Updates a single document by id in a HPE Ezmeral Data Fabric Database JSON table

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
id `string` *(path)*	**Required**: Id of the document to update. If the document with the specified id does not exist, the mode parameter determines the behavior.
condition `string` *(query)*	Query condition (in JSON format) used to perform OJAI `DocumentStore.checkAndReplace` evaluation. See OJAI Query Condition Syntax on page 3422 for a description of the syntax.
mode `string` *(query)*	Defines the behavior of the operation. The following are the possible values: • `insertOrReplace` - Inserts new document if specified document ID does not exist; otherwise, replaces existing document specified by the ID. • `insert` - Inserts new document; if the specified document ID already exists, returns an error. • `replace` - Replaces document with specified ID if it exists Default: `insertOrReplace`
body *(body)*	**Required**: The body of the new document

Request Example

The following replaces the document with id `user001` in `/apps/employees` with an employee who has only a first name:

```
curl -X PUT \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"_id":"user001","first_name":"Jonathan"}'
```

Response Example

```
200 OK
```

POST /api/v2/table/{path}/document/{id}
Updates a partial document by id in a HPE Ezmeral Data Fabric Database JSON table using mutations

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
id `string` *(path)*	**Required**: Id of the document to update. If the document does not exist, inserts a new document.
condition `string` *(query)*	Query condition (in JSON format) used to perform OJAI `DocumentStore.checkAndUpdate` evaluation. See OJAI Query Condition Syntax on page 3422 for a description of the syntax.
body *(body)*	**Required**: The mutation specifying updates to the document. See Using OJAI Mutation Syntax on page 3377 for a description of the syntax.

Request Example

The following updates the `first_name` field the document in `/apps/employees` with id `user001`, replacing the field with the value `Jay`:

```
curl -X POST \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"$set":{"first_name":"Jay"}}'
```

Response Example

```
200 OK
```

DELETE /api/v2/table/{path}/document/{id}
Deletes a single document by id in a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
id `string` *(path)*	**Required**: Id of the document to delete
condition `string` *(query)*	Query condition (in JSON format) used to perform OJAI `DocumentStore.checkAndDelete` evaluation. See OJAI Query Condition Syntax on page 3422 for a description of the syntax.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Request Example

The following deletes the document with id `user003` in `/apps/employees`:

```
curl -X DELETE \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user003' \
  -u <username>:<password>
```

Response Example

```
200 OK
```

GET /api/v2/table/{path}
Retrieves one or more documents from a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
condition `string` *(query)*	Query condition (in JSON format) to evaluate on documents retrieved. See OJAI Query Condition Syntax on page 3422 for a description of the syntax.
fields `string` *(query)*	The fields from the document to retrieve. See JSON Document Field Paths on page 630 for details about how to specify field paths.
fromId `string` *(query)*	Starting id of the range of documents to retrieve (inclusive)
toId `string` *(query)*	Ending id of the range of documents to retrieve (exclusive)
getPlan `string` *(query)*	If set to `true`, returns the query plan used to retrieve the documents Value: True|False Default: False
limit `integer` *(query)*	The maximum number of documents to retrieve
offset `integer` *(query)*	The number of documents to skip past before returning results

©Copyright 2024 Hewlett Packard Enterprise Development LP

Name	Description
orderBy `string` *(query)*	The fields on which to sort the result. Specify the fields in a comma separated list, in the format `<field name>:<sort order>` where `<sort order>` is either `asc` or `desc`. `<sort order>` is optional and defaults to `asc`.
query `string` *(query)*	Query string with predefined keywords that define the behavior of the query. See Query with --query on page 5735 for syntax details.
withTags `string` *(query)*	Enables or disables output with extended type tags Value: True|False Default: True

Request Examples

1. The following retrieves all documents from `/apps/employees`:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

2. The following specifies an offset and limit in the GET request:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F?
offset=1&limit=2' \
  -u root:mapr
```

3. The following retrieves only the first names in the documents:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
fields=first_name' \
  -u root:mapr
```

4. The following retrieves all documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}' \
  -u root:mapr
```

NOTE: You must pass `'-g'` in the cURL command due to the nested braces in the condition.

5. The following retrieves the id and first name of documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}&fields=_id,first_name' \
  -u root:mapr
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

6. The following runs the same command and includes a request for the query plan:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":
{"last_name":"Doe"}}&fields=_id,first_name&getPlan=true' \
  -u root:mapr
```

Response Examples

```
200 OK

{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        },
        {
            "_id": "user003",
            "first_name": "Simon",
            "last_name": "Davis"
        }
    ]
}
```

If you have configured the MapR Data Access Gateway to limit the number of documents in retrieval requests, and your result set exceeds the limit, the API response includes a warning. In the following example, the limit is set to 2:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        }
    ],
    "WARNING": "result truncated due to limit set to 2."
}
```

The following shows an example of output that includes a query plan. It corresponds to the output from example #6 in the previous section:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John"
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
        },
        {
            "_id": "user002",
            "first_name": "Jane"
        }
    ],
    "QueryPlan": [
        [
            {
                "streamName": "DBDocumentStream",
                "parameters": {
                    "queryConditionPath": true,
                    "projectionPath": [
                        "_id",
                        "first_name"
                    ],
                    "primaryTable": "/apps/employees"
                }
            }
        ]
    ]
}
```

GET /api/v2/table/{path}/document/{id}
Retrieves a single document by id from a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
id `string` *(path)*	**Required**: Id of the document to retrieve
condition `string` *(query)*	Query condition (in JSON format) to evaluate on document retrieved. See OJAI Query Condition Syntax on page 3422 for a description of the syntax.
fields `string` *(query)*	The fields from the document to retrieve. See JSON Document Field Paths on page 630 for details about how to specify field paths.
withTags `string` *(query)*	Enables or disables output with extended type tags Value: True|False Default: True

Request Example

The following retrieves the document with id `user003` from `/apps/employees`:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
user003' \
  -u <username>:<password>
```

Response Example

```
200 OK

{
    "_id": "user003",
    "first_name": "Simon",
    "last_name": "Davis"
}
```

HPE Ezmeral Data Fabric Database JSON MapReduce API
This API library extends the Apache Hadoop MapReduce framework, so that you can write your own MapReduce applications to write data from one JSON table to another.

Prerequisites to using this API Library

- Ensure that you have a firm grasp of MapReduce concepts and experience writing MapReduce applications.
- Before running a MapReduce application that uses this API, ensure that the destination JSON table or tables already exist and that any column families other than the default are already created on the destination tables.

Classes

The following table summarizes the information that is in the HPE Ezmeral Data Fabric Database JSON MapReduce API, which you can refer to for complete details of the classes.

Category	Class	Description
Utility	`MapRDBMapReduceUtil`	Simplifies the use of the API for most use cases.
Input formatters	`TableInputFormat`	Describes how to read documents from HPE Ezmeral Data Fabric Database JSON tables.
Record reader	`TableRecordReader`	Reads documents (records) from HPE Ezmeral Data Fabric Database JSON tables.
	`TableRecordReaderImpl`	Iterates over HPE Ezmeral Data Fabric Database JSON table data. Returns key-value pair as `ByteBufWritableComparable` and `Document` respectively.
Record writers	`BulkLoadRecordWriter`	Bulk loads documents into HPE Ezmeral Data Fabric Database JSON tables.
	`TableMutationRecordWriter`	Modifies documents that are in HPE Ezmeral Data Fabric Database JSON tables.
	`TableRecordWriter`	Writes documents to HPE Ezmeral Data Fabric Database JSON tables.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Category	Class	Description
Output formatters	`BulkLoadOutputFormat`	Describes how to bulk load documents into HPE Ezmeral Data Fabric Database JSON tables.
	`TableOutputFormat`	Describes how to write documents to HPE Ezmeral Data Fabric Database JSON tables.
	`TableMutationOutputFormat`	Writes `DocumentMutation` from the MapReduce phase to JSON tables . The key is of type `Value` and the value is a `DocumentMutation`.
Serializers	`DocumentSerialization`	Defines the serializer and deserializer for passing data from `Document` objects between map and reduce phases.
	`DBDocumentSerialization`	Converts a JSON document from HPE Ezmeral Data Fabric Database format to binary SequenceFile format.
	`ValueSerialization`	Serializes a JSON key and passes it between MapReduce phases.
Partitioner	`TablePartitioner`	Specifies how to partition data from the source JSON table.
	`TotalOrderPartitioner<K,V>`	Globally sorts data according to row key and then partitions the sorted data. This class is useful when the destination table has been pre-split into two or more tablets.

Using MapRDBMapReduceUtil to Set Default Values in Configurations and Jobs

The centerpiece of this API is the `MapRDBMapReduceUtil` class, which you can use in the `createSubmittableJob()` method of your applications to perform these actions:

- Set default values in the configuration for a MapReduce application and set the input and output format classes.
- Set default types for output keys and values.
- Configure a `TotalOrderPartitioner` and return the number of reduce tasks to use for a job.

To set default values in the configuration for a MapReduce application and set the input and output format classes, use the following methods:

```
configureTableInputFormat(org.apache.hadoop.mapreduce.Job job, String
srcTable)
```

The `configureTableInputFormat` method performs the following actions:

- Set the serialization class for `Document` and `Value` objects. These interfaces are part of the OJAI (Open JSON Application Interface) API.
- Set the field `INPUT_TABLE` in `TableInputFormat` to the path and name of the source table, and pass this value to the configuration for the MapReduce application.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- Set the input format class for the job to `TableInputFormat`.

```
configureTableOutputFormat(org.apache.hadoop.mapreduce.Job job, String
destTable)
```

The `configureTableOutputFormat` method performs the following actions:

- Set the field `OUTPUT_TABLE` in `TableOutputFormat` to the path and name of the destination table, and pass this value to the configuration for the MapReduce applications.
- Set the output format class for the job to `TableOutputFormat`.

If you want to set values for other fields in `TableInputFormat` or `TableOutputFormat`, or write your own logic for them, you can pass field values to configurations and specify these classes for jobs as you would in common MapReduce applications.

To set default types for output keys and values, use the following methods:

```
setMapOutputKeyValueClass(org.apache.hadoop.mapreduce.Job job)
setOutputKeyValueClass(org.apache.hadoop.mapreduce.Job job)
```

NOTE: You can also set types for output keys and values from the map phase, if those types will differ from the final output types.

To configure `TotalOrderPartitioner` and return the number of reduce tasks to use for a job, you can use a code line similar to the following in your application's method for creating a job:

```
int numReduceTasks =
MapRDBMapReduceUtil.setPartitioner(org.apache.hadoop.mapreduce.Jobjob,
String destPath);
```

The `setPartitioner()` method finds out whether a table has been pre-split into two or more tablets, counts the number of tablets, writes the number to a partitioner file, and sends that file to an instance of `TotalOrderPartitioner`. This line also returns the number of tablets to `numReduceTasks`. Your code can then use that variable to set the number of reducers, like the following:

```
job.setNumReduceTasks(numReduceTasks);
```

NOTE: The sample application gives an example of how to use `MapRDBMapReduceUtil`.

Mutating Rows in Destination Tables

Use the `TableMutationRecordWriter` class when you need to mutate rows.

For example, suppose that you are tracking the number of users who are performing various actions on your retail website. To do this, at intervals you run your MapReduce application and save the results in JSON documents in HPE Ezmeral Data Fabric Database. Suppose that you count the number of users who went through the order process but abandoned their orders. After every run of the application, you want to update an JSON document by adding the current count to the total count and by updating a field that tracks the date and time that the MapReduce application was last run.

You could do that by setting values in a DocumentMutation object (see the OJAI (Open JSON Application Interface) Javadoc. You would then serialize that and write it to the table with `TableMutationRecordWriter`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Compiling and Running Applications

You can compile applications that use the HPE Ezmeral Data Fabric Database Java API by using the required JAR file from the MapR installation. Run applications with the mapr command.

To compile an application, use the following command:

```
javac -cp 'mapr classpath' <Application jars>
```

To launch an application, use the following command

```
mapr <Main class jar> <commandline arguments>
```

NOTE: If you want to add JAR files to the classpath that the mapr command uses, add them with the environment variable MAPR_CLASSPATH. For example:

```
export MAPR_CLASSPATH=/home/apps/awesome-1.0.jar
         mapr com.company.MyAwesomeApp
```

IMPORTANT: Turn off speculative execution

Speculative execution of MapReduce tasks is on by default. For custom applications that load HPE Ezmeral Data Fabric Database tables, it is recommended to turn speculative execution off. When it is on, the tasks that import data might run multiple times. Multiple tasks for an incremental bulkload could insert one or more versions of a record into a table. Multiple tasks for a full bulkload could cause loss of data if the source data continues to be updated during the load.

If your custom MapReduce application uses `MapRDBMapReduceUtil.configureTableOutputFormat()`, you do not have to turn off speculative execution manually. This method turns it off automatically.

Turn off speculative execution by using either of these methods:

- Set the following MapReduce version 2 parameter to false: `mapreduce.map.speculative`
- Include the following line in the method in your application that sets parameters for jobs:

  ```
  job.setSpeculativeExecution(false);
  ```

HPE Ezmeral Data Fabric Database JSON MapReduce: Sample App

This sample application reads records (JSON documents) from a JSON table and inserts new documents into another JSON table.

After reading records from a JSON table, the application aggregates data within those records, creates new JSON documents that contain the aggregated records, and then inserts the new documents into another JSON table. Each record contains the name of an author and the name of a book that the author has written.

The JSON documents have this structure:

```
{
    "_id" : <string or binary>,
    "authorid":"<string>",
    "name":"<string>",
    "book":{
        "id":<int>,
        "title":"<string>"
    }
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

The structure of each aggregate record will look like this:

```
{
    "_id" : <string or binary>,
    "authorid":"<string>",
    "book":{
        [
            "title":"<string>",
            "title":"<string>",
            ...
        ]
    }
}
```

Prerequisites

- Ensure that your user ID has the `-readAce` and `-writeAce` privileges on the volumes where you plan to create the source and destination tables.
- Create the source JSON table. You can create the source table and populate it with sample records by running sample_dataset.txt from the `mapr dbshell` utility.

  ```
  $ mapr dbshell < sample_dataset.txt
  ```

- Create the destination JSON table. A simple way to create this table is to use the `create` command in the HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5728 utility.

Compiling and Running

To compile an application, use the following command:

```
javac -cp <classpath> <java source file(s)>
```

To launch an application, use the following command:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class>
<command line arguments>
```

To run the application, supply the paths and names of the source and destination tables as arguments:

```
CombineBookList <source_table> <destination_table>
```

Code Walkthrough

```
  private static Job createSubmittableJob(Configuration conf, String[]
otherArgs)
      throws IOException {

    srcTable = otherArgs[0];
    destTable = otherArgs[1];

    Job job = new Job(conf, NAME + "_" + destTable);
    job.setJarByClass(CombineBookList.class);
    MapRDBMapReduceUtil.configureTableInputFormat(job, srcTable);
    job.setMapperClass(CombineBookListMapper.class);
    MapRDBMapReduceUtil.setMapOutputKeyValueClass(job);
    MapRDBMapReduceUtil.configureTableOutputFormat(job, destTable);
    job.setReducerClass(CombineBookListReducer.class);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    MapRDBMapReduceUtil.setOutputKeyValueClass(job);
    job.setNumReduceTasks(1);
    return job;
  }
```

The `createSubmittableJob()` method uses methods that are in the `MapRDBMapReduceUtil` class to perform the following tasks:

Set the input format to the default table input format

You can call the `configureTableInputFormat()` method, passing in the job and also passing in the path and name of the source table:

```
MapRDBMapReduceUtil.configureTableInputFormat(job, srcTable);
```

The default behavior is to do the following:

- Set the serialization class for `Document` and `Value` objects. These interfaces are part of the OJAI (Open JSON Application Interface) API.
- Set the field `INPUT_TABLE` in `TableInputFormat` to the path and name of the source table, and pass this value to the configuration for the MapReduce application.
- Set the input format class for the job to `TableInputFormat`.

If you want to customize `TableInputFormat` , you can call it as you would normally set the input format for a job:

```
job.setInputFormatClass(TableInputFormat.class);
```

Set the type for keys and values that are output from the mapper

You can call the `setMapOutputKeyValueClass()` method to use the default type for keys and values:

```
MapRDBMapReduceUtil.setMapOutputKeyValueClass(job);
```

If you want to customize the output keys and values, you can call `Job.setMapOutputKeyClass()` and `Job.setMapOuputValueClass()` as you would normally for MapReduce applications.

Set the output format to the default table output format

You can call the `configureTableOutputFormat()` method, passing in the job and also passing in the path and name of the destination table, which must already exist at runtime:

```
MapRDBMapReduceUtil.configureTableOutputFormat(job, destTable);
```

The default behavior is to do the following:

- Set the field `OUTPUT_TABLE` in `TableOutputFormat` to the path and name of the destination table, and pass this value to the configuration for the MapReduce applications.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- Set the output format class for the job to `TableOutputFormat`.

If you want to customize `TableOutputFormat`, you can call it as you would normally set the output format for a job:

```
job.setOutputFormatClass(TableOutputFo
rmat.class);
```

You also have the option of using the `BulkLoadOutputFormat` class for bulk loading.

Set the type of the keys and values that are output from the reducer

You can call the `setOutputKeyValueClass()` method to use the default type for keys and values:

```
MapRDBMapReduceUtil.setOutputKeyValueC
lass(job);
```

If you want to customize the output keys and values, you can call `Job.setOutputKeyClass()` and `Job.setOuputValueClass()` as you would normally for MapReduce applications.

The `map()` method in the mapper class `CombineBookListMapper` takes the value of the `_id` field in a document as a key and the JSON document with that `_id` field value as a `Document`. The mapper does nothing with the `Value` object. For each `record`, the mapper writes the value of the `authorid` field and the full JSON document itself to the context.

```
  public static class CombineBookListMapper extends Mapper<Value, Document,
Value, Document> {
    @Override
    public void map(Value key, Document record, Context context) throws
IOException, InterruptedException {
      context.write(record.getValue("authorid"), record);
    }
  }
```

Both the `Value` and `Document` interfaces are part of the OJAI (Open JSON Application Interface) API. The javadoc for the OJAI API is here.

The `reduce()` method in the reducer class `CombineBookListReducer` takes the map output key, which is the value of the `authorid` field, and the map output value, which is an iterator of `Document` objects that each contain a full record. For each author ID, the reducer creates a document. For each document in the iterator, the reducer extracts the value of the `book` field and adds that value to the list `books` within a new JSON document.

```
  public static class CombineBookListReducer extends Reducer<Value,
Document, Value, Document> {

    @Override
    public void reduce(Value key, Iterable<Document> values,
        Context context) throws IOException, InterruptedException {
      Document d = MapRDB.newDocument();
      List<Document> books = new ArrayList<Document>();

      for (Document b : values) {
        books.add((Document)b.getValue("book"));
      }

      d.setId(key);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
      d.set("books", books);
      context.write(key, d);
    }
  }
```

The MapRDB class is part of the HPE Ezmeral Data Fabric Database JSON API, not the HPE Ezmeral Data Fabric Database JSON MapReduce API.

Apache Kafka Wire Protocol Service

HPE Ezmeral Data Fabric Streams supports Apache Kafka Wire Protocol Service. Apache Kafka Wire Protocol Service is a TCP/IP service that emulates a Kafka cluster backed by HPE Ezmeral Data Fabric Streams. The service makes it possible for Apache Kafka clients written in any programming language to access topics in HPE Ezmeral Data Fabric Streams.

Before Apache Kafka Wire Protocol Service was introduced, you had to use a modified version of the open-source libraries (`kafka-clients.jar` and `librdkafka.so`) for user applications to connect and publish/subscribe messages to topics in HPE Ezmeral Data Fabric Streams. With Apache Kafka Wire Protocol Service, you can simply use the Apache Kafka client libraries.

Apache Kafka Wire Protocol Service provides the following benefits:

- User applications can connect, publish, and subscribe to HPE Ezmeral Data Fabric Streams topics using standard Apache Kafka client libraries. Starting with data access gateway 6.0, only topics created through Apache Kafka Wire Protocol Service are supported.
- User applications developed using Apache Kafka clients do not require any modification to work with this new system, including recompilation, reconfiguration, or dependency management.
- Supports available Apache Kafka clients in multiple programming languages, both from the Apache Software Foundation and the community.

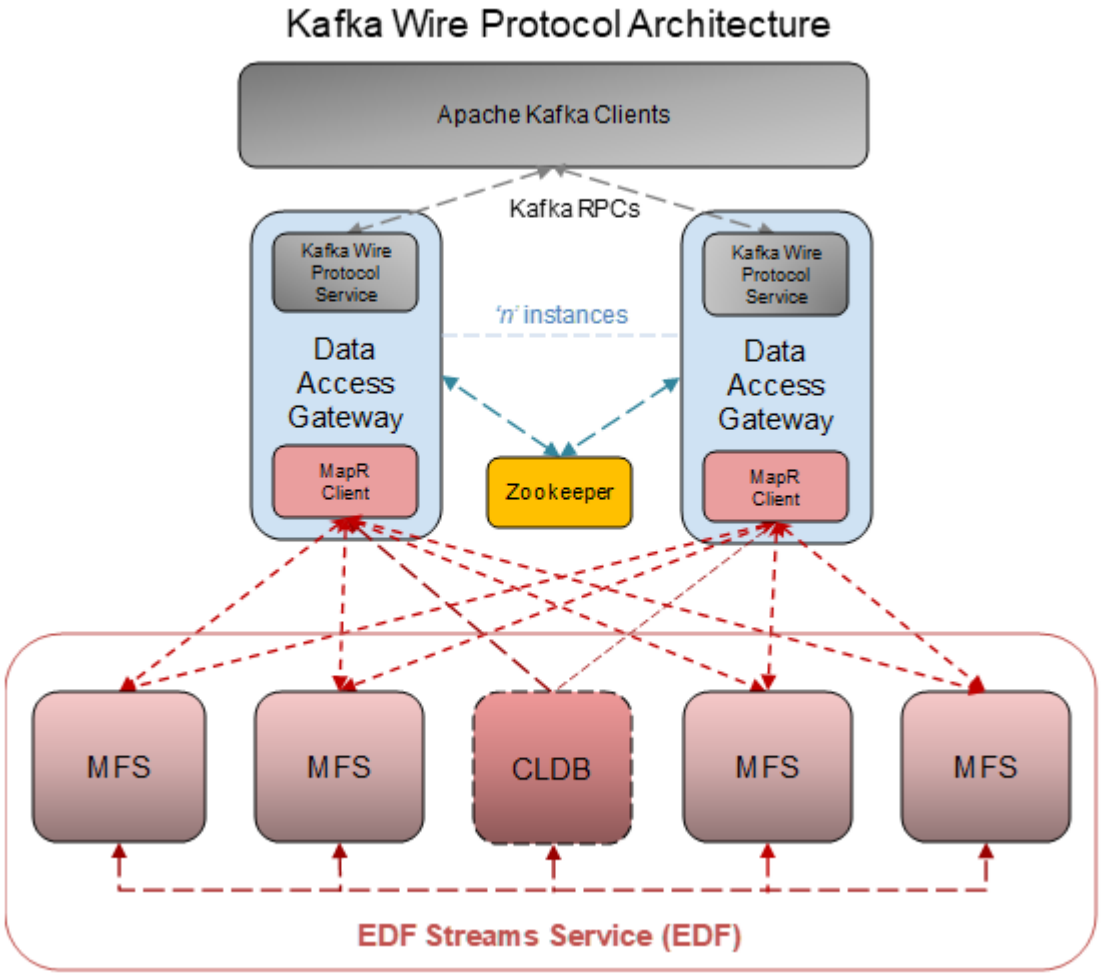
For more information, see Getting Started with Apache Kafka Wire Protocol Service on page 3538.

Architecture

The Apache Kafka Wire Protocol Service works within DAG (data access gateway) to act as a Kafka Broker (server in an Apache Kafka cluster). For all application purposes, the HPE Ezmeral Data Fabric cluster (with DAG and Apache Kafka Wire Protocol Service) runs like an Apache Kafka cluster.

The following image shows the communication paths between Apache Kafka clients and HPE Ezmeral Data Fabric with DAG and Apache Kafka Wire Protocol Service acting as brokers:

©Copyright 2024 Hewlett Packard Enterprise Development LP



Monitoring

DAG is not a Kafka Broker; therefore, Broker metrics are not available. However, you can monitor Data Fabric core services, as described in Using HPE Ezmeral Data Fabric Monitoring (Spyglass Initiative) on page 1677.

Limitations

The following list describes unsupported functionality in the initial release of Apache Kafka Wire Protocol Service:

- Quotas
- Transactions
- Idempotent Producer
- Kafka ACL-based security
- Topic-level security using ACEs.
- Group ACEs for Consumer Groups
- Delegation tokens
- Log directories

last-updated: Nov 14, 2024

Getting Started with Apache Kafka Wire Protocol Service

Describes the steps required to install, configure, and use Apache Kafka Wire Protocol Service.

The following sections describe the prerequisites and steps required to use Apache Kafka Wire Protocol Service.

Prerequisites

Apache Kafka Wire Protocol Service has the following component version requirements:

- HPE Ezmeral Data Fabric 7.4.0
- DAG 6.1 (available in EEP 9.1.2)
- Apache Kafka clients 2.6.x

1 - Install Data Access Gateway

Apache Kafka Wire Protocol Service is included with the Data Access Gateway (DAG) package (`mapr-data-access-gateway`) and is installed when you install DAG.

You can install DAG on multiple Data Fabric *data node*s alongside the `mfs` (file server) service through the Data Fabric Installer or manually using package managers. For more information about installing DAG, see Installing Data Access Gateway on page 242 and Data Access Gateway Support Matrix on page 6067.

High Availability	Apache Kafka Wire Protocol Service runs on all Data Fabric nodes that run DAG.
Port	The default DAG port for Apache Kafka Wire Protocol Service is 9092; however, you can change the port as described in Configuring Apache Kafka Wire Protocol Service on page 3542.

2 - Configure Apache Kafka Wire Protocol Service

Set cluster and node-specific settings, as described in Configuring Apache Kafka Wire Protocol Service on page 3542.

3 - Administer Kafka Topic

Use maprcli commands to administer Kafka topics as described in kafkatopic on page 2402.

4 - Secure Apache Kafka Wire Protocol Service

See Securing Apache Kafka Wire Protocol Service on page 3543.

5 - Use Apache Kafka Client Libraries to Connect to HPE Ezmeral Data Fabric Streams

For a list of available clients, see https://cwiki.apache.org/confluence/display/KAFKA/Clients.

6 - (Optional) - View Sample Applications

See Sample Kafka Python Producer and Consumer on page 3538.

Sample Kafka Python Producer and Consumer

This topic provides `kafka-python` examples with SASL and SSL client configurations for Apache Kafka Wire Protocol Service.

©Copyright 2024 Hewlett Packard Enterprise Development LP

1. If you have not done so already, install `kafka-python`:

```
pip3 install kafka-python
        $pip3 install kafka-python
        $pip3 list | grep kafka-python
```

2. Save the Sample Kafka Python Producer and Consumer on page 3538 code in a file with the following name:
   - SASL: `saslPlaintextKafkaPythonClient.py`
   - SSL: `sslPlaintextKafkaPythonClient.py`
3. Run the sample code with the following command:

   NOTE: When running the SASL sample code, you must fill in the username and password. When running the SSL sample code, you must fill the `ssl_password` from the file `/opt/mapr/conf/store-passwords.txt`.

SASL

```
python3
saslPlaintextKafkaPythonClient.py
<broker> <topicName>
```

For example:

```
python3
saslPlaintextKafkaPythonClient.py
localhost:9092
topicTestKafkaPythonClient_SASL
```

SSL

```
python3
sslPlaintextKafkaPythonClient.py
<broker> <topicName>
```

For example:

```
python3
sslPlaintextKafkaPythonClient.py
localhost:9092
topicTestKafkaPythonClient_SSL
```

Sample Kafka Python Producer and Consumer

SASL

```
from kafka import KafkaProducer
from kafka import KafkaConsumer
import sys
import time

#Specify 'broker' and 'topic'
arguments. Example: 'python3
saslPlaintestKafkaPythonClient.py
localhost:9092
topicTestKafkaPythonClient_SASL'
server = sys.argv[1]
print("BROKER: " + server)
topic = sys.argv[2]
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
print("TOPIC: " + topic)

#PRODUCER
print("\n**Starting Producer**")
producer=KafkaProducer(bootstrap_serve
rs=[server],

security_protocol='SASL_PLAINTEXT',

sasl_mechanism='PLAIN',

sasl_plain_username='<username>',

sasl_plain_password='<user-password>')

numMsgProduced = 0
for _ in range(100):
    producer.send(topic, b'msg')
    numMsgProduced += 1
producer.flush()
print("Messages produced: " +
str(numMsgProduced))
time.sleep(2)

# CONSUMER
print("\n**Starting Consumer**")
consumer =
KafkaConsumer(bootstrap_servers=[serve
r],

auto_offset_reset='earliest',

security_protocol='SASL_PLAINTEXT',

sasl_mechanism='PLAIN',

sasl_plain_username='<username>',

sasl_plain_password='<user-password>')

consumer.subscribe(topic)
numMsgConsumed = 0
for _ in range(10):
    records =
consumer.poll(timeout_ms=500)
    for topic_data, consumer_records
in records.items():
        for consumer_record in
consumer_records:
#            print("Received message:
" +
str(consumer_record.value.decode('ut
f-8')))
            numMsgConsumed += 1
print("Messages consumed: " +
str(numMsgConsumed))
```

SSL

```
from kafka import KafkaProducer
from kafka import KafkaConsumer
import sys
import time
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
#Specify 'broker' and 'topic'
arguments. Example 'python3
sslPlaintestKafkaPythonClientJSK.py
localhost:9092
topicTestKafkaPythonClient_SSL'
server = sys.argv[1]
print("BROKER: " + server)
topic = sys.argv[2]
print("TOPIC: " + topic)

#PRODUCER
print("\n**Starting Producer**")
producer=KafkaProducer(bootstrap_serve
rs=[server],

security_protocol='SSL',

ssl_check_hostname=False,

ssl_password='<>', #from /opt/mapr/
conf/store-passwords.txt
ssl.server.keystore.password

ssl_cafile='/opt/mapr/conf/
ssl_truststore.pem',

ssl_certfile='/opt/mapr/conf/
ssl_keystore-signed.pem',

ssl_keyfile='/opt/mapr/conf/
ssl_keystore.pem')

numMsgProduced = 0
for _ in range(100):
    producer.send(topic, b'msg')
    numMsgProduced += 1
producer.flush()
print("Messages produced: " +
str(numMsgProduced))
time.sleep(2)

# CONSUMER
print("\n**Starting Consumer**")
consumer =
KafkaConsumer(bootstrap_servers=[serve
r],

auto_offset_reset='earliest',

security_protocol='SSL',

ssl_check_hostname=False,

ssl_password='<>', #from /opt/mapr/
conf/store-passwords.txt
ssl.server.keystore.password

ssl_cafile='/opt/mapr/conf/
ssl_truststore.pem',

ssl_certfile='/opt/mapr/conf/
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
ssl_keystore-signed.pem',

ssl_keyfile='/opt/mapr/conf/
ssl_keystore.pem')

consumer.subscribe(topic)
numMsgConsumed = 0
for _ in range(10):
    records =
consumer.poll(timeout_ms=500)
    for topic_data, consumer_records
in records.items():
        for consumer_record in
consumer_records:
#            print("Received message:
" +
str(consumer_record.value.decode('ut
f-8')))
            numMsgConsumed += 1
print("Messages consumed: " +
str(numMsgConsumed))
```

Configuring Apache Kafka Wire Protocol Service

Describes the Apache Kafka Wire Protocol Service configuration files and instructions.

The following sections provide configuration information for DAG (Data Access Gateway) and Apache Kafka clients and applications:

Configuring Apache Kafka Wire Protocol Service

DAG packages include the following configuration files for Apache Kafka Wire Protocol Service:

`kafka-server.conf`

- This file is stored in `/opt/mapr/data-access-gateway/conf` and loaded from the local file system.
- This file contains node-specific options, such as the port number and security protocol. Set the options in this file on a per-node basis.
- By default, the Apache Kafka Wire Protocol Service listens on port 9092.
- If the DAG service instances are behind a firewall, the firewall rules must be configured to allow this traffic.

For a list of configurable parameters, see Apache Kafka Wire Protocol Service Settings on page 3542.

Configuring Apache Kafka Clients and Applications

Standard Apache Kafka client configurations are supported. For additional information on configuration, see the official Apache Kafka documentation.

Apache Kafka Wire Protocol Service Settings

Lists and describes parameters that you can configure in `kafka-server.conf`.

You can configure the following parameters in `/opt/mapr/data-access-gateway/conf/kafka-server.conf`:

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameter	Description
kafka.server.rpc.port	TCP port that Apache Kafka Wire Protocol Service listens to for incoming client requests. Default is 9092.
kafka.server.rpc.security-protocol	Configures authentication and encryption schemes. Supports PLAINTEXT or SASL_PLAINTEXT as the value. To enable authentication, set to SASL_PLAINTEXT. Note that DAG 5.0 does not support encryption.
kafka.server.rpc.sasl-mechanism	Configures the list of SASL authentication mechanisms. This parameter is only effective when `kafka.server.rpc.security-protocol` is set to SASL_PLAINTEXT. In DAG 5.0, only PLAIN is supported.

Securing Apache Kafka Wire Protocol Service

Describes the security mechanisms that Apache Kafka Wire Protocol Service does and does not support.

Authentication

Starting from Data Access Gateway 5.1, Apache Kafka Wire Protocol Service supports SASL/PLAIN and SSL authentication between clients and file servers.

Authorization

Kafka Wire Protocol Service does not support ACLs. The topic owner has all permissions.

On-Wire Encryption

Starting from Data Access Gateway 5.1, on-wire encryption for Apache Kafka Wire Protocol Service is supported using SSL. See Enabling SSL for Apache Kafka Wire Protocol Service on page 3543.

Enabling SSL for Apache Kafka Wire Protocol Service

Describes the security protocol values that are needed to enable SSL for Apache Kafka Wire Protocol Service.

Data Access Gateway 5.1 and later added SSL support for the Apache Kafka Wire Protocol Service. This section provides examples for configuring `/opt/mapr/data-access-gateway/conf/kafka-server.conf` to enable SASL_SSL and SSL security in server-side and client-side configurations.

New Security Protocol Values

Release 7.2.0 and later support two new values for the `security-protocol` parameter of `kafka-server.conf`:

- SASL_SSL
- SSL

When you specify the SASL_SSL value, you must also specify the corresponding `sasl-mechanism` value as indicated in the following table:

Specifying `security-protocol` as . . .	With `sasl-mechanism` as . . .	Enables
SASL_SSL	PLAIN[1]	Username/password-based (PAM) client authentication with SSL encryption and one-way SSL server authentication.
SSL	(Unspecified)	SSL authentication (two-way mutual SSL authentication) and SSL encryption.

©Copyright 2024 Hewlett Packard Enterprise Development LP

[1]`PLAIN` is the only mechanism currently supported.

SASL_SSL Server-Side Configuration Example

Here is a typical SASL_SSL server-side configuration example:

```
kafka.server = {
  rpc = {
    # TCP port for the Kafka Wire protocol service. Default is 9092
    port = 9092

    # Configures authentication and encryption schemes
    # Supported values are PLAINTEXT|SASL_PLAINTEXT|SASL_SSL|SSL
    # To enable authentication, set to SASL_PLAINTEXT, SASL_SSL or SSL
    # Encryption is supported for SASL_SSL and SSL
    security-protocol = SASL_SSL

    # Configures list of SASL authentication mechanisms
    # The only supported mechanism in this release is PLAIN
    # Effective only if "security-protocol" is set to SASL_PLAINTEXT or
SASL_SSL
    sasl-mechanism = PLAIN
  }
}
```

SASL_SSL Client-Side Configuration

You can configure the SASL_SSL client-side configuration the same way it is configured in Apache Kafka. In this configuration, `/opt/mapr/conf/ssl_truststore` performs the one-way SSL server authentication. For example:

```
security.protocol=SASL_SSL
ssl.truststore.location=/opt/mapr/conf/ssl_truststore
ssl.truststore.password=<some_password>
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
sasl.mechanism=PLAIN
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
required username="user1" password="user1";
```

SSL Server-Side Configuration

To make the SSL protocol work correctly in a server-side configuration, the cluster administrator MUST specify the `rpc.ssl.principal-mapping-rules` in the server config file. For example:

```
kafka.server = {
  rpc = {
    # TCP port for the Kafka Wire protocol service. Default is 9092
    port = 9092

    # Configures authentication and encryption schemes
    # Supported values are PLAINTEXT|SASL_PLAINTEXT|SASL_SSL|SSL
    # To enable authentication, set to SASL_PLAINTEXT, SASL_SSL or SSL
    # Encryption is supported for SASL_SSL and SSL
    security-protocol = SSL

    ssl.principal-mapping-rules = [
      "RULE:^CN=.*O=(.*?),.*$/$1/L,",
      "DEFAULT"
    ]
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
  }
}
```

The `ssl.principal-mapping-rules` parameter specifies a list of mapping rules. For information about how to configure the mapping rules, see Customizing the SSL User Name in the Kafka documentation.

SSL Client-Side Configuration

You can configure the client-side configuration the same way it is configured in Apache Kafka. In this configuration, the `/opt/mapr/conf/ssl_truststore` performs the SSL server authentication. To perform client authentication by the server, you must add the CA of the client certificate to the `/opt/mapr/conf/ssl_truststore`. Both the server and the client use this trust store file.

```
security.protocol=SSL
ssl.truststore.location=/opt/mapr/conf/ssl_truststore
ssl.truststore.password=<some_password>
ssl.keystore.location=/<client_cert_path>/example_ssl_client_keystore
ssl.keystore.password=<some_password>
ssl.key.password=<some_password>
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
```

Supported Apache Kafka RPCs

Lists the Apache Kafka RPCs that Apache Kafka Wire Protocol Service supports and provides links to the correlating API request documentation in the Kafka Protocol Guide.

Cluster Management and Metadata RPCs

- HEARTBEAT
- API_VERSIONS
- METADATA

Admin RPCs

- CREATE_TOPICS

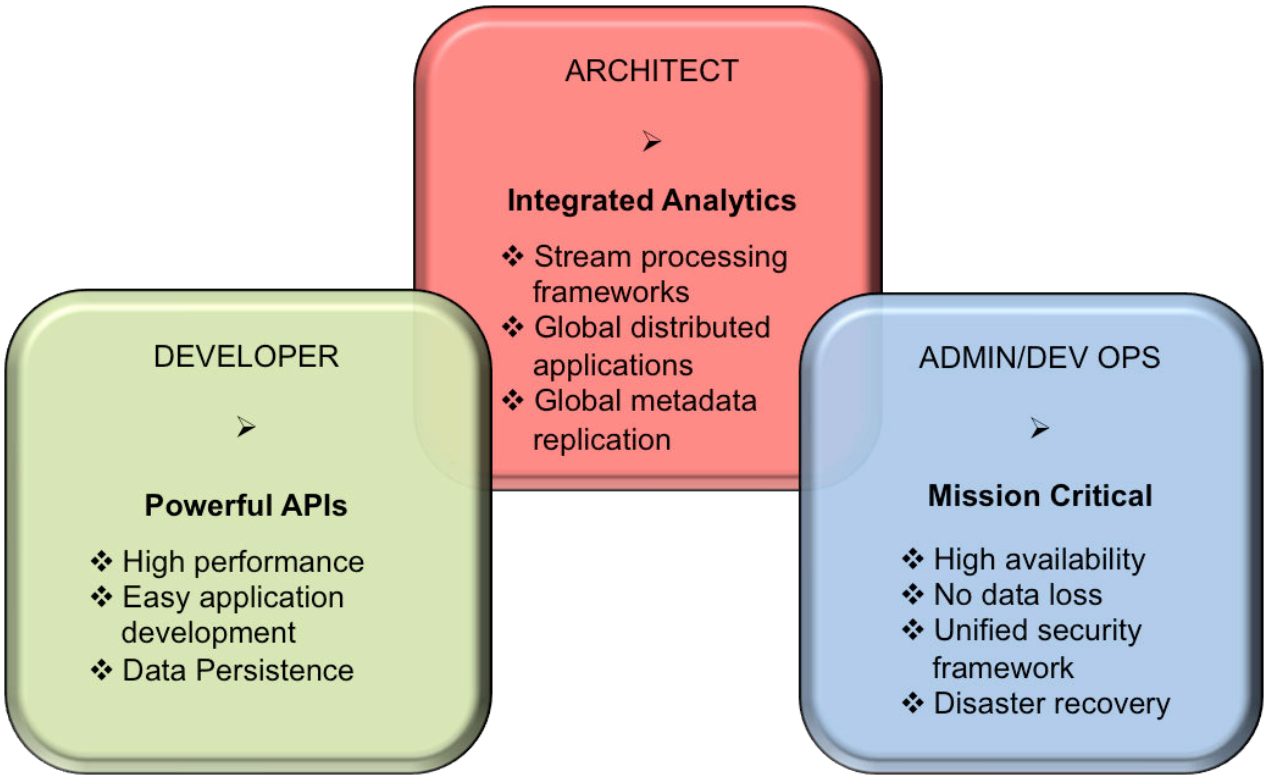
SASL Authentication RPCs

- SASL_HANDSHAKE
- SASL_AUTHENTICATE

HPE Ezmeral Data Fabric Streams and Apps

HPE Ezmeral Data Fabric Streams brings integrated publish and subscribe messaging to HPE Ezmeral Data Fabric.

HPE Ezmeral Data Fabric Streams is built into the HPE Ezmeral Data Fabric. It requires no additional process to manage, leverages the same architecture as the rest of the platform, and requires minimal additional management.



1. The Getting Started with HPE Ezmeral Data Fabric Streams section provides overall instructions for setting up, producing, and consuming streams.
2. The HPE Ezmeral Data Fabric Streams section provides conceptual information.
3. The Administering Streams section provides information about creating and managing streams, topics, and stream replication.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

ATTENTION: As of core version 6.1, the HPE Ezmeral Data Fabric Streams API enforces a maximum of 4096 partitions for a topic. If you create an application with the HPE Ezmeral Data Fabric Streams 6.1 API, the maximum number of partitions is 4096. If you previously created an application with HPE Ezmeral Data Fabric Streams 6.0.1 API (or older) and you have upgraded, the original number of partitions can be used. For example, if you were using more than 4096 partitions in core version 6.0.1 or earlier, you can continue with the same number of partitions after upgrading.

Getting Started with HPE Ezmeral Data Fabric Streams

If you have a basic understanding of HPE Ezmeral Data Fabric Streams components and the typical flow of messages from producers to consumers, you can get started.

Prerequisites

- Ensure that your Linux, Windows, or OS X system has Java SDK 7 or later installed.
- Install the latest version of HPE Ezmeral Data Fabric on a cluster.
- Install the core client (mapr-client) package, if you want to run the producer and consumer from a machine outside the cluster. See Installing the Data Fabric Client (Non-FIPS) on page 383 for more information.

Procedure

1. On a node in the HPE Ezmeral Data Fabric cluster, follow these steps:
   a) Create a stream.
      - Run this command if you plan to run the producer and consumer with the same user ID that you are using to create the stream:

        ```
        maprcli stream create -path /<path to and name of the stream>
        ```

      - Run this command if you plan to run the producer and consumer with user IDs that are different from the user ID that you are using to create the stream:

        ```
        maprcli stream create -path /<path to and name of the
        stream> -consumeperm u:<user ID> -produceperm u:<user ID>
        ```

        The two additional parameters grant security permissions. By default, these permissions are granted to the user ID that ran the `maprcli stream create` command.

`-consumeperm`	Grants permission to read messages from topics that are in the stream.
`-produceperm`	Grants permission to publish messages to topics that are in the stream.

   b) Create a topic.

      Run this command to create the topic:

      ```
      maprcli stream topic create -path <path and name of the stream> -topic
      <name of the topic>
      ```

2. On the system where the mapr-client is installed, compile and launch the Java consumer first and then launch the Java producer.

   In both the consumer and producer, change this text to the path and name of your stream and to the name of the first of the topics:

   ```
   /<path to and name of the stream>:<name of topic>
   ```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

For the steps of compiling and launching, see Compiling and Running HPE Ezmeral Data Fabric Streams Java Apps on page 3605.

Launch the consumer first, and then launch the producer. If you launch the producer first and then the consumer, the producer publishes 50 messages, but the consumer (as consumers do by default) starts reading from the head of the partition, which is after the 50 messages.

NOTE: As of MapR 6.0, the message offset in a partition starts from zero (0). If you are upgrading and do not enable the HPE Ezmeral Data Fabric Database/HPE Ezmeral Data Fabric Streams feature, **mfs.feature.db.streams.v6.support**, the message offset in a partition starts from one (1).

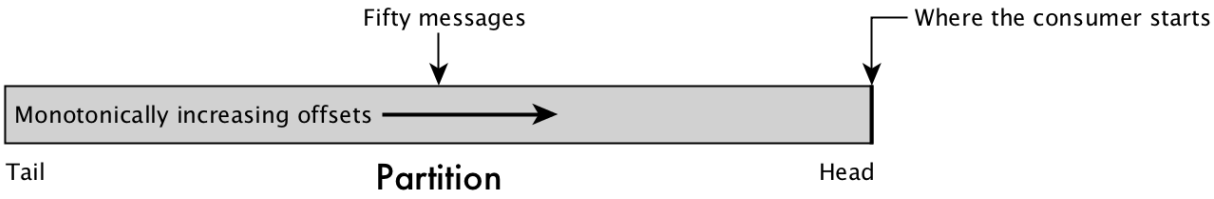


Figure 32: Result of starting the producer before starting the consumer for this step

If you launch the consumer first, the partition is empty and the consumer continuously polls for new messages.

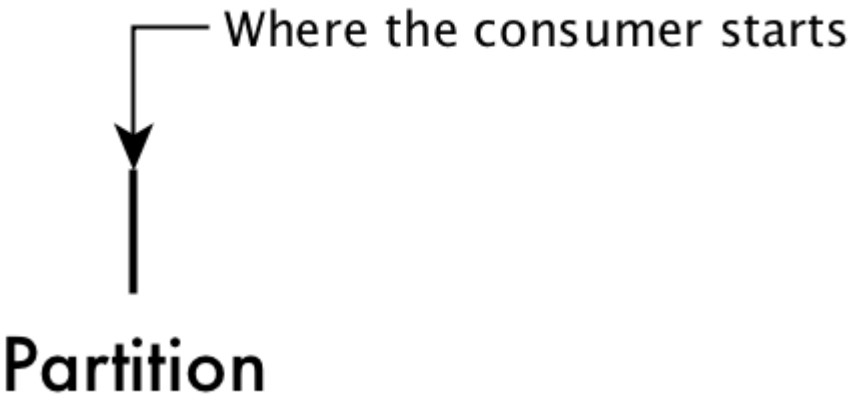

Figure 33: The position of a consumer on an empty partition

After you launch the producer, the fifty messages are published to the partition, and the consumer can move forward in the partition, reading the messages.

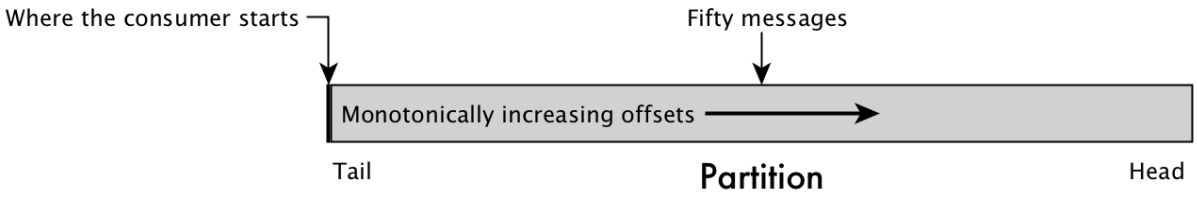

Figure 34: Result of starting the consumer first and then starting the producer for this step

Sample Java Consumer

©Copyright 2024 Hewlett Packard Enterprise Development LP

You need to first add the following dependency to the POM file:

```
<dependency>
  <groupId>commons-logging</groupId>
  <artifactId>commons-logging</artifactId>
  <version>1.1.1</version>
</dependency>
```

```
/* This code is successfully tested for common-logging version 1.11 and
1.2. */

import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;

public class SampleConsumer {
    // Set the stream and topic to read from
    public static String topic = "/<path to and name of the stream>:<name
of topic>";

    // Declare a new consumer.
    public static KafkaConsumer<Integer, String> consumer;

    public static void main(String[] args) {
        configureConsumer();

        // Subscribe to the topic.
        consumer.subscribe(Collections.singletonList(topic));

        // Set the timeout interval for requests for unread messages.
        Duration pollTimeout = Duration.ofMillis(1000);

        try {
            while (true) {
                ConsumerRecords<Integer, String> records =
consumer.poll(pollTimeout);
                records.forEach(record -> {
                    System.out.printf("%s %d %d %s %s \n", record.topic(),
                            record.partition(), record.offset(),
record.key(), record.value());

                });
            }
        } finally {
            consumer.close();
        }
    }

    /* Set the value for a configuration parameter.
       This configuration parameter specifies which
       class to use to deserialize the value of each message. */
    public static void configureConsumer() {
        Properties props = new Properties();
        props.put(ConsumerConfig.GROUP_ID_CONFIG, "consumer-group");
        props.put(ConsumerConfig.AUTO_OFFSET_RESET_CONFIG, "earliest");
        props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,

Consuming CDC Records

The OJAI changelog interfaces are used to consume changed data records (propagated by the Change Data Capture feature).

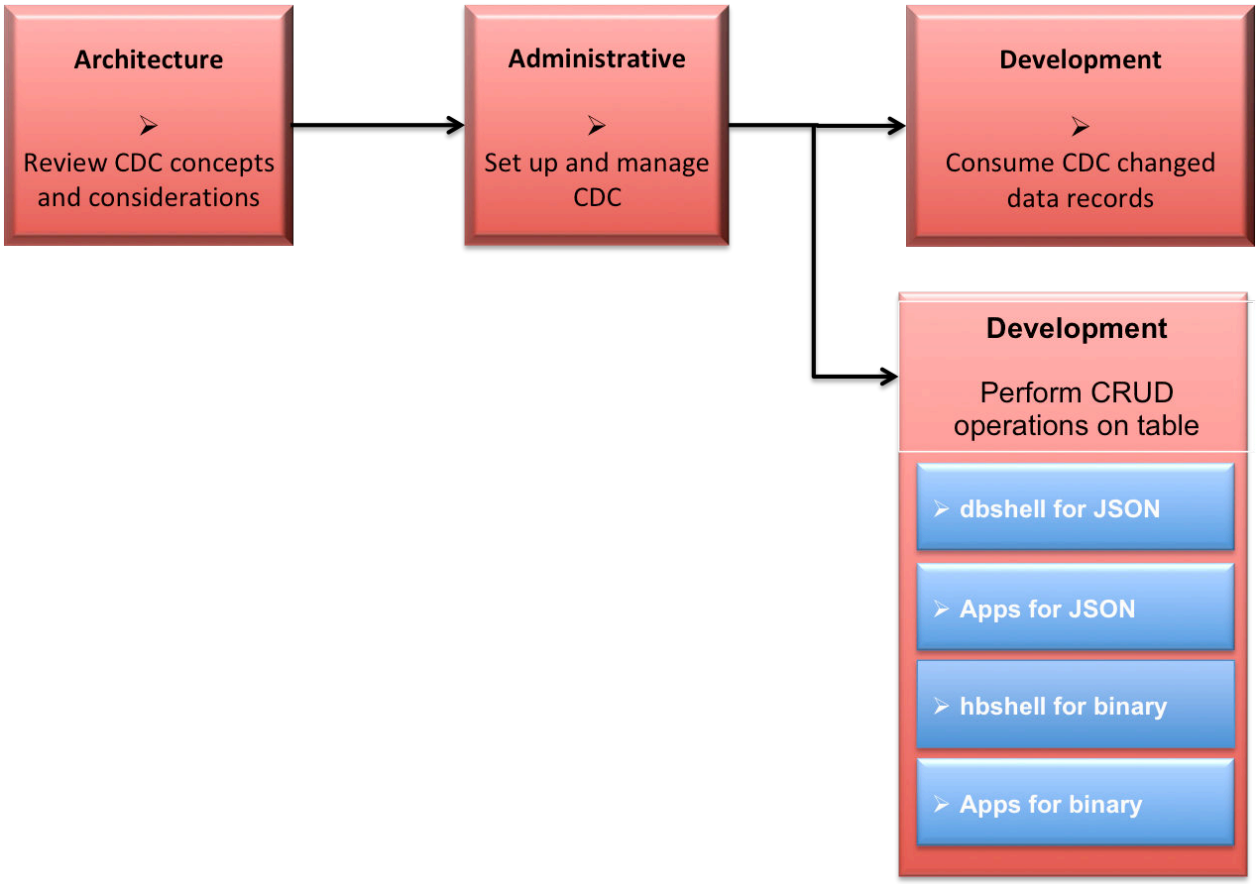
last-updated: Nov 14, 2024

The general CDC flow of understanding architectural concepts, performing administrative tasks to set up and use CDC, performing CRUD operations on a database table, and developing applications for consuming CDC changed data records. This diagram provides hotspot links to help you navigate to the applicable documentation.



1. Learning about CDC
2. Administering Change Data Capture
3. Building a consumer app for CDC
4. Using dbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database JSON tables
5. Developing client applications for HPE Ezmeral Data Fabric Database JSON tables.
6. Using hbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database binary tables.
7. Developing client applications for HPE Ezmeral Data Fabric Database binary tables.

Javadoc

See the following Java documentation for detailed information about CDC APIs.

QueryResult

Deserializer for consuming CDC records

The deserializer converts stream messages into individual change data records. When your application creates a CDC consumer, you must also register the

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

ChangeData deserializer by setting the `value.deserializer` configuration parameter to `com.mapr.db.cdc.ChangeDataRecordDeserializer`.

NOTE: When applications consume from a CDC change topic, the record key retrieved from `poll()` is not deserialized. The record key is not equal to the `_id` field of the document. If you want to retrieve the exact `_id` of the document, you must call the `ChangeDataRecord.getId()` method.

Interfaces for working with CDC records

The following OJAI interfaces and enumerations create consumers for CDC changed data.

ChangeNode	Contains the change to a single field in a document.
ChangeEvent	Identifies the change event associated with the current change node. The value of ChangeEvent can be one of the following: • NULL (no event) • NODE (a change with real value) • START_MAP (a node representing the beginning of a map) • END_MAP (a node representing the end of a map) • START_ARRAY (a node representing the beginning of an array) • END_ARRAY (a node representing the end of an array)
ChangeOp	Identifies the type of the operation performed on the current field. The values of ChangeOp can be one of the following: • NULL (no operation) • SET (replace the current field with the given value) • PUT (add an extra version of the value) • MERGE (combine the given value with the existing values in the table) • DELETE (delete all values older than or equal to the delete operation timestamp) • DELETE_EXACT (delete the version of the value with the given timestamp)
ChangeDataRecord	Contains all the changes made on a single document/row in the source table.
ChangeDataRecordType	Specifies the mode of change for the change data record. The following values are specified: • RECORD_INSERT • RECORD_UPDATE • RECORD_DELETE
ChangeDataReader	Is a parser that traverses over the individual change tree nodes on a change data record. It provides

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

cursor-like semantics that can be moved, one tree node at a time, by invoking the `next` method. The APIs retrieve the properties of individual change nodes (for example: data type, field name, field value, and so on).

Open Data Format

The CDC Open Format feature allows you to create applications in languages other then Java that consume CDC (Change Data Capture) changed data records. For example, C/C++, Python, and C#/.NET) are supported.

This functionality is provided with an open format decoder/serializer in the HPE Ezmeral Data Fabric Streams C library. The decoder translates the internal format to the open data format, decodes/deserializes the data, and returns the value of the changed data record as a human readable JSON string.

All languages that are binding through the HPE Ezmeral Data Fabric Streams C library can retrieve the open data format and, with a simple JSON parser, consume changed data records.

Building Consumers for CDC

HPE Ezmeral Data Fabric Streams consumers read and process CDC changed data records. The consumer is built with the OJAI API library.

Description

When building a consumer, the general steps are to:

- Set the consumer properties using Apache Kafka and HPE Ezmeral Data Fabric configuration parameters.
- Subscribe to the stream topic.
- Consume the events and determine record type.
- Process the change data records.

The following examples refer to the MapR CDC Sample. See the QueryResult for specific API information.

Set Configuration

This code snippet configures the consumer properties using the Apache Kafka configuration parameters. See HPE Ezmeral Data Fabric Streams Configuration Parameters for Consumers. This could be externalized in a file or hard coded in the application code. The following code examples show both methods.

NOTE: CDC uses a optimized serialization format for all the events, so `value.deserializer` must be set to **com.mapr.db.cdc.ChangeDataRecordDeserializer**.

```
// Consumer configuration parameters specified in application

    Properties consumerProperties = new Properties();
    consumerProperties.setProperty("group.id",
"cdc.consumer.demo_table.fts_geo");
    consumerProperties.setProperty("enable.auto.commit", "true");
    consumerProperties.setProperty("auto.offset.reset", "latest");
    consumerProperties.setProperty("key.deserializer",
"org.apache.kafka.common.serialization.ByteArrayDeserializer");
    consumerProperties.setProperty("value.deserializer",
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
"com.mapr.db.cdc.ChangeDataRecordDeserializer");
```

```
// Consumer configuration parameters specified in an external file

key.deserializer=org.apache.kafka.common.serialization.ByteArrayDeserializer
value.deserializer=com.mapr.db.cdc.ChangeDataRecordDeserializer
enable.auto.commit=true
auto.offset.reset=latest
group.id=cdc.consumer.demo_table.fts_geo
```

Subscribe to topic

This code snippet creates the consumer and subscribes to the HPE Ezmeral Data Fabric Streams topic that contains the change data records. The consumer is created using a key (bytes[]) and a `ChangeDataRecord` object for the value.

```
// Consumer used to consume MapR-DB CDC events

KafkaConsumer<byte[], ChangeDataRecord> consumer = new
KafkaConsumer<byte[], ChangeDataRecord>(consumerProperties);
consumer.subscribe(Arrays.asList("/demo_changelog:demo_table"));
```

Consume the events and determine record type

This code snippet polls the topic to determine whether there are any changes and, if so, iterates through the change data records to retrieve the change data record IDs based on the change data record type. The ChangeDataRecordType interface is used to determine the type of record and the ChangeDataRecord interface is used to retrieve the record type and record ID.

```
    while (true) {
      ConsumerRecords<byte[], ChangeDataRecord> changeRecords =
consumer.poll(500);
      Iterator<ConsumerRecord<byte[], ChangeDataRecord>> iter =
changeRecords.iterator();

      while (iter.hasNext()) {
        ConsumerRecord<byte[], ChangeDataRecord> crec = iter.next();
        // The ChangeDataRecord contains all the changes made to a document
        ChangeDataRecord changeDataRecord = crec.value();
        String documentId = changeDataRecord.getId().getString();

        if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_INSERT) {
          System.out.println("\n\t Document Inserted " + documentId);
          insertAndUpdateDocument(changeDataRecord, producer);
        } else if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_UPDATE) {
          System.out.println("\n\t Document Updated " + documentId);
          insertAndUpdateDocument(changeDataRecord, producer);
        } else if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_DELETE) {
          System.out.println("\n\t Document Deleted " + documentId);
          deleteDocument(changeDataRecord, producer);
        }

      }
    }
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
  }
```

Process the records

This code snippet processes the change data records and based on the type of event (insert, update, delete), using the `ChangeDataRecordType` class and the `changeDataRecord.getType()` method, checks and retrieves the record type.

```
// Use the ChangeNode Iterator to capture all the individual changes

    Iterator<KeyValue<FieldPath, ChangeNode>> cdrItr =
changeDataRecord.iterator();

    while (cdrItr.hasNext()) {
      Map.Entry<FieldPath, ChangeNode> changeNodeEntry = cdrItr.next();
      String fieldPathAsString = changeNodeEntry.getKey().asPathString();
      ChangeNode changeNode = changeNodeEntry.getValue();
      ...
      ...
    }
```

To process and retrieve an inserted new document, you can check to see if the field path is NULL or empty. When *a new document is inserted*, all the changes are made in a single object represented as a Map. You then retrieve the map value by using the `changeNode.getMap()` or `changeNode.getString()` methods depending on the field value.

```
if (fieldPathAsString == null || fieldPathAsString.equals("")) { // Insert
        Map<String, Object> documentInserted = changeNode.getMap();

        if (documentInserted.containsKey("firstName")) {
          fieldToIndex.put("firstName", (String)
documentInserted.get("firstName"));
          sendIndexingMessage = true;
        }

        if (documentInserted.containsKey("lastName")) {
          fieldToIndex.put("lastName", (String)
documentInserted.get("lastName"));
          sendIndexingMessage = true;
        }

        if (documentInserted.containsKey("address")) {
          addressMessage.set("address",
jsonMapper.convertValue((Map)documentInserted.get("address"),
JsonNode.class) );
          sendAddressMessage = true;
        }
     }
```

To process and retrieve updated documents, you can check the field path and retrieve the value depending on the expected value type. When *a document is updated*, the iterator contains one ChangeNode by updated field. You can then access the field path and value directly. You then retrieve the map value by using the `changeNode.getMap()` or `changeNode.getString()` methods depending on the field value.

```
if (fieldPathAsString.equalsIgnoreCase("firstName")) {
          fieldToIndex.put("firstName", changeNode.getString());
          sendIndexingMessage = true;
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
        }
          else if (fieldPathAsString.equalsIgnoreCase("lastName")) {
          fieldToIndex.put("lastName", changeNode.getString());
          sendIndexingMessage = true;
        }
          else if (fieldPathAsString.equalsIgnoreCase("address")) {
          addressMessage.set("address",
jsonMapper.convertValue( changeNode.getMap(), JsonNode.class) );
          sendAddressMessage = true;
        }
```

To process delete operations, you can directly retrieve the document ID using the `changeDataRecord.getId()` method and process the document deletion with the `deleteDocument` method. The delete operation is a single change data record.

Consumer Application for CDC JSON Data
This example consumes changed data records from HPE Ezmeral Data Fabric Database JSON tables.

Example of Consuming JSON Changed Data Records

In this example, the following occurs:

- Initialize the consumer properties using Apache Kafka and Data Fabric configuration parameters.
- Display the change data record properties.
- Iterate through the change nodes, determine the type of operation, and retrieve the operation value.
- Retrieve the properties of individual change node (for example: data type, field name, field value, and so on) by using various methods of the `ChangeDataReader` interface.
- Display the change data record values by using the `ChangeNode` interface.
- Subscribe to the stream topic, consume the events, and determine record type.

For changed data records from HPE Ezmeral Data Fabric Database JSON table data, the following are unique:

- There are multiple property values that can be retrieved through the `ChangeDataReader` interface. For example, getDouble or getFloat.
- There are multiple values for single fields in documents that can be retrieved through `ChangeNode` interface. See the code line: `Value value = changeNode.getValue();`

                readerDisplay(id, changeDataRecordType,
                        recordOpTime, recordServerOpTime,
                        consumerRecordkey, changeDataRecord);
            }
        }
        consumer.close();
    }

    /**
     * Driver
     * @param args
     */
    public static void main(String[] args) {
        Long pollTimeout = Long.parseLong(args[0]);
        String topic = args[1];
        boolean method = Boolean.parseBoolean(args[2]);
        CDPConsumer cdpConsumer = new CDPConsumer();
        cdpConsumer.consume(pollTimeout, topic, method);
    }
}
```

Consumer Application for CDC Binary Data
This example consumes changed data records from HPE Ezmeral Data Fabric Database Binary tables.

Example of Consuming Binary Changed Data Records

In this example, the following occurs:

- Initialize the consumer properties using Apache Kafka and HPE Ezmeral Data Fabric configuration parameters.
- Display the change data record properties.
- Iterate through the change nodes, determine the type of operation, and retrieve the operation value.
- Display the change data record values by using the `ChangeNode` interface.
- Subscribe to the stream topic, consume the events, and determine record type.

For changed data records from HPE Ezmeral Data Fabric Database Binary table data, the following are unique:

- An additional package must be imported: `java.nio.ByteBuffer`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- There is single value for single fields in documents that can be retrieved through `ChangeNode` interface. See the code line: `ByteBuffer value = changeNode.getBinary();`

```
package com.mapr.qa.cdc.tests.binary;

Open Format
Describes the CDC open format.

Open Format Mapping

The following shows the mapping between the HPE Ezmeral Data Fabric CDC data types and the JSON open format data types.

```
{
        "map": {
        "null": null,
        "boolean" : true,
        "string": "eureka",
        "byte" : {"$numberByte": 127},
        "short": {"$numberShort": 32767},
        "int": {"$numberInt": 2147483647},
        "long": {"$numberLong":92233720368547758O7},
        "float" : {"$numberFloat":3.4028235E38},
        "double" : 1.7976931348623157e308,
        "decimal": {"$decimal":
"12345678901234567890189012345678901.23456789"},
        "date": {"$dateDay": "yyyy-mm-dd"},
        "time" : {"$time" : "HH:mm:ss[.sss]"},
        "timestamp" : {"$date" : "yyyy-MM-ddTHH:mm:ss.SSSXXX"},
        "interval" : {"$interval" : number_of_millisecods},
        "binary" : {"$binary" : "base64_encoded_binary_value"},
        "array" : [42, "open sesame", 3.14, {"$dateDay": "2015-01-21"}]
        }
}
```

JSON Record Format

When the consumer retrieves the changed data record (by the key-value pair), the record is returned as a string in JSON format (a readable open format). The information about the mutation is returned as an array where each array element is one (1) change.

NOTE: If you use the default print, the string returns float values of up to six (6) digits of precision and double values of up to fifteen (15) digits. If the data exceeds this default and you want the exact number returned, use the CDC API that returns a float or double value.

The following example changed data record shows two (2) mutations.

```
{
        "_id":"row1"
        "$opType":"$RECORD_UPDATE",
        "$opTime":1518654391801,

        "$mutations":[
        {"$fieldPath":"arrayB,
        "$fieldOp":"$SET",
        "$fieldValue":[{"$numberInt":100},false,"set a map"]
        }
        {"$fieldPath":"arrayC,
        "$fieldOp":"$SET",
        "$fieldValue":[{"$numberInt":200},false,"set a map"]
        }
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
        ]
}
```

Example

The following sample code initialized consumer properties for open format and consumes the changelog data from the topic.

```
/*
 * Initialize Basic Consumer Properties for Open Format
 * @return
 */

private Properties getOpenFormatListenerProperties() {
   Properties props = new Properties();
   props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
"org.apache.kafka.common.serialization.StringDeserializer");
   props.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
"org.apache.kafka.common.serialization.StringDeserializer");
   return props; }

/*
 * Consume from changelog topic
 *
 */
public void startConsume(String topic) {
   KafkaConsumer<String, String> consumer = new KafkaConsumer<String,
String> (getOpenFormatListnerProperties());
   List<String> topicList = new ArrayList<>();
   topicList.add(topic);
   consumer.subscribe(topicList);

   ConsumerRecords<String, String> consumerRecords =
consumer.poll(pollTimeout);
   Iterator<ConsumerRecord<String, String>> iterator =
consumerRecords.iterator();
   while (iterator.hasNext())

      { ConsumerRecord<String, String> record = iterator.next(); String
cdcResult = record.value(); }

}
```

Consuming Audit Logs

Audit Streaming (available from v6.0.1) provides a way to process the audit data in real-time.

When audit streaming is enabled, the HPE Ezmeral Data Fabric generates audit logs that are sent as an audit stream, opening the possibility of real-time processing of the audit data. See Streaming Audit Logs on page 831 for more information.

Use the sample consumer application, or build your custom consumer application, to consume the audit logs that are available as a stream topic, when audit streaming is enabled.

The sample application uses file system APIs to get the file path and name from the FID, and the volume name from the volume ID.

Determine When to use Cached or Uncached Version of the File System API

Caching the file path and file name, along with the volume name at the initial API call, reduces the load on CLDB for subsequent API calls.

©Copyright 2024 Hewlett Packard Enterprise Development LP

However, there could be cases when the uncached version of the application is more suitable for use. Consider the following example:

For the initial API call, File1 is returned as the file name for FID 1. The result is cached.

The file is then renamed to File2. For subsequent API calls, to get the file name for FID 1, the result from the cache is used. The cache, unaware of the rename operation, returns the name as File1, which is incorrect, as the file is already renamed to File2. For such a case, use the uncached version.

Evaluate your use case, and then use the cached, or the uncached version, as appropriate.

Sample Cached Consumer Application for Audit Stream
The Consumer.java application demonstrates how to connect to the file system, and consume the messages in a stream topic.

Sample Application

Before running this application, ensure that you have access to a cluster running file system. To build and run this application:

1. Set the classpath as shown below:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the Java file as shown below:

```
javac -cp .:`mapr classpath` Consumer.java
```

3. Run the final `Consumer.class` file. For example:

```
java -cp .:`mapr classpath` Consumer
```

This application requires the following imports:

- `org.apache.kafka.clients.consumer.ConsumerRecord`
- `org.apache.kafka.clients.consumer.ConsumerRecords`
- `org.apache.kafka.clients.consumer.KafkaConsumer`
- `org.apache.hadoop.conf.Configuration`
- `com.mapr.fs.MapRFileSystem`
- `com.google.common.io.Resources`
- `java.net.URI`
- `java.io.IOException`
- `java.io.InputStream`
- `java.util.Iterator`
- `java.util.Properties`
- `java.util.Random`

©Copyright 2024 Hewlett Packard Enterprise Development LP

- `java.util.StringTokenizer`
- `java.util.regex.Pattern`

The application performs the actions described in the following sections.

Initializes the consumer properties

The configuration parameters for the consumer are stored in `consumer.props` file. This file should be present in the current directory or mapr classpath. For example, your `consumer.props` file could look similar to the following:

```
#bootstrap.servers=localhost:9092
group.id=test
enable.auto.commit=true
key.deserializer=org.apache.kafka.comm
on.serialization.StringDeserializer
value.deserializer=org.apache.kafka.co
mmon.serialization.StringDeserializer
# fast session timeout makes it more
fun to play with failover
## apps specific ?
session.timeout.ms=10000

# These buffer sizes are needed to
avoid consumer switching to
# a mode where it processes one
bufferful every 5 seconds with
multiple
# timeouts along the way.
fetch.min.bytes=50000
# receive.buffer.bytes=262144 //
fixed size buffer
max.partition.fetch.bytes=2097152

auto.offset.reset=earliest
```

The application initializes the consumer properties stored in the `consumer.props` file.

```
public static void main(String[]
args) throws
IOException,InterruptedException {
    KafkaConsumer<String, String>
consumer;
    try (InputStream props =
Resources.getResource("consumer.props"
).openStream()) {
        Properties properties = new
Properties();
        properties.load(props);
        if
(properties.getProperty("group.id")
== null) {

properties.setProperty("group.id",
"group-" + new
Random().nextInt(100000));
        }
        consumer = new
KafkaConsumer<>(properties);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    }
}
```

Subscribes to the topic to read from

The application initializes the file system object, with the last parameter as `true` so that the audit logs generated by the operations for converting fid to file path and volid to volume name are sent to the `ExpandAudit.json.log` file used by the `expandaudit` on page 2873 utility and not to the stream. It then selects the stream and subscribes to the topic to read at path `/var/mapr/auditstream/auditlogstream:<clustername>`.

```
Configuration conf = new
Configuration();
String uri = MAPRFS_URI;
uri = uri + "mapr/";
conf.set("fs.default.name", uri);
MapRFileSystem fs = new
MapRFileSystem();
fs.initialize(URI.create(uri), conf,
true);
Pattern pattern
= Pattern.compile("/var/
mapr/auditstream/
auditlogstream:<clustername>.+");
consumer.subscribe(pattern);
```

Requests unread messages from the topic

The application requests to read unread messages in the subscribed topic. It then iterates through the returned records, extracts the value of each message, and prints the value to the standard output.

```
boolean stop = false;
int pollTimeout = 1000;
while (!stop) {
    ConsumerRecords<String,
String> consumerRecords =
consumer.poll(pollTimeout);
    Iterator<ConsumerRecord<String,
String>> iterator =
consumerRecords.iterator();
    if (iterator.hasNext()) {
      while (iterator.hasNext()) {
        ConsumerRecord<String,
String> record = iterator.next();
        String value = record.value();
        String rvalue =
value.replace("\"","");
        String recordValue
= processRecord(fs, rvalue,
value);
        System.out.println(("
Consumed Record: " + recordValue));
      }
    } else {
      Thread.sleep(1000);
      //stop = true;
    }
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Gets the record and expands individual fields

The application then takes the record and expands fid in the message to path to file using the `getMountPathFidCached()` API and volid in the message to volume name using the `getVolumeNameCached()` API.

```
while (st.hasMoreTokens()) {
    String field = st.nextToken();
    StringTokenizer st1 = new
StringTokenizer(field, ":");
    while (st1.hasMoreTokens()) {
        String token =
st1.nextToken();
        if (token.endsWith("Fid")) {
           String lfidStr =
st1.nextToken();
           String path= null;
           try {
              path =
fs.getMountPathFidCached(lfidStr); //
Expand FID to path
           } catch (IOException e){
        }
        lfidPath =
"\"FidPath\":\""+path+"\",";
        // System.out.println("\nPAth
for fid " + lfidStr +  "is " +  path);
    }
    if (token.endsWith("volumeId")) {
        String volid =
st1.nextToken();
        String name= null;
        try {
            int volumeId =
Integer.parseInt(volid);
            name =
fs.getVolumeNameCached(volumeId); //
Cached API to convert volume Id to
volume Name
        } catch (IOException e){
        }
        lvolName =
"\"VolumeName\":\""+name+"\",";
        //
System.out.println("\nVolume Name for
volid " + volid +  "is " +  name);
    }
}
```

Returns the record

The application finally returns the record after expanding the fid and volid to file path and volume name respectively.

```
String result = "";
StringTokenizer st2 = new
StringTokenizer(value,",");
while (st2.hasMoreTokens()) {
     String tokens = st2.nextToken();
     result = result + tokens + ",";
     if (tokens.contains("Fid")) {
         result = result + lfidPath;
     }
```

Sample Uncached Consumer Application for Audit Stream

The ConsumerUncached.java application demonstrates how to connect to the HPE Ezmeral Data Fabric file system, and consume the messages in a stream topic.

Sample Application

Before running this application, ensure that you have access to a cluster running file system. To build and run this application:

1. Set the classpath as shown below:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the Java file as shown below:

```
javac -cp .:`mapr classpath` ConsumerUncached.java
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

3. Run the final `ConsumerUncached.class` file. For example:

```
java -cp .:`mapr classpath` ConsumerUncached
```

This application requires the following:

- `org.apache.kafka.clients.consumer.ConsumerRecord`
- `org.apache.kafka.clients.consumer.ConsumerRecords`
- `org.apache.kafka.clients.consumer.KafkaConsumer`
- `org.apache.hadoop.conf.Configuration`
- `com.mapr.fs.MapRFileSystem`
- `com.google.common.io.Resources`
- `java.net.URI`
- `java.io.IOException`
- `java.io.InputStream`
- `java.util.Iterator`
- `java.util.Properties`
- `java.util.Random`
- `java.util.StringTokenizer`
- `java.util.regex.Pattern`

The application performs the actions described in the following sections.

Initializes the consumer properties

The configuration parameters for the consumer are stored in `consumer.props` file. This file should be present in the current directory or mapr classpath. For example, your `consumer.props` file could look similar to the following:

```
#bootstrap.servers=localhost:9092
group.id=test
enable.auto.commit=true
key.deserializer=org.apache.kafka.comm
on.serialization.StringDeserializer
value.deserializer=org.apache.kafka.co
mmon.serialization.StringDeserializer

# fast session timeout makes it more
fun to play with failover
## apps specific ?
session.timeout.ms=10000

# These buffer sizes are needed to
avoid consumer switching to
# a mode where it processes one
bufferful every 5 seconds with
multiple
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
# timeouts along the way.
fetch.min.bytes=50000
# receive.buffer.bytes=262144 //
fixed size buffer
max.partition.fetch.bytes=2097152

auto.offset.reset=earliest
```

The application initializes the consumer properties stored in the `consumer.props` file.

```
public static void main(String[]
args) throws
IOException,InterruptedException {
    KafkaConsumer<String, String>
consumer;
    try (InputStream props =
Resources.getResource("consumer.props"
).openStream()) {
          Properties properties = new
Properties();
          properties.load(props);
          if
(properties.getProperty("group.id")
== null) {

properties.setProperty("group.id",
"group-" + new
Random().nextInt(100000));
          }
      consumer = new
KafkaConsumer<>(properties);
      }
}
```

Subscribes to the topic to read from

The application initializes the filesystem object, with the last parameter as `true` so that the audit logs generated by the operations for converting fid to file path and volid to volume name are sent to the `ExpandAudit.json.log` file used by the `expandaudit` on page 2873 utility and not to the stream. It then selects the stream and subscribes to the topic to read at path `/var/mapr/auditstream/auditlogstream:<clustername>`.

```
Configuration conf = new
Configuration();
String uri = MAPRFS_URI;
uri = uri + "mapr/";
conf.set("fs.default.name", uri);
MapRFileSystem fs = new
MapRFileSystem();
fs.initialize(URI.create(uri), conf,
true);

Pattern pattern =
Pattern.compile("/var/mapr/
auditstream/
auditlogstream:<clustername>.+");
consumer.subscribe(pattern);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Requests unread messages from the topic

The application requests to read unread messages in the subscribed topic. It then iterates through the returned records, extracts the value of each message, and prints the value to the standard output.

```
boolean stop = false;
int pollTimeout = 1000;
while (!stop) {
      ConsumerRecords<String,
String> consumerRecords =
consumer.poll(pollTimeout);
      Iterator<ConsumerRecord<String,
String>> iterator =
consumerRecords.iterator();
      if (iterator.hasNext()) {
          while (iterator.hasNext()) {
              ConsumerRecord<String,
String> record = iterator.next();
              String value =
record.value();
              String rvalue =
value.replace("\"","");
              String recordValue =
processRecord(fs, rvalue, value);
              System.out.println(("
Consumed Record: " + recordValue));
          }
      } else {
                  //stop = true;
      }
}
```

Gets the record and expands individual fields

The application then takes the record and expands fid in the message to path to file using the `getMountPathFid()` API and volid in the message to volume name using the `getVolumeName()` API.

```
public static String
processRecord(MapRFileSystem fs,
String rvalue, String value)
  {
     StringTokenizer st = new
StringTokenizer(rvalue, ",");
     String lfidPath = "";
     String lvolName = "";

     while (st.hasMoreTokens()) {
          String field =
st.nextToken();
          StringTokenizer st1 = new
StringTokenizer(field, ":");
          while (st1.hasMoreTokens())
{
               String token =
st1.nextToken();
               if
(token.endsWith("Fid")) {
             String lfidStr =
st1.nextToken();
             String path= null;
             try {
                   path =
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
fs.getMountPathFid(lfidStr);
            } catch (IOException e)
{ }
            lfidPath =
"\"FidPath\":\""+path+"\",";
             if
(token.endsWith("volumeId")) {
          String volid =
st1.nextToken();
          String name= null;
          try {
              int volumeId =
Integer.parseInt(volid);
                name =
fs.getVolumeName(volumeId);
            }
          catch (IOException e){ }
          lvolName =
"\"VolumeName\":\""+name+"\",";
             }
       }
    }
```

Returns the record

The application finally returns the record after expanding the fid and volid to file path and volume name respectively.

```
String result = "";
StringTokenizer st2 = new
StringTokenizer(value,",");
while (st2.hasMoreTokens()) {
    String tokens = st2.nextToken();
    result = result + tokens + ",";
    if (tokens.contains("Fid")) {
       result = result + lfidPath;
    }
    if (tokens.contains("volumeId")) {
       result = result + lvolName;
    }
    return result.substring(0,
result.length() - 1);
}
```

            if (tokens.contains("Fid")) {
                result = result + lfidPath;
            }
            if (tokens.contains("volumeId")) {
                result = result + lvolName;
            }
        }
        return result.substring(0, result.length() - 1);
    }
}
```

HPE Ezmeral Data Fabric Streams Java Applications

This section contains information about developing client applications with Java, including information about the HPE Ezmeral Data Fabric Streams and Apache Kafka Java APIs, configuration parameters, and compiling and running producers and consumers.

Apache Kafka Support

HPE Ezmeral Data Fabric supports the following Apache Kafka Java API versions:

Table

Core version	Apache Kafka API
7.8 and later	3.6.1
7.0 through 7.7	2.6.1
6.2 and later	2.1
6.1 and later	1.1
6.0.1 and later	1.0
6.0.0 and earlier	0.9.0

Partition Assignment in Release 7.8.0 and Later

Release 7.8.0 added a significant change to the Consumer behavior related to partition assignment flow. In release 7.8.0 and later, partition assignment happens synchronously, according to the Apache Kafka contract defined in ConsumerRebalanceListener.

The process of updating the consumer assignment from the client side and invoking all related callbacks (in ConsumerRebalanceListener) happens within the `consumer.poll()` call in the user thread. This means that even after you call `consumer.assign()` / `consumer.subscribe()`, the new assignment will not come up to your consumer (the result of the `consumer.assignment()` call will not update) until you invoke `consumer.poll()`. You might need to do this multiple times or configure a longer timeout to complete the assignment in time. Also, the callback methods of the ConsumerRebalanceListener class are now guaranteed to be called synchronously from within the poll call by the user thread.

By comparison, with the old behavior, the partition assignment happened asynchronously in a background thread after you called `consumer.assign()` / `consumer.subscribe()`. It was enough to sleep for a couple of seconds to update your `consumer.assignment()` result and invoke the callback methods of the ConsumerRebalanceListener class in a background thread.

The new (synchronous) behavior is toggleable and can be disabled (switched to asynchronous behavior) by setting `streams.async.subscription.callback.enabled=true` in `core-site.xml`. In release 7.8.0 and later, the default value is `false`, meaning that by default the new behavior is enabled.

So, if you're planning to upgrade to release 7.8.0 or later and your application relies on the old behavior in a way that it sleeps right after `consumer.assign()` / `consumer.subscribe()` until partition assignment happens (that is, ConsumerRebalanceListener callbacks are invoked and the `consumer.assignment()` result is updated), do one of the following:

- Disable the new behavior.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- Redesign your application so that it starts polling without the new assignment and uses ConsumerRebalanceListener#onPartitionsAssigned() as a way to notify about successful assignment.

Synchronous Consumer Partition Assignment

As of HPE Ezmeral Data Fabric 7.8, synchronous consumer partition assignment is supported. For streams created with HPE Ezmeral Data Fabric 7.8 and later, this feature is enabled by default. To disable this feature, set `streams.async.subscription.callback.enabled=true` in `core-site.xml`. By default, this value is set to `false`.

With this feature enabled, consumer assignment updates and the invocation of related callbacks (in ConsumerRebalanceListener) occur synchronously within the `consumer.poll()` call in the user thread.

When setting a new consumer partition assignment, `consumer.assignment()` does not update until you invoke `consumer.poll()`.

NOTE: For the call to update, you might have to invoke `consumer.poll()` multiple times, or with a long enough timeout for assignment to be completed.

IMPORTANT: If you have an application that is set to sleep until consumer partition assignment is updated, you must perform one of the following actions to ensure the application continues to work as intended:

- Disable synchronous consumer partition assignment with `streams.async.subscription.callback.enabled=true` in `core-site.xml`.
- Enable the application to begin polling without the new user assignment. You can use ConsumerRebalanceListener#onPartitionsAssigned() to notify of successful consumer partition assignment.

Log Compaction

As of HPE Ezmeral Data Fabric 6.1, log compaction is supported. Log compaction can be enabled for streams created with HPE Ezmeral Data Fabric core 6.1 and later. In addition, clients older than HPE Ezmeral Data Fabric 6.1 are prevented from consuming from streams that have had log compaction enabled on them at least once in their lifetime.

When a stream on a source cluster has both log compaction and replication enabled, the replica cluster does not automatically have log compaction enabled. You must explicitly enable log compaction on the replica cluster.

- If a replica cluster has been upgraded and the stream data for a source cluster is compacted (that is, one or more messages have been deleted), then the source cluster replicates the compacted data to the replica cluster.
- If a replica cluster has ***not*** been upgraded, then the source cluster fails the replication and an error is generated that requests an replica cluster upgrade.

In the context of a scan by a client that is **not** upgraded, the (upgraded) server inspects the row header to check if it is serving a compacted row. If it is serving a compacted row, then the server fails the consumer request. This behavior applies both to a stream that is explicitly configured for compaction and a replica that has received a compacted row.

IMPORTANT: To perform log compaction on older streams, the `-force` option can be used. The `-force` option should only be used when ALL clients have been upgraded to HPE Ezmeral Data Fabric 6.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Idempotent Producer

As of HPE Ezmeral Data Fabric 6.1, the idempotent producer (exactly once) feature is supported. You can implement the idempotent producer with HPE Ezmeral Data Fabric core 6.1 and later.

NOTE: For HPE Ezmeral Data Fabric 7.8 and later, the idempotent producer feature is enabled by default.

When creating a producer instance, use the following configuration:

```
props.put(ProducerConfig.ENABLE_IDEMPOTENCE_CONFIG, true)
```

The idempotent producer feature is supported by EEP HPE Ezmeral Data Fabric 6.0 clients and HPE Ezmeral Data Fabric 6.1.0 servers.

- You must upgrade all servers to v6.1.0 and enable all the v6.1.0 features, before you enable the idempotent producer.
- If you use a pre-HPE Ezmeral Data Fabric 6.1 client and a HPE Ezmeral Data Fabric 6.1 server, and if a group of messages are atomically persisted without a valid producer ID, the server treats the request as a non-idempotent producer.
- If you use a HPE Ezmeral Data Fabric 6.1 client and a pre-HPE Ezmeral Data Fabric 6.1 server, the idempotent producer is not supported. In this case, the idempotent producer fails to produce to the stream and the following exception is thrown:

```
Exception in thread "main" java.util.concurrent.ExecutionException:
org.apache.kafka.common.errors.UnknownTopicOrPartitionException:
Operation not permitted (1) null

```

TimestampType Permissions

The following discussion describes the *ACE* permissions that you need when using the timestamp type parameter. See Stream Security on page 782 for general information about HPE Ezmeral Data Fabric Streams streams security.

A HPE Ezmeral Data Fabric Streams stream topic inherits the default timestamp type value from its stream. To override the stream's default value, set the timestamp type for the topic to a different value.

- Setting the value at the stream-level requires `adminperm` permissions. The stream-level timestamp type parameter is `defaulttimestamptype`. See stream create on page 2373 and stream edit on page 2379 for more information on setting this parameter using the `maprcli` command.
- Setting the `timestamptype` at the topic-level requires `topicperm` permissions. The topic-level timestamp type parameter is `timestamptype`. See stream topic create on page 2395 and stream topic edit on page 2398 for more information on setting this parameter using the `maprcli` command.

last-updated: Nov 14, 2024

User Impersonation

As of HPE Ezmeral Data Fabric 6.0, user impersonation is supported for HPE Ezmeral Data Fabric Streams.

You can set up user impersonation programmatically. To do so, use the `UserGroupInformation.doAs()` method in the Hadoop documentation. See Class UserGroupInformation for more information.

If you are setting up user impersonation in a secure cluster, you need to generate an impersonation ticket. See the Generating and Printing Service with Impersonation Ticket section in the maprlogin Command Examples on page 2921 topic.

After generating the ticket:

1. Ensure that user `mapruser1` has read permissions on the ticket.
2. If you moved the ticket file to a different location, set the `$MAPR_TICKETFILE_LOCATION` environment variable with the appropriate path.

For more information about impersonation, see:

- How Impersonation Works on page 1930
- Generating a Service with Impersonation Ticket on page 1819
- Managing Impersonation on page 1929

Backward Compatibility

As of HPE Ezmeral Data Fabric 6.0.1, along with the support of Apache Kafka, the `java.util.Collection` interface is being used. This impacts applications using certain APIs. See HPE Ezmeral Data Fabric Streams Java API Library on page 3584 for detailed information.

References

- HPE Ezmeral Data Fabric Streams Sample Programs on GitHub.

HPE Ezmeral Data Fabric Streams Java API Library

Use the HPE Ezmeral Data Fabric Streams Admin Java API library as an alternative to `maprcli` commands and the REST APIs for performing administrative tasks on streams and topics. This library can also be used for analysis of the contents of streams.

Javadoc

The following Apache Kafka Java API versions are supported:

Table

Core version	Apache Kafka API
7.8 and later	3.6.1
7.0 through 7.7	2.6.1
6.2 and later	2.1.1
6.1 and later	1.1
6.0.1 and later	1.0
6.0.0 and earlier	0.90

See the following APIs for detailed information:

HPE Ezmeral Data Fabric Streams Java APIs (as of 7.8)

The following HPE Ezmeral Data Fabric Streams Java APIs are available as of HPE Ezmeral Data Fabric 7.8:

Table

Interface	Method	Description
`StreamDescriptor`	`void setCompact(boolean compact)`	Sets log compaction on a stream.
`StreamDescriptor`	`boolean getCompact()`	Gets the log compaction on a stream. Returns true if the stream has log compaction on the stream.
`StreamDescriptor`	`void setMinCompactionLagMS(long ts)`	Sets the time in (milliseconds) that a message should remain uncompacted in the topic-partition. Applies only if log compaction is enabled on the stream.
`StreamDescriptor`	`long getMinCompactionLagMS()`	Returns the minimum time (in milliseconds) a message will remain uncompacted in the topic-partition. Applies only if log compaction is enabled on the stream.
`StreamDescriptor`	`void setDeleteRetentionMS(long ts)`	Sets the time (in milliseconds) for which deleted records are retained. Applies only if log compaction is enabled on the stream.
`StreamDescriptor`	`long getDeleteRetentionMS()`	Returns the time (in milliseconds) for which deleted records are retained. Applies only if log compaction is enabled on the stream.
`Producer`	`ProducerConfig` class	The idempotence producer option is set by setting the `enable.idempotence` value of **true** passed through the ProducerConfig class.

NOTE: For Apache Kafka 3.6.1, some methods are not suppported.

Admin methods:

- Using Topic IDs:
  - `DescribeTopicsResult describeTopics(TopicCollection topics, DescribeTopicsOptions options)`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- ```
  DeleteTopicsResult deleteTopics(TopicCollection topics,
  DeleteTopicsOptions options)
  ```

- With more than one group:

  ```
  ListConsumerGroupOffsetsResult
  listConsumerGroupOffsets(Map<String,ListConsumerGroupOffsetsSpec>
  groupSpecs, ListConsumerGroupOffsetsOptions options)
  ```

- And the following additional methods:

  ```
  public DescribeUserScramCredentialsResult
  describeUserScramCredentials(List<String> users,
  DescribeUserScramCredentialsOptions options) {
  public AlterUserScramCredentialsResult
  alterUserScramCredentials(List<UserScramCredentialAlteration>
  alterations, AlterUserScramCredentialsOptions options) {
  public DescribeFeaturesResult
  describeFeatures(DescribeFeaturesOptions options) {
  public UpdateFeaturesResult updateFeatures(Map<String, FeatureUpdate>
  featureUpdates, UpdateFeaturesOptions options) {
  public DescribeMetadataQuorumResult
  describeMetadataQuorum(DescribeMetadataQuorumOptions options) {
  public UnregisterBrokerResult unregisterBroker(int brokerId,
  UnregisterBrokerOptions options) {
  public DescribeProducersResult
  describeProducers(Collection<TopicPartition> partitions,
  DescribeProducersOptions options) {
  public DescribeTransactionsResult
  describeTransactions(Collection<String> transactionalIds,
  DescribeTransactionsOptions options) {
  public AbortTransactionResult abortTransaction(AbortTransactionSpec
  spec, AbortTransactionOptions options) {
  ```

Consumer methods:

- ```
  OptionalLong currentLag(TopicPartition topicPartition)
  ```

- ```
  void enforceRebalance(String reason)
  ```

HPE Ezmeral Data Fabric Streams Java APIs (as of 6.0.1)

The following table lists the new Interfaces and APIs for HPE Ezmeral Data Fabric 6.0.1. They are the delta between HPE Ezmeral Data Fabric 6.0.1 and 6.0.0, meaning, they are applicable to HPE Ezmeral Data Fabric6.0.1 but not HPE Ezmeral Data Fabric 6.0.0.

Table

Interface and Methods	Description
Admin.close	Long duration for TimeUnit.
Admin.createTopic	TopicDescriptor array for topic attributes.
Admin.editTopic	TopicDescriptor array for topic attributes.
Admin.getTopicDescriptor	Method for retrieving topic attributes.

©Copyright 2024 Hewlett Packard Enterprise Development LP
  ```

Table (Continued)

Interface and Methods	Description
Admin.listTopic	Method for listing all the topics in a stream.
Admin.streamExists	Method for determining whether a stream exists.
StreamDescriptor.getDefaultTimestampType	Method for retrieving the timestamp type.
StreamDescriptor.setDefaultTimestampType	Method for setting the timestamp type.
TopicDescriptor	New HPE Ezmeral Data Fabric interface.
TopicDescriptor.getPartitions	Method associated with the new interface.
TopicDescriptor.setPartitions	Method associated with the new interface.
TopicDescriptor.getTimestampType	Method associated with the new interface.
TopicDescriptor.setTimestampType	Method associated with the new interface.
Enum TimestampType	New Enum class and associated methods.

Backward Compatibility

As of HPE Ezmeral Data Fabric 6.0.1, Apache Kafka 1.0 is supported. The following `pause`, `resume`, `seekToBeginning`, and `seekToEnd` APIs support the Collection Interface. The deprecated APIs will continue to run unchanged, however, they may be removed in a future release.

Table

Replacement Collection APIs	Deprecated APIs
void pause(Collection<TopicPartition> partitions);	void pause(TopicPartition... partitions);
void resume(Collection<TopicPartition>partitions);	void resume(TopicPartition... partitions);
void seekToBeginning(Collection<TopicPartition>);	void seekToBeginning(TopicPartition... partitions);
void seekToEnd(Collection<TopicPartition>);	void seekToEnd(TopicPartition... partitions);

The following `subscribe` and `assign` APIs support the Collection Interface (which is more generalized) as well as the List Interface. Support for the List Interface has been retained for backward binary compatibility.

Table

Replacement Collection APIs	Retained APIs
void subscribe(Collection<String> topics);	void subscribe(java.util.List<java.lang.String> topics);
void subscribe(Collection<String> topics, ConsumerRebalanceListener);	void subscribe(java.util.List<java.lang.String> topics, ConsumerRebalanceListener listener);
void assign(Collection<TopicPartition> partitions);	void assign(java.util.List<TopicPartition> partitions);

Stream and Topic Operations Summary

Provides a summary of stream topic operations and the interface, class, or method used for the operation.

The following stream and topic operations is not an inclusive list, but a sampling. For detailed information, see the following libraries:

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Table

Operation	Interface/Method Used
Creating streams	`StreamDescriptor` is used to set the attributes for streams that you plan to create. `Admin.createStream(String streamPathAndName, StreamDescriptor desc)` - create the stream.
Editing stream attributes	`StreamDescriptor` is used to edit the stream's attribute values. `Admin.editStream(String streamPathAndName, StreamDescriptor desc)` - set or modify the stream's attribute values.
Retrieving the default timestamp type on a stream	`StreamDescriptor.getDefaultTimestampType()` - retrieves the default timestamp type on the stream. **NOTE:** This method is new as of 6.0.1
Sets the default timestamp type on a stream	`StreamDescriptor.setDefaultTimestampType(TimestampType logAppendTime)` - sets the default timestamp type on the stream. **NOTE:** TimestampType Enum is new as of 6.0.1
Deleting streams	`Admin.deleteStream(String streamPathAndName)`
Determining stream existence	`Admin.streamExists(String streamPathAndName)` - determines whether a stream exists or not. Returns: true | false **NOTE:** This method is new as of 6.0.1
Creating topics	`Admin.createTopic(String streamPathAndName, String topicName, TopicDescriptor desc)` is used when creating a topic with the defaults for partitions and timestamp type. **NOTE:** TopicDescriptor is new as of 6.0.1 `Admin.createTopic(String streamPathAndName, String topicName)` is used when accepting the default number of partitions. `Admin.createTopic(String streamPathAndName, String topicName, int npartitions)` - creates a topic with a specific number of partitions. **NOTE:** If you do not specify the number of partitions for a stream topic, the default number of partitions is inherited from the stream.
Editing topics	`Admin.editTopic(String streamPathAndName, String topicName, TopicDescriptor desc)` - sets the partitions and timestamp type attributes of a topic. **NOTE:** TopicDescriptor is new as of 6.0.1 `Admin.editTopic(String streamPathAndName, String topicName, int npartitions)`
Retrieving topic attributes	`Admin.getTopicDescriptor(String streamPathAndName, String topicName)` - retrieves topic attributes. **NOTE:** This method is new as of 6.0.1
Deleting topics	`Admin.deleteTopic(String streamPathAndName, String topicName)` - deletes topics.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Table (Continued)

Operation	Interface/Method Used
Listing topics	`Admin.listTopics(String streamPathAndName)` - lists all topics in a stream. **NOTE:** This method is new as of 6.0.1
Counting topics	`Admin.countTopics(String streamPathAndName)` - counts the number of topics in a stream.
Gets/Sets topic timestamp type	`TopicDescriptor` is used to retrieve the timestamp type attribute value of a topic. **NOTE:** TopicDescriptor is new as of 6.0.1 `TopicDescriptor.getTimestampType()` - retrieves the default timestamp type of a topic. `TopicDescriptor.setTimestampType(TimestampType timestampType)` - sets the default timestamp type of a topic.
Gets/Sets topic partitions	`TopicDescriptor` is used to retrieve the partition attribute value of a topic. **NOTE:** TopicDescriptor is new as of 6.0.1 `TopicDescriptor.getPartitions()` - retrieves the partitions of a topic. `TopicDescriptor.setParitions(int numPartitions)` - sets the partitions of a topic.
Enabling and tuning log compaction	`TopicDescriptor` is used to enable and tune log compaction at the stream-level. • `setCompact(boolean compact)` - sets log compaction. • `getCompact()` - returns **true** if log compaction is set on the stream. • `setMinCompactionLagMS(long ts)` - set the lag time (in milliseconds) that a message should remain uncompacted. • `getMinCompactionLagMS()` - retrieves the value of the lag time. • `setDeleteRetentionMS(long ts)` - sets the time (in milliseconds) for which deleted records are retained. • `getDeleteRetentionMS()` - returns the time value of which deleted records are retained. In addition, the `Admin` interface is used with the following method to set compaction at the topic-level: • `compactTopic(java.lang.String streamPath, java.lang.String topicName)`
Enabling an Idempotent Producer	The `Producer` interface along with the `ProducerConfig` class is used to enable idempotence (exact-once message delivery semantics) publishing.

Managing Streams with Java
Provides Java code snippets for performing CRUD operations on HPE Ezmeral Data Fabric Streams streams.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Creating Streams

`StreamDescriptor` is used to set attributes for streams that you want to create.

```
public StreamDescriptor createStreamDescriptor(int numPartitions, String
adminUsers, String producerUsers, String consumerUsers, String copyUsers,
String topicUsers) {
        StreamDescriptor desc = Streams.newStreamDescriptor();
        desc.setDefaultPartitions(numPartitions);
        desc.setCompressionAlgo("zlib");
        desc.setAutoCreateTopics(false);
        desc.setAdminPerms(adminUsers);
        desc.setConsumePerms(consumerUsers);
        desc.setCopyPerms(copyUsers);
        desc.setTopicPerms(topicUsers);

        return desc;
}
```

`Admin` is used with the `createStream` method to create the stream with the pre-established attribute values.

```
public void createStreamUtilFunction(String streamPathAndName,
StreamDescriptor desc) throws IllegalArgumentException, IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.createStream(streamPathAndName, desc);
        streamAdmin.close();
}
```

Editing Stream Attributes

`StreamDescriptor` is used to retrieve the stream's attribute values. `Admin` with the `editStream` method is used to set or modify the stream's attribute values.

```
Admin.editStream(String streamPathAndName, StreamDescriptor desc)
```

```
Configuration conf = new Configuration();
Admin streamAdmin = Streams.newAdmin(conf);
        StreamDescriptor desc =
streamAdmin.getStreamDescriptor(streamPathAndName);
```

```
public void editStreamUtilFunction(String streamPathAndName,
StreamDescriptor desc) throws IllegalArgumentException, IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.editStream(streamPathAndName, desc);
        streamAdmin.close();
}
```

Deleting Streams

```
public void deleteStreamUtilFunction(String streamPathAndName) throws
IllegalArgumentException, IOException{
          Configuration conf = new Configuration();
          Admin streamAdmin = Streams.newAdmin(conf);
          streamAdmin.deleteStream(streamPathAndName);
          streamAdmin.close();
}
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Managing Topics with Java
Provides Java code snippets for performing CRUD operations on HPE Ezmeral Data Fabric Streams stream topics.

Creating Topics

The `createTopic` API is used to create a topic with the default number of partitions.

```
Admin.createTopic(String streamPathAndName, String topicName)
```

NOTE: If you do not specify the number of partitions for a stream topic, the default number of partitions is inherited from the stream.

```
public void createTopicUtilFunction(String streamPathAndName, String
topicName) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.createTopic(streamPathAndName, topicName);
        streamAdmin.close();
}
```

The `createTopic` API is used to create a topic with a specific number of partitions.

```
Admin.createTopic(String streamPathAndName, String topicName, int
npartitions)
```

```
public void createTopicWithPartitionsUtilFunction(String streamPathAndName,
String topicName, int npartitions) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.createTopic(streamPathAndName, topicName, npartitions);
        streamAdmin.close();
}
```

Editing Topics

The `editTopic` API is used to change timestamp type and the number of partitions for a topic.

```
Admin.editTopic(String streamPathAndName, String topicName, int npartitions)
```

```
public void editTopicUtilFunction(String streamPathAndName, String
topicName, int npartitions) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.editTopic(streamPathAndName, topicName, npartitions);
        streamAdmin.close();
}
```

Retrieving Topic Attributes

The `getTopicDescriptor` API is used to get or set the topic's attribute values. `TopicDescriptor` is passed into methods to set and retrieve topic partitions and timestamp type. The `Enum TimestampType` values are CREATE_TIME and LOG_APPEND_TIME.

NOTE: `TopicDescriptor` is available as of MapR 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Deleting Topics

The `deleteTopic` API is used to delete a topic from a stream.

```
Admin.deleteTopic(String streamPathAndName, String topicName)
```

```
public void deleteTopicUtilFunction(String streamPathAndName, String
topicName) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.deleteTopic(streamPathAndName, topicName);
        streamAdmin.close();
}
```

Counting Topics

The `countTopics` API is used to count the number of topics in a stream. See the mapr streamanalyzer on page 5791 utility for a sample application that counts and queries topic messages.

```
Admin.countTopics(String streamPathAndName)
```

```
public int countTopicsUtilFunction(String streamPathAndName){
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        int count = streamAdmin.countTopics(streamPathAndName);
        streamAdmin.close();

        return count;
}
```

Using Timestamps on Streams and Topics

Provides a code example for using timestamps on HPE Ezmeral Data Fabric Streams streams and topics.

Passing Timestamp Value

The timestamp value can be passed as part of the `ProducerRecord`, for example:

```
ProducerRecord<String, String> producerRecord =
        new ProducerRecord<String, String>(topicName, partition, timestamp,
key, value);
```

NOTE: The timestamp value is retained if the timestamp type is `createtime`. If the timestamp type is `logappendtime`, then the timestamp value is ignored and instead the server timestamp is used.

Retrieving Timestamp Type

This example sets and retrieves the timestamp type. The following code example performs the following:

- Creates a stream with a default timestamp type of LogAppendTime.
- Creates a topic with a specific timestamp type of CreateTime.
- Retrieves the topics's timestamp type.

```
// Create stream with default timestamp type as "LogAppendTime"
// Create a topic with timestamp type as "CreateTime"
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
// Create a stream
        StreamDescriptor sDesc = Streams.newStreamDescriptor();
        sDesc.setDefaultTimestampType(TimestampType.LOG_APPEND_TIME);
        streamAdmin.createStream(streamName, sDesc);

// Create a topic
        TopicDescriptor tDesc = Streams.newTopicDescriptor();
        tDesc.setTimestampType(TimestampType.CREATE_TIME);
        streamAdmin.createTopic(streamName, topicName, tDesc);

// Get topic timestamp type
        TopicDescriptor rDesc = streamAdmin.getTopicDescriptor(streamName,
topicName);
        System.out.println(rDesc.getTimestampType().name);
```

Enabling Log Compaction

Provides a code example for using timestamps on HPE Ezmeral Data Fabric Streams streams and topics.

Log compaction is enabled through the HPE Ezmeral Data Fabric Streams `StreamDescriptor` interface with the `setCompact` method where the compact value is set to **true**. Additionally, use the `setDeleteRetentionMS` and `setMinCompactionLagMS` methods to set the time delay before compacting records and the time that deleted records are retained.

Configuration values include:

- compact - used to set log compaction at the stream-level.
- min.compaction.lag.ms - used to set a **minimum** time delay (milliseconds) before starting to compact records after they are written. Records won't get compacted until after this period. The setting gives consumers time to retrieve every record.
- delete.retention.ms - used to set the **minimum** time (milliseconds) that deleted records are retained.

NOTE: You can set not set log compaction when creating the stream; only when editing the stream configuration. The configuration parameters, `min.compaction.lag.ms` and `delete.retention.ms` can be set when both creating and editing streams.

Enabling Log Compaction

The following code example performs the following:

- Enables log compaction at the stream-level.
- Sets the minumum time delay before log compaction starts
- Set the minimum time that deleted record are retained.

```
// Creates a stream
// Sets log compaction on the stream
// Sets the minimum time for a message to stay uncompacted
// Sets the time that deleted records are retained.

(Admin streamAdmin = Streams.newAdmin(conf))
    StreamDescriptor streamDescriptor = Streams.newStreamDescriptor();
       streamDescriptor.setCompact(true);
       streamDescriptor.setDeleteRetentionMS(deleteRetentionMs);
    streamDescriptor.setMinCompactionLagMS(minCompactionLagMs);
       streamAdmin.editStream(streamName, streamDesc);
}
```

- Preparing Clusters for Log Compaction on page 1495

Enabling an Idempotent Producer
Describes how to enable an idempotent producer. Idempotence refers to exactly-once message delivery semantics.

To enable idempotence, the `enable.idempotence` configuration must be set to **true**. When set, the retries configuration defaults to Integer.MAX_VALUE and the Acks configuration defaults to all.

The idempotence producer option is set by setting the `enable.idempotence` value of true passed through the `ProducerConfig` class.

Constant Field Values
`org.apache.kafka.clients.producer.ProducerConfig`

Modifier and Type	Constant Field	Value
`public static final java.lang.String`	`ENABLE_IDEMPOTENCE_CONFIG`	enable.idempotence

Example Code Snippet:

```
props.put(ProducerConfig.ENABLE_IDEMPOTENCE_CONFIG, true);
```

NOTE: The default is false, which retains at-least-once message delivery semantics.

TIP: There are no API changes for the Idempotent Producer functionality, so existing applications do not need to be modified except to enable the producer configuration property.

Example: Subscribing and Querying with Timestamps
This sample Java consumer application uses the `subscribe` API to subscribe to the input topics and queries offsets upon partition-assignment.

In the query, the `offsetsForTimes` API returns the earliest offset in a topic-partition with a timestamp greater than or equal to the input timestamp. The consumer then seeks to that offset if it is greater than the consumer's current position. Following this, the consumer polls for messages. If there are messages following that offset with timestamps earlier than the input timestamp, then those messages are skipped by the consumer.

```

Querying Topic Messages
Describes how HPE Ezmeral Data Fabric Streams topic messages can be queried.

Time-based Querying

The **consumer.offsetsForTimes**API is used to get offsets in a topic-partition. This API takes in a `Map` of `TopicPartition` and timestamp. The offset is returned in an `OffsetAndTimestamp` object when `offsetsForTime` is called.

The following shows how the Map is constructed:

```
Long timestamp = 1522195205L;
TopicPartition topicPartition = new TopicPartition(topic,partition);

HashMap<TopicPartition, Long> offsetsForTimesMap = new
HashMap<TopicPartition, Long>();
offsetsForTimesMap.put(topicPartition, timestamp);

// Invocation to offsetsForTimes
Map<TopicPartition, OffsetAndTimestamp> offsetForTimesResultMap =
consumer.offsetsForTimes(offsetsForTimesMap);
```

Direct Querying

The `Streams` class is used to directly query topic messages. See the mapr streamanalyzer on page 5791 utility for a sample application that counts and queries topic messages.

- The `getMessageStore()` APIs are used to get the `DocumentStore` object which represents the underlying topic messages for a specified stream.

©Copyright 2024 Hewlett Packard Enterprise Development LP

- The `DocumentStore.find()` APIs are used to query the messages that are in the `DocumentStore` object. While running `find()` on the returned DocumentStore object, message fields can be projected based on the specified field name.

NOTE: DocumentStore is a part of the open-source OJAI API.

The logical schema of each message is the same, where analytics applications can run queries on these fields. See Logical Schema of Messages on page 753 for more information.

```
{
        "_id":<STRING>,
        "topic":<STRING>,
        "partition":<SHORT>,
        "offset":<LONG>,
        "timestamp":<LONG>,
        "producer":<VARCHAR>,
        "key":<BINARY>,
        "value":<VARBINARY>
}
```

Apache Kafka Java APIs
HPE Ezmeral Data Fabric Streams supports these Apache Kafka Java APIs.

Javadoc

For information about EEP and core version support, see EEP Support and Lifecycle Status on page 5989.

See the following APIs for detailed information:

- HPE Ezmeral Data Fabric Streams Java API Library
- For core 7.8 and above: Apache Kafka 3.6.1 APIs used with HPE Ezmeral Data Fabric Streams
- For core 7.7 and below: Apache Kafka 2.6.1 APIs used with HPE Ezmeral Data Fabric Streams

Admin APIs

The following Admin APIs, `org.apache.kafka.clients.admin` package, are applicable to HPE Ezmeral Data Fabric support of Apache Kafka.

NOTE: The AdminClient API options (CreateTopicsOptions, DeleteTopicsOptions, DescribeTopicsOptions, ListTopicsOptions, CreatePartitionsOptions, and DescribeTopicsOptions), are ignored. All of the methods assume that a topic belongs to the default stream unless a stream path is specified in the topic name.

If a default stream name is not specified and the topic path does not contain a stream name, the an exception is reported via the Result object. For example:

- If the topic name is specified as `topic1`, then the API assumes the full topic path as `/defaultStream:topic1`.
- If the topic name is specified as `/defaultStream:topic1`, then that will be the full topic path.

NOTE: The `AdminClient` default stream configuration parameter is `streams.admin.default.stream`. See Configuration Parameters on page 3600 for more information.

©Copyright 2024 Hewlett Packard Enterprise Development LP

NOTE: For a complete list of supported APIs, see:

- For core 7.8 and above: Apache Kafka 3.6.1 APIs used with HPE Ezmeral Data Fabric Streams
- For core 7.7 and below: Apache Kafka 2.6.1 APIs used with HPE Ezmeral Data Fabric Streams

Consumer APIs

The following Consumer APIs, `org.apache.kafka.clients.consumer` package, are applicable to HPE Ezmeral Data Fabric support of Apache Kafka.

Table

Modifier and Type	Method
long	timestamp()
long	timestamptype()

Table

Modifier and Type	Method
void	pause(Collection<TopicPartition> partitions)
void	resume(Collection<TopicPartition>partitions)
void	seekToBeginning(Collection<TopicPartition>)
void	seekToEnd(Collection<TopicPartition>)
void	subscribe(Collection<String> topics);
void	subscribe(Collection<String> topics, ConsumerRebalanceListener)
void	assign(Collection<TopicPartition> partitions)
java.util.Map<TopicPartition,OffsetAndTimestamp>	offsetsForTimes(java.util.Map<TopicPartition,java.lang.Long> timestampsToSearch)
java.util.Map<TopicPartition,java.lang.Long>	beginningOffsets(Collection<TopicPartition>)
java.util.Map<TopicPartition,java.lang.Long>	endOffsets(Collection<TopicPartition> partitions)
ConsumerRecords<K,V>	poll(long timeout)
void	commitSync()
void	commitAsync()

The following consumer interface and classes are applicable to HPE Ezmeral Data Fabric support of Apache Kafka.

- org.apache.kafka.clients.consumer.ConsumerConfig
- org.apache.kafka.clients.consumer.ConsumerRebalanceCallback (interface)
- org.apache.kafka.clients.consumer.ConsumerRecord<K,V>
- org.apache.kafka.clients.consumer.ConsumerRecords<K,V>
- org.apache.kafka.clients.consumer.KafkaConsumer<K, V> implements Consumer<K, V>

last-updated: Nov 14, 2024

NOTE: For a complete list of supported APIs, see:

- For core 7.8 and above: Apache Kafka 3.6.1 APIs used with HPE Ezmeral Data Fabric Streams
- For core 7.7 and below: Apache Kafka 2.6.1 APIs used with HPE Ezmeral Data Fabric Streams

Producer APIs

The following producer interface and classes, `org.apache.kafka.clients.producer` package, are applicable to HPE Ezmeral Data Fabric support of Apache Kafka.

Table

Modifier and Type	Method
java.util.concurrent.Future<RecordMetadata>	send(ProducerRecord<K,V> record)
void	flush()
void	close()

The following producer interface and classes are applicable to HPE Ezmeral Data Fabric support of Apache Kafka.

- org.apache.kafka.clients.producer.Callback (Interface)
- org.apache.kafka.clients.producer.KafkaProducer<K,V>
- org.apache.kafka.clients.producer.ProducerConfig
- org.apache.kafka.clients.producer.ProducerRecord<K,V>
- org.apache.kafka.clients.producer.RecordMetadata

NOTE: For a complete list of supported APIs, see:

- For core 7.8 and above: Apache Kafka 3.6.1 APIs used with HPE Ezmeral Data Fabric Streams
- For core 7.7 and below: Apache Kafka 2.6.1 APIs used with HPE Ezmeral Data Fabric Streams

Common APIs

The following common APIs, `org.apache.kafka.clients.common` packages, are applicable toHPE Ezmeral Data Fabric support of Apache Kafka.

Table

Modifier and Type	Method
java.lang.String	key()
byte[]	value()

The following APIs are applicable to HPE Ezmeral Data Fabric support for Apache Kafka.

- org.apache.kafka.common.PartitionInfo

  Supported methods in PartitionInfo:

  - int partition()
  - java.lang.String topic()

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

    - java.lang.String toString()
- org.apache.kafka.common.serialization.Serializer<T> (Interface)
- org.apache.kafka.common.serialization.Deserializer<T> (interface)
- org.apache.kafka.common.TopicPartition

NOTE: For a complete list of supported APIs, see:

- For core 7.8 and above: Apache Kafka 3.6.1 APIs used with HPE Ezmeral Data Fabric Streams
- For core 7.7 and below: Apache Kafka 2.6.1 APIs used with HPE Ezmeral Data Fabric Streams

Configuration Parameters

This topic describes configuration parameters that are either specific to HPE Ezmeral Data Fabric Streams or supported from Apache Kafka.

AdminClient

Table

Parameter	Description
`streams.admin.default.stream`	This parameter, when set during creation of the AdminClient instance, ensures that the specified stream is using the the AdminClient instance for all administrative operations. Syntax: `/mapr/<cluster name>/<volume name>/<stream name>`
`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 120000 Minimum: 30000 **NOTE:** Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout` For producer and consumer applications, make sure the `streams.rpc.timeout.ms` configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Table (Continued)

Parameter	Description
`use.brokers`	A boolean flag that specifies whether or not the Apache Kafka clients (Producer, Consumer, Admin) should connect to Apache Kafka brokers or HPE Ezmeral Data Fabric Streams services. Default: false **false** — To connect the Apache Kafka clients to HPE Ezmeral Data Fabric Streams services, set this flag as `false`. The `bootstrap.servers` property is optional and is ignored. **true** — To connect the Apache Kafka clients to Apache Kafka brokers, set this flag as `true`. The `bootstrap.servers` property is required, and must be filled in the client configuration and console scripts.

Consumer

Table

Parameter	Description
`streams.consumer.buffer.memory`	Specifies how much memory to use for caching pre-fetched messages. Messages that are in subscribed topics and partitions are pre-fetched and cached to improve performance. Default 64MB
`streams.consumer.default.stream`	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream.
`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if a soft mount is configured (fs.mapr.hardmount is set to false). Default: 305000 Minimum: 300000 For producer and consumer applications, make sure the `streams.rpc.timeout.ms` configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Table (Continued)

Parameter	Description
`use.brokers`	A boolean flag that specifies whether or not the Apache Kafka clients (Producer, Consumer, Admin) should connect to Apache Kafka brokers or HPE Ezmeral Data Fabric Streams services. Default: false **false** — To connect the Apache Kafka clients to HPE Ezmeral Data Fabric Streams services, set this flag as `false`. The `bootstrap.servers` property is optional and is ignored. **true** — To connect the Apache Kafka clients to Apache Kafka brokers, set this flag as `true`. The `bootstrap.servers` property is required, and must be filled in the client configuration and console scripts.

Table

Parameter	Description
`auto.commit.interval.ms`	The frequency in milliseconds that the offsets are committed. Default: 1000ms
`auto.offset.reset`	Specifies what HPE Ezmeral Data Fabric Streams should do when there is no initial offset, such as when a consumer starts reading from a partition. Default: latest **`earliest`** — Reset the offset to the offset of the earliest message in the partition. **`latest`** — Reset the offset to the offset of the latest message in the partition.
`enable.auto.commit`	If true, periodically commits the highest offsets of the messages fetched by the consumer in all of the partitions for the topics that the consumer is subscribed to. Default: true

©Copyright 2024 Hewlett Packard Enterprise Development LP

Table (Continued)

Parameter	Description
`fetch.min.bytes`	The minimum amount of data the server should return for a fetch request. If insufficient data is available, the server will wait for this minimum amount of data to accumulate before answering the request. This minimum applies to the totality of what a consumer has subscribed to. Works in conjunction with the timeout interval that is specified in the poll function. If the minimum number of bytes is not reached by the time that the interval expires, the poll returns with nothing. For example, suppose the value is set to 6 bytes and the timeout on a poll is set to 100ms. If there are 5 bytes available and no further bytes come in before the 100ms expire, the poll returns with nothing. Default: 1 byte
`fetch.max.bytes`	The maximum amount of data the server should return for a fetch request. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress. **NOTE:** This parameter is new as of MapR 6.0.1.
`fetch.max.wait.ms`	The maximum amount of time the HPE Ezmeral Data Fabric Streams server will block before answering the fetch request if there isn't sufficient data to satisfy the requirement given by `fetch.min.bytes`.
`group.id`	A string 2457 up to bytes long that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group ID, multiple consumer processes indicate that they are all part of the same consumer group. Putting consumers into groups provides benefits that are described in Consumer Groups. It is possible for a single consumer to be in a group.
`max.poll.records`	Places an upper bound on the number of records returned from each call. **NOTE:** This parameter is new as of MapR 6.0.1.
`max.partition.fetch.bytes`	The number of bytes of message data to attempt to fetch for each partition in each poll request. These bytes will be read into memory for each partition, so this parameter helps control the memory that the consumer uses. Default: 64KB The size of the poll request must be at least as large as the maximum message size that the server allows or else it is possible for producers to send messages that are larger than the consumer can fetch. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress. **NOTE:** This is a behavior change as of MapR 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Producer

Table

Parameter	Description
`streams.buffer.max.time.ms`	Messages are buffered in the producer for at most the specified time. A thread will flush all the messages that have been buffered for more than the time specified. Default: 3 * 1000 msec create default stream
`streams.parallel.flushers.per.partition`	If enabled, producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order. Default: true create default stream
`streams.producer.default.stream`	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. Syntax: `/mapr/<cluster name>/<volume name>/<stream name>` create default stream
`fs.mapr.hardmount`	Specifies whether to use a hard mount or a soft mount for connections to the MapR Streams server. The default is to use a hard mount and the value is `true`. If a value for this parameter is set in the `core-site.xml` file, the value in that file is ignored. create default stream
`fs.mapr.rpc.timeout`	Specifies the length of time in seconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if the configuration parameter `fs.mapr.hardmount` is set to false. Default: 300. Minimum value: 30. **NOTE:** Applicable to MapR 6.0.0 and earlier. As of MapR 6.0.1, use `streams.mapr.timeout.ms`. If a soft mount is used, the time expires while a producer waits for a response from the HPE Ezmeral Data Fabric Streams server, and the producer used the `KafkaProducer.send(ProducerRecord<K,V> record, Callback callback)` method, the callback is invoked with the error `EAGAIN`, which means "Resource temporarily unavailable." create default stream
`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 30000 Minimum: 30000 For producer and consumer applications, make sure the `streams.rpc.timeout.ms` configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Table (Continued)

Parameter	Description
`use.brokers`	A boolean flag that specifies whether or not the Apache Kafka clients (Producer, Consumer, Admin) should connect to Apache Kafka brokers or HPE Ezmeral Data Fabric Streams services. Default: false **false** — To connect the Apache Kafka clients to HPE Ezmeral Data Fabric Streams services, set this flag as `false`. The `bootstrap.servers` property is optional and is ignored. **true** — To connect the Apache Kafka clients to Apache Kafka brokers, set this flag as `true`. The `bootstrap.servers` property is required, and must be filled in the client configuration and console scripts.

Table

Parameter	Description
`buffer.memory`	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are generated faster than they can be delivered to the server the producer will block. Default: 33554432
`client.id`	Producers can tag records with a client ID that identifies the producer. Consumers can then be aware of which producer sent a message or set of messages. Apache Drill or other analytic tools querying messages can include this ID in the filters for their queries. Default: No client ID.
`metadata.max.age.ms`	The producer generally refreshes the topic metadata from the server when there is a failure. It will also poll for this data regularly. Default: 300 * 1000 msec

Compiling and Running HPE Ezmeral Data Fabric Streams Java Apps

For producer and consumer applications that use the HPE Ezmeral Data Fabric Streams Java API, use Maven to compile and determine the application dependencies. Then, when you run the application, specify those dependencies in the application classpath.

Compile and Determine Dependencies

For an example `pom.xml` file, see HPE Ezmeral Data Fabric Streams Streams Sample Programs on GitHub.

©Copyright 2024 Hewlett Packard Enterprise Development LP

1. Add the HPE Maven repository to your `pom.xml` file, if it is not already added:

```
<repositories>
    <repository>
      <id>mapr-releases</id>
      <url>https://repository.mapr.com/nexus/content/repositories/
releases</url>
      <snapshots><enabled>true</enabled></snapshots>
      <releases><enabled>true</enabled></releases>
    </repository>
</repositories>
```

2. Add a dependency to the Data Fabric Streams Java client (kafka-clients) project:

```
<dependency>
      <groupId>org.apache.kafka</groupId>
      <artifactId>kafka-clients</artifactId>
      <version><version selected from the repository></version>
</dependency>
```

NOTE: The kafka-clients version mentioned above is an example. The actual version that your application requires is based on the current EEP and Data Fabric core version that you are running. The versions are listed in the following locations: https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/kafka/kafka-clients/

3. Add a dependency to the Data Fabric Streams project:

   If you are using EEP version 9.1.2 and later:

```
<dependency>
      <groupId>org.apache.kafka</groupId>
      <artifactId>kafka-eventstreams</artifactId>
      <version><version selected from the repository></version>
</dependency>
```

   If you are using EEP version 8.1.0 through 9.1.1:

```
<dependency>
      <groupId>com.mapr.kafka</groupId>
      <artifactId>mapr-streams</artifactId>
      <version><version selected from the repository></version>
</dependency>
```

NOTE: The Data Fabric Streams project version mentioned above is an example. The actual version that your application requires is based on the current EEP and Data Fabric version that you are running. The versions are listed in the following locations:

- For EEP version 9.1.2 and later: https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/kafka/kafka-eventstreams/
- For EEP version 8.1.0 through 9.1.1: https://repository.mapr.com/nexus/content/groups/mapr-public/com/mapr/kafka/kafka-eventstreams/
- Starting with EEP 8.1.0, this library is deprecated: https://repository.mapr.com/nexus/content/groups/mapr-public/com/mapr/streams/mapr-streams/

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

4. Use Maven to compile the application and resolve dependencies. For example, you can run `mvn clean package`.

Run the Application

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 3186.

When the cluster is secure, the node must also have a Data Fabric ticket configured for the user that runs the application.

Use the following command to launch HPE Ezmeral Data Fabric Streams applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

Migrating Apache Kafka Java Applications to HPE Ezmeral Data Fabric Streams

There are only two steps that you need to follow to migrate applications written with the Apache Kafka Java API to HPE Ezmeral Data Fabric Streams.

About this task

The following steps assume that migration is from either:

- Apache Kafka 2.6.1 to HPE Ezmeral Data Fabric Streams 6.2 or higher
- Apache Kafka 2.1.1 to HPE Ezmeral Data Fabric Streams 6.2 or higher
- Apache Kafka 1.1 to HPE Ezmeral Data Fabric Streams 6.1 or higher
- Apache Kafka 1.0 to HPE Ezmeral Data Fabric Streams 6.0.1 or higher
- Apache Kafka 0.9.0 to HPE Ezmeral Data Fabric Streams 6.0.0 or earlier

IMPORTANT: For information on backward compatibility, see HPE Ezmeral Data Fabric Streams Java API Library on page 3584

©Copyright 2024 Hewlett Packard Enterprise Development LP

Procedure

1. Change the names of topics to include the path and name of the MapR Stream stream in which the topic is located.

   Here is the syntax to use:

   ```
   /<path and name of stream>:<name of topic>
   ```

   For example, you might have a stream in a MapR cluster that is named `stream_A`, and the stream might be in a volume named `IoT` and in a directory named `automobile_sensors`. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this:

   ```
   /mapr/IoT/automobile_sensors/stream_A:<name of topic>
   ```

2. If a producer application uses the Kafka interface Partitioner to compute which partitions to publish messages to, revise the application so that it uses the Kafka StreamsPartitioner interface instead.

Differences between HPE Ezmeral Data Fabric Streams and Apache Kafka Configuration
Describes the HPE Ezmeral Data Fabric Streams supportability of Apache Kafka configuration parameters for producers and consumers.

Kafka Producer

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`bootstrap.servers`	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form `host1:port1,host2:port2,...` Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).	No. Cluster details are discovered from the file `mapr-clusters.conf`.
`key.serializer`	`Serializer` class for key that implements the `Serializer` interface.	Yes
`value.serializer`	`Serializer` class for value that implements the `Serializer` interface.	Yes

©Copyright 2024 Hewlett Packard Enterprise Development LP

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`acks`	The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common:	Ignored, all writes in HPE Ezmeral Data Fabric Streams are synchronous, and number of replicas is determined at the volume level, with a default of 3.
	`acks=0` If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won't generally know of any failures). The offset given back for each record will always be set to -1.	
	`acks=1` This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost.	
	`acks=all` This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee.	
`buffer.memory`	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server the producer will either block or throw an exception based on the preference specified by `block.on.buffer.full`.	Yes
	This setting should correspond roughly to the total memory the producer will use, but is not a hard bound since not all memory the producer uses is used for buffering. Some additional memory will be used for compression (if compression is enabled) as well as for maintaining in-flight requests.	

©Copyright 2024 Hewlett Packard Enterprise Development LP

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`compression.type`	The compression type for all data generated by the producer. The default is none (i.e. no compression). Valid values are `none`, `gzip`, `snappy`, or `lz4`. Compression is of full batches of data, so the efficacy of batching will also impact the compression ratio (more batching means better compression).	Ignored. Compression is configured per stream.
`retries`	Setting a value greater than zero will cause the client to resend any record whose send fails with a potentially transient error. Note that this retry is no different than if the client resent the record upon receiving the error. Allowing retries will potentially change the ordering of records because if two records are sent to a single partition, and the first fails and is retried but the second succeeds, then the second record may appear first.	Ignored. HPE Ezmeral Data Fabric Streams always does automatic retries on transient errors.
`ssl.key.password`	The password of the private key in the key store file. This is optional for client.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.keystore.location`	The location of the key store file. This is optional for client and can be used for two-way authentication for client.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.keystore.password`	The store password for the key store file.This is optional for client and only needed if `ssl.keystore.location` is configured.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.truststore.location`	The location of the trust store file.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.truststore.password`	The password for the trust store file.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`batch.size`	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. This configuration controls the default batch size in bytes.	Ignored. HPE Ezmeral Data Fabric always batches records for optimal performance.
	No attempt will be made to batch records larger than this size.	
	Requests sent to brokers will contain multiple batches, one for each partition with data available to be sent.	
	A small batch size will make batching less common and may reduce throughput (a batch size of zero will disable batching entirely). A very large batch size may use memory a bit more wastefully as we will always allocate a buffer of the specified batch size in anticipation of additional records.	
`client.id`	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just ip/port by allowing a logical application name to be included in server-side request logging.	Yes
`connections.max.idle.ms`	Close idle connections after the number of milliseconds specified by this config.	Ignored.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`linger.ms`	The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay —that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle's algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get batch.size worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will 'linger' for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting linger.ms=5, for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absense of load.	Ignored.
`max.block.ms`	The configuration controls how long {@link KafkaProducer#send()} and {@link KafkaProducer#partitionsFor} will block. These methods can be blocked for multiple reasons. For e.g: buffer full, metadata unavailable.This configuration imposes maximum limit on the total time spent in fetching metadata, serialization of key and value, partitioning and allocation of buffer memory when doing a send(). In case of partitionsFor(), this configuration imposes a maximum time threshold on waiting for metadata	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`max.request.size`	The maximum size of a request. This is also effectively a cap on the maximum record size. Note that the server has its own cap on record size which may be different from this. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.	Ignored.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`partitioner.class`	Partitioner class that implements the Partitioner interface.	Use the Kafka StreamsPartitioner interface.
`receive.buffer.bytes`	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	Ignored.
`request.timeout.ms`	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`sasl.kerberos.service.name`	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`security.protocol`	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`send.buffer.bytes`	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	Ignored.
`ssl.enabled.protocols`	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.	Ignored.
`ssl.keystore.type`	The file format of the key store file. This is optional for client. Default value is JKS	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.protocol`	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.provider`	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.truststore.type`	The file format of the trust store file. Default value is JKS.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`timeout.ms`	The configuration controls the maximum amount of time the server will wait for acknowledgments from followers to meet the acknowledgment requirements the producer has specified with the acks configuration. If the requested number of acknowledgments are not met when the timeout elapses an error will be returned. This timeout is measured on the server side and does not include the network latency of the request.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`block.on.buffer.full`	When our memory buffer is exhausted we must either stop accepting new records (block) or throw errors. By default this setting is true and we block, however in some scenarios blocking is not desirable and it is better to immediately give an error. Setting this to false will accomplish that: the producer will throw a BufferExhaustedException if a recrord is sent and the buffer space is full.	Ignored.
`max.in.flight.requests.per.connection`	The maximum number of unacknowledged requests the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries (i.e., if retries are enabled).	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.parallel.flushers.per.partition`
`metadata.fetch.timeout.ms`	The first time data is sent to a topic we must fetch metadata about that topic to know which servers host the topic's partitions. This fetch to succeed before throwing an exception back to the client.	Ignored.
`metadata.max.age.ms`	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	Yes
`metric.reporters`	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	No
`metrics.num.samples`	The number of samples maintained to compute metrics.	No.
`metrics.sample.window.ms`	The number of samples maintained to compute metrics.	No.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`reconnect.backoff.ms`	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`retry.backoff.ms`	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`sasl.kerberos.kinit.cmd`	Kerberos kinit command path. Default is /usr/bin/kinit	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`sasl.kerberos.min.time.before.relogin`	Login thread sleep time between refresh attempts.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`sasl.kerberos.ticket.renew.jitter`	Percentage of random jitter added to the renewal time.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`sasl.kerberos.ticket.renew.window.factor`	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.cipher.suites`	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol.By default all the available cipher suites are supported.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.endpoint.identification.algorithm`	The endpoint identification algorithm to validate server hostname using server certificate.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.keymanager.algorithm`	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
`ssl.trustmanager.algorithm`	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.

Kafka Consumer

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
bootstrap.servers	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form host1:port1,host2:port2,.... Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).	No. Cluster details are discovered from the file `mapr-clusters.conf`.
key.deserializer	Deserializer class for key that implements the Deserializer interface.	Yes
value.deserializer	Deserializer class for value that implements the Deserializer interface.	Yes
fetch.min.bytes	The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request. The default setting of 1 byte means that fetch requests are answered as soon as a single byte of data is available or the fetch request times out waiting for data to arrive. Setting this to something greater than 1 will cause the server to wait for larger amounts of data to accumulate which can improve server throughput a bit at the cost of some additional latency.	Yes
fetch.max.bytes	The maximum amount of data the server should return for a fetch request. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress. **NOTE:** This is new as of MapR 6.0.1.	Yes, as of MapR 6.0.1.
group.id	A unique string that identifies the consumer group this consumer belongs to. This property is required if the consumer uses either the group management functionality by using subscribe(topic) or the Kafka-based offset management strategy.	Yes

©Copyright 2024 Hewlett Packard Enterprise Development LP

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
heartbeat.interval.ms	The expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than session.timeout.ms, but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	No
max.poll.records	Places an upper bound on the number of records returned from each call. **NOTE:** This parameter is new as of MapR 6.0.1.	Yes, as of MapR 6.0.1.
max.partition.fetch.bytes	The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be #partitions * max.partition.fetch.bytes. This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress. **NOTE:** This is a behavior change as of MapR 6.0.1.	Yes
session.timeout.ms	The timeout used to detect failures when using Kafka's group management facilities.	Ignored
ssl.key.password	The password of the private key in the key store file. This is optional for client.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.keystore.location	The location of the key store file. This is optional for client and can be used for two-way authentication for client.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
ssl.keystore.password	The store password for the key store file.This is optional for client and only needed if ssl.keystore.location is configured.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.truststore.location	The location of the trust store file.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.truststore.password	The password for the trust store file.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
auto.offset.reset	What to do when there is no initial offset in Kafka or if the current offset does not exist any more on the server (e.g. because that data has been deleted): **earliest** automatically reset the offset to the earliest offset **latest** automatically reset the offset to the latest offset **none** throw exception to the consumer if no previous offset is found for the consumer's group **anything else** throw exception to the consumer.	Yes
connections.max.idle.ms	Close idle connections after the number of milliseconds specified by this config.	Ignored
enable.auto.commit	If true the consumer's offset will be periodically committed in the background.	Yes
partition.assignment.strategy	The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used	Ignored. HPE Ezmeral Data Fabric Streams distributes partitions equally among the consumers in a group.
receive.buffer.bytes	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	Ignored.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
request.timeout.ms	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
sasl.kerberos.service.name	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
security.protocol	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
send.buffer.bytes	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	Ignored.
ssl.enabled.protocols	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.keystore.type	The file format of the key store file. This is optional for client. Default value is JKS	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.protocol	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.provider	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.truststore.type	The file format of the trust store file. Default value is JKS.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
auto.commit.interval.ms	The frequency in milliseconds that the consumer offsets are auto-committed to Kafka if enable.auto.commit is set to true.	Yes

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
check.crcs	Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.	Ignored. HPE Ezmeral Data Fabric Streams always does end-to-end crc computation and verification.
client.id	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just ip/port by allowing a logical application name to be included in server-side request logging.	Yes
fetch.max.wait.ms	The maximum amount of time the server will block before answering the fetch request if there isn't sufficient data to immediately satisfy the requirement given by fetch.min.bytes.	No
metadata.max.age.ms	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	Yes
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	No
metrics.num.samples	The number of samples maintained to compute metrics.	No
metrics.sample.window.ms	The number of samples maintained to compute metrics.	No
reconnect.backoff.ms	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
retry.backoff.ms	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
sasl.kerberos.kinit.cmd	Kerberos kinit command path. Default is /usr/bin/kinit	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
sasl.kerberos.min.time.before.relogin	Login thread sleep time between refresh attempts.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
sasl.kerberos.ticket.renew.jitter	Percentage of random jitter added to the renewal time.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
sasl.kerberos.ticket.renew.window.factor	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.cipher.suites	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol.By default all the available cipher suites are supported.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate server hostname using server certificate.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.keymanager.algorithm	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.
ssl.trustmanager.algorithm	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 809 for more information.

HPE Ezmeral Data Fabric Streams Parameters

The following HPE Ezmeral Data Fabric Streams parameters are for the Admin API.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Table

HPE Ezmeral Data Fabric Streams Parameter	Description	Kafka Parameter Replaced

`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 120000 Minimum: 30000
	 NOTE: Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout`
		`request.timeout.ms`
		`reconnect.backoff.ms`
		`retry.backoff.ms`

The following HPE Ezmeral Data Fabric Streams parameter are for the Producer API:

Table

HPE Ezmeral Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
`streams.buffer.max.time.ms`	Messages are buffered in the producer for at most the specified time. A thread will flush all the messages that have been buffered for more than the time specified. Default: 3 * 1000 msec	`linger.ms`
`streams.parallel.flushers.per.partition`	If enabled, producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order. Default: true	`max.in.flight.requests.per.connection`
`streams.partitioner.class`	The class that implements the `StreamsPartitioner` interface. This interface lets you write custom algorithms for determining which topic and partition to use for messages that match specific criteria. Use this configuration parameter only for producers that are written in Java.	Not applicable.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Table (Continued)

HPE Ezmeral Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
`streams.producer.default.stream`	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>/<topic> However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Ezmeral Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.	Not applicable.

`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 30000 Minimum: 30000
	If the time expires while a producer waits for a response from the HPE Ezmeral Data Fabric Streams server, and the producer used the `KafkaProducer.send(ProducerRecord<K,V> record, Callback callback)` method, the callback is invoked with the error `EAGAIN`, which means "Resource temporarily unavailable."
	NOTE: Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout`
		`max.block.ms`
		`request.timeout.ms`
		`timeout.ms`
		`reconnect.backoff.ms`
		`retry.backoff.ms`

The following HPE Ezmeral Data Fabric Streams parameters are for the Consumer API:

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Table

HPE Ezmeral Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
`streams.consumer.default.stream`	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. This default value is also used for the KafkaConsumer.listTopics() method.	Not applicable.

`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if a soft mount is configured (fs.mapr.hardmount is set to false). Default: 305000 Minimum: 300000
	NOTE: Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout`
		`request.timeout.ms`
		`reconnect.backoff.ms`
		`retry.backoff.ms`

HPE Ezmeral Data Fabric Streams C Applications

You can develop C applications for HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams C Client is available in Ecosystem Pack (EEP) 3.0 and later.

The following Apache Kafka librdkafka versions are supported:

Table

Core release	EEP Release	Kafka librdkafka version
As of 7.9.0	As of 9.3.1	2.0.2*
As of 6.0.1	As of 5.0	0.11.3
As of 5.2.1 through 6.0.0	As of 3.0	0.9.0

*Librdkafka 2.0.2 in core 7.9 is **not** compatible with HPE Ezmeral Data Fabric Stream clients for Python[1] or C#[2] applications. Nodes running Python or C# applications should not be upgraded to HPE Ezmeral Data Fabric 7.9.

[1]HPE Ezmeral Data Fabric Streams Python Applications on page 3982

[2]HPE Ezmeral Data Fabric Streams C#/.NET Applications on page 3993

The HPE Ezmeral Data Fabric Streams C Client supports a majority of the librdkafka C APIs plus additional configuration properties that are available only with HPE Ezmeral Data Fabric Streams. When developing applications for HPE Ezmeral Data Fabric Streams or migrating Kafka applications to HPE Ezmeral Data Fabric Streams, see the list of librdkafka APIs Supported by HPE Ezmeral Data Fabric Streams C Client on page 3640 which also describes API behavior. Reference rdkafka.h for API signatures.

When developing and running HPE Ezmeral Data Fabric Streams C applications, note the following:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- As of HPE Ezmeral Data Fabric 6.0, the HPE Ezmeral Data Fabric Streams offset values start at 0.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- HPE Ezmeral Data Fabric Security is supported. Kafka application-level security is not supported. See Security on page 809.
- User impersonation is not supported.

CAUTION: As of HPE Ezmeral Data Fabric 6.1, the mapr-core package has a dependency on mapr-librdkafka. If the mapr-librdkafka package is installed, do not remove it manually. Doing so could result in the removal of HPE Ezmeral Data Fabric core packages, rendering the node unusable.

Configuring the HPE Ezmeral Data Fabric Streams C Client
After installing the HPE Ezmeral Data Fabric Client and before developing applications, you must configure your client C library by setting the library path.

Linux

For Linux installations, add `/opt/mapr/lib` to the end of LD_LIBRARY_PATH.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib
```

IMPORTANT: For HPE Ezmeral Data Fabric 6.0.1, the libjvm.so configuration is *not* required.

For HPE Ezmeral Data Fabric 6.0.0 and earlier, add the /opt/mapr/lib *and the path to the directory that contains libjvm.so* to the end of LD_LIBRARY_PATH.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/
lib:<path_to_libjvm.so_directory>
```

The location of the libjvm.so differs based on where you installed Java. You can use `find / -name libjvm*` to determine the file location. For example, if the libjvm.so file is in the following location:

```
/usr/lib/jvm/java-7-openjdk-amd64/jre/lib/amd64/server/libjvm.so
```

Then, you set the library path like this:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib:/usr/lib/jvm/
java-7-openjdk-amd64/jre/lib/amd64/server/
```

Mac

For Mac installations, add `/opt/mapr/lib` to the end of DYLD_LIBRARY_PATH.

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

IMPORTANT: For HPE Ezmeral Data Fabric 6.0.1, the libjvm.so configuration is *not* required.

For HPE Ezmeral Data Fabric 6.0.0 and earlier, add /opt/mapr/lib *and the path to the directory that contains libjvm.dylib* to the end of DYLD_LIBRARY_PATH.

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/
lib:<path_to_libjvm.dylib_directory>
```

The location of the libjvm.dylib differs based on where you installed Java. You can use `find / -name libjvm*` to determine the file location. For example, if the libjvm.dylib file is in the following location:

```
/Library/Java/JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/
Home/jre/lib/server/libjvm.dylib
```

Then, you set the library path like this:

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib:/Library/Java/
JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/Home/jre/lib/server
```

Windows

NOTE: As of HPE Ezmeral Data Fabric 6.0.1, the HPE Ezmeral Data Fabric C client is available on Windows.

For Windows installations, no additional configuration is required. Link your application and run your programs against the HPE Ezmeral Data Fabric Client dynampic link libraries (dll) located at: `C:\opt\mapr\lib`. The corresponding librdkafka header is `C:\opt\mapr\include\librdkafka`.

Developing a HPE Ezmeral Data Fabric Streams C Application

This topic includes basic information about how to develop a HPE Ezmeral Data Fabric Streams C application. Sample applications are provided.

Before you Begin

Confirm that your environment meets the following requirements:

- The HPE Ezmeral Data Fabric cluster version is 5.2.1 or greater.
- HPE Ezmeral Data Fabric core client (mapr-client) packagei s installed on the node and it is configured to access the cluster. Or, it is a HPE Ezmeral Data Fabric cluster node. See Installing the Data Fabric Client (Non-FIPS) on page 383 for more information.
- The HPE Ezmeral Data Fabric Streams C Client is installed and configured on the node. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.
- GNU Compiler Collection (GCC) is installed on the node.

Creating, Compiling and Running C Apps

The following sections describes how to create a producer and consumer in C, compile the source code, generate executables, and run the applications.

Create Producer

This topic describes how to create a HPE Ezmeral Data Fabric Streams streams producer in C. While the code to generate a HPE Ezmeral Data Fabric Streams stream producer varies depending on the use case, in general, the producer code should contain the following:

©Copyright 2024 Hewlett Packard Enterprise Development LP

1. Include the rdkafka.h header file (/opt/mapr/include/librdkafka/rdkafka.h)
2. Use `rd_kafka_conf_new()` to create the producer configuration.
3. Use `rd_kafka_new ()` to create the producer handle.
4. Use `rd_kafka_topic_conf_new()` to create the topic configuration.
5. Use `rd_kafka_topic_new ()` to create a topic handle for the producer.
6. Use `rd_kafka_produce()` to produce messages.
7. Optionally, use `rd_kafka_poll()`to poll for callbacks. This is useful to see if there are messages that have yet to be sent to the server.
8. Use `rd_kafka_topic_destroy ()` to destroy the topic handle destroy
9. Use `rd_kafka_destroy ()` to destroy the producer handle.

NOTE: For more details on the APIs, see Supported APIs for HPE Ezmeral Data Fabric Streams C Client and rdkafka.h on page 3721

For example, the following source code produces 5 messages to topic /MapR_Streams:MapR-Topic1:

```
/*
 * This file contains the producer function.
 *
 */

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <rdkafka.h>
#include <errno.h>

/* msgDeliveryCB: Is the delivery callback.
 * The delivery report callback will be called once for each message
 * accepted by rd_kafka_produce() with err set to indicate
 * the result of the produce request. An application must call
rd_kafka_poll()
 * at regular intervals to serve queued delivery report callbacks.
 */
static void msgDeliveryCB (rd_kafka_t *rk,
                           const rd_kafka_message_t *rkmessage, void
*opaque) {
    if (rkmessage->err != RD_KAFKA_RESP_ERR_NO_ERROR) {
        printf("FAILURE: Message not delivered to partition.\n");
        printf("ERROR: %s", rd_kafka_err2str(rkmessage->err));
    } else {
        printf("Produced: %.*s\n",(int)rkmessage->len, (const
char*)rkmessage->payload);
    }
}

/*
 * Method      : int producer(int nummsgs_p, const char *fullTopicName)
 * Description : This is a simple producer method. In this method the
producer
 *               produces messages to a topic.
 */
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
int producer(int nummsgs_p, const char *fullTopicName) {
    printf("********************** PRODUCER **********************\n");
    rd_kafka_t *prodHndle;
    rd_kafka_conf_t *prodCfg;
    char errstr[1000];
    int totalMsgs = nummsgs_p;

    printf("Create producer configuration object\n");
    /*
     * rd_kafka_conf_new(): This API creates default rd_kafka_conf_t object
to
     * be passed at the time of producer object creation using rd_kafka_new
call.
     */
    prodCfg = rd_kafka_conf_new();
    if (prodCfg == NULL) {
        printf("Failed to create conf\n");
        return (EXIT_FAILURE);
    }
    /* rd_kafka_conf_set_dr_msg_cb(): This API sets the producer callback
     * 'msgDeliveryCB' in producer config 'prodCfg'
     * The delivery report callback will be called once for each message
     * accepted by rd_kafka_produce() with err set to indicate
     * the result of the produce request. An application must call
rd_kafka_poll()
     * at regular intervals to serve queued delivery report callbacks.
     */
    rd_kafka_conf_set_dr_msg_cb(prodCfg, msgDeliveryCB);

    printf("Create Producer Kafka handle\n");
    /*
     * rd_kafka_new():Creates a new Kafka handle and starts its operation
     * according to the specified type (RD_KAFKA_CONSUMER or
RD_KAFKA_PRODUCER).
     * prodCfg object passed here is freed by this function and must not be
used
     * or destroyed by the application subsequently. errstr must be a
pointer to
     * memory of at least size errstr_size where
     * `rd_kafka_new()` may write a human readable error message in case the
     * creation of a new handle fails. In which case the function returns
NULL.
     */
    prodHndle = rd_kafka_new(RD_KAFKA_PRODUCER, prodCfg, errstr,
sizeof(errstr));
    if (prodHndle == NULL) {
        printf("Failed to create producer: %s\n", errstr);
        return (EXIT_FAILURE);
    }

    /*
     * Following code does following:
     * 1. Create a topic handle for each producer-topic combination
     * 2. Produce 'totalMsgs' # of messages using topic handle created in
step 1
     * 3. Wait for all messages to be produced and callback to be delivered.
     * 4. Move on to next topic and repeat.
     */

    int totalTopics = 1;
    for (int nTopics = 0; nTopics < totalTopics ; nTopics++) {
        printf("Create topic handle\n");
        rd_kafka_topic_conf_t *prodTopicCfg;
        /*
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
         * rd_kafka_topic_conf_new(): This API Creates topic conf object
         * required to create topic handle which then will be used for each
         * producer-topic combination
         */

        prodTopicCfg = rd_kafka_topic_conf_new();
        if (prodTopicCfg == NULL) {
            printf("Failed to create new topic conf\n");
            return (EXIT_FAILURE);
        }

            rd_kafka_topic_t *prodTopicHndl;
            /*
             * rd_kafka_topic_new(): This API Creates topic handle for a
given
             * producer, topic name and topic config. Topic handles are
refcounted
             * internally and calling rd_kafka_topic_new()
             * again with the same topic name will return the previous
topic handle
             * without updating the original handle's configuration.
             * Applications must eventually call rd_kafka_topic_destroy()
for each
             * succesfull call to rd_kafka_topic_new() to clear up
resources.
             */
            prodTopicHndl = rd_kafka_topic_new(prodHndle, fullTopicName,
prodTopicCfg);
            if (prodTopicHndl == NULL) {
                printf("Failed to create new topic handle\n");
                return (EXIT_FAILURE);
            }
            prodTopicCfg = NULL; /* Now owned by topic */

            const char* key ="Key";
            printf("Send/Produce message to topic: %s\n", fullTopicName);
            for (int i = 0; i < totalMsgs; i++) {
                    char payload[1000];
                    if (i == 0)
                         sprintf(payload, "%s", "Welcome to MapR Streams
CAPI");
                    else
                         sprintf(payload, "MapR Streams CAPI Message
Payload %d", i);
                    /*
                    * rd_kafka_produce(): This API produces a single message
                    * to the cluster. prodTopicHandle must be created using
                    * rd_kafka_topic_new() api. This is an asynch
non-blocking API.
                    * RD_KAFKA_PARTITION_UA is used to indicate automatic
                    * partitioning, using topics partitioner or fixed
partition
                    * can be provided. RD_KAFKA_MSG_F_COPY flag indicates
that
                    * library copies the payload and application manages
its own
                    * payload memory. If API fails to send, errno will be
set
                    * accordingly and will be able to access librdkafka
specific
                    * error using rd_kafka_last_error() api.
                    */
                    if (rd_kafka_produce(prodTopicHndl,
                                         RD_KAFKA_PARTITION_UA,
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
                                        RD_KAFKA_MSG_F_COPY,

                        printf("Failed to produce to topic : %s\n",
rd_kafka_topic_name(prodTopicHndl));
                        printf("Error Number: %d ERROR NAME: %s\n"
                                ,errNum,
rd_kafka_err2str(rd_kafka_last_error()));
                        return (errNum);
                    }
            }

            printf("Wait for messages to be delivered\n");
            /*
            * rd_kafka_outq_len(): This API out queue contains messages
waiting
            * to be sent to, or acknowledged by, server.
            * An application should wait for this queue to reach zero before
            * terminating to make sure outstanding requests are fully
processed.
            *
            * rd_kafka_poll(): This API polls the producer handle for
events,
            * which will cause application provided callbacks to be called.
            * An application must call rd_kafka_poll() at regular intervals
to
            * serve queued delivery report callbacks. In this case
            * 'msgDeliveryCB' will get called.
            */
            while (rd_kafka_outq_len(prodHndle) > 0)
                rd_kafka_poll(prodHndle, 100);

            printf("\nDestroy topic handle\n");
            /*
            * Applications must eventually call rd_kafka_topic_destroy()
for each
            * succesfull call to rd_kafka_topic_new() to clear up resources.
            */
            rd_kafka_topic_destroy(prodTopicHndl);
    }
    printf("Destroy producer handle\n");
    /*
     * rd_kafka_destroy(): This API destroys the producer handle created
using
     * rd_kafka_new call and frees resources.
     */
    rd_kafka_destroy(prodHndle);

    return(EXIT_SUCCESS);
}

/* MAIN */
int main(int argc, char *argv[]) {

  /* Number of messages the producer will produce */
  int nummsgs_p = 5;

  /* This is pre created Stream with one topic and one partition*/
  const char* fullTopicName = "/MapR_Streams:MapR-Topic1";
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```

  } else {
    printf("\nPASS: %d messages produced and sent to topic partition %s
\n", nummsgs_p, fullTopicName);
  }
}
```

Create Consumer

This topic describes how to create a HPE Ezmeral Data Fabric Streams streams consumer in C. While the code to generate a HPE Ezmeral Data Fabric Streams stream consumer varies depends on the use case, in general, the consumer code should contain the following:

1. Include the rdkafka.h header file (/opt/mapr/include/librdkafka/rdkafka.h).
2. Use `rd_kafka_conf_new()` to create the consumer configuration.
3. Use `rd_kafka_conf_set()` to set the configuration parameters. For this API, you must set the "group.id."
4. Use `rd_kafka_new ()` to create the consumer handle.
5. Use `rd_kafka_subscribe()` or `rd_kafka_assign()` to specify which topics to consume.
6. Use `rd_kafka_consumer_poll()` to poll for messages that are ready to be consumed.
7. Use `rd_kafka_consumer_close()` to perform auto commits and prepare to destroy the consumer handle.
8. Use `rd_kafka_destroy ()` to destroy the consumer handle.

For example, the following source code consumes 5 messages from topic /MapR_Streams:MapR-Topic1:

```
/*
 * This file contains the consumer function.
 *
 */

#include <stdio.h>
#include <stdlib.h>
#include <rdkafka.h>
#include <string.h>

/*
 * Method      : int consumer(int expected_nummsgs, const char
*fullTopicName)
 * Description : This is a simple consumer method. In this method the
consumer
 *               consumes messages from a topic.
 */

int consumer(int expected_nummsgs, const char *fullTopicName) {
    printf("*********  CONSUMER START  *********\n");
    rd_kafka_t *consHndle;
    rd_kafka_conf_t *consCfg;
    rd_kafka_topic_conf_t *consTopicCfg;
    char errstr[1000];
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    rd_kafka_resp_err_t errCode;

    printf("Create new consumer configuration object\n");
    /*
    * rd_kafka_conf_new(): This API creates default rd_kafka_conf_t object
to
    * be passed at the time of consumer object creation using rd_kafka_new
call.
    */
    consCfg = rd_kafka_conf_new();
    if(consCfg == NULL) {
        printf("Failed to create consumer conf\n");
        return(EXIT_FAILURE);
    }
    /*
    * rd_kafka_conf_set(): This API is used to set config parameters in the
    * rd_kafka_conf_t object. group.id Must be set for all the consumers.
    * All changes to the consCfg must be done before creating consumer
object.
    */
    if(RD_KAFKA_CONF_OK != rd_kafka_conf_set(consCfg,
                     "group.id", "consumerGroup",
                     errstr, sizeof(errstr))) {
        printf("rd_kafka_conf_set() failed with error: %s\n", errstr);
        return (EXIT_FAILURE);
    }
   /*
    * rd_kafka_topic_conf_new(): This API Creates topic conf object
    * required to set the default topic configuration.
    */
    printf("Set topic configurations\n");
    consTopicCfg = rd_kafka_topic_conf_new();

    /* rd_kafka_topic_conf_set(): This API sets the config property by name.
    * consTopicCfg should have been previously set up with
`rd_kafka_topic_conf_new()`
    * property set in this call is 'auto.offset.reset', when set to
    * earliest will return messages on rd_kafka_consumer_poll from
beginning of
    * time (for the very first time consumption) or from last commited
offset
    * for online consumer. If property is set to 'latest' it will return the
    * messages produced after consumer has started(for first time consumer)
or
    * from the last committed offset for online consumer
    */
    if (RD_KAFKA_CONF_OK != rd_kafka_topic_conf_set(consTopicCfg,
"auto.offset.reset",
                            "earliest" ,errstr, sizeof(errstr))) {
        printf("rd_kafka_topic_conf_set() failed with error: %s\n", errstr);
        return (EXIT_FAILURE);
    }

    /*
    * rd_kafka_conf_set_default_topic_conf(): This API sets the default
topic
    * configuration to use for automatically subscribed topics
    * The topic config object is not usable after this call.
    */
    rd_kafka_conf_set_default_topic_conf(consCfg, consTopicCfg);

    printf("Create consumer Kafka handle\n");
    /*
     * rd_kafka_new():Creates a new Kafka handle and starts its operation
```

  }
}
```

NOTE: For more details on the APIs, see Supported APIs for HPE Ezmeral Data Fabric Streams C Client and rdkafka.h on page 3721

Compile the Apps

This topic describes how to compile HPE Ezmeral Data Fabric Streams streams producers and consumers in C. When you compile a HPE Ezmeral Data Fabric Streams C application, you must link it with the librdkafka library in the /opt/mapr/lib/ library path and include the header file directory to ensure that your application references the header file included with HPE Ezmeral Data Fabric Streams C Client.

IMPORTANT: For MapR 6.0.0 and earlier, When you compile a HPE Ezmeral Data Fabric Streams C application, you must link it with the librdkafka library in the /opt/mapr/lib/ library path, *the libjvm library*, and include the header file directory to ensure that your application references the header file included with HPE Ezmeral Data Fabric Streams C Client.

The following steps compile the source code and generate executables in the same directory as the Makefile. For example, in the **librdkafka_example** directory, the `consumer` and `producer` executables are generated from the producer.c and consumer.c source files.

1. On your node, create a directory. For example: **librdkafka_example**.
2. In your directory (**librdkafka_example**), create a producer application. For example, if you are using the provided sample producer application:
   a. Create a file named producer.c.
   b. Copy the contents of the sample producer application into that file.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

3. In your directory (**librdkafka_example**), create a consumer application. For example, if you are using the provided sample consumer application:
   a. Create a file named consumer.c.
   b. Copy the contents of the sample consumer application into that file.
4. In your directory (**librdkafka_example**), create a file named Makefile with the following content:

```
CC= g++
HEADERDIR=/opt/mapr/include/librdkafka/
CCFLAGS= -Wall -I$(HEADERDIR) -g -std=c99

export LD_LIBRARY_PATH=/opt/mapr/lib

LIBDIR= /opt/mapr/lib/
%.o: %.c
    gcc $(CCFLAGS) -c $<

consumer: consumer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

producer: producer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

all: consumer producer

clean:
    /bin/rm -f *.o consumer producer
```

   IMPORTANT: For MapR 6.0.0 and earlier, use the following Makefile:

```
CC= g++
HEADERDIR=/opt/mapr/include/librdkafka/
CCFLAGS= -Wall -I$(HEADERDIR) -g -std=c99

#Edit JAVA_HOME to be appropriate for your environment
JAVA_HOME=/usr/lib/jvm/java-7-openjdk-amd64/
export LD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/amd64/
server

LIBDIR= /opt/mapr/lib/
%.o: %.c
    gcc $(CCFLAGS) -c $<

consumer: consumer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

producer: producer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

all: consumer producer

clean:
    /bin/rm -f *.o consumer producer
```

5. Complete the following edits to the Makefile:

   For Mac users, locate the following line of code:

```
export LD_LIBRARY_PATH=/opt/mapr/lib
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Then, replace this line with the following line of code:

```
export DYLD_LIBRARY_PATH=/opt/mapr/lib
```

IMPORTANT: For MapR 6.0.0 and earlier, the following steps apply:

a. For Mac users, locate the following line of code:

```
export LD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/amd64/
server
```

Then, replace this line with the following line of code:

```
export DYLD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/server
```

b. Based on your environment, edit JAVA_HOME. This ensures that LD_LIBRARY_PATH or DYLD_LIBRARY_PATH will include the full path to the directory containing the libjvm library.

NOTE: You can use `find / -name libjvm*` to determine the JAVA_HOME directory on your machine. However, note that the results of this command include the full path to the libjvm file not just the JAVA_HOME directory.

For example, JAVA_HOME may be set to `Library/Java/JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/Home/` on a Mac and JAVA_HOME may be set to `/usr/lib/jvm/java-1.7.0-openjdk-1.7.0.79.x86_64/` on Linux.

6. From your directory (**librdkafka_example**), run the following commands to compile the source code:

```
make clean
```

```
make all
```

Run the Apps

Once you have the application executables, complete the following steps to run the application:

1. On a cluster node, use the maprcli to create a stream. For example, **MapR_Streams**.

```
maprcli stream create -path /MapR_Streams
```

NOTE: As long as autocreate is enabled for the stream when you run `stream create`,the producer will create the topic. By default, autocreate is enabled. For more information, see stream create on page 2373.

2. At the command line, set the library path to include **/opt/mapr/lib** and the path to the directory that contains the **libjvm** library. For more information, see Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.

NOTE: You must complete this step at the command line even though you already set the library path in the Makefile. If you do not complete the step, an error similar to the following displays when you run the application in the next step: `error while loading shared libraries: librdkafka.so.1: cannot open shared object file: No such file or directory`

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

3. From your directory (**librdkafka_example**), run the producer application from the command line. For example, if the application is called producer:

```
./producer
```

   The following appears on the console assuming that the stream name is MapR_Streams:

```
********************** PRODUCER ***********************
Create producer configuration object
Create Producer Kafka handle
Create topic handle
Send/Produce message to topic: /MapR_Streams:MapR-Topic1
Wait for messages to be delivered
Produced: Welcome to MapR Streams CAPI
Produced: MapR Streams CAPI Message Payload 1
Produced: MapR Streams CAPI Message Payload 2
Produced: MapR Streams CAPI Message Payload 3
Produced: MapR Streams CAPI Message Payload 4

Destroy topic handle
Destroy producer handle

PASS: 5 messages produced and sent to topic partition /
MapR_Streams:MapR-Topic1
```

4. From your directory (**librdkafka_example**), run the consumer application from the command line. For example, if the application is called consumer:

```
./consumer
```

   The following appears on the console assuming that the stream name is MapR_Streams:

```
*********  CONSUMER START  *********
Create new consumer configuration object
Set topic configurations
Create consumer Kafka handle
Create topic partition list for topic: /MapR_Streams:MapR-Topic1
Subscribe consumer to the topic:
Destroy topic partition list:

Start message consumption:
1 Consumed: Welcome to MapR-ES CAPI
2 Consumed: MapR Streams CAPI Message Payload 1
3 Consumed: MapR Streams CAPI Message Payload 2
4 Consumed: MapR Streams CAPI Message Payload 3
5 Consumed: MapR Streams CAPI Message Payload 4

Commit the offsets before closing the consumer

Close and destroy consumer handle

PASS: 5 messages consumed from topic /MapR_Streams:MapR-Topic1
```

Migrating Kafka C Applications to HPE Ezmeral Data Fabric Streams

With some modification, you can use existing Kafka C applications to consume and produce topics in HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that is compatible with HPE Ezmeral Data Fabric Streams.

1. Install and configure the MapR Streams C Client.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

2. When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

   ```
   /<path and name of stream>:<name of topic>
   ```

   For example, you might have a stream in a HPE Ezmeral Data Fabric cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

   NOTE: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream. To use these HPE Ezmeral Data Fabric-specific parameters in your application, compile your application with the rdkafka.h file (/opt/mapr/include/librdkafka/rdkafka.h) that was installed with the HPE Ezmeral Data Fabric Streams C Client. See the Compile the Apps on page 3635 section of Developing a HPE Ezmeral Data Fabric Streams C Application on page 3626.

3. See Configuration Properties for HPE Ezmeral Data Fabric Streams C Client on page 3711 for the list of supported configuration parameters, including a few parameters that are HPE Ezmeral Data Fabric-specific. Make changes to your application, as needed.

   NOTE: SSL-related configuration parameters are ignored. When you set these parameters, the HPE Ezmeral Data Fabric Streams Client issues a warning indicating that the parameters are not supported.

4. Review the list of librdkafka APIs that are **not** supported by the HPE Ezmeral Data Fabric Streams C Client and make changes to your application, as needed.

Simple/low level consumer APIs that are not supported	• rd_kafka_queue_new • rd_kafka_queue_destroy • rd_kafka_consume_start • rd_kafka_consume_start_queue • rd_kafka_consume_stop • rd_kafka_consume • rd_kafka_consume_batch • rd_kafka_consume_callback • rd_kafka_consume_queue • rd_kafka_consume_batch_queue • rd_kafka_consume_callback_queue • rd_kafka_offset_store • rd_kafka_pause_partitions • rd_kafka_resume_partitions
Producer/Consumer common APIs that are not supported	• rd_kafka_conf_set_dr_cb

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

- rd_kafka_conf_set_throttle_cb
- rd_kafka_conf_set_stats_cb
- rd_kafka_conf_set_socket_cb
- rd_kafka_conf_set_open_cb
- rd_kafka_conf_dump
- rd_kafka_conf_dump_free
- rd_kafka_name
- rd_kafka_set_log_level
- rd_kafka_mem_free
- rd_kafka_set_log_level
- rd_kafka_mem_free

Topic APIs that are not supported

- rd_kafka_query_watermark_offsets

  NOTE: As of HPE Ezmeral Data Fabric 6.0.1, this API *is* supported.

- rd_kafka_get_watermark_offsets

  NOTE: As of HPE Ezmeral Data Fabric 6.0.1, this API *is* supported.

Cluster APIs that are not supported

- rd_kafka_memberid
- rd_kafka_metadata
- rd_kafka_metadata_destroy

Miscellaneous APIs that are not supported

- rd_kafka_version
- rd_kafka_version_str
- rd_kafka_get_debug_contexts
- rd_kafka_dump
- rd_kafka_thread_cnt
- rd_kafka_message_timestamp

librdkafka APIs Supported by HPE Ezmeral Data Fabric Streams C Client

This topic lists the librdkafka APIs supported by the HPE Ezmeral Data Fabric Streams C Client. It also describes behavior differences between librdkafka and the HPE Ezmeral Data Fabric Streams C Client.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 7.9.0	As of 9.3.1	2.0.2*
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Table (Continued)

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

*Librdkafka 2.0.2 in core 7.9 is **not** compatible with HPE Ezmeral Data Fabric Stream clients for Python[1] or C#[2] applications. Nodes running Python or C# applications should not be upgraded to HPE Ezmeral Data Fabric 7.9.

[1]HPE Ezmeral Data Fabric Streams Python Applications on page 3982

[2]HPE Ezmeral Data Fabric Streams C#/.NET Applications on page 3993

This topic contains the following supported APIs:

- Producer APIs on page 3641
- Consumer APIs on page 3643
- Producer/Consumer Common APIs on page 3650
- Topic APIs on page 3657
- Queue APIs on page 3672
- Event APIs on page 3678
- Timestamp APIs on page 3683
- Interceptors APIs on page 3684
- Cluster Configuration APIs on page 3702
- Miscellaneous API on page 3703

Producer APIs

API	Behavior
rd_kafka_flush	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

API	Behavior
rd_kafka_poll	Same as librdkafka.
rd_kafka_produce	When this API is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.
rd_kafka_producev	Same as librdkafka. This API should be used with either RD_KAFKA_V_TOPIC or RD_KAFKA_V_RKT. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

API	Behavior
rd_kafka_produce_batch	When this API is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.
rd_kafka_outq_len	This API returns a positive number to indicate that messages are waiting to be produced to a streams topic but the value does not indicate the actual number of messages. librdkafka returns the actual number of messages that are waiting to be sent to or acknowledged by the broker.

Consumer APIs

API	Behavior
rd_kafka_assign	If this API is called for a consumer that is already subscribed to topics, no operation is performed.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_assignment	This API returns the number of topic partitions the consumer is assigned to. However, it returns 0 when topic partitions have yet to be created by the producer. librdkafka returns the number of partitions assigned to a consumer even when the partitions have not been created. **NOTE:** For this API to work, the argument partitions must be explicitly allocated or initialized with either `rd_kafka_topic_partition_list_t *parts = NULL` or `rd_kafka_topic_partition_list_new(0);`. For example: `RD_EXPORT rd_kafka_resp_err_t rd_kafka_assignment (rd_kafka_t *rk, rd_kafka_topic_partition_list_t **partitions);`
rd_kafka_commit	Same as librdkafka.
rd_kafka_commit_message	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_committed	Same as librdkafka. **NOTE:** The HPE Ezmeral Data Fabric Streams offset starts at 1.
rd_kafka_consumer_close	Same as librdkafka.

API	Behavior
rd_kafka_consumer_poll	Same as librdkafka. **NOTE:** For librdkafka 0.9: If the consume callback was set and messages were polled using rd_kafka_consumer_poll(), then the consume callback gets called and the messages can be consumed in the callback. For librdkafka 0.11.3: If the consume callback is set and messages are polled using rd_kafka_consumer_poll(), the consume callback is not called. The result is that you cannot consume messages in the consume callback when using rd_kafka_consumer_poll().
rd_kafka_group_list_destroy	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_list_groups	This API can only be used by consumers that are subscribed to at least one stream on the cluster and have a default stream configured with the streams.consumer.default.stream parameter. It returns the group list of subscribed consumers associated with the default stream. librdkafka returns all consumer groups from the cluster instead. **NOTE:** This API returns RD_KAFKA_RESP_ERR__TIMED_OUT when the querying consumer is not subscribed to any topic.
rd_kafka_message_destroy	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_poll_set_consumer	Same as librdkafka.
rd_kafka_position	This API returns 0 when the messages have not yet been consumed from partitions. librdkafka returns -1001 instead.
rd_kafka_seek	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

API	Behavior
rd_kafka_subscribe	Same as librdkafka.
rd_kafka_subscription	This API allows either a list of topics from one or more streams or a regex expression for topics from a single streams. For example, regex expression `/streamA:^t*a,/streamA:^t*b` is supported but `/streamA:^t*a,/streamB:^t*a` is not supported. librdkafka accepts both options in the same call. **NOTE:** You cannot use the rd_kafka_subscribe API to subscribe a consumer to topics when that consumer is already assigned to topics. If you call this API for an assigned consumer, error RD_KAFKA_RESP_ERR__CONFLICT is returned.
rd_kafka_unsubscribe	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Producer/Consumer Common APIs

API	Behavior
rd_kafka_conf_destroy	Same as librdkafka.
rd_kafka_conf_dup	Same as librdkafka.
rd_kafka_conf_get	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

API	Behavior
rd_kafka_conf_new	Same as librdkafka.
rd_kafka_conf_set	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_topic_partition_list_del_by_idx	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_topic_partition_list_destroy	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_topic_partition_list_find	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_topic_partition_list_new	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_topic_partition_list_set_offset	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Queue APIs

API	Behavior
rd_kafka_queue_new	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_queue_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

API	Behavior
rd_kafka_queue_get_main	For this API, produce events are batched as well as the APIs that use this API, such as, `rd_kafka_event_message_count` and `rd_kafka_event_message_next`. The messages produce events can be consumed together in batches, wheras, opensource librdkafka events are obtained one at a time. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_queue_get_consumer	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

API	Behavior
rd_kafka_queue_length	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_queue_poll	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_queue_poll_callback	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_commit_queue	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_queue_forward	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_set_log_queue	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_queue_length	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_queue_io_event_enable	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_queue_get_partition	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Event APIs

API	Behavior
rd_kafka_event_type	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_event_name	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_event_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_event_message_array	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_event_message_count	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

rd_kafka_interceptor_add_on_send	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_interceptor_add_on_acknowledgement	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_interceptor_add_on_consume	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_interceptor_add_on_commit	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Cluster Configuration APIs

API	Behavior
rd_kafka_brokers_add	This API has no impact on HPE Ezmeral Data Fabric Streams since HPE Ezmeral Data Fabric Streams does not utilize Kafka brokers. When this API is called, the HPE Ezmeral Data Fabric Streams client may print a `brokers are down error` message to the console.

last-updated: Nov 14, 2024

Miscellaneous API

API	Behavior
rd_kafka_err2name	Same as librdkafka.
rd_kafka_err2str	Same as librdkafka.
rd_kafka_error_No	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_errNo2errr	Same as librdkafka.
rd_kafka_get_err_descs	Same as librdkafka.
rd_kafka_last_error	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_log_print	Same as librdkafka.
rd_kafka_log_syslog	Same as librdkafka.
rd_kafka_message_errstr	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

API	Behavior
rd_kafka_set_logger	Same as librdkafka.
rd_kafka_query_watermark_offsets	When you are querying or retrieving a topic that is non-existent topic/partition (using `rd_kafka_query_watermark_offsets()` and `rd_kafka_get_watermark_offsets()` APIs), the timeout is honored even though you still receive the correct error message. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

API	Behavior
rd_kafka_get_watermark_offsets	When you are querying or retrieving a topic that is non-existent topic/partition (using `rd_kafka_query_watermark_offsets()` and `rd_kafka_get_watermark_offsets()` APIs), the timeout is honored even though you still receive the correct error message. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Additional Information

For more information and API signatures, see rdkafka.h on page 3721.

librdkafka APIs NOT Supported by HPE Ezmeral Data Fabric Streams C Client
This topic lists the librdkafka APIs that are *not* supported by the HPE Ezmeral Data Fabric Streams C Client.

These APIs are also documented in the rdkafka.h on page 3721 as not support by HPE Ezmeral Data Fabric Streams. If you want to see the list of supported librdkafka APIs, see librdkafka APIs Supported by HPE Ezmeral Data Fabric Streams C Client on page 3640.

NOTE: This list of librdkafka APIs *not* supported is applicable to HPE Ezmeral Data Fabric 6.0.1 and librdkafka 0.11.3.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 7.9.0	As of 9.3.1	2.0.2*
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Ezmeral Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

*Librdkafka 2.0.2 in core 7.9 is **not** compatible with HPE Ezmeral Data Fabric Stream clients for Python[1] or C#[2] applications. Nodes running Python or C# applications should not be upgraded to HPE Ezmeral Data Fabric 7.9.

Configuration Properties for HPE Ezmeral Data Fabric Streams C Client

This topic describes the configuration properties supported by the HPE Ezmeral Data Fabric Streams C Client. This includes librdkafka configuration properties that HPE Ezmeral Data Fabric Streams supports and additional properties that are specific to HPE Ezmeral Data Fabric Streams.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka.
message.max.bytes	See Configuring Properties for Message Size on page 4012.

last-updated: Nov 14, 2024

Property Name	Behavior
receive.message.max.bytes	See Configuring Properties for Message Size on page 4012.
topic.blacklist	Same as librdkafka.
error_cb	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
opaque	Same as librdkafka.
queue.buffering.max.ms	Same as librdkafka.
enable.partition.eof	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
queue.buffering.max.kbytes	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Consumer Configuration Properties

Property Name	Behavior
default_topic_conf	Same as librdkafka.
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
delivery.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Topic Configuration

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: beginning, end, earliest, latest, none, smallest, and largest. As of HPE Ezmeral Data Fabric 6.0.1, beginning and end are supported. **NOTE:** librdkafka additionally supports error.

©Copyright 2024 Hewlett Packard Enterprise Development LP

HPE Ezmeral Data Fabric-Specific Configurations

Property Name	Behavior
streams.consumer.default.stream	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. **NOTE:** rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
streams.parallel.flushners.per.partition	Enables the producer to have multiple parallel send requests to the server for each topic partition. When this property is set to true, the default value, it is possible for messages to be sent out of order.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
streams.producer.default.stream	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Ezmeral Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.

Additional Information

For more information, see rdkafka.h on page 3721.

rdkafka.h
This rdkafka header file has been updated to be compatible with HPE Ezmeral Data Fabric Streams. After you install the HPE Ezmeral Data Fabric Streams C Client, this file is available in the following directory: /opt/mapr/include/librdkafka/

librdkafka 2.0.2

Apache librdkafka 2.0.2 is supported as of HPE Ezmeral Data Fabric 7.9.0/EEP 9.3.1.

IMPORTANT: As of release 6.0.1, the RD_KAFKA_MSG_F_BLOCK call provides *blocking* behavior, whereas, the RD_KAFKA_MSG_F_COPY and RD_KAFKA_MSG_F_FREE calls are *non-blocking*.

/**
 * @brief Returns the last error code generated by a legacy API call
 *        in the current thread.
 *
 * The legacy APIs are the ones using errno to propagate error value,
namely:
 *  - rd_kafka_topic_new()
 *  - rd_kafka_consume_start()
 *  - rd_kafka_consume_stop()
 *  - rd_kafka_consume()
 *  - rd_kafka_consume_batch()
 *  - rd_kafka_consume_callback()
 *  - rd_kafka_consume_queue()
 *  - rd_kafka_produce()
 *
 * The main use for this function is to avoid converting system \p errno
 * values to rd_kafka_resp_err_t codes for legacy APIs.
 *
 * @remark The last error is stored per-thread, if multiple rd_kafka_t
handles
 *         are used in the same application thread the developer needs to
 *         make sure rd_kafka_last_error() is called immediately after
 *         a failed API call.
 *
 * @remark errno propagation from librdkafka is not safe on Windows
 *         and should not be used, use rd_kafka_last_error() instead.
 */

/**
 * @brief Generic event callback to be used with the event API to trigger
 *        callbacks for \c rd_kafka_event_t objects from a background
 *        thread serving the background queue.
 *
 * How to use:
 *  1. First set the event callback on the configuration object with this
 *     function, followed by creating an rd_kafka_t instance
 *     with rd_kafka_new().
 *  2. Get the instance's background queue with
rd_kafka_queue_get_background()
 *     and pass it as the reply/response queue to an API that takes an
 *     event queue, such as rd_kafka_CreateTopics().
 *  3. As the response event is ready and enqueued on the background queue
the
 *     event callback will be triggered from the background thread.
 *  4. Prior to destroying the client instance, loose your reference to the
 *     background queue by calling rd_kafka_queue_destroy().
 *
```

 *
 * The \p consume_cb \p opaque argument is the opaque set with
 * rd_kafka_conf_set_opaque().
 */
RD_EXPORT
void rd_kafka_conf_set_consume_cb(
    rd_kafka_conf_t *conf,
    void (*consume_cb)(rd_kafka_message_t *rkmessage, void *opaque));

/**
 * @brief \b Consumer: Set rebalance callback for use with
 *                     coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 *
 * Registering a \p rebalance_cb turns off librdkafka's automatic
 * partition assignment/revocation and instead delegates that responsibility
 * to the application's \p rebalance_cb.
 *
 * The rebalance callback is responsible for updating librdkafka's
 * assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
 * arbitrary rebalancing failures where \p err is neither of those.
 * @remark In this latter case (arbitrary error), the application must
 *         call rd_kafka_assign(rk, NULL) to synchronize state.
 *
 * For eager/non-cooperative `partition.assignment.strategy` assignors,
 * such as `range` and `roundrobin`, the application must use
 * rd_kafka_assign() to set or clear the entire assignment.
 * For the cooperative assignors, such as `cooperative-sticky`, the
application
 * must use rd_kafka_incremental_assign() for
 * RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS and rd_kafka_incremental_unassign()
 * for RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS.
 *
 * Without a rebalance callback this is done automatically by librdkafka
 * but registering a rebalance callback gives the application flexibility
 * in performing other operations along with the assigning/revocation,
 * such as fetching offsets from an alternate location (on assign)
 * or manually committing offsets (on revoke).
 *
 * rebalance_cb is always triggered exactly once when a rebalance completes
 * with a new assignment, even if that assignment is empty. If an
 * eager/non-cooperative assignor is configured, there will eventually be
 * exactly one corresponding call to rebalance_cb to revoke these partitions
 * (even if empty), whether this is due to a group rebalance or lost
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 * partitions. In the cooperative case, rebalance_cb will never be called if
 * the set of partitions being revoked is empty (whether or not lost).
 *
 * The callback's \p opaque argument is the opaque set with
 * rd_kafka_conf_set_opaque().
 *
 * @remark The \p partitions list is destroyed by librdkafka on return
 *         return from the rebalance_cb and must not be freed or
 *         saved by the application.
 *
 * @remark Be careful when modifying the \p partitions list.
 *         Changing this list should only be done to change the initial
 *         offsets for each partition.
 *         But a function like `rd_kafka_position()` might have unexpected
 *         effects for instance when a consumer gets assigned a partition
 *         it used to consume at an earlier rebalance. In this case, the
 *         list of partitions will be updated with the old offset for that
 *         partition. In this case, it is generally better to pass a copy
 *         of the list (see `rd_kafka_topic_partition_list_copy()`).
 *         The result of `rd_kafka_position()` is typically outdated in
 *         RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS.
 *
 * @sa rd_kafka_assign()
 * @sa rd_kafka_incremental_assign()
 * @sa rd_kafka_incremental_unassign()
 * @sa rd_kafka_assignment_lost()
 * @sa rd_kafka_rebalance_protocol()
 *
 * The following example shows the application's responsibilities:
 * @code
 *    static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
 *                              rd_kafka_topic_partition_list_t *partitions,
 *                              void *opaque) {
 *
 *        switch (err)
 *        {
 *          case RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS:
 *             // application may load offets from arbitrary external
 *             // storage here and update \p partitions
 *             if (!strcmp(rd_kafka_rebalance_protocol(rk), "COOPERATIVE"))
 *                     rd_kafka_incremental_assign(rk, partitions);
 *             else // EAGER
 *                     rd_kafka_assign(rk, partitions);
 *             break;
 *
 *          case RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS:
 *             if (manual_commits) // Optional explicit manual commit

/**
 * @brief Set SASL/OAUTHBEARER token refresh callback in provided conf
object.
 *
 * @param conf the configuration to mutate.
 * @param oauthbearer_token_refresh_cb the callback to set; callback
function
 *  arguments:<br>
 *   \p rk - Kafka handle<br>
 *   \p oauthbearer_config - Value of configuration property
 *                           sasl.oauthbearer.config.
 *   \p opaque - Application-provided opaque set via
 *               rd_kafka_conf_set_opaque()
 *
 * The SASL/OAUTHBEARER token refresh callback is triggered via
rd_kafka_poll()
 * whenever OAUTHBEARER is the SASL mechanism and a token needs to be
retrieved,
 * typically based on the configuration defined in \c
sasl.oauthbearer.config.
 *
 * The callback should invoke rd_kafka_oauthbearer_set_token()
 * or rd_kafka_oauthbearer_set_token_failure() to indicate success
 * or failure, respectively.
 *
 * The refresh operation is eventable and may be received via
 * rd_kafka_queue_poll() with an event type of
 * \c RD_KAFKA_EVENT_OAUTHBEARER_TOKEN_REFRESH.
 *
 * Note that before any SASL/OAUTHBEARER broker connection can succeed the
 * application must call rd_kafka_oauthbearer_set_token() once -- either
 * directly or, more typically, by invoking either rd_kafka_poll(),
 * rd_kafka_consumer_poll(), rd_kafka_queue_poll(), etc, in order to cause
 * retrieval of an initial token to occur.
 *
```

/**
 * @brief Sets the verification callback of the broker certificate
 *
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 * The verification callback is triggered from internal librdkafka threads
 * upon connecting to a broker. On each connection attempt the callback
 * will be called for each certificate in the broker's certificate chain,
 * starting at the root certification, as long as the application callback
 * returns 1 (valid certificate).
 * \c broker_name and \c broker_id correspond to the broker the connection
 * is being made to.
 * The \c x509_error argument indicates if OpenSSL's verification of
 * the certificate succeed (0) or failed (an OpenSSL error code).
 * The application may set the SSL context error code by returning 0
 * from the verify callback and providing a non-zero SSL context error code
 * in \c x509_error.
 * If the verify callback sets \c x509_error to 0, returns 1, and the
 * original \c x509_error was non-zero, the error on the SSL context will
 * be cleared.
 * \c x509_error is always a valid pointer to an int.
 *
 * \c depth is the depth of the current certificate in the chain, starting
 * at the root certificate.
 *
 * The certificate itself is passed in binary DER format in \c buf of
 * size \c size.
 *
 * The callback must return 1 if verification succeeds, or
 * 0 if verification fails and then write a human-readable error message
 * to \c errstr (limited to \c errstr_size bytes, including nul-term).
 *
 * The callback's \p opaque argument is the opaque set with

/**
 * @brief Produce and send a single message to broker.
 *
 * \p rkt is the target topic which must have been previously created with
 * `rd_kafka_topic_new()`.
 *
 * `rd_kafka_produce()` is an asynchronous non-blocking API.
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 * See `rd_kafka_conf_set_dr_msg_cb` on how to setup a callback to be called
 * once the delivery status (success or failure) is known. The delivery
report
 * is triggered by the application calling `rd_kafka_poll()` (at regular
 * intervals) or `rd_kafka_flush()` (at termination).
 *
 * Since producing is asynchronous, you should call `rd_kafka_flush()`
before
 * you destroy the producer. Otherwise, any outstanding messages will be
 * silently discarded.
 *
 * When temporary errors occur, librdkafka automatically retries to produce
the
 * messages. Retries are triggered after retry.backoff.ms and when the
 * leader broker for the given partition is available. Otherwise, librdkafka
 * falls back to polling the topic metadata to monitor when a new leader is
 * elected (see the topic.metadata.refresh.fast.interval.ms and
 * topic.metadata.refresh.interval.ms configurations) and then performs a
 * retry. A delivery error will occur if the message could not be produced
 * within message.timeout.ms.
 *
 * See the "Message reliability" chapter in INTRODUCTION.md for more
 * information.
 *
 * \p partition is the target partition, either:
 *   - RD_KAFKA_PARTITION_UA (unassigned) for
 *     automatic partitioning using the topic's partitioner function, or
 *   - a fixed partition (0..N)
 *
 * \p msgflags is zero or more of the following flags OR:ed together:
 *    RD_KAFKA_MSG_F_BLOCK - block \p produce*() call if
 *                           \p queue.buffering.max.messages or
 *                           \p queue.buffering.max.kbytes are exceeded.
 *                           Messages are considered in-queue from the point
 * they are accepted by produce() until their corresponding delivery report
 * callback/event returns. It is thus a requirement to call rd_kafka_poll()
(or
 * equiv.) from a separate thread when F_BLOCK is used. See WARNING on \c
 * RD_KAFKA_MSG_F_BLOCK above.
 *
 *    RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done
 *                          with it.
 *    RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
 *                          \p payload pointer will not be used by rdkafka
 *                          after the call returns.
 *    RD_KAFKA_MSG_F_PARTITION - produce_batch() will honour per-message
 *                               partition, either set manually or by the
 *                               configured partitioner.
 *
 *    .._F_FREE and .._F_COPY are mutually exclusive. If neither of these
are
 *    set, the caller must ensure that the memory backing \p payload remains
 *    valid and is not modified or reused until the delivery callback is
 *    invoked. Other buffers passed to `rd_kafka_produce()` don't have this
 *    restriction on reuse, i.e. the memory backing the key or the topic
name
 *    may be reused as soon as `rd_kafka_produce()` returns.
 *
 *    If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
 *    the memory associated with the payload is still the caller's
 *    responsibility.
 *
 * \p payload is the message payload of size \p len bytes.
 *
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 * \p key is an optional message key of size \p keylen bytes, if non-NULL it
 * will be passed to the topic partitioner as well as be sent with the
 * message to the broker and passed on to the consumer.
 *
 * \p msg_opaque is an optional application-provided per-message opaque
 * pointer that will provided in the message's delivery report callback
 * (\c dr_msg_cb or \c dr_cb) and the \c rd_kafka_message_t \c _private
field.
 *
 * @remark on_send() and on_acknowledgement() interceptors may be called
 *         from this function. on_acknowledgement() will only be called if
the
 *         message fails partitioning.
 *
 * @remark If the producer is transactional (\c transactional.id is
configured)
 *         producing is only allowed during an on-going transaction, namely
 *         after rd_kafka_begin_transaction() has been called.
 *
 * @returns 0 on success or -1 on error in which case errno is set
accordingly:
 *  - ENOBUFS  - maximum number of outstanding messages has been reached:
 *               "queue.buffering.max.messages"
 *               (RD_KAFKA_RESP_ERR__QUEUE_FULL)

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a ,-separated list of brokers in the format:
 *   \c \<broker1\>,\<broker2\>,..
 * Where each broker is in either the host or URL based format:
 *   \c \<host\>[:\<port\>]
 *   \c \<proto\>://\<host\>[:port]
 * \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *    brokerlist = "broker1:10000,broker2"
 *    brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.
 *
 * @remark Brokers may also be defined with the \c metadata.broker.list or
 *         \c bootstrap.servers configuration property (preferred method).
 *
 * @deprecated Set bootstrap servers with the \c bootstrap.servers

/**
 * @name Interceptors
 *
 * @{
 *
 * @brief A callback interface that allows message interception for both
 *        producer and consumer data pipelines.
 *
 * Except for the on_new(), on_conf_set(), on_conf_dup() and
on_conf_destroy()
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 * interceptors, interceptors are added to the
 * newly created rd_kafka_t client instance. These interceptors MUST only
 * be added from on_new() and MUST NOT be added after rd_kafka_new()
returns.
 *
 * The on_new(), on_conf_set(), on_conf_dup() and on_conf_destroy()
interceptors
 * are added to the configuration object which is later passed to
 * rd_kafka_new() where on_new() is called to allow addition of
 * other interceptors.
 *
 * Each interceptor reference consists of a display name (ic_name),
 * a callback function, and an application-specified opaque value that is
 * passed as-is to the callback.
 * The ic_name must be unique for the interceptor implementation and is used
 * to reject duplicate interceptor methods.
 *
 * Any number of interceptors can be added and they are called in the order
 * they were added, unless otherwise noted.
 * The list of registered interceptor methods are referred to as
 * interceptor chains.
 *
 * @remark Contrary to the Java client the librdkafka interceptor interface
 *         does not support message key and value modification.
 *         Message mutability is discouraged in the Java client and the
 *         combination of serializers and headers cover most use-cases.
 *
 * @remark Interceptors are NOT copied to the new configuration on
 *         rd_kafka_conf_dup() since it would be hard for interceptors to
 *         track usage of the interceptor's opaque value.
 *         An interceptor should rely on the plugin, which will be copied
 *         in rd_kafka_conf_conf_dup(), to set up the initial interceptors.
 *         An interceptor should implement the on_conf_dup() method
 *         to manually set up its internal configuration on the newly
created
 *         configuration object that is being copied-to based on the
 *         interceptor-specific configuration properties.
 *         conf_dup() should thus be treated the same as conf_init().
 *
 * @remark Interceptors are keyed by the interceptor type (on_..()), the
 *         interceptor name (ic_name) and the interceptor method function.
 *         Duplicates are not allowed and the .._add_on_..() method will
 *         return RD_KAFKA_RESP_ERR__CONFLICT if attempting to add a
duplicate
 *         method.
 *         The only exception is on_conf_destroy() which may be added
multiple
 *         times by the same interceptor to allow proper cleanup of
 *         interceptor configuration state.
 */

/**
 * @brief on_conf_set() is called from rd_kafka_*_conf_set() in the order
 *        the interceptors were added.
 *
 * @param conf Configuration object.
 * @param ic_opaque The interceptor's opaque pointer specified in ..add..().
 * @param name The configuration property to set.
 * @param val The configuration value to set, or NULL for reverting to
default
 *            in which case the previous value should be freed.
 * @param errstr A human readable error string in case the interceptor
fails.
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 * @param errstr_size Maximum space (including \0) in \p errstr.
 *
 * @returns RD_KAFKA_CONF_OK if the property was known and successfully
 *          handled by the interceptor, RD_KAFKA_CONF_INVALID if the
 *          property was handled by the interceptor but the value was
invalid,
 *          or RD_KAFKA_CONF_UNKNOWN if the interceptor did not handle
 *          this property, in which case the property is passed on on the
 *          interceptor in the chain, finally ending up at the built-in
 *          configuration handler.

/**
 * @name Admin API
 * @{
 *
 * @brief The Admin API enables applications to perform administrative
 *        Apache Kafka tasks, such as creating and deleting topics,
 *        altering and reading broker configuration, etc.
 *
 * The Admin API is asynchronous and makes use of librdkafka's standard
 * \c rd_kafka_queue_t queues to propagate the result of an admin operation
 * back to the application.
 * The supplied queue may be any queue, such as a temporary single-call
queue,
 * a shared queue used for multiple requests, or even the main queue or
 * consumer queues.
 *
 * Use \c rd_kafka_queue_poll() to collect the result of an admin operation
 * from the queue of your choice, then extract the admin API-specific result
 * type by using the corresponding \c rd_kafka_event_CreateTopics_result,
 * \c rd_kafka_event_DescribeConfigs_result, etc, methods.
 * Use the getter methods on the \c .._result_t type to extract response
 * information and finally destroy the result and event by calling
 * \c rd_kafka_event_destroy().
 *
 * Use rd_kafka_event_error() and rd_kafka_event_error_string() to acquire
 * the request-level error/success for an Admin API request.
 * Even if the returned value is \c RD_KAFKA_RESP_ERR_NO_ERROR there
 * may be individual objects (topics, resources, etc) that have failed.
 * Extract per-object error information with the corresponding
 * \c rd_kafka_..._result_topics|resources|..() to check per-object errors.
 *
 * Locally triggered errors:
 *  - \c RD_KAFKA_RESP_ERR__TIMED_OUT - (Controller) broker connection did
not
 *    become available in the time allowed by
AdminOption_set_request_timeout.

 * as well as abort any stale transactions and fence any still running
producer
 * instances with the same \c transactional.id.
 *
 * Once transactions are initialized the application may begin a new
 * transaction by calling rd_kafka_begin_transaction().
 * A producer instance may only have one single on-going transaction.
 *
 * Any messages produced after the transaction has been started will
 * belong to the ongoing transaction and will be committed or aborted
 * atomically.
 * It is not permitted to produce messages outside a transaction
 * boundary, e.g., before rd_kafka_begin_transaction() or after
 * rd_kafka_commit_transaction(), rd_kafka_abort_transaction(), or after
 * the current transaction has failed.
 *
 * If consumed messages are used as input to the transaction, the consumer
 * instance must be configured with \c enable.auto.commit set to \c false.
 * To commit the consumed offsets along with the transaction pass the
 * list of consumed partitions and the last offset processed + 1 to
 * rd_kafka_send_offsets_to_transaction() prior to committing the
transaction.
 * This allows an aborted transaction to be restarted using the previously
 * committed offsets.
 *
 * To commit the produced messages, and any consumed offsets, to the
 * current transaction, call rd_kafka_commit_transaction().
 * This call will block until the transaction has been fully committed or
 * failed (typically due to fencing by a newer producer instance).
 *
 * Alternatively, if processing fails, or an abortable transaction error is
 * raised, the transaction needs to be aborted by calling
 * rd_kafka_abort_transaction() which marks any produced messages and
 * offset commits as aborted.
 *
 * After the current transaction has been committed or aborted a new
 * transaction may be started by calling rd_kafka_begin_transaction() again.
 *
 * @par Retriable errors
 * Some error cases allow the attempted operation to be retried, this is
 * indicated by the error object having the retriable flag set which can
 * be detected by calling rd_kafka_error_is_retriable().
 * When this flag is set the application may retry the operation immediately
 * or preferably after a shorter grace period (to avoid busy-looping).
 * Retriable errors include timeouts, broker transport failures, etc.
 *
 * @par Abortable errors
 * An ongoing transaction may fail permanently due to various errors,
 * such as transaction coordinator becoming unavailable, write failures to
the
 * Apache Kafka log, under-replicated partitions, etc.
 * At this point the producer application must abort the current transaction
 * using rd_kafka_abort_transaction() and optionally start a new transaction
 * by calling rd_kafka_begin_transaction().
 * Whether an error is abortable or not is detected by calling
 * rd_kafka_error_txn_requires_abort() on the returned error object.
 *
 * @par Fatal errors
 * While the underlying idempotent producer will typically only raise
 * fatal errors for unrecoverable cluster errors where the idempotency
 * guarantees can't be maintained, most of these are treated as abortable by
 * the transactional producer since transactions may be aborted and retried
 * in their entirety;
 * The transactional producer on the other hand introduces a set of
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
additional
 * fatal errors which the application needs to handle by shutting down the
 * producer and terminate. There is no way for a producer instance to
recover
 * from fatal errors.
 * Whether an error is fatal or not is detected by calling
 * rd_kafka_error_is_fatal() on the returned error object or by checking
 * the global rd_kafka_fatal_error() code.
 * Fatal errors are raised by triggering the \c error_cb (see the
 * Fatal error chapter in INTRODUCTION.md for more information), and any
 * subsequent transactional API calls will return RD_KAFKA_RESP_ERR__FATAL
 * or have the fatal flag set (see rd_kafka_error_is_fatal()).
 * The originating fatal error code can be retrieved by calling
 * rd_kafka_fatal_error().
 *
 * @par Handling of other errors
 * For errors that have neither retriable, abortable or the fatal flag set
 * it is not always obvious how to handle them. While some of these errors
 * may be indicative of bugs in the application code, such as when
 * an invalid parameter is passed to a method, other errors might originate
 * from the broker and be passed thru as-is to the application.
 * The general recommendation is to treat these errors, that have
 * neither the retriable or abortable flags set, as fatal.
 *
 * @par Error handling example
 * @code
 *     retry:
 *        rd_kafka_error_t *error;
 *
 *        error = rd_kafka_commit_transaction(producer, 10*1000);
 *        if (!error)
 *            return success;
 *        else if (rd_kafka_error_txn_requires_abort(error)) {
 *            do_abort_transaction_and_reset_inputs();
 *        } else if (rd_kafka_error_is_retriable(error)) {
 *            rd_kafka_error_destroy(error);
 *            goto retry;
 *        } else { // treat all other errors as fatal errors
 *            fatal_error(rd_kafka_error_string(error));
 *        }
 *        rd_kafka_error_destroy(error);
 * @endcode
 *
 *
 * @{
 */

/**
 * @brief Initialize transactions for the producer instance.
 *
 * This function ensures any transactions initiated by previous instances
 * of the producer with the same \c transactional.id are completed.
 * If the previous instance failed with a transaction in progress the
 * previous transaction will be aborted.
 * This function needs to be called before any other transactional or
 * produce functions are called when the \c transactional.id is configured.
 *
 * If the last transaction had begun completion (following transaction
commit)
 * but not yet finished, this function will await the previous transaction's
 * completion.
 *
 * When any previous transactions have been fenced this function
```

```
 * will acquire the internal producer id and epoch, used in all future
 * transactional messages issued by this producer instance.
 *
 * @param rk Producer instance.
 * @param timeout_ms The maximum time to block. On timeout the operation
 *                   may continue in the background, depending on state,
 *                   and it is okay to call init_transactions() again.
 *                   If an infinite timeout (-1) is passed, the timeout will
 *                   be adjusted to 2 * \c transaction.timeout.ms.
 *
 * @remark This function may block up to \p timeout_ms milliseconds.
 *
 * @remark This call is resumable when a retriable timeout error is
returned.
 *         Calling the function again will resume the operation that is
 *         progressing in the background.
 *
 * @returns NULL on success or an error object on failure.
 *          Check whether the returned error object permits retrying
 *          by calling rd_kafka_error_is_retriable(), or whether a fatal
 *          error has been raised by calling rd_kafka_error_is_fatal().
 *          Error codes:
 *          RD_KAFKA_RESP_ERR__TIMED_OUT if the transaction coordinator
 *          could be not be contacted within \p timeout_ms (retriable),
 *          RD_KAFKA_RESP_ERR_COORDINATOR_NOT_AVAILABLE if the transaction
 *          coordinator is not available (retriable),
 *          RD_KAFKA_RESP_ERR_CONCURRENT_TRANSACTIONS if a previous
transaction
 *          would not complete within \p timeout_ms (retriable),
 *          RD_KAFKA_RESP_ERR__STATE if transactions have already been
started
 *          or upon fatal error,
 *          RD_KAFKA_RESP_ERR__UNSUPPORTED_FEATURE if the broker(s) do not
 *          support transactions (<Apache Kafka 0.11), this also raises a
 *          fatal error,
 *          RD_KAFKA_RESP_ERR_INVALID_TRANSACTION_TIMEOUT if the configured
 *          \c transaction.timeout.ms is outside the broker-configured
range,
 *          this also raises a fatal error,
 *          RD_KAFKA_RESP_ERR__NOT_CONFIGURED if transactions have not been
 *          configured for the producer instance,
 *          RD_KAFKA_RESP_ERR__INVALID_ARG if \p rk is not a producer
instance,
 *          or \p timeout_ms is out of range.
 *          Other error codes not listed here may be returned, depending on
 *          broker version.
 *
 * @remark The returned error object (if not NULL) must be destroyed with
 *         rd_kafka_error_destroy().

 */
RD_EXPORT
rd_kafka_error_t *rd_kafka_begin_transaction(rd_kafka_t *rk);

/**
 * @brief Sends a list of topic partition offsets to the consumer group
 *        coordinator for \p cgmetadata, and marks the offsets as part
 *        part of the current transaction.
 *        These offsets will be considered committed only if the
transaction is
 *        committed successfully.
 *
 *        The offsets should be the next message your application will
consume,
 *        i.e., the last processed message's offset + 1 for each partition.
 *        Either track the offsets manually during processing or use
 *        rd_kafka_position() (on the consumer) to get the current offsets
for
 *        the partitions assigned to the consumer.
 *
 *        Use this method at the end of a consume-transform-produce loop
prior
 *        to committing the transaction with rd_kafka_commit_transaction().
 *
 * @param rk Producer instance.
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 * @param offsets List of offsets to commit to the consumer group upon
 *                successful commit of the transaction. Offsets should be
 *                the next message to consume, e.g., last processed message
+ 1.
 * @param cgmetadata The current consumer group metadata as returned by
 *                   rd_kafka_consumer_group_metadata() on the consumer
 *                   instance the provided offsets were consumed from.
 * @param timeout_ms Maximum time allowed to register the offsets on the
broker.
 *
 * @remark This function must be called on the transactional producer
instance,
 *         not the consumer.
 *
 * @remark The consumer must disable auto commits
 *         (set \c enable.auto.commit to false on the consumer).
 *
 * @remark Logical and invalid offsets (such as RD_KAFKA_OFFSET_INVALID) in
 *         \p offsets will be ignored, if there are no valid offsets in
 *         \p offsets the function will return NULL and no action will be
taken.
 *
 * @remark This call is retriable but not resumable, which means a new
request
 *         with a new set of provided offsets and group metadata will be
 *         sent to the transaction coordinator if the call is retried.
 *
 * @remark It is highly recommended to retry the call (upon retriable error)
 *         with identical \p offsets and \p cgmetadata parameters.
 *         Failure to do so risks inconsistent state between what is
actually
 *         included in the transaction and what the application thinks is
 *         included in the transaction.
 *
 * @returns NULL on success or an error object on failure.
 *          Check whether the returned error object permits retrying
 *          by calling rd_kafka_error_is_retriable(), or whether an
abortable
 *          or fatal error has been raised by calling
 *          rd_kafka_error_txn_requires_abort() or rd_kafka_error_is_fatal()
 *          respectively.
 *          Error codes:
 *          RD_KAFKA_RESP_ERR__STATE if not currently in a transaction,
 *          RD_KAFKA_RESP_ERR_INVALID_PRODUCER_EPOCH if the current producer
 *          transaction has been fenced by a newer producer instance,
 *          RD_KAFKA_RESP_ERR_TRANSACTIONAL_ID_AUTHORIZATION_FAILED if the
 *          producer is no longer authorized to perform transactional
 *          operations,
 *          RD_KAFKA_RESP_ERR_GROUP_AUTHORIZATION_FAILED if the producer is
 *          not authorized to write the consumer offsets to the group
 *          coordinator,
 *          RD_KAFKA_RESP_ERR__NOT_CONFIGURED if transactions have not been
 *          configured for the producer instance,
 *          RD_KAFKA_RESP_ERR__INVALID_ARG if \p rk is not a producer
instance,
 *          or if the \p consumer_group_id or \p offsets are empty.
 *          Other error codes not listed here may be returned, depending on
 *          broker version.
 *
 * @remark The returned error object (if not NULL) must be destroyed with
 *         rd_kafka_error_destroy().
 */

```
    rd_kafka_t *rk,
    const rd_kafka_topic_partition_list_t *offsets,
    const rd_kafka_consumer_group_metadata_t *cgmetadata,
    int timeout_ms);

/**
 * @brief Commit the current transaction (as started with
 *        rd_kafka_begin_transaction()).
 *
 *        Any outstanding messages will be flushed (delivered) before
actually
 *        committing the transaction.
 *
 *        If any of the outstanding messages fail permanently the current
 *        transaction will enter the abortable error state and this
 *        function will return an abortable error, in this case the
application
 *        must call rd_kafka_abort_transaction() before attempting a new
 *        transaction with rd_kafka_begin_transaction().
 *
 * @param rk Producer instance.
 * @param timeout_ms The maximum time to block. On timeout the operation
 *                   may continue in the background, depending on state,
 *                   and it is okay to call this function again.
 *                   Pass -1 to use the remaining transaction timeout,
 *                   this is the recommended use.
 *
 * @remark It is strongly recommended to always pass -1 (remaining
transaction
 *         time) as the \p timeout_ms. Using other values risk internal
 *         state desynchronization in case any of the underlying protocol
 *         requests fail.
 *
 * @remark This function will block until all outstanding messages are
 *         delivered and the transaction commit request has been
successfully
 *         handled by the transaction coordinator, or until \p timeout_ms
 *         expires, which ever comes first. On timeout the application may
 *         call the function again.
 *
 * @remark Will automatically call rd_kafka_flush() to ensure all queued
 *         messages are delivered before attempting to commit the
 *         transaction.
 *         If the application has enabled RD_KAFKA_EVENT_DR it must
 *         serve the event queue in a separate thread since rd_kafka_flush()
 *         will not serve delivery reports in this mode.
 *
 * @remark This call is resumable when a retriable timeout error is
returned.
 *         Calling the function again will resume the operation that is
 *         progressing in the background.
 *

/**
 * @brief \b Consumer: Set rebalance callback for use with
 *                     coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 *
 * Registering a \p rebalance_cb turns off librdkafka's automatic
 * partition assignment/revocation and instead delegates that responsibility
 * to the application's \p rebalance_cb.
 *
 * The rebalance callback is responsible for updating librdkafka's
 * assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
 * arbitrary rebalancing failures where \p err is neither of those.
 * @remark In this latter case (arbitrary error), the application must
 *         call rd_kafka_assign(rk, NULL) to synchronize state.
 *
 * Without a rebalance callback this is done automatically by librdkafka
 * but registering a rebalance callback gives the application flexibility
 * in performing other operations along with the assinging/revocation,
 * such as fetching offsets from an alternate location (on assign)
 * or manually committing offsets (on revoke).
 *
 * @remark The \p partitions list is destroyed by librdkafka on return
 *         return from the rebalance_cb and must not be freed or
 *         saved by the application.
 *
 * The following example shows the application's responsibilities:
 * @code
 *    static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
 *                              rd_kafka_topic_partition_list_t *partitions,
 *                              void *opaque) {
 *
 *        switch (err)
 *        {
 *          case RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS:

/**
 * @brief Produce and send a single message to broker.
 *
 * \p rkt is the target topic which must have been previously created with
 * `rd_kafka_topic_new()`.
 *
 * `rd_kafka_produce()` is an asynch non-blocking API.
 *
 * \p partition is the target partition, either:
 *   - RD_KAFKA_PARTITION_UA (unassigned) for
 *     automatic partitioning using the topic's partitioner function, or
 *   - a fixed partition (0..N)
 *
 * \p msgflags is zero or more of the following flags OR:ed together:
 *    RD_KAFKA_MSG_F_BLOCK - block \p produce*() call if
 *                           \p queue.buffering.max.messages or
 *                           \p queue.buffering.max.kbytes are exceeded.
 *                           Messages are considered in-queue from the
point they
 *                           are accepted by produce() until their
corresponding
 *                           delivery report callback/event returns.
 *                           It is thus a requirement to call
 *                           rd_kafka_poll() (or equiv.) from a separate
 *                           thread when F_BLOCK is used.
 *                           See WARNING on \c RD_KAFKA_MSG_F_BLOCK above.
 *
 *    RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done
 *                          with it.
 *    RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
 *                          \p payload pointer will not be used by rdkafka
 *                          after the call returns.
 *
 *    ..._F_FREE and ..._F_COPY are mutually exclusive.
 *
 *    If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
 *    the memory associated with the payload is still the caller's
 *    responsibility.
 *
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 * \p payload is the message payload of size \p len bytes.
 *
 * \p key is an optional message key of size \p keylen bytes, if non-NULL it
 * will be passed to the topic partitioner as well as be sent with the
 * message to the broker and passed on to the consumer.
 *
 * \p msg_opaque is an optional application-provided per-message opaque
 * pointer that will provided in the delivery report callback (`dr_cb`) for
 * referencing this message.
 *
 * @remark on_send() and on_acknowledgement() interceptors may be called
 *         from this function. on_acknowledgement() will only be called if
the
 *         message fails partitioning.
 *
 * @returns 0 on success or -1 on error in which case errno is set
accordingly:
 *  - ENOBUFS  - maximum number of outstanding messages has been reached:
 *               "queue.buffering.max.messages"
 *               (RD_KAFKA_RESP_ERR__QUEUE_FULL)
 *  - EMSGSIZE - message is larger than configured max size:
 *               "messages.max.bytes".
 *               (RD_KAFKA_RESP_ERR_MSG_SIZE_TOO_LARGE)
 *  - ESRCH    - requested \p partition is unknown in the Kafka cluster.
 *               (RD_KAFKA_RESP_ERR__UNKNOWN_PARTITION)
 *  - ENOENT   - topic is unknown in the Kafka cluster.
 *               (RD_KAFKA_RESP_ERR__UNKNOWN_TOPIC)
 *
 * @sa Use rd_kafka_errno2err() to convert `errno` to rdkafka error code.

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a ,-separated list of brokers in the format:
 *   \c \<broker1\>,\<broker2\>,..
 * Where each broker is in either the host or URL based format:
 *   \c \<host\>[:\<port\>]
 *   \c \<proto\>://\<host\>[:port]
 * \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *    brokerlist = "broker1:10000,broker2"
 *    brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.
 *
 * @remark Brokers may also be defined with the \c metadata.broker.list or
 *         \c bootstrap.servers configuration property (preferred method).

/**
 * @name Interceptors
 *
 * @{
 *
 * @brief A callback interface that allows message interception for both
 *        producer and consumer data pipelines.
 *
 * Except for the on_new(), on_conf_set(), on_conf_dup() and
on_conf_destroy()
 * interceptors, interceptors are added to the
 * newly created rd_kafka_t client instance. These interceptors MUST only
 * be added from on_new() and MUST NOT be added after rd_kafka_new()
returns.
 *
 * The on_new(), on_conf_set(), on_conf_dup() and on_conf_destroy()
interceptors
 * are added to the configuration object which is later passed to
 * rd_kafka_new() where on_new() is called to allow addition of
 * other interceptors.
 *
 * Each interceptor reference consists of a display name (ic_name),
 * a callback function, and an application-specified opaque value that is
 * passed as-is to the callback.
 * The ic_name must be unique for the interceptor implementation and is used
 * to reject duplicate interceptor methods.
 *
 * Any number of interceptors can be added and they are called in the order
 * they were added, unless otherwise noted.
 * The list of registered interceptor methods are referred to as
 * interceptor chains.
 *
 * @remark Contrary to the Java client the librdkafka interceptor interface
 *         does not support message modification. Message mutability is
 *         discouraged in the Java client and the combination of
 *         serializers and headers cover most use-cases.
 *
 * @remark Interceptors are NOT copied to the new configuration on
 *         rd_kafka_conf_dup() since it would be hard for interceptors to
 *         track usage of the interceptor's opaque value.
 *         An interceptor should rely on the plugin, which will be copied
 *         in rd_kafka_conf_conf_dup(), to set up the initial interceptors.
 *         An interceptor should implement the on_conf_dup() method
 *         to manually set up its internal configuration on the newly
created
 *         configuration object that is being copied-to based on the
 *         interceptor-specific configuration properties.
 *         conf_dup() should thus be treated the same as conf_init().
 *
 * @remark Interceptors are keyed by the interceptor type (on_..()), the
 *         interceptor name (ic_name) and the interceptor method function.
 *         Duplicates are not allowed and the .._add_on_..() method will
 *         return RD_KAFKA_RESP_ERR__CONFLICT if attempting to add a
duplicate
 *         method.
 *         The only exception is on_conf_destroy() which may be added
multiple
 *         times by the same interceptor to allow proper cleanup of
 *         interceptor configuration state.
 */

/**
 * @brief \b Consumer: Set rebalance callback for use with
 *                     coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 *
 * Registering a \p rebalance_cb turns off librdkafka's automatic
 * partition assignment/revocation and instead delegates that responsibility
 * to the application's \p rebalance_cb.
 *
 * The rebalance callback is responsible for updating librdkafka's
 * assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
 * arbitrary rebalancing failures where \p err is neither of those.
 * @remark In this latter case (arbitrary error), the application must
 *         call rd_kafka_assign(rk, NULL) to synchronize state.
 *
 * Without a rebalance callback this is done automatically by librdkafka
 * but registering a rebalance callback gives the application flexibility
 * in performing other operations along with the assinging/revocation,
 * such as fetching offsets from an alternate location (on assign)
 * or manually committing offsets (on revoke).
 *
 * @remark The \p partitions list is destroyed by librdkafka on return
 *         return from the rebalance_cb and must not be freed or
 *         saved by the application.
 *
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 * The following example shows the application's responsibilities:
 * @code
 *    static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,

/**
 * @name Miscellaneous APIs
 * @{
 *
 */

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a ,-separated list of brokers in the format:
 *   \c \<broker1\>,\<broker2\>,..
 * Where each broker is in either the host or URL based format:
 *   \c \<host\>[:\<port\>]
 *   \c \<proto\>://\<host\>[:port]
 * \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *    brokerlist = "broker1:10000,broker2"
 *    brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.
 *

HPE Ezmeral Data Fabric Streams Python Applications

As of HPE Ezmeral Data Fabric 5.2.1, you can create python applications for HPE Ezmeral Data Fabric Streams using the HPE Ezmeral Data Fabric Streams Python client. The HPE Ezmeral Data Fabric Streams Python client is a binding for librdkafka and the HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams.

The HPE Ezmeral Data Fabric Streams Python client is available in a Ecosystem Pack (EEP) starting with EEP 3.0.

The following Apache Kafka librdkafka versions are supported:

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 7.9.0	As of 9.3.1	2.0.2*
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Ezmeral Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

*Librdkafka 2.0.2 in core 7.9 is **not** compatible with HPE Ezmeral Data Fabric Stream clients for Python or C# applications. Nodes running Python or C# applications should not be upgraded to HPE Ezmeral Data Fabric 7.9.

©Copyright 2024 Hewlett Packard Enterprise Development LP

NOTE: Because the HPE Ezmeral Data Fabric Streams Python Client is dependent on the HPE Ezmeral Data Fabric Streams C Client, the HPE Ezmeral Data Fabric Streams C Client must be configured before using the HPE Ezmeral Data Fabric Streams Python Client.

When developing and running HPE Ezmeral Data Fabric Streams Python applications, note the following points:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- HPE Ezmeral Data Fabric Streams offset values start at 1, not 0.
- HPE Ezmeral Data Fabric security is supported including ACLs and ACEs for authorization. The unique Kafka security features that are part of Apache Kafka are not supported. See Security on page 809 for more information about HPE Ezmeral Data Fabric security features.
- User impersonation is not supported.

Developing HPE Ezmeral Data Fabric Streams Python Applications
This topic includes basic information about how to develop a HPE Ezmeral Data Fabric Streams Python application and an example program that you can run.

Before you Begin

Confirm that your environment meets the following requirements:

- HPE Ezmeral Data Fabric cluster version 5.2.1 or greater.
- HPE Ezmeral Data Fabric core client (mapr-client) package. See Installing the Data Fabric Client (Non-FIPS) on page 383 for more information.
- HPE Ezmeral Data Fabric Streams C Client (mapr-librdkafka) is installed and configured on the node. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.
- HPE Ezmeral Data Fabric Streams Python Client (mapr-streams-python) is installed on the node. See Installing HPE Ezmeral Data Fabric Streams Python Client on page 236.
- Python installed on the node (Python version 2.7.x and above, up to version 3.6.x).

Create a HPE Ezmeral Data Fabric Streams Producer Application

In general, you want to create a producer that performs the following steps:

1. Import the producer class.
2. Define the producer and its configuration.
3. Produce data.
4. Wait for all messages to be sent to consumer.

As of EEP 5.0 HPE Ezmeral Data Fabric Streams Python Client: In the following example code, three messages are produced to a topic named `mytopic` in a stream named `my_stream`.

```
from confluent_kafka import Producer
p = Producer({'streams.producer.default.stream': '/my_stream'})
some_data_source= ["msg1", "msg2", "msg3"]
for data in some_data_source:
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    p.produce('mytopic', data.encode('utf-8'))
    p.flush()
```

Create a HPE Ezmeral Data Fabric Streams Consumer Application

In general, you want to create a consumer that performs the following steps:

1. Import the consumer class.
2. Define the consumer and its configuration.
3. Consume data.
4. Wait for all messages to be consumed.

As of EEP 5.0 HPE Ezmeral Data Fabric Streams Python Client: In following example code, the HPE Ezmeral Data Fabric Streams consumer is subscribed to `my_stream/mytopic` and it prints the content of each message that it reads.

```
from confluent_kafka import Consumer, KafkaError
c = Consumer({'group.id': 'mygroup',
              'default.topic.config': {'auto.offset.reset': 'earliest'}})
c.subscribe(['/my_stream:mytopic'])
running = True
while running:
  msg = c.poll(timeout=1.0)
  if msg is None: continue
  if not msg.error():
    print('Received message: %s' % msg.value().decode('utf-8'))
  elif msg.error().code() != KafkaError._PARTITION_EOF:
    print(msg.error())
    running = False
c.close()
```

Run the Example Applications

To run the sample producer and consumer applications:

1. Create a stream named `mystream`.
2. Create a file named producer.py.
3. Add the producer example code into the producer.py file.
4. Create a file named consumer.py.
5. Add the consumer example code into the consumer.py file.
6. Verify that you have completed the steps to configure the HPE Ezmeral Data Fabric Streams C client or complete the steps now. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.

   NOTE: The HPE Ezmeral Data Fabric Streams Python Client is dependent on the HPE Ezmeral Data Fabric Streams C Client. Therefore, the HPE Ezmeral Data Fabric Streams C Client must be configured before you can run the application.

7. Run producer.py from the command line to generate messages.

   ```
   $ python producer.py
   ```

©Copyright 2024 Hewlett Packard Enterprise Development LP

8. Run consumer.py from the command line:

```
$ python consumer.py
```

Migrating Kafka Python Applications to HPE Ezmeral Data Fabric Streams
With some modification, you can use existing confluent-kafka python applications to consume and produce topics in HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams Python Client is a binding for Apache librdkafka that works with HPE Ezmeral Data Fabric Streams.

1. Install the HPE Ezmeral Data Fabric Streams Python Client.

   NOTE: This required that you also install and configure the HPE Ezmeral Data Fabric Streams C Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.

2. Do one of the following depending on whether you are using the EEP 5.0 (or higher) HPE Ezmeral Data Fabric Streams Python Client or the EEP 3.0 (or higher) HPE Ezmeral Data Fabric Streams Python Client.
   - If you are using HPE Ezmeral Data Fabric Streams Python EEP 5.0 (or higher), skip this step. The references to `confluent_kafka` should be retained.
   - If you are using HPE Ezmeral Data Fabric Streams Python EEP 3.0 (or higher), update import statements to refer to the MapR Stream Python API. References to `confluent_kafka` should be updated to `mapr_streams_python`.

     NOTE: For example, update `from confluent_kafka import Consumer` to `from mapr_streams_python import Consumer`.

3. When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

   ```
   /<path and name of stream>:<name of topic>
   ```

   For example, you might have a stream in a HPE Ezmeral Data Fabric cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

   NOTE: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream.

4. Review the APIs that are supported and make changes to your application, as needed. See API for HPE Ezmeral Data Fabric Streams Python Client on page 3985.

5. See Configuration Properties for HPE Ezmeral Data Fabric Streams Python Client on page 3991 for the list of supported configuration parameters and make changes to your application, as needed.

   NOTE: SSL-related configuration parameters are ignored. When you set these parameters, the HPE Ezmeral Data Fabric Streams Client issues a warning indicating that the parameters are not supported.

API for HPE Ezmeral Data Fabric Streams Python Client
HPE Ezmeral Data Fabric Streams Python Client is a binding for librdkafka and it supports the following APIs.

©Copyright 2024 Hewlett Packard Enterprise Development LP

As of HPE Ezmeral Data Fabric 5.2.1, you can create python applications for HPE Ezmeral Data Fabric Streams using the HPE Ezmeral Data Fabric Streams Python client. The HPE Ezmeral Data Fabric Streams Python client is a binding for librdkafka and the HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Ezmeral Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

class mapr_streams_python.Consumer

A high-level Kafka Consumer.

Method	Behavior
Consumer(**kwargs)	Create new Consumer instance using provided configuration dictionary.
assign(partitions)	Set consumer partition assignment to the provided list of TopicPartition and starts consuming. Parameters(s): • partitions (list(TopicPartition)) – List of topic+partitions and optionally initial offsets to start consuming
unassign()	Unassign from all TopicPartitions that have been assigned with the `.assign(*topic_partition_list) method.` **NOTE:** This method is applicable as of HPE Ezmeral Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.
assignment()	Return a list of assignments for a consumer object. **NOTE:** This method is applicable as of HPE Ezmeral Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.
close()	Close down and terminate the Kafka Consumer. Actions(s): • Stops consuming • Commits offsets • Leave consumer group

©Copyright 2024 Hewlett Packard Enterprise Development LP

Method	Behavior
commit([message=None][, offsets=None][, async=True])	Commit a message or a list of offsets. Message and offsets are mutually exclusive, if neither is set the current partition assignment's offsets are used instead. Parameters(s): • message (confluent_kafka.Message) – Commit message's offset+1. • offsets (list(TopicPartition)) – List of topic+partitions+offsets to commit. • async (bool) – Asynchronous commit, return immediately.
committed(partitions[, timeout=None])	Retrieve committed offsets for the list of partitions. Parameters(s): • partitions (list(TopicPartition)) - List of topic+partitions to query for stored offsets. • timeout (float) – Request timeout Returns: List of topic+partitions with offset and possibly error set. Return type: list(TopicPartition) Raises: KafkaException **NOTE:** As of HPE Ezmeral Data Fabric 6.0, the message offset in a partition starts from zero (0). If you are upgrading and do not enable the HPE Ezmeral Data Fabric Database/HPE Ezmeral Data Fabric Streams feature, **mfs.feature.db.streams.v6.support**, the message offset in a partition starts from one (1).
on_commit(err, partitions)	A callback for Consumer.commit() that triggers custom actions when a commit request completes. Parameters(s): • err (KafkaError) – Commit error object, or None on success. • Partitions (list(TopicPartition)) – List of partitions with their committed offsets or per-partition errors
poll([timeout=None])	Consume messages, calls callbacks and returns events. The application must check the returned Message object's Message.error() method to distinguish between proper messages (error() returns None), or an event or error (see error().code() for specifics). Parameter(s): timeout (*float*) – Maximum time to block waiting for message, event or callback Returns: A Message object or None on timeout Return type: Message or None

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Method	Behavior
position(partitions[, timeout=None])	Retrieve current positions (offsets) for the list of partitions. Parameter(s): partitions (list(TopicPartition)) – List of topic+partitions to return current offsets for. The current offset is the offset of the last consumed message + 1 Returns: List of topic+partitions with offset and possibly error set. Return type: list(TopicPartition) Raises: KafkaException This function returns 0 when the messages have not yet been consumed from partitions. librdkafka returns -1001 instead.
subscribe(topics[, listener=None])	Set subscription to supplied list of topics This replaces a previous subscription. Parameters: • topics (list(str)) – List of topics (strings) to subscribe to. • on_assign (callable) – callback to provide handling of customized offsets on completion of a successful partition re-assignment. • on_revoke (callable) – callback to provide handling of offset commits to a customized store on the start of a rebalance operation. Raises: KafkaException **NOTE:** You cannot use the rd_kafka_subscribe API to subscribe a consumer to topics when that consumer is already assigned to topics. If you call this API for an assigned consumer, error RD_KAFKA_RESP_ERR__CONFLICT is returned.
on_assign(consumer, partitions)	Same as librdkafka.
unsubscribe()	Same as librdkafka.
on_revoke(consumer, partitions)	Parameter(s): • consumer (Consumer) – Consumer instance. • partitions (list(TopicPartition)) – Absolute list of partitions being assigned or revoked.
get_watermark_offsets(confluent_kafka.TopicPartition)	Get WatermarkOffsets for a given Topic Partition. Parameter(s): TopicPartition - Gets the watermark offset **NOTE:** This method is applicable as of HPE Ezmeral Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.

class mapr_streams_python.Producer

Asynchronous Kafka Producer.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Method	Behavior
Producer(**kwargs)	Create new Producer instance using provided configuration dict.
len()	This API returns a positive number to indicate that messages are waiting to be produced to a streams topic but the value does not indicate the actual number of messages. librdkafka returns the actual number of messages that are waiting to be sent to or acknowledged by the broker. Return type: int
flush()	Wait for all messages in the Producer queue to be delivered. This is a convenience method that calls poll() until len()is zero.
poll([timeout])	Polls the producer for events and calls the corresponding callbacks (if registered). Parameter(s): • timeout (float) – Maximum time to block waiting for events Returns: Number of events processed (callbacks served). Return type: int
produce(topic[, value][, key][, partition][, callback])	Produce message to topic. This is an asynchronous operation, an application may use the callback(alias on_delivery) argument to pass a function (or lambda) that will be called from poll() when the message has been successfully delivered or permanently fails delivery. Parameters: • topic (str) – Topic to produce message to • value (str|bytes) – Message payload • key (str|bytes) – Message key • partition (int) – Partition to produce to, else uses the configured partitioner. • on_delivery(err,msg) (func) – Delivery report callback to call (from poll() or flush()) on successful or failed deliver Raises: • BufferError – if the internal producer message queue is full (queue.buffering.max.messages exceeded) • KafkaException – for other errors, see exception code **NOTE:** When this function is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

class mapr_streams_python.Message

The Message object represents either a single consumed or produced message, or an event . An application must check with error() to see if the object is a proper message (error() returns None) or an error/event. This class is not user-instantiable.

Method	Behavior
len()	Returns: Message value (payload) size in bytes. Return type: int
error()	The message object is also used to propagate errors and events. Applications must check error() to determine if the Message is a proper message (error() returns None) or an error or event (error() returns a KafkaError object) Return type: None or KafkaError
key()	Returns: message key or None if not available Return type: str|bytes or None
offset()	Returns: message offset or None if not available Return type: int or None
partition()	Returns: partition number or None if not available Return type: int or None
topic()	Returns: topic name or None if not available Return type: str or None
value()	Returns: message value (payload) or None if not available Return type: str|bytes or None
timestamp()	Returns: message timestamp **NOTE:** This method is applicable as of HPE Ezmeral Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.

class mapr_streams_python.TopicPartition

TopicPartition is a generic type to hold a single partition and various information about it. It is typically used to provide a list of topics or partitions for various operations, such as Consumer.assign().

Method	Behavior
TopicPartition(topic[, partition][, offset])	Instantiate a TopicPartition object. Parameter(s) • topic (string) – Topic name • partition (int) – Partition id • offset (int) – Initial partition offset Return type: TopicPartition

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Method	Behavior
error	Attribute that indicates an error (with KafkaError) unless None.
offset	Attribute for offset.
partition	Attribute for partition number.
topic	Attribute for topic name.

class mapr_streams_python.KafkaError

Kafka error and event object.

The KafkaError class serves multiple purposes:

- Propagation of errors
- Propagation of events
- Exceptions

This class is not user-instantiable.

Method	Behavior
code()	Returns the error/event code for comparison toKafkaError.<ERR_CONSTANTS>. Returns: error/event code Return type: int
name()	Returns the enum name for error/event. Returns: error/event enum name string Return type: str
str()	Returns the human-readable error/event string. Returns: error/event enum message string Return type: str

Configuration Properties for HPE Ezmeral Data Fabric Streams Python Client

In the instance constructor of a HPE Ezmeral Data Fabric Streams Python application, you can use a dictionary to set the following configuration properties. HPE Ezmeral Data Fabric Streams Python client supports a superset of the configuration properties supported by the HPE Ezmeral Data Fabric Streams C client.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka
default.topic.config	A dictionary of topic-level configuration properties that are applied to all used topics for the instance.
message.max.bytes	Supports a value less than or equal to 10MB (10000000). If this property is set to a value that is higher than 10MB, the client issues a warning and sets the configuration to 10MB. Produce calls fail when the message size is greater than 10MB.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Property Name	Behavior
receive.message.max.bytes	Same as librdkafka
topic.blacklist	Same as librdkafka
error_cb	A callback for generic/global error events. This callback is served by poll().
opaque	Same as librdkafka.

Consumer Configuration Properties

Property Name	Behavior
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.
delivery.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.
on_commit	A callback used to indicate success or failure of commit requests.

Topic Configuration Properties

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: earliest, latest, none, smallest, and largest. librdkafka also supports biggest, end and error.

Producer Configuration Properties

Property Name	Behavior
on_delivery(kafka.KafkaError, kafka.Message)	A Python function reference that is called once for each produced message to indicate the final delivery result (success or failure). This property may also be set per-message by passing callback=callable (or on_delivery=callable) to the confluent_kafka.Producer.produce() function.

©Copyright 2024 Hewlett Packard Enterprise Development LP

HPE Ezmeral Data Fabric-Specific Configuration Properties

Property Name	Behavior
streams.consumer.default.stream	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. **NOTE:** rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.
streams.parallel.flushers.per.partition	Enables the producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order.
streams.producer.default.stream	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Ezmeral Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.

Additional Information

Here is a consumer configuration example:

```
conf = {'group.id': 'mygroup',

'session.timeout.ms': 6000,

'on_commit': my_commit_callback,

'default.topic.config': {'auto.offset.reset': 'smallest'}}

consumer = mapr_streams_python.Consumer(**conf)
```

HPE Ezmeral Data Fabric Streams C#/.NET Applications

As of HPE Ezmeral Data Fabric 6.0.1/EEP5.0, you can create C#/.NET applications for HPE Ezmeral Data Fabric Streams using the HPE Ezmeral Data Fabric Streams C#/.NET client. The HPE Ezmeral Data Fabric Streams C#/.NET client is a binding for librdkafka and the HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Requirements

- HPE Ezmeral Data Fabric Client on Windows 7 (or higher) x64 operating systems
- HPE Ezmeral Data Fabric cluster version 6.0.1 or greater
- Java 8 SDK and set Java HOME
- HPE Ezmeral Data Fabric Streams C Client (mapr-librdkafka 0.11.3)
- HPE Ezmeral Data Fabric Streams C#/.NET Client (mapr-streams-dotnet)
- .NET SDK 4.5.x or 4.6.x or .NET Core SDK 1.1
- nuget.exe

See Installing HPE Ezmeral Data Fabric Streams C#/.NET Client on page 238 for installation information.

General Information

When developing and running HPE Ezmeral Data Fabric Streams C#/.NET applications, note the following points:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- HPE Ezmeral Data Fabric Streams offset values start at 1, not 0.
- HPE Ezmeral Data Fabric security is supported including ACLs and ACEs for authorization. The unique Kafka security features that are part of Apache Kafka are not supported. See Security on page 809 for more information about HPE Ezmeral Data Fabric security features.
- User impersonation is not supported.

Developing HPE Ezmeral Data Fabric Streams C#/.NET Applications

Describes general tasks for developing C#/.NET applications.

Before Your Begin

Confirm that your environment meets the following requirements:

- HPE Ezmeral Data Fabric cluster version 6.0.1 or greater.
- HPE Ezmeral Data Fabric Streams C Client (mapr-librdkafka 0.11.3) is installed and configured on the node. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.
- HPE Ezmeral Data Fabric Streams C#/.NET Client (mapr-streams-dotnet) is installed on the node.
- .NET SKD 4.5.x or 4.6.x
- .NET Core SDK 1.1
- nuget.exe

Create a Producer Application

In general, you want to create a producer that performs the following steps:

1. Import the producer class.
2. Define the producer and its configuration.

©Copyright 2024 Hewlett Packard Enterprise Development LP

3. Produce data.
4. Wait for all messages to be sent to consumer.

In the following example code, three messages are produced to a topic named mytopic in a stream named my_stream.

```
class Producer
    {
        public static async void Produce()
        {
            string stream = "/my_stream";
            string topicName = "mytopic";

            var config = new Dictionary<string, object>
{ { "streams.producer.default.stream", stream } };
            var messages = new string[] { "Msg1", "Msg2", "Msg3" };

            using (var producer = new Producer<Null, string>(config, null,
new StringSerializer(Encoding.UTF8)))
            {
                foreach (var msg in messages)
                {
                    var deliveryReport = await
producer.ProduceAsync(topicName, null, msg);
                    Console.WriteLine($"Delivery report:
{deliveryReport.TopicPartitionOffset}");
                }

                producer.Flush(TimeSpan.FromSeconds(1));
            }
        }
    }
```

Create a Consumer Application

In general, you want to create a consumer that performs the following steps:

1. Import the consumer class.
2. Define the consumer and its configuration.
3. Consume data.
4. Wait for all messages to be consumed.

In following example code, the HPE Ezmeral Data Fabric Streams consumer is subscribed to `my_stream/mytopic` and it prints the content of each message that it reads.

```
using Confluent.Kafka;
using Confluent.Kafka.Serialization

    class Consumer
    {
        public static void Consume()
        {
            var stream = "/mystream";
            var topic = "mytopic";

            var config = new Dictionary<string, object>
            {
                { "group.id", "simple-csharp-consumer" },
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
                { "streams.consumer.default.stream", stream }
            };

            bool running = true;

            using (var consumer = new Consumer<Ignore, string>(config,
null, new StringDeserializer(Encoding.UTF8)))
            {
                var l = new List<TopicPartitionOffset> { new
TopicPartitionOffset(topic, 0, 0) };
                consumer.Assign(l);

                // Raised on critical errors, e.g. connection failures.
                consumer.OnError += (_, error) =>
                {
                    Console.WriteLine($"Error: {error}");
                    running = false;
                };

                // Raised on deserialization errors or when a consumed
message has an error != NoError.
                consumer.OnConsumeError += (_, error) =>
                {
                    Console.WriteLine($"Consume error: {error}");
                    running = false;
                };

                while (running)
                {
                    Message<Ignore, string> msg;
                    if (consumer.Consume(out msg, TimeSpan.FromSeconds(10)))
                    {
                        Console.WriteLine($"Topic: {msg.Topic} Partition:
{msg.Partition} Offset: {msg.Offset} {msg.Value}");
                    }
                }
            }
        }
    }
```

Run the Example Applications

To run the sample producer and consumer applications:

1. Create a stream named **mystream**.
2. Create a folder application.
3. Create a file named **example.cs**.
4. Add producer example code into the **example.cs** file.
5. Add consumer example code into the **example.cs** file.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

6. Add an entry point for your application:

```
    class Demo
              {
              public static void Main(string[] args)
              {
              Producer.Produce();
              Consumer.Consume();
              }
              }
```

7. Create a project file named **example.csproj**.

8. Add the following dependency properties into the **example.csproj** file:

```
<?xml version="1.0" encoding="utf-8"?>
<Project ToolsVersion="15.0" xmlns="http://schemas.microsoft.com/
developer/msbuild/2003">
  <Import Project="$(MSBuildExtensionsPath)\$(MSBuildToolsVersion)
\Microsoft.Common.props" Condition="Exists('$(MSBuildExtensionsPath)\$
(MSBuildToolsVersion)\Microsoft.Common.props')" />
  <PropertyGroup>
    <Configuration Condition=" '$(Configuration)' == '' ">Debug</
Configuration>
    <Platform Condition=" '$(Platform)' == '' ">AnyCPU</Platform>
    <ProjectGuid>{99EDBA4B-D7DA-48BB-8D0C-AF4B12387935}</ProjectGuid>
    <OutputType>Exe</OutputType>
    <RuntimeIdentifiers>win10-x64</RuntimeIdentifiers>
    <RootNamespace>app</RootNamespace>
    <AssemblyName>app</AssemblyName>
    <TargetFrameworkVersion>v4.6.1</TargetFrameworkVersion>
    <FileAlignment>512</FileAlignment>
    <AutoGenerateBindingRedirects>true</AutoGenerateBindingRedirects>
  </PropertyGroup>
  <PropertyGroup Condition=" '$(Configuration)|$(Platform)' == 'Debug|
AnyCPU' ">
    <PlatformTarget>AnyCPU</PlatformTarget>
    <DebugSymbols>true</DebugSymbols>
    <DebugType>full</DebugType>
    <Optimize>false</Optimize>
    <OutputPath>bin\Debug\</OutputPath>
    <DefineConstants>DEBUG;TRACE</DefineConstants>
    <ErrorReport>prompt</ErrorReport>
    <WarningLevel>4</WarningLevel>
  </PropertyGroup>
  <ItemGroup>
    <Compile Include="app.cs" />
  </ItemGroup>
  <ItemGroup>
    <PackageReference Include="mapr-streams-dotnet" Version="0.11.3" />
  </ItemGroup>
    <Import Project="$(MSBuildToolsPath)\Microsoft.CSharp.targets" />
</Project>
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

9. Verify that you have completed the steps to configure the HPE Ezmeral Data Fabric Streams C client or complete the steps now. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.

   NOTE: The HPE Ezmeral Data Fabric Streams C#/.NET Client is dependent on the HPE Ezmeral Data Fabric Streams C Client. Therefore, the HPE Ezmeral Data Fabric Streams C Client must be configured before you can run the application.

10. Open your project folder on the command line and run:

```
dotnet run
```

Migrating Kafka C#/.NET Applications to HPE Ezmeral Data Fabric Streams

With some modification, you can use existing confluent-kafka C#/.NET applications to consume and produce topics in HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams C#/.NET Client is a binding for Apache librdkafka that works with HPE Ezmeral Data Fabric Streams.

Migrating a .NET 4.5 or 4.6 Application

NOTE: This migration information is applicable for Windows (Win7-x64) platform *only*.

To migrate an existing .NET 4.5 or 4.6 application:

1. Install and configure the HPE Ezmeral Data Fabric Streams C Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.
2. Replace the librdkafka.dll with the HPE Ezmeral Data Fabric librdkafka 0.11.3 from **/bin/.../runtimes/<win7-x64>/<native folder>**.
3. Add a symlink from the **MapRClient.dll** to the **librdkafka.dll**.
4. Restart the application.

Migrating a .NET Core Application1

NOTE: This migration information is applicable for Windows (Win7-x64) and Linux platforms.

To migrate an existing .NET Core application:

1. Install and configure the HPE Ezmeral Data Fabric Streams C Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.
2. Replace the librdkafka.dll with the MapR librdkafka 0.11.3 from **USER_HOME/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/<platform>/<native folder>**.
3. Add a symlink from the **MapRClient.dll** to the **librdkafka.dll**.
4. Restart the application.

Migrating a .NET Core Application2

NOTE: This migration information is applicable for Linux platforms *only*.

To migrate an existing .NET Core application:

1. Remove all **.so** files from the **~/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/<platform>/<native folder>** directory.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

2. Install and configure the HPE Ezmeral Data Fabric Streams C Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3625.
3. Replace the librdkafka.dll with the MapR librdkafka 0.11.3 from **USER_HOME/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/** directory.
4. If the MapR Client doesn not install into the ID search path, add a symlink from the **MapRClient.dll** to the **l/usr/local/lib**.
5. Restart the application.

General Migration Information

- When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

  ```
  /<path and name of stream>:<name of topic>
  ```

  For example, you might have a stream in a MapR cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

  NOTE: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream.

- Review the APIs that are supported and make changes to your application, as needed. See API for HPE Ezmeral Data Fabric Streams C#/.NET on page 3999.
- See Configuration Properties for HPE Ezmeral Data Fabric Streams C#/.NET Client on page 4001 for the list of supported configuration parameters and make changes to your application, as needed.

  NOTE: SSL-related configuration parameters are ignored. When you set these parameters, the HPE Ezmeral Data Fabric Streams Client issues a warning indicating that the parameters are not supported.

API for HPE Ezmeral Data Fabric Streams C#/.NET

HPE Ezmeral Data Fabric Streams C#/.NET Client is a binding for librdkafka and the HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3

Classes

Classes	Descripton
CommittedOffsets	Encapsulates information provided to a Consumer's OnOffsetsCommitted event - per-partition offsets and success/error together with overall success/error of the commit operation.
Consumer	Implements a high-level Apache Kafka consumer (without deserialization).

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Classes	Descripton
Consumer<TKey, TValue>	Implements a high-level Apache Kafka consumer (with key and value deserialization).
Error	Represents an error that occured when interacting with a Kafka broker or the librdkafka library.
ErrorCodeExtensions	Provides extension methods on the ErrorCode enumeration.
GroupInfo	Encapsulates information describing a particular Kafka group.
GroupMemberInfo	Encapsulates information describing a particular member of a Kafka group.
Ignore	A type for use in conjunction with that enables message keys or values to be read as null, regardless of their value.
KafkaException	Represents an error that occured during an interaction with Kafka.
Library	Methods that relate to the native librdkafka library itself (do not require a Producer or Consumer broker connection).
Loggers	OnLog callback event handler implementations.
LogMessage	Encapsulates information provided to the Producer/ Consumer OnLog event.
Message	Represents a message stored in Kafka.
Message<TKey, TValue>	Represents a (deserialized) message stored in Kafka.
Metadata	Kafka cluster metadata.
Null	A type for use in conjunction with and that enables null key or values to be enforced when producing or consuming messages.
PartitionMetadata	Metadata pertaining to a single Kafka topic partition.
Producer	Implements a high-level Apache Kafka producer (without serialization).
Producer<TKey, TValue>	Implements a high-level Apache Kafka producer with key and value serialization.
TopicMetadata	Metadata pertaining to a single Kafka topic.
TopicPartition	Represents a Kafka (topic, partition) tuple.
TopicPartitionError	Represents a Kafka (topic, partition, error) tuple.
TopicPartitionOffset	Represents a Kafka (topic, partition, offset) tuple.
TopicPartitionOffsetError	Represents a Kafka (topic, partition, offset, error) tuple.
TopicPartitionTimestamp	Represents a Kafka (topic, partition, timestamp) tuple.
WatermarkOffsets	Represents the low and high watermark offsets of a Kafka topic/partition.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Interfaces

Interface	Description
IDeliveryHandler	This interface is implemented by types that handle delivery report callbacks as a result of calls to Producer.ProduceAsync().
IDeliveryHandler<TKey, TValue>	This interface is implemented by types that handle delivery report callbacks as a result of calls to Producer<TKey,TValue>.ProduceAsync().
ISerializingProducer<TKey, TValue>	This interface describes the minimum functionality to be provided by a high level (serializing) Kafka producer.

Structs

Struct	Descripton
Offset	Represents a Kafka partition offset value.
Timestamp	Encapsulates a Kafka timestamp and its type.

Enums

Enum	Descripton
ErrorCode	Enumeration of local and broker generated error codes.
TimestampType	Enumerates the different meanings of a message timestamp value.

Configuration Properties for HPE Ezmeral Data Fabric Streams C#/.NET Client

Describes the C#/.NET client configuration properties.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Property Name	Behavior
message.max.bytes	Supports a value less than or equal to 10MB (10000000). If this property is set to a value that is higher than 10MB, the client issues a warning and sets the configuration to 10MB. Produce calls fail when the message size is greater than 10MB.
receive.message.max.bytes	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
topic.blacklist	Same as librdkafka.
error_cb	Same as librdkafka.
opaque	Same as librdkafka.
enable.partition.eof	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
queue.buffering.max.kbytes	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Consumer Configuration Properties

Property Name	Behavior
default_topic_conf	Same as librdkafka.
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Property Name	Behavior
delivery.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Topic Configuration

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: beginning, end, earliest, latest, none, smallest, and largest. As of HPE Ezmeral Data Fabric 6.0.1, beginning and end are supported. **NOTE:** librdkafka additionally supports error.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

HPE Ezmeral Data Fabric-Specific Configurations

Property Name	Behavior
streams.consumer.default.stream	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. **NOTE:** rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Property Name	Behavior
streams.parallel.flushers.per.partition	Enables the producer to have multiple parallel send requests to the server for each topic partition. When this property is set to true, the default value, it is possible for messages to be sent out of order.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Property Name	Behavior
streams.producer.default.stream	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Ezmeral Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.

Utilities for HPE Ezmeral Data Fabric Streams

HPE Ezmeral Data Fabric Streams provides the utilities for operating on streams and topics.

NOTE: HPE Ezmeral Data Fabric Streams cannot use HPE Ezmeral Data Fabric Database Shell to perform operations on streams or topics.

`mapr copystream`	This utility copies data from one HPE Ezmeral Data Fabric Stream to another HPE Ezmeral Data Fabric Stream. You can use it, for example, if you want to set up replication manually from one stream to another.
`mapr diffstreams`	This utility compares the message IDs, metadata, and data in two HPE Ezmeral Data Fabric Streams. Then, generates two directories that contain sequence files

©Copyright 2024 Hewlett Packard Enterprise Development LP

	that you can use to merge the rows from the two HPE Ezmeral Data Fabric Streams.
`mapr diffstreamswithcrc`	This utility uses a cyclic redundancy check to detect differences between sets of messages in the specified HPE Ezmeral Data Fabric Streams. Then, for each set of non-identical messages, it performs a detailed comparison. Finally, it generates one or more directories of sequence files.
`mapr exportstream` and `mapr importstream`	Use these utilities together to export data from HPE Ezmeral Data Fabric Streams into binary sequence files, and then import the data from the binary sequence files into other HPE Ezmeral Data Fabric Streams. You can also use the `mapr importstream` utility to import changes that are specified in sequence files output by the `mapr diffstreams` utility.
`mapr perfconsumer`	This utility runs a consumer reading messages from topics in a HPE Ezmeral Data Fabric Stream. Use this utility to run consumers when you want to estimate the performance of consumers for your HPE Ezmeral Data Fabric Streams applications, given your network configuration.
`mapr perfproducer`	This utility runs a producer, generating messages and publishing them to a HPE Ezmeral Data Fabric Stream. Use this utility to run producers when you want to estimate the performance of producers for your HPE Ezmeral Data Fabric Streams applications, given your network configuration.
`mapr streamanalyzer`	This light-weight utility, which is a sample application for the `Streams` Java class for analytics on HPE Ezmeral Data Fabric Streams, lets you count the messages in a stream or a subset of the topics in a stream. The utility also lets you print either whole retrieved messages or a subset of the fields in each message.

Configuring Properties for Message Size

Describes the `message.max.bytes` and `receive.message.max.bytes` properties for configuring message size.

message.max.bytes	For a C producer, the `message.max.bytes` value is 1000000 B by default. The minimum value is 1000 B and maximum value is 32000000 B. The maximum message size produced by a C API is decided by the `message.max.bytes` value set on the C producer. From C, Python, and C# APIs, the maximum message size that can be produced is 32000000 B. If a C consumer needs to consume a message that is greater than 32000000 B in size, which may be produced by a Java client, the consumer needs to update the `message.max.bytes` or `receive.message.max.bytes` properties to a higher value to consume it. If the `message.max.bytes` property is set to greater than 32000000 B, it is by default capped at 32000000 B. Though a consumer can consume messages greater than 32000000 B (produced say by a Java client), only up to 32000000 B is produced from

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

	the Data Fabric C client. The maximum message size consumed by a C API is limited by the value that is higher among the `message.max.bytes` and `receive.message.max.bytes` values.
receive.message.max.bytes	For a C consumer, the `receive.message.max.bytes` is 1000000 B by default. The minimum value is 1000 B and maximum value is 1000000000 B.

Using a Java API, a larger message size can be produced if the cluster-side property is changed using the following `maprcli config save` command:

```
Cluster side:

maprcli config save -values
{"mfs.db.max.rowsize.kb":<value in KB>}
```

In this case, the row size is 32 MB by default and the maximum is a little less than 2 GB.

The `mfs.db.max.rowsize.kb` setting is a cluster-wide setting that applies to HPE Ezmeral Data Fabric Database (Binary+JSON) and MapR Event Store for Apache Kafka, and it is not configurable per stream or topic.

MapReduce and Apps

This section contains information associated with developing YARN applications.

External Applications and Classpath

Describes how to configure the class path for external applications.

MapReduce version 2 applications require the hadoop 2.x or the yarn classpath, and other applications that can run on YARN require the yarn classpath.

The method to specify the classpath differs based on how the job or application is submitted:

Method used to Submit the Job	Method to Specify Classpath
The external application uses the `hadoop jar` or the `yarn jar` command.	YARN applications (MapReduce or custom applications) that are submitted using the `yarn jar` command will automatically use the yarn classpath. If the external application has a service that submits the job, you can set the CLASSPATH environment variable to point to a different classpath prior to starting the service. In this case, the hadoop classpath that you set in the CLASSPATH environment variable takes priority over the hadoop classpath for the `hadoop jar` command.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Method used to Submit the Job	Method to Specify Classpath
The external application does not use the `hadoop jar` or the `yarn jar` command.	Set the classpath using one of the following options: • If the external application has a service that submits the job or application, you can set the CLASSPATH environment variable to point to the hadoop or yarn classpath prior to starting the service. • Set the classpath within the application. Use one of the following methods to get the classpath: • `hadoop2 classpath` or `hadoop -yarn classpath`: Gets the classpath for MRv2 applications. • `yarn classpath`: Gets the classpath for YARN applications (MRv2 or other applications that can run on YARN).

IMPORTANT: When you launch a spring boot application, ensure that you prefix the classpath with `/opt/mapr/conf:/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop`. Alternatively, copy the `core-site.xml` file to the `/src/main/resources/` folder.

Classpath Construction

This section describes how the MapReduce classpath is constructed.

The classpath that is used to run a MapReduce program is constructed based on how the program is submitted.

When you submit an application from the command line, the classpath used to process the program is based on the following items in this order of priority:

1. JARs in the program's classpath, such as the hadoop 2.x or yarn classpath.
2. JARs specified with the `-libjar` parameter which can be appended to `hadoop jar` or `yarn jar` commands.

If an external application submits the application, the classpath that is used to process the jar file is based on the following items in this order of priority:

1. JARs in the classpath of the external application.
2. JARs in the program's classpath, such as the hadoop 2.x or yarn classpath.
3. JARs specified with `-libjar` parameter which can be appended to `hadoop jar` or `yarn jar` commands.

Managing Third-Party Libraries

Any third-party library that is required by a MapReduce program must be accessible to the data node that processes the application.

A data node is a node in the cluster that includes the NodeManager role. You can provide the third-party libraries when you submit the program, or you can install the third-party libraries on each node that processes the application.

Include the third-party libraries with each program

Including the third-party libraries with each program is the preferred method.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Perform one the following operations to include the third-party jars when you submit the program:

- Package the third-party libraries with the MapReduce jar file. The benefit of this method is that the node from which you submit the program and the node that runs the program are not required to have the libraries files.
- Use the `-libjars` parameter to specify the third-party libraries on the command line. With this option, the library files are submitted to the data node along with the program. The benefit of this method is that the node that runs the program does not need to have the library files installed. However, the node that submits the program must have the library files installed.

Install the third-party libraries on each node that runs the program

You can also install the third-party libraries on each data node. However, this may not be preferred as there could be conflicts between library versions or library files.

To install the third-party libraries on each data node, perform one of the following operations:

- Install the third-party libraries in the following directory on each Node Manager node: `/opt/mapr/hadoop/hadoop-3.x/share/hadoop/common`
- On each node with the NodeManager role, install the required third-party libraries and then specify the location(s) of the third-party libraries with the HADOOP_CLASSPATH env variable in the `env_override.sh` file. The `env_override.sh` file is located in the following directory: `/opt/mapr/conf`. For more information about the file, see About env_override.sh on page 3113.

Kubernetes Interfaces for Data Fabric

This section describes how to leverage the capabilities of the Kubernetes Interfaces for Data Fabric.

Container Storage Interface (CSI) Storage Plugin Configuration

This section describes how to use and troubleshoot the Container Storage Interface (CSI) Storage Plugin.

See Container Storage Interface (CSI) Storage Plugin Overview on page 784 for more information.

Using the Container Storage Interface (CSI) Storage Plugin

This section describes how to configure for static and dynamic provisioning and mounting using example configuration files.

For an overview of the Container Storage Interface (CSI) Storage Plugin, see Container Storage Interface (CSI) Storage Plugin Overview on page 784.

Before You Begin CSI Configuration

Before configuring the Container Storage Interface (CSI) Storage Plugin, be sure to review the following notes about supported and unsupported features and parameters. For an overview of the Container Storage Interface (CSI) Storage Plugin, see Container Storage Interface (CSI) Storage Plugin Overview on page 784.

Data Fabric Parameters for Static and Dynamic Provisioning

In dynamic provisioning, you can specify parameters for the Data Fabric volume to be created. For a list of the parameters that you can use, see `volume create` on page 2592. Note these considerations for using the parameters:

©Copyright 2024 Hewlett Packard Enterprise Development LP

- Volume attributes must be represented as a string (enclosed within quotations). Using an integer or boolean is not supported. In the following example, the `aetype` attribute generates an error because the value (`1`) is not enclosed in quotations.

```
namePrefix: "pv"
mountPrefix: "/pv"
type: "rw"
advisoryquota: "100M"
aetype: 1
```

- The following parameters are ignored because they are redundant. The CSI Driver configures these parameters automatically during volume creation:
  - `mount`
  - `quota*`
  - `createparent`
  - `path`
  - `name`

*Specifying `resources: requests: storage` in a PersistentVolumeClaim (PVC) makes it unnecessary to set the `quota` parameter. For an example, see Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin on page 4023.

Kubernetes Access Modes

Kubernetes access modes control how a PersistentVolume (PV) is mounted on the host. Access modes can be specified on both PVs and PVCs. Only Volumes with a matching Access Mode will be bound to a PVC. The Container Storage Interface (CSI) Storage Plugin supports the following access modes for the PV and PVC spec:

- ROX (ReadOnlyMany)
- RWO (ReadWriteOnce)
- RWX (ReadWriteMany)
- RWOP (ReadWriteOncePod)*

*Supported for the latest CSI drivers (FUSE 1.2.11 and Loopback NFS 1.0.11 or later) on Kubernetes 1.29.

For more information, see the Kubernetes CSI documentation.

Reclaim Policy

The Kubernetes `reclaimPolicy` parameter controls what happens to a PersistentVolume if the corresponding PersistentVolumeClaim is deleted. The `Recycle` Reclaim Policy is not supported by Kubernetes CSI Drivers, so it cannot be used with the Kubernetes Interfaces for Data Fabric. You can specify the reclaim policy normally when you configure a persistent volume.

The following table shows the supported values for the reclaim policy:

Reclaim Policy Value	Description	Support
Delete (default value)	The PersistentVolume and the Data Fabric volume are deleted when	Supported

©Copyright 2024 Hewlett Packard Enterprise Development LP

Reclaim Policy Value	Description	Support
	the user deletes the corresponding PersistentVolumeClaim.	
Retain	The PersistentVolume and the Data Fabric volume are not deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported

For more information about the reclaim policy, see Change the Reclaim Policy of a PersistentVolume.

Kubernetes Mount Options

The Kubernetes `mountOptions` parameter is not supported for use with the Container Storage Interface (CSI) Storage Plugin.

Configuring Static and Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin

About this task

This page summarizes the high-level steps for configuring the Container Storage Interface (CSI) Storage Plugin after installation to provide static or dynamic provisioning. To learn more about static and dynamic provisioning, see Static and Dynamic Volume Provisioning Using Container Storage Interface (CSI) Storage Plugin on page 785.

Static Provisioning

Procedure

1. Create the ticket secret and deploy the secret in the Pod only if the volume is on a secure cluster.
   See Configuring a Secret on page 4081 for more information.
2. Configure a PersistentVolume in your Pod spec or as part of a separate configuration file and provide information about the volume.
   See Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin on page 4023, Persistent Volumes, and Example: Mounting a PersistentVolume for Static Provisioning on page 4026.
3. Configure a PersistentVolumeClaim in your Pod spec or as part of a separate configuration file.
   See PersistentVolumeClaims.
4. Run the Pod spec using `kubectl` commands.
   See Overview of kubectl.

Dynamic Provisioning

Procedure

1. Create the REST and ticket secrets and deploy the secrets in the Pod only if the volume is on a secure cluster.
   See Configuring a Secret on page 4081 for more information.
2. Create a storage class in your Pod spec or in a separate configuration file.
   See Storage Classes and Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin on page 4033.

©Copyright 2024 Hewlett Packard Enterprise Development LP

3. Configure a PersistentVolumeClaim in your Pod spec or in a separate configuration file.
   See Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin on page 4033.
4. Run the Pod spec using `kubectl` commands.
   See Overview of kubectl.

Configuring Static and Dynamic Provisioning for a Raw Block Volume

Raw block volumes are supported for both static and dynamic provisioning. To request a raw-block PersistentVolumeClaim, set `volumeMode: Block`. If not specified, `volumeMode` defaults to `Filesystem` in the PersistentVolumeClaimSpec. PersistentVolumes also have a `volumeMode` field in the PersistentVolumeSpec that is used for static provisioning. `Block`-type PVCs can only bind to `Block`-type PVs.

All the features supported on `Filesystem`-persistent volumes are supported on `Block` volumes. For example:

- Create and Delete Volumes
- Expand Volumes
- Clone Volumes
- Create and Delete Snapshot
- Snapshot Restore

Block volumes are supported only in single-node-writer access modes. At any given time, they can only be published once as read/write on a single node. For `Block` volumes, the CSI driver does not format the block device; it just binds the block device to the target path. The application pod can choose to format the block device to any required Linux file system, such as ext4, xfs, btrfs, and others.

Each block volume is stored in an HPE Ezmeral Data Fabric file. Statically provisioned block files are located at the path designated in the `volumePath` specified in the persistent volume definition. Dynamically provisioned block files are located at the path designated by the `mountPrefix` in the storage class. For fast, random block-write performance, these files should not be erasure coded (warm tiering) or tiered off to an objectstore (cold tiering).

Static Provisioning Example

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-blockpv
  namespace: test-csi
spec:
  accessModes:
  - ReadWriteOnce
  volumeMode: Block
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5G
  csi:
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/user/guest/myblockvolume"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
      platinum: "true"
      capacityBytes: "5000000000"
```

NOTE: For the Loopback NFS CSI driver, change `driver` to `com.mapr.csi-nfskdf`.

Dynamic Provisioning Example

Note that no change in the StorageClass is required:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-block-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  volumeMode: Block
  resources:
    requests:
      storage: 5G
```

Pod Specification

In the pod specification, you must specify `volumeDevices` and `devicePath` for the block volume instead of `volumeMounts` and `mountPath`.

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure-block-pod
spec:
  containers:
    - name: fc-container
      image: fedora:26
      command: ["/bin/sh", "-c"]
      args: [ "tail -f /dev/null" ]
      volumeDevices:
        - name: data
          devicePath: /dev/xvda
  volumes:
    - name: data
      persistentVolumeClaim:
        claimName: test-secure-block-pvc
```

Configuring a Secret

Kubernetes Secrets enable you to inject sensitive data into a pod. The examples in this section show how Secrets can be used in static and dynamic provisioning. Secrets are not by themselves secure. It is important to turn on encryption at rest for Secrets. See Encrypting Secret Data at Rest. For more information about security and Secrets, see Security Properties.

During installation of the driver, the Kubernetes token that was moved into the pod is written to the host node so that the plugin can query a Secret to pull the ticket for mounting. This Kubernetes token is sensitive and should be protected. The token is placed in `/var/run/secrets/kubernetes.io/serviceaccount`.

Here is an example of a configuration file for a Kubernetes Secret:

```
apiVersion: v1
kind: Secret
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
  ...
```

The following table describes the fields in the sample Secret file. For more information, see Secrets in the Kubernetes documentation.

Parameter	Description
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.

REST Secrets

For dynamic provisioning, you must use a Secret to pass the user name and password of a Data Fabric user to the provisioner. This user must have privileges to create and delete a Data Fabric volume. The credentials allow the provisioner to make REST calls to the Data Fabric webserver. Secrets are protected by the Kubernetes RBAC.

The following example shows a REST secret in the Secret file:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
 MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

The following table describes the REST secret fields in the REST Secret example:

Parameter	Description
`MAPR_CLUSTER_CLIENTCERT`	Parameter for specifying the client certificate. You must express the parameter as a base64 representation of the client certificate. See Converting a String to Base64 on page 4083.
`MAPR_CLUSTER_CLIENTKEY`	Parameter for specifying the client key for the client certificate. You must express the parameter as a base64 representation of the client key. See Converting a String to Base64 on page 4083.
`MAPR_CLUSTER_USER`	The base64 representation of a Data Fabric user that has the ability to create and delete Data Fabric volumes. See Converting a String to Base64 on page 4083.
`MAPR_CLUSTER_PASSWORD`	The base64 representation of the password for the user defined by the `MAPR_CLUSTER_USER` parameter. See Converting a String to Base64 on page 4083
`MAPR_CLUSTER_TICKET`	The base64 representation of the ticket contents generated on the data-fabric cluster using the `maprlogin` utility. For dynamic provisioning, with the latest CSI drivers, you can configure a data-fabric ticket to authenticate to the data-fabric webserver to make REST calls. This parameter is provided as a Beta feature.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Parameter	Description
MAPR_CLUSTER_TLSCERT	Parameter for providing the CA certificate. If MAPR_CLUSTER_TLSCERT is not specified, the CSI driver uses a nonsecure HTTP connection to the Data Fabric REST servers. You must express the parameter as a base64 representation of the TLS certificate. See Converting a String to Base64 on page 4083.

Ticket Secrets

For static and dynamic provisioning, you must specify a Secret, which is the base64 representation of the ticket, to enable the POSIX client to communicate with a secure Data Fabric cluster. The ticket for the POSIX client can be generated on the Data Fabric cluster by using the maprlogin on page 2917 utility.

The following example shows a ticket Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: CHANGETHIS!
```

The following table describes the CONTAINER_TICKET field in the ticket Secret example:

Parameter	Description
CONTAINER_TICKET	Base64-encoded ticket value. See Converting a String to Base64 on page 4083.

Ticket secret specified in CONTAINER_TICKET is used to perform read/write operation on the provisioned volumes. To specify/edit ticket secret, the user must have access to volumes.

Use different types of CONTAINER_TICKET based on the conditions that follow:

- If a pod user (via Linux or LDAP user) exists on the Data Fabric cluster, and:
  - if both the ticket and pod user have same UserID and GroupID, use service ticket.
  - if the ticket and pod user have different UserID and GroupID, use **servicewithimpersonation** ticket.
- If the pod user does not exist in Data Fabric cluster, use tenant ticket of the user that exists on Data Fabric cluster (via Linux or LDAP user). Use UserID and GroupID of the pod user for all operations.

  TIP: Tenant ticket user can only access the tenant volumes (passing tenantuser in StorageClass) created by the Data Fabric administrator for that user.

To create the secret:

1. Run the following command to create the Secret file:

   ```
   kubectl create -f <secret-file-name>.yaml
   ```

2. Convert sensitive data, such as a user name and password, to a base64 representation.

   See Converting a String to Base64 on page 4083.

3. Add the base64 representation of sensitive data in the Secret file.

   For more information about the format of the Secret files, see REST Secrets on page 4020 and Ticket Secrets on page 4021 earlier in this section.

©Copyright 2024 Hewlett Packard Enterprise Development LP

4. Deploy the secret on the pod by running the following command:

```
kubectl apply -f <secret-file-name>.yaml
```

Converting a String to Base64

Sensitive data contained in a Secret must be represented in base64. Use these steps to convert such information to the base64 representation:

For example, in Linux:

```
echo -n 'mapr' | base64
```

The output shows the base64 representation of the user name `mapr` is `bWFwcg==`.

MapR tickets include a cluster name followed by a base64-encoded string. It is not sufficient to insert the base64-encoded string into a Kubernetes Secret. You must convert *both* the cluster name and string into base64 representation and then insert the result into the Secret.

The following command shows how to convert a MapR ticket to base64 representation:

```
echo -n "cluster-name <base64-encoded ticket-value>" | base64
```

For example:

```
echo -n "cluster2 PuG0lpuPXuDxj9ERgKCTXOqsXYPTnqRJl6/
mlWJjdVKvE5r46QS2Bh9nC+I4Rcu0GtnWRUOtKBG9gp65bsZN9Kphnr/
Wp15z8D3O2go951CANes/
7QQllYVP7l2BOpGR6I1zIrC3XGwI8OQWT61qpsjSVZv8zO5oQ5GDYQTkPttI/yAk/
uJBES1ohCz38n9HgYALLvMALVsBPtUtG+cNGc1ktUDDMR2q1EgVzdJbuYsOuHnZX3LO3euKDGl4C
4MCmrv9DWiWJxwiZ1yZu69GbZJlXxqLOQBlkdMoTXk=" | base64

Y2x1c3RlcjIgUHVHMGxwdVBYdUR4ajlFUmdLQ1RYT3FzWFlQVG5xUkpsNi9tbFdKamRWS3ZFNXI0
NlFTMkJoOW5DK0k0UmN1MEd0bldSVU90S0JHOWdwNjVic1pOOUtwaG5yL1dwMTV6OEQzTzJnbzk1
MUNBTmVzLzdRUWxsWVZQN2wyQk9wR1I2STF6SXJDM1hHd0k4T1FXVDYxcXBzalNWWnY4ek81b1E1
R0RZUVRrUHR0SS95QWsvdUpCRVMxb2hDejM4bjlIZ1lBTEx2TUFMVnNCUHRVdEcrY05HYzFrdFVE
RE1SMnExRWdWemRKYnVZc091SG5aWDNMTzNldUtER2w0QzRNQ21ydjlEV2lXSnh3aVoxeVp1NjlH
YlpKbFh4cUxPUUJsa2RNb1RYaz0K
```

NOTE: Another method for converting values to base64 is to use an Internet tool such as https://www.base64encode.org to encode or decode data.

Best Practices for Using Tickets

When using secure data-fabric clusters with the Kubernetes Interfaces for Data Fabric, you must generate tickets for your containers. Here are some best practices:

- Create a different user for each container.
- To avoid frequent renewals, use long-lived user tickets or servicewithimpersonation tickets. If you refresh or update a ticket, you must restart your containers.
- If you use an impersonation ticket, it is CRITICAL that you use security contexts in the pod definitions to avoid a misbehaving container impersonating all user IDs. For restrictions that apply to the use of impersonation tickets, see How Impersonation Works on page 1930 and maprlogin on page 2917.
- Match the security context `runAsUser:` ID and `fsGroup:` group to the ID or group used to create the ticket.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Here is an example of a pod spec that specifies a security context:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
```

Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin

About this task

You can designate a volume for use with Kubernetes by specifying the volume parameters directly inside the PersistentVolume spec.

Suppose you want to get an application container up and running quickly in the HPE Ezmeral Data Fabric. You already have a file-system path that you want to use for the application. You only need the data accessible to read. To make this work, you must do the following:

Procedure

1. Generate a service ticket and set the `securityType` parameter in the PersistentVolume spec to `secure` if the volume to mount is on a secure cluster.

   See Generating a Service Ticket on page 1819 for more information. For example:

   ```
   kind: PersistentVolume
   metadata:
     name: pv-securepv-test
     namespace: test-csi
     spec:
       accessModes:
       …
       csi:
         …
         volumeAttributes:
           …
           securityType: "secure"
   ```

2. If the volume to mount is on a secure cluster, configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret.

   For more information, see Configuring a Secret on page 4081. The following table describes the properties of the Secret file:

Property	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`namespace`	The namespace in which the Secret runs.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

`CONTAINER_TICKET`	The contents of the ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 4083. You may remove the ticket if the cluster is not secure.

3. Set the `runAsUser` and the `fsGroup` parameters in the pod spec to the UID and GID of the user that created the ticket.

   For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-pv1
  namespace: test-csi
spec:
  ...
  securityContext:
    runAsUser: 1000
    fsGroup:2000
  ...
```

   The following table lists the properties specified in the sample pod spec:

Parameter	Notes
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. For clarity, the example uses a naked pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability (HA) and ease of upgrade.
`metadata: name`	The pod name.
`metadata: namespace`	The namespace in which the pod runs.
`securityContext: runAsUser`	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
`securityContext: fsGroup`	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.

4. Point the `volumePath` in the CSI driver setting to the desired path, and fill in the `cldbHosts` and `cluster` information.

   For the complete list of volume attributes, see `volume create` on page 2592; however, note that volume attributes like `mount`, `quota`, `createparent`, `path`, and `name` are ignored when provisioning a volume. For more information, see Data Fabric Parameters for Static and Dynamic Provisioning on page 4015.

   For example:

   FUSE

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
  csi:
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      platinum: "true"
```

Loopback NFS

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    driver: com.mapr.csi-nfskdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
```

The following table lists the properties shown in the sample PersistentVolume spec:

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs.
`accessModes`	How the PersistentVolume is mounted on the host. All modes work the same. **NOTE:** The PV and PVC modes must be the same so that they can bind. For more information, see Access Modes.
`csi: driver`	The CSI Driver being used. Call it using one of these drivers: • FUSE driver: `com.mapr.csi-kdf` • Loopback NFS driver: `com.mapr.csi-nfskdf`
`csi: volumeHandle`	The existing volume name or unique volume name for static provisioning.
`volumePath`	The mount point within the filesystem. This parameter specifies an existing MapR path.
`cluster`	The cluster name.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

`cldbHosts`	The DNS names or IP addresses of the CLDB hosts for the cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`securityType`	A parameter that indicates whether tickets are used or not used. If tickets are used, specify `secure`. Otherwise, specify `unsecure`.

Example: Mounting a PersistentVolume for Static Provisioning

About this task

The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX driver (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS driver (`com.mapr.csi-nfskdf`).

For static provisioning, configuring a PersistentVolume has some advantages over annotating Kubernetes volume information in a pod spec:

- The configuration file can be shared for use by multiple pod specs.
- The configuration file enables the PersistentVolume to be mounted and available even when the pod spec that references it is removed.

For example, suppose a marketing volume exists in the secure file system under the path `/Departments/Marketing`. An administrator wants to statically provision this volume and make it available to multiple users. It is critical that data access is as fast as possible. To make this work, the administrator must do the following:

Procedure

1. Create a PersistentVolume (PV) (if you have already not statically provisioned a volume as described in this example) and set the following volumeAttributes:
   - `accessMode` of the PV to `ReadWriteOnce`
   - `securityType` parameter to `secure` because the volume is on a secure cluster
   - `volumePath` in the CSI driver setting to the desired path, and fill in the `cldbHosts` and `cluster` information
   - `platinum` parameter to use the POSIX platinum client or the `license` parameter to select from three POSIX clients

   For example:

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
  labels:
    name: pv-simplepv-test
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
    nodePublishSecretRef:
      name: "mapr-ticket-secret"
      namespace: "test-csi"
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.102.96"
      securityType: "secure"
      platinum: "true"
```

The preceding example specifies the high-performance Platinum POSIX license by including `platinum: "true"` in the `volumeAttributes`.

If you have a Platinum FUSE POSIX license, Release 1.0.2 and later provide another way to control the POSIX client. Instead of specifying `platinum: "true"`, you can specify `license: "<license-name>"` and select one of three POSIX licenses (Basic, Container, or Platinum). Release 1.0.2 also adds support for a `startupConfig` line that lets you pass custom startup parameters to the FUSE process. The following example shows these options:

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
  labels:
    name: pv-simplepv-test
spec:
  accessModes:
  - ReadWriteMany
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    nodePublishSecretRef:
      name: "mapr-ticket-secret"
      namespace: "test-csi"
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterB"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      license: "container"
      startupConfig: "-o allow_other -o big_writes -o auto_unmount -o
async_dio -o max_background=24 -o auto_inval_data --disable_writeback"
```

The following table shows the properties defined in the sample PersistentVolume:

Parameter	Notes
`metadata: name`	The PersistentVolume name.
`metadata: namespace`	The namespace in which the PersistentVolume is stored.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

`accessModes`	How the PersistentVolume is mounted on the host. **NOTE:** The accessMode is not used to set the access mode bit on the volume. The accessMode of the PV and PVC should be the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes.
`persistentVolumeReclaimPolicy`	Specifies what happens to the volume when it is released by its claim. The `Retain` value keeps the PVC around for manual cleanup. `Delete` deletes the PV from Kubernetes. **NOTE:** If this volume was created using dynamic provisioning, `Delete` causes the underlying volume to be deleted. For more information, see Reclaiming.
`capacity`	Specifies how big the allocated storage should be. This value is not validated against the quota or advisory quota. It is up to the person creating the PV to specify this value accurately.
`csi: nodePublishSecretRef`	The Ticket Secret for the CSI driver.
`nodePublishSecretRef:name`	The name of the Ticket Secret that contains the ticket to use when mounting to the cluster. See Configuring a Secret on page 4081.
`nodePublishSecretRef:namespace`	The namespace that contains the Ticket Secret. Use the same namespace as the namespace used by the PersistentVolume.
`csi: driver`	The CSI driver being used. Call it by specifying driver: `mapr.com/maprfs`.
`volumeHandle`	The existing volume name or unique volume name for static provisioning.
`volumePath`	The mount point within the file system. This parameter specifies an existing path. For example, you can specify the root volume as `"/"`, providing access to the entire filesystem.
`cluster`	The data-fabric cluster name.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`securityType`	A parameter that indicates whether tickets are used or not used. If tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`platinum`	If set to `platinum: "true"`, the POSIX client uses the platinum driver for better performance. Note that the platinum driver consumes more host resources and Platinum licenses.

©Copyright 2024 Hewlett Packard Enterprise Development LP

`license` (FUSE POSIX)	Release 1.0.2 and later support the `license: "<license-name>"` parameter in addition to the `platinum: "<true | false>"` parameter for the FUSE POSIX plugin. The `license: "<license-name>"` parameter can have one of three values that control the number of host resources that are consumed: • `"container"` for the Container driver (one binary, 8 threads) • `"basic"` for the Basic driver (one binary, 64 threads) • `"platinum"` for the Platinum driver (multiple binaries, each running 64 threads) Note the following considerations for using the `license: "<license-name>"` parameter: • To use the `license: "<license-name>"` parameter, you must have a Platinum license. • If you specify both the `platinum: "<true | false>"` parameter and the `license: "<license-name>"` parameter, the `platinum: "<true | false>"` parameter overrides the `license: "<license-name>"` parameter. • If neither the `platinum: "<true | false>"` nor the `license:` parameter is specified, the `container` driver is implemented.

`startupConfig` (FUSE POSIX)	Release 1.0.2 and later support specifying the `startupConfig` line. The `startupConfig` line allows you to specify FUSE configuration parameters that are passed to the `fuse.conf` file. For the parameters that can be passed, see Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client on page 1596.
	If no `startupConfig` line is specified, these default startup settings are used:
	`"-o allow_other -o big_writes -o auto_unmount"`
	The default settings allow other users to access the mount point, enable writes larger than 4 KB, and automatically unmount the filesystem when the process is terminated.
	The following example includes the three default settings and adds some additional settings (shown in **bold**):
	`startupConfig: "-o allow_other -o big_writes -o auto_unmount` **`-o async_dio -o max_background=24 -o auto_inval_data --disable_writeback`**`"`
	The additional settings enable asynchronous direct I/O, set the maximum number of asynchronous requests to 24, automatically invalidate the kernel FUSE cache for any data change that causes a change in the files, and disable the writeback cache.

`startupConfig` (Loopback NFS)	The `startupConfig` line allows you to specify configuration parameters that are passed to the `nfsserver.conf` file. For the parameters that can be passed, see nfsserver.conf on page 3024. The `startupConfig` values supported for Loopback NFS are all the configs supported in the `nfsserver.conf` file. Values must be separated by a space. If no `startupConfig` line is specified, these default startup settings are used: `startupConfig: "NFS_HEAPSIZE=1024 DrCacheSize=1024000"`
`numrpcthreads`	Sets the number of RPC threads for the data-fabric client. The default value is 1. The maximum value is 4. Use this option to increase throughput with FUSE basic or container licenses or with the Loopback NFS driver.
`trackMemory`	Enables memory profiling to debug memory leaks in the FUSE or Loopback NFS process. To be enabled after direction from the DF support team. The default value is `false`.
`logLevel`	Sets the log level to one of the following values: `error`, `warn`, `info`, or `debug`. For the FUSE POSIX driver (`com.mapr.csi-kdf`), the default value is `error`. For the Loopback NFS driver (`com.mapr.csi-nfskdf`), the default value is `info`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

`retainLogs`	Retains the logs for the pod on the host machine. The default value is `false`.
`startDelay`	Sets the wait time after launching the FUSE or Loopback NFS processes and before making the mount available to the application pod. The default value is 5. **CAUTION:** Setting the value below 2 to 3 seconds may affect the availability of the mount.

See Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin on page 4023 for more information.

2. Create a PersistentVolumeClaim (PVC) spec and set the `accessMode` of the PVC to `ReadWriteOnce`.

   For example:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-simplepvc
  namespace: test-csi
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

   The following table shows the properties used in the sample PersistentVolumeClaim:

Parameter	Notes
`metadata: name`	The PersistentVolumeClaim name.
`metadata: namespace`	The namespace in which the PersistentVolumeClaim is configured.
`accessMode`	How the requested PersistentVolume is mounted on the host. **NOTE:** The PV and PVC modes should be the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes.

3. Generate a service ticket, and create and deploy a ticket secret on the pod (if you have already not done it as described in steps 1 and 2 of this example).

   See `maprlogin on page 2917` for information on generating a ticket and Configuring a Secret on page 4081 for information on creating and deploying a ticket secret.

4. Create the pod spec and set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.

   For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-pv
  namespace: test-csi
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
  containers:
  - name: busybox
    image: busybox
    args:
    - sleep
    - "1000000"
    resources:
      requests:
        memory: "2Gi"
        cpu: "500m"
    volumeMounts:
    - mountPath: /mapr
      name: maprflex
  volumes:
    - name: maprflex
      persistentVolumeClaim:
        claimName: test-simplepvc
```

The following table shows the properties defined in the sample pod spec:

Parameter	Notes
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. The example uses a naked pod for clarity. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The pod name.
`metadata: namespace`	The namespace in which the pod runs.
`securityContext: runAsUser`	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
`securityContext: fsGroup`	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. Matches with `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. The value should match `volumeMounts: name`.
`persistentVolumeClaim: claimName`	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

5. Deploy the `.yaml` file on the pod by running the following command:

```
kubectl apply -f <filename>.yaml
```

For each Pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the data-fabric cluster. You can run the `node list` command on the data-fabric cluster to determine the number of POSIX clients. For example:

FUSE POSIX

```
# maprcli node list -clientsonly true
clienttype       clienthealth hostname
ip                                        lasthb  id
posixclientbasic Inactive     4f3d34fe-2007-11e9-8980-0cc47ab39644

```

Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin

About this task

This example also uses a PersistentVolume. However, unlike the previous example, when you use the dynamic provisioner, you do not need to create a PersistentVolume manually. The PersistentVolume is created automatically based on the parameters specified in the referenced StorageClass.

Dynamic provisioning is useful in cases where you do not want Data Fabric and Kubernetes cluster administrators to create storage manually to store the pod storage state.

The following example uses a PersistentVolumeClaim that references a Storage Class. In this example, a Kubernetes administrator has created a storage class called `test-secure-sc` for pod creators to use when they want to create persistent storage for their pods. In this example, it is important for the created pod storage to survive the deletion of a pod.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX provisioner (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS provisioner (`com.mapr.csi-nfskdf`).

To dynamically provision a volume, you must do the following:

Procedure

1. Generate a user ticket, and create and deploy a ticket secret on the pod. See:
   - Best Practices for Using Tickets on page 4084 to select the right ticket
   - maprlogin on page 2917 for information about generating a ticket
   - Configuring a Secret on page 4081 for information about creating and deploying a ticket secret
2. Create the REST secret and deploy the secret on the pod.
   See Configuring a Secret on page 4081 for information about creating and deploying a ticket secret.
3. Create a StorageClass similar to the following:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: test-secure-sc
  namespace: test-csi
provisioner: com.mapr.csi-kdf
allowVolumeExpansion: true
reclaimPolicy: Delete
parameters:
    csiProvisionerSecretName: "mapr-provisioner-secrets"
    csiProvisionerSecretNamespace: "test-csi"
    csiNodePublishSecretName: "mapr-ticket-secret"
    csiNodePublishSecretNamespace: "test-csi"
    restServers: "10.10.10.210:8443"
    cldbHosts: "10.10.10.210:7222"
    cluster: "clusterA"
    securityType: "secure"
    namePrefix: "csi-pv"
    mountPrefix: "/csi"
    advisoryquota: "100M"
    trackMemory: "false"
    logLevel: "error"
    retainLogs: "false"
    startupConfig: "-o allow_other -o big_writes -o auto_unmount -o
async_dio -o max_background=24 -o auto_inval_data --disable_writeback"
```

For more information, see Storage Classes. The following table shows the properties defined in the sample StorageClass:

Property	Description
`apiVersion`	The Kubernetes API version for the StorageClass spec.
`kind`	The kind of object being created. This is a StorageClass.
`metadata: name`	The name of the StorageClass. Administrators should specify the name carefully because it will be used by pod authors to help select the right StorageClass for their needs.
`metadata: namespace`	The namespace in which the StorageClass runs. This namespace can be different from the namespace used by the PVC and pod, since the StorageClass namespace can be a cross-namespace resource.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Property	Description
`provisioner`	The provisioner being used. For the FUSE POSIX provisioner, specify `com.mapr.csi-kdf`. For the Loopback NFS provisioner, specify `com.mapr.csi-nfskdf`.
`csiNodePublishSecretName`	The name of the Secret that contains the ticket to use when mounting to the HPE Ezmeral Data Fabric cluster. See Configuring a Secret on page 4081.
`csiNodePublishSecretNamespace`	The namespace that contains the Secret. Use the same namespace as the namespace used by the pod.
`csiProvisionerSecretName` (deprecated) `csi.storage.k8s.io/provisioner-secret-name`	The name of the Kubernetes Secret that is used to store Data Fabric administrative credentials (user, password, and ticket information for the Data Fabric webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 4081.
`csiProvisionerSecretNamespace` (deprecated) `csi.storage.k8s.io/provisioner-secret-namespace`	The namespace for the Secret containing the Data Fabric administrative credentials (user name and password information for a Data Fabric user that has the privileges to create volumes). This namespace can be different from the namespace used by the pod, since a pod author or namespace admin might not be trusted to create administration Secrets for the Data Fabric cluster.
`restServers`	A space-separated list of Data Fabric webservers. Specify the hostname or IP address and port number of each REST server for the cluster. For fault tolerance, providing multiple REST server hosts is recommended.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the Data Fabric cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`cluster`	The Data Fabric cluster name.
`securityType`	A parameter that indicates whether Data Fabric tickets are used or not used. If Data Fabric tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`namePrefix`	A prefix for the Data Fabricvolume to be created. For example, if you specify `PV` as the `namePrefix`, the first dynamically created volume might be named `PV.bevefsescr`. The provisioner generates random names using lower-case letters. If you do not specify a prefix, the provisioner uses `maprprovisioner` as a prefix.
`mountPrefix`	The parent path of the mount in the Data Fabricfile system. If you do not specify a mount prefix, the provisioner mounts your volume under the Data Fabric root. **NOTE:** User provisioning a volume under this `mountPrefix` requires read-write permissions to mount the newly created volume; otherwise, the volume provision will fail.
`advisoryquota`	The advisory storage quota for the volume. The `advisoryquota` is one of the Data Fabric parameters that you can specify for dynamic provisioning. For more information, see Before You Begin on page 4064.
`trackMemory`	Enables memory profiling to debug memory leaks in the FUSE or Loopback NFS process. To be enabled after direction from the DF support team. The default value is `false`.
`logLevel`	Sets the log level to one of the following values: `error`, `warn`, `info`, or `debug`. For the FUSE POSIX driver (`com.mapr.csi-kdf`), the default value is `error`. For the Loopback NFS driver (`com.mapr.csi-nfskdf`), the default value is `info`.
`retainLogs`	Retains the logs for the pod on the host machine. The default value is `false`.

last-updated: Nov 14, 2024

Property	Description

`startupConfig` (FUSE POSIX)	Release 1.0.2 and later support specifying the `startupConfig` line. The `startupConfig` line allows you to specify FUSE configuration parameters that are passed to the `fuse.conf` file. For the parameters that can be passed, see Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client on page 1596.
	If no `startupConfig` line is specified, these default startup settings are used:
	`"-o allow_other -o big_writes -o auto_unmount"`
	The default settings allow other users to access the mount point, enable writes larger than 4 KB, and automatically unmount the file system when the process is terminated.
	The following example includes the three default settings and adds some additional settings (shown in **bold**):
	`startupConfig: "-o allow_other -o big_writes -o auto_unmount`
	`-o async_dio`
	`-o max_background=24 -o auto_inval_data --disable_writeback``"`
	The additional settings enable asynchronous direct I/O, set the maximum number of asynchronous requests to 24, automatically invalidate the kernel FUSE cache for any data change that causes a change in the files, and disable the writeback cache.

`startupConfig` (Loopback NFS)	The `startupConfig` line allows you to specify configuration parameters that are passed to the `nfsserver.conf` file. For the parameters that can be passed, see nfsserver.conf on page 3024. The `startupConfig` values supported for Loopback NFS are all the configs supported in the `nfsserver.conf` file. Values must be separated by a space. If no `startupConfig` line is specified, these default startup settings are used: `startupConfig: "NFS_HEAPSIZE=1024 DrCacheSize=1024000"`
`numrpcthreads`	Sets the number of RPC threads for the Data Fabric client. The default value is 1. The maximum value is 4. Use this option to increase throughput with FUSE basic or container licenses or with the Loopback NFS driver.
`startDelay`	Sets the wait time after launching the FUSE or Loopback NFS processes and before making the mount available to the application pod. The default value is 5. **CAUTION:** Setting the value below 2 to 3 seconds may affect the availability of the mount.

4. Configure a PersistentVolumeClaim similar to the following:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

The following table shows the properties defined in the sample PersistentVolumeClaim:

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Property	Description
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. This is a PersistentVolumeClaim (PVC).
`metadata: name`	The PVC name.
`metadata: namespace`	The namespace in which the PVC runs. This should be the same namespace used by the pod.
`storageClassName`	The name of the storage class requested by the PersistentVolumeClaim. For more information, see Dynamic Provisioning and Storage Classes.
`accessModes`	How the PersistentVolume is mounted on the host. For more information, see Access Modes.
`requests: storage`	The storage resources being requested, or that were requested and have been allocated. The pod author can use this parameter to specify how much quota is needed for the Data Fabric volume. For the units, see Resource Model.

5. Create the pod spec similar to the following:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure-pod
  namespace: test-csi
spec:
  containers:
  - name: busybox
    image: busybox
    args:
    - sleep
    - "1000000"
    resources:
      requests:
        memory: "2Gi"
        cpu: "500m"
    volumeMounts:
    - mountPath: /mapr
      name: maprflex
  volumes:
    - name: maprflex
      persistentVolumeClaim:
        claimName: test-secure-pvc
```

The following table shows the properties defined in the sample pod spec:

Property	Description
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. For clarity, this example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The pod name.
`metadata: namespace`	The namespace in which the pod runs. It should be the same namespace in which the PVC runs.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Property	Description
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. The value should match `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. The value should match `volumeMounts: name`.
`persistentVolumeClaim: claimName`	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims.

6. Deploy the `.yaml` file on the pod by running the following command:

```
kubectl apply -f <filename>.yaml
```

For each pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the Data Fabric cluster. You can run the `node list` on page 2268 command on the cluster to determine the number of POSIX clients. For example:

FUSE POSIX

```
# maprcli node list -clientsonly true
clienttype clienthealth hostname ip lasthb id
posixclientbasic Inactive 4f3d34fe-2007-11e9-8980-0cc47ab39644

    - name: maprflex
      persistentVolumeClaim:
        claimName: test-secure-pvc
```

Example: Volume Cloning for Dynamic Provisioning

About this task

You can clone a volume from an existing volume by configuring a PersistentVolumeClaim that specifies the volume PVC as the data source. In the following example, the PVC named `testcsi-secure-pvc` serves as the data source for creating a new volume named `testcsi-secure-pvc-clone`:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: testcsi-secure-pvc-clone
 namespace: test-csi
spec:
 storageClassName: testcsi-secure-sc
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
 accessModes:
    - ReadWriteOnce
 resources:
 requests:
 storage: 10G
 dataSource:
 kind: PersistentVolumeClaim
 name: testcsi-secure-pvc
```

When cloning extra large volumes (volumes measuring hundreds of GB), you might experience timeouts or a failure to clone the volume. To prevent timeouts with extra large volumes, increase the retry timeout setting for the `csi-provisioner` sidecar container. See the `--timeout` argument in the latest `csi-maprkdf-<version>.yaml`.

For more information, see CSI Volume Cloning.

Example: Volume Expansion for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin

About this task

The following versions of the Container Storage Interface (CSI) Storage Plugin support a volume expansion feature for dynamically provisioned volumes:

- FUSE POSIX plugin versions 1.1.0 and later
- Loopback NFS plugin versions 1.0.0 and later

Volume expansion means you can increase the storage quota of volumes created by the CSI driver. Note that the `StorageClass` must have `allowVolumeExpansion` set to `true` for volume expansion to succeed. For more information about volume expanssion, see Expanding Persistent Volume Claims.

To use volume expansion, increase the storage value and reapply the PersistentVolumeClaim configuration. For example, in the following PVC configuration, to increase the storage quota for the volume from 5G to 10G, change `storage: 5G` to `storage: 10G`, and run the `kubectl apply -f <path_to_pvc>.yaml` command:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

Verifying Creation of a Kubernetes PersistentVolumeClaim and Persistent Volume

About this task

Once the pod spec is installed, you can verify the status of a PersistentVolumeClaim and/or a PersistentVolume by using the `kubectl` command. For example:

Procedure

1. Run the Kubernetes `get` command to verify the status of the PersistentVolumeClaim:

©Copyright 2024 Hewlett Packard Enterprise Development LP

NOTE: The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX driver (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS driver (`com.mapr.csi-nfskdf`).

Static Provisioning

```

3. Run the `node list` on page 2268 command on the cluster to determine the number of POSIX clients.

   For each pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the cluster. For example:

```
# maprcli node list -clientsonly true
clienttype        clienthealth  hostname
ip                                      lasthb  id
posixclientbasic  Inactive      4f3d34fe-2007-11e9-8980-0cc47ab39644

Managing Snapshots Using the Container Storage Interface (CSI) Storage Plugin

This section describes how to create and delete one or more snapshots of volumes dynamically provisioned by the Container Storage Interface (CSI) Storage Plugin on the data-fabric cluster.

The Container Storage Interface (CSI) Storage Plugin v1.x.x uses the `csi-snapshotter` to support snapshot provisioning.

CSI now supports snapshot restore, which allows you to create a new volume from the snapshot data of another volume. See Creating a Volume from a Snapshot on page 4060. To manually restore a volume, see Copying From a Snapshot Using the CLI on page 1256.

Creating a Snapshot Using the Container Storage Interface (CSI) Storage Plugin

About this task

You can create one or more snapshots of a dynamically provisioned volume using the Container Storage Interface (CSI) Storage Plugin.

Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster

©Copyright 2024 Hewlett Packard Enterprise Development LP

Procedure

1. Verify that the volume was successfully provisioned by checking the PersistentVolume (PV) and PersistentVolumeClaim (PVC) for the volume.

   For example, run the `kubectl describe` command to verify the PV and then the PVC.

```
# kubectl describe pv -n test-csi
Name:            mapr-pv-e46a50cd-2012-11e9-84c0-0cc47ab39644
Labels:          <none>
Annotations:     pv.kubernetes.io/provisioned-by: com.mapr.csi-kdf
Finalizers:      [kubernetes.io/pv-protection]
StorageClass:    test-secure-sc
Status:          Bound
Claim:           test-csi/test-secure-pvc
Reclaim Policy:  Delete
Access Modes:    RWO
VolumeMode:      Filesystem
Capacity:        5Gi
Node Affinity:   <none>
Message:
Source:
    Type:              CSI (a Container Storage Interface (CSI) volume
source)

                                                  -------
  Normal     ExternalProvisioning   3m43s
persistentvolume-controller
   waiting for a volume to be created, either by external provisioner
"com.mapr.csi-kdf" or manually created by system administrator
  Normal     Provisioning           3m43s
com.mapr.csi-kdf_csi-controller-kdf-0_69805ad1-2010-11e9-88dc-d610076b9fb
3  External provisioner is provisioning volume for claim "test-csi/
test-secure-pvc"
  Normal     ProvisioningSucceeded  3m40s
com.mapr.csi-kdf_csi-controller-kdf-0_69805ad1-2010-11e9-88dc-d610076b9fb
3  Successfully provisioned volume
mapr-pv-e46a50cd-2012-11e9-84c0-0cc47ab39644
Mounted By:  test-secure-pod
```

2. Deploy the REST secret `.yaml` file by running the following command:

```
kubectl apply -f <secret filename>.yaml
```

   The Secret file should look similar to the following:

```
# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved
apiVersion: v1
kind: Secret
metadata:
  name: mapr-snapshot-secrets
  namespace: test-csi
type: Opaque
data:
  MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

   For more information, see Configuring a Secret on page 4081.

3. Create a snapshot class for provisioning a snapshot of the volume. For example, the snapshot class file should look similar to the following:

   FUSE

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshotClass
metadata:
 name: testcsi-snapshotclass
 namespace: test-csi
driver: com.mapr.csi-kdf
deletionPolicy: Delete
parameters:
 restServers: "10.10.102.95:8443"
 cluster: "mycluster"
 csi.storage.k8s.io/snapshotter-secret-name: mapr-snapshot-secrets
 csi.storage.k8s.io/snapshotter-secret-namespace: test-csi
```

   Loopback NFS

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshotClass
metadata:
 name: testcsi-snapshotclass
 namespace: test-csi
driver: com.mapr.csi-nfskdf
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
deletionPolicy: Delete
parameters:
 restServers: "10.10.102.95:8443"
 cluster: "mycluster"
 csi.storage.k8s.io/snapshotter-secret-name: mapr-snapshot-secrets
 csi.storage.k8s.io/snapshotter-secret-namespace: test-csi
```

The sample snapshot class file shown above contains the following properties:

Property	Description
`apiVersion`	The Kubernetes APi version for the StorageClass spec.
`kind`	The kind of object being created. This is a StorageClass.
`metadata: name`	The name of the snapshot calss. Administrators should specify the name carefully because it will be used by Pod authors to help select the right snapshot class for their needs.
`metadata: namespace`	The namespace in which the snapshot class runs.
`driver`	The CSI volume plugin to use for provisioning the volume snapshots. For example: `com.mapr.csi-kdf`.
`restServers`	A space-separated list of webservers. Specify the hostname or IP address and port number of each REST server for the cluster. For fault tolerance, providing multiple REST server hosts is recommended.
`cluster`	The cluster name.
`csiSnapshotterSecretName` (deprecated) `csi.storage.k8s.io/snapshotter-secret-name`	The name of the Kubernetes Secret that is used to store administrative credentials (user, password, and ticket information for the webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 4081.
`csiSnapshotterSecretNamespace` (deprecated) `csi.storage.k8s.io/snapshotter-secret-namespace`	The namespace for the Secret containing the administrative credentials (user name and password information for a user that has the privileges to create volumes). This namespace can be different from the namespace used by the Pod, since a Pod author or namespace admin might not be trusted to create administration Secrets for the cluster.

4. Deploy the snapshot class by running the following command:

```
kubectl apply -f <snapshot class>.yaml
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

5. Verify whether the snapshot class was successfully deployed by running one of the following commands:

```
# kubectl get volumesnapshotclass -n test-csi
NAME                 AGE
test-snapshotclass   41s
root@qa102-92:~/csi-kdf-3/csi-kdf/examples/snapshot# kubectl describe
volumesnapshotclass -n test-csi
Name:         test-snapshotclass
Namespace:
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
                {"apiVersion":"snapshot.storage.k8s.io/
v1","kind":"VolumeSnapshotClass","metadata":{"annotations":
{},"name":"test-snapshotclass"},"p...
API Version:  snapshot.storage.k8s.io/v1

last-updated: Nov 14, 2024

```
metadata:
  resourceVersion: ""
  selfLink: ""
```

6. Associate the snapshot class with the PersistentVolumeClaim (for the volume to take a snapshot of) by creating a VolumeSnapshot. For example, the VolumeSnapshot file should look similar to the following:

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshot
metadata:
 name: testcsi-secure-snapshot
 namespace: test-csi
spec:
 volumeSnapshotClassName: testcsi-snapshotclass
 source:
    persistentVolumeClaimName: testcsi-secure-pvc
```

   The sample VolumeSnapshot file shown above contains the following properties:

Property	Description
`metadata: name`	The VolumeSnapshot name.
`metadata: namespace`	The namespace in which the VolumeSnapshot runs.
`snapshotClassName`	The volumeSnapshotClassName.
`source: name`	The persistentVolumeClaimName.

7. Deploy the VolumeSnapshot by running the following command:

```
kubectl apply -f <volume snapshot>.yaml
```

8. Verify whether VolumeSnapshot was successfully deployed by doing the following:

©Copyright 2024 Hewlett Packard Enterprise Development LP

a) Run one of the following commands to retrieve the VolumeSnapshot:

```
# kubectl get volumesnapshot -n test-csi -o yaml
apiVersion: v1
items:
- apiVersion: snapshot.storage.k8s.io/v1
  kind: VolumeSnapshot
  metadata:
    annotations:
      kubectl.kubernetes.io/last-applied-configuration: |
        {"apiVersion":"snapshot.storage.k8s.io/

9. Log in to the cluster and verify by running the `volume snapshot list` on page 2710 command. For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvsdxwu -cluster clusterA -json
{
    "timestamp":1548365090744,
    "timeofday":"2019-01-24 01:24:50.744 GMT-0800 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000051",

"snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:16:22 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        }
    ]
}
```

Creating Multiple Snapshots of a Dynamically Provisioned Volume

©Copyright 2024 Hewlett Packard Enterprise Development LP

Procedure

1. Perform steps 1 - 5 described in the Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster on page 4048 section.
2. Create a VolumeSnapshot similar to the one shown in step 6 of the Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster on page 4048 section for each additional snapshot to create for the volume.

   For example:

   ```
   apiVersion: snapshot.storage.k8s.io/v1
   kind: VolumeSnapshot
   metadata:
     name: test-snapshot1
     namespace: test-csi
   spec:
     snapshotClassName: test-snapshotclass
     source:
       name: test-secure-pvc
       kind: PersistentVolumeClaim
   ```

3. Repeat step 7 in Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster on page 4048 for each additional volume snaphots you have created.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

4. Log in to the cluster and verify by running the `volume snapshot list` on page 2710 command. For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvsdxwu -cluster clusterA -json
{
    "timestamp":1548365359138,
    "timeofday":"2019-01-24 01:29:19.138 GMT-0800 PM",
    "status":"OK",
    "total":2,
    "data":[
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000051",

"snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:16:22 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        },
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000052",

"snapshotname":"mapr-snapshot-19282d27-201f-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:29:15 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        }
    ]
}
```

Deleting a Snapshot of a Dynamically Provisioned Volume

About this task

You can delete snapshots you created using Container Storage Interface (CSI) Storage Plugin. To delete:

©Copyright 2024 Hewlett Packard Enterprise Development LP

Procedure

1. Run the following command:

```
kubectl delete -f <volume snapshot>.yaml
```

   For example:

```
# kubectl delete -f test-snapshot1.yaml
volumesnapshot.snapshot.storage.k8s.io "test-snapshot1" deleted
```

2. Log in to the cluster and verify that the snapshot was deleted by running the `volume snapshot list` on page 2710 command.

   For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvsdxwu -cluster clusterA -json
{
    "timestamp":1548365417772,
    "timeofday":"2019-01-24 01:30:17.772 GMT-0800 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000051",

"snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:16:22 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        }
    ]
}
```

Creating a Volume from a Snapshot

You can restore a volume from a volume snapshot by configuring a PersistentVolumeClaim that specifies the volume snapshot as the data source.

In the following example, the snapshot named `testcsi-secure-snapshot` serves as the data source for creating a new volume named `testcsi-secure-pvc-restore`:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: testcsi-secure-pvc-restore
  namespace: test-csi
spec:
  storageClassName: testcsi-secure-sc
  accessModes:
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

```
    - ReadWriteOnce
  resources:
    requests:
      storage: 10G
  dataSource:
    kind: VolumeSnapshot
    apiGroup: snapshot.storage.k8s.io
    name: testcsi-secure-snapshot
```

When creating a volume from snapshots of extra large volumes (volumes measuring hundreds of GB), you might experience timeouts or a failure to create the volume. To prevent timeouts with extra large volumes, increase the retry timeout setting of the `csi-snapshotter` sidecar container. See the `--timeout` argument in the latest `csi-maprkdf-<version>.yaml`.

For more information, see Persistent Volumes.

Enabling the Platinum POSIX Client for Container Storage Interface (CSI) Storage Plugin

When you install the Container Storage Interface (CSI) Storage Plugin, the Container FUSE-based POSIX client package is installed on the CSI Driver container. The CSI Driver also supports the use of the Basic, Container, and Platinum FUSE-based POSIX client. For a comparison of the POSIX client packages, see Preparing for Installation (HPE Ezmeral Data Fabric POSIX Client) on page 411.

NOTE: Enabling the Platinum POSIX client is not required for the Loopback NFS plug-in.

To install the Platinum POSIX client, include the `platinum` parameter in your pod spec. For example:

```
volumeAttributes:
    volumePath: "/"
    cluster: "clusterA"
    cldbHosts: "10.10.102.96"
    securityType: "secure"
    platinum: "true"
```

Release 1.0.2 and later support another method for specifying the POSIX client. You can use the `license` parameter and specify the Container, Basic, or Platinum driver. For example:

```
volumeAttributes:
    volumePath: "/"
    cluster: "clusterA"
    cldbHosts: "10.10.102.96"
    securityType: "secure"
    license: "platinum"
```

For more information, see Example: Mounting a PersistentVolume for Static Provisioning on page 4026.

Logging for the CSI Driver and Provisioner
Describes the event logs for the CSI driver and provisioner for both FUSE and Loopback NFS plugins.

Logs for the Container Storage Interface (CSI) Storage Plugin can be found in `/var/log/csi-maprkdf/`. The following table shows the new log-file format. Before the FUSE 1.2.2 and Loopback NFS 1.0.2 drivers were introduced, the log files included a version in the file name.

Log File Type	FUSE or Loopback NFS	Log File	Description	Which Nodes
Driver events log	FUSE	`csi-plugin.log`	Captures CSI Driver events such as registering the driver and CSI Driver logs for node mount and unmount operations.	All Kubernetes nodes.
	Loopback NFS	`csi-nfsplugin.log`		

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Log File Type	FUSE or Loopback NFS	Log File	Description	Which Nodes
Provisioner events log	FUSE	`csi-provisioner.log`	Captures provisioner events such as registering the CSI provisioner and CSI Controller events such as Create/Delete volumes, Create/Delete Snapshots etc.	The Kubernetes node where the provisioner StatefulSet pod is running.
	Loopback NFS	`csi-nfsprovisioner.log`		

NOTE: The directory must grant `rw` permissions for creating the logs and must grant write/append permissions to the plug-in and provisioner.

Troubleshooting the Container Storage Interface (CSI) Storage Plugin
This section describes how to resolve common problems you might encounter when installing and using the Container Storage Interface (CSI) Storage Plugin.

Troubleshooting CSI Driver installation

Run the following commands to display information about the pods that are deployed for the CSI plugin and provisioner:

FUSE

```
kubectl get pods -n mapr-csi
```

Loopback NFS

```
kubectl get pods -n mapr-nfscsi
```

The installation is considered successful if the `get pods` command shows the pods in the `Running` state. For example, your output should look similar to the following when the CSI plugin is deployed on three worker nodes:

FUSE

```
mapr-csi       csi-controller-kdf-0         5/5     Running     0
4h25m
mapr-csi       csi-nodeplugin-kdf-2kfrf     3/3     Running     0
4h25m
mapr-csi       csi-nodeplugin-kdf-lq5nw     3/3     Running     0
4h25m
mapr-csi       csi-nodeplugin-kdf-pkrzt     3/3     Running     0
4h25m
```

Loopback NFS

```
csi-controller-nfskdf-0       7/7     Running   0          22h
csi-nodeplugin-nfskdf-5rjt2   3/3     Running   0          18h
csi-nodeplugin-nfskdf-7d9cs   3/3     Running   0          22h
csi-nodeplugin-nfskdf-qw7kg   3/3     Running   0          22h
```

The preceding output shows the following:

FUSE

- `csi-nodeplugin-kdf-*`: Daemonset pods are deployed on all the Kubernetes worker nodes.
- `csi-controller-kdf-0`: A StatefulSet pod is deployed on a single Kubernetes worker node.

©Copyright 2024 Hewlett Packard Enterprise Development LP

Loopback NFS

- `csi-nodeplugin-nfskdf-*`: Daemonset pods are deployed on all the Kubernetes worker nodes.
- `csi-controller-nfskdf-0`: A StatefulSet pod is deployed on a single Kubernetes worker node.

Troubleshoot CSI Plugin Deployment Failures

If the pods show a failure in the deployment, run the following `kubectl` commands to see the container logs:

FUSE

```
kubectl logs <csi-nodeplugin-*> -n mapr-csi -c <nodeplugin-pod-container>
```

Loopback NFS

```
kubectl logs csi-controller-nfskdf-0 -n mapr-nfscsi -c
<controller-pod-container>
```

Here, replace `<nodeplugin-pod-container>` with the container that is failing. You can also run the following `kubectl` command to see the controller logs:

```
kubectl logs csi-controller-kdf-0 -n mapr-csi -c <controller-pod-container>
```

Here, replace `<controller-pod-container>` with the container that is failing.

Troubleshooting Volume Provisioning

To check for provisioner errors, check the provisioner log:

FUSE

```
tail -100f /var/log/csi-maprkdf/csi-provisioner.log
```

Loopback NFS

```
tail -100f /var/log/csi-maprkdf/csi-nfsprovisioner.log
```

Troubleshooting Mount Operation

Check the CSI Storage plug-in log for mount or unmount errors:

FUSE

```
tail -100f /var/log/csi-maprkdf/csi-plugin.log
```

Loopback NFS

```
tail -100f /var/log/csi-maprkdf/csi-nfsplugin.log
```

If you don’t see any errors, see the kubelet logs on the node where the pod is scheduled to run. For specific errors, check the CSI Storage plugin logs.

Troubleshooting CSI Storage Plugin Discovery with kubelet

Check the kubelet path for Kubernetes deployment from the kubelet process running with `--root-dir`. The `--root-dir` is a string that contains the directory path for managing kubelet files (such as volume mounts, etc.,) and defaults to `/var/lib/kubelet`. If the Kubernetes environment has a different kubelet

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

path, modify the CSI driver deployment `.yaml` file with the new path, and redeploy the CSI Storage Plugin again.

Troubleshooting Snapshot Provisioning

See the provisioner log and check for any provisioner errors:

```
tail -100f /var/log/csi-maprkdf/csi-provisioner.log
```

If there are no errors, run the following `kubectl` command to check the snapshot:

```
kubectl describe volumesnapshot.snapshot.storage.k8s.io <snapshot-name> -n
<namespace-name>
```

Here:

- `<snapshot-name>`: Name of the VolumeSnapshot Object defined in yaml.
- `<namespace-name>`: Namespace where the VolumeSnapshot object is created.

Troubleshooting No Space on Disk Error

The `devicemapper` storage driver used for Docker allows only 10 GB by default, resulting in "no space left on device" errors when writing to new directories for a new volume mount request.
If `--maxvolumepernode` is configured to be greater than 20 and the underlying Docker is using the `devicemapper` storage driver, do the following to increase the storage size:

1. Change the storage driver to a value other than `devicemapper`, which restricts container storage to 10 GB by default.
2. Increase the default container storage to more than the default of 10 GB for the `devicemapper` storage driver for the Docker container running on a Kubernetes worker node.

For example, do the following to increase the storage size to 50 GB:

1. In the `/etc/sysconfig/docker-storage` file, add `--storage-opt dm.basesize=50G` under `DOCKER_STORAGE_OPTIONS` section.
2. Restart Docker.
3. Run the following command to confirm that the setting is correctly applied:

   ```
   docker info | grep "Base Device Size"
   ```

Kubernetes FlexVolume Driver Configuration

This section describes how to use and troubleshoot the HPE Ezmeral Data Fabric for Kubernetes FlexVolume Driver.

For more information about the HPE Ezmeral Data Fabric for Kubernetes, see Kubernetes Interfaces for Data Fabric FlexVolume Driver Overview on page 788.

Using Data Fabric for Kubernetes FlexVolume Driver

This section describes how to configure Kubernetes objects to enable persistent storage and includes example configuration files for static and dynamic provisioning.

Before You Begin

Before configuration, be sure to review the following notes about supported and unsupported features and parameters:

©Copyright 2024 Hewlett Packard Enterprise Development LP

Data Fabric Parameters for Dynamic Provisioning

In dynamic provisioning, you can specify Data Fabric parameters for the Data Fabric volume to be created. For a list of the Data Fabric parameters that you can use, see volume create on page 2592. Note these considerations for using the Data Fabric parameters:

- Volume attributes must be represented as a string (enclosed within quotations). Using an integer or boolean is not supported. In the following example, the `aetype` attribute will generate an error because the value (`1`) is not enclosed in quotations.

```
namePrefix: "pv"
mountPrefix: "/pv"
type: "rw"
advisoryquota: "100M"
aetype: 1
```

- The following Data Fabric parameters are ignored because they are redundant or not supported in the Kubernetes implementation:
  - `mount`
  - `quota*`
  - `createparent`
  - `path`
  - `name`

*Specifying `resources: requests: storage` in a PersistentVolumeClaim (PVC) (see Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver on page 4069) makes it unnecessary to set the Data Fabric `quota` parameter.

Kubernetes Access Modes

Kubernetes access modes control how a PersistentVolume (PV) is mounted on the host. Access modes can be specified on both PVs and PVCs. Only Volumes with a matching Access Mode will be bound to a PVC. Unfortunately, beyond the PVC/PV binding behavior, PVs using FlexVolume drivers ignore these access modes in the current version of Kubernetes. All access modes will work with the Data Fabric for Kubernetes. However, they will appear the same. This means the ROX mode will not make the volume read only. If you want read-only behavior, specify `readOnly:` in the FlexVolume driver flags.

PersistentVolumeClaim Protection

PVC protection is a Kubernetes 1.9 alpha feature that restricts the user from deleting a PVC while it is being used by an active Pod. Alpha features are not tested for use with the volume plug-in and provisioner. However, without PVC protection, you should not delete a PVC that is still attached to Pods. If you have not turned on PVC protection, ensure that you do not delete PVC's that are in use. In the current release of the Data Fabric for Kubernetes, deleting a PVC causes undefined behavior.

Reclaim Policy

The Kubernetes `reclaimPolicy` parameter controls what happens to a PersistentVolume if the corresponding PersistentVolumeClaim is deleted. The `Recycle` Reclaim Policy is not supported by Kubernetes FlexVolume Drivers, so it cannot be used with KDF. The Retain Policy is currently broken in Kubernetes 1.9 StoragePolicies but not in static PersistentVolumes. The Data Fabric for Kubernetes has a workaround that allows Retain policy on dynamically provisioned volumes by passing the

©Copyright 2024 Hewlett Packard Enterprise Development LP

`reclaimPolicy:` in the parameters rather than in the standard place that FlexVolumes ignore. You can specify the reclaim policy normally when you configure a persistent volume.

The following table shows the supported values for the reclaim policy:

Reclaim Policy Value	Description	Support
Delete (default value)	The PersistentVolume and the Data Fabric volume are deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported
Retain	The PersistentVolume and the Data Fabric volume are not deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported*
Recycle	Performs a basic scrub on a PersistentVolume and makes it available for a new PersistentVolumeClaim.	Not Supported by Kubernetes Flexvolumes

*Not supported for dynamic provision without a workaround.

For more information about the reclaim policy, see Change the Reclaim Policy of a PersistentVolume.

Kubernetes Mount Options

The Kubernetes `mountOptions` parameter is not supported for use with the Data Fabric for Kubernetes because it is not supported for use with the FlexVolume plug-in.

Steps for Configuring the Data Fabric for Kubernetes FlexVolume Driver

This page summarizes the high-level steps for configuring the Data Fabric for Kubernetes FlexVolume Driver to provide static or dynamic provisioning. To learn more about static and dynamic provisioning, see Static and Dynamic Provisioning Using FlexVolume Driver on page 790.

Static Provisioning

1. Install the Data Fabric for Kubernetes.

   See Installing the Data Fabric for Kubernetes FlexVolume Driver on page 272.

2. In your Pod spec or as part of a separate configuration file, configure a PersistentVolume.

   See Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver on page 4069 and Persistent Volumes.

3. Do *one* of the following:

   - Annotate the Pod spec to provide information about the Data Fabric volume.

     See Example: Statically Provisioning a Data Fabric Volume Using the FlexVolume Plug-in on page 4067.

   - In your Pod spec or as part of a separate configuration file, configure a PersistentVolumeClaim.

     See PersistentVolumeClaims.

4. Run the Pod spec by using `kubectl` commands. See Overview of kubectl.

Dynamic Provisioning

1. Install the Data Fabric for Kubernetes.

   See Installing the Data Fabric for Kubernetes FlexVolume Driver on page 272.

©Copyright 2024 Hewlett Packard Enterprise Development LP

2. In your Pod spec or in a separate configuration file, create a storage class.

   See Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver on page 4073 and Storage Classes.

3. In your Pod spec or in a separate configuration file, configure a PersistentVolumeClaim.

   See Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver on page 4073.

4. Run the Pod spec by using `kubectl` commands. See Overview of kubectl.

Example: Statically Provisioning a Data Fabric Volume Using the FlexVolume Plug-in

You can designate a Data Fabric volume for use with Kubernetes by specifying the Data Fabric FlexVolume parameters directly inside the Pod spec. In the Pod spec, you define a Kubernetes volume and add the Data Fabric FlexVolume information to it. You can supply path information by using the `volumePath` parameter. The Kubernetes volume is only as persistent as the Pod. By defining the volume this way, when the Pod is removed, the Kubernetes volume is also immediately unmounted and removed. This approach to static provisioning is most appropriate when you want to get up and running quickly or when you want the Pod and Kubernetes volume lifecycle to be the same.

For example, a developer wants to get her application container up and running quickly with Data Fabric. She already has a Data Fabric path that she wants to use for the application. She only needs the data accessible to read. To make this work, she must:

1. Generate a Data Fabric service ticket, and set the `securityType` parameter in the Pod spec to `secure`. See Generating a Service Ticket on page 1819.

2. Configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret. See Configuring a Secret on page 4081.

3. Set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.

4. Point the `volumePath` in the `flexVolume` setting to the desired path, and fill in the `cldbHosts` and `cluster` information.

NOTE: The following example works for on-premise deployments. For GKE and AWS deployments, you must set a default StorageClass to the `maprfs` StorageClass. If a default StorageClass is not provided for GKE and AWS deployments, the volume is created using your default StorageClass, which might not be a good fit. For information about changing the default StorageClass, see Change the default StorageClass.

```

  CONTAINER_TICKET: <BASE64 ENCODED VERSION OF CONTENTS OF TICKET FILE>
```

The following tables describe the parameters in the example:

Pod

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. For clarity, the example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability (HA) and ease of upgrade.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs.
`securityContext: runAsUser`	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
`securityContext: fsGroup`	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. Matches with `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. Matches with `volumeMounts: name`.
`flexVolume: driver`	The Data Fabric FlexVolume driver being used. Call it using this driver: `mapr.com/maprfs`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

`flexVolume: readOnly`	Specifies that the FlexVolume driver should tell the Data Fabric POSIX Client to mount the volume with the read-only flag.
`volumePath`	The mount point within the Data Fabric file system. This parameter specifies an existing Data Fabric path. For example, you can specify the root volume as `"/"`, providing access to the entire filesystem.
`cluster`	The Data Fabric cluster name.
`cldbHosts`	The DNS names or IP addresses of the CLDB hosts for the Data Fabric cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`securityType`	A parameter that indicates whether Data Fabric tickets are used or not used. If Data Fabric tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`ticketSecretName`	The name of the Secret that contains the ticket to use when mounting to the Data Fabric cluster. See Configuring a Secret on page 4081.
`ticketSecretNamespace`	The namespace that contains the Secret. See Configuring a Secret on page 4081

Secret

Parameter	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`namespace`	The namespace in which the Secret runs.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.
`CONTAINER_TICKET`	The contents of the Data Fabric ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 4083. You may remove the ticket if the Data Fabric cluster is not secure.

Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver

For static provisioning, configuring a PersistentVolume has some advantages over annotating Kubernetes volume information in a Pod spec:

- The configuration file can be shared for use by multiple Pod specs.
- The configuration file enables the PersistentVolume to be mounted and available even when the Pod spec that references it is removed.

For example: A marketing volume exists in the Data Fabric file system under the path `/Departments/Marketing`. An administrator wants to statically provision this volume and make it available to multiple users. It is critical that data access is as fast as possible. To make this work, the administrator must:

1. Create a PersistentVolume (PV).
2. Set the `AccessMode` of the PV to `ReadWriteOnce`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

3. Create a PersistentVolumeClaim (PVC) spec.
4. Set the `AccessMode` of the PVC to `ReadWriteOnce`.
5. Create the Pod spec.
6. Generate a Data Fabric service ticket, and set the `flexVolume securityType` parameter to `secure`. For information about generating a service ticket, see Generating a Service Ticket on page 1819.
7. Configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret. See Configuring a Secret on page 4081.
8. Set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.
9. Set the `platinum` parameter in the Pod spec to `platinum: "true"`. See Enabling the Platinum Posix Client for Kubernetes Interfaces for Data Fabric FlexVolume Driver on page 4080.
10. Point the `volumePath` in the `flexVolume` setting to the desired Data Fabric path.
11. Fill in the `cldbHosts` and `cluster` information.

```

PersistentVolume (PV)

Parameter	Notes
`Capacity`	Specifies how big the allocated storage should be. This value is not validated against the Data Fabric quota or advisory quota. It is up to the person creating the PV to specify this value accurately.
`accessModes`	How the PersistentVolume is mounted on the host. It's important that the PV and PVC modes are the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes.
`persistentVolumeReclaimPolicy`	Specifies what happens to the volume when it is released by its claim. The `Retain` value keeps the PVC around for manual cleanup. `Delete` deletes the PV from Kubernetes. **NOTE:** If this volume was created using dynamic provisioning, `Delete` causes the underlying volume to be deleted. `Recycle` is not supported by Kubernetes FlexVolumes. For more information, see Reclaiming.
`claimRef`	Specifies a default PVC to bind to. If unspecified, the PV selected for a PVC is randomly allocated based on the access mode and provides at least as much storage capacity as requested by the PVC.
`flexVolume: driver`	The Data Fabric FlexVolume driver being used. Call it by specifying driver: `mapr.com/maprfs`.

©Copyright 2024 Hewlett Packard Enterprise Development LP

`platinum`	If set to `platinum: "true"`, the POSIX client uses the platinum driver for better performance. Note that the platinum driver consumes more host resources and Data Fabric Platinum licenses.
`cluster`	The Data Fabric cluster name.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the Data Fabric cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`volumePath`	The mount point within the Data Fabric file system. This parameter specifies an existing Data Fabric path. For example, you can specify the root volume as `"/"`, providing access to the entire filesystem.
`securityType`	A parameter that indicates whether Data Fabric tickets are used or not used. If Data Fabric tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`ticketSecretName`	The name of the Ticket Secret that contains the ticket to use when mounting to the Data Fabric cluster. See Configuring a Secret on page 4081.
`ticketSecretNamespace`	The namespace that contains the Ticket Secret. Use the same namespace as the namespace used by the Pod.

Pod

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. The example uses a naked Pod for clarity. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. This value should match `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. This value should match `volumeMounts: name`.

PersistentVolumeClaim (PVC)

Parameter	Notes
`AccessMode`	How the requested PersistentVolume is mounted on the host. It's important that the PV and PVC modes are the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes.

Secret

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameter	Notes
`metadata: name`	The name of the Ticket Secret. See Configuring a Secret on page 4081
`metadata: namespace`	The namespace in which the Ticket Secret runs.
`CONTAINER_TICKET`	The contents of the Data Fabric ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 4083. You may remove the ticket if the Data Fabric cluster is not secure.

Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver

This example also uses a PersistentVolume. However, unlike the previous example, when you use the Data Fabric dynamic provisioner, you do not need to create a PersistentVolume manually. The PersistentVolume is created automatically based on the parameters specified in the referenced StorageClass.

Dynamic provisioning is useful in cases where you do not want Data Fabric and Kubernetes administrators to create storage manually to store the Pod storage state.

The following example uses a PersistentVolumeClaim that references a Storage Class. In this example, a Kubernetes Administrator has created a storage class called `secure-maprfs` for Pod creators to use when they want to create persistent storage for their Pods. In this example, it is important for the created Pod storage to survive the deletion of a Pod.

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
   name: secure-maprfs
   namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
    restServers: "rest1:8443"
    cldbHosts: "cldb1 cldb2 cldb3"
    cluster: "mysecurecluster"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
    ticketSecretNamespace: "mapr-examples"
    maprSecretName: "mapr-provisioner-secrets"
    maprSecretNamespace: "mapr-examples"
    namePrefix: "pv"
    mountPrefix: "/pv"
    readOnly: "true"
    reclaimPolicy: "Retain"
    advisoryquota: "100M"
    readonly: "1"

---

kind: Pod

type: Opaque
data:
  CONTAINER_TICKET: <BASE64 ENCODED VERSION OF CONTENTS OF TICKET FILE>
```

The following tables describe the parameters in the example:

StorageClass

Parameter	Notes
`apiVersion`	The Kubernetes APi version for the StorageClass spec.
`kind`	The kind of object being created. This is a StorageClass.
`metadata: name`	The name of the StorageClass. Administrators should specify the name carefully because it will be used by Pod authors to help select the right StorageClass for their needs.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameter	Notes
`metadata: namespace`	The namespace in which the StorageClass runs. This namespace can be different from the namespace used by the PVC and Pod, since the StorageClass namespace can be a cross-namespace resource.
`provisioner`	The provisioner being used. for the Data Fabric provisioner, specify `mapr.com/maprfs`.
`restServers`	A space-separated list of Data Fabric webservers. Specify the hostname or IP address and port number of each REST server for the Data Fabric cluster. For fault tolerance, providing multiple REST server hosts is recommended.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the Data Fabric cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`cluster`	The Data Fabric cluster name.
`securityType`	A parameter that indicates whether Data Fabric tickets are used or not used. If Data Fabric tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`ticketSecretName`	The name of the Secret that contains the ticket to use when mounting to the Data Fabric cluster. See Configuring a Secret on page 4081.
`ticketSecretNamespace`	The namespace that contains the Secret. Use the same namespace as the namespace used by the Pod.
`maprSecretName`	The name of the Kubernetes Secret that is used to store Data Fabric administrative credentials (user, password, and ticket information for the Data Fabric webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 4081.
`maprSecretNamespace`	The namespace for the Secret containing the Data Fabric administrative credentials (user name and password information for a Data Fabric user that has the privileges to create Data Fabric volumes). This namespace can be different from the namespace used by the Pod, since a Pod author or namespace admin might not be trusted to create administration Secrets for the Data Fabric cluster.
`namePrefix`	A prefix for the Data Fabric volume to be created. For example, if you specify `PV` as the `namePrefix`, the first dynamically created volume might be named `PV.bevefsescr`. The provisioner generates random names using lower-case letters. If you do not specify a prefix, the provisioner uses `maprprovisioner` as a prefix.
`mountPrefix`	The parent path of the mount in Data Fabric file system. If you do not specify a mount prefix, the provisioner mounts your volume under the Data Fabric root.
`readOnly`	This parameter specifies that the POSIX driver should mount the Data Fabric path as read only. This is different from the `readonly` parameter for volume creation that creates the volume as read only.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameter	Notes
`reclaimPolicy`	Kubernetes does not currently support passing a non-delete reclaim policy to the StorageClass. This parameter allows you to specify `Retain`. This ensures that provisioned volumes are not automatically deleted when their calling Pods are deleted. If you specify `Retain`, you must clean up your provisioned volumes manually.
`advisoryquota`	The advisory storage quota for the Data Fabric volume. `advisoryquota` is one of the Data Fabric parameters that you can specify for dynamic provisioning. For more information, see Before You Begin on page 4064.
`readonly`	When the value is `1`, this parameter specifies that the Data Fabric volume should be created as read-only. This is different from the `readOnly` parameter that mounts the Data Fabric path as read only.

Pod

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. For clarity, this example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs. It should be the same namespace in which the PVC runs.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. The value should match `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. The value should match `volumeMounts: name`.
`persistentVolumeClaim: claimName`	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims.

PVC

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. This is a PersistentVolumeClaim (PVC).
`metadata: name`	The PVC name.
`metadata: namespace`	The namespace in which the PVC runs. This should be the same namespace used by the Pod.

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Parameter	Notes
`accessModes`	How the PersistentVolume is mounted on the host. (This is a limitation of the FlexVolume driver.) For more information, see Access Modes.
`storageClassName`	The name of the storage class requested by the PersistentVolumeClaim. For more information, see Dynamic Provisioning and Storage Classes.
`requests: storage`	The storage resources being requested, or that were requested and have been allocated. The Pod author can use this parameter to tell Data Fabric how much quota is needed for the Data Fabric volume. For the units, see Resource Model.

Provisioner Secret

In the mapr-provisioner-secrets Secret:

Parameter	Notes
`MAPR_CLUSTER_USER`	This is the base64-encoded user ID used to log in to the Data Fabric REST server and create or delete volumes. See Converting a String to Base64 on page 4083. For more information about Secrets, see Secrets.
`MAPR_CLUSTER_PASSWORD`	This is the base64-encoded password for the MAPR_CLUSTER_USER. See Converting a String to Base64 on page 4083. For more information about Secrets, see Secrets.

Ticket Secret

In the mapr-ticket-secret Secret:

Parameter	Notes
`CONTAINER_TICKET`	The contents of the Data Fabric ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 4083. You may remove the ticket if the Data Fabric cluster is not secure. For more information about Secrets, see Secrets.

Identifying the Data Fabric Volume Created During Dynamic Provisioning

Describes how to find the name of the Data Fabric volume created during dynamic provisioning.

In dynamic provisioning, the provisioner creates a new Data Fabric volume with a name that is randomly generated using lower-case letters. For example, if you specify `PV` as the `namePrefix` in the StorageClass, the first dynamically created volume might be named `PV.bevefsescr`. If you do not specify a prefix, the provisioner uses `maprprovisioner` as a prefix.

To find the name of the new Data Fabric volume and the path to the volume:

©Copyright 2024 Hewlett Packard Enterprise Development LP

1. Use the `kubectl describe` command to get information about the PVC:

   ```
   kubectl describe pvc -n <namespace> <pvc-name>
   ```

   The command output shows the name of the PersistentVolume (PV) that was created: For example:

   ```
   kubectl describe pvc -n mapr-examples maprfs-secure-pvc109
   Name:          maprfs-secure-pvc109
   Namespace:     mapr-examples
   StorageClass:  secure-maprfs
   Status:        Bound
   Volume:        pv-ikmqxfwtjh
   Labels:        <none>
   Annotations:   control-plane.alpha.kubernetes.io/
   leader={holderIdentity":"ed60e649-0c68-11e8-acd5-36117e0e7e02","leaseDura
   tionSeconds":15, "acquireTime":"2018-02-09T22:09:43Z"
                  pv.kubernetes.io/bind-competed=yes
                  pv.kubernetes.io/bound-by-controller=yes
                  volume.beta.kubernetes.io/storage-provisioner=mapr.com/
   maprfs
   Finalizers:    []
   Capacity:      300M
   Access Modes:  RWO
   Events:
   ```

©Copyright 2024 Hewlett Packard Enterprise Development LP

2. Use the `kubectl get` command and the PersistentVolume (PV) name to obtain a description of the PersistentVolume:

   ```
   kubectl get pv <pv-name> -o yaml
   ```

   The command output shows the path to the Data Fabric volume. For example:

```
kubectl get pv pv-ikmqxfwtjh -o yaml
apiVersion: v1
kind: PersistentVolume
metadata:
  annotations:
    mapr.com/description: 'Dynamically provisioned PV for MapR-FS:
pv.ikmqxfwtjh'
    mapr.com/maprProvisionerIdentity: mapr.com/maprfs
    mapr.com/provisionerVersion: v1.0.0
    mapr.com/restServers: 10.10.88.214:8443
    mapr.com/secretName: mapr-provisioner-secrets
    mapr.com/secretNamespace: mapr-examples
    mapr.com/volumeName: pv.ikmqxfwtjh
    pv.kubernetes.io/provisioned-by: mapr.com/maprfs
  creationTimestamp: 2018-02-09T22:21:22Z
  name: pv-ikmqxfwtjh
  resourceVersion: "2875820"
  selfLink: /api/v1/persistentvolumes/pv-ikmqxfwtjh
  uid: 8f11aa11-0de7-11e8-bdd6-84a9c4fbf7cb

```

Creating a Default StorageClass

As noted in Example: Statically Provisioning a Data Fabric Volume Using the FlexVolume Plug-in on page 4067, some deployments can require a default StorageClass. A default StorageClass can reduce the effort it takes to create Pods. For example, you could use a default StorageClass to provision storage dynamically to a Data Fabric location for any PersistentVolumeClaim that you create.

©Copyright 2024 Hewlett Packard Enterprise Development LP

If you set the `DefaultStorageClass` admission controller (see PodSecurityPolicy), and you wish to enable a Data Fabric StorageClass as the default, follow the instructions in Change the default StorageClass.

Verifying Creation of a Kubernetes PersistentVolumeClaim and Persistent Volume

Once the Pod spec is installed, you can verify the status of a PersistentVolumeClaim or a PersistentVolume by using the Kubernetes `get` command. For example:

```
$ kubectl get pvc
NAME        STATUS  VOLUME         CAPACITY  ACCESS MODES  STORAGECLASS
AGE
Maprfs-pvc  Bound   pv-rsojpoapxy  8Mi       RWO           simple-maprfs  3d
$ kubectl get pv
NAME           CAPACITY ACCESS MODES  RECLAIM POLICY STATUS
CLAIM             ...
Pv-rsojpoapxy  8Mi      RWO           Delete         Bound  mapr-demo/
maprfs-pvc
```

For an example of creating a PersistentVolumeClaim and a PersistentVolume, see Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver on page 4069.

Enabling the Platinum Posix Client for Kubernetes Interfaces for Data Fabric FlexVolume Driver

When you install the Kubernetes Interfaces for Data Fabric FlexVolume Driver, the Basic FUSE-based POSIX client package is installed on all nodes by default. The FlexVolume Driver also supports the use of the Platinum FUSE-based POSIX client. For a comparison of the two POSIX client packages, see Preparing for Installation (HPE Ezmeral Data Fabric POSIX Client) on page 411.

To install the Platinum POSIX client, include the `platinum` parameter in your Pod spec. For example:

```
options:
cluster: "cluster2"
platinum: "true"
cldbHosts: "10.10.102.96"
```

Mounting a Read-Only Volume

This page describes how to specify a volume that should be mounted as read-only.

The following example specifies a volume that should be mounted as read-only in a Data Fabric path or PersistentVolume during static provisioning:

```
flexVolume:
        driver: "mapr.com/maprfs"
        readOnly: true
        options:
          volumePath: "/path/to/data/in/mapr"
          cluster: "mycluster"
          cldbHosts: "cldb1 cldb2 cldb3"
          securityType: "secure"
          ticketSecretName: "mapr-ticket-secret"
          ticketSecretNamespace: "mapr-examples"
```

The following example shows how to specify that the volume should be mounted read-only in a StorageClass for dynamic provisioning. The example specifies that the POSIX driver should mount the Data Fabric path as read only. This is different from the `readonly` parameter for volume creation that creates the volume as `readonly`.

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
   name: secure-maprfs
   namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
    restServers: "rest1:8443"
    cldbHosts: "cldb1 cldb2 cldb3"
    cluster: "mysecurecluster"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
    ticketSecretNamespace: "mapr-examples"
    maprSecretName: "mapr-provisioner-secrets"
    maprSecretNamespace: "mapr-examples"
    namePrefix: "pv"
    mountPrefix: "/pv"
    readOnly: "true"
    reclaimPolicy: "Retain"
    advisoryquota: "100M"
```

The following example specifies that the volume should be created as `readOnly` in a StorageClass for dynamic provisioning:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
   name: secure-maprfs
   namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
    restServers: "rest1:8443"
    cldbHosts: "cldb1 cldb2 cldb3"
    cluster: "mysecurecluster"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
    ticketSecretNamespace: "mapr-examples"
    maprSecretName: "mapr-provisioner-secrets"
    maprSecretNamespace: "mapr-examples"
    namePrefix: "pv"
    mountPrefix: "/pv"
    reclaimPolicy: "Retain"
    advisoryquota: "100M"
    readonly: "1"
```

Configuring a Secret

Kubernetes Secrets enable you to inject sensitive data into a pod. The examples in this section show how Secrets can be used in static and dynamic provisioning. Secrets are not by themselves secure. It is important to turn on encryption at rest for Secrets. See Encrypting Secret Data at Rest. For more information about security and Secrets, see Security Properties.

During installation of the driver, the Kubernetes token that was moved into the pod is written to the host node so that the plugin can query a Secret to pull the ticket for mounting. This Kubernetes token is sensitive and should be protected. The token is placed in `/var/run/secrets/kubernetes.io/serviceaccount`.

Here is an example of a configuration file for a Kubernetes Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
data:
  ...
```

The following table describes the fields in the sample Secret file. For more information, see Secrets in the Kubernetes documentation.

Parameter	Description
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.

REST Secrets

For dynamic provisioning, you must use a Secret to pass the user name and password of a Data Fabric user to the provisioner. This user must have privileges to create and delete a Data Fabric volume. The credentials allow the provisioner to make REST calls to the Data Fabric webserver. Secrets are protected by the Kubernetes RBAC.

The following example shows a REST secret in the Secret file:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
 MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

The following table describes the REST secret fields in the REST Secret example:

Parameter	Description
`MAPR_CLUSTER_CLIENTCERT`	Parameter for specifying the client certificate. You must express the parameter as a base64 representation of the client certificate. See Converting a String to Base64 on page 4083.
`MAPR_CLUSTER_CLIENTKEY`	Parameter for specifying the client key for the client certificate. You must express the parameter as a base64 representation of the client key. See Converting a String to Base64 on page 4083.
`MAPR_CLUSTER_USER`	The base64 representation of a Data Fabric user that has the ability to create and delete Data Fabric volumes. See Converting a String to Base64 on page 4083.
`MAPR_CLUSTER_PASSWORD`	The base64 representation of the password for the user defined by the `MAPR_CLUSTER_USER` parameter. See Converting a String to Base64 on page 4083
`MAPR_CLUSTER_TICKET`	The base64 representation of the ticket contents generated on the data-fabric cluster using the `maprlogin` utility. For dynamic provisioning, with the latest CSI drivers, you can configure a data-fabric ticket to authenticate to the data-fabric webserver to make REST calls. This parameter is provided as a Beta feature.
`MAPR_CLUSTER_TLSCERT`	Parameter for providing the CA certificate. If `MAPR_CLUSTER_TLSCERT` is not specified, the CSI driver uses a nonsecure HTTP connection to the Data Fabric REST servers. You must express the parameter as a base64 representation of the TLS certificate. See Converting a String to Base64 on page 4083.

Ticket Secrets

For static and dynamic provisioning, you must specify a Secret, which is the base64 representation of the ticket, to enable the POSIX client to communicate with a secure Data Fabric cluster. The ticket for the POSIX client can be generated on the Data Fabric cluster by using the `maprlogin` on page 2917 utility.

The following example shows a ticket Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: CHANGETHIS!
```

The following table describes the `CONTAINER_TICKET` field in the ticket Secret example:

Parameter	Description
`CONTAINER_TICKET`	Base64-encoded ticket value. See Converting a String to Base64 on page 4083.

Ticket secret specified in `CONTAINER_TICKET` is used to perform read/write operation on the provisioned volumes. To specify/edit ticket secret, the user must have access to volumes.

Use different types of `CONTAINER_TICKET` based on the conditions that follow:

- If a pod user (via Linux or LDAP user) exists on the Data Fabric cluster, and:
  - if both the ticket and pod user have same `UserID` and `GroupID`, use `service` ticket.
  - if the ticket and pod user have different `UserID` and `GroupID`, use **`servicewithimpersonation`** ticket.
- If the pod user does not exist in Data Fabric cluster, use `tenant` ticket of the user that exists on Data Fabric cluster (via Linux or LDAP user). Use `UserID` and `GroupID` of the pod user for all operations.

  TIP: `Tenant` ticket user can only access the tenant volumes (passing `tenantuser` in `StorageClass`) created by the Data Fabric administrator for that user.

To create the secret:

1. Run the following command to create the Secret file:

   ```
   kubectl create -f <secret-file-name>.yaml
   ```

2. Convert sensitive data, such as a user name and password, to a base64 representation.

   See Converting a String to Base64 on page 4083.

3. Add the base64 representation of sensitive data in the Secret file.

   For more information about the format of the Secret files, see REST Secrets on page 4082 and Ticket Secrets on page 4083 earlier in this section.

4. Deploy the secret on the pod by running the following command:

   ```
   kubectl apply -f <secret-file-name>.yaml
   ```

Converting a String to Base64

©Copyright 2024 Hewlett Packard Enterprise Development LP

last-updated: Nov 14, 2024

Sensitive data contained in a Secret must be represented in base64. Use these steps to convert such information to the base64 representation:

For example, in Linux:

```
echo -n 'mapr' | base64
```

The output shows the base64 representation of the user name `mapr` is `bWFwcg==`.

MapR tickets include a cluster name followed by a base64-encoded string. It is not sufficient to insert the base64-encoded string into a Kubernetes Secret. You must convert *both* the cluster name and string into base64 representation and then insert the result into the Secret.

The following command shows how to convert a MapR ticket to base64 representation:

```
echo -n "cluster-name <base64-encoded ticket-value>" | base64
```

For example:

```
echo -n "cluster2 PuG0lpuPXuDxj9ERgKCTXOqsXYPTnqRJl6/
mlWJjdVKvE5r46QS2Bh9nC+I4Rcu0GtnWRUOtKBG9gp65bsZN9Kphnr/
Wp15z8D3O2go951CANes/
7QQllYVP7l2BOpGR6I1zIrC3XGwI8OQWT61qpsjSVZv8zO5oQ5GDYQTkPttI/yAk/
uJBES1ohCz38n9HgYALLvMALVsBPtUtG+cNGc1ktUDDMR2q1EgVzdJbuYsOuHnZX3LO3euKDGl4C
4MCmrv9DWiWJxwiZ1yZu69GbZJlXxqLOQBlkdMoTXk=" | base64

Y2x1c3RlcjIgUHVHMGxwdVBYdUR4ajlFUmdLQ1RYT3FzWFlQVG5xUkpsNi9tbFdKamRWS3ZFNXI0
NlFTMkJoOW5DK0k0UmN1MEd0bldSVU90S0JHOWdwNjVic1pOOUtwaG5yL1dwMTV6OEQzTzJnbzk1
MUNBTmVzLzdRUWxsWVZQN2wyQk9wR1I2STF6SXJDM1hHd0k4T1FXVDYxcXBzalNWWnY4ek81b1E1
R0RZUVRrUHR0SS95QWsvdUpCRVMxb2hDejM4bjlIZ1lBTEx2TUFMVnNCUHRVdEcrY05HYzFrdFVE
RE1SMnExRWdWemRKYnVZc091SG5aWDNMTzNldUtER2w0QzRNQ21ydjlEV2lXSnh3aVoxeVp1NjlH
YlpKbFh4cUxPUUJsa2RNb1RYaz0K
```

NOTE: Another method for converting values to base64 is to use an Internet tool such as https://www.base64encode.org to encode or decode data.

Best Practices for Using Tickets

When using secure data-fabric clusters with the Kubernetes Interfaces for Data Fabric, you must generate tickets for your containers. Here are some best practices:

- Create a different user for each container.
- To avoid frequent renewals, use long-lived user tickets or servicewithimpersonation tickets. If you refresh or update a ticket, you must restart your containers.
- If you use an impersonation ticket, it is CRITICAL that you use security contexts in the pod definitions to avoid a misbehaving container impersonating all user IDs. For restrictions that apply to the use of impersonation tickets, see How Impersonation Works on page 1930 and maprlogin on page 2917.
- Match the security context `runAsUser:` ID and `fsGroup:` group to the ID or group used to create the ticket.

Here is an example of a pod spec that specifies a security context:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples
spec:
  securityContext:
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

```
    runAsUser: 1000
    fsGroup: 2000
```

Troubleshooting the Kubernetes Interfaces for Data Fabric FlexVolume Driver

This section describes how to resolve common problems you might encounter when using the Kubernetes Interfaces for Data Fabric FlexVolume driver.

Shared Memory Lock Causes POSIX Failure

Problem	On an upgrade from a previous version of the volume plug-in, POSIX can fail with the following error in the POSIX log file: `Create/Attach to stats shared memory failed.`
Possible Cause	A shared-memory segment lock can prevent the mount from becoming available to the requested pod.
Resolution	Follow the steps in Troubleshooting loopbacknfs POSIX Client Upgrades on page 319 to remove the lock. Then retry the operation.

Unable to Access file system

Problem	Storage is not mounted and no errors are generated in the plugin or provisioner logs.
Possible Cause	The fusermount symlink might be broken.
Resolution	If the symlink points to a location other than `/opt/mapr/k8s/bin/fusermount`, unlink it using the following command from the command line on the host: `unlink /bin/fusermount` Then re-create the Kubernetes Pod.

Pod Container Stuck in Container Creation State During Installation

Problem	During installation, the Pod container can become stuck in the container creation state on a node, and the`/opt/mapr/k8s` directory is not created. As a result, the plug-in does not get copied to the node.
Possible Cause	Unknown.
Resolution	Check the installation logs for an indication that the installation is not completed or the `/opt/mapr/k8s` directory is not created. Restart the kubelet service in the node: `systemctl restart kubelet`

Logs for the Data Fabric for Kubernetes FlexVolume Driver

Logs for the Data Fabric for Kubernetes can be found in:

```
/opt/mapr/logs
```

©Copyright 2024 Hewlett Packard Enterprise Development LP

Log File	Description	Which Nodes
`install-k8s-plugin.log`	Captures events related to the copying of files from the plug-in container to each Kubernetes host node.	All Kubernetes nodes.
`plugin-k8s.log`	Captures events from the FlexVolume plug-in.	All Kubernetes nodes. **NOTE:** In Azure deployments, this log is hidden in the container. See Azure AKS Considerations on page 277.
`provisioner-k8s.log`	Captures events from the provisioner.	The Kubernetes node where the provisioner Pod is running.

Useful Troubleshooting Commands

The following Kubernetes commands can help you gather information about the resources used byData Fabric for Kubernetes:

- `kubectl describe <resourcetype> <resource> -n <namespace>`
- `kubectl get <resourcetype> <resource> -n <namespace> -o yaml`
- `kubectl logs <pod-name> -n <namespace>`
- `journalctl -u kubelet -r` (on the relevant node)

kubectl describe command

In this example, the `kubectl describe` command displays information about the `mapr-kdfprovisioner-5dff68656-ln6vh` Pod. Note that the `kubectl describe` output includes an event section.

```
kubectl describe pod mapr-kdfprovisioner-5dff68656-ln6vh -n mapr-system
Name:         mapr-kdfprovisioner-5dff68656-ln6vh
Namespace:    mapr-system
Node:         qa101-139/10.10.101.139
