After connecting to the filesystem, the application returns a handle to the filesystem.

```
hdfsFS fs = hdfsConnect("default", 0);
if (!fs) {
  fprintf(stderr, "Oops! Failed to
connect to hdfs!\n");
  exit(-1);
}
```

Stores the values of the arguments

The application stores them in a character array and in a variable of type `tSize`. This datatype is defined in `hdfs.h` and is a fixed-width, signed 32-byte integer type for storing the size of data for read or write operations.

```
const char* rfile = argv[1];
tSize bufferSize = strtoul(argv[2],
NULL, 10);
```

Opens the file that you specified

The application opens the specified file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the filesystem
- The name of the file, which you supplied when you launched the application.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_RDONLY`, which specifies read-only mode.
- The default chunk size for the directory in which the file is either located or will be created. This value is specified by the 0 in the last parameter.

Although there are two other parameters in the `hdfsOpenFile()` function – the fourth and fifth, the `libMapRClient` version of `libhdfs`ignores them.

```
hdfsFile readFile = hdfsOpenFile(fs,
rfile, O_RDONLY, 0, 0, 0);
if (!readFile) {
  fprintf(stderr, "Failed to open %s
for reading!\n", rfile);
  exit(-2);
}
```

Creates a buffer of the size that you specified

This is the buffer that the application will read data into.

```
  char* buffer = malloc(sizeof(char)
* bufferSize);
if(buffer == NULL) {
  fprintf(stderr, "Failed to allocate
memory!\n");
  return -2;
}
```

Reads an entire file with hdfsRead

The application calls the function `readEntireFile()`:

```
//Read entire file from the beginning
int ret = readEntireFile(fs,
readFile, buffer, bufferSize);
if (ret < 0) {
  goto done;
}
```

This function uses a WHILE loop. In each loop iteration, the function reads an amount of data that is equal to the size of the buffer. When the amount of bytes read is less than the size of the buffer, the end of the file has been reached and the function breaks the loop. The number of bytes read is added to a total in each iteration.

```
int
readEntireFile(hdfsFS fs, hdfsFile
readFile, char *buffer, tSize
bufferSize)
{
  tSize readBytes = bufferSize;
  uint64_t totalRead = 0;
  if (fs == NULL || readFile == NULL
|| buffer == NULL) {
    return -1;
  }
  while (readBytes == bufferSize) {
    readBytes = hdfsRead(fs,
readFile, (void*)buffer, bufferSize);
    if (readBytes > 0) {
      totalRead += readBytes;
    } else {
      if (readBytes < 0) {
        fprintf(stderr, "hdfsRead
failed with error %d \n", errno);
        hdfsCloseFile(fs, readFile);
        return -1;
      }
      break;
    }
  }
  return 0;
}
```

Seeks an offset and reads from that offset with hdfsRead()

The application next calls the function `readAtOffset()`, passing in 0 as the offset from which to start reading the file.

```
//Read file at a particular offset
//In this case, we are reading from
offset 0
tSize readBytes = readAtOffset(fs,
readFile, 0, buffer, bufferSize);
if (readBytes < 0) {
  goto done;
}
```

This function calls `hdfsSeek()` to move to the specified offset in the file.

If the seek is successful, the function reads from that offset until the buffer is full. The function then returns the number of bytes that were read.

If the seek or the read is not successful (meaning `hdfsSeek()` or `hdfsRead()` returned -1), the function closes the file and returns -1.

The offset in the file is the next byte after the end of the data that was read.

```
tSize
readFromOffset(hdfsFS fs, hdfsFile
readFile, tOffset offset,
               char *buffer, tSize
bufferSize)
{
  tSize ret = 0;
  if (fs == NULL || readFile == NULL
|| buffer == NULL) {
    return -1;
  }
  ret = hdfsSeek(fs, readFile,
offset);
  if (!ret) {
    ret = hdfsRead(fs, readFile,
buffer, bufferSize);
    if (ret < 0) {
      fprintf(stderr, "hdfsRead
failed with error %d \n", errno);
    }
  } else {
    fprintf(stderr, "hdfsSeek failed
with error %d \n", errno);
  }
  if (ret < 0) {
    hdfsCloseFile(fs, readFile);
  }
  //Current offset within the file
will be positioned at (offset +
readBytes)th byte.
  return ret;
}
```

Performs a positional read with hdfsPread()

The application calls `positionalRead()`, passing 100 as the offset from which to start the read.

```
  readBytes = positionalRead(fs,
readFile, 100, buffer, bufferSize);
if (readBytes < 0) {
  goto done;
}
```

The function reads data into the buffer, starting at offset 100, without first calling `hdfsSeek()` to move the offset to that position. The offset is not moved to 100 before the read begins. The offset stays where it is, the read begins at offset 100, and (after the read) the offset remains where it was before the read. The offset in the file is ignored by the positional read.

```
tSize
positionalRead(hdfsFS fs, hdfsFile
```

```
readFile, tOffset offset,
                char *buffer, tSize
bufferSize)
{
  tSize readBytes = 0;
  if (fs == NULL || readFile == NULL
|| buffer == NULL) {
    return -1;
  }
  readBytes = hdfsPread(fs, readFile,
offset, buffer, bufferSize);
  if (readBytes < 0) {
    fprintf(stderr, "hdfsPread failed
with error %d \n", errno);
    hdfsCloseFile(fs, readFile);
  }
  //Current offset within the file
will not be advanced if hdfsPread is
used
  return readBytes;
}
```

Closes the file

```
hdfsCloseFile(fs, readFile);
```

Frees the buffer

```
free(buffer);
```

Disconnects from the filesystem

```
hdfsDisconnect(fs);
```

hdfs_connect_as_user.c

Sample Application

This application demonstrates how to create and write to files impersonating another user by using the API `hdfsConnectAsUser()`.

Before running this application, ensure that you have access to a cluster running MapR filesystem.

To build and run it, download it from this page and copy it to a MapR client or to a system with the mapr-core package installed. Then, modify the `run.sh` script in Building and Running C Applications on file system Clients to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `stdlib.h`
- `string.h`

NOTE: The impersonation APIs are defined in `hdfs.h`.

The application performs the actions that are described in the following sections.

Takes two usernames and a hostname as input

After compiling the application, type the following command to launch the application and pass in the two usernames (to impersonate) and host name:

```
hdfs_connect_as_user <username1>
<username2> <hostname>if (argc < 4) {
  fprintf (stderr, "Provide two
usernames to impersonate and the host
name\n");
  printf ("USAGE: ./
hdfs_connect_as_user mapruser1
mapruser2 10.10.xx.xxx\n");
  exit(EXIT_FAILURE);
}
```

Stores the values of the arguments

The application stores the values of the arguments in character arrays. The application uses the port, 7222, to connect to the given host, and uses character arrays for user directory and file path.

```
char *impersonate_user1 = argv[1];
char *impersonate_user2 = argv[2];
char *host_addr = argv[3];
```

```
int port_num = 7222;
char user1_dir[100];
char writePath[100];
int ret_val;
```

Populates the directory path and file path

The application creates a default path for the user directory and file.

```
sprintf(user1_dir, "/tmp/%s_dir",
impersonate_user1);
sprintf(writePath, "%s/test_file",
user1_dir);
```

Sets an RPC timeout

The `hdfsSetRpcTimeout()` is specific to the libMapRClient version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.

```
int err = hdfsSetRpcTimeout(30);
if (err) {
  fprintf(stderr, "Failed to set rpc
timeout!\n");
  exit(-1);
}
```

Connects to the filesystem as the impersonated user

The application connects to the filesystem as the impersonated user (<username1>) using `hdfsConnectAsUser()`. If successful, this operation returns a handle to the filesystem.

```
printf("Impersonate user: %s\n",
impersonate_user1);
printf("Connecting using
hdfsConnectAsUser() as user %s\n",
impersonate_user1);
hdfsFS fs_handle =
hdfsConnectAsUser(host_addr,
port_num, impersonate_user1);
if (fs_handle == NULL) {
    printf("hdfsConnectAsUser()
failed.\n");
    exit(EXIT_FAILURE);
}
```

Creates a directory as the impersonated user

The application creates a directory under `/tmp` as the impersonated user (<username1>).

```
printf("User1: Create a directory :
%s\n", user1_dir);
ret_val =
hdfsCreateDirectory(fs_handle,
user1_dir);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsCreateDirectory()
failed.\n");
  exit(EXIT_FAILURE);
}
```

Creates and opens a file

The application creates a file and opens the file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the filesystem.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_WRONLY|O_CREAT`. This flag creates the file and opens it for writing.

For more details, see `hdfsOpenFile()` documentation.

```
printf("User1: Create and write to
the file as user1 : %s\n", writePath);
hdfsFile writeFile =
hdfsOpenFile(fs_handle, writePath,
O_WRONLY|O_CREAT, 0, 0, 0);
if(!writeFile) {
  printf("hdfsOpenFile() failed.\n");
  exit(EXIT_FAILURE);
}
```

Writes to the open file

The application writes to the open file as the impersonated user (<username1>).

```
char* buffer = "Hello, from user 1!";
tSize num_written_bytes =
hdfsWrite(fs_handle, writeFile,
(void*)buffer, strlen(buffer)+1);
if (hdfsFlush(fs_handle, writeFile)) {
  printf("failed to flush %s\n",
writePath);
  exit(EXIT_FAILURE);
}
```

Closes the file

The application closes the file after successfully writing to the file as the impersonated user (<username1>).

```
printf("User1: Close file %s.\n",
writePath);
hdfsCloseFile(fs_handle, writeFile);
```

Connects to the filesystem as the impersonating user

The application connects to the filesystem as the second user (<username2>) using `hdfsConnectAsUser()` and returns a handle to the filesystem.

```
printf("Impersonate user: %s\n",
impersonate_user2);
printf("Connecting using
hdfsConnectAsUser() as user %s\n",
impersonate_user2);
hdfsFS fs_handle2 =
hdfsConnectAsUser(host_addr,
port_num, impersonate_user2);
if (fs_handle2 == NULL) {
  printf("hdfsConnectAsUser()
failed.\n");
```

last-updated: Jun 06, 2024

```
  exit(EXIT_FAILURE);
}
```

Tries to write to the file as the impersonating user

The application tries to open the file created by the impersonated user (<username1>) and write to the file as the impersonating user (<username2>). This operation fails as the impersonating user (<username2>) is denied access to the file created by the impersonated user (<username1>) and the application returns error EACCES.

```
printf("User2: Try opening file
created by user1 for writing : %s\n",
writePath);
hdfsFile writeFile2 =
hdfsOpenFile(fs_handle2, writePath,
O_WRONLY, 0, 0, 0);
int errNum = errno;
if(writeFile2) {
    printf("User2: hdfsOpenFile()
should have failed for %s.\n",
impersonate_user2);
    exit(EXIT_FAILURE);
} else {
    if (errNum == EACCES) {
        printf("User2: As expected
hdfsOpenFile() with EACCES.\n");
    } else {
        printf("User2: hdfsOpenFile()
failed with errno:%d expected %d.\n",
errNum, EACCES);
        exit(EXIT_FAILURE);
    }
}
```

Deletes a directory

The application deletes a directory as the impersonated user (<username1>) using the filesystem handle created for this user.

```
printf("Delete directory : %s\n",
user1_dir);
ret_val = hdfsDelete(fs_handle,
user1_dir, 1);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsDelete() failed.\n");
  exit(EXIT_FAILURE);
}
```

Disconnects the impersonating user

The application disconnect the impersonating user (<username2>) from the filesystem.

```
printf("Disconnect the impersonation
user2.\n");
ret_val = hdfsDisconnect(fs_handle2);
if (ret_val != EXIT_SUCCESS) {
  printf("hdfsDisconnect()
failed.\n");
  exit(EXIT_FAILURE);
}
```

last-updated: Jun 06, 2024

Disconnects the impersonated user	The application disconnect the impersonated user (<username1>) from the filesystem.
	`printf("Disconnect the impersonation user1.\n");`
	`ret_val = hdfsDisconnect(fs_handle);`
	`if (ret_val != EXIT_SUCCESS) {`
	`  printf("hdfsDisconnect() failed.\n");`
	`  exit(EXIT_FAILURE);`
	`}`

        exit(EXIT_FAILURE);
    }
    exit(EXIT_SUCCESS);
}
```

Reference for the file system C APIs

The following sections describe the custom datatypes, structures, and APIs in the `libMapRClient` version of `libhdfs`:

Type Definitions

`libhdfs` defines the following custom data types, which are supported by `libMapRClient`:

tObjectKind

An enumeration, the values of which are ‘F’ for file and ‘D’ for directory. Used to specify whether an object is a file or directory.

tOffset

A signed 64-bit integer that is used to specify an offset within a file and the size of a file.

tPort

An unsigned 16-bit integer that is used to specify a port to use in connections to filesystems.

tSize

A signed 32-bit integer that is used to specify the size of data in bytes to read or write.

last-updated: Jun 06, 2024

tTime

A data type of `time_t` that is used to specify a time in seconds.

Structures

`libhdfs` defines these structures, which are supported by `libMapRClient`.

hdfsBuilder

Supported by libhdfs for hadoop-2.x

This structure can be passed to `hdfsBuilderConnect()` for creating connections to file system clusters. In the `libMapRClient`, four of the parameters are ignored. `forceNewInstance` is ignored, though the header file does not indicate this.

```
struct hdfsBuilder {
    int forceNewInstance;
    const char *nn;
    tPort port;
    const char *kerbTicketCachePath; // Ignored
    const char *userName;            // Ignored
    struct hdfsBuilderConfOpt *opts; // Ignored
};
```

Parameters

`nn`

Specifies the CLDB node to connect to when `hdfsBuilderConnect()` is called. This value is set by `hdfsBuilderSetNameNode()`.

- If `default` is specified for the `host` parameter, `hdfsBuilderConnect()` will connect to the first cluster listed in the file `MAPR_HOME/conf/mapr-clusters.conf`. (`MAPR_HOME` defaults to `/opt/mapr`.)
- If a hostname or IP address is specified for the `host` parameter, `hdfsBuilderConnect()`, look in `MAPR_HOME/conf/mapr-clusters.conf` on the client node to match the specified hostname or IP address to a CLDB host and port.
  - If they find a match, they try to connect to the cluster and all standard features for connections to MapR clusters are available. These features include high availability across CLDBs and secure connections.
  - If they do not find a match or if they cannot locate a `mapr-clusters.conf` file, they try to connect to the CLDB host specified in the call to create the connection. However, the standard features for connections to MapR clusters are not available. For example, if the cluster is secured, the connection will fail.

`port`

Specifies the port to connect to on the CLDB node. This value is set by `hdfsBuilderSetNameNodePort()`.

hdfsFileInfo

Supported by libhdfs for hadoop-2.x

This structure is returned by `hdfsGetPathInfo()` and deleted by `hdfsFreeFileInfo()`. It contains information about the file or directory that is specified in the call to `hdfsGetPathInfo()`.

`ParameterstObjectKind mKind`

last-updated: Jun 06, 2024

Specifies whether the object is a file or directory.

`char *mName`

Specifies the name of the object.

`tTime mLastMod`

Specifies the epoch time in milliseconds of the last modification to the object.

`tOffset mSize`

Specifies the size of the object in bytes.

`short mReplication`

Specifies the count of replicas of the object.

`tOffset mBlockSize`

Specifies the block size for the object.

`char *mOwner`

Specifies the owner of the object.

`char *mGroup`

Specifies the group that is associated with the object.

`short mPermissions`

Specifies the permissions on the object.

`tTime mLastAccess`

Specifies the epoch time in milliseconds at which the object was created.

APIs

The following sections provide information about the hdfs APIs:

hdfsAvailable()

Supported by `libMapRClient` for hadoop-2.x

Returns the number of bytes that can be read from an input stream without blocking. This number is simply the size of the file in bytes.

Signature

```
int hdfsAvailable(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns the size of the file in bytes, -1 on error.

Check errno for error codes and meanings.

last-updated: Jun 06, 2024

errno is set to EINVAL if the arguments provided are invalid.

hdfsBuilderConnect()

Supported by `libMapRClient` for hadoop-2.x

Connects to a MapR file system using the parameters that are specified in an `hdfsBuilder` structure.

Signature

```
hdfsFS hdfsBuilderConnect(struct hdfsBuilder *bld)
```

Parameters

Parameter	Description
bld	The builder to use for the connection. This value cannot be NULL.

Return Value

Returns the handle to the file system or NULL on error.

hdfsBuilderSetForceNewInstance()

Not supported for file system

This API is ignored.

hdfsBuilderSetKerbTicketCachePath()

Not supported for file system

This API is ignored.

hdfsBuilderSetNameNode()

Supported by `libMapRClient` for hadoop-2.x

Specifies a CLDB node for an `hdfsBuilder` structure.

Signature

```
void hdfsBuilderSetNameNode(struct hdfsBuilder *bld, const char *nn)
```

Parameters

Parameter	Description
bld	An `hdfsBuilder` structure. This value cannot be NULL.
nn	The hostname or IP address of a name node. Use NULL to connect to the local file system. Use `default` to connect to the first file system cluster that is listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

hdfsBuilderSetNameNodePort()

Supported by `libMapRClient` for hadoop-2.x

Sets the port in an `hdfsBuilder` structure.

Signature

```
void hdfsBuilderSetNameNodePort(struct hdfsBuilder *bld, tPort port)
```

Parameters

Parameter	Description
bld	An `hdfsBuilder` structure. This value cannot be NULL.
port	The port to use for connections. If the CLDB node is set to NULL or `default`, use 0.

hdfsBuilderSetUserName()

Not supported for file system

This API is ignored.

hdfsChmod()

Supported by `libMapRClient` for hadoop-2.x

Changes permissions on a file or directory in the manner of the `chmod` command.

Signature

```
int hdfsChmod(hdfsFS fs, const char* path, short mode)
```

Parameters

Parameter	Description
fs	The handle to the file system. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path to the file or directory.
mode	The bitmask for the new permissions.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

errno is set to EPERM if the process does not have enough privileges to perform the operation.

hdfsChown()

Supported by `libMaprClient` for hadoop-2.x

Changes ownership of a file or directory in the manner of the `chown` command.

ATTENTION:

- To permit a client to resolve user or group from a server, set the `fs.mapr.server.resolve.user` parameter to `true` in `core-site.xml`, for both secure and non secure clusters. Setting this is essential when the client does not belong to the same domain as the mapr cluster nodes, and does not have any knowledge of users present in that domain.
- To permit CLDB to resolve user or group, set the `cldb.security.resolve.user` configuration parameter to `1` on a non-secure cluster as follows:

  ```
  maprcli config save -values {"cldb.security.resolve.user":1}
  ```

  You do not have to set this parameter for a secure cluster, as it is already set to `1`.

Signature

```
int hdfsChown(hdfsFS fs, const char* path, const char *owner, const char
*group)
```

Parameters

Parameter	Description
fs	The handle to the file system. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path to the file or directory
owner	The user to own the file or directory. Set to NULL to keep the owner as is.
group	The group to own the file or directory. Set to NULL to keep the owner as is.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

errno is set to EPERM if the process does not have enough privileges to perform the operation.

hdfsCloseFile()

Supported by `libMapRClient` for hadoop-2.x

Closes an open file. Flushes all pending write buffers for the file and releases resources that are associated with the file.

Signature

```
int hdfsCloseFile(hdfsFS fs, hdfsFile file)
```

last-updated: Jun 06, 2024

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsConnect()

Supported by `libMapRClient` for hadoop-2.x

Connects to a file system cluster.

If a connection to the cluster in which the remote host is located already exists, the functions return a handle to this existing connection.

If a connection to the cluster does not already exist, the functions return a handle to a new connection instance.

Note that if `default` is used for the `host` parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to file system.

Signature

```
hdfsFS hdfsConnect(const char* host, tPort port)
```

Parameters

Parameter	Description
host	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value `default` and use the port number 0. This parameter does not accept NULL as a value.
port	The port on which the host is listening.

Return Value

Returns a handle to the connected file system, or NULL on error.

Check errno for error codes and meanings.

hdfsConnectAsUser()

Supported by `libMapRClient` for hadoop-2.x

Connects to a file system cluster as specified user.

last-updated: Jun 06, 2024

If a connection to the cluster in which the remote host is located already exists, the functions return a handle to this existing connection.

If a connection to the cluster does not already exist, the functions return a unique handle to a connection instance for each user.

NOTE: If `default` is used for the host parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to file system.

Signature

```
hdfsFS hdfsConnectAsUser(const char* host, tPort port, const char* user)
```

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.
`user`	The user connected to the cluster.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsConnectAsUid()
Connects to a file system cluster as specified user ID.

Supported by `libMapRClient` for hadoop-2.x

If a connection to the cluster in which the remote host is located already exists, the function returns a handle to this existing connection.

If a connection to the cluster does not already exist, the function returns a unique handle to a connection instance for the specified user ID.

NOTE: To connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client, use `default` as the value for the `host` parameter.

For more information about connections, see Establishing Connections to the File System on page 3165.

Signature

```
hdfsFS hdfsConnectAsUid(const char* host, tPort port, uid_t uid)
```

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.
`user ID`	The ID of the user connected to the cluster.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsConnectAsUserNewInstance()

Supported by libMapRClient for hadoop-2.x

Connects to a file system cluster as specified user.

The function returns a handle to a new connection instance.

NOTE: If default is used for the host parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to file system.

Signature

```
hdfsFS hdfsConnectAsUserNewInstance(const char* host, tPort port, const
char* user)
```

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsConnectNewInstance()

Supported by `libMapRClient` for hadoop-2.x

Connects to a file system cluster.

The function returns a handle to a new connection instance.

last-updated: Jun 06, 2024

NOTE: If `default` is used for the host parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see Establishing Connections to file system.

Signature

```
hdfsFS hdfsConnectNewInstance(const char* host, tPort port)
```

Parameters

Parameter	Description
`host`	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in `MAPR_HOME/conf/mapr-clusters.conf` on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
`port`	The port on which the host is listening.
`user`	The user connected to the cluster.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsCopy()

This API is not supported.

hdfsCreateDirectory()

Supported by `libMapRClient` for hadoop-2.x

Creates a file or directory at the specified path. Intermediate directories in the path that do not exist are created.

Signature

```
int hdfsCreateDirectory(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The handle of the file system in which to create the file or directory. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the directory.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

last-updated: Jun 06, 2024

errno is set to EINVAL if the input arguments are not valid, EEXIST if the directory already exists, or EACCES if the parent directory does not allow the user write permission.

hdfsCreateDirectory2()

Supported by `libMapRClient` for hadoop-2.x

Makes the given file and all non-existent parents into directories. Stores the size of the name container in a location that you pass a pointer into, so that you can keep track of this size. The size is in bytes.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Signature

```
int hdfsCreateDirectory2(hdfsFS fs, const char* path, tSize
*nameSizeInBytes)
```

Parameters

Parameter	Description
fs	The handle of the file system in which to create the file or directory. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the directory.
nameSizeInBytes	A pointer to a memory buffer that can store the size in bytes of the name container.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsDelete()

Supported by `libMapRClient` for hadoop-2.x

Deletes the specified directory or file.

Signature

```
int hdfsDelete(hdfsFS fs, const char* path, int recursive)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file or directory to delete is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the file.

last-updated: Jun 06, 2024

Parameter	Description
recursive	A value of 0 deletes the specified directory, if the directory is empty. If the directory is not empty, an error is returned. A non-zero value deletes the specified directory and all of its subdirectories. If the specified object is a file, not a directory, this parameter is ignored.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings. Some of the key errors are ESTALE, EACCES, and EPERM.

hdfsDisconnect()

Supported by `libMapRClient` for hadoop-2.x

Disconnects from the specified file system.

Even if there is an error, the resources that are associated with the file system handle are freed.

Signature

```
int hdfsDisconnect(hdfsFS fs)
```

Parameter

Parameter	Description
fs	The handle of the file system to disconnect from. Obtain this handle with one of the `hdfsConnect()` APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsExists()

Supported by `libMapRClient` for hadoop-2.x

Checks whether a given directory or file exists on the file system.

Signature

```
int hdfsExists(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The directory or file to check the existence of.

Return Value

Returns 0 if the directory or file exists, -1 on error.

Check errno for error codes and meanings.

hdfsExists2()

Supported by `libMapRClient` for hadoop-2.x

Checks the file system directly (avoiding a client cache) to determine whether a given file or directory exists.

Signature

```
int hdfsExists2(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The directory or file to check the existence of.

Return Value

Returns 0 if the directory or file exists, -1 on error.

Check errno for error codes and meanings.

hdfsFileFreeReadStatistics()

This API is not supported.

hdfsFileGetReadStatistics()

This API is not supported.

hdfsFileIsOpenForRead()

This API is not supported.

hdfsFileIsOpenForWrite()

This API is not supported.

hdfsFlush()

Supported by `libMapRClient` for hadoop-2.x

Flushes the write buffer for the specified file to the server

Signature

```
int hdfsFlush(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle with one of the `hdfsConnect()` APIs.

last-updated: Jun 06, 2024

Parameter	Description
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

hdfsFreeBuilder()

Supported by `libMapRClient` for hadoop-2.x

Frees the memory that was used by an `hdfsBuilder` structure and its parameter values.

Signature

```
void hdfsFreeBuilder(struct hdfsBuilder *bld)
```

Parameters

Parameter	Description
bld	An `hdfsBuilder` structure. The value cannot be NULL.

hdfsFreeFileInfo()

Supported by `libMapRClient` for hadoop-2.x

Frees up the array of `hdfsFileInfo` structures that is returned by `hdfsListDirectory()`, including allocated fields.

Signature

```
void hdfsFreeFileInfo(hdfsFileInfo *hdfsInfo, int numEntries)
```

Parameters

Parameter	Description
hdfsInfo	The array of dynamically-allocated `hdfsFileInfo` structures.
numEntries	The size of the array.

hdfsFreeHosts()

Supported by `libMapRClient` for hadoop-2.x

Frees an array that was returned by `hdfsGetHosts()`.

Signature

```
void hdfsFreeHosts(char ***blockHosts)
```

last-updated: Jun 06, 2024

Parameters

Parameter	Description
blockHosts	The two-dimensional array that was returned by `hdfsGetHosts()`.

hdfsGetCapacity()

Supported by `libMapRClient` for hadoop-2.x

Returns the capacity in bytes of the connected file system.

Signature

```
tOffset hdfsGetCapacity(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle by calling one of the `hdfsConnect()` APIs.

Return Value

Returns the capacity in bytes of the connected file system, -1 on error.

Check errno for error codes and meanings.

errno can be set to EINVAL in case of error.

hdfsGetDefaultBlockSize()

Supported by libMapRClient for hadoop-2.x

Gets the default size of blocks for the connected file system.

Signature

```
tOffset hdfsGetDefaultBlockSize(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The handle of file system. Obtain this handle with one of the `hdfsConnect()` APIs.

Return Value

Returns 256 MB.

Returns -1 on error.

Check errno for error codes and meanings.

hdfsGetDefaultBlockSizeAtPath()

Supported by `libMapRClient` for hadoop-2.x

Gets the block size of a file at the specified path.

Signature

```
tOffset hdfsGetDefaultBlockSizeAtPath(hdfsFS fs, const char *path)
```

Parameters

Parameter	Description
fs	The handle of the file system. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The location and name of the file.

Return Value

Returns 256 MB.

Check errno for error codes and meanings.

hdfsGetHosts()

Supported by `libMapRClient` for hadoop-2.x

Gets hostnames where a particular block, as determined by the offset and block size, is stored. Due to replication, a single block could be present on multiple hosts.

This function can be useful for understanding the performance implications of file access, and to validate or verify changes to the replication factor.

Signature

```
char*** hdfsGetHosts(hdfsFS fs, const char* path, tOffset start, tOffset
length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the file.
start	The start of the block.
length	The length of the block.

Return Value

If successful, returns a dynamically-allocated two-dimensional array of hostnames. The last element in the array is NULL.

Returns NULL on error.

Check errno for error codes and meanings.

hdfsGetNameContainerSizeBytes()

Unique to libMapRClient

Get the size of the container hosting the path.

last-updated: Jun 06, 2024

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Signature

```
int tSize hdfsGetNameContainerSizeBytes(hdfsFS fs, const char *path)
```

Parameters

Parameter	Description
path	Path of the file or directory residing on the container.

Return Value

Returns size of the container on success; -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

hdfsGetPathInfo()

Supported by libMapRClient for hadoop-2.x

Returns a dynamically-allocated `hdfsFileInfo` structure that contains information about the given path.

Call `hdfsFreeFileInfo()` when the structure is no longer needed.

See `hdfsFileInfo()` for information about the information that this object contains.

Signature

```
hdfsFileInfo * hdfsGetPathInfo(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this by calling one of the `hdfsConnect()` APIs.
path	The path of the file.

Return Value

Returns a dynamically-allocated `hdfsFileInfo` structure on success, and NULL on error.

errno is set to EINVAL for invalid arguments and to EACCES for invalid access.

hdfsGetUsed()

Supported by libMapRClient for hadoop-2.x

Returns the total number of bytes bytes that are being used by all of the files in the file system.

Signature

```
tOffset hdfsGetUsed(hdfsFS fs)
```

last-updated: Jun 06, 2024

Parameters

Parameter	Description
fs	The file system handle.

Return Value

Returns the total size in bytes or -1 on error.

Check errno for error codes and meanings.

hdfsGetWorkingDirectory()

Supported by libMapRClient for hadoop-2.x

Gets the current working directory for the file system. Before calling this method, the application must have called `hdfsSetWorkingDirectory()`.

Signature

```
char* hdfsGetWorkingDirectory(hdfsFS fs, char *buffer, size_t bufferSize)
```

Parameters

Parameter	Description
fs	The file system handle.
buffer	The buffer in which to copy path of current working directory.
bufferSize	The length of user-buffer.

Return Value

Returns the buffer on success, NULL on error.

errno is set to EINVAL for invalid arguments.

hdfsGetXattr()

Supported by libMapRClient for hadoop-2.x

Gets extended attribute values from a file.

Signature

```
int hdfsGetXattr(hdfsFS fs, const char* path, const char *name, char
*value,  size_t size);
```

Parameters

Parameter	Description
`fs`	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
`name`	The name of the extended attribute.
`path`	The path to the file.
`size`	The size of the buffer.

Parameter	Description
`value`	The value for the extended attribute that is read from the system and written to the buffer.

Return Value

Returns:

- Current size of the value of the extended attribute on success
- -1 on error

  Check `errno` for error codes and meanings.

hdfsListDirectory()

Supported by `libMapRClient` for hadoop-2.x

Gets list of files and directories for a given path. Returns the information in a dynamically allocated array of `hdfsFileInfo` structures.

`hdfsFreeFileInfo()` should be called to deallocate memory when this structure is no longer needed.

This method is the equivalent of the `ls -l` command.

Signature

```
hdfsFileInfo *hdfsListDirectory(hdfsFS fs, const char* path, int
*numEntries)
```

Parameters

Parameter	Description
fs	The handle of the file system. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the directory.
numEntries	Set to the number of files/directories in path. Cannot be 0 or NULL.

Return Value

Returns a dynamically-allocated array of `hdfsFileInfo` structures on success and NULL on error.

Check errno for error codes and meanings.

hdfsMove()

This API is not supported.

hdfsNewBuilder()

Supported by `libMapRClient` for hadoop-2.x

Returns an `hdfsBuilder` structure. You can set values for its parameters and then pass it to `hdfsBuilderConnect()`.

Signature

```
struct hdfsBuilder *hdfsNewBuilder(void)
```

last-updated: Jun 06, 2024

Return Value

Returns a new `hdfsBuilder` structure.

Returns ENOMEM if unable to allocate memory for a new `hdfsBuilder` structure.

hdfsOpenFile()

Supported by `libMapRClient` for hadoop-2.x

Opens a file in the specified mode. Creates the file and intermediate directories if they do not exist.

Requires a valid file system handle, which one of the `hdfsConnect()` APIs can provide.

Before the call to `hdfsOpenFile()`, `hdfsExists()` can check that the file exists, if a check is needed.

After finishing work on a file, call `hdfsCloseFile()` to free the memory that is associated with the file.

Signature

```
hdfsFile hdfsOpenFile(hdfsFS fs, const char* path, int flags, int
bufferSize, short replication, tSize blocksize)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The full path to the file.

Parameter	Description
flags	One of the following values. These flags are included in the fcntl.h header file. **O_RDONLY** — Opens the file in read-only mode with the current offset at 0. **O_RDWR** — Opens the file in read-write mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file to offset 0. **O_RDWR** | **O_APPEND** — Opens the file in read-write mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API. **O_WRONLY** — Opens the file in write-only mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file. **O_WRONLY** | **O_APPEND** — Opens the file in write-only mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API.
bufferSize	*Ignored for files on MapR file system*
replication	*Ignored for files on MapR file system*
blocksize	The size of chunks for the file in bytes. Specify 0 if you want to use the value that is specified for the `fs.mapr.block.size` parameter in the `/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml` file on the client (if the client is using the libMapRClient version of hadoop-2.x). If this parameter is not set in `core-site.xml`, the default value is taken from the directory's `.dfs_attrributes` file.

Return Value

Returns the handle to the open file or NULL on error.

Check errno for error codes and meanings.

last-updated: Jun 06, 2024

hdfsOpenFile2()

Supported by `libMapRClient` for hadoop-2.x

Opens a file in a given mode. Creates the file if the file does not exist.

If `hdfsOpenFile2()` creates a file, it stores the size of the name container in a location that you pass a pointer into, so that you can keep track of this size. The size is in bytes.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Before the call to `hdfsOpenFile2()`, `hdfsExists()` can check that the file exists, if a check is needed.

After finishing work on a file, call `hdfsCloseFile()` to free the resources that are associated with the file.

Signature

```
hdfsFile hdfsOpenFile2(hdfsFS fs, const char* path, int flags, int
bufferSize, short replication, tSize blocksize, tSize *nameSizeInBytes)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The full path to the file.

last-updated: Jun 06, 2024

Parameter	Description
flags	One of the following values. These flags are included in the fcntl.h header file. **O_RDONLY** — Opens the file in read-only mode with the current offset at 0. **O_RDWR** — Opens the file in read-write mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file. **O_RDWR | O_APPEND** — Opens the file in read-write mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API. **O_WRONLY** — Opens the file in write-only mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file. **O_WRONLY | O_APPEND** — Opens the file in write-only mode with the current offset at 0. Writing to the file with `hdfsWrite()` appends the written data to the end of the file. Data written with `hdfsPwrite()` is not appended, but written starting at the offset specified in the call to that API.
bufferSize	*Ignored for files on MapR file system*
replication	*Ignored for files on MapR file system*
blocksize	The size of chunks for the file in bytes. Use 0 if you want to use the value that is specified for the `fs.mapr.block.size` parameter in the `/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml` file on the client (if the client is using the libMapRClient version of hadoop-2.x). If this parameter is not set in `core-site.xml`, the default value is taken from the directory's `.dfs_attrributes` file.
nameSizeInBytes	A pointer to a memory buffer that can store the size in bytes of the name container. The value is returned only if `hdfsOpenFile2()` creates the specified file because the file does not already exist.

last-updated: Jun 06, 2024

Return Value

Returns the handle to the open file or NULL on error.

Check errno for error codes and meanings.

hdfsPread()

Supported by libMapRClient for hadoop-2.x

Reads an open file from a specified offset.

Whereas `hdfsRead()` increments the current offset in the file by the number of bytes that are read, `hdfsPread()` does not change the current offset. For example, if the current offset is 0 and `hdfsPread()` starts reading from offset 100, after the read the current offset is still 0.

Signature

```
tSize  hdfsPread(hdfsFS fs, hdfsFile file, tOffset position, void* buffer,
tSize length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.
position	Offset from which to read.
buffer	The buffer to copy read bytes into.
length	The length of the buffer. The maximum size of `tSize` is the maximum buffer length.

Return Value

Returns the number of bytes actually read, which can be less than than the length of the buffer if the end of the file is reached during the read. Returns -1 on error.

On error, errno is set to one of the following values:

- EACCES if the access permissions are violated.
- ESTALE if the file doesn't exist on the server.
- EINVAL if the arguments are invalid or if the file type doesn't support read operations.

To recover from errors, close the file by calling `hdfsCloseFile()`.

hdfsPwrite()

Supported by libMapRClient for hadoop-2.x

Writes starting at a specified position in an open file.

Whereas `hdfsWrite()` increments the current offset by the amount of bytes returned by the API (except in case of error), `hdfsPwrite()` does not change the value of current offset. If the current offset before the call to `hdfsPwrite()` is 0 and you specify the offset 10 for the write operation, after the write the current offset remains 0.

last-updated: Jun 06, 2024

If a call to `hdfsPwrite()` specifies an offset that is past the end of the file, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

On error, pending write buffers are flushed to the server.

Signature

```
tSize hdfsPwrite(hdfsFS fs, hdfsFile file, tOffset position, const void*
buffer, tSize length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The handle of the file. Obtain this handle with one of the `hdfsOpenFile()` APIs.
position	The offset at which to start writing.
buffer	The data to write.
length	The number of bytes to write. The maximum length is the maximum size of `tSize`.

Return Value

Returns the number of bytes written, -1 on error.

Check errno for error codes and meanings.

hdfsRead()

Supported by libMapRClient for hadoop-2.x

Reads data from the current offset in an open file. After the read, the current offset is incremented by the number of bytes read.

To read from a specific offset, first call `hdfsSeek()` to move to that offset in the file. Then, call `hdfsRead()`.

Alternatively, call `hdfsPread()`, specifying an offset in the call. `hdfsPread()` does not increment the current offset in the file. The offset that you specify in the call is used only for the read.

Signature

```
tSize hdfsRead(hdfsFS fs, hdfsFile file, void* buffer, tSize length)
```

Parameters

Parameter	Description
fs	The file system handle. File system handle can be obtained using one of the `hdfsConnect()` APIs.

last-updated: Jun 06, 2024

Parameter	Description
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.
buffer	The buffer to copy bytes into during the read.
length	The length of the buffer. The maximum length of the buffer is the maximum size of `tSize`.

Returned Value

Returns the number of bytes actually read, which can be less than than the length of the buffer if the end of the file is reached during the read. Returns -1 on error.

Check errno for error codes and meanings.

hdfsReadStatisticsGetRemoteBytesRead()

This API is not supported.

hdfsRename()

Supported by libMapRCient for hadoop-2.x

Renames the specified file. For information about the format to use for paths, see Specifying Paths to Files and Directories.

Signature

```
int hdfsRename(hdfsFS fs, const char* oldPath, const char* newPath)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
oldPath	The path of the source file.
newPath	The path of the destination file.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSeek()

Supported by `libMapRClient` for hadoop-2.x

Moves the current offset to another offset in the specified file.

Signature

```
int hdfsSeek(hdfsFS fs, hdfsFile file, tOffset desiredPos)
```

last-updated: Jun 06, 2024

Parameters

Parameter	Description
fs	The handle for the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The handle to the file. Obtain this handle with one of the `hdfsConnect()` APIs.
desiredPos	The offset to move forward to.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetTicketAndKeyFile()
Dynamically loads a ticket file

Supported by `libMapRClient` for hadoop-2.x

Use this API to dynamically load a ticket file to connect to newly added clusters and nodes, without restarting your application.

Signature

```
int hdfsSetTicketAndKeyFile(const char *fname)
```

Parameters

Parameter	Description
fname	The name of the ticket file to reload.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetReplication()

This API is not supported.

hdfsSetRpcTimeout()

Unique to libMapRClient

Sets the RPC timeout in seconds. Before creating a connection to a file system cluster, you can set an RPC timeout for your connections to CLDB nodes and fileservers, passing the number of seconds for the timeout as an integer.

Signature

```
int hdfsSetRpcTimeout(int seconds)
```

last-updated: Jun 06, 2024

Parameters

Parameter	Description
seconds	The time in seconds to wait before timing out. The default is 99 seconds. If you change the value, set it either to 0 or to greater than 30 seconds. If RPC timeout is set to 0, remote procedure calls will continue to be retried until they are successful.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetThreads()

Unique to libMapRClient

Configures the number of threads for flushing write buffers. This number is specific to individual clients. The default number is 8.

The number of threads must be positive. If it isn't, EINVAL is returned.

Signature

```
int hdfsSetThreads(int threads)
```

Parameters

Parameter	Description
threads	The number of threads for flushing write buffers.

Return Value

Returns the current number of flush threads for the client, -1 on error. Check errno for error codes and meanings.

hdfsSetWorkingDirectory()

Supported by libMapRClient for hadoop-2.x

Set the working directory. All relative paths will be resolved relative to it.

For example, if you call this API to set the working directory to `/mycluster/myvolume` and subsequently call `hdfsOpenFile()` with the path `/temp/tmp.txt`, the full path to the file to open is assumed to be `/mycluster/myvolume/temp/tmp.txt`.

Signature

```
int hdfsSetWorkingDirectory(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The handle of the file system where the directory is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path of the new working directory.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL for invalid arguments.

hdfsSetXattr()

Supported by libMapRClient for hadoop-2.x

Sets extended attribute on a file.

Signature

```
int hdfsSetXattr(hdfsFS fs, const char* path, const char *name, int
nameLen, char *value, int valueLen);
```

Parameters

Parameter	Description
`fs`	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
`name`	The name of the extended attribute.
`nameLen`	The length of the name of the extended attribute.
`path`	The path to the file.
`value`	The value for the extended attribute.
`valueLen`	The length of the value of the extended attribute.

Return Value

Returns `0` on success, `-1` on error.

Check `errno` for error codes and meanings.

hdfsTell()

Supported by libMapRClient for hadoop-2.x

Gets the current offset in the file in bytes.

Signature

```
tOffset hdfsTell(hdfsFS fs, hdfsFile file)
```

last-updated: Jun 06, 2024

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The file handle. Obtain this handle with one of the `hdfsOpenFile()` APIs.

Return Value

Returns the current offset in bytes, or -1 on error.

Check errno for error codes and meanings.

hdfsUtime()
Changes the access and modification times of a file or directory.

Supported by libMapRClient for hadoop-2.x

Signature

```
int hdfsUtime(hdfsFS fs, const char* path, tTime mtime, tTime atime)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file or directory is located. Obtain this handle with one of the `hdfsConnect()` APIs.
path	The path to the file or directory.
mtime	The new modification time or 0 (if you want to set only the access time) in seconds.
atime	The new access time or 0 (if you want to set only the modification time) in seconds. For more information, see the `atimeUpdateTimeInterval` entry in volume create on page 2588.

Return Value

Returns 0 on success, -1 on error.

errno is set to EINVAL if the input arguments are invalid.

errno is set to EPERM if the process does not have enough privileges to perform the operation.

hdfsWrite()

Supported by libMapRClient for hadoop-2.x

Writes to the specified open file.

If the file is opened in write-only mode, writes start at offset 0 because write-only mode causes the content of the file to be truncated when the file is opened.

If the file is opened in append mode, data is appended to the end of the file.

If there are concurrent writes that start at the same offset, only the last write to finish persists.

last-updated: Jun 06, 2024

If a call to `hdfsSeek()` moves the offset past the end of the file before a call to `hdfsWrite()`, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

On error, pending write buffers are flushed to the server.

Signature

```
tsize hdfsWrite(hdfsFS fs, hdfsFile file, const void* buffer, tSize length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the `hdfsConnect()` APIs.
file	The handle of the file. Obtain this handle with one of the `hdfsOpenFile()` APIs.
buffer	The buffer containing the data to be written.
length	The number of bytes to write. This value cannot be zero. The maximum length of the buffer is the maximum size of the `tSize` data type.

Return Value

Returns the number of bytes written, -1 on error.

Check errno for error codes and meanings.

Accessing HPE Ezmeral Data Fabric File Store in Java Applications

As a high-performance file system, portions of the HPE Ezmeral Data Fabric File Store file client are based on a native maprfs library. When developing an application, specifying dependence on the JAR file that includes the maprfs library enables you to build applications without having to manage platform-specific dependencies.

The following sections describe how to access the HPE Ezmeral Data Fabric File Store in a Java program.

Writing a Java Application

In your Java application, you will use a Configuration object to interface with the file system. When you instantiate a Configuration object, it is created with values from Hadoop configuration files.

If the program is built with JAR files from the Data Fabric installation, the Hadoop 1 configuration files are in the `$MAPR_HOME/hadoop/hadoop-<version>/conf` directory, and the Hadoop 2 configuration files are in the `$HADOOP_HOME/etc/hadoop` directory. This Hadoop configuration directory is in the hadoop classpath that you include when you compile and run the Java program.

If the program is built through maven using mapr maven artifacts, the default Hadoop configuration files are included in the maven artifacts. The user needs to programmatically update the Hadoop configuration to match the Hadoop configuration files on the Data Fabric cluster.

last-updated: Jun 06, 2024

Sample Code

The following sample code shows how to interface with MapR file system using Java. The example creates a directory, writes a file, then reads the contents of the file.

```
/* Copyright (c) 2009 & onwards. MapR
Tech, Inc., All rights reserved */

//package com.mapr.fs;

import java.net.*;
import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;

/**
* Assumes mapr installed in /opt/mapr
*
* Compilation:
* javac -cp $(hadoop classpath)
MapRTest.java
*
* Run:
* java -cp .:$(hadoop classpath)
MapRTest /test
*/
public class MapRTest
{
 public static void main(String
args[]) throws Exception {
        byte buf[] = new
byte[ 65*1024];
        int ac = 0;
        if (args.length != 1) {

System.out.println("usage: MapRTest
pathname");
        return;
        }

        // maprfs:/// -> uses
the first entry in /opt/mapr/conf/
mapr-clusters.conf
        // maprfs:///mapr/
my.cluster.com/
        // /mapr/my.cluster.com/

        // String uri = "maprfs:///";
        String dirname = args[ac++];

        Configuration conf = new
Configuration();

        //FileSystem fs =
FileSystem.get(URI.create(uri),
conf); // if wanting to use a
different cluster
        FileSystem fs =
FileSystem.get(conf);

        Path dirpath = new
Path( dirname + "/dir");
        Path wfilepath = new
```

last-updated: Jun 06, 2024

```
Path( dirname + "/file.w");
        //Path rfilepath = new
Path( dirname + "/file.r");
        Path rfilepath = wfilepath;

        // try mkdir
        boolean res =
fs.mkdirs( dirpath);
        if (!res) {

System.out.println("mkdir failed,
path: " + dirpath);
        return;
        }

        System.out.println( "mkdir( "
+ dirpath + ") went ok, now writing
file");

        // create wfile
        FSDataOutputStream ostr =
fs.create( wfilepath,
                true, // overwrite
                512, // buffersize
                (short) 1, //
replication
                (long)
(64*1024*1024) // chunksize
                );
        ostr.write(buf);
        ostr.close();

        System.out.println( "write( "
+ wfilepath + ") went ok");

        // read rfile
        System.out.println( "reading
file: " + rfilepath);
        FSDataInputStream istr =
fs.open( rfilepath);
        int bb = istr.readInt();
        istr.close();
        System.out.println( "Read
ok");
        }
}
```

Compiling and Running a Java Application

You can compile and run the Java application using JAR files from the mapr maven repository or from the Data Fabric installation.

Using JARs from the Maven Repository

Maven artifacts from version 2.1.2 onward are published to https://repository.mapr.com/maven/. When compiling for Data Fabric core version 6.1, add the following dependency to the `pom.xml` file for your project:

```
<dependency>
   <groupId>org.apache.hadoop</
```

```
groupId>
  <artifactId>hadoop-common</
artifactId>
  <version>2.7.0-mapr-1808</version>
</dependency>
```

This dependency adds the dependencies from the mapr maven repository the next time you do a `mvn clean install`. The JAR that includes the `maprfs` library is a dependency for the `hadoop-common` artifact.

For a complete list of artifacts and further details, see Maven Artifacts for the HPE Ezmeral Data Fabric on page 4745.

Using JARs from the Data Fabric Installation

The `maprfs` library is included in the hadoop classpath. Add the hadoop classpath to the JAVA classpath when you compile and run the Java application.

- To compile the sample code, use the following command:

```
javac -cp $(hadoop classpath)
MapRTest.java
```

- To run the sample code, use the following command:

```
java -cp .:$(hadoop classpath)
MapRTest /test
```

Loading the Data Fabric Native Library

By default, the root class loader will load the native library to allow all children to see and access it. If the native library is loaded by a child class, other classes will not be able to access the library. To allow applications and associated child classes to access the symbols and variables in the native library, we recommend loading the native library via the root loader.

The loading of the native library via the root class loader is accomplished by injecting code into the root loader. If Data Fabric runs on top of applications (such as Tomcat) where it does not have access to the root class loader, the native library will not be loaded. Child classes that try to access the symbols under the assumption that the root class loader successfully loaded the native library will fail.

The parameter `-Dmapr.library.flatclass`, when specified with Java, disables the injection of code via the root class loader, thus disabling the loading of the native library using the root class loader. Instead, the application trying to access the symbols can load the native library themselves. However, since the native library can be loaded only once and can only be seen by the application loading it, ensure that only one application within the JVM attempts to load and access the native library.

Garbage Collection in Data Fabric

The garbage collection (GC) algorithms in Java provide opportunities for performance optimizations for your application. Java provides the following GC algorithms:

- *Serial* GC. This algorithm is typically used in client-style applications that don't require low pause times. Specify `-XX:+UseSerialGC` to use this algorithm.

last-updated: Jun 06, 2024

- *Parallel* GC, which is optimized to maximize throughput. Specify `-XX:+UseParNewGC` to use this algorithm.
- *Mostly-Concurrent* or *Concurrent Mark-Sweep* GC, which is optimized to minimize latency. Specify `-XX:+UseConcMarkSweepGC` to use this algorithm.
- *Garbage First* GC, a new GC algorithm intended to replace Concurrent Mark-Sweep GC. Specify `-XX:+UseG1GC` to use this algorithm.

Consider testing your application with different GC algorithms to determine their effects on performance.

Flags for GC Debugging

Set the following flags in Java to log the GC algorithm's behavior for later analysis:

```
-verbose:gc
-Xloggc:<filename>
-XX:+PrintGCDetails
-XX:+PrintGCDateStamps
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
```

For more information, see the Java Garbage Collection Tuning document or the Java Garbage Collection links.

Converting fid and volid

The following file system APIs are available in `com.mapr.fs.MapRFileSystem` for converting fid to file path and volid to volume name:

- `public String getMountPathFidCached(String fidStr) throws IOException`
- `public String getVolumeNameCached(int volId) throws IOException`
- `public String getVolumeName(int volId) throws IOException`
- `public String getMountPathFid(String fidStr) throws IOException`

Converting fid to File Path

The `getMountPathFid(string)` and `getMountPathFidCached(string)` APIs can be used for converting file ID to the full path to the file. The `getMountPathFid()` API makes a call to CLDB and file system to get the file path from the fid. Because this API does not cache or store this information locally, it might make repeated requests to CLDB and file system for the same fid and this might result in many RPCs to both CLDB and file system. The `getMountPathFidCached()` API makes a call the CLDB and file system one time and stores the information locally in the shared library of the client. For subsequent calls, it uses the locally stored information to retrieve the file path from the fid. However, if there are many files in the volume, there might still be a large number of calls to CLDB and file system to determine the file path for each fid in the volume. The caching is useful if the API attempts to determine the file path for the same fid repeatedly. The cache is purged after 15 seconds. If the file name changes before the cache is purged, you will see the old name for the file until the cache expires. You can use these APIs to convert the fid to the file path.

last-updated: Jun 06, 2024

For example, the sample consumer application and the sample uncached consumer application for consuming audit logs as stream messages use these methods as shown below.

- **Sample Cached Consumer**

```
{
     String token =
st1.nextToken();
     /* If the field has fid,
expand it using Cached API */
     if (token.endsWith("Fid")) {
       String lfidStr =
st1.nextToken();
       String path= null;
       try {
           path =
fs.getMountPathFidCached(lfidStr);
// Expand FID to path
       } catch (IOException e){
     }
     lfidPath =
"\"FidPath\":\""+path+"\",";
     // System.out.println("\nPAth
for fid " + lfidStr +  "is " +
path);
}
```

- **Sample Uncached Consumer**

```
{
     String token =
st1.nextToken();
     if (token.endsWith("Fid")) {
         String lfidStr =
st1.nextToken();
         String path= null;
         try {
           path =
fs.getMountPathFid(lfidStr);//
Expand FID to path
         } catch (IOException e){
         }
     lfidPath =
"\"FidPath\":\""+path+"\",";
     // System.out.println("\nPAth
for fid " + lfidStr +  "is " +
path);
}
```

Converting volid to Volume Name

The `getVolumeName()` and `getVolumeNameCached()` APIs can be used for converting volume IDs to volume name. The `getVolumeName()` API makes a call to the CLDB every time to get the volume name from the volid and this may result in too many RPCs to CLDB. The `getVolumeNameCached()` API makes a call to the CLDB one time and stores the information locally in the shared library of the client. For subsequent calls, it uses the locally stored information to retrieve the

last-updated: Jun 06, 2024

volume name from the volid. The cache is purged after 15 seconds. You can use these APIs to convert the volid to volume name.

For example, the sample consumer application and the sample uncached consumer application for consuming audit logs as stream messages uses these methods as shown below.

- **Sample Cached Consumer**

```
if (token.endsWith("volumeId")) {
       String volid =
st1.nextToken();
       String name= null;
       try {
         int volumeId =
Integer.parseInt(volid);
           // Cached API to
convert volume Id to volume Name
           name =
fs.getVolumeNameCached(volumeId);
         }
       catch (IOException e){
       }
       lvolName =
"\"VolumeName\":\""+name+"\",";
       //
System.out.println("\nVolume Name
for volid " + volid +  "is " +
name);
}
```

- **Sample Uncached Consumer**

```
if (token.endsWith("volumeId")) {
       String volid =
st1.nextToken();
       String name= null;
       try {
         int volumeId =
Integer.parseInt(volid);
           // API to convert
volume Id to volume Name
           name =
fs.getVolumeName(volumeId);
         }
       catch (IOException e){
       }
       lvolName =
"\"VolumeName\":\""+name+"\",";
       //
System.out.println("\nVolume Name
for volid " + volid +  "is " +
name);
}
```

Sample Applications
Demonstrates how to set ACEs using the Java APIs.

Sample Application

The sample application demonstrates how to set, get, modify, and delete ACES on files using the Java APIs.

Before running this application, verify that you have access to a cluster running file system. To build and run this application:

1. Set the classpath:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the java file:

```
javac FileAceTest.java
```

3. Run the final `FileAceTest.class` file.

The application imports the following libraries:

- `java.io.*`
- `java.net.*`
- `java.util.*`

The application performs the actions described in the following sections.

Connects to a file system

The application tries to connect to the first file system cluster that is specified in the `mapr-clusters.conf` file in the `$MAPR_HOME/conf` directory on the client. After connecting to the file system, the application returns a handle to the file system.

```
Configuration conf = new
Configuration();
FileSystem fs = FileSystem.get(conf);
//MapRFileSystem fs =
getMapRFileSystem();
```

Creates a new directory and a new file in the directory

The application creates a new directory and a file in the directory.

```
Path testDir = new Path(rootDir +
"FileAceTest");
mkDir(fs, testDir);

Path testFile = new Path(testDir + "/
testFile");
createFile(fs, testFile);
```

Sets ACEs on the new directory and the file

The application then sets ACEs to grant m7user1 user or the root user permissions to list the contents of the directory, which is required for the user to write and/or execute files in the directory. In addition, the

last-updated: Jun 06, 2024

application sets ACEs on the file in the directory to grant the m7user1 user read access on the file.

```
MapRFileAce ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DFILE);
ace.setBooleanExpression("u:m7user1");
aces.add(ace);
ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DDIR);
ace.setBooleanExpression("u:m7user1|
u:root");
aces.add(ace);
((MapRFileSystem)fs).setAces(testDir,
aces);
((MapRFileSystem)fs).setAces(testFile,
 aces);
```

Verifies the ACEs set on the directory and file

The application then prints the ACEs set on the directory and file.

```
List<MapRFileAce> newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
for (int i = 0; i <
newDirAces.size(); ++i) {

System.out.println(newDirAces.get(i).g
etAccessType() + ": " +

newDirAces.get(i).getBooleanExpressio
n());
}

List<MapRFileAce> newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
for (int i = 0; i <
newFileAces.size(); ++i) {

System.out.println(newFileAces.get(i).
getAccessType() + ": " +

newFileAces.get(i).getBooleanExpressio
n());
}
```

Modifies the ACEs on the directory and file

The application modifies the ACEs on the directory to grant m7user2 user also permissions to list the contents of the directory, which is required for the users to write and/or execute files in the directory. It also modifies the ACEs on the file to grant write access on the file to m7user2 user. Please note that when modifying ACEs on the file to grant write access

to m7user2 user, the application does not change read access, which was granted to m7user1 user.

```
aces = new ArrayList<MapRFileAce>();
ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DDIR);
ace.setBooleanExpression("u:m7user1|
u:root|u:m7user2");
aces.add(ace);
ace = new
MapRFileAce(MapRFileAce.AccessType.WRI
TEFILE);
ace.setBooleanExpression("u:m7user2");
aces.add(ace);
((MapRFileSystem)fs).modifyAces(testDi
r, aces);
((MapRFileSystem)fs).modifyAces(testFi
le, aces);
```

Verifies the changes to ACEs on the directory and file

The application prints the changes in ACEs on the directory and the file.

```
newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
for (int i = 0; i <
newDirAces.size(); ++i) {

System.out.println(newDirAces.get(i).g
etAccessType() + ": " +

newDirAces.get(i).getBooleanExpressio
n());
}

newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
for (int i = 0; i <
newFileAces.size(); ++i) {

System.out.println(newFileAces.get(i).
getAccessType() + ": " +

newFileAces.get(i).getBooleanExpressio
n());
}
```

Deletes ACEs on directory and file

The application deletes all ACEs on the directory and the file.

```
((MapRFileSystem)fs).deleteAces(testDi
r);
((MapRFileSystem)fs).deleteAces(testFi
le);
```

Verifies the ACEs on the directory and the file	The application prints the ACEs on the directory and the file after they are deleted.

```
newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
if (newDirAces == null ||
newDirAces.size() == 0)
  System.out.println("AceCount: 0");
else
  System.out.println("AceCount: " +
newDirAces.size());
System.out.println("");
newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
if (newFileAces == null ||
newFileAces.size() == 0)
  System.out.println("AceCount: 0");
else
  System.out.println("AceCount: " +
newFileAces.size());
```

Example FileAceTest.java File

```
import java.io.*;
import java.net.*;
import java.util.*;

import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;

import com.mapr.fs.MapRFileAce;
import com.mapr.fs.MapRFileSystem;

public class FileAceTest {
  public FileSystem fs = null;

  public static void mkDir(FileSystem fs, Path path) throws IOException {
    boolean res = fs.mkdirs(path);
    if (!res) {
      throw new IOException("mkdir failed, path: " + path);
    }
  }

  public static void createFile(FileSystem fs, Path path) throws Exception {
    byte buf[] = new byte[1024];

    FSDataOutputStream ostr = fs.create(path,
                                        true, // overwrite
                                        512, // buffersize
                                        (short) 1, // replication
                                        (long)(64*1024*1024) // chunksize
                                       );
    ostr.write(buf);
    ostr.close();
  }
```

```
  public static void rmR(FileSystem fs, Path path) throws IOException {
    boolean res = fs.delete(path, true /*recursive*/);
    if (!res) {
      throw new IOException("rmR failed, path: " + path);
    }
  }

  public static void main(String args[]) throws Exception {
    String rootDir = "maprfs:///";

    Configuration conf = new Configuration();
    FileSystem fs = FileSystem.get(conf);

    Path testDir = new Path(rootDir + "FileAceTest");

    System.out.println("Path: " + testFile);
    for (int i = 0; i < newFileAces.size(); ++i) {
      System.out.println(newFileAces.get(i).getAccessType() + ": " +
                         newFileAces.get(i).getBooleanExpression());
    }

    // Remove path
    rmR(fs, testDir);
  }
}
```

Troubleshooting

My application that includes maprfs-0.1.jar is now missing dependencies and fails to link.

As of version 2.1.2 , the contents of `maprfs-0.1.jar` are now in two JAR files:

- `maprfs-<version>.jar`

- `maprfs-jni-<version>.jar`

The `<version>` refers to the version of the distribution. For example, if you have an existing application written for `maprfs-0.1.jar` and you update it to load `maprfs-2.1.2.jar`, you must also include `maprfs-jni-2.1.2.jar`. This change was made to enable loading on distributed class-loader environments that use the `maprfs` libraries to access the filesystem from multiple contexts.

These JAR files are installed in the `/opt/mapr/hadoop/hadoop<version>/lib/` directory, or can be accessed via the Maven Central Repository.

HPE Ezmeral Data Fabric Database and Apps

This section contains information about developing client applications for JSON and key-value tables.

Why use HPE Ezmeral Data Fabric Database?

From a developer's point-of-view, HPE Ezmeral Data Fabric Database provides the following capabilities:

- **Extreme scale for CRUD operations**: Enabled by the integration of HPE Ezmeral Data Fabric Database with the HPE Ezmeral Data Fabric Filesystem, CRUD operations are extremely fast and efficient.
- **Flexible data model**: HPE Ezmeral Data Fabric Database can be used as both a document database and a column-oriented database. So if the content structure changes, the applications do not need to be re-written.
- **Rich query**: Integration with Apache Drill on page 3920 for HPE Ezmeral Data Fabric Database provides a low-latency distributed query engine for large-scale datasets, including structured and semi-structured/nested data.
- **Integration with Apache Spark**: HPE Ezmeral Data Fabric Database provides HPE Ezmeral Data Fabric Database Connectors for Apache Spark on page 4633 that allow you to access HPE Ezmeral Data Fabric Database tables through Spark applications.
- **Strong data consistency**: Consistently fast response with strong data consistency with row/document level ACID transactions and in-memory database options for faster speeds.

HPE Ezmeral Data Fabric Database JSON provides additional benefits:

- **High performance via Secondary Indexes on page 682**: No memory copying. No need to retrieve the full document to make updates due the log-based database architecture. No application changes needed to leverage secondary indexes for efficient query execution.
- **Easy application development**: JSON constructs such as maps, arrays, and data types are supported natively.
- **Language-specific client APIs:** Java, Python, and Node.js client APIs

NOTE: HPE Ezmeral Data Fabric has a universal namespace which means that the same namespace is used for files, tables, and streams. A universal namespace streamlines application development for different operations.

How Do I Get Started with HPE Ezmeral Data Fabric Database JSON?

The following diagram illustrates an end-to-end flow associated with getting started with HPE Ezmeral Data Fabric Database JSON.

NOTE: *This flow is not the only way to get started!*

You can also run through end-to-end examples using preconfigured, single node HPE Ezmeral Data Fabric clusters. The following table describes an option:

Container for Developers	Development Environment for HPE Ezmeral Data Fabric on page 71 is a Docker container that runs a single node cluster. Using HPE Ezmeral Data Fabric Database JSON: Getting Started, you can do the following: • Set up the Docker container • Import data into HPE Ezmeral Data Fabric Database JSON tables • Use HPE Ezmeral Data Fabric Database Shell to query, insert, and update JSON documents in HPE Ezmeral Data Fabric Database JSON tables • Use Drill to query HPE Ezmeral Data Fabric Database JSON tables • Run sample Java OJAI applications • Run a sample Spark application using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark

	HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark on page 4684	

Installing the mapr-client Package

The `mapr-client` package must be installed on each node where you will be building and running your applications. This package installs all of the MapR Libraries needed for application development regardless of programming language or type of HPE Ezmeral Data Fabric Database table (binary or JSON).

About this task

NOTE: The `mapr-core` package contains the files that are in the `mapr-client` package. If you have installed the `mapr-core` package, you do not need to install the `mapr-client` package.

Complete the following steps to install the `mapr-client` package from a repository:

Procedure

1. Configure the repository to point to `https://package.ezmeral.hpe.com/releases/<release version>/<operating system>`

   For example, if your VM has a CentOS operating system, edit the **/etc/yum.repos.d/mapr_core.repo** file to add the location.

2. Based on your operating system, run one of the following commands to install the package:
   - On RHEL/Centos: `yum install mapr-client`
   - On Ubuntu: `apt-get install mapr-client`
   - On SLES: `zypper install mapr-client`

last-updated: Jun 06, 2024

Passing the HPE Ezmeral Data Fabric Database Table Path

This topic describes the methods for passing a HPE Ezmeral Data Fabric Database table name. Binary table names can be passed by either specifying the table path in the API or by setting the table path in the **core-site.xml** file. JSON table names are passed by specifying the table path in the API.

Specifying the Table Path in the API

With this method, you provide the complete path to the table using the following format: `/mapr/<cluster>/<volume>/<table>`

NOTE: This format is independent of the programming language. This method is used for both HPE Ezmeral Data Fabric Database binary and JSON tables.

For example, if you were adding a new column family to a table and you had the following information:

- Cluster name: `newyork`
- Volume name: `vol1`
- Table name: `table1`

The table path would be `/mapr/newyork/vol1/table1`

Specifying the Table Path in the core-site.xml File

With this method, you specify the table path with `hbase.table.namespace.mappings` property in the **/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/core-site.xml** file.

NOTE: This method is specific to HPE Ezmeral Data Fabric Database binary tables only. This method is independent of the programming language.

In the following example, all tables that you create and access via the API, will be in the `/tables_dir1` directory. If you specified the table name `table1` in the API, the full path to the table would be `/tables_dir1/table1`.

```
<property>
   <name>hbase.table.namespace.mappings</name>
   <value>*:/tables_dir1</value>
</property>
```

Tuning Parameters for Client Apps

Though tuning client applications is generally not necessary, MapR does offer tuning parameters to change the behavior of client-side caching.

Client application cache pending puts in buffers that are unique to each tablet (*region*, in HBase terminology). Individual put buffers are flushed when they are full or idle. As a result of this architecture and behavior, client applications tend to send RPCs of 128KB when flushing puts to disk, which results in better performance than flushing a single global buffer would, as that could result in a large number of small RPCs.

You can change the values of parameters that affect how put buffers are flushed. Set values for them in the `hbase-site.xml` file or `core-site.xml` file in your MapR installation. If a non-default value for a parameter is set in both files, the value in the `hbase-site.xml` file is used.

db.mapr.putbuffer.threshold.mb	Specifies the size of the cumulative put buffer for all tablets in the client application. When this threshold is reached, the put buffer that is most full is flushed to its tablet.

last-updated: Jun 06, 2024

	The default value is 32MB. Increasing this value can improve performance when an application performs operations on very large tables or on a very large number of tables.
db.mapr.putbuffer.threshold.sec	Specifies the number of seconds that HPE Ezmeral Data Fabric Database should wait before flushing an idle put buffer. The default value is 3. This parameter has no effect if automatic flushing is enabled.
fs.mapr.tabletlru.size.kb	Specifies the size of the metadata cache for all tables in a client application.. The metadata for each tablet is 128 bytes. The default value of this parameter is 512KB, which allows for the caching of the metadata of 4,096 tablets. When this metadata cache is full, any operation on a tablet for which the metadata is not cached requires an RPC to fetch that tablet's metadata. Moreover, caching the newly retrieved metadata removes from the cache the metadata of a different tablet. Increasing this value can improve performance when an application performs operations on very large tables or on a very large number of tables.
fs.mapr.threads	Specifies the number of threads to use when flushing put buffers. Each thread makes synchronous RPCs when flushing. The default value is 64.

Developing Applications for Binary Tables

HPE Ezmeral Data Fabric Database provides a C API, `libMapRClient` and partially supports the Apache HBase 1.1 Java APIs for performing operation on HPE Ezmeral Data Fabric Database binary tables.

The HPE Ezmeral Data Fabric Database C API, `libMapRClient`, runs more efficiently on HPE Ezmeral Data Fabric Database and performs faster against HPE Ezmeral Data Fabric Database tables than the open source library of C APIs, `libhbase`, that is used to create and access Apache HBase tables. The `libMapRClient` header files are in this directory: **/opt/mapr/include/hbase**

HPE Ezmeral Data Fabric Database also supports all of the Apache HBase 1.1 Java APIs, except where noted in this documentation. For a number of critical Java APIs, for filters, and for comparators, this documentation explicitly lists what is supported, rather than what is not supported.

You can easily port existing applications that use the open-source version of `libhbase` or the HBase Java APIs to use HPE Ezmeral Data Fabric Database binary tables.

Current Limitations

- Custom HBase filters are not supported.
- HBase co-processors are not supported.

NOTE: Filters used with Scan operations support regular expressions. When you filter scans on HPE Ezmeral Data Fabric Database tables, you can use regular expressions that comprise the Perl Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in java.util.regex.pattern. See HBase Java Regular Expressions Support on page 3292 for a list of supported regular expressions.

Creating C Apps - Binary Tables

MapR provides a library of C APIs – `libMapRClient` – for performing operations on HPE Ezmeral Data Fabric Database binary tables.

The HPE Ezmeral Data Fabric Database `libMapRClient` C API library is MapR's extension of the `libhbase` C API library. The `libMapRClient` header files are in this directory: **/opt/mapr/include/hbase**

`libMapRClient` uses the following conventions:

- All data types are prefixed with 'hb_'.
- All exported functions are annotated with HBASE_API, prefixed with 'hb_' and named using the following convention: `'hb_<subject>_<operation>_[<object>|<property>]'`
- All asynchronous APIs take a callback which is triggered when a request completes. This callback can be triggered in the caller's thread or in another thread. To avoid any potential deadlock or starvation, applications should not block in the callback routine.
- All callbacks take a void pointer for application developers to supply their own data. This void pointer is passed when callback is triggered.

NOTE: No explicit batching is supported for asynchronous APIs.

WARNING: It is the responsibility of applications to free up all backing data buffers. However, for asynchronous APIs, applications must wait before freeing buffers until after receiving callbacks or manipulating results. For better performance of asynchronous APIs, `libMapRClient` does not copy data buffers that are allocated for mutations, gets, and scans. These buffers hold table names, name space identifiers, row keys, column-family names, and column names or qualifiers. Instead, libMaprClient temporarily takes ownership of the buffers and references them with pointers until the callback is triggered. Therefore, applications should not free memory buffers before receiving callbacks for mutations. Applications also should not free memory buffers before receiving results for gets and scans. If applications must read results, the applications should not free memory buffers until the results are destroyed.

last-updated: Jun 06, 2024

NOTE: When one of these asynchronous APIs is invoked, a work item is created and queued for processing on the client:

- `hb_client_destroy()`
- `hb_get_send()`
- `hb_mutation_send()`
- `hb_scanner_destroy()`
- `hb_scanner_next()`

The work item is picked up as soon as possible by a thread in a thread pool.

Client applications can often call these asynchronous APIs faster than the work items are processed. To ensure that the queue of work items does not grow without bound, the configuration parameter `fs.mapr.pool.queue.max_size` is set by default to 10,000. You can modify this parameter in the `/opt/mapr/conf/dbclient.conf` file for a client.

Whenever the number of work items in the queue reaches this limit, `libMapRClient` returns the `ENOBUFS` error for each asynchronous call. Client applications are expected to handle this error, and can try the call again later.

libMapRClient C APIs

This section provides the HPE Ezmeral Data Fabric Database `libMapRClient` C API library. This library is MapR's extension of the `libhbase` C API library. The `libMapRClient` header files are in the directory: **/opt/mapr/include/hbase**.

The `libMapRClient` API implements functions in addition to the functions in the `libhbase` API.

NOTE: Your applications need include only the `hbase.h` header file. The header files are provided for display purposes.

admin.h	Describes the APIs for Apache HBase table administration operations such as creating and enabling tables, checking if tables exist, and deleting tables, to name a few .
client.h	Describes the APIs for Apache HBase client side operations such as creating and terminating client connections, and flushing buffered client-side writes to Apache HBase.
coldesc.h	Describes the APIs for performing operations such as creation, deletion, and setting the maximum and minimum number of cell versions to be retained for each Apache HBase column family.
connection.h	`libMapRClient` includes a function in the `connection.h` header file: `hb_connection_create_as_user()`. This function provides support for impersonation, so that you can connect to a HPE Ezmeral Data Fabric cluster and access HPE Ezmeral Data Fabric Database tables by using a specific username. The user that is passed with the `hb_connection_create_as_user()` API must have permissions on the tables that the application accesses. For example, to read from a table, the user must have the `readperm` permission. To write to a

last-updated: Jun 06, 2024

	table, the user must have the `writeperm` permission. See Enabling Table and Stream Authorizations with ACEs on page 1363. For `hb_connection_create()` and `hb_connection_create_as_user()`, the standard C APIs for Apache HBase require a list of ZooKeeper nodes. For HPE Ezmeral Data Fabric Database, this list is interpreted as a list of CLDB nodes. The `zk_root` parameter is ignored. If `zk_quorum` is NULL, then the connection is created to the default cluster that is listed in the `mapr-clusters.conf` file.
get.h	Describes the APIs to query and fetch data from Apache HBase tables.
hbase.h	Describes the APIs and data structures of a C client for Apache HBase.
log.h	Describes the APIs to manage Apache HBase logs.
macros.h	Defines internal macros that Apache HBase uses for its operations.
multiget.h	Describes the APIs to queue and manage multiple GET requests to fetch data from Apache HBase tables.
mutations.h	Describes the APIs for row and column mutations on Apache HBase tables.
result.h	Describes the buffers for internal temporary storage of results.
scanner.h	Describes the APIs for the client side scanner to scan and request rows from the Apache HBase server.
types.h	Defines the data types and error codes that Apache HBase uses.

C API Examples

This section provides examples using the HPE Ezmeral Data Fabric Database `libMapRClient` C API to operate on HPE Ezmeral Data Fabric Database binary tables.

The HPE Ezmeral Data Fabric Database `libMapRClient` C API library is MapR's extension of the `libhbase` C API library. The libMapRClient header files are in this directory: `/opt/mapr/include/hbase`

Filtering SCAN Operation Results Example

This example shows filtering on the results of a SCAN operation.

```
for (uint32_t i = 0; i < num_filters; ++i) {
    hb_scanner_t scanner = NULL;
    hb_scanner_create(client, &scanner);
    hb_scanner_set_table(scanner, table_name, table_name_len);
    hb_scanner_set_num_max_rows(scanner, 3);  // maximum 3 rows at a time
    hb_scanner_set_num_versions(scanner, 10); // up to 10 versions of the
cell
    hb_scanner_set_filter(scanner, (byte_t *)filters[i],
strlen(filters[i]));
    hb_scanner_next(scanner, scan_callback, NULL); // dispatch the call
```

```
    wait_for_scan();
 }
```

This example uses the following array of filters:

```
static char filters[][200] = {"RandomRowFilter(0.5)",
       "ColumnCountGetFilter(2)",
       "ColumnPaginationFilter(1)",
       "ColumnPrefixFilter('column-a')",
       "FamilyFilter(=,'binaryprefix:f')",
       "PrefixFilter('row_') AND QualifierFilter(<,'binaryprefix:g')",
       "SKIP TimestampsFilter(1392222222222)",
       "WHILE ValueFilter(=,'binaryprefix:cell2_value_v1')",
       "FuzzyRowFilter('row00','00001')",
       "TimestampsFilter(1430937732000,1431024132000)"};
       }
```

NOTE: For more information about suppport for HBase Java Filters by the HPE Ezmeral Data Fabric Database C API, see HBase Java Filters Support on page 3258

Filtering GET Operation Results Example
This example shows filtering on the results of a GET operation.

```
{
    bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
    hb_get_t get = NULL;
    hb_get_create(rowKey->buffer, rowKey->length, &get);
    hb_get_add_column(get, FAMILIES[0], 1, NULL, 0);
    hb_get_add_column(get, FAMILIES[1], 1, NULL, 0);
    hb_get_set_table(get, table_name, table_name_len);
    hb_get_set_num_versions(get, 10); // up to ten versions of each column
    hb_get_set_filter(get, (byte_t *)filters[9], strlen(filters[9]));
    get_done = false;
    hb_get_send(client, get, get_callback, rowKey);
    wait_for_get();
 }
```

This example uses the following array of filters:

```
static char filters[][200] = {"RandomRowFilter(0.5)",
       "ColumnCountGetFilter(2)",
       "ColumnPaginationFilter(1)",
       "ColumnPrefixFilter('column-a')",
       "FamilyFilter(=,'binaryprefix:f')",
       "PrefixFilter('row_') AND QualifierFilter(<,'binaryprefix:g')",
       "SKIP TimestampsFilter(1392222222222)",
       "WHILE ValueFilter(=,'binaryprefix:cell2_value_v1')",
       "FuzzyRowFilter('row00','00001')",
       "TimestampsFilter(1430937732000,1431024132000)"};
       }
```

NOTE: For more information about suppport for HBase Java Filters by the HPE Ezmeral Data Fabric Database C API, see HBase Java Filters Support on page 3258

Impersonation Example
This sample application demonstrates the capabilities of the new C API for impersonation.

The sample also shows how to use the API in your own programs. The application is located in the `/opt/mapr/examples/interactive` directory.

Prerequisite for compiling and running this sample application

Install the `mapr-client` package on the node where you will build the application. See Installing the Data Fabric Client (Non-FIPS) on page 404. If the `mapr-core` package is already installed, you do not need to install the `mapr-client` package.

Compiling this sample application

To compile and run this sample application, set the `MAPR_IMPERSONATION_ENABLED` environment variable to `true` and then read the instructions in the `README` file in the `/opt/mapr/examples/interactive` directory.

Though the application links against `libjvm`, a Java virtual machine (JVM) is not spawned. However, the `libMapRClient` does have Java dependencies.

Set Time Range Example
This example scans HPE Ezmeral Data Fabric Database binary tables and sets the time range.

```
int32_t scanWithTimeranges( std::string table_name, int32_t num_versions,
uint64_t max_num_rows, std::string start_row_key,
                std::string end_row_key, int64_t min_ts, int64_t max_ts,
std::string name_space, std::string column_name) {
        hb_scanner_t scanner = NULL;
        int32_t retCode;

        scan_num_rows = 0;
        scan_cell_count = 0;
        scan_done = false;
        // scanner object create
        hb_scanner_create(client, &scanner);

        scan_data_t *scan_data = (scan_data_t *) calloc(1,
sizeof(scan_data_t));

        // set the table to scan
        scan_data->table_name_ = bytebuffer_printf("%s",
table_name.c_str());
        hb_scanner_set_table(scanner, (char *)
scan_data->table_name_->buffer, scan_data->table_name_->length));

        // start and end row - optional
        scan_data->start_row_key_ = bytebuffer_printf("%s",
start_row_key.c_str());
        hb_scanner_set_start_row(scanner, scan_data->start_row_key_->buffer,
                        scan_data->start_row_key_->length);

        scan_data->end_row_key_ = bytebuffer_printf("%s",
end_row_key.c_str());
        hb_scanner_set_end_row(scanner, scan_data->end_row_key_->buffer,
                        scan_data->end_row_key_->length);

        // add columns
        bytebuffer cfName   = bytebuffer_printf("%s",
data_qualifier[0].c_str());
        bytebuffer columnName   = bytebuffer_printf("%s",
data_qualifier[1].c_str());
        retCode=hb_scanner_add_column(scanner,(byte_t
*)cfName->buffer,cfName->length,columnName->buffer,columnName->length);

        // set versions
        hb_scanner_set_num_versions(scanner, num_versions);

        // set timerange
```

```
        hb_scanner_set_timerange(scanner, min_ts, max_ts);

        // scan data
        retCode = hb_scanner_next(scanner, scan_callback, scan_data);
        return retCode;
}
```

Set Time Stamp Example

This example scans HPE Ezmeral Data Fabric Database binary tables and sets the time stamp.

```
int32_t scanWithTimestamp( std::string table_name, int32_t num_versions,
uint64_t max_num_rows, std::string start_row_key,
                std::string end_row_key, int64_t ts, std::string
name_space, std::string column_name) {
        hb_scanner_t scanner = NULL;
        int32_t retCode;

        scan_num_rows = 0;
        scan_cell_count = 0;
        scan_done = false;

        // scanner object create
        hb_scanner_create(client, &scanner);

        scan_data_t *scan_data = (scan_data_t *) calloc(1,
sizeof(scan_data_t));

        // set the table to scan
        scan_data->table_name_ = bytebuffer_printf("%s",
table_name.c_str());
        hb_scanner_set_table(scanner, (char *)
scan_data->table_name_->buffer, scan_data->table_name_->length));

        // start and end row - optional
        scan_data->start_row_key_ = bytebuffer_printf("%s",
start_row_key.c_str());
        hb_scanner_set_start_row(scanner, scan_data->start_row_key_->buffer,
                        scan_data->start_row_key_->length);

        scan_data->end_row_key_ = bytebuffer_printf("%s",
end_row_key.c_str());
        hb_scanner_set_end_row(scanner, scan_data->end_row_key_->buffer,
                        scan_data->end_row_key_->length);

        // add columns
        bytebuffer cfName   = bytebuffer_printf("%s",
data_qualifier[0].c_str());
        bytebuffer columnName   = bytebuffer_printf("%s",
data_qualifier[1].c_str());
        retCode=hb_scanner_add_column(scanner,(byte_t
*)cfName->buffer,cfName->length,columnName->buffer,columnName->length);

        // set versions
        hb_scanner_set_num_versions(scanner, num_versions);

        // set timestamp
        hb_scanner_set_timestamp(scanner, ts);

        // scan data
        retCode = hb_scanner_next(scanner, scan_callback, scan_data);
        return retCode;
}
```

Delete Specific Cells Example
This example deletes specific cells that correspond to a specific timestamp.

```
nt32_t deleteRowExactTS(std::string table_name, std::string row_key,
        std::vector<std::string> data, int64_t ts) {

        int32_t retCode = 0;
        // initialize delete object
        hb_delete_t del = NULL;

        row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
        row_data->key = bytebuffer_printf("%s", row_key.c_str());
        row_data->tablename = bytebuffer_printf("%s",table_name.c_str());

        // create delete object
        hb_delete_create(row_data->key->buffer, row_data->key->length,
&del);

        cell_data_t *prevCell=NULL;
        // add cells that needs to be deleted
        for(int t=0; t < (int)data.size(); t++) {
             vector<string> data_qualifier = split(data.at(t),':');
             cell_data_t *cell_data= new_cell_data();
             if(t==0)
                row_data->first_cell = cell_data;
             else
                prevCell->next_cell = cell_data;

             cell_data->columnFamily =
bytebuffer_printf("%s",data_qualifier[0].c_str());
             cell_data->columnName =
bytebuffer_printf("%s",data_qualifier[1].c_str());

             //add column, fam/column/ts to delete the exact version
             retCode=hb_delete_add_column_exact(del,
cell_data->columnFamily->buffer, cell_data->columnFamily->length,

cell_data->columnName->buffer,cell_data->columnName->length,ts);
             prevCell = cell_data;
        }

        // set the table name in delete mutation object
        hb_mutation_set_table(del, (const char
*)row_data->tablename->buffer,row_data->tablename->length);

        //send the delete request
        retCode = hb_mutation_send(client, del, delete_callback, row_data);
        return retCode;
}
```

HPE Ezmeral Data Fabric Database Sample C Application
MapR provides a sample C application that accesses and performs operations on HPE Ezmeral Data Fabric Database binary tables. This section describes the various operation performed by the application.

The sample C application is located in the `/opt/mapr/examples/sample` directory.

Prerequisites

In order to compile and run the sample application, install the `mapr-client` package on the node where you will build the application. See Impersonation Example on page 3241. If the `mapr-core` package is already installed, you do not need to install the `mapr-client` package.

Compiling

To compile and run the sample application, read the instructions in the `README` file in the `/opt/mapr/examples/sample` directory.

Set the log level and specify the log stream

APIs used

These two APIs are defined in the header file `log.h`:

- `hb_log_set_level()`: Sets the log output level. The levels are defined in the header file types.h.
- `hb_log_set_stream()`: Sets the location of the log output. By default, log messages are sent to stderr.

Code

```
hb_log_set_level(HBASE_LOG_LEVEL_DEBUG); // defaults to INFO
const char *logFilePath = getenv("HBASE_LOG_FILE");
if (logFilePath != NULL) {
  FILE* logFile = fopen(logFilePath, "a");
  if (!logFile) {
    retCode = errno;
    fprintf(stderr, "Unable to open log file \"%s\"", logFilePath);
    perror(NULL);
    goto cleanup;
  }
  hb_log_set_stream(logFile); // defaults to stderr
}
```

Log levels are specified in the header file `types.h`.

```
/**
 *  Log levels
 */
typedef enum {
  HBASE_LOG_LEVEL_INVALID = 0,
  HBASE_LOG_LEVEL_FATAL   = 1,
  HBASE_LOG_LEVEL_ERROR   = 2,
  HBASE_LOG_LEVEL_WARN    = 3,
  HBASE_LOG_LEVEL_INFO    = 4,
  HBASE_LOG_LEVEL_DEBUG   = 5,
  HBASE_LOG_LEVEL_TRACE   = 6
} HBaseLogLevel;
```

Create a connection

API used: `hb_connection_create()`

Use this function to connect to the MapR cluster.

This API takes three parameters:

```
const char *zk_ensemble,     /* [in] NULL terminated, comma separated
                                     *   string of CLDB servers. e.g.
                                     *   "<server1[:port]>,...".
const char *zk_root,              /* [in] Ignored for MapR-DB. */
hb_connection_t *connection_ptr); /* [out] pointer to hb_connection_t */
```

last-updated: Jun 06, 2024

There are two methods by which you can use the `zk_ensemble` parameter to determine how the MapR client connection locates the MapR cluster to connect to:

Set `zk_ensemble` to NULL to connect to the default cluster that is defined in the `mapr-clusters.conf` file.	MapR recommends this method, which uses the configuration information that is listed for the cluster in the `mapr-clusters.conf` file.
Set `zk_ensemble` to a string that includes hostnames or IP addresses.	With this method, the client application can connect to a non-default cluster explicitly. The client application searches through the `mapr-clusters.conf` file to find a cluster entry with a matching hostname/IP address. The first entry that is found to contain a matching hostname[:port]/IP address[:port} is used for the connection, as is the configuration information for that entry. If none of the hostnames or IP addresses specified for `zk_ensemble` are located in entries in `mapr-clusters.conf`, or if `mapr-clusters.conf` does not exist, the client application tries to connect to the first specified hostname[:port]/IP address[:port]. If the client application cannot make a connection, it moves to the next specified hostname[:port]/IP address[:port]. **WARNING:** Because no `mapr-clusters.conf` file is involved, no additional configuration information is used for connections. For example, connections made in this way cannot be secure because no security parameters are provided.

Examples

```
//connect to default cluster specified in mapr-clusters.conf (preferred)
if ((err = hb_connection_create(NULL,
                                NULL,
                                &connection)) != 0) {
  HBASE_LOG_ERROR("Could not create MapR-DB connection : errorCode = %d.",
err);
  goto cleanup;
}

//Connect directly to cluster with these specified IP addresses.
//Typically this means there is no mapr-clusters.conf and security not used.
if ((err = hb_connection_create("192.168.1.1:7222,192.168.1.2:7222",
                                NULL /* ignored */,
                                &connection)) != 0) {
  HBASE_LOG_ERROR("Could not create MapR-DB connection : errorCode = %d.",
err);
  goto cleanup;
}
```

Code in the sample application

```
if ((retCode = hb_connection_create(zk_ensemble,
                                    zk_root_znode,
                                    &connection)) != 0) {
  HBASE_LOG_ERROR("Could not create HBase connection : errorCode = %d.",
retCode);
  goto cleanup;
}
```

last-updated: Jun 06, 2024

This API is defined in the header file `connection.h`:

Create a table

The sample application creates a table by calling a function named ensureTable.

APIs used

The definition of this function uses these APIs:

APIs defined in the header file `admin.h`.

- `hb_admin_table_create()`: Creates a table. Returns 0 on success or an error code.
- `hb_admin_table_delete()`: Deletes a table. Returns 0 on success or an error code.
- `hb_admin_destroy()`: Disconnects the hb_admin object, releasing any internal objects or connections that were created in the background.
- `hb_admin_table_disable()`: Disables an HBase table. Returns 0 on success or an error code. Only sets a flag in memory to say that the table is disabled.

  NOTE: Tables never need to be disabled or enabled in HPE Ezmeral Data Fabric Database, which has no notion of disabling or enabling tables. However, applications ported from HBase to HPE Ezmeral Data Fabric Database will attempt to disable and enable tables. By placing a flag in memory, HPE Ezmeral Data Fabric Database allows those applications to proceed without error when performing admin functions on tables.
- `hb_admin_table_enable()`: Enables an HBase table. Returns 0 on success or an error code. As with hb_admin_table_enable, this function sets a flag in memory and performs no other operation.
- `hb_admin_table_enabled()`: Checks whether an HBase table is enabled. Returns 0 if the table is enabled. If the table is disabled, returns either the error message HBASE_TABLE_DISABLED or an error code, if an error occurs. In HPE Ezmeral Data Fabric Database, this API only checks for the existence of an in-memory flag that indicates whether to consider a table as disabled or enabled.
- `hb_admin_table_exists()`: Checks whether a table exists. Returns 0 on success or an error code.

APIs defined in the header file `coldesc.h`.

- `hb_coldesc_create()`: Creates a column-family descriptor. Returns a handle to an hb_columndesc object or NULL, if unsuccessful.
- `hb_coldesc_set_maxversions()`: Sets the maximum number of cell versions to be retained for the column family. The default is 3.
- `hb_coldesc_set_minversions()`: Sets the minimum number of cell versions to be retained for the column family. The default is 0.
- `hb_coldesc_set_ttl()`: Sets the time-to-live value in seconds for data in column cells. The default is forever.

- `hb_coldesc_set_inmemory()`: Boolean. Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.

  For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if its `inmemory` parameter is set to `false`, but preference will be given to column families where this parameter is set to `true`. A column family can have more than 32 bytes stored inline if its `inmemory` parameter is set to `true`.

  If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have the `inmemory` parameter set to `true`. All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data at all will be stored in-line for that column family.

  The default value for the `inmemory` parameter is `false`.

- `hb_coldesc_destroy()`: Releases resources that are held by a column-family descriptor.

Sequence of steps in the ensureTable function

1. Create an admin handle from the connection.
2. Using the admin handle, check whether the specified table exists.
3. If the table exists, delete it.
4. Specify columns and column families for the table.
5. Create the table.
6. Check whether the table is enabled. If it isn't enabled, enable it.
7. Disable the table and then enable it again.
8. Destroy the column descriptors.
9. Destroy the `hb_admin` structure.

Code for the ensureTable function at line 325

```
static int
ensureTable(hb_connection_t connection, const char *table_name) {
  int32_t retCode = 0;
  hb_admin_t admin = NULL;

  if ((retCode = hb_admin_create(connection, &admin)) != 0) {
    HBASE_LOG_ERROR("Could not create HBase admin : errorCode = %d.",
retCode);
    goto cleanup;
  }

  if ((retCode = hb_admin_table_exists(admin, NULL, table_name)) == 0) {
    HBASE_LOG_INFO("Table '%s' exists, deleting...", table_name);
    if ((retCode = hb_admin_table_delete(admin, NULL, table_name)) != 0) {
      HBASE_LOG_ERROR("Could not delete table %s[%d].", table_name,
retCode);
```

```
      goto cleanup;
    }
  } else if (retCode != ENOENT) {
    HBASE_LOG_ERROR("Error while checking if the table exists: errorCode =
%d.", retCode);
    goto cleanup;
  }

  hb_coldesc_create(FAMILIES[0], 1, &HCD[0]);
  hb_coldesc_set_maxversions(HCD[0], 2);
  hb_coldesc_set_minversions(HCD[0], 1);
  hb_coldesc_set_ttl(HCD[0], 2147480000);
  hb_coldesc_set_inmemory(HCD[0], 1);

  hb_coldesc_create(FAMILIES[1], 1, &HCD[1]);

  }
  return retCode;
}
```

Code to call the ensureTable function

```
if ((retCode = ensureTable(connection, table_name)) != 0) {
  HBASE_LOG_ERROR("Failed to ensure table %s : errorCode = %d", table_name,
retCode);
  goto cleanup;
}
```

Create a client

API used

`hb_client_create()`: Initializes a handle to `hb_client_t` object that can be passed to other APIs. You need to use this method only once per cluster. The returned handle is thread-safe. This API is defined in the `client.h` header file.

Code

```
if ((retCode = hb_client_create(connection, &client)) != 0) {
  HBASE_LOG_ERROR("Could not connect to HBase cluster : errorCode = %d.",
retCode);
  goto cleanup;
}
```

Asynchronously put ten rows of one cell each

APIs used in this operation

The first 6 APIs are defined in the header file `mutations.h`:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the name of the table for the put operation.
- `hb_mutation_set_bufferable()`: Sets whether or not the RPC call for the put operation can be buffered on the client side.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

The last API is defined in the header file `client.h`:

- `hb_client_flush()`: Flushes any buffered client-side write operations to the server. The callback is invoked after everything that was buffered at the time of the call is flushed. Invocation of the callback is a guarantee that all outstanding RPC calls are complete.

Sequence of steps in this code extract

1. Create a row object named row_data.
2. Create a put object.
3. Specify the name of the table.
4. Set whether or not the RPC call for the put operation can be buffered on the client side.
5. Create cell data.
6. Create a cell.
7. Add the cell to the row.

last-updated: Jun 06, 2024

8. Queue the put.
9. After following the steps above 10 times, flush the puts to the server.
10. Wait for the RPC calls to complete.

Code

```
// let's send a batch of 10 puts with single cell asynchronously
outstanding_puts_count += num_puts;
for (int i = 0; i < num_puts; ++i) {
  row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
  row_data->key   = bytebuffer_printf("%s%02d", rowkey_prefix, i);
  hb_put_create(row_data->key->buffer, row_data->key->length, &put);
  hb_mutation_set_table(put, table_name, table_name_len);
  hb_mutation_set_durability(put, DURABILITY_SKIP_WAL);
  hb_mutation_set_bufferable(put, false);

  cell_data_t *cell_data = new_cell_data();
  row_data->first_cell = cell_data;
  cell_data->value = bytebuffer_printf("%s%02d", value_prefix, i);

  hb_cell_t *cell = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
  cell_data->hb_cell = cell;

  cell->row = row_data->key->buffer;
  cell->row_len = row_data->key->length;
  cell->family = FAMILIES[rand() % 2];
  cell->family_len = 1;
  cell->qualifier = column_a->buffer;
  cell->qualifier_len = column_a->length;
  cell->value = cell_data->value->buffer;
  cell->value_len = cell_data->value->length;
  cell->ts = HBASE_LATEST_TIMESTAMP;

  hb_put_add_cell(put, cell);
  HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                 cell->row_len, cell->row);
  hb_mutation_send(client, put, put_callback, row_data);
}
hb_client_flush(client, client_flush_callback, NULL);
wait_for_flush();

wait_for_puts(); // outside the loop, wait for 10 puts to complete
```

Asynchronously put two cells in a single row

APIs used

These APIs are defined in the header file `mutations.h`:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

last-updated: Jun 06, 2024

Sequence of steps

1. Create a row object named row_data.
2. Create a put object.
3. Specify the name of the table.
4. Create cell data for the first cell.
5. Create the first cell.
6. Add the data to the first cell.
7. Add the first cell to the row.
8. Create cell data for the second cell.
9. Create the second cell.
10. Add the data to the second cell.
11. Add the second cell to the row.
12. Queue the put.
13. Wait 3 seconds, flush the queue, and wait for the RPC calls to complete.

`wait_for_puts()` without `hb_client_flush()`: Waits for all outstanding put requests to be flushed. If hb_client_flush() is not called before wait_for_puts(), it can take up to three seconds for outstanding put requests to be flushed.

Code

```
// now, let's put two cells in a single row
outstanding_puts_count++;
{
  row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
  row_data->key = bytebuffer_printf("row_with_two_cells");
  hb_put_create(row_data->key->buffer, row_data->key->length, &put);
  hb_mutation_set_table(put, table_name, table_name_len);
  hb_mutation_set_durability(put, DURABILITY_SYNC_WAL);

  // first cell
  cell_data_t *cell1_data = new_cell_data();
  row_data->first_cell = cell1_data;
  cell1_data->value = bytebuffer_printf("cell1_value_v1");

  hb_cell_t *cell1 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
  cell1_data->hb_cell = cell1;

  cell1->row = row_data->key->buffer;
  cell1->row_len = row_data->key->length;
  cell1->family = FAMILIES[0];
  cell1->family_len = 1;
  cell1->qualifier = column_a->buffer;
  cell1->qualifier_len = column_a->length;
  cell1->value = cell1_data->value->buffer;
  cell1->value_len = cell1_data->value->length;
  cell1->ts = 1391111111111L;
  hb_put_add_cell(put, cell1);
```

last-updated: Jun 06, 2024

```
    // second cell
    cell_data_t *cell2_data = new_cell_data();
    cell1_data->next_cell = cell2_data;
    cell2_data->value = bytebuffer_printf("cell2_value_v1");

    hb_cell_t *cell2 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
    cell2_data->hb_cell = cell2;

    cell2->row = row_data->key->buffer;
    cell2->row_len = row_data->key->length;
    cell2->family = FAMILIES[1];
    cell2->family_len = 1;
    cell2->qualifier = column_b->buffer;
    cell2->qualifier_len = column_b->length;
    cell2->value = cell2_data->value->buffer;
    cell2->value_len = cell2_data->value->length;
    cell2->ts = 1391111111111L;
    hb_put_add_cell(put, cell2);

    HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                   cell1->row_len, cell1->row);
    hb_mutation_send(client, put, put_callback, row_data);
    wait_for_puts();
  }
```

Asynchronously put a second version in one column of one row

APIs used

These APIs are defined in the header file mutations.h:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a row object named row_data.
2. Create a put object.
3. Specify the name of the table.
4. Create cell data for the first cell.
5. Create the first cell.
6. Add the data to the cell, using a later timestamp than in the previous operation.
7. Add the first cell to the row.
8. Queue the put.

last-updated: Jun 06, 2024

9. Wait 3 seconds, flush the queue, and wait for the RPC calls to complete.

Code

```
// now, let's put second version in one column
outstanding_puts_count++;
{
  row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
  row_data->key = bytebuffer_printf("row_with_two_cells");
  hb_put_create(row_data->key->buffer, row_data->key->length, &put);
  hb_mutation_set_table(put, table_name, table_name_len);
  hb_mutation_set_durability(put, DURABILITY_SYNC_WAL);

  // first cell
  cell_data_t *cell1_data = new_cell_data();
  row_data->first_cell = cell1_data;
  cell1_data->value = bytebuffer_printf("cell1_value_v2");

  hb_cell_t *cell1 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
  cell1_data->hb_cell = cell1;

  cell1->row = row_data->key->buffer;
  cell1->row_len = row_data->key->length;
  cell1->family = FAMILIES[0];
  cell1->family_len = 1;
  cell1->qualifier = column_a->buffer;
  cell1->qualifier_len = column_a->length;
  cell1->value = cell1_data->value->buffer;
  cell1->value_len = cell1_data->value->length;
  cell1->ts = 1392222222222L;
  hb_put_add_cell(put, cell1);

  HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                 cell1->row_len, cell1->row);
  hb_mutation_send(client, put, put_callback, row_data);
  wait_for_puts();
}
```

Scan the entire table

APIs used

These APIs and more are defined in the header file `scanner.h`:

- `hb_scanner_create()`: Creates a client side row scanner. The returned scanner is not thread safe. No RPC will be invoked until the call to fetch the next set of rows is made. You can set the various attributes of this scanner until that point. @returns 0 on success, non-zero error code in case of failure.
- `hb_scanner_next()`: Request the next set of results from the server. You can set the maximum number of rows returned by this call using hb_scanner_set_num_max_rows().
- `hb_scanner_num_max_rows()`: Sets the maximum number of rows to scan per call to hb_scanner_next().
- `hb_scanner_num_versions()`: Sets the maximum versions of a column to fetch.
- `hb_scanner_set_table()`: Sets the name of the table to scan.

Sequence of steps

1. Create the scanner object.

2. Set the name of the table to scan.
3. Set the number of rows to scan at a time.
4. Set the number of versions to scan.
5. Request the next set of results from the server.
6. `wait_for_scan()`: wait for the rpc call to complete.

Code

```
  // now, scan the entire table
  {
    hb_scanner_t scanner = NULL;
    hb_scanner_create(client, &scanner);
    hb_scanner_set_table(scanner, table_name, table_name_len);
    hb_scanner_set_num_max_rows(scanner, 3);  // maximum 3 rows at a time
    hb_scanner_set_num_versions(scanner, 10); // up to 10 versions of the
cell
    hb_scanner_next(scanner, scan_callback, NULL); // dispatch the call
    wait_for_scan();
  }
```

Fetch a row that has two cells

APIs used

- `hb_get_add_column()`: Adds a column family and optionally a column qualifier to an hb_get_t object.
- `hb_get_create()`: Creates an `hb_get_t` object and populates the handle `get_ptr`.
- `hb_get_send()`: Queues the get request. The callback specified by `cb` is called on completion. Any buffers attached to the get object can be reclaimed only after the callback is received.
- `hb_get_set_num_versions()`: Sets maximum number of latest values of each column to be fetched. This API is optional.
- `hb_get_set_table()`: Sets the name of the table to get data from.

Sequence of steps

1. Create a row object named `rowKey`.
2. Create a get object.
3. Specify the column families and optional column qualifiers to get values from.
4. Specify the name of the table.
5. Specify the number of versions of the column values to get.
6. Queue the get request.
7. Wait for the get to complete.

last-updated: Jun 06, 2024

Code

```
// fetch a row with row-key="row_with_two_cells"
{
  bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
  hb_get_t get = NULL;
  hb_get_create(rowKey->buffer, rowKey->length, &get);
  hb_get_add_column(get, FAMILIES[0], 1, NULL, 0);
  hb_get_add_column(get, FAMILIES[1], 1, NULL, 0);
  hb_get_set_table(get, table_name, table_name_len);
  hb_get_set_num_versions(get, 10); // up to ten versions of each column
  get_done = false;
  hb_get_send(client, get, get_callback, rowKey);
  wait_for_get();
}
```

Delete a specific version of a column in the row that was fetched

APIs used

The APIs that are used are defined in the header file `mutations.h`.

- `hb_delete_add_column()`: Set the column criteria for hb_delete_t object. Set the qualifier to NULL to delete all columns of a family. Only the cells with timestamp less than or equal to the specified timestamp are deleted. Set the timestamp to `INT64_MAX` to delete all versions of the column. This API is optional for deletes.
- `hb_delete_create()`: Creates a structure for delete operation and return its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a delete object for a row with a particular row key.
2. Add a column to the delete object.
3. Specify the name of the table from which to delete the cell version.
4. Queue the delete.
5. Wait three seconds for the delete to be flushed, then wait for the RPC call to complete.

Code

```
// delete a specific version of a column
{
  bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
  hb_delete_t del = NULL;
  hb_delete_create(rowKey->buffer, rowKey->length, &del);
  hb_delete_add_column(del, FAMILIES[0], 1,
      column_a->buffer, column_a->length, 1391111111112L);
  hb_mutation_set_table(del, table_name, table_name_len);
  delete_done = false;
  hb_mutation_send(client, del, delete_callback, rowKey);
```

last-updated: Jun 06, 2024

```
    wait_for_delete();
  }
```

Destroy the client and the connection

APIs used

- `hb_client_destroy()`: Cleans up `hb_client_t` handle and releases any held resources. The callback is called after the connections are closed, but just before the client is freed. This API is defined in the header file `client.h`.
- `hb_connection_destroy()`: Destroys the connection and frees all resources allocated at creation time. This API is defined in the header file `connection.h`.

Sequence of steps

1. Destroy the client.
2. Destroy the connection.

Code

```
  if (client) {
    HBASE_LOG_INFO("Disconnecting client.");
    hb_client_destroy(client, client_disconnection_callback, NULL);
    wait_client_disconnection();
  }
  if (connection) {
    hb_connection_destroy(connection);
  }
```

Building and Launching C Applications

This topic describes basic setup for building and launching C application using the MapR `libMapRClient` C API library

Prerequisites

The HPE Ezmeral Data Fabric Database `libMapRClient` C API library is MapR's extension of the `libhbase` C API library). The libMapRClient header files are in this directory: **/opt/mapr/include/hbase**

- Verify that the `mapr-client` package is installed on the node. The `mapr-client` package must be installed on each node that builds an application. The `libMapRClient` header files are in this directory: `/opt/mapr/include/hbase`.
- Verify that both the `libMapRClient` library and `libjvm` shared libraries are in the application's library search path.

Building Applications

When building applications that use `libMapRClient`, run this command:

```
gcc -o <application_name> <source_file> -I/opt/mapr/include/hbase -L/opt/
mapr/lib/ -lMapRClient -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

For example, the following command builds the `hello_hbase` application with the `hello_hbase.c` source code:

```
gcc -o hello_hbase hello_hbase.c -I/opt/mapr/include/hbase -L/opt/
mapr/lib/ -lMapRClient -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

NOTE:

- The compiled libMapRClient is statically linked to the following third-party libraries: Crypto++: libcryptoapp.a (v5.6.2)Protobuf: libprotobuf-lite.a (v2.5.0)
- The `libMapRClient` library has dependencies on `libjvm`, though a JVM is not instantiated. In general, the `libjvm` library is located within the JDK/JRE installation directory.

Launching Applications

Before launching an application, set this value for the environment variable `LD_LIBRARY_PATH`:

```
/opt/mapr/lib:/usr/lib/jvm/java-6-openjdk-amd64/jre/lib/amd64/server
```

If the client is on Windows, append the following directories to the `PATH` environment variable:

- `$MAPR_HOME/lib`
- `$JAVA_HOME/bin/server`

If the application uses the `hb_connection_create_as_user` API for impersonation, set the `MAPR_IMPERSONATION_ENABLED` environment variable to `true`.

What To Do Next

Launch the application!

HBase Java Filters Support
The hb_get_set_filter() and hb_scanner_set_filter() C APIs are used to filter the results of GET and SCAN operations. These APIs are in the **get.h** and **scanner.h** header files.

They both take filters that are passed as strings, as well as the length of these strings. HPE Ezmeral Data Fabric Database parses the strings to construct filters.

Their signatures are:

```
int32_t hb_get_set_filter(hb_get_t get, const byte_t *filter, const int32_t
filterLen);
int32_t hb_scanner_set_filter(hb_scanner_t scanner, const byte_t *filter,
const int32_t filterLen);
```

For examples, see Filtering GET Operation Results Example on page 3241 and Filtering SCAN Operation Results Example on page 3240.

Filter Format and Arguments
Filters are specified in the Thrift Filter Language and are in this format: `FilterName (argument, argument,... , argument)`. Arguments that represent strings are enclosed in single quotation marks (‘). Arguments that represent booleans, integers, or comparison operators (<, <=, =, !=, >, >=) are not enclosed in single quotation marks.

Binary Operators

You can combine filters by using the binary operators `AND` and `OR`. For example, `PrefixFilter ('Row') AND PageFilter (1) AND FirstKeyOnlyFilter ()` returns all key-value pairs that match the following conditions:

- The row containing the key-value must start with the prefix "Row".
- The key-value must be located in the first row of the table.
- The key-value must be the first key-value pair in the row.

For another example, `(RowFilter (=, 'binary:Row 1') AND TimeStampsFilter (74689, 89734)) OR ColumnRangeFilter ('abc', true, 'xyz', false))` returns all key-value pairs that

Match both of the following conditions:

- The key-value is in a row for which the row key is "Row 1".
- The key-value has a timestamp of either 74689 or 89734.

Or match this condition:

- The key-value is located in a column that is lexicographically greater than or equal to "abc" and less than "xyz".

Unary Operators

You can also use the following unary operators with filters:

- SKIP

  For a particular row, if any of the key-values don't pass the filter condition, the entire row is skipped. For example, `SKIP ValueFilter (0)` omits rows in which any values are not 0.

- WHILE

  Rows are tested in order against the filter condition. Rows that meed the condition are included in the result set. When a row fails to meet the condition, filter processing stops and no more rows are tested.

Evaluation of Filters

When filters are combined with the binary operators, unary operators, or both, they are evaluated according to these rules:

1. First, evaluate the contents of parentheses.
2. Next, evaluate filters that use unary operators. Both SKIP and WHILE operators have the same precedence.
3. Finally, evaluate filters that use the binary operators. AND has higher precedence than OR.

For example, in a filter of the form `Filter1 AND Filter2 OR Filter`, `Filter1 AND Filter2` is evaluated and the result is *X*. Then, *X* `OR Filter3` is evaluated.

For another example, a filter of the form `Filter1 AND SKIP Filter2 OR Filter3` is evaluated in these steps:

1. Evaluate `SKIP Filter2` with the result being *X*.
2. Evaluate `Filter1 AND` *X* with the result being *Y*.
3. Evaluate *Y* `OR Filter3`.

last-updated: Jun 06, 2024

Compare Operators and Comparators
This topic describesthe compare operators and comparators for comparison filters.

The comparison filters DependentColumnFilter, FamilyFilter, QualifierFilter, RowFilter, and ValueFilter use the following syntax:

```
filter(<compareOperator>, <comparatorType:Value>)
```

Compare Operators

The following compare operators are supported: <,<=, =, !=, >, >=

Comparators

There are four comparators:

Comparator	Description
BinaryComparator	This comparator lexicographically compares against the specified byte array . Values are byte arrays. For example, `binary:abc` matches values that are lexicographically greater than "abc”.
BinaryPrefixComparator	This comparator lexicographically compares against a specified byte array. It only compares up to the length of this byte array. Values are byte arrays. For example, `binaryprefix:abc` matches values in which the first 3 characters are lexicographically equal to "abc"
RegexStringComparator	This comparator compares against the specified byte array using the given regular expression. You can use only the = and != compare operators with this comparator. Values are regular expressions. For example, `regexstring:ab*yz` matches values that begin with "ab" and end with "yz”.
SubStringComparator	This comparator tests whether the given substring appears in a specified byte array. The comparison is case insensitive. You can use only the = and != compare operators with this comparator. Values are strings. For example, `substring:abc123` matches values that contains the substring "abc123”.

Supported Filters

Filter	Format	Description
ColumnCountGetFilter	`ColumnCountGetFilter(`*`x`*`)`	Returns the first x columns in a row. Used for GET operations.

last-updated: Jun 06, 2024

Filter	Format	Description
ColumnPaginationFilter	`ColumnPaginationFilter(x,y)`	Returns the first x columns after the number y of columns that is specified for the offset.
ColumnPrefixFilter	`ColumnPrefixFilter('prefix')`	Returns only those key-values in columns that have names that start with the specified prefix. The column prefix must be of the form “qualifier”.
ColumnRangeFilter	`ColumnRangFilter('minColumn','maxColumn',boolean,boolean)`	Returns only those key-values that are in columns that have names between minColumn and maxColumn. For example, if minColumn is 'an', and maxColumn is 'be', the filter returns key-values from columns named 'ana', 'bad', but not from columns named 'bed' or'eye' If minColumn is null, there is no lower bound. If maxColumn is null, there is no upper bound. This filter also takes two boolean variables to indicate whether to include the minColumn and maxColumn.
DependentColumnFilter	`DependentColumnFilter('family','qualifier')`	Tries to locate the specified column in each row and returns all key-values that have the same timestamp in that column. If a row does not contain the specified column, none of the key-values in that row are returned.
FamilyFilter	`FamilyFilter(compareOperator,'comparator:value')`	Filters by column family. If the comparison returns true, the filter returns all of the key-values in the matching column family.
FirstKeyOnlyFilter	`FirstKeyOnlyFilter()`	Returns the first key-value from each row.
FirstKeyValueMatchingQualifiersFilter	`FirstKeyValueMatchingQualifier('qualifier_1','qualifier_2',...'qualifier_n')`	Serially compares each qualifier in a row with the given qualifiers. If the current qualifier matches any of the given qualifiers, the filter stops and includes the current row (up to the current qualifier) in the result set.

last-updated: Jun 06, 2024

Filter	Format	Description
FuzzyRowFilter	`FuzzyRowFilter('rowkey','fuzzy_info')`	Filters data based on fuzzy row key. Performs fast-forwards during scanning. It takes pairs (row key, fuzzy info) to match row keys. Where fuzzy info is a byte array with 0 or 1 as its values: 0 - means that this byte in provided row key is fixed, i.e. row key's byte at same position must match 1 - means that this byte in provided row key is NOT fixed, i.e. row key's byte at this position can be different from the one in provided row key Example: Let's assume row key format is userId_actionId_year_month. Length of userId is fixed and is 4, length of actionId is 2 and year and month are 4 and 2 bytes long respectively. Let's assume that we need to fetch all users that performed certain action (encoded as "99") in Jan of any year. Then the pair (row key, fuzzy info) would be the following: row key = "????_99_????_01" (one can use any value instead of "?") fuzzy info = "\x01\x01\x01\x01\x00\x00\x00\x00\x01\x01\x01\x01\x00\x00\x00" I.e. fuzzy info tells the matching mask is "????_99_????_01", where at ? can be any value.
InclusiveStopFilter	`InclusiveStopFilter('rowKey')`	Returns all key-values that are in the rows up to and including the specified row that has the specified row key.
KeyOnlyFilter	`KeyOnlyFilter()`	Returns the key component of each key-value.
MultipleColumnPrefixFilter	`MultipleColumnPrefixFilter('prefix_1','prefix_2',...,'prefix_n')`	Returns the key-values from columns that have names that begin with any of the specified prefixes.
PageFilter	`PageFilter(pageSize)`	Returns the number of rows that is equivalent to the specified page size..
PrefixFilter	`PrefixFilter('rowKey_prefix')`	Returns the key-values from a row that has a key which starts with the specified row-key prefix.
QualifierFilter	`QualifierFilter(compareOperator,'comparator:value')`	Filters by column. If the comparison returns true, the filter returns all of the key-values in the matching column.
RandomRowFilter	`RandomRowFilter(probability)`	Filters by probability. For example, RandomRowFilter(0.25) means that there is a 1 in 4 chance that the filter will pick the first row, a 1 in 4 chance that the filter will pick the next row, and so on until all rows in the table have been processed in this way.

last-updated: Jun 06, 2024

Filter	Format	Description
RowFilter	`RowFilter(compareOperator,'comparator:value')`	Filters by row key. If the comparison returns true, the filter returns all of the key-values in the matching row.
SingleColumnValueExcludeFilter	`SingleColumnValueExcludeFilter('columnFamily','qualifier', compareOperator,'comparator:value')`	This filter takes the same arguments and behaves the same as SingleColumnValueFilter: however, if the column is found and the condition passes, all of the columns of the row will be returned except for the tested column value.
SingleColumnValueFilter	`SingleColumnValueFilter('columnFamily','qualifier', compareOperator,'comparator:value')`	This filter takes a column family, a qualifier, a compare operator and a comparator. If the specified column is not found: all of the columns of that row will be emitted. If the column is found and the comparison with the comparator returns true, all of the columns of the row will be emitted. If the condition fails, the row will not be returned.
SkipFilter	`SKIP filter`	See the description of the SKIP unary operator above .
TimeStampsFilter	`TimeStampsFilter('timestamp_1','timestamp_2',..., 'timestamp_n')`	Returns the key-values that have timestamps that match any of the specified timestamps.
ValueFilter	`ValueFilter(compareOperator,'comparator:value')`	Filters by key-value. If the comparison returns true, the filter returns the matching key-value.
WhileMatchFilter	`WHILE filter`	See the description of the WHILE unary operator above .

Creating Java Apps - Binary Tables

This topics describes the supported Apache HBase Java APIs used for CRUD operations on HPE Ezmeral Data Fabric Database binary tables.

HPE Ezmeral Data Fabric Database supports all of the Apache HBase 1.0 Java APIs, except where noted in this documentation. For a number of critical Java APIs, for filters, and for comparators, this documentation explicitly lists what is supported, rather than what is not supported.

Code written for Apache HBase can be easily ported to use HPE Ezmeral Data Fabric Database binary tables.

HPE Ezmeral Data Fabric Database binary tables do not support low-level HBase API calls that are used to manipulate the state of an Apache HBase cluster. HBase API calls that are not supported by HPE Ezmeral Data Fabric Database tables report successful completion to allow legacy code written for Apache HBase to continue executing, but do not perform any actual operations.

NOTE: For the list of supported HBase v0.98 APIs, refer to the HBase Java API Support on page 3265.

Compiling and Running HPE Ezmeral Data Fabric Database Binary Applications

For applications that use the HPE Ezmeral Data Fabric Database Java API for binary tables, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

Compile and Determine Dependencies

1. Add the Data Fabric maven repository to the list of repositories in your application's `pom.xml`, if it is not there already:

```
<repository>
      <id>mapr-releases</id>
      <url>https://repository.mapr.com/maven/</url>
      <snapshots><enabled>true</enabled></snapshots>
      <releases><enabled>true</enabled></releases>
</repository>
```

   For more information, see Maven Artifacts for the HPE Ezmeral Data Fabric on page 4745.

2. Add a dependency to the HBase client project:

```
<dependencies>
<dependency>
  <groupId>org.apache.hbase</groupId>
  <artifactId>hbase-client</artifactId>
  <version><version selected from the repository></version>
</dependency>
<dependencies>
```

   NOTE:

   - The hbase-client version mentioned above is an example. The actual version that your application requires is based on the current EEP and Data Fabric core version that you are running. The file versions are listed in the following location: https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/hbase/hbase-client/ Ensure that the version tags include reference to m7-<maprversion>. Otherwise, your applications will not be able to access HPE Ezmeral Data Fabric Database binary tables.
   - If your application uses both the HPE Ezmeral Data Fabric Database JSON and HPE Ezmeral Data Fabric Database Binary APIs, you may encounter a conflict in the netty library used by each API. To avoid this, exclude the netty library from your `hbase-client` dependency as follows:

```
<dependency>
   <groupId>org.apache.hbase</groupId>
   <artifactId>hbase-client</artifactId>
   <version><version selected from the repository></version>
   <exclusions>
     <exclusion>
        <artifactId>netty-all</artifactId>
           <groupId>io.netty</groupId>
     </exclusion>
   </exclusions>
</dependency>
```

3. Use Maven to compile the application and resolve dependencies. For example, you can run `mvn clean package`.

Running Applications

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 3151.

If the cluster is secure, the node must also have a Data Fabric ticket configured for the user that runs the application. See Managing Tickets on page 1828.

You can use the following command to launch HPE Ezmeral Data Fabric Database binary applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

NOTE: The classpath should include items that are part of the 'hbase classpath' script plus any other required dependencies.

HBase Java API Support

This topic describes the methods in the Apache HBase Java API library that are supported for HPE Ezmeral Data Fabric Database tables.

Admin Method Support

This topic lists the methods that the HPE Ezmeral Data Fabric Database supports in the HBase interface `Admin`.

The HPE Ezmeral Data Fabric Database tables support the following HBase methods, except where noted.

`abort(String why, Throwable e)`	*Modifier and Type*: `void` *Purpose*: Aborts the server or client *Supported*: No
`addColumn(TableName tableName, HColumnDescriptor column)`	*Modifier and Type*: `void` *Purpose*: Adds a column to an existing table *Supported*: Yes
`assign(byte[] regionName)`	*Modifier and Type*: `void` *Purpose*: Assigns a region *Supported*: No
`balancer()`	*Modifier and Type*: `boolean` *Purpose*: Invokes the balancer **NOTE:** The HPE Ezmeral Data Fabric Database does not require balancing. Therefore, the method is ignored. *Supported*: No
`cloneSnapshot(byte[] snapshotName, TableName tableName)`	*Modifier and Type*: `void` *Purpose*: Creates a new table by cloning the snapshot content *Supported*: No

cloneSnapshot(String snapshotName, TableName tableName)	*Modifier and Type*: `void` *Purpose*: Creates a new table by cloning the snapshot content *Supported*: No
close()	*Modifier and Type*: `void` *Purpose*: Releases any resources held *Supported*: Yes
closeRegion(byte[] regionname, String serverName)	*Modifier and Type*: `void` *Purpose*: Closes a region *Supported*: No
closeRegion(ServerName sn, HRegionInfo hri)	*Modifier and Type*: `void` *Purpose*: Closes a region *Supported*: No
closeRegion(String regionname, String serverName)	*Modifier and Type*: `void` *Purpose*: Closes a region *Supported*: No
closeRegionWithEncodedRegionName(String encodedRegionName, String serverName)	*Modifier and Type*: `boolean` *Purpose*: For expert administrators. *Supported*: No
compact(TableName tableName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a table *Supported*: No
compact(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Compacts a table *Supported*: No
compactRegion(byte[] regionName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a region *Supported*: No
compactRegion(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Compacts an individual region *Supported*: No
compactRegionServer(ServerName sn, boolean major)	*Modifier and Type*: `void` *Purpose*: Compacts all regions on the region server *Supported*: No
coprocessorService()	*Modifier and Type*: `CoprocessorRpcChannel` *Purpose*: Creates and returns a RpcChannel instance connected to the active master *Supported*: No
coprocessorService(ServerName sn)	*Modifier and Type*: `CoprocessorRpcChannel` *Purpose*: Creates and returns a RpcChannel instance connected to the active master *Supported*: No
createNamespace(NamespaceDescriptor descriptor)	*Modifier and Type*: `void`

	Purpose: Creates a new namespace *Supported*: No
createTable(HTableDescriptor desc, byte[] startKey, byte[] endKey, int numRegions)	*Modifier and Type*: `void` *Purpose*: Creates a new table with the specified number of regions *Supported*: Yes
createTable(HTableDescriptor desc, byte[][] splitKeys)	*Modifier and Type*: `void` *Purpose*: Creates a new table with an initial set of empty regions defined by the specified split keys *Supported*: Yes
createTable(HTableDescriptor desc)	*Modifier and Type*: `void` *Purpose*: Creates a new table *Supported*: Yes
createTableAsync(HTableDescriptor desc, byte[][] splitKeys)	*Modifier and Type*: `void` *Purpose*: Creates a new table but does not block and wait for it to come online **NOTE:** The HPE Ezmeral Data Fabric Database treats this method as synchronous and returns null when the table is created. *Supported*: Yes
deleteColumn(String tableName, String columnName)	*Modifier and Type*: `void` *Purpose*: Deletes a column from a table *Supported*: Yes
deleteColumn(TableName tableName, byte[] columnName)	*Modifier and Type*: `void` *Purpose*: Deletes a column from a table *Supported*: Yes
deleteNamespace(String name)	*Modifier and Type*: `void` *Purpose*: Deletes an existing namespace. *Supported*: No
deleteSnapshot(byte[] snapshotName)	*Modifier and Type*: `void` *Purpose*: Deletes an existing snapshot *Supported*: No
deleteSnapshot(String snapshotName)	*Modifier and Type*: `void` *Purpose*: Deletes an existing snapshot *Supported*: No
deleteSnapshots(Pattern pattern)	*Modifier and Type*: `void` *Purpose*: Deletes existing snapshots whose names match the specified pattern *Supported*: No
deleteSnapshots(String regex)	*Modifier and Type*: `void` *Purpose*: Deletes existing snapshots whose names match the specified pattern *Supported*: No
deleteTable(String tableName)	*Modifier and Type*: `void`

last-updated: Jun 06, 2024

	Purpose: Deletes a table *Supported*: Yes
deleteTable(byte[] tableName)	*Modifier and Type*: `void` *Purpose*: Deletes a table *Supported*: Yes
deleteTable(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Deletes a table *Supported*: Yes
deleteTables(Pattern pattern)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Delete tables that match the passed-in pattern, and waits on completion *Supported*: Yes
deleteTables(String regex)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Delete tables that match the passed-in regular expression, and waits on completion *Supported*: Yes
disableTable (String tableName)	*Modifier and Type*: `void` *Purpose*: Disables table, and waits for completion **NOTE:** The HPE Ezmeral Data Fabric Database does not require disabling of tables. Therefore, although it supports these methods, it only flags the table as disabled, and does not perform any other operation. *Supported*: Yes
disableTable(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Disables table, and waits for completion **NOTE:** The HPE Ezmeral Data Fabric Database does not require disabling of tables. Therefore, although it supports these methods, it only flags the table as disabled, and does not perform any other operation. *Supported*: Yes
disableTableAsync (String tableName)	*Modifier and Type*: `void` *Purpose*: Disables the table, but does not block and wait for it be completely disabled *Supported*: Yes
disableTableAsync(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Disables the table, but does not block and wait for it be completely disabled *Supported*: Yes
disableTables(Pattern pattern)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Disables tables that match the passed-in pattern, and waits on completion *Supported*: Yes
disableTables(String regex)	*Modifier and Type*: `HTableDescriptor[]`

last-updated: Jun 06, 2024

	Purpose: Disable tables that match the passed-in regular expression, and waits on completion *Supported*: Yes
enableCatalogJanitor(boolean enable)	*Modifier and Type*: `boolean` *Purpose*: Enables/Disables the catalog janitor *Supported*: No
enableTable(String tableName)	*Modifier and Type*: `void` *Purpose*: Enables a table **NOTE:** The HPE Ezmeral Data Fabric Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation. *Supported*: Yes
enableTable(bye[] tableName)	*Modifier and Type*: `void` *Purpose*: Enables a table **NOTE:** The HPE Ezmeral Data Fabric Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation. *Supported*: Yes
enableTable(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Enables a table **NOTE:** The HPE Ezmeral Data Fabric Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation. *Supported*: Yes
enableTableAsync (String tableName)	*Modifier and Type*: `void` *Purpose*: Enables the table, but does not block and wait for it be completely enabled *Supported*: Yes
enableTableAsync(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Enables the table, but does not block and wait for it be completely enabled *Supported*: Yes
enableTables(Pattern pattern)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Enable tables that match the passed-in pattern, and waits on completion *Supported*: Yes
enableTables(String regex)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Enable tables that match the passed-in regular expression. and waits on completion *Supported*: Yes
execProcedure(String signature, String instance, Map<String,String> props)	*Modifier and Type*: `void`

last-updated: Jun 06, 2024

	Purpose: Executes a distributed procedure on a cluster *Supported*: No
execProcedureWithRet(String signature, String instance, Map<String,String> props)	*Modifier and Type*: `>byte[]` *Purpose*: Executes a distributed procedure on a cluster. *Supported*: No
flush(TableName tableName)	*Modifier and Type*: `>void` *Purpose*: Flushes a table *Supported*: Yes
flush(byte[] tableNameOrRegionName)	*Modifier and Type*: `>void` *Purpose*: Flushes a table *Supported*: Yes
flush(String tableNameOrRegionName)	*Modifier and Type*: `>void` *Purpose*: Flushes a table *Supported*: Yes
flushRegion(byte[] regionName)	*Modifier and Type*: `>void` *Purpose*: Flushes an individual region *Supported*: Yes
getAlterStatus(byte[] tableName)	*Modifier and Type*: `Pair<Integer,Integer>` *Purpose*: Gets the status of the alter command - indicates the number of regions that have received the updated schema Asynchronous operation **NOTE:** The HPE Ezmeral Data Fabric Database always returns (0,0). *Supported*: No
getAlterStatus(TableName tableName)	*Modifier and Type*: `Pair<Integer,Integer>` *Purpose*: Gets the status of the alter command - indicates the number of regions that have received the updated schema Asynchronous operation **NOTE:** The HPE Ezmeral Data Fabric Database always returns (0,0). *Supported*: No
getClusterStatus()	*Modifier and Type*: `ClusterStatus` *Purpose*: Gets the status of the cluster *Supported*: No
getCompactionState(String tableNameOrRegionName)	*Modifier and Type*: `CompactionState` *Purpose*: Get the current compaction state of a table *Supported*: No
getCompactionState(TableName tableName)	*Modifier and Type*: `org.apache.hadoop.hbase.protobuf.generated.AdminProtos.GetRegionInfoResponse.CompactionState` *Purpose*: Gets the current compaction state of a table *Supported*: No

last-updated: Jun 06, 2024

getCompactionStateForRegion(byte[] regionName)	*Modifier and Type*: `org.apache.hadoop.hbase.protobuf.generated.AdminProtos.GetRegionInfoResponse.CompactionState` *Purpose*: Gets the current compaction state of a region *Supported*: No
getConfiguration()	*Modifier and Type*: `org.apache.hadoop.conf.Configuration` *Purpose*: Gets the configuration used by the instance *Supported*: Yes
getConnection()	*Modifier and Type*: `Connection` *Purpose*: Gets the connection used by this object *Supported*: Yes
getMasterCoprocessors()	*Modifier and Type*: `String[]` *Purpose*: Helper delegate to getClusterStatus().getMasterCoprocessors() *Supported*: No
getMasterInfoPort()	*Modifier and Type*: `int` *Purpose*: Gets the information port of the current master, if one is available *Supported*: No
getNamespaceDescriptor(String name)	*Modifier and Type*: `NamespaceDescriptor` *Purpose*: Gets a namespace descriptor by name *Supported*: No
getOnlineRegions(ServerName sn)	*Modifier and Type*: `List<HRegionInfo>` *Purpose*: Gets all the online regions on a region server *Supported*: No
getOperationTimeout()	*Modifier and Type*: `int` *Purpose*: The HPE Ezmeral Data Fabric Database never uses the timeout value **NOTE:** If you use the v1.1 API with the HPE Ezmeral Data Fabric Database, the method is ignored. *Supported*: No
getQuotaRetriever(QuotaFilter filter)	*Modifier and Type*: `QuotaRetriever` *Purpose*: Returns a QuotaRetriever to list the quotas based on the filter *Supported*: No
getTableDescriptor (byte[] tableName)	*Modifier and Type*: `HTableDescriptor` *Purpose*: Gets the table descriptor *Supported*: Yes
getTableDescriptor(TableName tableName)	*Modifier and Type*: `HTableDescriptor` *Purpose*: Gets the table descriptor *Supported*: Yes
getTableDescriptors(List<String> names)	*Modifier and Type*: `HTableDescriptor[]`

last-updated: Jun 06, 2024

	Purpose: Gets table descriptors *Supported*: Yes
getTableDescriptorsByTableName(List<TableName> tableNames)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Gets table descriptors *Supported*: Yes
getTableRegions (byte[] tableName)	*Modifier and Type*: `List<HRegionInfo>` *Purpose*: Gets the regions of a given table *Supported*: Yes
getTableRegions(TableName tableName)	*Modifier and Type*: `List<HRegionInfo>` *Purpose*: Gets the regions of a given table *Supported*: Yes
isAborted()	*Modifier and Type*: `boolean` *Purpose*: Queries on the catalog janitor state. The HPE Ezmeral Data Fabric Database always returns false. *Supported*: No
isCatalogJanitorEnabled()	*Modifier and Type*: `boolean` *Purpose*: Queries on the catalog janitor state. The HPE Ezmeral Data Fabric Database always returns false. *Supported*: No
isProcedureFinished(String signature, String instance, Map<String,String> props)	*Modifier and Type*: `boolean` *Purpose*: Checks the current state of the specified procedure *Supported*: No
isSnapshotFinished(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	*Modifier and Type*: `boolean` *Purpose*: Checks the current state of the passed snapshot *Supported*: No
isTableAvailable(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if all regions of the table are available *Supported*: Yes
isTableAvailable(TableName tableName, byte[][] splitKeys)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table has been created with the specified number of splitkeys that was used while creating the given table *Supported*: No
isTableAvailable(TableName tableName)>	*Modifier and Type*: `boolean` *Purpose*: Returns true if all regions of the table are available *Supported*: Yes
isTableDisabled(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is offline

	NOTE: Although the HPE Ezmeral Data Fabric Database supports this method, it only checks the flag. *Supported*: Yes
isTableDisabled(TableName tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is offline **NOTE:** Although the HPE Ezmeral Data Fabric Database supports this method, it only checks the flag. *Supported*: Yes
isTableEnabled(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is online **NOTE:** Although the HPE Ezmeral Data Fabric Database supports this method, it only checks the flag, and does not change the flag. *Supported*: Yes
isTableEnabled(TableName tableName)	*Modifier and Type*: `boolean` *Purpose*: Checks if the table is online **NOTE:** Although the HPE Ezmeral Data Fabric Database supports this method, it only checks the flag, and does not change the flag. *Supported*: Yes
listNamespaceDescriptors()	*Modifier and Type*: `NamespaceDescriptor[]` *Purpose*: Lists available namespace descriptors *Supported*: No
listSnapshots()	*Modifier and Type*: `List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>` *Purpose*: Lists completed snapshots *Supported*: No
listSnapshots(Pattern pattern)	*Modifier and Type*: `List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>` *Purpose*: Lists all the completed snapshots that match the given pattern *Supported*: No
listSnapshots(String regex)	*Modifier and Type*: `List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>` *Purpose*: Lists all the completed snapshots that match the given regular expression *Supported*: No
listTableDescriptorsByNamespace(String name)	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Gets the list of table descriptors by namespace *Supported*: No
listTableNames()	*Modifier and Type*: `TableName[]`

last-updated: Jun 06, 2024

	Purpose: Lists all the names of userspace tables *Supported*: Yes
`listTableNames(Pattern pattern, boolean includeSysTables)`	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified pattern *Supported*: Yes
`listTableNames(Pattern pattern)`	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified pattern *Supported*: Yes
`listTableNames(String regex, boolean includeSysTables)`	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified regular expression *Supported*: Yes
`listTableNames(String regex)`	*Modifier and Type*: `TableName[]` *Purpose*: Lists all the names of userspace tables that match the specified regular expression *Supported*: Yes
`listTableNamesByNamespace(String name)`	*Modifier and Type*: `TableName[]` *Purpose*: Gets the list of table names by namespace *Supported*: Yes
`listTables()`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the userspace tables *Supported*: Yes
`listTables(Pattern pattern, boolean includeSysTables)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the tables that match the given pattern. **NOTE:** The HPE Ezmeral Data Fabric Database does not have system tables and therefore, the boolean value is ignored. *Supported*: Yes
`listTables(Pattern pattern)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the userspace tables matching the given pattern. *Supported*: Yes
`listTables(String regex, boolean includeSysTables)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the tables matching the given pattern. **NOTE:** The HPE Ezmeral Data Fabric Database does not have system tables and therefore, the boolean value is ignored. *Supported*: Yes
`listTables(String regex)`	*Modifier and Type*: `HTableDescriptor[]` *Purpose*: Lists all the userspace tables that match the given regular expression. *Supported*: Yes

last-updated: Jun 06, 2024

majorCompact(byte[] tableNameOrRegionName)	*Modifier and Type*: `void` *Purpose*: Compacts a table, or an individual region. *Supported*: Deprecated
majorCompact(String tableNameOrRegionName)	*Modifier and Type*: `void` *Purpose*: Compacts a table, or an individual region. *Supported*: Deprecated
majorCompact(byte[] tableNameOrRegionName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a table, or a region *Supported*: Deprecated
majorCompact(String tableNameOrRegionName, String columnFamily)	*Modifier and Type*: `void` *Purpose*: Compact a column family within a table, or a region *Supported*: Deprecated
majorCompactRegion(byte[] regionName, byte[] columnFamily)	*Modifier and Type*: `void` *Purpose*: Compacts a column family within a region *Supported*: No
majorCompactRegion(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Compacts a table, or an individual region *Supported*: No
mergeRegions(byte[] nameOfRegionA, byte[] nameOfRegionB, boolean forcible)	*Modifier and Type*: `void` *Purpose*: Merges two regions *Supported*: No
modifyColumn(TableName tableName, HColumnDescriptor columnFamily)	*Modifier and Type*: `void` *Purpose*: Modifies an existing column family on a table *Supported*: Yes
modifyColumn(TableName tableName, HColumnDescriptor columnFamily)	*Modifier and Type*: `void` *Purpose*: Modifies an existing column family on a table *Supported*: Yes
modifyNamespace(NamespaceDescriptor descriptor)	*Modifier and Type*: `void` *Purpose*: Modifies an existing namespace *Supported*: No
modifyTable (byte[] tableName, HTableDescriptor htd)	*Modifier and Type*: `void` *Purpose*: Modifies an existing table *Supported*: Yes
modifyTable(final String tableName, final HTableDescriptor htd)	*Modifier and Type*: `void` *Purpose*: Modifies an existing table *Supported*: Yes
modifyTable(TableName tableName, HTableDescriptor htd)	*Modifier and Type*: `void` *Purpose*: Modifies an existing table. This method is the more IRB friendly version. *Supported*: Yes
move(byte[] encodedRegionName, byte[] destServerName)	*Modifier and Type*: `void`

last-updated: Jun 06, 2024

	Purpose: Moves the region to the destination *Supported*: No
offline(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Offlines specified region from master's in-memory state *Supported*: No
restoreSnapshot(byte[] snapshotName, boolean takeFailSafeSnapshot)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
restoreSnapshot(byte[] snapshotName)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
restoreSnapshot(String snapshotName, boolean takeFailSafeSnapshot)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
restoreSnapshot(String snapshotName)	*Modifier and Type*: `void` *Purpose*: Restores the specified snapshot on the original table *Supported*: No
rollWALWriter(ServerName serverName)	*Modifier and Type*: `void` *Purpose*: Rolls the log writer. *Supported*: No
runCatalogScan()	*Modifier and Type*: `int` *Purpose*: Requests a scan of the catalog table *Supported*: No
setBalancerRunning(boolean on, boolean synchronous)	*Modifier and Type*: `boolean` *Purpose*: Turns the load balancer on or off **NOTE:** The HPE Ezmeral Data Fabric Database does not require balancing. Therefore, the method just sets a flag. There is no impact on the MapR table. *Supported*: No
setQuota(QuotaSettings quota)	*Modifier and Type*: `void` *Purpose*: Applies the new quota settings *Supported*: No
shutdown()	*Modifier and Type*: `void` *Purpose*: Shuts down the HBase cluster *Supported*: No
snapshot(byte[] snapshotName, TableName tableName)	*Modifier and Type*: `void` *Purpose*: Creates a timestamp consistent snapshot for the given table *Supported*: No

last-updated: Jun 06, 2024

snapshot(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	*Modifier and Type*: `void` *Purpose*: Takes a snapshot, and waits for the server to complete that snapshot (blocking). *Supported*: No
snapshot(String snapshotName, TableName tableName, org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription.Type type)	*Modifier and Type*: `void` *Purpose*: Creates a typed snapshot of the table *Supported*: No
snapshot(String snapshotName, TableName tableName)	*Modifier and Type*: `void` *Purpose*: Takes a snapshot for the given table *Supported*: No
split(byte[] tableNameOrRegionName)	*Modifier and Type*: `void` *Purpose*: Splits a table **NOTE:** The tableNameOrRegionName parameter has a different format when used with MapR tables than with Apache HBase tables. With MapR tables, specify both the table path and the FID as a comma-separated list. *Supported*: Yes
split(TableName tableName, byte[] splitPoint)	*Modifier and Type*: `void` *Purpose*: Splits a table. **NOTE:** The tableNameOrRegionName parameter has a different format when used with MapR tables than with Apache HBase tables. With MapR tables, specify both the table path and the FID as a comma-separated list. *Supported*: No
split(TableName tableName)	*Modifier and Type*: `void` *Purpose*: Splits a table. **NOTE:** The tableNameOrRegionName parameter has a different format when used with MapR tables than with Apache HBase tables. With MapR tables, specify both the table path and the FID as a comma-separated list. *Supported*: Yes
splitRegion(byte[] regionName, byte[] splitPoint)	*Modifier and Type*: `void` *Purpose*: Splits an individual region. *Supported*: No
splitRegion(byte[] regionName)	*Modifier and Type*: `void` *Purpose*: Splits an individual region *Supported*: Yes
stopMaster()	*Modifier and Type*: `void` *Purpose*: Shuts down the current HBase master only *Supported*: No
stopRegionServer(String hostnamePort)	*Modifier and Type*: `void` *Purpose*: Stops the designated region server

last-updated: Jun 06, 2024

	Supported: No
tableExists(TableName tableName)	*Modifier and Type*: `boolean` *Purpose*: Returns whether a table with the specified name exists *Supported*: Yes
tableExists(byte[] tableName)	*Modifier and Type*: `boolean` *Purpose*: Returns whether a table with the specified name exists *Supported*: Yes
tableExists(String tableName)	*Modifier and Type*: `boolean` *Purpose*: Returns whether a table with the specified name exists *Supported*: Yes
takeSnapshotAsync(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	*Modifier and Type*: `org.apache.hadoop.hbase.protobuf.generated.MasterProtos.SnapshotResponse` *Purpose*: Takes a snapshot without waiting for the server to complete that snapshot (asynchronous). Ensure that you take only a single snapshot at a time, or the results may be undefined. *Supported*: No
truncateTable(TableName tableName, boolean preserveSplits)	*Modifier and Type*: `void` *Purpose*: Truncates a table *Supported*: Yes
unassign(byte[] regionName, boolean force)	*Modifier and Type*: `void` *Purpose*: Unassigns a region from the current hosting region server *Supported*: No
updateConfiguration()	*Modifier and Type*: `void` *Purpose*: Updates the configuration, and triggers an online configuration change on all the region servers *Supported*: No
updateConfiguration(ServerName server)	*Modifier and Type*: `void` *Purpose*: Updates the configuration, and triggers an online configuration change on all the region servers *Supported*: No

BufferedMutator Method Support

This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase interface `BufferedMutator`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted.

Method Name	Modifier and Type	Description	Supported?
`close()`	void	Performs a flush() and releases any resources held.	Yes

last-updated: Jun 06, 2024

Method Name	Modifier and Type	Description	Supported?
`flush()`	void	Executes all the buffered, asynchronous Mutation operations and waits until they are done.	Yes
`getConfiguration()`	org.apache.hadoop.conf.Configuration	Returns the Configuration object used by this instance.	Yes
`getName()`	TableName	Gets the fully qualified table name instance of the table that this BufferedMutator writes to.	Yes
`getWriteBuffer()`	long	Get the internal write buffer.	No
`getWriteBufferSize()`	long	Returns the maximum size in bytes of the write buffer for this HTable.	No
`mutate(List<? extends Mutation> mutations)`	void	Send some Mutation objects to the table.	Yes
`mutate(Mutation mutation)`	void	Sends a Mutation to the table.	Yes
`setWriteBufferSize()`	long	Sets the maximum size (in bytes) of the write buffer for this HTable	No

Connection Method Support
This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase interface `Connection`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted. For full details about this interface, see `Interface Connection`.

Method Name	Modifier and Type	Description	Supported?
`close()`	void	Close this connection.	Yes
`getAdmin()`	Admin	Retrieve an Admin implementation to administer an HBase cluster.	Yes
`getBufferedMutator(BufferedMutatorParams params)`	BufferedMutator	Retrieve a BufferedMutator for performing client-side buffering of writes.	Yes
`getBufferedMutator(TableName tableName)`	BufferedMutator		Yes
`getConfiguration()`	org.apache.hadoop.conf.Configuration	Retrieve the Configuration object used by this connection.	Yes
`getRegionLocator(TableName tableName)`	RegionLocator	Retrieve a RegionLocator implementation to inspect region information on a table.	Yes

last-updated: Jun 06, 2024

Method Name	Modifier and Type	Description	Supported?
`getTable(TableName tableName)`	Table	Retrieve a Table implementation for accessing a table.	Yes
`getTable(TableName tableName, ExecutorService pool)`	Table		Yes
`isClosed()`	boolean	Returns whether the connection is closed or not.	Yes

ConnectionFactory Method Support
This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase class `ConnectionFactory`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted. For full details about this class, see the `ConnectionFactory` class in the Client package..

Method Name	Modifier and Type	Description	Supported?
`createConnection()`	static Connection	Create a new Connection instance using default HBaseConfiguration.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf, ExecutorService pool)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf, ExecutorService pool, User user)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes
`createConnection(org.apache.hadoop.conf.Configuration conf, User user)`	static Connection	Create a new Connection instance using the passed conf instance.	Yes

RegionLocator Method Support
This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase interface `RegionLocator`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted. For full details about this interface, see `Interface RegionLocator` interface in the Client package.

Method Name	Modifier and Type	Description	Supported?
`close()`	void	Close this connection.	Yes
`getAllRegionLocations()`	List<HRegionLocation>	Retrieves all of the regions associated with this table.	Yes
`getConfiguration()`	Configuration	Retrieve the Configuration Object used by this RegionLocator.	Yes

last-updated: Jun 06, 2024

Method Name	Modifier and Type	Description	Supported?
`getEndKeys()`	byte[][]	Gets the ending row key for every region in the currently open table.	Yes
`getName()`	TableName	Gets the fully qualified table name instance of this table.	Yes
`getRegionLocation(byte[] row)`	HRegionLocation	Finds the region on which the given row is being served.	Yes
`getRegionLocation(byte[] row, boolean reload)`	HRegionLocation		Yes
`getStartEndKeys()`	Pair<byte[][],byte[][]>	Gets the starting and ending row keys for every region in the currently open table.	Yes
`getStartKeys()`	byte[][]	Gets the starting row key for every region in the currently open table.	Yes

Table Method Support
This table indicates which methods HPE Ezmeral Data Fabric Database supports in the HBase interface `Table`.

The following HBase methods are supported with HPE Ezmeral Data Fabric Database tables, except where noted. For full details about this interface, see `Interface Table` in the Client package.

Method Name	Modifier and Type	Description	Supported?
`append(Append append)`	Result	Appends values to one or more columns within a single row.	Yes
`batch(List<? extends Row> actions)`	Object[]	A batch call on Deletes, Gets, Puts, Increments, Appends and RowMutations.	Deprecated
`batch(List<? extends Row> actions, Object[] results)`	void	Method that does a batch call on Deletes, Gets, Puts, Increments and Appends.	Yes
`batchCallback(List<? extends Row> actions, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	Object[]	Method that does a batch call on Deletes, Gets, Puts, Increments and Appends with a callback.	YesFootnote.

[1] Not fully supported. When used with HPE Ezmeral Data Fabric Database, the callback is ignored.
[2] Not fully supported. When used with HPE Ezmeral Data Fabric Database, the durability is ignored.

last-updated: Jun 06, 2024

Method Name	Modifier and Type	Description	Supported?
`batchCallback(List<? extends Row> actions, Object[] results, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	<R> void	Same as batch(List, Object[]), but with a callback. HPE Ezmeral Data Fabric Database ignores the callback.	YesFootnote.
`batchCoprocessorService(com.google.protobuf.Descriptors.MethodDescriptor methodDescriptor, com.google.protobuf.Message request, byte[] startKey, byte[] endKey, R responsePrototype, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	<R extends com.google.protobuf.Message> void	Creates an instance of the given Service subclass for each table region spanning the range from the startKey row to endKey row (inclusive), all the invocations to the same region server will be batched into one call.	No
`batchCoprocessorService(com.google.protobuf.Descriptors.MethodDescriptor methodDescriptor, com.google.protobuf.Message request, byte[] startKey, byte[] endKey, R responsePrototype)`	<R extends com.google.protobuf.Message> Map<byte[],R>		No

last-updated: Jun 06, 2024

Method Name	Modifier and Type	Description	Supported?
`checkAndDelete(byte[] row, byte[] family, byte[] qualifier, byte[] value, Delete delete)`	boolean	Atomically checks if a row/family/qualifier value matches the expected value.	Yes
`checkAndDelete(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, Delete delete)`	boolean		Yes
`checkAndMutate(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, RowMutations mutation)`	boolean		Yes
`checkAndPut(byte[] row, byte[] family, byte[] qualifier, byte[] value, Put put)`	boolean		Yes
`checkAndPut(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, Put put)`	boolean		Yes
`close()`	void	Releases any resources held or pending changes in internal buffers.	Yes
`coprocessorService(byte[] row)`	CoprocessorRpcChannel	Creates and returns a RpcChannel instance connected to the table region containing the specified row.	No

last-updated: Jun 06, 2024

Method Name	Modifier and Type	Description	Supported?
`coprocessorService(Class<T> service, byte[] startKey, byte[] endKey, org.apache.hadoop.hbase.client.coprocessor.Batch.Call<T,R> callable, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)`	<T extends com.google.protobuf.Service,R> void	Creates an instance of the given Service subclass for each table region spanning the range from the startKey row to endKey row (inclusive), and invokes the passed Batch.Call.call(T) method with each Service instance.	No
`coprocessorService(Class<T> service, byte[] startKey, byte[] endKey, org.apache.hadoop.hbase.client.coprocessor.Batch.Call<T,R> callable)`	<T extends com.google.protobuf.Service,R> Map<byte[],R>		No
`delete(Delete delete)`	void	Deletes the specified cells/row.	Yes
`delete(List<Delete> deletes)`	void	Deletes the specified cells/rows in bulk.	Yes
`exists(Get get)`	boolean	Test for the existence of columns in the table, as specified by the Get.	Yes
`existsAll(List<Get> gets)`	boolean[]	Test for the existence of columns in the table, as specified by the Gets, in batch.	Yes
`get(Get get)`	Result	Extracts certain cells from a given row.	Yes
`get(List<Get> gets)`	Result[]	Extracts certain cells from the given rows, in batch.	Yes
`getConfiguration()`	org.apache.hadoop.conf.Configuration	Returns the Configuration object used by this instance.	Yes
`getName()`	TableName	Gets the fully qualified table name instance of this table.	Yes
`getScanner(byte[] family, byte[] qualifier)`	ResultScanner	Gets a scanner on the current table for the given family and qualifier.	Yes
`getScanner(byte[] family)`	ResultScanner	Gets a scanner on the current table for the given family.	Yes
`getScanner(Scan scan)`	ResultScanner	Returns a scanner on the current table as specified by the Scan object.	Yes
`getTableDescriptor()`	HTableDescriptor	Gets the table descriptor for this table.	Yes
`getWriteBufferSize()`	long	Returns the maximum size in bytes of the write buffer for this HTable.	No

last-updated: Jun 06, 2024

Method Name	Modifier and Type	Description	Supported?
`increment(Increment increment)`	Result	Increments one or more columns within a single row.	Yes
`incrementColumnValue(byte[] row, byte[] family, byte[] qualifier, long amount, Durability durability)`	long	Atomically increments a column value.	YesFootnote.
`incrementColumnValue(byte[] row, byte[] family, byte[] qualifier, long amount)`	long	See incrementColumnValue(byte[], byte[], byte[], long, Durability).	Yes
`mutateRow(RowMutations rm)`	void	Performs multiple mutations atomically on a single row.	Yes
`put(List<Put> puts)`	void	Puts some data in the table, in batch.	Yes
`put(Put put)`	void	Puts some data in the table.	Yes
`setWriteBufferSize(long writeBufferSize)`	void	Sets the size of the buffer in bytes.	No

HColumnDescriptor and HTableDescriptor Support
This section describes the supported fields in the HColumnDescriptor and the HTableDescriptor classes.

HPE Ezmeral Data Fabric Database supports all of the methods that are in these classes. However, it supports only a subset of their fields.

HColumnDescriptor Class

Field	Description
BLOCKSIZE	Size of blocks in files stored to the filesytem (hfiles).
BLOOMFILTER	Whether or not to use bloomfilters.
COMPRESSION	Compression type.
IN_MEMORY	Whether to serve from memory or not.
MIN_VERSIONS	Minimum number of versions to keep.
NAME	Name of the column family.
TTL	Time to live of cell contents.
VERSIONS	Number of versions to keep.

HTableDescriptor Class

Field	Description
AUTOSPLIT	Specifies whether to split the table into regions automatically as the table grows. The average size of each region is determined by the`regionsizemb` parameter. The default value is `true`.

last-updated: Jun 06, 2024

Field	Description
BULKLOAD	Boolean. Specifies whether to perform a full bulk load of the table. The default is `false`. For more information, see Bulk Loading and MapR Tables.

last-updated: Jun 06, 2024

Field	Description
DELETE_TTL	Used for multi-master replication. Normally, delete operations are purged after the affected table cells are updated. Whereas the result of an update is saved in a table until another change overwrites or deletes it, the result of a delete is not saved. In multi-master replication, this difference can lead to tables being unsynchronized. Example Suppose that you have set up multi-master replication between table `customers` in the cluster `sanfrancisco` and table `customers` in the cluster `newyork`. Client applications then make these two changes: **1.** On `/mapr/sanfrancisco/customers`, put row A at 10:00:00 AM. **2.** On `/mapr/newyork/customers`, delete row A at 10:00:01 AM. On `/mapr/sanfrancisco/customers`, the order of operations is: **1.** Put row A with a timestamp of 10:00:00 AM **2.** Delete row A with a timestamp of 10:00:01 AM (This operation is repllicated from `/mapr/newyork/customers`.) On `/mapr/newyork/customers`, the order of operations is: **1.** Delete row A with a timestamp of 10:00:01 AM **2.** Put row A with a timestamp of 10:00:00 AM (This operation is replicated from `/mapr/sanfrancisco/customers`.) Now, though the put happened on `/mapr/sanfrancisco/customers` at 10:00:00 AM, the put reaches `/mapr/newyork/customers` several seconds after that. Suppose that the actual time that the put arrives at `/mapr/newyork/customers` is 10:00:03 AM. To ensure that both tables stay synchronized, `/mapr/newyork/customers` should preserve the delete until after the put is replicated. Then, the delete can be applied after the put. Therefore, the time-to-live for the delete should be at least long enough for the put to arrive at `/mapr/newyork/customers`. In this case, the time-to-live should be at least 3 seconds. In general, the time-to-live for deletes should be greater than the amount of time that it takes replicated operations to reach replicas. By default, the value is 24 hours. For example, suppose (to extend the scenario above) that you pause replication during weekdays and resume it on weekends. The put takes place on Monday morning `/mapr/sanfrancisco/customers` at 10:00:00 AM and the delete takes place at `/mapr/newyork/customers` at 10:00:01 AM. Replication does not resume until 12:00:00 AM Saturday morning. Given the volume of operations to be replicated and the potential for network problems, it is possible that these operations will not be replicated until Sunday. In this scenario, a value of 7 days for DELETE_TTL (7 multiplied by 24 hours) should provide sufficient margin.

Field	Description
NAME	Name of the table.

Support for HBase Java Filters Support

HPE Ezmeral Data Fabric Database supports the following Java filters, which work identically to their Apache HBase versions. See the Apache HBase API for more information, specifically, the Apache HBase Filter package.

Filter	Description
`ColumnCountGetFilter`	Simple filter that returns first N columns on row only. This filter was written to test filters in Get and as soon as it gets its quota of columns, `filterAllRemaining()` returns true. This makes this filter unsuitable as a Scan filter.
`ColumnPaginationFilter`	A filter, based on the `ColumnCountGetFilter`, takes two arguments: limit and offset. This filter can be used for row-based indexing, where references to other tables are stored across many columns, in order to efficient lookups and paginated results for end users. Only most recent versions are considered for pagination.
`ColumnPrefixFilter`	This filter is used for selecting only those keys with columns that matches a particular prefix. For example, if prefix is 'an', it will pass keys with columns like 'and', 'anti' but not keys with columns like 'ball', 'act'.
`ColumnRangeFilter`	This filter is used for selecting only those keys with columns that are between minColumn to maxColumn. For example, if minColumn is 'an', and maxColumn is 'be', it will pass keys with columns like 'ana', 'bad', but not keys with columns like 'bed', 'eye' If minColumn is null, there is no lower bound. If maxColumn is null, there is no upper bound. minColumnInclusive and maxColumnInclusive specify if the ranges are inclusive or not.
`DependentColumnFilter`	A filter for adding inter-column timestamp matching Only cells with a correspondingly timestamped entry in the target column will be retained Not compatible with Scan.setBatch as operations need full rows for correct filtering
`FamilyFilter`	This filter is used to filter based on the column family. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the column family portion of a key. This filter can be wrapped with `WhileMatchFilter` and `SkipFilter` to add more control. Multiple filters can be combined using `FilterList` . If an already known column family is looked for, use `Get.addFamily(byte[])` directly rather than a filter.

last-updated: Jun 06, 2024

Filter	Description
`FilterList`	Implementation of `Filter` that represents an ordered List of Filters which will be evaluated with a specified boolean operator `FilterList.Operator.MUST_PASS_ALL` (`AND`) or `FilterList.Operator.MUST_PASS_ONE` (`OR`). Since you can use Filter Lists as children of Filter Lists, you can create a hierarchy of filters to be evaluated. `FilterList.Operator.MUST_PASS_ALL` evaluates lazily: evaluation stops as soon as one filter does not include the KeyValue. `FilterList.Operator.MUST_PASS_ONE` evaluates non-lazily: all filters are always evaluated. Defaults to `FilterList.Operator.MUST_PASS_ALL` .
`FirstKeyOnlyFilter`	A filter that will only return the first KV from each row. This filter can be used to more efficiently perform row count operations.
`FirstKeyValueMatchingQualifiersFilter`	The filter looks for the given columns in KeyValue. Once there is a match for any one of the columns, it returns ReturnCode.NEXT_ROW for remaining KeyValues in the row. **Note**: It may emit KVs which do not have the given columns in them, if these KVs happen to occur before a KV which does have a match. Given this caveat, this filter is only useful for special cases like `RowCounter` .
`FuzzyRowFilter`	Filters data based on fuzzy row key. Performs fast-forwards during scanning. It takes pairs (row key, fuzzy info) to match row keys. Where fuzzy info is a byte array with 0 or 1 as its values: • 0 - means that this byte in provided row key is fixed, i.e. row key's byte at same position must match • 1 - means that this byte in provided row key is NOT fixed, i.e. row key's byte at this position can be different from the one in provided row key Example: Let's assume row key format is userId_actionId_year_month. Length of userId is fixed and is 4, length of actionId is 2 and year and month are 4 and 2 bytes long respectively. Let's assume that we need to fetch all users that performed certain action (encoded as "99") in Jan of any year. Then the pair (row key, fuzzy info) would be the following: row key = "????_99_????_01" (one can use any value instead of "?") fuzzy info = "\x01\x01\x01\x01\x00\x00\x00\x00\x01\x01\x01\x01\x00\x00\x00" I.e. fuzzy info tells the matching mask is "????_99_????_01", where at ? can be any value.
`InclusiveStopFilter`	A Filter that stops after the given row. There is no "RowStopFilter" because the Scan spec allows you to specify a stop row. Use this filter to include the stop row, eg: [A,Z].
`KeyOnlyFilter`	A filter that will only return the key component of each KV (the value will be rewritten as empty). This filter can be used to grab all of the keys without having to also grab the values.

last-updated: Jun 06, 2024

Filter	Description
`MultipleColumnPrefixFilter`	This filter is used for selecting only those keys with columns that matches a particular prefix. For example, if prefix is 'an', it will pass keys will columns like 'and', 'anti' but not keys with columns like 'ball', 'act'.
`PageFilter`	Implementation of Filter interface that limits results to a specific page size. It terminates scanning once the number of filter-passed rows is > the given page size. Note that this filter cannot guarantee that the number of results returned to a client are <= page size. This is because the filter is applied separately on different region servers. It does however optimize the scan of individual HRegions by making sure that the page size is never exceeded locally.
`PrefixFilter`	Pass results that have same row prefix.
`QualifierFilter`	This filter is used to filter based on the column qualifier. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the column qualifier portion of a key. This filter can be wrapped with `WhileMatchFilter` and `SkipFilter` to add more control. Multiple filters can be combined using `FilterList` . If an already known column qualifier is looked for, use `Get.addColumn(byte[], byte[])` directly rather than a filter.
`RandomRowFilter`	A filter that includes rows based on a chance.
`RowFilter`	This filter is used to filter based on the key. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the row, and column qualifier portions of a key. This filter can be wrapped with `WhileMatchFilter` to add more control. Multiple filters can be combined using `FilterList`. If an already known row range needs to be scanned, use `CellScanner` start and stop rows directly rather than a filter.
`SingleColumnValueExcludeFilter`	A `Filter` that checks a single column value, but does not emit the tested column. This will enable a performance boost over `SingleColumnValueFilter` , if the tested column value is not actually needed as input (besides for the filtering itself).

last-updated: Jun 06, 2024

Filter	Description
`SingleColumnValueFilter`	This filter is used to filter cells based on value. It takes a `CompareFilter.CompareOp` operator (equal, greater, not equal, etc), and either a byte [] value or a ByteArrayComparable. If we have a byte [] value then we just do a lexicographic compare. For example, if passed value is 'b' and cell has 'a' and the compare operator is LESS, then we will filter out this cell (return true). If this is not sufficient (eg you want to deserialize a long and then compare it to a fixed long value), then you can pass in your own comparator instead. You must also specify a family and qualifier. Only the value of this column will be tested. When using this filter on a `CellScanner` with specified inputs, the column to be tested should also be added as input (otherwise the filter will regard the column as missing). To prevent the entire row from being emitted if the column is not found on a row, use `setFilterIfMissing(boolean)` . Otherwise, if the column is found, the entire row will be emitted only if the value passes. If the value fails, the row will be filtered out. In order to test values of previous versions (timestamps), set `setLatestVersionOnly(boolean)` to false. The default is true, meaning that only the latest version's value is tested and all previous versions are ignored. To filter based on the value of all scanned columns, use `ValueFilter`.
`SkipFilter`	A wrapper filter that filters an entire row if any of the Cell checks do not pass. For example, if all columns in a row represent weights of different things, with the values being the actual weights, and we want to filter out the entire row if any of its weights are zero. In this case, we want to prevent rows from being emitted if a single key is filtered. Combine this filter with a `ValueFilter`: `scan.setFilter(new SkipFilter(new ValueFilter(CompareOp.NOT_EQUAL, new BinaryComparator(Bytes.toBytes(0))));` Any row which contained a column whose value was 0 will be filtered out (since ValueFilter will not pass that Cell). Without this filter, the other non-zero valued columns in the row would still be emitted.
`TimestampsFilter`	Filter that returns only cells whose timestamp (version) is in the specified list of timestamps (versions). Note: Use of this filter overrides any time range/time stamp options specified using `Get.setTimeRange(long, long)`, `Scan.setTimeRange(long, long)`, or `Scan.setTimeStamp(long)`. See the Apache HBase API, Client package for detailed information.

last-updated: Jun 06, 2024

Filter	Description
`ValueFilter`	This filter is used to filter based on column value. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the cell value. This filter can be wrapped with `WhileMatchFilter` and `SkipFilter` to add more control. Multiple filters can be combined using `FilterList`. To test the value of a single qualifier when scanning multiple qualifiers, use `SingleColumnValueFilter`.
`WhileMatchFilter`	A wrapper filter that returns true from `filterAllRemaining()` as soon as the wrapped filters `Filter.filterRowKey(byte[], int, int)`, `Filter.filterKeyValue(org.apache.hadoop.hbase.Cell)`, `Filter.filterRow()` or `Filter.filterAllRemaining()` methods returns true.

HBase Java Regular Expressions Support

This topics defines the subset of Java regular expressions that are supported for HPE Ezmeral Data Fabric Database tables.

Filters used with Scan operations support regular expressions. When you filter scans on HPE Ezmeral Data Fabric Database tables, you can use regular expressions that comprise the Perl-Compatible Regular Expressions library, as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`.

Characters

Pattern	Description
x	The character x
\\	The backslash character
\0n	The character with octal value 0n (0 <= n <= 7)
\0nn	The character with octal value 0nn (0 <= n <= 7)
\xhh	The character with hexadecimal value 0xhh
\t	The tab character ('\u0009')
\n	The newline (line feed) character ('\u000A')
\r	The carriage-return character ('\u000D')
\f	The form-feed character ('\u000C')
\a	The alert (bell) character ('\u0007')
\e	The escape character ('\u001B')
\cx	The control character corresponding to x

last-updated: Jun 06, 2024

Character Classes

Pattern	Description
[abc]	a, b, or c (simple class)
[Supported Regular Expressions in MapR Tables^abc]	Any character except a, b, or c (negation)
[a-zA-Z]	a through z or A through Z, inclusive (range)

Predefined Character Classes

Pattern	Description
.	Any character (may or may not match line terminators)
\d	A digit: [0-9]
\D	A non-digit: [Supported Regular Expressions in MapR Tables^0-9]
\s	A whitespace character: [\t\n\x0B\f\r]
\S	A non-whitespace character: [Supported Regular Expressions in MapR Tables^\s]
\w	A word character: [a-zA-Z_0-9]
\W	A non-word character: [Supported Regular Expressions in MapR Tables^\w]

Classes for Unicode Blocks and Categories

Pattern	Description
\p{Lu}	An uppercase letter (simple category)
\p{Sc}	A currency symbol

Boundaries

Pattern	Description
^	The beginning of a line
$	The end of a line
\b	A word boundary
\B	A non-word boundary
\A	The beginning of the input
\G	The end of the previous match
\Z	The end of the input but for the final terminator, if any

last-updated: Jun 06, 2024

Pattern	Description
\z	The end of the input

Greedy Quantifiers

Pattern	Description
X?	X, once or not at all
X*	X, zero or more times
X+	X, one or more times
X{n}	X, exactly n times
X{n,}	X, at least n times
X{n,m}	X, at least n but not more than m times

Reluctant Quantifiers

Pattern	Description
X??	X, once or not at all
X*?	X, zero or more times
X+?	X, one or more times
X{n}?	X, exactly n times
X{n,}?	X, at least n times
X{n,m}?	X, at least n but not more than m times

Possessive Quantifiers

Pattern	Description
X?+	X, once or not at all
X*+	X, zero or more times
X++	X, one or more times
X{n}+	X, exactly n times
X{n,}+	X, at least n times
X{n,m}+	X, at least n but not more than m times

last-updated: Jun 06, 2024

Logical Operators

Pattern	Description
XY	X followed by Y
X|Y	Either X or Y
(X)	X, as a capturing group

Back References

Pattern	Description
\n	Whatever the nth capturing group matches

Quotation

Pattern	Description
\	Nothing, but quotes the following character
\Q	Nothing, but quotes all characters until \E
\E	Nothing, but ends quoting started by \Q

Special Constructs

Pattern	Description
(?:X)	X, as a non-capturing group
(?=X)	X, via zero-width positive lookahead
(?!X)	X, via zero-width negative lookahead
(?<=X)	X, via zero-width positive lookbehind
(?<!X)	X, via zero-width negative lookbehind
(?>X)	X, as an independent, non-capturing group

HBase Java Comparators Support

HPE Ezmeral Data Fabric Database supports the following Java filters, which work identically to their Apache HBase versions. See the Apache HBase API for more information, specifically, the Apache HBase Filter package.

Comparator	Description
`>BinaryComparator`	A binary comparator which lexicographically compares against the specified byte array using `Bytes.compareTo(byte[], byte[])`.
`BinaryPrefixComparator`	A comparator which compares against a specified byte array, but only compares up to the length of this byte array. For the rest it is similar to BinaryComparator.

last-updated: Jun 06, 2024

Comparator	Description
`BitComparator`	A bit comparator which performs the specified bitwise operation on each of the bytes with the specified byte array. Then returns whether the result is non-zero.
`NullComparator`	A binary comparator which lexicographically compares against the specified byte array using `Bytes.compareTo(byte[], byte[])`.
`RegexStringComparator`	This comparator is for use with `CompareFilter` implementations, such as `RowFilter` , `QualifierFilter` , and `ValueFilter` , for filtering based on the value of a given column. Use it to test if a given regular expression matches a cell value in the column. Only EQUAL or NOT_EQUAL comparisons are valid with this comparator. For example: `ValueFilter vf = new ValueFilter(CompareOp.EQUAL, new RegexStringComparator(// v4 IP address "(((25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?)\\.){3,3}" + "(25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?))(\\/[0-9]+)?" + "|" + // v6 IP address "((([\\dA-Fa-f]{1,4}:){7}[\\dA-Fa-f]{1,4})(:([\\d]{1,3}.)" + "{3}[\\d]{1,3})?)(\\/[0-9]+)?"));`
`SubstringComparator`	This comparator is for use with SingleColumnValueFilter, for filtering based on the value of a given column. Use it to test if a given substring appears in a cell value in the column. The comparison is case insensitive. Only EQUAL or NOT_EQUAL tests are valid with this comparator. For example: `SingleColumnValueFilter scvf = new SingleColumnValueFilter("col", CompareOp.EQUAL, new SubstringComparator("substr"));`

Unsupported HBase Java Methods

This topic identifies the HBase Java methods that are not supported for HPE Ezmeral Data Fabric Database tables. Attempts to call any of these methods results in an `UnsupportedOperationException` exception.

Methods for ACLs for cells:

- `Put.setACL(String user, org.apache.hadoop.hbase.security.access.Permission perms)`

last-updated: Jun 06, 2024

- `Append.setACL(Map<String,org.apache.hadoop.hbase.security.access.Permission> perms)`
- `Delete.setACL(Map<String,org.apache.hadoop.hbase.security.access.Permission> perms)`
- `Increment.setACL(Map<String,org.apache.hadoop.hbase.security.access.Permission> perms)`

Methods for cell visibility:

- `Put.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Append.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Delete.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Increment.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`

Methods for time-to-live for cell values:

- `Put.setTTL(long ttl)`
- `Append.setTTL(long ttl)`
- `Delete.setTTL(long ttl)`
- `Increment.setTTL(long ttl)`

Other methods

- `Delete.deleteFamilyVersion(byte[] family, long timestamp)`
- `Scan.setReversed(boolean reversed)`
- `Scan.setBatch()`
- `Scan.setCaching()`
- `Scanner.next(int nbRows)`

Impersonation through the HBase REST Gateway
Impersonation enables access to tables via user IDs other than the user that runs the Gateway.

You can enable user impersonation to access HPE Ezmeral Data Fabric Database tables via the HBase REST Gateway. This feature is not supported in earlier combinations of MapR and HBase packages.

Impersonation is only supported if the REST Gateway is running as the mapr user (MAPR_USER).

You can enable impersonation via the Gateway on both non-secure and secure MapR clusters (secured using either MapR SASL or Kerberos). HPE Ezmeral Data Fabric Database does not support gateway impersonation using a Thrift interface.

NOTE: Impersonation for HBase REST Gateway is enabled by default on secure clusters.

last-updated: Jun 06, 2024

Enabling Impersonation on a Non-Secure Cluster

About this task
To enable impersonation on a non-secure cluster, follow these steps:

Procedure
1. Install the `mapr-hbase` package on a cluster that is running version 4.0.2 or later. This package contains all of the HBase binaries. For installation details, see HBase Client and HPE Ezmeral Data Fabric Database.
2. Enable simple authentication via the REST Gateway by appending the following property to the `hbase-site.xml` file (`/opt/mapr/hbase/hbase<hbase_version>/conf/hbase-site.xml`): The simple authentication protocol is a Hadoop pseudo authenticator that serves as an example and is part of the hadoop-common package.

   ```
   <property>
   <name>hbase.rest.authentication.type</name>
   <value>simple</value>
   </property>
   ```

3. Set the following environment variable to enable impersonation:

   ```
   export MAPR_IMPERSONATION_ENABLED=1
   ```

4. Start the REST Gateway server as the MAPR_USER.

   ```
   /opt/mapr/hbase/hbase<hbase_version>/bin/hbase-daemon.sh start rest -p
   port
   ```

Using Custom Authentication
This section describes how to use Hadoop pseudo authentication for custom authentication.

About this task
Editing the `hbase-site.xml` file is the procedure to follow if you want to use Hadoop pseudo authentication. Alternatively, you can write and use your own authenticator to substitute for the "simple" configuration by implementing the Hadoop AuthenticationHandler interface. If you are using custom authentication, place your authenticator jar in the following directory:

```
/opt/mapr/hbase/hbase-<hbase_version>/lib/
```

Then start the REST Gateway.

Mapping to HBase Table Namespaces
This section describes mapping table namespaces between Apache HBase tables and HPE Ezmeral Data Fabric Database binary tables.

The MapR implementations of the HBase Java API and libhbase differentiate between Apache HBase tables and HPE Ezmeral Data Fabric Database tables according to table names. In certain cases, such as migrating code from Apache HBase tables to HPE Ezmeral Data Fabric Database tables, users need to force the API they are using to access a HPE Ezmeral Data Fabric Database table, even though the table name could map to an Apache HBase table. The `hbase.table.namespace.mappings` property allows you to map Apache HBase table names to HPE Ezmeral Data Fabric Database tables. This property is typically set in the configuration file `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml`.

In general, if a table name includes a slash (`/`), the name is assumed to be a path to a HPE Ezmeral Data Fabric Database table, because slash is not a valid character for Apache HBase table names. In the case of "flat" table names without a slash, namespace conflict is possible, and you might need to use table mappings.

Table Mapping Naming Conventions

A table mapping takes the form *`name`*`:`*`map`*, where *`name`* is the table name to redirect and *`map`* is the modification made to the name. The value in *`name`* can be a literal string or contain the `*` wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

Mappings and Table Listing Behaviors

When you use the `list` command without specifying a directory, the command's behavior depends on two factors:

- Whether a table mapping exists
- Whether Apache HBase is installed and running

Here are three different scenarios and the resulting `list` command behavior for each.

- There is a table mapping for *, as in `*:/tables`. In this case, the `list` command lists the tables in the mapped directory.
- There is no mapping for *, and Apache HBase is installed and running. In this case, the `list` command lists the HBase tables.
- There is no mapping for *, and Apache HBase is not installed or is not running.
  - For HBase 0.98.12, the shell will try to connect to an HBase cluster but it will return an error instead.
  - For HBase 1.1 or above, if the `mapr.hbase.default.db` property in the hbase-site.xml is set to `hbase`, the list command will return an error stating that HBase is not available. If the `mapr.hbase.default.db` property is set to `maprdb`, list command will list the HPE Ezmeral Data Fabric Database tables under the user's home directory.

Example 1: Map all HBase tables to HPE Ezmeral Data Fabric Database tables in a directory

In this example, any flat table name `foo` is treated as a HPE Ezmeral Data Fabric Database table in the directory `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>*:/tables_dir</value>
        </property>
```

last-updated: Jun 06, 2024

Example 2: Map specific Apache HBase tables to specific HPE Ezmeral Data Fabric Database tables

In this example, the Apache HBase table name `mytable1` is treated as a HPE Ezmeral Data Fabric Database table at `/user/aaa/mytable1`. The Apache Hbase table name `mytable2` is treated as a HPE Ezmeral Data Fabric Database table at `/user/bbb/mytable2`. All other Apache HBase table names are treated as stock Apache HBase tables.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/</value>
        </property>
```

Example 3: Combination of specific table names and wildcards

Mappings are evaluated in order. In this example, the flat table name `mytable1` is treated as a HPE Ezmeral Data Fabric Database table at `/user/aaa/mytable1`. The flat table name `mytable2` is treated as a HPE Ezmeral Data Fabric Database table at `/user/bbb/mytable2`. Any other flat table name `foo` is treated as a HPE Ezmeral Data Fabric Database table at `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/,*:/tables_dir</value>
        </property>
```

Thread-pool Settings for Performance

The HPE Ezmeral Data Fabric Database C APIs internally have one thread pool per client. Threads work on the async tasks enqueued by a client application. There are two thread-pool parameters that you can modify in the `/opt/mapr/conf/dbclient.conf` file for better application performance.

fs.mapr.pool.threads

This parameter controls the number of connections that a client application makes with HPE Ezmeral Data Fabric Database for append, increment, read, and scan requests. For a higher rate of throughput to HPE Ezmeral Data Fabric Database, you can increase this value. The default value is 10.

fs.mapr.highpri.pool.threads

This parameter controls the number of threads that invoke application-provided callbacks. If an application's callbacks are not lightweight but instead perform complex calculations that require significant processing, increase this value to avoid delays in invoking callbacks. The default value is 2.

Building MapReduce Applications

This section provides information about building and running custom MapReduce application that access HPE Ezmeral Data Fabric Database binary tables.

The steps for building and running custom MapReduce applications that run against HPE Ezmeral Data Fabric Database are the same as the steps for building and running custom MapReduce applications that run against Apache HBase. The steps are documented in the Apache HBase Reference Guide at http://hbase.apache.org/book.html#mapreduce.

However, you must use an HBase JAR file from MapR's Maven repository at https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/hbase/hbase-server/. The name of the JAR file that you use must contain the version of HBase and the version of MapR that you are using.

For example, if you are using HBase 1.1 and MapR version 5.1, you would use the file `hbase-server-1.1.1-mapr-1602.jar`.

last-updated: Jun 06, 2024

Performing Bulkloads with MapReduce
This section describes custom MapReduce applications used to perform bulkloads for HPE Ezmeral Data Fabric Database binary tables.

You can use the `HFileOutputFormat configureIncrementalLoad()` method for writing custom MapReduce applications to perform bulk loads. Although the name of the method implies that you can use it only for incremental bulk loads, the method also works for full bulk loads, provided that the `-bulkload`, `BULKLOAD`, or `Bulkload` parameter for a table is set to true, as described in Bulk Loading and HPE Ezmeral Data Fabric Database Tables.

If you have a custom MapReduce applications that does not use `HFileOutputFormat.configureIncrementalLoad()`, simply use the path to the HPE Ezmeral Data Fabric Database table that you want to load. Using `HFileOutputFormat.configureIncrementalLoad()` provides at least two advantages:

This method performs a number of tasks that your application would otherwise need to do explicitly:

1. Inspects the table to configure a total order partitioner
2. Uploads the partitions file to the cluster and adds it to the DistributedCache
3. Sets the number of reduce tasks to match the current number of regions
4. Sets the output key/value class to match `HFileOutputFormat`'s requirements
5. Sets the reducer up to perform the appropriate sorting (either `KeyValueSortReducer` or `PutSortReducer`)

This method turns off Speculative Execution automatically. For details, see the note below.

WARNING: Turning off Speculative Execution

Speculative Execution of MapReduce tasks is on by default. For custom applications that load HPE Ezmeral Data Fabric Database binary tables, it is recommended to turn Speculative Execution off. When it is on, the tasks that import data might run multiple times. Multiple tasks for an incremental bulkload could insert one or more versions of a record into a table. Multiple tasks for a full bulkload could cause loss of data if the source data continues to be updated during the load.

If your custom MapReduce application uses `HFileOutputFormat.configureIncrementalLoad()`, you do not have to turn off Speculative Execution manually. `HFileOutputFormat.configureIncrementalLoad()` turns it off automatically. Speculative Execution is automatically turned off for MapReduce utilities such as `CopyTable` and `ImportTsv`.

If you are writing a custom MapReduce application that does not use the `HFileOutputFormat configureIncrementalLoad()` method for bulk loading, you must turn off Speculative Execution manually.

Turn off Speculative Execution by setting the following MapReduce version 2 parameter to false: `mapreduce.map.speculative`

If the job is programmatically written, you can turn off Speculative Execution at the code level: `job.setSpeculativeExecution(false);`

Setting for OJAI Applications to Use Data Fabric Client Features

Describes how to set the classpath for OJAI applications to use data-fabric client features.

When you launch an OJAI application that needs to submit MapReduce or YARN applications, or to run `hadoop fs` or `hadoop mfs` commands, ensure that you prefix the classpath with `/opt/mapr/conf:/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop`. Alternatively, copy the `core-site.xml` file to the `/src/main/resources/` folder.

last-updated: Jun 06, 2024

Developing Applications for JSON Tables

As part of its support for JSON tables, HPE Ezmeral Data Fabric Database implements the OJAI API. The OJAI API provides methods for creating, reading, updating, and deleting JSON documents in HPE Ezmeral Data Fabric Database JSON tables. It is available in Java, and starting in EEP 6.0, also available in Node.js, Python, C#, and Go. HPE Ezmeral Data Fabric Database also provides a HPE Ezmeral Data Fabric Database JSON Client API for managing JSON tables and a HPE Ezmeral Data Fabric Database JSON REST API for performing basic operations using HTTP calls.

The following shows the general flow for developing an OJAI client application that accesses HPE Ezmeral Data Fabric Database JSON tables:

1. Make a connection to HPE Ezmeral Data Fabric Database using the OJAI Connection and Driver interfaces.
2. Request a HPE Ezmeral Data Fabric Database JSON table using the JSON DocumentStore.
3. Specify the table, document, or column family operation.
4. Perform the operation on the table.
5. Return the results.

For additional information about OJAI, refer to the following:

- OJAI wiki page
- OJAI github repository - The README file provides an introduction to OJAI

The HPE Ezmeral Data Fabric Database JSON Client API, implemented in Java, enables you to create, drop, and alter HPE Ezmeral Data Fabric Database JSON tables and column families.

You can also use HTTP calls to create, delete, and query HPE Ezmeral Data Fabric Database JSON tables Using the HPE Ezmeral Data Fabric Database JSON REST API on page 3478.

API Documentation

The following are links to the detailed API pages:

- Java OJAI Client API
- Node.js OJAI Client API
- Python OJAI Client API
- C# OJAI Client API
- Go OJAI Client API
- HPE Ezmeral Data Fabric Database JSON Client API

NOTE: Beginning with MapR version 6.0, the HPE Ezmeral Data Fabric Database `Table` interface in the HPE Ezmeral Data Fabric Database JSON Client API is deprecated and replaced by the `DocumentStore` interface in the OJAI API.

Managing JSON Tables

This section describes how to create, list, and delete JSON tables, alter JSON table attributes, set permissions, and manage column families. You can perform these operations using either the HPE Ezmeral Data Fabric Database JSON Client API library or HPE Ezmeral Data Fabric Database Shell commands.

last-updated: Jun 06, 2024

HPE Ezmeral Data Fabric Database JSON Client API

The HPE Ezmeral Data Fabric Database JSON Client API is a Java library. There is not a Python implementation of the library, but you can create and drop HPE Ezmeral Data Fabric Database JSON tables in the Python OJAI client.

Admin API

Use the methods in this interface to perform these tasks:

- Create JSON tables
- Alter JSON tables
- Delete JSON tables
- List JSON tables in a folder
- See if a JSON table exists

For a full list of methods, see the MapR Admin interface

TableDescriptor API

Use the methods in this interface to perform these tasks:

- Create tables with non-default values for one or more of their parameters
- Alter tables

For a full list of interfaces and methods, see the MapR TableDescriptor interface.

HPE Ezmeral Data Fabric Database Shell

The mapr dbshell is a tool for the creation and lightweight manipulation of JSON tables and documents. To run dbshell, enter `mapr dbshell` on the command line after logging into a node in a MapR cluster. See HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5469 for more information.

Creating JSON Tables

This topic describes how to create HPE Ezmeral Data Fabric Database JSON tables using either programmatic APIs or dbshell.

NOTE: Before creating a table, you typically create a directory and MapR volume. This is not required; however, it is a good practice. For example, assuming both the directory and volume names are `sample`, the command would be:

```
// Create directories with hadoop
hadoop fs -mkdir /sample

// Create a MapR volume using maprcli create volume
maprcli volume create -name sample -path /sample -type rw
```

Java

The following Java code examples show you how to create a table in the following ways:

- By using the default values for the table attributes,
- By setting specific values for the table attributes.

See the Admin and TableDescriptor APIs for more information.

last-updated: Jun 06, 2024

The following example shows how to create a table by calling an `Admin` object's `createTable()` `method` and passing, as an argument, the path that you want to use for the new table:

```
public void createJSONTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tablePath);
         }
    }
}
```

Tables created with this version of the `createTable()` method use the default values for their attributes.

Alternatively, the following example how to create a table by passing a `TableDescriptor` object as an argument to the `createTable() method`:

```
/* Create a TableDescriptor for the table to create,
 * passing in the path of the table.
 */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Pass the TableDescriptor object and the path to the table
 * to the Admin.createTable() method.
 */
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tableDescriptor);
        }
    }
}
```

This alternative allows you to set values for some of the table's attributes.

Node.js

To create a table in the Node.js OJAI client, call the `Connection.createStore()` method:

```
connection.createStore(table_path)
    .then((store) => {
        // Process result
        ...
    });
```

The method returns a `DocumentStore` object.

Python

To create a table in the Python OJAI client, call the `Connection.create_store()` method:

```
store = connection.create_store(store_path=table_path)
```

The method returns a `DocumentStore` object.

dbshell

The following **dbshell** command shows code syntax for creating a table:

```
# mapr dbshell
maprdb root:> create /<tablePath>/<tableName>
```

C#

To create a table in the C# OJAI client, call the `connection.CreateStore(string storePath)` method:

```
var store = connection.CreateStore(string storePath);
```

The method returns a `DocumentStore` object.

Go

To create a table in the Go OJAI client, call the `connection.CreateStore()` function:

```
store, error := connection.CreateStore("/store_path")
```

The function returns a new `DocumentStore` and an error.

Listing JSON Tables

This topic describes how to list the JSON tables by using either the HPE Ezmeral Data Fabric Database JSON Client API or HPE Ezmeral Data Fabric Database Shell.

Permission Required

The `readAce` permission on the volumes where the JSON tables are located. Setting Whole Volume ACEs on page 1365

Java

The table is listed by calling HPE Ezmeral Data Fabric Database JSON Client API `Admin` object's `listTables()` method and passing, as an argument, the path of the folder.

Use a conditional loop to iterate through the returned list and retrieve the names of the tables.

```
public void listTables(String parentFolder) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        for(Path tablePath : admin.listTables(parentFolder)) {
            System.out.println(tablePath);
        }
    }
}
```

NOTE: The parameter `parentFolder` provides a path to a folder that is in the MapR filesystem. See "**Table Paths**" in HPE Ezmeral Data Fabric Database JSON Tables for examples.

dbshell

```
# mapr dbshell
maprdb root:> list /demo
/demo/user
/demo/checkin
/demo/review
/demo/business
```

last-updated: Jun 06, 2024

```
/demo/tip
5 table(s) found.
```

See dbshell list on page 5487 for further details.

Altering JSON Table Attributes
This topic describes how to change the values of table attributes by using the HPE Ezmeral Data Fabric Database JSON Client API.

In this example, the code turns off the `bulkload` flag on the table. Applications will typically need to turn off this flag after a bulk load of the table with the `import`, `importJSON`, or `copytable` utility.

Create a `TableDescriptor` object for an existing table by passing the path of the table to the `Admin` interface's `getTableDescriptor()` method.

Permissions Required

The `readAce` and `writeAce` permissions on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1365.

Example

Tables are altered a by using the `TableDescriptor` object and then passing that object to the `Admin` interface's `altertable()` method.

```
public void alterTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        TableDescriptor tableDesc = admin.getTableDescriptor(tablePath);
        // set bulk load to false
        tableDesc.setBulkLoad(false);
        admin.alterTable(tableDesc);
    }
}
```

Deleting JSON Tables
This topic describes how to delete HPE Ezmeral Data Fabric Database JSON tables using either programmatic APIs or dbshell.

Java

To delete a table in the Java OJAI client, call an `Admin` object's `deleteTable()` method and pass, as an argument, the path of the table to delete:

```
public void deleteTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (admin.tableExists(tablePath)) {
            admin.deleteTable(tablePath);
        }
    }
}
```

Node.js

To delete a table in the Node.js OJAI client, call the `Connection.deleteStore()` method:

```
connection.deleteStore(table_path)
    then((deleteResponse) => {
        // Process deleteReponse
        ...
    });
```

Python

To delete a table in the Python OJAI client, call the `Connection.delete_store()` method:

```
rc = connection.delete_store(store_path=table_path)
```

dbshell

```
# mapr dbshell
maprdb root:> drop <table path>
```

See dbshell drop on page 5473 for additional details.

C#

To delete a table in the C# OJAI client, call the `connection.DeleteStore(string storePath)` method:

```
connection.DeleteStore(string storePath);
```

Go

To delete a table in the Go OJAI client, call the `connection.DeleteStore()` function:

```
err := connection.DeleteStore("/store_path")
```

Permissions Required

You must have both the `readAce` and `writeAce` permissions on the volumes where the JSON tables are located to delete it. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1365.

Permission Types for Fields and Column Families in JSON Tables
By using ACEs, you can grant or deny access to fields and column families that are in JSON tables.

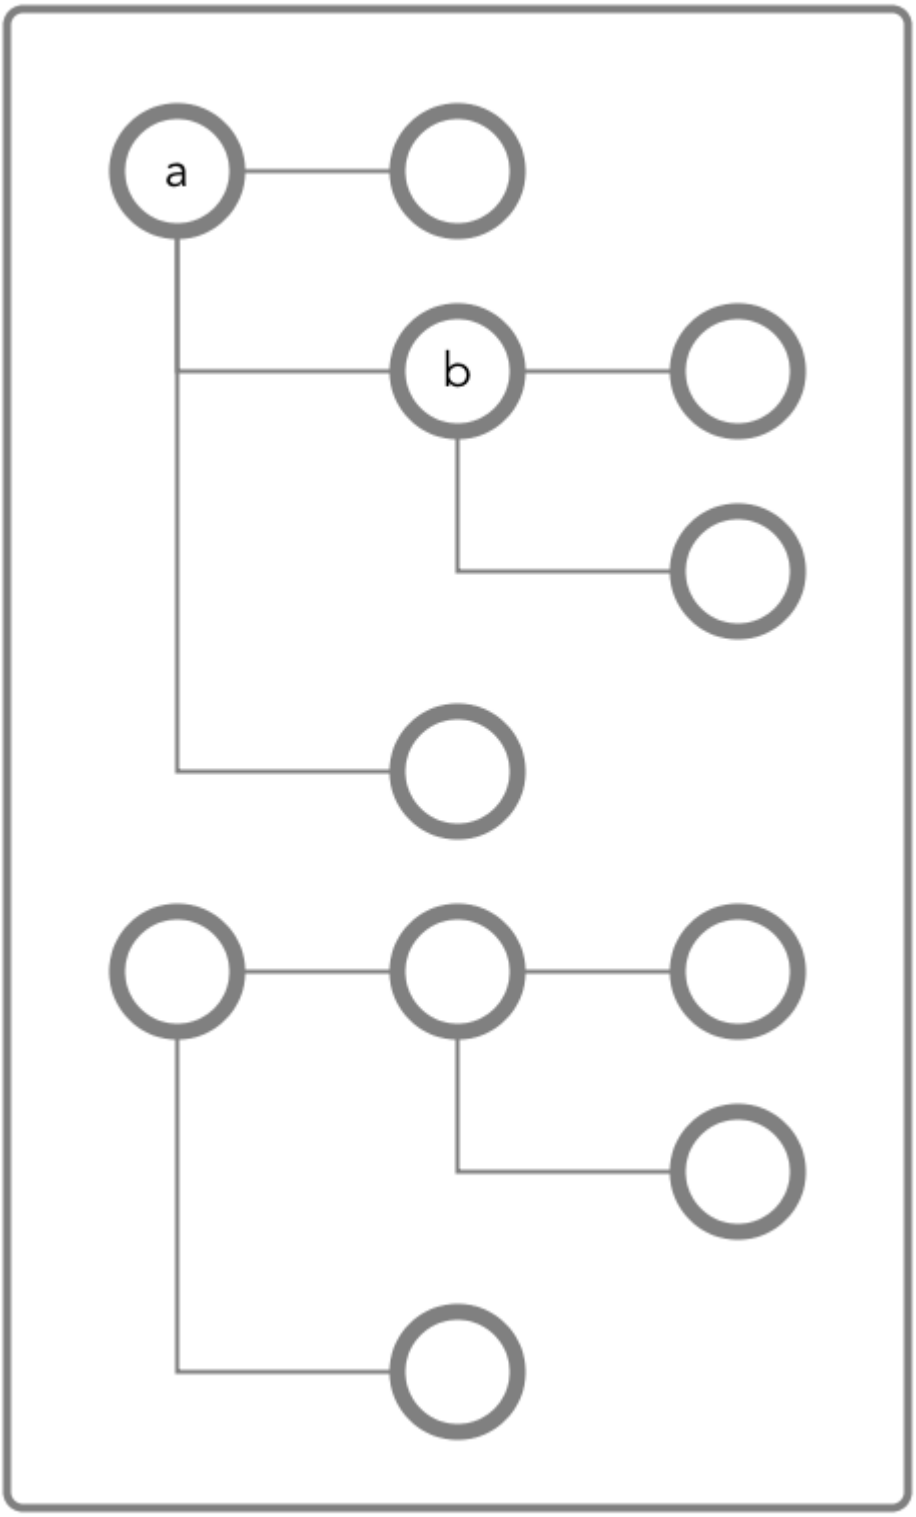
There are three types of permission:

- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access fields on which the grantee has write or read permission.

For example, suppose that a user has read and write access to only field b below.

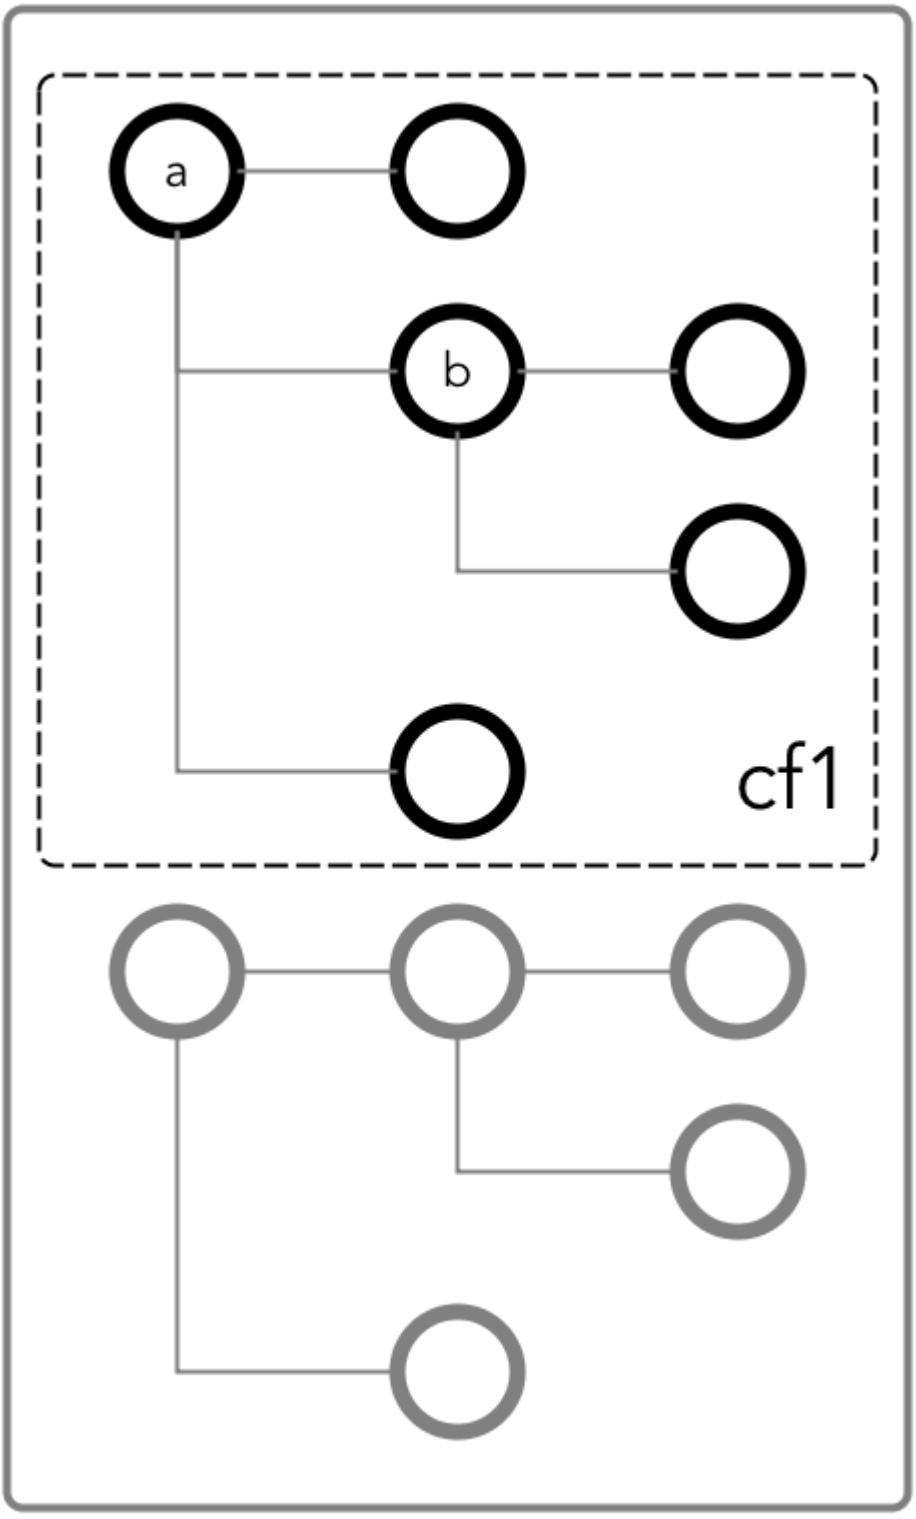


To access field b, the user would need to be able to traverse (pass through) field a. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If a user was denied traverse permission on the default column family, the user would not be able to access field b. Granting traverse permission on field a in this case would have no effect.

last-updated: Jun 06, 2024

In the example below, field a is part of the `cf1` column family.



To be able to read and write at field b, the user could be granted the traverse permission on the column family.

last-updated: Jun 06, 2024

Read (`readperm`)

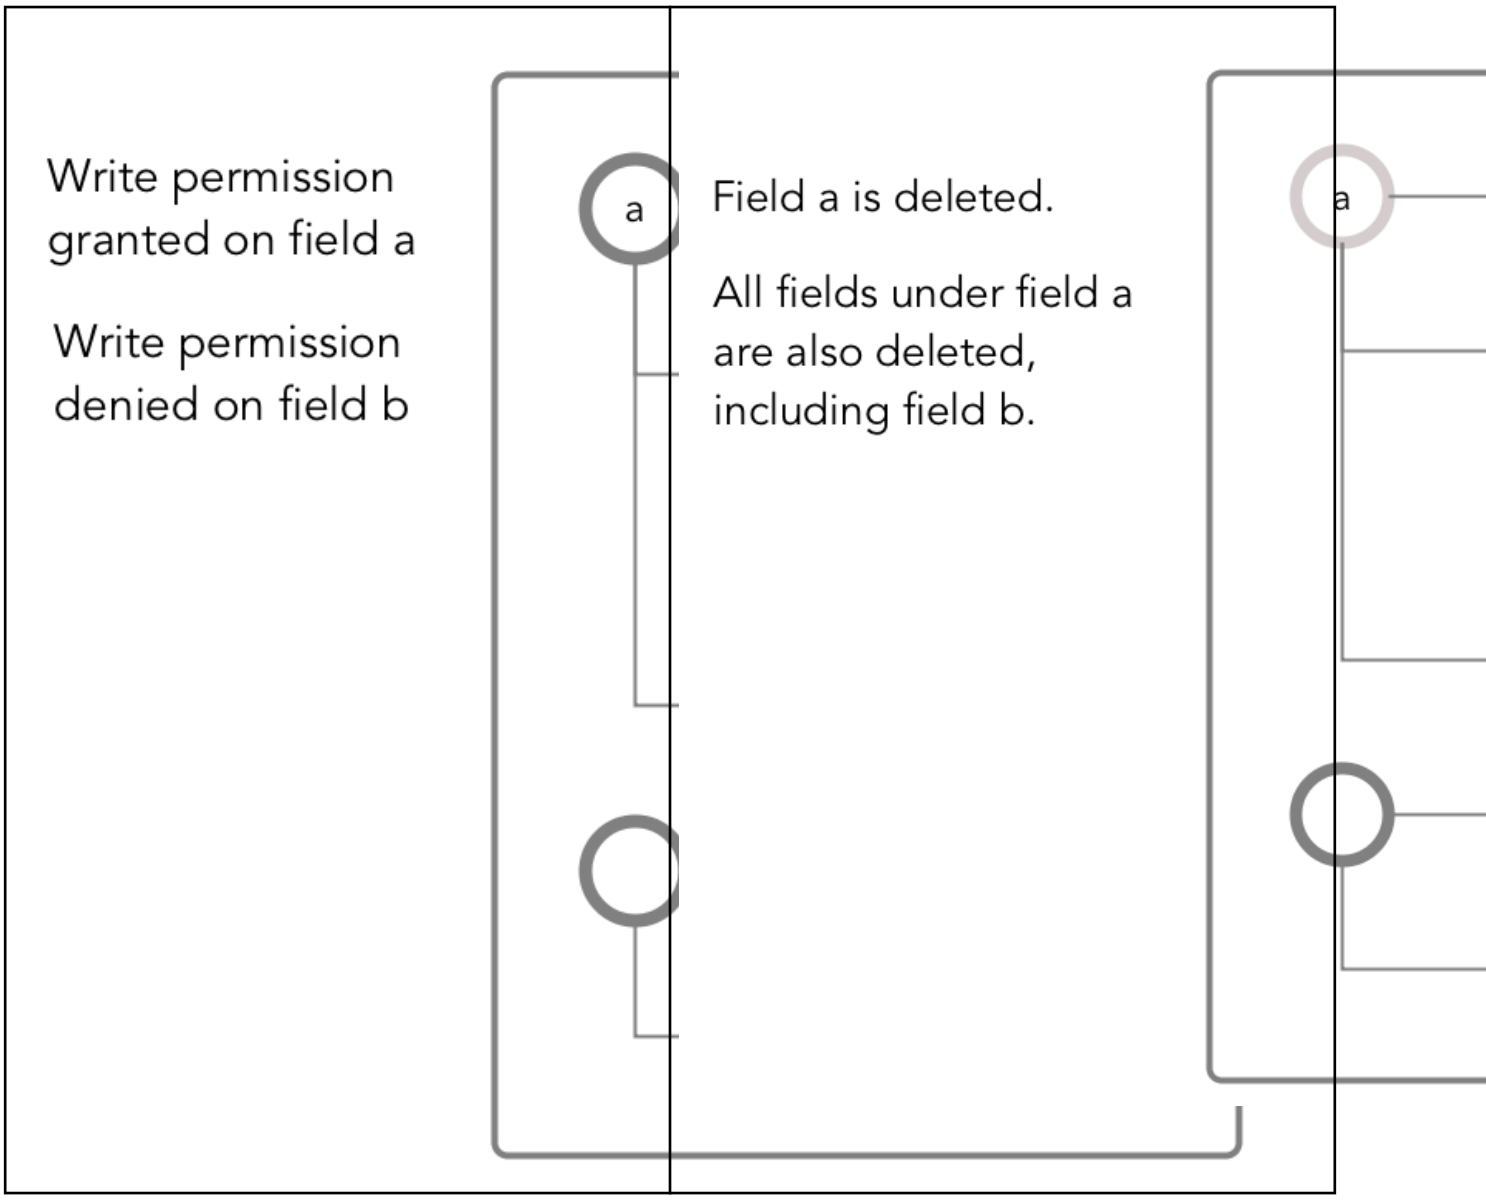
The read permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field on which the permission was granted. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (`writeperm`)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite field value.

As illustrated in the two diagrams below, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.



Obtaining `readperm` and `writeperm` on Fields
In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

last-updated: Jun 06, 2024

If the field is in the default column family

In the document below, you want to perform an operation on field c, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field c.

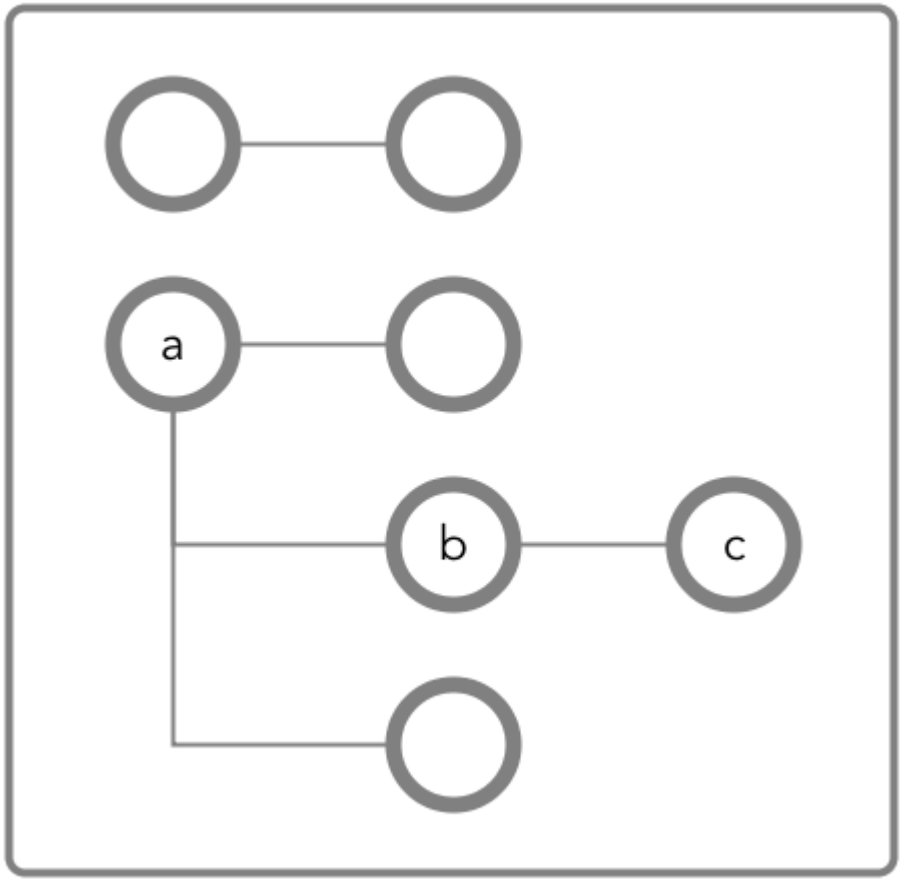


Figure 28: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field c inherits these permissions, assuming that the permissions were not denied on field a or b.

If you do not have `readperm` and `writeperm` on field a or b, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field c. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```
maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
```

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have `readperm` and `writeperm` on the default column family

In this case, you need the `traverseperm` permission on the default column family. Fields a and b inherit this permission. You also need `readperm` and `writeperm` on field c.

You could be granted these permissions with commands similar to these:

```
maprcli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see Column Families in JSON table.

In the following document, you want to perform an operation on field c, which is in the column family `cf1` that is defined at field b with the path `a.b`.

last-updated: Jun 06, 2024

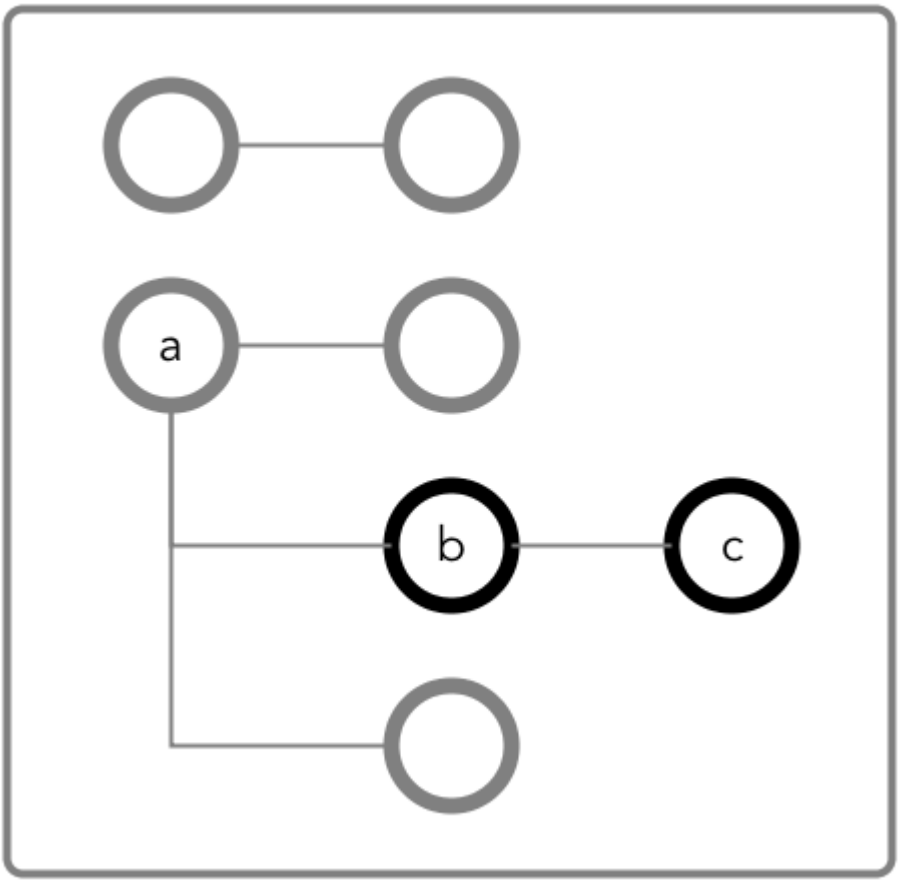

Figure 29: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have `readperm` and `writeperm` on field `b`	You need `traverseperm` on field b and both `readperm` and `writeperm` on field c. You can be granted these permissions with commands similar to these:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field> -writeperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have `readperm` and `writeperm` on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Obtaining `readperm` or `writeperm` on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm or writeperm permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

If the field is in the default column family

In the following document, you want to perform an operation on field `c,` which is in the default column family. The operation requires you to have `readperm` or `writeperm` on field `c`.

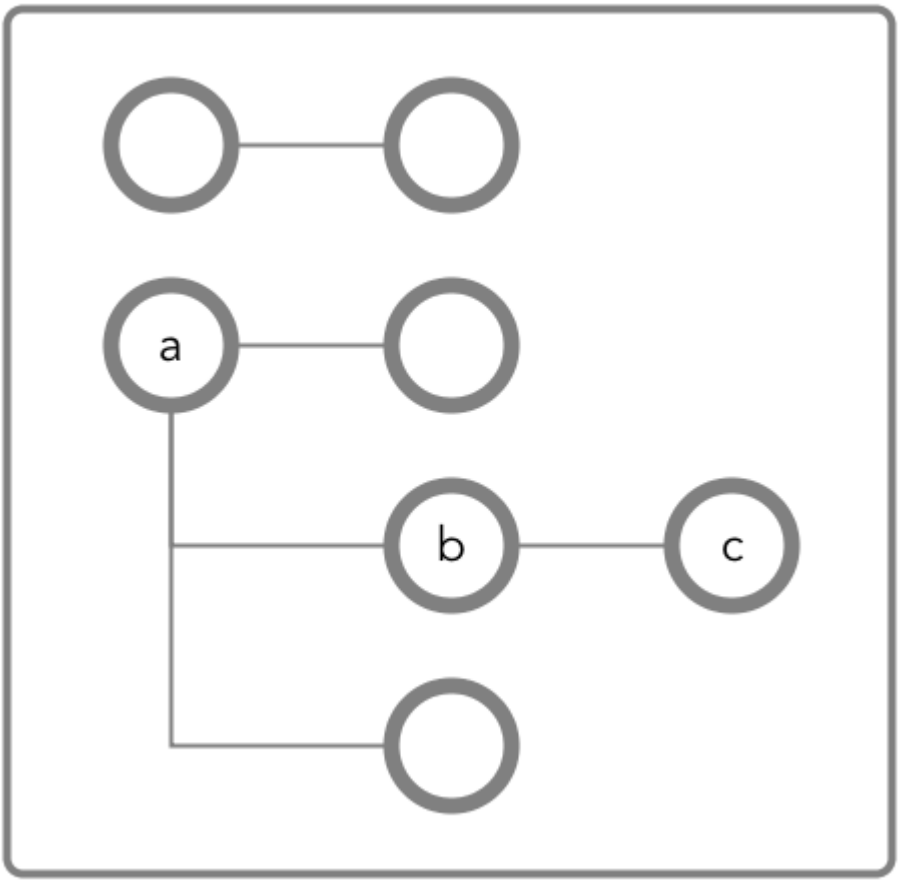

Figure 30: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (`readperm` or `writeperm`) on the default column family

In this case, field c inherits the permission, assuming that the permission was not denied on field a or b.

If you do not have `readperm` or `writeperm` on field a or b, you need `traverseperm` on the field that denied you the permission that you need. You also need `readperm` or `writeperm` explicitly granted to you on field c.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
```

```
default -name a.b -traverseperm
u:<user ID> | <existing ACE for this
field>
```

The next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (`readperm` or `writeperm`) on the default column family

In this case, you need the `traverseperm` permission on the default column family. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see Column Families in JSON Tables.

In the following document, you want to perform an operation on field `c`, which is in the column family that is defined at field `b` with the path `a.b`. The operation requires you to have `readperm` or `writeperm` on field `c`.

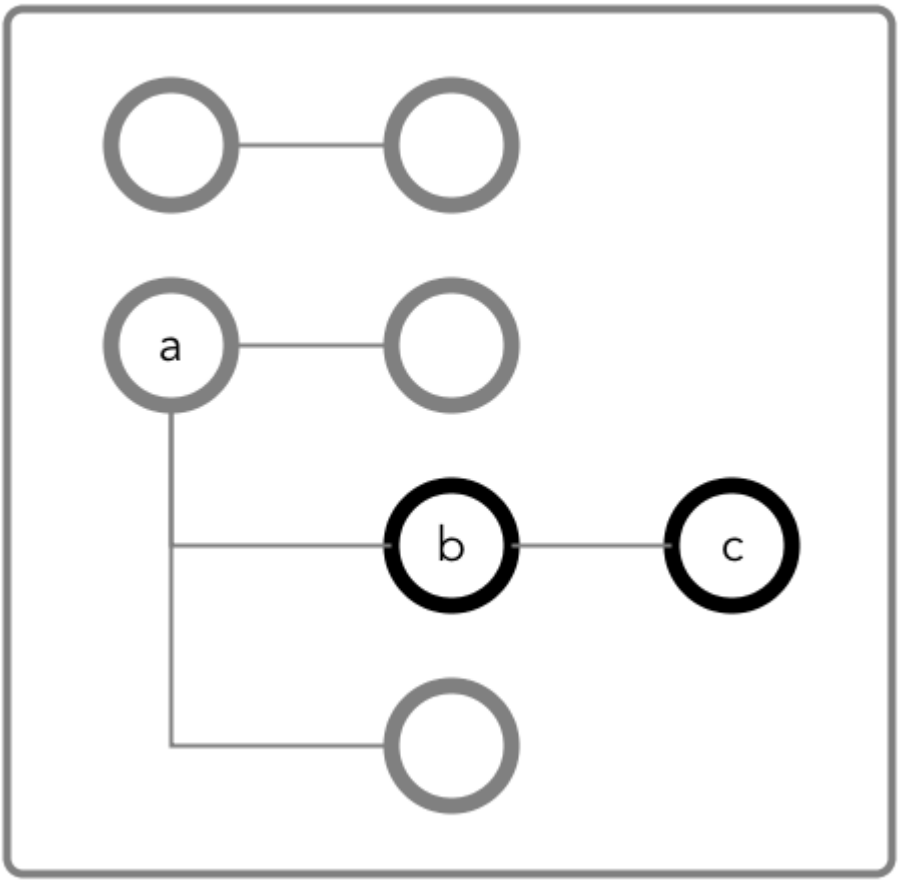

Figure 31: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have the permission you need (`readperm` or `writeperm`) on field `b`	You need `traverseperm` on field b, and you need `readperm` or `writeperm` granted to you explicitly on field c.
	Example commands to grant these permissions:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have the permission you need (`readperm` or `writeperm`) on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Setting Permissions on Arrays

If you are granting permissions on a field and the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and

scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

NOTE: This topic describes the behavior of permissions in HPE Ezmeral Data Fabric Database version 6.1 and later, regardless of the data-fabric version you used to grant the permissions.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
    "_id" : "id001",
    "person" : [
        {"name" : {"last" : "Smith", "first" : "John"}},
        {"name" : {"last" : "Subramanium", "first" : "Ananya"}}
    ]
}
{
    "_id" : "id002",
    "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
    "_id" : "id003",
    "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person` to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

last-updated: Jun 06, 2024

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables
Summarizes the default ACEs for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

Action	Method	Permissions	Default Access-Control Expressions
Set default permissions on new column families when creating a JSON table.	Java API	`-defaultreadperm -defaulttraverseperm -defaultwriteperm`	`u:<ID of the process>`
	`maprcli table create`		`u:<user ID of table creator>`
	mapr dbshell		
	Control System		
Set default permissions on new column families when editing a JSON table.	`maprcli table edit`		Current ACEs
	Control System		
Set permissions on a column family when creating the column family.	`maprcli table cf create`	`-readperm -traverseperm -writeperm -indexperm`	ACEs for `-defaultreadperm`, `-defaulttraverseperm`, and `-defaultwriteperm`
	Control System		
Set permissions on a column family when editing the column family.	`maprcli table cf edit`		Current ACEs
	Control System		
Set permissions on individual fields.	`maprcli table cf colperm set`		Inherited from column family or parent field
	Control System		
Set the dynamic mask	`maprcli table cf column datamask set`	`-defaultunmaskedreadperm -unmaskedreadperm`	Set to the table creator
	`maprcli table cf colperm set`		
	`maprcli table create`		
	`maprcli table edit`		
	`maprcli table cf create`		
	`maprcli table cf edit`		
	`maprcli table cf colperm set`		
	Control System		

Managing Column Families

JSON tables store data in column families, which are collections of fields that are stored together on disk.

Each table has a default column family, which is default storage for all fields in the documents of a table. You can create additional column families to store data for a collection of fields in a separate location on disk. Queries that operate only on data that is stored in a column family are more efficient and better performing than queries on the same data when that data is stored with other data in a table. You can also cache values from a column family in memory.

Applications do not need to be aware of the existence of column families. They perform CRUD operations by using the paths of fields in a document. For example, to update any of the fields below `a.c`, an application does not need to be aware that the field is in the column family at the path `a.c`. The application simply moves through the document along the path to the field.

For more information, see Column Families in JSON Tables on page 662.

Creating Column Families

You can create column families with the HPE Ezmeral Data Fabric Database JSON Java API library by using the `Admin.createTable(TableDescriptor tableDescriptor)` method.

Add a column family to the `TableDescriptor` object before passing that object to the `createTable()` method.

Restriction

If any existing column family in a JSON table, including the default column family, uses a time-to-live that is greater than 0, you cannot create any additional column families in that table. See Setting TTL for Data.

Permissions Required

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `createrenamefamilyperm` on the table

Example

Here is an example of using the API to create two column families -- the default column family and a custom column family -- during the creation of a table:

```
/* Create a TableDescriptor for the table to create,
   passing in the path of the table. */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Create a FamilyDescriptor for the default column family.
   When you create a table with the API, you must also create
   the default column family.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor defaultfamilyDesc = MapRDB.newDefaultFamilyDescriptor();
tableDescriptor.addFamily(defaultfamilyDesc);

/* Create a FamilyDescriptor for the custom column family
   to create. The setJsonFieldPath() method specifies the field
   at which to create the column family.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor familyDescriptor = MapRDB.newFamilyDescriptor()
  .setName("CF1")
  .setJsonFieldPath("a.b");
tableDescriptor.addFamily(familyDescriptor);
```

last-updated: Jun 06, 2024

```
// Pass the TableDescriptor to the Admin.createTable() method.
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
  try (Admin admin = MapRDB.newAdmin()) {
    if (!admin.tableExists(tablePath)) {
      admin.createTable(tableDescriptor);
    }
  }
}
```

Alternative Method

You can also create column families in JSON tables by running the command `table cf create`.

Altering Column Families
You can alter column families, including the default column family for a table, by using the `Admin.alterFamily()` method in the HPE Ezmeral Data Fabric Database JSON Java API library.

Permissions Required

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `createrenamefamilyperm` on the table

Example

Here is an example of using the API to change the name of a column family:

```
public void alterColumnFamily(String tablePath, String familyName,
  String newFamilyName) throws DBException {
  try (Admin admin = MapRDB.newAdmin()) {

    /* Get a TableDescriptor object for the table. This object
       gives access to the column families that are in the table. */
    TableDescriptor tableDesc = admin.getTableDescriptor(tablePath);

    /* Get a FamilyDescriptor object for the column family to
       change the name of. /
    FamilyDescriptor familyDesc = tableDesc.getFamily(familyName);

    // Rename the column family.
    familyDesc.setName(newFamilyName);

    /* Call alterFamily(), passing in the path of the table,
       the original name of the column family, and the
       FamilyDescriptor in which the new name was set. */
    admin.alterFamily(tablePath, familyName, familyDesc);
  }
}
```

Alternative Method

You can also edit column families in JSON tables by running the command `table cf edit`.

Deleting Column Families
You can delete a column family (except for the default column family) in a JSON table with the `Admin.deleteFamily()` Java method.

IMPORTANT: Starting in the 6.0 release, you cannot delete a column family from a JSON table.

Permissions Required

The `readAce` and `writeAce` permissions on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1365.

Behavior

The data that is in the specified column family is deleted. If the column family is followed by one or more column families in a hierarchy, the other column families in the hierarchy are unaffected and still accessible. For example, if column family `CF1` at path `a.c` is followed by column family `CF2` at path `a.c.f`, `CF2` remains accessible and only the data in `CF1` is deleted.

Before deleting the column family `CF1` at `a.c`	After deleting the column family `CF1` at `a.c`
`{ "a" : { "b" : "value_b", "c" : { "d" : "value_d", "e" : "value_e", "f" : { "g" : "value_g", "h" : "value_h" } } } }`	`{ "a" : { "b" : "value_b", "c" : { "d" : "", "e" : "", "f" : { "g" : "value_g", "h" : "value_h" } } } }`

Example of using the `Admin.deleteFamily()` method

```
public void deleteColumnFamily(String tablePath, String familyName) throws
DBException {
    try (Admin admin = MapRDB.newAdmin()) {
      if (admin.tableExists(tablePath)) {
        admin.deleteFamily(tablePath, familyName);
      }
    }
}
```

Parameter	Description
`tablePath`	The path of the table in the MapR filesystem. See the "Table Paths" section in HPE Ezmeral Data Fabric Database JSON Tables on page 659.
`familyName`	The name of the column family to delete. You cannot delete the default column family. If familyName is equal to "default", the API returns an exception.

Setting TTL for Data
You can delete stale JSON documents in JSON tables automatically by setting a time-to-live (TTL) value on the column family.

TTL is set only on the default column family in a JSON table. The duration that you set applies to each entire JSON document in the JSON table.

last-updated: Jun 06, 2024

NOTE: Only the default column family can exist in order to set TTL; no other column families can exist in the JSON table. You also cannot set the TTL for a JSON table if it has secondary indexes.

Data can become stale. If the data in an JSON document has not been updated within a certain period of time, you might want to delete the document. In the case of a large amount of JSON documents, applications should not have to track the time between updates and then delete the expired documents.

Because the time-to-live that is set on a column family affects an entire JSON table, only the default column family is allowed to have a non-default time-to-live value. In addition, to prevent multiple column families from having non-default time-to-live values, additional column families can not be created in a table if the default column family has a non-default value. This is because if more than one column family had a non-default TTL value, fragments of documents would expire at different times, leading to inconsistent views of data.

Permission Required

The `writeAce` permission on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1365.

Example: Setting the default column family to a non-default time-to-live value
If you set the time-to-live parameter for the default column family to 864,000 seconds, JSON documents in that table are considered to be stale if the document's data has not been updated within 10 days and are automatically deleted.

The following code example creates a JSON table, the default column family and sets the TTL to a non-default value of 10 days (864,000 seconds).

```
/* Create a TableDescriptor for the table to create,
   passing in the path of the table. */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Create a FamilyDescriptor for the default column family.
   When you create a table with the API, you must also create
   the default column family.
   Set the TTL to 10 days.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor defaultfamilyDesc = MapRDB.newDefaultFamilyDescriptor()
   .setTTL(864000);
tableDescriptor.addFamily(defaultfamilyDesc);

// Pass the TableDescriptor to the Admin.createTable() method.
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
  try (Admin admin = MapRDB.newAdmin()) {
    if (!admin.tableExists(tablePath)) {
      admin.createTable(tableDescriptor);
    }
  }
}
```

Managing JSON Documents
To perform CRUD operations (create, read, update, and delete) on JSON documents in HPE Ezmeral Data Fabric Database JSON tables using the OJAI API, you use `Document`, `DocumentStore`, and `DocumentMutation` objects.

You can also perform these operations using HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5469.

`Document`

To create a JSON document, you must create a `Document` object. See the following for information specific to each language:

Java	To create a JSON document in Java OJAI, use the Document interface. See Creating JSON Documents in Java OJAI on page 3325 to learn about the different ways to create `Document` objects in Java.
Node.js	To create a `Document` object in Node.js OJAI, simply create a JSON object. See Sample OJAI Code for Creating JSON Documents on page 3330 for an example of how to do this.
Python	The preferred approach is to create a `Document` object in Python is to create a Python dictionary. You can also use the Document interface. See Creating JSON Documents in Python OJAI on page 3329 to learn about these two ways to create JSON documents in Python.
C#	To create a `Document` object in C# OJAI, create a C# object. See Sample OJAI Code for Creating JSON Documents on page 3330 for an example of how to do this. For C# OJAI examples, see this Github page.
Go	To create a `Document` object in Go OJAI, create a Go structure. See Sample OJAI Code for Creating JSON Documents on page 3330 for an example of how to do this.

`DocumentStore`

After you create a `Document` object, you can pass it to the `DocumentStore` interface. The interface has methods to perform the following tasks:

- Delete documents from tables
- Insert documents into tables
- Replace documents in tables

See the following for API links to the `DocumentStore` interface in each language:

Java	DocumentStore

NOTE: By default, OJAI implements non-buffered writes. If you want buffered writes instead, use the `ojai.mapr.documentstore.buffer-writes` option and with the `Document` object. This option is available only in the Java OJAI API. See Enabling Buffered Writes in Java OJAI on page 3450 for more information.

Node.js	DocumentStore
Python	DocumentStore
C#	DocumentStore For C# OJAI examples, see this Github page.
Go	DocumentStore

`DocumentMutation`

To make changes to JSON documents, create a `DocumentMutation` object. A `DocumentMutation` enables you to perform OJAI mutations, which includes replacing, updating, combining, and deleting fields in a JSON document. For a list of available mutations, see Using OJAI Mutation Syntax on page 3342.

Java	To create a `DocumentMutation` object, call the methods in the `DocumentMutation` class corresponding to the mutation operations you want to perform. See DocumentMutation for a list of available methods. Pass the `DocumentMutation` object to either the DocumentStore.checkAndUpdate or DocumentStore.update method to apply the changes to the document. The first method accepts a QueryCondition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.
Node.js	To create a `DocumentMutation` object, create a JSON object Using OJAI Mutation Syntax on page 3342. Pass the `DocumentMutation` object to either the DocumentStore.checkAndUpdate or DocumentStore.update method to apply the changes to the document. The `DocumentStore.checkAndUpdate()` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.
Python	To create a `DocumentMutation` object, create a Python dictionary object Using OJAI Mutation Syntax on page 3342. Pass the `DocumentMutation` object to either the DocumentStore.check_and_update or DocumentStore.update method to apply the changes to the document. The `DocumentStore.check_and_update()` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both

	methods have an `_id` parameter corresponding to the document to be updated.
C#	To create a `DocumentMutation` object, create a C# object Using OJAI Mutation Syntax on page 3342. Pass the `DocumentMutation` object to either the `DocumentStore.CheckAndUpdate` or `DocumentStore.Update` method to apply the changes to the document. The `DocumentStore.CheckAndUpdate` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated. For C# OJAI examples, see this Github page.
Go	To create a `DocumentMutation` object, create a Go structure Using OJAI Mutation Syntax on page 3342. Pass the `DocumentMutation` structure to either the `DocumentStore.CheckAndUpdate` or `DocumentStore.Update` method to apply the changes to the document. The `DocumentStore.CheckAndUpdate` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.

By default, the default maximum size of a JSON document is 32 MB. A `DocumentMutation` does not enforce this limit. HPE Ezmeral Data Fabric Database enforces the limit when you pass your `DocumentMutation` object to the `DocumentStore` method. See JSON Document Size on page 645 for information about how to increase this limit.

See Examples: Updating JSON Documents on page 3350 for examples that use mutations.

Creating JSON Documents in OJAI

The way you create a JSON document in your OJAI application depends on the language you use.

Creating JSON Documents in Java OJAI

There are several ways to create JSON documents in your Java OJAI application. They all require you to call the `Connection.newDocument` method to create a `Document` object.

More information

Connection

Document

Create a Document Using a Document Object in Java OJAI

You can create a new JSON document in your Java OJAI client by first calling the `Connection.newDocument()` method to create a `Document` object, and then calling methods on the object to specify document fields and values.

The following shows the detailed sequence of steps:

1. Create a new JSON document by calling the `newDocument()` method in the `Connection` class.
2. Specify the ID of the document with the `setId()` method.
3. Specify field names and their values with the `set()` or `setArray()` method.
4. Return the results in a `Document` object.

For example, suppose you want to create the following JSON document:

```
{
    "_id" : "movie0000001",
    "title" : "OJAI -- The Documentary",
    "studio" : "MapR Technologies, Inc.",
    "release_date" : "2015-09-29",
    "trailers" : {
        "teaser" : "https://10.10.21.90/trailers/teaser",
        "theatrical" : "https://10.10.21.90/trailers/theatrical"
    },
    "characters" : [
        "Heroic Developer",
        "Evil Release Manager",
        "Mad Development Manager"
    ],
    "box_office_gross" : 1000000000L
}
```

The following method creates the document:

```
public Document buildDocument() {
    return connection.newDocument()
        .setId("movie0000001")
        .set("title", "OJAI -- The Documentary")
        .set("studio", "MapR Technologies, Inc.")
        .set("release_date", Values.parseDate("2015-09-29"))
        .set("trailers.teaser", "https://10.10.21.90/trailers/teaser")
        .set("trailers.theatrical", "https://10.10.21.90/trailers/
theatrical")
        .setArray("characters",
            ImmutableList.of(
                "Heroic Developer", "Evil Release Manager", "Mad
Development Manager"))
        .set("box_office_gross", 1000000000L);
}
```

Create a Document from a JSON String in Java OJAI

You can create a new JSON document in your Java OJAI client by passing a JSON string to the `Connection.newDocument()` method.

To create the following JSON document:

```
{
    "_id":"id001",
    "a":1,
    "b":"aString",
    "array":[
        1,
        2,
        "arrStr",
        {
            "c":"arrMapStr"
        }
    ]
}
```

Call `Connection.newDocument()`, passing in a JSON string with escaped quotes:

```
Document pojoDoc = connection.newDocument(
    "{\"_id\":\"id001\",\"a\":1,\"b\":\"aString\",\"array\":[1,2,\"arrStr\",
{\"c\":\"arrMapStr\"}]}");
```

Create a Document from a JavaBean

You can create a new JSON document in your Java OJAI client by passing a JavaBean to the `Connection.newDocument(Object bean)` method. Through an example, the content shows you a sample JavaBean class, how to create a bean for that class, how to create a JSON document from the bean, and how to convert a JSON document back to a bean.

Sample JavaBean Class

Suppose that you are using a JavaBean class named `ExampleJson`:

```
package com.example;

import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import javax.annotation.Generated;
import com.fasterxml.jackson.annotation.JsonAnyGetter;
import com.fasterxml.jackson.annotation.JsonAnySetter;
import com.fasterxml.jackson.annotation.JsonIgnore;
import com.fasterxml.jackson.annotation.JsonInclude;
import com.fasterxml.jackson.annotation.JsonProperty;
import com.fasterxml.jackson.annotation.JsonPropertyOrder;

@JsonInclude(JsonInclude.Include.NON_NULL)
@Generated("org.jsonschema2pojo")
@JsonPropertyOrder({

    "b",
    "array"
})

public class ExampleJson {

    @JsonProperty("a")
    private Double a;
    @JsonProperty("b")
    private String b;
    @JsonProperty("array")
    private List<Object> array = new ArrayList<Double>();
    @JsonIgnore
    private Map<String, Object> additionalProperties = new HashMap<String,
Object>();

    /**
      *
      * @return
      * The a
      */
    @JsonProperty("a")
    public Double getA() {
        return a;
    }

    /**
      *
```

```
      * @param a
      * The a
      */
    @JsonProperty("a")
    public void setA(Double a) {
        this.a = a;
    }

    /**
      *
      * @return
      * The b
      */
    @JsonProperty("b")
    public String getB() {
        return b;
    }

    /**
      *
      * @param b
      * The b
      */
    @JsonProperty("b")
    public void setB(String b) {
        this.b = b;
    }

    /**
      *
      * @return
      * The array
      */
    @JsonProperty("array")
    public List<Object> getArray() {
        return array;
    }

    /**
      *
      * @param array
      * The array
      */
    @JsonProperty("array")
    public void setArray(List<Object> array) {
        this.array = array;
    }

    @JsonAnyGetter
    public Map<String, Object> getAdditionalProperties() {
        return this.additionalProperties;
    }

    @JsonAnySetter
    public void setAdditionalProperty(String name, Object value) {
        this.additionalProperties.put(name, value);
    }
}
```

Create a Bean

You can create a bean for the `ExampleJson` class with the following code:

```
ExampleJson bean = new ExampleJson();

bean.setA(1);
bean.setB("aString");

List arrList = new ArrayList();
arrList.add(1);
arrList.add(2);
arrList.add("arrStr");

Map arrMap = new HashMap();
arrMap.put("c","arrMapStr");
arrList.add(arrMap);
bean.setArray(arrList);
```

Create a New Document from a Bean

After creating the `ExampleJson` bean, you can create a JSON document using the bean with the following call:

```
Document pojoDoc = connection.newDocument(bean);
```

The document will have the following structure:

```
{
    "a":1,
    "b":"aString",
    "array":[
        1,
        2,
        "arrStr",
        {
            "c":"arrMapStr"
        }
    ]
}
```

Create a JavaBean from a JSON Document

You can also create a JavaBean from a JSON document. For example, suppose you modify the document that you created earlier:

```
pojoDoc.set("d","10");
```

The following converts the modified document back into an `ExampleJson` bean:

```
ExampleJson bean = pojoDoc.toJavaBean(ExampleJson.class);
```

Creating JSON Documents in Python OJAI
There are two ways to create JSON documents in your Python OJAI application, one of which is the preferred approach.

The preferred way to create a Python dictionary object and then pass it to the `Connection.new_document()` method:

```
json_dict = {
    "_id" : "movie0000001",
    "title" : "OJAI -- The Documentary",
    "studio" : "MapR Technologies, Inc.",
    "release_date" : "2015-09-29",
    "trailers" : {
        "teaser" : "https://10.10.21.90/trailers/teaser",
        "theatrical" : "https://10.10.21.90/trailers/theatrical"
    },
    "characters" : [
        "Heroic Developer",
        "Evil Release Manager",
        "Mad Development Manager"
    ],
    "box_office_gross" : 1000000000L
}
new_document = connection.new_document(dictionary=json_dict)
```

Alternatively, you can call `Document` interface methods to set fields and values:

```
doc = connection.new_document()
        .set_id("movie0000001")
        .set('title', 'OJAI - The Documentary')
        .set('studio', 'MapR Technologies, Inc.')
        .set('release_date', ODate.parse(date_str='2015-09-29'))
        .set('trailers.teaser', 'https://10.10.21.90/trailers/teaser')
        .set('trailers.theatrical', 'https://10.10.21.90/trailers/
theatrical')
        .set('characters', ['Heroic Developer', 'Evil Release Manager',
'Mad Development Manager'])
        .set('box_office_gross', 1000000000)
```

See the following for more details about the APIs:

- Connection
- Document

Sample OJAI Code for Creating JSON Documents
The sample code in this section shows you how to create a JSON document.

Java

The code is available at OJAI_001_GetConnectionCreateDocument.java.

```
/**

    // close the OJAI connection and release any resources held by the
connection
    connection.close();
  });
```

Python

The code is available at 001_get_connection_create_document.py.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Json string or json dictionary
json_dict = {"_id": "id001",
             "name": "Joe",
             "age": 50,
             "address": {
                 "street": "555 Moon Way",
                 "city": "Gotham"}
             }

# Create new document from json_document
new_document = connection.new_document(dictionary=json_dict)

# Print the OJAI Document
print(new_document.as_json_str())

# close the OJAI connection
connection.close()
```

C#

The code is available at 001_GetConnectionCreateDocument.cs.

```
using System;
using MapRDB.Driver;

public class GetConnectionCreateDocument
{
    public void GetConnectionCreateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Json string
        var jsonStr =
            @"{" +
                @"""_id"":""id001""," +
                @"""name"":""Joe""," +
                @"""age"":{""$numberInt"":""50""}," +
                @"""address"":" +
                    @"{" +
                        @"""street"":""555 Moon Way""," +
                        @"""city"":""Gotham""" +
                    @"}" +
            @"}";

        // Create a document from jsonStr
        var documentJson = connection.NewDocument(jsonStr);

        // Print the OJAI Document
        Console.WriteLine(documentJson.ToJsonString());

        // Create new document with the same fields using constructor
        var documentConstructed = connection.NewDocument()
            .SetID("id001")
            .Set("name", "Joe")
            .Set("age", 50)
            .Set("address.street", "555 Moon Way")
            .Set("address.city", "Gotham");

        // Print the OJAI Document
        Console.WriteLine(documentConstructed.ToJsonString());

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The code is available at 001_get_connection_create_document.go.

```
package main

import (
    "fmt"
```

```
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    // Create a connection to data access server
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Json string or map from which the Document will be created
    newMap := map[string]interface{}{
        "_id":  "id001",
        "name": "Joe",
        "age":  50,
        "address": map[string]interface{}{
            "street": "555 Moon Way",
            "city":   "Gotham",
        },
    }

    // Create new document from json_document
    newDocument := connection.CreateDocumentFromMap(newMap)

    // Print the new OJAI Document
    fmt.Println(newDocument.AsJsonString())

    // Close connection
    connection.Close()
}
```

Examples: Inserting JSON Documents

This section contains sample code that inserts a JSON document into a HPE Ezmeral Data Fabric Database JSON table. It also shows the HPE Ezmeral Data Fabric Database Shell syntax for inserting documents.

Java

The following code is available at OJAI_002_GetStoreAndInsertDocuments.java.

After you create the JSON document, call the DocumentStore.insertOrReplace method to insert the document into HPE Ezmeral Data Fabric Database.

```
/**

                        'zipCode': 95142
                    },
                    'phoneNumbers': [
                        {'areaCode': 555, 'number': 5425639},
                        {'areaCode': '555', 'number': '542-5656'}]
                    }
                   ]

for doc_dict in document_list:
    # Create new document from json_document
    new_document = connection.new_document(dictionary=doc_dict)
    # Print the OJAI Document
    print(new_document.as_json_str())

    # Insert the OJAI Document into the DocumentStore
    store.insert_or_replace(new_document)

# close the OJAI connection
connection.close()
```

dbshell

The following shows the syntax to insert a document with HPE Ezmeral Data Fabric Database Shell. See dbshell insert on page 5485 for more information and examples.

```
# mapr dbshell
maprdb root:>

// Syntax for inserting a document using the document ID
maprdb root:> insert <table path> --value '{"_id": "<row-key", < table
field >}'

// Syntax for inserting a document using document value
maprdb root:> insert <table path> --id <row-key> --value '{"_id":
"<row-key", < table field >}'
```

C#

The following code is available at 002_GetStoreAndInsertDocuments.cs.

The following code creates a list of JSON strings, creates Documents from the list, and calls the `DocumentStore.InsertOrReplace` method to insert the documents into the HPE Ezmeral Data Fabric Database.

```
using System;
using MapRDB.Driver;
using System.Collections.Generic;

public class GetStoreAndInsertDocuments
{
    public void GetStoreAndInsertDocuments()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        if (!connection.StoreExist("/demo_table"))
            connection.CreateStore("/demo_table");
        var store = connection.GetStore("/demo_table");

        var documentList = new List<string>
            {
                @"{""_id"":""user0000"","" +
                @"""age"":{""$numberInt"":""35""}," +
                @"""firstName"":""John""," +
                @"""lastName"":""Doe""," +
                @"""address"":{" +
                    @"""street"":""350 Hoger Way""," +
                    @"""city"":""San Jose""," +
                    @"""state"":""CA""," +
                    @"""zipCode"":{""$numberLong"":""95134""}" +
                    @"}," +
                @"""phoneNumbers"":[" +
                    @"{""areaCode"":{""$numberInt"":""555""},""number"":
{""$numberLong"":""5555555""}}," +
                    @"{""areaCode"":""555"",""number"":""555-5556""}]" +
                @"}",

                    @"""state"":""CA""," +
                    @"""zipCode"":{""$numberLong"":""95142""}" +
                    @"}," +
                @"""phoneNumbers"":[" +
                    @"{""areaCode"":{""$numberInt"":""555""},""number"":
{""$numberLong"":""5425639""}}," +
                    @"{""areaCode"":""555"",""number"":""542-5656""}]" +
                @"}"
            };

        foreach (var doc in documentList)
        {
            // Create new document from json string
            var document = connection.NewDocument(doc);

            // Print the OJAI Document
            Console.WriteLine(document.ToJsonString());

            // Insert the OJAI Document into the DocumentStore
            store.InsertOrReplace(document);
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The following code is available at 002_get_store_and_insert_documents.go.

The following code creates a list of JSON dictionary objects, creates Document objects, and calls the DocumentStore.InsertOrReplaceDocument function to insert the documents into HPE Ezmeral Data Fabric Database.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
```

last-updated: Jun 06, 2024

```
    isExists, err := connection.IsStoreExists(storeName)
    if err != nil {
        panic(err)
    }
    var store *client.DocumentStore
    if isExists {
        store, err = connection.GetStore(storeName)
        if err != nil {
            panic(err)
        }
    } else {
        store, err = connection.CreateStore(storeName)
        if err != nil {
            panic(err)
        }
    }

    // Slice of maps from which the Document will be created
    documentArray := []map[string]interface{}{
        {
            "_id":       "user0000",
            "age":       35,
            "firstName": "John",
            "lastName":  "Doe",
            "address": map[string]interface{}{
                "street":  "350 Hoger Way",
                "city":    "San Jose",
                "state":   "CA",
                "zipCode": 95134,
            },
            "phoneNumbers": []interface{}{
                map[string]interface{}{"areaCode": 555, "number": 5555555},
                map[string]interface{}{"areaCode": "555", "number":
"555-5556"},
            },
        },
        {
            "_id":       "user0001",
            "age":       26,
            "firstName": "Jane",
            "lastName":  "Dupont",
            "address": map[string]interface{}{
                "street":  "320 Blossom Hill Road",
                "city":    "San Jose",
                "state":   "CA",
                "zipCode": 95196,
            },
            "phoneNumbers": []interface{}{
                map[string]interface{}{"areaCode": 555, "number": 5553827},
                map[string]interface{}{"areaCode": "555", "number":
"555-6289"},
            },
        },
        {
            "_id":       "user0002",
            "age":       45,
            "firstName": "Simon",
            "lastName":  "Davis",
            "address": map[string]interface{}{
                "street":  "38 De Mattei Court",
                "city":    "San Jose",
                "state":   "CA",
                "zipCode": 95142,
            },
```

```
            "phoneNumbers": []interface{}{
                map[string]interface{}{"areaCode": 555, "number": 5425639},
                map[string]interface{}{"areaCode": "555", "number":
"542-5656"},
            },
        },
    }

    for _, docMap := range documentArray {
        // Create new document from json_document
        newDocument := connection.CreateDocumentFromMap(docMap)
        // Print the new OJAI Document
        fmt.Println(newDocument.AsJsonString())
        //Insert the OJAI Document into the DocumentStore
        store.InsertOrReplaceDocument(newDocument)
    }

    // Close connection
    connection.Close()
}
```

Using OJAI Mutation Syntax

To perform updates using OJAI, you specify the document you want to update using its `_id` field, create *mutations* for that document, and then update it in your document store. OJAI defines a syntax for specifying mutations. Mutations allow you to append, decrement, delete, increment, combine, replace, and update fields in a document. This topic describes the syntax for the supported mutation operations and provides examples.

The following table lists the mutations OJAI supports. Each entry in the table contains a brief description of the mutation and a link to a section in this topic that describes the mutation in more detail.

Mutation Operation	Description
Append	Appends values to binary, string, and array fields
Decrement	Decrements field values
Delete	Deletes fields
Increment	Increments field values
Merge	Combines a nested document with an existing document
Put	Replaces field values or adds new fields
Set	Updates field values or adds new fields

The examples in this topic use the following sample JSON document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 10,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

last-updated: Jun 06, 2024

OJAI Append Mutations

Syntax

```
{"$append":{"fieldpath":value}}
```

```
{"$append":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The `$append` mutation is a read-modify-write operation. Use it to append specified values to existing binary, string, or array type fields. If there is type mismatch in any intermediate field specified in a *fieldpath* for the document, the mutation fails with an error. For example, an append mutation on field path `a.b.c` fails if the field `a` is a scalar.

To append multiple field paths, use an array notation to list the field paths.

Example

The following mutation appends an element to the array `a.b` and appends the string `" MapR"` to the end of the string already in the field path `a.c.e`:

```
{"$append":[{"a.b":{"appd":1}},
{"a.c.e":" MapR"}]}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 }, { "appd" :
1 } ],
    "c" : {
      "d" : 10,
      "e" : "Hello MapR"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Decrement Mutations

Syntax

```
{"$decrement":"fieldpath"}
```

```
{"$decrement":
{"fieldpath":decrementValue}}
```

```
{"$decrement":
[{"fieldpath1":decrementValue1},
{"fieldpath2":decrementValue2},...]}
```

Description

The `$decrement` mutation decrements the value in the *fieldpath*. To decrement multiple field paths, use an array notation to list the field paths.

If the *fieldpath* does not exist, the mutation adds a new field to the document with the value *decrementValue*.

The *decrementValue* is optional and defaults to -1.

The mutation fails if there is a type mismatch in the field.

Example

The following updates the value 10 in `a.c.d` to 5 by using the decrement mutation:

```
{"$decrement":{"a.c.d":5}}
```

The mutation results in the following document, with the field update highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 5,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Delete Mutations

Syntax

```
{"$delete":"fieldpath"}
```

```
{"$delete":
["fieldpath1","fieldpath2",...]}
```

Description

The `$delete` mutation removes either a single field or a list of fields from a document. If the field does not exist, the delete ignores that field.

Example

The following mutation removes two fields from the document:

```
{"$delete":["a.b[1]","a.c.e"]}
```

The mutation results in the following document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false } ],
    "c" : {
      "d" : 10
    }
  },
  "m" : "MapR wins"
}
```

last-updated: Jun 06, 2024

OJAI Increment Mutations

Syntax

```
{"$increment":"fieldpath"}
```

```
{"$increment":
{"fieldpath":incrementValue}}
```

```
{"$increment":
[{"fieldpath1":incrementValue1},
{"fieldpath2":decrementValue2},...]}
```

Description

The `$increment` mutation increments the value in the *fieldpath*. To increment multiple field paths, use an array notation to list the field paths.

If the *fieldpath* does not exist, the mutation adds a new field to the document with the value *incrementValue*.

The *incrementValue* is optional and defaults to 1.

The mutation fails if there is a type mismatch in the field.

Example

The following updates the value 10 in `a.c.d` to 15 by using the increment mutation:

```
{"$increment":{"a.c.d":5}}
```

The mutation results in the following document, with the field update highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 15,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Merge Mutations

Syntax

```
{"$merge":
{"fieldpath":nestedDocument}}
```

Description

The `$merge` mutation combines a *nestedDocument* with an existing document at a specified *fieldpath*. If the original document already contains subfields specified in the *nestedDocument*, then the mutation replaces the values for those subfields. Otherwise, it adds new subfields to the document.

NOTE: The `$merge` mutation does not support the array notation that other mutation operations provide.

last-updated: Jun 06, 2024

To specify more than one merge operation in a single mutation, use the syntax described at either Specifying Multiple Mutation Operations on page 3348 or OJAI Mutations Without Explicit Mutation Operation Names on page 3349. When using these syntax variations, avoid specifying overlapping field paths. HPE Ezmeral Data Fabric Database treats these as conflicting mutations and discards conflicts.

Examples

The following mutation replaces the pre-existing field path `a.c.d` with the value 11. It adds a new subfield y to the nested document `a.c`.

```
{"$merge":{"a.c":{"d":11,"y":"yo"}}}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello",
      "y" : "yo"
    }
  },
  "m" : "MapR wins"
}
```

The following mutation replaces the value in the field path `a.b` and adds a new subfield `a.d`:

```
{"$merge":{"a":{"b":1,"d":"MapR"}}}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : 1,
    "c" : {
      "d" : 10,
      "e" : "Hello"
    },
    "d" : "MapR"
  },
  "m" : "MapR wins"
}
```

OJAI Put Mutations

Syntax

```
{"$put":{"fieldpath":value}}
```

```
{"$put":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The `$put` mutation is a replace operation. It is not a read-modify-write operation; it does no validation on the data. If the specified *fieldpath* exists, the mutation replaces the *fieldpath*'s value with the new *value,* regardless of the type of the original value. For example, you can update a field `a.b` from an array to a nested document. If the *fieldpath* does not exist, the mutation creates a new field with the given *value*. Because the operation does no data validation, it is significantly faster than the set operation.

To replace multiple field paths, use an array notation to list the field paths.

Example

The following example replaces the pre-existing fields `a.b` and `a.c.d` with values whose types differ from the original types. It also adds a new field `a.x`.

```
{"$put":[{"a.b":{"boolean":true}},
{"a.c.d":"eureka"},{"a.x":1}]}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : { "boolean" : true },
    "c" : {
      "d" : "eureka",
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

The mutation behaves as follows for the pre-existing fields:

- For `a.b`, the mutation replaces the original array of nested documents with a single nested document.
- For `a.c.d`, the mutation changes the field from an integer to a string.

OJAI Set Mutations

Syntax

```
{"$set":{"fieldpath":value}}
```

```
{"$set":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The `$set` mutation updates one or more fields in a document. It is a read-modify-write operation. It validates the type of the existing value before applying the mutation. If the specified *fieldpath* does not exist in a document, the mutation creates a new field. If the *fieldpath* exists but is not of the same type as the type of new *value*, then the entire mutation fails.

last-updated: Jun 06, 2024

To update multiple field paths, use an array notation to list the field paths.

Example

The following example updates the pre-existing fields `a.b.[0]` and `a.c.d`. It also adds a new field `a.x`.

```
{"$set":[{"a.b[0].boolean":true},
{"a.c.d":11},{"a.x":1}]}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : true },
{ "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

Specifying Multiple Mutation Operations

You can specify more than one operation in a single mutation by specifying each operation separated by a comma.

The following is a mutation with six operations:

```
{
   "$set":{"x":[1,2,3]},
   "$put":{"a.c.e":{"$binary":"AAAADg=="}},
   "$increment":"a.b[1].decimal",
   "$delete":"a.b[0]",
   "$merge":{"newDoc":{"k":"MapR DBShell rocks!!"}},
   "$append":{"m":"!!!"}
}
```

It results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "decimal" : 124.456 } ],
    "c" : {
      "d" : 10,
      "e" : { "$binary" : "AAAADg==" }
    }
  },
  "m" : "MapR wins!!!",
  "newDoc" : { "k" : "MapR DBShell rocks!!" },
  "x" : [ 1, 2, 3 ]
}
```

The mutation applies the updates in the following manner:

- The `$set` mutation adds a new array field `x` with the value `[1, 2, 3]`.

last-updated: Jun 06, 2024

- The `$put` mutation replaces the string `"Hello"` with the nested document `{"$binary":"AAAADg=="}`.
- The `$increment` mutation increments the value `123.456` in the second element of the array `a.b`.
- The `$delete` mutation deletes the field path `a.b[0]`, resulting in a single element array `a.b`.
- The `$merge` mutation adds a new field `newDoc` with the nested document `{"k":"MapR DBShell rocks!!"}` as its value.
- The `$append` mutation appends the string `"!!!"` to the end of the string `"MapR wins"`.

Conflicting Mutations

When you specify a mutation with field paths that are overlapping, HPE Ezmeral Data Fabric Database detects the conflict, discards the previous conflicting operation, and proceeds with the next operation.

For example, suppose you have the following document:

```
{"_id":"id1", "a":{"b":{"c":5}}}
```

The following mutation has two operations with overlapping fields `a.b`:

```
{"$delete":"a.b","$set":{"a.b.d":10}}
```

You may have intended for the mutation to first delete `a.b` and then to replace it with `a.b.d` as follows:

```
{"_id":"id1", "a":{"b":{"d":"10"}}}
```

But the *actual* result is the following:

```
{"_id":"id1", "a":{"b":{"c":5,"d":"10"}}}
```

In this case, the set operation on **`a.b.d`** causes the delete operation on **`a.b`** to be discarded.

NOTE: In the earlier example in this section, the `$increment` and `$delete` operations are not conflicting because one operates on `a.b[1]`, while the other operates on `a.b[0]`. On the other hand, the following are conflicting operations:

```
{"$increment":"a.b[1].decimal","$delete":"a.b"}
```

OJAI Mutations Without Explicit Mutation Operation Names

You can specify a mutation without using an explicit mutation name. These mutations run as merge operations.

For example, the following mutation merges the fields `k` and `a.c.d` to the document by adding a new field `k` and updating `a.c.d`:

```
{"k":"eureka","a":{"c":{"d":1234}}}
```

The mutation results in the following document, with updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
```

last-updated: Jun 06, 2024

```
      "d" : 1234,
      "e" : "Hello"
    }
  },
  "k" : "eureka",
  "m" : "MapR wins"
}
```

Examples: Updating JSON Documents
This section contains sample code that updates a JSON document in a HPE Ezmeral Data Fabric Database JSON table using an OJAI mutation. It also shows the HPE Ezmeral Data Fabric Database Shell syntax for updating documents.

See Using OJAI Mutation Syntax on page 3342 for more details about OJAI mutations.

Java

The following code is available at OJAI_012_UpdateDocument.java. It does the following:

- Finds a document using the DocumentStore.findById method
- Creates a DocumentMutation that updates a field
- Updates the document by calling the DocumentStore.update method

```

package com.mapr.ojai.examples;

import org.ojai.store.Connection;
import org.ojai.store.DocumentMutation;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

public class OJAI_012_UpdateDocument {

  public static void main(String[] args) {

    System.out.println("==== Start Application ===");

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI DocumentStore
    final DocumentStore store = connection.getStore("/demo_table");

    String docId = "user0002";

    // Print the document before update
```

```
    System.out.println( "\t"+
store.findById(docId).getMap("address").toString() );

    // Create a DocumentMutation to update the zipCode field
    DocumentMutation mutation = connection.newMutation()
        .set("address.zipCode", 95196L);

    System.out.println("\tUpdating document "+ docId);

    // Update the Document with '_id' = "user0002"
    store.update(docId, mutation);

    // Print the document after update
    System.out.println( "\t"+
store.findById(docId).getMap("address").toString() );

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Node.js - Update

The following code is available at OJAI_011_UpdateDocument.js. It does the following:

- Finds a document using the DocumentStore.findById method
- Creates an OJAI mutation that updates a field
- Updates the document by calling the DocumentStore.update method

```

  });
```

Python - Update

The following code is available at 012_update_document.py. It does the following:

- Finds a document using the DocumentStore.find_by_id method
- Creates an OJAI mutation that updates a field

last-updated: Jun 06, 2024

- Updates the document by calling the DocumentStore.update method

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

doc_id = 'user0002'

# Print the document before update
document_before_update = store.find_by_id(doc_id)
print("Document with id {0} before update".format(doc_id))
print(document_before_update)

# Create mutation to update the zipCode field
mutation = {'$set': {'address.zipCode': 95196}}

# Execute update
store.update(_id=doc_id, mutation=mutation)

document_after_update = store.find_by_id(doc_id)
print('Document with id {0} after update'.format(doc_id))
print(document_after_update)
```

Python - Check and Update

The following code is available at 013_check_and_update_document.py. It does the following:

- Finds a document using the DocumentStore.find_by_id method
- Creates an OJAI mutation that updates a field
- Creates an OJAI condition to apply in the check and update
- Performs the check and update on the document by calling the DocumentStore.check_and_update method

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
                 "ssl=true;" \
                 "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
                 "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

doc_id = 'user0001'

# Print the document before update
document_before_update = store.find_by_id(doc_id)
print("Document with id {0} before update".format(doc_id))
print(document_before_update)
```

last-updated: Jun 06, 2024

```
# Create mutation to update the zipCode field
mutation = {'$put': {'address.zipCode': 99999}}

# Create condition
condition = {'$eq': {'address.street': '320 Blossom Hill Road'}}

# Execute check_and_update.
# Returns True if condition True and document was updated.
update_result = store.check_and_update(_id=doc_id,
                                       mutation=mutation,
                                       query_condition=condition)

print(update_result)

document_after_update = store.find_by_id(doc_id)
print('Document with id {0} after update'.format(doc_id))
print(document_after_update)
```

dbshell

The following dbshell command is equivalent to the code examples. See dbshell update on page 5488 for more information and examples.

```
# mapr dbshell
maprdb root:> update /demo_table --id user002 --m {"$set":
{"address.zipCode":95196}}
```

C# - Update

The following code is available at 012_UpdateDocument.cs. It does the following:

- Finds a document using the `DocumentStore.FindById` method to print the document before update.
- Creates an OJAI mutation that updates a field.
- Updates the document by calling the `DocumentStore.Update` method.

```
using System;
using MapRDB.Driver;

public class UpdateDocument
{
    public void UpdateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        var docId = "user0002";

        // Print the document before update
        var documentBeforeUpdate = store.FindById(docId);
```

```
        Console.WriteLine($"Document with id {docId} before update:");
        Console.WriteLine(documentBeforeUpdate);

        // Create mutation to update the zipCode field
        var mutation =
connection.NewDocumentMutation().Set("address.zipCode", (long)95196);

        // Execute update
        store.Update(docId, mutation);

        // Print the document after update
        var documentAfterUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} after update:");
        Console.WriteLine(documentAfterUpdate);

        // Close the OJAI connection
        connection.Close();
    }
}
```

C# - Check and Update

The following code is available at 013_CheckAndUpdateDocument.cs. It does the following:

- Finds a document using the `DocumentStore.FindById` method to print the document before update.
- Creates an OJAI mutation that updates a field.
- Creates an OJAI condition to apply in the check and update.
- Performs the check and update on the document by calling the `DocumentStore.CheckAndUpdate` method.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class CheckAndUpdateDocument
{
    public void CheckAndUpdateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        var docId = "user0001";

        // Print the document before update
        var documentBeforeUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} before update:");
        Console.WriteLine(documentBeforeUpdate);

        // Create mutation to update the zipCode field
        var mutation =
```

```
connection.NewDocumentMutation().SetOrReplace("address.zipCode", 99999);

        // Create condition
        var condition = connection
            .NewQueryCondition()
                .Is("address.street", QueryOp.EQUAL, "320 Blossom Hill
Road")
                .Close()
            .Build();

        // Execute CheckAndUpdate.
        // Returns True if condition True and document was updated
        var updateResult = store.CheckAndUpdate(docId, condition, mutation);

        Console.WriteLine(updateResult);

        // Print the document after update
        var documentAfterUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} after update:");
        Console.WriteLine(documentAfterUpdate);

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - Update

The following code is available at 012_update_document.go. It does the following:

- Finds a document using the `DocumentStore.FindByIdString` function to print the document before update
- Creates an OJAI mutation that updates a field
- Updates the document by calling the `DocumentStore.Update` function

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"
    documentId := "user0002"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }
```

```
    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Print the document before update
    documentBeforeUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Document with id %v before update.\n %v", documentId,
documentBeforeUpdate.AsJsonString())

    // Create mutation to update the zipCode field
    mutation := map[string]interface{}{"$set": map[string]interface{}
{"address.zipCode": 95196}}

    // Execute update
    err = store.Update(client.BosiFromString(documentId),
client.MosmFromMap(mutation))
    if err != nil {
        panic(err)
    }

    // Print the document after update
    documentAfterUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Document with id %v after update.\n %v", documentId,
documentAfterUpdate.AsJsonString())

    // Close connection
    connection.Close()
}
```

Go - Check and Update

The following code is available at 013_check_and_update_document.go. It does the following:

- Finds a document using the DocumentStore.FindByIdString function to print the document before update
- Creates an OJAI mutation that updates a field
- Creates an OJAI condition to apply in the check and update
- Performs the check and update on the document by calling the `DocumentStore.CheckAndUpdate` function

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
```

```
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"
    documentId := "user0001"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Print the document before update
    documentBeforeUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Document with id %v before update.\n %v\n", documentId,
documentBeforeUpdate.AsJsonString())

    // Create mutation to update the zipCode field
    mutation := map[string]interface{}{"$put": map[string]interface{}
{"address.zipCode": 99999}}

    // Create condition
    condition := map[string]interface{}{"$eq": map[string]interface{}
{"address.street": "320 Blossom Hill Road"}}

    // Execute update
    // Returns True if condition True and document was updated.
    res, err := store.CheckAndUpdate(
        client.BosiFromString(documentId),
        client.MoscFromMap(condition),
        client.MosmFromMap(mutation))
    if err != nil {
        panic(err)
    }

    // Print the document after update
    documentAfterUpdate, err := store.FindByIdString(documentId)
    if err != nil {
        panic(err)
    }
    fmt.Printf("Update result: %v.\nDocument with id %v after update.\n
%v\n",
        res,
        documentId,
        documentAfterUpdate.AsJsonString())

    // Close connection
    connection.Close()
}
```

last-updated: Jun 06, 2024

Querying JSON Documents
This section describes how to query JSON documents in HPE Ezmeral Data Fabric Database JSON tables using the OJAI API library and HPE Ezmeral Data Fabric Database Shell. It includes sample programs using the OJAI API library and shows how to run the same queries in HPE Ezmeral Data Fabric Database Shell.

Querying in OJAI Applications
To query HPE Ezmeral Data Fabric Database JSON tables in your OJAI applications, you use the OJAI `Query` interface. The typical flow of your application involves creating a connection, obtaining a handle to the HPE Ezmeral Data Fabric Database JSON table you want to query, constructing the query, performing the query, and then processing the results.

NOTE: The Node.js, Python, C#, and Go OJAI clients are supported starting in EEP 6.0.

Description

The `DocumentStore` interface includes a `Query` interface. The `Query` interface allows you to build a query programmatically.

Java	To construct an OJAI query, call the following methods in the `Query` interface: • Query.select • Query.where • Query.orderBy • Query.offset • Query.limit To run the query, pass the `Query` object to the DocumentStore.find method.
Node.js	To construct an OJAI query, create a Node.js JSON object using OJAI Query Syntax on page 3384. To run the query, pass the `Query` object to the DocumentStore.find method.
Python	To construct an OJAI query, create a Python dictionary object using OJAI Query Syntax on page 3384. To run the query, pass the `Query` object to the DocumentStore.find method. **NOTE:** The following `Query` methods are available in the Python OJAI API, but creating a Python dictionary is the preferred approach: • Query.select • Query.where • Query.order_by • Query.offset • Query.limit
C#	To construct an OJAI query, create a C# object.

To run the query, pass the `Query` object to the `DocumentStore.Find` method.

NOTE: The following `Query` methods are available in the C# OJAI API:

- Query.Select
- Query.Where
- Query.OrderBy
- Query.Offset
- Query.Limit

Go

To construct an OJAI query, create a Go object.

To run the query, pass the `Query` object to the `DocumentStore.FindQuery` function.

NOTE: The following `Query` functions are available in the Go OJAI API:

- `Query.Select`
- `Query.WhereCondition`
- `Query.OrderBy`
- `Query.Offset`
- `Query.Limit`

Basic Application Flow

The following steps describe the basics in developing client applications that query HPE Ezmeral Data Fabric Database JSON tables using the OJAI API.

Java

1. Create a Connection instance to your MapR cluster using the DriverManager class:

```
Connection connection =
DriverManager.getConnection("ojai:m
apr:");
```

NOTE: Do not omit the ending colon in the connection string.

2. Obtain a DocumentStore handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
DocumentStore store =
connection.getStore(tablePath);
```

3. Create a Query object using the connection object:

```
Query query =
connection.newQuery();
```

4. Perform the query operation on the table:

```
QueryResult result =
store.find(query);
```

5. Process the results.

   The following code snippet iterates through the QueryResult and prints each document as a JSON string:

```
for (final Document userDocument :
result) {
    // Print the OJAI Document

System.out.println(userDocument.asJ
sonString());
}
```

   To process individual fields within a document, use the DocumentReader interface. The following code snippet iterates through the fields in a document and prints the fields that are strings:

```
Iterable it =
result.documentReaders();
for (DocumentReader reader : it) {
    EventType et = null;
    while ((et = reader.next()) !=
null) {
        if (et ==
EventType.STRING) {

System.out.println("Value of field
" + reader.getFieldName() + ": " +
reader.getString());
        }
    }
}
```

6. Close the result stream, the connection to the document store, and the connection to MapR:

```
result.close();
store.close;
connection.close();
```

Node.js

1. Create a connection:

```
ConnectionManager.getConnection('lo
calhost:5678?;user=mapr;password=ma
pr;ssl=false')
    .then((connection) => {
        // Process connection
        ...
    });
```

2. Obtain a handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
connection.getStore(tablePath)
    .then((store) => {
        // Process store
        ...
    });
```

3. Create a query object:

```
const query = {};
```

4. Perform the query operation on the table:

```
const stream = store.find(query)
```

5. Process the results:

```
stream.on('data', (document) =>
console.log(document));
```

6. Close the connection to MapR:

```
stream.on('end', () => {
  console.log('end');
  connection.close();
});
```

Python

1. Create a Connection instance to your MapR cluster using the `ConnectionFactory` class:

```
connection_str =
'localhost:5678?;user=mapr;password
=mapr;ssl=false'
connection =
ConnectionFactory.get_connection(co
nnection_str=connection_str)
```

last-updated: Jun 06, 2024

2. Obtain a DocumentStore handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
store =
connection.get_store(table_path)
```

3. Create a Query object using the connection object:

```
query =
connection.new_query().build()
```

4. Perform the query operation on the table:

```
query_result = store.find(query)
```

5. Process the results.

   The following code snippet iterates through the QueryResult and prints each document as a Python dictionary:

```
for doc in query_result:
    print(doc)
```

6. Close the connection to MapR:

```
connection.close()
```

C#

1. Create a `Connection` instance to your MapR cluster using the `ConnectionFactory` class:

```
var connectionStr =
$"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/
ssl_truststore.pem;" +

$"sslTargetNameOverride=node1.mapr.
com";
var connection =
ConnectionFactory.CreateConnection(
connectionStr);
```

2. Obtain a `DocumentStore` handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
var store =
connection.GetStore(storePath);
```

3. Create a `Query` object using the connection object:

```
var query =
connection.NewQuery().Build();
```

4. Perform the query operation on the table:

```
var queryResult =
store.Find(query);
```

5. Process the results.

   The following code snippet iterates through the `QueryResult` and prints each document as a JSON:

```
var documentStream = await
queryResult.GetDocumentAsyncStream(
).GetAllDocuments();
foreach (var document in
documentStream)
{

Console.WriteLine(document.ToJsonSt
ring());
}
```

6. Close the connection to MapR:

```
connection.Close();
```

Go

1. Create a `Connection` instance to your MapR cluster:

```
connectionString :=
"localhost:5678?
auth=basic;user=mapr;password=mapr;
ssl=false"
connection, error :=
client.MakeConnection(connectionStr
ing)
```

2. Obtain a `DocumentStore` handle to a HPE Ezmeral Data Fabric Database JSON table using the connection object:

```
store,
error := connection.CreateStore("/
store_path")
```

last-updated: Jun 06, 2024

3. Create a Query object:

```
query, err := client.MakeQuery()
query.Build()
```

4. Perform the query operation on the table:

```
queryResult, err :=
store.FindQuery(query,
&client.FindOptions{})
```

5. Process the results.

   The following code snippet iterates through the QueryResult and prints each document as a JSON:

```
    for _, doc := range
queryResult.DocumentList() {
        fmt.Println(doc)
    }
```

6. Close the connection to MapR:

```
connection.Close()
```

See Examples: Querying JSON Documents on page 3405 for complete code examples.

Related concepts

OJAI Distributed Query Service on page 640
OJAI queries either directly access HPE Ezmeral Data Fabric Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for HPE Ezmeral Data Fabric Database JSON, powered by Apache Drill. The data-fabric client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of Drill.

Comparisons and Sorts in OJAI Queries

When running OJAI queries with comparisons and sorts, you need to be aware of how different data types behave. You also need to understand how sorting works in MapR-DB queries. Depending on the component that runs the sort, you may encounter unexpected behavior.

OJAI supports comparisons using the `QueryCondition` interface. For information about how to use this interface, see Query Conditions in OJAI Applications on page 3370.

When using the OJAI `Query` `where` and `orderby`, and comparing and sorting across different data types, there are subtleties you should take into consideration. See Using Comparable JSON Document Data Types in Comparisons and Sorts on page 649 and Using Non-comparable JSON Document Data Types in Comparisons and Sorts on page 650 for more information.

If you do not have a secondary index defined that can generate your query's specified `orderby`, then your query requires an explicit sort. If you have installed the OJAI Distributed Query Service on page 640, the service performs the sort. If you have not, the MapR client performs the sort, but restricts the amount of data it can sort. The default sort limit is 5000 documents. For example, if your query returns 10,000 documents, and you specify a query result `limit` of 5000 documents, the MapR client can perform the sort.

IMPORTANT: The MapR client returns an error if your query result size exceeds the client's sort limit.

You can avoid errors due to the client sort limitation by adhering to the following guidelines:

- If you know the largest possible query result size when your queries specify an `order by`, you can increase the sort limit of your client to that maximum size by setting the `ojai.mapr.query.max-client-sort-limit` parameter.

  The following code snippets increase the limit to 6000:

Java

```
query.setOption("ojai.mapr.query.ma
x-client-sort-limit", 6000);
```

NOTE: This option is not applicable to the Java OJAI Thin Client.

Node.js

```
const query
= {"$select":"col","$options":
{"ojai":{"mapr":{"query":
{"max-client-sort:6000}}}}
const stream = store.find(query)
```

Python

```
query = {"$select":"col","$options":
{"ojai":{"mapr":{"query":
{"max-client-sort:6000}}}}
query_result = store.find(query)
```

C#

```
            var query =
connection.NewQuery()
                .Select("col")
                .SetMaxClientSortLimi
t(6000)
                .Build();

            var queryResult =
store.Find(query);
```

Go

```
query := map[string]interface{}{
    "$select":"col",
    "$options":map[string]interface{}
{
        "ojai":map[string]interface{}
{
```

last-updated: Jun 06, 2024

```
"mapr":map[string]interface{}{

"query":map[string]interface{}{

"max-client-sort":6000}}}}
queryResult, err :=
store.FindQueryMap(query,
&client.FindOptions{})
```

You can also set this option across all your OJAI clients by modifying a data access gateway property. See Administering the MapR Data Access Gateway - Application Properties for details.

- If you do not know the largest possible query result size, specify a `limit` in your queries. If your query result size exceeds that `limit`, the client sorts the entire result set but returns only a subset of the rows up to the specified limit. This avoids the error, but may result in unintended behavior if your application is not expecting a truncated result. You should take corrective action if necessary.

  See Querying with Order By on page 3435 for an example of how to set a query `limit`.

Permissions and OJAI Queries
You need to understand permission requirements because they affect filter conditions in your OJAI queries.

HPE Ezmeral Data Fabric Database enforces permissions when your application processes the query result. In the basic application flow shown in the previous section, this corresponds to step 5. In an application, if user1 performs the query while user2 processes the result, then the result corresponds to user2's permissions.

You should create a separate OJAI connection for each unique user. Sharing a connection across users can result in non-optimal queries or invalid permission errors.

The following permissions are required to query documents:

- The `readAce` permission on the volumes where the JSON tables that contain the documents are located. See Setting Whole Volume ACEs on page 1365.
- The `readperm` permission on the JSON table's column families containing fields being queried. See Enabling Table and Stream Authorizations with ACEs on page 1363.

If the user does not have the `readperm` permission on a field, HPE Ezmeral Data Fabric Database treats the field as non-existent for that user. When a query selects a non-existent field, HPE Ezmeral Data Fabric Database ignores the field. If a query filters on a non-existent field, the query behaves as follows:

Filter Condition on Non-existent Field	Behavior
Filter for specific values in the field	No documents qualify the filter because a non-existent field does not match any value.
Filter for non-matches in the field	All documents qualify the filter because a non-match on a non-existent field is a no-op.

The exception is the rowkey field. Access control on the rowkey is not available. Users can always select and filter on rowkey.

For information about setting permissions, see Permission Types for Fields and Column Families in JSON Tables on page 1400.

OJAI Query Options
OJAI supports query options that enable you to modify the behavior of your queries. This includes an option to force secondary index usage and options to influence the behavior of sorts.

Available Query Options

The following table lists available query options. Some options may or may not apply, depending on whether your query uses the OJAI Distributed Query Service. The detailed descriptions make a note of this.

Option Name	Description	Details
`ojai.mapr.query.hint-using-index`	Forces the MapR client to use a particular index, regardless of cost considerations	Forcing Secondary Index Usage in OJAI on page 3369
`ojai.mapr.query.force-noncovering-sort`	Enables sort behavior to avoid partial sorts due to secondary index lags	Avoiding Partial Sorts with Secondary Indexes in OJAI on page 3369
`ojai.mapr.query.max-client-sort-limit`	Sets the MapR client sort limit	Comparisons and Sorts in OJAI Queries on page 3366
`ojai.mapr.query.force-drill`	When set to `true`, forces the MapR client to use the OJAI Distributed Query Service	Forcing Usage of the OJAI Distributed Query Service on page 3370
`ojai.mapr.drill.<OJAI Distributed Query Service Property Name>`	Sets options for the OJAI Distributed Query Service	Setting OJAI Distributed Query Service Properties on page 3370

Setting Query Options

To set these options in your OJAI application, see the following topics:

Java	Setting Query Options in Java OJAI on page 3450
Node.js	Setting Query Options in Node.js Using OJAI Query Syntax on page 3458
Python	Setting Query Options in Python Using OJAI Query Syntax on page 3468
C#	Setting Query Options in C# OJAI on page 3472
Go	Setting Query Options in Go OJAI on page 3476

Forcing Secondary Index Usage in OJAI

To force the MapR client to use an index, specify the name of the index with the `ojai.mapr.query.hint-using-index` option.

Regardless of cost considerations, the MapR client attempts to use the specified index. To use the index, the index must benefit filter conditions, the order by, or projections in the query as described at Queries that Benefit from Secondary Indexes on page 708. Otherwise, the MapR client ignores the option.

To force the MapR client to *not* use any indexes, specify the table name without the full path as the second parameter in the calls shown earlier. For example, if the full path of your table is `/mapr/sanfrancisco/volume1/customer`, pass the name `customer` as the second parameter.

NOTE: Setting this option in your OJAI application has no effect if you are using the OJAI Distributed Query Service.

Avoiding Partial Sorts with Secondary Indexes in OJAI

Partial sorts can occur due to secondary index lags. To avoid these lags, set the `ojai.mapr.query.force-noncovering-sort` option to TRUE.

last-updated: Jun 06, 2024

This option forces the OJAI Distributed Query Service to explicitly sort the data. Do not set this option if you do not expect to encounter index lags. Otherwise, you lose the ordering advantage that secondary indexes provide.

For more information about why partial sorts occur, see Partial Sorts with Non-Covering Indexes on page 718.

Forcing Usage of the OJAI Distributed Query Service

When set to `true`, the MapR client uses the OJAI Distributed Query Service execution path, rather than selecting an execution path that it determines to be most optimal. See OJAI Distributed Query Service on page 640 for more information about the different query execution paths.

Setting OJAI Distributed Query Service Properties

OJAI queries may leverage the OJAI Distributed Query Service. To modify OJAI Distributed Query Service property settings in your OJAI application, prefix the OJAI Distributed Query Service property name with `ojai.mapr.drill`.

For example, the option `ojai.mapr.drill.planner.enable_index_planning` disables using secondary indexes when queries use the Query Service.

See Index Planning and Execution Configuration Options on page 4103 for the list of available OJAI Distributed Query Service properties.

Related concepts

OJAI Distributed Query Service on page 640
OJAI queries either directly access HPE Ezmeral Data Fabric Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for HPE Ezmeral Data Fabric Database JSON, powered by Apache Drill. The data-fabric client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of Drill.

Query Conditions in OJAI Applications

You can create a query condition in an OJAI application in either of two ways. One way is to create an OJAI `QueryCondition` object and call methods in the class to construct your query condition. Another way is to create an OJAI query condition in a JSON format.

Creating an OJAI QueryCondition Object

The Java and Python OJAI clients support a `QueryCondition` interface. After you create a `QueryCondition` object, call methods in the class to construct your query condition.

Creating a `QueryCondition` Object

Java

Java OJAI provides a `QueryCondition.is()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryCondition.Op`
- The value to compare the field path against

The field path is either a field in a JSON document, a subfield within a nested document, or an array element.

Depending on the type of the field path, you specify the comparison value as follows:

last-updated: Jun 06, 2024

Scalar Data	You can specify the value using either a Java typed value (for example, `int`, `float`, or `String`) or a Java OJAI object. The API supports the following OJAI types: • `ODate` • `OInterval` • `OTime` • `OTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Java `Map` object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a Java `List` object. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.is()`, `QueryCondition` also supports the following methods:

`QueryCondition` Method	**Description**
`equals()` `notequals()`	Match for equality or non-equality on nested documents and arrays
`in()`	Search for individual elements in an array
`like()`	Search for string values using SQL LIKE expressions

QueryCondition Method	Description
`matches()`	Search for string values using regular expressions. You can use regular expressions that compose the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See HBase Java Regular Expressions Support on page 3292 for a list of supported regular expressions.
`and()`	Begins a new AND condition block
`or()`	Begins a new OR condition block
`elementAnd()`	Begins a new `elementAnd` block. See OJAI Query Condition Operators on page 3387 for a detailed description of this operator.
`close()`	Closes a compound condition block
`build()`	Builds the condition

NOTE: The material described in this section is a subset of the `QueryCondition` API. It introduces you to the basics of the API. For the complete API, see the QueryCondition interface.

Python

Python OJAI provides a `QueryCondition.is_()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryConditionOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. See OJAI Query Conditions Using Container Field Paths on page 3396 for details.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data — You can specify the value using either a Python scalar value (for example, `int`, `float`, or `str`) or a Python OJAI object.

last-updated: Jun 06, 2024

	The API supports the following OJAI types: • `ODate` • `OInterval` • `OTime` • `OTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Python `dictionary` object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a Python `list` object. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.is_()`, `QueryCondition` also supports the following methods:

`QueryCondition` Method	**Description**
`equals_()` `not_equals_()`	Match for equality or non-equality on nested documents and arrays
`in_()`	Search for individual elements in an array
`like_()`	Search for string values using SQL LIKE expressions
`matches_()`	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See HBase Java Regular Expressions Support on page 3292 for a list of supported regular expressions.

last-updated: Jun 06, 2024

QueryCondition Method	Description
`and_()`	Begins a new `AND` condition block
`or_()`	Begins a new `OR` condition block
`element_and()`	Begins a new `elementAnd` block. See OJAI Query Condition Operators on page 3387 for a detailed description of this operator.
`close()`	Closes a compound condition block
`build()`	Builds the condition

NOTE:

- The material described in this section is a subset of the `QueryCondition` API. It introduces you to the basics of the API. For the complete API, see the QueryCondition interface.
- The preferred approach for creating query conditions in Python is to create the condition in a JSON format. See Creating an OJAI Query Condition Using a JSON String on page 3382

C#

C# OJAI provides a `QueryCondition.ls()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. For details, see OJAI Query Conditions Using Container Field Paths on page 3396.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data

You can specify the value using either a C# scalar value (for example, `int`, `float`, or `string`) or a C# OJAI object. The API supports the following OJAI types:

- `OjaiDate`
- `OjaiInterval`

	• `OjaiTime` • `OjaiTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a C# object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a C# `list` of values of the specified type. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.ls()`, `QueryCondition` also supports the following methods:

`QueryCondition` Method	**Description**
`Condition()`	Search for values using a specific condition.
`Equals()` `NotEquals()`	Match for equality or non-equality on nested documents and arrays.
`Exists()` `NotExists()`	Search for a field if the given field path exists, or verify that a field path does not exist.
`In()` `NotIn()`	Search for individual elements in an array or verify their absence.
`Like()` `NotLike()`	Search for string values using SQL LIKE expressions or verify they do not match the specified SQL LIKE expression.

last-updated: Jun 06, 2024

QueryCondition Method	Description
`Matches()` `NotMatches()`	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library, as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. For a list of supported regular expressions, see HBase Java Regular Expressions Support on page 3292.
`SizeOf()`	Search for a value of the specified size. The value must be one of the following types: • `string` • `binary` • `iDictionary` • `iList`
`TypeOf()` `NotTypeOf()`	Search for value of the specified Type or verify its absence.
`And()`	Begins a new `AND` condition block.
`Or()`	Begins a new `OR` condition block.
`ElementAnd()`	Begins a new `ElementAnd` block. For a detailed description of this operator, see OJAI Query Condition Operators on page 3387.
`Close()`	Closes a compound condition block.
`Build()`	Builds the condition.

NOTE:

- The material described in this section is a subset of the QueryCondition API. It introduces you to the basics of the API. For the complete API, see the QueryCondition interface.
- The preferred approach for creating query conditions in C# is to create the condition in a JSON format. See 009_FindQueryWithSelectAndCondition.cs or Example: Creating a QueryCondition Object on page 3379.

last-updated: Jun 06, 2024

Go

Go OJAI provides a `QueryCondition.ls()` function for specifying query conditions. The function takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. For details, see OJAI Query Conditions Using Container Field Paths on page 3396.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data	You can specify the value using either a Go scalar value (for example, `int`, `float64`, or `string`) or a Go OJAI object. The API supports the following OJAI types: • `OjaiDate` • `OjaiTime` • `OjaiTimestamp`
Nested Documents	You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Go object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.
Arrays	You can specify only equality and non-equality conditions on arrays. You specify an array using a Go `list` of values of the specified type. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.ls()`, `QueryCondition` also supports the following functions:

`QueryCondition` Function	**Description**
`AddCondition()`	Search for values using a specific condition.

last-updated: Jun 06, 2024

`QueryCondition` Function	Description
`Equals()` `NotEquals()`	Match for equality or non-equality on nested documents and arrays.
`Exists()` `NotExists()`	Search for a field if the given field path exists, or verify that it does not exist.
`In()` `NotIn()`	Search for individual elements in an array or verify their absence.
`Like()` `NotLike()`	Search for string values using SQL LIKE expressions or verify they do not match the specified SQL LIKE expression.
`Matches()` `NotMatches()`	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library, as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. For a list of supported regular expressions, see HBase Java Regular Expressions Support on page 3292.
`TypeOf()` `NotTypeOf()`	Search for value of the specified Type or verify its absence.
`And()`	Begins a new `AND` condition block.
`Or()`	Begins a new `OR` condition block.
`ElementAnd()`	Begins a new `ElementAnd` block. For a detailed description of this operator, see OJAI Query Condition Operators on page 3387.
`Close()`	Closes a compound condition block.
`Build()`	Builds the condition.

NOTE:

- The material described in this section is a subset of the `Query` API. It introduces you to the basics of the API. For the complete API, see the Query interface.
- The preferred approach for creating query conditions in Go is to create the condition in a JSON format. See 009_find_query_with_select_and_condition.go or Example: Creating a QueryCondition Object on page 3379.

Example: Creating a `QueryCondition` Object

The following example shows how to define a `QueryCondition` object for this query condition:

```
(a.b.[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

Java

```
QueryCondition qc =
connection.newCondition()
    .and()
        .is("a.b[0].boolean",
Op.EQUAL, false)
        .or()
            .is("a.c.d",
Op.NOT_EQUAL, 5)
            .is("a.b[1].decimal",
Op.GREATER, 1)
            .is("a.b[1].decimal",
Op.LESS, 10)
            .close()
    .close()
    .build();
```

Pass the `QueryCondition` object to the Query.where method. For a complete Java code example, see the *Java - OJAI QueryCondition Object* example at Querying with Conditions on page 3422.

Python

```
qc = connection.new_condition()
    .and_()
        .is_('a.b[0].boolean',
QueryConditionOp.EQUAL, False)
        .or_()
            .is_('a.c.d',
QueryConditionOp.NOT_EQUAL, 5)
            .is_('a.b[1].decimal',
QueryConditionOp.GREATER, 1)
            .is_('a.b[1].decimal',
QueryConditionOp.LESS, 10)
            .close()
    .close()
    .build()
```

Pass the `QueryCondition` object to the Query.where method. For a complete Python code example, see

the *Python - OJAI QueryCondition Object* example at Querying with Conditions on page 3422.

C#

```
var condition =
connection.NewQueryCondition()
    .And()
        .Is("a.b[0].boolean",
QueryOp.EQUAL, false)
        .Or()
            .Is("a.c.d",
QueryOp.NOT_EQUAL, 5)
            .Is("a.b[1].decimal",
QueryOp.GREATER, 1)
            .Is("a.b[1].decimal",
QueryOp.LESS, 10)
            .Close()
    .Close()
    .Build();
```

Pass the `Condition` object to the `Query.Where` method. For a complete C# code example, see the *C# - OJAI QueryCondition Object* example at Querying with Conditions on page 3422.

Go

```
    condition, err :=
client.MakeCondition(
        client.And(),

client.Is("a.b[0].boolean",
client.EQUAL, false),
            client.Or(),
                client.Is("a.c.d",
client.NOT_EQUAL, 5),

client.Is("a.b[1].decimal",
client.GREATER, 1),

client.Is("a.b[1].decimal",
client.LESS, 10),
            client.Close(),
        client.Close())
    condition.Build()
```

Pass the `Condition` object to the `Query.WhereCondition` function. For a complete Go code example, see the *Go - OJAI QueryCondition Object* example at Querying with Conditions on page 3422.

Examples: Using the `QueryCondition.elementAnd` Method

The following example shows how to write the `elementAnd` condition described at Using elementAnd with Nested Documents on page 3399, using a `QueryCondition` object:

Java

```
QueryCondition qc =
connection.newCondition()
    .elementAnd("grades[]")
        .is("course",
QueryConditionOp.EQUALS, "history")
```

```
        .is("score",
QueryConditionOp.EQUALS, 12)
        .close()
    .build();
```

Python

```
qc = connection.new_condition()
    .element_and("grades[]")
        .is_("course",
QueryConditionOp.EQUALS, "history")
        .is_("score",
QueryConditionOp.EQUALS, 12)
        .close()
    .build()
```

C#

```
var condition =
connection.NewQueryCondition()
    .ElementAnd("grades[]")
        .Is("course", QueryOp.EQUALS,
"history")
        .Is("score", QueryOp.EQUALS,
12)
        .Close()
    .Build();
```

Go

```
    condition, err :=
client.MakeCondition(
        client.ElementAnd("grades[]"),
            client.Is("course",
client.EQUAL, "history"),
            client.Is("score",
client.EQUAL, 12),
        client.Close())
    condition.Build()
```

The following code corresponds to the example described at Using elementAnd with Scalar Values on page 3401 using a `QueryCondition` object:

Java

```
QueryCondition qc =
connection.newCondition()
    .elementAnd("values[]")
        .is("$",
QueryConditionOp.GREATER, 7)
        .is("$",
QueryConditionOp.LESS, 14)
        .close()
    .build();
```

Python

```
qc = connection.new_condition()
    .element_and("values[]")
        .is_("$",
QueryConditionOp.GREATER, 7)
        .is_("$",
QueryConditionOp.LESS, 14)
        .close()
    .build()
```

C#

```
var condition =
connection.NewQueryCondition()
    .EementAnd("values[]")
        .Is("$", QueryOp.GREATER, 7)
        .Is("$", QueryOp.LESS, 14)
        .Close()
    .Build();
```

Go

```
    condition, err :=
client.MakeCondition(
        client.ElementAnd("values[]"),
            client.Is("$",
client.EQUAL, 7),
            client.Is("$",
client.EQUAL, 14),
        client.Close())
    condition.Build()
```

Creating an OJAI Query Condition Using a JSON String
You can create a query condition using OJAI syntax to specify the condition in JSON format. This is the preferred approach for the Node.js, Python, C#, and Go OJAI clients.

The following example shows you how to create the following query condition using the syntax:

```
(a.b.[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

Java

This is a Java string for the condition:

```
String jc = new String(
    '{ \
        "$and":[ \
            {"$eq":
{"a.b[0].boolean":false}}, \
            {"$or":[ \
                {"$ne":{"a.c.d":5}}, \
                {"$gt":
{"a.b[1].decimal":1}}, \
                {"$lt":
{"a.b[1].decimal":10}} \
            ]} \
        ]} \
    )';
```

Pass the string to the Query.where method. See the *Java - OJAI Query Condition in JSON Format* example at Querying with Conditions on page 3422 for a complete Java code example.

Node.js

This is a Node.js JSON object for the condition:

```
query =
    {"$where":
        {"$and":[
            {"$eq":
{"a.b[0].boolean":false}},
            {"$or":[
                {"$ne":{"a.c.d":5}},
                {"$gt":
```

```
{"a.b[1].decimal":1}},
                {"$lt":
{"a.b[1].decimal":10}}
            ]}
        ]}
    };
```

See the *Node.js - OJAI Query Condition in JSON Format* example at Querying with Conditions on page 3422 for a complete Node.js code example.

Python

This is a Python dictionary for the condition:

```
query =
    {"$where":
        {"$and":[
            {"$eq":
{"a.b[0].boolean":false}},
            {"$or":[
                {"$ne":{"a.c.d":5}},
                {"$gt":
{"a.b[1].decimal":1}},
                {"$lt":
{"a.b[1].decimal":10}}
            ]}
        ]}
    }
```

See the *Python - OJAI Query Condition in JSON Format* example at Querying with Conditions on page 3422 for a complete Python code example.

C#

This is a JSON string for the condition:

```
var query =
    @"{""$where"":" +
        @"{""$and"":[" +
            @"{""$eq"":
{""a.b[0].boolean"":false}}," +
            @"{""$or"":["
+
                @"{""$ne"":{""a.c.d"":
{""$numberInt"":""5""}}}," +

@"{""$gt"":{""a.b[1].decimal"":
{""$decimal"":""1""}}}," +

@"{""$lt"":{""a.b[1].decimal"":
{""$decimal"":""10""}}}" +
            @"]}" +
        @"]" +
   @"}";
```

Go

This is a JSON string for the condition:

```
query := "{\"$where\": +
                "{\"$and\":[" +
                    "{\"$eq\":
{\"a.b[0].boolean\":false}}," +
                    "{\"$or\":[" +
                        "{\"$ne\":
```

last-updated: Jun 06, 2024

```
{\"a.c.d\":5}}," +
                                "{\"$gt\":
{\"a.b[1].decimal\":1}}," +
                                "{\"$lt\":
{\"a.b[1].decimal\":10}}" +
                              "]}" +
                    "]}" +
               "}"
```

To learn about the complete OJAI syntax for query conditions, see OJAI Query Condition Syntax on page 3387.

NOTE: The OJAI clients are supported starting in EEP 6.0.0.

OJAI Query Syntax
OJAI defines a syntax for specifying queries on JSON documents. You can use this syntax in Node.js and Python OJAI client applications and HPE Ezmeral Data Fabric Database shell.

See Query with --query on page 5476 to learn about how to use this syntax in HPE Ezmeral Data Fabric Database shell.

An OJAI query can include the following components:

- Projection
- Condition
- Order by
- Limit
- Offset
- Options

You can specify some or all these components in a query, separating each component with a comma.

OJAI Query Projection

Syntax	`"$select":"fieldpath"`
	
	`"$select": ["fieldpath1","fieldpath2",...]`

Description	The projection is the list of field paths to select in your query. You can specify a single field path or multiple. When specifying multiple, use an array notation to list the field paths. See JSON Document Field Paths on page 651 for more information about the syntax of different JSON document field paths.
Examples	Single field path: `"$select":"a.c.d"`

Multiple field paths:

```
"$select":["a.c.d", "a.c.e", "m[0]"]
```

OJAI Query Condition

Syntax

```
"$where":OJAIQueryCondition
```

Description

The condition filters your query result. See OJAI Query Condition Syntax on page 3387 for more information about the syntax of an *OJAIQueryCondition*.

Example

If you have the following condition:

```
(a.b.[0].boolean == false && (a.c.d !
= 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

This is the OJAI JSON syntax for the condition:

```
"$where":{
    "$and":[
        {"$eq":
{"a.b[0].boolean":false}},
        {"$or":[
            {"$ne":{"a.c.d":5}},
            {"$gt":
{"a.b[1].decimal":1}},
            {"$lt":
{"a.b[1].decimal":10}}
            ]
        }
    ]
}
```

OJAI Query Order By

Syntax

```
"$orderby":"fieldpath"
```

```
"$orderby":{"fieldpath":"order"}
```

```
"$orderby":[fieldpath1,fieldpath2,...]
```

```
"$orderby":[{"fieldpath1":"order"},
{"fieldpath2":"order"},...]
```

Description

The order by specifies the field paths on which to sort your query result. You can specify a single field path or multiple. When specifying multiple, use an array notation to list the field paths. For each field path, you can optionally specify an *order* of either `asc` or `desc`. Both *order* keywords are case insensitive. The default is `asc`. When specifying an *order*, enclose the *fieldpath* and *order* with curly braces.

last-updated: Jun 06, 2024

Examples

Order on a single field path in the default `asc` order:

```
"$orderby":"a.c.e"
```

Order on a single field path in the `desc` order:

```
"$orderby":{"a.c.e":"desc"}
```

Order on two field paths, where the second specifies a `desc` order:

```
"$orderby":["a.c.d",{"a.c.e":"desc"}]
```

OJAI Query Limit

Syntax

```
"$limit":positive-integer
```

Description

The number of documents to return from the query.

Example

Return only ten documents:

```
"$limit:10
```

OJAI Query Offset

Syntax

```
"$offset":positive-integer
```

Description

The number of documents to skip before returning results to the client. The offset value has a direct effect on query time; as the offset value increases, query time also increases.

Example

Process the query and skip the first five documents in the result set before returning the results to the client.

```
"$offset":5
```

OJAI Query Options

Syntax

```
"$options":{optionName:optionValue}
```

```
"$options":
[{optionName1:optionValue1},
{optionName2:optionValue2},...]
```

Description

Settings that influence a query's execution path. See OJAI Query Options on page 3368 for a list of available options.

When specifying the *optionName*, you must separate the components of the option name, replacing the dots with curly braces and colons and enclosing each component in quotes.

last-updated: Jun 06, 2024

Example

Force the query to use the OJAI Distributed Query Service by setting the `ojai.mapr.query.force-drill` option:

```
"$options":{"ojai":{"mapr":{"query":
{"force-drill":true}}}}
```

OJAI Query Condition Syntax

OJAI defines a syntax for specifying query conditions that allows you to express query conditions in a JSON format. This topic describes the supported operators and provides examples of these query conditions.

When writing an OJAI application, you can also apply query conditions by calling OJAI API methods, corresponding to specific operators. This section does not discuss this alternative. For details on that alternative, see Query Conditions in OJAI Applications on page 3370.

NOTE: Using the JSON format is the preferred approach for Python and Node.js OJAI clients.

OJAI Query Condition Operators

OJAI supports comparison, existence, between, match, like, type of, size of, in, and logical operators.

Click the name in the following box to navigate to the section that provides details on each operator.

- Equals
- Greater Than
- Greater Than or Equals
- Less Than
- Less Than or Equals
- Not Equals
- Exists
- Not Exists
- Between on page 3388
- Matches
- Not Matches
- Like
- Not Like
- Type Of
- Not Type Of
- Size Of on page 3391
- In
- Not In
- And
- Or
- Element And

Comparison Operators

Operators

Operator	Syntax
Equals	`{"$eq": {"fieldpath":value}}`
Greater Than	`{"$gt": {"fieldpath":value}}`
Greater Than or Equals	`{"$ge": {"fieldpath":value}}`
Less Than	`{"$lt": {"fieldpath":value}}`

last-updated: Jun 06, 2024

Operator	Syntax
Less Than or Equals	`{"$le": {"fieldpath":value}}`
Not Equals	`{"$ne": {"fieldpath":value}}`

Description

Compares the data in *fieldpath* against *value* for the specified operator.

Float and double data are approximate representations of decimal values. They may not return true in equality comparisons against their equivalent decimal values.

You can specify only equality and non-equality conditions on nested documents and arrays.

In the case of equality on nested documents, all of the fields in the nested document must match. The order of the fields is not relevant.

In the case of equality on arrays, both the order of the elements and the element values must match.

Existence Operators

Exists

Syntax

```
{"$exists":"fieldpath"}
```

Description

Checks for existence of *fieldpath*.

Not Exists

Syntax

```
{"$notexists":"fieldpath"}
```

Description

Checks for non-existence of *fieldpath*.

See Existence Conditions with Container Field Paths on page 3397 for details about how these operators behave when you use them with container field paths.

Between

Syntax

```
{"$between":{"fieldpath":
[startValue,endValue]}}
```

Description

Checks if the value in *fieldpath* is in the range specified by *startValue* and *endValue*, where the values are inclusive.

Matches Operators

Operators

Operator	Syntax
Matches	`{"$matches": {"fieldpath":matchValue}}`
Not Matches	`{"$notmatches": {"fieldpath":matchValue}}`

Description

Performs a regular expression match on *`fieldPath`* using *`matchValue`*.

You can use regular expressions that compose the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See HBase Java Regular Expressions Support for a list of supported regular expressions.

Like Operators

Operators

Operator	Syntax
Like	`{"$like": {"fieldpath":likeValue}}`
Not Like	`{"$notlike": {"fieldpath":likeValue}}`

Description

Performs a SQL LIKE comparison on `fieldPath` where *`likeValue`* is a string with wildcard characters '%' and '_'.

Special-Purpose Characters for the Like Operators

The OJAI API allows you to use four special-purpose characters or patterns with `$like` operator expressions:

Special-Purpose Character	Description	Example
%	Matches any string of zero or more characters.	`"abc%"` matches `"abc"`, `"abcd"`, `"abcde232136"`, etc. `"%abc"` matches `"abc"`, `"pqrabc"`, etc.
_	Matches a single character.	`"_am"` matches `"ram"`, `"sam"`, `"Sam"`, `"cam"`.

last-updated: Jun 06, 2024

Special-Purpose Character	Description	Example
`[]`	Matches a single character in the specified set or range.	`"[r-t]am"` matches `"ram"`, `"sam"`, and `"tam"` but not `"Sam"` or `"cam"`.
`[^]`	Matches a single character **not** in the specified set or range.	`"[^r-t]am"` matches `"Sam"`, `"pam"`, `"jam"`, or `"cam"` but not `"ram"`, `"sam"` and `"tam"`.

When any of these special characters is used as a literal, the character can be enclosed within `[]`:

Literal	Corresponding Like Expression
`"[a]"`	`"[[]a]"`
`"a%"`	`"a[%]"`
`"a_c"`	`"a[_]c"`

Note that `"^"` and `"]"` need not be escaped.

Type of Operators

Type Of

Syntax

```
{"$typeof":{"fieldpath":"typeValue"}}
```

Description

Checks whether *`fieldpath`* is of type *`typeValue`*.

Not Type Of

Syntax

```
{"$nottypeof":{"fieldpath":"typeValue"}}
```

Description

Checks whether *`fieldpath`* is not of type *`typeValue`*.

`typeValue` can be any of `map`, `array`, `binary`, `date`, `time`,

last-updated: Jun 06, 2024

`timestamp`, `interval`, `double`, `float`, `long`, `int`, `short`, `byte`, `string`, `boolean`, or `null`.

Size Of

Syntax

```
{"$sizeof":{"fieldpath":
{"comparisonOp":intValue}}}
```

Description

Compares the size of the data in *`fieldpath`* against *`intValue`*, using *`comparisonOp`* . The size varies depending on the type of *`fieldPath`*:

String	Length of string
Array	Number of elements in the array
Nested document	Number of subfields in the nested document

`comparisonOp` can be any of `$eq`, `$lt`, `$le`, `$gt`, `$ge`, or `$ne`.

In Operators

In

Syntax

```
{"$in":
{"fieldpath":inOp
Values}}
```

Description

Checks whether the data in *`fieldpath`* is in the list specified by *`inOpValues`*.

Not In

Syntax

```
{"$notin":
{"fieldpath":inOp
Values}}
```

Description

Checks whether the data in *`fieldpath`* is not in the list specified by *`inOpValues`*

Logical Operators

And

Syntax

```
{"$and":
[OJAIQueryConditi
ons]}
```

Description

Applies logical AND on a list of conditions. *`OJAIQueryConditions`* is a comma-separated list of OJAI query conditions.

Or

Syntax

```
{"$or":
[OJAIQueryConditions]}
```

Description

Applies logical OR on a list of conditions. *`OJAIQueryConditions`* is a comma-separated list of OJAI query conditions.

Element And

Syntax

```
{

"$elementAnd":{

"containerFieldPath":

[OJAIQueryConditions]
    }
}
```

NOTE: Supported starting in MapR 6.1.

Description

Applies multiple conditions as part of a group. All conditions must be true for a common array element.

`OJAIQueryConditions` is the comma-separated list of the OJAI query conditions.

`containerFieldPath` exhibits the following behaviors:

- *`containerFieldPath`* specifies the container path prefix of the common container element.

last-updated: Jun 06, 2024

- If *containerFieldPath* refers to a container of nested documents, then you must use field paths relative to the common prefix in your *OJAIQueryConditions* .
- If the *containerFieldPath* refers to a container of scalar values, then you use the $ symbol to refer to individual elements in your *OJAIQueryConditions*.

NOTE: There is no `elementOr` operator because it is semantically equivalent to an OR operator.

Related concepts

OJAI Query Condition Examples on page 3393
This section contains examples that show you how to use different OJAI query condition operators in combination with different field references and data types.

OJAI Query Conditions Using Container Field Paths on page 3396
Starting in MapR 6.1, HPE Ezmeral Data Fabric Database supports the notion of a *container field path*. A container field path enables you to perform comparisons on a field path that is either a single value or an arbitrary array element. You can use container field paths with arrays and nested documents, including nested documents with multiple levels of nesting and multidimensional arrays.

OJAI Query Conditions Using elementAnd on page 3399
The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

OJAI Query Condition Examples

This section contains examples that show you how to use different OJAI query condition operators in combination with different field references and data types.

The examples in this section use the following JSON documents:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "003", "name" : "Ipod 003", "tags" : 10 }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
```

```
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

Example	Documents Returned
`{"$exists":"tags.v"}` Matches documents where `tags` is a nested document that has a `v` subfield.	008
`{"$eq":{"tags":10}}` Matches documents where `tags` equals the scalar value 10.	003
`{"$eq":{"tags.t":"ipod"}}` Matches documents where `tags` is a nested document with a subfield `t` equal to "ipod".	005, 008
`{"$eq":{"tags":{"t":"ipod"}}}` Matches documents where `tags` is a nested document with a single subfield `t` equal to "ipod".	005
`{"$eq":{"tags":{"v":10,"t":"ipod"}}}` Matches documents where `tags` is a nested document with two subfields, `v` and `t`. `v` is equal to 10, and `t` is equal to "ipod". The order of subfields in the condition does not matter.	008
`{"$eq":{"tags":["electronics","ipod","apple"]}}` Matches documents where `tags` is an array with the three elements listed.	001
`{"$eq":{"tags":["ipod","electronics","apple"]}}` This example does not match any document, whereas the previous does, because the order of the elements in this example does not match the order in document 001.	None
`{"$between":{"tags":[5,15]}}` Matches documents where `tags` is a scalar value between 5 and 15.	003
`{"$like":{"tags[1]":"ip%"}}` Matches documents where the first array element in `tags` qualifies the wildcard string `"ip%"`	001, 004
`{"$typeof":{"tags":"map"}}` Matches documents where `tags` is a nested document.	005, 008
`{"$typeof":{"tags":"array"}}` Matches documents where `tags` is an array.	001, 004, 006, 007

last-updated: Jun 06, 2024

Example	Documents Returned
`{"$sizeof":{"tags":{"$ge":3}}}` Matches documents where the size of the data in `tags` is greater than or equal to three. • 001 matches because the array has three elements • 002 matches because the string is of length four • 004 matches because the nested document has three subfields	001, 002, 004
`{"$in":{"tags":["ipod", 10, {"t":"ipod"}]}}` Matches documents where `tags` equals any of the values listed. Note that the values can be of different types.	002, 003, 005
`{ "$and":[ {"$lt":{"tags[1].v":10}}, {"$matches":{"tags[1].t":"ap{2}"}} ] }` Matches documents where the first array element in `tags` has a nested document with a subfield `v` less than one, and the same nested document also matches the regular expression `"ap{2}"`.	007
`{ "$or":[ {"$exists":"tags.v"}, {"$typeof":{"tags":"string"}} ] }` Matches documents where either `tags` is a nested document with a subfield `v`, or `tags` is a scalar string.	002, 008

NOTE: You can improve the performance of queries with conditions by using secondary indexes. See Queries that Benefit from Secondary Indexes on page 708 for more details.

OJAI Query Conditions Using Container Field Paths
Starting in MapR 6.1, HPE Ezmeral Data Fabric Database supports the notion of a *container field path*. A container field path enables you to perform comparisons on a field path that is either a single value or an arbitrary array element. You can use container field paths with arrays and nested documents, including nested documents with multiple levels of nesting and multidimensional arrays.

Conditions with Container Field Paths on Arrays

If you have a field that has a single value rather than an array of values, when using the container notation, HPE Ezmeral Data Fabric Database treats the single value as an array with one element. This enables you to use a container field path to access a field that has both array elements and scalar values. The array elements and scalar values can be of any type.

Suppose you have the following set of documents:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "003", "name" : "Ipod 003", "tags" : 10 }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

To find all documents that contain the tag named `"ipod"`, you can use the following OJAI query condition, where you reference `tags` using a container field path:

```
{"$eq":{"tags[]":"ipod"}}
```

The expression matches the following documents, with the matching condition highlighted in bold:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
```

Note that the matching documents have the following characteristics:

- In 001 and 004, `tags` are array fields.
- In 002, `tags` is a scalar value.
- In 001 and 004, the `tags` arrays have elements in addition to `"ipod"`.

You can also use the `AND` operator to match multiple container field path conditions.

For example, the following condition finds all documents that have both `"ipod"` and `"apple"` tags:

```
{
    "$and":[
        {"$eq":{"tags[]":"ipod"}},
        {"$eq":{"tags[]":"apple"}}
    ]
}
```

The expression matches the following document, with the matching conditions highlighted in bold:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ]
```

Conditions with Container Field Paths on Nested Documents

You can also use the container field path in combination with a nested document subfield reference.

For example, using the same set of documents shown earlier, the following OJAI query condition finds all documents in which `"ipod"` is specified in the subfield named `t` within the `tags` nested document:

```
{"$eq":{"tags[].t":"ipod"}}
```

This expression returns the following documents, with the matching condition highlighted in bold:

```
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" : "ipod"
} ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

Note that the matching documents have the following characteristics:

- In 005 and 008, `tags` is a single nested document.
- In 006 and 007, `tags` is an array of nested documents.
- In 004, the `tags` array has both scalar data and a nested document.
- In 004 and 006, the `tags` array have other array elements that do not match the nested document subfield `t`.

Existence Conditions with Container Field Paths

Existence Operators on page 3388 check for the existence and non-existence of a specified field path. When you use `$exists` with a container field path, the specified field path can be any element in an array.

Using the same set of documents shown earlier, the following OJAI query condition finds all documents where the `tags` array has a nested document with a subfield `t`:

```
{"$exists":"tags[].t"}
```

The expression matches the following documents with the matching condition highlighted in bold:

```
{"_id":"004","name":"Ipod 004","tags":[10,"ipod",{"t":"ipod"}]}
{"_id":"005","name":"Ipod 005","tags":{"t":"ipod"}}
{"_id":"006","name":"Ipod 006","tags":[{"t":"ipod"},{"t":"apple"}]}
{"_id":"007","name":"Ipod 007","tags":[{"t":"ipod","v":10},
{"t":"apple","v":9}]}
```

When you use `$notexists` with a container field path, it matches *any* element in the array that does not meet the existence condition:

```
{"$notexists":"tags[].t"}
```

last-updated: Jun 06, 2024

The expression returns the following documents with the matching condition highlighted in bold:

```
{"_id":"001","name":"Ipod 001","tags":[**"electronics","ipod","apple"**]}
{"_id":"002","name":"Ipod 002","tags":**"ipod"**}
{"_id":"003","name":"Ipod 003","tags":**10**}
{"_id":"004","name":"Ipod 004","tags":[**10,"ipod"**,{"t":"ipod"}]}
```

Even document `004` has a `tags[].t` element, the other elements in that document's `tags` array do not; therefore, the document qualifies the condition.

Conditions with Container Field Paths Across Multiple Levels of Nested Documents

The following are examples of query conditions that match the sample document shown at Container Field Paths Across Multiple Levels of Nested Documents:

```
{"$eq":{"projects[].customer.contacts[].emails[].value":"jdoe@gmail.com"}}
```

```
{"$eq":{"projects[].customer.contacts[].role":"CEO"}}
```

Conditions with Container Field Paths on Multidimensional Arrays

The following examples reference documents that store the high and low temperatures for each day in a week. They use a two-dimensional array to store this data. The first element of each nested array element is the high temperature for a day, and the second element is the low. Typically, the two-dimensional array has seven array pairs, one for each day of the week. But in cases where data is unavailable, the document has only the days available.

For example, document 002 has a single dimensional array because it has data for only one day that week.

```
{
   "_id" : "001",
   "temps" : [[61,49],[74,51],[75,51],[74,52],[78,54],[75,53],[75,54]],
   "weekOf" : "4/29/2018"
}
{
   "_id" : "002",
   "temps" : [81,60],
   "weekOf" : "5/12/2018"
}
{
   "_id" : "003",
   "temps" : [[80,55],[78,54],[79,54],[77,53],[79,54],[77,54],[78,54]],
   "weekOf" : "5/13/2018"
}
```

As described at Container Field Paths with Multidimensional Arrays, you can specify a container field path in a dimension only if it does not precede a dimension that specifies an explicit element. For example, the following condition is not allowed because the first dimension specifies a container field path and precedes element 1 in the second dimension:

```
// Invalid condition
{"$ge":{"temps[][1]":60}}
```

The following table shows examples of conditions on multidimensional arrays that HPE Ezmeral Data Fabric Database supports:

Example	Documents Returned
`{"$ge":{"temps[][]":60}}` Matches documents that have any temperature greater than 60. • Documents 001 and 003 match because all days have high temperatures above 60. • Document 002 matches because day 1 has a low temperature of 60. Although `temps` in this document is a one-dimensional array, the container notation treats it as a two-dimensional array.	001, 002, 003
`{"$ge":{"temps[1][]":75}}` Matches documents that have any temperature greater than 75 on the second day of the week	003
`{"$eq":{"temps[]":[78,54]}}` Matches documents that have a high and low temperature of 78 and 54 on the same day. • Day 5 from document 001 matches this condition. • Days 2 and 7 from document 003 match this condition.	001, 003

Related concepts

OJAI Query Conditions Using elementAnd on page 3399
The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

OJAI Query Conditions Using `elementAnd`

The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

Using `elementAnd` with Nested Documents

Assume that you have the following set of documents that reflect student scores on courses. Each document has an array of `grades`. `Grades` is a nested document that reflects how the students scored on each course they took.

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"score":12,"course":"history"},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"course":"history","score":12,"cmts":"..."},
{"course":"english","score":18}]}
{"_id":"003","grades":[{"course":"math","score":11},
{"course":"history","score":15},{"course":"english","score":12},
{"course":"sports","score":4}]}
```

```
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
{"_id":"005","grades":[{"course":"math","score":15.5},
{"course":"history","score":10},{"course":"physics","score":11}]}
```

If you want to find the students who scored 12 in history, you use the following `elementAnd` condition:

```
{
    "$elementAnd":{
        "grades[]":[
            {"$eq":{"course":"history"}},
            {"$eq":{"score":12}}
        ]
    }
}
```

The condition matches the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"course":"history","score":12,"cmts":"..."},
{"course":"english","score":18}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

The example illustrates the following behavior:

- The positions of the subfields in the nested document are not significant.
- In document 002, there are other subfields in the nested document that do not match the specified conditions.

In contrast, the following example expresses a different condition, using `and` instead of `elementAnd`:

```
{
    "$and":[
        {"$eq":{"grades[].course":"history"}},
        {"$eq":{"grades[].score":12}}
    ]
}
```

This condition returns documents corresponding to students who have taken history and scored 12 on *any* course. The following are the matching documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"course":"history","score":12,"cmts":"..."},
{"course":"english","score":18}]}
{"_id":"003","grades":[{"course":"math","score":11},
{"course":"history","score":15},{"course":"english","score":12},
{"course":"sports","score":4}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

The example illustrates the following behavior:

- Besides returning the same documents as the previous `elementAnd` example, this condition also returns document 003.

last-updated: Jun 06, 2024

- Document 003 matches because that student took history and scored 12 on english, rather than history.
- Document 005 does not match because although the student took history, the student did not score 12 on any courses.

Using `elementAnd` with Scalar Values

If you apply `elementAnd` to a container of scalar values, you use the $ symbol to denote an unspecified container element.

Suppose you have the following documents:

```
{"_id" : "001", "name" : "a", "values" : [1, 2, 3, 6, 15] }
{"_id" : "002", "name" : "b", "values" : [3, 6, 9, 10, 15] }
{"_id" : "003", "name" : "c", "values" : [14] }
{"_id" : "004", "name" : "c", "values" : 11 }
```

To find all documents where `values[]` contains a number between 7 and 11 (inclusive), you can use the following condition:

```
{
    "$elementAnd":{
        "values[]":[
            {"$ge":{"$":7}},
            {"$le":{"$":11}}
        ]
    }
}
```

The condition returns the following documents, with the matching numbers highlighted in bold:

```
{"_id":"002","name":"b","values":[3,6,9,10,15]}
{"_id":"004","name":"c","values":11}
```

The example illustrates the following behavior:

- In document 002, multiple elements in the array match the condition.
- In document 004, `values` is a scalar value.

Suppose you apply the following condition that uses `and` instead of `elementAnd`:

```
{
    "$and":[
        {"$ge":{"values[]":7}},
        {"$le":{"values[]":11}}
    ]
}
```

All documents except 003 match this `and` condition because in the matching documents, `values[]` contains *some* number greater than or equal to 7 and *some* number less than or equal to 11. The difference is that the same number does not need to match both conditions, which is the case for document 001.

Using `between` with `elementAnd`

You cannot use a container field path in a `between` condition. To use the `between` operator to match against an arbitrary array element, you must include the `between` condition in an `elementAnd` condition.

last-updated: Jun 06, 2024

The following table shows the proper way to specify a `between` condition that is equivalent to the `elementAnd` example from the previous section:

Correct Condition	Incorrect Condition
`{ "$elementAnd":{ "values[]":[ {"$between":{"$":[7,11]}} ] } }`	`{"$between":{"values[]":[7,11]}}`

This example uses `between` to match against an arbitrary scalar array element. You can also use `between` to match against a subfield in a nested document, in which the nested document is an arbitrary array element.

For example, using the sample documents shown earlier, the following table shows the correct way to apply the `between` operator on the subfield `score` in the nested documents that are elements in the `grades` array:

Correct Condition	Incorrect Condition
`{ "$elementAnd":{ "grades[]":[ {"$between":{"score": [15.5,20]}} ] } }`	`{"$between":{"grades[].score": [15.5,20]}}`

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"cmts":"...","course":"history","score":12},
{"course":"english","score":18}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","details":{"info":"..."},"score":12}]}
{"_id":"005","grades":[{"course":"math","score":15.5},
{"course":"history","score":10},{"course":"physics","score":11}]}
```

Using Other Operators in `elementAnd` Conditions

You can also use operators like `or` in `elementAnd`'s query condition list.

For example, the following condition finds all students who scored 12 in either history or english:

```
{
    "$elementAnd":{
        "grades[]":[
            {"$or":[
                {"$eq":{"course":"history"}},
                {"$eq":{"course":"english"}}
            ]},
            {"$eq":{"score":12}}
```

last-updated: Jun 06, 2024

```
        ]
    }
}
```

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"002","grades":[{"course":"math","score":4},
{"cmts":"...","course":"history","score":12},
{"course":"english","score":18}]}
{"_id":"003","grades":[{"course":"math","score":11},
{"course":"history","score":15},{"course":"english","score":12},
{"course":"sports","score":4}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

Combining `elementAnd` with Other Operators

You can combine `elementAnd` with other operators like `and`.

For example, using the sample documents shown earlier, suppose you want to find all students who scored 12 in history as well scored 15.5 in math. The following condition expresses this criteria:

```
{
   "$and":[
      {
         "$elementAnd":{
            "grades[]":[
               {"$eq":{"course":"history"}},
               {"$eq":{"score":12}}
            ]
         }
      },
      {
         "$elementAnd":{
            "grades[]":[
               {"$eq":{"course":"math"}},
               {"$eq":{"score":15.5}}
            ]
         }
      }
   ]
}
```

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{"_id":"001","grades":[{"course":"math","score":15.5},
{"course":"history","score":12},{"course":"english","score":8}]}
{"_id":"004","grades":[{"course":"math","score":15.5},
{"course":"history","score":12,"details":{"info":"..."}}]}
```

Querying with HPE Ezmeral Data Fabric Database Shell

This section describes how to query JSON documents using either the `find` or `findbyid` command in HPE Ezmeral Data Fabric Database Shell (dbshell). It introduces the functionality the `find` command supports and describes the two ways to specify your queries. It also provides links to reference pages and examples.

The `findbyid` command allows you to retrieve a single document with a specified id from a HPE Ezmeral Data Fabric Database JSON table.

The `find` command allows you to specify projections and filter conditions (using JSON strings) to retrieve specific documents. It also allows you to specify the following options:

- Range of document IDs to retrieve
- Offset from which to start retrieval
- Order by to sort fields in the document
- Limit on the number of documents to retrieve

To invoke HPE Ezmeral Data Fabric Database shell, run the following command on a MapR cluster node:

```
% mapr dbshell
```

For a complete list and description of options available, see dbshell find or findbyid on page 5473.

Alternatives for Writing Dbshell Query Commands

You can construct your dbshell queries in one of two ways:

- Use individual options in the `find` command
- Use the `--query` option in the `find` command and specify keywords as arguments to `--query`

The following example illustrates the differences between the two alternatives.

Suppose you want to query the table `/apps/tab` with the following criteria:

- Select fields `f1` and `f2`
- Limit the result to ten documents
- Skip the first two documents
- Filter documents where the field `f3` equals 15
- Sorts on field `f1`

Click on each of the following tabs to see the syntax for each alternative:

Use Individual Options in `find`

```
find /apps/tab --fields f1,f2 --limit
10 --offset 2 --where {"$eq":
{"f3":15}} --orderby f1
```

Use the `--query` Option in `find`

```
find /apps/tab --query {"$select":
["f1","f2"],"$limit":10,"$offset":2,"$
where":{"$eq":
{"f3":15}},"$orderby":"f1"}
```

last-updated: Jun 06, 2024

For more examples on how to use the two query alternatives, see the following links:

Use Individual Options in `find`	Use the `--query` Option in `find`
Query Examples with Other Options on page 5481	• Query with --query on page 5476 • Query with --orderby on page 5480

NOTE: With both options, you need to specify the query condition using OJAI Query Condition Syntax on page 3387.

Examples: Querying JSON Documents
This section provides query examples using the OJAI API. The examples include querying by document ID, retrieving all documents in a store, selecting individual fields, specifying query conditions, and ordering your query result. For reference, the examples also include the equivalent HPE Ezmeral Data Fabric Database Shell (dbshell) commands.

If you hover over the right hand side of all code examples, you can use the 
icon to copy and paste the code.

You can also download the code examples from github at https://github.com/mapr-demos/ojai-examples.git.

Querying By ID
The examples in this section show you how to query for a single document ID.

Java

This example retrieves a single document identified by the ID `user001`.

NOTE: To query for a range of document IDs, you must specify an OJAI QueryCondition. See Querying with Conditions on page 3422 for examples of the syntax.

package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

public class OJAI_003_FindById {

  public static void main(String[] args) {

    System.out.println("==== Start Application ===");
```

```
    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI DocumentStore
    final DocumentStore store = connection.getStore("/demo_table");

    // fetch the OJAI Document by its '_id' field
    final Document userDocument = store.findById("user0001");

    // Print the OJAI Document
    System.out.println(userDocument.asJsonString());

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Node.js

This example retrieves a single document identified by the ID `user0001`.

NOTE: To query for a range of document IDs, you must specify an OJAI query condition. See Querying with Conditions on page 3422 for examples of the syntax.

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

let connection;

ConnectionManager.getConnection(connectionString)
  .then((conn) => {
```

```
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // fetch the OJAI Document by its '_id' field
    return store.findById('user0001');
  })
  .then((doc) => {
    // Print the OJAI Document
    console.log(doc);
    connection.close();
  });
```

Python

This example retrieves a single document identified by the ID `user0001`.

NOTE: To query for a range of document IDs, you must specify an OJAI QueryCondition. See Querying with Conditions on page 3422 for examples of the syntax.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# fetch the OJAI Document by its '_id' field
doc = store.find_by_id("user0001")

# Print the OJAI Document
print(doc)

# close the OJAI connection
connection.close()
```

dbshell

The following is the equivalent of the code examples using dbshell. See dbshell find or findbyid on page 5473 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> findbyid /demo_table --id user0001
```

C#

This example retrieves a single document identified by the ID `user0001`.

NOTE: To query for a range of document IDs, you must specify an OJAI `QueryCondition`. See Querying with Conditions on page 3422 for examples of the syntax.

```
using System;
using MapRDB.Driver;
```

```

last-updated: Jun 06, 2024

```
        panic(err)
    }

    // Fetch the OJAI Document by its '_id' field
    doc, err := store.FindByIdString("id0001")
    if err != nil {
        panic(err)
    }

    // Print the OJAI Document
    fmt.Println(doc.AsJsonString())

    // Close connection
    connection.Close()
}
```

Querying and Returning All Documents

The examples in this section show you two ways of retrieving all documents from a document store.

Java - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.find method.

```
/**
 * Copyright (c) 2017 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License");
 * you may not use this file except in compliance with the License.
 * You may obtain a copy of the License at
 *
 *   http://www.apache.org/licenses/LICENSE-2.0
 *
 * Unless required by applicable law or agreed to in writing, software
 * distributed under the License is distributed on an "AS IS" BASIS,
 * WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
 * See the License for the specific language governing permissions and
 * limitations under the License.
 */
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.DocumentStream;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

public class OJAI_004_FindAll {

  public static void main(String[] args) {

    System.out.println("==== Start Application ===");

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI DocumentStore
    final DocumentStore store = connection.getStore("/demo_table");

    // fetch all OJAI Documents from this store
    final DocumentStream stream = store.find();
```

last-updated: Jun 06, 2024

```
    for (final Document userDocument : stream) {
      // Print the OJAI Document
      System.out.println(userDocument.asJsonString());
    }

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Java - Example 2

The following example queries a document store and returns all documents. It creates a Query object and passes that to the DocumentStore.findQuery method.

```
/**
 * Copyright (c) 2017 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License"); you may
not use this file except in compliance with
 * the License. You may obtain a copy of the License at

 * an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either
express or implied. See the License for the
 * specific language governing permissions and limitations under the
License.
 */
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.DocumentStream;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;
import org.ojai.store.Query;

public class OJAI_005_FindAllQuery {

  public static void main(final String[] args) {

    System.out.println("==== Start Application ===");

    // Create an OJAI connection to MapR cluster
    final Connection connection = DriverManager.getConnection("ojai:mapr:");

    // Get an instance of OJAI DocumentStore
    final DocumentStore store = connection.getStore("/demo_table");

    // Build an OJAI query
    final Query query = connection.newQuery().build();
```

last-updated: Jun 06, 2024

```
    // fetch all OJAI Documents from this store
    final DocumentStream stream = store.find(query);

    for (final Document userDocument : stream) {
      // Print the OJAI Document
      System.out.println(userDocument.asJsonString());
    }

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
  }

}
```

Node.js - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.find method.

```
/*

 */

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // fetch all OJAI Documents from table
```

```
    return store.find({});
  })
  .then((queryResult) => {
    queryResult.on('data', (document) => console.log(document));
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });
```

Node.js - Example 2

The following example queries a document store and returns all documents. It creates an empty query and passes that to the DocumentStore.find method.

```
/*
 * Copyright (c) 2018 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License");
 * you may not use this file except in compliance with the License.

 */

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // options for find request
    const options = {
      'ojai.mapr.query.include-query-plan': true,
      'ojai.mapr.query.timeout-milliseconds': 10000
    }
    // fetch all OJAI Documents from table
    return store.find({}, options)
  })
  .then((queryResult) => {
    // get query plan
    console.log(queryResult.queryPlan);
```

```
    queryResult.on('data', (document) => {
      // Print OJAI Documents from document stream
      console.log(document);
    });
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });
```

Python - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.find method.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# fetch all OJAI Documents from table
query_result = store.find()

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc)

# close the OJAI connection
connection.close()
```

Python - Example 2

The following example queries a document store and returns all documents. It creates a Query object and passes that to the DocumentStore.find method.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Build an OJAI query
query = connection.new_query().build()

# options for find request
options = {
    'ojai.mapr.query.include-query-plan': True,
```

last-updated: Jun 06, 2024

```
    'ojai.mapr.query.result-as-document': True,
    'ojai.mapr.query.timeout-milliseconds': 10000
}

# fetch all OJAI Documents from table
query_result = store.find(query, options=options)

# get query plan
print(query_result.get_query_plan())

doc_stream = query_result
# Print OJAI Documents from document stream
for doc in doc_stream:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following is the equivalent of the code examples using dbshell. See dbshell find or findbyid on page 5473 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> find /demo_table
```

C# - Example 1

The following example queries a document store and returns all documents by using the `GetAllDocuments` method.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindAllDocuments
{
    public async void FindAllDocuments()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Fetch all OJAI Documents from table
        var queryResult = store.Find();
        var documentStream = await queryResult.GetAllDocuments();

        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }
```

last-updated: Jun 06, 2024

```
        // Close the OJAI connection
        connection.Close();
    }
}
```

C# - Example 2

The following example queries a document store and returns all documents. It creates a `Query` object and passes that to the `DocumentStore.Find` method.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindAllQuery
{
    public async void FindAllQuery()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Build an OJAI query
        var query = connection.NewQuery().Build();

        // Options for find request
        var options = new QueryOptions()
        {
            IncludeQueryPlan = true,
            Timeout = 1000
        };

        // Fetch all OJAI Documents from table
        var queryResult = store.Find(query, options);

        // Get query plan
        Console.WriteLine(queryResult.GetQueryPlan());

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - Example 1

The following example queries a document store and returns all documents by using the DocumentStore.FindAll function.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Fetch all OJAI Documents from table
    findResult, err := store.FindAll(&client.FindOptions{IncludeQueryPlan:
false, ResultAsDocument: true})

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Go - Example 2

The following example queries a document store and returns all documents. It creates a Query object and passes that to the DocumentStore.FindQuery function.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
```

```
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{IncludeQueryPlan: true,
ResultAsDocument: true}

    // Build an OJAI query
    query, err := client.MakeQuery()
    if err != nil {
        panic(err)
    }

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQuery(query, options)

    // Get query plan
    fmt.Println(findResult.QueryPlan())

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Paginating Your Result

An alternative to returning all documents from a store is to specify a limit in the query. Another alternative is to paginate the result using offset and limit. Querying with Order By on page 3435 contains an example that shows you how to use offset and limit. Although the example also uses order by, you can use offset and limit independent of order by.

Querying with Select

The examples in this section query a document store and retrieve specific fields from the documents.

NOTE: Selecting a specific field is also known as a *projection*. You can improve the performance of projection queries by using secondary indexes. See Using Indexes to Optimize Projections in Queries on page 719 for more details.

Java

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using the Query.select method.

```
/**

  })
  .then((store) => {
    // Create an OJAI query
    const query = {"$select": ["_id", "address.zipCode"]};
    // fetch OJAI Documents by query
    return store.find(query);
  })
  .then((queryResult) => {
    queryResult.on('data', (document) => {
      // Print OJAI Documents from document stream
      console.log(document);
    });
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });
```

Python

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using an OJAI query.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$select": ["_id", "address.zipCode"]}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
    }

# fetch OJAI Documents by query
query_result = store.find(query, options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following two dbshell commands are equivalent to the code examples. See dbshell find or findbyid on page 5473 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> find /demo_table --query {"$select":["_id","address.zipcode"]}

maprdb root:> find /demo_table --fields _id,address.zipcode
```

C#

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using an OJAI query.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithSelect
{
    public async void FindQueryWithSelect()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
```

```
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        //Create an OJAI query
        var query = connection.NewQuery().Select("_id",
"address.zipCode").Build();

        // Options for find request
        var options = new QueryOptions(1000, true);

        // Fetch OJAI Documents by query
        var queryResult = store.Find(query, options);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using an OJAI query.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }
```

```
    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"_id",
"address.zipCode"}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Querying with Conditions

The examples in this section query a document store and return documents that have specific conditions.

For more information about how to specify query conditions in OJAI, see Query Conditions in OJAI Applications on page 3370.

NOTE: You can improve the performance of queries with conditions by using secondary indexes. See Queries that Benefit from Secondary Indexes on page 708 for more details.

Java - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the Query.where method. It uses an OJAI QueryCondition to specify the condition.

```

      connection.close();
    });
  });
```

Python - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the Query.where method. It uses an OJAI QueryCondition to specify the condition.

```
from mapr.ojai.ojai_query.QueryOp import QueryOp
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')
```

```
# Create an OJAI query
query = connection.new_query()\
    .where(connection.new_condition()
           .is_('address.zipCode', QueryOp.EQUAL, 95196)
           .close()
           .build())\
    .build()

# fetch the OJAI Documents by query
query_result = store.find(query)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc)

# close the OJAI connection
connection.close()
```

Python - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$where": {"$eq": {"address.zipCode": 95196}}}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
    }

# fetch OJAI Documents by query
query_result = store.find(query, options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following two dbshell commands are equivalent to the code examples. See dbshell find or findbyid on page 5473 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> find /demo_table --q {"$where":{"$eq":
{"address.zipCode":95196}}}
```

```
maprdb root:> find /demo_table --where {"$eq":
{"address.zipCode":95196}}
```

C# - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the `Query.Where` method. It uses an OJAI QueryCondition to specify the condition.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithCondition
{
    public async void FindQueryWithCondition()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        //Create an OJAI query
        var query = connection
            .NewQuery()
                .Where(connection
                        .NewQueryCondition()
                            .Is("address.zipCode", QueryOp.EQUAL, 95196)
                            .Close()
                        .Build())
                 .Build();

        // Fetch the OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document);
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

C# - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithConditionJson
{
    public async void FindQueryWithConditionJson()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI query
        var query =
            @"{" +
                @"""$where"":" +
                    @"{" +
                        @"""$eq"":{""address.zipCode"":
{""$numberLong"":""95196""}}" +
                    @"}" +
            @"}";

        // Fetch OJAI Documents by query
        var queryResult = store.FindQuery(query);

        var documentStream = await queryResult.GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - OJAI `QueryCondition` Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the `Query.WhereCondition` function. It uses an OJAI Condition to specify the condition.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)
```

last-updated: Jun 06, 2024

```
func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create a condition
    condition, err := client.MakeCondition(client.Is("address.zipCode",
client.EQUAL, 95196), client.Close())
    if err != nil {
        panic(err)
    }
    condition.Build()

    // Create an OJAI query
    query, err := client.MakeQuery(client.WhereCondition(condition))
    if err != nil {
        panic(err)
    }
    query.Build()

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQuery(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Go - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
package main

import (
```

last-updated: Jun 06, 2024

```
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

  });
```

Python

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses an OJAI query and condition.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$select": ["name",
                     "adress.zipCode",
                     "age",
                     "phoneNumbers[0]"],
         "$where": {"$eq": {"address.zipCode": 95196}}}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
    }

# fetch OJAI Documents by query
query_result = store.find(query,
                          options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following two dbshell commands are equivalent to the code examples. See dbshell find or findbyid on page 5473 for more details about the syntax dbshell provides.

```
find /demo_table --query {
   "$select":["name","address.zipCode","age","phoneNumber[0]"],
   "$where":{"$eq":{"address.zipCode":95196}}
}

find /demo_table
   --fields name,address.zipCode,age,phoneNumber[0]
   --where {"$eq":{"address.zipCode":95196}}
```

NOTE: The commands are shown split across multiple lines for readability. When using dbshell, you must enter them in a single line.

C#

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses an OJAI query and condition.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithSelectAndCondition
{
    public async void FindQueryWithSelectAndCondition()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI condition
        var condition = connection
            .NewQueryCondition()
                .Is("address.zipCode", QueryOp.EQUAL, 95196)
                .Close()
            .Build();

        // Create an OJAI query
        var query = connection
            .NewQuery()
                .Select("name", "adress.zipCode", "age", "phoneNumbers[0]")
                .Where(condition)
            .Build();

        // Fetch OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The following example shows how to return the `name`, `address.zipCode`, `age`, and `phoneNumber` fields from documents that have `address.zipCode` equal to 95196. It uses an OJAI query and condition.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"firstName",
"address.zipCode", "age", "phoneNumbers[0]"},
        "$where": map[string]interface{}{
            "$eq": map[string]interface{}{"address.zipCode": 95196}}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Querying with Order By

The examples in this section query a document store and return specific fields from the documents, sorted in a specific order. One of the examples also uses offset and limit.

NOTE: You can improve the performance of order by queries by using secondary indexes. See Using Indexes to Optimize ORDER BY Queries on page 716 for more information.

Java - Order By

The following example shows how to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sorting the documents by `_id`. It uses the Query.select and Query.orderBy methods.

NOTE: The example sorts in the default ascending order. To sort in descending order, modify the `orderby` method call as follows:

```
orderBy("_id", SortOrder.DESC)
```

```

        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI query
        var query = connection
            .NewQuery()
```

```
                .Select("_id", "firstName", "lastName", "address.zipCode")
                .Offset(2)
                .Limit(1)
                .OrderBy("_id", SortOrder.ASC)
            .Build();

        // Fetch OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - Order By

The following example uses an OJAI query to return the `_id` and `firstName` fields from documents in a store and to sort the documents by `_id`.

The example sorts in the default ascending order. To sort in descending order, modify the `orderby` specification as follows:

```
"$orderby": map[string]interface{}{"_id": "desc"}}
```

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }
```

last-updated: Jun 06, 2024

```
    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"_id",
"firstName"},
        "$orderby": map[string]interface{}{"_id": "asc"}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Go - Order By with Offset and Limit

The following example uses an OJAI query to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sort the documents by `_id`, offset the result by two documents, and limit the result to a single document.

The example sorts in the default ascending order. To sort in descending order, modify the `orderby` function call as follows:

```
"$orderby": map[string]interface{}{"_id": "desc"}}
```

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }
```

```
    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"_id",
"firstName", "lastName", "address.zipCode"},
        "$offset":  2,
        "$limit":   1,
        "$orderby": map[string]interface{}{"_id": "asc"}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Using the Java OJAI Client
This topic describes HPE Ezmeral Data Fabric Database functionality that is applicable to only the Java OJAI client. This includes instructions on how to compile your Java OJAI application, enable buffered writes, use the read your own writes feature, and enable available query options.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/java/src/main/java/com/mapr/ojai/examples

Compiling and Running Java OJAI Applications
For applications that use the Java OJAI API, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

Compile and Determine Dependencies

Use Maven to compile and determine the application dependencies.

1. Add MapR's Maven repository to your `pom.xml` file, if it is not already added:

```
<repositories>
    <repository>
        <id>mapr-releases</id>
        <url>https://repository.mapr.com/nexus/content/repositories/
releases</url>
        <snapshots><enabled>true</enabled></snapshots>
        <releases><enabled>true</enabled></releases>
    </repository>
</repositories>
```

2. Add a dependency to the MapR OJAI driver project:

```
<dependencies>
    <dependency>
        <groupId>com.mapr.ojai</groupId>
        <artifactId>mapr-ojai-driver</artifactId>
        <version>6.0.0-mapr</version>
    </dependency>
</dependencies>
```

   NOTE: Replace the `<version>` property with the HPE Ezmeral Data Fabric Database version that you are using.

3. Use Maven to compile the application and resolve dependencies.

Run the Application

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 3151.

When the cluster is secure, the node must also have a MapR ticket configured for the user that runs the application.

You can use the following command to launch HPE Ezmeral Data Fabric Database JSON applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

Enable OJAI Tracing

To help debug your Java OJAI application, you can enable OJAI tracing. MapR uses the `log4j` API to log tracing messages. To enable writing these messages to standard output, follow these steps:

1. Set the following property in your `/opt/mapr/conf/log4j.properties` file:

```
log4j.logger.com.mapr.ojai.store.impl=TRACE, stdout
```

2. Add the following to your `java` launch command:
   - In your java classpath, add the library that includes custom MapR `log4j` classes:

```
-cp /opt/mapr/lib/central-logging-7.7.0-mapr.jar:<other classpaths>:.
```

   - Define the location of the `log4j.properties` file:

```
-Dlog4j.configuration=file:/opt/mapr/conf/log4j.properties
```

last-updated: Jun 06, 2024

Reading Your Own Writes in Java OJAI

The Java OJAI `DocumentStore` and `Query` APIs provide the ability to track writes to JSON tables. Use these APIs to ensure your application reads recent writes on JSON tables with secondary indexes.

Description

You should use this feature if it is important for your query results to reflect synchronized data between a JSON table and its secondary indexes. Because HPE Ezmeral Data Fabric Database updates secondary indexes asynchronously, it is possible for a JSON table and its secondary indexes to become out-of-sync while the index update is in progress.

For example, consider the following scenario:

- Your application updates a JSON table.
- The JSON table includes an `address` field that is a nested document with a `zipCode` subfield.
- You have a secondary index on `zipCode`.
- Later in your application, you query the JSON table filtering on `zipCode`.

You want your query result to reflect the updates from earlier in your application. To achieve this, use the `DocumentStore` and `Query` APIs that enable you to retrieve up-to-date information from the index. The APIs synchronize write operations on the JSON table with read operations on a secondary index.

See Asynchronous Secondary Index Updates on page 726 for more information about index updates.

NOTE: The Python and Node.js OJAI APIs do not support this feature.

API Details

The OJAI `DocumentStore` and `Query` interfaces provide the following methods to support this functionality.

`DocumentStore.beginTrackingWrites`	Begins tracking the write operations performed through this instance of `DocumentStore`. The method takes an optional `previousWritesContext` parameter. If you specify this parameter, the tracking uses that context as the base state.
`DocumentStore.endTrackingWrites`	Flushes any buffered writes operations for this `DocumentStore` and returns a `writesContext`. Use this context to ensure that writes are visible to later queries. You can use the context across `DocumentStore` objects in the same, as well as different, client processes, when the stores refer to the same JSON table. For example, you can pass the `writesContext` returned by one `DocumentStore` to a second `DocumentStore`, to begin write tracking on the second store.
`DocumentStore.clearTrackedWrites`	Stops the write tracking and clears any state on this `DocumentStore` instance.
`Query.waitForTrackedWrites`	Sets the `writesContext` parameter for this query. A `writesContext` allows this query to "see" all the writes that happened inside the `writesContext` of a `DocumentStore`.

For the complete API, see Java OJAI Client API.

last-updated: Jun 06, 2024

Read Your Own Writes Example

A complete code example is available on github at OJAI_013_ReadYourOwnWrite.java. The following are code snippets from that example. Each step contains links to corresponding lines of code in the github example:

1. Call beginWriteTracking to set the starting point for the commit context on the JSON table `/demo_table`:

```
// Create an OJAI connection to MapR cluster
final Connection connectionNode1 =
DriverManager.getConnection("ojai:mapr:");

// Get an instance of OJAI DocumentStore
final DocumentStore storeNode1 = connectionNode1.getStore("/demo_table");

// initiate tracking of commit-context
storeNode1.beginTrackingWrites();
```

2. Update the `zipCode` of an existing user and insert a new user in `/demo_table`:

```
// issue a set of mutations/insert/delete/etc
storeNode1.update("user0000",
connectionNode1.newMutation().set("address.zipCode", 95110L));
storeNode1.insertOrReplace(connectionNode1.newDocument(
    "{\"_id\": \"user0004\", \"firstName\": \"Joel\",
\"lastName\": \"Smith\", \"age\": 56, \"address\": {\"zipCode\":
{\"$numberLong\":95110}}}"));
```

3. Call endWriteTracking to flush the write operations after step 1, including updates to the secondary index:

```
final String commitContext = storeNode1.endTrackingWrites();
```

   The call also returns a `commitContext`.

4. Issue a query that calls waitForTrackedWrites with the `commitContext` from step 3:

```
/*
 * Next section of the code can run on the same or on a different node,
 * the `commitContext` obtained earlier needs to be propagated to that
node.
 */

// Create an OJAI connection to MapR cluster
final Connection connectionNode2 =
DriverManager.getConnection("ojai:mapr:");

// Get an instance of OJAI DocumentStore
final DocumentStore storeNode2 = connectionNode2.getStore("/demo_table");

// Build an OJAI query and set its commit context with timeout of 2
seconds
final Query query = connectionNode2.newQuery()
    .select("_id", "firstName", "lastName", "address.zipCode")
    .where("{\"$gt\": {\"address.zipCode\": 95110}}")
    .waitForTrackedWrites(commitContext)
    .build();
```

   The query filters on the indexed subfield `address.zipCode`. The `commitContext` ensures that the query result includes the changes made in step 2.

Setting Query Options in Java OJAI
This topic describes how to set query options in your Java OJAI application.

See OJAI Query Options on page 3368 for a list of available query options.

To set an option, pass the option name as the first parameter to the Query.setOption method:

```
query.setOption("ojai.mapr.query.hint-using-index", indexName);
```

Enabling Buffered Writes in Java OJAI
By default, HPE Ezmeral Data Fabric Database JSON does not buffer writes. You can improve performance by enabling buffered writes in your Java OJAI application.

Description

The buffered writes option can be set in the Connection.getStore method. You pass the option setting through a `Document` object in the second parameter to the method. The `Document` object sets `ojai.mapr.documentstore.buffer-writes` to either `true` or `false`. The default value is `false`, which means that writes are not buffered.

Example Code Snippet

The following code sample enables buffered writes:

```
final DocumentStore store =
    connection.getStore(
        "/demo_table",

connection.newDocument().set("ojai.mapr.documentstore.buffer-writes",
true));
```

Using the Java OJAI Thin Client
Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write HPE Ezmeral Data Fabric Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the

OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Java OJAI Thin Client Benefits

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface
- An OJAI interface that is tailored to Java developers
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

Comparing the Java OJAI Client and the Java OJAI Thin Client

Note these considerations when deciding whether to use the Java OJAI Client or the Java OJAI Thin Client:

- Both the Java OJAI client and Java OJAI Thin Client use the same API (Java OJAI Client API).
- The Java OJAI client is more scalable, more performant, and more fault tolerant, but also more complicated to deploy. See Using the Java OJAI Client on page 3446.
- The Java OJAI Thin Client requires you to specify the service (MapR Data Access Gateway) to which you will connect.
- The Java OJAI Thin Client is a pure Java client, while the Java OJAI client requires a JNI library.

Installing the MapR Data Access Gateway

To use the Java OJAI Thin Client, you must install the MapR Data Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the Java OJAI Thin Client and the HPE Ezmeral Data Fabric cluster. To administer the gateway and configure load balancing, see Administering the Data Access Gateway on page 1961.

Java OJAI Thin Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Java OJAI Thin Client Connection String

The string you use to connect your OJAI client to a HPE Ezmeral Data Fabric cluster must have the following format:

```
"ojai:mapr:thin:@<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

<hostname>	Name of the HPE Ezmeral Data Fabric Data Access Gateway host
<port>	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3079) that gRPC clients use to connect to the HPE Ezmeral Data Fabric Data Access Gateway

	Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only `basic`
user=<username>	The user name for `basic` authentication
password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and cluster security settings. The default for this option is `true`, which is the required setting if connecting to a secure HPE Ezmeral Data Fabric cluster. If connecting to a nonsecure HPE Ezmeral Data Fabric cluster, set it to `false`. If set to `false`, the other SSL parameters are ignored.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3477. Must be set if the `ssl` option is `true`.

Here is an example of a connection string:

```
"ojai:mapr:thin:@localhost:5678?
auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
```

Advanced Parameters

Advanced parameters such as `maxmsgsize` are optional for the Java OJAI Thin Client connection string:

maxmsgsize	If you use thin-client version `1.0.2-mapr` and later, `maxmsgsize` sets the maximum message size that the gRPC client accepts. The default is set to 32 MB, as this is the default maximum document size for HPE Ezmeral Data Fabric Database JSON tables. The value specified in the connection string should be less than or equal to the value set in the Data Access Gateway configuration on the server side (see Administering the Data Access Gateway on page 1961).

Maven Coordinates

The Maven coordinates are:

```
<dependency>
    <groupId>com.mapr.ojai</groupId>
    <artifactId>mapr-ojai-driver-thin</artifactId>
    <version>1.0.3-mapr</version>
</dependency>
```

Additional Resources

The Java OJAI Client examples at the following location also apply to the Java OJAI Thin Client. Only the connection string and the Maven artifact name will be different for the thin client: https://github.com/mapr-demos/ojai-examples/tree/master/java/src/main/java/com/mapr/ojai/examples

Using the Node.js OJAI Client

Starting with EEP 6.0, you can use the Node.js OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON from middleware components, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface in Node.js
- An OJAI interface that is tailored to Node.js developers
- Support for Callback and Promise/Async Node.js asynchronous programming models
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing
- Use of JavaScript to manipulate HPE Ezmeral Data Fabric Database JSON documents

To use the Node.js OJAI client, you must install the MapR Data Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the Node.js client and the HPE Ezmeral Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. See Administering the Data Access Gateway on page 1961 for information about how to administer the gateway and configure load balancing.

IMPORTANT: HPE Ezmeral Data Fabric does not support running the Node.js OJAI client in a web browser.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/nodejs

Source Code: https://github.com/mapr/maprdb-node-client

Getting Started with the Node.js OJAI Client

This section describes the software required to run the Node.js OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Node.js OJAI applications.

The Node.js OJAI client is available starting in the EEP 6.0 release.

Software Requirements

You must have the following software installed to run the client:

last-updated: Jun 06, 2024

Client Software	Installation Notes
Node.js	Supported versions: • 6.x • 8.x • 9.x • 10.x
Node.js OJAI client	Install the client by using the following command: `npm install node-maprdb`

You also must have access to the following software:

- MapR cluster 6.1 or later
- MapR Data Access Gateway 2.0 or later

To run a Node.js OJAI application, you simply need to install and configure the MapR Data Access Gateway:

- Installing the Data Access Gateway Service on page 1961
- Modifying Configuration Settings for the Data Access Gateway Service on page 1962

Node.js OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Node.js OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

`<hostname>`	Name of the Data Access Gateway host. For information about the host name, see Configuring SSL for OJAI Clients on page 3477.
`<port>`	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3079) that gRPC clients use to connect to the Data Access Gateway Default: 5678
`auth=<scheme_name>`	The authentication scheme for the current connection; currently, only `basic`
`user=<username>`	The user name for `basic` authentication

last-updated: Jun 06, 2024

password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a non-secure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 1961.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3477. Required when the `ssl` option is set to `true`.

sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string.
	For example, imagine that you are using the following:
	• Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`.
	• Internal DNS is `node1.mydomain.com`.
	• CA signed certificate is issued to `node1.mydomain.com`.
	Using these names, you must specify the following connection string:
	`"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;`**`sslTargetNameOverride=node1.mydomain.com`**`"`
	Other examples of connection strings are the following:
	`"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"`
	`"localhost:5678?ssl=false;auth=basic;user=fred;password=george"`

Node.js OJAI Connection Retry Options

If your OJAI client cannot connect to your cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

last-updated: Jun 06, 2024

Connection Option Parameter	Description	Default Value
`ojai.mapr.rpc.wait-multiplier`	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
`ojai.mapr.rpc.wait-max-attempt`	Maximum wait time between attempts regardless of the multiplier parameter	18000 ms
`ojai.mapr.rpc.max-retries`	Maximum number of retry attempts	7

The following examples demonstrate how these parameters work, including the default case:

Attempt #	Wait Time (in ms) for each Retry Attempt	
	Default Parameters: `{ 'ojai.mapr.rpc.wait-multiplier': 1000, 'ojai.mapr.rpc.wait-max-attempt': 18000, 'ojai.mapr.rpc.max-retries': 7 }`	`{ 'ojai.mapr.rpc.wait-multiplier': 2, 'ojai.mapr.rpc.wait-max-attempt': 90, 'ojai.mapr.rpc.max-retries': 5 }`
1	10	10
2	10*1000 = 10000	10*2 = 20
3	18000 10000*1000 = 10,000,000, which exceeds 18000	20*2 = 40
4	18000	40*2 = 80
5	18000	90 80*2 = 160, which exceeds 90
6	18000	Error
7	18000	N/A
8	Error	N/A

To set these retry options, you must pass them in the `ConnectionManager.getConnection` call:

```
const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';
const options = {
  'ojai.mapr.rpc.wait-multiplier': 5,
  'ojai.mapr.rpc.wait-max-attempt': 50,
  'ojai.mapr.rpc.max-retries': 3
}

let connection;
```

last-updated: Jun 06, 2024

```
ConnectionManager.getConnection(connectionString,options)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
```

Writing Node.js OJAI Applications

For information about writing a Node.js OJAI application, see the Node.js sections in the following topics:

Querying in OJAI Applications on page 3360	Provides an introduction to the basic flow of an OJAI application that queries a HPE Ezmeral Data Fabric Database JSON table
Examples: Querying JSON Documents on page 3405	Contains code samples of OJAI applications that query HPE Ezmeral Data Fabric Database JSON tables
Managing JSON Documents on page 3322	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Ezmeral Data Fabric Database JSON tables

Node.js OJAI Client Classes and Methods

This topic lists and describes the classes supported by the Node.js OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
`ConnectionManager`	Manages connections to HPE Ezmeral Data Fabric Database JSON.
`Connection`	Provides a logical connection to an OJAI data source: for example, HPE Ezmeral Data Fabric Database JSON.
`DocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Ezmeral Data Fabric Database JSON tables.
`QueryResult`	Encapsulates the stream of result sets for an OJAI query.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.

See Node.js OJAI Client API for details about each class, including the methods available in each class.

Setting Query Options in Node.js OJAI

There are two categories of options you can set in your Node.js OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a Node.js OJAI Method Call

Option Name	Description
`ojai.mapr.query.include-query-plan`	Enables or disables availability of the query plan for retrieval Value: `true|false` Default: `false`

last-updated: Jun 06, 2024

Option Name	Description
`ojai.mapr.query.timeout-milliseconds`	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.find` method.

The following code snippet sets the query timeout to 3000 milliseconds:

```
const docStream = store.find(
    query,
    { 'ojai.mapr.query.timeout-milliseconds': 3000 }
);
```

Setting Query Options in Node.js Using OJAI Query Syntax

OJAI Query Options on page 3368 describes query options that are available in all OJAI clients. To use these options in Node.js OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the Python OJAI Client

Starting with EEP 6.0, you can use the Python OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface in Python
- An OJAI interface that is tailored to Python developers
- Use of Python types to manipulate HPE Ezmeral Data Fabric Database JSON documents
- Support for Python multiprocessing and multithreading modules
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the Python OJAI client, you must install the MapR Data Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the Python client and the HPE Ezmeral Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. See Administering the Data Access Gateway on page 1961 for information about how to administer the gateway and configure load balancing.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/python

Source Code: https://github.com/mapr/maprdb-python-client

Getting Started with the Python OJAI Client

This section describes the software required to run the Python OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Python OJAI applications.

The Python OJAI client is available starting with the EEP 6.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Python	Use Python 2.7 or later
pip	See https://pip.pypa.io/en/stable/installing/ for instructions specific to your environment.
Python OJAI client	Install the client by using the following command: `pip install maprdb-python-client`

You also must have access to the following software:

- MapR cluster 6.1 or later
- MapR Data Access Gateway 2.0 or later

To run a Python OJAI application, you simply need to install and configure the MapR Data Access Gateway:

- Installing the Data Access Gateway Service on page 1961
- Modifying Configuration Settings for the Data Access Gateway Service on page 1962

Python OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Python OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

`<hostname>`	Name of the Data Access Gateway host. For information about the host name, see Configuring SSL for OJAI Clients on page 3477.
`<port>`	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3079) that gRPC clients use to connect to the Data Access Gateway Default: 5678
`auth=<scheme_name>`	The authentication scheme for the current connection; currently, only `basic`
`user=<username>`	The user name for `basic` authentication
`password=<password>`	The password for `basic` authentication

last-updated: Jun 06, 2024

ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a non-secure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 1961.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3477. Required when the `ssl` option is set to `true`.

sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string.
	
	For example, imagine that you are using the following:
	• Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`.
	• Internal DNS is `node1.mydomain.com`.
	• CA signed certificate is issued to `node1.mydomain.com`.
	
	Using these names, you must specify the following connection string:
	`"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;`**`sslTargetNameOverride=node1.mydomain.com`**`"`
	
	Other examples of connection strings are the following:
	`"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"`
	`"localhost:5678?ssl=false;auth=basic;user=fred;password=george"`

Python OJAI Connection Retry Options

If your OJAI client cannot connect to your cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

last-updated: Jun 06, 2024

Connection Option Parameter	Description	Default Value
`ojai.mapr.rpc.wait-multiplier`	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
`ojai.mapr.rpc.wait-max-attempt`	Maximum wait time between attempts regardless of the multiplier parameter	18000 ms
`ojai.mapr.rpc.max-retries`	Maximum number of retry attempts	7

The following examples demonstrate how these parameters work, including the default case:

Attempt #	Wait Time (in ms) for each Retry Attempt	
	Default Parameters: `{ 'ojai.mapr.rpc.wait-multiplier': 1000, 'ojai.mapr.rpc.wait-max-attempt': 18000, 'ojai.mapr.rpc.max-retries': 7 }`	`{ 'ojai.mapr.rpc.wait-multiplier': 2, 'ojai.mapr.rpc.wait-max-attempt': 90, 'ojai.mapr.rpc.max-retries': 5 }`
1	10	10
2	10*1000 = 10000	10*2 = 20
3	18000 10000*1000 = 10,000,000, which exceeds 18000	20*2 = 40
4	18000	40*2 = 80
5	18000	90 80*2 = 160, which exceeds 90
6	18000	Error
7	18000	N/A
8	Error	N/A

To set these retry options, you must pass them in the `ConnectionFactory.get_connection` call:

```
connection_str = 'localhost:5678?auth=basic;user=mapr;password=mapr;' \
    'ssl=true;' \
    'sslCA=/opt/mapr/conf/ssl_truststore.pem;' \
    'sslTargetNameOverride=node1.mapr.com'
options = {
    'ojai.mapr.rpc.wait-multiplier': 5,
    'ojai.mapr.rpc.wait-max-attempt': 50,
    'ojai.mapr.rpc.max-retries': 3
}
connection =
ConnectionFactory.get_connection(connection_str=connection_str,options=optio
ns)
```

last-updated: Jun 06, 2024

Writing a Python OJAI Application

For information about writing a Python OJAI application, see the Python sections in the following topics:

Querying in OJAI Applications on page 3360	Provides an introduction to the basic flow of an OJAI application that queries a HPE Ezmeral Data Fabric Database JSON table
Examples: Querying JSON Documents on page 3405	Contains code samples of OJAI applications that query HPE Ezmeral Data Fabric Database JSON tables
Managing JSON Documents on page 3322	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Ezmeral Data Fabric Database JSON tables

Python OJAI Client Classes and Methods

This topic lists and describes the classes supported by the Python OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
`Connection`	Provides a logical connection to an OJAI data source: for example, HPE Ezmeral Data Fabric Database JSON.
`ConnectionDriver`	Provides a connection handler, which enables you to get and check connections
`ConnectionManager`	Manages connections to HPE Ezmeral Data Fabric Database JSON.
`Document`	Provides the primary, DOM-based interface for inspecting OJAI documents.
`DocumentMutation`	Encapsulates a mutation to an existing OJAI document in a store.
`DocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Ezmeral Data Fabric Database JSON tables.
`DocumentStream`	Encapsulates the result set of an OJAI query.
`QueryResult`	Encapsulates the result set of an OJAI query.
`Query`	Encapsulates an OJAI query.
`QueryCondition`	Encapsulates a query condition; similar to a SQL `where` clause.
`Value`	Encapsulates the value of a field, scalar, or complex type in an OJAI document.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.
`OInterval`	Encapsulates the OJAI `INTERVAL` type.

See Python OJAI Client API for details about each class, including the methods available in each class.

Multiprocessing and Multithreading in Python OJAI Applications

Python supports multiprocessing and multithreading modules that enable you to spawn either multiple processes or multiple threads in a Python program. This section contains examples that show you how to use these modules in your Python OJAI application.

Multiprocessing in Python OJAI Applications

The following code example spawns multiple processes using the Python `multiprocessing` module. When you use the module, you must create a separate OJAI connection for each process.

last-updated: Jun 06, 2024

The code example is available at 014_multiprocessing_example.py.

```
"""Following example works with Python Client"""

import multiprocessing
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

"""Create a connection, get store, insert_or_replace/update document in
 store via multiprocessing"""

# Create a connection string using path:user@password
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
          "sslTargetNameOverride=node1.mapr.com"

# Create method which will be used for multiprocessing
def sample():
    # Create connection from connection_url
    # Cannot share connection for processes,
    # so need to create connection for each process.
    connection =
ConnectionFactory().get_connection(connection_str=connection_str)

    # Get a store and assign it as a DocumentStore object
    store = connection.get_or_create_store('/tmp/store_name')

    # Insert 15 documents, represented as Python dictionaries,
    # into DocumentStore
    for i in range(15):
        store.insert_or_replace(doc={'_id': str(i), 'name': 'Greg'})

    # Create DocumentMutation object using the OJAIConnection object
    mutation = connection.new_mutation()

    # Set mutation value
    mutation.set_or_replace(field_path='name', value='T')

    # Update 15 Document in store
    for i in range(15):
        store.update(_id=str(i), mutation=mutation)

# Create simple method for run process from Pool
def run(unused_var):
    pass

# Create data for multiprocessing
proces_count = 7
map_iterable = [1]  # simple iterator

# Create Pool object using the function and process_count value
p = multiprocessing.Pool(proces_count, initializer=sample)

# Run processes from the Pool
p.map(run, map_iterable)
```

Multithreading in Python OJAI Applications

You can use either the Python `thread` or `threading` module to spawn multiple threads in your Python application. When you use these modules, you can share an OJAI connection across threads.

Thread Module

The following code example uses the `thread` module. It is available at 015_thread_example.py.

```
"""Following example works with
Python Client"""
import thread
import time
from
mapr.ojai.storage.ConnectionFactory
import ConnectionFactory

"""Create a connection, get store,
insert_or_replace/update document in
 store via thread using same
connection"""

# Create method which will be used
for threads
def run_thread(name, conn):
    # Print that thread started with
threadName
    print('\n Start thread ', name)

    # Get a store and assign it as a
DocumentStore object
    store =
conn.get_or_create_store('/tmp/
store_name')

    # Insert 15 documents,
represented as Python dictionaries,
    # into DocumentStore
    for index in range(15):

store.insert_or_replace(doc={'_id':
str(index), 'name': 'Greg'})

    # Create DocumentMutation object
using the OJAIConnection object
    mutation = conn.new_mutation()

    # Set mutation value

mutation.set_or_replace(field_path='na
me', value='T')

    # Update 15 Document in store
    for index in range(15):
        store.update(_id=str(index),
mutation=mutation)

    # Print that thread done with
threadName
    print('\n Done thread ', name)

# Create a connection string using
```

last-updated: Jun 06, 2024

```
path:user@password
connection_str = "localhost:5678?
auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/
ssl_truststore.pem;" \

"sslTargetNameOverride=node1.mapr.com"

# Create connection from
connection_url
# Can share connection for processes,
# so need to only one connection
instance for all threads
connection =
ConnectionFactory.get_connection(conne
ction_str)

# Create 10 threads using the same
connection instance
for i in range(10):
    thread_name =
'Thread-{}'.format(str(i))

thread.start_new_thread(run_thread,
(thread_name, connection,))

# This thread implementation doesn't
return thread object
# so thread status cannot be checked
# Wait 10 seconds
time.sleep(10)

# Close connection
connection.close()
```

Threading Module

The following code example uses the `threading` module. It is available at 016_threading_example.py.

```
"""Following example works with
Python Client"""
import threading
import time

from
mapr.ojai.storage.ConnectionFactory
import ConnectionFactory

"""Create a connection, get store,
insert_or_replace/update document in
 store via thread using same
connection"""

# Create a connection string using
path:user@password
connection_str = "localhost:5678?
auth=basic;user=mapr;password=mapr;" \
          "ssl=true;" \
          "sslCA=/opt/mapr/conf/
ssl_truststore.pem;" \
```

```
"sslTargetNameOverride=node1.mapr.com"

# Create connection from
connection_url
# Can share connection for processes,
# so need to only one connection
instance for all threads
connection =
ConnectionFactory.get_connection(conne
ction_str)

# Create child for sample threading
implementation
class MyThread(threading.Thread):
    # Implement __init__() method,
which takes thread name and
    # connection object
    def __init__(self, name,
connection):

threading.Thread.__init__(self)
        self.name = name
        self.connection = connection

    # Implement run() method
    def run(self):
        # Print that thread started
with threadName
        print('\n Start thread ',
self.name)

        # Get a store and assign it
as a DocumentStore object
        store =
connection.get_or_create_store('/tmp/
store_name')

        # Insert 15 documents,
represented as Python dictionaries,
        # into DocumentStore
        for index in range(15):

store.insert_or_replace(doc={'_id':
str(index), 'name': 'Greg'})

        # Create DocumentMutation
object using the OJAIConnection object
        mutation =
connection.new_mutation()

        # Set mutation value

mutation.set_or_replace(field_path='na
me', value='T')

        # Update 15 Document in store
        for index in range(15):

store.update(_id=str(index),
mutation=mutation)
```

```
        # Print that thread done with
threadName
        print('\n Done thread ',
self.name)

# This thread implementation return
thread object
# so thread status can be checked via
native methods
# Simple thread waiter for thread
list:
def waiter(threads):
    for my_thread in threads:
        # Check that current thread
is alive
        if my_thread.is_alive():
            time.sleep(1)
            # Wait until current
thread finished
            waiter(threads)
        # Move to the next thread if
this is not alive
        elif not my_thread.is_alive():
            pass

# Create list instance for storing
created threads objects
thread_list = []

# Create and run 10 threads
for i in range(10):
    # Create thread instance using
MyThread and OJAIConnection object
    thread =
MyThread(name='Thread-{0}'.format(str(
i)),

connection=connection)

    # Start current thread
    thread.start()

    # Append thread object into
thread_list
    thread_list.append(thread)

# Wait until all threads will finished
waiter(thread_list)

# Close connection
connection.close()
```

Setting Query Options in Python OJAI

There are two categories of options you can set in your Python OJAI application. This topic describes both and shows you how to set each.

last-updated: Jun 06, 2024

Setting Query Options Using a Python OJAI Method Call

Option Name	Description
`ojai.mapr.query.include-query-plan`	Enables or disables availability of the query plan for retrieval Value: `True`|`False` Default: `False`
`ojai.mapr.query.result-as-document`	Enables or disables returning the query result as an OJAI `Document` class object versus a Python dictionary Value: `True`|`False` Default: `False`; returns query result as a Python dictionary
`ojai.mapr.query.timeout-milliseconds`	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the DocumentStore.find method.

The following code snippet sets the option to return the query result as a Document object:

```
options = {'ojai.mapr.query.result-as-document': True}
query_result = store.find(query, options=options)
```

Setting Query Options in Python Using OJAI Query Syntax

OJAI Query Options on page 3368 describes query options that are available in all OJAI clients. To use these options in Python OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the C# OJAI Client

Starting with EEP 6.1.0, you can use the C# OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface in C#
- An OJAI interface that is tailored to C# developers
- Use of C# types to manipulate HPE Ezmeral Data Fabric Database JSON documents
- Support for C# asynchronous programming and threading mechanism
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the C# OJAI client, you must install the MapR Data Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the C# client and the HPE Ezmeral Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. See

last-updated: Jun 06, 2024

Administering the Data Access Gateway on page 1961 for information about how to administer the gateway and configure load balancing.

Additional Resources

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/csharp

Getting Started with the C# OJAI Client

This section describes the software required to run the C# OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write C# OJAI applications.

The C# OJAI client is available starting in the EEP 6.0.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Visual Studio 2017	https://visualstudio.microsoft.com/vs/

C# OJAI client	• Install the client by using the NuGet Command Line Interface (CLI).
	• Install the `MapRDB.Driver` using the NuGet Package Manager Console:
	`Install-Package MapRDB.Driver -Version 1.0.0`
	• Use the dotnet command line interface:
	`dotnet add package MapRDB.Driver`
	• Use the NuGet Package Manager UI. For instructions, follow this link.

You also must have access to the following software:

- MapR cluster 6.1 or later
- MapR Data Access Gateway 2.0 or later

To run a C# OJAI application, you simply need to install and configure the MapR Data Access Gateway:

- Installing the Data Access Gateway Service on page 1961
- Modifying Configuration Settings for the Data Access Gateway Service on page 1962

C# OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

C# OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

<hostname>	Name of the Data Access Gateway host. For information about the host name, see Configuring SSL for OJAI Clients on page 3477.
<port>	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3079) that gRPC clients use to connect to the Data Access Gateway Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only `basic`
user=<username>	The user name for `basic` authentication
password=<password>	The password for `basic` authentication
ssl=true|false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a non-secure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 1961.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3477. Required when the `ssl` option is set to `true`.
sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string. For example, imagine that you are using the following: • Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`. • Internal DNS is `node1.mydomain.com`. • CA signed certificate is issued to `node1.mydomain.com`.

last-updated: Jun 06, 2024

Using these names, you must specify the following connection string:

```
"ec2-203-0-113-25.compute-1.amazonaws.
com:5678?ssl=true;sslCA=/opt/app/conf/
rootca.pem;sslTargetNameOverride=node1
.mydomain.com"
```

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?
auth=basic;user=fred;password=george;s
slCA=/opt/app/conf/rootca.pem"
"localhost:5678?
ssl=false;auth=basic;user=fred;passwor
d=george"
```

C# OJAI Connection Retry Options

If your OJAI client cannot connect to your MapR cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
`retryExponentialMultiplier`	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
`retryCount`	Maximum number of retry attempts	7

To set these retry options, you must pass them in the `ConnectionFactory.CreateConnection` call:

```
var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
var connection = ConnectionFactory.CreateConnection(connectionStr, 3, 5);
```

Writing a C# OJAI Application

For information about writing a C# OJAI application, see the C# sections in the following topics:

Querying in OJAI Applications on page 3360	Provides an introduction to the basic flow of an OJAI application that queries a HPE Ezmeral Data Fabric Database JSON table
Examples: Querying JSON Documents on page 3405	Contains code samples of OJAI applications that query HPE Ezmeral Data Fabric Database JSON tables
Managing JSON Documents on page 3322	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Ezmeral Data Fabric Database JSON tables

last-updated: Jun 06, 2024

C# OJAI Client Classes and Methods

This topic lists and describes the classes supported by the C# OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
`Value`	Encapsulates the value of a field, scalar, or complex in an OJAI document.
`OjaiDocument`	Provides the primary, DOM-based interface for inspecting OJAI documents
`OjaiDocumentStream`/ `QueryResult`	Encapsulates the result set of an OJAI query.
`OjaiDocumentMutation`	Encapsulates a mutation to an existing OJAI document in a store.
`Query`	Encapsulates an OJAI query.
`QueryCondition`	Encapsulates a query condition; similar to a SQL `where` clause.
`ConnectionFactory`	Provides a logical connection to an OJAI data source: for example, HPE Ezmeral Data Fabric Database JSON.
`MapRDBConnection`	Provides a connection handler, which enables you to get and check connections.
`OjaiDocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Ezmeral Data Fabric Database JSON tables.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.
`OInterval`	Encapsulates the OJAI `INTERVAL` type.

See the C# OJAI Client API for details about each class, including the methods available in each class.

Setting Query Options in C# OJAI

There are two categories of options you can set in your C# OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a C# OJAI Method Call

Option Name	Description
`IncludeQueryPlan`	Enables or disables availability of the query plan for retrieval Value: `true|false` Default: `false`
`Timeout`	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.Find` method.

The following code snippet sets the query timeout to 3000 milliseconds:

```
var queryResult = store.Find(query, new QueryOptions() { Timeout = 3000 });

var queryResult = store.Find(query, new QueryOptions(3000));
```

last-updated: Jun 06, 2024

Setting Query Options in C# Using OJAI Query Syntax

OJAI Query Options on page 3368 describes query options that are available in all OJAI clients. To use these options in C# OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Using the Go OJAI Client

Starting with EEP 6.0.0, you can use the Go OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Ezmeral Data Fabric Database JSON through the OJAI interface in Go
- An OJAI interface that is tailored to Go developers
- Use of Go types to manipulate HPE Ezmeral Data Fabric Database JSON documents
- Support for Go multithreading using Goroutines
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the Go OJAI client, you must install the MapR Data Access Gateway on your HPE Ezmeral Data Fabric cluster. The gateway serves as a proxy for translating requests between the Go client and the HPE Ezmeral Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. To administer the gateway and configure load balancing, see Administering the Data Access Gateway on page 1961.

Additional Resources

Blog: CRUD with the New Golang Client for MapR Database

Examples: https://github.com/mapr-demos/ojai-examples/tree/master/golang

Source Code: https://github.com/mapr/maprdb-go-client

Getting Started with the Go OJAI Client

This section describes the software required to run the Go OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Go OJAI applications.

The Go OJAI client is available starting in the EEP 6.0.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Golang 1.10 (or later)	
Go OJAI client	Install the client using the following command: `go get github.com/mapr/maprdb-go-client`

You also must have access to the following software:

- Data-fabric cluster 6.1 or later

last-updated: Jun 06, 2024

- MapR Data Access Gateway 2.0 or later

To run a Go OJAI application, you must install and configure the Data Access Gateway:

- Installing the Data Access Gateway Service on page 1961
- Modifying Configuration Settings for the Data Access Gateway Service on page 1962

For some sample code, see https://github.com/magpierre/mapr_go_client_mqtt. `main.go` shows a simple Go client that reads from an MQTT messaging protocol and writes to a data-fabric JSON database.

Go OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Go OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

`<hostname>`	Name of the Data Access Gateway host
`<port>`	Port number (see Ports Used by HPE Ezmeral Data Fabric Software on page 3079) that gRPC clients use to connect to the Data Access Gateway Default: 5678
`auth=<scheme_name>`	The authentication scheme for the current connection; currently, only `basic`
`user=<username>`	The user name for `basic` authentication
`password=<password>`	The password for `basic` authentication
`ssl=true|false`	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a nonsecure Data Access Gateway, set it to `false`. If set to `false`, the other SSL parameters are ignored. Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 1961.
`sslCA=<path to PEM file containing CA certificate>`	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information

about the PEM format, see Configuring SSL for OJAI Clients on page 3477.

Must be set if the `ssl` option is `true`.

`sslTargetNameOverride=<CA certificate common name>`

Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string.

For example, imagine that you are using the following:

- Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`.
- Internal DNS is `node1.mydomain.com`.
- CA signed certificate is issued to `node1.mydomain.com`.

Using these names, you must specify the following connection string:

```
"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;sslTargetNameOverride=node1.mydomain.com"
```

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
"localhost:5678?ssl=false;auth=basic;user=fred;password=george"
```

`sslValidate=true|false`

When `ssl=true`, indicates whether or not the client should validate the server certificate against a list of CA certificates. The default is `true`.

Go OJAI Connection Retry Options

If your OJAI client cannot connect to your data-fabric cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
`MaxAttempt`	Maximum number of retry attempts	9
`WaitBetweenSeconds`	Maximum wait time between attempts	12 s
`CallTimeoutSeconds`	Maximum call timeout	60 s

To set these retry options, you must pass them in the `client.MakeConnectionWithRetryOptions` call:

```
    connectionString := "localhost:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
```

last-updated: Jun 06, 2024

```
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"
    options := &client.ConnectionOptions{MaxAttempt:3,
WaitBetweenSeconds:10, CallTimeoutSeconds:60}
    connection, _ :=
client.MakeConnectionWithRetryOptions(connectionString, options)
```

Writing a Go OJAI Application

For information about writing a Go OJAI application, see the Go sections in the following topics:

Querying in OJAI Applications on page 3360	Provides an introduction to the basic flow of an OJAI application that queries a HPE Ezmeral Data Fabric Database JSON table
Examples: Querying JSON Documents on page 3405	Contains code samples of OJAI applications that query HPE Ezmeral Data Fabric Database JSON tables
Managing JSON Documents on page 3322	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Ezmeral Data Fabric Database JSON tables

Go OJAI Client Structures and Functions

This topic lists and describes the structures supported by the Go OJAI client and provides a link to document pages that describe the functions in each structure.

Structure Name	Description
`Document`	Provides the primary, DOM-based interface for inspecting OJAI documents.
`QueryResult`	Encapsulates the result set of an OJAI query.
`DocumentMutation`	Encapsulates a mutation to an existing OJAI document in a store.
`Query`	Encapsulates an OJAI query.
`Condition`	Encapsulates a query condition; similar to a SQL `where` clause.
`Connection`	Provides a logical connection to an OJAI data source: for example, HPE Ezmeral Data Fabric Database JSON.
`DocumentStore`	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Ezmeral Data Fabric Database JSON tables.
`OTime`	Encapsulates the OJAI `TIME` type.
`OTimestamp`	Encapsulates the OJAI `TIMESTAMP` type.
`ODate`	Encapsulates the OJAI `DATE` type.

For details about each structure, including the functions available in each structure, see the Go OJAI Client API.

Setting Query Options in Go OJAI

There are two categories of options you can set in your Go OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a Go OJAI Function Call

Option Name	Description
`IncludeQueryPlan`	Enables or disables availability of the query plan for retrieval. Value: `true|false` Default: `false`
`ResultAsDocument`	Enables or disables returning the query result as an OJAI `Document` object list versus a Go map list. Value: `True|False` Default: `False`: returns query result as a Go map list
`Timeout`	Query timeout in milliseconds. Maximum allowed value is 2147483647 Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.FindQueryWithContext` function.

The following code snippet sets the query timeout to 3000 milliseconds:

```
timeoutCtx, cancel := context.WithTimeout(context.Background(),
time.Duration(3*time.Second))
result, err := suite.store.FindQueryWithContext(query, findOptions,
timeoutCtx)
cancel()
```

Setting Query Options in Go Using OJAI Query Syntax

OJAI Query Options on page 3368 describes query options that are available in all OJAI clients. To use these options in Go OJAI, you must construct your query in JSON format and use the `$options` keyword. See OJAI Query Syntax for details about the syntax, including an example.

Configuring SSL for OJAI Clients
Describes certificates and how to configure SSL for OJAI clients, including which PEM file to point to and how to determine which DAG host name to use.

The process of installing Data Fabric with security enabled automatically generates default `ssl_keystore` and `ssl_truststore` files on the first CLDB server used by all clients and servers. Data Access Gateway (DAG) and other cluster services use these certificates to perform authentication and encryption for websites that use the HTTPS protocol.

The certificates are generated in the `/opt/mapr/conf` directory under `ssl_truststore.*` and `ssl_keystore.*`. The `ssl_truststore.*` files contain the client side certificates (signer for the certificate in the `ssl_keystore`). The `ssl_keystore.*` files contain the server side certificates (a single self-signed certificate with a wildcard SubjectDN).

When you configure a client to connect to a cluster, you create a connection string. If the connection is SSL enabled, you must include the path to the certificate of trust. You can either configure the client to use the default certificates or you can point to custom certificates. However, if the certificate on the server side is signed using a real certificate signing authority, you do not need to include an `ssl_truststore` in the connection string because the default `ssl_truststore` will recognize the signed certificate.

For additional information, see SSL Certificates on page 838.

Using the Default Certificates Generated by Data Fabric

For an application running on a cluster node, provide the path to the PEM file, as shown in the following example:

```
sslCA=/opt/mapr/conf/ssl_truststore.pem
```

For an application that is not running on a cluster node, copy the `ssl_truststore.pem` file from `/opt/mapr/conf/` to a location on the non-cluster node and then specify the path to the `ssl_truststore.pem` file:

```
sslCA=/path/to/certificate/ssl_truststore.pem
```

Using Custom Certificates

If an administrator created custom certificates for the cluster (as described in SSL Certificates on page 838), the certificates must have an equivalent truststore in PEM format. Create a PEM version of the truststore file and use that PEM file with the clients. For example, `sslCA=/path/to/custom/certificates/ssl_truststore.pem`.

For additional information, see Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a Cluster.

Determining which DAG Host Name to Use

Open the `ssl_truststore.pem` file and locate the certificate with `Subject = C`. The certificate with `Subject = C` also has a CN host name. Use this CN host name.

If you see a wildcard character (*) instead of a file name, you can use any host that is running DAG and suffix it with `.ec2.internal`, as shown:

```
*.ec2.internal
```

Using the HPE Ezmeral Data Fabric Database JSON REST API

Starting in the EEP 5.0 release, you can use a REST API to access HPE Ezmeral Data Fabric Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on HPE Ezmeral Data Fabric Database JSON tables.

The API supports the following operations:

- Create and delete HPE Ezmeral Data Fabric Database JSON tables
- Insert, update, and delete documents from a table
- Retrieve documents while specifying filter conditions and projections

The REST API has the following characteristics:

- Operations are stateless
- Operations are synchronous
- Request responses are not buffered
- Web connections are secure when connecting to secure MapR clusters
- Supports the following methods of authentication:
  - Basic authentication

last-updated: Jun 06, 2024

  - Token-based authentication using JSON Web Tokens (JWT)
- Supports user impersonation - All data access calls are run on behalf of the authenticated user
- Returns HTTP error codes and detailed error responses in the response message body

When connecting to a MapR cluster, you must use HTTPS in your requests.

With basic authentication, you pass a username and password in your Web client. With token based authentication, you generate a token and then pass the token in the header of subsequent API requests.

The MapR Data Access Gateway is the service that supports this web API. You should configure multiple instances of this service across your MapR cluster to distribute request processing. To achieve load balancing, you must install an external load balancer. Using token based authentication and an external load balancer, you can achieve high availability and failover. Because the REST API is stateless, you do not have to regenerate your authentication token when different service instances process your API request. This applies even in the event of failovers and service restart. You must regenerate your token when it expires.

The API does not support the following features:

- HPE Ezmeral Data Fabric Database JSON administrative commands, except the commands noted earlier
- Read Your Own Writes

To modify properties that the HPE Ezmeral Data Fabric Database JSON REST API uses, see Application Properties.

Related concepts

Understanding the HPE Ezmeral Data Fabric Data Access Gateway on page 1024
The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster.

Administering the Data Access Gateway on page 1961
The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Getting Started with the HPE Ezmeral Data Fabric Database JSON REST API

A simple way to invoke the HPE Ezmeral Data Fabric Database JSON REST API is to use cURL commands. This section contains a sequence cURL commands that demonstrate the basic functionality of the API.

NOTE: The HPE Ezmeral Data Fabric Database JSON REST API is available starting in the EEP 5.0 release.

The operations shown are the following:

- Create a HPE Ezmeral Data Fabric Database JSON table
- Insert documents into the table
- Retrieve documents from the table, including retrievals that contain field projections and conditions
- Update individual documents and fields within a document

To learn about the complete API, see the reference material at Understanding the HPE Ezmeral Data Fabric Database JSON REST API on page 3485.

last-updated: Jun 06, 2024

The examples in this section assume that you installed the MapR Data Access Gateway on the host `10.10.100.42`. The examples use HTTPS with the default HTTPS port of `8243`. For information about installing the Data Access Gateway, see Installing the Data Access Gateway Service on page 1961.

NOTE: The examples URL encode the slashes in the table path (%2F) to differentiate them from the slashes in the command API.

Using Basic Authentication

The commands in this section use basic authentication. To use this form of authentication, you must pass the username and password in all commands, using the `-u` option.

1. Create a HPE Ezmeral Data Fabric Database JSON table in the path `/apps/employees`:

```
curl -X PUT \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

2. Insert 3 documents into the table:

```
curl -X POST \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr \
  -H 'Content-Type: application/json' \
  -d '[{"_id":"user001","first_name":"John","last_name":"Doe"},
 {"_id":"user002","first_name":"Jane","last_name":"Doe"},
 {"_id":"user003","first_name":"Simon","last_name":"Davis"}]'
```

3. Retrieve all of the documents:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F' \
  -u root:mapr
```

The command returns the following:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        },
        {
            "_id": "user003",
            "first_name": "Simon",
            "last_name": "Davis"
        }
    ]
}
```

4. Limit the GET request to 2 documents starting at offset 1:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F?
offset=1&limit=2' \
  -u root:mapr
```

The command returns the following:

```
{
    "DocumentStream": [
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        },
        {
            "_id": "user003",
            "first_name": "Simon",
            "last_name": "Davis"
        }
    ]
}
```

5. Retrieve only the first names in the documents:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
fields=first_name' \
  -u root:mapr
```

The command returns the following:

```
{
    "DocumentStream": [
        {
            "first_name": "John"
        },
        {
            "first_name": "Jane"
        },
        {
            "first_name": "Simon"
        }
    ]
}
```

last-updated: Jun 06, 2024

6. Retrieve all documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}' \
  -u root:mapr
```

NOTE: You must pass `'-g'` in the cURL command due to the nested braces in the condition.

The command returns 2 documents:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        }
    ]
}
```

7. Retrieve the id and first name of documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}&fields=_id,first_name' \
  -u root:mapr
```

NOTE: You must pass `'-g'` in the cURL command due to the nested braces in the condition.

The command returns the following:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John"
        },
        {
            "_id": "user002",
            "first_name": "Jane"
        }
    ]
}
```

8. Run the same command, also retrieving the query plan:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":
{"last_name":"Doe"}}&fields=_id,first_name&getPlan=true' \
  -u root:mapr
```

   The output includes the query plan:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John"
        },
        {
            "_id": "user002",
            "first_name": "Jane"
        }
    ],
    "QueryPlan": [
        [
            {
                "streamName": "DBDocumentStream",
                "parameters": {
                    "queryConditionPath": true,
                    "projectionPath": [
                        "_id",
                        "first_name"
                    ],
                    "primaryTable": "/apps/employees"
                }
            }
        ]
    ]
}
```

9. Update the first name in one of the documents, specifying the `id` in the command:

```
curl -X POST \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"$set":{"first_name":"Jay"}}'
```

10. Retrieve the updated document, specifying the `id` in the command:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -u root:mapr
```

The document contains an updated first name:

```
{
    "_id": "user001",
    "first_name": "Jay",
    "last_name": "Doe"
}
```

11. Replace the same document, but this time with a user who has only a first name:

```
curl -X PUT \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"_id":"user001","first_name":"Jonathan"}'
```

12. Retrieve the new document by passing the `id` in the request:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -u root:mapr
```

The document contains only a first name:

```
{
    "_id": "user001",
    "first_name": "Jonathan"
}
```

Using Token-Based Authentication

To use token-based authentication, you first create a token, authenticating with a username and password. You then pass the generated token in all subsequent commands.

1. Generate a token using the following command:

```
curl -X POST \
  'https://10.10.100.42:8243/auth/v2/token' \
  -u root:mapr
```

The command returns the following token:

```
{
    "token":
"eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJyb290IiwiYXVkIjoid2ViIiwiZXhwIjoxNTIwMjY
5MTQwLCJpYXQiOjE1MjAyNjczNDB9.NT8L2deiA6v55bfbU_opiG1XXGPP0IwfSex3jW5A1Zs
oI1ar09it7-XwNtRqfL_I29IHLyfmuHcT5eSIpwq6ng"
}
```

2. Pass the token in your cURL command, as shown in the following GET:

```
curl -X GET \
  https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees \
  -H 'Authorization:
Bearer
eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJyb290IiwiYXVkIjoid2ViIiwiZXhwIjoxNTIwMjY5MTQwLCJpYXQiOjE1MjAyNjczNDB9.NT8L2deiA6v55bfbU_opiG1XXGPP0IwfSex3jW5A1Zso
I1ar09it7-XwNtRqfL_I29IHLyfmuHcT5eSIpwq6ng'
```

Understanding the HPE Ezmeral Data Fabric Database JSON REST API
The section describes the details of the HPE Ezmeral Data Fabric Database JSON REST API.

The following table summarizes the commands the API supports. Click on the command for details about the command parameters and examples.

Category	REST API Command	Description
Authentication	POST /auth/v2/token on page 3485	Creates an authentication token
Table Operations	PUT /api/v2/table/{path} on page 3486	Creates a HPE Ezmeral Data Fabric Database JSON table
	DELETE /api/v2/table/{path} on page 3486	Drops a HPE Ezmeral Data Fabric Database JSON table
Table Document Operations	POST /api/v2/table/{path} on page 3487	Adds one or more documents to a HPE Ezmeral Data Fabric Database JSON table
	PUT /api/v2/table/{path}/document/{id} on page 3487	Updates a document by id in a HPE Ezmeral Data Fabric Database JSON table
	POST /api/v2/table/{path}/document/{id} on page 3488	Updates a partial document by id in a HPE Ezmeral Data Fabric Database JSON table using mutations
	DELETE /api/v2/table/{path}/document/{id} on page 3489	Deletes a single document by id in a HPE Ezmeral Data Fabric Database JSON table
	GET /api/v2/table/{path} on page 3490	Retrieves one or more documents from a HPE Ezmeral Data Fabric Database JSON table
	GET /api/v2/table/{path}/document/{id} on page 3493	Retrieves a single document by id from a HPE Ezmeral Data Fabric Database JSON table

POST /auth/v2/token
Authenticates a user. If successful, creates an authentication token that you use in subsequent API requests. By default, the token expires in 30 minutes. After a token expires, you must rerun this command to generate a new token.

Request Example

The following creates an authentication token for user `root`:

```
curl -X POST \
  'https://10.10.100.42:8243/auth/v2/token' \
  -u root:mapr
```

Response Example

```
200 OK

{
  "token":
"eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJtYXByIiwiYXVkIjoid2ViIiwiZXhwIjoxNTE2NzQ2MD
c4LCJpYXQiOjE1MTY3NDQyNzh9.6YXWX72UP9_U9DPmT8c-_DQRDwY_TL0DEdsBaBqoaLf8iK0qH
NctyBTbFO5ktUJMTubVOj6D7pFOEyEuV8lhjA"
}
```

For an example that shows how to use the token returned by this API call in a subsequent `GET` command, see Using Token-Based Authentication on page 3484.

PUT /api/v2/table/{path}
Creates a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the new HPE Ezmeral Data Fabric Database JSON table

Request Example

The following creates a table with the path `/apps/employees`:

```
curl -X PUT \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps/employees' \
  -u root:mapr
```

Response Example

```
201 Created
```

DELETE /api/v2/table/{path}
Drops a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table

Request Example

The following drops a table with the path `/apps/employees`:

```
curl -X DELETE \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

Response Example

```
200 OK
```

POST /api/v2/table/{path}
Adds or replaces one or more documents in a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
fieldAsKey `string` *(query)*	The name of the field that serves as the key in the JSON document
mode `string` *(query)*	Defines the behavior of the operation. The following are the possible values: • `insertOrReplace` - Inserts new document if specified document ID does not exist; otherwise, replaces existing document specified by the ID. • `insert` - Inserts new document; if the specified document ID already exists, returns an error. • `replace` - Replaces document with specified ID; returns an error if document does not exist. Default: `insertOrReplace`
body *(body)*	The body of the documents to add or replace

Request Example

The following inserts 3 documents into `/apps/employees`:

```
curl -X POST \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr \
  -H 'Content-Type: application/json' \
  -d '[{"_id":"user001","first_name":"John","last_name":"Doe"},
 {"_id":"user002","first_name":"Jane","last_name":"Doe"},
 {"_id":"user003","first_name":"Simon","last_name":"Davis"}]'
```

Response Example

```
200 OK
```

PUT /api/v2/table/{path}/document/{id}
Updates a single document by id in a HPE Ezmeral Data Fabric Database JSON table

last-updated: Jun 06, 2024

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
id `string` *(path)*	**Required**: Id of the document to update. If the document with the specified id does not exist, the mode parameter determines the behavior.
condition `string` *(query)*	Query condition (in JSON format) used to perform OJAI `DocumentStore.checkAndReplace` evaluation. See OJAI Query Condition Syntax on page 3387 for a description of the syntax.
mode `string` *(query)*	Defines the behavior of the operation. The following are the possible values: • `insertOrReplace` - Inserts new document if specified document ID does not exist; otherwise, replaces existing document specified by the ID. • `insert` - Inserts new document; if the specified document ID already exists, returns an error. • `replace` - Replaces document with specified ID if it exists Default: `insertOrReplace`
body *(body)*	**Required**: The body of the new document

Request Example

The following replaces the document with id `user001` in `/apps/employees` with an employee who has only a first name:

```
curl -X PUT \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"_id":"user001","first_name":"Jonathan"}'
```

Response Example

```
200 OK
```

POST /api/v2/table/{path}/document/{id}
Updates a partial document by id in a HPE Ezmeral Data Fabric Database JSON table using mutations

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
id `string` *(path)*	**Required**: Id of the document to update. If the document does not exist, inserts a new document.
condition `string` *(query)*	Query condition (in JSON format) used to perform OJAI `DocumentStore.checkAndUpdate` evaluation. See OJAI Query Condition Syntax on page 3387 for a description of the syntax.
body *(body)*	**Required**: The mutation specifying updates to the document. See Using OJAI Mutation Syntax on page 3342 for a description of the syntax.

Request Example

The following updates the `first_name` field the document in `/apps/employees` with id `user001`, replacing the field with the value `Jay`:

```
curl -X POST \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
  -H 'Content-Type: application/json' \
  -u root:mapr \
  -d '{"$set":{"first_name":"Jay"}}'
```

Response Example

```
200 OK
```

DELETE /api/v2/table/{path}/document/{id}
Deletes a single document by id in a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
id `string` *(path)*	**Required**: Id of the document to delete
condition `string` *(query)*	Query condition (in JSON format) used to perform OJAI `DocumentStore.checkAndDelete` evaluation. See OJAI Query Condition Syntax on page 3387 for a description of the syntax.

Request Example

The following deletes the document with id `user003` in `/apps/employees`:

```
curl -X DELETE \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user003' \
  -u root:mapr
```

Response Example

```
200 OK
```

GET /api/v2/table/{path}
Retrieves one or more documents from a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
condition `string` *(query)*	Query condition (in JSON format) to evaluate on documents retrieved. See OJAI Query Condition Syntax on page 3387 for a description of the syntax.
fields `string` *(query)*	The fields from the document to retrieve. See JSON Document Field Paths on page 651 for details about how to specify field paths.
fromId `string` *(query)*	Starting id of the range of documents to retrieve (inclusive)
toId `string` *(query)*	Ending id of the range of documents to retrieve (exclusive)
getPlan `string` *(query)*	If set to `true`, returns the query plan used to retrieve the documents Value: True|False Default: False
limit `integer` *(query)*	The maximum number of documents to retrieve
offset `integer` *(query)*	The number of documents to skip past before returning results

Name	Description
orderBy `string` *(query)*	The fields on which to sort the result. Specify the fields in a comma separated list, in the format `<field name>:<sort order>` where `<sort order>` is either `asc` or `desc`. `<sort order>` is optional and defaults to `asc`.
query `string` *(query)*	Query string with predefined keywords that define the behavior of the query. See Query with --query on page 5476 for syntax details.
withTags `string` *(query)*	Enables or disables output with extended type tags Value: True|False Default: True

Request Examples

1. The following retrieves all documents from `/apps/employees`:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

2. The following specifies an offset and limit in the GET request:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F?
offset=1&limit=2' \
  -u root:mapr
```

3. The following retrieves only the first names in the documents:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
fields=first_name' \
  -u root:mapr
```

4. The following retrieves all documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}' \
  -u root:mapr
```

   NOTE: You must pass `'-g'` in the cURL command due to the nested braces in the condition.

5. The following retrieves the id and first name of documents with a last name of `'Doe'`:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}&fields=_id,first_name' \
  -u root:mapr
```

last-updated: Jun 06, 2024

6. The following runs the same command and includes a request for the query plan:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":
{"last_name":"Doe"}}&fields=_id,first_name&getPlan=true' \
  -u root:mapr
```

Response Examples

```
200 OK

{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        },
        {
            "_id": "user003",
            "first_name": "Simon",
            "last_name": "Davis"
        }
    ]
}
```

If you have configured the MapR Data Access Gateway to limit the number of documents in retrieval requests, and your result set exceeds the limit, the API response includes a warning. In the following example, the limit is set to 2:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John",
            "last_name": "Doe"
        },
        {
            "_id": "user002",
            "first_name": "Jane",
            "last_name": "Doe"
        }
    ],
    "WARNING": "result truncated due to limit set to 2."
}
```

The following shows an example of output that includes a query plan. It corresponds to the output from example #6 in the previous section:

```
{
    "DocumentStream": [
        {
            "_id": "user001",
            "first_name": "John"
```

last-updated: Jun 06, 2024

```
        },
        {
            "_id": "user002",
            "first_name": "Jane"
        }
    ],
    "QueryPlan": [
        [
            {
                "streamName": "DBDocumentStream",
                "parameters": {
                    "queryConditionPath": true,
                    "projectionPath": [
                        "_id",
                        "first_name"
                    ],
                    "primaryTable": "/apps/employees"
                }
            }
        ]
    ]
}
```

GET /api/v2/table/{path}/document/{id}
Retrieves a single document by id from a HPE Ezmeral Data Fabric Database JSON table

Parameters

Name	Description
path `string` *(path)*	**Required**: Path to the HPE Ezmeral Data Fabric Database JSON table
id `string` *(path)*	**Required**: Id of the document to retrieve
condition `string` *(query)*	Query condition (in JSON format) to evaluate on document retrieved. See OJAI Query Condition Syntax on page 3387 for a description of the syntax.
fields `string` *(query)*	The fields from the document to retrieve. See JSON Document Field Paths on page 651 for details about how to specify field paths.
withTags `string` *(query)*	Enables or disables output with extended type tags Value: True|False Default: True

Request Example

The following retrieves the document with id `user003` from `/apps/employees`:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
```

last-updated: Jun 06, 2024

```
user003' \
  -u root:mapr
```

Response Example

```
200 OK

{
    "_id": "user003",
    "first_name": "Simon",
    "last_name": "Davis"
}
```

HPE Ezmeral Data Fabric Database JSON MapReduce API
This API library extends the Apache Hadoop MapReduce framework, so that you can write your own MapReduce applications to write data from one JSON table to another.

Prerequisites to using this API Library

- Ensure that you have a firm grasp of MapReduce concepts and experience writing MapReduce applications.
- Before running a MapReduce application that uses this API, ensure that the destination JSON table or tables already exist and that any column families other than the default are already created on the destination tables.

Classes

The following table summarizes the information that is in the HPE Ezmeral Data Fabric Database JSON MapReduce API, which you can refer to for complete details of the classes.

Category	Class	Description
Utility	`MapRDBMapReduceUtil`	Simplifies the use of the API for most use cases.
Input formatters	`TableInputFormat`	Describes how to read documents from HPE Ezmeral Data Fabric Database JSON tables.
Record reader	`TableRecordReader`	Reads documents (records) from HPE Ezmeral Data Fabric Database JSON tables.
	`TableRecordReaderImpl`	Iterates over HPE Ezmeral Data Fabric Database JSON table data. Returns key-value pair as `ByteBufWritableComparable` and `Document` respectively.
Record writers	`BulkLoadRecordWriter`	Bulk loads documents into HPE Ezmeral Data Fabric Database JSON tables.
	`TableMutationRecordWriter`	Modifies documents that are in HPE Ezmeral Data Fabric Database JSON tables.
	`TableRecordWriter`	Writes documents to HPE Ezmeral Data Fabric Database JSON tables.

last-updated: Jun 06, 2024

Category	Class	Description
Output formatters	`BulkLoadOutputFormat`	Describes how to bulk load documents into HPE Ezmeral Data Fabric Database JSON tables.
	`TableOutputFormat`	Describes how to write documents to HPE Ezmeral Data Fabric Database JSON tables.
	`TableMutationOutputFormat`	Writes `DocumentMutation` from the MapReduce phase to JSON tables . The key is of type `Value` and the value is a `DocumentMutation`.
Serializers	`DocumentSerialization`	Defines the serializer and deserializer for passing data from `Document` objects between map and reduce phases.
	`DBDocumentSerialization`	Converts a JSON document from HPE Ezmeral Data Fabric Database format to binary SequenceFile format.
	`ValueSerialization`	Serializes a JSON key and passes it between MapReduce phases.
Partitioner	`TablePartitioner`	Specifies how to partition data from the source JSON table.
	`TotalOrderPartitioner<K,V>`	Globally sorts data according to row key and then partitions the sorted data. This class is useful when the destination table has been pre-split into two or more tablets.

Using MapRDBMapReduceUtil to Set Default Values in Configurations and Jobs

The centerpiece of this API is the `MapRDBMapReduceUtil` class, which you can use in the `createSubmittableJob()` method of your applications to perform these actions:

- Set default values in the configuration for a MapReduce application and set the input and output format classes.
- Set default types for output keys and values.
- Configure a `TotalOrderPartitioner` and return the number of reduce tasks to use for a job.

To set default values in the configuration for a MapReduce application and set the input and output format classes, use the following methods:

```
configureTableInputFormat(org.apache.hadoop.mapreduce.Job job, String
srcTable)
```

The `configureTableInputFormat` method performs the following actions:

- Set the serialization class for `Document` and `Value` objects. These interfaces are part of the OJAI (Open JSON Application Interface) API.
- Set the field `INPUT_TABLE` in `TableInputFormat` to the path and name of the source table, and pass this value to the configuration for the MapReduce application.

last-updated: Jun 06, 2024

- Set the input format class for the job to `TableInputFormat`.

```
configureTableOutputFormat(org.apache.hadoop.mapreduce.Job job, String
destTable)
```

The `configureTableOutputFormat` method performs the following actions:

- Set the field `OUTPUT_TABLE` in `TableOutputFormat` to the path and name of the destination table, and pass this value to the configuration for the MapReduce applications.
- Set the output format class for the job to `TableOutputFormat`.

If you want to set values for other fields in `TableInputFormat` or `TableOutputFormat`, or write your own logic for them, you can pass field values to configurations and specify these classes for jobs as you would in common MapReduce applications.

To set default types for output keys and values, use the following methods:

```
setMapOutputKeyValueClass(org.apache.hadoop.mapreduce.Job job)
setOutputKeyValueClass(org.apache.hadoop.mapreduce.Job job)
```

NOTE: You can also set types for output keys and values from the map phase, if those types will differ from the final output types.

To configure `TotalOrderPartitioner` and return the number of reduce tasks to use for a job, you can use a code line similar to the following in your application's method for creating a job:

```
int numReduceTasks =
MapRDBMapReduceUtil.setPartitioner(org.apache.hadoop.mapreduce.Jobjob,
String destPath);
```

The `setPartitioner()` method finds out whether a table has been pre-split into two or more tablets, counts the number of tablets, writes the number to a partitioner file, and sends that file to an instance of `TotalOrderPartitioner`. This line also returns the number of tablets to `numReduceTasks`. Your code can then use that variable to set the number of reducers, like the following:

```
job.setNumReduceTasks(numReduceTasks);
```

NOTE: The sample application gives an example of how to use `MapRDBMapReduceUtil`.

Mutating Rows in Destination Tables

Use the `TableMutationRecordWriter` class when you need to mutate rows.

For example, suppose that you are tracking the number of users who are performing various actions on your retail website. To do this, at intervals you run your MapReduce application and save the results in JSON documents in HPE Ezmeral Data Fabric Database. Suppose that you count the number of users who went through the order process but abandoned their orders. After every run of the application, you want to update an JSON document by adding the current count to the total count and by updating a field that tracks the date and time that the MapReduce application was last run.

You could do that by setting values in a DocumentMutation object (see the OJAI (Open JSON Application Interface) Javadoc. You would then serialize that and write it to the table with `TableMutationRecordWriter`.

Compiling and Running Applications

You can compile applications that use the HPE Ezmeral Data Fabric Database Java API by using the required JAR file from the MapR installation. Run applications with the mapr command.

To compile an application, use the following command:

```
javac -cp 'mapr classpath' <Application jars>
```

To launch an application, use the following command

```
mapr <Main class jar> <commandline arguments>
```

NOTE: If you want to add JAR files to the classpath that the mapr command uses, add them with the environment variable MAPR_CLASSPATH. For example:

```
export MAPR_CLASSPATH=/home/apps/awesome-1.0.jar
         mapr com.company.MyAwesomeApp
```

IMPORTANT: Turn off speculative execution

Speculative execution of MapReduce tasks is on by default. For custom applications that load HPE Ezmeral Data Fabric Database tables, it is recommended to turn speculative execution off. When it is on, the tasks that import data might run multiple times. Multiple tasks for an incremental bulkload could insert one or more versions of a record into a table. Multiple tasks for a full bulkload could cause loss of data if the source data continues to be updated during the load.

If your custom MapReduce application uses `MapRDBMapReduceUtil.configureTableOutputFormat()`, you do not have to turn off speculative execution manually. This method turns it off automatically.

Turn off speculative execution by using either of these methods:

- Set the following MapReduce version 2 parameter to false: `mapreduce.map.speculative`
- Include the following line in the method in your application that sets parameters for jobs:

  ```
  job.setSpeculativeExecution(false);
  ```

HPE Ezmeral Data Fabric Database JSON MapReduce: Sample App

This sample application reads records (JSON documents) from a JSON table and inserts new documents into another JSON table.

After reading records from a JSON table, the application aggregates data within those records, creates new JSON documents that contain the aggregated records, and then inserts the new documents into another JSON table. Each record contains the name of an author and the name of a book that the author has written.

The JSON documents have this structure:

```
{
    "_id" : <string or binary>,
    "authorid":"<string>",
    "name":"<string>",
    "book":{
        "id":<int>,
        "title":"<string>"
    }
}
```

last-updated: Jun 06, 2024

The structure of each aggregate record will look like this:

```
{
    "_id" : <string or binary>,
    "authorid":"<string>",
    "book":{
        [
            "title":"<string>",
            "title":"<string>",
            ...
        ]
    }
}
```

Prerequisites

- Ensure that your user ID has the `-readAce` and `-writeAce` privileges on the volumes where you plan to create the source and destination tables.
- Create the source JSON table. You can create the source table and populate it with sample records by running sample_dataset.txt from the `mapr dbshell` utility.

  ```
  $ mapr dbshell < sample_dataset.txt
  ```

- Create the destination JSON table. A simple way to create this table is to use the `create` command in the HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5469 utility.

Compiling and Running

To compile an application, use the following command:

```
javac -cp <classpath> <java source file(s)>
```

To launch an application, use the following command:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class>
<command line arguments>
```

To run the application, supply the paths and names of the source and destination tables as arguments:

```
CombineBookList <source_table> <destination_table>
```

Code Walkthrough

```
  private static Job createSubmittableJob(Configuration conf, String[]
otherArgs)
      throws IOException {

    srcTable = otherArgs[0];
    destTable = otherArgs[1];

    Job job = new Job(conf, NAME + "_" + destTable);
    job.setJarByClass(CombineBookList.class);
    MapRDBMapReduceUtil.configureTableInputFormat(job, srcTable);
    job.setMapperClass(CombineBookListMapper.class);
    MapRDBMapReduceUtil.setMapOutputKeyValueClass(job);
    MapRDBMapReduceUtil.configureTableOutputFormat(job, destTable);
    job.setReducerClass(CombineBookListReducer.class);
```

last-updated: Jun 06, 2024

```
    MapRDBMapReduceUtil.setOutputKeyValueClass(job);
    job.setNumReduceTasks(1);
    return job;
  }
```

The `createSubmittableJob()` method uses methods that are in the `MapRDBMapReduceUtil` class to perform the following tasks:

Set the input format to the default table input format

You can call the `configureTableInputFormat()` method, passing in the job and also passing in the path and name of the source table:

```
MapRDBMapReduceUtil.configureTableInputFormat(job, srcTable);
```

The default behavior is to do the following:

- Set the serialization class for `Document` and `Value` objects. These interfaces are part of the OJAI (Open JSON Application Interface) API.
- Set the field `INPUT_TABLE` in `TableInputFormat` to the path and name of the source table, and pass this value to the configuration for the MapReduce application.
- Set the input format class for the job to `TableInputFormat`.

If you want to customize `TableInputFormat` , you can call it as you would normally set the input format for a job:

```
job.setInputFormatClass(TableInputFormat.class);
```

Set the type for keys and values that are output from the mapper

You can call the `setMapOutputKeyValueClass()` method to use the default type for keys and values:

```
MapRDBMapReduceUtil.setMapOutputKeyValueClass(job);
```

If you want to customize the output keys and values, you can call `Job.setMapOutputKeyClass()` and `Job.setMapOuputValueClass()` as you would normally for MapReduce applications.

Set the output format to the default table output format

You can call the `configureTableOutputFormat()` method, passing in the job and also passing in the path and name of the destination table, which must already exist at runtime:

```
MapRDBMapReduceUtil.configureTableOutputFormat(job, destTable);
```

The default behavior is to do the following:

- Set the field `OUTPUT_TABLE` in `TableOutputFormat` to the path and name of the destination table, and pass this value to the configuration for the MapReduce applications.

last-updated: Jun 06, 2024

	• Set the output format class for the job to `TableOutputFormat`. If you want to customize `TableOutputFormat`, you can call it as you would normally set the output format for a job: `job.setOutputFormatClass(TableOutputFormat.class);` You also have the option of using the `BulkLoadOutputFormat` class for bulk loading.
Set the type of the keys and values that are output from the reducer	You can call the `setOutputKeyValueClass()` method to use the default type for keys and values: `MapRDBMapReduceUtil.setOutputKeyValueClass(job);` If you want to customize the output keys and values, you can call `Job.setOutputKeyClass()` and `Job.setOuputValueClass()` as you would normally for MapReduce applications.

The `map()` method in the mapper class `CombineBookListMapper` takes the value of the `_id` field in a document as a key and the JSON document with that `_id` field value as a `Document`. The mapper does nothing with the `Value` object. For each `record`, the mapper writes the value of the `authorid` field and the full JSON document itself to the context.

```
  public static class CombineBookListMapper extends Mapper<Value, Document,
Value, Document> {
    @Override
    public void map(Value key, Document record, Context context) throws
IOException, InterruptedException {
      context.write(record.getValue("authorid"), record);
    }
  }
```

Both the `Value` and `Document` interfaces are part of the OJAI (Open JSON Application Interface) API. The javadoc for the OJAI API is here.

The `reduce()` method in the reducer class `CombineBookListReducer` takes the map output key, which is the value of the `authorid` field, and the map output value, which is an iterator of `Document` objects that each contain a full record. For each author ID, the reducer creates a document. For each document in the iterator, the reducer extracts the value of the `book` field and adds that value to the list `books` within a new JSON document.

```
  public static class CombineBookListReducer extends Reducer<Value,
Document, Value, Document> {

    @Override
    public void reduce(Value key, Iterable<Document> values,
        Context context) throws IOException, InterruptedException {
      Document d = MapRDB.newDocument();
      List<Document> books = new ArrayList<Document>();

      for (Document b : values) {
        books.add((Document)b.getValue("book"));
      }

      d.setId(key);
```

last-updated: Jun 06, 2024

```
      d.set("books", books);
      context.write(key, d);
    }
  }
```

The MapRDB class is part of the HPE Ezmeral Data Fabric Database JSON API, not the HPE Ezmeral Data Fabric Database JSON MapReduce API.

Apache Kafka Wire Protocol Service

HPE Ezmeral Data Fabric Streams supports Apache Kafka Wire Protocol Service. Apache Kafka Wire Protocol Service is a TCP/IP service that emulates a Kafka cluster backed by HPE Ezmeral Data Fabric Streams. The service makes it possible for Apache Kafka clients written in any programming language to access topics in HPE Ezmeral Data Fabric Streams.

Before Apache Kafka Wire Protocol Service was introduced, you had to use a modified version of the open-source libraries (`kafka-clients.jar` and `librdkafka.so`) for user applications to connect and publish/subscribe messages to topics in HPE Ezmeral Data Fabric Streams. With Apache Kafka Wire Protocol Service, you can simply use the Apache Kafka client libraries.

Apache Kafka Wire Protocol Service provides the following benefits:

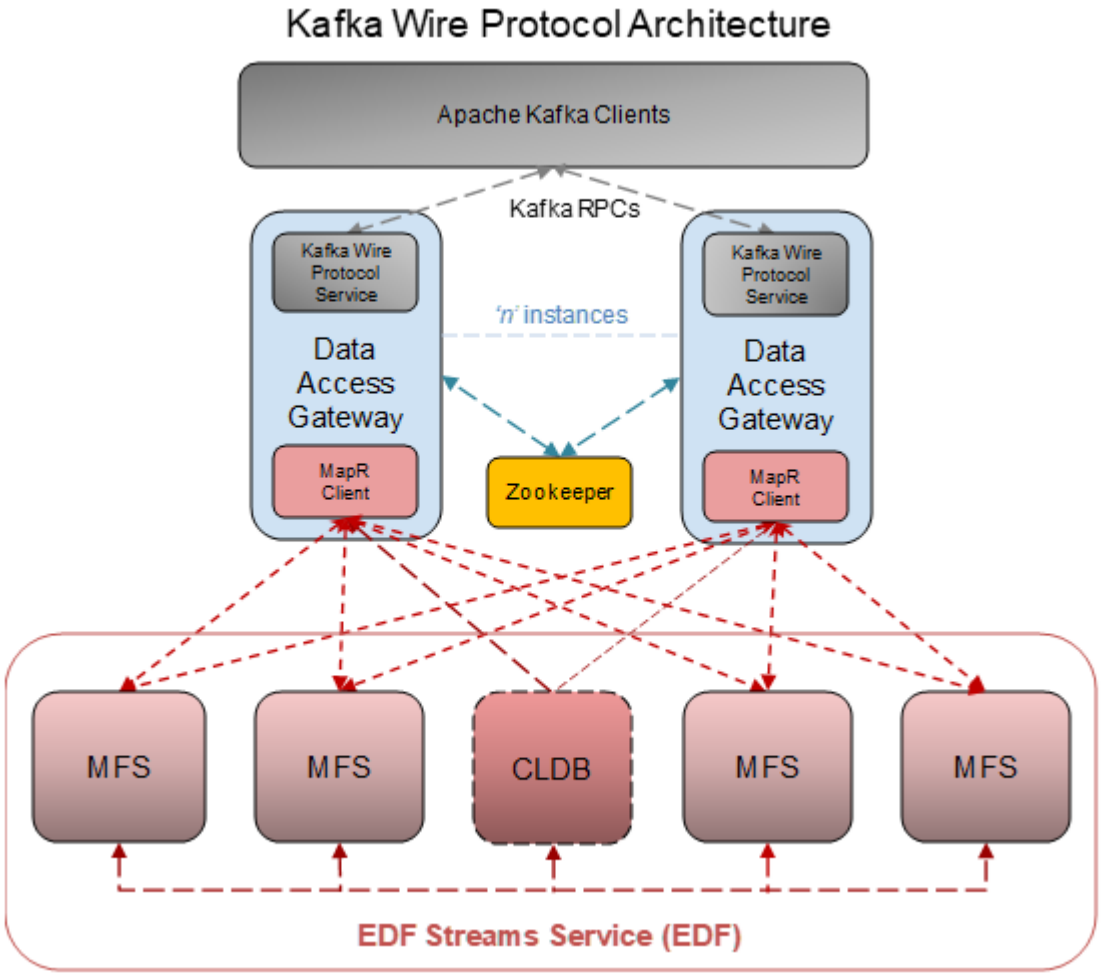
- User applications can connect, publish, and subscribe to HPE Ezmeral Data Fabric Streams topics using standard Apache Kafka client libraries. Starting with data access gateway 6.0, only topics created through Apache Kafka Wire Protocol Service are supported.
- User applications developed using Apache Kafka clients do not require any modification to work with this new system, including recompilation, reconfiguration, or dependency management.
- Supports available Apache Kafka clients in multiple programming languages, both from the Apache Software Foundation and the community.

For more information, see Getting Started with Apache Kafka Wire Protocol Service on page 3503.

Architecture

The Apache Kafka Wire Protocol Service works within DAG (data access gateway) to act as a Kafka Broker (server in an Apache Kafka cluster). For all application purposes, the HPE Ezmeral Data Fabric cluster (with DAG and Apache Kafka Wire Protocol Service) runs like an Apache Kafka cluster.

The following image shows the communication paths between Apache Kafka clients and HPE Ezmeral Data Fabric with DAG and Apache Kafka Wire Protocol Service acting as brokers:



Monitoring

DAG is not a Kafka Broker; therefore, Broker metrics are not available. However, you can monitor Data Fabric core services, as described in Using HPE Ezmeral Data Fabric Monitoring (Spyglass Initiative) on page 1695.

Limitations

The following list describes unsupported functionality in the initial release of Apache Kafka Wire Protocol Service:

- Quotas
- Transactions
- Idempotent Producer
- Kafka ACL-based security
- Topic-level security using ACEs.
- Group ACEs for Consumer Groups
- Delegation tokens
- Log directories

last-updated: Jun 06, 2024

Getting Started with Apache Kafka Wire Protocol Service

Describes the steps required to install, configure, and use Apache Kafka Wire Protocol Service.

The following sections describe the prerequisites and steps required to use Apache Kafka Wire Protocol Service.

Prerequisites

Apache Kafka Wire Protocol Service has the following component version requirements:

- HPE Ezmeral Data Fabric 7.4.0
- DAG 6.1 (available in EEP 9.1.2)
- Apache Kafka clients 2.6.x

1 - Install Data Access Gateway

Apache Kafka Wire Protocol Service is included with the Data Access Gateway (DAG) package (`mapr-data-access-gateway`) and is installed when you install DAG.

You can install DAG on multiple Data Fabric *data node*s alongside the `mfs` (file server) service through the Data Fabric Installer or manually using package managers. For more information about installing DAG, see Installing Data Access Gateway on page 262 and Data Access Gateway Support Matrix on page 5801.

High Availability	Apache Kafka Wire Protocol Service runs on all Data Fabric nodes that run DAG.
Port	The default DAG port for Apache Kafka Wire Protocol Service is 9092; however, you can change the port as described in Configuring Apache Kafka Wire Protocol Service on page 3507.

2 - Configure Apache Kafka Wire Protocol Service

Set cluster and node-specific settings, as described in Configuring Apache Kafka Wire Protocol Service on page 3507.

3 - Administer Kafka Topic

Use maprcli commands to administer Kafka topics as described in kafkatopic on page 2398.

4 - Secure Apache Kafka Wire Protocol Service

See Securing Apache Kafka Wire Protocol Service on page 3508.

5 - Use Apache Kafka Client Libraries to Connect to HPE Ezmeral Data Fabric Streams

For a list of available clients, see https://cwiki.apache.org/confluence/display/KAFKA/Clients.

6 - (Optional) - View Sample Applications

See Sample Kafka Python Producer and Consumer on page 3503.

Sample Kafka Python Producer and Consumer

This topic provides `kafka-python` examples with SASL and SSL client configurations for Apache Kafka Wire Protocol Service.

1. If you have not done so already, install `kafka-python`:

```
pip3 install kafka-python
        $pip3 install kafka-python
        $pip3 list | grep kafka-python
```

2. Save the Sample Kafka Python Producer and Consumer on page 3503 code in a file with the following name:
   - SASL: `saslPlaintextKafkaPythonClient.py`
   - SSL: `sslPlaintextKafkaPythonClient.py`
3. Run the sample code with the following command:

   NOTE: When running the SASL sample code, you must fill in the username and password. When running the SSL sample code, you must fill the `ssl_password` from the file `/opt/mapr/conf/store-passwords.txt`.

SASL

```
python3
saslPlaintextKafkaPythonClient.py
<broker> <topicName>
```

For example:

```
python3
saslPlaintextKafkaPythonClient.py
localhost:9092
topicTestKafkaPythonClient_SASL
```

SSL

```
python3
sslPlaintextKafkaPythonClient.py
<broker> <topicName>
```

For example:

```
python3
sslPlaintextKafkaPythonClient.py
localhost:9092
topicTestKafkaPythonClient_SSL
```

Sample Kafka Python Producer and Consumer

SASL

```
from kafka import KafkaProducer
from kafka import KafkaConsumer
import sys
import time

#Specify 'broker' and 'topic'
arguments. Example: 'python3
saslPlaintestKafkaPythonClient.py
localhost:9092
topicTestKafkaPythonClient_SASL'
server = sys.argv[1]
print("BROKER: " + server)
topic = sys.argv[2]
```

```
print("TOPIC: " + topic)

#PRODUCER
print("\n**Starting Producer**")
producer=KafkaProducer(bootstrap_serve
rs=[server],

security_protocol='SASL_PLAINTEXT',

sasl_mechanism='PLAIN',

sasl_plain_username='<username>',

sasl_plain_password='<user-password>')

numMsgProduced = 0
for _ in range(100):
    producer.send(topic, b'msg')
    numMsgProduced += 1
producer.flush()
print("Messages produced: " +
str(numMsgProduced))
time.sleep(2)

# CONSUMER
print("\n**Starting Consumer**")
consumer =
KafkaConsumer(bootstrap_servers=[serve
r],

auto_offset_reset='earliest',

security_protocol='SASL_PLAINTEXT',

sasl_mechanism='PLAIN',

sasl_plain_username='<username>',

sasl_plain_password='<user-password>')

consumer.subscribe(topic)
numMsgConsumed = 0
for _ in range(10):
    records =
consumer.poll(timeout_ms=500)
    for topic_data, consumer_records
in records.items():
        for consumer_record in
consumer_records:
#            print("Received message:
" +
str(consumer_record.value.decode('ut
f-8')))
            numMsgConsumed += 1
print("Messages consumed: " +
str(numMsgConsumed))
```

SSL

```
from kafka import KafkaProducer
from kafka import KafkaConsumer
import sys
import time
```

```
#Specify 'broker' and 'topic'
arguments. Example 'python3
sslPlaintestKafkaPythonClientJSK.py
localhost:9092
topicTestKafkaPythonClient_SSL'
server = sys.argv[1]
print("BROKER: " + server)
topic = sys.argv[2]
print("TOPIC: " + topic)

#PRODUCER
print("\n**Starting Producer**")
producer=KafkaProducer(bootstrap_serve
rs=[server],

security_protocol='SSL',

ssl_check_hostname=False,

ssl_password='<>', #from /opt/mapr/
conf/store-passwords.txt
ssl.server.keystore.password

ssl_cafile='/opt/mapr/conf/
ssl_truststore.pem',

ssl_certfile='/opt/mapr/conf/
ssl_keystore-signed.pem',

ssl_keyfile='/opt/mapr/conf/
ssl_keystore.pem')

numMsgProduced = 0
for _ in range(100):
    producer.send(topic, b'msg')
    numMsgProduced += 1
producer.flush()
print("Messages produced: " +
str(numMsgProduced))
time.sleep(2)

# CONSUMER
print("\n**Starting Consumer**")
consumer =
KafkaConsumer(bootstrap_servers=[serve
r],

auto_offset_reset='earliest',

security_protocol='SSL',

ssl_check_hostname=False,

ssl_password='<>', #from /opt/mapr/
conf/store-passwords.txt
ssl.server.keystore.password

ssl_cafile='/opt/mapr/conf/
ssl_truststore.pem',

ssl_certfile='/opt/mapr/conf/
```

```
ssl_keystore-signed.pem',

ssl_keyfile='/opt/mapr/conf/
ssl_keystore.pem')

consumer.subscribe(topic)
numMsgConsumed = 0
for _ in range(10):
    records =
consumer.poll(timeout_ms=500)
    for topic_data, consumer_records
in records.items():
        for consumer_record in
consumer_records:
#            print("Received message:
" +
str(consumer_record.value.decode('ut
f-8')))
            numMsgConsumed += 1
print("Messages consumed: " +
str(numMsgConsumed))
```

Configuring Apache Kafka Wire Protocol Service

Describes the Apache Kafka Wire Protocol Service configuration files and instructions.

The following sections provide configuration information for DAG (Data Access Gateway) and Apache Kafka clients and applications:

Configuring Apache Kafka Wire Protocol Service

DAG packages include the following configuration files for Apache Kafka Wire Protocol Service:

`kafka-server.conf`

- This file is stored in `/opt/mapr/data-access-gateway/conf` and loaded from the local file system.
- This file contains node-specific options, such as the port number and security protocol. Set the options in this file on a per-node basis.
- By default, the Apache Kafka Wire Protocol Service listens on port 9092.
- If the DAG service instances are behind a firewall, the firewall rules must be configured to allow this traffic.

For a list of configurable parameters, see Apache Kafka Wire Protocol Service Settings on page 3507.

Configuring Apache Kafka Clients and Applications

Standard Apache Kafka client configurations are supported. For additional information on configuration, see the official Apache Kafka documentation.

Apache Kafka Wire Protocol Service Settings

Lists and describes parameters that you can configure in `kafka-server.conf`.

You can configure the following parameters in `/opt/mapr/data-access-gateway/conf/kafka-server.conf`:

last-updated: Jun 06, 2024

Parameter	Description
kafka.server.rpc.port	TCP port that Apache Kafka Wire Protocol Service listens to for incoming client requests. Default is 9092.
kafka.server.rpc.security-protocol	Configures authentication and encryption schemes. Supports PLAINTEXT or SASL_PLAINTEXT as the value. To enable authentication, set to SASL_PLAINTEXT. Note that DAG 5.0 does not support encryption.
kafka.server.rpc.sasl-mechanism	Configures the list of SASL authentication mechanisms. This parameter is only effective when `kafka.server.rpc.security-protocol` is set to SASL_PLAINTEXT. In DAG 5.0, only PLAIN is supported.

Securing Apache Kafka Wire Protocol Service

Describes the security mechanisms that Apache Kafka Wire Protocol Service does and does not support.

Authentication

Starting from Data Access Gateway 5.1, Apache Kafka Wire Protocol Service supports SASL/PLAIN and SSL authentication between clients and file servers.

Authorization

Kafka Wire Protocol Service does not support ACLs. The topic owner has all permissions.

On-Wire Encryption

Starting from Data Access Gateway 5.1, on-wire encryption for Apache Kafka Wire Protocol Service is supported using SSL. See Enabling SSL for Apache Kafka Wire Protocol Service on page 3508.

Enabling SSL for Apache Kafka Wire Protocol Service

Describes the security protocol values that are needed to enable SSL for Apache Kafka Wire Protocol Service.

Data Access Gateway 5.1 and later added SSL support for the Apache Kafka Wire Protocol Service. This section provides examples for configuring `/opt/mapr/data-access-gateway/conf/kafka-server.conf` to enable SASL_SSL and SSL security in server-side and client-side configurations.

New Security Protocol Values

Release 7.2.0 and later support two new values for the `security-protocol` parameter of `kafka-server.conf`:

- SASL_SSL
- SSL

When you specify the SASL_SSL value, you must also specify the corresponding `sasl-mechanism` value as indicated in the following table:

Specifying `security-protocol` as . . .	With `sasl-mechanism` as . . .	Enables
SASL_SSL	PLAIN[1]	Username/password-based (PAM) client authentication with SSL encryption and one-way SSL server authentication.
SSL	(Unspecified)	SSL authentication (two-way mutual SSL authentication) and SSL encryption.

last-updated: Jun 06, 2024

[1]`PLAIN` is the only mechanism currently supported.

SASL_SSL Server-Side Configuration Example

Here is a typical SASL_SSL server-side configuration example:

```
kafka.server = {
  rpc = {
    # TCP port for the Kafka Wire protocol service. Default is 9092
    port = 9092

    # Configures authentication and encryption schemes
    # Supported values are PLAINTEXT|SASL_PLAINTEXT|SASL_SSL|SSL
    # To enable authentication, set to SASL_PLAINTEXT, SASL_SSL or SSL
    # Encryption is supported for SASL_SSL and SSL
    security-protocol = SASL_SSL

    # Configures list of SASL authentication mechanisms
    # The only supported mechanism in this release is PLAIN
    # Effective only if "security-protocol" is set to SASL_PLAINTEXT or
SASL_SSL
    sasl-mechanism = PLAIN
  }
}
```

SASL_SSL Client-Side Configuration

You can configure the SASL_SSL client-side configuration the same way it is configured in Apache Kafka. In this configuration, `/opt/mapr/conf/ssl_truststore` performs the one-way SSL server authentication. For example:

```
security.protocol=SASL_SSL
ssl.truststore.location=/opt/mapr/conf/ssl_truststore
ssl.truststore.password=<some_password>
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
sasl.mechanism=PLAIN
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
required username="user1" password="user1";
```

SSL Server-Side Configuration

To make the SSL protocol work correctly in a server-side configuration, the cluster administrator MUST specify the `rpc.ssl.principal-mapping-rules` in the server config file. For example:

```
kafka.server = {
  rpc = {
    # TCP port for the Kafka Wire protocol service. Default is 9092
    port = 9092

    # Configures authentication and encryption schemes
    # Supported values are PLAINTEXT|SASL_PLAINTEXT|SASL_SSL|SSL
    # To enable authentication, set to SASL_PLAINTEXT, SASL_SSL or SSL
    # Encryption is supported for SASL_SSL and SSL
    security-protocol = SSL

    ssl.principal-mapping-rules = [
      "RULE:^CN=.*O=(.*?),.*$/$1/L,",
      "DEFAULT"
    ]
```

```
  }
}
```

The `ssl.principal-mapping-rules` parameter specifies a list of mapping rules. For information about how to configure the mapping rules, see Customizing the SSL User Name in the Kafka documentation.

SSL Client-Side Configuration

You can configure the client-side configuration the same way it is configured in Apache Kafka. In this configuration, the `/opt/mapr/conf/ssl_truststore` performs the SSL server authentication. To perform client authentication by the server, you must add the CA of the client certificate to the `/opt/mapr/conf/ssl_truststore`. Both the server and the client use this trust store file.

```
security.protocol=SSL
ssl.truststore.location=/opt/mapr/conf/ssl_truststore
ssl.truststore.password=<some_password>
ssl.keystore.location=/<client_cert_path>/example_ssl_client_keystore
ssl.keystore.password=<some_password>
ssl.key.password=<some_password>
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
```

Supported Apache Kafka RPCs

Lists the Apache Kafka RPCs that Apache Kafka Wire Protocol Service supports and provides links to the correlating API request documentation in the Kafka Protocol Guide.

Cluster Management and Metadata RPCs

- HEARTBEAT
- API_VERSIONS
- METADATA

Admin RPCs

- CREATE_TOPICS
- DELETE_TOPICS
- DESCRIBE_CONFIGS

Producer RPCs

- PRODUCE

Consumer RPCs

- FETCH
- LIST_OFFSETS
- OFFSET_COMMIT
- OFFSET_FETCH
- FIND_COORDINATOR
- JOIN_GROUP

last-updated: Jun 06, 2024

- LEAVE_GROUP
- SYNC_GROUP

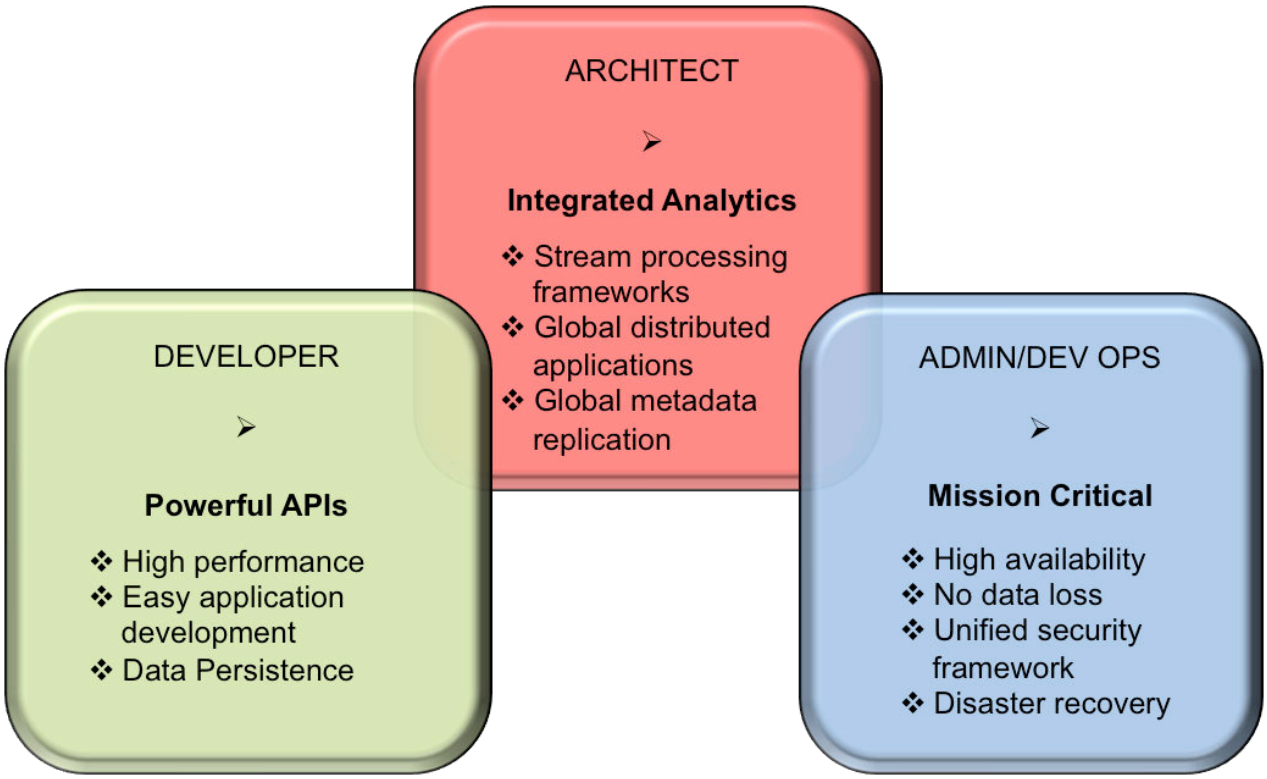
SASL Authentication RPCs

- SASL_HANDSHAKE
- SASL_AUTHENTICATE

HPE Ezmeral Data Fabric Streams and Apps

HPE Ezmeral Data Fabric Streams brings integrated publish and subscribe messaging to HPE Ezmeral Data Fabric.

HPE Ezmeral Data Fabric Streams is built into the HPE Ezmeral Data Fabric. It requires no additional process to manage, leverages the same architecture as the rest of the platform, and requires minimal additional management.



1. The Getting Started with HPE Ezmeral Data Fabric Streams section provides overall instructions for setting up, producing, and consuming streams.
2. The HPE Ezmeral Data Fabric Streams section provides conceptual information.
3. The Administering Streams section provides information about creating and managing streams, topics, and stream replication.

last-updated: Jun 06, 2024

ATTENTION: As of core version 6.1, the HPE Ezmeral Data Fabric Streams API enforces a maximum of 4096 partitions for a topic. If you create an application with the HPE Ezmeral Data Fabric Streams 6.1 API, the maximum number of partitions is 4096. If you previously created an application with HPE Ezmeral Data Fabric Streams 6.0.1 API (or older) and you have upgraded, the original number of partitions can be used. For example, if you were using more than 4096 partitions in core version 6.0.1 or earlier, you can continue with the same number of partitions after upgrading.

Getting Started with HPE Ezmeral Data Fabric Streams

If you have a basic understanding of HPE Ezmeral Data Fabric Streams components and the typical flow of messages from producers to consumers, you can get started.

Prerequisites

- Ensure that your Linux, Windows, or OS X system has Java SDK 7 or later installed.
- Install the latest version of HPE Ezmeral Data Fabric on a cluster.
- Install the core client (mapr-client) package, if you want to run the producer and consumer from a machine outside the cluster. See Installing the Data Fabric Client (Non-FIPS) on page 404 for more information.

Procedure

1. On a node in the HPE Ezmeral Data Fabric cluster, follow these steps:
   a) Create a stream.
      - Run this command if you plan to run the producer and consumer with the same user ID that you are using to create the stream:

        ```
        maprcli stream create -path /<path to and name of the stream>
        ```

      - Run this command if you plan to run the producer and consumer with user IDs that are different from the user ID that you are using to create the stream:

        ```
        maprcli stream create -path /<path to and name of the
        stream> -consumeperm u:<user ID> -produceperm u:<user ID>
        ```

        The two additional parameters grant security permissions. By default, these permissions are granted to the user ID that ran the `maprcli stream create` command.

`-consumeperm`	Grants permission to read messages from topics that are in the stream.
`-produceperm`	Grants permission to publish messages to topics that are in the stream.

   b) Create a topic.

      Run this command to create the topic:

      ```
      maprcli stream topic create -path <path and name of the stream> -topic
      <name of the topic>
      ```

2. On the system where the mapr-client is installed, compile and launch the Java consumer first and then launch the Java producer.

   In both the consumer and producer, change this text to the path and name of your stream and to the name of the first of the topics:

   ```
   /<path to and name of the stream>:<name of topic>
   ```

For the steps of compiling and launching, see Compiling and Running HPE Ezmeral Data Fabric Streams Java Apps on page 3566.

Launch the consumer first, and then launch the producer. If you launch the producer first and then the consumer, the producer publishes 50 messages, but the consumer (as consumers do by default) starts reading from the head of the partition, which is after the 50 messages.

NOTE: As of MapR 6.0, the message offset in a partition starts from zero (0). If you are upgrading and do not enable the HPE Ezmeral Data Fabric Database/HPE Ezmeral Data Fabric Streams feature, **mfs.feature.db.streams.v6.support**, the message offset in a partition starts from one (1).

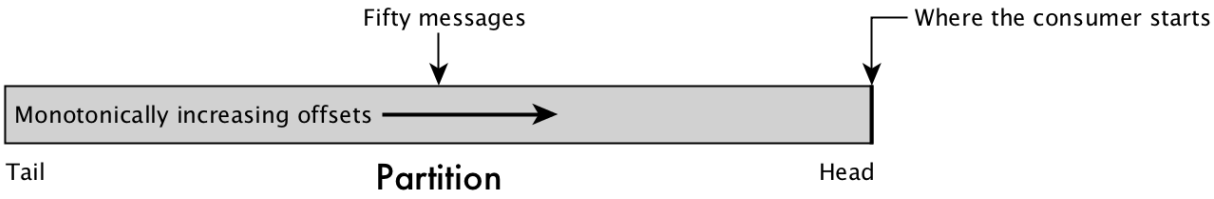


Figure 32: Result of starting the producer before starting the consumer for this step

If you launch the consumer first, the partition is empty and the consumer continuously polls for new messages.

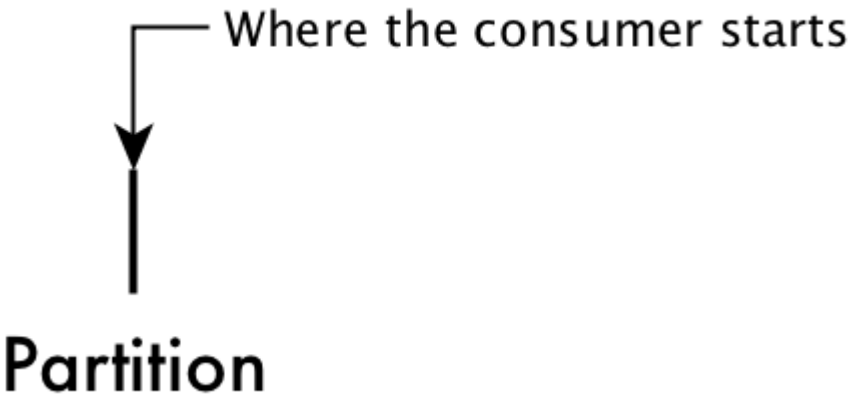

Figure 33: The position of a consumer on an empty partition

After you launch the producer, the fifty messages are published to the partition, and the consumer can move forward in the partition, reading the messages.

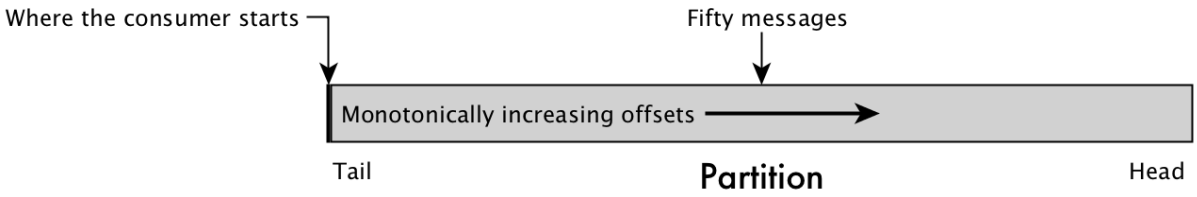

Figure 34: Result of starting the consumer first and then starting the producer for this step

Sample Java Consumer

You need to first add the following dependency to the POM file:

```
<dependency>
  <groupId>commons-logging</groupId>
  <artifactId>commons-logging</artifactId>
  <version>1.1.1</version>
</dependency>
```

```
/* This code is successfully tested for common-logging version 1.11 and
1.2. */

import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;

public class SampleConsumer {
    // Set the stream and topic to read from
    public static String topic = "/<path to and name of the stream>:<name
of topic>";

    // Declare a new consumer.
    public static KafkaConsumer<Integer, String> consumer;

    public static void main(String[] args) {
        configureConsumer();

        // Subscribe to the topic.
        consumer.subscribe(Collections.singletonList(topic));

        // Set the timeout interval for requests for unread messages.
        Duration pollTimeout = Duration.ofMillis(1000);

        try {
            while (true) {
                ConsumerRecords<Integer, String> records =
consumer.poll(pollTimeout);
                records.forEach(record -> {
                    System.out.printf("%s %d %d %s %s \n", record.topic(),
                            record.partition(), record.offset(),
record.key(), record.value());

                });
            }
        } finally {
            consumer.close();
        }
    }

    /* Set the value for a configuration parameter.
       This configuration parameter specifies which
       class to use to deserialize the value of each message. */
    public static void configureConsumer() {
        Properties props = new Properties();
        props.put(ConsumerConfig.GROUP_ID_CONFIG, "consumer-group");
        props.put(ConsumerConfig.AUTO_OFFSET_RESET_CONFIG, "earliest");
        props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,

"org.apache.kafka.common.serialization.IntegerDeserializer");
        props.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
```

```
                "org.apache.kafka.common.serialization.StringDeserializer");
        consumer = new KafkaConsumer(props);
    }
}
```

Sample Java Producer

```
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;

import java.util.Properties;

public class SampleProducer {
    // Set the stream and topic to publish to.
    public static String topic = "/<path to and name of the stream>:<name
of topic>";
    // Set the number of messages to send.
    public static int numMessages = 50;

    // Declare a new producer.
    public static KafkaProducer<Integer, String> producer;

    public static void main(String[] args) {
        configureProducer();

        for(int i = 0; i < numMessages; i++) {
            // Set content of each message.
            String messageText = "Msg " + i;

           /* Add each message to a record. A ProducerRecord object
              identifies the topic or specific partition to publish
           a message to. */
            ProducerRecord<Integer, String> rec = new ProducerRecord(topic,
i, messageText);

            // Send the record to the producer client library.
            producer.send(rec);
            System.out.println("Sent message number " + i);
        }
        producer.close();
        System.out.println("All done.");
    }

    /* Set the value for a configuration parameter.
       This configuration parameter specifies which class
       to use to serialize the value of each message. */
    public static void configureProducer() {
        Properties props = new Properties();
        props.put(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
                "org.apache.kafka.common.serialization.IntegerSerializer");
        props.put(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
                "org.apache.kafka.common.serialization.StringSerializer");
        producer = new KafkaProducer(props);
    }
}
```

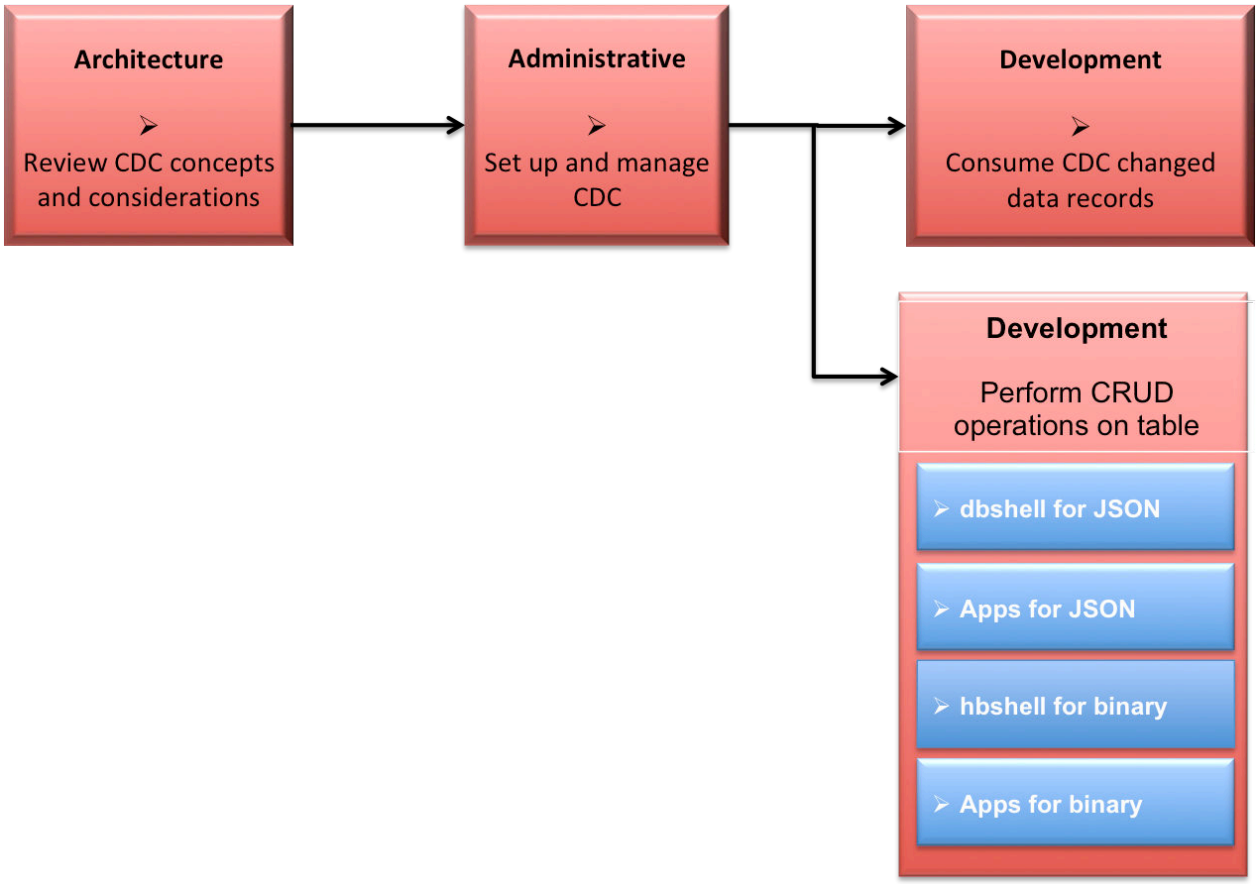
Consuming CDC Records

The OJAI changelog interfaces are used to consume changed data records (propagated by the Change Data Capture feature).

last-updated: Jun 06, 2024

The general CDC flow of understanding architectural concepts, performing administrative tasks to set up and use CDC, performing CRUD operations on a database table, and developing applications for consuming CDC changed data records. This diagram provides hotspot links to help you navigate to the applicable documentation.



1. Learning about CDC
2. Administering Change Data Capture
3. Building a consumer app for CDC
4. Using dbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database JSON tables
5. Developing client applications for HPE Ezmeral Data Fabric Database JSON tables.
6. Using hbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database binary tables.
7. Developing client applications for HPE Ezmeral Data Fabric Database binary tables.

Javadoc

See the following Java documentation for detailed information about CDC APIs.

QueryResult

Deserializer for consuming CDC records

The deserializer converts stream messages into individual change data records. When your application creates a CDC consumer, you must also register the

last-updated: Jun 06, 2024

ChangeData deserializer by setting the `value.deserializer` configuration parameter to `com.mapr.db.cdc.ChangeDataRecordDeserializer`.

NOTE: When applications consume from a CDC change topic, the record key retrieved from `poll()` is not deserialized. The record key is not equal to the `_id` field of the document. If you want to retrieve the exact `_id` of the document, you must call the `ChangeDataRecord.getId()` method.

Interfaces for working with CDC records

The following OJAI interfaces and enumerations create consumers for CDC changed data.

ChangeNode	Contains the change to a single field in a document.
ChangeEvent	Identifies the change event associated with the current change node. The value of ChangeEvent can be one of the following: • NULL (no event) • NODE (a change with real value) • START_MAP (a node representing the beginning of a map) • END_MAP (a node representing the end of a map) • START_ARRAY (a node representing the beginning of an array) • END_ARRAY (a node representing the end of an array)
ChangeOp	Identifies the type of the operation performed on the current field. The values of ChangeOp can be one of the following: • NULL (no operation) • SET (replace the current field with the given value) • PUT (add an extra version of the value) • MERGE (combine the given value with the existing values in the table) • DELETE (delete all values older than or equal to the delete operation timestamp) • DELETE_EXACT (delete the version of the value with the given timestamp)
ChangeDataRecord	Contains all the changes made on a single document/row in the source table.
ChangeDataRecordType	Specifies the mode of change for the change data record. The following values are specified: • RECORD_INSERT • RECORD_UPDATE • RECORD_DELETE
ChangeDataReader	Is a parser that traverses over the individual change tree nodes on a change data record. It provides

last-updated: Jun 06, 2024

cursor-like semantics that can be moved, one tree node at a time, by invoking the `next` method. The APIs retrieve the properties of individual change nodes (for example: data type, field name, field value, and so on).

Open Data Format

The CDC Open Format feature allows you to create applications in languages other then Java that consume CDC (Change Data Capture) changed data records. For example, C/C++, Python, and C#/.NET) are supported.

This functionality is provided with an open format decoder/serializer in the HPE Ezmeral Data Fabric Streams C library. The decoder translates the internal format to the open data format, decodes/deserializes the data, and returns the value of the changed data record as a human readable JSON string.

All languages that are binding through the HPE Ezmeral Data Fabric Streams C library can retrieve the open data format and, with a simple JSON parser, consume changed data records.

Building Consumers for CDC

HPE Ezmeral Data Fabric Streams consumers read and process CDC changed data records. The consumer is built with the OJAI API library.

Description

When building a consumer, the general steps are to:

- Set the consumer properties using Apache Kafka and HPE Ezmeral Data Fabric configuration parameters.
- Subscribe to the stream topic.
- Consume the events and determine record type.
- Process the change data records.

The following examples refer to the MapR CDC Sample. See the QueryResult for specific API information.

Set Configuration

This code snippet configures the consumer properties using the Apache Kafka configuration parameters. See HPE Ezmeral Data Fabric Streams Configuration Parameters for Consumers. This could be externalized in a file or hard coded in the application code. The following code examples show both methods.

NOTE: CDC uses a optimized serialization format for all the events, so `value.deserializer` must be set to **com.mapr.db.cdc.ChangeDataRecordDeserializer**.

```
// Consumer configuration parameters specified in application

    Properties consumerProperties = new Properties();
    consumerProperties.setProperty("group.id",
"cdc.consumer.demo_table.fts_geo");
    consumerProperties.setProperty("enable.auto.commit", "true");
    consumerProperties.setProperty("auto.offset.reset", "latest");
    consumerProperties.setProperty("key.deserializer",
"org.apache.kafka.common.serialization.ByteArrayDeserializer");
    consumerProperties.setProperty("value.deserializer",
```

```
"com.mapr.db.cdc.ChangeDataRecordDeserializer");
```

```
// Consumer configuration parameters specified in an external file

key.deserializer=org.apache.kafka.common.serialization.ByteArrayDeserializer
value.deserializer=com.mapr.db.cdc.ChangeDataRecordDeserializer
enable.auto.commit=true
auto.offset.reset=latest
group.id=cdc.consumer.demo_table.fts_geo
```

Subscribe to topic

This code snippet creates the consumer and subscribes to the HPE Ezmeral Data Fabric Streams topic that contains the change data records. The consumer is created using a key (bytes[]) and a `ChangeDataRecord` object for the value.

```
// Consumer used to consume MapR-DB CDC events

KafkaConsumer<byte[], ChangeDataRecord> consumer = new
KafkaConsumer<byte[], ChangeDataRecord>(consumerProperties);
consumer.subscribe(Arrays.asList("/demo_changelog:demo_table"));
```

Consume the events and determine record type

This code snippet polls the topic to determine whether there are any changes and, if so, iterates through the change data records to retrieve the change data record IDs based on the change data record type. The ChangeDataRecordType interface is used to determine the type of record and the ChangeDataRecord interface is used to retrieve the record type and record ID.

```
    while (true) {
      ConsumerRecords<byte[], ChangeDataRecord> changeRecords =
consumer.poll(500);
      Iterator<ConsumerRecord<byte[], ChangeDataRecord>> iter =
changeRecords.iterator();

      while (iter.hasNext()) {
        ConsumerRecord<byte[], ChangeDataRecord> crec = iter.next();
        // The ChangeDataRecord contains all the changes made to a document
        ChangeDataRecord changeDataRecord = crec.value();
        String documentId = changeDataRecord.getId().getString();

        if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_INSERT) {
          System.out.println("\n\t Document Inserted " + documentId);
          insertAndUpdateDocument(changeDataRecord, producer);
        } else if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_UPDATE) {
          System.out.println("\n\t Document Updated " + documentId);
          insertAndUpdateDocument(changeDataRecord, producer);
        } else if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_DELETE) {
          System.out.println("\n\t Document Deleted " + documentId);
          deleteDocument(changeDataRecord, producer);
        }

      }
    }
```

```
  }
```

Process the records

This code snippet processes the change data records and based on the type of event (insert, update, delete), using the `ChangeDataRecordType` class and the `changeDataRecord.getType()` method, checks and retrieves the record type.

```
// Use the ChangeNode Iterator to capture all the individual changes

    Iterator<KeyValue<FieldPath, ChangeNode>> cdrItr =
changeDataRecord.iterator();

    while (cdrItr.hasNext()) {
      Map.Entry<FieldPath, ChangeNode> changeNodeEntry = cdrItr.next();
      String fieldPathAsString = changeNodeEntry.getKey().asPathString();
      ChangeNode changeNode = changeNodeEntry.getValue();
      ...
      ...
    }
```

To process and retrieve an inserted new document, you can check to see if the field path is NULL or empty. When *a new document is inserted*, all the changes are made in a single object represented as a Map. You then retrieve the map value by using the `changeNode.getMap()` or `changeNode.getString()` methods depending on the field value.

```
if (fieldPathAsString == null || fieldPathAsString.equals("")) { // Insert
        Map<String, Object> documentInserted = changeNode.getMap();

        if (documentInserted.containsKey("firstName")) {
          fieldToIndex.put("firstName", (String)
documentInserted.get("firstName"));
          sendIndexingMessage = true;
        }

        if (documentInserted.containsKey("lastName")) {
          fieldToIndex.put("lastName", (String)
documentInserted.get("lastName"));
          sendIndexingMessage = true;
        }

        if (documentInserted.containsKey("address")) {
          addressMessage.set("address",
jsonMapper.convertValue((Map)documentInserted.get("address"),
JsonNode.class) );
          sendAddressMessage = true;
        }
     }
```

To process and retrieve updated documents, you can check the field path and retrieve the value depending on the expected value type. When *a document is updated*, the iterator contains one ChangeNode by updated field. You can then access the field path and value directly. You then retrieve the map value by using the `changeNode.getMap()` or `changeNode.getString()` methods depending on the field value.

```
if (fieldPathAsString.equalsIgnoreCase("firstName")) {
          fieldToIndex.put("firstName", changeNode.getString());
          sendIndexingMessage = true;
```

```
        }
          else if (fieldPathAsString.equalsIgnoreCase("lastName")) {
          fieldToIndex.put("lastName", changeNode.getString());
          sendIndexingMessage = true;
        }
          else if (fieldPathAsString.equalsIgnoreCase("address")) {
          addressMessage.set("address",
jsonMapper.convertValue( changeNode.getMap(), JsonNode.class) );
          sendAddressMessage = true;
        }
```

To process delete operations, you can directly retrieve the document ID using the `changeDataRecord.getId()` method and process the document deletion with the `deleteDocument` method. The delete operation is a single change data record.

Consumer Application for CDC JSON Data
This example consumes changed data records from HPE Ezmeral Data Fabric Database JSON tables.

Example of Consuming JSON Changed Data Records

In this example, the following occurs:

- Initialize the consumer properties using Apache Kafka and MapR configuration parameters.
- Display the change data record properties.
- Iterate through the change nodes, determine the type of operation, and retrieve the operation value.
- Retrieve the properties of individual change node (for example: data type, field name, field value, and so on) by using various methods of the `ChangeDataReader` interface.
- Display the change data record values by using the `ChangeNode` interface.
- Subscribe to the stream topic, consume the events, and determine record type.

For changed data records from HPE Ezmeral Data Fabric Database JSON table data, the following are unique:

- There are multiple property values that can be retrieved through the `ChangeDataReader` interface. For example, getDouble or getFloat.
- There are multiple values for single fields in documents that can be retrieved through `ChangeNode` interface. See the code line: `Value value = changeNode.getValue();`

        CDPConsumer cdpConsumer = new CDPConsumer();
        cdpConsumer.consume(pollTimeout, topic, method);
    }
}
```

Consumer Application for CDC Binary Data
This example consumes changed data records from HPE Ezmeral Data Fabric Database Binary tables.

Example of Consuming Binary Changed Data Records

In this example, the following occurs:

- Initialize the consumer properties using Apache Kafka and HPE Ezmeral Data Fabric configuration parameters.
- Display the change data record properties.
- Iterate through the change nodes, determine the type of operation, and retrieve the operation value.
- Display the change data record values by using the `ChangeNode` interface.
- Subscribe to the stream topic, consume the events, and determine record type.

For changed data records from HPE Ezmeral Data Fabric Database Binary table data, the following are unique:

- An additional package must be imported: `java.nio.ByteBuffer`

- There is single value for single fields in documents that can be retrieved through `ChangeNode` interface. See the code line: `ByteBuffer value = changeNode.getBinary();`

```
package com.mapr.qa.cdc.tests.binary;

import org.apache.kafka.clients.consumer.ConsumerRecord;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.ojai.*;
import org.ojai.store.Connection;
import org.ojai.store.Driver;
import org.ojai.store.DriverManager;
import org.ojai.store.cdc.*;

import java.nio.ByteBuffer;
import java.util.*;

        cdcBinaryExample.consume(pollTimeout, topic, method);
```

last-updated: Jun 06, 2024

```
    }
}
```

Open Format
Describes the CDC open format.

Open Format Mapping

The following shows the mapping between the HPE Ezmeral Data Fabric CDC data types and the JSON open format data types.

```
{
        "map": {
        "null": null,
        "boolean" : true,
        "string": "eureka",
        "byte" : {"$numberByte": 127},
        "short": {"$numberShort": 32767},
        "int": {"$numberInt": 2147483647},
        "long": {"$numberLong":92233720368547758O7},
        "float" : {"$numberFloat":3.4028235E38},
        "double" : 1.7976931348623157e308,
        "decimal": {"$decimal":
"12345678901234567890189012345678901.23456789"},
        "date": {"$dateDay": "yyyy-mm-dd"},
        "time" : {"$time" : "HH:mm:ss[.sss]"},
        "timestamp" : {"$date" : "yyyy-MM-ddTHH:mm:ss.SSSXXX"},
        "interval" : {"$interval" : number_of_millisecods},
        "binary" : {"$binary" : "base64_encoded_binary_value"},
        "array" : [42, "open sesame", 3.14, {"$dateDay": "2015-01-21"}]
        }
}
```

JSON Record Format

When the consumer retrieves the changed data record (by the key-value pair), the record is returned as a string in JSON format (a readable open format). The information about the mutation is returned as an array where each array element is one (1) change.

NOTE: If you use the default print, the string returns float values of up to six (6) digits of precision and double values of up to fifteen (15) digits. If the data exceeds this default and you want the exact number returned, use the CDC API that returns a float or double value.

The following example changed data record shows two (2) mutations.

```
{
        "_id":"row1"
        "$opType":"$RECORD_UPDATE",
        "$opTime":1518654391801,

        "$mutations":[
        {"$fieldPath":"arrayB,
        "$fieldOp":"$SET",
        "$fieldValue":[{"$numberInt":100},false,"set a map"]
        }
        {"$fieldPath":"arrayC,
        "$fieldOp":"$SET",
        "$fieldValue":[{"$numberInt":200},false,"set a map"]
        }
```

```
        ]
}
```

Example

The following sample code initialized consumer properties for open format and consumes the changelog data from the topic.

```
/*
 * Initialize Basic Consumer Properties for Open Format
 * @return
 */

private Properties getOpenFormatListenerProperties() {
   Properties props = new Properties();
   props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
"org.apache.kafka.common.serialization.StringDeserializer");
   props.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
"org.apache.kafka.common.serialization.StringDeserializer");
   return props; }

/*
 * Consume from changelog topic
 *
 */
public void startConsume(String topic) {
   KafkaConsumer<String, String> consumer = new KafkaConsumer<String,
String> (getOpenFormatListnerProperties());
   List<String> topicList = new ArrayList<>();
   topicList.add(topic);
   consumer.subscribe(topicList);

   ConsumerRecords<String, String> consumerRecords =
consumer.poll(pollTimeout);
   Iterator<ConsumerRecord<String, String>> iterator =
consumerRecords.iterator();
   while (iterator.hasNext())

      { ConsumerRecord<String, String> record = iterator.next(); String
cdcResult = record.value(); }

}
```

Consuming Audit Logs

Audit Streaming (available from v6.0.1) provides a way to process the audit data in real-time.

When audit streaming is enabled, the HPE Ezmeral Data Fabric generates audit logs that are sent as an audit stream, opening the possibility of real-time processing of the audit data. See Streaming Audit Logs on page 852 for more information.

Use the sample consumer application, or build your custom consumer application, to consume the audit logs that are available as a stream topic, when audit streaming is enabled.

The sample application uses file system APIs to get the file path and name from the FID, and the volume name from the volume ID.

Determine When to use Cached or Uncached Version of the File System API

Caching the file path and file name, along with the volume name at the initial API call, reduces the load on CLDB for subsequent API calls.

last-updated: Jun 06, 2024

However, there could be cases when the uncached version of the application is more suitable for use. Consider the following example:

For the initial API call, File1 is returned as the file name for FID 1. The result is cached.

The file is then renamed to File2. For subsequent API calls, to get the file name for FID 1, the result from the cache is used. The cache, unaware of the rename operation, returns the name as File1, which is incorrect, as the file is already renamed to File2. For such a case, use the uncached version.

Evaluate your use case, and then use the cached, or the uncached version, as appropriate.

Sample Cached Consumer Application for Audit Stream
The Consumer.java application demonstrates how to connect to the file system, and consume the messages in a stream topic.

Sample Application

Before running this application, ensure that you have access to a cluster running file system. To build and run this application:

1. Set the classpath as shown below:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the Java file as shown below:

```
javac -cp .:`mapr classpath` Consumer.java
```

3. Run the final `Consumer.class` file. For example:

```
java -cp .:`mapr classpath` Consumer
```

This application requires the following imports:

- `org.apache.kafka.clients.consumer.ConsumerRecord`
- `org.apache.kafka.clients.consumer.ConsumerRecords`
- `org.apache.kafka.clients.consumer.KafkaConsumer`
- `org.apache.hadoop.conf.Configuration`
- `com.mapr.fs.MapRFileSystem`
- `com.google.common.io.Resources`
- `java.net.URI`
- `java.io.IOException`
- `java.io.InputStream`
- `java.util.Iterator`
- `java.util.Properties`
- `java.util.Random`

- `java.util.StringTokenizer`
- `java.util.regex.Pattern`

The application performs the actions described in the following sections.

Initializes the consumer properties

The configuration parameters for the consumer are stored in `consumer.props` file. This file should be present in the current directory or mapr classpath. For example, your `consumer.props` file could look similar to the following:

```
#bootstrap.servers=localhost:9092
group.id=test
enable.auto.commit=true
key.deserializer=org.apache.kafka.comm
on.serialization.StringDeserializer
value.deserializer=org.apache.kafka.co
mmon.serialization.StringDeserializer
# fast session timeout makes it more
fun to play with failover
## apps specific ?
session.timeout.ms=10000

# These buffer sizes are needed to
avoid consumer switching to
# a mode where it processes one
bufferful every 5 seconds with
multiple
# timeouts along the way.
fetch.min.bytes=50000
# receive.buffer.bytes=262144 //
fixed size buffer
max.partition.fetch.bytes=2097152

auto.offset.reset=earliest
```

The application initializes the consumer properties stored in the `consumer.props` file.

```
public static void main(String[]
args) throws
IOException,InterruptedException {
    KafkaConsumer<String, String>
consumer;
    try (InputStream props =
Resources.getResource("consumer.props"
).openStream()) {
        Properties properties = new
Properties();
        properties.load(props);
        if
(properties.getProperty("group.id")
== null) {

properties.setProperty("group.id",
"group-" + new
Random().nextInt(100000));
        }
        consumer = new
KafkaConsumer<>(properties);
```

```
    }
}
```

Subscribes to the topic to read from

The application initializes the file system object, with the last parameter as `true` so that the audit logs generated by the operations for converting fid to file path and volid to volume name are sent to the `ExpandAudit.json.log` file used by the `expandaudit` on page 2868 utility and not to the stream. It then selects the stream and subscribes to the topic to read at path `/var/mapr/auditstream/auditlogstream:<clustername>`.

```
Configuration conf = new
Configuration();
String uri = MAPRFS_URI;
uri = uri + "mapr/";
conf.set("fs.default.name", uri);
MapRFileSystem fs = new
MapRFileSystem();
fs.initialize(URI.create(uri), conf,
true);
Pattern pattern
= Pattern.compile("/var/
mapr/auditstream/
auditlogstream:<clustername>.+");
consumer.subscribe(pattern);
```

Requests unread messages from the topic

The application requests to read unread messages in the subscribed topic. It then iterates through the returned records, extracts the value of each message, and prints the value to the standard output.

```
boolean stop = false;
int pollTimeout = 1000;
while (!stop) {
    ConsumerRecords<String,
String> consumerRecords =
consumer.poll(pollTimeout);
    Iterator<ConsumerRecord<String,
String>> iterator =
consumerRecords.iterator();
    if (iterator.hasNext()) {
      while (iterator.hasNext()) {
        ConsumerRecord<String,
String> record = iterator.next();
        String value = record.value();
        String rvalue =
value.replace("\"","");
        String recordValue
= processRecord(fs, rvalue,
value);
        System.out.println(("
Consumed Record: " + recordValue));
      }
    } else {
      Thread.sleep(1000);
      //stop = true;
    }
}
```

Gets the record and expands individual fields

The application then takes the record and expands fid in the message to path to file using the `getMountPathFidCached()` API and volid in the message to volume name using the `getVolumeNameCached()` API.

```
while (st.hasMoreTokens()) {
    String field = st.nextToken();
    StringTokenizer st1 = new
StringTokenizer(field, ":");
    while (st1.hasMoreTokens()) {
        String token =
st1.nextToken();
        if (token.endsWith("Fid")) {
           String lfidStr =
st1.nextToken();
           String path= null;
           try {
              path =
fs.getMountPathFidCached(lfidStr); //
Expand FID to path
           } catch (IOException e){
        }
        lfidPath =
"\"FidPath\":\""+path+"\",";
        // System.out.println("\nPAth
for fid " + lfidStr +  "is " +  path);
    }
    if (token.endsWith("volumeId")) {
        String volid =
st1.nextToken();
        String name= null;
        try {
            int volumeId =
Integer.parseInt(volid);
            name =
fs.getVolumeNameCached(volumeId); //
Cached API to convert volume Id to
volume Name
        } catch (IOException e){
        }
        lvolName =
"\"VolumeName\":\""+name+"\",";
        //
System.out.println("\nVolume Name for
volid " + volid +  "is " +  name);
    }
}
```

Returns the record

The application finally returns the record after expanding the fid and volid to file path and volume name respectively.

```
String result = "";
StringTokenizer st2 = new
StringTokenizer(value,",");
while (st2.hasMoreTokens()) {
     String tokens = st2.nextToken();
     result = result + tokens + ",";
     if (tokens.contains("Fid")) {
         result = result + lfidPath;
     }
```

last-updated: Jun 06, 2024

```
     if (tokens.contains("volumeId"))
{
         result = result + lvolName;
     }
}
return result.substring(0,
result.length() - 1);
```

Sample Uncached Consumer Application for Audit Stream

The ConsumerUncached.java application demonstrates how to connect to the HPE Ezmeral Data Fabric file system, and consume the messages in a stream topic.

Sample Application

Before running this application, ensure that you have access to a cluster running file system. To build and run this application:

1. Set the classpath as shown below:

   ```
   export CLASSPATH=`hadoop classpath`
   ```

2. Compile the Java file as shown below:

   ```
   javac -cp .:`mapr classpath` ConsumerUncached.java
   ```

3. Run the final `ConsumerUncached.class` file. For example:

```
java -cp .:`mapr classpath` ConsumerUncached
```

This application requires the following:

- `org.apache.kafka.clients.consumer.ConsumerRecord`
- `org.apache.kafka.clients.consumer.ConsumerRecords`
- `org.apache.kafka.clients.consumer.KafkaConsumer`
- `org.apache.hadoop.conf.Configuration`
- `com.mapr.fs.MapRFileSystem`
- `com.google.common.io.Resources`
- `java.net.URI`
- `java.io.IOException`
- `java.io.InputStream`
- `java.util.Iterator`
- `java.util.Properties`
- `java.util.Random`
- `java.util.StringTokenizer`
- `java.util.regex.Pattern`

The application performs the actions described in the following sections.

Initializes the consumer properties

The configuration parameters for the consumer are stored in `consumer.props` file. This file should be present in the current directory or mapr classpath. For example, your `consumer.props` file could look similar to the following:

```
#bootstrap.servers=localhost:9092
group.id=test
enable.auto.commit=true
key.deserializer=org.apache.kafka.comm
on.serialization.StringDeserializer
value.deserializer=org.apache.kafka.co
mmon.serialization.StringDeserializer

# fast session timeout makes it more
fun to play with failover
## apps specific ?
session.timeout.ms=10000

# These buffer sizes are needed to
avoid consumer switching to
# a mode where it processes one
bufferful every 5 seconds with
multiple
```

```
# timeouts along the way.
fetch.min.bytes=50000
# receive.buffer.bytes=262144 //
fixed size buffer
max.partition.fetch.bytes=2097152

auto.offset.reset=earliest
```

The application initializes the consumer properties stored in the `consumer.props` file.

```
public static void main(String[]
args) throws
IOException,InterruptedException {
    KafkaConsumer<String, String>
consumer;
    try (InputStream props =
Resources.getResource("consumer.props"
).openStream()) {
          Properties properties = new
Properties();
          properties.load(props);
          if
(properties.getProperty("group.id")
== null) {

properties.setProperty("group.id",
"group-" + new
Random().nextInt(100000));
          }
      consumer = new
KafkaConsumer<>(properties);
      }
}
```

Subscribes to the topic to read from

The application initializes the filesystem object, with the last parameter as `true` so that the audit logs generated by the operations for converting fid to file path and volid to volume name are sent to the `ExpandAudit.json.log` file used by the `expandaudit` on page 2868 utility and not to the stream. It then selects the stream and subscribes to the topic to read at path `/var/mapr/auditstream/auditlogstream:<clustername>`.

```
Configuration conf = new
Configuration();
String uri = MAPRFS_URI;
uri = uri + "mapr/";
conf.set("fs.default.name", uri);
MapRFileSystem fs = new
MapRFileSystem();
fs.initialize(URI.create(uri), conf,
true);

Pattern pattern =
Pattern.compile("/var/mapr/
auditstream/
auditlogstream:<clustername>.+");
consumer.subscribe(pattern);
```

Requests unread messages from the topic

The application requests to read unread messages in the subscribed topic. It then iterates through the returned records, extracts the value of each message, and prints the value to the standard output.

```
boolean stop = false;
int pollTimeout = 1000;
while (!stop) {
      ConsumerRecords<String,
String> consumerRecords =
consumer.poll(pollTimeout);
      Iterator<ConsumerRecord<String,
String>> iterator =
consumerRecords.iterator();
      if (iterator.hasNext()) {
          while (iterator.hasNext()) {
              ConsumerRecord<String,
String> record = iterator.next();
              String value =
record.value();
              String rvalue =
value.replace("\"","");
              String recordValue =
processRecord(fs, rvalue, value);
              System.out.println(("
Consumed Record: " + recordValue));
          }
      } else {
                  //stop = true;
      }
}
```

Gets the record and expands individual fields

The application then takes the record and expands fid in the message to path to file using the `getMountPathFid()` API and volid in the message to volume name using the `getVolumeName()` API.

```
public static String
processRecord(MapRFileSystem fs,
String rvalue, String value)
  {
     StringTokenizer st = new
StringTokenizer(rvalue, ",");
     String lfidPath = "";
     String lvolName = "";

     while (st.hasMoreTokens()) {
          String field =
st.nextToken();
          StringTokenizer st1 = new
StringTokenizer(field, ":");
          while (st1.hasMoreTokens())
{
               String token =
st1.nextToken();
               if
(token.endsWith("Fid")) {
             String lfidStr =
st1.nextToken();
             String path= null;
             try {
                   path =
```

```
fs.getMountPathFid(lfidStr);
            } catch (IOException e)
{ }
            lfidPath =
"\"FidPath\":\""+path+"\",";
             if
(token.endsWith("volumeId")) {
          String volid =
st1.nextToken();
          String name= null;
          try {
              int volumeId =
Integer.parseInt(volid);
                name =
fs.getVolumeName(volumeId);
            }
          catch (IOException e){ }
          lvolName =
"\"VolumeName\":\""+name+"\",";
             }
       }
    }
```

Returns the record

The application finally returns the record after expanding the fid and volid to file path and volume name respectively.

```
String result = "";
StringTokenizer st2 = new
StringTokenizer(value,",");
while (st2.hasMoreTokens()) {
    String tokens = st2.nextToken();
    result = result + tokens + ",";
    if (tokens.contains("Fid")) {
       result = result + lfidPath;
    }
    if (tokens.contains("volumeId")) {
       result = result + lvolName;
    }
    return result.substring(0,
result.length() - 1);
}
```

                    lvolName = "\"VolumeName\":\""+name+"\",";
                    //  System.out.println("\nVolume Name for volid " +
volid +  "is " +  name);
                }
            }
        }
        String result = "";
        StringTokenizer st2 = new StringTokenizer(value,",");
        while (st2.hasMoreTokens()) {
            String tokens = st2.nextToken();
            result = result + tokens + ",";
            if (tokens.contains("Fid")) {
                result = result + lfidPath;
            }
            if (tokens.contains("volumeId")) {
                result = result + lvolName;
            }
        }
        return result.substring(0, result.length() - 1);
    }
}
```

HPE Ezmeral Data Fabric Streams Java Applications

This section contains information on developing client applications with Java including information about the HPE Ezmeral Data Fabric Streams and Apache Kafka Java APIs, configuration parameters, and compiling and running producers and consumers.

Apache Kafka Support

HPE Ezmeral Data Fabric supports the following Apache Kafka Java API versions:

Table

Core version	Apache Kafka API
As of 6.2	2.1
As of 6.1	1.1
As of 6.0.1	1.0
6.0.0 and earlier	0.9.0

Log Compaction

As of HPE Ezmeral Data Fabric 6.1, log compaction is supported. Log compaction can be enabled for streams created with HPE Ezmeral Data Fabric core 6.1 and later. In addition, clients older thanHPE Ezmeral Data Fabric 6.1 are prevented from consuming from streams that have had log compaction enabled on them at least once in their lifetime.

When a stream on a source cluster has both log compaction and replication enabled, the replica cluster does not automatically have log compaction enabled. You must explicitly enable log compaction on the replica cluster.

- If a replica cluster has been upgraded and the stream data for a source cluster is compacted (that is, one or more messages have been deleted), then the source cluster replicates the compacted data to the replica cluster.
- If a replica cluster has ***not*** been upgraded, then the source cluster fails the replication and an error is generated that requests an replica cluster upgrade.

In the context of a scan by a client that is **not** upgraded, the (upgraded) server inspects the row header to check if it is serving a compacted row. If it is serving a compacted row, then the server fails the consumer request. This behavior applies both to a stream that is explicitly configured for compaction and a replica that has received a compacted row.

IMPORTANT: To perform log compaction on older streams, the `-force` option can be used. The `-force` option should only be used when ALL clients have been upgraded to HPE Ezmeral Data Fabric 6.1.

Idempotent Producer

As of HPE Ezmeral Data Fabric 6.1, the idempotent producer (exactly once) feature is supported. You can implement the idempotent producer with HPE Ezmeral Data Fabric core 6.1 and later.

last-updated: Jun 06, 2024

When creating a producer instance, use the following configuration:

```
props.put(ProducerConfig.ENABLE_IDEMPOTENCE_CONFIG, true)
```

The idempotent producer feature is supported by EEP HPE Ezmeral Data Fabric 6.0 clients and HPE Ezmeral Data Fabric 6.1.0 servers.

- You must upgrade all servers to v6.1.0 and enable all the v6.1.0 features, before you enable the idempotent producer.
- If you use a pre-HPE Ezmeral Data Fabric 6.1 client and a HPE Ezmeral Data Fabric 6.1 server, and if a group of messages are atomically persisted without a valid producer ID, the server treats the request as a non-idempotent producer.
- If you use a HPE Ezmeral Data Fabric 6.1 client and a pre-HPE Ezmeral Data Fabric 6.1 server, the idempotent producer is not supported. In this case, the idempotent producer fails to produce to the stream and the following exception is thrown:

```
Exception in thread "main" java.util.concurrent.ExecutionException:
org.apache.kafka.common.errors.UnknownTopicOrPartitionException:
Operation not permitted (1) null
        at

Caused by:
org.apache.kafka.common.errors.UnknownTopicOrPartitionException:
Operation not permitted (1) null
```

TimestampType Permissions

The following discussion describes the *ACE* permissions that you need when using the timestamp type parameter. See Stream Security on page 803 for general information about HPE Ezmeral Data Fabric Streams streams security.

A HPE Ezmeral Data Fabric Streams stream topic inherits the default timestamp type value from its stream. To override the stream's default value, set the timestamp type for the topic to a different value.

- Setting the value at the stream-level requires `adminperm` permissions. The stream-level timestamp type parameter is `defaulttimestamptype`. See stream create on page 2368 and stream edit on page 2375 for more information on setting this parameter using the `maprcli` command.
- Setting the `timestamptype` at the topic-level requires `topicperm` permissions. The topic-level timestamp type parameter is `timestamptype`. See stream topic create on page 2391 and stream topic edit on page 2394 for more information on setting this parameter using the `maprcli` command.

User Impersonation

As of HPE Ezmeral Data Fabric 6.0, user impersonation is supported for HPE Ezmeral Data Fabric Streams.

You can set up user impersonation programmatically. To do so, use the `UserGroupInformation.doAs()` method in the Hadoop documentation. See Class UserGroupInformation for more information.

If you are setting up user impersonation in a secure cluster, you need to generate an impersonation ticket. See the Generating and Printing Service with Impersonation Ticket section in the maprlogin Command Examples on page 2915 topic.

After generating the ticket:

1. Ensure that user `mapruser1` has read permissions on the ticket.
2. If you moved the ticket file to a different location, set the `$MAPR_TICKETFILE_LOCATION` environment variable with the appropriate path.

For more information about impersonation, see:

- How Impersonation Works on page 1943
- Generating a Service with Impersonation Ticket on page 1833
- Managing Impersonation on page 1942

Backward Compatibility

As of HPE Ezmeral Data Fabric 6.0.1, along with the support of Apache Kafka, the `java.util.Collection` interface is being used. This impacts applications using certain APIs. See HPE Ezmeral Data Fabric Streams Java API Library on page 3548 for detailed information.

HPE Ezmeral Data Fabric Streams Java API Library

Use the HPE Ezmeral Data Fabric Streams Admin Java API library as an alternative to `maprcli` commands and the REST APIs for performing administrative tasks on streams and topics. This library can also be used for analysis of the contents of streams.

Javadoc

The following Apache Kafka Java API versions are supported:

Table

Core version	Apache Kafka API
As of 6.2	2.1.1
As of 6.1	1.1
As of 6.0.1	1.0
6.0.0 and earlier	0.90

See the following APIs for detailed information:

HPE Ezmeral Data Fabric Streams Java APIs (as of 6.1 and 6.2)

The following HPE Ezmeral Data Fabric Streams Java APIs are available as of HPE Ezmeral Data Fabric 6.1 and HPE Ezmeral Data Fabric 6.2:

Table

Interface	Method	Description
`StreamDescriptor`	`void setCompact(boolean compact)`	Sets log compaction on a stream.

Table (Continued)

Interface	Method	Description
`StreamDescriptor`	`boolean getCompact()`	Gets the log compaction on a stream. Returns true if the stream has log compaction on the stream.
`StreamDescriptor`	`void setMinCompactionLagMS(long ts)`	Sets the time in (milliseconds) that a message should remain uncompacted in the topic-partition. Applies only if log compaction is enabled on the stream.
`StreamDescriptor`	`long getMinCompactionLagMS()`	Returns the minimum time (in milliseconds) a message will remain uncompacted in the topic-partition. Applies only if log compaction is enabled on the stream.
`StreamDescriptor`	`void setDeleteRetentionMS(long ts)`	Sets the time (in milliseconds) for which deleted records are retained. Applies only if log compaction is enabled on the stream.
`StreamDescriptor`	`long getDeleteRetentionMS()`	Returns the time (in milliseconds) for which deleted records are retained. Applies only if log compaction is enabled on the stream.
`Producer`	`ProducerConfig` class	The idempotence producer option is set by setting the `enable.idempotence` value of **true** passed through the ProducerConfig class.

HPE Ezmeral Data Fabric Streams Java APIs (as of 6.0.1)

The following table lists the new Interfaces and APIs for HPE Ezmeral Data Fabric 6.0.1. They are the delta between HPE Ezmeral Data Fabric 6.0.1 and 6.0.0, meaning, they are applicable to HPE Ezmeral Data Fabric6.0.1 but not HPE Ezmeral Data Fabric 6.0.0.

Table

Interface and Methods	Description
Admin.close	Long duration for TimeUnit.
Admin.createTopic	TopicDescriptor array for topic attributes.
Admin.editTopic	TopicDescriptor array for topic attributes.
Admin.getTopicDescriptor	Method for retrieving topic attributes.
Admin.listTopic	Method for listing all the topics in a stream.
Admin.streamExists	Method for determining whether a stream exists.
StreamDescriptor.getDefaultTimestampType	Method for retrieving the timestamp type.
StreamDescriptor.setDefaultTimestampType	Method for setting the timestamp type.
TopicDescriptor	New HPE Ezmeral Data Fabric interface.
TopicDescriptor.getPartitions	Method associated with the new interface.
TopicDescriptor.setPartitions	Method associated with the new interface.
TopicDescriptor.getTimestampType	Method associated with the new interface.

last-updated: Jun 06, 2024

Table (Continued)

Interface and Methods	Description
TopicDescriptor.setTimestampType	Method associated with the new interface.
Enum TimestampType	New Enum class and associated methods.

Backward Compatibility

As of HPE Ezmeral Data Fabric 6.0.1, Apache Kafka 1.0 is supported. The following `pause`, `resume`, `seekToBeginning`, and `seekToEnd` APIs support the Collection Interface. The deprecated APIs will continue to run unchanged, however, they may be removed in a future release.

Table

Replacement Collection APIs	Deprecated APIs
void pause(Collection<TopicPartition> partitions);	void pause(TopicPartition... partitions);
void resume(Collection<TopicPartition>partitions);	void resume(TopicPartition... partitions);
void seekToBeginning(Collection<TopicPartition>);	void seekToBeginning(TopicPartition... partitions);
void seekToEnd(Collection<TopicPartition>);	void seekToEnd(TopicPartition... partitions);

The following `subscribe` and `assign` APIs support the Collection Interface (which is more generalized) as well as the List Interface. Support for the List Interface has been retained for backward binary compatibility.

Table

Replacement Collection APIs	Retained APIs
void subscribe(Collection<String> topics);	void subscribe(java.util.List<java.lang.String> topics);
void subscribe(Collection<String> topics, ConsumerRebalanceListener);	void subscribe(java.util.List<java.lang.String> topics, ConsumerRebalanceListener listener);
void assign(Collection<TopicPartition> partitions);	void assign(java.util.List<TopicPartition> partitions);

Stream and Topic Operations Summary

Provides a summary of stream topic operations and the interface, class, or method used for the operation.

The following stream and topic operations is not an inclusive list, but a sampling. For detailed information, see the following libraries:

Table

Operation	Interface/Method Used
Creating streams	`StreamDescriptor` is used to set the attributes for streams that you plan to create. `Admin.createStream(String streamPathAndName, StreamDescriptor desc)` - create the stream.
Editing stream attributes	`StreamDescriptor` is used to edit the stream's attribute values. `Admin.editStream(String streamPathAndName, StreamDescriptor desc)` - set or modify the stream's attribute values.
Retrieving the default timestamp type on a stream	`StreamDescriptor.getDefaultTimestampType()` - retrieves the default timestamp type on the stream. **NOTE:** This method is new as of 6.0.1

last-updated: Jun 06, 2024

Table (Continued)

Operation	Interface/Method Used
Sets the default timestamp type on a stream	`StreamDescriptor.setDefaultTimestampType(TimestampType logAppendTime)` - sets the default timestamp type on the stream.  **NOTE:** TimestampType Enum is new as of 6.0.1
Deleting streams	`Admin.deleteStream(String streamPathAndName)`
Determining stream existence	`Admin.streamExists(String streamPathAndName)` - determines whether a stream exists or not. Returns: true | false  **NOTE:** This method is new as of 6.0.1
Creating topics	`Admin.createTopic(String streamPathAndName, String topicName, TopicDescriptor desc)` is used when creating a topic with the defaults for partitions and timestamp type.  **NOTE:** TopicDescriptor is new as of 6.0.1 `Admin.createTopic(String streamPathAndName, String topicName)` is used when accepting the default number of partitions. `Admin.createTopic(String streamPathAndName, String topicName, int npartitions)` - creates a topic with a specific number of partitions.  **NOTE:** If you do not specify the number of partitions for a stream topic, the default number of partitions is inherited from the stream.
Editing topics	`Admin.editTopic(String streamPathAndName, String topicName, TopicDescriptor desc)` - sets the partitions and timestamp type attributes of a topic.  **NOTE:** TopicDescriptor is new as of 6.0.1 `Admin.editTopic(String streamPathAndName, String topicName, int npartitions)`
Retrieving topic attributes	`Admin.getTopicDescriptor(String streamPathAndName, String topicName)` - retrieves topic attributes.  **NOTE:** This method is new as of 6.0.1
Deleting topics	`Admin.deleteTopic(String streamPathAndName, String topicName)` - deletes topics.
Listing topics	`Admin.listTopics(String streamPathAndName)` - lists all topics in a stream.  **NOTE:** This method is new as of 6.0.1
Counting topics	`Admin.countTopics(String streamPathAndName)` - counts the number of topics in a stream.
Gets/Sets topic timestamp type	`TopicDescriptor` is used to retrieve the timestamp type attribute value of a topic.  **NOTE:** TopicDescriptor is new as of 6.0.1 `TopicDescriptor.getTimestampType()` - retrieves the default timestamp type of a topic. `TopicDescriptor.setTimestampType(TimestampType timestampType)` - sets the default timestamp type of a topic.

last-updated: Jun 06, 2024

Table (Continued)

Operation	Interface/Method Used
Gets/Sets topic partitions	`TopicDescriptor` is used to retrieve the partition attribute value of a topic. **NOTE:** TopicDescriptor is new as of 6.0.1 `TopicDescriptor.getPartitions()` - retrieves the partitions of a topic. `TopicDescriptor.setParitions(int numPartitions)` - sets the partitions of a topic.
Enabling and tuning log compaction	`TopicDescriptor` is used to enable and tune log compaction at the stream-level. • `setCompact(boolean compact)` - sets log compaction. • `getCompact()` - returns **true** if log compaction is set on the stream. • `setMinCompactionLagMS(long ts)` - set the lag time (in milliseconds) that a message should remain uncompacted. • `getMinCompactionLagMS()` - retrieves the value of the lag time. • `setDeleteRetentionMS(long ts)` - sets the time (in milliseconds) for which deleted records are retained. • `getDeleteRetentionMS()` - returns the time value of which deleted records are retained. In addition, the `Admin` interface is used with the following method to set compaction at the topic-level: • `compactTopic(java.lang.String streamPath, java.lang.String topicName)`
Enabling an Idempotent Producer	The `Producer` interface along with the `ProducerConfig` class is used to enable idempotence (exact-once message delivery semantics) publishing.

Managing Streams with Java

Provides Java code snippets for performing CRUD operations on HPE Ezmeral Data Fabric Streams streams.

Creating Streams

`StreamDescriptor` is used to set attributes for streams that you want to create.

```
public StreamDescriptor createStreamDescriptor(int numPartitions, String
adminUsers, String producerUsers, String consumerUsers, String copyUsers,
String topicUsers) {
        StreamDescriptor desc = Streams.newStreamDescriptor();
        desc.setDefaultPartitions(numPartitions);
        desc.setCompressionAlgo("zlib");
        desc.setAutoCreateTopics(false);
        desc.setAdminPerms(adminUsers);
        desc.setConsumePerms(consumerUsers);
        desc.setCopyPerms(copyUsers);
        desc.setTopicPerms(topicUsers);

        return desc;
}
```

last-updated: Jun 06, 2024

`Admin` is used with the `createStream` method to create the stream with the pre-established attribute values.

```
public void createStreamUtilFunction(String streamPathAndName,
StreamDescriptor desc) throws IllegalArgumentException, IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.createStream(streamPathAndName, desc);
        streamAdmin.close();
}
```

Editing Stream Attributes

`StreamDescriptor` is used to retrieve the stream's attribute values. `Admin` with the `editStream` method is used to set or modify the stream's attribute values.

```
Admin.editStream(String streamPathAndName, StreamDescriptor desc)
```

```
Configuration conf = new Configuration();
Admin streamAdmin = Streams.newAdmin(conf);
        StreamDescriptor desc =
streamAdmin.getStreamDescriptor(streamPathAndName);
```

```
public void editStreamUtilFunction(String streamPathAndName,
StreamDescriptor desc) throws IllegalArgumentException, IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.editStream(streamPathAndName, desc);
        streamAdmin.close();
}
```

Deleting Streams

```
public void deleteStreamUtilFunction(String streamPathAndName) throws
IllegalArgumentException, IOException{
          Configuration conf = new Configuration();
          Admin streamAdmin = Streams.newAdmin(conf);
          streamAdmin.deleteStream(streamPathAndName);
          streamAdmin.close();
}
```

Managing Topics with Java

Provides Java code snippets for performing CRUD operations on HPE Ezmeral Data Fabric Streams stream topics.

Creating Topics

The `createTopic` API is used to create a topic with the default number of partitions.

```
Admin.createTopic(String streamPathAndName, String topicName)
```

NOTE: If you do not specify the number of partitions for a stream topic, the default number of partitions is inherited from the stream.

```
public void createTopicUtilFunction(String streamPathAndName, String
topicName) throws IOException{
        Configuration conf = new Configuration();
```

last-updated: Jun 06, 2024

```
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.createTopic(streamPathAndName, topicName);
        streamAdmin.close();
}
```

The `createTopic` API is used to create a topic with a specific number of partitions.

```
Admin.createTopic(String streamPathAndName, String topicName, int
npartitions)
```

```
public void createTopicWithPartitionsUtilFunction(String streamPathAndName,
String topicName, int npartitions) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.createTopic(streamPathAndName, topicName, npartitions);
        streamAdmin.close();
}
```

Editing Topics

The `editTopic` API is used to change timestamp type and the number of partitions for a topic.

```
Admin.editTopic(String streamPathAndName, String topicName, int npartitions)
```

```
public void editTopicUtilFunction(String streamPathAndName, String
topicName, int npartitions) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.editTopic(streamPathAndName, topicName, npartitions);
        streamAdmin.close();
}
```

Retrieving Topic Attributes

The `getTopicDescriptor` API is used to get or set the topic's attribute values. `TopicDescriptor` is passed into methods to set and retrieve topic partitions and timestamp type. The `Enum TimestampType` values are CREATE_TIME and LOG_APPEND_TIME.

NOTE: `TopicDescriptor` is available as of MapR 6.0.1.

Deleting Topics

The `deleteTopic` API is used to delete a topic from a stream.

```
Admin.deleteTopic(String streamPathAndName, String topicName)
```

```
public void deleteTopicUtilFunction(String streamPathAndName, String
topicName) throws IOException{
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        streamAdmin.deleteTopic(streamPathAndName, topicName);
        streamAdmin.close();
}
```

Counting Topics

The `countTopics` API is used to count the number of topics in a stream. See the mapr streamanalyzer on page 5532 utility for a sample application that counts and queries topic messages.

```
Admin.countTopics(String streamPathAndName)
```

```
public int countTopicsUtilFunction(String streamPathAndName){
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);
        int count = streamAdmin.countTopics(streamPathAndName);
        streamAdmin.close();

        return count;
}
```

Using Timestamps on Streams and Topics

Provides a code example for using timestamps on HPE Ezmeral Data Fabric Streams streams and topics.

Passing Timestamp Value

The timestamp value can be passed as part of the `ProducerRecord`, for example:

```
ProducerRecord<String, String> producerRecord =
        new ProducerRecord<String, String>(topicName, partition, timestamp,
key, value);
```

NOTE: The timestamp value is retained if the timestamp type is `createtime`. If the timestamp type is `logappendtime`, then the timestamp value is ignored and instead the server timestamp is used.

Retrieving Timestamp Type

This example sets and retrieves the timestamp type. The following code example performs the following:

- Creates a stream with a default timestamp type of LogAppendTime.
- Creates a topic with a specific timestamp type of CreateTime.
- Retrieves the topics's timestamp type.

```
// Create stream with default timestamp type as "LogAppendTime"
// Create a topic with timestamp type as "CreateTime"
        Configuration conf = new Configuration();
        Admin streamAdmin = Streams.newAdmin(conf);

// Create a stream
        StreamDescriptor sDesc = Streams.newStreamDescriptor();
        sDesc.setDefaultTimestampType(TimestampType.LOG_APPEND_TIME);
        streamAdmin.createStream(streamName, sDesc);

// Create a topic
        TopicDescriptor tDesc = Streams.newTopicDescriptor();
        tDesc.setTimestampType(TimestampType.CREATE_TIME);
        streamAdmin.createTopic(streamName, topicName, tDesc);

// Get topic timestamp type
        TopicDescriptor rDesc = streamAdmin.getTopicDescriptor(streamName,
topicName);
        System.out.println(rDesc.getTimestampType().name);
```

Enabling Log Compaction

Provides a code example for using timestamps on HPE Ezmeral Data Fabric Streams streams and topics.

Log compaction is enabled through the HPE Ezmeral Data Fabric Streams `StreamDescriptor` interface with the `setCompact` method where the compact value is set to **true**. Additionally, use the `setDeleteRetentionMS` and `setMinCompactionLagMS` methods to set the time delay before compacting records and the time that deleted records are retained.

Configuration values include:

- compact - used to set log compaction at the stream-level.
- min.compaction.lag.ms - used to set a **minimum** time delay (milliseconds) before starting to compact records after they are written. Records won't get compacted until after this period. The setting gives consumers time to retrieve every record.
- delete.retention.ms - used to set the **minimum** time (milliseconds) that deleted records are retained.

NOTE: You can set not set log compaction when creating the stream; only when editing the stream configuration. The configuration parameters, `min.compaction.lag.ms` and `delete.retention.ms` can be set when both creating and editing streams.

Enabling Log Compaction

The following code example performs the following:

- Enables log compaction at the stream-level.
- Sets the minumum time delay before log compaction starts
- Set the minimum time that deleted record are retained.

```
// Creates a stream
// Sets log compaction on the stream
// Sets the minimum time for a message to stay uncompacted
// Sets the time that deleted records are retained.

(Admin streamAdmin = Streams.newAdmin(conf))
    StreamDescriptor streamDescriptor = Streams.newStreamDescriptor();
       streamDescriptor.setCompact(true);
       streamDescriptor.setDeleteRetentionMS(deleteRetentionMs);
    streamDescriptor.setMinCompactionLagMS(minCompactionLagMs);
       streamAdmin.editStream(streamName, streamDesc);
}
```

For More Information

See the following topics for more information:

- Log Compaction on page 780
- maprcli stream create on page 2368 and stream edit on page 2375
- Preparing Clusters for Log Compaction on page 1514

Enabling an Idempotent Producer

Describes how to enable an idempotent producer. Idempotence refers to exactly-once message delivery semantics.

last-updated: Jun 06, 2024

To enable idempotence, the `enable.idempotence` configuration must be set to **true**. When set, the retries configuration defaults to Integer.MAX_VALUE and the Acks configuration defaults to all.

The idempotence producer option is set by setting the `enable.idempotence` value of true passed through the `ProducerConfig` class.

Constant Field Values
`org.apache.kafka.clients.producer.ProducerConfig`

Modifier and Type	Constant Field	Value
`public static final java.lang.String`	`ENABLE_IDEMPOTENCE_CONFIG`	enable.idempotence

Example Code Snippet:

```
props.put(ProducerConfig.ENABLE_IDEMPOTENCE_CONFIG, true);
```

NOTE: The default is false, which retains at-least-once message delivery semantics.

TIP: There are no API changes for the Idempotent Producer functionality, so existing applications do not need to be modified except to enable the producer configuration property.

Example: Subscribing and Querying with Timestamps
This sample Java consumer application uses the `subscribe` API to subscribe to the input topics and queries offsets upon partition-assignment.

In the query, the `offsetsForTimes` API returns the earliest offset in a topic-partition with a timestamp greater than or equal to the input timestamp. The consumer then seeks to that offset if it is greater than the consumer's current position. Following this, the consumer polls for messages. If there are messages following that offset with timestamps earlier than the input timestamp, then those messages are skipped by the consumer.

```

    // poll and process the records.
    while (numRecords < kNumRecordsToProcess) {
      ConsumerRecords<String, String> records =
consumer.poll(kPollTimeout );
      for (ConsumerRecord<String, String> record : records) {
        // The offsetsForTimes API returns the earliest offset in a
topic-partition with a timestamp
        // greater than or equal to the input timestamp. There could be
messages following that offset
        // with timestamps lesser than the input timestamp. Let's skip such
messages.
        if (record.timestamp() < startTimestamp) {
          System.out.println("Skipping out of order record with key " +
record.key() +
                             " timestamp " + record.timestamp());
          continue;
        }
        numRecords++;
        System.out.println("record key " + record.key() +
                           "record timestamp " + record.timestamp() +
                           "record offset " + record.offset());
      }
    }
    consumer.close();
  }

  public static class SeekToTimeOnRebalance implements
ConsumerRebalanceListener {
    private Consumer<?, ?> consumer;
    private final Long startTimestamp;

    public SeekToTimeOnRebalance(Consumer<?, ?> consumer, Long
startTimestamp) {
      this.consumer = consumer;
      this.startTimestamp = startTimestamp;
    }

    @Override
    public void onPartitionsAssigned(Collection<TopicPartition> partitions)
{
      Map<TopicPartition, Long> timestampsToSearch = new HashMap<>();
      for (TopicPartition partition : partitions) {
        timestampsToSearch.put(partition,  startTimestamp);
      }
      // for each assigned partition, find the earliest offset in that
partition with a timestamp
      // greater than or equal to the input timestamp
      Map<TopicPartition, OffsetAndTimestamp> outOffsets =
```

```
consumer.offsetsForTimes(timestampsToSearch);
      for (TopicPartition partition : partitions) {
        Long seekOffset = outOffsets.get(partition).offset();
        Long currentPosition = consumer.position(partition);
        // seek to the offset returned by the offsetsForTimes API
        // if it is beyond the current position
        if (seekOffset.compareTo(currentPosition) > 0) {
          consumer.seek(partition, seekOffset);
        }
      }
    }

    @Override
    public void onPartitionsRevoked(Collection<TopicPartition> partitions) {
    }

  }

}
```

Querying Topic Messages
Describes how HPE Ezmeral Data Fabric Streams topic messages can be queried.

Time-based Querying

The **consumer.offsetsForTimes**API is used to get offsets in a topic-partition. This API takes in a `Map` of `TopicPartition` and timestamp. The offset is returned in an `OffsetAndTimestamp` object when `offsetsForTime` is called.

The following shows how the Map is constructed:

```
Long timestamp = 1522195205L;
TopicPartition topicPartition = new TopicPartition(topic,partition);

HashMap<TopicPartition, Long> offsetsForTimesMap = new
HashMap<TopicPartition, Long>();
offsetsForTimesMap.put(topicPartition, timestamp);

// Invocation to offsetsForTimes
Map<TopicPartition, OffsetAndTimestamp> offsetForTimesResultMap =
consumer.offsetsForTimes(offsetsForTimesMap);
```

Direct Querying

The `Streams` class is used to directly query topic messages. See the mapr streamanalyzer on page 5532 utility for a sample application that counts and queries topic messages.

- The `getMessageStore()` APIs are used to get the `DocumentStore` object which represents the underlying topic messages for a specified stream.
- The `DocumentStore.find()` APIs are used to query the messages that are in the `DocumentStore` object. While running `find()` on the returned DocumentStore object, message fields can be projected based on the specified field name.

NOTE: DocumentStore is a part of the open-source OJAI API.

The logical schema of each message is the same, where analytics applications can run queries on these fields. See Logical Schema of Messages on page 774 for more information.

```
{
        "_id":<STRING>,
```

```
        "topic":<STRING>,
        "partition":<SHORT>,
        "offset":<LONG>,
        "timestamp":<LONG>,
        "producer":<VARCHAR>,
        "key":<BINARY>,
        "value":<VARBINARY>
}
```

Apache Kafka Java APIs
HPE Ezmeral Data Fabric Streams supports these Apache Kafka Java APIs.

Javadoc

In HPE Ezmeral Data Fabric 7.0, Apache Kafka is supported.

EEP 8.1.0 supports Apache Kafka 2.6.1.

See the following APIs for detailed information:

- HPE Ezmeral Data Fabric Streams Java API Library
- Apache Kafka 2.6.1 APIs used with HPE Ezmeral Data Fabric Streams

NOTE: The Apache Kafka 2.1 APIs are also supported in Apache Kafka 2.6.1.

Admin APIs

The following Admin APIs, `org.apache.kafka.clients.admin` package, are applicable to HPE Ezmeral Data Fabric support of Apache Kafka.

NOTE: The AdminClient API options (CreateTopicsOptions, DeleteTopicsOptions, DescribeTopicsOptions, ListTopicsOptions, CreatePartitionsOptions, and DescribeTopicsOptions), are ignored. All of the methods assume that a topic belongs to the default stream unless a stream path is specified in the topic name.

If a default stream name is not specified and the topic path does not contain a stream name, the an exception is reported via the Result object. For example:

- If the topic name is specified as `topic1`, then the API assumes the full topic path as `/defaultStream:topic1`.
- If the topic name is specified as `/defaultStream:topic1`, then that will be the full topic path.

NOTE: The `AdminClient` default stream configuration parameter is `streams.admin.default.stream`. See Configuration Parameters on page 3562 for more information.

NOTE: For a complete list of supported APIs, see Apache Kafka 2.1 APIs used with HPE Ezmeral Data Fabric Event Data Streams

Consumer APIs

The following Consumer APIs, `org.apache.kafka.clients.consumer` package, are applicable to HPE Ezmeral Data Fabric support of Apache Kafka 2.1 and 2.6.1. .

last-updated: Jun 06, 2024

Table

Modifier and Type	Method
long	timestamp()
long	timestamptype()

Table

Modifier and Type	Method
void	pause(Collection<TopicPartition> partitions)
void	resume(Collection<TopicPartition>partitions)
void	seekToBeginning(Collection<TopicPartition>)
void	seekToEnd(Collection<TopicPartition>)
void	subscribe(Collection<String> topics);
void	subscribe(Collection<String> topics, ConsumerRebalanceListener)
void	assign(Collection<TopicPartition> partitions)
java.util.Map<TopicPartition,OffsetAndTimestamp>	offsetsForTimes(java.util.Map<TopicPartition,java.lang.Long> timestampsToSearch)
java.util.Map<TopicPartition,java.lang.Long>	beginningOffsets(Collection<TopicPartition>)
java.util.Map<TopicPartition,java.lang.Long>	endOffsets(Collection<TopicPartition> partitions)
ConsumerRecords<K,V>	poll(long timeout)
void	commitSync()
void	commitAsync()

The following consumer interface and classes are applicable to HPE Ezmeral Data Fabric support of Apache Kafka.

- org.apache.kafka.clients.consumer.ConsumerConfig
- org.apache.kafka.clients.consumer.ConsumerRebalanceCallback (interface)
- org.apache.kafka.clients.consumer.ConsumerRecord<K,V>
- org.apache.kafka.clients.consumer.ConsumerRecords<K,V>
- org.apache.kafka.clients.consumer.KafkaConsumer<K, V> implements Consumer<K, V>

NOTE: For a complete list of supported APIs, see Apache Kafka 2.1 APIs used with HPE Ezmeral Data Fabric Event Data Streams

Producer APIs

The following producer interface and classes, `org.apache.kafka.clients.producer` package, are applicable to HPE Ezmeral Data Fabric support of Apache Kafka 2.1. .

last-updated: Jun 06, 2024

Table

Modifier and Type	Method
java.util.concurrent.Future<RecordMetadata>	send(ProducerRecord<K,V> record)
void	flush()
void	close()

The following producer interface and classes are applicable to HPE Ezmeral Data Fabric support of Apache Kafka.

- org.apache.kafka.clients.producer.Callback (Interface)
- org.apache.kafka.clients.producer.KafkaProducer<K,V>
- org.apache.kafka.clients.producer.ProducerConfig
- org.apache.kafka.clients.producer.ProducerRecord<K,V>
- org.apache.kafka.clients.producer.RecordMetadata

NOTE: For a complete list of supported APIs, see Apache Kafka 2.1 APIs used with HPE Ezmeral Data Fabric Event Data Streams

Common APIs

The following common APIs, `org.apache.kafka.clients.common` packages, are applicable toHPE Ezmeral Data Fabric support of Apache Kafka 2.1. .

Table

Modifier and Type	Method
java.lang.String	key()
byte[]	value()

The following APIs are applicable to HPE Ezmeral Data Fabric support for Apache Kafka.

- org.apache.kafka.common.PartitionInfo

  Supported methods in PartitionInfo:

  - int partition()
  - java.lang.String topic()
  - java.lang.String toString()
- org.apache.kafka.common.serialization.Serializer<T> (Interface)
- org.apache.kafka.common.serialization.Deserializer<T> (interface)
- org.apache.kafka.common.TopicPartition

NOTE: For a complete list of supported APIs, see Apache Kafka 2.1 APIs used with HPE Ezmeral Data Fabric Event Data Streams

Configuration Parameters

This topic describes configuration parameters that are either specific to HPE Ezmeral Data Fabric Streams or supported from Apache Kafka.

last-updated: Jun 06, 2024

AdminClient

Table

Parameter	Description
`streams.admin.default.stream`	This parameter, when set during creation of the AdminClient instance, ensures that the specified stream is using the the AdminClient instance for all administrative operations. Syntax: `/mapr/<cluster name>/<volume name>/<stream name>`
`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 120000 Minimum: 30000 **NOTE:** Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout` For producer and consumer applications, make sure the `streams.rpc.timeout.ms` configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

Consumer

Table

Parameter	Description
`streams.consumer.buffer.memory`	Specifies how much memory to use for caching pre-fetched messages. Messages that are in subscribed topics and partitions are pre-fetched and cached to improve performance. Default 64MB
`streams.consumer.default.stream`	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream.
`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if a soft mount is configured (fs.mapr.hardmount is set to false). Default: 305000 Minimum: 300000 For producer and consumer applications, make sure the `streams.rpc.timeout.ms` configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

Table

Parameter	Description
`auto.commit.interval.ms`	The frequency in milliseconds that the offsets are committed. Default: 1000ms

last-updated: Jun 06, 2024

Table (Continued)

Parameter	Description
`auto.offset.reset`	Specifies what HPE Ezmeral Data Fabric Streams should do when there is no initial offset, such as when a consumer starts reading from a partition. Default: latest **`earliest`** Reset the offset to the offset of the earliest message in the partition. **`latest`** Reset the offset to the offset of the latest message in the partition.
`enable.auto.commit`	If true, periodically commits the highest offsets of the messages fetched by the consumer in all of the partitions for the topics that the consumer is subscribed to. Default: true
`fetch.min.bytes`	The minimum amount of data the server should return for a fetch request. If insufficient data is available, the server will wait for this minimum amount of data to accumulate before answering the request. This minimum applies to the totality of what a consumer has subscribed to. Works in conjunction with the timeout interval that is specified in the poll function. If the minimum number of bytes is not reached by the time that the interval expires, the poll returns with nothing. For example, suppose the value is set to 6 bytes and the timeout on a poll is set to 100ms. If there are 5 bytes available and no further bytes come in before the 100ms expire, the poll returns with nothing. Default: 1 byte
`fetch.max.bytes`	The maximum amount of data the server should return for a fetch request. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress. **NOTE:** This parameter is new as of MapR 6.0.1.
`fetch.max.wait.ms`	The maximum amount of time the HPE Ezmeral Data Fabric Streams server will block before answering the fetch request if there isn't sufficient data to satisfy the requirement given by `fetch.min.bytes`.
`group.id`	A string 2457 up to bytes long that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group ID, multiple consumer processes indicate that they are all part of the same consumer group. Putting consumers into groups provides benefits that are described in Consumer Groups. It is possible for a single consumer to be in a group.
`max.poll.records`	Places an upper bound on the number of records returned from each call. **NOTE:** This parameter is new as of MapR 6.0.1.

last-updated: Jun 06, 2024

Table (Continued)

Parameter	Description
`max.partition.fetch.bytes`	The number of bytes of message data to attempt to fetch for each partition in each poll request. These bytes will be read into memory for each partition, so this parameter helps control the memory that the consumer uses. Default: 64KB The size of the poll request must be at least as large as the maximum message size that the server allows or else it is possible for producers to send messages that are larger than the consumer can fetch. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress. **NOTE:** This is a behavior change as of MapR 6.0.1.

Producer

Table

Parameter	Description
`streams.buffer.max.time.ms`	Messages are buffered in the producer for at most the specified time. A thread will flush all the messages that have been buffered for more than the time specified. Default: 3 * 1000 msec create default stream
`streams.parallel.flushers.per.partition`	If enabled, producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order. Default: true create default stream
`streams.producer.default.stream`	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. Syntax: `/mapr/<cluster name>/<volume name>/<stream name>` create default stream
`fs.mapr.hardmount`	Specifies whether to use a hard mount or a soft mount for connections to the MapR Streams server. The default is to use a hard mount and the value is `true`. If a value for this parameter is set in the `core-site.xml` file, the value in that file is ignored. create default stream

last-updated: Jun 06, 2024

Table (Continued)

Parameter	Description
`fs.mapr.rpc.timeout`	Specifies the length of time in seconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if the configuration parameter `fs.mapr.hardmount` is set to false. Default: 300. Minimum value: 30. **NOTE:** Applicable to MapR 6.0.0 and earlier. As of MapR 6.0.1, use `streams.mapr.timeout.ms`. If a soft mount is used, the time expires while a producer waits for a response from the HPE Ezmeral Data Fabric Streams server, and the producer used the `KafkaProducer.send(ProducerRecord<K,V> record, Callback callback)` method, the callback is invoked with the error `EAGAIN`, which means "Resource temporarily unavailable." create default stream
`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 30000 Minimum: 30000 For producer and consumer applications, make sure the `streams.rpc.timeout.ms` configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

Table

Parameter	Description
`buffer.memory`	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are generated faster than they can be delivered to the server the producer will block. Default: 33554432
`client.id`	Producers can tag records with a client ID that identifies the producer. Consumers can then be aware of which producer sent a message or set of messages. Apache Drill or other analytic tools querying messages can include this ID in the filters for their queries. Default: No client ID.
`metadata.max.age.ms`	The producer generally refreshes the topic metadata from the server when there is a failure. It will also poll for this data regularly. Default: 300 * 1000 msec

Compiling and Running HPE Ezmeral Data Fabric Streams Java Apps

For producer and consumer applications that use the HPE Ezmeral Data Fabric Streams Java API, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

Compile and Determine Dependencies

See HPE Ezmeral Data Fabric Streams Streams Sample Programs on GitHub for an example pom.xml file.

last-updated: Jun 06, 2024

1. Add MapR's Maven repository to your `pom.xml` file, if it is not already added:

```
<repositories>
    <repository>
      <id>mapr-releases</id>
      <url>https://repository.mapr.com/nexus/content/repositories/
releases</url>
      <snapshots><enabled>true</enabled></snapshots>
      <releases><enabled>true</enabled></releases>
    </repository>
</repositories>
```

2. Add a dependency to the MapR Streams Java client (kakfa-clients) project:

```
<dependency>
      <groupId>org.apache.kafka</groupId>
      <artifactId>kafka-clients</artifactId>
      <version><version selected from the repository></version>
</dependency>
```

NOTE: The kafka-clients version mentioned above is an example. The actual version that your application requires is based on the current EEP and MapR version that you are running. The versions are listed in the following location: https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/kafka/kafka-clients/

3. Add a dependency to the MapR Streams project:

```
<dependency>
      <groupId>com.mapr.streams</groupId>
      <artifactId>mapr-streams</artifactId>
      <version><version selected from the repository></version>
</dependency>
```

NOTE: The MapR Streams project version mentioned above is an example. The actual version that your application requires is based on the current EEP and MapR version that you are running. The versions are listed in the following location:https://repository.mapr.com/nexus/content/groups/mapr-public/com/mapr/streams/mapr-streams/

4. Use Maven to compile the application and resolve dependencies. For example, you can run `mvn clean package`.

Run the Application

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see Using the File System JAR to Connect to the Cluster on page 3151.

When the cluster is secure, the node must also have a mapr ticket configured for the user that runs the application.

You can use the following command to launch HPE Ezmeral Data Fabric Streams applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

Migrating Apache Kafka Java Applications to HPE Ezmeral Data Fabric Streams
There are only two steps that you need to follow to migrate applications written with the Apache Kafka Java API to HPE Ezmeral Data Fabric Streams.

About this task
The following steps assume that migration is from either:

- Apache Kafka 2.6.1 to HPE Ezmeral Data Fabric Streams 6.2 or higher
- Apache Kafka 2.1.1 to HPE Ezmeral Data Fabric Streams 6.2 or higher
- Apache Kafka 1.1 to HPE Ezmeral Data Fabric Streams 6.1 or higher
- Apache Kafka 1.0 to HPE Ezmeral Data Fabric Streams 6.0.1 or higher
- Apache Kafka 0.9.0 to HPE Ezmeral Data Fabric Streams 6.0.0 or earlier

IMPORTANT: For information on backward compatibility, see HPE Ezmeral Data Fabric Streams Java API Library on page 3548

Procedure

1. Change the names of topics to include the path and name of the MapR Stream stream in which the topic is located.

   Here is the syntax to use:

   ```
   /<path and name of stream>:<name of topic>
   ```

   For example, you might have a stream in a MapR cluster that is named `stream_A`, and the stream might be in a volume named `IoT` and in a directory named `automobile_sensors`. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this:

   ```
   /mapr/IoT/automobile_sensors/stream_A:<name of topic>
   ```

2. If a producer application uses the Kafka interface Partitioner to compute which partitions to publish messages to, revise the application so that it uses the Kafka StreamsPartitioner interface instead.

Differences between HPE Ezmeral Data Fabric Streams and Apache Kafka Configuration
Describes the HPE Ezmeral Data Fabric Streams supportability of Apache Kafka configuration parameters for producers and consumers.

last-updated: Jun 06, 2024

Kafka Producer

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`bootstrap.servers`	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form `host1:port1,host2:port2,...` Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).	No. Cluster details are discovered from the file `mapr-clusters.conf`.
`key.serializer`	`Serializer` class for key that implements the `Serializer` interface.	Yes
`value.serializer`	`Serializer` class for value that implements the `Serializer` interface.	Yes

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`acks`	The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common:	Ignored, all writes in HPE Ezmeral Data Fabric Streams are synchronous, and number of replicas is determined at the volume level, with a default of 3.
	`acks=0` If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won't generally know of any failures). The offset given back for each record will always be set to -1.	
	`acks=1` This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost.	
	`acks=all` This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee.	
`buffer.memory`	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server the producer will either block or throw an exception based on the preference specified by `block.on.buffer.full`.	Yes
	This setting should correspond roughly to the total memory the producer will use, but is not a hard bound since not all memory the producer uses is used for buffering. Some additional memory will be used for compression (if compression is enabled) as well as for maintaining in-flight requests.	

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`compression.type`	The compression type for all data generated by the producer. The default is none (i.e. no compression). Valid values are `none`, `gzip`, `snappy`, or `lz4`. Compression is of full batches of data, so the efficacy of batching will also impact the compression ratio (more batching means better compression).	Ignored. Compression is configured per stream.
`retries`	Setting a value greater than zero will cause the client to resend any record whose send fails with a potentially transient error. Note that this retry is no different than if the client resent the record upon receiving the error. Allowing retries will potentially change the ordering of records because if two records are sent to a single partition, and the first fails and is retried but the second succeeds, then the second record may appear first.	Ignored. HPE Ezmeral Data Fabric Streams always does automatic retries on transient errors.
`ssl.key.password`	The password of the private key in the key store file. This is optional for client.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.keystore.location`	The location of the key store file. This is optional for client and can be used for two-way authentication for client.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.keystore.password`	The store password for the key store file.This is optional for client and only needed if `ssl.keystore.location` is configured.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.truststore.location`	The location of the trust store file.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.truststore.password`	The password for the trust store file.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.

last-updated: Jun 06, 2024

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`batch.size`	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. This configuration controls the default batch size in bytes.	Ignored. HPE Ezmeral Data Fabric always batches records for optimal performance.
	No attempt will be made to batch records larger than this size.	
	Requests sent to brokers will contain multiple batches, one for each partition with data available to be sent.	
	A small batch size will make batching less common and may reduce throughput (a batch size of zero will disable batching entirely). A very large batch size may use memory a bit more wastefully as we will always allocate a buffer of the specified batch size in anticipation of additional records.	
`client.id`	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just ip/port by allowing a logical application name to be included in server-side request logging.	Yes
`connections.max.idle.ms`	Close idle connections after the number of milliseconds specified by this config.	Ignored.

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`linger.ms`	The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay —that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle's algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get batch.size worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will 'linger' for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting linger.ms=5, for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absense of load.	Ignored.
`max.block.ms`	The configuration controls how long {@link KafkaProducer#send()} and {@link KafkaProducer#partitionsFor} will block. These methods can be blocked for multiple reasons. For e.g: buffer full, metadata unavailable.This configuration imposes maximum limit on the total time spent in fetching metadata, serialization of key and value, partitioning and allocation of buffer memory when doing a send(). In case of partitionsFor(), this configuration imposes a maximum time threshold on waiting for metadata	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`max.request.size`	The maximum size of a request. This is also effectively a cap on the maximum record size. Note that the server has its own cap on record size which may be different from this. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.	Ignored.

last-updated: Jun 06, 2024

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`partitioner.class`	Partitioner class that implements the Partitioner interface.	Use the Kafka StreamsPartitioner interface.
`receive.buffer.bytes`	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	Ignored.
`request.timeout.ms`	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`sasl.kerberos.service.name`	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`security.protocol`	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`send.buffer.bytes`	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	Ignored.
`ssl.enabled.protocols`	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.	Ignored.
`ssl.keystore.type`	The file format of the key store file. This is optional for client. Default value is JKS	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.protocol`	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.provider`	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.truststore.type`	The file format of the trust store file. Default value is JKS.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.

last-updated: Jun 06, 2024

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`timeout.ms`	The configuration controls the maximum amount of time the server will wait for acknowledgments from followers to meet the acknowledgment requirements the producer has specified with the acks configuration. If the requested number of acknowledgments are not met when the timeout elapses an error will be returned. This timeout is measured on the server side and does not include the network latency of the request.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`block.on.buffer.full`	When our memory buffer is exhausted we must either stop accepting new records (block) or throw errors. By default this setting is true and we block, however in some scenarios blocking is not desirable and it is better to immediately give an error. Setting this to false will accomplish that: the producer will throw a BufferExhaustedException if a recrord is sent and the buffer space is full.	Ignored.
`max.in.flight.requests.per.connection`	The maximum number of unacknowledged requests the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries (i.e., if retries are enabled).	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.parallel.flushers.per.partition`
`metadata.fetch.timeout.ms`	The first time data is sent to a topic we must fetch metadata about that topic to know which servers host the topic's partitions. This fetch to succeed before throwing an exception back to the client.	Ignored.
`metadata.max.age.ms`	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	Yes
`metric.reporters`	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	No
`metrics.num.samples`	The number of samples maintained to compute metrics.	No.
`metrics.sample.window.ms`	The number of samples maintained to compute metrics.	No.

Name	Description	Supported for producers in HPE Ezmeral Data Fabric Streams?
`reconnect.backoff.ms`	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`retry.backoff.ms`	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
`sasl.kerberos.kinit.cmd`	Kerberos kinit command path. Default is /usr/bin/kinit	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`sasl.kerberos.min.time.before.relogin`	Login thread sleep time between refresh attempts.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`sasl.kerberos.ticket.renew.jitter`	Percentage of random jitter added to the renewal time.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`sasl.kerberos.ticket.renew.window.factor`	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.cipher.suites`	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol.By default all the available cipher suites are supported.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.endpoint.identification.algorithm`	The endpoint identification algorithm to validate server hostname using server certificate.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.keymanager.algorithm`	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
`ssl.trustmanager.algorithm`	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.

last-updated: Jun 06, 2024

Kafka Consumer

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
bootstrap.servers	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form host1:port1,host2:port2,.... Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).	No. Cluster details are discovered from the file `mapr-clusters.conf`.
key.deserializer	Deserializer class for key that implements the Deserializer interface.	Yes
value.deserializer	Deserializer class for value that implements the Deserializer interface.	Yes
fetch.min.bytes	The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request. The default setting of 1 byte means that fetch requests are answered as soon as a single byte of data is available or the fetch request times out waiting for data to arrive. Setting this to something greater than 1 will cause the server to wait for larger amounts of data to accumulate which can improve server throughput a bit at the cost of some additional latency.	Yes
fetch.max.bytes	The maximum amount of data the server should return for a fetch request. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress.  **NOTE:** This is new as of MapR 6.0.1.	Yes, as of MapR 6.0.1.
group.id	A unique string that identifies the consumer group this consumer belongs to. This property is required if the consumer uses either the group management functionality by using subscribe(topic) or the Kafka-based offset management strategy.	Yes

last-updated: Jun 06, 2024

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
heartbeat.interval.ms	The expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than session.timeout.ms, but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	No
max.poll.records	Places an upper bound on the number of records returned from each call.  **NOTE:** This parameter is new as of MapR 6.0.1.	Yes, as of MapR 6.0.1.
max.partition.fetch.bytes	The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be #partitions * max.partition.fetch.bytes. This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress.  **NOTE:** This is a behavior change as of MapR 6.0.1.	Yes
session.timeout.ms	The timeout used to detect failures when using Kafka's group management facilities.	Ignored
ssl.key.password	The password of the private key in the key store file. This is optional for client.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.keystore.location	The location of the key store file. This is optional for client and can be used for two-way authentication for client.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.

last-updated: Jun 06, 2024

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
ssl.keystore.password	The store password for the key store file.This is optional for client and only needed if ssl.keystore.location is configured.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.truststore.location	The location of the trust store file.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.truststore.password	The password for the trust store file.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
auto.offset.reset	What to do when there is no initial offset in Kafka or if the current offset does not exist any more on the server (e.g. because that data has been deleted): **earliest** automatically reset the offset to the earliest offset **latest** automatically reset the offset to the latest offset **none** throw exception to the consumer if no previous offset is found for the consumer's group **anything else** throw exception to the consumer.	Yes
connections.max.idle.ms	Close idle connections after the number of milliseconds specified by this config.	Ignored
enable.auto.commit	If true the consumer's offset will be periodically committed in the background.	Yes
partition.assignment.strategy	The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used	Ignored. HPE Ezmeral Data Fabric Streams distributes partitions equally among the consumers in a group.
receive.buffer.bytes	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	Ignored.

last-updated: Jun 06, 2024

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
request.timeout.ms	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
sasl.kerberos.service.name	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
security.protocol	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
send.buffer.bytes	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	Ignored.
ssl.enabled.protocols	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.keystore.type	The file format of the key store file. This is optional for client. Default value is JKS	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.protocol	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.provider	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.truststore.type	The file format of the trust store file. Default value is JKS.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
auto.commit.interval.ms	The frequency in milliseconds that the consumer offsets are auto-committed to Kafka if enable.auto.commit is set to true.	Yes

last-updated: Jun 06, 2024

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
check.crcs	Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.	Ignored. HPE Ezmeral Data Fabric Streams always does end-to-end crc computation and verification.
client.id	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just ip/port by allowing a logical application name to be included in server-side request logging.	Yes
fetch.max.wait.ms	The maximum amount of time the server will block before answering the fetch request if there isn't sufficient data to immediately satisfy the requirement given by fetch.min.bytes.	No
metadata.max.age.ms	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	Yes
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	No
metrics.num.samples	The number of samples maintained to compute metrics.	No
metrics.sample.window.ms	The number of samples maintained to compute metrics.	No
reconnect.backoff.ms	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
retry.backoff.ms	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	Ignored. HPE Ezmeral Data Fabric Streams has a similar parameter: `streams.rpc.timeout.ms`
sasl.kerberos.kinit.cmd	Kerberos kinit command path. Default is /usr/bin/kinit	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.

last-updated: Jun 06, 2024

Name	Description	Supported for consumers in HPE Ezmeral Data Fabric Streams?
sasl.kerberos.min.time.before.relogin	Login thread sleep time between refresh attempts.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
sasl.kerberos.ticket.renew.jitter	Percentage of random jitter added to the renewal time.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
sasl.kerberos.ticket.renew.window.factor	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.cipher.suites	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol.By default all the available cipher suites are supported.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate server hostname using server certificate.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.keymanager.algorithm	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.
ssl.trustmanager.algorithm	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Ezmeral Data Fabric security. See Security on page 830 for more information.

HPE Ezmeral Data Fabric Streams Parameters

The following HPE Ezmeral Data Fabric Streams parameters are for the Admin API.

Table

HPE Ezmeral Data Fabric Streams Parameter	Description	Kafka Parameter Replaced

`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 120000 Minimum: 30000
	
	NOTE: Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout`
		`request.timeout.ms`
		`reconnect.backoff.ms`
		`retry.backoff.ms`

The following HPE Ezmeral Data Fabric Streams parameter are for the Producer API:

Table

HPE Ezmeral Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
`streams.buffer.max.time.ms`	Messages are buffered in the producer for at most the specified time. A thread will flush all the messages that have been buffered for more than the time specified. Default: 3 * 1000 msec	`linger.ms`
`streams.parallel.flushers.per.partition`	If enabled, producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order. Default: true	`max.in.flight.requests.per.connection`
`streams.partitioner.class`	The class that implements the `StreamsPartitioner` interface. This interface lets you write custom algorithms for determining which topic and partition to use for messages that match specific criteria. Use this configuration parameter only for producers that are written in Java.	Not applicable.

last-updated: Jun 06, 2024

Table (Continued)

HPE Ezmeral Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
`streams.producer.default.stream`	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>/<topic> However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Ezmeral Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.	Not applicable.

`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 30000 Minimum: 30000
	If the time expires while a producer waits for a response from the HPE Ezmeral Data Fabric Streams server, and the producer used the `KafkaProducer.send(ProducerRecord<K,V> record, Callback callback)` method, the callback is invoked with the error `EAGAIN`, which means "Resource temporarily unavailable."
	NOTE: Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout`
		`max.block.ms`
		`request.timeout.ms`
		`timeout.ms`
		`reconnect.backoff.ms`
		`retry.backoff.ms`

The following HPE Ezmeral Data Fabric Streams parameters are for the Consumer API:

last-updated: Jun 06, 2024

Table

HPE Ezmeral Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
`streams.consumer.default.stream`	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. This default value is also used for the KafkaConsumer.listTopics() method.	Not applicable.

`streams.rpc.timeout.ms`	Specifies the length of time in milliseconds to wait for a response from the HPE Ezmeral Data Fabric Streams server if a soft mount is configured (fs.mapr.hardmount is set to false). Default: 305000 Minimum: 300000
	NOTE: Applicable as of MapR 6.0.1, is used instead of `fs.mapr.rpc.timeout`
		`request.timeout.ms`
		`reconnect.backoff.ms`
		`retry.backoff.ms`

HPE Ezmeral Data Fabric Streams C Applications

You can develop C applications for HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams C Client is available in Ecosystem Pack (EEP) 3.0 and later.

The following Apache Kafka librdkafka versions are supported:

Table

Core release	EEP Release	Kafka librdkafka version
As of 6.0.1	As of 5.0	0.11.3
As of 5.2.1 through 6.0.0	As of 3.0	0.9.0

The HPE Ezmeral Data Fabric Streams C Client supports a majority of the librdkafka C APIs plus additional configuration properties that are available only with HPE Ezmeral Data Fabric Streams. When developing applications for HPE Ezmeral Data Fabric Streams or migrating Kafka applications to HPE Ezmeral Data Fabric Streams, see the list of librdkafka APIs Supported by HPE Ezmeral Data Fabric Streams C Client on page 3601 which also describes API behavior. Reference rdkafka.h for API signatures.

When developing and running HPE Ezmeral Data Fabric Streams C applications, note the following:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- As of HPE Ezmeral Data Fabric 6.0, the HPE Ezmeral Data Fabric Streams offset values start at 0.
- HPE Ezmeral Data Fabric Security is supported. Kafka application-level security is not supported. See Security on page 830.
- User impersonation is not supported.

CAUTION: As of HPE Ezmeral Data Fabric 6.1, the mapr-core package has a dependency on mapr-librdkafka. If the mapr-librdkafka package is installed, do not remove it manually. Doing so could result in the removal of HPE Ezmeral Data Fabric core packages, rendering the node unusable.

last-updated: Jun 06, 2024

Configuring the HPE Ezmeral Data Fabric Streams C Client

After installing the HPE Ezmeral Data Fabric Client and before developing applications, you must configure your client C library by setting the library path.

Linux

For Linux installations, add `/opt/mapr/lib` to the end of LD_LIBRARY_PATH.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib
```

IMPORTANT: For HPE Ezmeral Data Fabric 6.0.1, the libjvm.so configuration is *not* required.

For HPE Ezmeral Data Fabric 6.0.0 and earlier, add the /opt/mapr/lib *and the path to the directory that contains libjvm.so* to the end of LD_LIBRARY_PATH.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/
lib:<path_to_libjvm.so_directory>
```

The location of the libjvm.so differs based on where you installed Java. You can use `find / -name libjvm*` to determine the file location. For example, if the libjvm.so file is in the following location:

```
/usr/lib/jvm/java-7-openjdk-amd64/jre/lib/amd64/server/libjvm.so
```

Then, you set the library path like this:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib:/usr/lib/jvm/
java-7-openjdk-amd64/jre/lib/amd64/server/
```

Mac

For Mac installations, add `/opt/mapr/lib` to the end of DYLD_LIBRARY_PATH.

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib
```

IMPORTANT: For HPE Ezmeral Data Fabric 6.0.1, the libjvm.so configuration is *not* required.

For HPE Ezmeral Data Fabric 6.0.0 and earlier, add /opt/mapr/lib *and the path to the directory that contains libjvm.dylib* to the end of DYLD_LIBRARY_PATH.

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/
lib:<path_to_libjvm.dylib_directory>
```

The location of the libjvm.dylib differs based on where you installed Java. You can use `find / -name libjvm*` to determine the file location. For example, if the libjvm.dylib file is in the following location:

```
/Library/Java/JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/
Home/jre/lib/server/libjvm.dylib
```

Then, you set the library path like this:

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib:/Library/Java/
JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/Home/jre/lib/server
```

last-updated: Jun 06, 2024

Windows

NOTE: As of HPE Ezmeral Data Fabric 6.0.1, the HPE Ezmeral Data Fabric C client is available on Windows.

For Windows installations, no additional configuration is required. Link your application and run your programs against the HPE Ezmeral Data Fabric Client dynampic link libraries (dll) located at: `C:\opt\mapr\lib`. The corresponding librdkafka header is `C:\opt\mapr\include\librdkafka`.

Developing a HPE Ezmeral Data Fabric Streams C Application

This topic includes basic information about how to develop a HPE Ezmeral Data Fabric Streams C application. Sample applications are provided.

Before you Begin

Confirm that your environment meets the following requirements:

- The HPE Ezmeral Data Fabric cluster version is 5.2.1 or greater.
- HPE Ezmeral Data Fabric core client (mapr-client) packagei s installed on the node and it is configured to access the cluster. Or, it is a HPE Ezmeral Data Fabric cluster node. See Installing the Data Fabric Client (Non-FIPS) on page 404 for more information.
- The HPE Ezmeral Data Fabric Streams C Client is installed and configured on the node. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.
- GNU Compiler Collection (GCC) is installed on the node.

Creating, Compiling and Running C Apps

The following sections describes how to create a producer and consumer in C, compile the source code, generate executables, and run the applications.

Create Producer

This topic describes how to create a HPE Ezmeral Data Fabric Streams streams producer in C. While the code to generate a HPE Ezmeral Data Fabric Streams stream producer varies depending on the use case, in general, the producer code should contain the following:

1. Include the rdkafka.h header file (/opt/mapr/include/librdkafka/rdkafka.h)
2. Use `rd_kafka_conf_new()` to create the producer configuration.
3. Use `rd_kafka_new ()` to create the producer handle.
4. Use `rd_kafka_topic_conf_new()` to create the topic configuration.
5. Use `rd_kafka_topic_new ()` to create a topic handle for the producer.
6. Use `rd_kafka_produce()` to produce messages.
7. Optionally, use `rd_kafka_poll()`to poll for callbacks. This is useful to see if there are messages that have yet to be sent to the server.
8. Use `rd_kafka_topic_destroy ()` to destroy the topic handle destroy
9. Use `rd_kafka_destroy ()` to destroy the producer handle.

NOTE: For more details on the APIs, see Supported APIs for HPE Ezmeral Data Fabric Streams C Client and rdkafka.h on page 3682

For example, the following source code produces 5 messages to topic /MapR_Streams:MapR-Topic1:

```
/*
 * This file contains the producer function.
 *
 */

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <rdkafka.h>
#include <errno.h>

/* msgDeliveryCB: Is the delivery callback.
 * The delivery report callback will be called once for each message

Create Consumer

This topic describes how to create a HPE Ezmeral Data Fabric Streams streams consumer in C. While the code to generate a HPE Ezmeral Data Fabric Streams stream consumer varies depends on the use case, in general, the consumer code should contain the following:

1. Include the rdkafka.h header file (/opt/mapr/include/librdkafka/rdkafka.h).

last-updated: Jun 06, 2024

2. Use `rd_kafka_conf_new()` to create the consumer configuration.
3. Use `rd_kafka_conf_set()` to set the configuration parameters. For this API, you must set the "group.id."
4. Use `rd_kafka_new ()` to create the consumer handle.
5. Use `rd_kafka_subscribe()` or `rd_kafka_assign()` to specify which topics to consume.
6. Use `rd_kafka_consumer_poll()` to poll for messages that are ready to be consumed.
7. Use `rd_kafka_consumer_close()` to perform auto commits and prepare to destroy the consumer handle.
8. Use `rd_kafka_destroy ()` to destroy the consumer handle.

For example, the following source code consumes 5 messages from topic /MapR_Streams:MapR-Topic1:

```
/*
 * This file contains the consumer function.
 *
 */

#include <stdio.h>
#include <stdlib.h>
#include <rdkafka.h>
#include <string.h>

/*
 * Method      : int consumer(int expected_nummsgs, const char
*fullTopicName)
 * Description : This is a simple consumer method. In this method the
consumer
 *               consumes messages from a topic.
 */

int consumer(int expected_nummsgs, const char *fullTopicName) {
    printf("*********  CONSUMER START  *********\n");
    rd_kafka_t *consHndle;
    rd_kafka_conf_t *consCfg;
    rd_kafka_topic_conf_t *consTopicCfg;
    char errstr[1000];
    rd_kafka_resp_err_t errCode;

    printf("Create new consumer configuration object\n");
    /*
    * rd_kafka_conf_new(): This API creates default rd_kafka_conf_t object
to
    * be passed at the time of consumer object creation using rd_kafka_new
call.
    */
    consCfg = rd_kafka_conf_new();
    if(consCfg == NULL) {
        printf("Failed to create consumer conf\n");
        return(EXIT_FAILURE);
    }
    /*
    * rd_kafka_conf_set(): This API is used to set config parameters in the
    * rd_kafka_conf_t object. group.id Must be set for all the consumers.
    * All changes to the consCfg must be done before creating consumer
object.
    */
```

```
    if(RD_KAFKA_CONF_OK != rd_kafka_conf_set(consCfg,
                      "group.id", "consumerGroup",

  }
}
```

NOTE: For more details on the APIs, see Supported APIs for HPE Ezmeral Data Fabric Streams C Client and rdkafka.h on page 3682

Compile the Apps

This topic describes how to compile HPE Ezmeral Data Fabric Streams streams producers and consumers in C. When you compile a HPE Ezmeral Data Fabric Streams C application, you must link it with the librdkafka library in the /opt/mapr/lib/ library path and include the header file directory to ensure that your application references the header file included with HPE Ezmeral Data Fabric Streams C Client.

IMPORTANT: For MapR 6.0.0 and earlier, When you compile a HPE Ezmeral Data Fabric Streams C application, you must link it with the librdkafka library in the /opt/mapr/lib/ library path, *the libjvm library*, and include the header file directory to ensure that your application references the header file included with HPE Ezmeral Data Fabric Streams C Client.

The following steps compile the source code and generate executables in the same directory as the Makefile. For example, in the **librdkafka_example** directory, the `consumer` and `producer` executables are generated from the producer.c and consumer.c source files.

1. On your node, create a directory. For example: **librdkafka_example**.
2. In your directory (**librdkafka_example**), create a producer application. For example, if you are using the provided sample producer application:
   a. Create a file named producer.c.
   b. Copy the contents of the sample producer application into that file.
3. In your directory (**librdkafka_example**), create a consumer application. For example, if you are using the provided sample consumer application:
   a. Create a file named consumer.c.
   b. Copy the contents of the sample consumer application into that file.

4. In your directory (**librdkafka_example**), create a file named Makefile with the following content:

```
CC= g++
HEADERDIR=/opt/mapr/include/librdkafka/
CCFLAGS= -Wall -I$(HEADERDIR) -g -std=c99

export LD_LIBRARY_PATH=/opt/mapr/lib

LIBDIR= /opt/mapr/lib/
%.o: %.c
    gcc $(CCFLAGS) -c $<

consumer: consumer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

producer: producer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

all: consumer producer

clean:
    /bin/rm -f *.o consumer producer
```

IMPORTANT: For MapR 6.0.0 and earlier, use the following Makefile:

```
CC= g++
HEADERDIR=/opt/mapr/include/librdkafka/
CCFLAGS= -Wall -I$(HEADERDIR) -g -std=c99

#Edit JAVA_HOME to be appropriate for your environment
JAVA_HOME=/usr/lib/jvm/java-7-openjdk-amd64/
export LD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/amd64/
server

LIBDIR= /opt/mapr/lib/
%.o: %.c
    gcc $(CCFLAGS) -c $<

consumer: consumer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

producer: producer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

all: consumer producer

clean:
    /bin/rm -f *.o consumer producer
```

5. Complete the following edits to the Makefile:

   For Mac users, locate the following line of code:

```
export LD_LIBRARY_PATH=/opt/mapr/lib
```

   Then, replace this line with the following line of code:

```
export DYLD_LIBRARY_PATH=/opt/mapr/lib
```

last-updated: Jun 06, 2024

IMPORTANT: For MapR 6.0.0 and earlier, the following steps apply:

a. For Mac users, locate the following line of code:

```
export LD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/amd64/
server
```

Then, replace this line with the following line of code:

```
export DYLD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/server
```

b. Based on your environment, edit JAVA_HOME. This ensures that LD_LIBRARY_PATH or DYLD_LIBRARY_PATH will include the full path to the directory containing the libjvm library.

NOTE: You can use `find / -name libjvm*` to determine the JAVA_HOME directory on your machine. However, note that the results of this command include the full path to the libjvm file not just the JAVA_HOME directory.

For example, JAVA_HOME may be set to `Library/Java/JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/Home/` on a Mac and JAVA_HOME may be set to `/usr/lib/jvm/java-1.7.0-openjdk-1.7.0.79.x86_64/` on Linux.

6. From your directory (**librdkafka_example**), run the following commands to compile the source code:

```
make clean
```

```
make all
```

Run the Apps

Once you have the application executables, complete the following steps to run the application:

1. On a cluster node, use the maprcli to create a stream. For example, **MapR_Streams**.

```
maprcli stream create -path /MapR_Streams
```

NOTE: As long as autocreate is enabled for the stream when you run `stream create`,the producer will create the topic. By default, autocreate is enabled. For more information, see stream create on page 2368.

2. At the command line, set the library path to include **/opt/mapr/lib** and the path to the directory that contains the **libjvm** library. For more information, see Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.

NOTE: You must complete this step at the command line even though you already set the library path in the Makefile. If you do not complete the step, an error similar to the following displays when you run the application in the next step: `error while loading shared libraries: librdkafka.so.1: cannot open shared object file: No such file or directory`

3. From your directory (**librdkafka_example**), run the producer application from the command line. For example, if the application is called producer:

```
./producer
```

   The following appears on the console assuming that the stream name is MapR_Streams:

```
************************ PRODUCER ************************
Create producer configuration object
Create Producer Kafka handle
Create topic handle
Send/Produce message to topic: /MapR_Streams:MapR-Topic1
Wait for messages to be delivered
Produced: Welcome to MapR Streams CAPI
Produced: MapR Streams CAPI Message Payload 1
Produced: MapR Streams CAPI Message Payload 2
Produced: MapR Streams CAPI Message Payload 3
Produced: MapR Streams CAPI Message Payload 4

Destroy topic handle
Destroy producer handle

PASS: 5 messages produced and sent to topic partition /
MapR_Streams:MapR-Topic1
```

4. From your directory (**librdkafka_example**), run the consumer application from the command line. For example, if the application is called consumer:

```
./consumer
```

   The following appears on the console assuming that the stream name is MapR_Streams:

```
*********  CONSUMER START  *********
Create new consumer configuration object
Set topic configurations
Create consumer Kafka handle
Create topic partition list for topic: /MapR_Streams:MapR-Topic1
Subscribe consumer to the topic:
Destroy topic partition list:

Start message consumption:
1 Consumed: Welcome to MapR-ES CAPI
2 Consumed: MapR Streams CAPI Message Payload 1
3 Consumed: MapR Streams CAPI Message Payload 2
4 Consumed: MapR Streams CAPI Message Payload 3
5 Consumed: MapR Streams CAPI Message Payload 4

Commit the offsets before closing the consumer

Close and destroy consumer handle

PASS: 5 messages consumed from topic /MapR_Streams:MapR-Topic1
```

Migrating Kafka C Applications to HPE Ezmeral Data Fabric Streams

With some modification, you can use existing Kafka C applications to consume and produce topics in HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that is compatible with HPE Ezmeral Data Fabric Streams.

1. Install and configure the MapR Streams C Client.

last-updated: Jun 06, 2024

2. When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

   ```
   /<path and name of stream>:<name of topic>
   ```

   For example, you might have a stream in a HPE Ezmeral Data Fabric cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

   NOTE: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream. To use these HPE Ezmeral Data Fabric-specific parameters in your application, compile your application with the rdkafka.h file (/opt/mapr/include/librdkafka/rdkafka.h) that was installed with the HPE Ezmeral Data Fabric Streams C Client. See the Compile the Apps on page 3596 section of Developing a HPE Ezmeral Data Fabric Streams C Application on page 3587.

3. See Configuration Properties for HPE Ezmeral Data Fabric Streams C Client on page 3672 for the list of supported configuration parameters, including a few parameters that are HPE Ezmeral Data Fabric-specific. Make changes to your application, as needed.

   NOTE: SSL-related configuration parameters are ignored. When you set these parameters, the HPE Ezmeral Data Fabric Streams Client issues a warning indicating that the parameters are not supported.

4. Review the list of librdkafka APIs that are **not** supported by the HPE Ezmeral Data Fabric Streams C Client and make changes to your application, as needed.

Simple/low level consumer APIs that are not supported	• rd_kafka_queue_new • rd_kafka_queue_destroy • rd_kafka_consume_start • rd_kafka_consume_start_queue • rd_kafka_consume_stop • rd_kafka_consume • rd_kafka_consume_batch • rd_kafka_consume_callback • rd_kafka_consume_queue • rd_kafka_consume_batch_queue • rd_kafka_consume_callback_queue • rd_kafka_offset_store • rd_kafka_pause_partitions • rd_kafka_resume_partitions
Producer/Consumer common APIs that are not supported	• rd_kafka_conf_set_dr_cb

last-updated: Jun 06, 2024

- rd_kafka_conf_set_throttle_cb
- rd_kafka_conf_set_stats_cb
- rd_kafka_conf_set_socket_cb
- rd_kafka_conf_set_open_cb
- rd_kafka_conf_dump
- rd_kafka_conf_dump_free
- rd_kafka_name
- rd_kafka_set_log_level
- rd_kafka_mem_free
- rd_kafka_set_log_level
- rd_kafka_mem_free

Topic APIs that are not supported

- rd_kafka_query_watermark_offsets

  NOTE: As of HPE Ezmeral Data Fabric 6.0.1, this API *is* supported.

- rd_kafka_get_watermark_offsets

  NOTE: As of HPE Ezmeral Data Fabric 6.0.1, this API *is* supported.

Cluster APIs that are not supported

- rd_kafka_memberid
- rd_kafka_metadata
- rd_kafka_metadata_destroy

Miscellaneous APIs that are not supported

- rd_kafka_version
- rd_kafka_version_str
- rd_kafka_get_debug_contexts
- rd_kafka_dump
- rd_kafka_thread_cnt
- rd_kafka_message_timestamp

librdkafka APIs Supported by HPE Ezmeral Data Fabric Streams C Client

This topic lists the librdkafka APIs supported by the HPE Ezmeral Data Fabric Streams C Client. It also describes behavior differences between librdkafka and the HPE Ezmeral Data Fabric Streams C Client.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Ezmeral Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

last-updated: Jun 06, 2024

This topic contains the following supported APIs:

Producer APIs

API	Behavior
rd_kafka_flush	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_poll	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_produce	When this API is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.
rd_kafka_produceva	Same as librdkafka. This API should be used with either RD_KAFKA_V_TOPIC or RD_KAFKA_V_RKT. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_produce_batch	When this API is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.

API	Behavior
rd_kafka_outq_len	This API returns a positive number to indicate that messages are waiting to be produced to a streams topic but the value does not indicate the actual number of messages. librdkafka returns the actual number of messages that are waiting to be sent to or acknowledged by the broker.

Consumer APIs

API	Behavior
rd_kafka_assign	If this API is called for a consumer that is already subscribed to topics, no operation is performed.
rd_kafka_assignment	This API returns the number of topic partitions the consumer is assigned to. However, it returns 0 when topic partitions have yet to be created by the producer. librdkafka returns the number of partitions assigned to a consumer even when the partitions have not been created. **NOTE:** For this API to work, the argument partitions must be explicitly allocated or initialized with either `rd_kafka_topic_partition_list_t *parts = NULL` or `rd_kafka_topic_partition_list_new(0);`. For example: `RD_EXPORT rd_kafka_resp_err_t rd_kafka_assignment (rd_kafka_t *rk, rd_kafka_topic_partition_list_t **partitions);`

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_commit	Same as librdkafka.
rd_kafka_commit_message	Same as librdkafka.
rd_kafka_committed	Same as librdkafka. **NOTE:** The HPE Ezmeral Data Fabric Streams offset starts at 1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_consumer_close	Same as librdkafka.
rd_kafka_consumer_poll	Same as librdkafka. **NOTE:** For librdkafka 0.9: If the consume callback was set and messages were polled using rd_kafka_consumer_poll(), then the consume callback gets called and the messages can be consumed in the callback. For librdkafka 0.11.3: If the consume callback is set and messages are polled using rd_kafka_consumer_poll(), the consume callback is not called. The result is that you cannot consume messages in the consume callback when using rd_kafka_consumer_poll().

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_group_list_destroy	Same as librdkafka.
rd_kafka_list_groups	This API can only be used by consumers that are subscribed to at least one stream on the cluster and have a default stream configured with the streams.consumer.default.stream parameter. It returns the group list of subscribed consumers associated with the default stream. librdkafka returns all consumer groups from the cluster instead. **NOTE:** This API returns RD_KAFKA_RESP_ERR__TIMED_OUT when the querying consumer is not subscribed to any topic.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_message_destroy	Same as librdkafka.
rd_kafka_poll_set_consumer	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_position	This API returns 0 when the messages have not yet been consumed from partitions. librdkafka returns -1001 instead.
rd_kafka_seek	Same as librdkafka.
rd_kafka_subscribe	Same as librdkafka.

API	Behavior
rd_kafka_subscription	This API allows either a list of topics from one or more streams or a regex expression for topics from a single streams. For example, regex expression `/streamA:^t*a,/streamA:^t*b` is supported but `/streamA:^t*a,/_streamB:^t*a` is not supported. librdkafka accepts both options in the same call. **NOTE:** You cannot use the rd_kafka_subscribe API to subscribe a consumer to topics when that consumer is already assigned to topics. If you call this API for an assigned consumer, error RD_KAFKA_RESP_ERR__CONFLICT is returned.
rd_kafka_unsubscribe	Same as librdkafka.

last-updated: Jun 06, 2024

Producer/Consumer Common APIs

API	Behavior
rd_kafka_conf_destroy	Same as librdkafka.
rd_kafka_conf_dup	Same as librdkafka.
rd_kafka_conf_get	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_conf_new	Same as librdkafka.
rd_kafka_conf_set	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_conf_set_consume_cb	Same as librdkafka.
rd_kafka_conf_set_dr_msg_cb	Same as librdkafka.

API	Behavior
rd_kafka_conf_set_error_cb	Same as librdkafka.
rd_kafka_conf_set_offset_commit_cb	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_conf_set_opaque	Same as librdkafka.
rd_kafka_conf_set_rebalance_cb	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_conf_set_throttle_cb	Same as librdkafka.
rd_kafka_destroy	Same as librdkafka.
rd_kafka_new	Same as librdkafka.

API	Behavior
rd_kafka_opaque	Same as librdkafka.
rd_kafka_wait_destroyed	Same as librdkafka.
rd_kafka_yield	Same as librdkafka.

Topic APIs

API	Behavior
rd_kafka_conf_set_default_topic_conf	Same as librdkafka.

API	Behavior
rd_kafka_topic_conf_destroy	Same as librdkafka.
rd_kafka_topic_conf_dup	Same as librdkafka.

API	Behavior
rd_kafka_topic_conf_new	Same as librdkafka.
rd_kafka_topic_conf_set	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_conf_set_opaque	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_conf_set_partitioner_cb	Same as librdkafka.
rd_kafka_topic_destroy	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_name	Same as librdkafka.
rd_kafka_topic_new	Same as librdkafka..

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_partition_list_add	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_add_range	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_partition_list_copy	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_partition_list_del	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_partition_list_del_by_idx	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_partition_list_destroy	Same as librdkafka.

API	Behavior
rd_kafka_topic_partition_list_find	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_partition_list_new	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_topic_partition_list_set_offset	Same as librdkafka.

Queue APIs

API	Behavior
rd_kafka_queue_new	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_queue_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_queue_get_main	For this API, produce events are batched as well as the APIs that use this API, such as, `rd_kafka_event_message_count` and `rd_kafka_event_message_next`. The messages produce events can be consumed together in batches, wheras, opensource librdkafka events are obtained one at a time. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_queue_get_consumer	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_queue_length	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_queue_poll	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_queue_poll_callback	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_commit_queue	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_queue_forward	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_set_log_queue	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_queue_length	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_queue_io_event_enable	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_queue_get_partition	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Event APIs

API	Behavior
rd_kafka_event_type	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_event_name	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_event_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_event_message_array	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_event_message_count	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_event_error	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_event_error_string	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_event_topic_partition_list	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
rd_kafka_event_message_next	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_event_opaque	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric6.0.1.

Timestamp APIs

API	Behavior
rd_kafka_offsets_for_times	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_message_timestamp	Same as librdkafka. Available as of librdkafka 0.9.1. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Interceptors APIs

ATTENTION: Modifying the message in interceptors is not supported and can result in undefined behavior.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_interceptor_f_on_conf_set_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_conf_dup	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_conf_destroy_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_new_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_interceptor_f_on_destroy_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_send_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_acknowledgement_f	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_consumer_	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_interceptor_f_on_commit_t	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_conf_interceptor_add_on_conf_set	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_conf_interceptor_add_on_conf_dup	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_conf_interceptor_add_on_conf_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_conf_interceptor_add_on_new	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_conf_interceptor_add_on_destroy	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_interceptor_add_on_send	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_interceptor_add_on_acknowledgement	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_interceptor_add_on_consume	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

API	Behavior
rd_kafka_interceptor_add_on_commit	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Cluster Configuration APIs

API	Behavior
rd_kafka_brokers_add	This API has no impact on HPE Ezmeral Data Fabric Streams since HPE Ezmeral Data Fabric Streams does not utilize Kafka brokers. When this API is called, the HPE Ezmeral Data Fabric Streams client may print a `brokers are down error` message to the console.

Miscellaneous API

API	Behavior
rd_kafka_err2name	Same as librdkafka.
rd_kafka_err2str	Same as librdkafka.
rd_kafka_error_No	Same as librdkafka.

API	Behavior
rd_kafka_err_No2err	Same as librdkafka.
rd_kafka_get_err_descs	Same as librdkafka.
rd_kafka_last_error	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_log_print	Same as librdkafka.
rd_kafka_log_syslog	Same as librdkafka.
rd_kafka_message_errstr	Same as librdkafka.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_set_logger	Same as librdkafka.
rd_kafka_query_watermark_offsets	When you are querying or retrieving a topic that is non-existent topic/partition (using `rd_kafka_query_watermark_offsets()` and `rd_kafka_get_watermark_offsets()` APIs), the timeout is honored even though you still receive the correct error message. Supported as of HPE Ezmeral Data Fabric 6.0.1.

last-updated: Jun 06, 2024

API	Behavior
rd_kafka_get_watermark_offsets	When you are querying or retrieving a topic that is non-existent topic/partition (using `rd_kafka_query_watermark_offsets()` and `rd_kafka_get_watermark_offsets()` APIs), the timeout is honored even though you still receive the correct error message. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Additional Information

For more information and API signatures, see rdkafka.h on page 3682.

librdkafka APIs NOT Supported by HPE Ezmeral Data Fabric Streams C Client
This topic lists the librdkafka APIs that are *not* supported by the HPE Ezmeral Data Fabric Streams C Client.

These APIs are also documented in the rdkafka.h on page 3682 as not support by HPE Ezmeral Data Fabric Streams. If you want to see the list of supported librdkafka APIs, see librdkafka APIs Supported by HPE Ezmeral Data Fabric Streams C Client on page 3601.

NOTE: This list of librdkafka APIs *not* supported is applicable to HPE Ezmeral Data Fabric 6.0.1 and librdkafka 0.11.3.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Ezmeral Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

Configuration Properties for HPE Ezmeral Data Fabric Streams C Client

This topic describes the configuration properties supported by the HPE Ezmeral Data Fabric Streams C Client. This includes librdkafka configuration properties that HPE Ezmeral Data Fabric Streams supports and additional properties that are specific to HPE Ezmeral Data Fabric Streams.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka.
message.max.bytes	See Configuring Properties for Message Size on page 3818.

last-updated: Jun 06, 2024

Property Name	Behavior
receive.message.max.bytes	See Configuring Properties for Message Size on page 3818.
topic.blacklist	Same as librdkafka.
error_cb	Same as librdkafka.

Property Name	Behavior
opaque	Same as librdkafka.
queue.buffering.max.ms	Same as librdkafka.
enable.partition.eof	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Property Name	Behavior
queue.buffering.max.kbytes	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Consumer Configuration Properties

Property Name	Behavior
default_topic_conf	Same as librdkafka.
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.

Property Name	Behavior
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.

Property Name	Behavior
dr_msg_cb.deliverymsg.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.

last-updated: Jun 06, 2024

Topic Configuration

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: beginning, end, earliest, latest, none, smallest, and largest. As of HPE Ezmeral Data Fabric 6.0.1, beginning and end are supported. **NOTE:** librdkafka additionally supports error.

last-updated: Jun 06, 2024

HPE Ezmeral Data Fabric-Specific Configurations

Property Name	Behavior
streams.consumer.default.stream	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. **NOTE:** rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.

last-updated: Jun 06, 2024

Property Name	Behavior
streams.parallel.flushers.per.partition	Enables the producer to have multiple parallel send requests to the server for each topic partition. When this property is set to true, the default value, it is possible for messages to be sent out of order.

last-updated: Jun 06, 2024

Property Name	Behavior
streams.producer.default.stream	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Ezmeral Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.

Additional Information

For more information, see rdkafka.h on page 3682.

rdkafka.h
This rdkafka header file has been updated to be compatible with HPE Ezmeral Data Fabric Streams. After you install the HPE Ezmeral Data Fabric Streams C Client, this file is available in the following directory: /opt/mapr/include/librdkafka/

librdkafka 0.11.3

Apache librdkafka 0.11.3 is supported as of HPE Ezmeral Data Fabric 6.0.1/EEP5.0.

IMPORTANT: With this release, the RD_KAFKA_MSG_F_BLOCK call provides *blocking* behavior, whereas, the RD_KAFKA_MSG_F_COPY and RD_KAFKA_MSG_F_FREE calls are *non-blocking* (this is a behavior change from previous releases.

/**
 * @brief \b Consumer: Set rebalance callback for use with
 *                     coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 *
 * Registering a \p rebalance_cb turns off librdkafka's automatic
 * partition assignment/revocation and instead delegates that responsibility
 * to the application's \p rebalance_cb.
 *
 * The rebalance callback is responsible for updating librdkafka's
 * assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
 * arbitrary rebalancing failures where \p err is neither of those.
 * @remark In this latter case (arbitrary error), the application must
 *         call rd_kafka_assign(rk, NULL) to synchronize state.
 *
 * Without a rebalance callback this is done automatically by librdkafka
 * but registering a rebalance callback gives the application flexibility
 * in performing other operations along with the assinging/revocation,
 * such as fetching offsets from an alternate location (on assign)
 * or manually committing offsets (on revoke).
 *
 * @remark The \p partitions list is destroyed by librdkafka on return
 *         return from the rebalance_cb and must not be freed or
 *         saved by the application.
 *
 * The following example shows the application's responsibilities:
 * @code
 *    static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
 *                              rd_kafka_topic_partition_list_t *partitions,
 *                              void *opaque) {
 *
 *        switch (err)
 *        {
 *          case RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS:
```

```
 *              // application may load offets from arbitrary external
 *              // storage here and update \p partitions
 *
 *              rd_kafka_assign(rk, partitions);
 *              break;
 *
 *          case RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS:
 *              if (manual_commits) // Optional explicit manual commit
 *                  rd_kafka_commit(rk, partitions, 0); // sync commit
 *
 *              rd_kafka_assign(rk, NULL);
 *              break;
 *
 *          default:
 *              handle_unlikely_error(err);
 *              rd_kafka_assign(rk, NULL); // sync state
 *              break;
 *         }

/**
 * @brief Produce and send a single message to broker.
 *
 * \p rkt is the target topic which must have been previously created with
 * `rd_kafka_topic_new()`.
 *
 * `rd_kafka_produce()` is an asynch non-blocking API.
 *
 * \p partition is the target partition, either:
 *   - RD_KAFKA_PARTITION_UA (unassigned) for
 *     automatic partitioning using the topic's partitioner function, or
 *   - a fixed partition (0..N)
 *
 * \p msgflags is zero or more of the following flags OR:ed together:
 *    RD_KAFKA_MSG_F_BLOCK - block \p produce*() call if
 *                           \p queue.buffering.max.messages or
 *                           \p queue.buffering.max.kbytes are exceeded.
 *                           Messages are considered in-queue from the
point they
 *                           are accepted by produce() until their
corresponding
 *                           delivery report callback/event returns.
 *                           It is thus a requirement to call
```

```
 *                            rd_kafka_poll() (or equiv.) from a separate
 *                            thread when F_BLOCK is used.
 *                            See WARNING on \c RD_KAFKA_MSG_F_BLOCK above.
 *
 *    RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done
 *                          with it.
 *    RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
 *                          \p payload pointer will not be used by rdkafka
 *                          after the call returns.
 *
 *    ..._F_FREE and ..._F_COPY are mutually exclusive.
 *
 *    If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
 *    the memory associated with the payload is still the caller's
 *    responsibility.
 *
 * \p payload is the message payload of size \p len bytes.
 *
 * \p key is an optional message key of size \p keylen bytes, if non-NULL it
 * will be passed to the topic partitioner as well as be sent with the
 * message to the broker and passed on to the consumer.
 *
 * \p msg_opaque is an optional application-provided per-message opaque
 * pointer that will provided in the delivery report callback (`dr_cb`) for
 * referencing this message.
 *
 * @remark on_send() and on_acknowledgement() interceptors may be called
 *         from this function. on_acknowledgement() will only be called if
the
 *         message fails partitioning.
 *
 * @returns 0 on success or -1 on error in which case errno is set
accordingly:
 *  - ENOBUFS  - maximum number of outstanding messages has been reached:
 *               "queue.buffering.max.messages"
 *               (RD_KAFKA_RESP_ERR__QUEUE_FULL)
 *  - EMSGSIZE - message is larger than configured max size:
 *               "messages.max.bytes".
 *               (RD_KAFKA_RESP_ERR_MSG_SIZE_TOO_LARGE)
 *  - ESRCH    - requested \p partition is unknown in the Kafka cluster.
 *               (RD_KAFKA_RESP_ERR__UNKNOWN_PARTITION)
 *  - ENOENT   - topic is unknown in the Kafka cluster.
 *               (RD_KAFKA_RESP_ERR__UNKNOWN_TOPIC)
 *
 * @sa Use rd_kafka_errno2err() to convert `errno` to rdkafka error code.

/**
 * @name Miscellaneous APIs
 * @{
 *
 */

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a ,-separated list of brokers in the format:
 *   \c \<broker1\>,\<broker2\>,..
 * Where each broker is in either the host or URL based format:
 *   \c \<host\>[:\<port\>]
 *   \c \<proto\>://\<host\>[:port]
 * \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *    brokerlist = "broker1:10000,broker2"
 *    brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.
 *
 * @remark Brokers may also be defined with the \c metadata.broker.list or

/**
 * @name Interceptors
 *
 * @{
 *
 * @brief A callback interface that allows message interception for both
 *        producer and consumer data pipelines.
 *
 * Except for the on_new(), on_conf_set(), on_conf_dup() and
on_conf_destroy()
 * interceptors, interceptors are added to the
 * newly created rd_kafka_t client instance. These interceptors MUST only
 * be added from on_new() and MUST NOT be added after rd_kafka_new()
returns.
 *
 * The on_new(), on_conf_set(), on_conf_dup() and on_conf_destroy()
interceptors
 * are added to the configuration object which is later passed to
 * rd_kafka_new() where on_new() is called to allow addition of
 * other interceptors.
 *
 * Each interceptor reference consists of a display name (ic_name),
 * a callback function, and an application-specified opaque value that is
 * passed as-is to the callback.
 * The ic_name must be unique for the interceptor implementation and is used
 * to reject duplicate interceptor methods.
 *
 * Any number of interceptors can be added and they are called in the order
 * they were added, unless otherwise noted.
 * The list of registered interceptor methods are referred to as
 * interceptor chains.
 *
 * @remark Contrary to the Java client the librdkafka interceptor interface
 *         does not support message modification. Message mutability is
 *         discouraged in the Java client and the combination of
 *         serializers and headers cover most use-cases.
 *
 * @remark Interceptors are NOT copied to the new configuration on
 *         rd_kafka_conf_dup() since it would be hard for interceptors to
 *         track usage of the interceptor's opaque value.
 *         An interceptor should rely on the plugin, which will be copied
 *         in rd_kafka_conf_conf_dup(), to set up the initial interceptors.
 *         An interceptor should implement the on_conf_dup() method
 *         to manually set up its internal configuration on the newly
created
```

```
 *         configuration object that is being copied-to based on the
 *         interceptor-specific configuration properties.
 *         conf_dup() should thus be treated the same as conf_init().
 *
 * @remark Interceptors are keyed by the interceptor type (on_..()), the
 *         interceptor name (ic_name) and the interceptor method function.
 *         Duplicates are not allowed and the .._add_on_..() method will
 *         return RD_KAFKA_RESP_ERR__CONFLICT if attempting to add a
duplicate
 *         method.
 *         The only exception is on_conf_destroy() which may be added
multiple
 *         times by the same interceptor to allow proper cleanup of
 *         interceptor configuration state.
 */

/**
 * @brief on_conf_set() is called from rd_kafka_*_conf_set() in the order
 *        the interceptors were added.
 *
 * @param ic_opaque The interceptor's opaque pointer specified in ..add..().
 * @param name The configuration property to set.
 * @param val The configuration value to set, or NULL for reverting to
default
 *            in which case the previous value should be freed.
 * @param errstr A human readable error string in case the interceptor
fails.
 * @param errstr_size Maximum space (including \0) in \p errstr.
 *
 * @returns RD_KAFKA_CONF_RES_OK if the property was known and successfully
 *          handled by the interceptor, RD_KAFKA_CONF_RES_INVALID if the
 *          property was handled by the interceptor but the value was
invalid,
 *          or RD_KAFKA_CONF_RES_UNKNOWN if the interceptor did not handle
 *          this property, in which case the property is passed on on the
 *          interceptor in the chain, finally ending up at the built-in
 *          configuration handler.

/**
 * @brief \b Consumer: Set rebalance callback for use with
 *                     coordinated consumer group balancing.
 *
 * The \p err field is set to either RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
 * or RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS and 'partitions'
 * contains the full partition set that was either assigned or revoked.
 *
 * Registering a \p rebalance_cb turns off librdkafka's automatic
 * partition assignment/revocation and instead delegates that responsibility
 * to the application's \p rebalance_cb.
 *
 * The rebalance callback is responsible for updating librdkafka's
 * assignment set based on the two events:
RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS
```

```
 * and RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS but should also be able to
handle
 * arbitrary rebalancing failures where \p err is neither of those.
 * @remark In this latter case (arbitrary error), the application must
 *         call rd_kafka_assign(rk, NULL) to synchronize state.
 *
 * Without a rebalance callback this is done automatically by librdkafka
 * but registering a rebalance callback gives the application flexibility
 * in performing other operations along with the assinging/revocation,
 * such as fetching offsets from an alternate location (on assign)
 * or manually committing offsets (on revoke).
 *
 * @remark The \p partitions list is destroyed by librdkafka on return
 *         return from the rebalance_cb and must not be freed or
 *         saved by the application.
 *
 * The following example shows the application's responsibilities:
 * @code
 *    static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
 *                              rd_kafka_topic_partition_list_t *partitions,
 *                              void *opaque) {
 *
 *        switch (err)
 *        {
 *          case RD_KAFKA_RESP_ERR__ASSIGN_PARTITIONS:
 *             // application may load offets from arbitrary external
 *             // storage here and update \p partitions
 *
 *             rd_kafka_assign(rk, partitions);
 *             break;
 *
 *          case RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS:
 *             if (manual_commits) // Optional explicit manual commit
 *                 rd_kafka_commit(rk, partitions, 0); // sync commit
 *
 *             rd_kafka_assign(rk, NULL);
 *             break;
 *
 *          default:
 *             handle_unlikely_error(err);
 *             rd_kafka_assign(rk, NULL); // sync state
 *             break;
 *         }
 *    }
 * @endcode

 * @brief Produce and send a single message to broker.
 *
 * \p rkt is the target topic which must have been previously created with
 * `rd_kafka_topic_new()`.
 *
 * `rd_kafka_produce()` is an asynch non-blocking API.
 *
 * \p partition is the target partition, either:
 *   - RD_KAFKA_PARTITION_UA (unassigned) for
```

```
 *     automatic partitioning using the topic's partitioner function, or
 *   - a fixed partition (0..N)
 *
 * \p msgflags is zero or more of the following flags OR:ed together:
 *    RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done
 *                          with it.
 *    RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
 *                          \p payload pointer will not be used by rdkafka
 *                          after the call returns.
 *
 *    ..._F_FREE and ..._F_COPY are mutually exclusive.
 *
 *    If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
 *    the memory associated with the payload is still the caller's
 *    responsibility.
 *
 * \p payload is the message payload of size \p len bytes.
 *
 * \p key is an optional message key of size \p keylen bytes, if non-NULL it
 * will be passed to the topic partitioner as well as be sent with the
 * message to the broker and passed on to the consumer.
 *
 * \p msg_opaque is an optional application-provided per-message opaque
 * pointer that will provided in the delivery report callback (`dr_cb`) for
 * referencing this message.
 *
 * Returns 0 on success or -1 on error in which case errno is set
accordingly:
 *  - ENOBUFS  - maximum number of outstanding messages has been reached:

 *
 */

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a ,-separated list of brokers in the format:
 *   \c \<broker1\>,\<broker2\>,..
 * Where each broker is in either the host or URL based format:
 *   \c \<host\>[:\<port\>]
 *   \c \<proto\>://\<host\>[:port]
 * \c \<proto\> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *    brokerlist = "broker1:10000,broker2"
 *    brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.

HPE Ezmeral Data Fabric Streams Python Applications

As of HPE Ezmeral Data Fabric 5.2.1, you can create python applications for HPE Ezmeral Data Fabric Streams using the HPE Ezmeral Data Fabric Streams Python client. The HPE Ezmeral Data Fabric Streams Python client is a binding for librdkafka and the HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams.

The HPE Ezmeral Data Fabric Streams Python client is available in a Ecosystem Pack (EEP) starting with EEP 3.0.

last-updated: Jun 06, 2024

The following Apache Kafka librdkafka versions are supported:

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Ezmeral Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

NOTE: Because the HPE Ezmeral Data Fabric Streams Python Client is dependent on the HPE Ezmeral Data Fabric Streams C Client, the HPE Ezmeral Data Fabric Streams C Client must be configured before using the HPE Ezmeral Data Fabric Streams Python Client.

When developing and running HPE Ezmeral Data Fabric Streams Python applications, note the following points:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- HPE Ezmeral Data Fabric Streams offset values start at 1, not 0.
- HPE Ezmeral Data Fabric security is supported including ACLs and ACEs for authorization. The unique Kafka security features that are part of Apache Kafka are not supported. See Security on page 830 for more information about HPE Ezmeral Data Fabric security features.
- User impersonation is not supported.

Developing HPE Ezmeral Data Fabric Streams Python Applications

This topic includes basic information about how to develop a HPE Ezmeral Data Fabric Streams Python application and an example program that you can run.

Before you Begin

Confirm that your environment meets the following requirements:

- HPE Ezmeral Data Fabric cluster version 5.2.1 or greater.
- HPE Ezmeral Data Fabric core client (mapr-client) package. See Installing the Data Fabric Client (Non-FIPS) on page 404 for more information.
- HPE Ezmeral Data Fabric Streams C Client (mapr-librdkafka) is installed and configured on the node. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.
- HPE Ezmeral Data Fabric Streams Python Client (mapr-streams-python) is installed on the node. See Installing HPE Ezmeral Data Fabric Streams Python Client on page 256.
- Python installed on the node (Python version 2.7.x and above, up to version 3.6.x).

Create a HPE Ezmeral Data Fabric Streams Producer Application

In general, you want to create a producer that performs the following steps:

1. Import the producer class.
2. Define the producer and its configuration.
3. Produce data.
4. Wait for all messages to be sent to consumer.

last-updated: Jun 06, 2024

As of EEP 5.0 HPE Ezmeral Data Fabric Streams Python Client: In the following example code, three messages are produced to a topic named `mytopic` in a stream named `my_stream`.

```
from confluent_kafka import Producer
p = Producer({'streams.producer.default.stream': '/my_stream'})
some_data_source= ["msg1", "msg2", "msg3"]
for data in some_data_source:
     p.produce('mytopic', data.encode('utf-8'))
     p.flush()
```

Create a HPE Ezmeral Data Fabric Streams Consumer Application

In general, you want to create a consumer that performs the following steps:

1. Import the consumer class.
2. Define the consumer and its configuration.
3. Consume data.
4. Wait for all messages to be consumed.

As of EEP 5.0 HPE Ezmeral Data Fabric Streams Python Client: In following example code, the HPE Ezmeral Data Fabric Streams consumer is subscribed to `my_stream/mytopic` and it prints the content of each message that it reads.

```
from confluent_kafka import Consumer, KafkaError
c = Consumer({'group.id': 'mygroup',
              'default.topic.config': {'auto.offset.reset': 'earliest'}})
c.subscribe(['/my_stream:mytopic'])
running = True
while running:
  msg = c.poll(timeout=1.0)
  if msg is None: continue
  if not msg.error():
    print('Received message: %s' % msg.value().decode('utf-8'))
  elif msg.error().code() != KafkaError._PARTITION_EOF:
    print(msg.error())
    running = False
c.close()
```

Run the Example Applications

To run the sample producer and consumer applications:

1. Create a stream named `mystream`.
2. Create a file named producer.py.
3. Add the producer example code into the producer.py file.
4. Create a file named consumer.py.
5. Add the consumer example code into the consumer.py file.

6. Verify that you have completed the steps to configure the HPE Ezmeral Data Fabric Streams C client or complete the steps now. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.

   NOTE: The HPE Ezmeral Data Fabric Streams Python Client is dependent on the HPE Ezmeral Data Fabric Streams C Client. Therefore, the HPE Ezmeral Data Fabric Streams C Client must be configured before you can run the application.

7. Run producer.py from the command line to generate messages.

   ```
   $ python producer.py
   ```

8. Run consumer.py from the command line:

   ```
   $ python consumer.py
   ```

Migrating Kafka Python Applications to HPE Ezmeral Data Fabric Streams

With some modification, you can use existing confluent-kafka python applications to consume and produce topics in HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams Python Client is a binding for Apache librdkafka that works with HPE Ezmeral Data Fabric Streams.

1. Install the HPE Ezmeral Data Fabric Streams Python Client.

   NOTE: This required that you also install and configure the HPE Ezmeral Data Fabric Streams C Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.

2. Do one of the following depending on whether you are using the EEP 5.0 (or higher) HPE Ezmeral Data Fabric Streams Python Client or the EEP 3.0 (or higher) HPE Ezmeral Data Fabric Streams Python Client.

   - If you are using HPE Ezmeral Data Fabric Streams Python EEP 5.0 (or higher), skip this step. The references to `confluent_kafka` should be retained.
   - If you are using HPE Ezmeral Data Fabric Streams Python EEP 3.0 (or higher), update import statements to refer to the MapR Stream Python API. References to `confluent_kafka` should be updated to `mapr_streams_python`.

     NOTE: For example, update `from confluent_kafka import Consumer` to `from mapr_streams_python import Consumer`.

3. When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

   ```
   /<path and name of stream>:<name of topic>
   ```

   For example, you might have a stream in a HPE Ezmeral Data Fabric cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

   NOTE: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream.

last-updated: Jun 06, 2024

4. Review the APIs that are supported and make changes to your application, as needed. See API for HPE Ezmeral Data Fabric Streams Python Client on page 3792.

5. See Configuration Properties for HPE Ezmeral Data Fabric Streams Python Client on page 3798 for the list of supported configuration parameters and make changes to your application, as needed.

   NOTE: SSL-related configuration parameters are ignored. When you set these parameters, the HPE Ezmeral Data Fabric Streams Client issues a warning indicating that the parameters are not supported.

API for HPE Ezmeral Data Fabric Streams Python Client

HPE Ezmeral Data Fabric Streams Python Client is a binding for librdkafka and it supports the following APIs.

As of HPE Ezmeral Data Fabric 5.2.1, you can create python applications for HPE Ezmeral Data Fabric Streams using the HPE Ezmeral Data Fabric Streams Python client. The HPE Ezmeral Data Fabric Streams Python client is a binding for librdkafka and the HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Ezmeral Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

class mapr_streams_python.Consumer

A high-level Kafka Consumer.

Method	Behavior
Consumer(**kwargs)	Create new Consumer instance using provided configuration dictionary.
assign(partitions)	Set consumer partition assignment to the provided list of TopicPartition and starts consuming. Parameters(s): • partitions (list(TopicPartition)) – List of topic+partitions and optionally initial offsets to start consuming
unassign()	Unassign from all TopicPartitions that have been assigned with the `.assign(*topic_partition_list) method.` **NOTE:** This method is applicable as of HPE Ezmeral Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.
assignment()	Return a list of assignments for a consumer object. **NOTE:** This method is applicable as of HPE Ezmeral Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.

last-updated: Jun 06, 2024

Method	Behavior
close()	Close down and terminate the Kafka Consumer. Actions(s): • Stops consuming • Commits offsets • Leave consumer group
commit([message=None][, offsets=None][, async=True])	Commit a message or a list of offsets. Message and offsets are mutually exclusive, if neither is set the current partition assignment's offsets are used instead. Parameters(s): • message (confluent_kafka.Message) – Commit message's offset+1. • offsets (list(TopicPartition)) – List of topic+partitions+offsets to commit. • async (bool) – Asynchronous commit, return immediately.
committed(partitions[, timeout=None])	Retrieve committed offsets for the list of partitions. Parameters(s): • partitions (list(TopicPartition)) - List of topic+partitions to query for stored offsets. • timeout (float) – Request timeout Returns: List of topic+partitions with offset and possibly error set. Return type: list(TopicPartition) Raises: KafkaException **NOTE:** As of HPE Ezmeral Data Fabric 6.0, the message offset in a partition starts from zero (0). If you are upgrading and do not enable the HPE Ezmeral Data Fabric Database/HPE Ezmeral Data Fabric Streams feature, **mfs.feature.db.streams.v6.support**, the message offset in a partition starts from one (1).
on_commit(err, partitions)	A callback for Consumer.commit() that triggers custom actions when a commit request completes. Parameters(s): • err (KafkaError) – Commit error object, or None on success. • Partitions (list(TopicPartition)) – List of partitions with their committed offsets or per-partition errors

last-updated: Jun 06, 2024

Method	Behavior
poll([timeout=None])	Consume messages, calls callbacks and returns events. The application must check the returned Message object's Message.error() method to distinguish between proper messages (error() returns None), or an event or error (see error().code() for specifics). Parameter(s): timeout (*float*) – Maximum time to block waiting for message, event or callback Returns: A Message object or None on timeout Return type: Message or None
position(partitions[, timeout=None])	Retrieve current positions (offsets) for the list of partitions. Parameter(s): partitions (list(TopicPartition)) – List of topic+partitions to return current offsets for. The current offset is the offset of the last consumed message + 1 Returns: List of topic+partitions with offset and possibly error set. Return type: list(TopicPartition) Raises: KafkaException This function returns 0 when the messages have not yet been consumed from partitions. librdkafka returns -1001 instead.
subscribe(topics[, listener=None])	Set subscription to supplied list of topics This replaces a previous subscription. Parameters: • topics (list(str)) – List of topics (strings) to subscribe to. • on_assign (callable) – callback to provide handling of customized offsets on completion of a successful partition re-assignment. • on_revoke (callable) – callback to provide handling of offset commits to a customized store on the start of a rebalance operation. Raises: KafkaException **NOTE:** You cannot use the rd_kafka_subscribe API to subscribe a consumer to topics when that consumer is already assigned to topics. If you call this API for an assigned consumer, error RD_KAFKA_RESP_ERR__CONFLICT is returned.
on_assign(consumer, partitions)	Same as librdkafka.
unsubscribe()	Same as librdkafka.
on_revoke(consumer, partitions)	Parameter(s): • consumer (Consumer) – Consumer instance. • partitions (list(TopicPartition)) – Absolute list of partitions being assigned or revoked.

last-updated: Jun 06, 2024

Method	Behavior
get_watermark_offsets(confluent_kafka.TopicPartition)	Get WatermarkOffsets for a given Topic Partition. Parameter(s): TopicPartition - Gets the watermark offset **NOTE:** This method is applicable as of HPE Ezmeral Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.

class mapr_streams_python.Producer

Asynchronous Kafka Producer.

Method	Behavior
Producer(**kwargs)	Create new Producer instance using provided configuration dict.
len()	This API returns a positive number to indicate that messages are waiting to be produced to a streams topic but the value does not indicate the actual number of messages. librdkafka returns the actual number of messages that are waiting to be sent to or acknowledged by the broker. Return type: int
flush()	Wait for all messages in the Producer queue to be delivered. This is a convenience method that calls poll() until len()is zero.
poll([timeout])	Polls the producer for events and calls the corresponding callbacks (if registered). Parameter(s): • timeout (float) – Maximum time to block waiting for events Returns: Number of events processed (callbacks served). Return type: int

last-updated: Jun 06, 2024

Method	Behavior
produce(topic[, value][, key][, partition][, callback])	Produce message to topic. This is an asynchronous operation, an application may use the callback(alias on_delivery) argument to pass a function (or lambda) that will be called from poll() when the message has been successfully delivered or permanently fails delivery. Parameters: • topic (str) – Topic to produce message to • value (str|bytes) – Message payload • key (str|bytes) – Message key • partition (int) – Partition to produce to, else uses the configured partitioner. • on_delivery(err,msg) (func) – Delivery report callback to call (from poll() or flush()) on successful or failed deliver Raises: • BufferError – if the internal producer message queue is full (queue.buffering.max.messages exceeded) • KafkaException – for other errors, see exception code **NOTE:** When this function is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.

class mapr_streams_python.Message

The Message object represents either a single consumed or produced message, or an event . An application must check with error() to see if the object is a proper message (error() returns None) or an error/event. This class is not user-instantiable.

Method	Behavior
len()	Returns: Message value (payload) size in bytes. Return type: int
error()	The message object is also used to propagate errors and events. Applications must check error() to determine if the Message is a proper message (error() returns None) or an error or event (error() returns a KafkaError object) Return type: None or KafkaError
key()	Returns: message key or None if not available Return type: str|bytes or None
offset()	Returns: message offset or None if not available Return type: int or None
partition()	Returns: partition number or None if not available Return type: int or None

last-updated: Jun 06, 2024

Method	Behavior
topic()	Returns: topic name or None if not available Return type: str or None
value()	Returns: message value (payload) or None if not available Return type: str|bytes or None
timestamp()	Returns: message timestamp **NOTE:** This method is applicable as of HPE Ezmeral Data Fabric Streams Python Client EEP 5.0 which is associated with librdkafka 0.11.3.

class mapr_streams_python.TopicPartition

TopicPartition is a generic type to hold a single partition and various information about it. It is typically used to provide a list of topics or partitions for various operations, such as Consumer.assign().

Method	Behavior
TopicPartition(topic[, partition][, offset])	Instantiate a TopicPartition object. Parameter(s) • topic (string) – Topic name • partition (int) – Partition id • offset (int) – Initial partition offset Return type: TopicPartition
error	Attribute that indicates an error (with KafkaError) unless None.
offset	Attribute for offset.
partition	Attribute for partition number.
topic	Attribute for topic name.

class mapr_streams_python.KafkaError

Kafka error and event object.

The KafkaError class serves multiple purposes:

- Propagation of errors
- Propagation of events
- Exceptions

This class is not user-instantiable.

last-updated: Jun 06, 2024

Method	Behavior
code()	Returns the error/event code for comparison toKafkaError.<ERR_CONSTANTS>. Returns: error/event code Return type: int
name()	Returns the enum name for error/event. Returns: error/event enum name string Return type: str
str()	Returns the human-readable error/event string. Returns: error/event enum message string Return type: str

Configuration Properties for HPE Ezmeral Data Fabric Streams Python Client

In the instance constructor of a HPE Ezmeral Data Fabric Streams Python application, you can use a dictionary to set the following configuration properties. HPE Ezmeral Data Fabric Streams Python client supports a superset of the configuration properties supported by the HPE Ezmeral Data Fabric Streams C client.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka
default.topic.config	A dictionary of topic-level configuration properties that are applied to all used topics for the instance.
message.max.bytes	Supports a value less than or equal to 10MB (10000000). If this property is set to a value that is higher than 10MB, the client issues a warning and sets the configuration to 10MB. Produce calls fail when the message size is greater than 10MB.
receive.message.max.bytes	Same as librdkafka
topic.blacklist	Same as librdkafka
error_cb	A callback for generic/global error events. This callback is served by poll().
opaque	Same as librdkafka.

Consumer Configuration Properties

Property Name	Behavior
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.
delivery.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.

last-updated: Jun 06, 2024

Property Name	Behavior
on_commit	A callback used to indicate success or failure of commit requests.

Topic Configuration Properties

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: earliest, latest, none, smallest, and largest. librdkafka also supports biggest, end and error.

Producer Configuration Properties

Property Name	Behavior
on_delivery(kafka.KafkaError, kafka.Message)	A Python function reference that is called once for each produced message to indicate the final delivery result (success or failure). This property may also be set per-message by passing callback=callable (or on_delivery=callable) to the confluent_kafka.Producer.produce() function.

HPE Ezmeral Data Fabric-Specific Configuration Properties

Property Name	Behavior
streams.consumer.default.stream	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. **NOTE:** rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.
streams.parallel.flushers.per.partition	Enables the producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order.
streams.producer.default.stream	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Ezmeral Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.

last-updated: Jun 06, 2024

Additional Information

Here is a consumer configuration example:

```
conf = {'group.id': 'mygroup',
'session.timeout.ms': 6000,
'on_commit': my_commit_callback,
'default.topic.config': {'auto.offset.reset': 'smallest'}}
consumer = mapr_streams_python.Consumer(**conf)
```

HPE Ezmeral Data Fabric Streams C#/.NET Applications

As of HPE Ezmeral Data Fabric 6.0.1/EEP5.0, you can create C#/.NET applications for HPE Ezmeral Data Fabric Streams using the HPE Ezmeral Data Fabric Streams C#/.NET client. The HPE Ezmeral Data Fabric Streams C#/.NET client is a binding for librdkafka and the HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams.

Requirements

- HPE Ezmeral Data Fabric Client on Windows 7 (or higher) x64 operating systems
- HPE Ezmeral Data Fabric cluster version 6.0.1 or greater
- Java 8 SDK and set Java HOME
- HPE Ezmeral Data Fabric Streams C Client (mapr-librdkafka 0.11.3)
- HPE Ezmeral Data Fabric Streams C#/.NET Client (mapr-streams-dotnet)
- .NET SDK 4.5.x or 4.6.x or .NET Core SDK 1.1
- nuget.exe

See Installing HPE Ezmeral Data Fabric Streams C#/.NET Client on page 258 for installation information.

General Information

When developing and running HPE Ezmeral Data Fabric Streams C#/.NET applications, note the following points:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- HPE Ezmeral Data Fabric Streams offset values start at 1, not 0.
- HPE Ezmeral Data Fabric security is supported including ACLs and ACEs for authorization. The unique Kafka security features that are part of Apache Kafka are not supported. See Security on page 830 for more information about HPE Ezmeral Data Fabric security features.

- User impersonation is not supported.

Developing HPE Ezmeral Data Fabric Streams C#/.NET Applications
Describes general tasks for developing C#/.NET applications.

Before Your Begin

Confirm that your environment meets the following requirements:

- HPE Ezmeral Data Fabric cluster version 6.0.1 or greater.
- HPE Ezmeral Data Fabric Streams C Client (mapr-librdkafka 0.11.3) is installed and configured on the node. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.
- HPE Ezmeral Data Fabric Streams C#/.NET Client (mapr-streams-dotnet) is installed on the node.
- .NET SKD 4.5.x or 4.6.x
- .NET Core SDK 1.1
- nuget.exe

Create a Producer Application

In general, you want to create a producer that performs the following steps:

1. Import the producer class.
2. Define the producer and its configuration.
3. Produce data.
4. Wait for all messages to be sent to consumer.

In the following example code, three messages are produced to a topic named mytopic in a stream named my_stream.

```
class Producer
    {
        public static async void Produce()
        {
            string stream = "/my_stream";
            string topicName = "mytopic";

            var config = new Dictionary<string, object>
{ { "streams.producer.default.stream", stream } };
            var messages = new string[] { "Msg1", "Msg2", "Msg3" };

            using (var producer = new Producer<Null, string>(config, null,
new StringSerializer(Encoding.UTF8)))
            {
                foreach (var msg in messages)
                {
                    var deliveryReport = await
producer.ProduceAsync(topicName, null, msg);
                    Console.WriteLine($"Delivery report:
{deliveryReport.TopicPartitionOffset}");
                }

                producer.Flush(TimeSpan.FromSeconds(1));
            }
```

```
        }
    }
```

Create a Consumer Application

In general, you want to create a consumer that performs the following steps:

1. Import the consumer class.
2. Define the consumer and its configuration.
3. Consume data.
4. Wait for all messages to be consumed.

In following example code, the HPE Ezmeral Data Fabric Streams consumer is subscribed to `my_stream/mytopic` and it prints the content of each message that it reads.

```
using Confluent.Kafka;
using Confluent.Kafka.Serialization

    class Consumer
    {
        public static void Consume()
        {
            var stream = "/mystream";
            var topic = "mytopic";

            var config = new Dictionary<string, object>
            {
                { "group.id", "simple-csharp-consumer" },
                { "streams.consumer.default.stream", stream }
            };

            bool running = true;

            using (var consumer = new Consumer<Ignore, string>(config,
null, new StringDeserializer(Encoding.UTF8)))
            {
                var l = new List<TopicPartitionOffset> { new
TopicPartitionOffset(topic, 0, 0) };
                consumer.Assign(l);

                // Raised on critical errors, e.g. connection failures.
                consumer.OnError += (_, error) =>
                {
                    Console.WriteLine($"Error: {error}");
                    running = false;
                };

                // Raised on deserialization errors or when a consumed
message has an error != NoError.
                consumer.OnConsumeError += (_, error) =>
                {
                    Console.WriteLine($"Consume error: {error}");
                    running = false;
                };

                while (running)
                {
                    Message<Ignore, string> msg;
```

last-updated: Jun 06, 2024

```
                    if (consumer.Consume(out msg, TimeSpan.FromSeconds(10)))
                    {
                        Console.WriteLine($"Topic: {msg.Topic} Partition:
{msg.Partition} Offset: {msg.Offset} {msg.Value}");
                    }
                }
            }
        }
    }
```

Run the Example Applications

To run the sample producer and consumer applications:

1. Create a stream named **mystream**.
2. Create a folder application.
3. Create a file named **example.cs**.
4. Add producer example code into the **example.cs** file.
5. Add consumer example code into the **example.cs** file.
6. Add an entry point for your application:

```
    class Demo
              {
              public static void Main(string[] args)
              {
              Producer.Produce();
              Consumer.Consume();
              }
              }
```

7. Create a project file named **example.csproj**.

last-updated: Jun 06, 2024

8. Add the following dependency properties into the **example.csproj** file:

```
<?xml version="1.0" encoding="utf-8"?>
<Project ToolsVersion="15.0" xmlns="http://schemas.microsoft.com/
developer/msbuild/2003">
  <Import Project="$(MSBuildExtensionsPath)\$(MSBuildToolsVersion)
\Microsoft.Common.props" Condition="Exists('$(MSBuildExtensionsPath)\$
(MSBuildToolsVersion)\Microsoft.Common.props')" />
  <PropertyGroup>
    <Configuration Condition=" '$(Configuration)' == '' ">Debug</
Configuration>
    <Platform Condition=" '$(Platform)' == '' ">AnyCPU</Platform>
    <ProjectGuid>{99EDBA4B-D7DA-48BB-8D0C-AF4B12387935}</ProjectGuid>
    <OutputType>Exe</OutputType>
    <RuntimeIdentifiers>win10-x64</RuntimeIdentifiers>
    <RootNamespace>app</RootNamespace>
    <AssemblyName>app</AssemblyName>
    <TargetFrameworkVersion>v4.6.1</TargetFrameworkVersion>
    <FileAlignment>512</FileAlignment>
    <AutoGenerateBindingRedirects>true</AutoGenerateBindingRedirects>
  </PropertyGroup>
  <PropertyGroup Condition=" '$(Configuration)|$(Platform)' == 'Debug|
AnyCPU' ">
    <PlatformTarget>AnyCPU</PlatformTarget>
    <DebugSymbols>true</DebugSymbols>
    <DebugType>full</DebugType>
    <Optimize>false</Optimize>
    <OutputPath>bin\Debug\</OutputPath>
    <DefineConstants>DEBUG;TRACE</DefineConstants>
    <ErrorReport>prompt</ErrorReport>
    <WarningLevel>4</WarningLevel>
  </PropertyGroup>
  <ItemGroup>
    <Compile Include="app.cs" />
  </ItemGroup>
  <ItemGroup>
    <PackageReference Include="mapr-streams-dotnet" Version="0.11.3" />
  </ItemGroup>
    <Import Project="$(MSBuildToolsPath)\Microsoft.CSharp.targets" />
</Project>
```

9. Verify that you have completed the steps to configure the HPE Ezmeral Data Fabric Streams C client or complete the steps now. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.

   NOTE: The HPE Ezmeral Data Fabric Streams C#/.NET Client is dependent on the HPE Ezmeral Data Fabric Streams C Client. Therefore, the HPE Ezmeral Data Fabric Streams C Client must be configured before you can run the application.

10. Open your project folder on the command line and run:

```
dotnet run
```

Migrating Kafka C#/.NET Applications to HPE Ezmeral Data Fabric Streams

With some modification, you can use existing confluent-kafka C#/.NET applications to consume and produce topics in HPE Ezmeral Data Fabric Streams. The HPE Ezmeral Data Fabric Streams C#/.NET Client is a binding for Apache librdkafka that works with HPE Ezmeral Data Fabric Streams.

last-updated: Jun 06, 2024

Migrating a .NET 4.5 or 4.6 Application

NOTE: This migration information is applicable for Windows (Win7-x64) platform *only*.

To migrate an existing .NET 4.5 or 4.6 application:

1. Install and configure the HPE Ezmeral Data Fabric Streams C Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.
2. Replace the librdkafka.dll with the HPE Ezmeral Data Fabric librdkafka 0.11.3 from **/bin/.../runtimes/<win7-x64>/<native folder>**.
3. Add a symlink from the **MapRClient.dll** to the **librdkafka.dll**.
4. Restart the application.

Migrating a .NET Core Application1

NOTE: This migration information is applicable for Windows (Win7-x64) and Linux platforms.

To migrate an existing .NET Core application:

1. Install and configure the HPE Ezmeral Data Fabric Streams C Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.
2. Replace the librdkafka.dll with the MapR librdkafka 0.11.3 from **USER_HOME/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/<platform>/<native folder>**.
3. Add a symlink from the **MapRClient.dll** to the **librdkafka.dll**.
4. Restart the application.

Migrating a .NET Core Application2

NOTE: This migration information is applicable for Linux platforms *only*.

To migrate an existing .NET Core application:

1. Remove all **.so** files from the **~/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/<platform>/<native folder>** directory.
2. Install and configure the HPE Ezmeral Data Fabric Streams C Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.
3. Replace the librdkafka.dll with the MapR librdkafka 0.11.3 from **USER_HOME/.NUGET/PACKAGES/LIBRDKAFKA.REDIST/0.11.3/runtimes/** directory.
4. If the MapR Client doesn not install into the ID search path, add a symlink from the **MapRClient.dll** to the **l/usr/local/lib**.
5. Restart the application.

General Migration Information

- When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

  ```
  /<path and name of stream>:<name of topic>
  ```

  For example, you might have a stream in a MapR cluster that is named stream_A, and the stream might be in a volume named IoT and in a directory named automobile_sensors. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

  NOTE: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream.

- Review the APIs that are supported and make changes to your application, as needed. See API for HPE Ezmeral Data Fabric Streams C#/.NET on page 3806.

- See Configuration Properties for HPE Ezmeral Data Fabric Streams C#/.NET Client on page 3808 for the list of supported configuration parameters and make changes to your application, as needed.

  NOTE: SSL-related configuration parameters are ignored. When you set these parameters, the HPE Ezmeral Data Fabric Streams Client issues a warning indicating that the parameters are not supported.

API for HPE Ezmeral Data Fabric Streams C#/.NET

HPE Ezmeral Data Fabric Streams C#/.NET Client is a binding for librdkafka and the HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Ezmeral Data Fabric 6.0.1	As of 5.0	0.11.3

Classes

Classes	Descripton
CommittedOffsets	Encapsulates information provided to a Consumer's OnOffsetsCommitted event - per-partition offsets and success/error together with overall success/error of the commit operation.
Consumer	Implements a high-level Apache Kafka consumer (without deserialization).
Consumer<TKey, TValue>	Implements a high-level Apache Kafka consumer (with key and value deserialization).
Error	Represents an error that occured when interacting with a Kafka broker or the librdkafka library.
ErrorCodeExtensions	Provides extension methods on the ErrorCode enumeration.
GroupInfo	Encapsulates information describing a particular Kafka group.
GroupMemberInfo	Encapsulates information describing a particular member of a Kafka group.

Classes	Descripton
Ignore	A type for use in conjunction with that enables message keys or values to be read as null, regardless of their value.
KafkaException	Represents an error that occured during an interaction with Kafka.
Library	Methods that relate to the native librdkafka library itself (do not require a Producer or Consumer broker connection).
Loggers	OnLog callback event handler implementations.
LogMessage	Encapsulates information provided to the Producer/ Consumer OnLog event.
Message	Represents a message stored in Kafka.
Message<TKey, TValue>	Represents a (deserialized) message stored in Kafka.
Metadata	Kafka cluster metadata.
Null	A type for use in conjunction with and that enables null key or values to be enforced when producing or consuming messages.
PartitionMetadata	Metadata pertaining to a single Kafka topic partition.
Producer	Implements a high-level Apache Kafka producer (without serialization).
Producer<TKey, TValue>	Implements a high-level Apache Kafka producer with key and value serialization.
TopicMetadata	Metadata pertaining to a single Kafka topic.
TopicPartition	Represents a Kafka (topic, partition) tuple.
TopicPartitionError	Represents a Kafka (topic, partition, error) tuple.
TopicPartitionOffset	Represents a Kafka (topic, partition, offset) tuple.
TopicPartitionOffsetError	Represents a Kafka (topic, partition, offset, error) tuple.
TopicPartitionTimestamp	Represents a Kafka (topic, partition, timestamp) tuple.
WatermarkOffsets	Represents the low and high watermark offsets of a Kafka topic/partition.

Interfaces

Interface	Description
IDeliveryHandler	This interface is implemented by types that handle delivery report callbacks as a result of calls to Producer.ProduceAsync().
IDeliveryHandler<TKey, TValue>	This interface is implemented by types that handle delivery report callbacks as a result of calls to Producer<TKey,TValue>.ProduceAsync().
ISerializingProducer<TKey, TValue>	This interface describes the minimum functionality to be provided by a high level (serializing) Kafka producer.

last-updated: Jun 06, 2024

Structs

Struct	Descripton
Offset	Represents a Kafka partition offset value.
Timestamp	Encapsulates a Kafka timestamp and its type.

Enums

Enum	Descripton
ErrorCode	Enumeration of local and broker generated error codes.
TimestampType	Enumerates the different meanings of a message timestamp value.

Configuration Properties for HPE Ezmeral Data Fabric Streams C#/.NET Client

Describes the C#/.NET client configuration properties.

Global Configuration Properties

Property Name	Behavior
client.id	Same as librdkafka.
message.max.bytes	Supports a value less than or equal to 10MB (10000000). If this property is set to a value that is higher than 10MB, the client issues a warning and sets the configuration to 10MB. Produce calls fail when the message size is greater than 10MB.

last-updated: Jun 06, 2024

Property Name	Behavior
receive.message.max.bytes	Same as librdkafka.
topic.blacklist	Same as librdkafka.
error_cb	Same as librdkafka.

Property Name	Behavior
opaque	Same as librdkafka.
enable.partition.eof	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.
queue.buffering.max.kbytes	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Ezmeral Data Fabric 6.0.1.

Consumer Configuration Properties

Property Name	Behavior
default_topic_conf	Same as librdkafka.
group.id	Same as librdkafka.
enable.auto.commit	Same as librdkafka.

Property Name	Behavior
auto.commit.interval.ms	Same as librdkafka.
rebalance_cb	Same as librdkafka.
offset_commit_cb	Same as librdkafka.

Property Name	Behavior
delivery.report.only.error	Same as librdkafka.
dr_msg_cb	Same as librdkafka.

last-updated: Jun 06, 2024

Topic Configuration

Property Name	Behavior
partitioner_cb	Same as librdkafka.
auto.offset.reset	Supports the following values: beginning, end, earliest, latest, none, smallest, and largest. As of HPE Ezmeral Data Fabric 6.0.1, beginning and end are supported. **NOTE:** librdkafka additionally supports error.

last-updated: Jun 06, 2024

HPE Ezmeral Data Fabric-Specific Configurations

Property Name	Behavior
streams.consumer.default.stream	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. **NOTE:** rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.

last-updated: Jun 06, 2024

Property Name	Behavior
streams.parallel.flushers.per.partition	Enables the producer to have multiple parallel send requests to the server for each topic partition. When this property is set to true, the default value, it is possible for messages to be sent out of order.

last-updated: Jun 06, 2024

Property Name	Behavior
streams.producer.default.stream	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Ezmeral Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.

Utilities for HPE Ezmeral Data Fabric Streams

HPE Ezmeral Data Fabric Streams provides the utilities for operating on streams and topics.

NOTE: HPE Ezmeral Data Fabric Streams cannot use HPE Ezmeral Data Fabric Database Shell to perform operations on streams or topics.

`mapr copystream`	This utility copies data from one HPE Ezmeral Data Fabric Stream to another HPE Ezmeral Data Fabric Stream. You can use it, for example, if you want to set up replication manually from one stream to another.
`mapr diffstreams`	This utility compares the message IDs, metadata, and data in two HPE Ezmeral Data Fabric Streams. Then, generates two directories that contain sequence files

	that you can use to merge the rows from the two HPE Ezmeral Data Fabric Streams.
`mapr diffstreamswithcrc`	This utility uses a cyclic redundancy check to detect differences between sets of messages in the specified HPE Ezmeral Data Fabric Streams. Then, for each set of non-identical messages, it performs a detailed comparison. Finally, it generates one or more directories of sequence files.
`mapr exportstream` and `mapr importstream`	Use these utilities together to export data from HPE Ezmeral Data Fabric Streams into binary sequence files, and then import the data from the binary sequence files into other HPE Ezmeral Data Fabric Streams. You can also use the `mapr importstream` utility to import changes that are specified in sequence files output by the `mapr diffstreams` utility.
`mapr perfconsumer`	This utility runs a consumer reading messages from topics in a HPE Ezmeral Data Fabric Stream. Use this utility to run consumers when you want to estimate the performance of consumers for your HPE Ezmeral Data Fabric Streams applications, given your network configuration.
`mapr perfproducer`	This utility runs a producer, generating messages and publishing them to a HPE Ezmeral Data Fabric Stream. Use this utility to run producers when you want to estimate the performance of producers for your HPE Ezmeral Data Fabric Streams applications, given your network configuration.
`mapr streamanalyzer`	This light-weight utility, which is a sample application for the `Streams` Java class for analytics on HPE Ezmeral Data Fabric Streams, lets you count the messages in a stream or a subset of the topics in a stream. The utility also lets you print either whole retrieved messages or a subset of the fields in each message.

Configuring Properties for Message Size

Describes the `message.max.bytes` and `receive.message.max.bytes` properties for configuring message size.

message.max.bytes	For a C producer, the `message.max.bytes` value is 1000000 B by default. The minimum value is 1000 B and maximum value is 32000000 B. The maximum message size produced by a C API is decided by the `message.max.bytes` value set on the C producer. From C, Python, and C# APIs, the maximum message size that can be produced is 32000000 B. If a C consumer needs to consume a message that is greater than 32000000 B in size, which may be produced by a Java client, the consumer needs to update the `message.max.bytes` or `receive.message.max.bytes` properties to a higher value to consume it. If the `message.max.bytes` property is set to greater than 32000000 B, it is by default capped at 32000000 B. Though a consumer can consume messages greater than 32000000 B (produced say by a Java client), only up to 32000000 B is produced from

last-updated: Jun 06, 2024

	the MapR C client. The maximum message size consumed by a C API is limited by the value that is higher among the `message.max.bytes` and `receive.message.max.bytes` values.
receive.message.max.bytes	For a C consumer, the `receive.message.max.bytes` is 1000000 B by default. The minimum value is 1000 B and maximum value is 1000000000 B.

Using a Java API, a larger message size can be produced if the cluster-side property is changed using the following `maprcli config save` command:

```
Cluster side:

maprcli config save -values
{"mfs.db.max.rowsize.kb":<value in KB>}
```

In this case, the row size is 32 MB by default and the maximum is a little less than 2 GB.

The `mfs.db.max.rowsize.kb` setting is a cluster-wide setting that applies to HPE Ezmeral Data Fabric Database (Binary+JSON) and MapR Event Store for Apache Kafka, and it is not configurable per stream or topic.

MapReduce and Apps

This section contains information associated with developing YARN applications.

External Applications and Classpath

Describes how to configure the class path for external applications.

MapReduce version 2 applications require the hadoop 2.x or the yarn classpath, and other applications that can run on YARN require the yarn classpath.

The method to specify the classpath differs based on how the job or application is submitted:

Method used to Submit the Job	Method to Specify Classpath
The external application uses the `hadoop jar` or the `yarn jar` command.	YARN applications (MapReduce or custom applications) that are submitted using the `yarn jar` command will automatically use the yarn classpath. If the external application has a service that submits the job, you can set the CLASSPATH environment variable to point to a different classpath prior to starting the service. In this case, the hadoop classpath that you set in the CLASSPATH environment variable takes priority over the hadoop classpath for the `hadoop jar` command.

last-updated: Jun 06, 2024

Method used to Submit the Job	Method to Specify Classpath
The external application does not use the `hadoop jar` or the `yarn jar` command.	Set the classpath using one of the following options: • If the external application has a service that submits the job or application, you can set the CLASSPATH environment variable to point to the hadoop or yarn classpath prior to starting the service. • Set the classpath within the application. Use one of the following methods to get the classpath: • `hadoop2 classpath` or `hadoop -yarn classpath`: Gets the classpath for MRv2 applications. • `yarn classpath`: Gets the classpath for YARN applications (MRv2 or other applications that can run on YARN).

IMPORTANT: When you launch a spring boot application, ensure that you prefix the classpath with `/opt/mapr/conf:/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop`. Alternatively, copy the `core-site.xml` file to the `/src/main/resources/` folder.

Classpath Construction

This section describes how the MapReduce classpath is constructed.

The classpath that is used to run a MapReduce program is constructed based on how the program is submitted.

When you submit an application from the command line, the classpath used to process the program is based on the following items in this order of priority:

1. JARs in the program's classpath, such as the hadoop 2.x or yarn classpath.
2. JARs specified with the `-libjar` parameter which can be appended to `hadoop jar` or `yarn jar` commands.

If an external application submits the application, the classpath that is used to process the jar file is based on the following items in this order of priority:

1. JARs in the classpath of the external application.
2. JARs in the program's classpath, such as the hadoop 2.x or yarn classpath.
3. JARs specified with `-libjar` parameter which can be appended to `hadoop jar` or `yarn jar` commands.

Managing Third-Party Libraries

Any third-party library that is required by a MapReduce program must be accessible to the data node that processes the application.

A data node is a node in the cluster that includes the NodeManager role. You can provide the third-party libraries when you submit the program, or you can install the third-party libraries on each node that processes the application.

Include the third-party libraries with each program

Including the third-party libraries with each program is the preferred method.

Perform one the following operations to include the third-party jars when you submit the program:

- Package the third-party libraries with the MapReduce jar file. The benefit of this method is that the node from which you submit the program and the node that runs the program are not required to have the libraries files.
- Use the `-libjars` parameter to specify the third-party libraries on the command line. With this option, the library files are submitted to the data node along with the program. The benefit of this method is that the node that runs the program does not need to have the library files installed. However, the node that submits the program must have the library files installed.

Install the third-party libraries on each node that runs the program

You can also install the third-party libraries on each data node. However, this may not be preferred as there could be conflicts between library versions or library files.

To install the third-party libraries on each data node, perform one of the following operations:

- Install the third-party libraries in the following directory on each Node Manager node: `/opt/mapr/hadoop/hadoop-2.x/share/hadoop/common`
- On each node with the NodeManager role, install the required third-party libraries and then specify the location(s) of the third-party libraries with the HADOOP_CLASSPATH env variable in the `env_override.sh` file. The `env_override.sh` file is located in the following directory: `/opt/mapr/conf`. For more information about the file, see About env_override.sh on page 3077.

Kubernetes Interfaces for Data Fabric

This section describes how to leverage the capabilities of the Kubernetes Interfaces for Data Fabric.

Container Storage Interface (CSI) Storage Plugin Configuration

This section describes how to use and troubleshoot the Container Storage Interface (CSI) Storage Plugin.

See Container Storage Interface (CSI) Storage Plugin Overview on page 805 for more information.

Using the Container Storage Interface (CSI) Storage Plugin

This section describes how to configure for static and dynamic provisioning and mounting using example configuration files.

For an overview of the Container Storage Interface (CSI) Storage Plugin, see Container Storage Interface (CSI) Storage Plugin Overview on page 805.

Before You Begin CSI Configuration

Before configuring the Container Storage Interface (CSI) Storage Plugin, be sure to review the following notes about supported and unsupported features and parameters. For an overview of the Container Storage Interface (CSI) Storage Plugin, see Container Storage Interface (CSI) Storage Plugin Overview on page 805.

Data Fabric Parameters for Static and Dynamic Provisioning

In dynamic provisioning, you can specify parameters for the data-fabric volume to be created. For a list of the parameters that you can use, see `volume create` on page 2588. Note these considerations for using the parameters:

- Volume attributes must be represented as a string (enclosed within quotations). Using an integer or boolean is not supported. In the following example, the `aetype` attribute will generate an error because the value (`1`) is not enclosed in quotations.

```
namePrefix: "pv"
mountPrefix: "/pv"
type: "rw"
advisoryquota: "100M"
aetype: 1
```

- The following parameters are ignored because they are redundant, and the CSI Driver configures these parameters automatically during volume creation:
  - `mount`
  - `quota*`
  - `createparent`
  - `path`
  - `name`

*Specifying `resources: requests: storage` in a PersistentVolumeClaim (PVC) makes it unnecessary to set the `quota` parameter. For an example, see Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin on page 3828.

Kubernetes Access Modes

Kubernetes access modes control how a PersistentVolume (PV) is mounted on the host. Access modes can be specified on both PVs and PVCs. Only Volumes with a matching Access Mode will be bound to a PVC. Container Storage Interface (CSI) Storage Plugin supports ROX (ReadOnlyMany), RWO (ReadWriteOnce) and RWX (ReadWriteMany) access modes for the PV and PVC spec. See Kubernetes CSI documentation for more information.

Reclaim Policy

The Kubernetes `reclaimPolicy` parameter controls what happens to a PersistentVolume if the corresponding PersistentVolumeClaim is deleted. The `Recycle` Reclaim Policy is not supported by Kubernetes CSI Drivers, so it cannot be used with the Kubernetes Interfaces for Data Fabric. You can specify the reclaim policy normally when you configure a persistent volume.

The following table shows the supported values for the reclaim policy:

Reclaim Policy Value	Description	Support
Delete (default value)	The PersistentVolume and the data-fabric volume are deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported
Retain	The PersistentVolume and the data-fabric volume are not deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported

For more information about the reclaim policy, see Change the Reclaim Policy of a PersistentVolume.

Kubernetes Mount Options

The Kubernetes `mountOptions` parameter is not supported for use with the Container Storage Interface (CSI) Storage Plugin.

Configuring Static and Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin

About this task

This page summarizes the high-level steps for configuring the Container Storage Interface (CSI) Storage Plugin after installation to provide static or dynamic provisioning. To learn more about static and dynamic provisioning, see Static and Dynamic Volume Provisioning Using Container Storage Interface (CSI) Storage Plugin on page 806.

Static Provisioning

Procedure

1. Create the ticket secret and deploy the secret in the Pod only if the volume is on a secure MapR cluster.

   See Configuring a Secret on page 3886 for more information.

2. Configure a PersistentVolume in your Pod spec or as part of a separate configuration file and provide information about the MapR volume.

   See Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin on page 3828, Persistent Volumes, and Example: Mounting a PersistentVolume for Static Provisioning on page 3831.

3. Configure a PersistentVolumeClaim in your Pod spec or as part of a separate configuration file.

   See PersistentVolumeClaims.

4. Run the Pod spec using `kubectl` commands.

   See Overview of kubectl.

Dynamic Provisioning

Procedure

1. Create the REST and ticket secrets and deploy the secrets in the Pod only if the volume is on a secure MapR cluster.

   See Configuring a Secret on page 3886 for more information.

2. Create a storage class in your Pod spec or in a separate configuration file.

   See Storage Classes and Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin on page 3838.

3. Configure a PersistentVolumeClaim in your Pod spec or in a separate configuration file.

   See Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin on page 3838.

4. Run the Pod spec using `kubectl` commands.

   See Overview of kubectl.

Configuring Static and Dynamic Provisioning for a Raw Block Volume

Raw block volumes are supported for both static and dynamic provisioning. To request a raw-block PersistentVolumeClaim, set `volumeMode: Block`. If not specified, `volumeMode` defaults to

`Filesystem` in the PersistentVolumeClaimSpec. PersistentVolumes also have a `volumeMode` field in the PersistentVolumeSpec that is used for static provisioning. `Block`-type PVCs can only bind to `Block`-type PVs.

All the features supported on `Filesystem`-persistent volumes are supported on `Block` volumes. For example:

- Create and Delete Volumes
- Expand Volumes
- Clone Volumes
- Create and Delete Snapshot
- Snapshot Restore

Block volumes are supported only in single-node-writer access modes. At any given time, they can only be published once as read/write on a single node. For `Block` volumes, the CSI driver does not format the block device; it just binds the block device to the target path. The application pod can choose to format the block device to any required Linux file system, such as ext4, xfs, btrfs, and others.

Each block volume is stored in an HPE Ezmeral Data Fabric file. Statically provisioned block files are located at the path designated in the `volumePath` specified in the persistent volume definition. Dynamically provisioned block files are located at the path designated by the `mountPrefix` in the storage class. For fast, random block-write performance, these files should not be erasure coded (warm tiering) or tiered off to an objectstore (cold tiering).

Static Provisioning Example

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-blockpv
  namespace: test-csi
spec:
  accessModes:
  - ReadWriteOnce
  volumeMode: Block
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5G
  csi:
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/user/guest/myblockvolume"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      platinum: "true"
      capacityBytes: "5000000000"
```

NOTE: For the Loopback NFS CSI driver, change `driver` to `com.mapr.csi-nfskdf`.

Dynamic Provisioning Example

Note that no change in the StorageClass is required:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
```

last-updated: Jun 06, 2024

```
  name: test-secure-block-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  volumeMode: Block
  resources:
    requests:
      storage: 5G
```

Pod Specification

In the pod specification, you must specify `volumeDevices` and `devicePath` for the block volume instead of `volumeMounts` and `mountPath`.

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure-block-pod
spec:
  containers:
    - name: fc-container
      image: fedora:26
      command: ["/bin/sh", "-c"]
      args: [ "tail -f /dev/null" ]
      volumeDevices:
        - name: data
          devicePath: /dev/xvda
  volumes:
    - name: data
      persistentVolumeClaim:
        claimName: test-secure-block-pvc
```

Configuring a Secret

Kubernetes Secrets enable you to inject sensitive data into a pod. For more information about Secrets, see Secrets.

The examples in this section show how Secrets can be used in static and dynamic provisioning. Secrets are not by themselves secure. For more information about security and Secrets, see Security Properties. Specifically, it is important to turn on encryption at rest for Secrets. See Encrypting Secret Data at Rest.

During installation of the Driver, the Kubernetes token that was moved into the pod is written to the host node so that the plugin can query a Secret to pull the ticket for mounting. This Kubernetes token is sensitive and should be protected. The token is placed in `/var/run/secrets/kubernetes.io/serviceaccount`.

Here is an example of a configuration file for a Kubernetes Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
  ...
```

The following table describes the fields in the sample Secret file. For more information, see Secrets in the Kubernetes documentation.

Parameter	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.

REST Secrets

For dynamic provisioning, you must use a Secret to pass the user name and password of a data-fabric user to the provisioner. This user must have privileges to create and delete a data-fabric volume. The credentials allow the provisioner to make REST calls to the data-fabric webserver. Secrets are protected by the Kubernetes RBAC.

The following example shows a REST secret in the Secret file:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
 MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

The following table describes the REST secret fields in the REST Secret example.

Parameter	Notes
`MAPR_CLUSTER_USER`	The base64 representation of a data-fabric user that has the ability to create and delete data-fabric volumes. See Converting a String to Base64 on page 3888.
`MAPR_CLUSTER_PASSWORD`	The base64 representation of the password for the user defined by the `MAPR_CLUSTER_USER` parameter. See .Converting a String to Base64 on page 3888
`MAPR_CLUSTER_TICKET`	The base64 representation of the ticket contents generated on the data-fabric cluster using the `maprlogin` utility. For dynamic provisioning, with the latest CSI drivers, you can configure a data-fabric ticket to authenticate to the data-fabric webserver to make REST calls. This parameter is provided as a Beta feature.

Ticket Secrets

For static and dynamic provisioning, you must specify a Secret, which is the base64 representation of the ticket, to enable the POSIX client to communicate with a secure MapR cluster. The ticket for the POSIX client can be generated on the data-fabric cluster using the `maprlogin` on page 2911 utility.

The following example shows a ticket Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
```

last-updated: Jun 06, 2024

```
data:
  CONTAINER_TICKET: CHANGETHIS!
```

The following table describes the CONTAINER_TICKET field in the ticket Secret example.

Parameter	Notes
CONTAINER_TICKET	Base64-encoded ticket value. See Converting a String to Base64 on page 3888.

To create the secret:

1. Run the following command to create the Secret file:

   ```
   kubectl create -f <secret-file-name>.yaml
   ```

2. Convert sensitive data, such as a user name and password, to a base64 representation.

   See Converting a String to Base64 on page 3888.

3. Add the base64 representation of sensitive data in the Secret file.

   For more information about the format of the Secret files, see REST Secrets on page 3826 and Ticket Secrets on page 3826 earlier in this section.

4. Deploy the secret on the pod by running the following command:

   ```
   kubectl apply -f <secret-file-name>.yaml
   ```

Converting a String to Base64

Sensitive data contained in a Secret must be represented in base64. Use these steps to convert such information to the base64 representation:

For example, in Linux:

```
echo -n 'mapr' | base64
```

The output shows the base64 representation of the user name mapr is bWFwcg==.

MapR tickets include a cluster name followed by a base64-encoded string. It is not sufficient to insert the base64-encoded string into a Kubernetes Secret. You must convert *both* the cluster name and string into base64 representation and then insert the result into the Secret.

The following command shows how to convert a MapR ticket to base64 representation:

```
echo -n "cluster-name <base64-encoded ticket-value>" | base64
```

For example:

```
echo -n "cluster2 PuG0lpuPXuDxj9ERgKCTXOqsXYPTnqRJl6/
mlWJjdVKvE5r46QS2Bh9nC+I4Rcu0GtnWRUOtKBG9gp65bsZN9Kphnr/
Wp15z8D3O2go951CANes/
7QQllYVP7l2BOpGR6I1zIrC3XGwI8OQWT61qpsjSVZv8zO5oQ5GDYQTkPttI/yAk/
uJBES1ohCz38n9HgYALLvMALVsBPtUtG+cNGc1ktUDDMR2q1EgVzdJbuYsOuHnZX3LO3euKDGl4C
4MCmrv9DWiWJxwiZ1yZu69GbZJlXxqLOQBlkdMoTXk=" | base64

Y2x1c3RlcjIgUHVHMGxwdVBYdUR4ajlFUmdLQ1RYT3FzWFlQVG5xUkpsNi9tbFdKamRWS3ZFNXI0
NlFTMkJoOW5DK0k0UmN1MEd0bldSVU90S0JHOWdwNjVic1pOOUtwaG5yL1dwMTV6OEQzTzJnbzk1
MUNBTmVzLzdRUWxsWVZQN2wyQk9wR1I2STF6SXJDM1hHd0k4T1FXVDYxcXBzalNWWnY4ek81b1E1
R0RZUVRrUHR0SS95QWsvdUpCRVMxb2hDejM4bjlIZ1lBTEx2TUFMVnNCUHRVdEcrY05HYzFrdFVE
```

last-updated: Jun 06, 2024

```
RE1SMnExRWdWemRKYnVZc091SG5aWDNMTzNldUtER2w0QzRNQ21ydjlEV2lXSnh3aVoxeVp1NjlH
YlpKbFh4cUxPUUJsa2RNb1RYaz0K
```

NOTE: Another method for converting values to base64 is to use an Internet tool such as https://www.base64encode.org to encode or decode data.

Best Practices for Using Tickets

When using secure data-fabric clusters with the Kubernetes Interfaces for Data Fabric, you must generate tickets for your containers. Here are some best practices:

- Create a different user for each container.
- To avoid frequent renewals, use long-lived user tickets or servicewithimpersonation tickets. If you refresh or update a ticket, you must restart your containers.
- If you use an impersonation ticket, it is CRITICAL that you use security contexts in the pod definitions to avoid a misbehaving container impersonating all user IDs. For restrictions that apply to the use of impersonation tickets, see How Impersonation Works on page 1943 and maprlogin on page 2911.
- Match the security context `runAsUser:` ID and `fsGroup:` group to the ID or group used to create the ticket.

Here is an example of a pod spec that specifies a security context:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
```

Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin

About this task

You can designate a volume for use with Kubernetes by specifying the volume parameters directly inside the PersistentVolume spec.

Suppose you want to get an application container up and running quickly in the HPE Ezmeral Data Fabric. You already have a file-system path that you want to use for the application. You only need the data accessible to read. To make this work, you must do the following:

Procedure

1. Generate a service ticket and set the `securityType` parameter in the PersistentVolume spec to `secure` if the volume to mount is on a secure cluster.

   See Generating a Service Ticket on page 1832 for more information. For example:

```
kind: PersistentVolume
metadata:
  name: pv-securepv-test
  namespace: test-csi
  spec:
    accessModes:
    …
    csi:
      …
      volumeAttributes:
        …
        securityType: "secure"
```

2. If the volume to mount is on a secure cluster, configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret.

   For more information, see Configuring a Secret on page 3886. The following table describes the properties of the Secret file:

Property	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`namespace`	The namespace in which the Secret runs.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.
`CONTAINER_TICKET`	The contents of the ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 3888. You may remove the ticket if the cluster is not secure.

3. Set the `runAsUser` and the `fsGroup` parameters in the pod spec to the UID and GID of the user that created the ticket.

   For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-pv1
  namespace: test-csi
spec:
  ...
  securityContext:
    runAsUser: 1000
    fsGroup:2000
  ...
```

   The following table lists the properties specified in the sample pod spec:

Parameter	Notes

last-updated: Jun 06, 2024

`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. For clarity, the example uses a naked pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability (HA) and ease of upgrade.
`metadata: name`	The pod name.
`metadata: namespace`	The namespace in which the pod runs.
`securityContext: runAsUser`	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
`securityContext: fsGroup`	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.

4. Point the `volumePath` in the CSI driver setting to the desired path, and fill in the `cldbHosts` and `cluster` information.

   For the complete list of volume attributes, see `volume create` on page 2588; however, note that volume attributes like `mount`, `quota`, `createparent`, `path`, and `name` are ignored when provisioning a volume. For more information, see Data Fabric Parameters for Static and Dynamic Provisioning on page 3821.

   For example:

   FUSE

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      platinum: "true"
```

   Loopback NFS

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    driver: com.mapr.csi-nfskdf
```

last-updated: Jun 06, 2024

```
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
```

The following table lists the properties shown in the sample PersistentVolume spec:

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs.
`accessModes`	How the PersistentVolume is mounted on the host. All modes work the same.  **NOTE:** The PV and PVC modes must be the same so that they can bind. For more information, see Access Modes.
`csi: driver`	The CSI Driver being used. Call it using one of these drivers: • FUSE driver: `com.mapr.csi-kdf` • Loopback NFS driver: `com.mapr.csi-nfskdf`
`csi: volumeHandle`	The existing volume name or unique volume name for static provisioning.
`volumePath`	The mount point within the filesystem. This parameter specifies an existing MapR path.
`cluster`	The cluster name.
`cldbHosts`	The DNS names or IP addresses of the CLDB hosts for the cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`securityType`	A parameter that indicates whether tickets are used or not used. If tickets are used, specify `secure`. Otherwise, specify `unsecure`.

Example: Mounting a PersistentVolume for Static Provisioning

About this task

The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX driver (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS driver (`com.mapr.csi-nfskdf`).

For static provisioning, configuring a PersistentVolume has some advantages over annotating Kubernetes volume information in a pod spec:

- The configuration file can be shared for use by multiple pod specs.
- The configuration file enables the PersistentVolume to be mounted and available even when the pod spec that references it is removed.

For example, suppose a marketing volume exists in the secure file system under the path `/Departments/Marketing`. An administrator wants to statically provision this volume and make it

last-updated: Jun 06, 2024

available to multiple users. It is critical that data access is as fast as possible. To make this work, the administrator must do the following:

Procedure

1. Create a PersistentVolume (PV) (if you have already not statically provisioned a volume as described in this example) and set the following volumeAttributes:
   - `accessMode` of the PV to `ReadWriteOnce`
   - `securityType` parameter to `secure` because the volume is on a secure cluster
   - `volumePath` in the CSI driver setting to the desired path, and fill in the `cldbHosts` and `cluster` information
   - `platinum` parameter to use the POSIX platinum client or the `license` parameter to select from three POSIX clients

   For example:

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
  labels:
    name: pv-simplepv-test
spec:
  accessModes:
  - ReadWriteOnce
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    nodePublishSecretRef:
      name: "mapr-ticket-secret"
      namespace: "test-csi"
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterA"
      cldbHosts: "10.10.102.96"
      securityType: "secure"
      platinum: "true"
```

   The preceding example specifies the high-performance Platinum POSIX license by including `platinum: "true"` in the `volumeAttributes`.

   If you have a Platinum FUSE POSIX license, Release 1.0.2 and later provide another way to control the POSIX client. Instead of specifying `platinum: "true"`, you can specify `license: "<license-name>"` and select one of three POSIX licenses (Basic, Container, or Platinum). Release 1.0.2 also adds support for a `startupConfig` line that lets you pass custom startup parameters to the FUSE process. The following example shows these options:

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: test-simplepv
  namespace: test-csi
  labels:
```

last-updated: Jun 06, 2024

```
    name: pv-simplepv-test
spec:
  accessModes:
  - ReadWriteMany
  persistentVolumeReclaimPolicy: Delete
  capacity:
    storage: 5Gi
  csi:
    nodePublishSecretRef:
      name: "mapr-ticket-secret"
      namespace: "test-csi"
    driver: com.mapr.csi-kdf
    volumeHandle: test-simplepv
    volumeAttributes:
      volumePath: "/"
      cluster: "clusterB"
      cldbHosts: "10.10.10.210"
      securityType: "secure"
      license: "container"
      startupConfig: "-o allow_other -o big_writes -o auto_unmount -o
async_dio -o max_background=24 -o auto_inval_data --disable_writeback"
```

The following table shows the properties defined in the sample PersistentVolume:

Parameter	Notes
`metadata: name`	The PersistentVolume name.
`metadata: namespace`	The namespace in which the PersistentVolume is stored.
`accessModes`	How the PersistentVolume is mounted on the host. **NOTE:** The accessMode is not used to set the access mode bit on the volume. The accessMode of the PV and PVC should be the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes.
`persistentVolumeReclaimPolicy`	Specifies what happens to the volume when it is released by its claim. The `Retain` value keeps the PVC around for manual cleanup. `Delete` deletes the PV from Kubernetes. **NOTE:** If this volume was created using dynamic provisioning, `Delete` causes the underlying volume to be deleted. For more information, see Reclaiming.
`capacity`	Specifies how big the allocated storage should be. This value is not validated against the quota or advisory quota. It is up to the person creating the PV to specify this value accurately.
`csi: nodePublishSecretRef`	The Ticket Secret for the CSI driver.
`nodePublishSecretRef:name`	The name of the Ticket Secret that contains the ticket to use when mounting to the cluster. See Configuring a Secret on page 3886.
`nodePublishSecretRef:namespace`	The namespace that contains the Ticket Secret. Use the same namespace as the namespace used by the PersistentVolume.
`csi: driver`	The CSI driver being used. Call it by specifying driver: `mapr.com/maprfs`.
`volumeHandle`	The existing volume name or unique volume name for static provisioning.
`volumePath`	The mount point within the file system. This parameter specifies an existing path. For example, you can specify the root volume as `"/"`, providing access to the entire filesystem.
`cluster`	The data-fabric cluster name.

last-updated: Jun 06, 2024

`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`securityType`	A parameter that indicates whether tickets are used or not used. If tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`platinum`	If set to `platinum: "true"`, the POSIX client uses the platinum driver for better performance. Note that the platinum driver consumes more host resources and Platinum licenses.
`license` (FUSE POSIX)	Release 1.0.2 and later support the `license: "<license-name>"` parameter in addition to the `platinum: "<true | false>"` parameter for the FUSE POSIX plugin. The `license: "<license-name>"` parameter can have one of three values that control the number of host resources that are consumed: • `"container"` for the Container driver (one binary, 8 threads) • `"basic"` for the Basic driver (one binary, 64 threads) • `"platinum"` for the Platinum driver (multiple binaries, each running 64 threads) Note the following considerations for using the `license: "<license-name>"` parameter: • To use the `license: "<license-name>"` parameter, you must have a Platinum license. • If you specify both the `platinum: "<true | false>"` parameter and the `license: "<license-name>"` parameter, the `platinum: "<true | false>"` parameter overrides the `license: "<license-name>"` parameter. • If neither the `platinum: "<true | false>"` nor the `license:` parameter is specified, the `container` driver is implemented.

`startupConfig` (FUSE POSIX)	Release 1.0.2 and later support specifying the `startupConfig` line. The `startupConfig` line allows you to specify FUSE configuration parameters that are passed to the `fuse.conf` file. For the parameters that can be passed, see Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client on page 1615.
	If no `startupConfig` line is specified, these default startup settings are used:
	`"-o allow_other -o big_writes -o auto_unmount"`
	The default settings allow other users to access the mount point, enable writes larger than 4 KB, and automatically unmount the filesystem when the process is terminated.
	The following example includes the three default settings and adds some additional settings (shown in **bold**):
	`startupConfig: "-o allow_other -o big_writes -o auto_unmount` **`-o async_dio -o max_background=24 -o auto_inval_data --disable_writeback`**`"`
	The additional settings enable asynchronous direct I/O, set the maximum number of asynchronous requests to 24, automatically invalidate the kernel FUSE cache for any data change that causes a change in the files, and disable the writeback cache.

`startupConfig` (Loopback NFS)	The `startupConfig` line allows you to specify configuration parameters that are passed to the `nfsserver.conf` file. For the parameters that can be passed, see nfsserver.conf on page 2989. The `startupConfig` values supported for Loopback NFS are all the configs supported in the `nfsserver.conf` file. Values must be separated by a space. If no `startupConfig` line is specified, these default startup settings are used: `startupConfig: "NFS_HEAPSIZE=1024 DrCacheSize=1024000"`

last-updated: Jun 06, 2024

`numrpcthreads`	Sets the number of RPC threads for the data-fabric client. The default value is 1. The maximum value is 4. Use this option to increase throughput with FUSE basic or container licenses or with the Loopback NFS driver.
`trackMemory`	Enables memory profiling to debug memory leaks in the FUSE or Loopback NFS process. To be enabled after direction from the DF support team. The default value is `false`.
`logLevel`	Sets the log level to one of the following values: `error`, `warn`, `info`, or `debug`. For the FUSE POSIX driver (`com.mapr.csi-kdf`), the default value is `error`. For the Loopback NFS driver (`com.mapr.csi-nfskdf`), the default value is `info`.
`retainLogs`	Retains the logs for the pod on the host machine. The default value is `false`.
`startDelay`	Sets the wait time after launching the FUSE or Loopback NFS processes and before making the mount available to the application pod. The default value is 5.  **CAUTION:** Setting the value below 2 to 3 seconds may affect the availability of the mount.

See Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin on page 3828 for more information.

2. Create a PersistentVolumeClaim (PVC) spec and set the `accessMode` of the PVC to `ReadWriteOnce`.

   For example:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-simplepvc
  namespace: test-csi
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

   The following table shows the properties used in the sample PersistentVolumeClaim:

Parameter	Notes
`metadata: name`	The PersistentVolumeClaim name.
`metadata: namespace`	The namespace in which the PersistentVolumeClaim is configured.
`accessMode`	How the requested PersistentVolume is mounted on the host.  **NOTE:** The PV and PVC modes should be the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes.

3. Generate a service ticket, and create and deploy a ticket secret on the pod (if you have already not done it as described in steps 1 and 2 of this example).

   See `maprlogin on page 2911` for information on generating a ticket and Configuring a Secret on page 3886 for information on creating and deploying a ticket secret.

4. Create the pod spec and set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.

last-updated: Jun 06, 2024

For example:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-pv
  namespace: test-csi
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
  containers:
  - name: busybox
    image: busybox
    args:
    - sleep
    - "1000000"
    resources:
      requests:
        memory: "2Gi"
        cpu: "500m"
    volumeMounts:
    - mountPath: /mapr
      name: maprflex
  volumes:
    - name: maprflex
      persistentVolumeClaim:
        claimName: test-simplepvc
```

The following table shows the properties defined in the sample pod spec:

Parameter	Notes
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. The example uses a naked pod for clarity. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The pod name.
`metadata: namespace`	The namespace in which the pod runs.
`securityContext: runAsUser`	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
`securityContext: fsGroup`	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. Matches with `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. The value should match `volumeMounts: name`.
`persistentVolumeClaim: claimName`	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims.

last-updated: Jun 06, 2024

5. Deploy the `.yaml` file on the pod by running the following command:

```
kubectl apply -f <filename>.yaml
```

For each Pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the data-fabric cluster. You can run the `node list` command on the data-fabric cluster to determine the number of POSIX clients. For example:

FUSE POSIX

```
# maprcli node list -clientsonly true
clienttype       clienthealth hostname
ip                                        lasthb  id

Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin

About this task

This example also uses a PersistentVolume. However, unlike the previous example, when you use the dynamic provisioner, you do not need to create a PersistentVolume manually. The PersistentVolume is created automatically based on the parameters specified in the referenced StorageClass.

Dynamic provisioning is useful in cases where you do not want Data Fabric and Kubernetes cluster administrators to create storage manually to store the pod storage state.

The following example uses a PersistentVolumeClaim that references a Storage Class. In this example, a Kubernetes administrator has created a storage class called `test-secure-sc` for pod creators to use when they want to create persistent storage for their pods. In this example, it is important for the created pod storage to survive the deletion of a pod.

last-updated: Jun 06, 2024

The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX provisioner (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS provisioner (`com.mapr.csi-nfskdf`).

To dynamically provision a volume, you must do the following:

Procedure

1. Generate a user ticket, and create and deploy a ticket secret on the pod. See:
   - Best Practices for Using Tickets on page 3889 to select the right ticket
   - maprlogin on page 2911 for information about generating a ticket
   - Configuring a Secret on page 3886 for information about creating and deploying a ticket secret
2. Create the REST secret and deploy the secret on the pod.
   See Configuring a Secret on page 3886 for information about creating and deploying a ticket secret.
3. Create a StorageClass similar to the following:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: test-secure-sc
  namespace: test-csi
provisioner: com.mapr.csi-kdf
allowVolumeExpansion: true
reclaimPolicy: Delete
parameters:
    csiProvisionerSecretName: "mapr-provisioner-secrets"
    csiProvisionerSecretNamespace: "test-csi"
    csiNodePublishSecretName: "mapr-ticket-secret"
    csiNodePublishSecretNamespace: "test-csi"
    restServers: "10.10.10.210:8443"
    cldbHosts: "10.10.10.210:7222"
    cluster: "clusterA"
    securityType: "secure"
    namePrefix: "csi-pv"
    mountPrefix: "/csi"
    advisoryquota: "100M"
    trackMemory: "false"
    logLevel: "error"
    retainLogs: "false"
    startupConfig: "-o allow_other -o big_writes -o auto_unmount -o
async_dio -o max_background=24 -o auto_inval_data --disable_writeback"
```

   For more information, see Storage Classes. The following table shows the properties defined in the sample StorageClass:

Property	Description
`apiVersion`	The Kubernetes API version for the StorageClass spec.
`kind`	The kind of object being created. This is a StorageClass.
`metadata: name`	The name of the StorageClass. Administrators should specify the name carefully because it will be used by pod authors to help select the right StorageClass for their needs.
`metadata: namespace`	The namespace in which the StorageClass runs. This namespace can be different from the namespace used by the PVC and pod, since the StorageClass namespace can be a cross-namespace resource.

last-updated: Jun 06, 2024

Property	Description
`provisioner`	The provisioner being used. For the FUSE POSIX provisioner, specify `com.mapr.csi-kdf`. For the Loopback NFS provisioner, specify `com.mapr.csi-nfskdf`.
`csiNodePublishSecretName`	The name of the Secret that contains the ticket to use when mounting to the HPE Ezmeral Data Fabric cluster. See Configuring a Secret on page 3886.
`csiNodePublishSecretNamespace`	The namespace that contains the Secret. Use the same namespace as the namespace used by the pod.
`csiProvisionerSecretName` (deprecated) `csi.storage.k8s.io/provisioner-secret-name`	The name of the Kubernetes Secret that is used to store Data Fabric administrative credentials (user, password, and ticket information for the Data Fabric webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 3886.
`csiProvisionerSecretNamespace` (deprecated) `csi.storage.k8s.io/provisioner-secret-namespace`	The namespace for the Secret containing the Data Fabric administrative credentials (user name and password information for a Data Fabric user that has the privileges to create volumes). This namespace can be different from the namespace used by the pod, since a pod author or namespace admin might not be trusted to create administration Secrets for the Data Fabric cluster.
`restServers`	A space-separated list of Data Fabric webservers. Specify the hostname or IP address and port number of each REST server for the cluster. For fault tolerance, providing multiple REST server hosts is recommended.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the Data Fabric cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`cluster`	The Data Fabric cluster name.
`securityType`	A parameter that indicates whether Data Fabric tickets are used or not used. If Data Fabric tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`namePrefix`	A prefix for the Data Fabricvolume to be created. For example, if you specify `PV` as the `namePrefix`, the first dynamically created volume might be named `PV.bevefsescr`. The provisioner generates random names using lower-case letters. If you do not specify a prefix, the provisioner uses `maprprovisioner` as a prefix.
`mountPrefix`	The parent path of the mount in the Data Fabricfile system. If you do not specify a mount prefix, the provisioner mounts your volume under the Data Fabric root.  **NOTE:** User provisioning a volume under this `mountPrefix` requires read-write permissions to mount the newly created volume; otherwise, the volume provision will fail.
`advisoryquota`	The advisory storage quota for the volume. The `advisoryquota` is one of the Data Fabric parameters that you can specify for dynamic provisioning. For more information, see Before You Begin on page 3870.
`trackMemory`	Enables memory profiling to debug memory leaks in the FUSE or Loopback NFS process. To be enabled after direction from the DF support team. The default value is `false`.
`logLevel`	Sets the log level to one of the following values: `error`, `warn`, `info`, or `debug`. For the FUSE POSIX driver (`com.mapr.csi-kdf`), the default value is `error`. For the Loopback NFS driver (`com.mapr.csi-nfskdf`), the default value is `info`.
`retainLogs`	Retains the logs for the pod on the host machine. The default value is `false`.

last-updated: Jun 06, 2024

Property	Description

`startupConfig` (FUSE POSIX)	Release 1.0.2 and later support specifying the `startupConfig` line. The `startupConfig` line allows you to specify FUSE configuration parameters that are passed to the `fuse.conf` file. For the parameters that can be passed, see Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client on page 1615.
	If no `startupConfig` line is specified, these default startup settings are used:
	`"-o allow_other -o big_writes -o auto_unmount"`
	The default settings allow other users to access the mount point, enable writes larger than 4 KB, and automatically unmount the file system when the process is terminated.
	The following example includes the three default settings and adds some additional settings (shown in **bold**):
	`startupConfig: "-o allow_other -o big_writes -o auto_unmount`
	`-o async_dio`
	`-o max_background=24 -o auto_inval_data --disable_writeback``"`
	The additional settings enable asynchronous direct I/O, set the maximum number of asynchronous requests to 24, automatically invalidate the kernel FUSE cache for any data change that causes a change in the files, and disable the writeback cache.

`startupConfig` (Loopback NFS)	The `startupConfig` line allows you to specify configuration parameters that are passed to the `nfsserver.conf` file. For the parameters that can be passed, see nfsserver.conf on page 2989. The `startupConfig` values supported for Loopback NFS are all the configs supported in the `nfsserver.conf` file. Values must be separated by a space. If no `startupConfig` line is specified, these default startup settings are used: `startupConfig: "NFS_HEAPSIZE=1024 DrCacheSize=1024000"`
`numrpcthreads`	Sets the number of RPC threads for the Data Fabric client. The default value is 1. The maximum value is 4. Use this option to increase throughput with FUSE basic or container licenses or with the Loopback NFS driver.
`startDelay`	Sets the wait time after launching the FUSE or Loopback NFS processes and before making the mount available to the application pod. The default value is 5. **CAUTION:** Setting the value below 2 to 3 seconds may affect the availability of the mount.

4. Configure a PersistentVolumeClaim similar to the following:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

The following table shows the properties defined in the sample PersistentVolumeClaim:

last-updated: Jun 06, 2024

Property	Description
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. This is a PersistentVolumeClaim (PVC).
`metadata: name`	The PVC name.
`metadata: namespace`	The namespace in which the PVC runs. This should be the same namespace used by the pod.
`storageClassName`	The name of the storage class requested by the PersistentVolumeClaim. For more information, see Dynamic Provisioning and Storage Classes.
`accessModes`	How the PersistentVolume is mounted on the host. For more information, see Access Modes.
`requests: storage`	The storage resources being requested, or that were requested and have been allocated. The pod author can use this parameter to specify how much quota is needed for the Data Fabric volume. For the units, see Resource Model.

5. Create the pod spec similar to the following:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure-pod
  namespace: test-csi
spec:
  containers:
  - name: busybox
    image: busybox
    args:
    - sleep
    - "1000000"
    resources:
      requests:
        memory: "2Gi"
        cpu: "500m"
    volumeMounts:
    - mountPath: /mapr
      name: maprflex
  volumes:
    - name: maprflex
      persistentVolumeClaim:
        claimName: test-secure-pvc
```

The following table shows the properties defined in the sample pod spec:

Property	Description
`apiVersion`	The Kubernetes API version for the pod spec.
`kind`	The kind of object being created. For clarity, this example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The pod name.
`metadata: namespace`	The namespace in which the pod runs. It should be the same namespace in which the PVC runs.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.

last-updated: Jun 06, 2024

Property	Description
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. The value should match `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. The value should match `volumeMounts: name`.
`persistentVolumeClaim: claimName`	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims.

6. Deploy the `.yaml` file on the pod by running the following command:

```
kubectl apply -f <filename>.yaml
```

For each pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the Data Fabric cluster. You can run the `node list` on page 2264 command on the cluster to determine the number of POSIX clients. For example:

FUSE POSIX

```
# maprcli node list -clientsonly true
clienttype clienthealth hostname ip lasthb id
posixclientbasic Inactive 4f3d34fe-2007-11e9-8980-0cc47ab39644

  volumes:
    - name: maprflex
      persistentVolumeClaim:
        claimName: test-secure-pvc
```

Example: Volume Cloning for Dynamic Provisioning

About this task

You can clone a volume from an existing volume by configuring a PersistentVolumeClaim that specifies the volume PVC as the data source. In the following example, the PVC named `testcsi-secure-pvc` serves as the data source for creating a new volume named `testcsi-secure-pvc-clone`:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
 name: testcsi-secure-pvc-clone
 namespace: test-csi
spec:
 storageClassName: testcsi-secure-sc
```

last-updated: Jun 06, 2024

```
 accessModes:
    - ReadWriteOnce
 resources:
 requests:
 storage: 10G
 dataSource:
 kind: PersistentVolumeClaim
 name: testcsi-secure-pvc
```

When cloning extra large volumes (volumes measuring hundreds of GB), you might experience timeouts or a failure to clone the volume. To prevent timeouts with extra large volumes, increase the retry timeout setting for the `csi-provisioner` sidecar container. See the `--timeout` argument in the latest `csi-maprkdf-<version>.yaml`.

For more information, see CSI Volume Cloning.

Example: Volume Expansion for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin

About this task

The following versions of the Container Storage Interface (CSI) Storage Plugin support a volume expansion feature for dynamically provisioned volumes:

- FUSE POSIX plugin versions 1.1.0 and later
- Loopback NFS plugin versions 1.0.0 and later

Volume expansion means you can increase the storage quota of volumes created by the CSI driver. Note that the `StorageClass` must have `allowVolumeExpansion` set to `true` for volume expansion to succeed. For more information about volume expanssion, see Expanding Persistent Volume Claims.

To use volume expansion, increase the storage value and reapply the PersistentVolumeClaim configuration. For example, in the following PVC configuration, to increase the storage quota for the volume from 5G to 10G, change `storage: 5G` to `storage: 10G`, and run the `kubectl apply -f <path_to_pvc>.yaml` command:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: test-secure-pvc
  namespace: test-csi
spec:
  storageClassName: test-secure-sc
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5G
```

Verifying Creation of a Kubernetes PersistentVolumeClaim and Persistent Volume

About this task

Once the pod spec is installed, you can verify the status of a PersistentVolumeClaim and/or a PersistentVolume by using the `kubectl` command. For example:

Procedure

1. Run the Kubernetes `get` command to verify the status of the PersistentVolumeClaim:

NOTE: The information on this page is valid for both FUSE POSIX and Loopback NFS plugins. Examples or tables that mention the FUSE POSIX driver (`com.mapr.csi-kdf`) are equally valid for the Loopback NFS driver (`com.mapr.csi-nfskdf`).

Static Provisioning

```
# kubectl describe pvc -n test-csi
Name:          mapr-secure-claim
Namespace:     test-csi
StorageClass:
Status:        Bound
Volume:        pv-securepv-test
Labels:        <none>
Annotations:
kubectl.kubernetes.io/
last-applied-configuration:

{"apiVersion":"v1","kind":"Persisten
tVolumeClaim","metadata":
{"annotations":

3. Run the `node list` on page 2264 command on the cluster to determine the number of POSIX clients.

   For each pod mount request, the POSIX client starts with the pod's hostname and new generated hostid, which is tracked on the cluster. For example:

```
# maprcli node list -clientsonly true
clienttype        clienthealth  hostname
ip                                      lasthb  id
posixclientbasic  Inactive      4f3d34fe-2007-11e9-8980-0cc47ab39644
10.10.102.94,172.17.0.1,192.168.28.0    11225   7407394893618656436

Managing Snapshots Using the Container Storage Interface (CSI) Storage Plugin

This section describes how to create and delete one or more snapshots of volumes dynamically provisioned by the Container Storage Interface (CSI) Storage Plugin on the data-fabric cluster.

The Container Storage Interface (CSI) Storage Plugin v1.x.x uses the `csi-snapshotter` to support snapshot provisioning.

CSI now supports snapshot restore, which allows you to create a new volume from the snapshot data of another volume. See Creating a Volume from a Snapshot on page 3865. To manually restore a volume, see Copying From a Snapshot Using the CLI on page 1276.

Creating a Snapshot Using the Container Storage Interface (CSI) Storage Plugin

About this task

You can create one or more snapshots of a dynamically provisioned volume using the Container Storage Interface (CSI) Storage Plugin.

Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster

Procedure

1. Verify that the volume was successfully provisioned by checking the PersistentVolume (PV) and PersistentVolumeClaim (PVC) for the volume.

   For example, run the `kubectl describe` command to verify the PV and then the PVC.

```
# kubectl describe pv -n test-csi
Name:            mapr-pv-e46a50cd-2012-11e9-84c0-0cc47ab39644
Labels:          <none>
Annotations:     pv.kubernetes.io/provisioned-by: com.mapr.csi-kdf
Finalizers:      [kubernetes.io/pv-protection]
StorageClass:    test-secure-sc
Status:          Bound
Claim:           test-csi/test-secure-pvc
Reclaim Policy:  Delete
Access Modes:    RWO
VolumeMode:      Filesystem
Capacity:        5Gi
Node Affinity:   <none>
Message:
Source:
    Type:              CSI (a Container Storage Interface (CSI) volume
source)

com.mapr.csi-kdf_csi-controller-kdf-0_69805ad1-2010-11e9-88dc-d610076b9fb
3  External provisioner is provisioning volume for claim "test-csi/
test-secure-pvc"
  Normal     ProvisioningSucceeded  3m40s
com.mapr.csi-kdf_csi-controller-kdf-0_69805ad1-2010-11e9-88dc-d610076b9fb
3  Successfully provisioned volume
mapr-pv-e46a50cd-2012-11e9-84c0-0cc47ab39644
Mounted By:  test-secure-pod
```

2. Deploy the REST secret `.yaml` file by running the following command:

```
kubectl apply -f <secret filename>.yaml
```

   The Secret file should look similar to the following:

```
# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved
apiVersion: v1
kind: Secret
metadata:
  name: mapr-snapshot-secrets
  namespace: test-csi
type: Opaque
data:
  MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

   For more information, see Configuring a Secret on page 3886.

3. Create a snapshot class for provisioning a snapshot of the volume. For example, the snapshot class file should look similar to the following:

   FUSE

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshotClass
metadata:
 name: testcsi-snapshotclass
 namespace: test-csi
driver: com.mapr.csi-kdf
deletionPolicy: Delete
parameters:
 restServers: "10.10.102.95:8443"
 cluster: "mycluster"
 csi.storage.k8s.io/snapshotter-secret-name: mapr-snapshot-secrets
 csi.storage.k8s.io/snapshotter-secret-namespace: test-csi
```

   Loopback NFS

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshotClass
metadata:
 name: testcsi-snapshotclass
 namespace: test-csi
driver: com.mapr.csi-nfskdf
```

```
deletionPolicy: Delete
parameters:
 restServers: "10.10.102.95:8443"
 cluster: "mycluster"
 csi.storage.k8s.io/snapshotter-secret-name: mapr-snapshot-secrets
 csi.storage.k8s.io/snapshotter-secret-namespace: test-csi
```

The sample snapshot class file shown above contains the following properties:

Property	Description
`apiVersion`	The Kubernetes APi version for the StorageClass spec.
`kind`	The kind of object being created. This is a StorageClass.
`metadata: name`	The name of the snapshot calss. Administrators should specify the name carefully because it will be used by Pod authors to help select the right snapshot class for their needs.
`metadata: namespace`	The namespace in which the snapshot class runs.
`driver`	The CSI volume plugin to use for provisioning the volume snapshots. For example: `com.mapr.csi-kdf`.
`restServers`	A space-separated list of webservers. Specify the hostname or IP address and port number of each REST server for the cluster. For fault tolerance, providing multiple REST server hosts is recommended.
`cluster`	The cluster name.
`csiSnapshotterSecretName` (deprecated) `csi.storage.k8s.io/snapshotter-secret-name`	The name of the Kubernetes Secret that is used to store administrative credentials (user, password, and ticket information for the webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 3886.
`csiSnapshotterSecretNamespace` (deprecated) `csi.storage.k8s.io/snapshotter-secret-namespace`	The namespace for the Secret containing the administrative credentials (user name and password information for a user that has the privileges to create volumes). This namespace can be different from the namespace used by the Pod, since a Pod author or namespace admin might not be trusted to create administration Secrets for the cluster.

4. Deploy the snapshot class by running the following command:

```
kubectl apply -f <snapshot class>.yaml
```

5. Verify whether the snapshot class was successfully deployed by running one of the following commands:

```
# kubectl get volumesnapshotclass -n test-csi
NAME                 AGE
test-snapshotclass   41s
root@qa102-92:~/csi-kdf-3/csi-kdf/examples/snapshot# kubectl describe
volumesnapshotclass -n test-csi
Name:         test-snapshotclass
Namespace:
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
                {"apiVersion":"snapshot.storage.k8s.io/
v1","kind":"VolumeSnapshotClass","metadata":{"annotations":
{},"name":"test-snapshotclass"},"p...

```
metadata:
  resourceVersion: ""
  selfLink: ""
```

6. Associate the snapshot class with the PersistentVolumeClaim (for the volume to take a snapshot of) by creating a VolumeSnapshot. For example, the VolumeSnapshot file should look similar to the following:

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshot
metadata:
 name: testcsi-secure-snapshot
 namespace: test-csi
spec:
 volumeSnapshotClassName: testcsi-snapshotclass
 source:
    persistentVolumeClaimName: testcsi-secure-pvc
```

   The sample VolumeSnapshot file shown above contains the following properties:

Property	Description
`metadata: name`	The VolumeSnapshot name.
`metadata: namespace`	The namespace in which the VolumeSnapshot runs.
`snapshotClassName`	The volumeSnapshotClassName.
`source: name`	The persistentVolumeClaimName.

7. Deploy the VolumeSnapshot by running the following command:

```
kubectl apply -f <volume snapshot>.yaml
```

8. Verify whether VolumeSnapshot was successfully deployed by doing the following:

last-updated: Jun 06, 2024

a) Run one of the following commands to retrieve the VolumeSnapshot:

```
# kubectl get volumesnapshot -n test-csi -o yaml
apiVersion: v1
items:
- apiVersion: snapshot.storage.k8s.io/v1
  kind: VolumeSnapshot
  metadata:
    annotations:
      kubectl.kubernetes.io/last-applied-configuration: |
        {"apiVersion":"snapshot.storage.k8s.io/
v1","kind":"VolumeSnapshot","metadata":{"annotations":
{},"name":"test-snapshot","namespace":"test-csi"},"spec":
{"snapshotClassName":"test-snapshotclass","source":
{"kind":"PersistentVolumeClaim","name":"test-secure-pvc"}}}
    creationTimestamp: "2019-01-24T21:16:21Z"
    finalizers:
    - snapshot.storage.kubernetes.io/volumesnapshot-protection
    generation: 5
    name: test-snapshot
    namespace: test-csi
    resourceVersion: "1039445"
    selfLink: /apis/snapshot.storage.k8s.io/v1/namespaces/test-csi/
volumesnapshots/test-snapshot
    uid: 4c5293bc-201d-11e9-84c0-0cc47ab39644

```

9. Log in to the cluster and verify by running the `volume snapshot list` on page 2705 command. For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvsdxwu -cluster clusterA -json
{
    "timestamp":1548365090744,
    "timeofday":"2019-01-24 01:24:50.744 GMT-0800 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000051",

"snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:16:22 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        }
    ]
}
```

Creating Multiple Snapshots of a Dynamically Provisioned Volume

Procedure

1. Perform steps 1 - 5 described in the Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster on page 3853 section.

2. Create a VolumeSnapshot similar to the one shown in step 6 of the Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster on page 3853 section for each additional snapshot to create for the volume.

   For example:

   ```
   apiVersion: snapshot.storage.k8s.io/v1
   kind: VolumeSnapshot
   metadata:
     name: test-snapshot1
     namespace: test-csi
   spec:
     snapshotClassName: test-snapshotclass
     source:
       name: test-secure-pvc
       kind: PersistentVolumeClaim
   ```

3. Repeat step 7 in Creating a Snapshot of a Dynamically Provisioned Volume on the Cluster on page 3853 for each additional volume snaphots you have created.

last-updated: Jun 06, 2024

4. Log in to the cluster and verify by running the `volume snapshot list` on page 2705 command. For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvsdxwu -cluster clusterA -json
{
    "timestamp":1548365359138,
    "timeofday":"2019-01-24 01:29:19.138 GMT-0800 PM",
    "status":"OK",
    "total":2,
    "data":[
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000051",

"snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:16:22 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        },
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000052",

"snapshotname":"mapr-snapshot-19282d27-201f-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:29:15 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        }
    ]
}
```

Deleting a Snapshot of a Dynamically Provisioned Volume

About this task

You can delete snapshots you created using Container Storage Interface (CSI) Storage Plugin. To delete:

Procedure

1. Run the following command:

```
kubectl delete -f <volume snapshot>.yaml
```

   For example:

```
# kubectl delete -f test-snapshot1.yaml
volumesnapshot.snapshot.storage.k8s.io "test-snapshot1" deleted
```

2. Log in to the cluster and verify that the snapshot was deleted by running the `volume snapshot list` on page 2705 command.

   For example:

```
# maprcli volume snapshot list -path /csisc/
csisc-securesc-txiqvsdxwu -cluster clusterA -json
{
    "timestamp":1548365417772,
    "timeofday":"2019-01-24 01:30:17.772 GMT-0800 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "ownername":"root",
            "ownertype":"1",
            "volumeid":"234021649",
            "volumename":"csisc-securesc.txiqvsdxwu",
            "volumepath":"/csisc/csisc-securesc-txiqvsdxwu",
            "snapshotid":"256000051",

"snapshotname":"mapr-snapshot-4c5293bc-201d-11e9-84c0-0cc47ab39644",
            "creationtime":"Thu Jan 24 13:16:22 PST 2019",
            "cumulativeReclaimSizeMB":"0",
            "ownedsize":"0",
            "sharedSize":"0",
            "volumeSnapshotAces":{
                "readAce":"p",
                "writeAce":"p"
            }
        }
    ]
}
```

Creating a Volume from a Snapshot

You can restore a volume from a volume snapshot by configuring a PersistentVolumeClaim that specifies the volume snapshot as the data source.

In the following example, the snapshot named `testcsi-secure-snapshot` serves as the data source for creating a new volume named `testcsi-secure-pvc-restore`:

```
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: testcsi-secure-pvc-restore
  namespace: test-csi
spec:
  storageClassName: testcsi-secure-sc
  accessModes:
```

last-updated: Jun 06, 2024

```
    - ReadWriteOnce
  resources:
    requests:
      storage: 10G
  dataSource:
    kind: VolumeSnapshot
    apiGroup: snapshot.storage.k8s.io
    name: testcsi-secure-snapshot
```

When creating a volume from snapshots of extra large volumes (volumes measuring hundreds of GB), you might experience timeouts or a failure to create the volume. To prevent timeouts with extra large volumes, increase the retry timeout setting of the `csi-snapshotter` sidecar container. See the `--timeout` argument in the latest `csi-maprkdf-<version>.yaml`.

For more information, see Persistent Volumes.

Enabling the Platinum POSIX Client for Container Storage Interface (CSI) Storage Plugin

When you install the Container Storage Interface (CSI) Storage Plugin, the Container FUSE-based POSIX client package is installed on the CSI Driver container. The CSI Driver also supports the use of the Basic, Container, and Platinum FUSE-based POSIX client. For a comparison of the POSIX client packages, see Preparing for Installation (HPE Ezmeral Data Fabric POSIX Client) on page 432.

NOTE: Enabling the Platinum POSIX client is not required for the Loopback NFS plug-in.

To install the Platinum POSIX client, include the `platinum` parameter in your pod spec. For example:

```
volumeAttributes:
    volumePath: "/"
    cluster: "clusterA"
    cldbHosts: "10.10.102.96"
    securityType: "secure"
    platinum: "true"
```

Release 1.0.2 and later support another method for specifying the POSIX client. You can use the `license` parameter and specify the Container, Basic, or Platinum driver. For example:

```
volumeAttributes:
    volumePath: "/"
    cluster: "clusterA"
    cldbHosts: "10.10.102.96"
    securityType: "secure"
    license: "platinum"
```

For more information, see Example: Mounting a PersistentVolume for Static Provisioning on page 3831.

Logging for the CSI Driver and Provisioner
Describes the event logs for the CSI driver and provisioner for both FUSE and Loopback NFS plugins.

Logs for the Container Storage Interface (CSI) Storage Plugin can be found in `/var/log/csi-maprkdf/`. The following table shows the new log-file format. Before the FUSE 1.2.2 and Loopback NFS 1.0.2 drivers were introduced, the log files included a version in the file name.

Log File Type	FUSE or Loopback NFS	Log File	Description	Which Nodes
Driver events log	FUSE	`csi-plugin.log`	Captures CSI Driver events such as registering the driver and CSI Driver logs for node mount and unmount operations.	All Kubernetes nodes.
	Loopback NFS	`csi-nfsplugin.log`		

last-updated: Jun 06, 2024

Log File Type	FUSE or Loopback NFS	Log File	Description	Which Nodes
Provisioner events log	FUSE	`csi-provisioner.log`	Captures provisioner events such as registering the CSI provisioner and CSI Controller events such as Create/Delete volumes, Create/Delete Snapshots etc.	The Kubernetes node where the provisioner StatefulSet pod is running.
	Loopback NFS	`csi-nfsprovisioner.log`		

NOTE: The directory must grant `rw` permissions for creating the logs and must grant write/append permissions to the plug-in and provisioner.

Troubleshooting the Container Storage Interface (CSI) Storage Plugin
This section describes how to resolve common problems you might encounter when installing and using the Container Storage Interface (CSI) Storage Plugin.

Troubleshooting CSI Driver installation

Run the following commands to get the pods that are deployed for the CSI plugin and provisioner:

FUSE

```
kubectl get pods -n mapr-csi
```

Loopback NFS

```
kubectl get pods -n mapr-nfscsi
```

The installation is considered successful if the `get pods` command shows the pods in the `Running` state. For example, your output should look similar to the following when CSI plugin is deployed on three worker nodes:

FUSE

```
mapr-csi       csi-controller-kdf-0         5/5     Running     0
4h25m
mapr-csi       csi-nodeplugin-kdf-2kfrf     3/3     Running     0
4h25m
mapr-csi       csi-nodeplugin-kdf-lq5nw     3/3     Running     0
4h25m
mapr-csi       csi-nodeplugin-kdf-pkrzt     3/3     Running     0
4h25m
```

Loopback NFS

```
csi-controller-nfskdf-0       7/7     Running   0          22h
csi-nodeplugin-nfskdf-5rjt2   3/3     Running   0          18h
csi-nodeplugin-nfskdf-7d9cs   3/3     Running   0          22h
csi-nodeplugin-nfskdf-qw7kg   3/3     Running   0          22h
```

The preceding output shows the following:

FUSE

- `csi-nodeplugin-kdf-*`: Daemonset pods deployed on all the Kubernetes worker nodes
- `csi-controller-kdf-0`: StatefulSet pod deployed on a single Kubernetes worker node

Loopback NFS

last-updated: Jun 06, 2024

- `csi-nodeplugin-nfskdf-*`: Daemonset pods deployed on all the Kubernetes worker nodes
- `csi-controller-nfskdf-0`: StatefulSet pod deployed on a single Kubernetes worker node

Troubleshoot CSI Plugin Deployment Failures

If the pods show a failure in the deployment, run the following kubectl command to see the container logs:

FUSE

```
kubectl logs <csi-nodeplugin-*> -n mapr-csi -c <nodeplugin-pod-container>
```

Loopback NFS

```
kubectl logs <csi-nodeplugin-*> -n mapr-nfscsi -c <nodeplugin-pod-container>
```

If the pods show a failure in the deployment, run the following kubectl commands to see the container logs:

FUSE

```
kubectl logs <csi-nodeplugin-*> -n mapr-csi -c <nodeplugin-pod-container>
```

Loopback NFS

```
kubectl logs csi-controller-nfskdf-0 -n mapr-nfscsi -c
<controller-pod-container>
```

Here, replace `<nodeplugin-pod-container>` with the container that is failing. You can also run the following kubectl command to see the controller logs:

```
kubectl logs csi-controller-kdf-0 -n mapr-csi -c <controller-pod-container>
```

Here, replace `<controller-pod-container>` with the container which is failing.

Troubleshooting Volume Provisioning

Check the provisioner log and check for any provisioner errors:

FUSE

```
tail -100f /var/log/csi-maprkdf/csi-provisioner.log
```

Loopback NFS

```
tail -100f /var/log/csi-maprkdf/csi-nfsprovisioner.log
```

Troubleshooting Mount Operation

Check the CSI Storage plug-in log for any mount/unmount errors:

FUSE

```
tail -100f /var/log/csi-maprkdf/csi-plugin.log
```

Loopback NFS

```
tail -100f /var/log/csi-maprkdf/csi-nfsplugin.log
```

If you don't see any errors, see the kubelet logs on the node where the pod is scheduled to run. Check the MapR CSI Storage plugin logs for specific errors.

Troubleshooting CSI Storage Plugin Discovery with kubelet

Check the kubelet path for kubernetes deployment from the kubelet process running with `--root-dir`. The `--root-dir` is a string that contains the directory path for managing kubelet files (such as volume mounts, etc.,) and defaults to `/var/lib/kubelet`. If the Kubernetes environment has a different kubelet path, modify the CSI driver deployment `.yaml` file with the new path, and redeploy the CSI Storage Plugin again.

Troubleshooting Snapshot Provisioning

See the provisioner log and check for any provisioner errors:

```
tail -100f /var/log/csi-maprkdf/csi-provisioner.log
```

If there are no errors, run the following kubectl command to check the snapshot:

```
kubectl describe volumesnapshot.snapshot.storage.k8s.io <snapshot-name> -n
<namespace-name>
```

Here:

- `<snapshot-name>`: Name of the VolumeSnapshot Object defined in yaml
- `<namespace-name>`: Namespace where the VolumeSnapshot object is created

Troubleshooting No Space on Disk Error

The devicemapper storage driver used for Docker allows only 10 GB by default resulting in "no space left on device" errors when writing to new directories for a new volume mount request. If `--maxvolumepernode` is configured to be greater than 20 and underlying docker is using devicemapper storagedriver, do the following to increase the storage size:

1. Change storagedriver to be other than devicemapper, which restricts container storage to 10 GB by default.
2. Increase default container storage to more than the default of 10 GB for devicemapper storagedriver for the Docker container running on Kubernetes worker node.

For example, do the following to increase the storage size to 50 GB:

1. In `/etc/sysconfig/docker-storage` file, add `--storage-opt dm.basesize=50G` under `DOCKER_STORAGE_OPTIONS` section.
2. Restart Docker.
3. Confirm that the setting is correctly applied by running the following command:

   ```
   docker info | grep "Base Device Size"
   ```

Kubernetes FlexVolume Driver Configuration

This section describes how to use and troubleshoot the HPE Ezmeral Data Fabric for Kubernetes FlexVolume Driver.

For more information about the HPE Ezmeral Data Fabric for Kubernetes, see Kubernetes Interfaces for Data Fabric FlexVolume Driver Overview on page 809.

Using the MapR Data Fabric for Kubernetes FlexVolume Driver

This section describes how to configure Kubernetes objects to enable persistent storage and includes example configuration files for static and dynamic provisioning.

Before You Begin

Before configuration, be sure to review the following notes about supported and unsupported features and parameters:

MapR Parameters for Dynamic Provisioning

In dynamic provisioning, you can specify MapR parameters for the MapR volume to be created. For a list of the MapR parameters that you can use, see volume create on page 2588. Note these considerations for using the MapR parameters:

- Volume attributes must be represented as a string (enclosed within quotations). Using an integer or boolean is not supported. In the following example, the `aetype` attribute will generate an error because the value (`1`) is not enclosed in quotations.

```
namePrefix: "pv"
mountPrefix: "/pv"
type: "rw"
advisoryquota: "100M"
aetype: 1
```

- The following MapR parameters are ignored because they are redundant or not supported in the Kubernetes implementation:
  - `mount`
  - `quota*`
  - `createparent`
  - `path`
  - `name`

*Specifying `resources: requests: storage` in a PersistentVolumeClaim (PVC) (see Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver on page 3874) makes it unnecessary to set the MapR `quota` parameter.

Kubernetes Access Modes

Kubernetes access modes control how a PersistentVolume (PV) is mounted on the host. Access modes can be specified on both PVs and PVCs. Only Volumes with a matching Access Mode will be bound to a PVC. Unfortunately, beyond the PVC/PV binding behavior, PVs using FlexVolume drivers ignore these access modes in the current version of Kubernetes. All access modes will work with the MapR Data Fabric for Kubernetes. However, they will appear the same. This means the ROX mode will not make the volume read only. If you want read-only behavior, specify `readOnly:` in the FlexVolume driver flags.

PersistentVolumeClaim Protection

PVC protection is a Kubernetes 1.9 alpha feature that restricts the user from deleting a PVC while it is being used by an active Pod. Alpha features are not tested for use with the volume plug-in and provisioner. However, without PVC protection, you should not delete a PVC that is still attached to Pods. If you have not turned on PVC protection, ensure that you do not delete PVC's that are in use. In the current release of the MapR Data Fabric for Kubernetes, deleting a PVC causes undefined behavior.

last-updated: Jun 06, 2024

Reclaim Policy

The Kubernetes `reclaimPolicy` parameter controls what happens to a PersistentVolume if the corresponding PersistentVolumeClaim is deleted. The `Recycle` Reclaim Policy is not supported by Kubernetes FlexVolume Drivers, so it cannot be used with KDF. The Retain Policy is currently broken in Kubernetes 1.9 StoragePolicies but not in static PersistentVolumes. The MapR Data Fabric for Kubernetes has a workaround that allows Retain policy on dynamically provisioned volumes by passing the `reclaimPolicy:` in the parameters rather than in the standard place that FlexVolumes ignore. You can specify the reclaim policy normally when you configure a persistent volume.

The following table shows the supported values for the reclaim policy:

Reclaim Policy Value	Description	Support
Delete (default value)	The PersistentVolume and the MapR volume are deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported
Retain	The PersistentVolume and the MapR volume are not deleted when the user deletes the corresponding PersistentVolumeClaim.	Supported*
Recycle	Performs a basic scrub on a PersistentVolume and makes it available for a new PersistentVolumeClaim.	Not Supported by Kubernetes Flexvolumes

*Not supported for dynamic provision without a workaround.

For more information about the reclaim policy, see Change the Reclaim Policy of a PersistentVolume.

Kubernetes Mount Options

The Kubernetes `mountOptions` parameter is not supported for use with the MapR Data Fabric for Kubernetes because it is not supported for use with the FlexVolume plug-in.

Steps for Configuring the MapR Data Fabric for Kubernetes FlexVolume Driver

This page summarizes the high-level steps for configuring the MapR Data Fabric for Kubernetes FlexVolume Driver to provide static or dynamic provisioning. To learn more about static and dynamic provisioning, see Static and Dynamic Provisioning Using FlexVolume Driver on page 811.

Static Provisioning

1. Install the MapR Data Fabric for Kubernetes.

   See Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 292.

2. In your Pod spec or as part of a separate configuration file, configure a PersistentVolume.

   See Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver on page 3874 and Persistent Volumes.

3. Do *one* of the following:

   - Annotate the Pod spec to provide information about the MapR volume.

     See Example: Statically Provisioning a MapR Volume Using the FlexVolume Plug-in on page 3872.

   - In your Pod spec or as part of a separate configuration file, configure a PersistentVolumeClaim.

     See PersistentVolumeClaims.

4. Run the Pod spec by using `kubectl` commands. See Overview of kubectl.

last-updated: Jun 06, 2024

Dynamic Provisioning

1. Install the MapR Data Fabric for Kubernetes.

   See Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 292.

2. In your Pod spec or in a separate configuration file, create a storage class.

   See Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver on page 3878 and Storage Classes.

3. In your Pod spec or in a separate configuration file, configure a PersistentVolumeClaim.

   See Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver on page 3878.

4. Run the Pod spec by using `kubectl` commands. See Overview of kubectl.

Example: Statically Provisioning a MapR Volume Using the FlexVolume Plug-in

You can designate a MapR volume for use with Kubernetes by specifying the MapR FlexVolume parameters directly inside the Pod spec. In the Pod spec, you define a Kubernetes volume and add the MapR FlexVolume information to it. You can supply path information by using the `volumePath` parameter. The Kubernetes volume is only as persistent as the Pod. By defining the volume this way, when the Pod is removed, the Kubernetes volume is also immediately unmounted and removed. This approach to static provisioning is most appropriate when you want to get up and running quickly or when you want the Pod and Kubernetes volume lifecycle to be the same.

For example, a developer wants to get her application container up and running quickly with MapR. She already has a MapR path that she wants to use for the application. She only needs the data accessible to read. To make this work, she must:

1. Generate a MapR service ticket, and set the `securityType` parameter in the Pod spec to `secure`. See Generating a Service Ticket on page 1832.

2. Configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret. See Configuring a Secret on page 3886.

3. Set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.

4. Point the `volumePath` in the `flexVolume` setting to the desired path, and fill in the `cldbHosts` and `cluster` information.

NOTE: The following example works for on-premise deployments. For GKE and AWS deployments, you must set a default StorageClass to the `maprfs` StorageClass. If a default StorageClass is not provided for GKE and AWS deployments, the volume is created using your default StorageClass, which might not be a good fit. For information about changing the default StorageClass, see Change the default StorageClass.

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples

apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: <BASE64 ENCODED VERSION OF CONTENTS OF TICKET FILE>
```

The following tables describe the parameters in the example:

Pod

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. For clarity, the example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability (HA) and ease of upgrade.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs.
`securityContext: runAsUser`	The user ID to run the container under. This user ID must be the same as the user ID for which the ticket was generated.
`securityContext: fsGroup`	The group ID to run the container under. This group ID must be the same as the group ID of the user for which the ticket was generated.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. Matches with `Volumes: name`.

last-updated: Jun 06, 2024

`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. Matches with `volumeMounts: name`.
`flexVolume: driver`	The MapR FlexVolume driver being used. Call it using this driver: `mapr.com/maprfs`.
`flexVolume: readOnly`	Specifies that the FlexVolume driver should tell the MapR POSIX Client to mount the volume with the read-only flag.
`volumePath`	The mount point within the MapR filesystem. This parameter specifies an existing MapR path. For example, you can specify the root volume as `"/"`, providing access to the entire filesystem.
`cluster`	The MapR cluster name.
`cldbHosts`	The DNS names or IP addresses of the CLDB hosts for the MapR cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`securityType`	A parameter that indicates whether MapR tickets are used or not used. If MapR tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`ticketSecretName`	The name of the Secret that contains the ticket to use when mounting to the MapR cluster. See Configuring a Secret on page 3886.
`ticketSecretNamespace`	The namespace that contains the Secret. See Configuring a Secret on page 3886

Secret

Parameter	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`namespace`	The namespace in which the Secret runs.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.
`CONTAINER_TICKET`	The contents of the MapR ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 3888. You may remove the ticket if the MapR cluster is not secure.

Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver

For static provisioning, configuring a PersistentVolume has some advantages over annotating Kubernetes volume information in a Pod spec:

- The configuration file can be shared for use by multiple Pod specs.
- The configuration file enables the PersistentVolume to be mounted and available even when the Pod spec that references it is removed.

last-updated: Jun 06, 2024

For example: A marketing volume exists in the MapR filesystem under the path `/Departments/Marketing`. An administrator wants to statically provision this volume and make it available to multiple users. It is critical that data access is as fast as possible. To make this work, the administrator must:

1. Create a PersistentVolume (PV).
2. Set the `AccessMode` of the PV to `ReadWriteOnce`.
3. Create a PersistentVolumeClaim (PVC) spec.
4. Set the `AccessMode` of the PVC to `ReadWriteOnce`.
5. Create the Pod spec.
6. Generate a MapR service ticket, and set the `flexVolume securityType` parameter to `secure`. For information about generating a service ticket, see Generating a Service Ticket on page 1832.
7. Configure a Ticket Secret, and include the base64-encoded contents of the ticket file in the Ticket Secret. See Configuring a Secret on page 3886.
8. Set the `runAsUser` and the `fsGroup` parameters to the UID and GID of the user that created the ticket.
9. Set the `platinum` parameter in the Pod spec to `platinum: "true"`. See Enabling the Platinum Posix Client for Kubernetes Interfaces for Data Fabric FlexVolume Driver on page 3885.
10. Point the `volumePath` in the `flexVolume` setting to the desired MapR path.
11. Fill in the `cldbHosts` and `cluster` information.

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: pv-testsecure1
  namespace: mapr-examples
spec:
  capacity:
    storage: 5Gi
  accessModes:
    - ReadWriteOnce
  persistentVolumeReclaimPolicy: Retain
  claimRef:
    namespace: mapr-examples
    name: pvc-testsecure1
  flexVolume:
    driver: "mapr.com/maprfs"
    options:
      platinum: "true"
      cluster: "mycluster"
      cldbHosts: "cldb1 cldb2 cldb3"
      volumePath: "/path/in/mapr"

  CONTAINER_TICKET: <BASE64-ENCODED VERSION OF TICKET-FILE CONTENTS>
```

PersistentVolume (PV)

Parameter	Notes
`Capacity`	Specifies how big the allocated storage should be. This value is not validated against the MapR quota or advisory quota. It is up to the person creating the PV to specify this value accurately.
`accessModes`	How the PersistentVolume is mounted on the host. It's important that the PV and PVC modes are the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes.
`persistentVolumeReclaimPolicy`	Specifies what happens to the volume when it is released by its claim. The `Retain` value keeps the PVC around for manual cleanup. `Delete` deletes the PV from Kubernetes. **NOTE:** If this volume was created using dynamic provisioning, `Delete` causes the underlying volume to be deleted. `Recycle` is not supported by Kubernetes FlexVolumes. For more information, see Reclaiming.

last-updated: Jun 06, 2024

`claimRef`	Specifies a default PVC to bind to. If unspecified, the PV selected for a PVC is randomly allocated based on the access mode and provides at least as much storage capacity as requested by the PVC.
`flexVolume: driver`	The MapR FlexVolume driver being used. Call it by specifying driver: `mapr.com/maprfs`.
`platinum`	If set to `platinum: "true"`, the POSIX client uses the platinum driver for better performance. Note that the platinum driver consumes more host resources and MapR Platinum licenses.
`cluster`	The MapR cluster name.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the MapR cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`volumePath`	The mount point within the MapR filesystem. This parameter specifies an existing MapR path. For example, you can specify the root volume as `"/"`, providing access to the entire filesystem.
`securityType`	A parameter that indicates whether MapR tickets are used or not used. If MapR tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`ticketSecretName`	The name of the Ticket Secret that contains the ticket to use when mounting to the MapR cluster. See Configuring a Secret on page 3886.
`ticketSecretNamespace`	The namespace that contains the Ticket Secret. Use the same namespace as the namespace used by the Pod.

Pod

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. The example uses a naked Pod for clarity. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. This value should match `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. This value should match `volumeMounts: name`.

PersistentVolumeClaim (PVC)

last-updated: Jun 06, 2024

Parameter	Notes
`AccessMode`	How the requested PersistentVolume is mounted on the host. It's important that the PV and PVC modes are the same so that they can bind. For more information, see Kubernetes Access Modes and Access Modes.

Secret

Parameter	Notes
`metadata: name`	The name of the Ticket Secret. See Configuring a Secret on page 3886
`metadata: namespace`	The namespace in which the Ticket Secret runs.
`CONTAINER_TICKET`	The contents of the MapR ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 3888. You may remove the ticket if the MapR cluster is not secure.

Example: Mounting a PersistentVolume for Dynamic Provisioning Using the FlexVolume Driver

This example also uses a PersistentVolume. However, unlike the previous example, when you use the MapR dynamic provisioner, you do not need to create a PersistentVolume manually. The PersistentVolume is created automatically based on the parameters specified in the referenced StorageClass.

Dynamic provisioning is useful in cases where you do not want MapR and Kubernetes administrators to create storage manually to store the Pod storage state.

The following example uses a PersistentVolumeClaim that references a Storage Class. In this example, a Kubernetes Administrator has created a storage class called `secure-maprfs` for Pod creators to use when they want to create persistent storage for their Pods. In this example, it is important for the created Pod storage to survive the deletion of a Pod.

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
   name: secure-maprfs
   namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
    restServers: "rest1:8443"
    cldbHosts: "cldb1 cldb2 cldb3"
    cluster: "mysecurecluster"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
    ticketSecretNamespace: "mapr-examples"
    maprSecretName: "mapr-provisioner-secrets"
    maprSecretNamespace: "mapr-examples"
    namePrefix: "pv"
    mountPrefix: "/pv"
    readOnly: "true"
    reclaimPolicy: "Retain"
    advisoryquota: "100M"
    readonly: "1"

---

kind: Pod
apiVersion: v1

  CONTAINER_TICKET: <BASE64 ENCODED VERSION OF CONTENTS OF TICKET FILE>
```

The following tables describe the parameters in the example:

StorageClass

Parameter	Notes
`apiVersion`	The Kubernetes APi version for the StorageClass spec.
`kind`	The kind of object being created. This is a StorageClass.
`metadata: name`	The name of the StorageClass. Administrators should specify the name carefully because it will be used by Pod authors to help select the right StorageClass for their needs.
`metadata: namespace`	The namespace in which the StorageClass runs. This namespace can be different from the namespace used by the PVC and Pod, since the StorageClass namespace can be a cross-namespace resource.
`provisioner`	The provisioner being used. for the MapR provisioner, specify `mapr.com/maprfs`.
`restServers`	A space-separated list of MapR webservers. Specify the hostname or IP address and port number of each REST server for the MapR cluster. For fault tolerance, providing multiple REST server hosts is recommended.
`cldbHosts`	The hostname or IP addresses of the CLDB hosts for the MapR cluster. You must provide at least one CLDB host. For fault-tolerance, providing multiple CLDB hosts is recommended. To specify multiple hosts, separate each name or IP address by a space.
`cluster`	The MapR cluster name.
`securityType`	A parameter that indicates whether MapR tickets are used or not used. If MapR tickets are used, specify `secure`. Otherwise, specify `unsecure`.
`ticketSecretName`	The name of the Secret that contains the ticket to use when mounting to the MapR cluster. See Configuring a Secret on page 3886.
`ticketSecretNamespace`	The namespace that contains the Secret. Use the same namespace as the namespace used by the Pod.
`maprSecretName`	The name of the Kubernetes Secret that is used to store MapR administrative credentials (user, password, and ticket information for the MapR webserver). To use the provisioner, you must configure a Secret. See Configuring a Secret on page 3886.
`maprSecretNamespace`	The namespace for the Secret containing the MapR administrative credentials (user name and password information for a MapR user that has the privileges to create MapR volumes). This namespace can be different from the namespace used by the Pod, since a Pod author or namespace admin might not be trusted to create administration Secrets for the MapR cluster.
`namePrefix`	A prefix for the MapR volume to be created. For example, if you specify PV as the `namePrefix`, the first dynamically created volume might be named `PV.bevefsescr`. The provisioner generates random names using lower-case letters. If you do not specify a prefix, the provisioner uses `maprprovisioner` as a prefix.

last-updated: Jun 06, 2024

Parameter	Notes
`mountPrefix`	The parent path of the mount in MapR filesystem. If you do not specify a mount prefix, the provisioner mounts your volume under the MapR root.
`readOnly`	This parameter specifies that the POSIX driver should mount the MapR path as read only. This is different from the `readonly` parameter for volume creation that creates the volume as read only.
`reclaimPolicy`	Kubernetes does not currently support passing a non-delete reclaim policy to the StorageClass. This parameter allows you to specify `Retain`. This ensures that provisioned volumes are not automatically deleted when their calling Pods are deleted. If you specify `Retain`, you must clean up your provisioned volumes manually.
`advisoryquota`	The advisory storage quota for the MapR volume. `advisoryquota` is one of the MapR parameters that you can specify for dynamic provisioning. For more information, see Before You Begin on page 3870.
`readonly`	When the value is `1`, this parameter specifies that the MapR volume should be created as read-only. This is different from the `readOnly` parameter that mounts the MapR path as read only.

Pod

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. For clarity, this example uses a naked Pod. Generally, it is better to use a Deployment, DaemonSet, or StatefulSet for high availability and ease of upgrade.
`metadata: name`	The Pod name.
`metadata: namespace`	The namespace in which the Pod runs. It should be the same namespace in which the PVC runs.
`volumeMounts: mountPath`	A directory inside the container that is designated as the mount path.
`volumeMounts: name`	A name that you assign to the Kubernetes `volumeMounts` resource. The value should match `Volumes: name`.
`Volumes: name`	A string to identify the name of the Kubernetes `volumes` resource. The value should match `volumeMounts: name`.
`persistentVolumeClaim: claimName`	The name of the PersistentVolumeClaim (PVC). For more information, see PersistentVolumeClaims.

PVC

Parameter	Notes
`apiVersion`	The Kubernetes API version for the Pod spec.
`kind`	The kind of object being created. This is a PersistentVolumeClaim (PVC).

last-updated: Jun 06, 2024

Parameter	Notes
`metadata: name`	The PVC name.
`metadata: namespace`	The namespace in which the PVC runs. This should be the same namespace used by the Pod.
`accessModes`	How the PersistentVolume is mounted on the host. (This is a limitation of the FlexVolume driver.) For more information, see Access Modes.
`storageClassName`	The name of the storage class requested by the PersistentVolumeClaim. For more information, see Dynamic Provisioning and Storage Classes.
`requests: storage`	The storage resources being requested, or that were requested and have been allocated. The Pod author can use this parameter to tell MapR how much quota is needed for the MapR volume. For the units, see Resource Model.

Provisioner Secret

In the mapr-provisioner-secrets Secret:

Parameter	Notes
`MAPR_CLUSTER_USER`	This is the base64-encoded user ID used to log in to the MapR REST server and create or delete volumes. See Converting a String to Base64 on page 3888. For more information about Secrets, see Secrets.
`MAPR_CLUSTER_PASSWORD`	This is the base64-encoded password for the MAPR_CLUSTER_USER. See Converting a String to Base64 on page 3888. For more information about Secrets, see Secrets.

Ticket Secret

In the mapr-ticket-secret Secret:

Parameter	Notes
`CONTAINER_TICKET`	The contents of the MapR ticket encoded in base64. If you specified `secure` for the `securityType`, you must provide the ticket. To encode the ticket, see Converting a String to Base64 on page 3888. You may remove the ticket if the MapR cluster is not secure. For more information about Secrets, see Secrets.

Identifying the MapR Volume Created During Dynamic Provisioning

Describes how to find the name of the MapR volume created during dynamic provisioning.

In dynamic provisioning, the provisioner creates a new MapR volume with a name that is randomly generated using lower-case letters. For example, if you specify `PV` as the `namePrefix` in the StorageClass, the first dynamically created volume might be named `PV.bevefsescr`. If you do not specify a prefix, the provisioner uses `maprprovisioner` as a prefix.

To find the name of the new MapR volume and the path to the volume:

last-updated: Jun 06, 2024

1. Use the `kubectl describe` command to get information about the PVC:

   `kubectl describe pvc -n <namespace> <pvc-name>`

   The command output shows the name of the PersistentVolume (PV) that was created: For example:

```
kubectl describe pvc -n mapr-examples maprfs-secure-pvc109
Name:          maprfs-secure-pvc109
Namespace:     mapr-examples
StorageClass:  secure-maprfs
Status:        Bound
Volume:        pv-ikmqxfwtjh
Labels:        <none>
Annotations:   control-plane.alpha.kubernetes.io/
leader={holderIdentity":"ed60e649-0c68-11e8-acd5-36117e0e7e02","leaseDura
tionSeconds":15, "acquireTime":"2018-02-09T22:09:43Z"
               pv.kubernetes.io/bind-competed=yes
               pv.kubernetes.io/bound-by-controller=yes
               volume.beta.kubernetes.io/storage-provisioner=mapr.com/
maprfs
Finalizers:    []
Capacity:      300M
Access Modes:  RWO
Events:
```

2. Use the `kubectl get` command and the PersistentVolume (PV) name to obtain a description of the PersistentVolume:

   ```
   kubectl get pv <pv-name> -o yaml
   ```

   The command output shows the path to the MapR volume. For example:

```
kubectl get pv pv-ikmqxfwtjh -o yaml
apiVersion: v1
kind: PersistentVolume
metadata:
  annotations:
    mapr.com/description: 'Dynamically provisioned PV for MapR-FS:
pv.ikmqxfwtjh'
    mapr.com/maprProvisionerIdentity: mapr.com/maprfs
    mapr.com/provisionerVersion: v1.0.0
    mapr.com/restServers: 10.10.88.214:8443
    mapr.com/secretName: mapr-provisioner-secrets
    mapr.com/secretNamespace: mapr-examples
    mapr.com/volumeName: pv.ikmqxfwtjh
    pv.kubernetes.io/provisioned-by: mapr.com/maprfs
  creationTimestamp: 2018-02-09T22:21:22Z
  name: pv-ikmqxfwtjh
  resourceVersion: "2875820"
  selfLink: /api/v1/persistentvolumes/pv-ikmqxfwtjh
  uid: 8f11aa11-0de7-11e8-bdd6-84a9c4fbf7cb
spec:
  accessModes:
  - ReadWriteOnce
  capacity:
    storage: 300M
  claimRef:

      cluster: Test5
      mountOptions: ""
      platinum: "true"
      readOnly: "false"
      securityType: secure
      ticketSecretName: mapr-ticket-secret
      ticetSecretNamespace: mapr-examples
      volumePath: /pv/pv-ikmqxfwtjh
  persistentVolumeReclaimPolicy: Delete
  storageclassName: secure-maprfs
status:
  phase: Bound
```

Creating a Default StorageClass

As noted in Example: Statically Provisioning a MapR Volume Using the FlexVolume Plug-in on page 3872, some deployments can require a default StorageClass. A default StorageClass can reduce the effort it takes to create Pods. For example, you could use a default StorageClass to provision storage dynamically to a MapR location for any PersistentVolumeClaim that you create.

last-updated: Jun 06, 2024

If you set the `DefaultStorageClass` admission controller (see PodSecurityPolicy), and you wish to enable a MapR StorageClass as the default, follow the instructions in Change the default StorageClass.

Verifying Creation of a Kubernetes PersistentVolumeClaim and Persistent Volume

Once the Pod spec is installed, you can verify the status of a PersistentVolumeClaim or a PersistentVolume by using the Kubernetes `get` command. For example:

```
$ kubectl get pvc
NAME        STATUS  VOLUME         CAPACITY  ACCESS MODES  STORAGECLASS
AGE
Maprfs-pvc  Bound   pv-rsojpoapxy  8Mi       RWO           simple-maprfs  3d
$ kubectl get pv
NAME           CAPACITY ACCESS MODES  RECLAIM POLICY STATUS
CLAIM             ...
Pv-rsojpoapxy  8Mi      RWO           Delete         Bound  mapr-demo/
maprfs-pvc
```

For an example of creating a PersistentVolumeClaim and a PersistentVolume, see Example: Mounting a PersistentVolume for Static Provisioning Using the FlexVolume Driver on page 3874.

Enabling the Platinum Posix Client for Kubernetes Interfaces for Data Fabric FlexVolume Driver

When you install the Kubernetes Interfaces for Data Fabric FlexVolume Driver, the Basic FUSE-based POSIX client package is installed on all nodes by default. The FlexVolume Driver also supports the use of the Platinum FUSE-based POSIX client. For a comparison of the two POSIX client packages, see Preparing for Installation (HPE Ezmeral Data Fabric POSIX Client) on page 432.

To install the Platinum POSIX client, include the `platinum` parameter in your Pod spec. For example:

```
options:
cluster: "cluster2"
platinum: "true"
cldbHosts: "10.10.102.96"
```

Mounting a Read-Only Volume

This page describes how to specify a volume that should be mounted as read-only.

The following example specifies a volume that should be mounted as read-only in a MapR path or PersistentVolume during static provisioning:

```
flexVolume:
        driver: "mapr.com/maprfs"
        readOnly: true
        options:
          volumePath: "/path/to/data/in/mapr"
          cluster: "mycluster"
          cldbHosts: "cldb1 cldb2 cldb3"
          securityType: "secure"
          ticketSecretName: "mapr-ticket-secret"
          ticketSecretNamespace: "mapr-examples"
```

The following example shows how to specify that the volume should be mounted read-only in a StorageClass for dynamic provisioning. The example specifies that the POSIX driver should mount the MapR path as read only. This is different from the `readonly` parameter for volume creation that creates the volume as `readonly`.

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
   name: secure-maprfs
   namespace: mapr-examples
```

last-updated: Jun 06, 2024

```
provisioner: mapr.com/maprfs
parameters:
    restServers: "rest1:8443"
    cldbHosts: "cldb1 cldb2 cldb3"
    cluster: "mysecurecluster"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
    ticketSecretNamespace: "mapr-examples"
    maprSecretName: "mapr-provisioner-secrets"
    maprSecretNamespace: "mapr-examples"
    namePrefix: "pv"
    mountPrefix: "/pv"
    readOnly: "true"
    reclaimPolicy: "Retain"
    advisoryquota: "100M"
```

The following example specifies that the volume should be created as `readOnly` in a StorageClass for dynamic provisioning:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
   name: secure-maprfs
   namespace: mapr-examples
provisioner: mapr.com/maprfs
parameters:
    restServers: "rest1:8443"
    cldbHosts: "cldb1 cldb2 cldb3"
    cluster: "mysecurecluster"
    securityType: "secure"
    ticketSecretName: "mapr-ticket-secret"
    ticketSecretNamespace: "mapr-examples"
    maprSecretName: "mapr-provisioner-secrets"
    maprSecretNamespace: "mapr-examples"
    namePrefix: "pv"
    mountPrefix: "/pv"
    reclaimPolicy: "Retain"
    advisoryquota: "100M"
    readonly: "1"
```

Configuring a Secret

Kubernetes Secrets enable you to inject sensitive data into a pod. For more information about Secrets, see Secrets.

The examples in this section show how Secrets can be used in static and dynamic provisioning. Secrets are not by themselves secure. For more information about security and Secrets, see Security Properties. Specifically, it is important to turn on encryption at rest for Secrets. See Encrypting Secret Data at Rest.

During installation of the Driver, the Kubernetes token that was moved into the pod is written to the host node so that the plugin can query a Secret to pull the ticket for mounting. This Kubernetes token is sensitive and should be protected. The token is placed in `/var/run/secrets/kubernetes.io/serviceaccount`.

Here is an example of a configuration file for a Kubernetes Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
```

last-updated: Jun 06, 2024

```
data:
  ...
```

The following table describes the fields in the sample Secret file. For more information, see Secrets in the Kubernetes documentation.

Parameter	Notes
`apiVersion`	The Kubernetes API version.
`kind`	The type of object being created.
`name`	A string to identify the Secret.
`type`	The type of Secret being created. For type `Opaque`, clients must treat these values as opaque and pass them unmodified back to the server.

REST Secrets

For dynamic provisioning, you must use a Secret to pass the user name and password of a data-fabric user to the provisioner. This user must have privileges to create and delete a data-fabric volume. The credentials allow the provisioner to make REST calls to the data-fabric webserver. Secrets are protected by the Kubernetes RBAC.

The following example shows a REST secret in the Secret file:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-provisioner-secrets
  namespace: test-driver
type: Opaque
data:
 MAPR_CLUSTER_USER: cm9vdA==
  MAPR_CLUSTER_PASSWORD: bWFwcg==
```

The following table describes the REST secret fields in the REST Secret example.

Parameter	Notes
`MAPR_CLUSTER_USER`	The base64 representation of a data-fabric user that has the ability to create and delete data-fabric volumes. See Converting a String to Base64 on page 3888.
`MAPR_CLUSTER_PASSWORD`	The base64 representation of the password for the user defined by the `MAPR_CLUSTER_USER` parameter. See .Converting a String to Base64 on page 3888
`MAPR_CLUSTER_TICKET`	The base64 representation of the ticket contents generated on the data-fabric cluster using the `maprlogin` utility. For dynamic provisioning, with the latest CSI drivers, you can configure a data-fabric ticket to authenticate to the data-fabric webserver to make REST calls. This parameter is provided as a Beta feature.

Ticket Secrets

For static and dynamic provisioning, you must specify a Secret, which is the base64 representation of the ticket, to enable the POSIX client to communicate with a secure MapR cluster. The ticket for the POSIX client can be generated on the data-fabric cluster using the `maprlogin on page 2911` utility.

last-updated: Jun 06, 2024

The following example shows a ticket Secret:

```
apiVersion: v1
kind: Secret
metadata:
  name: mapr-ticket-secret
  namespace: mapr-examples
type: Opaque
data:
  CONTAINER_TICKET: CHANGETHIS!
```

The following table describes the `CONTAINER_TICKET` field in the ticket Secret example.

Parameter	Notes
`CONTAINER_TICKET`	Base64-encoded ticket value. See Converting a String to Base64 on page 3888.

To create the secret:

1. Run the following command to create the Secret file:

   ```
   kubectl create -f <secret-file-name>.yaml
   ```

2. Convert sensitive data, such as a user name and password, to a base64 representation.

   See Converting a String to Base64 on page 3888.

3. Add the base64 representation of sensitive data in the Secret file.

   For more information about the format of the Secret files, see REST Secrets on page 3887 and Ticket Secrets on page 3887 earlier in this section.

4. Deploy the secret on the pod by running the following command:

   ```
   kubectl apply -f <secret-file-name>.yaml
   ```

Converting a String to Base64

Sensitive data contained in a Secret must be represented in base64. Use these steps to convert such information to the base64 representation:

For example, in Linux:

```
echo -n 'mapr' | base64
```

The output shows the base64 representation of the user name `mapr` is `bWFwcg==`.

MapR tickets include a cluster name followed by a base64-encoded string. It is not sufficient to insert the base64-encoded string into a Kubernetes Secret. You must convert *both* the cluster name and string into base64 representation and then insert the result into the Secret.

The following command shows how to convert a MapR ticket to base64 representation:

```
echo -n "cluster-name <base64-encoded ticket-value>" | base64
```

For example:

```
echo -n "cluster2 PuG0lpuPXuDxj9ERgKCTXOqsXYPTnqRJl6/
mlWJjdVKvE5r46QS2Bh9nC+I4Rcu0GtnWRUOtKBG9gp65bsZN9Kphnr/
Wp15z8D3O2go951CANes/
7QQllYVP7l2BOpGR6I1zIrC3XGwI8OQWT61qpsjSVZv8zO5oQ5GDYQTkPttI/yAk/
```

last-updated: Jun 06, 2024

```
uJBES1ohCz38n9HgYALLvMALVsBPtUtG+cNGc1ktUDDMR2q1EgVzdJbuYsOuHnZX3LO3euKDGl4C
4MCmrv9DWiWJxwiZ1yZu69GbZJlXxqLOQBlkdMoTXk=" | base64

Y2x1c3RlcjIgUHVHMGxwdVBYdUR4ajlFUmdLQ1RYT3FzWFlQVG5xUkpsNi9tbFdKamRWS3ZFNXI0
NlFTMkJoOW5DK0k0UmN1MEd0bldSVU90S0JHOWdwNjVic1pOOUtwaG5yL1dwMTV6OEQzTzJnbzk1
MUNBTmVzLzdRUWxsWVZQN2wyQk9wR1I2STF6SXJDM1hHd0k4T1FXVDYxcXBzalNWWnY4ek81b1E1
R0RZUVRrUHR0SS95QWsvdUpCRVMxb2hDejM4bjlIZ1lBTEx2TUFMVnNCUHRVdEcrY05HYzFrdFVE
RE1SMnExRWdWemRKYnVZc091SG5aWDNMTzNldUtER2w0QzRNQ21ydjlEV2lXSnh3aVoxeVp1NjlH
YlpKbFh4cUxPUUJsa2RNb1RYaz0K
```

NOTE: Another method for converting values to base64 is to use an Internet tool such as https://www.base64encode.org to encode or decode data.

Best Practices for Using Tickets

When using secure data-fabric clusters with the Kubernetes Interfaces for Data Fabric, you must generate tickets for your containers. Here are some best practices:

- Create a different user for each container.
- To avoid frequent renewals, use long-lived user tickets or servicewithimpersonation tickets. If you refresh or update a ticket, you must restart your containers.
- If you use an impersonation ticket, it is CRITICAL that you use security contexts in the pod definitions to avoid a misbehaving container impersonating all user IDs. For restrictions that apply to the use of impersonation tickets, see How Impersonation Works on page 1943 and maprlogin on page 2911.
- Match the security context `runAsUser:` ID and `fsGroup:` group to the ID or group used to create the ticket.

Here is an example of a pod spec that specifies a security context:

```
apiVersion: v1
kind: Pod
metadata:
  name: test-secure
  namespace: mapr-examples
spec:
  securityContext:
    runAsUser: 1000
    fsGroup: 2000
```

Troubleshooting the Kubernetes Interfaces for Data Fabric FlexVolume Driver

This section describes how to resolve common problems you might encounter when using the Kubernetes Interfaces for Data Fabric FlexVolume driver.

Shared Memory Lock Causes POSIX Failure

Problem	On an upgrade from a previous version of the volume plug-in, POSIX can fail with the following error in the POSIX log file: `Create/Attach to stats shared memory failed.`
Possible Cause	A shared-memory segment lock can prevent the mount from becoming available to the requested pod.
Resolution	Follow the steps in Troubleshooting loopbacknfs POSIX Client Upgrades on page 339 to remove the lock. Then retry the operation.

Unable to Access file system

Problem	Storage is not mounted and no errors are generated in the plugin or provisioner logs.
Possible Cause	The fusermount symlink might be broken.
Resolution	If the symlink points to a location other than `/opt/mapr/k8s/bin/fusermount`, unlink it using the following command from the command line on the host: `unlink /bin/fusermount` Then re-create the Kubernetes Pod.

Pod Container Stuck in Container Creation State During Installation

Problem	During installation, the Pod container can become stuck in the container creation state on a node, and the`/opt/mapr/k8s` directory is not created. As a result, the plug-in does not get copied to the node.
Possible Cause	Unknown.
Resolution	Check the installation logs for an indication that the installation is not completed or the `/opt/mapr/k8s` directory is not created. Restart the kubelet service in the node: `systemctl restart kubelet`

Logs for the MapR Data Fabric for Kubernetes FlexVolume Driver

Logs for the MapR Data Fabric for Kubernetes can be found in:

```
/opt/mapr/logs
```

Log File	Description	Which Nodes
`install-k8s-plugin.log`	Captures events related to the copying of files from the plug-in container to each Kubernetes host node.	All Kubernetes nodes.
`plugin-k8s.log`	Captures events from the FlexVolume plug-in.	All Kubernetes nodes. **NOTE:** In Azure deployments, this log is hidden in the container. See Azure AKS Considerations on page 297.
`provisioner-k8s.log`	Captures events from the provisioner.	The Kubernetes node where the provisioner Pod is running.

Useful Troubleshooting Commands

The following Kubernetes commands can help you gather information about the resources used by the MapR Data Fabric for Kubernetes:

last-updated: Jun 06, 2024

- `kubectl describe <resourcetype> <resource> -n <namespace>`
- `kubectl get <resourcetype> <resource> -n <namespace> -o yaml`
- `kubectl logs <pod-name> -n <namespace>`
- `journalctl -u kubelet -r` (on the relevant node)

kubectl describe command

In this example, the `kubectl describe` command displays information about the `mapr-kdfprovisioner-5dff68656-ln6vh` Pod. Note that the `kubectl describe` output includes an event section.

```
kubectl describe pod mapr-kdfprovisioner-5dff68656-ln6vh -n mapr-system
Name:         mapr-kdfprovisioner-5dff68656-ln6vh
Namespace:    mapr-system
Node:         qa101-139/10.10.101.139
Start Time:   Fri, 09 Feb 2018 12:58:36 -0800
Labels:       app=mapr-kdfprovisioner
              pod-template-hash=189924212
Annotations:  openshift.ix/scc-maprkdf-scc
Status:       Running

  Normal  Created                8m    kubelet, qa101-139 Created container
  Normal  Started                8m    kubelet, qa101-139 Started container
```

kubectl get command

In this example, the `kubectl get` returns the `.yaml` parameters for the `test-secure-provisioner86` Pod:

```
kubectl get pods test-secure-provisioner86 -n mapr-examples -o yaml
apiVersion: v1
kind: Pod
metadata:
  creationTimestamp: 2018-02-09T00:42:06Z
  name: test-secure-provisioner86
  namespace: mapr-examples
  resourceVersion: "721689"
  selfLink: /api/v1/namespaces/mapr-examples/pods/test-secure-provisioner86
```

last-updated: Jun 06, 2024

```
  uid: 0dd21274-0d32-11e8-bdd6-84a9c4fbf7cb
spec:
  containers:
  - args:
    - sleep
    - "1000000"
    image: busybox
    imagePullPolicy: Always
    name: busybox
    resources: {}
    terminationMessagePath: /dev/termination-log
    terminationMessagePolicy: file
    volumeMounts:
    - mountPath: /dynvolume
      name: maprfs-pvc
    - mountPath: /var/run/secrets/kubernetes.io/serviceaccount
      name: default-token-zpv69
      readOnly: true
  dnsPolicy: ClusterFirst
  nodeName: qa108-165.qa.lab
  restartPolicy: Never
  schedulerName: default-scheduler
  securityContext: {}
  serviceAccount: default
  serviceAccountName: default
  terminationGracePeriodSeconds: 30
  tolerations:
  - effect: NoExecute
    key:node.kubernetes.io/not-ready
    operator: Exists
    tolerationSeconds: 300
  - effect: NoExecute
    key: node.kubernetes.io/unreachable
    operator: Exists
    tolerationSeconds: 300
  volumes:
  -name: maprfs-pvc
```

Running the `kubectl get` command without the `-o yaml` parameter generates less output:

```
kubectl get pods test-secure-provisioner86 -n mapr-examples
NAME                        READY    STATUS   RESTARTS   AGE
test-secure-provisioner86  1/1      Running  0          14m
```

kubectl logs command

In this example, the `kubectl logs` command returns logged output for the `mapr-kdfprovisioner-5dff68656-ln6vh` Pod:

```
kubectl logs mapr-kdfprovisioner-5dff68656-ln6vh -n mapr-system
I0209 12:58:39.956822    1 controller.go:407] Starting provisioner
controller 013d58b3-0ddc-11e8-b0dd-0242acl10003!
```

journalctl -u command

In this example, the `journalctl` command returns events for the kubelet service for the node:

```
journalctl -u kubelet -r
-- Logs begin at Thu 2017-12-28 06:24:47 PST, end at Thu 2018-02-08
17:01:49 PST. --
Feb 08 17:01:49 k8s-master kubelet[26521]: E0206 17:01:49,047595  26521
```

last-updated: Jun 06, 2024

```

Ecosystem Components

The following sections provide information about each open-source project that is supported by the HPE Ezmeral Data Fabric.

This section contains documentation for each open-source project. You can learn how to configure, use, and integrate each project within the context of a data-fabric cluster.

Documentation Covers All Component Versions

Unless noted, the ecosystem-component information in this content hierarchy applies to all component versions included in EEPs that are supported on the core software. For a list of the supported EEPs, see EEP Support and Lifecycle Status on page 5728. For deprecated and discontinued components, see Discontinued Ecosystem Components on page 5748.

Ecosystem Packs

An Ecosystem Pack (EEP) provides a set of ecosystem components that work together on one or more data-fabric cluster versions. Each EEP contains only one version of an ecosystem component. For example, each EEP supports only one version of Hive and one version of Spark.

HPE creates a new EEP version when a new ecosystem component is available or a patch is applied to an ecosystem component that is already in a released EEP.

A single version of core can support multiple EEPs, but only one at a time. For detailed information about each EEP, see Ecosystem Pack (EEP) Reference on page 6120. For a list of currently supported EEPs, see EEP Support and Lifecycle Status on page 5728.

Hadoop Ecosystem and Monitoring Components

Hadoop ecosystem components within an EEP undergo extensive interoperability testing to validate that the components can work together. Examples of Hadoop ecosystem components include Hive, Pig, Spark, and Oozie.

The following open-source components are included in the EEP for monitoring and logging use cases, but NOT for third-party use cases:

- Collectd
- Elasticsearch
- Fluentd
- Grafana

- Kibana
- OpenTSDB

NOTE: Developer previews for fast-moving ecosystem components continue to be available in addition to EEPs. However, developer preview releases of ecosystem components are not tested for production environments, and they do not undergo the same interoperability testing.

For more information, see the EEP Release Notes on page 5804.

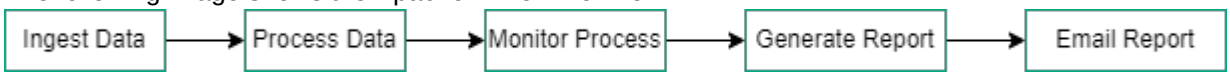
Apache Airflow

This topic provides an overview of Apache Airflow on HPE Ezmeral Data Fabric.

Starting from EEP 8.1.0, HPE Ezmeral Data Fabric supports Apache Airflow on core 6.2.x and core 7.0.0.

You can use Airflow to author, schedule, or monitor workflows or data pipelines.

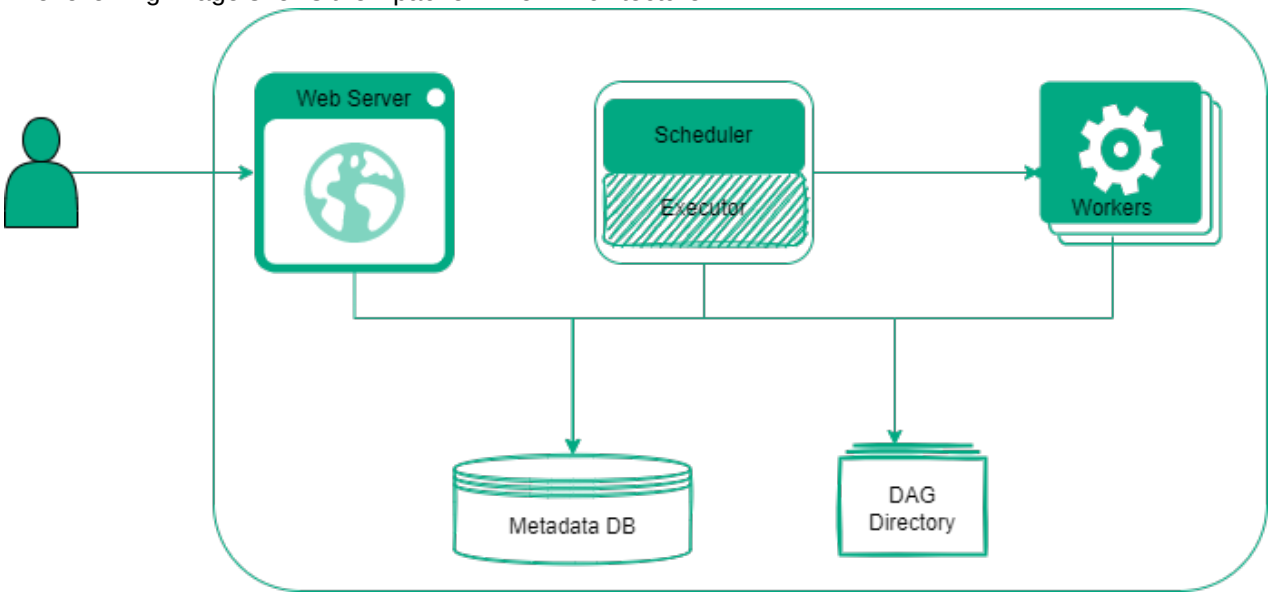
The following image shows the Apache Airflow workflow:



A workflow is a Directed Acyclic Graph (DAG) of tasks used to handle big data processing pipelines. The workflows are started on a schedule or triggered by an event. DAGs define the order to run the tasks or rerun in case of failures. The tasks define the actions to be performed, like ingest, monitor, report, and others.

Airflow Architecture

The following image shows the Apache Airflow Architecture:



Airflow Components

Airflow consists of the following components:

Scheduler	Triggers the scheduled workflows and submits the tasks to an executor to run.
Executor	Executes the tasks or delegates the tasks to workers for execution.
Worker	Executes the tasks.

last-updated: Jun 06, 2024

Web Server	Provides a user interface to analyze, schedule, monitor, and visualize the tasks and DAG. The Web Server enables you to manage users, roles, and set configuration options.
DAG Directory	Contains DAG files read by Scheduler, Executor, and Web Server.
Metadata Database	Stores the metadata about DAGs' state, runs, and Airflow configuration options.

To learn more about Airflow, see Airflow Concepts.

Starting, Stopping, and Restarting Airflow Services

This topic describes how to start, stop, and restart Airflow services on HPE Ezmeral Data Fabric.

About this task

The Warden daemon starts the Airflow server (airflow-webserver and airflow-scheduler) automatically at installation time.

You can start and stop Airflow from the command line or from the Control System. You can use the `maprcli node services` command to start Airflow on multiple nodes at one time.

Perform the following steps to start or stop or restart Airflow from the command line:

Procedure

1. Make a list of nodes on which Airflow is configured.
2. Run the `maprcli node services` command with either `start`, `restart`, or `stop`, and specify the nodes on which Airflow is configured, separated by spaces.

```
maprcli node services -name airflow-webserver  -action start|stop|
restart -nodes <nodes list>
```

```
maprcli node services -name airflow-scheduler -action start|stop|
restart -nodes <nodes list>
```

Considerations for Using Airflow CLI Commands

Describes security considerations for using Airflow CLI commands.

EEP 9.1.2 and Airflow 2.6.1.0 introduced security checks related to the use of Airflow CLI commands. In EEP 9.1.2 and later ecosystem packs:

- Only users with Data Fabric tickets can use Airflow CLI commands.

last-updated: Jun 06, 2024

- If a user that has no ticket issues a CLI command, the command line returns an error. For example:

```
$ airflow users create --username mapr1 --firstname mapr1 --lastname
mapr1 -p mapr1 --role Admin --email admin3@example.org
Traceback (most recent call last):
  File "/opt/mapr/airflow/airflow-2.6.1/bin/airflow", line 8, in <module>
    sys.exit(main())
  File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/__main__.py", line 45, in main
    resp = security_client.start("maprsasl")[2]
  File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/security/maprsasl.py", line 73, in start
    return True, mechanism, self.get_init_response()
  File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/security/maprsasl.py", line 55, in get_init_response
    server_key_bytes =
maprsecurity.GetTicketAndKeyForClusterInternal(MAPR_CLUSTER_NAME, 1)
SystemError: <built-in function GetTicketAndKeyForClusterInternal>
returned NULL without setting an error
```

- Only the cluster administrator (typically the `mapr` user) can issue commands related to Airflow users. For example, only the cluster admin can issue the `airflow users list` command or create the `admin` user role. An exception is generated if a non-cluster-admin user issues a command such as `airflow users list`. For example:

```
$ airflow users list
Traceback (most recent call last):
  File "/opt/mapr/airflow/airflow-2.6.1/bin/airflow", line 8, in <module>
    sys.exit(main())
..............................................................................
.............................
  File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/cli/commands/user_command.py", line 38, in <module>
    class UserSchema(Schema):
  File "/opt/mapr/airflow/airflow-2.6.1/build/env/lib/python3.9/
site-packages/airflow/cli/commands/user_command.py", line 42, in
UserSchema
    raise Exception("Only admin cluster user can manage Airflow users
list")
Exception: Only admin cluster user can manage Airflow users list
```

Configuring a Remote MySQL Database for Airflow

This topic describes how to configure a remote MySQL database for Airflow on the HPE Ezmeral Data Fabric.

Prerequisites

To connect to MySQL from Airflow, install the **mysqlclient** by using these steps:

1. Run `. <airflow_home>/build/env/bin/activate`
2. Run `pip install mysqlclient==2.2.0`
3. Run `deactivate`

About this task

Airflow uses SQLAlchemy to connect to the metadata database. The metadata database stores the information about Airflow configurations, user information, roles and policies, and statistics of each DAG state, run, and task.

Airflow supports MySQL database engine versions 5.7 and 8. For a list of the supported databases, see Choosing database backend.

Procedure

1. To configure the remote MySQL Database for Airflow, see Setting Up a MYSQL Database.
2. After you have configured a database user that Airflow can use to access the database and `<AIRFLOW-HOME>/conf/airflow.cfg` is updated with your SQLAlchemy connection string, run this command:

   ```
   sql_alchemy_conn = mysql+mysqldb://
   <airflow-user>:<airflow-password>@<host>[:<port>]/<airflow-dbname>
   ```

3. Create the database schema using the steps that apply to the currently-installed EEP. To identify the EEP that is installed, see Checking the EEP Version on page 5598:
   - EEP 9.2.0 and later:
     a. Run the `airflow db migrate` command:

        ```
        airflow db migrate
        ```

     b. Run the `airflow connections create-default-connections` command:

        ```
        airflow connections create-default-connections
        ```

   - EEP 9.1.x and earlier:

     ```
     airflow db init
     ```

4. After MySQL configuration is completed, create a user by following the steps in the Command Line Interface and Environment Variables Reference. For example:

   ```
   airflow users create --username mapr --firstname mapr --lastname mapr -p
   mapr --role Admin --email admin@example.org
   ```

5. Restart Airflow services as described in Starting, Stopping, and Restarting Airflow Services on page 3895.

Configuring SSL Security for Airflow

This topic describes the security configurations for Airflow on HPE Ezmeral Data Fabric.

Airflow enables SSL by default on secure clusters and you can manually configure SSL for nonsecure clusters in HPE Ezmeral Data Fabric.

Enabling SSL on Secure Clusters

Airflow enables SSL by default on secure clusters and uses the standard Data-Fabric SSL configuration.

Enabling SSL on Nonsecure Clusters

To enable SSL on non-secure clusters, provide a certificate and a key to the webserver.

Add the following configuration options at `<airflow_home>/conf/airflow.cfg`.

```
[webserver]

web_server_ssl_cert = <path to certificate>

web_server_ssl_key = <path to private key>
```

Once you enable the SSL, you must use `https://` in the browser for secure connection.

Configuring Data Fabric SASL and SSL for Hooks Connections
This topic decribes configuration options for Data Fabric SASL and SSL for hook connections in Airflow.

Using Airflow, you can import and export data to multiple systems. Airflow provides a high-level interface called Hooks to connect to these systems by integrating with Connections.

A connection is an object that stores credentials such as your username, password and hostname, the type of system you are connecting to, and other configuration options.

HPE Ezmeral Data Fabric 7.0.0 supports Data Fabric SASL authentication for Airflow.

To support Data Fabric SASL authentication for HPE Ezmeral Data Fabric 6.2.x, see Applying a Patch on page 473.

Airflow authenticates with Data Fabric SASL in the following ways:

Using the Ecosystem Component Client

To authenticate with Data Fabric SASL, Airflow uses the clients of ecosystem component installed on the node. To submit the tasks, configure a Data Fabric User Ticket on a secure cluster. See Generating a HPE Ezmeral Data Fabric User Ticket on page 1831.

Using the REST API or Thrift protocol

To authenticate with Data Fabric SASL, you can use REST API or Thrift protocol by setting the additional configuration options.

WebEZFSHook (webezfs_default connection id)	To connect with file system, set the following configuration options on `extra` section of connection configuration. **Data Fabric SASL**: Set `{"auth": "maprsasl"}`. **SSL**: On secure clusters, set `{"use_ssl": "true"}` option. For nondefault SSL configuration, set `{"cert":"/path_to_truststore.pem"}`.
EzHiveCliHook (hive_cli_default connection_id, auth authenticationMethod)	To connect with Hive, set the following configuration options on connection configuration. **Data Fabric SASL**: Set `{"use_beeline": true, "ssl":"true"}`. Add `auth` parameter to `EzHiveCliHook`. For example: `hive = EzHiveCliHook(auth="maprsasl")`.
EzHiveMetastoreHook (metastore_default connection id)	To connect with Hive Metastore, set the following configuration options on `extra` section of connection configuration. **Data Fabric SASL**: Set `{"authMechanism":"MAPRSASL"}`.
EzHiveServer2Hook (hiveserver2_default connection id)	To connect with HiveServer2, set the following configuration options on `extra` section of connection configuration.

	Data Fabric SASL: Set `{"authMechanism":"MAPRSASL"}`. **SSL**: On secure clusters, set `{"ssl": "true"}` option. For nondefault SSL configuration, set `{"certificate":"/path_to_truststore.pem"}`.
EzLivyHook (livy_default connection id)	To connect with Livy, set the following configuration options on `extra` section of connection configuration. **Data Fabric SASL**: Set `{"auth":"maprsasl"}`. **SSL**: On secure clusters, set `{"use_ssl": "true"}` option. For nondefault SSL configuration, set `{"cert":"/path_to_truststore.pem"}`.
EzS3Hook (aws_default connection id)	To connect with S3, set the following configuration options on the `extra` section of connection configuration. **SSL**: On secure clusters, set the `{"cert":"/path_to_truststore.pem"}` option for nondefault SSL configuration. To connect with the HPE Ezmeral Data Fabric Object Store and AWS, you must also add the endpoint URL to the `extra` section of the connection configuration. For example: `{"endpoint_url": "https://<hostname>:9000"}`

Airflow Providers

This topic describes the Apache Airflow Provider packages available in HPE Ezmeral Data Fabric.

Providers contains operators, hooks, sensors, and transfer operators that enhances the core Airflow scheduling capabilities. To learn more about Providers, see Airflow Providers.

Airflow provides an interface to Ecosystem Pack components, databases, and filesystem by using the providers.

The classes on Providers package in HPE Ezmeral Data Fabric are located inside `airflow.providers.ezmeral` Python package.

The following topics describes interfaces on Airflow Providers in HPE Ezmeral Data Fabric.

Interface to HPE Ezmeral Data Fabric Database

Airflow provides an interface to HPE Ezmeral Data Fabric Database by using the Providers.

See Provider examples of HPE Ezmeral Data Fabric Database at `<airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/database/example_dags/`.

Hooks

BinaryDbCliHook	*Python path:* airflow.providers.ezmeral.database.hooks.binary_shell *Description:* This hook is a wrapper around the `hbase shell` command that must have `hbase` binary in the PATH.
JsonDbCliHook	*Python path:* airflow.providers.ezmeral.database.hooks.json_shell

last-updated: Jun 06, 2024

	Description: This hook is a wrapper around the `mapr dbshell` command.
EzTableHook	*Python path:* airflow.providers.ezmeral.database.hooks.table *Description:* This hook is a wrapper around the `maprcli table` command.

Operators

BinaryDbCliOperator	*Python path:* airflow.providers.ezmeral.database.operators.binary_shell *Description:* Executes HPE Ezmeral Data Fabric Database Binary `hbase shell` command.
JsonDbCliOperator	*Python path:* airflow.providers.ezmeral.database.operators.json_shell *Description:* Executes HPE Ezmeral Data Fabric Database Binary `mapr dbshell` command.
CreateEzTableOperator	*Python path:* airflow.providers.ezmeral.database.operators.table *Description:* Creates HPE Ezmeral Data Fabric Database table.
DropEzTableOperator	*Python path:* airflow.providers.ezmeral.database.operators.table *Description:* Drops HPE Ezmeral Data Fabric Database table.
ImportJsonEzTableOperator	*Python path:* airflow.providers.ezmeral.database.operators.table *Description:* Imports HPE Ezmeral Data Fabric Database JSON table.
ExportJsonEzTableOperator	*Python path:* airflow.providers.ezmeral.database.operators.table *Description:* Exports HPE Ezmeral Data Fabric Database JSON table.
ImportBinaryEzTableOperator	*Python path:* airflow.providers.ezmeral.database.operators.table *Description:* Imports HPE Ezmeral Data Fabric Database Binary table.
ExportBinaryEzTableOperator	*Python path:* airflow.providers.ezmeral.database.operators.table *Description:* Exports HPE Ezmeral Data Fabric Database Binary table.

Sensors

EzTableSensor	*Python path:* airflow.providers.ezmeral.database.sensors.table *Description:* Waits for the table to show up inHPE Ezmeral Data Fabric Database.

Interface to the File System

Airflow provides an interface to the file system by using the Providers.

last-updated: Jun 06, 2024

See Provider examples of the file system at `<airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/fs/example_dag/`.

Hooks

EZFSHook	*Python path:* airflow.providers.ezmeral.fs.hooks.ezfs.EZFSHook *Description:* Interacts with file system. *API::*class airflow.providers.ezmeral.fs.hooks.ezfs.EZFSHook(classpath: list = '/opt/mapr/lib/*') The *classpath* parameter provides a path for Java and binaries libraries to access the file system Java client.
WebEZFSHook	*Python path:* airflow.providers.ezmeral.fs.hooks.web_ezfs.WebEZFSHook *Description:* Interacts with file system through HttpFS. *API:* The same API as Apache Web HDFS.

Sensors

EzfsSensor	*Python path:* airflow.providers.ezmeral.fs.sensors.ezfs.EzfsSensor *Description:* Waits for a file or folder to show up in the file system. *API:* The same API as Apache HDFS Sensor.
EzfsRegexSensor	*Python path:* airflow.providers.ezmeral.fs.sensors.ezfs.EzfsRegexSensor *Description:*Waits for matching files by matching on regex. *API:* The same API as Apache HDFS Regex sensor.
EzfsFolderSensor	*Python path:* airflow.providers.ezmeral.fs.sensors.ezfs.EzfsFolderSensor *Description:*Waits for a non-empty directory. *API:* The same API as Apache HDFSFolder sensor.
WebEzfsSensor	*Python path:* airflow.providers.ezmeral.fs.sensors.web_ezfs.WebEzfsSensor *Description:* Waits for a file or folder to show up in the file system. *API:* The same API as Apache WebHDFS sensor.

Interface to Hive

Airflow provides an interface to Hive by using the Providers.

See Provider examples of Hive at `<airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/hive/example_dags/`.

Hooks

All hooks have the same API as Apache Hive Hooks.

last-updated: Jun 06, 2024

EzHiveCliHook	*Python path:* airflow.providers.ezmeral.hive.hooks.ezhive.EzHiveCliHook *Description:* Provides access to Hive using Hive client.
EzHiveMetastoreHook	*Python path:* airflow.providers.ezmeral.hive.hooks.ezhive.EzHiveMetastoreHook *Description:* Provides access to Hive Metastore using HMSClient.
EzHiveServer2Hook	*Python path:* airflow.providers.ezmeral.hive.hooks.ezhive.EzHiveServer2Hook *Description:* Provides access to HiveServer using PyHive.

Operators

EzHiveOperator	*Python path:* airflow.providers.ezmeral.hive.operators.ezhive.EzHiveOperator *Description:* Executes HiveQL code or Hive script in a specific Hive database. *API:* The same API as Apache Hive Operator.
EzHiveStatsCollectionOperator	*Python path:* airflow.providers.ezmeral.hive.operators.ezhive_stats.EzHiveStatsCollectionOperator *Description:* Gathers partition statistics using a dynamically generated Presto query and inserts the statistics into a MySQL table. *API:* The same API as Apache Hive Stats Operator.

Sensors

EzHivePartitionSensor	*Python path:* airflow.providers.ezmeral.hive.sensors.ezhive_partition.EzHivePartitionSensor *Description:* Waits for a partition to show up in Hive. *API:* The same API as Apache Hive Partition Sensor.
EzMetastorePartitionSensor	*Python path:* airflow.providers.ezmeral.hive.sensors.ezmetastore_partition.EzMetastorePartitionSensor *Description:* An alternative to the HivePartitionSensor that talks directly to the MySQL database. *API:* The same API as Apache Hive Metastore Partition Sensor.
EzNamedHivePartitionSensor	*Python path:* airflow.providers.ezmeral.hive.sensors.eznamed_hive_partition.EzNamedHivePartitionSensor *Description:* Waits for a set of partitions to show up in Hive. *API:* The same API as Apache Hive Named Partition Sensor.

last-updated: Jun 06, 2024

Transfers

EzHiveToMySqlOperator	*Python path:* airflow.providers.ezmeral.hive.transfers.ez_hive_to_mysql.EzHiveToMySqlOperator *Description:* Moves data from Hive to MySQL. Use this operator to move small amount of data as data first loads into the memory and then into the MySQL. *API:* The same API as Apache HiveToMySqlOperator.
EzHiveToSambaOperator	*Python path:* airflow.providers.ezmeral.hive.transfers.ez_hive_to_samba.EzHiveToSambaOperator *Description:* Moves data from Hive to Samba. Executes HiveQL code in a specific Hive database and loads the results of the query as a CSV to a Samba location. *API:* The same API as Apache HiveToSambaOperator.
EzMsSqlToHiveOperator	*Python path:* airflow.providers.ezmeral.hive.transfers.ez_mssql_to_hive.EzMsSqlToHiveOperator *Description:* Moves data from Microsoft SQL Server to Hive. *API:* The same API as Apache MsSqlToHiveOperator.
EzMySqlToHiveOperator	*Python path:* airflow.providers.ezmeral.hive.transfers.ez_mysql_to_hive.EzMySqlToHiveOperator *Description:* Moves data from MySQL to Hive. *API:* The same API as Apache MySqlToHiveOperator.
EzS3ToHiveOperator	*Python path:* airflow.providers.ezmeral.hive.transfers.ez_s3_to_hive.EzS3ToHiveOperato *Description:* Moves data from Amazon S3 to Hive. *API:* The same API as Apache S3ToHiveOperator.
EzVerticaToHiveOperator	*Python path:* airflow.providers.ezmeral.hive.transfers.ez_vertica_to_hive.EzVerticaToHiveOperator *Description:* Moves data from Vertica to Hive. *API:* The same API as Apache VerticaToHiveOperator.

Configuring a HiveCliHook

Describes the properties that must be added to configure a HiveCliHook for Airflow on a secure cluster.

The HiveCliHook is a simple wrapper around the Hive CLI. To configure the HiveCliHook for Airflow:

1. Use the following connection properties:

Property	Value
`use_beeline`	`true`
`auth`	`maprsasl`
`ssl`	`true`

last-updated: Jun 06, 2024

2. Add the following property to the `hive-site.xml` file:

```
<property>
    <name>hive.security.authorization.sqlstd.confwhitelist.append</name>
    <value>mapred.job.name|airflow.ctx.*</value>
</property>
```

Configuring Hook Connections for Hive High Availability
Describes how to configue the EZHiveServer2Hook, the EzHiveCLIHook, and the EzHiveMetastoreHook to connect to Hive with High Availability (HA) enabled.

EEP 9.2.1 and later include hook connection support in Airflow to connect to HiveServer2 with High Availability (HA) enabled. When any of the hooks are configured, if one of the HS2 servers is unreachable, Airflow connects to another server in the list of hosts that you specify.

Configuring the EzHiveServer2Hook for Hive HA

The EZHiveServer2Hook supports a `pyhive` connection to HiveServer 2 HA. To configure the `pyhive` connection with HiveServer 2 HA:

1. Add the `hive_ha` property to the `extra` section of the connection configuration. For example:

```
{  "authMechanism": "MAPRSASL",
  "ssl": "true",
  "hive_ha": "true"
}
```

2. Add the list of your active HS2 instances in the `host` section using this format:

```
<hs2_hostname1>:<port1>,<hs2_hostname2>:<port2>,<hs2_hostname3>:<port3>…
```

   For example:

```
myhost-48-n2.storage.mycorp.net:10000,myhost-23-n2.storage.mycorp.net:100
00
```

In the following example, one of the HS2 servers is unusable, so Airflow reconnects to another server:

```
{ezhive.py:196} INFO - Trying to connect to
myhost-23-n2.storage.mycorp.net:10000
{TSocket.py:142} INFO - Could not connect to ('<ip_address>', 10000)
Traceback (most recent call last):
  File "/opt/mapr/airflow/airflow-2.7.3/build/env/lib/python3.9/
site-packages/thrift/transport/TSocket.py", line 137, in open
    handle.connect(sockaddr)
  File "/opt/mapr/airflow/airflow-2.7.3/build/python/lib/python3.9/ssl.py",
line 1343, in connect
    self._real_connect(addr, False)
  File "/opt/mapr/airflow/airflow-2.7.3/build/python/lib/python3.9/ssl.py",
line 1330, in _real_connect
    super().connect(addr)
ConnectionRefusedError: [Errno 111] Connection refused
{TSocket.py:145} ERROR - Could not connect to any of [('<ip_address>',
10000)]
[2023-12-15, 09:06:32 UTC] {ezhive.py:210} WARNING - Failed to connect to
myhost-23-n2.storage.mycorp.net:10000
{ezhive.py:196} INFO - Trying to connect to
```

```
myhost-48-n2.storage.mycorp.net:10000
{hive.py:475} INFO - USE 'default'
```

Configuring the EzHiveCliHook for Hive HA

The EZHiveCliHook supports a `beeline` connection to HiveServer 2 HA. To configure the `beeline` connection with HiveServer 2 HA:

1. Add the following properties to the `extra` section of the connection configuration:

```
{
  "use_beeline": true,
  "ssl": "true",
  "hive_ha": "true",
  "serviceDiscoveryMode": "zooKeeper",
  "zooKeeperNamespace": "hiveserver2"
}
```

2. Add the list of your active ZooKeeper instances in the `host` section using this format:

```
<ZK_FQDN1>:5181,<ZK_FQDN2>:5181,<ZK_FQDN3>:5181
```

Configuring the EzHiveMetastoreHook for Hive HA

The EZHiveMetastoreHook supports an `hmsclient` connection to HiveServer 2 HA. To configure the `hmsclient` connection with HiveServer 2 HA:

1. Configure Hive Metastore HA as described in Enabling High Availability for Hive Metastore on page 4295.
2. Add the following properties to the `extra` section of the connection configuration:

```
{  "authMechanism": "MAPRSASL"}
```

3. In the `host` section, specify the list of active Hive metastore hosts using the following format:

```
<hive_metastore1>,<hive_metastore2>,<hive_metastore3>
```

With this configuration, if one Hive metastore host is unavailable, a connection will be made to another host in the list. For example:

```
[2023-12-15, 12:57:54 UTC] {base.py:73} INFO - Using connection ID
'metastore_default' for task execution.
[2023-12-15, 12:57:54 UTC] {hive.py:576} INFO - Trying to connect to
myhost-23-n2.storage.mycorp.net:9083
[2023-12-15, 12:57:54 UTC] {hive.py:582} ERROR - Could not connect to
myhost-23-n2.storage.mycorp.net:9083
[2023-12-15, 12:57:54 UTC] {hive.py:576} INFO - Trying to connect to
myhost-48-n2.storage.mycorp.net:9083
[2023-12-15, 12:57:54 UTC] {hive.py:578} INFO - Connected to

This page shows the EEPs that are supported for different core releases and the current lifecycle status for each EEP.

More information

Enabling High Availability for Hive on page 4292
This section describes how to enable High Availability for HiveServer2 and HiveMetastore.

Interface to Livy

Airflow provides an interface to Livy by using the Providers.

See Provider examples of Livy at `<airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/livy/example_dags/`.

Hooks

EzLivyHook	*Python path:* airflow.providers.ezmeral.livy.hooks.ezlivy.EzLivyHook *Description:* Apache Livy hook on HPE Ezmeral Data Fabric through the REST API. *API:* The same API as Apache LivyHook.

Operators

EzLivyOperator	*Python path:* airflow.providers.ezmeral.livy.operators.ezlivy.EzLivyOperator *Description:* Wraps the Livy batch REST API, enabling to submit a Spark application to the underlying cluster. *API:* The same API as Apache LivyOperator.

Sensors

EzLivySensor	*Python path:* airflow.providers.ezmeral.livy.sensors.ezlivy.EzLivySensor *Description:* Monitors Livy sessions for termination. *API:* The same API as Apache LivySensor.

Interface to Amazon S3

Airflow provides an interface to Amazon S3 by using the Providers.

See Provider examples of Amazon S3 at `<airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/s3/example_dags/`.

Hooks

EzS3Hook	*Python path:* airflow.providers.ezmeral.s3.hooks.s3 *Description:* Interacts with Amazon S3 using Boto3 library.

Operators

EzS3CreateBucketOperator	*Python path:* airflow.providers.ezmeral.s3.operators.s3_bucket *Description:* Creates an S3 bucket.
EzS3DeleteBucketOperator	*Python path:* airflow.providers.ezmeral.s3.operators.s3_bucket *Description:* Deletes an S3 bucket.

last-updated: Jun 06, 2024

EzS3GetBucketTaggingOperator	*Python path:* airflow.providers.ezmeral.s3.operators.s3_bucket_tagging *Description:* Gets tagging from an S3 bucket.
EzS3PutBucketTaggingOperator	*Python path:* airflow.providers.ezmeral.s3.operators.s3_bucket_tagging *Description:* Puts tagging for an S3 bucket.
EzS3DeleteBucketTaggingOperator	*Python path:* airflow.providers.ezmeral.s3.operators.s3_bucket_tagging *Description:* Deletes tagging from an S3 bucket.
EzS3CopyObjectOperator	*Python path:* airflow.providers.ezmeral.s3.operators.s3_copy_object *Description:* Creates a copy of the stored S3 object.
EzS3DeleteObjectsOperator	*Python path:* airflow.providers.ezmeral.s3.operators.s3_delete_objects *Description:* Deletes single or multiple objects from a bucket using a single HTTP request.
EzS3ListOperator	*Python path:* airflow.providers.ezmeral.s3.operators.s3_list *Description:* List all objects from the bucket with the given string prefix in name.

Sensors

EzS3KeySensor	*Python path:* airflow.providers.ezmeral.s3.sensors.s3_key *Description:* Waits for a key to show up in a S3 bucket. S3 is a key-value store and key uniquely identifies the object in the bucket. S3 does not support folders and the path is just a key of resource.
EzS3KeyUnchangedSensor	*Python path:* airflow.providers.ezmeral.s3.sensors.s3_keys_unchanged *Description:* Checks for changes in the number of objects at prefix in S3 bucket. This sensor returns `True` if the inactivity period has passed with no increase in the number of objects. This sensor might give an error when you use it in reschedule mode. Between rescheduled invocations, S3 bucket loses the state of the listed objects.

Transfers

EzGCSToS3Operator	*Python path:* airflow.providers.ezmeral.s3.transfers.gcs_to_s3 *Description:* Synchronizes a Google Cloud Storage bucket with an Amazon S3 bucket.
EzLocalFilesystemToS3Operator	*Python path:* airflow.providers.ezmeral.s3.transfers.local_to_s3 *Description:* Uploads a file from a local filesystem to S3.

last-updated: Jun 06, 2024

EzMongoToS3Operator	*Python path:* airflow.providers.ezmeral.s3.transfers.mongo_to_s3 *Description:* Moves data from MongoDB using PyMongo to Amazon S3 using Boto.
EzSQLToS3Operator	*Python path:* `airflow.providers.ezmeral.s3.transfers.sql_to_s3`. *Description:* Saves data from a specific SQL query into a file in S3.
EzS3ToFTPOperator	*Python path:* airflow.providers.ezmeral.s3.transfers.s3_to_ftp *Description:* Enables the transfer of files from S3 to a FTP server.
EzS3ToSFTPOperator	*Python path:* airflow.providers.ezmeral.s3.transfers.s3_to_sftp *Description:* Enables the transfer of files from S3 to a SFTP server.
EzSFTPToS3Operator	*Python path:* airflow.providers.ezmeral.s3.transfers.sftp_to_s3 *Description:* Enables the transfer of files from a SFTP server to S3.

Interface to Spark

Airflow provides an interface to Spark by using the Providers.

See Provider examples of Spark at `<airflow_home>/build/env/lib/python3.9/site-packages/airflow/providers/ezmeral/spark/example_dags/`.

Hooks

EzSparkSubmitHook	*Python path:* airflow.providers.ezmeral.spark.hooks.ezspark_submit *Description:* Launches Spark applications. This hook is a wrapper around the `spark-submit` binary to run a `spark-submit` job.
EzSparkSqlHook	*Python path:* airflow.providers.ezmeral.spark.hooks.ezspark_sql *Description:* Enables interaction with binary tables through `spark-sql`. This hook is a wrapper around the `spark-sql` binary.
EzSparkJDBCHook	*Python path:* airflow.providers.ezmeral.spark.hooks.ezspark_jdbc *Description:* Enables data transfers between JDBC databases and Apache Spark.

Operators

EzSparkSubmitOperator	*Python path:* airflow.providers.ezmeral.spark.operators.ezspark_submit *Description:* This operator is a wrapper around the `spark-submit` binary to run a `spark-submit` job.
EzSparkSqlOperator	*Python path:* airflow.providers.ezmeral.spark.operators.ezspark_sql

last-updated: Jun 06, 2024

	Description: Executes Spark SQL query.
EzSparkJDBCOperator	*Python path:* airflow.providers.ezmeral.spark.operators.ezspark_jdbc *Description:* Extends the `SparkSubmitOperator` to enable data transfers between JDBC databases and Apache Spark.

AsyncHBase

MapR provides a version of AsyncHBase that is modified to work with HPE Ezmeral Data Fabric Database binary tables. The MapR version of AsyncHBase is based on the AsyncHBase library provides asynchronous Java APIs to access HPE Ezmeral Data Fabric Database binary tables. The HBase Client version is based on the current EEP and MapR version you are running. For more information, see the Interoperability Matrices on page 5715.

Configuring the Default Database for AsyncHBase

For AsynchHBase 1.7 and later, you can configure whether AsyncHBase accesses HBase tables or MapR-DB tables by default. If this value is not configured, AsyncHBase will determine the table type.

You can configure the default database in the `asynchbase.conf` file and the client application. A default database setting in the client application overrides the default database configuration in the `aynchbase.conf` file.

The process that AsyncHBase uses to access tables differs based on the default database configuration.

- When the default database is HBase, AsyncHBase accesses the table using the HBase port that was used to initialize the AsyncHBase client and the table name provided to the application.
- When the default database is MapR-DB, the table name provided to the application is translated to the MapR-DB table path, and then AsyncHBase accesses the table.
- When a default database is not configured, AsyncHBase first tries to access the table as a MapR-DB table. If that fails, it tries to access the table as an HBase table.

Set the Default Database using asynchbase.conf

To specify if AsyncHBase accesses HBase tables or MapR-DB tables:

1. Add the `mapr.hbase.default.db` parameter in the `asynchbase.conf` (`/opt/mapr/asynchbase/asynchbase-<version>/conf/asynchbase.conf`) file.
2. Set the value of `mapr.hbase.default.db` to one of the following values which will indicate the default database:
   - `hbase`
   - `maprdb`

Set the Default Database in the Client Application

Based on the database that you want as the default, add the following code in the client application:

- To access MapR-DB tables:

```
Config config = new Config();
String dbString = "maprdb";
config.overrideConfig(HBaseClient.CONFIG_PARAM_DEFAULT_DB,dbString);
HBaseClient client = new
HBaseClient(config);
```

- To access HBase tables:

```
Config config = new Config();
String dbString = "hbase";
config.overrideConfig(HBaseClient.CONFIG_PARAM_DEFAULT_DB,dbString);
HBaseClient client = new
HBaseClient(config);
```

Compiling and Running AsyncHBase Applications

When you compile or run AsyncHBase applications, you need to include the required AsyncHBase libraries.

To compile the application:

```
javac -cp `asynchbase
classpath`:$APP_CLASSPATH
<ProgramName>
```

To run the application, use one of the following commands:

- ```
  java -cp `asynchbase
  classpath`:$APP_CLASSPATH
  <ProgramName>
  ```

- ```
  asynchbase $APP_CLASSPATH
  <ProgramName>
  ```

To include the AsyncHBase library in your maven project:

1. Add MapR's maven repository to the list of repositories in your project's pom.xml:

   ```
   <repository>
   <id>mapr-releases</id>
   <url>https://repository.mapr.com/
   maven/</url>
   <snapshots><enabled>true</
   enabled></snapshots>
   <releases><enabled>true</enabled></
   releases>
   </repository>
   ```

last-updated: Jun 06, 2024

2. Add the following dependency to the list of dependencies:

```
<dependency> <groupId>org.hbase</
groupId>
<artifactId>asynchbase</
artifactId>
<version><AsyncHBaseVersion>-mapr-<
MapREcoVersion></version> </
dependency>
```

NOTE: For example, if you are using AsyncHBase 1.7-1603, configure the following for the version dependency: `<version>1.7.0-mapr-1603</version>`

AsyncHBase Script

MapR provides an AsyncHBase script that you can use to run applications and generate the AsyncHBase classpath.

The asynchbase script has the following syntax:

```
asynchbase <command> [<args>]
Commands:
classpath Dump AsyncHBase CLASSPATH
CLASSNAME Run the class named CLASSNAME
```

Parameters	Description
classpath	Dumps the AsyncHBase classpath. For example, you can use `aynchbase classpath` when you compile an application: `javac -cp `asynchbase classpath`:$APP_CLASSPATH <ProgramName>`
CLASSNAME	Runs the named class. For example: `asynchbase <path to application> CLASSNAME`

AsyncHBase Behavior with HPE Ezmeral Data Fabric Database Binary Tables

After you install AsyncHBase, you can use the AsyncHBase libraries to provide asynchronous access to HPE Ezmeral Data Fabric Database binary tables. However, it is important to note the behavior that is specific to using AsyncHBase with HPE Ezmeral Data Fabric Database.

The `Scanner.setMaxNumKeyValues` method, when run against HPE Ezmeral Data Fabric Database binary tables, does not behave as documented.	According to the AsyncHBase documentation, this method sets “the maximum number of KeyValues the server is allowed to return in a single RPC response.” When you use this method with HPE Ezmeral Data Fabric Database binary tables, the value for the maximum number of key values is ignored and the full set of KeyValues is always returned.
List<RegionClientStats> regionStats() is not supported	As of AsyncHBase 1.7-1603, `List<RegionClientStats> regionStats()` is

	not supported and when it is used the API does not return statistics.
HPE Ezmeral Data Fabric Database ignores HBase configurations in the asynchbase.conf file	As of AsyncHBase 1.7-1603, the conf object can be used to override Hbase properties that were previously only configured in the asynchbase.conf file. The asynchbase.conf file is located in the asynchbase installation directory. HPE Ezmeral Data Fabric Database does not use these Hbase configurations and therefore they are ignored by HPE Ezmeral Data Fabric Database

Using OpenTSDB with AsyncHBase

OpenTSDB can use MapR's AsyncHBase to perform time-series data-plots on HPE Ezmeral Data Fabric Database binary tables.

The OpenTSDB software package provides a time-series database that collects user-specified data.

To use OpenTSDB with AsyncHBase, install and configure OpenTSBD from source files or from a package.

Installing OpenTSDB from Source Files

The following steps describe how to install OpenTSDB from source files.

Prerequisites

Be sure to install the OpenTSDB version that is required for your AsyncHBase version. AsyncHBase 1.6 requires OpenTSDB 2.0. AsyncHBase 1.7 requires OpenTSDB 2.2.

Procedure

1. Clone the opentsdb.git project and check out the OpenTSDB branch that you require.

   NOTE:

   For example:

   ```
   $ git clone https://github.com/OpenTSDB/opentsdb.git
   Cloning into 'opentsdb'...
   remote: Counting objects: 5625, done.
   remote: Compressing objects: 100% (76/76), done.
   remote: Total 5625 (delta 51), reused 64 (delta 30)
   Receiving objects: 100% (5625/5625), 27.15 MiB | 2.67 MiB/s, done.
   Resolving deltas: 100% (3755/3755), done.
   Checking connectivity... done.
   $ cd opentsdb
   $ git tag -l
   mapr-1.1.0-release+5
   v1.0.0
   v2.0.0
   ...
   $ git checkout v2.0.0
   Switched to a new branch 'v2.0.0'
   ```

2. Install dependencies for graph generation:

   ```
   $ yum install autoconf automake gnuplot
   ```

3. Replace the `asynchbase.jar` file with the MapR version of that file:

```
$ yum install mapr-asynchbase
```

4. Run the build script:

```
./build.sh
```

5. If you want to use OpenTSDB with HPE Ezmeral Data Fabric Database tables, open the create_table.sh file (<OPENTSDB_ROOT_INSTALL_DIR>/src/create_table.sh) and add "/" before the table names so that MapR recognizes them as HPE Ezmeral Data Fabric Database tables: See Example: create_table.sh on page 3914.

6. Create tables:

```
env COMPRESSION=NONE;HBASE_HOME=/opt/mapr/hbase/hbase-<version>
<OPENTSDB_ROOT_INSTALL_DIR>/src/create_table.sh
```

7. Run the following command to verify that the tables are created successfully:

```
hadoop fs -ls /
```

8. Create a simple metric to store, such as “sys.cpu.user”:

```
./build/tsdb mkmetric sys.cpu.user --table=/tsdb --uidtable=/tsdb-uid
```

9. Run the OpenTSDB daemon (tsd).

```
./build/tsdb tsd --port=4242 --staticroot=build/staticroot
--cachedir=/tmp/opentsdb_tmp --zkquorum=10.10.101.50:5181 --table=/tsdb
--uidtable=/tsdb-uid
```

NOTE: Instead of providing these options on command line, you can configure the values in the opentsdb.conf file. This file must be in the root folder so the option settings are read when tsd is run. Also note that the staticroot argument points to the static UI files. You do not need to create cachedir because openstdb creates it automatically. Specifying the destination cachedir argument is enough. You do need to explicitly specify tsdb tables (tsdb, tsdb-uid) and Zookeeper quorum nodes.

10. Log into the web UI: `http://<TSD_Installed_Node_IP>:<Port>`
For example: `http://10.10.10.230:4242/`

11. Run a simple test program that generates data and sends repeated puts for the metric over a socket connection: <UI-IP>:<UI-Port> . See Data Generator Program on page 3915.

12. Check the plot in the UI.
    a) Select **From date** and check **autoreload**.
    b) Fill in the metric (in this case, `sys.cpu.user`) and the Tag keys (`cpu, host`) values (`webserver 0, webserver 1`). You should see a graph with a random plot.

Example: create_table.sh

create_table.sh is used to set up HPE Ezmeral Data Fabric Database to accepts `puts` from OpenTSDB. This example create_table.sh script was updated to work with HPE Ezmeral Data Fabric Database tables.

Note the changed sections for the `*_TABLE` variables.

```
#!/bin/sh
# Small script to setup the HBase tables used by OpenTSDB.

test -n "$HBASE_HOME" || {
  echo >&2 'The environment variable HBASE_HOME must be set'
  exit 1
}
test -d "$HBASE_HOME" || {
  echo >&2 "No such directory: HBASE_HOME=$HBASE_HOME"
  exit 1
}

TSDB_TABLE=${TSDB_TABLE-'/tsdb'}
UID_TABLE=${UID_TABLE-'/tsdb-uid'}
TREE_TABLE=${TREE_TABLE-'/tsdb-tree'}
META_TABLE=${META_TABLE-'/tsdb-meta'}
BLOOMFILTER=${BLOOMFILTER-'ROW'}
# LZO requires lzo2 64bit to be installed + the hadoop-gpl-compression jar.
COMPRESSION=${COMPRESSION-'LZO'}
# All compression codec names are upper case (NONE, LZO, SNAPPY, etc).
COMPRESSION=`echo "$COMPRESSION" | tr a-z A-Z`

case $COMPRESSION in
  (NONE|LZO|GZIP|SNAPPY)  :;;  # Known good.
  (*)
    echo >&2 "warning: compression codec '$COMPRESSION' might not be
supported."
    ;;
esac

# HBase scripts also use a variable named `HBASE_HOME', and having this
# variable in the environment with a value somewhat different from what
# they expect can confuse them in some cases.  So rename the variable.
hbh=$HBASE_HOME
unset HBASE_HOME
exec "$hbh/bin/hbase" shell <<EOF
create '$UID_TABLE',
  {NAME => 'id', COMPRESSION => '$COMPRESSION', BLOOMFILTER =>
'$BLOOMFILTER'},
  {NAME => 'name', COMPRESSION => '$COMPRESSION', BLOOMFILTER =>
'$BLOOMFILTER'}

create '$TSDB_TABLE',
  {NAME => 't', VERSIONS => 1, COMPRESSION => '$COMPRESSION', BLOOMFILTER
=> '$BLOOMFILTER'}

create '$TREE_TABLE',
  {NAME => 't', VERSIONS => 1, COMPRESSION => '$COMPRESSION', BLOOMFILTER
=> '$BLOOMFILTER'}

create '$META_TABLE',
  {NAME => 'name', COMPRESSION => '$COMPRESSION', BLOOMFILTER =>
'$BLOOMFILTER'}
EOF
```

Data Generator Program

This simple test program generates data and sends repeated puts for the metric over a socket connection.

```
import java.io.PrintWriter;
import java.net.Socket;
import java.util.Date;
import java.util.Random;

public class TestOpenTsdbAPI {
   public static Random random = new Random();
   public static long timeStamp = new Date().getTime()/1000; //in secs
   public static void testTSDBConnection() throws Exception {
       Socket sock = null;
       PrintWriter pw = null;
       String hostname = "10.10.10.230";
       int port = 4242;
       int count=1;
       while(true) {
           if(null==sock) {
               sock = new Socket(hostname, port);
               pw = new PrintWriter(sock.getOutputStream(), true);
           }
           pw.println(dataGen(0, 0, count));
           pw.flush();
           pw.println(dataGen(0, 1, count));
           pw.flush();
           pw.println(dataGen(1, 0, count));
           pw.flush();
           pw.println(dataGen(1, 1, count));
           pw.flush();

           if(++count==Integer.MAX_VALUE) break;
           Thread.sleep(60000);
       }
   }
   public static void main(String [] args) {
       try {
           testTSDBConnection();
       } catch(Exception ex) {
           ex.printStackTrace();
       }
   }

   public static String dataGen(int web, int cpu, int count) {
       int Low = 1;
       int High = 99;
       int val = random.nextInt(High-Low) + Low;
       long timeStamp1 = new Date().getTime()/1000;
       String dat = "put sys.cpu.user "+(timeStamp1)+" "+val+"
host=webserver"+ web +" cpu="+cpu;//(timeStamp+count)
       System.out.println(dat);
       return dat;
   }
}
```

For example, this program tries to put metrics for 2 hosts (webserver 0 and webserver 1). Each host has 2 CPUs (cpu 0 and cpu 1). Sample puts look like this:

```
put sys.cpu.user 1415300810 87 host=webserver0 cpu=0
put sys.cpu.user 1415300810 66 host=webserver0 cpu=1
put sys.cpu.user 1415300810 18 host=webserver1 cpu=0
put sys.cpu.user 1415300810 26 host=webserver1 cpu=1
```

last-updated: Jun 06, 2024

```
put <metric> <timestamp> <value> <tag1>=<> <tag2>=<>
```

When you run the program, you should see entries that indicate that the tags for the metric were created, and they should auto-complete on the UI.

```
UniqueId: Creating an ID for kind='tagv' name='webserver0'
```

You can also verify this from command line instead of the UI:

```
<OpenTSDB-Root>/build/tsdb query 1y-ago sum sys.cpu.user
```

Installing OpenTSDB with a Package
The following steps describe how to install OpenTSDB from a package.

About this task
Be sure to install the OpenTSDB version that is required for your AsyncHBase version. AsyncHBase 1.6 requires OpenTSDB 2.0. AsyncHBase 1.7 requires OpenTSDB 2.2.

Procedure

1. Install the OpenTSDB RPM:
   a) `mkdir /root/opentsdbrpm`
   b) `cd /root/opentsdbrpm`
   c) Download the version of OpenTSDB that you required.
      For OpenTSDB 2.0: `wget` https://github.com/OpenTSDB/opentsdb/releases/download/v2.0.0/opentsdb-2.0.0.noarch.rpm `-O opentsdb-2.0.0.noarch.rpm`
      For OpenTSDB 2.2: `wget`https://github.com/OpenTSDB/opentsdb/releases/download/v2.2.0/opentsdb-2.2.0.noarch.rpm`-o opentsdb-2.2.0.noarch.rpm`
   d) `rpm -ivh opentsdb-<version>.noarch.rpm`
2. Configure OpenTSDB to work with MapR:
   a) Edit the following `tsdb` scripts to cover MapR-specific dependencies: `/usr/share/opentsdb/bin/tsdb` and `/usr/bin/tsdb`

```
# Base of MapR installation
BASEMAPR=${MAPR_HOME:-/opt/mapr}

# Add MapR hadoop jars to classpath
if test -d "$BASEMAPR/hadoop/hadoop-0.20.2/lib"; then
 # hadoop conf directory to beginning of classpath (for core-site.xml)
 CLASSPATH="$BASEMAPR/hadoop/hadoop-0.20.2/conf:$CLASSPATH"

 for jar in "$BASEMAPR"/hadoop/hadoop-0.20.2/lib/*.jar; do
   if [ "`echo $jar | grep slf4j`" != "" ]; then
     continue
   fi
   CLASSPATH="$CLASSPATH:$jar"
 done
fi
```

b) Replace the asynchbase jar file (provide the current jar file name in the `cp` command):

```
cp
/opt/mapr/asynchbase/asynchbase-<version>/
asynchbase-<version>-mapr-*.jar
/usr/share/opentsdb/lib/
rm -f /usr/share/opentsdb/lib/asynchbase-<previous_version>.jar
```

c) Configure the `opentsdb.conf` files: These files must have the following settings:

```
/usr/share/opentsdb/etc/opentsdb/opentsdb.conf
/etc/opentsdb/opentsdb.conf
```

```
tsd.network.port = 4242
tsd.http.staticroot = /usr/share/opentsdb/static/
tsd.core.auto_create_metrics = false (for testing purposes only)
tsd.storage.hbase.data_table = /tsdb
tsd.storage.hbase.uid_table = /tsdb-uid
tsd.storage.hbase.zk_quorum = <zookeeperNode>:<zookeeperP>
```

d) Edit the `<OPENTSDB_ROOT_INSTALL_DIR>/src/create_table.sh` file and add "/" before the table names so that MapR recognizes them as HPE Ezmeral Data Fabric Database tables. Then, create tables in HPE Ezmeral Data Fabric Database: .

```
export COMPRESSION=NONE; export HBASE_HOME=/opt/mapr/hbase/
hbase-<version>; /usr/share/opentsdb/tools/create_table.sh
```

See Example: create_table.sh on page 3914

e) Confirm that the tables are created:

```
hadoop fs -ls /
tr--------   3 root root           2 2014-12-12 01:47 /tsdb
tr--------   3 root root           2 2014-12-12 01:47 /tsdb-meta
tr--------   3 root root           2 2014-12-12 01:47 /tsdb-tree
tr--------   3 root root           2 2014-12-12 01:47 /tsdb-uid
```

3. Start the `tsd` daemon. You can give executable permissions to the tsdb script in `/usr/share/opentsdb/bin`, or you can directly use `tsdb` (because of the dependencies you added earlier).

```
chmod +x /usr/share/opentsdb/bin/tsdb
/usr/share/opentsdb/bin/tsdb tsd --port=4242
--staticroot="/usr/share/opentsdb/static/"
--cachedir="/tmp/opentsdb" --auto-metric
```

4. Create a metric: `/usr/share/opentsdb/bin/tsdb mkmetric mymetric.stock`

5. Test the metric:

a) Run a Test Program for OpenTSDB on page 3918 that reads from the tmp_input on page 3918 file and sends put requests to opentsdb, which saves the data to a HPE Ezmeral Data Fabric Database table (tsdb/tsdb-uid).

b) Run aggregation queries (such as SUM) from the command line: `/usr/share/opentsdb/bin/tsdb query 1y-ago sum mymetric.stock` or `tsdb query 1y-ago sum mymetric.stock`

c) When you run the SUM command, the results should look like the following:

```
====
mymetric.stock 1407165399000 680.500015 {}
mymetric.stock 1407165401000 904.625000 {}
mymetric.stock 1407165402000 904.612495 {}
mymetric.stock 1407165403000 904.599991 {}
mymetric.stock 1407165404000 904.599991 {}
mymetric.stock 1407165405000 904.599991 {}
mymetric.stock 1407165406000 904.599991 {}

Test Program for OpenTSDB

```
public static void testTSDBConnection() throws Exception {
       Socket sock = null;
```

```
       PrintWriter pw = null;
       String hostname = "10.10.10.220"; //replace with the node where tsd
runs
       int port = 4242; //replace with your port
       sock = new Socket(hostname, port);
       pw = new PrintWriter(sock.getOutputStream(), true);
       File dir = new File(".");
       File fin = new File(dir.getCanonicalPath() + File.separator +
"tmp_input");
       BufferedReader br = new BufferedReader(new FileReader(fin));
String line = null;
while ((line = br.readLine()) != null) {
           System.out.println(line);
           pw.println(line);
           pw.flush();
}
br.close();
}
```

GetRequest API
MapR includes an additional constructor for the GetRequest class which takes an extra qualifier.

This additional constructor allows you to use one GetRequest to retrieve the key and value for tables that consist of multiple column families with different qualifiers:

```
public GetRequest(final byte[] table,
                  final byte[] key,
                  final byte[][] families,
                  final byte[][][] qualifiers) {
    super(table, key);
    this.families(families);
    this.qualifiers(qualifiers);
  }
```

Cascading

Cascading™ is a Java application framework produced by Concurrent, Inc. that enables developers to quickly and easily build rich enterprise-grade Data Processing and Machine Learning applications that can be deployed and managed across private or cloud-based Hadoop clusters.

last-updated: Jun 06, 2024

NOTE: Cascading is ***not*** part of the HPE Ezmeral Data Fabric distribution and not supported by HPE. However, like many other open source technologies, it can be used with HPE Ezmeral Data Fabric. The following information provides relevant details about using Cascading with HPE Ezmeral Data Fabric.

The `mt` command is the wrapper around Cascading. Multitool, a command line tool for processing large text files and datasets (like sed and grep on unix). The `mt` command is located in the `/opt/mapr/contrib/multitool/bin` directory.

Apache Drill

Drill is a low-latency distributed query engine for large-scale datasets, including structured and semi-structured/nested data. Inspired by Google's Dremel, Drill is designed to scale to several thousands of nodes and query petabytes of data at interactive speeds that BI/Analytics environments require.

Drill includes a distributed environment, purpose built for large-scale data processing. At the core of Drill is the "Drillbit" service which is responsible for accepting requests from the client, processing the queries, and returning results to the client.

Installing Drill

You can install Drill on one node or multiple nodes in a cluster. When Drill runs on each data node in a cluster, Drill can maximize data locality without moving data over the network or between nodes. Drill uses ZooKeeper to maintain cluster membership and health check information.

See Installing Drill on page 236 for instructions and additional information.

Configuring Data Source Connections

Drill connects to data sources through storage plugins. Drill can connect to several types of data sources including databases, local or distributed filesystems, and Hive metastores.

See Connecting Drill to Data Sources on page 3989 and Connect a Data Source for instructions and additional information.

Accessing Drill

After you install Drill and configure connections to your data sources, you can access Drill from any of the following user interfaces:

- Drill shell (SQLLine)
- Drill Web Console
- ODBC
- JDBC
- C++ API
- REST API

Additional Resources

Drill documentation is accessible from following the locations:

- Drill Release Notes on page 5848
- Apache Drill

Drill Tutorial

Drill is included as part of the Hadoop distribution. Refer to the Drill web site and Drill documentation for more details.

Hadoop is not a prerequisite for Drill and users can start learning Drill by running SQL queries directly on the local filesystem.

Getting to Know the Drill Setup

This section describes the configuration of the Drill system that you have installed and introduces the overall use case for the tutorial.

Storage Plugins Overview

The Hadoop cluster is set up with file system, HPE Ezmeral Data Fabric Database, and Hive, which all serve as data sources for Drill in this tutorial. Before you can run queries against these data sources, you need to connect to the data source through an interface called a storage plugin. A storage plugin defines interfaces to read/write and get metadata from the data source. Each storage plugin also exposes optimization rules for Drill to leverage for efficient query execution.

Jump directly to the queries in Lesson 1: Learn About the Data Set, or first, get some important background information about pre-configured storage plugins by following these steps:

1. Start the Drill Web Console.
2. Go to the Storage tab.
3. Open the configured storage plugins one at a time by clicking Update. You will see the following plugins configured.

dfs

This is a storage plugin configuration for the file system. The connection attribute indicates the type of distributed filesystem: in this case, file system. Drill can work with any distributed system, including HDFS, S3, and so on.

The configuration also includes a set of workspaces; each one represents a location in file system:

- root: access to the root filesystem location
- clicks: access to nested JSON log data
- logs: access to flat (non-nested) JSON log data in the logs directory and its subdirectories
- views: a workspace for creating views

A workspace in Drill is a location where users can easily access a specific set of data and collaborate with each other by sharing artifacts. Users can create as many workspaces as they need within Drill.

Each workspace can also be configured as “writable” or not, which indicates whether users can write data to this location and defines the storage format in which the data will be written (parquet, csv, json). These attributes become relevant when you explore Drill SQL commands, especially CREATE TABLE AS (CTAS) and CREATE VIEW.

Drill can query files and directories directly and can detect the file formats based on the file extension or the first few bits of data within the file. However, additional information around formats is required for Drill, such as delimiters for text files, which are specified in the “formats” section as follows.

```
{
 "type": "file",
 "enabled": true,
 "connection": "maprfs:///",
 "workspaces": {
   "root": {
     "location": "/mapr/demo.mapr.com/data",
     "writable": false,
     "storageformat": null
   },
   "clicks": {
     "location": "/mapr/demo.mapr.com/data/nested",
     "writable": true,
     "storageformat": "parquet"
   },
   "logs": {
     "location": "/mapr/demo.mapr.com/data/flat",
     "writable": true,
     "storageformat": "parquet"
   },
   "views": {
     "location": "/mapr/demo.mapr.com/data/views",
     "writable": true,
     "storageformat": "parquet"
 },
 "formats": {
   "psv": {
     "type": "text",
     "extensions": [
       "tbl"
     ],
     "delimiter": "|"
   },
   "csv": {
     "type": "text",
     "extensions": [
       "csv"
     ],
     "delimiter": ","
   },
   "tsv": {
     "type": "text",
     "extensions": [
       "tsv"
     ],
     "delimiter": "\t"
   },
   "parquet": {
     "type": "parquet"
   },
   "json": {
     "type": "json"
   }
 }
}
```

last-updated: Jun 06, 2024

hive

A storage plugin configuration for a Hive data warehouse. Drill connects to the Hive metastore by using the configured metastore thrift URI. Metadata for Hive tables is automatically available for users to query.

```
{
 "type": "hive",
 "enabled": true,
 "configProps": {
   "hive.metastore.uris": "thrift://localhost:9083",
   "hive.metastore.sasl.enabled": "false"
 }
}
```

Client Application Interfaces

Drill also provides additional application interfaces for the client tools to connect and access from Drill. The interfaces include the following.

ODBC/JDBC drivers

Drill provides ODBC/JDBC drivers to connect from BI tools such as Tableau, MicroStrategy, SQUirrel, and Jaspersoft; refer to Drill Interfaces Introduction to learn more.

SQLLine

SQLLine is a JDBC application that comes packaged with Drill. In order to start working with it, you can use the command line on the demo cluster to log in as root, then enter `sqlline`. Use `mapr` as the login password. For example:

```
$ ssh root@localhost -p 2222
Password:
Last login: Mon Sep 15 13:46:08 2014 from 10.250.0.28
Welcome to your Mapr Demo virtual machine.
[root@maprdemo ~]# sqlline
sqlline version 1.1.6
0: jdbc:drill:>
```

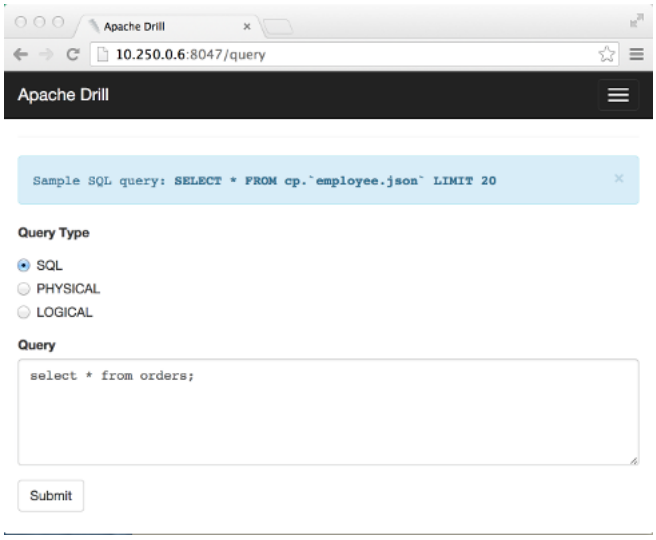
Drill Web UI

The Drill Web UI is a simple user interface for configuring and manage Drill. This UI can be launched from any of the nodes in the Drill cluster. The configuration for Drill includes setting up storage plugins that represent the data sources on which Drill performs queries. .

Users and developers can get the necessary information for tuning and performing diagnostics on queries, such as the list of queries executed in a session and detailed query plan profiles for each.

Detailed configuration and management of Drill is out of scope for this tutorial.

The following Web Console for Drill also provides a query UI where users can submit queries to Drill and observe results.



What's Next

Start running queries by going to Lesson 1: Learn About the Data Set.

Lesson 1: Learn About the Data Set

Goal

This lesson is simply about discovering what data is available, in what format, using simple SQL SELECT statements. Drill is capable of analyzing data without prior knowledge or definition of its schema. This means that you can start querying data immediately (and even as it changes), regardless of its format.

The data set for the tutorial consists of:

- Transactional data: stored as a Hive table
- Product catalog and primary customer data: stored as HPE Ezmeral Data Fabric Database binary tables
- Clickstream and logs data: stored in the file system as JSON files

Queries in This Lesson

This lesson consists of select * queries on each data source.

Before You Begin

Start sqlline

If sqlline is not already started, use a Terminal or Command window to log into the demo VM as root, then enter `sqlline`:

```
$ ssh root@10.250.0.6
Password:
Last login: Mon Sep 15 13:46:08 2014 from 10.250.0.28
Welcome to your Mapr Demo virtual machine.
[root@maprdemo ~]# sqlline
sqlline version 1.1.6
0: jdbc:drill:>
```

last-updated: Jun 06, 2024

You can run queries from this prompt to complete the tutorial. To exit from `sqlline`, type:

```
0: jdbc:drill:> !quit
```

Note that though this tutorial demonstrates the queries using SQLLine, you can also execute queries using the Drill Web UI.

Enable the DECIMAL Data Type

This tutorial uses the DECIMAL data type in some examples. The DECIMAL data type is disabled by default in this release, so enable the DECIMAL data type before proceeding:

```
alter session set `planner.enable_decimal_data_type`=true;

+-------+--------------------------------------------+
|  ok   |                  summary                   |
+-------+--------------------------------------------+
| true  | planner.enable_decimal_data_type updated.  |
+-------+--------------------------------------------+
1 row selected
```

List the available workspaces and databases:

```
0: jdbc:drill:> show databases;
+-------------+
| SCHEMA_NAME |
+-------------+
| hive.default |
| dfs.default |
| dfs.logs    |
| dfs.root    |
| dfs.views   |
| dfs.clicks  |
| dfs.data    |
| dfs.tmp     |
| sys         |
| maprdb      |
| cp.default  |
| INFORMATION_SCHEMA |
+-------------+
12 rows selected
```

Note that this command exposes all the metadata available from the storage plugins configured with Drill as a set of schemas. This includes the Hive and HPE Ezmeral Data Fabric Database databases as well as the workspaces configured in the file system. As you run queries in the tutorial, you will switch among these schemas by submitting the USE command. This behavior resembles the ability to use different database schemas (namespaces) in a relational database system.

Query Hive Tables

The orders table is a six-column Hive table defined in the Hive metastore. This is a Hive external table pointing to the data stored in flat files on the file system. The orders table contains 122,000 rows.

Set the schema to hive:

```
0: jdbc:drill:> use hive;
+------------+------------+
| ok | summary |
+------------+------------+
```

```
| true | Default schema changed to 'hive' |
+------------+------------+
```

You will run the USE command throughout this tutorial. The USE command sets the schema for the current session.

Describe the table:

You can use the DESCRIBE command to show the columns and data types for a Hive table:

```
0: jdbc:drill:> describe orders;
+-------------+------------+-------------+
| COLUMN_NAME | DATA_TYPE  | IS_NULLABLE |
+-------------+------------+-------------+
| order_id    | BIGINT     | YES         |
| month       | VARCHAR    | YES         |
| cust_id     | BIGINT     | YES         |
| state       | VARCHAR    | YES         |
| prod_id     | BIGINT     | YES         |
| order_total | INTEGER    | YES         |
+-------------+------------+-------------+
```

The DESCRIBE command returns complete schema information for Hive tables based on the metadata available in the Hive metastore.

Select 5 rows from the orders table:

```
0: jdbc:drill:> select * from orders limit 5;
+------------+------------+------------+------------+------------+-------------+

| order_id | month | cust_id | state | prod_id | order_total |
+------------+------------+------------+------------+------------+-------------+

| 67212 | June | 10001 | ca | 909 | 13 |
| 70302 | June | 10004 | ga | 420 | 11 |
| 69090 | June | 10011 | fl | 44 | 76 |
| 68834 | June | 10012 | ar | 0 | 81 |
| 71220 | June | 10018 | az | 411 | 24 |
+------------+------------+------------+------------+------------+-------------+
```

Because orders is a Hive table, you can query the data in the same way that you would query the columns in a relational database table. Note the use of the standard LIMIT clause, which limits the result set to the specified number of rows. You can use LIMIT with or without an ORDER BY clause.

Drill provides seamless integration with Hive by allowing queries on Hive tables defined in the metastore with no extra configuration. Note that Hive is not a prerequisite for Drill, but simply serves as a storage plugin or data source for Drill. Drill also lets users query all Hive file formats (including custom serdes). Additionally, any UDFs defined in Hive can be leveraged as part of Drill queries.

Because Drill has its own low-latency SQL query execution engine, you can query Hive tables with high performance and support for interactive and ad-hoc data exploration.

Query HPE Ezmeral Data Fabric Database Binary Tables

The customers and products tables are HPE Ezmeral Data Fabric Database binary tables. HPE Ezmeral Data Fabric Database is an enterprise in-Hadoop NoSQL database. It exposes the HBase API to support application development. Every HPE Ezmeral Data Fabric Database binary table has a row_key, in addition to one or more column families. Each column family contains one or more specific columns. The row_key value is a primary key that uniquely identifies each row.

last-updated: Jun 06, 2024

Drill allows direct queries on HPE Ezmeral Data Fabric Database binary tables. Unlike other SQL on Hadoop options, Drill requires no overlay schema definitions in Hive to work with this data. Think about a HPE Ezmeral Data Fabric Database table with thousands of columns, such as a time-series database, and the pain of having to management duplicate schemas for it in Hive!

Products Table

The products table has two column families.

Column Family	Columns
details	name category
pricing	price

The products table contains 965 rows.

Customers Table

The Customers table has three column families.

Column Family	Columns
address	state
loyalty	agg_rev membership
personal	age gender

The customers table contains 993 rows.

Set the workspace to maprdb:

```
0: jdbc:drill:> use maprdb;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'maprdb' |
+------------+------------+
```

Describe the tables:

```
0: jdbc:drill:> describe customers;
+-------------+------------+-------------+
| COLUMN_NAME | DATA_TYPE  | IS_NULLABLE |
+-------------+------------+-------------+
| row_key     | ANY        | NO          |
| address     | (VARCHAR(1), ANY) MAP | NO          |
| loyalty     | (VARCHAR(1), ANY) MAP | NO          |
| personal    | (VARCHAR(1), ANY) MAP | NO          |
+-------------+------------+-------------+

0: jdbc:drill:> describe products;
+-------------+------------+-------------+
```

```
| COLUMN_NAME | DATA_TYPE  | IS_NULLABLE |
+-------------+------------+-------------+
| row_key     | ANY        | NO          |
| details     | (VARCHAR(1), ANY) MAP | NO          |
| pricing     | (VARCHAR(1), ANY) MAP | NO          |
+-------------+------------+-------------+
```

Unlike the Hive example, the DESCRIBE command does not return the full schema up to the column level. Column-oriented NoSQL databases such as HPE Ezmeral Data Fabric Database can be schema-less by design; every row has its own set of column name-value pairs in a given column family, and the column value can be of any data type, as determined by the application inserting the data.

A “MAP” complex type in Drill represents this variable column name-value structure, and “ANY” represents the fact that the column value can be of any data type. Observe the row_key, which is also simply bytes and has the type ANY.

Select 5 rows from the products table:

```
0: jdbc:drill:> select * from products limit 5;
+-----------+-----------+-----------+
| row_key | details | pricing |
+-----------+-----------+-----------+
| [B@a1a3e25 | {"category":"bGFwdG9w","name":"IlNvbnkgbm90ZWJvb2si"} |
{"price":"OTU5"} |
| [B@103a43af |
{"category":"RW52ZWxvcGVz","name":"IzEwLTQgMS84IHggOSAxLzIgUHJlbWl1bSBEaWFnb
25hbCBTZWFtIEVudmVsb3Blcw=="} | {"price":"MT |
| [B@61319e7b |
{"category":"U3RvcmFnZSAmIE9yZ2FuaXphdGlvbg==","name":"MjQgQ2FwYWNpdHkgTWF4a
SBEYXRhIEJpbmRlciBSYWNrc1BlYXJs"} | {"price" |
| [B@9bcf17 | {"category":"TGFiZWxz","name":"QXZlcnkgNDk4"} |
{"price":"Mw=="} |
| [B@7538ef50 | {"category":"TGFiZWxz","name":"QXZlcnkgNDk="} |
{"price":"Mw=="} |
```

Given that Drill requires no up front schema definitions indicating data types, the query returns the raw byte arrays for column values, just as they are stored in HPE Ezmeral Data Fabric Database. Observe that the column families (details and pricing) have the map data type and appear as JSON strings.

In Lesson 2, you will use CAST functions to return typed data for each column.

Select 5 rows from the customers table:

```
0: jdbc:drill:> select * from customers limit 5;
+------------+------------+------------+------------+
| row_key | address | loyalty | personal |
+------------+------------+------------+------------+
| [B@284bae62 | {"state":"Imt5Ig=="} |
{"agg_rev":"IjEwMDEtMzAwMCI=","membership":"ImJhc2ljIg=="} |
{"age":"IjI2LTM1Ig==","gender":"Ik1B |
| [B@7ffa4523 | {"state":"ImNhIg=="}
| {"agg_rev":"IjAtMTAwIg==","membership":"ImdvbGQi"} |
{"age":"IjI2LTM1Ig==","gender":"IkZFTUFMRSI= |
| [B@7d13e79 | {"state":"Im9rIg=="} |
{"agg_rev":"IjUwMS0xMDAwIg==","membership":"InNpbHZlciI="} |
{"age":"IjI2LTM1Ig==","gender":"IkZFT |
| [B@3a5c7df1 | {"state":"ImtzIg=="} |
{"agg_rev":"IjMwMDEtMTAwMDAwIg==","membership":"ImdvbGQi"} |
{"age":"IjUxLTEwMCI=","gender":"IkZF |
| [B@e507726 | {"state":"Im5qIg=="}
| {"agg_rev":"IjAtMTAwIg==","membership":"ImJhc2ljIg=="} |
```

```
{"age":"IjIxLTI1Ig==","gender":"Ik1BTEUi" |
+------------+------------+------------+------------+
```

Again the table returns byte data that needs to be cast to readable data types.

Query the File System

Along with querying a data source with full schemas (such as Hive) and partial schemas (such as HPE Ezmeral Data Fabric Database), Drill offers the unique capability to perform SQL queries directly on file system. The file system could be a local file system, or a distributed file system such as file system, HDFS, or S3.

In the context of Drill, a file or a directory is considered as synonymous to a relational database “table.” Therefore, you can perform SQL operations directly on files and directories without the need for up-front schema definitions or schema management for any model changes. The schema is discovered on the fly based on the query. Drill supports queries on a variety of file formats including text, CSV, Parquet, and JSON in the 0.5 release.

In this example, the clickstream data coming from the mobile/web applications is in JSON format. The JSON files have the following structure:

```
{"trans_id":31920,"date":"2014-04-26","time":"12:17:12","user_info":
{"cust_id":22526,"device":"IOS5","state":"il"},"trans_info":{"prod_id":
[174,2],"purch_flag":"false"}}
{"trans_id":31026,"date":"2014-04-20","time":"13:50:29","user_info":
{"cust_id":16368,"device":"AOS4.2","state":"nc"},"trans_info":{"prod_id":
[],"purch_flag":"false"}}
{"trans_id":33848,"date":"2014-04-10","time":"04:44:42","user_info":
{"cust_id":21449,"device":"IOS6","state":"oh"},"trans_info":{"prod_id":
[582],"purch_flag":"false"}}
```

The clicks.json and clicks.campaign.json files contain metadata as part of the data itself (referred to as “self-describing” data). Also note that the data elements are complex, or nested. The initial queries below do not show how to unpack the nested data, but they show that easy access to the data requires no setup beyond the definition of a workspace.

Query nested clickstream data

Set the workspace to dfs.clicks:

```
 0: jdbc:drill:> use dfs.clicks;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.clicks' |
+------------+------------+
```

In this case, setting the workspace is a mechanism for making queries easier to write. When you specify a file system workspace, you can shorten references to files in the FROM clause of your queries. Instead of having to provide the complete path to a file, you can provide the path relative to a directory location specified in the workspace. For example:

```
"location": "/mapr/demo.mapr.com/data/nested"
```

Any file or directory that you want to query in this path can be referenced relative to this path. The clicks directory referred to in the following query is directly below the nested directory.

Select 2 rows from the clicks.json file:

```
0: jdbc:drill:> select * from `clicks/clicks.json` limit 2;
+------------+------------+------------+------------+------------+
|  trans_id  |    date    |    time    | user_info  | trans_info |
+------------+------------+------------+------------+------------+
| 31920      | 2014-04-26 | 12:17:12
| {"cust_id":22526,"device":"IOS5","state":"il"} | {"prod_id":
[174,2],"purch_flag":"false"} |
| 31026      | 2014-04-20 | 13:50:29
| {"cust_id":16368,"device":"AOS4.2","state":"nc"} | {"prod_id":
[],"purch_flag":"false"} |
+------------+------------+------------+------------+------------+
2 rows selected
```

Note that the FROM clause reference points to a specific file. Drill expands the traditional concept of a “table reference” in a standard SQL FROM clause to refer to a file in a local or distributed file system.

The only special requirement is the use of back ticks to enclose the file path. This is necessary whenever the file path contains Drill reserved words or characters.

Select 2 rows from the campaign.json file:

```
0: jdbc:drill:> select * from `clicks/clicks.campaign.json` limit 2;
+------------+------------+------------+------------+------------+------------+

|  trans_id  |    date    |    time    | user_info  |  ad_info   |
trans_info |
+------------+------------+------------+------------+------------+------------+

| 35232      | 2014-05-10 | 00:13:03   |
{"cust_id":18520,"device":"AOS4.3","state":"tx"} | {"camp_id":"null"} |
{"prod_id":[7,7],"purch_flag":"true"} |
| 31995      | 2014-05-22 | 16:06:38   |
{"cust_id":17182,"device":"IOS6","state":"fl"} | {"camp_id":"null"} |
{"prod_id":[],"purch_flag":"false"} |
+------------+------------+------------+------------+------------+------------+

2 rows selected
```

Notice that with a select * query, any complex data types such as maps and arrays return as JSON strings. You will see how to unpack this data using various SQL functions and operators in the next lesson.

Query Logs Data

Unlike the previous example where we performed queries against clicks data in one file, logs data is stored as partitioned directories on the file system. The logs directory has three subdirectories:

- 2012
- 2013
- 2014

Each of these year directories fans out to a set of numbered month directories, and each month directory contains a JSON file with log records for that month. The total number of records in all log files is 48000.

The files in the logs directory and its subdirectories are JSON files. There are many of these files, but you can use Drill to query them all as a single data source, or to query a subset of the files.

last-updated: Jun 06, 2024

Set the workspace to dfs.logs:

```
 0: jdbc:drill:> use dfs.logs;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.logs' |
+------------+------------+
```

Select 2 rows from the logs directory:

```
0: jdbc:drill:> select * from logs limit 2;
+------------+------------+------------+------------+------------+------------+--------

| dir0 | dir1 | trans_id | date | time | cust_id | device | state | camp_id
| keywords | prod_id | purch_fl |
+------------+------------+------------+------------+------------+------------+--------

| 2014 | 8 | 24181 | 08/02/2014 | 09:23:52 | 0 | IOS5 | il | 2 | wait | 128
| false |
| 2014 | 8 | 24195 | 08/02/2014 | 07:58:19 | 243 | IOS5 | mo | 6 | hmm |
107 | false |
+------------+------------+------------+------------+------------+------------+--------
```

Note that this is flat JSON data. The dfs.clicks workspace location property points to a directory that contains the logs directory, making the FROM clause reference for this query very simple. You do not have to refer to the complete directory path on the file system.

The column names dir0 and dir1 are special Drill variables that identify subdirectories below the logs directory. In Lesson 3, you will do more complex queries that leverage these dynamic variables.

Find the total number of rows in the logs directory (all files):

```
0: jdbc:drill:> select count(*) from logs;
+------------+
| EXPR$0 |
+------------+
| 48000 |
+------------+
```

This query traverses all of the files in the logs directory and its subdirectories to return the total number of rows in those files.

What's Next

Go to Lesson 2: Run Queries with ANSI SQL.

Lesson 2: Run Queries with ANSI SQL

Goal

This lesson shows how to do some standard SQL analysis in Drill: for example, summarizing data by using simple aggregate functions and connecting data sources by using joins. Note that Drill provides ANSI SQL support, not a “SQL-like” interface.

Queries in This Lesson

Now that you know what the data sources look like in their raw form, using select * queries, try running some simple but more useful queries on each data source. These queries demonstrate how Drill supports

last-updated: Jun 06, 2024

ANSI SQL constructs and also how you can combine data from different data sources in a single SELECT statement.

- Show an aggregate query on a single file or table. Use GROUP BY, WHERE, HAVING, and ORDER BY clauses.
- Perform joins between Hive, HPE Ezmeral Data Fabric Database, and filesystem data sources.
- Use table and column aliases.
- Create a Drill view.

Aggregation

Set the schema to hive:

```
0: jdbc:drill:> use hive;
+------------+------------+
|     ok     |  summary   |
+------------+------------+
| true       | Default schema changed to 'hive' |
+------------+------------+
1 row selected
```

Return sales totals by month:

```
0: jdbc:drill:> select `month`, sum(order_total)
from orders group by `month` order by 2 desc;
+------------+------------+
| month | EXPR$1 |
+------------+------------+
| June | 950481 |
| May | 947796 |
| March | 836809 |
| April | 807291 |
| July | 757395 |
| October | 676236 |
| August | 572269 |
| February | 532901 |
| September | 373100 |
| January | 346536 |
+------------+------------+
```

Drill supports SQL aggregate functions such as SUM, MAX, AVG, and MIN. Standard SQL clauses work in the same way in Drill queries as in relational database queries.

Note that back ticks are required for the “month” column only because “month” is a reserved word in SQL.

Return the top 20 sales totals by month and state:

```
0: jdbc:drill:> select `month`, state, sum(order_total) as sales from
orders group by `month`, state
order by 3 desc limit 20;
+------------+------------+------------+
|   month    |   state    |   sales    |
+------------+------------+------------+
| May        | ca         | 119586     |
| June       | ca         | 116322     |
| April      | ca         | 101363     |
| March      | ca         | 99540      |
```

last-updated: Jun 06, 2024

```
| July       | ca         | 90285      |
| October    | ca         | 80090      |
| June       | tx         | 78363      |
| May        | tx         | 77247      |
| March      | tx         | 73815      |
| August     | ca         | 71255      |
| April      | tx         | 68385      |
| July       | tx         | 63858      |
| February   | ca         | 63527      |
| June       | fl         | 62199      |
| June       | ny         | 62052      |
| May        | fl         | 61651      |
| May        | ny         | 59369      |
| October    | tx         | 55076      |
| March      | fl         | 54867      |
| March      | ny         | 52101      |
+------------+------------+------------+
20 rows selected
```

Note the alias for the result of the SUM function. Drill supports column aliases and table aliases.

HAVING Clause

This query uses the HAVING clause to constrain an aggregate result.

Set the workspace to dfs.clicks

```
0: jdbc:drill:> use dfs.clicks;
+------------+------------+
|     ok     |  summary   |
+------------+------------+
| true       | Default schema changed to 'dfs.clicks' |
+------------+------------+
1 row selected
```

Return total number of clicks for devices that indicate high click-throughs:

```
0: jdbc:drill:> select t.user_info.device, count(*) from `clicks/
clicks.json` t
group by t.user_info.device
having count(*) > 1000;
+------------+------------+
|   EXPR$0   |   EXPR$1   |
+------------+------------+
| IOS5       | 11814      |
| AOS4.2     | 5986       |
| IOS6       | 4464       |
| IOS7       | 3135       |
| AOS4.4     | 1562       |
| AOS4.3     | 3039       |
+------------+------------+
```

The aggregate is a count of the records for each different mobile device in the clickstream data. Only the activity for the devices that registered more than 1000 transactions qualify for the result set.

UNION Operator

Use the same workspace as before (dfs.clicks).

Combine clicks activity from before and after the marketing campaign

```
0: jdbc:drill:> select t.trans_id transaction, t.user_info.cust_id customer
from `clicks/clicks.campaign.json` t
union all
select u.trans_id, u.user_info.cust_id  from `clicks/clicks.json` u limit 5;
+-------------+-------------+
| transaction |  customer   |
+-------------+-------------+
| 35232       | 18520       |
| 31995       | 17182       |
| 35760       | 18228       |
| 37090       | 17015       |
| 37838       | 18737       |
+-------------+-------------+
```

This UNION ALL query returns rows that exist in two files (and includes any duplicate rows from those files): `clicks.campaign.json` and `clicks.json`.

Subqueries

Set the workspace to hive:

```
0: jdbc:drill:> use hive;
+-------------+-------------+
|     ok      |  summary    |
+-------------+-------------+
| true        | Default schema changed to 'hive' |
+-------------+-------------+
```

Compare order totals across states:

```
0: jdbc:drill:> select ny_sales.cust_id, ny_sales.total_orders,
ca_sales.total_orders
    from
    (select o.cust_id, sum(o.order_total) as total_orders
    from hive.orders o where state = 'ny' group by o.cust_id) ny_sales
    left outer join
    (select o.cust_id, sum(o.order_total) as total_orders
    from
    hive.orders o where state = 'ca' group by o.cust_id) ca_sales
    on ny_sales.cust_id = ca_sales.cust_id
    order by ny_sales.cust_id
    limit 20;
+-------------+-------------+-------------+
|  cust_id    |  ny_sales   |  ca_sales   |
+-------------+-------------+-------------+
| 1001        | 72          | 47          |
| 1002        | 108         | 198         |
| 1003        | 83          | null        |
| 1004        | 86          | 210         |
| 1005        | 168         | 153         |
| 1006        | 29          | 326         |
| 1008        | 105         | 168         |
| 1009        | 443         | 127         |
| 1010        | 75          | 18          |
| 1012        | 110         | null        |
| 1013        | 19          | null        |
| 1014        | 106         | 162         |
| 1015        | 220         | 153         |
```

last-updated: Jun 06, 2024

```
| 1016       | 85         | 159        |
| 1017       | 82         | 56         |
| 1019       | 37         | 196        |
| 1020       | 193        | 165        |
| 1022       | 124        | null       |
| 1023       | 166        | 149        |
| 1024       | 233        | null       |
+------------+------------+------------+
```

This example demonstrates Drill support for correlated subqueries. This query uses a subquery in the select list and correlates the result of the subquery with the outer query, using the cust_id column reference. The subquery returns the sum of order totals for California, and the outer query returns the equivalent sum, for the same cust_id, for New York.

The result set is sorted by the cust_id and presents the sales totals side by side for easy comparison. Null values indicate customer IDs that did not register any sales in that state.

CAST Function

Use the maprdb workspace:

```
0: jdbc:drill:> use maprdb;
+------------+------------+
|     ok     |  summary   |
+------------+------------+
| true       | Default schema changed to 'maprdb' |
+------------+------------+
1 row selected
```

Return customer data with appropriate data types

```
0: jdbc:drill:> select cast(row_key as int) as cust_id,
cast(t.personal.name as varchar(20)) as name,
cast(t.personal.gender as varchar(10)) as gender, cast(t.personal.age as
varchar(10)) as age,
cast(t.address.state as varchar(4)) as state, cast(t.loyalty.agg_rev as
dec(7,2)) as agg_rev,
cast(t.loyalty.membership as varchar(20)) as membership
from customers t limit 5;
+------------+------------+------------+------------+------------+------------+---------

|  cust_id   |    name    |   gender   |    age     |   state    |
agg_rev   | membership |
+------------+------------+------------+------------+------------+------------+---------

| 10001      | "Corrine Mecham" | "FEMALE"   | "15-20"    | "va"       |
197.00     | "silver"   |
| 10005      | "Brittany Park" | "MALE"     | "26-35"    | "in"       |
230.00     | "silver"   |
| 10006      | "Rose Lokey" | "MALE"     | "26-35"    | "ca"       |
250.00     | "silver"   |
| 10007      | "James Fowler" | "FEMALE"   | "51-100"   | "me"       |
263.00     | "silver"   |
| 10010      | "Guillermo Koehler" | "OTHER"    | "51-100"   | "mn"       |
202.00     | "silver"   |
+------------+------------+------------+------------+------------+------------+---------

5 rows selected
```

Note the following features of this query:

- The CAST function is required for every column in the table. This function returns the HPE Ezmeral Data Fabric Database/HBase binary data as readable integers and strings. Depending on what encoding is used while populating the HPE Ezmeral Data Fabric Database binary tables/HBase tables, you might have to use CONVERT_TO/CONVERT_FROM functions to decode them.
- The row_key column functions as the primary key of the table (a customer ID in this case).
- The table alias t is required; otherwise the column family names would be parsed as table names and the query would return an error.

Remove the quotes from the strings:

You can use the regexp_replace function to remove the quotes around the strings in the query results. For example, to return a state name va instead of “va”:

```
0: jdbc:drill:> select cast(row_key as int),
regexp_replace(cast(t.address.state as varchar(10)),'"','')
from customers t limit 1;
+------------+------------+
|   EXPR$0   |   EXPR$1   |
+------------+------------+
| 10001      | va         |
+------------+------------+
1 row selected
```

CREATE VIEW Command

Use a mutable workspace:

```
0: jdbc:drill:> use dfs.views;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.views' |
+------------+------------+
```

A mutable (or writable) workspace is a workspace that is enabled for “write” operations. This attribute is part of the storage plugin configuration. You can create Drill views and tables in mutable workspaces.

Create a view on a HPE Ezmeral Data Fabric Database binary table

```
0: jdbc:drill:> create or replace view custview as select cast(row_key as
int) as cust_id,
cast(t.personal.name as varchar(20)) as name,
cast(t.personal.gender as varchar(10)) as gender,
cast(t.personal.age as varchar(10)) as age,
cast(t.address.state as varchar(4)) as state,
cast(t.loyalty.agg_rev as dec(7,2)) as agg_rev,
cast(t.loyalty.membership as varchar(20)) as membership
from maprdb.customers t;
+------------+------------+
|     ok     |  summary   |
+------------+------------+
| true       | View 'custview' replaced successfully in 'dfs.views' schema |
+------------+------------+
1 row selected
```

Drill provides CREATE OR REPLACE VIEW syntax similar to relational databases to create views. Use the OR REPLACE option to make it easier to update the view later without having to remove it first. Note

that the FROM clause in this example must refer to maprdb.customers. The HPE Ezmeral Data Fabric Database binary tables are not directly visible to the dfs.views workspace.

Unlike a traditional database where views typically are DBA/developer-driven operations, filesystem-based views in Drill are very lightweight. A view is simply a special file with a specific extension (.drill). You can store views even in your local filesystem or point to a specific workspace. You can specify any query against any Drill data source in the body of the CREATE VIEW statement.

Dril provides a decentralized metadata model. Drill is able to query metadata defined in data sources such as Hive, HBase, and the filesystem. Drill also supports the creation of metadata in the filesystem.

Query data from the view:

```
0: jdbc:drill:> select * from custview limit 1;
+------------+------------+------------+------------+------------+------------+---------
|  cust_id   |    name    |   gender   |    age     |   state    |
agg_rev   | membership |
+------------+------------+------------+------------+------------+------------+---------
| 10001      | "Corrine Mecham" | "FEMALE"   | "15-20"    | "va"       |
197.00     | "silver"   |
+------------+------------+------------+------------+------------+------------+---------
```

Once the users know what data is available by exploring it directly from the file system, views can be used as a way to read the data into downstream tools such as Tableau and MicroStrategy for analysis and visualization. For these tools, a view appears simply as a “table” with selectable “columns” in it.

Query Across Data Sources

Continue using dfs.views for this query.

Join the customers view and the orders table:

```
0: jdbc:drill:> select membership, sum(order_total) as sales from
hive.orders, custview
where orders.cust_id=custview.cust_id
group by membership order by 2;
+------------+------------+
| membership |   sales    |
+------------+------------+
| "basic"    | 380665     |
| "silver"   | 708438     |
| "gold"     | 2787682    |
+------------+------------+
3 rows selected
```

In this query, we are reading data from a HPE Ezmeral Data Fabric Database binary table (represented by custview) and combining it with the order information in Hive. When doing cross data source queries such as this, you need to use fully qualified table/view names. For example, the orders table is prefixed by “hive,” which is the storage plugin name registered with Drill. We are not using any prefix for “custview” because we explicitly switched the dfs.views workspace where custview is stored.

NOTE: Note: If the results of any of your queries appear to be truncated because the rows are wide, set the maximum width of the display to 10000:

```
0: jdbc:drill:> !set maxwidth 10000
```

Do not use a semicolon for this SET command.

last-updated: Jun 06, 2024

Join the customers, orders, and clickstream data:

```
0: jdbc:drill:> select custview.membership, sum(orders.order_total) as
sales from hive.orders, custview,
dfs.`/mapr/demo.mapr.com/data/nested/clicks/clicks.json` c
where orders.cust_id=custview.cust_id and
orders.cust_id=c.user_info.cust_id
group by custview.membership order by 2;
+------------+------------+
| membership |   sales    |
+------------+------------+
| "basic"    | 372866     |
| "silver"   | 728424     |
| "gold"     | 7050198    |
+------------+------------+
3 rows selected
```

This three-way join selects from three different data sources in one query:

- hive.orders table
- custview (a view of the HBase customers table)
- clicks.json file

The join column for both sets of join conditions is the cust_id column. The views workspace is used for this query so that custview can be accessed. The hive.orders table is also visible to the query.

However, note that the JSON file is not directly visible from the views workspace, so the query specifies the full path to the file:

```
dfs.`/mapr/demo.mapr.com/data/nested/clicks/clicks.json`
```

What's Next

Go to Lesson 3: Run Queries on Complex Data Types

Lesson 3: Run Queries on Complex Data Types

Goal

This lesson focuses on queries that exercise functions and operators on self-describing data and complex data types. Drill offers intuitive SQL extensions to work with such data and offers high query performance with an architecture built from the ground up for complex data.

Queries in This Lesson

Now that you have run ANSI SQL queries against different tables and files with relational data, you can try some examples including complex types.

- Access directories and subdirectories of files in a single SELECT statement.
- Demonstrate simple ways to access complex data in JSON files.
- Demonstrate the repeated_count function to aggregate values in an array.

Query Partitioned Directories

You can use special variables in Drill to refer to subdirectories in your workspace path:

- dir0

last-updated: Jun 06, 2024

- dir1
- …

Note that these variables are dynamically determined based on the partitioning of the file system. No up-front definitions are required on what partitions exist.

Set workspace to dfs.logs

```
0: jdbc:drill:> use dfs.logs;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.logs' |
+------------+------------+
```

Query logs data for a specific year

```
0: jdbc:drill:> select * from logs where dir0='2013' limit 10;
+------------+------------+------------+------------+------------+------------+--------

| dir0 | dir1 | trans_id | date | time | cust_id | device | state | camp_id
| keywords | prod_id | purch_flag |
+------------+------------+------------+------------+------------+------------+--------

| 2013 | 11 | 12119 | 11/09/2013 | 02:24:51 | 262 | IOS5 | ny | 0 | chamber
| 198 | false |
| 2013 | 11 | 12120 | 11/19/2013 | 09:37:43 | 0 | AOS4.4 | il | 2 | outside

+------------+------------+------------+------------+------------+------------+--------
```

This query constrains files inside the subdirectory named 2013. The variable dir0 refers to the first level down from logs, dir1 to the next level, and so on. So this query returned 10 of the rows for February 2013.

Further constrain the results using multiple predicates in the query

```
0: jdbc:drill:> select dir0 as yr, dir1 as mth, cust_id from logs
where dir0='2013' and dir1='8' and device='IOS5' and purch_flag='true'
order by `date`;
+------------+------------+------------+
| yr | mth | cust_id |
+------------+------------+------------+
| 2013 | 8 | 4 |
| 2013 | 8 | 521 |
```

```
| 2013 | 8 | 1 |
| 2013 | 8 | 2 |
| 2013 | 8 | 4 |
| 2013 | 8 | 549 |
| 2013 | 8 | 72827 |
| 2013 | 8 | 38127 |
...
```

This query returns a list of customer IDs for people who made a purchase via an IOS5 device in August 2013.

Return monthly counts per customer for a given year

```
0: jdbc:drill:> select cust_id, dir1 month_no, count(*) month_count from
logs
where dir0=2014 group by cust_id, dir1 order by cust_id, month_no limit 10;
+------------+------------+-------------+
|  cust_id   |  month_no  | month_count |
+------------+------------+-------------+
| 0          | 1          | 143         |
| 0          | 2          | 118         |
| 0          | 3          | 117         |
| 0          | 4          | 115         |
| 0          | 5          | 137         |
| 0          | 6          | 117         |
| 0          | 7          | 142         |
| 0          | 8          | 19          |
| 1          | 1          | 66          |
| 1          | 2          | 59          |
+------------+------------+-------------+
10 rows selected
```

This query groups the aggregate function by customer ID and month for one year: 2014.

Query Complex Data

Drill provides some specialized operators and functions that you can use to analyze nested data natively without transformation. If you are familiar with JavaScript notation, you will already know how some of these extensions work.

Set the workspace to dfs.clicks

```
0: jdbc:drill:> use dfs.clicks;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.clicks' |
+------------+------------+
```

Explore clickstream data

```
0: jdbc:drill:> select * from `clicks/clicks.json` limit 5;
+------------+------------+------------+------------+------------+
| trans_id | date | time | user_info | trans_info |
+------------+------------+------------+------------+------------+
| 31920 | 2014-04-26 | 12:17:12
| {"cust_id":22526,"device":"IOS5","state":"il"} | {"prod_id":
[174,2],"purch_flag":"false"} |
| 31026 | 2014-04-20 | 13:50:29
| {"cust_id":16368,"device":"AOS4.2","state":"nc"} | {"prod_id":
```

```
[],"purch_flag":"false"} |
| 33848 | 2014-04-10 | 04:44:42
| {"cust_id":21449,"device":"IOS6","state":"oh"} | {"prod_id":
[582],"purch_flag":"false"} |
| 32383 | 2014-04-18 | 06:27:47
| {"cust_id":20323,"device":"IOS5","state":"oh"} | {"prod_id":
[710,47],"purch_flag":"false"} |
| 32359 | 2014-04-19 | 23:13:25 |
{"cust_id":15360,"device":"IOS5","state":"ca"} | {"prod_id":
[0,8,170,173,1,124,46,764,30,711,0,3,25],"purch_flag":"true"} |
+------------+------------+------------+------------+------------+
```

Note that the user_info and trans_info columns contain nested data: arrays and arrays within arrays. The following queries show how to access this complex data.

Unpack the user_info column

```
0: jdbc:drill:> select t.user_info.cust_id as custid, t.user_info.device as
device,
t.user_info.state as state
from `clicks/clicks.json` t limit 5;
+------------+------------+------------+
| custid | device | state |
+------------+------------+------------+
| 22526 | IOS5 | il |
| 16368 | AOS4.2 | nc |
| 21449 | IOS6 | oh |
| 20323 | IOS5 | oh |
| 15360 | IOS5 | ca |
+------------+------------+------------+
```

This query uses a simple table.column.column notation to extract nested column data. For example:

```
t.user_info.cust_id
```

where `t` is the table alias provided in the query, `user_info` is a top-level column name, and `cust_id` is a nested column name.

The table alias is required; otherwise column names such as `user_info` are parsed as table names by the SQL parser.

Unpack the trans_info column

```
0: jdbc:drill:> select t.trans_info.prod_id as prodid,
t.trans_info.purch_flag as
purchased
from `clicks/clicks.json` t limit 5;
+------------+------------+
| prodid | purchased |
+------------+------------+
| [174,2] | false |
| [] | false |
| [582] | false |
| [710,47] | false |
| [0,8,170,173,1,124,46,764,30,711,0,3,25] | true |
+------------+------------+
5 rows selected
```

Note that this result reveals that the prod_id column contains an array of IDs (one or more product ID values per row, separated by commas). The next step shows how you to access this kind of data.

Query Arrays

Now use the [n] notation, where n is the position of the value in an array, starting from position 0 (not 1) for the first value. You can use this notation to write interesting queries against nested array data.

For example:

`trans_info.prod_id[0]`

refers to the first value in the nested prod_id column and

`trans_info.prod_id[20]`

refers to the 21st value, assuming one exists.

Find the first product that is searched for in each transaction:

```
0: jdbc:drill:> select t.trans_id, t.trans_info.prod_id[0] from `clicks/
clicks.json` t limit 5;
+------------+------------+
|  trans_id  |   EXPR$1   |
+------------+------------+
| 31920      | 174        |
| 31026      | null       |
| 33848      | 582        |
| 32383      | 710        |
| 32359      | 0          |
+------------+------------+
5 rows selected
```

For which transactions did customers search on at least 21 products?

```
0: jdbc:drill:> select t.trans_id, t.trans_info.prod_id[20]
from `clicks/clicks.json` t
where t.trans_info.prod_id[20] is not null
order by trans_id limit 5;
+------------+------------+
|  trans_id  |   EXPR$1   |
+------------+------------+
| 10328      | 0          |
| 10380      | 23         |
| 10701      | 1          |
| 11100      | 0          |
| 11219      | 46         |
+------------+------------+
5 rows selected
```

This query returns transaction IDs and product IDs for records that contain a non-null product ID at the 21st position in the array.

Return clicks for a specific product range:

```
0: jdbc:drill:> select * from (select t.trans_id, t.trans_info.prod_id[0]
as prodid,
t.trans_info.purch_flag as purchased
from `clicks/clicks.json` t) sq
where sq.prodid between 700 and 750 and sq.purchased='true' order by
sq.prodid;
+------------+------------+------------+
| trans_id | prodid | purchased |
+------------+------------+------------+
| 21886 | 704 | true |
```

last-updated: Jun 06, 2024

```
| 20674 | 708 | true |
| 22158 | 709 | true |
| 34089 | 714 | true |
| 22545 | 714 | true |
| 37500 | 717 | true |
| 36595 | 718 | true |
...
```

This query assumes that there is some meaning to the array (that it is an ordered list of products purchased rather than a random list).

Perform Operations on Arrays

Rank successful click conversions and count product searches for each session:

```
0: jdbc:drill:> select t.trans_id, t.`date` as session_date,
t.user_info.cust_id as
cust_id, t.user_info.device as device, repeated_count(t.trans_info.prod_id)
as
prod_count, t.trans_info.purch_flag as purch_flag
from `clicks/clicks.json` t
where t.trans_info.purch_flag = 'true' order by prod_count desc;
+------------+--------------+------------+------------+------------+------------+

| trans_id | session_date | cust_id | device | prod_count | purch_flag |
+------------+--------------+------------+------------+------------+------------+

| 37426 | 2014-04-06 | 18709 | IOS5 | 34 | true |
| 31589 | 2014-04-16 | 18576 | IOS6 | 31 | true |
| 11600 | 2014-04-07 | 4260 | AOS4.2 | 28 | true |
| 35074 | 2014-04-03 | 16697 | AOS4.3 | 27 | true |
| 17192 | 2014-04-22 | 2501 | AOS4.2 | 26 | true |
...
```

This query uses a Drill SQL extension, the repeated_count function, to get an aggregated count of the array values. The query returns the number of products searched for each session that converted into a purchase and ranks the counts in descending order. Only clicks that have resulted in a purchase are counted.

Store a Result Set in a Table for Reuse and Analysis

To facilitate additional analysis on this result set, you can easily and quickly create a Drill table from the results of the query.

Continue to use the dfs.clicks workspace

```
0: jdbc:drill:> use dfs.clicks;
+------------+------------+
| ok | summary |
+------------+------------+
| true | Default schema changed to 'dfs.clicks' |
+------------+------------+
```

Return product searches for high-value customers:

```
0: jdbc:drill:> 0: jdbc:drill:> select o.cust_id, o.order_total,
t.trans_info.prod_id[0] as prod_id
from
hive.orders as o
```

```
join `clicks/clicks.json` t
on o.cust_id=t.user_info.cust_id
where o.order_total > (select avg(inord.order_total)
                       from hive.orders inord
                       where inord.state = o.state);
+----------+--------------+----------+
| cust_id  | order_total  | prod_id  |
+----------+--------------+----------+
| 1328     | 73           | 26       |
| 1328     | 146          | 26       |
| 1328     | 56           | 26       |
| 1328     | 91           | 26       |
| 1328     | 74           | 26       |
...
+----------+--------------+----------+
107,482 rows selected (14.863 seconds)
```

This query returns a list of products that are being searched for by customers who have made transactions that are above the average in their states.

Materialize the result of the previous query:

```
0: jdbc:drill:> 0: jdbc:drill:> create table product_search as select
o.cust_id, o.order_total, t.trans_info.prod_id[0] as prod_id
from
hive.orders as o
join `clicks/clicks.json` t
on o.cust_id=t.user_info.cust_id
where o.order_total > (select avg(inord.order_total)
                       from hive.orders inord
                       where inord.state = o.state);
+-----------+----------------------------+
| Fragment  | Number of records written  |
+-----------+----------------------------+
| 0_0       | 107482                     |
+-----------+----------------------------+
1 row selected
```

This example uses a CTAS statement to create a table based on a correlated subquery that you ran previously. This table contains all of the rows that the query returns (107,482) and stores them in the format specified by the storage plugin (Parquet format in this example). You can create tables that store data in csv, parquet, and json formats.

Query the new table to verify the row count

```
0: jdbc:drill:> select count(*) from product_search;
+------------+
|   EXPR$0   |
+------------+
| 107482     |
+------------+
1 row selected
```

This example simply checks that the CTAS statement worked by verifying the number of rows in the table.

Find the storage file for the table

```
[root@maprdemo product_search]# cd /mapr/demo.mapr.com/data/nested/
product_search
[root@maprdemo product_search]# ls -la
```

```
total 451
drwxr-xr-x. 2 mapr mapr      1 Sep 15 13:41 .
drwxr-xr-x. 4 root root      2 Sep 15 13:41 ..
-rwxr-xr-x. 1 mapr mapr 460715 Sep 15 13:41 0_0_0.parquet
```

Note that the table is stored in a file called `0_0_0.parquet`. This file is stored in the location defined by the `dfs.clicks` workspace:

```
"location": "/mapr/demo.mapr.com/data/nested"
```

with a subdirectory that has the same name as the table you created.

Summary

This tutorial introduced Drill and its ability to run ANSI SQL queries against various data sources, including Hive tables, HPE Ezmeral Data Fabric Database binary tables, and file system directories. The tutorial also showed how to work with and manipulate complex and multi-structured data commonly found in Hadoop/ NoSQL systems.

Now that you are familiar with different ways to access the sample data with Drill, you can try writing your own queries against your own data sources. Refer to the Apache Drill documentation for more information.

Drill-on-YARN

You can install and run Drill under Warden or you can install and run Drill under YARN. YARN (Yet Another Resource Negotiator) is a cluster management tool that automates the resource sharing process in a cluster.

NOTE: The MapR default security feature introduced in 6.0 is not supported with Drill-on-YARN.

The following sections provide information about Drill-on-YARN, including overview material, installation and configuration instructions, and additional information related to Drill-on-YARN:

Drill-on-YARN Overview

Running Drill as a YARN application (Drill-on-YARN) enables Drill to work alongside other applications, such as Hadoop and Spark, in a YARN-managed cluster. If you are currently running Drill under Warden, you can upgrade Drill and continue to run Drill under Warden, or you can migrate Drill to run under YARN. See Migrate Drill to Run Under YARN for instructions.

YARN assigns resources, such as memory and CPU, to applications in the cluster and eliminates the manual steps associated with installation and resource allocation for stand-alone applications in a multi-tenant environment. YARN automatically deploys (localizes) the Drill software onto each Drill node and manages the Drill cluster. Drill becomes a long-running application with YARN. You can monitor the Drill-on-YARN cluster using the Application Master web UI.

Resource Usage

By design, Drill aggressively uses all of the resources available to run queries at optimal speed. When Drill runs under YARN, you must inform YARN of the resources that Drill needs. The resource settings are descriptive, not proscriptive. Drill does not limit itself to the YARN settings, instead the YARN settings inform YARN of the resources that Drill will consume so that YARN does not over-allocate those resources to other tasks.

YARN manages CPU, memory, and disks. YARN calls settings for memory and CPU “vcores." You configure Drill’s memory and then inform YARN of the Drill configuration. Drill uses all available disk I/O and CPU.

Components

Several software components work together to run Drill as a YARN application. Drill, YARN, and the Drill-on-YARN application collectively provide the components required to run Drill under YARN.

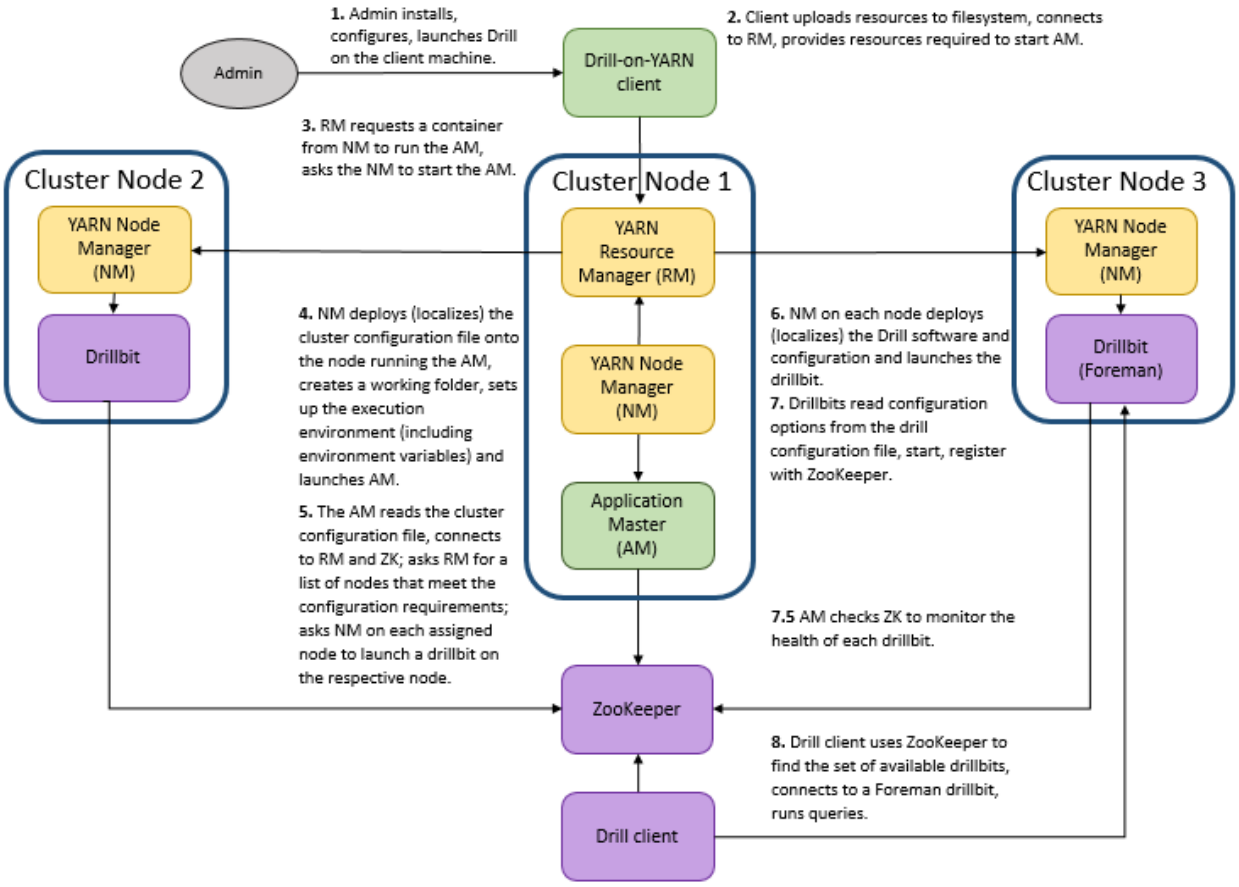
The following table lists the software components with their descriptions:

Software	Component	Description
YARN	Resource Manager	The Resource Manager manages the set of applications running on the cluster. Each cluster must have one Resource Manager.
	Node Manager	The Node Manager manages the application tasks running on a particular node. Each node in a cluster must have one Node Manager.
Drill	Drillbit	A Drillbit is the Drill daemon software that YARN runs on each node in the cluster. SeeDrill Query Execution. The Drillbit process on the node acts as the application task.
	Client	A client, such as JDBC, ODBC, or SQLLine sends queries to a Drillbit. The client uses ZooKeeper to discover a Drillbit that the client treats as the Foreman. SeeDrill Clients.
	Drill distribution archive	The Drill distribution archive is a Drill distribution .tar.gz file included with the Drill installation. Drill-on-YARN uploads this archive to the distributed filesystem (DFS). YARN downloads (localizes) the file to each worker node.
ZooKeeper	ZooKeeper	ZooKeeper is the service that tracks the available set of Drillbit processes. The Foreman for a query uses ZooKeeper to identify the set of available drill nodes that can run the query. SeeDrill Query Execution.
Drill-on-YARN Application	Application Master (AM)	The Application Manager requests containers from the Resource Manager and launches Drillbits using those containers. The AM monitors Drillbits, detects failures, and restarts failed Drillbits. The AM also provides a web UI to manage the Drill cluster.
	Drill-on-YARN client	The Drill-on-YARN client is a command-line program that starts, stops, and monitors the Drill cluster. The client provides the information that YARN needs to start the Application Master. The client can run on any machine that has both the Drill and YARN client software. The client does not have to be part of the YARN cluster.
	drill-on-yarn.conf	The drill-on-yarn.conf configuration file provides the information that Drill-on-YARN needs to manage the Drill cluster. This file is separate from the configuration files for Drill itself.

Component Workflow

Running Drill as a YARN application is mostly an automated process carried out by the Drill and YARN components. After an administrator installs, configures, and launches Drill from the Drill-on-YARN client, YARN deploys (localizes) Drill on to designated nodes and starts the Drill process on each node.

The following diagram shows the workflow between the components in a cluster with the steps that Drill and YARN complete to deploy and run Drill as a YARN application:



Configuring Drill to Run Under YARN

To run Drill under YARN, you must have the YARN version of Drill installed on the node designated as the Drill-on-YARN client. If you have not already planned your cluster and installed the YARN-ready version of Drill, see Install Drill to Run Under YARN and then return to this topic to configure Drill to run as a YARN application.

Configuring Drill to run under YARN requires modifications to Drill, Drill-on-YARN, and YARN configuration files. The following sections provide the information needed to make the changes to the configuration files, as well as information about how to launch Drill under YARN and validate the cluster configuration and status of the Drill nodes.

Complete the following steps to configure Drill to run under YARN, launch Drill as a YARN application, and validate the cluster:

Before You Configure Drill to Run Under YARN
Provides the steps required to repackage the Drill-on-YARN archive.

During Drill-on-YARN installation, the system fails to upload the Drill archive because JNI finds a mismatch for Java and native libraries. If you install and try to start Drill-on-YARN using the `mapr-drill-yarn` package, the system returns an error.

To prevent this issue from occurring, complete the following steps to repackage the Drill-on-YARN archive:

last-updated: Jun 06, 2024

1. Install Drill-on-YARN, as described in Installing Drill to Run Under YARN on page 240, but do not configure or start Drill-on-YARN.

last-updated: Jun 06, 2024

2. Create a file named `recreate_archive.sh` with the following information:

   TIP: You can create and run this file in any location you choose.

```
read -p "This operation will recreate drill.tar.gz in drill home
directory. Continue? " -n 1 -r
echo
if [[ ! $REPLY =~ ^[Yy]$ ]]
then
        exit 1
fi

drillHome="/opt/mapr/drill/drill-$(cat /opt/mapr/drill/drillversion)"
hadoopHome="/opt/mapr/hadoop/hadoop-$(cat /opt/mapr/hadoop/
hadoopversion)"

hbaseJar="$(ls /opt/mapr/lib/mapr-hbase-*-mapr.jar)"
maprWebJar="$(ls /opt/mapr/lib/mapr-security*-mapr.jar)"
maprdbJar="$(ls /opt/mapr/lib/maprdb-[0-9].[0-9].[0-9].[0-9]-mapr.jar)"
mapredJar="$(ls /opt/mapr/lib/maprdb-mapreduce-*-mapr.jar)"
maprfsJar="$(ls /opt/mapr/lib/maprfs-[0-9].[0-9].[0-9].[0-9]-mapr.jar)"
jerseyClientJar="$(ls ${hadoopHome}/share/hadoop/yarn/lib/
jersey-client-*.jar)"
jerseyCoreJar="$(ls ${hadoopHome}/share/hadoop/yarn/lib/
jersey-core-*.jar)"

echo "Drop old mapr jars from ${drillHome}/jars/3rdparty/"
rm -f ${drillHome}/jars/3rdparty/mapr-hbase*
rm -f ${drillHome}/jars/3rdparty/mapr-security-web-*
rm -f ${drillHome}/jars/3rdparty/maprdb-*
rm -f ${drillHome}/jars/3rdparty/maprfs-*

echo "Copy new jars from /opt/mapr/lib/"
cp ${hbaseJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${hbaseJar} has been copied"
cp ${maprWebJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${maprWebJar} has been copied"
cp ${maprdbJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${maprdbJar} has been copied"
cp ${mapredJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${mapredJar} has been copied"
cp ${maprfsJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${maprfsJar} has been copied"

echo "Copy jersey jars from hadoop for timeline client"
cp ${jerseyClientJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${jerseyClientJar} has been copied"
cp ${jerseyCoreJar} ${drillHome}/jars/3rdparty/
[ $? == 0 ] && echo "${jerseyCoreJar} has been copied"

if [ -f ${drillHome}/drill.tar.gz ]; then
    rm -f ${drillHome}/drill.tar.gz
    echo "${drillHome}/drill.tar.gz has been dropped"
fi

tempDir=drill-$(date +%s)

mkdir /tmp/$tempDir
[ $? == 0 ] && echo "Created temporary directory ${tempDir}"

cd /tmp/$tempDir

mkdir drill
```

```
[ $? == 0 ] && echo "Created drill directory"

cp -r ${drillHome}/* ./drill/
echo "${drillHome} copied to drill directory"

tar -czf drill.tar.gz ./drill
echo "Created new drill archive"

cp drill.tar.gz ${drillHome}/
echo "drill.tar.gz copied to ${drillHome}"

rm -rf /tmp/$tempDir
echo -e "\033[0;32mDONE.\033[0m"
```

3. Issue the following command to run the script:

   ```
   sh recreate_archive.sh
   ```

   When the script runs, a prompt appears:

   ```
   This operation will recreate drill.tar.gz in drill home directory.
   Continue?
   ```

   Reply with y to allow the script to update the JAR files in Drill-on-YARN.

   You should see output similar to the following (versions may differ):

   ```
   Drop old mapr jars from /opt/mapr/drill/drill-1.16.1/jars/3rdparty/
   Copy new jars from /opt/mapr/lib/
   /opt/mapr/lib/mapr-hbase-6.2.0.0-mapr.jar has been copied
   /opt/mapr/lib/mapr-security-web-6.2.0.0-mapr.jar has been copied
   /opt/mapr/lib/maprdb-6.2.0.0-mapr.jar has been copied
   /opt/mapr/lib/maprdb-mapreduce-6.2.0.0-mapr.jar has been copied
   /opt/mapr/lib/maprfs-6.2.0.0-mapr.jar has been copied
   Copy jersey jars from hadoop for timeline client
   /opt/mapr/hadoop/hadoop-2.7.6/share/hadoop/yarn/lib/
   jersey-client-1.19.jar has been copied
   /opt/mapr/hadoop/hadoop-2.7.6/share/hadoop/yarn/lib/jersey-core-1.19.jar
   has been copied
   /opt/mapr/drill/drill-1.16.1/drill.tar.gz has been dropped
   Created temporary directory drill-1656424210
   Created drill directory
   /opt/mapr/drill/drill-1.16.1 copied to drill directory
   Created new drill archive
   drill.tar.gz copied to /opt/mapr/drill/drill-1.16.1
   DONE.
   ```

4. Continue to Step 1: Configure Drill on page 3950.

Step 1: Configure Drill

Drill configuration under Drill-on-YARN differs from Drill configuration under Warden. You must create a site directory to contain the site-specific files for Drill. Drill-on-YARN copies the site directory to every node so that each node has the configuration settings. Having a site directory also simplifies upgrades because you can just delete the old Drill distribution and install the new one while the site-specific files remain unchanged in the site directory.

The drill-env.sh file contains only custom configurations. Data Fabric-specific configuration settings reside in distrib-env.sh, a file separate from the site-specific settings. When you migrate an existing Drill

installation to run under YARN, you must modify the drill-env.sh to remove the Drill and Data Fabric settings, leaving only your site-specific settings.

When you finish configuring Drill, use the site directory to test Drill, including starting, checking status, and stopping Drill.

NOTE: If you installed the mapr-drill-yarn package on nodes other than the Drill-on-YARN client in order to make SQLLine accessible to users, the site directory must be accessible from all nodes. You can copy the configurations across all the nodes, as you did when you ran Drill under the Warden service. Alternatively, you can put the site directory in a shared filesystem nfs mount to extend the configuration. When users launch SQLLine, they should provide the ZooKeeper connection string to launch Drill.

Create the Site Directory

To create the `site` directory, complete the following steps as the user that installed Drill and will run the Drill-on-YARN client application:

1. Create the site directory and an environment variable for the directory:

```
export DRILL_SITE=/opt/mapr/drill/site
mkdir $DRILL_SITE
```

   NOTE: The variable is not required. It is used for convenience in the documentation.

2. Change the owner of `$DRILL_SITE` and of the parent directory `/opt/mapr/drill` to the cluster admin user (`mapr` by default).

```
sudo chown mapr:mapr /opt/mapr/drill
sudo chown mapr:mapr /opt/mapr/drill/site
```

3. Copy the drill-env.sh, drill-override.conf, drill-on-yarn.conf, and distrib-env.sh files from $DRILL_HOME/conf/ into the `site` directory. In the following example, $DRILL_HOME is the location of the new Drill installation (usually /opt/mapr/drill/drill-<version>).

```
cp $DRILL_HOME/conf/drill-override.conf $DRILL_SITE
cp $DRILL_HOME/conf/drill-env.sh $DRILL_SITE
cp $DRILL_HOME/conf/drill-on-yarn.conf $DRILL_SITE
cp $DRILL_HOME/conf/distrib-env.sh $DRILL_SITE
```

   NOTE: Copy any configuration changes from drill-env.sh file in the previous Drill installation over to the drill-env.sh file in the `site` directory. Do not include the memory settings when you copy over your previous configurations. These changes must be made in the drill-on-yarn.conf file described in Step 3: Configure YARN to Run Drill.

   NOTE: Never modify `distrib-env.sh`. The `distrib-env.sh` script contains Data Fabric settings that you should not change. You copy this file to the `site` directory because it often contains values set during Drill installation. When you upgrade Drill, replace the file with the latest version from $DRILL_HOME/conf.

last-updated: Jun 06, 2024

4. If you developed custom code (data sources or user-defined functions), place the Java JAR files in $DRILL_SITE/jars. If you have code from your prior Drill installation, copy the JAR files from $PREV_DRILL/jars/3rdparty to $DRILL_SITE/jars.

   ```
   cp $PREV_DRILL/jars/3rdparty/yourJarName.jar $DRILL_SITE/jars
   ```

   NOTE: Only copy the JAR files that you added. Do not copy JAR files that shipped with the prior Drill version.

5. Add native libraries to the `site` directory. If you used a native library, such as the JPAM library in prior versions of Drill, place the native libraries in $DRILL_SITE/lib to enable YARN to automatically copy (localize) them to each node that runs Drill.

   ```
   cp native_libraries $DRILL_SITE/lib
   ```

Modify the drill-env.sh File

Copy any configuration changes from the drill-env.sh file in the previous Drill installation over to the drill-env.sh file in the `site` directory. Memory settings under Drill-on-YARN are now part of the drill-on-yarn.conf file. Modify the memory settings in $DRILL_SITE/drill-env.sh, as shown below, to ensure that the Drill memory settings match the amount of memory that Drill-on-YARN requires.

To modify drill-env.sh, complete the following steps:

1. Review each line in $PREV_DRILL/conf/drill-env.sh for settings you added, and copy them into the new $DRILL_SITE/drill-env.sh file.

   NOTE: If you do not recall whether you customized settings, you can compare your file with the original version of drill-env.sh that shipped with the prior Drill version.

2. Locate the following lines in `drill-env.sh` and note the values:

   ```
   DRILL_MAX_DIRECT_MEMORY="<value>"
   DRILL_HEAP="<value>"
   ```

   Replace those lines with the following lines, substituting the values in the new lines with the values from the old lines:

   ```
   export DRILL_MAX_DIRECT_MEMORY=${DRILL_MAX_DIRECT_MEMORY:-"<value>"}
   export DRILL_HEAP=${DRILL_HEAP:-"<value>"}
   ```

   NOTE: If you do not intend to run Drill outside of YARN, you can remove the two lines shown above from drill-env.sh.

   NOTE: If you do not make this change, Drill ignores the memory settings in the drill-on-yarn.conf file. If you are installing Drill fresh, and do not have an existing file, you can skip this step. Files in Drill 1.8 and later have the correct format.

   NOTE: When you install Drill, the Installer automatically adds the HADOOP_HOME variable, which points the current Data Fabric-provided Hadoop to your distrib-env.sh. If HADOOP_HOME is located elsewhere, change this location in drill-env.sh

last-updated: Jun 06, 2024

Use the Site Directory to Test Drill

You will use the `site` directory each time you start Drill using the `--site` or `--config` option. Use the option to verify that the configuration works by starting Drill as a stand-alone service on a single node.

```
drillbit.sh --site $DRILL_SITE start
```

Wait a few seconds and then verify that Drill continues to run:

```
drillbit.sh --site $DRILL_SITE status
```

You can also use the Drill Web Console for the Drillbit to verify that Drill has the proper settings. Once satisfied that the configuration is connect, stop Drill:

```
drillbit.sh --site $DRILL_SITE stop
```

NOTE: If you run a Drilbit with the `--site` (`--config`) option and you want to use SQLLine, you must add the option to SQLLine:

```
sqlline --site $DRILL_SITE
```

TIP: If you find that specifying the `--site` option becomes tedious, you can set the DRILL_CONF_DIR variable in your environment:

```
export DRILL_CONF_DIR="$DRILL_SITE"
drillbit.sh start
```

Step 2: Configure Drill-on-YARN

To configure Drill to run as a YARN application, modify the $DRILL_SITE/drill-on-yarn.conf cluster configuration file to suit the needs of your cluster. This file is a “starter” configuration file that corresponds to the simplest Drill cluster. The drill-on-yarn.conf file is in the same HOCON format as drill-override.conf.

Consult the $DRILL_HOME/conf/drill-on-yarn-example.conf file as an example. However, do not just copy the example file. Instead, copy only the specific configuration settings that you need; the others will automatically take the Drill-defined default values.

NOTE: Make sure that resources can accommodate the Drill memory, CPU, and disk requirements.

The following sections list the configuration settings required to run Drill under YARN:

Drill Memory Settings

The following configuration sets the Java heap size and amount of direct memory the node can allocate to Drill:

```
drillbit: { heap: "<value>" max-direct-memory: "<value>" }
```

When you add the configuration, use the same values set in the following parameters of the `drill-env.sh` file, if you did not remove these lines when you modified `drill-env.sh`:

```
export DRILL_MAX_DIRECT_MEMORY=${DRILL_MAX_DIRECT_MEMORY:-"<value>"}
export DRILL_HEAP=${DRILL_HEAP:-"<value>"}
```

Drill-on-YARN copies these values into the environment variables when launching each Drillbit. Drill also uses additional JVM memory. For example, Drill uses a code cache to hold classes generated at runtime. The default size of the cache is 1 GB:

```
drillbit: { code-cache: "1G" }
```

Typically, you do not need to change the code cache size, but you must account for it when computing the YARN container size.

YARN Container Size

The following configuration sets the YARN container size required to run Drill as a YARN application.

```
drillbit: {
   memory-mb: 14336
 }
```

The default value is 14GB. Typically, this size is the sum of the heap and direct memory. However, if you use custom libraries that perform their own memory allocation, or launch sub-processes, you must account for that memory usage as well. Note that YARN memory is expressed in MB. To compute the container size, start with the values used for the heap, direct memory, and code cache settings, as shown in the following example:

```
drillbit: {
    heap: "4G"
    max-direct-memory: "8G"
    code-cache: "1G"
    memory-mb: 14336
  }
```

The values shown above are the Drill defaults. You may use larger values. Although the three values account for the bulk of Drill memory, the JVM itself also has a certain overhead. Assume that the overhead is about 1 GB, though the amount varies depending on the workload.

Add the four values together to get a memory requirement in GB.

```
Total memory = 8G + 4G + 1G + 1G = 14G
```

YARN sizes containers in megabytes. Convert GB to MB:

```
Container size = 14G * 1024 = 14336 MB
```

Set this size in drill-on-yarn.conf:

```
drillbit: { memory-mb: 14336 }
```

CPU

The following configuration sets the CPU to allocate to Drill:

```
drillbit: { vcores: <value> }
```

Drill is a CPU-intensive operation and greatly benefits from each additional core. YARN does not limit the number of cores used by an application. Rather, this number reports to YARN the average CPU usage of Drill so that YARN can use the number when deciding how many other applications to run on the same node.

Drillbit Cluster Configuration

The following configuration sets the cluster group:

```
cluster: [ { name: "drillbits" type: "basic" count: 1 } ]
```

Drill-on-YARN uses the concept of a “cluster group” of Drillbits to describe the set of drillbits to launch. Currently, only the “basic” type of group is supported. A basic group launches drillbits anywhere in the YARN cluster where a container is available. For a basic group, specify the group type and the number of drillbits to launch.

NOTE: The syntax says that cluster is a list that contains cluster group objects contained in braces. Drill currently supports just one group.

The name is optional. It appears in the Application Master web UI. Type must be set to “basic.” Set the count to the number of hosts on which Drill is to run at launch time. You can resize the Drill cluster after the cluster is launched.

YARN Queue Labels

The following configuration sets the YARN queue labels that identify the cluster nodes that run Drill:

```
yarn: { queue: "<queue_name>" }
```

The distribution of YARN provides queue labels for assigning YARN applications to specific queues. See Label-Based Scheduling for YARN Applications. You can use queue labels with Drill to identify the YARN queue that should run Drill.

To use queue labels, complete the following steps:

1. Create a node label.
2. Assign the label to the nodes that are to run Drill.
3. Create a Drill-specific queue that uses the node label.
4. Configure Drill-on-YARN to use the queue.

Suppose you create a queue called “drill.” Setting the following configuration causes Drill-on-YARN to launch through the drill queue:

```
yarn: { queue: "drill" }
```

Set queue to the name a name of your choice. When Drill-on-YARN launches, both the Application Master and drillbits run only on nodes with the same node label as the queue.

DFS Location

The following configuration sets the dfs location:

```
dfs: { app-dir: "/user/drill" }
```

Drill copies the archive in to the filesystem in a location you provide. The default is /user/drill, however you can specify a different location. You do not have to specify the file system connection information; this information is automatically defined.

Step 3: Configure YARN to Run Drill

YARN default settings are optimized for MapReduce applications. MapReduce applications use a limited amount of memory; however, Drill is long-running and consumes a significant amount of resources. Adjust the YARN memory configuration to allow YARN to allocate containers large enough to run Drill. Exclude the

YARN container directory from `systemd-tmpfiles` to prevent `systemd-tmpfiles` from removing Drill's container files while Drill runs.

Increase Maximum Container Size

YARN provides a number of parameters to control the amount of resources available to applications. The data-fabric distribution of YARN sets most of these parameters automatically, except for the maximum container size, which is left at the Apache YARN default of 8 GB. Typical Drill configurations use significantly more memory. Therefore, you must increase the YARN maximum container size on each node to suit the needs of Drill. You can use the YARN Resource Manager web UI to determine the amount of memory available on each node.

NOTE: YARN resource requirements match the Drill resource requirements.

To increase the maximum container size, determine the required container size from the Drill setting in `drill-on-yarn.conf`, which you previously set in step 2:

```
drillbit: {
   memory-mb: 14336
 }
```

Use this number to set the `yarn.scheduler.maximum-allocation-mb` parameter in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop.<version>`, substituting the number of the version you have installed.

Edit `yarn-site.xml` to add the following:

```
<property>
   <name>yarn.scheduler.maximum-allocation-mb</name>
   <value>14336</value>
   <description>Set to allow Drill containers 14G.</description>
 </property>
```

NOTE: You must update this configuration on every YARN node.

Restart the YARN Resource Manager to pick up change, and use the YARN Resource Manager UI to verify that the maximum container size shows the new value.

Exclude the YARN Container Directory from systemd-tmpfiles

The system puts the YARN Node Manager container files in the `/tmp` directory. Most system administrators configure `systemd-tmpfiles` to periodically remove files in `/tmp`. Since Drill-on-YARN is a long-running YARN application, `systemd-tmpfiles` can remove Drill's container files while Drill runs. If this occurs, you must manually shut down the Drill cluster because `systemd-tmpfiles` will have removed the `pid` file that YARN needs to manage Drill.

You can prevent `systemd-tmpfiles` from cleaning up Drill's container files by adding a new configuration file to `/etc/tmpfiles.d/`, for example `/etc/tmpfiles.d/exclude-nm-local-dir.conf`, with the following configuration:

```
x /tmp/hadoop-mapr/nm-local-dir/*
```

NOTE: This configuration prevents `systemd-tmpfiles` from cleaning the `/nm-local-dir` directory when cleaning `/tmp`.

Example

```
$ cat /etc/tmpfiles.d/exclude-nm-local-dir.conf
x /tmp/hadoop-mapr/nm-local-dir/*
```

Step 4: Launch Drill Under YARN

Now that the Drill and YARN configuration is complete, you can issue the `start` command from the Drill-on-YARN client to launch Drill under YARN. Launching Drill-on-YARN from the client starts Drill and brings Drill up on other nodes.

Issuing the start command starts the YARN Application Master, which then works with YARN to start the Drillbits. The Application Master provides a web UI to monitor the cluster.

NOTE: To simplify debugging, you can set the cluster size to a single node. Once you confirm that a single node works, increase the node count.

Launch Drill under YARN as the `mapr` user. For example, if you installed Drill as `mapr` launch Drill as the `mapr` user.

NOTE: If you launch Drill as `root` and the system returns an error failing the launch attempt, launch Drill as a user with permissions, such as `mapr`.

Issue the following command to start Drill under YARN:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE start
```

NOTE: To run SQLLine, you must also add the `--site` option:

```
$DRILL_HOME/bin/sqlline --site $DRILL_SITE
```

TIP: To avoid typing the `site` argument each time you launch Drill under YARN, set an environment variable:

```
export DRILL_CONF_DIR=$DRILL_SITE
$DRILL_HOME/bin/drill-on-yarn.sh start
```

After you issue the start command, a number of lines describing the start-up process print. The tool automatically archives and uploads the site directory, which YARN copies (along with the Drill software) onto each node. A URL that includes both the host and the port number displays. Enter the URL in a web browser to access the Application Master web UI.

NOTE: When you launch Drill from the Drill-on-YARN client, the Application Master can come up on any node. Save the provided URL to share with other users so they can also access the Application Master. Alternatively, you can run the `status` command to see the URL or go to the YARN Resource Manager UI to get the link.

See Drill-on-YARN Command Line Tool for additional commands, including stop, status, and resize. See Application Master Web UI for cluster monitoring information.

Step 5: Validate Cluster Configuration and Status

The Drill-on-YARN command line tool prints a URL, for the Drill Application Master process, that you can use to monitor the cluster. The Drillbits should be up and running, unless the upload or launch failed.

Failed upload	If the upload fails, the most likely reason is that the HADOOP_HOME variable is not set, or the user launching Drill-on-YARN does not have permission

last-updated: Jun 06, 2024

	to create or write to the DFS location set in the Drill-on-YARN configuration file.
Failed launch	If the launch fails, verify that the YARN maximum container size was set to be at least as large as the Drill container size and that YARN can provide the number of vcores and disks you have requested for Drill.

Monitor Cluster Activity

When the cluster launches successfully, you can verify the status of the components in the Drill cluster from the command line or you can copy the Application Master URL into your browser to use the Application Master web UI.

To check the status from the command line, issue the following command:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE status
```

- Verify that the Drillbits are in the Running state (or transition to that state after a few moments.) If the Drillbits remain in the Requesting state, the likely cause is that YARN cannot provide a container of the requested size. You can access this information on the Drillbits page in the Application Master web UI.
- Verify that the Application Master has correctly picked up the YARN-related configuration from drill-override.conf and drill-on-yarn.conf. You can access this information on the Configuration page in the Application Master web UI.
- Verify that the Application Master is running. The Drill Application Master uses ZooKeeper to verify that only one Application Master runs per Drill cluster. The Application Master fails if ZooKeeper is down, is configured incorrectly in drill-override.conf, or if another Application Master is running for the same cluster.
- Verify that that the configurations in are correct in drill-override.conf if there are Drillbit failures. Drill-on-YARN detects Drillbit failures and retries each Drillbit a few times. If the Drillbit continues to fail, the node is black-listed for that run of Drill-on-YARN. You can see failures in the History page of the web UI. If your Drillbits fail, the most likely reason is misconfiguration within drill-override.conf. Use YARN to locate and view the Drill logs for the failed container.

Resize the Cluster

If the cluster works well for a single node, you can increase the number of nodes.

NOTE: In the Drill 1.8 release, adding nodes can be done while users run queries. However, removing nodes from the cluster causes queries to fail, and so should only be done when the cluster is idle.

To make a permanent change, modify the cluster size in drill-on-yarn.conf:

```
cluster: [
   {
     ...
     count: 5
   }
 ]
```

You can also resize the cluster dynamically. To add two nodes from the command line:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE resize +2
```

last-updated: Jun 06, 2024

To set the cluster size to a total of five nodes:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE resize 5
```

To remove one of the nodes:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE resize -1
```

You can also resize your cluster using the Manage page of the Application Master web UI, by entering the number of desired nodes and clicking **Go**.

Stop the Cluster

You can stop the cluster from the command line or from the Manage page in the Application Master web UI.

To stop the cluster from the command line, issue the following command:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE stop
```

Migrate Drill to Run Under YARN

Explains how to migrate Drill to run under YARN instead of the Warden service.

When you migrate Drill to run under YARN, you must back up configurations, including files and storage plugins, shutdown the Drill cluster running under Warden, and uninstall Drill on all Drill nodes in the cluster. You may also want to determine which system settings have been changed from the Drill defaults.

NOTE: Drill-on-YARN is an advanced feature used to manage a production Drill cluster. Only skilled administrators, familiar with YARN, should configure Drill to run under YARN. If you are new to Drill, consider running Drill under the Warden service until you are familiar with Drill and Drill cluster management.

The sections below provide the tasks required to migrate Drill under YARN:

Tasks

Complete the following tasks when you want to migrate Drill to run under YARN:

Backup configurations and UDFs	Back up configuration files, storage plugin configurations, and UDFs (user-defined functions) or custom JAR files. Back up the configuration files located in `/opt/mapr/drill/drill-<version>/conf`, including `drill-override.conf` and `drill-env.sh`, to preserve your ZooKeeper configuration and any options or custom configurations specified in the files. Also back up `logback.xml` if you configured the file for the Lilith software. • To back up configuration files, go to `/opt/mapr/drill/drill-<version>/conf`, and copy the files to a location outside of the Drill installation directory. `cp <file_name> drill-env.sh /path/to/directory`

- To back up custom JARs or UDFs, go to `/opt/mapr/drill/drill-<version>/jars/3rdparty` and copy the JARs or UDFs to a location outside of the Drill installation directory.
- To back up storage plugin configurations, complete the following steps:
  1. Start the Web Console. The Drill node that you use to access the Web Console must be a node that is currently running the Drillbit process.
  2. Click **Storage**.
  3. Click **Update** next to a storage plugin.
  4. Copy the configuration to a text file, and save the file.
  5. Repeat steps 3 and 4 for each storage plugin configuration that you want to save.

Verify system option settings

Drill should save set system options when you migrate Drill. However, you may want to verify which system options were changed from the default settings beforehand. You can run the following query to see which system options were changed from the defaults:

```
select * from sys.options where
status = 'CHANGED';
```

Example:

```
select * from sys.options where
status = 'CHANGED';
+-------------------------------------+----------+

|                name
|   kind   |  type   |  status  |
num_val  | string_val  | bool_val  |
float_val  |
+-------------------------------------+----------+

| exec.errors.verbose
| BOOLEAN  | SYSTEM  | CHANGED  |
null     | null        | true      |
null       |
| new_view_default_permissions
| STRING   | SYSTEM  | CHANGED  |
null     | 777         | null      |
null       |
| planner.enable_decimal_data_type
| BOOLEAN  | SYSTEM  | CHANGED  |
null     | null        | true      |
null       |
| planner.enable_limit0_optimization
| BOOLEAN  | SYSTEM  | CHANGED  |
null     | null        | true      |
null       |
+-------------------------------------+----------+

4 rows selected (0.541 seconds)
```

last-updated: Jun 06, 2024

After you migrate, run the query again to verify that the system options are still set. If not, set the options.

Shutdown the Drill cluster

Issue the following command to shutdown the existing Warden-managed Drill cluster:

```
maprcli node services -name
drill-bits -action stop -nodes <node
host names separated by a space>
```

NOTE: Do not shutdown nodes when queries are in progress.

Verify that Drillbits stopped

Run the following command to verify that the Drillbit service is no longer running on each node:

```
ps -ef | grep -i drill
```

No Drill processes should print to screen when you run this command.

You can also log in to the Control System at `https://<host name>:8443` to verify the status of the Drillbit service. You should not see Drillbit as a listed service.

Uninstall Drill

Uninstall Drill and then run `configure.sh -R` to refresh the configuration.

Issue the command appropriate for your system as root or using sudo to uninstall the mapr-drill package:

Operating System	Command
RedHat/CentOS	`yum remove mapr-drill`
Ubuntu	`apt-get remove mapr-drill`

NOTE: Verify that Drillbit processes stopped.

Additional Drill-on-YARN Configuration Options

You can include additional configuration options in the `$DRILL_SITE/drill-on-yarn.conf` file for specialized cases. For example, you can customize the Application Master web UI port or Application Master settings.

Refer to the `drill-on-yarn-example.conf` file in $DRILL_HOME/conf to see examples of the additional options. Do not use the example file.

The following list describes the changes that you can make for several of the Drill-on-YARN components:

Application Name

You can customize the application name that appears when starting or stopping the Drill cluster and in the Drill-on-YARN web UI. Change the value of the following option to a name you prefer:

```
app-name: "My Drill Cluster"
```

Application Master Web UI Port

If you run multiple Drill clusters in a YARN cluster, YARN may assign two Drill Application Master processes on the same node. To avoid port conflicts, change the HTTP port for one or both of the Drill

last-updated: Jun 06, 2024

clusters. Change the value of the following option to a different port number:

```
drill.yarn:
 http: {
   port: 12345
 }
}
```

Application Master Settings

You can customize certain Application Master properties. All of the Application Master properties are prefixed with `drill.yarn.am`, for example `drill.yarn.am.heap`.

The following table lists the Application Master properties with their default settings:

Name	Description	Default
memory-mb	Memory, in MB, to allocate to the Application Master.	14336
vcores	Number of CPUS to allocate to the Application Master.	1
heap	Java heap for the Application Master.	450M

Drillbit

You can customize certain properties that control the Drillbit processes. All of the Drillbit properties are prefixed with `drill.yarn.drillbit`, for example `drill.yarn.drillbit.disks`.

NOTE: You can specify Drill disk usage to YARN, however Drill uses all disks regardless of the setting.

The following table lists the Drillbit properties with their default settings:

Name	Description	Default
code-cache	Code cache that holds classes generated at runtime.	1G
memory-mb	Memory, in MB, to allocate to the Drillbit.	13000
vcores	Number of CPUS to allocate to the AM.	4

last-updated: Jun 06, 2024

disks	Number of disk equivalents consumed by Drill (on versions of YARN that support disk resources.)	1
heap	Java heap memory.	4G
max-direct-memory	Direct (off-heap) memory for the Drillbit.	4G
log-gc	Enables Java garbage collector logging.	false
class-path	Additional class-path entries.	blank

Mapping of drill-env.sh to drill-on-yarn.conf Options

When you run Drill as a standalone application, you set startup options, such as Drillbit memory, in the $DRILL_HOME/conf/drill-env.sh start up script. Under YARN, Drill still reads $DRILL_SITE/drill-env.sh for configuration options, however Drill-on-YARN provides the $DRILL_SITE/drill-on-yarn.conf file to configure options that were formerly set in drill-env.sh.

The following table maps the drill-env.sh environment variables to their equivalent configuration parameters in drill-on-yarn.conf:

drill-env.sh Environment Variable	**drill-on-yarn.conf Configuration Parameter**
DRILL_MAX_DIRECT_MEMORY *	drill.yarn.drillbit.max-direct-memory
DRILL_HEAP *	drill.yarn.drillbit.heap
DRILL_JAVA_OPTS	drill.yarn.drillbit.vm-args (Added to those in drill-env.sh.)
SERVER_GC_OPTS (to add GC logging)	Drill.yarn.drillbit.log-gc (To enable GC logging)
DRILL_HOME	Set automatically when files are localized (drill.yarn.drill-install. localize is true), else drill.yarn.drill-install. drill-home.
DRILL_CONF_DIR	Set automatically when files are localized, else uses the normal defaults.
DRILL_LOG_DIR	Set automatically to point to YARN's log directory unless disabled by setting drill.yarn.drillbit. disable-yarn-logs to false. If disabled, uses the normal Drill defaults.
DRILL_CLASSPATH_PREFIX *	Drill.yarn.drillbit. prefix-class-path
HADOOP_CLASSPATH *	drill.yarn.hadoop.class-path (or, better drill.yarn.drillbit. extn-class-path.)
HBASE_CLASSPATH *	Drill.yarn.hadoop. hbase-class-path (or, better drill.yarn.drillbit. extn-class-path.)
EXTN_CLASSPATH * (New in Drill 1.8.)	Drill.yarn.drillbit. extn-class-path
DRILL_CLASSPATH *	drill.yarn.drillbit.class-path

last-updated: Jun 06, 2024

Multiple Drill Clusters within YARN

You can define multiple Drill clusters within a single YARN cluster. Each Drill cluster is a collection of Drillbits that work as an independent unit. For example, you might define one test Drill cluster that consists of a few machines on the same physical cluster that runs larger Drill clusters for development and marketing.

You must assign each Drill cluster a distinct ZooKeeper entry. Drill uses ZooKeeper to coordinate activities. Each Drill cluster also needs a distinct set of ports because YARN may launch Drillbits from different clusters on the same physical node.

The following steps summarize the process for defining multiple Drill clusters on a single YARN cluster:

1. Create a new site directory.
2. Configure Drill.
3. Configure Drill-on-YARN.
4. Start the cluster.

The following task provides instructions for each of the steps required to configure and run multiple Drill clusters under YARN:

Defining Multiple Drill Clusters within YARN

About this task

Complete the following steps to define multiple Drill clusters under YARN:

Procedure

1. Create a new "site" directory under $DRILL_HOME, and create an environment variable for the directory.

   ```
   mkdir $DRILL_HOME/<site_name>
   export $<SITE_NAME>_SITE=$DRILL_HOME/<site_name>
   ```

2. Copy the following configuration files from the existing “site” directory into the new “site” directory:
   - drill-override.conf
   - drill-env.sh
   - drill-on-yarn.conf
   - distrib-env.sh

last-updated: Jun 06, 2024

3. Modify the settings in the `drill.exec` section of `$DRILL_SITE/drill-override.conf` to configure the new Drill cluster to act independently of the other Drill cluster(s), or share settings, such as storage plugin configurations. For the new Drill cluster to act independently, give `zk.root` a distinct name from the existing clusters. In the more advanced scenario where the clusters share configurations, give `zk.root` the same name as the existing Drill clusters. When the clusters share the same root, they must have distinct cluster-id values. The user, bit, and http ports must have values distinct from all the other Drill clusters.

   The following example shows a number 1 added to the first digit of the default port numbers, however you can choose any available ports.

   ```
   drill.exec: {
    cluster-id: "drillbits",
    zk: {
      root: "<site_name>"
      connect: "zk-host:5181"
    }

    rpc {
      user.server.port: 41010
      bit.server.port: 41011
    }
    http.port: 9047
   }
   ```

4. Modify the `drill-on-yarn.conf` configuration file for the new cluster. The new cluster must have a distinct name, a distinct upload directory in the filesystem, and a distinct port number.

   The following settings in the `drill.yarn` section must have distinct values for the new cluster:

   ```
   drill.yarn: {
    app-name: "Distinct Cluster Name"

    dfs: {
      app-dir: "/upload/directory"
    }

    http : {
      port: <distinct port number>
    }
   }
   ```

5. Start the new cluster from the "site" directory that correlates with the new cluster.

   ```
   $DRILL_HOME/bin/drill-on-yarn.sh --site $NEW_SITE start
   ```

Drill-on-YARN Command Line Tool

Run the Drill-on-YARN command line tool from the Drill-on-YARN client and use it to start, stop, resize, and check the status of the Drill cluster. When you launch Drill from the command line, the tool automatically archives and uploads the “site” directory, which YARN deploys (along with Drill) onto each node.

You can access the Drill-on-YARN command line tool in the following directory:

```
$DRILL_HOME/bin/drill-on-yarn.sh --site $DRILL_SITE command
```

where *command* is the operation you want to perform, such as `start`.

To avoid having to type the site argument for each command, set an environment variable:

```
export DRILL_CONF_DIR=$DRILL_SITE
```

The following example shows the start command after setting the environment variable:

```
$DRILL_HOME/bin/drill-on-yarn.sh start
```

Command Summary

The following table lists the commands and provides a brief summary for each:

Command	Description
start	Starts the Drill cluster. Prints the startup status followed by a summary of the application.
status	Retrieves basic information about the Drill cluster.
stop	Stops the Drill cluster.
resize <value> resize + <increase_node_count_by> resize - <decrease_ node_count_by>	Adds or removes nodes in the Drill cluster while the cluster runs. You can specify the exact number of nodes you want to run, or you can use +/- to increase or decrease the current node count by a certain amount.
clean	Removes the cached Drill archive from the designated DFS directory.

Commands

The following sections provide detailed information and examples for each of the commands listed in the command summary:

start

The start command launches Drill and provides a startup status followed by a summary of the application.

The first line in the summary displays the cluster name from the configuration file to confirm which cluster is starting.

```
Launching Drill-on-YARN...
```

The next line shows the YARN application ID and tracks the job status from Accepted to Running.

```
Application ID:
application_1462842354064_0001
Application State: ACCEPTED
Starting......
Application State: RUNNING
```

Once the job starts, you see the YARN job tracking URL with the Drill-on-YARN web UI URL.

```
Application Master URL: http://
<YARN_Job_Tracking_URL>:8048/
```

Once the application starts, the Drill-on-YARN writes an “appid” file into the Drill installation directory:

```
ls /opt/mapr/drill/drill-<version>
…
drillbits1.appid
```

The file name is the same as the Drill cluster ID. The file contains the ID of the Drill-on-YARN application. The other commands use this ID. You can run only one Drill application at a time. If you attempt to start a second from the same client machine on which you started the first, the client command complains that the appid file already exists. If you attempt to start the cluster from a different node, the second application detects a conflict and shuts down again.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh start

Launching Drill-on-YARN...
Application ID:
application_1462842354064_0001
Application State: ACCEPTED
Starting......
Application State: RUNNING
Tracking
URL: http://10.250.50.31:8088/proxy/
application_1462842354064_0001/
Application Master URL: http://
10.250.50.31:8048/
```

status

The status command retrieves basic information about the Drill cluster and provides a status summary.

The first several lines of the status summary provide information about the state of YARN, which includes the application ID, the application state, and YARN’s tracking URL for the application.

```
Application ID:
application_1462842354064_0001
Application State: RUNNING
Host: yosemite/10.250.50.31
Tracking URL:
```

Following the state of YARN information is the host on which the Drill application is running, the queue on which the application was placed, and the user who submitted the application. The start time tells you when YARN started the application.

```
http://10.250.50.31:8088/proxy/
application_1462842354064_0001/
Queue: default
User: drilluser
Start Time: 2016-05-09 16:56:40
```

The next few lines are specific to Drill, including the name of the application (which you configured in the drill-on-yarn.conf configuration file), the Drill

Application Master URL, the number of Drillbits you requested to run, and the number actually running.

```
Application Name: Drill-on-YARN
AM State: LIVE
Target Drillbit Count: 1
Live Drillbit Count: 1
```

Finally, the last line provides the URL for the Drill-on-YARN web UI.

```
For more information, visit: http://
10.250.50.31:8048/
```

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh
status

Application ID:
application_1462842354064_0001
Application State: RUNNING
Host: yosemite/10.250.50.31
Tracking
URL: http://10.250.50.31:8088/proxy/
application_1462842354064_0001/
Queue: default
User: drilluser
Start Time: 2016-05-09 16:56:40
Application Name: Drill-on-YARN
AM State: LIVE
Target Drillbit Count: 1
Live Drillbit Count: 1
For more information, visit: http://
10.250.50.31:8048/
```

stop

The stop command stops the Drill cluster. This command is forceful and kills any in-flight queries. The output tracks the shutdown and displays the final YARN application status.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh stop

Stopping Application ID:
application_1462842354064_0001
Stopping...
Stopped.
Final status: SUCCEEDED
```

resize

The resize command changes the number of nodes in the cluster. You can use this command to add or remove nodes in the Drill cluster as it runs. You can specify the change either by giving the number of nodes you want to run, or by using the + or - to specify the change in node count.

Drill adds nodes only if additional nodes are available from YARN. If you request to stop more nodes than are running, Drill stops all of the running nodes.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh
resize 10
$DRILL_HOME/bin/drill-on-yarn.sh
resize +2
$DRILL_HOME/bin/drill-on-yarn.sh
resize -3
```

clean

The clean command removes the cached Drill archive from the designated DFS directory. If you run Drill-on-YARN for a temporary cluster, Drill leaves the Drill software archive in your designated DFS directory. Specifically, the first start uploads the Drill archive to DFS. Stop leaves the archive in DFS. Subsequent start commands reuse the cached archive if it is the same size as the version on the local disk. Clean removes the cached file, forcing Drill to upload a fresh copy if you again restart the Drill cluster.

Example

```
$DRILL_HOME/bin/drill-on-yarn.sh clean
```

Application Master Web UI

Drill, running as a YARN application, provides the Drill-on-YARN Application Master (AM) process to manage the Drill cluster. The Drill AM provides a web UI where you can monitor cluster status and perform simple operations, such as increasing or decreasing cluster size, or stopping the cluster.

When you launch Drill using the Drill-on-YARN command line tool, the tool signals YARN to launch the AM, which in turn launches the Drillbits in the cluster. When Drill starts, you can access the web UI using the URL provided at startup.

The following sections describe the information that the Application Master web UI provides:

Main

The main page provides the following information about the Drill cluster:

Drill Cluster Status

The Drill cluster status show the state of the Drill cluster, which is one of the following:

- LIVE: This is the normal state and shows that the Drill cluster is running.
- ENDING: The cluster is in the process of shutting down

There is no “ENDED.” state. When the cluster shuts down, the web UI is no longer available.

Target Drillbit Count

The target Drillbit count is the number of Drillbits to run in the cluster. The actual number may be less if Drillbits have not yet started, or if YARN cannot allocate enough containers.

Live Drillbit Count

The live Drillbit count is the number of Drillbits that are ready for use. These have successfully started, have registered with ZooKeeper, and are ready for use. You can see the detail of all Drillbits (including those in the process of starting or stopping) using the Drillbits page. Each Drillbit must run on a separate node, so

last-updated: Jun 06, 2024

	this is also the number of nodes in the cluster running Drill.
Total Drillbit Memory and Virtual Cores	The total number of YARN resources currently allocated to running Drillbits.
YARN Node Count, Memory, and Virtual Cores	Reports general information about YARN itself including the number of nodes, the total cluster memory, and total number of virtual cores.
Groups	Lists the cluster groups defined in the configuration file (only one is currently supported), along with the target and actual number of Drillbits in that group.

Configuration

The configuration page shows the complete set of configuration values used for the current run. The values come from the configurations you set and the Drill-provided defaults. Use this page to diagnose configuration-related issues. Names are shown in fully-expanded form. That is the name “drill.yarn.http.port” refers to the parameter defined, as follows, in your configuration file:

```
drill.yarn:
 http: {
   port: 8048
 }
}
```

Drillbits

The Drillbits page provides the following information about each of the Drillbits:

ID	A sequential number assigned to each new Drillbit. Numbers may not start with 1 if you have previously shut down some Drillbits.
Group	The cluster group that started the Drillbit. Cluster groups configured in drill-on-yarn.conf.
Host	The host name or IP address on which the Drillbit runs. If the Drillbit is in a normal operating state, this field is also a hyperlink to the Web UI for the Drillbit.
State	The operating state of the Drillbit. The normal state is “Running.” The Drillbit passes through a number of states as YARN allocates a container and launches a process, as the AM waits for the Drillbit to become registered in ZooKeeper, and so on. Similarly, the Drillbit passes through a different set of states during shutdown. Use this value to diagnose problems. If the Drillbit is in a live state, this field shows an “[X]” link that you can use to kill this particular Drillbit. Use this if the Drillbit has startup problems or seems unresponsive. During the shut-down process, the kill link disappears and is replaced with a “Cancelled” note.
ZK State	The ZooKeeper handshake state. Normal state is “START_ACK”, meaning that the Drillbit has registered with ZooKeeper. This state is useful when diagnosing problems.
Container ID	The YARN-assigned container ID for the Drillbit task. The ID is a link that takes you to the YARN Node Manager UI for the Drillbit task.

last-updated: Jun 06, 2024

Memory and Virtual Cores (vcores)	The amount of resources actually allocated to the Drillbit by YARN.
Start Time	The date and time (in your local time-zone, displayed in ISO format) when the Drillbit launch started. This page also displays unmanaged Drillbits, if present. An unmanage Drillbit is one that is running, has registered with ZooKeeper, but was not started by the Application Master. Likely, the Drillbit was launched using the Drillbit.sh script directly. Use the host name to locate the machine running the Drillbit if you want to convert the Drillbit to run under YARN.

Manage

The Manage page provides options to resize or stop the Drill cluster. You can resize the cluster by adding or removing Drillbits or setting the cluster to a specific size.

Drill is a long-running application. Typically, Drill runs indefinitely, and you would only shut down the Drill cluster to perform an upgrade of the Drill software or to change configuration options. When you terminate the Drill cluster, any in-progress queries fail. Therefore, best practice is to perform the shutdown with users so that Drill is not processing any queries at the time of the shut-down.

When removing or shutting-down the cluster, you receive a confirmation page asking if you really do want to stop Drillbit processes. Click **Confirm** to continue.

History

The History page lists all failed, killed, and restarted Drillbits. You can detect failures and diagnose problems using the information on this page. Use the YARN container ID listed on this page to locate the log files for the Drillbit.

Enabling Application Master Web UI Security
By default, the Application Master Web UI is not secure and open to everyone. You can configure user authentication or implement a simple, predefined user name and password to secure the UI. Modify the drill-on-yarn.conf configuration file to enable Drill-on-YARN security.

The following sections describe how to enable security for the Application Master web UI.

User Authentication

You must enable user authentication in Drill if you want Drill-on-YARN to use this feature for security purposes. When user authentication is enabled, the user name and password must match that of the user that started the Drill-on-YARN application.

To secure the Application Master web UI by way of user authentication, modify `drill-on-yarn.conf` to include the following section with the `auth-type` set to `drill`:

```
drill.yarn.http: {
   auth-type: "drill"
}
```

Simple Security

Define a username and password in `drill-on-yarn.conf` and then restart the Drill-on-YARN Application Master to implement simple security for the Application Master web UI.

last-updated: Jun 06, 2024

Modify the `drill-on-yarn.conf` configuration file to include the following section, replacing the user-name and password settings with yours, and then restar the Drill-on-YARN Application Master:

```
drill.yarn.http: {
   auth-type: "simple"
   user-name: "tsmith"
   password: "secret"
}
```

When you visit the web UI, a login page prompts you for the username and password that you configured. These are the only valid credentials.

Drill-on-YARN Limitations

Drill-on-YARN has the following limitations:

Hanging requests	Drill-on-YARN and YARN “hang” if YARN cannot fulfill a container request. YARN provides no information about why a request “hangs.”
/tmp directory	The default YARN settings cause Drillbits to become unmanaged within a short amount of time due to a /tmp directory issue. See the Exclude the YARN Container Directory from tmpwatch section in Step 3: Configure YARN to Run Drill for information on how to resolve the issue.
Container size	The default YARN settings do not allow a default Drill cluster to run due to the default YARN container size. See the Increase Maximum Container Size section in Step 3: Configure YARN to Run Drill for information on how to resolve the issue.
Drill disk usage	You can specify Drill disk usage to YARN, but Drill will use all disks regardless of the setting. There is no effective way to manage a Drill cluster that: • resizes based on load. • is rack-aware in its smaller state. YARN chooses arbitrary nodes perhaps resulting in large network reads. (MD-1028, MD-1089)
Node Labels	Although the Apache YARN documentation states that you can associate node labels with YARN container requests, some people have noticed that the feature does not work in practice. While Drill-on-YARN configuration has settings to associate Drillbit container requests with node labels, doing so is not supported. To use node labels, associate node labels with YARN queues as described in the YARN configuration step in the Migrate Drill to Run Under YARN documenation.

Configuring Drill-on-Yarn on a Secure Cluster

Describes how to enable SASL for Drill and SQLLine to run Drill-on-YARN in a secure cluster.

About this task

Update the `drill_home/conf/distrib-env.sh` file with the required options. If you use `--site`, then use your site directory.

last-updated: Jun 06, 2024

The following options are requried for Drill and SQLLine to work with SASL security:

```
-Ddrill.customAuthFactories=org.apache.drill.exec.rpc.security.maprsasl.MapR
SaslFactory
-Dzookeeper.sasl.client=true
-Djava.security.auth.login.config=/opt/mapr/conf/mapr.login.conf
-Dzookeeper.saslprovider=com.mapr.security.maprsasl.MaprSaslProvider
-Dhadoop.login=hybrid_keytab
```

The following sections describe how to update the `drill_home/conf/distrib-env.sh` file with the options to ensure that Drill and SQLLine work with SASL for security.

Drill

To make Drill work with SASL, set DRILL_JAVA_OPTS as shown:

```
export DRILL_JAVA_OPTS="$
{DRILL_JAVA_OPTS} -Ddrill.customAuthFa
ctories=org.apache.drill.exec.rpc.secu
rity.maprsasl.MapRSaslFactory -Dzookee
per.sasl.client=true -Djava.security.a
uth.login.config=/opt/mapr/conf/
mapr.login.conf -Dzookeeper.saslprovid
er=com.mapr.security.maprsasl.MaprSasl
Provider -Dhadoop.login=hybrid_keytab"
```

SQLLine

To make SQLLine work with SASL, set SQLLINE_JAVA_OPTS as shown:

```
export SQLLINE_JAVA_OPTS="$
{SQLLINE_JAVA_OPTS} -Ddrill.customAuth
Factories=org.apache.drill.exec.rpc.se
curity.maprsasl.MapRSaslFactory -Dzook
eeper.sasl.client=true -Djava.security
.auth.login.config=/opt/mapr/conf/
mapr.login.conf -Dzookeeper.saslprovid
er=com.mapr.security.maprsasl.MaprSasl
Provider"
```

last-updated: Jun 06, 2024

TIP: The following table describes each of the options:

Option	Description
drill.customAuthFactories	Required to make Drill and SQLLine work with SASL. It points to the authentication factories used for authentication. Provides a full classpath to the SASL implementation.
zookeeper.sasl.client	Required to make Drill and SQLLine work with Zookeeper in a SASL-enabled environment and ZooKeeper client authentication. It enables or disables SASL authentication in Drill and SQLLine for ZooKeeper connections.
zookeeper.saslprovider	Required to make Drill and SQLLine work with ZooKeeper in a SASL-enabled environement and ZooKeeper client authentication. It points to the authentication factories used for authentication in Drill and SQLLine for ZooKeeper connections. Provides a full classpath to the SASL implementation.
java.security.auth.login.config	Required to make Drill and SQLLine work with security. It points to a file with JAAS configurations. In the HPE environment it is `/opt/mapr/conf/mapr.login.conf`.
hadoop.login=hybrid_keytab	Required to make Drill work with SASL security. It points to the required JAAS configuration name.

Configuring Drill

Lists the data-fabric-specific configuration for Drill.

Drill is highly configurable. This document focuses on data-fabric-related configurations and refers to the open source Apache Drill documentation for generic information. Key things to configure are:

Drill memory
Determine the amount of heap and direct memory allocated to a Drillbit for query processing in a Drill cluster. See Configuring Drill Memory on page 3976.

Parquet block size
Change the Parquet block size to match the filesystem chunk size. See Configuring the Parquet Block Size on page 3978.

Resources for a shared Drillbit
Configure queues and parallelization for supporting multiple users sharing a Drillbit. Support separate Drillbits running on different nodes in the cluster. See Configuring Resources for a Shared Drillbit.

Multitenancy
Configure a multitenant cluster to account for resources required for Drill. See Configuring a Multitenant Cluster on page 3983.

User Impersonation
Configure impersonation to allow a service to act on behalf of a client while performing the action requested by the client. See User Impersonation on page 4021.

User authentication and encryption
Configure user authentication when you want the identity of a user, before permitting the user access to a process running on a system. See Default Security (Tickets) on page 4033 .

SSL/TLS for Encryption
Enable and configure SSL/TLS for encryption when you need to use Plain authentication. See SSL/TLS for Encryption on page 4053.

Drill impersonation with Hive authorization
Configure Drill impersonation to work with Hive impersonation to authorize access to metadata in the Hive metastore repository and data in the Hive warehouse. See User Impersonation with Hive on page 4027.

Volumes to use for spooling	Use the drill.exec.spill.directories option to set MapReduce volumes or local volumes for spooling to improve performance and stripe data across as many disks as possible.
Persistent configuration storage	See Persistent Configuration Storage and Configuring the ZooKeeper PStore Location on page 3984.
Access rights	Configure access rights if you have 777 file-level permissions to a table, and a query returns no results. See Configuring Access Rights.

Drill typically runs along side other workloads, including the following:

- MapReduce
- Yarn
- Hive and Pig
- Spark

You need to plan and configure these resources for use with Drill and other workloads:

- Memory
- CPU
- Disk

Configuring Access Rights

If the security in your organization limits access to HPE Ezmeral Data Fabric Database tables, you might experience a problem querying the tables. If you have 777 file-level permissions to a table, yet a query returns no results, you might need to add your user name to the maprcli *ACL*.

Adding a Drill Node to a Cluster

About this task

To add a new node to a cluster that provides the Drillbit service, add the node to the cluster first, and then install Drill on the new node. If you install Drill first, and then add the node to the cluster, the cluster cannot detect ZooKeeper information and the cluster is misnamed. These problems require some work to resolve. You need to edit the drill-override.conf file in the `mapr/drill` directory and modify the name of the cluster. Avoid this extra work, and install Drill only after adding the node to the cluster by performing steps in the following order:

Procedure

1. Follow instructions for adding a node to a cluster.
2. Reconfigure the cluster as described in the same instructions.
3. Verify that the new node is up and running.
4. Stop Warden, as shown:

```
$ service mapr-warden stop
```

last-updated: Jun 06, 2024

5. Stop ZooKeeper service, as shown:

```
$ service mapr-zookeeper stop
```

6. Configure the repository to add the ecosystem repository.
7. Install Drill on the new node.
8. Reconfigure the node.

```
$ /opt/mapr/server/configure.sh -R
```

9. Start ZooKeeper if the node is a ZooKeeper node.
10. Start warden to make configuration changes effective.

Results
Verify that the Drillbit service is running on the node. It might take a minute or so for the Drillbit to start after starting warden.

Configuring Drill Memory
A system administrator can modify the amount of system memory that Warden allocates to the Drill service on each node in the `warden.drill-bits.conf` file. Drill users, with file permissions, can modify the amount of heap and direct memory allocated to the Drill service on each node in the `drill-env.sh` file.

NOTE: The cumulative memory allocation in `drill-env.sh` cannot exceed the memory allocation in `warden.drill-bits.conf`.

After modifying `drill-env.sh`, restart Drill:

```
$ maprcli node services -name drill-bits -action restart -nodes
<space-separated-list-of-drill-hostnames>
```

After modifying `warden.drill-bits.conf`, run the configuration script, configure.sh, to update the node configuration and then restart Drill:

```
/opt/mapr/server/configure.sh -R
$ maprcli node services -name drill-bits -action restart -nodes
<space-separated-list-of-drill-hostnames>
```

The following sections describe the `warden.drill-bits.conf` and `drill-env.sh` files in detail.

Drill Memory Allocation in a Warden-Managed Cluster

If you install and run Drill under the Warden service, Warden manages the amount of system memory that Drill can use. By default, Warden allocates 20% of the system memory on a node to the Drill service. For example, if a node has 50GB of memory, Warden allocates 10GB (20% of 50GB) to the Drill service.

A system administrator can define the amount of memory that Warden allocates to Drill by changing the value of the `DRILLBIT_MAX_PROC_MEM` variable in `/opt/mapr/drill/drill-<version>/conf/warden.drill-bits.conf`.

When starting, Drill verifies that the amount of memory configured in `drill-env.sh` does not exceed the limit set by the `service.env=DRILLBIT_MAX_PROC_MEM` variable in `warden.drill-bits.conf`. If the settings in `drill-env.sh` exceed the setting in Warden, the system prints a message stating the issue; Warden does not start the Drill service on the node.

The `warden.drill-bits.conf` file contains the following settings:

last-updated: Jun 06, 2024

NOTE: Drill automatically configures the `service.heapsize` parameters. Do not modify them.

```
#Default Drill Mem Distrib: 20% of System memory
service.env=DRILLBIT_MAX_PROC_MEM=20%
//Specifies the maximum amount of memory that Warden will allocate to the
Drill service on the node. You can set this value as a percentage of system
memory or as an absolute value in GB. Memory configured in drill-env.sh
cannot exceed this memory setting.

service.heapsize.min=5120
//Minimum heap size. Do not change this value. The value is auto-populated
and represents the minimum memory that the Drillbit process will take.

service.heapsize.max=13312
//Maximum heap size. Do not change this value. The value is auto-populated
and represents the maximum memory that the Drillbit process will take.

#Warden will allocate 20% of memory for Drill
service.heapsize.percent=20
//Do not change this value. Total heap size available based on the value
set for the DRILLBIT_MAX_PROC_MEM variable. If the variable is defined in
absolute values, it is represented as a percent of the system memory.
```

Drill Memory Allocation in drill-env.sh

You can configure the amount of heap and direct memory allocated to Drill on each node in the`/opt/mapr/conf/conf.d/drill-env.sh` file. If you do not manually configure the heap and direct memory, Drill calculates these values based on the amount of system memory that Warden allocates to Drill and auto-populates the settings for the variables.

The cumulative amount of memory allocated to Drill in `drill-env.sh` cannot exceed the amount of memory that Warden allocates to Drill, which is set by the `DRILLBIT_MAX_PROC_MEM` variable in `warden.drill-bits.conf`.

NOTE: The values in `drill-env.sh`, such as 13G, are examples and do not indicate the default memory limits for Drill. By default, Warden allocates 20% of the system memory on a node to Drill.

The `drill-env.sh` file contains the following memory variables that you can uncomment and modify:

```
#export DRILLBIT_MAX_PROC_MEM=${DRILLBIT_MAX_PROC_MEM:-"13G"}
//Specifies the maximum amount of system memory that the Drill service
can use on a node. Must be equal to or less than the value set for
DRILLBIT_MAX_PROC_MEM in warden.drill-bits.conf. You can set this value as
a percentage of system memory or as an absolute value in GB. If you define
this variable, without defining the heap and direct memory variables, Drill
automatically calculates the heap and direct memory values.

#export DRILL_HEAP=${DRILL_HEAP:-"4G"}
//Maximum theoretical heap limit for the JVM per node.

#export DRILL_MAX_DIRECT_MEMORY=${DRILL_MAX_DIRECT_MEMORY:-"8G"}
//Java direct memory limit per node.

#export DRILLBIT_CODE_CACHE_SIZE=${DRILLBIT_CODE_CACHE_SIZE:-"1G"}
//The memory limit for the compiled code generated by the JVM JIT compiler.
Do not modify. The value for this parameter is auto-computed based on the
heap size and cannot exceed 1GB.
```

last-updated: Jun 06, 2024

NOTE: If performance is an issue, add -Dbounds=false, as shown:

```
export DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Dbounds=false"
```

Configuring the Parquet Block Size

The default value for the `store.parquet.block-size` parameter is 268435456 (256 MB), the same size as file system chunk sizes. In previous versions of Drill, the default value was 536870912 (512 MB).

If you change the file system chunk size, change the Parquet block size to match using the ALTER SYSTEM or SET commands, as shown:

```
ALTER SYSTEM SET `store.parquet.block-size` = <value>;
[ALTER SESSION] SET `store.parquet.block-size` = <value>
```

Alternatively, you can override the default setting in the `<DRILL_HOME>/conf/drill-override.conf` file, as shown:

```
drill.exec: {
  ...
  options.store.parquet.block-size = 268435456
}
```

For information about setting the file system chunk size, see Setting Chunk Size.

Configuring Multiple Drill Clusters and Designating One Cluster as an OJAI Distributed Query Service

As of Core 6.0 and Drill 1.11, you can run operational queries through the OJAI Distributed Query Service, as well as analytical queries through Drill. If you want to run operational and analytical workloads in your cluster, you must configure multiple Drill clusters within the cluster and then configure a Drill cluster as the OJAI Distributed Query Service. Restricting each workload to its own cluster improves query performance.

NOTE: Installing Drill and the OJAI Distributed Query Service together through the Installer is not currently supported. Only one of these services running in the cluster is supported unless you manually install and configure multiple Drill clusters, as instructed here.

Data Distribution

If you install both Drill and the OJAI Distributed Query Service through the Installer, both workloads get processed across the entire cluster. When both services run together in the cluster, the system replicates data across the entire cluster, causing remote reads and impairing performance, which can lead to missed SLAs and memory issues.

Memory Allocation

The amount of memory allocated to Drill and the OJAI Distributed Query Service differ. By default, when you install Drill, 13 GB of memory is allocated to the Drillbit service running on a node:

- 8 GB direct
- 4 GB heap
- 1 GB core cache

The OJAI Distributed Query Service less memory than Drill. By default, the OJAI Distributed Query Service is allocated ~ 5 GB of memory:

- 1 GB direct
- 3 GB heap

last-updated: Jun 06, 2024

- 512 MB core cache

If you use the Installer and select both Drill and the OJAI Distributed Query Service, memory is configured for Drill. If you only run operational queries, which do not use as much memory as analytical queries, you unnecessarily lose an additional 8 GB of memory.

How to Run Drill and the OJAI Distributed Query Service Together in a Cluster

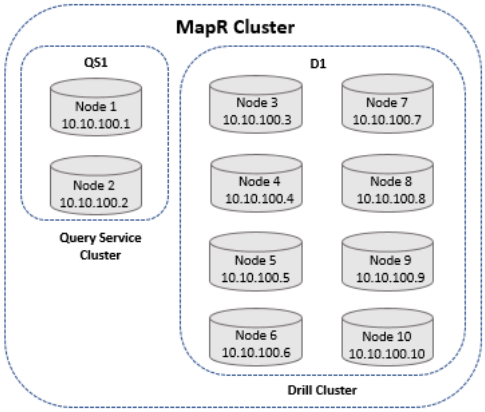
You can manually install Drill on several nodes and divide the nodes into multiple topologies (Drill clusters). For each of the topologies, create and mount a volume. Then, create directories within each volume to store your data. Configure these directories as workspaces in the Drill dsf storage plugin. Finally, configure a Drill cluster to run as an OJAI Distributed Query Service.

The following topics provide instructions for each of the required steps:

Step 1: Plan the Clusters
Decide which nodes in the cluster you want to run Drill and which nodes you want to run the OJAI Distributed Query Service.

The nodes you select to run Drill can form one or more Drill clusters, while the nodes you select to run the OJAI Distributed Query Service can form another Drill cluster. You can configure multiple Drill clusters.

For example, if you have a ten node cluster, you can configure one Drill cluster to run analytical queries and one OJAI Distributed Query Service cluster to run OJAI operational queries, as shown:



Track the nodes that you want to group into a cluster, as this information is needed to configure node topology and volumes. Also note the memory requirements of each service. Only non-overlapping Drill clusters are supported. You cannot install more than one Drillbit on a server node.

Step 2: Manually Install Drill on All Nodes
Manually install Drill on all nodes, including the nodes designated to run the OJAI Distributed Query Service.

For Drill installation instructions, see Installing Drill. You can install Drill to run under Warden or YARN, as described in the following following topics:

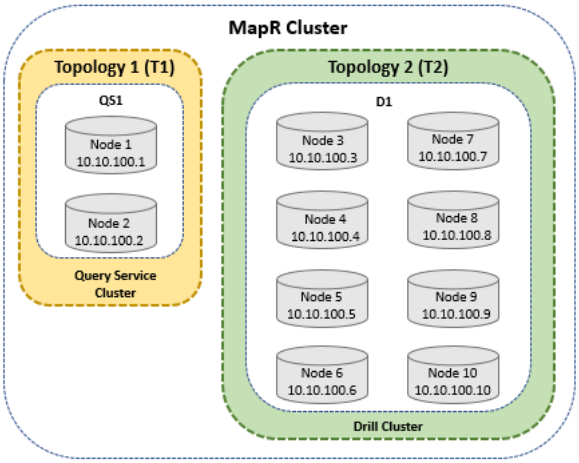
- Install Drill to Run Under Warden
- Install Drill to Run Under YARN

Step 3: Define Node Topologies
Node topologies restrict data to a designated set of nodes.

When you define a topology, data is only replicated on the nodes within the topology. Node topologies improve query performance because data is localized to the nodes specified in the topology instead of being distributed across the entire cluster.

You can create node topologies for the Drill clusters in the UI or from the CLI. See Changing Topology for One or More Nodes for instructions.

When you create a topology, you define the nodes that form a Drill cluster, as shown in the following image:



The image shows two node topologies, T1 and T2. T1 is the Drill cluster to be configured as the OJAI Distributed Query Service. T2 is the Drill cluster that will remain a Drill service cluster.

Step 4: Create Volumes
Volumes organize data and manage cluster performance. Create and mount a volume to each of the topologies (Drill clusters) you created.

For example, you can create a volume named "operational" and mount it to the T1 topology and then create a volume named "analytical" and mount it to the T2 topology.

See Administering Volumes for volume information and Creating a Volume on page 1177 for instructions.

Once you create the volumes, you have a place where you can create directories and store data. For example, you can create and store operational data in the `/operational/data/here` directory and analytical data in the `/analytical/data/here` directory.

Use these directories to configure the workspaces in the Drill dfs storage plugin configuration.

Step 5: Configure Multiple Drill Clusters
Update the /opt/mapr/drill/drill-<version>/conf/drill-override.conf file on each Drill node that is part of a cluster with the cluster ID and a ZooKeeper entry to define the Drill cluster. Each Drill cluster should have a unique cluster ID and ZooKeeper entry to separate the clusters.

NOTE: Each Drill node in a cluster must have the same configuration.

The Drillbit process reads the configuration file and communicates with ZooKeeper to see if the cluster it belongs to exists. If the cluster exists, ZooKeeper says to join the cluster. If the cluster does not exist, the Drillbit initiates a new Drill cluster based on the cluster ID.

The following table provides an example of unique cluster IDs and ZooKeeper entries based on the topologies in the image shown in step 3, Define Node Topologies:

Cluster	Nodes	Cluster ID	ZooKeeper Entry
QS1	10.10.100.1 10.10.100.2	cluster-id: "drillbits"	zk.root: "drill"

last-updated: Jun 06, 2024

D1	10.10.100.3 10.10.100.4 10.10.100.5 10.10.100.6 10.10.100.7 10.10.100.8 10.10.100.9 10.10.100.10	cluster-id: "drillbits2"	zk.root: "drill2"

For QS1, drill-override.conf must include the following configuration:

```
drill.exec: {
  zk.root: "drill",
  cluster-id: "drillbits",
  zk.connect: "<zk-node-ip-address>:5181",
}
```

For D1, drill-override.conf must include the following configuration:

```
drill.exec: {
  zk.root: "drill2",
  cluster-id: "drillbits2",
  zk.connect: "<zk-node-ip-address>:5181",
}
```

NOTE: If you installed Drill to run under YARN, follow the steps in Defining Multiple Drill Clusters Under YARN for each Drill node. Drill running under YARN requires some additional steps, such changing ZooKeeper ports.

Step 6: Configure Workspaces
You must configure a workspace on one Drill node in each Drill cluster that points to the volume directory where data is stored. When you create a workspace, you must include the volume mount point.

For example, if you created a volume with the mount point `/operational` for the OJAI Distributed Query Service cluster and stored your data in `/data/here/` within that volume, you would configure the workspace, as shown:

```
 {
    "type": "file",
    "enabled": true,
    "connection": "file:///",
    "workspaces": {
      "root": {
        "location": "/",
        "writable": false,
        "defaultInputFormat": null
      },
      "tmp": {
        "location": "/tmp",
        "writable": true,
        "defaultInputFormat": null
      },
      "operational": {
          "location": "/operational/data/here",
          "writable": true,
          "defaultInputFormat": null
```

```
          }
     }
```

Likewise, if you also created a volume with a mount point `/analytical` for the other Drill cluster that runs analytical queries and stored your data in `/data/here/` within that volume, you would configure the workspace, as shown:

```
{
     "type": "file",
     "enabled": true,
     "connection": "file:///",
     "workspaces": {
       "root": {
         "location": "/",
         "writable": false,
         "defaultInputFormat": null
       },
       "tmp": {
         "location": "/tmp",
         "writable": true,
         "defaultInputFormat": null
       },
       "analytical": {
         "location": "/analytical/data/here",
         "writable": true,
         "defaultInputFormat": null
        }
     }
```

You can define a workspace in the Drill dfs storage plugin configuration on the Storage page in the Drill Web UI at `https://<drill-node-ip-address>:8047`. You only need to configure the workspace on one Drill node in each Drill cluster.

See Plugin Configuration Basics and Workspaces for more information.

Step 7: Register a Drill Cluster as an OJAI Distributed Query Service
You can select any of the configured Drill clusters to act as the OJAI Distributed Query Service provider for operational queries, by running the `queryservice setconfig` command.

When you register the Drill cluster as the OJAI Distributed Query Service, adjust the memory setting on each node. The default Drill memory setting of 13 GB is unnecessarily high for the OJAI Distributed Query Service, which only requires ~ 5 GB. You must restart the Drillbits after you update the memory settings.

Registering a Drill Cluster as the OJAI Distributed Query Service

To register a Drill Cluster as an OJAI Distributed Query Service, run the following command:

```
maprcli cluster queryservice setconfig -enabled true -clusterid
<name_of_cluster> -storageplugin dfs -znode <zk_setting>
```

For example, drillbits2 and drill2 are the cluster ID and ZooKeeper settings used in examples in previous steps. For these configurations, the command is:

```
maprcli cluster queryservice setconfig -enabled true -clusterid
drillbits2 -storageplugin dfs -znode drill2
```

See queryservice setconfig for more information about the command.

Configuring Memory for the OJAI Distributed Query Service

Modify the memory settings on each node in the OJAI Distributed Query Service cluster and then restart Drill. See Configuring Drill Memory on page 3976 for instructions.

Configuring a Multitenant Cluster

Drill operations are memory and CPU-intensive. Currently, Drill resources are managed outside of any cluster management service, such as the Warden service. In a multi-tenant or any other type of cluster, YARN-enabled or not, you configure memory and memory usage limits for Drill by modifying `drill-env.sh` as described in the section, "Configuring Drill Memory" in Apache Drill documentation.

Configure a multitenant cluster to account for resources required for Drill. For example, on a cluster, ensure warden accounts for resources required for Drill. Configuring `drill-env.sh` allocates resources for Drill to use during query execution, while configuring the following properties in `warden-drill-bits.conf` prevents warden from committing the resources to other processes.

```
service.heapsize.min=<some value in MB>
service.heapsize.max=<some value in MB>
service.heapsize.percent=<a whole number>
```

Set the `service.heapsize` properties in `warden.drill-bits.conf` regardless of whether you changed defaults in `drill-env.sh` or not.

"Configuring Drill in a YARN-enabled MapR Cluster" shows an example of setting the `service.heapsize` properties. The `service.heapsize.percent` is the percentage of memory for the service bounded by minimum and maximum values. Typically, users change `service.heapsize.percent` because using a percentage setting increases or decreases resources according to different node configurations. For more information about the `service.heapsize` properties, see the section, "warden.<servicename>.conf."

You need to statically partition the cluster to designate which partition handles which workload. To configure resources for Drill in a cluster, modify one or more of the files created by the installation process in `/opt/mapr/conf/conf.d`:

```
warden.drill-bits.conf
warden.nodemanager.conf
warden.resourcemanager.conf
```

Configure Drill memory by modifying `warden.drill-bits.conf` in YARN and non-YARN clusters. Configure other resources by modifying `warden.nodemanager.conf` and `warden.resourcemanager.conf` in a YARN-enabled cluster.

Configuring Drill in a YARN-enabled Cluster

To add Drill to a YARN-enabled cluster, change memory resources to suit your application. For example, you have 120G of available memory that you allocate to following workloads in a Yarn-enabled cluster:

File system = 20G Yarn = 20G OS = 8G

If Yarn does most of the work, give Drill 20G, for example, and give Yarn 60G. If you expect a heavy query load, give Drill 60G and Yarn 20G.

YARN consists of two main services:

- ResourceManager: There is at least one instance in a cluster, more if you configure high availability.
- NodeManager: There is one instance per node.

The `warden.resourcemanager.conf` and `warden.nodemanager.conf` files set ResourceManager and NodeManager memory to the following defaults:

```
service.heapsize.min=64
service.heapsize.max=325
service.heapsize.percent=2
```

Change these settings for NodeManager and ResourceManager to reconfigure the total memory required for YARN services to run. If you want to place an upper limit on memory, set the YARN_NODEMANAGER_HEAPSIZE or YARN_RESOURCEMANAGER_HEAPSIZE environment variable in

```
 /opt/mapr/hadoop/hadoop-2.5.1/etc/hadoop/yarn-env.sh
```

You do not set the `-Xmx` option, allowing memory to grow as needed.

MapReduce Version 2 and other Resources

You configure memory for each service by setting three values in `warden.conf`.

```
service.command.<servicename>.heapsize.percent
service.command.<servicename>.heapsize.max
service.command.<servicename>.heapsize.min
```

Configure memory for other services in the same manner. For more information about managing memory in a cluster, see the following sections:

- Memory Allocation for Nodes
- Cluster Resource Allocation

How to Manage Drill CPU Resources

Currently, you do not manage CPU resources within Drill. Use Linux cgroups to manage the CPU resources.

Configuring the ZooKeeper PStore Location
By default, the ZooKeeper PStore offloads query profile data to `maprfs:///apps/drill/profiles`. You can override the default location in the `drill-override.conf` file.

When query profile data is stored on a distributed system, like the data-fabric filesystem, you can see a global query list (view of query profiles coordinated by all Drill nodes in one Web UI).

To change the ZooKeeper PStore location, update the `drill.exec` block in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf with the following` configuration, as shown:

```
drill.exec: {
    cluster-id: "my_cluster_com-drillbits",
    zk.connect: "<zkhostname>:5181",
    sys.store.provider.zk.blobroot: "maprfs:///new/storage/location/"
   }
```

NOTE: By default, the filesystem replicates the data three times. If you are concerned about storage consumption, you can create a new volume specifically for query profile data, and set the replication value to 1 for that volume. After you create the volume, update `sys.store.provider.zk.blobroot` to point to the volume. See Creating a Volume on page 1177 for additional information.

last-updated: Jun 06, 2024

After you modify `drill-override.conf`, restart Drill:

```
maprcli node services -name drill-bits -action restart -nodes
<drill-hostnames-separated-by-a-space>
```

Configuring HBase Persistent Storage Tables
Describes how to configure Drill to persist query profile data to a table that is unaffected by the TTL duration.

You can configure HBase persistent storage tables that do not have a TTL in the following versions of Drill:

- Drill 1.16.0.500 (EEP-8.1.1)
- Drill 1.20.2 (EEP 9.0.0 on Core 7.1.0) and later

By default, the Drill HBase persistent store persists the following information in one HBase table:

- Query profile data
- State information for storage plugins
- State information for ALTER SYSTEM settings

Data persists in the HBase table for the duration of the configured TTL, after which the data is automatically removed to free up space.

You can configure the system to persist query profiles to another table that does or does not have a TTL configured. Query profiles persist in the table until the query profiles are deleted or the TTL expires.

The following section describes how to configure HBase persistent storage.

Persistent Storage Configurations

Configure HBase persistent storage through the `sys.store.provider.hbase.table` option in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` or `/opt/mapr/drill/drill-<version>/conf/drill-distrib.conf` file.

The following sections provide HBase persistent storage configuration options.

IMPORTANT: For insecure Data Fabric clusters (maprsasl disabled), exclude the `hbase.security.authentication` property from the configuration.

Default Persistent Storage Configuration

The following example configuration shows the default persistent storage configuration:

```
drill.exec.sys.store.provider: {
    class:
"org.apache.drill.exec.store.hbase.con
fig.HBasePStoreProvider",
    hbase: {
      table: "drill_store",
      config: {
      "hbase.zookeeper.quorum":
"node1.com,node2.com,node3.com",

"hbase.zookeeper.property.clientPort":
 "5181",

"hbase.security.authentication":
"maprsasl"
      }
```

last-updated: Jun 06, 2024

```
    }
}
```

With this configuration, the HBase table `drill_store` stores query profile data and state information for storage plugins and ALTER SYSTEM settings until they expire based on the set TTL.

Query Profile Persistent Storage Configuration

If you want to store query profile data in a separate table, add the `drill.exec.sys.store.provider.hbase.blob.table` property to the persistent storage configuration, as shown in the following example:

```
drill.exec.sys.store.provider: {
    class:
"org.apache.drill.exec.store.hbase.con
fig.HBasePStoreProvider",
    hbase: {
      blob.table: "drill_blob_store",
      table: "drill_store",
      config: {
      "hbase.zookeeper.quorum":
"node1.com,node2.com,node3.com",

"hbase.zookeeper.property.clientPort":
 "5181",

"hbase.security.authentication":
"maprsasl"
      }
    }
}
```

With this configuration, the Hbase table `drill_blob_store` stores query profiles only. The HBase table `drill_store` stores storage plugins and ALTER SYSTEM settings.

IMPORTANT: Drill cannot access query profile data stored in `hbase.table` (`drill_store`) after you configure `blob.table` (`drill_blob_store`).

Configuring cgroups to Control CPU Usage

Starting in Drill 1.13, you can configure a Linux cgroup (control group) to enforce CPU limits on the Drillbit service running on a node. Linux cgroups enable you to limit system resources to defined user groups or processes. You can use the cgconfig service to configure a Drill cgroup to control CPU usage and then set the CPU limits for the Drill cgroup on each Drill node in the `/etc/cgconfig.conf` file.

NOTE: Cgroups V2 is recommended.

Before You Begin

Each Drill node must have the `libcgroup` package installed to configure CPU limits for a Drill cgroup. The `libcgroup` package installs the cgconfig service required to configure and manage the Drill cgroup.

Install the `libcgroup` package using the `yum install` command, as shown:

```
yum install libcgroup
```

last-updated: Jun 06, 2024

Enable Drill to Directly Manage CPU Resources

Starting in Drill 1.14, Drill can directly manage CPU resources through the start-up script, `drill-env.sh`, which means that you no longer have to manually add the PID (Drill process ID) to the `cgroup.procs` file each time a Drillbit restarts. This step occurs automatically upon restart. The start-up script checks for the specified cgroup, such as drillcpu, and then applies the cgroup to the launched Drillbit JVM. The Drillbit CPU resource usage is then managed under the cgroup, drillcpu.

For Drill to directly manage CPU resources, you must enable (uncomment) the following variables in the `drill-env.sh` script:

Variable	Description
export DRILLBIT_CGROUP=${DRILLBIT_CGROUP:-"drillcpu"}	Sets the cgroup to which the Drillbit belongs when running as a daemon using drillbit.sh start. Drill uses the cgroup for CPU enforcement only.
export SYS_CGROUP_DIR=${SYS_CGROUP_DIR:-"/sys/fs/cgroup"}	Drill assumes the default cgroup mount location set by systemd (the system and service manager for Linux operating systems). If your cgroup mount location is in a different location, change the setting to match your location.
export DRILL_PID_DIR=${DRILL_PID_DIR:-$DRILL_HOME}	The location of the Drillbit PID file when Drill is running as a daemon using drillbit.sh start. By default, this location is set to $DRILL_HOME.

IMPORTANT: If you have Drill 1.13 running on the node, or you have Drill 1.14 running on the node and you do not want to enable Drill to directly manage the CPU resources through `drill-env.sh`, you must manually update the `/cgroup/cpu/drillcpu/cgroup.procs` file with the PID (Drill process ID), as shown, each time a Drillbit restarts to enforce the CPU limit for the Drillbit service:

```
echo 25809 > /cgroup/cpu/drillcpu/cgroup.procs
```

Set the CPU Limit for the Drillbit Service

You can set the CPU limit as a soft or hard limit, or both. You set the limits with parameters in the `/etc/cgconfig.conf` file. The hard limit takes precedence over the soft limit. When Drill hits the hard limit, in-progress queries may not complete. Review the following sections that describe the soft and hard limit parameters and then configure CPU limits.

Soft Limit Parameter

You set the soft limit with the `cpu.shares` parameter. This parameter takes an integer value, which specifies a relative share of CPU time available to the tasks in a cgroup. For example, if there are two tasks and `cpu.shares` is set to 100, each task receives half of the CPU time. The value must be 2 or greater. When you set a soft limit, Drill can exceed the CPU allocated if extra CPU is available for use on the system. Drill can continue to use CPU until there is contention with other processes over the CPU or Drill hits the hard limit.

Hard Limit Parameters

You set the hard limit on the amount of CPU time that the Drill process can use through the `cpu.cfs_period_us` and `cpu.cfs_quota_us` parameters.

last-updated: Jun 06, 2024

- `cpu.cfs_period_us`

  Specifies a period in microseconds (represented by `us` for µs) to indicate how often a cgroup's access to CPU resources should be reallocated. For example, if you want tasks in a cgroup to have access to a single CPU for 0.2 seconds in a 1 second window, set `cpu.cfs_quota_us` to 200000 and `cpu.cfs_period_us` to 1000000. The upper limit of the `cpu.cfs_quota_us` parameter is 1 second and the lower limit is 1000 microseconds.

- `cpu.cfs_quota_us`

  Specifies the total amount of runtime in microseconds (represented by `us` for µs), for which all tasks in the Drill cgroup can run during one period (as defined by `cpu.cfs_period_us`). When tasks in the Drill cgroup use up all the time specified by the quota, the tasks are throttled for the remainder of the time specified by the period and they cannot run until the next period. For example, if tasks in the Drill cgroup can access a single CPU for 0.2 seconds out of every 1 second, set `cpu.cfs_quota_us` to 200000 and `cpu.cfs_period_us` to 1000000. Setting the `cpu.cfs_quota_us` value to -1 indicates that the group does not have any restrictions on CPU. This is the default value for every cgroup, except for the root cgroup.

Configuring CPU Limits

Complete the following steps to set a hard and/or soft CPU limit for the Drill process running on the node:

1. Start the cgconfig service:

```
service cgconfig start
```

2. Add a cgroup for Drill in the `/etc/cgconfig.conf` file:

```
group drillcpu {
                    cpu {
                           cpu.shares = 320;
                           cpu.cfs_quota_us = 400000;
                           cpu.cfs_period_us = 100000;
                           }
                    }
```

   In the configuration example above, the `cpu.shares` parameter sets the soft limit. The other two parameters, `cpu.cfs_quota_us` and `cpu.cfs_period_us`, set the hard limit. If you prefer to set only one type of limit, remove the parameters that do not apply. When setting a soft limit, allocate a specific number of CPU shares to the Drill cgroup in the configuration. Calculate the CPU shares as:

```
1024 (CPU allocated to Drill/Total available CPU)
```

   In the example, CPU shares is calculated as:

```
1024 (10/32) = 320
```

   When setting a hard limit, add limits to the `cpu.cfs_quota_us` and `cpu.cfs_period_us` parameters. In the example, the Drill process can fully utilize 4 CPU.

   TIP:

   The hard limit parameter settings persist after each cgroup service restart. Alternatively, you can set the parameters at the session level using the following commands:

```
echo 400000 > /cgroup/cpu/drillcpu/cpu.cfs_quota_us
       echo 100000 > /cgroup/cpu/drillcpu/cpu.cfs_period_us
```

3. (Optional) If you want the cgconfig service to automatically restart upon system reboots, run the following command:

```
chkconfig cgconfig on
```

Working with Drill

For general information about working with Drill, refer to the following key topics:

Connecting Drill to Data Sources
Choose and configure storage plugins to enable Drill to connect to a data source.

Drill serves as a query layer that connects to data sources through storage plugins. A storage plugin is a software module for connecting Drill to data sources. A storage plugin typically optimizes execution of Drill queries, provides the location of the data, and configures the workspace and file formats for reading data.

What you can do with Storage Plugins

Several storage plugins are installed with Drill that you can configure to suit your environment. Through a storage plugin, Drill connects to a data source, such as a database, a file on a local or distributed filesystem, or a Hive metastore. See the Drill Storage and Format Plugin Support Matrix.

last-updated: Jun 06, 2024

You can modify the default configuration of a storage plugin and give the new configuration a unique name. This document refers to Y as a different storage plugin, although it is actually just a reconfiguration of original interface.

On the Storage tab of the Web Console, you can view and reconfigure a storage plugin if you have permission. You can access each node running a Drillbit by starting the Drill Web Console. The way you start the Drill Web Console depends on your security setup.

When you install Drill using the `mapr-drill` package, storage plugin configurations are available for the following data sources:

- file system
- HPE Ezmeral Data Fabric Database

  NOTE: To access HPE Ezmeral Data Fabric Database tables, use the dfs storage plugin with the maprdb format plugin.
- Hive
- Kafka

Connecting Drill to HBase

As of the Core 6.0 and Drill 1.11, HBase is no longer supported, therefore the communication path between Drill and HBase is also not supported. If you have an hbase storage plugin configured in Drill, you should disable it.

Default Storage Plugin Configurations

The Drill documentation describes the attributes and definitions that you can configure for storage plugins, except for the HPE Ezmeral Data Fabric Database format. See HPE Ezmeral Data Fabric Database Format Plugin for Drill.

The Drill Web Console includes some default storage plugin configurations. The following table lists the default configurations and their descriptions:

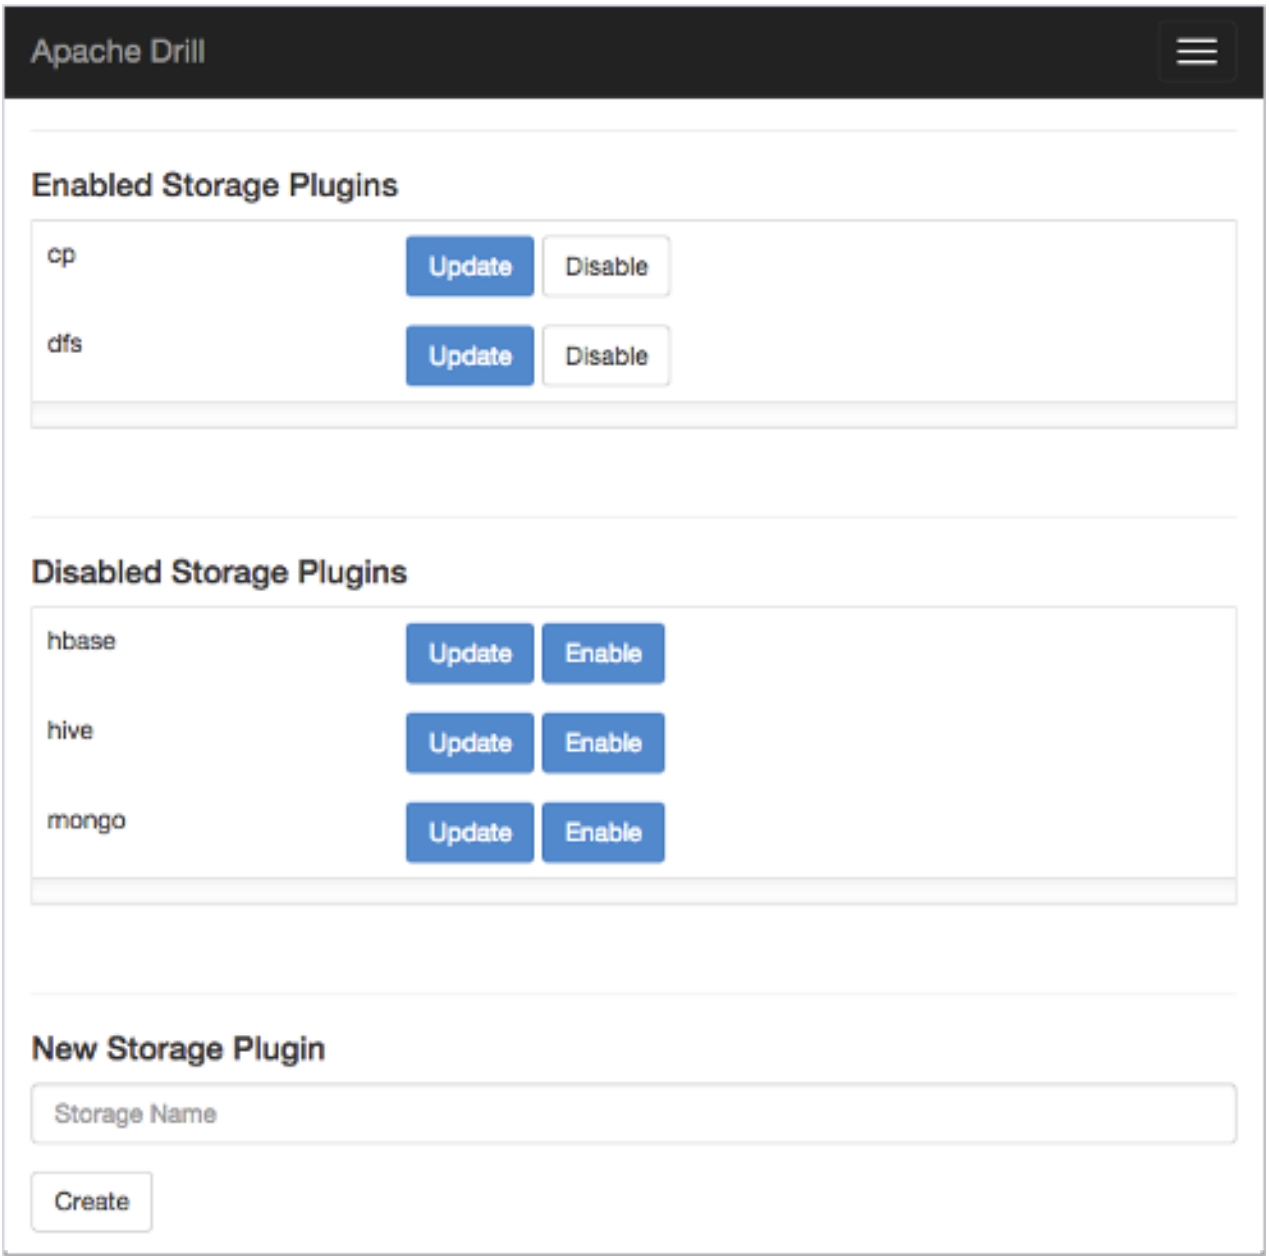
Instance	Description
cp	Points to a JAR file in the Drill classpath that contains the Transaction Processing Performance Council (TPC) benchmark schema TPC-H that you can query.
dfs	Points to file system by default. Drill automatically configures this instance when you install Drill in a the cluster. Includes a maprdb format plugin for HPE Ezmeral Data Fabric Database.
hive	Integrates Drill with the Hive metadata abstraction of files, HPE Ezmeral Data Fabric Database, and libraries to read data and operate on SerDes and UDFs.

When you add or update a storage plugin configuration on one Drill node in a Drill cluster, Drill broadcasts the information to all of the other Drill nodes. All nodes have identical storage plugin configurations. You do not need to restart any Drillbits when you add or update a storage plugin configuration.h

Configuring Storage Plugin Instances

You can add, remove, or update Drill storage plugin configurations using the Web Console. The following image shows the default storage plugin configurations in the Drill Web UI:

last-updated: Jun 06, 2024



If you click **Update** next to `dfs`, the following default configuration appears :

```
{
  "type": "file",
  "enabled": true,
  "connection": "maprfs:///",
  "workspaces": {
    "root": {
      "location": "/",
      "writable": false,
      "defaultInputFormat": null
    },
    "tmp": {
      "location": "/tmp",
      "writable": true,
      "defaultInputFormat": null
    }
  },
```

last-updated: Jun 06, 2024

```
  "formats": {
    "psv": {
      "type": "text",
      "extensions": [
        "tbl"
      ],
      "delimiter": "|"
    },
    "csv": {
      "type": "text",
      "extensions": [
        "csv"
      ],
      "delimiter": ","
    },
    "tsv": {
      "type": "text",
      "extensions": [
        "tsv"
      ],
      "delimiter": "\t"
    },
    "parquet": {
      "type": "parquet"
    },
    "json": {
      "type": "json"
    },
    "maprdb": {
      "type": "maprdb"
    }
  }
}
```

The `dfs` configuration includes the storage plugin type, connection information, default workspaces, and file formats that the data source supports. You can add and remove workspaces and file formats.

Changing the Connection Attribute

You can also change the connection if you want the configuration to point to a different cluster.

By default, Drill connects to the cluster that the Drill node belongs to. You do not need to modify the connection unless you want to connect Drill to a different cluster. To connect to a different cluster, edit the connection to include the name of the cluster that you want to connect to.

Example:

```
"connection": "maprfs://<cluster_name>/"
```

Drill Storage and Format Plugin Support Matrix

You can deploy Drill without Hadoop in a standalone configuration on a single node, however multi-node standalone cluster deployments of Drill are not supported. Note that Drill itself does not require Hadoop.

The following table lists the supported and unsupported data sources and formats in Drill:

Data Source	Storage Plugin Type	Formats	Supported
file system	dfs	Text (CSV, TSV, PSV)	Yes
		Parquet	Yes
		JSON	Yes

		Avro	No
HPE Ezmeral Data Fabric Database	dfs	Binary	Yes
		JSON	Yes
HBase	hbase	Binary	Yes
Hive	hive	Text (CSV, TSV, PSV)	Yes
		Parquet	Yes
		JSON	Yes
		Avro	Yes
		Other Hive built-in SerDes	Yes (Not recommended due to the memory overhead and performance implications.)
S3	s3	Supports the same formats as the dfs storage plugin.	Yes
MongoDB	mongodb	N/A	No
RDBMS	jdbc	N/A	No
Kudu	kudu	N/A	No
Kafka	kafka	JSON	Yes
OpenTSDB	openTSDB	N/A	**NOTE:** The openTSDB storage plugin is not officially supported. See OpenTSDB Storage Plugin for more information.

maprdb Format Plugin for Drill

Drill supports access to HPE Ezmeral Data Fabric Database JSON and binary tables through the maprdb format plugin.

When you install Drill, the maprdb format is automatically defined within the default dfs storage plugin configuration to make HPE Ezmeral Data Fabric Database a consumable data source for Drill. You can access the dfs storage plugin configuration from the Storage page in the Drill Web UI.

When you install Drill, you will see some options specific to the maprdb format plugin that you can change or configure. You can modify these options in the following places:

- dfs storage plugin configuration
- drill-override.conf file
- SET command

For additional information about storage plugins, see Plugin Configuration Basics.

Modifying the maprdb Format Settings within the dfs Storage Plugin Configuration

You can add or modify certain maprdb format plugin settings within the dfs storage plugin configuration on the Storage page in the Drill Web UI.

The following table lists the maprdb format options that you can set within the dfs storage plugin configuration:

last-updated: Jun 06, 2024

Option	Description	Value
allTextMode	When enabled, Drill reads all values as type varchar. Useful when the underlying data set has type values of mixed scalar types, such as integers, floating point, varchars, date, time, and timestamp. Disabled by default.	true|false
disableCountOptimization	When enabled, this option disables optimization for queries with the COUNT (*) aggregate function. Disabled by default.	true|false
enablePushdown	When enabled, Drill pushes down filters to HPE Ezmeral Data Fabric Database. Disabling this option is not recommended unless you intend to use it for troubleshooting purposes. Enabled by default.	true|false
ignoreSchemaChange	When enabled, Drill ignores schema changes. Disabled by default.	true|false
nonExistentColumnsProjection	When enabled, Drill can distinguish between null and non-existent fields. Disabled by default.	true|false
readNumbersAsDouble	When enabled, Drill reads all numeric values as type double. Useful when the underlying data set has type values of mixed numeric types, such as integers and floating point. Disabled by default.	true|false
readTimestampWithZoneOffset	When enabled (set to 'true'), Drill converts timestamp values from UTC to local time zone when reading the values from MapR Database. Disabled (set to 'false') by default. Does not impact the `store.hive.maprdb_json.read_timestamp_with_timezone_offset` setting.	true|false

The following example configuration shows you how to include the options in the maprdb format configuration within the dfs storage plugin configuration:

```
{
  "type": "file",
  "enabled": true,
  "connection": "maprfs:///",
  "config": null,
  "workspaces": {
    "root": {
      "location": "/",
      "writable": false,
      "defaultInputFormat": "maprdb",
      "allowAccessOutsideWorkspace": false
    },
  "formats": {
    "maprdb": {
      "type": "maprdb",
      "allTextMode": true,
      "disableCountOptimization": true,
```

```
      "enablePushdown": false
    },
    "parquet": {
      "type": "parquet"
    },
    "json": {
      "type": "json",
      "extensions": [
        "json"
      ]
    }
  }
}
```

See Plugin Configuration Basics and File System Storage Plugin for more information.

Overriding Default maprdb Format Plugin Settings in drill-override.conf

You can override the default maprdb format plugin settings that control the level of parallelism in Drill and the media type in the `drill-override.conf` file.

To override the default maprdb format plugin settings, add the options to the `format-maprdb.json` configuration in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file, as shown:

```
format-maprdb: {
                json: {
                    scanSizeMB: 512,
                    restrictedScanSizeMB: 4096
                    mediaType: HDD
                    }
                  }
```

The following sections describe how to modify the options in the configuration shown above:

Configuring the Level of Parallelism in Drill

The size of data chunks and number of minor fragments affect the level of parallelism in Drill. When querying JSON tables, Drill creates minor fragments that scan the chunks of data that HPE Ezmeral Data Fabric Database passes to Drill. Minor fragments are logical units of work that determine the level of parallelism in Drill. The level of parallelism increases with the number of minor fragments. See Drill Query Execution for more information about how Drill executes a query.

Modifying the Size of Data Chunks

The `format-maprdb.json.scanSizeMB` option changes the size of data chunks that HPE Ezmeral Data Fabric Database passes to Drill when querying JSON tables. Drill creates approximately one minor fragment per data chunk when querying JSON tables. For example, if a table has 4 GB of data and the chunk size is set to 128 MB, Drill creates approximately 32 minor fragments to scan the data chunks.

The default setting for data chunks is 128 MB, however you can override this default in the drill-override.conf file. The value of the `format-maprdb.json.scanSizeMB` option can range from 32 MB to 8192 MB (8 GB). Adjust the setting based on the size of your tables. Use a higher setting for larger tables and a lower setting for smaller tables. The right setting can reduce latency and increase throughput.

Modifying the Number of Minor Fragments Created

The `format-maprdb.json.restrictedScanSizeMB` option determines the number of minor fragments that Drill creates to scan the data and do the join-back to a JSON table when executing a non-covering index plan.

The default setting for this option is 4096 MB, however you can override this setting in the drill-override.conf file. The value of this option can range from 32 MB to 8192 MB (8 GB). Adjust the setting based on the

size of your tables, keeping in mind that due to the random I/O nature of the join-back, a smaller setting (increased parallelism) may not necessarily increase throughput.

NOTE: The `planner.slice_target` option in Drill determines the number of minor fragments that can run in parallel. See Modifying Query Planning Options for more information.

Configuring the Media Type

Drill is optimized for SSDs, however HPE Ezmeral Data Fabric Database and Drill can run on HDDs. If you run Drill and HPE Ezmeral Data Fabric Database on HDDs, use the mediaType option in the `drill-override.conf` file to override the default setting. The `mediaType` option accepts HDD or SSD (default) as the value. Specify SSD or HDD in upper case as the value in the `drill-override.conf` file.

Drill Options for the maprdb Format Plugin

You can enable certain Drill options for the maprdb format plugin from the Options page in the Drill Web UI or from the command line using the SET and ALTER SYSTEM commands.

To enable the options from the Drill Web UI, go to `http(s)://<drill-hostname-or-ip-address>:8047`, and select **Options** in the menu bar. Alternatively, enable options from the command line using the SET or ALTER SYSTEM commands, as shown:

```
SET `store.hive.maprdb_json.optimize_scan_with_native_reader` = true;
```

You can enable the following Drill options for the maprdb format plugin:

`store.hive.maprdb_json.optimize_scan_with_native_reader`	Starting in Drill 1.14 (EEP 6.0), enable the `store.hive.maprdb_json.optimize_scan_with_native_reader` option if you want Drill to use the native Drill reader to read Hive MapR-DB JSON tables. When you enable the native Drill reader, Drill typically performs faster reads of data and applies filter pushdown optimizations.
`store.hive.maprdb_json.read_timestamp_with_timezone_offset`	Starting in Drill 1.16, you can enable Drill to read timestamp values with a timezone offset when the hive plugin is used and the Drill native MaprDB JSON reader is enabled through the `store.hive.maprdb_json.optimize_scan_with_native_reader` option.

last-updated: Jun 06, 2024

IMPORTANT: Internally, Drill stores timestamp values in UTC format, for example 2018-01-01T20:12:12.123Z. When you enable the timezone offset option, select on a table returns different timestamp values. If you filter on timestamp values when this option is enabled, you must include the new timestamp value in the filter condition. For example, look at the timestamp values when the store.hive.maprdb_json.read_timestamp_with_timezone_offset option is disabled (set to 'false'):

```
select * from dfs.`/tmp/timestamp`;
----------------------------------------------------------
_id        datestring              datetimestamp
----------------------------------------------------------
1    2018-01-01 12:12:12.123    2018-01-01 20:12:12.123
2    9999-12-31 23:59:59.999    10000-01-01 07:59:59.999
----------------------------------------------------------
```

When the option is enabled (set to 'true'), you can see the difference in the timestamp values returned:

```
select * from dfs.`/tmp/timestamp`;
----------------------------------------------------------
_id     datestring            datetimestamp
----------------------------------------------------------
1    2018-01-01 12:12:12.123    2018-01-01 12:12:12.123
2    9999-12-31 23:59:59.999    9999-12-31 23:59:59.999
----------------------------------------------------------
```

When the option is enabled, queries that filter on timestamp values must include the new timestamp value in the filter condition, as shown:

```
select * from dfs.`/tmp/timestamp` where datetimestamp=timestamp
'2018-01-01 12:12:12.123';
----------------------------------------------------------
_id    datestring             datetimestamp
----------------------------------------------------------
1    2018-01-01 12:12:12.123   2018-01-01 12:12:12.123
----------------------------------------------------------
```

Notice that the WHERE clause uses the `2018-01-01 12:12:12.123` format versus the `2018-01-01 20:12:12.123` format.

HPE Ezmeral Data Fabric Database Tables

The `maprdb` format plugin enables you to query binary and JSON tables like you would query files in a file system because HPE Ezmeral Data Fabric Database and the file system share the same namespace.

Binary tables differ from JSON tables in that they store a multi-dimensional map in which both keys and values are a sequence of bytes. JSON tables store OJAI documents. JSON tables support rich data types, including complex and repeated types, that enable database servers to evaluate filter conditions for optimized query execution. Binary tables can pose performance limitations because the table columns do not contain the necessary type information.

You can query tables stored in any directory in HPE Ezmeral Data Fabric Database using the same syntax that you use to select from files in the file system. Instead of including the path of a file in a query, you include the table path. The user running the query must have read permission to access the table.

last-updated: Jun 06, 2024

NOTE: HPE Ezmeral Data Fabric Database is a case sensitive data source. To ensure that your queries return results, use the case that corresponds to the column names in the JSON tables and views that you query. For example, if you query the “age” column in a JSON table, the query must reference the column as “age” and cannot reference the column as “AGE” or the query will not return results. If you have a dataset where a column name has mixed cases, such as “age” and “AGE,” cleanse the data set so column names consist of one case and then reimport the data into the table to ensure a complete result set when you query the column.

The following sections describe the types of tables that HPE Ezmeral Data Fabric Database supports, provide examples of Drill queries on each type of table, and show you how to load data into a JSON table from JSON files.

JSON Tables

A JSON table is a collection of JSON documents stored in an optimized format in HPE Ezmeral Data Fabric Database. JSON tables support complex schema, like JSON files including nested and repeated types, but with additional support for more data types.

JSON tables leverage the OJAI API to natively support Drill data types making it possible for HPE Ezmeral Data Fabric Database to recognize, store, and interpret each of the Drill data types. This alleviates the need to encode data when an application writes to tables or use conversion functions when running queries against tables. For example, if a number or date is stored in a JSON table, you do not need to use the CAST or CONVERT functions for the query to return the actual values.

HPE Ezmeral Data Fabric Database's native support for Drill data types enables Drill to push down filters and projections to HPE Ezmeral Data Fabric Database which optimizes performance.

Querying a JSON Table

Querying JSON tables is simpler than querying binary tables because you do not have to include conversion functions in the queries to change the byte sequences into specific data types, and you do not have to include column families.

The following query examples show query results on a JSON table named “students” in HPE Ezmeral Data Fabric Database. Note that Drill returns human readable values without having to include the CAST or CONVERT functions in the queries.

Example 1

```
SELECT * FROM dfs.`/user/root/json/students`;
```

```
+-----------+-------------+--------+--------+-------------------+----------+
|    _id    |    date     |  name  | state  |      street       | zipcode  |
+-----------+-------------+--------+--------+-------------------+----------+
| student1  | 2016-01-15  | Alice  | CA     | 123 Ballmer Av    | 12345    |
| student2  | 2016-03-08  | Bob    | CA     | 1 Infinite Loop   | 12345    |
| student3  | 2015-12-22  | Frank  | CA     | 435 Walker Ct     | 12345    |
| student4  | 2015-09-15  | Mary   | CA     | 56 Southern Pkwy  | 12345    |
+-----------+-------------+--------+--------+-------------------+----------+
4 rows selected (0.233 seconds)
```

Example 2

```
SELECT _id, `date`, name, state, street, zipcode FROM dfs.`/user/root/json/
students`;
```

```
+-----------+-------------+--------+--------+-------------------+----------+
|    _id    |    date     |  name  | state  |      street       | zipcode  |
+-----------+-------------+--------+--------+-------------------+----------+
| student1  | 2016-01-15  | Alice  | CA     | 123 Ballmer Av    | 12345.0  |
| student2  | 2016-03-08  | Bob    | CA     | 1 Infinite Loop   | 12345.0  |
| student3  | 2015-12-22  | Frank  | CA     | 435 Walker Ct     | 12345.0  |
| student4  | 2015-09-15  | Mary   | CA     | 56 Southern Pkwy  | 12345.0  |
```

last-updated: Jun 06, 2024

```
+----------+-------------+--------+--------+------------------+----------+
4 rows selected (1.033 seconds)
```

Loading JSON Documents into a HPE Ezmeral Data Fabric Database Table with dbshell Commands

You can use the INSERT command in the `mapr dbshell` to load JSON documents into a HPE Ezmeral Data Fabric Database table.

The INSERT command is useful when inserting a small number of JSON documents into a JSON table.

NOTE: Alternatively, you can put JSON documents in a flat text file and use the `mapr importJSON` command to import the JSON documents into a table. The `mapr importJSON` command is useful when you need to insert many documents into a table. Refer to HPE Ezmeral Data Fabric Database JSON ImportJSON on page 5506 for instruction.

NOTE: The examples in this document use the student data in theQuerying HBase Tutorial to recreate the binary “students” table as a JSON table in HPE Ezmeral Data Fabric Database.

To load JSON documents into a HPE Ezmeral Data Fabric Database table through the `mapr dbshell`, complete the following steps:

1. Run the following command to start the `mapr dbshell`:

   ```
   mapr dbshell
   ```

2. Run the following command to create a table:

   ```
   create <table-name>

   Example:
    create students
   ```

   NOTE: By default, the table is stored in the default directory. The default directory is the current directory on the MapR Filesystem, which is set to the user’s home directory when the `mapr dbshell` starts. Include a file path, as shown, if you do not want the table stored in the default directory:

   ```
   create /file/path/table-name
   ```

3. Load the JSON documents into the table using the INSERT command, as shown:

   ```
   insert <table-name> --value '{JSON-document}'

   Example:
   insert students --value '{"_id":"student1", "name":"Alice",
   "street":"123 Ballmer Av", "zipcode":12345, "state":"CA"}'
   insert students --value '{"_id":"student2", "name":"Bob", "street":"1
   Infinite Loop", "zipcode":12345, "state":"CA"}'
   insert students --value '{"_id":"student3", "name":"Frank",
   "street":"435 Walker Ct", "zipcode":12345, "state":"CA"}'
   insert students --value '{"_id":"student4", "name":"Mary", "street":"56
   Southern Pkwy", "zipcode":12345, "state":"CA"}'
   ```

4. Run the following command to verify that the table was created:

```
find <table-name>

Example:
find students
```

5. Run the following command to close the `mapr dbshell`:

```
exit
```

6. If you need to start or restart Drill, run the following command:

```
maprcli node services -name drill-bits -action start|restart -nodes
<space-separated-list-of-drill-hostnames>
```

7. Run the following command to start the Drill shell (SQLLine):

```
sqlline
```

You can query the HPE Ezmeral Data Fabric Database JSON table from the Drill shell. If you did not include a file path when you created the table, the table was created in the current directory on the MapR Filesystem, which is set to the user's home directory. For example, the following query specifies the default directory if the root user created the table without indicating a file path:

```
SELECT * FROM dfs.`/user/root/table-name`;

Example:
SELECT * FROM dfs.`/user/root/students`;
```

If the user created the table in a specific directory, the query must include the directory in which the table was created, as shown:

```
SELECT * FROM dfs.`/file/path/table-name`;
```

Binary Tables

Binary tables store data in a flat table structure where the table consists of columns and column values. Every field in a binary table is stored as a sequence of bytes.

Binary tables do not store data type information. You manage the encoding for binary tables when storing data and then convert the sequence of bytes into a specific data type using the CAST or CONVERT functions when you run queries against the tables.

For example, if a string is stored in binary format, such as a UTF-8 encoded string, you must use the CAST function for the query to return a string type. If an integer is stored in binary format, such as 4-byte little endian encoding, you must use the CONVERT function for the query to return the integer value instead of the 4-byte sequence.

Querying a Binary Table

The following examples, from the Querying HBase Tutorial, display query results when the binary table "/user/root/binary/students" with two column families, "account" and "address," is queried without using a conversion function to convert the binary table data into specific data types.

Example 1

last-updated: Jun 06, 2024

```
SELECT * FROM `/user/root/binary/students` students;
```

```
+--------------+-----------------------------------------------------+----------------------
|   row_key    |                    account                          |
address                                  |
+--------------+-----------------------------------------------------+----------------------

| [B@78dfa1ed  | {"date":"MjAxNi0wMS0xNQ==","name":"QWxpY2U="}  |
{"state":"Q0E=","street":"MTIzIEJhbGxtZXIgQXY=","zipcode":"MTIzNDU="}      |
| [B@22000c9a  | {"date":"MjAxNi0wMy0wOA==","name":"Qm9i"}       |
{"state":"Q0E=","street":"MSBJbmZpbml0ZSBMb29w","zipcode":"MTIzNDU="}      |
| [B@313b63e6  | {"date":"MjAxNS0xMi0yMg==","name":"RnJhbms="}  |
{"state":"Q0E=","street":"NDM1IFdhbGtlciBDdA==","zipcode":"MTIzNDU="}      |
| [B@321baa4a  | {"date":"MjAxNS0wOS0xNQ==","name":"TWFyeQ=="}  |
{"state":"Q0E=","street":"NTYgU291dGhlcm4gUGt3eQ==","zipcode":"MTIzNDU="}  |
+--------------+-----------------------------------------------------+----------------------

4 rows selected (0.612 seconds)
```

In example 2, using the CONVERT_FROM and CAST functions in a query on the same table converts the binary table data to typed data.

Example 2

```
SELECT CONVERT_FROM(row_key, 'UTF8') AS studentid,
CONVERT_FROM(students.account.name, 'UTF8') AS name,
CONVERT_FROM(students.address.state, 'UTF8') AS state,
CONVERT_FROM(students.address.street, 'UTF8') AS street,
CONVERT_FROM(students.address.zipcode, 'UTF8') AS zipcode,
CAST(students.account.`date` as date) AS `date` FROM dfs.`/user/root/binary/
students` students;
```

```
+------------+--------+--------+-------------------+----------+-------------+

Working with Joda-Time Format

Describes queries on Joda-Time formatted columns and how to include annotations for successful queries.

Drill cannot read timestamp values in a maprdb column if the column is formatted in Joda-Time. You cannot CAST Joda-Time columns or values to another type unless you annotate the Joda-Time column with `"$date"` for timestamp values or `"$dateDay"` for date values, as shown:

```
"order_received_ts"  : { "$date": "1992-04-05T02:15:16Z"}
```

NOTE: The following set of annotations were used for internal purposes, but they do not provide any additional SQL benefits in Drill. Instead of using these annotations, you can CAST the data types.

```
$binary
$numberByte
$decimal
$numberFloat
$numberInt
$interval
$numberLong
$numberShort
$time
```

Querying Joda-Time Formatted Columns without Annotation

The following examples show you the results of two queries on a JSON database table (t2) with a Joda-Time formatted column, `order_received_ts`, that does not have the `"$date"` or `"$dateDay"` annotation. Table t2 contains the following data:

```
maprdb mapr:> find /test01/t2
{"_id":"472271675972670","amount":10433.28,"delivery_method":"TRUCK","discou
nt_rate":10.03,"instructions":"DELIVER IN PERSON","notes":"ccording to the
foo","order_date":"1993-09-11","order_received_ts":"1992-04-05T02:15:16Z","p
roduct_category_id":6,"quantity":6,"ship_date":"1993-09-21","store_id":"8134
660","tax_rate":10.06,"type_code":"F"}
1 document(s) found.
```

The following query filters on `order_received_ts` and casts the value to the timestamp data type:

```
apache drill> select _id, order_received_ts from dfs.`/test01/t2` where
order_received_ts > cast('1992-04-05 01:15:16' as timestamp);
+--+
|  |
+--+
+--+
No rows selected (0.402 seconds)
```

The following query casts the `order_received_ts` column to timestamp:

```
apache drill> select _id, cast(order_received_ts as
timestamp) ,customer_id, order_date from dfs.`/test01/t2`;
Error: SYSTEM ERROR: DateTimeParseException: Text '1992-04-05T02:15:16Z'
could not be parsed, unparsed text found at index 10

Fragment 0:0

Please, refer to logs for more information.

[Error Id: 039a92d4-43d6-4561-80b5-d87a588f5b10 on mycluster:31010]
(state=,code=0)
apache drill>
```

Both queries return unexpected results; however, adding an annotation can resolve the issue.

Adding an Annotation to Joda-Time Formatted Columns

You will need to update the table or recreate the table to add the annotation. You can do this through the maprdb shell or you can update the data in a JSON file and then import the JSON file into a maprdb JSON table. In this example, the annotation is added to a JSON file and then imported into a JSON table.

To add the annotation to the `order_received_ts` column:

1. Update the JSON file with the annotation:

```
{
  "_id" : "472271675972670",
  "store_id" : "8134660",
  "quantity" : 6,
  "product_category_id" : 6,
  "amount" : 10433.28,
  "discount_rate" : 10.03,
  "tax_rate" : 10.06,
  "type_code" : "F",
  "order_date" : {"$dateDay": "1993-09-11"},
  "ship_date" : "1993-09-21",
  "order_received_ts"  : {"$date": "1992-04-05T02:15:16Z"},
  "instructions" : "DELIVER IN PERSON",
  "delivery_method" : "TRUCK",
  "notes" : "ccording to the foo"
}
```

2. Put the JSON file in a `mapr` directory:

```
hadoop fs -put t2.json /user/mapr/.
```

3. Create the JSON database table:

```
maprcli table create -path /test01/t2 -tabletype json
```

4. Import the JSON file into the JSON table:

```
mapr importJSON -src /user/mapr/t2.json -dst /test01/t2 -mapreduce false
```

Now that the annotation is added, Drill queries against the table (t2) run successfully and return the expected results:

```
apache drill> select _id, order_received_ts from dfs.`/test01/t2` where
order_received_ts > cast('1992-04-05 01:15:16' as timestamp);
+-----------------+--------------------------+
|       _id       |    order_received_ts     |
+-----------------+--------------------------+
| 472271675972670 | 1992-04-05T02:15:16.000Z |
+-----------------+--------------------------+
1 row selected (0.334 seconds)

apache drill> select _id, order_date from dfs.`/test01/t2` where
order_date > cast('1993-08-10' as date);
+-----------------+------------+
|       _id       | order_date |
+-----------------+------------+
| 472271675972670 | 1993-09-11 |
+-----------------+------------+
1 row selected (0.156 seconds)
apache drill>
```

last-updated: Jun 06, 2024

Configuring the Hive Storage Plugin

About this task
You can connect Drill to a Hive data source through the hive storage plugin configuration in the Drill Web UI. After configuration, use Drill to query data stored in Hive.

Drill can work with only one version of Hive in a given cluster. To access Hive tables using custom SerDes or InputFormat/OutputFormat, all nodes running Drill must have the SerDes or InputFormat/OutputFormat JAR files in the `<drill_installation_directory>/jars/3rdparty` location.

To query across multiple versions of Hive, install each version of Hive on a separate Drill cluster. You must define separate storage plugins, each corresponding to the specific Hive version of the metastore.

NOTE: In EEP 6.0, Drill requires Hive version 2.3.3-mapr or later to successfully query Hive data sources.

Configuring a Hive Remote Metastore

A remote Hive metastore configuration runs as a separate service outside of Hive. The metastore service communicates with the Hive database over JDBC. Point Drill to the Hive metastore service address, and provide the connection parameters in the Hive storage plugin configuration to configure a connection to Drill. The Hive storage plugin (located on the **Storage** tab in the Drill Web UI) has the following default configuration if you install Drill:

```
{
 "type": "hive",
 "enabled": true,
 "configProps": {
  "hive.metastore.uris": "",
  "javax.jdo.option.ConnectionURL": "jdbc:derby:;databaseName=../
sample-data/drill_hive_db;create=true",
  "hive.metastore.warehouse.dir": "/tmp/drill_hive_wh",
  "fs.default.name": "file:///",
  "hive.metastore.sasl.enabled": "false",
  "datanucleus.schema.autoCreateAll": "true"
 }
}
```

Complete the following steps to modify the default Hive storage plugin configuration for your file system environment:

Procedure

1. Verify that Hive is running.
2. Issue the following command to start the Hive metastore service on the system specified in the `hive.metastore.uris`: `hive --service metastore`
3. Start the Drill Web UI.
4. Select the **Storage** tab. If Web UI security is enabled, you must have administrator privileges to perform this step.
5. In the list of disabled storage plugins in the Drill Web UI, click **Update** next to Hive.
6. Update the following Hive storage plugin parameters to match the system environment:
   - `"hive.metstore.uris"`
   - `"jdbc:<database>://<host:port>/<metastore database>"`

last-updated: Jun 06, 2024

- Change the default location of files to suit your environment. For example, change `"fs.default.name": "file:///"` to the file system location: `maprfs:///`
- To run Drill and Hive in a secure cluster, change the `"hive.metastore.sasl.enabled"` parameter to `"true"`.
- Change the `"datanucleus.schema.autoCreateAll"` property setting for your system environment. After it is enabled, `"datanucleus.schema.autoCreateAll"` initializes the Hive metastore schema.
  - In a production environment, remove the `"datanucleus.schema.autoCreateAll"` property from the Hive storage plugin configuration; the property is not required because the preferred schema information is already created for the Hive metastore service.
  - In a test environment with an embedded Hive metastore, you can disable (set to `false`) this property after the first query on the Hive data source that you submit from Drill. Alternatively, use the Hive schema tool to initialize or upgrade the Hive metastore schema. Using the Hive schema tool is recommended for queries on transactional tables. Run the `schematool` command as an initialization step:

    ```
    /opt/mapr/hive/hive-<version>/bin/schematool -dbType
    <databaseType> -initSchema
    ```

7. Click **Enable** in the Web UI to enable the Hive storage plugin configuration.

Configuring the Kafka Storage Plugin
To configure Kafka as a data source in Drill, update the `<drill_home>/jars/3rdParty` directory with the required JAR files, restart Drill, and configure the `kafka` storage plugin in the Drill Web UI.

Verify that the nodes in your cluster meet the requirements and then complete the steps listed.

Requirements

The Kafka storage plugin requires:

- HPE Ezmeral Data Fabric 7.0 or later cluster
- Drill 1.16.1 or later installed on nodes
- The HPE Ezmeral Data Fabric Kafka client package (kafka-2.1.1, 2.6.1, or later) installed on at least one node. The Kafka client installation provides the following kafka JAR files that you copy into the `<drill_home>/jars/3rdParty` directory (step 4):

  NOTE: Kafka 2.1.1 is used as an example. The version of your Kafka JAR files may differ.

  - Kafka-2.1.1
    - kafka_2.11-2.1.1.200-mapr-710.jar
    - kafka-clients-2.1.1.200-mapr-710.jar
  - Kafka-2.6.1 (if you have eep-800 or later installed)
    - kafka_2.13-2.6.1.0-eep-800.jar
    - kafka-clients-2.6.1.0-eep-800.jar
    - kafka-eventstreams-0.1.0.0-eep-800.jar

Steps

Complete the following steps to query Kafka Streams from Drill:

NOTE: Do not perform step 2 if you installed Drill using the RPM or Debian packages. Step 2 is only required if you installed Drill using a TAR file.

1. Remove the specified JAR files from the `<drill_home>/jars/3rdParty` directory based on the Drill installation method:
   - If you installed Drill using RPM or Debian packages, only remove JAR files that start with kafka, such as `kafka-clients-<version>.jar` and `kafka_<version>.jar`, from the `<drill_home>/jars/3rdParty` directory.
   - If you installed Drill using a TAR file, remove all the JAR files that start with `mapr` and `kafka`, such as `maprdb-<version>-mapr.jar, maprfs-<version>-mapr.jar`, `kafka_<version>-mapr.jar`, and `kafka-clients-<version>.jar`, from the `<drill_home>/jars/3rdParty` directory.
2. (Only perform this step if you installed Drill using a TAR file.) Copy the following JAR files from the `/opt/mapr/lib directory` into `<drill_home>/jars/3rdParty` directory:
3. Copy the `mapr-streams-6.2.0.0-mapr.jar` file from the `/opt/mapr/lib` directory into the `<drill_home>/jars/3rdParty` directory.
4. Copy the following kafka JAR files from the `/opt/mapr/kafka/kafka-*/libs` directory into the `<drill_home>/jars/3rdParty` directory:

   NOTE: Kafka 2.1.1 is used as an example. The version of your Kafka JAR files may differ.

   - Kafka-2.1.1
     - `kafka_2.11-2.1.1.200-mapr-710.jar`
     - `kafka-clients-2.1.1.200-mapr-710.jar`
   - Kafka-2.6.1 (if you have eep-800 or later installed)
     - `kafka_2.13-2.6.1.0-eep-800.jar`
     - `kafka-clients-2.6.1.0-eep-800.jar`
     - `kafka-eventstreams-0.1.0.0-eep-800.jar`
5. Issue the following command to restart Drill:

   ```
   $ maprcli node services -name drill-bits -action restart -nodes <node
   hostnames separated by a space>
   ```

6. Log in to the Drill Web UI, and configure the kafka storage plugin. See Kafka Storage Plugin for instructions.

   NOTE: When configuring the kafka storage plugin, you must also include the following parameter in the storage plugin configuration:

   ```
   "streams.consumer.default.stream": "<path-to-stream>"
   ```

last-updated: Jun 06, 2024

Usage Example

This example shows a Drill query on a Streams data set, which was made accessible to Drill through the kafka storage plugin.

For this example, tables that contain Yelp stream topics reside in a directory named /YelpStream. The kakfa storage plugin is configured with the `streams.consumer.default.stream` parameter pointing to the /YelpStream directory, as shown:

```
"streams.consumer.default.stream": "/YelpStream"
```

The USE command tells Drill to access data from only the kafka data source:

```
use kafka;
+-----+----------------------------------+
| ok | summary |
+-----+----------------------------------+
| true | Default schema changed to [kafka] |
+-----+----------------------------------+
```

The SHOW TABLES command lists the tables in the /YelpStream directory configured for the kafka data source:

```
show tables;
+-------------+---------------------------+
| TABLE_SCHEMA | TABLE_NAME |
+-------------+---------------------------+
| kafka | /YelpStream:UserTable |
| kafka | /YelpStream:ReviewTable |
| kafka | /YelpStream:BusinessTable |
+-------------+---------------------------+
```

The query selects all the data from the BusinessTable in the `/YelpStream` directory, limiting the results to one row data:

```
select * from `/YelpStream:BusinessTable` limit 1;
+---+----------+-----------+----------+----+------------+-----+--------+---------+----+-

| _id | attributes | business_id | categories | city | full_address | hours
| latitude | longitude | name | neighborhoods | open | review_count | stars
| state | type | kafkaTopic | kafkaPartitionId | kafkaMsgOffset |
kafkaMsgTimestamp | kafkaMsgKey |
+---+----------+-----------+----------+----+------------+-----+--------+---------+----+-

Configuring the HBase Storage Plugin
As a Hadoop database, Apache HBase is a distributed, scalable, and big data store. Use and configure the HBase storage plugin to connect with Apache Drill.

Prerequisites

Before configuring the HBase storage plugin, make sure that you have:

- HBase up and running.
- ZooKeeper installed.
- Administrator privileges.

About this task
This task outlines how to configure the HBase storage plugin.

Procedure

1. Verify that HBase is running.
2. Start the Drill Web UI.
3. Select the **Storage** tab.
4. Click **Update** to begin the configuration process.

   The following shows a typical HBase configuration:

```
{
   "type": "hbase",
   "config": {
     "hbase.zookeeper.quorum": "10.10.100.62,10.10.10.52,10.10.10.53",
     "hbase.zookeeper.property.clientPort": "2181"
  },
  "size.calculator.enabled": false,
  "enabled": true
}
```

   The following shows a secure cluster configuration:

```
{
     "type": "hbase",
     "config": {
       "hbase.zookeeper.quorum": "node1.cluster.com",
       "hbase.zookeeper.property.clientPort": "5181",
       "hbase.security.authentication": "MAPRSASL"
},
"size.calculator.enabled": false,
"enabled": true
}
```

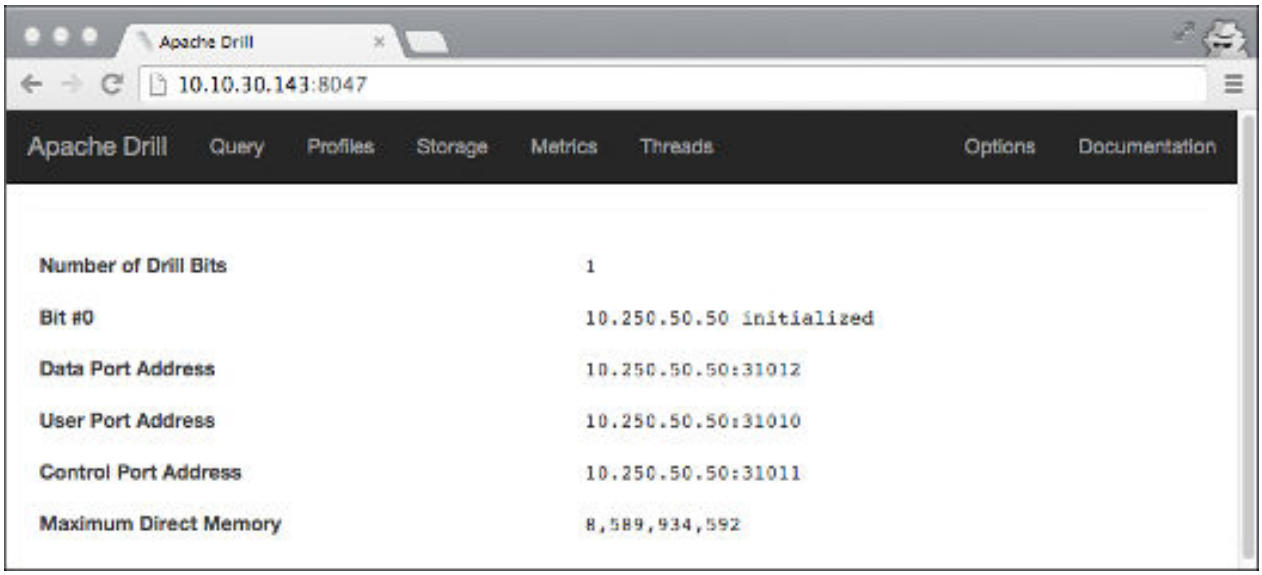
Start the Drill Web UI
The Drill Web UI is one of several client interfaces that you can use to access Drill.

Accessing the Drill Web UI

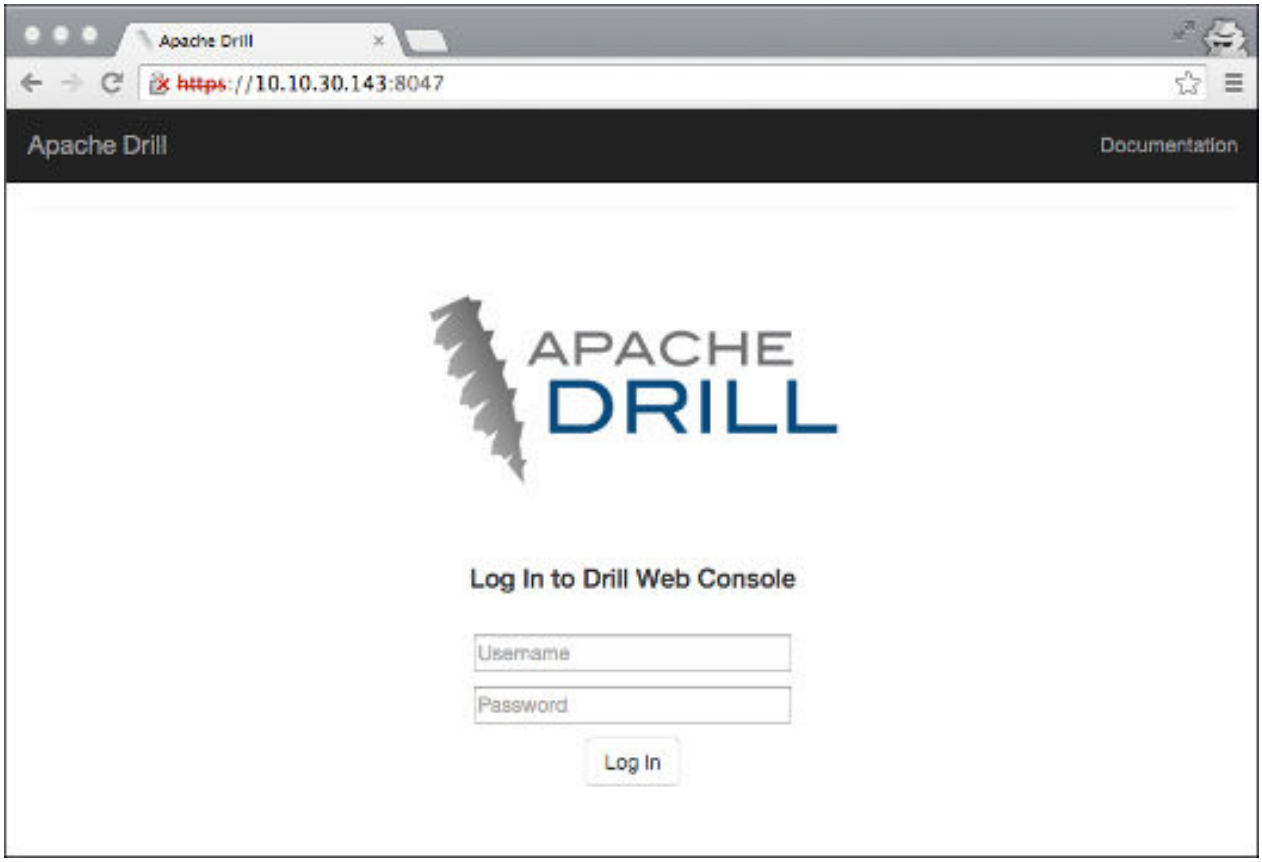
To open the Drill Web UI, launch a web browser, and go to one of the following URLs:

- If HTTPS support is disabled, use the default URL: http://<IP address or host name>:8047
- If HTTPS support is enabled, use this URL: https://<IP address or host name>:8047

If user authentication is *not* enabled, all the Drill Web UI controls appear to users and administrators, including Query, Profiles, Storage, Metrics, and Threads:



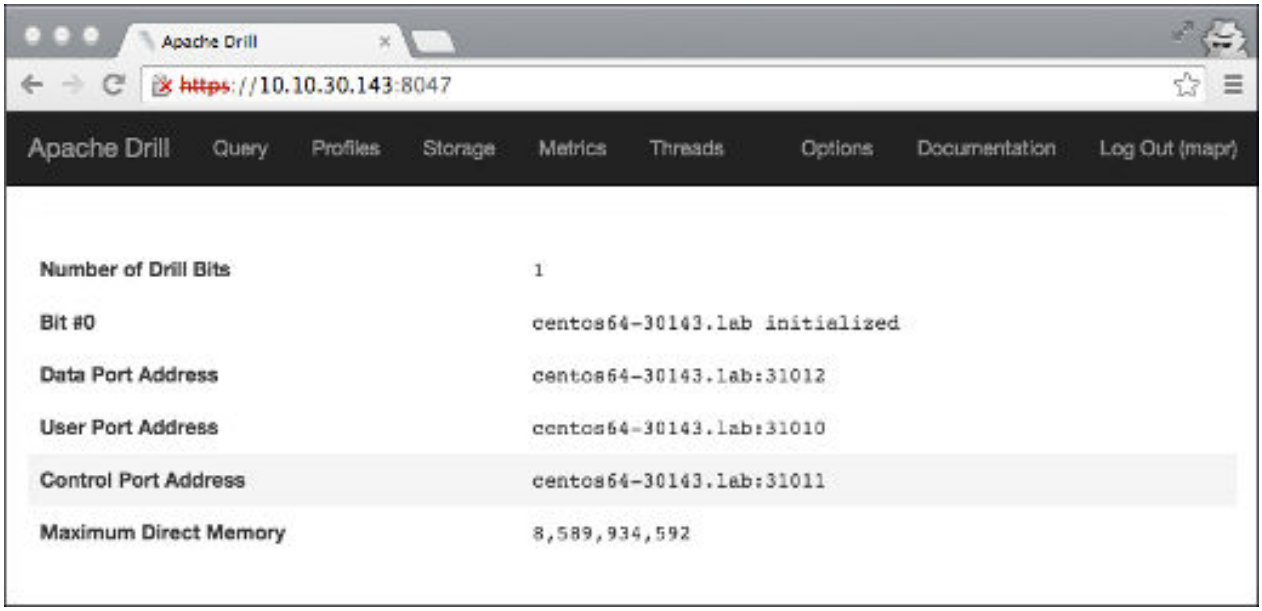
If user authentication is enabled, Drill prompts you for a user name and password:



If an administrator logs in, all the Drill Web UI controls appear, including Query, Profiles, Storage, Metrics, Threads, and Options. For administrators, the Profiles page contains the profiles of all queries executed

last-updated: Jun 06, 2024

on a cluster. Only administrators can see and use the Storage tab to view, update, or add a new storage plugin configuration. Only administrators can see and use the Threads tab, which provides information about threads running in Drill.



If a non-administrative user logs in, the Drill Web UI controls are limited to Query, Metrics, and Profiles. The Profiles tab for a non-administrative user contains the profiles of all queries the user issued either through ODBC, JDBC, or the Drill Web UI.

https://drill.apache.org/docs/architecture-introduction/#drill-clients

last-updated: Jun 06, 2024

https://drill.apache.org/docs/securing-drill/

Start the Drill Shell (SQLLine)
SQLLine is a JDBC application packaged with Drill that serves as the Drill shell. When you issue queries from the SQLLine, the SQLLine client sends the queries to the connected Drillbit (Drill node).

You can connect to Drill through SQLLine directly or through a connection-property file. If want to avoid exposing credentials, connecting through the connection-property file is recommended.

A JDBC connection string supplies the connection information to a Drill node or ZooKeeper cluster. When connecting to a ZooKeeper cluster, ZooKeeper selects the Drillbit that SQLLine connects to.

JDBC Connection String

This is an example of a JDBC connection string that connects SQLLine to drillnode1:

```
jdbc:drill:drillbit=drillnode1:31010
```

The default port on any Drill node is 31010.

Starting SQLLine

You start SQLLine from the Drill installation directory, as shown in the following example where SQLLine connects directly to a Drill node named `drillnode1`:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
jdbc:drill:drillbit=drillnode1:31010
```

Connection Parameters

You can include SQLLine connection parameters in the connection string and run various shell commands, as described in Configuring the Drill Shell.

In the following example, -u is the connection parameter for the JDBC connection string, -n is the parameter for the username, and –p is the parameter for the password:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=drillnode1:31010" -n mapr -p mapr
```

In the following example, the `!connect` shell command is used to hide the password when making an authenticated connection:

```
//From /opt/mapr/drill/drill-<version>/, run:

bin/sqlline

//The sqlline prompt appears. At the prompt, provide the connection string
with the !connect property:

sqlline> !connect jdbc:drill:drillbit=drillnode1:31010
//The system prompts you for the username and password.
Enter username for jdbc:drill:drillbit=drillnode1:31010: mapr
Enter password for jdbc:drill:drillbit=drillnode1:31010: ********
```

NOTICE: In Drill 1.15, the SQLLine `!connect` command incorrectly requests a username and password when connecting to a secure cluster via MAPRSASL or KERBEROS authentication:

```
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL

//!connect usage: connect <url> <username> <password> [driver]
//Driver is optional. Driver is the Apache Drill driver class,
org.apache.drill.jdbc.Driver.
```

To workaround this issue, provide your username when you connect and press Enter when prompted for the password:

```
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL
mapr
Enter password for jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL:
```

Alternatively, you can use an empty quote in place of a username:

```
sqlline> !connect jdbc:drill:drillbit=drillnode1:31010;auth=MAPRSASL ""
```

Configuration Options

You can also include configuration options, such as `schema` and `auth` (if authentication is enabled):

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u "jdbc:drill:drillbit
drillnode1:31010;schema=dfs;auth=MAPRSASL"
```

Schema	The `schema` is the name of a storage plugin configuration to use as the default for queries. If you indicate the schema in the connection string, you do not have to run the `USE <schema>;` query to switch to the schema you want to use. All queries run against the schema indicated in the JDBC connection string.
Authentication	If authentication is enabled (Plain, MAPRSASL, Kerberos), include the `auth` option in the connection string. If Drill is installed on a cluster secured by the default security, set `auth=MAPRSASL`. If using Plain authentication, include the username and password, as shown: `/opt/mapr/drill/drill-<version>/bin/ sqlline -u "jdbc:drill:drillbit drillnode1:31010;schema=dfs;auth=MAPRSASL"`

Connecting to a Specific Drill Node

Indicate which Drill node you want SQLLine to connect to in the JDBC connection string, using the following JDBC connection string format:

```
jdbc:drill:drillbit=<host>:<port>
```

Note that properties are case-sensitive. The `host` is the DNS or IP address of the server (Drill node). The default connection port is 31010.

Example

last-updated: Jun 06, 2024

The following example shows you how to start SQLLine with a JDBC connection string that includes the username, password, and auth parameters to authenticate to the server with Plain authentication:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=<ip-address>:<port>;auth=PLAIN" -n <username> -p
<password>
```

If you installed Drill on a a cluster secured by default security, set the `auth` type to `maprsasl`:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=<ip-address>:<port>;auth=MAPRSASL"
```

Connecting to ZooKeeper

When you include the ZooKeeper nodes in the JDBC connection string, ZooKeeper selects an available Drill node for SQLLine to connect to.

Indicate the ZooKeeper cluster you want SQLLine to connect to in the JDBC connection string, using the following JDBC connection string format:

```
jdbc:drill:zk=<zk-server-list>/drill/<clustername>
```

The `zk-server-list` is a comma-separated list of the ZooKeeper nodes in the cluster. The `clustername` is the unique name of the Drillbit cluster that you want to connect to.

You can locate the name of the Drillbit cluster in `/opt/mapr/drill/drill-<version>/conf/drill-distrib.conf`. The default name of the Drillbit cluster is `drillbits1`. The name is set by the `cluster-id` property. If you have multiple Drill clusters, you may want to override the Drillbit cluster name in `drill-override.conf`. However, first back-up your storage plugin configurations, as they may reset to the defaults when you change the cluster name. Restart Drill after you edit `drill-override.conf`.

Example

The following example shows you how to configure the JDBC connection string to connect SQLLine to the ZooKeeper cluster:

```
/opt/mapr/drill/drill-<version>/bin/sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-ip>:<port>,=<node-ip>:<port>/drill/
drillbits1;auth=PLAIN -n <username> -p <password>
```

The default port for ZooKeeper nodes is 5181.

If you installed Drill on a secure cluster, set the `auth` type to `MAPRSASL`:

```
/opt/mapr/drill/drill-<version>/bin/sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-ip>:<port>,=<node-ip>:<port>/drill/
drillbits1;auth=MAPRSASL
```

Using a Connection-Property File with SQLLine

Make sure you restrict access to the connection-property file to specific users.

Create a connection-property file named `login.properties`, as shown:

```
url:<jdbc-connection-url>
user:<username>
password:<password>

//Example
cat login.properties
```

last-updated: Jun 06, 2024

```
url:jdbc:drill:schema=dfs;drillbit=drill-lab-node01
user:drilluser
password:letsdrill
```

To connect to Drill, run SQLLine as shown:

```
sqlline <sqlline args> <path/to/login.properties file>
```

The following examples show you how you can use the connection-property file to connect to Drill:

Example 1: Connecting to Drill via the connection-property file

Run SQLLine from `/opt/mapr/drill/drill-<version>/bin`:

```
sqlline login.properties

//List the active connection:
0: jdbc:drill:schema=dfs> !list
1 active connection:
 #0  open
jdbc:drill:schema=dfs;drillbit=drill-l
ab-node01

//Exit SQLLine:
0: jdbc:drill:schema=dfs>!q
```

Example 2: Submitting a query when connecting to Drill via the connection-property file

Run SQLLine from `/opt/mapr/drill/drill-<version>/bin`:

```
sqlline -q "SELECT version FROM
sys.version" login.properties

//Run query:
0: jdbc:drill:schema=dfs> select
version from sys.version;
+----------+
| version  |
+----------+
| 1.16.0   |
+----------+
1 row selected (0.295 seconds)
```

Example 3: Use the properties command to connect to Drill via the connection-property

Run SQLLine from `/opt/mapr/drill/drill-<version>/bin`:

```
sqlline

//At sqlline the prompt, run:
sqlline> !properties /home/drilluser/
login.properties
0: jdbc:drill:schema=dfs>
0: jdbc:drill:schema=dfs> !list
1 active connection:
 #0  open
jdbc:drill:schema=dfs;drillbit=drill-l
ab-node01
0: jdbc:drill:schema=dfs>

Verify that Login Details are Secure

Run the following command to verify that login details are not exposed to other users:

```
ps -ef | grep sqlline

drilluser     18938 21924 99 14:14
pts/0    00:00:03 /opt/
jdk1.8.0_141/bin/
java -XX:MaxPermSize=512M -Djava.secur
ity.auth.login.config=/opt/mapr/conf/
mapr.login.conf \
-Dzookeeper.sasl.client=false -Dhadoop
.login=simple -Dlog.path=/opt/mapr/
drill/drill-1.10.0/logs/
sqlline.log -Dlog.query.path=/opt/
mapr/drill/drill-1.16.0/logs/
sqlline_queries.json \
-cp /opt/mapr/drill/drill-1.10.0/
conf:/opt/mapr/drill/drill-1.16.0/
jars/*:/opt/mapr/drill/drill-1.16.0/
jars/ext/*:/opt/mapr/drill/
drill-1.16.0/jars/3rdparty/*:/opt/
mapr/drill/drill-1.16.0/jars/classb/*
sqlline.SqlLine -d
org.apache.drill.jdbc.Driver --maxWidt
h=10000 --color=true login.properties
drilluser     20119  1691  0 14:14
pts/1    00:00:00 grep sqlline
```

Exit SQLLine

To exit SQLLine, run `!quit`.

Start|Stop the Drill Process

You can start|stop|restart the Drill process on one or more nodes using the Control System or the following command:

```
maprcli node services -name drill-bits -action start|restart|stop -nodes
<node host names separated by a space>
```

Use the host name if possible. Using host names instead of IP addresses is a best practice.

Related concepts

Drill Drivers on page 4075
HPE Ezmeral Data Fabric provides Drill ODBC and JDBC drivers that you can download and use to connect Drill to BI tools. The drivers are updated periodically to include support for new functionality in Drill.

Drill JDBC Drivers on page 4075
Download the Drill JDBC driver and use it on all platforms to connect BI tools, such as SQuirreL and Spotfire, to Drill. Drill also includes an embedded, open-source JDBC driver.

Hive to Drill Type Mapping

Using Drill you can read tables created in Hive that use data types in the Hive-to-Drill type mapping table. Currently, the Apache Hive version used by Drill does not support the timestamp in Unix Epoch format. The workaround is to use the JDBC format for the timestamp, which Hive accepts and Drill uses, as shown in the type mapping example.

For more information about connecting Drill to data sources, refer to Connect to Data Sources on the Apache Drill documentation web site. For information about workspaces, refer to Workspaces.

last-updated: Jun 06, 2024

Securing Drill

An administrator can install Drill with the default security configuration or manually configure custom security for Drill.

Drill supports several security features that secure the communication paths between Drill clients (such as ODBC/JDBC) and Drillbits and also between Drillbits. The following sections briefly describe the security configuration options for Drill and provide links to additional information and instructions.

Default Security Configuration

Starting in Core 6.0 and Drill 1.11 (EEP 4.0), Drill is automatically secured when you install Drill on a cluster that was installed with the default security configuration. The default security configuration provides authentication, authorization, and encryption through the data-fabric-SASL mechanism, except for HTTPS, which uses SSL/TLS with form-based authentication. See Drill Default Security and SSL/TLS for Encryption for more information. You may also want to reference the following topics:

- Installing Drill, which describes some Drill installation security scenarios.
- Drill Drivers on page 4075, where you can access the JDBC and ODBC driver information and downloads required to connect to Drill when using the default security configuration.

NOTE: The default security configuration does not include Kerberos or Plain authentication; however, you can manually configure these security mechanisms in addition to the default security configuration.

Security Features Supported in a Custom Configuration

Drill supports several security features that an administrator can manually configure to secure the communication paths between the Drill client and Drillbit and also between Drillbits.

The following table lists the security features and mechanisms supported by Drill, as well as the communication paths secured by each mechanism:

NOTE: In the following table, Drill client refers to the Drill ODBC and JDBC clients. See Drill Drivers for ODBC and JDBC driver information.

Security Features	Supported Mechanisms	Communication Paths Secured
Authentication	MapR Security (data-fabric-SASL/Tickets)	• Drill client to Drillbit • Drillbit to Drillbit • Drillbit to ZooKeeper **NOTE:** The Drillbit creates znodes, for which ZooKeeper ACLs provide security. See Security Between ZooKeeper and Drillbits for more information.
	Kerberos	• Drill client to Drillbit • Drillbit to Drillbit
	Plain (username and password)	• Drill client to Drillbit

Security Features	Supported Mechanisms	Communication Paths Secured
	Form-based	• Web client/REST API to Drillbit **NOTE:** You can configure SSL/TLS for encryption.
	SPNEGO for HTTP	• Web client/REST API to Drillbit **NOTE:** You can configure SSL/TLS for encryption.
Encryption	MapR Security (data-fabric/ Tickets)	• Drill client to Drillbit • Drillbit to Drillbit
	Kerberos	• Drill client to Drillbit • Drillbit to Drillbit
	SSL/TLS	• Drill client to Drillbit • Web client/REST API to Drillbit
Authorization	Based on filesystem permissions.	• Drill client to Drillbit
Impersonation	User Impersonation	• Drill client to Drillbit **NOTE:** Drill supports user impersonation, inbound impersonation, and user impersonation with Hive authorization.
	Inbound impersonation	• Drill client to Drillbit **NOTE:** Supports setting inbound impersonation policies, which are used to verify whether the user (set as the DelegationUID parameter passed in the client connection URL) can be impersonated by the connection user or not.

Views and File ACEs

In addition to the listed security features, you can create views on data to limit access to the data. You can also create file ACEs on the view definition files to protect the views.

Related concepts

Drill Drivers on page 4075
HPE Ezmeral Data Fabric provides Drill ODBC and JDBC drivers that you can download and use to connect Drill to BI tools. The drivers are updated periodically to include support for new functionality in Drill.

Start the Drill Shell (SQLLine) on page 4011
SQLLine is a JDBC application packaged with Drill that serves as the Drill shell. When you issue queries from the SQLLine, the SQLLine client sends the queries to the connected Drillbit (Drill node).

Connection URLs for Kerberos using JDBC Drivers to connect via SQLLine on page 4045

last-updated: Jun 06, 2024

You can use client-side connection URL parameters for Kerberos authentication in multiple combinations to authenticate a client with Drill.

Connection URL for Plain Authentication using the Apache JDBC Driver to connect via SQLLine on page 4052
When Plain authentication is enabled, each user that accesses the Drillbit process through a client, must provide username and password credentials for access.

SSL/TLS for Encryption on page 4053
You can enable SSL for Drill in a secure cluster. SSL (Secure Sockets Layer), more recently called TLS, is a security mechanism that encrypts data passed between the Drill client and Drillbit (server). SSL also provides one-way authentication through which the Drill client verifies the identity of the Drillbit.

Configuring Drill Web UI and Web API Security on page 4064
The Drill web client and web API communicate with web browsers or web tools, like curl, through the HTTP or HTTPS. Drill uses HTTP by default.

SPNEGO for HTTP Authentication on page 4069
Drill 1.13 and later supports the Simple and Protected GSS-API Negotiation mechanism (SPNEGO) to extend the Kerberos-based single sign-on authentication mechanism to HTTP. An administrator configures the web server (Drillbit) to use SPNEGO for authentication. Depending on the system, either the administrator or the user configures the client (web browser or web client tool) to use SPNEGO for authentication.

Roles and Privileges
Drill has USER and ADMIN roles. Each role can perform different functions in Drill.

Access in the Drill Web UI differs between users and administrators. Certain pages are exposed based on privilege. For example, only administrators can see the Storage tab and edit a storage plugin configuration.

The following sections describe a few additional differences between a user and an administrator in Drill.

USER Role

The following list notes the functions that a user can perform in Drill:

- Users can run queries on data to which they have access.
- Users can view and cancel their own queries in the Profiles tab of the Drill Web UI.
- Users can create views on data to provide granular access to that data.

NOTE: Each data source manages the read/write permissions.

ADMIN Role

When authentication is enabled, only Drill users assigned the administrator (ADMIN) role can perform the following tasks:

- Change system-level options by issuing the ALTER SYSTEM command or through the options tab in the Drill Web UI.
- Update a storage plugin configuration through the REST API or Drill Web UI.
- View the profiles of all queries run by all users.
- Cancel running queries that were launched by any user in the cluster.
- Shut down the Drillbit in the Drill Web UI.

last-updated: Jun 06, 2024

Configuring USER and ADMIN Roles

You can define administrative users through the `security.admin.user_groups` and `security.admin.users` options.

The default value for `admin.users` is the `drill_process_user`. The default value for `admin.user_groups` is `drill_process_user_groups`. These options accept a comma-separated list of users or user groups.

To edit these options, use the SET command, as shown in the following examples:

```
ALTER SYSTEM SET `security.admin.user_groups` = 'drill,
%drill_process_user_groups%';
ALTER SYSTEM SET `security.admin.users` = 'user1, %drill_process_user%';
ALTER SYSTEM SET `security.admin.users` = 'user1, user2';
```

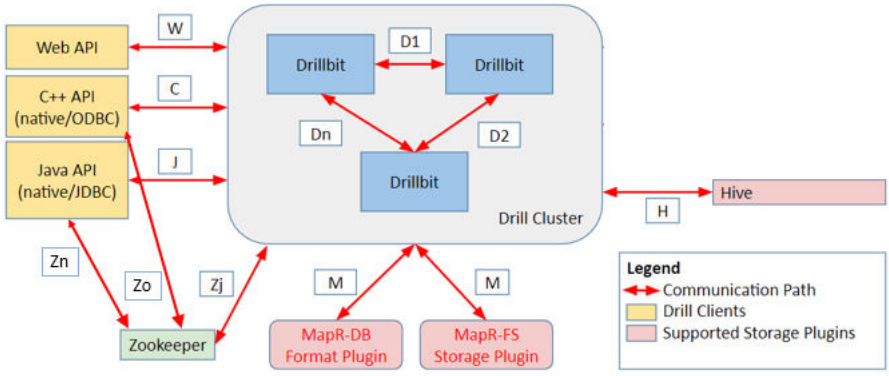
Drill Default Security

The default security configuration uses data-fabric-SASL (tickets) for authentication, authorization, and encryption to automatically secure the cluster and ecosystem components when you install them manually or using the Installer.

The default security configuration automatically secures all Drill communication paths with the following exceptions:

- The path between the web client and web server (W) uses SSL/TLS with form-based authentication.
- The path between the ODBC/JDBC client and ZooKeeper (Zn, Zo) is unsecure.

The following diagram shows the secured communication paths:



The following table describes the security support for each communication path in the diagram, along with the components involved in the communication:

Type of Security Supported	Communication Path	Component Communication
Authentication and encryption using data-fabric-SASL (tickets)	C	ODBC client/C++ API to Drillbits
	J	JDBC client/Java API to Drillbits
	D1, D2, Dn	Drillbit to Drillbit
	M	Drillbit to HPE Ezmeral Data Fabric Database/file system

last-updated: Jun 06, 2024

	H	Drillbit to Hive **NOTE:** The Hive storage plugin is not secured by default and requires that you manually modify the configuration to enable security. See Configuring the Hive Storage Plugin on page 4004.
Plain authentication with SSL encryption (HTTPS enabled)	W	Web client/Web API to Web server **NOTE:** The HTTPS channel (Web client) uses Plain authentication to authenticate a Web client with SSL/TLS for encryption. This is configured by default in a secure 6.x cluster with Drill 1.11 or later installed. Plain authentication does not support encryption. You must enable SSL to encrypt the communication channels when using Plain authentication. See Configuring Drill Web UI and Web API Security on page 4064.
Authentication with security (no encryption)	Zj	Drillbit to ZooKeeper **NOTE:** The Drillbit creates znodes, for which ZooKeeper *ACL*s provide security. See Security Between ZooKeeper and Drillbits on page 4063 for more information.
No security support	Zo, Zn	ODBC/JDBC client to ZooKeeper **NOTE:** Only znodes created for Drillbit endpoints in Zookeeper are readable by the client. All other znodes (not required by the client) are secured using ZooKeeper *ACL*s, and are only readable by Drillbits.

Note the following information:

- Kerberos and Plain authentication are not enabled or configured as part of the default security configuration. However, you can manually configure these security mechanisms in addition to the defaults. If you enable Plain authentication, you must use SSL/TLS for encryption.
- Drill clients running Drill 1.10 and earlier do not support encryption and cannot connect to Drillbits installed with the default security configuration.

Connecting Drill

See Drill Drivers on page 4075. Alternatively, you can use SQLLine, the Drill shell, as shown:

Additional Notes

Performance	The default security configuration enables encryption for all network channels, which can affect Drill performance. If performance is your highest priority, install the data-fabric and Drill without security enabled and have your security expert manually configure cluster security. Alternatively, you can install the data-fabric and Drill with security enabled, and then disable individual Drill security settings. For example, you can edit the `drill-override.conf` file and disable encryption, leaving authentication enabled.

	NOTE: Manually configuring security settings when default security is enabled is not recommended.
Drill Configuration Files	The default security configuration introduces new Drill configuration files. In addition to drill-override.conf, distrib-env.sh, and drill-env.sh, Drill includes a drill-distrib.conf file. See Drill Configuration Files on page 4095 for more information. Note that modifying drill distribution-specific files is highly discouraged. To customize any Drill configuration, use `drill-override.conf` and `drill-env.sh`.
HBase	As of Core 6.0 and Drill 1.11, HBase is no longer supported; therefore, the communication path between Drill and HBase is also not supported.

User Impersonation

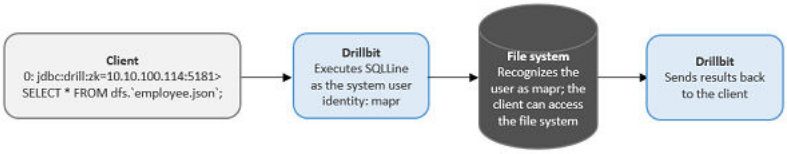
Impersonation allows a service to act on behalf of a client while performing the action requested by the client. By default, user impersonation is disabled in Drill. You can configure user impersonation in the `/opt/mapr/drill/drill-<version>/drill-override.conf` file.

When you enable impersonation, Drill executes all the client requests as the user logged in to the client. Drill passes the user credentials to the file system, and the file system checks to see if the user has permission to access the data. When you enable authentication, Drill uses the pluggable authentication module (PAM) to authenticate a user's identity before the user can access the Drillbit process.

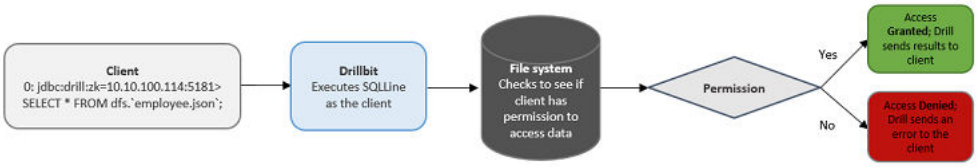
If impersonation is disabled, Drill executes all of the client requests against the file system as the user that started the Drillbit service on the node. This is typically a privileged user. The file system verifies that the system user has permission to access the data.

User Impersonation Example

When impersonation is disabled and user Bob issues a query through the SQLLine client, SQLLine passes the query to the connecting Drillbit. The Drillbit executes the query as the system user that started the Drill process on the node. For the purpose of this example, we will assume that the system user has full access to the file system. Drill executes the query and returns the results back to the client.



When impersonation is enabled and user Bob issues a query through the SQLLine client, the Drillbit uses Bob's credentials to access data in the file system. The file system checks to see if Bob has permission to access the data. If Bob has permission, Drill returns the query results to the client. If Bob does not have permission, Drill returns an error.



Impersonation Support

Drill supports impersonation with the following clients, storage plugins, and types of queries:

- **Clients**
  - ODBC

last-updated: Jun 06, 2024

- JDBC
- REST API
- Drill Web UI

- **Storage plugins**
  - file system
  - HPE Ezmeral Data Fabric Database
  - Hive
- **Types of queries**

  NOTE: When you enable impersonation, the setting applies to queries on data and metadata. For example, if you issue the SHOW SCHEMAS command, Drill impersonates the user logged into the client to access the requested metadata. If you issue a SELECT query on a workspace, Drill impersonates the user logged in to the client to access the requested data.

  Drill applies impersonation to queries issued using the following commands:

  - SHOW SCHEMAS
  - SHOW DATABASES
  - SHOW TABLES
  - CTAS
  - SELECT
  - CREATE VIEW
  - DROP VIEW
  - SHOW FILES.

    NOTE: To successfully run the CTAS and CREATE VIEW commands, a user must have write permissions on the directory where the table or view will exist. Running these commands creates artifacts on the file system.

Impersonation and Views
You can use views with impersonation to provide granular access to data and protect sensitive information.

When you create a view, Drill stores the view definition in a file and suffixes the file with `view.drill`. For example, if you create a view named myview, Drill creates a view file named `myview.view.drill` and saves it in the current workspace or the workspace specified, such as `dfs.views.myview`. See CREATE VIEW.

You can create a view and grant read permissions on the view to give other users access to the data that the view references. When a user queries a view on which s/he has read access, Drill impersonates the view owner to access the underlying data. If the user tries to query the data directly (instead of using the view), Drill returns a permission denied error. A user with read access to a view can create new views from the originating view to further restrict access on data.

View Permissions

A user must have write permission on a directory or workspace to create a view, as well as read access on the table(s) and/or view(s) that the view references. When a user creates a view, permission on the view is

set to owner by default. Users can query an existing view or create new views from the view if they have read permissions on the view file and the directory or workspace where the view file is stored.

When users query a view, Drill accesses the underlying data as the user that created the view. If a user does not have permission to access a view, the query fails and Drill returns an error. Only the view owner or a superuser can modify view permissions to change them from owner to group or world.

The view owner or a superuser can modify permissions on the view file directly or they can set view permissions at the system or session level prior to creating any views. Any user that alters view permissions must have write access on the directory or workspace in which they are working.

Modifying Permissions on a View File

Only a view owner or a super user can modify permissions on a view file to change them from owner to group or world readable. Before you grant permission to users to access a view, verify that they have access to the directory or workspace in which the view file is stored.

Use the `chmod` and `chown` commands with the appropriate octal code to change permissions on a view file:

```
hadoop fs -chmod <octal code> <file_name>
hadoop fs -chown <user>:<group> <file_name>
//hadoop fs -chmod 750 employees.view.drill
```

Modifying SYSTEM|SESSION Level View Permissions

Use the `ALTER SESSION|SYSTEM` command with the `new_view_default_permissions` parameter and the appropriate octal code to set view permissions at the system or session level prior to creating a view.

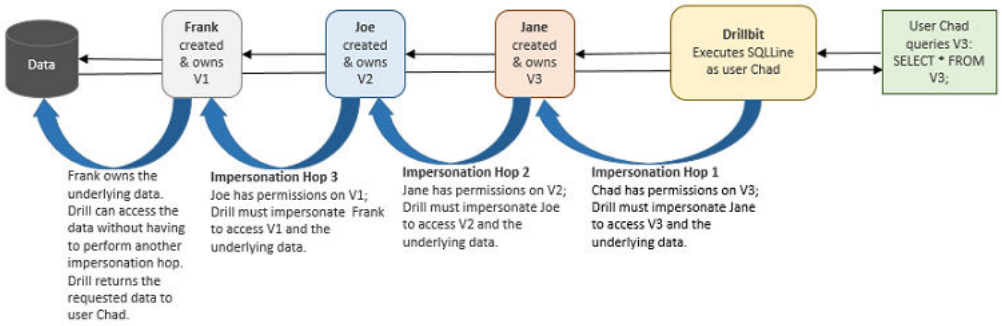
```
ALTER SESSION SET `new_view_default_permissions` = '<octal_code>';
ALTER SYSTEM SET `new_view_default_permissions` = '<octal_code>';
//ALTER SESSION SET `new_view_default_permissions` = '777';
```

After you set this parameter, Drill applies the same permissions on each view created during the session or across all sessions if set at the system level.

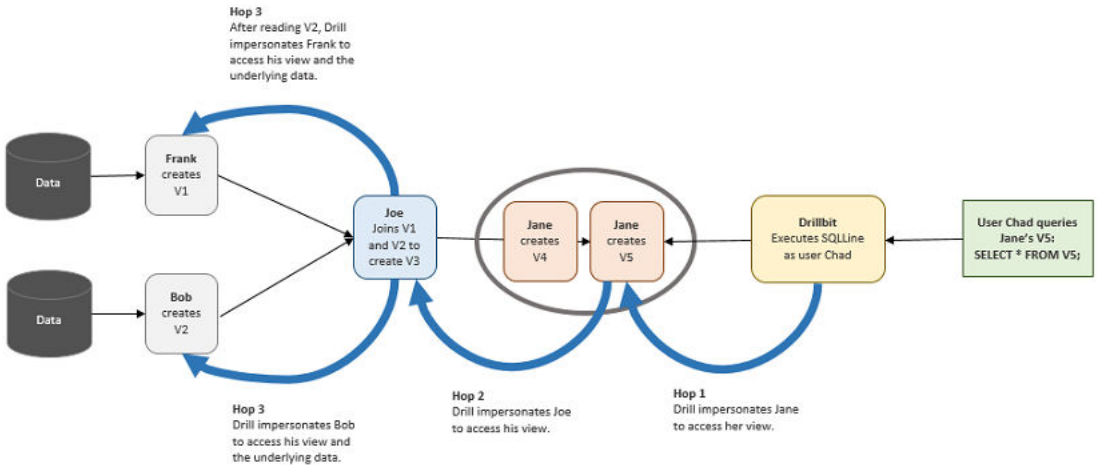
Chained Impersonation
You can configure Drill to allow chained impersonation on views when you enable impersonation in the `drill-override.conf` file. Chained impersonation controls the number of identity transitions that Drill can make when a user queries a view. Each identity transition is equal to one hop.

An administrator can set the maximum number of hops for impersonation to limit the number of times that Drill can impersonate a different user when other users query a view. The default maximum number of hops is set at 3. When the maximum number of hops is set to 0, Drill does not allow impersonation chaining, and a user can only read data for which they have direct permission to access. An administrator may set the chain length to 0 to protect highly sensitive data.

The following diagram depicts a scenario where the maximum hop number is set to 3, and Drill must impersonate three users to access data when Chad queries a view that Jane created:



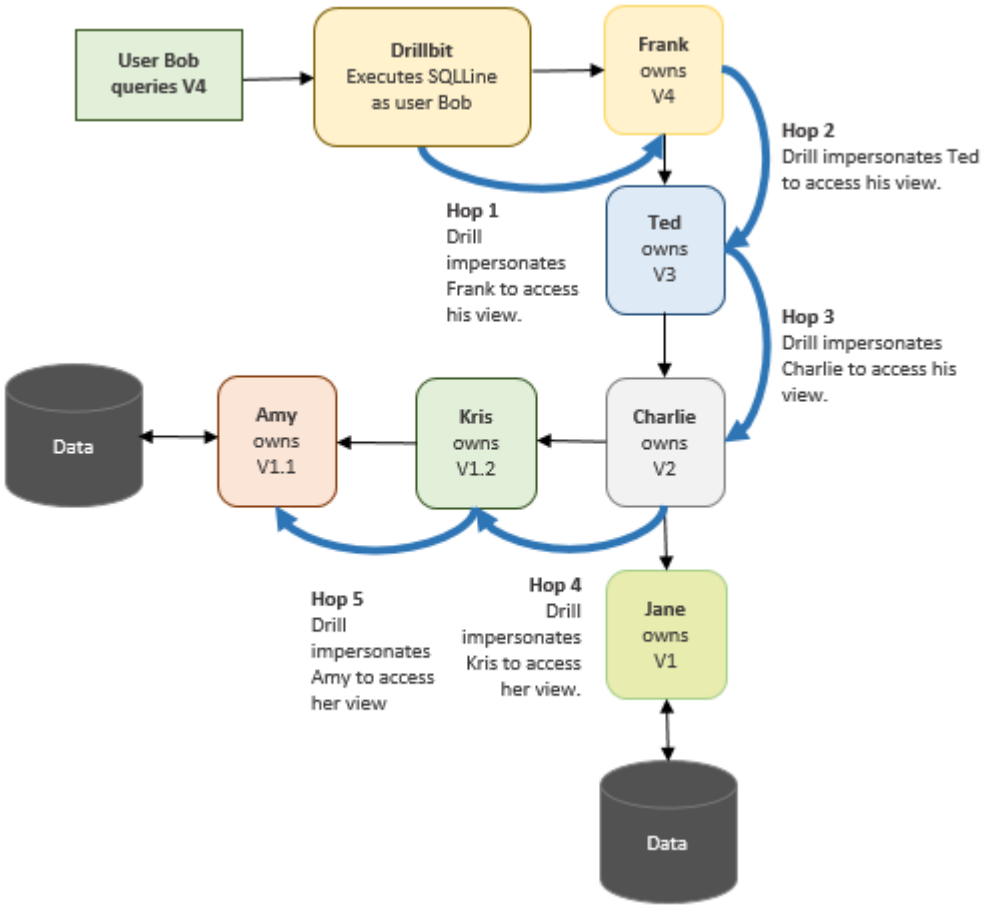
In the previous example, Joe created V2 from the view that user Frank created. In the following example, Joe created V3 by joining a view that Frank created with a view that Bob created.



Although V3 was created by joining two different views, the number of hops remains at 3 because Drill does not read the views at the same time. Drill reads V2 first and then reads V1.

In the next example, Bob queries V4 which was created by Frank. Frank's view was created from several underlying views. Charlie created V2 by joining Jane's V1 with Kris's V1.2. Kris's V1.2 was created from Amy's V1.1, increasing the complexity of the chaining. Assuming that the hop limit is set at 4, this scenario exceeds the limit.

last-updated: Jun 06, 2024



When Bob queries Franks's view, Drill returns an error stating that the query cannot complete because the number of hops required to access the data exceeds the maximum hop setting of 4.

If users encounter this error, the administrator can increase the maximum hop setting to accommodate users running queries on views.

Configuring Impersonation and Chaining

Impersonation allows a service to act on behalf of a client while performing the action requested by the client. Chaining is a system-wide setting that applies to all views. Currently, Drill does not provide an option to allow different chain lengths for different views.

Complete the following steps on each Drillbit node to enable user impersonation, and set the maximum number of chained user hops that Drill allows:

1. Navigate to `<drill_installation_directory>/conf/` and edit `drill-override.conf`.

last-updated: Jun 06, 2024

2. Under `drill.exec`, add the following:

```
drill.exec.impersonation: {
                  enabled: true,
                  max_chained_user_hops: 3
  }
```

   Alternatively, you can nest impersonation within the `drill.exec` block, as shown in the following example:

```
drill.exec: {
           cluster-id: "cluster_name",
           zk.connect:
"<hostname>:<port>,<hostname>:<port>,<hostname>:<port>",
           sys.store.provider.zk.blobroot: "hdfs://",
           impersonation: {
             enabled: true,
             max_chained_user_hops: 3
           }
         }
```

3. Set the maximum number of chained user hops.

4. In `<drill_installation_directory>/conf/drill-env.sh`, add one of the following lines:

   - If the underlying filesystem has security enabled, add the following line: `export MAPR_TICKETFILE_LOCATION=/opt/mapr/conf/maprusertickt`
   - If the underlying filesystem is not secure, add the following line: `export MAPR_IMPERSONATION_ENABLED=true`

5. Restart the Drillbit process on each Drill node.

   ```
   maprcli node services -name drill-bits -action restart -nodes
   <node-hostnames-separated-by-a-space> -f
   ```

Example: Impersonation and Chaining
This example demonstrates how to use impersonation and chaining to limit access to data. Impersonation allows a service to act on behalf of a client while performing the action requested by the client. Chaining controls the number of identity transitions that Drill can make when a user queries a view.

NOTE: The number of identity transitions in controled by the `max_chained_user_hops` option in the `drill-override.conf` file. See Chained Impersonation and Configuring Impersonation and Chaining for more information.

Frank is a senior HR manager at a company. Frank has access to all of the employee data because he is a member of the hr group. Frank created a table named “employees” in his home directory to store the employee data he uses. Only Frank has access to this table.

```
drwx------ frank:hr /user/frank/employees
```

Each record in the employees table consists of the following information: emp_id, emp_name, emp_ssn, emp_salary, emp_addr, emp_phone, emp_mgr

Frank needs to share a subset of this information with Joe who is an HR manager reporting to Frank. To share the employee data, Frank creates a view called emp_mgr_view that accesses a subset of the data. The emp_mgr_view filters out sensitive employee information, such as the employee social security

last-updated: Jun 06, 2024

numbers, and only shows data for the employees that report directly to Joe. Frank and Joe both belong to the mgr group. Managers have read permission on Frank's directory.

```
rwxr----- frank:mgr /user/frank/emp_mgr_view.view.drill
```

The emp_mgr_view.view.drill file contains the following view definition:

```
(view definition: SELECT emp_id, emp_name, emp_salary, emp_addr, emp_phone
FROM `/user/frank/employee` WHERE emp_mgr = 'Joe')
```

When Joe issues SELECT * FROM emp_mgr_view, Drill impersonates Frank when accessing the employee data, and the query returns the data that Joe has permission to see based on the view definition. The query results do not include any sensitive data because the view protects that information. If Joe tries to query the employees table directly, Drill returns an error or null values.

Because Joe has read permissions on the emp_mgr_view, he can create new views from it to give other users access to the employee data even though he does not own the employees table and cannot access the employees table directly.

Joe needs to share employee contact data with his direct reports, so he creates a special view called emp_team_view to share the employee contact information with his team. Joe creates the view and writes it to his home directory. Joe and his reports belong to a group named joeteam. The joeteam group has read permissions on Joe's home directory so they can query the view and create new views from it.

```
rwxr----- joe:joeteam /user/joe/emp_team_view.view.drill
```

The emp_team_view.view.drill file contains the following view definition:

```
(view definition: SELECT emp_id, emp_name, emp_phone FROM `/user/frank/
emp_mgr_view.drill`);
```

When anyone on Joe's team issues SELECT * FROM emp_team_view, Drill impersonates Joe to access the emp_team_view and then impersonates Frank to access the emp_mgr_view and the employee data. Drill returns the data that Joe's team has can see based on the view definition. If anyone on Joe's team tries to query the emp_mgr_view or employees table directly, Drill returns an error or null values.

Because Joe's team has read permissions on the emp_team_view, they can create new views from it and write the views to any directory for which they have write access. Creating views can continue until Drill reaches the maximum number of impersonation hops (chained impersonation).

User Impersonation with Hive

You can configure Drill impersonation with Hive impersonation to authorize access to metadata in the Hive metastore repository and data in the Hive warehouse. Drill impersonation works with Hive when Hive has impersonation enabled and optionally, storage based or SQL standard based authorization enabled. Drill impersonation can also work with Hive when the Hive metastore has Kerberos enabled on a secure cluster. Currently, Drill does not support Hive configured with Sentry authorization.

Storage Based Authorization

Hive storage based authorization is a remote metastore server security feature that uses the underlying filesystem permissions to determine permissions on databases, tables, and partitions. The permissions a user or group has on directories in the filesystem determines access to data. Because the filesystem controls access at the directory and file level, storage based authorization cannot control access to data at the column or view level.

You manage user and group privileges through permissions and access controls in the distributed filesystem. DDL statements that manage permissions, such as GRANT and REVOKE, do not have any effect on permissions in the storage based authorization model.

For more information, see Storage Based Authorization in the Metastore Server.

SQL Standard Based Authorization

The SQL standard based authorization model can control which users have access to columns, rows, and views. SQL standard based authorization is configured in HiverServer2 and enforced during query processing. Users with the appropriate permissions can issue the GRANT and REVOKE statements to manage privileges from Hive.

For more information, see SQL Standard Based Hive Authorization.

Prerequisites

To configure user impersonation with Hive, the system must meet the following requirements:

- Core version 4.1 or later
- Drill installed with Drillbits running as the `mapr` user
- Supported version of Hive installed with the following:
  - User impersonation enabled
  - Configured Hive remote metastore repository
  - (Optional) SQL standard based authorization or storage based authorization configured

NOTE: See EEP Components and OS Support on page 5734 for supported versions of Hive.

Configuration

Complete the steps listed in Configuring User Impersonation with Hive.

Configuring User Impersonation with Hive

Complete the following steps on a secure or insecure cluster to configure user impersonation with Hive:

Step 1: Modify drill-env.sh

Modify `<DRILL_HOME>/conf/drill-env.sh` to include the required environment variables on each Drill node.

Insecure Cluster

On an insecure cluster, include the following environment variable:

```
export MAPR_IMPERSONATION_ENABLED=true
```

Secure Cluster

On a secure cluster, include the following environment variables:

```
export
DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Dja
va.security.auth.login.config=/opt/
mapr/conf/
mapr.login.conf -Dzookeeper.sasl.clien
t=true"
export
DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Dma
pr_sec_enabled=true -Dhadoop.login=map
rsasl_keytab -Dzookeeper.saslprovider=
com.mapr.security.maprsasl.MaprSaslPro
vider -Dmapr.library.flatclass"
export MAPR_TICKETFILE_LOCATION=/opt/
mapr/conf/maprusertícket
```

last-updated: Jun 06, 2024

Step 2: Modify drill-override.conf
For secure and inecure clusters, modify `<DRILL_HOME>/conf/drill-override.conf` on each Drill node to enable impersonation in Drill, and set the maximum number of chained user hops that Drill allows.

Add the following configuration properties to the `drill.exec` block in `drill-override.conf`:

```
drill.exec: {
 cluster-id: "<drill_cluster_name>",
 zk.connect: "<hostname>:5181,<hostname>:5181,<hostname>:5181"
 impersonation: {
       enabled: true,
       max_chained_user_hops: 3
 }
}
```

Step 3: Modify the Hive Storage Plugin in Drill
Modify the Hive storage plugin configuration in the Drill Web UI based on the authorization and security scenario for the cluster. You can only access the Drill Web UI for a running Drillbit.

Complete the following steps to modify the Hive storage plugin configuration:

1. Navigate to `http://<drillbit_hostname>:8047`, and select the **Storage** tab.
2. Click **Update** next to the hive option.
3. In the configuration window, add the required properties based on the authorization type and security scenario:

Storage Based Authorization or No Authorization Enabled

For a *insecure cluster*, add the following properties to the configuration:

```
{
 type:"hive",
 enabled: true,
 configProps : {

"hive.metastore.uris" : "thrift://
<metastore_hostname>:9083",
   "fs.default.name" : "maprfs:///",
   "hive.metastore.sasl.enabled" :
"false",
   "hive.server2.enable.doAs" :
"true",

"hive.metastore.execute.setugi" :
"true"
 }
}
```

For a *secure cluster*, add the following properties to the configuration:

```
{
"type": "hive",
"enabled": true,
"configProps": {
  "hive.metastore.uris": "thrift://
<metastore_hostname>:9083",
  "fs.default.name": "maprfs:///",
  "hive.server2.enable.doAs": "true"
```

last-updated: Jun 06, 2024

```
   }
}
```

Add the following additional properties if the Hive metastore is configured with Kerberos in a secure cluster; include a comma after each line except for the last:

```
"hive.metastore.kerberos.principal":
 "hive/<metastore_thrift_server>"
"hive.metastore.sasl.enabled":
"true"
```

SQL Standard Based Authorization

For an *insecure cluster*, add the following properties to the configuration:

```
{
 type:"hive",
 enabled: true,
 configProps : {
   "hive.metastore.uris" :
"thrift://
<metastore_hostname>:9083",
   "fs.default.name" : "maprfs:///",

"hive.security.authorization.enabled
" : "true",

"hive.security.authenticator.manager
" :
"org.apache.hadoop.hive.ql.security.
SessionStateUserAuthenticator",

"hive.security.authorization.manager
" :
"org.apache.hadoop.hive.ql.security.
authorization.plugin.sqlstd.SQLStdHi
veAuthorizerFactory",
   "hive.metastore.sasl.enabled" :
"false",
   "hive.server2.enable.doAs" :
"false",

"hive.metastore.execute.setugi" :
"false"
 }
}
```

For a *secure cluster*, add the following properties to the configuration:

```
{
"type": "hive",
"enabled": true,
"configProps": {
  "hive.metastore.uris": " thrift://
<metastore_hostname>:9083",
  "fs.default.name": "maprfs:///",

"hive.security.authorization.enabled
```

```
": "true",

"hive.security.authenticator.manager
":
"org.apache.hadoop.hive.ql.security.
SessionStateUserAuthenticator",

"hive.security.authorization.manager
":
"org.apache.hadoop.hive.ql.security.
authorization.plugin.sqlstd.SQLStdHi
veAuthorizerFactory",
  "hive.server2.enable.doAs":
"false",
  "hive.metastore.execute.setugi":
"true"
 }
}
```

Add the following additional properties if the Hive metastore is configured with Kerberos in a secure cluster; include a comma after each line except for the last:

```
"hive.metastore.kerberos.principal":
 "hive/<metastore_thrift_server>"
"hive.metastore.sasl.enabled":
"true"
```

Step 4: Restart Warden
Run the following command on all nodes to restart the Warden service:

```
service mapr-warden restart
```

If you have `clush` installed, you can run the following command to restart Warden on all nodes at once:

```
clush -a "service mapr-warden restart"
```

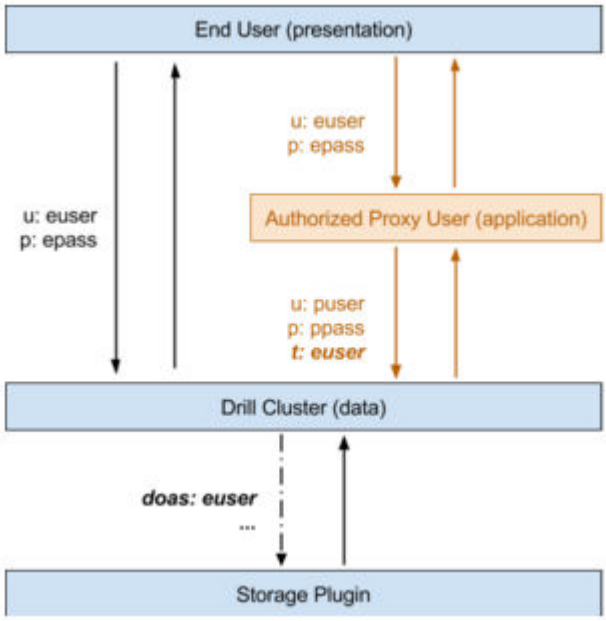
Inbound Impersonation
An administrator can define inbound impersonation policies to impersonate the end user.

Drill supports user impersonation where queries run as the user that created a connection. However, this user is not necessarily the end user who submits the queries. For example, in a classic three-tier architecture, the end user interacts with Tableau Desktop, which communicates with a Tableau Server, which in turn communicates with a Drill cluster. In this scenario, a proxy user creates a connection, and the queries are submitted to Drill by the proxy user on behalf of the end user, and not by the end user directly. In this particular case, the query needs run run as the end user.

The proxy user must be authorized to submit queries on behalf of the specified end user. Otherwise, any user can impersonate another user. The query runs as the end user, and data authorization is based on this user's access permissions. Note that without authentication enabled in both communication channels, a user can impersonate any other user.

Drill trusts proxy users to provide the correct end user identity information. Drill does not authenticate the end user. The proxy user (application) is responsible for end user authentication, which is usually enabled.

The following diagram shows how identity is propagated through various layers (with authentication enabled). The flow on the left is Drill with user impersonation enabled. The flow on the right is Drill with user impersonation and inbound impersonation enabled. `t:euser` is a property on the connection (`u` is `username`, `p` is `password`, `t` is `impersonation_target`).



The following topic provides instructions for configuring inbound impersonation:

Configuring Inbound Impersonation

Administrators can configure inbound impersonation in the `drill-override.conf` file.

Complete the following steps to enable inbound impersonation:

1. If user impersonation is not enabled, you must enable it before configuring inbound impersonation. To enable user impersonation, edit `/opt/mapr/drill/drill-<version>/drill-override.conf` and set the option to true, as shown:

```
{
      drill.exec.impersonation.enabled: true,
      ...
      }
```

2. Define inbound impersonation policies. For example, the following ALTER SYSTEM statement authorizes:

   - `puser1` to impersonate any user (use * as a wildcard character)
   - `puser2` to impersonate `euser1` and all users in `egroup2`
   - all users in `pgroup3` to impersonate all users in `egroup3`

```
ALTER SYSTEM SET `exec.impersonation.inbound_policies`='[
  { proxy_principals : { users: ["puser1"] },
    target_principals: { users: ["*"] } },
  { proxy_principals : { users: ["puser2"] },
    target_principals: { users: ["euser1"], groups :  ["egroup2"] } },
  { proxy_principals : { groups: ["pgroup3"] },
    target_principals: { groups: ["egroup3"] } } ]';
```

   Policy format:

```
{ proxy_principals : { users : ["...", "..."], groups : ["...", "..."] },
  target_principals: { users : ["...", "..."], groups : ["...",
"..."] } }
```

last-updated: Jun 06, 2024

3. Ensure that the proxy user (application) passes the username of the impersonation target user to Drill when creating a connection through the `impersonation_target` connection property. For example, through sqlline:

```
bin/sqlline -u
"jdbc:drill:schema=dfs;zk=myclusterzk;impersonation_target=euser1" -n
puser1 -p ppass1
```

NOTE: In this example, `puser1` is the user submitting the queries. This user is authenticated. Since this user is authorized to impersonate any user, queries through the established connection are run as `euser1`.

More information

https://drill.apache.org/docs/configuration-options-introduction/#system-options

Default Security (Tickets)

Drill supports authentication and encryption through the Default (tickets) security mechanism. Authentication is the process of establishing confidence of authenticity. Encryption is the process of converting information or data from plain text into ciphertext to prevent unauthorized access. An administrator can manually configure Drill to use Default Security. When Default Security is enabled, all Drill clients, such as JDBC and ODBC, must connect to Drillbits through Default Security.

The Default Security mechanism secures the communication path between the Drill client, such as JDBC/ODBC and Drillbit, Drillbit and ZooKeeper, and also between Drillbits.

NOTE: The Drill web communication path (web client to web server) does not support Default Security-based authentication and encryption.

NOTE: The Apache JDBC driver packaged with Drill does not support Default Security.

Configuration parameters in the Drill startup configuration file, `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`, enable or disable authentication and encryption.

Prerequisites

- Ensure that your cluster is secure. To manually configure secure clusters with Default Security, see Enable Wire-Level Security.
- When you configure Drill to use encryption, authentication must also be configured and enabled with the encryption-specific configurations.
- For encryption and authentication to work together, the Drill client and Drillbits must all run Drill 1.11 or later. Drill clients running earlier versions of Drill cannot connect to Drillbits when encryption is enabled.
- The client-side should have created a user mapr ticket for the authenticating user. See maprlogin for more information.

Post-requisite

You must restart the Drillbit process on each node after you enable security and/or modify the configuration options, as shown:

```
$ maprcli node services -name drill-bits -action restart -nodes <node host
names separated by a space>
```

Download and configure the JDBC or ODBC Drill drivers. See Drill Drivers for more information.

The following topics provide configuration information to enable authentication and encryption in Drill:

last-updated: Jun 06, 2024

Configuring Authentication
An administrator can enable Default Security as the only authentication mechanism, or in addition to other mechanisms, such as Kerberos and Plain authentication in `drill-override.conf`.

NOTE: When Drill is installed on the MapR Data Platform, Drill distribution defaults are stored in the `drill-distrib.conf` file. To override the defaults, you must explicitly disable them in the `drill-override.conf` file.

The following sections provide configuration examples for several configuration scenarios:

NOTE: For client-side configuration, see Drill Drivers.

Example 1: Drill Client to Drillbit Authentication using Default Security Only

```
drill.exec:{
              security: {
                 user.auth.enabled: true,
                 auth.mechanisms : ["MAPRSASL"]
          }
}
```

NOTE: Drill executes all queries as a service or process user when impersonation is disabled.

Example 2: Drill Client to Drillbit Authentication with User Impersonation using Default

```
drill.exec:{
                security: {
                   user.auth.enabled: true,
                   auth.mechanisms : ["MAPRSASL"],
                    }
                impersonation: {
                   enabled: true,
                   max_chained_user_hops: 3
              }
        }
```

NOTE: Drill executes all queries as the authenticated (ticket) user when impersonation is enabled. The client to Drillbit communication path will not be encrypted.

Example 3: Drill Client to Drillbit using Multiple Authentication Mechanisms

```
drill.exec:{
                 security: {
                     user.auth.enabled: true,
                     user.auth.impl: "pam4j",
                     security.user.auth.packages +=
"org.apache.drill.exec.rpc.user.security",
                     user.auth.pam_profiles: ["sudo", "login",
"mapr-admin"],
                     auth.mechanisms : ["MAPRSASL", "KERBEROS", "PLAIN"],
                     auth.principal : "mapr/_host@REALM.COM",
                     auth.keytab : "/opt/mapr/conf/mapr.keytab"
                   },
                  impersonation: {
                    enabled: true,
                    max_chained_user_hops: 3
              }
```

last-updated: Jun 06, 2024

```
          }
```

Example 4: Drillbit to Drillbit Authentication using Default Security

```
drill.exec:{
              security: {
                  auth.mechanisms : ["MAPRSASL"],
                  bit.auth.enabled : true
                  bit.auth.mechanism : "MAPRSASL"
       }
}
```

Example 5: Drill Client to Drillbit and Drillbit to Drillbit Authentication using Default Security

```
drill.exec {
              security: {
                  user.auth.enabled: true,
                  auth.mechanisms : ["MAPRSASL"],
                  bit.auth.enabled : true,
                  bit.auth.mechanism : "MAPRSASL"
                      },
              impersonation: {
                   enabled: true,
                   max_chained_user_hops: 3
              }
           }
```

Configuring Encryption
An administrator can enable encryption with Default Security (tickets).

NOTE: When the `sasl_encrypt` (for JDBC) or `EnforceSaslEncrypt` (for ODBC) connection parameter is set to `"true"` or `1`, the Drill client only accepts encrypted connections. If the client tries connecting to a Drillbit with encryption disabled, the connection fails.

NOTE: For client-side configuration, see Drill Drivers.

Set the encryption options to `"true"` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`.

The following table lists the encryption configuration options with their descriptions and default values:

NOTE: If you installed Drill on a cluster that was installed with the default security configuration, the following options are set to "true" by default.

Option	Description	Default
drill.exec.security.user.encryption.sasl.enabled	Determines if encryption on the server is enabled for negotiating privacy with the Drill client.	false
drill.exec.security.bit.encryption.sasl.enabled	Determines if the server is enabled for negotiating privacy with another Drillbit.	false

The following sections provide configuration examples for Drill client to Drillbit encryption and Drillbit to Drillbit encryption.

last-updated: Jun 06, 2024

Example 1: Drill Client to Drillbit Connection with Default Security Authentication and Encryption
In the following server configuration, the Drill client connection to the Drillbit is encrypted using the Default Security mechanism when the client is running with encryption support.

NOTE: Drill clients running Drill 1.10 and earlier cannot connect to the Drillbit through Default Security with encryption enabled.

```
drill.exec {
            security: {
                user.auth.enabled: true,
                auth.mechanisms : ["MAPRSASL"]
                user.encryption.sasl.enabled : true
                    }
                }
```

NOTE: Drill executes all queries as a service or process user when impersonation is disabled.

Example 2: Drillbit to Drillbit Connection with Default Security Authentication and Encryption
The following configuration authenticates and encrypts the path between Drillbits using the Default Security mechanism.

```
drill.exec {
              security: {
                  auth.mechanisms : ["MAPRSASL"],
                  bit.auth.enabled : true
                  bit.auth.mechanisms : "MAPRSASL"
                  bit.encryption.sasl.enabled : true
        }
}
```

Example 3: Drill Client to Drillbit and Drillbit to Drillbit Connection with Default Security Authentication and Encryption
The following configuration authenticates and encrypts the path between the Drill client and Drillbit, and between Drillbits using the Default Security mechanism.

```
drill.exec {
              security: {
                 user.auth.enabled: true,
                 auth.mechanisms : ["MAPRSASL"],
                 user.encryption.sasl.enabled : true

                 bit.auth.enabled : true
                 bit.auth.mechanism : "MAPRSASL"
                 bit.encryption.sasl.enabled : true
                    }
                }
```

NOTE: Drill executes all queries as a service or process user when impersonation is disabled.

Example 4: Drill Client to Drillbit and Drillbit to Drillbit Connection with Default Security Authentication and Encryption and Impersonation Enabled
The following configuration authenticates and encrypts the path between the Drill client and Drillbit, and between Drillbits using the Default Security mechanism.

```
drill.exec {
              security: {
                 user.auth.enabled: true,
```

last-updated: Jun 06, 2024

```
                auth.mechanisms : ["MAPRSASL"],
                user.encryption.sasl.enabled : true

                bit.auth.enabled : true
                bit.auth.mechanism : "MAPRSASL"
                bit.encryption.sasl.enabled : true
                   },
          impersonation: {
                 enabled: true,
                 max_chained_user_hops: 3
            }
        }
```

NOTE: Drill executes all queries as the authenticated (ticket) user when impersonation is enabled.

Example 5: Drill Client to Drillbit Authentication and Encryption Enabled using Multiple Mechanisms and Drillbit to Drillbit Authentication using Default Security
The following configuration authenticates and encrypts the connection between the Drill client and Drillbit using multiple authentication mechanisms, and also authenticates and encrypts the connection between Drillbits using the Default security mechanism.

NOTE: Plain authentication not supported in this configuration.

```
drill.exec {
            security: {
                user.auth.enabled: true,
                auth.mechanisms : ["MAPRSASL", "KERBEROS"],
                auth.principal : "mapr/_host@REALM.COM",
                auth.keytab : "/opt/mapr/conf/mapr.keytab",
                user.encryption.sasl.enabled : true,
                bit.auth.enabled : true,
                bit.auth.mechanism : "MAPRSASL",
                bit.encryption.sasl.enabled : true
                    }
            impersonation: {
                enabled: true,
                max_chained_user_hops: 3
            }
         }
```

NOTE: Drill executes all queries as a service or process user when impersonation is disabled.

Kerberos
Drill supports Kerberos v5 network security authentication and encryption. Kerberos is a network authentication protocol built on symmetric-key cryptography. Kerberos eliminates the need to store passwords locally or send them over the network and reduces the risk of impersonation.

Kerberos provides a security infrastructure called a Kerberos Realm. A Kerberos Realm is comprised of clients, services or hosts, and a KDC (key-distribution center). The KDC is a trusted third-party service that generates tickets to coordinate authentication between a client and server or host. Tickets are cached on the client machine, which allows for single sign-on.

Clients use a password or a special file called a “keytab” to get tickets from the KDC. Clients exchange the tickets and secret keys with the KDC and service or host to prove their identity for access to the requested service. This authentication process of exchanging tickets and secret keys runs in the background, unseen by the user trying to access the service. When a client request to access a service is granted, a unique session key is established between the client and service. The unique session key proves the authenticity of the user. The session key is used for all communication between the client and service. Kerberos also

supports encryption between the client and server to prevent data theft from a man-in-the-middle attack during communication.

A KDC administrator must create the password or keytab for the clients and servers, as well as a principal (a name for the user or server identity) to securely authenticate using the Kerberos infrastructure.

NOTE: Proper setup, configuration, administration, and usage of a Kerberos environment is beyond the scope of this documentation. See the MIT Kerberos documentation for more detailed information about Kerberos.

The following sections list the prerequisites for using Kerberos with Drill and describe the authentication process.

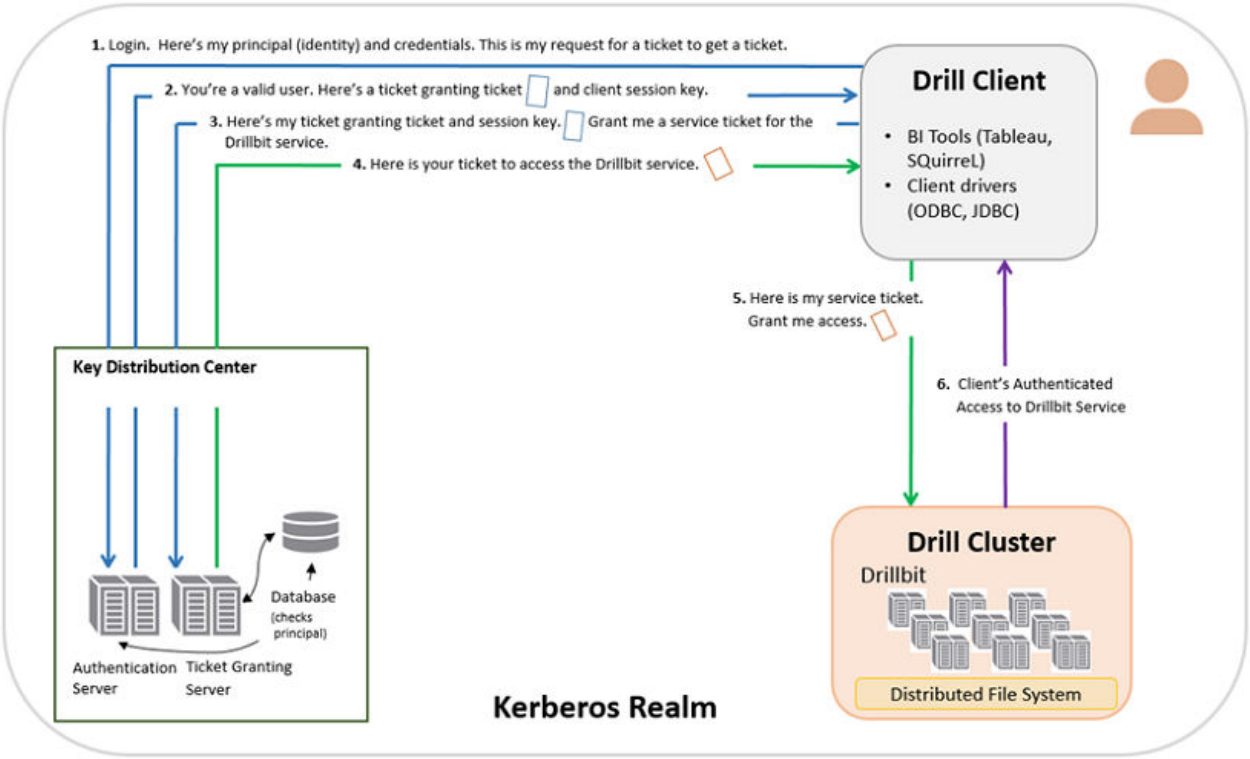
Prerequisites

- The MapR Drill driver includes the required Kerberos plugin to authenticate to secure Kerberos Drill clusters. To use Kerberos with Drill, you must have a working Kerberos infrastructure, which Drill does not provide.
- Either a ticket granting ticket (TGT) is pre-generated on the client node, or a keytab file and the client principal is available to provide in the connection URL for Kerberos authentication between the Drill client and Drill server. Drill does not generate the TGT.
- You must be working in a Linux-based or Windows Active Directory (AD) Kerberos environment with secure clusters and have a Drill server configured for Kerberos.

Client Authentication Process

This section provides a high-level overview of the Kerberos client authentication process. For this overview, assume that Kerberos credentials are present in the client.

The following diagram shows the process of authenticating a client:



last-updated: Jun 06, 2024

1. The client sends a request for a ticket granting ticket that contains the user principal to the Kerberos KDC, a network service that supplies tickets and temporary session keys.
2. The authentication server validates the principal's identity and sends the client a ticket granting ticket and session key encrypted with a secret key. A session key is a temporary encryption key used for one login session.
3. Using the ticket granting ticket, the principal requests access to a Drillbit service from the ticket granting server.
4. The ticket granting server checks for a valid ticket granting ticket and the principal identity. If the request is valid, the ticket granting server returns a ticket granting service ticket.
5. The client uses the service ticket to request access to the Drillbit.
6. The Drillbit service has access to the keytab, a file that contains a list of keys for principals. The key allows the service to decrypt the client's ticket granting service ticket, identify the principal, and grant access.

Server Authentication Process

For Kerberos server authentication information, see the MIT Kerberos administration documentation.

Configuring Drill with Kerberos

The topics listed below provide configuration and connection information.

Configuring Authentication and Encryption
To enable authentication and encryption, you must create a Kerberos principal identity and a keytab file. You add the principal and keytab file to `<DRILLINSTALL_HOME>/conf/drill-override.conf` with the specified configuration parameters. In addition, you can configure a mapping from a Kerberos principal to a Drill user account. This mapping is used by a Drillbit to convert an authenticated client principal to a corresponding Kerberos short name, which is used to determine administrator privileges for the client principal. After you complete the configuration steps, restart the Drillbit.

To enable authentication and encyption using the Kerberos mechanism, configure the following Kerberos-specific parameters in `drill-override.conf`:

NOTE: Only Drill 1.11 and later supports encryption.

NOTE: For client-side configuration, see Drill Drivers.

Parameters	Communication Path	Description	Default
drill.exec.security.auth.principal	Drill client (ODBC/ JDBC) to Drillbit	String representation of the Kerberos principal used by the Drillbit service.	N/A
drill.exec.security.auth.keytab	Drill client (ODBC/ JDBC) to Drillbit	Location of the keytab file for the configured Drillbit service principal. **NOTE:** The Kerberos keytab file that contains the encrypted key for the Drillbit service principal. The file should be readable by the Drillbit process user.	N/A

last-updated: Jun 06, 2024

Parameters	Communication Path	Description	Default
drill.exec.security.auth.auth_to_local	Drill client (ODBC/JDBC) to Drillbit	Custom rules to convert the Kerberos principal to the Kerberos short name. **NOTE:** Drill uses a Hadoop Kerberos name and rules to transform the Kerberos principal provided by client to the one it will use internally as the client's identity. This client identity is used to determine administrator privileges. See Mapping from Kerberos Principal to OS user account in the Hadoop in Secure Mode documentation for details about how the rule works.	The primary name of the Kerberos principal. By default, this mapping rule extracts the first part from the provided principal. For example, if the principal format is `<Name1>/<Name2>@realm`, the default rule extracts only `Name1` from the principal and `Name1` as the client's identity on server side.
drill.exec.security.user.encryption.sasl.enabled	Drill client (ODBC/JDBC) to Drillbit	Enables/disables encryption for the communication path between the Drill client and Drillbit.	false
drill.exec.security.bit.auth.use_login_principal	Drilbit to Drillbit	When set to true, the Drillbit uses the same logged in service principal configured with drill.exec.security.auth.principal for the Drillbit to Drillbit communication paths. When this parameter is set to false, a principal is constructed using the hostname from ZooKeeper for the remote Drillbit and keeping the primary and realm information the same as the logged in principal set by drill.exec.security.auth.principal .	false
drill.exec.security.bit.encryption.sasl.enabled	Drillbit to Drillbit	Enables/disables encryption for the communication path between the Drillbits.	false

Steps to Enable Kerberos Authentication and Encryption

Complete the following steps to enable Drill to use Kerberos for authentication and encryption:

1. Create a Kerberos principal identity and a keytab file. You can create one principal for each Drill node or one principal for all Drillb nodes in a cluster.

   For one principal per Drill node in the cluster:

   ```
   # kadmin
   : addprinc -randkey <username>/<FQDN>@<REALM>.COM
   : ktadd -k /opt/mapr/conf/drill.keytab <username>/<FQDN>@<REALM>.COM
   ```

   For one principal for all Drill nodes in the cluster: Use `<clustername>` instead of `<FQDN>`:

   ```
   # kadmin
   : addprinc -randkey <username>/
   ```

last-updated: Jun 06, 2024

```
<clustername>@<REALM>.COM
    : ktadd -k /opt/mapr/
conf/drill.keytab <username>/
<clustername>@<REALM>.COM
```

IMPORTANT: When creating the Kerberos principal identity and keytab file, note the following requirements:

- The administrator must own the `drill.keytab` file and have the ability to read the file.
- The instance name must be lowercase. If _HOST is set as the instance name in the principal, it is replaced with the fully qualified domain name of that host for the instance name. For example, if Drill running on `host01.aws.labuses drill/_HOST@<EXAMPLE>.COM` as the principal, the canonicalized principal is `drill/host01.aws.lab@<EXAMPLE>.COM`.
- When Drill runs on a secure cluster (maprsasl enabled), the username in the Drill service principal must correspond with the user running the Drill process. By default, the user is mapr:

```
mapr/_HOST@<EXAMPLE>.COM
```

2. Add the Kerberos principal identity, keytab file, and parameters specific to Kerberos to the `drill-override.conf` file. You can use the following configuration examples for enabling authentication, encryption, or both between the Drill client and Drillbit and between Drillbits.

Example 1: Enabling Kerberos Authentication Between the Drill Client and Drillbit

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {

user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab"
              }
        }
```

Example 2: Enabling Kerberos Authentication and Encryption Between the Drill Client and Drillbit

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {
```

```
user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab",

user.encryption.sasl.enabled: true
              }
            }
        }
```

Example 3: Enabling Kerberos Authentication Between Drill Client and Drillbits and Between Drillbits

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {

user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab"
              }
        security.bit: {
                auth.enabled: true,
                auth.mechanism:
"Kerberos",

auth.use_login_principal: true
              }
        }
```

Example 4: Enabling Kerberos Authentication and Encryption Between Drill Client and Drillbits and Between Drillbits

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {

user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
```

```
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab",

user.encryption.sasl.enabled: true
              }
        security.bit: {
                auth.enabled: true,
                auth.mechanism:
"Kerberos",

auth.use_login_principal: true,

encryption.sasl.enabled: true
              }
        }
```

NOTE: In examples 3 and 4 above, the Drillbit will use the same logged in service principal as configured in `drill.exec.security.auth.principal`.

Example 5: Enabling Kerberos Authentication and Encryption Between Drill Client and Drillbits and Between Drillbits. For Drillbit to Drillbit authentication, where the service principal is created using the hostname from ZooKeeper for a remote Drillbit as an instance name. The primary and the realm component of the service principal is used from the drill.exec.security.auth.principal parameter.

```
      drill.exec: {
        cluster-id: "drillbits1",
        zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.la
b:5181,qa102-83.qa.lab:5181",
        impersonation: {
          enabled: true,
          max_chained_user_hops: 3
        },
        security: {

user.auth.enabled:true,
                auth.mechanisms:
["KERBEROS"],

auth.principal:"drill/
<clustername>@<REALM>.COM",
                auth.keytab:"/etc/
drill/conf/drill.keytab",

user.encryption.sasl.enabled: true
              }
        security.bit: {
                auth.enabled: true,
                auth.mechanism:
"Kerberos",

encryption.sasl.enabled: true
              }
        }
```

NOTE: For the configuration in example 5, if the hostname of the remote Drillbit known to ZooKeeper is **host01.aws.lab**, then the service principal used by a Drillbit to authenticate with the remote Drillbit will be **drill/host01.aws.lab@<REALM>.COM**.

last-updated: Jun 06, 2024

3. Restart the Drillbit process on each Drill node.

```
$ maprcli node services -name drill-bits -action restart -nodes <node
host names separated by a space>
```

Related concepts

Plain Authentication on page 4050
An administrator can configure Drill to use the Linux pluggable authentication module (PAM) for Plain (username and password) authentication. PAM provides an authentication module that interfaces with any installed PAM authentication entity, such as the local operating system password file (/etc/passwd) or LDAP.

Configuring Drill to Use Kerberos with Hive Metastore

To configure Drill to use Kerberos with the Hive metastore, modify the hive storage plugin in the Drill Web UI and then restart the Warden service.

NOTE: When you configure Drill to use Kerberos with the Hive metastore, Drill submits requests to the Hive metastore as the `mapr` superuser. If you want Drill to submit requests to the Hive metastore as any other user, configure Drill impersonation with Hive instead of performing this task. Drill impersonation works with or without Kerberos configured for the Hive metastore.

Prerequisites

The configurations described in this document have the following dependencies:

- Data Fabric cluster.
- Drill installed with Drillbits running as the `mapr` user.
- Supported version of Hive installed with the following:
  - Hive Metastore configured to use Kerberos authentication
  - Configured Hive remote metastore repository

NOTE: See the Drill Support Matrix on page 5793 for supported versions of Hive.

Modify the Hive Storage Plugin in Drill

Modify the Hive storage plugin configuration in the Drill Web UI based on the authorization and security scenario for the cluster. You can only access the Drill Web UI for a running Drillbit.

Complete the following steps to configure Drill to use Kerberos with Hive Metastore:

1. Navigate to `http://<drillbit_hostname>:8047`, and select the **Storage** tab.

   NOTE: You can only access the Drill Web UI for a running Drillbit.

2. Click **Update** next to the hive option.

3. In the configuration window, add the `hive.metastore.sasl.enabled`, `hive.metastore.kerberos.principal`, and `hive.security.authorization.enabled` properties, as shown below, if configuration does not contain them already. Note that other properties shown may or may not be required in your environment:

```
{
  "type": "hive",
  "enabled": true,
  "configProps": {
    "hive.metastore.uris": "thrift://<metastore_hostname>:9083",
    "fs.default.name": "maprfs:///",
    "hive.server2.enable.doAs": "false",
    "hive.metastore.sasl.enabled": "true",
    "hive.metastore.kerberos.principal":
"<metastore_server_principal_name>",
    "hive.security.authorization.enabled": "true"
  }
}
```

Restart Warden

Issue the following command on all nodes to restart the Warden service:

```
service mapr-warden restart
```

If you have `clush` installed, you can run the following command to restart Warden on all nodes at once:

```
clush -a "service mapr-warden restart"
```

Connection URLs for Kerberos using JDBC Drivers to connect via SQLLine
You can use client-side connection URL parameters for Kerberos authentication in multiple combinations to authenticate a client with Drill.

Client Credentials

A client can provide its credentials in two ways:

- With a ticket granting ticket (TGT) generated on client side. The TGT must be present on client node; Drill does not generate the TGT.
- With a keytab file and the client principal provided in the user property of the connection URL.

Configuration Options

The following table lists configuration options for connection URLs. See the Connection URL Examples section for sample URLs.

Connection Parameter (Apache Drill JDBC Driver)	Description	Connection Parameter (Drill JDBC Driver)	Mandatory/Optional	Default Value
auth	Authentication mechanism. The value is deduced if not specified. Kerberos if principal is provided. Plain if a user and password is provided. A Drill client can also explicitly specify a particular authentication mechanism to use using this parameter. For example, for Kerberos along with service_name, service_host or principal and for the Plain authentication with username and password.	auth	Optional	The preference order is Kerberos and Plain.
principal	Drillbit service principal. The format of the principal is primary/instance@realm. For Kerberos, the Drill service principal is derived if the value is not provided using this configuration. service_name (primary) and service_host (instance) are used to generate a valid principal. Since the ticket or keytab contains the realm information, the realm is optional.	principal	Optional	

last-updated: Jun 06, 2024

keytab	For Kerberos, if you authenticate using a keytab, set the keytab parameter to the location of the keytab file. This is passed through the user parameter. A Kerberos ticket is used as the default credential (It is assumed to be present on the client-side. The Drill client does not generate the required credentials.)	If the client chooses to use a keytab rather than a ticket, the Kerberos client principal must be provided	Optional	
sasl_encrypt	When set to true, ensures that a client connects to a server with encryption capabilities. For example, Drill 1.11 clients require Drillbits, which support client-to-drillbit encryption.		Optional	FALSE
service_name	Primary name of the Drillbit service principal.		Optional	drill
service_host	Instance name of the Drillbit service principal.		Optional	Since this value is usually the hostname of the node where a Drillbit is running, the default value is the Drillbit hostname is provided either through ZooKeeper or through a direct connection string.
realm	Kerberos realm of the principal. The realm information.	Kerberos realm name for the Drillbit service ticket or keytab contains the realm	Optional	

Client Encryption

A client can specify that it requires a server with encryption capabilities only by setting the

`sasl_encrypt` connection parameter to "true." If the cluster to which client is connecting has encryption disabled, the client will fail to connect to that server.

```
drill.exec {
 security:  {
      user.auth.enabled: true,
      auth.mechanisms: ["KERBEROS"],
      auth.principal: "drill/serverhostname@REALM.COM",
      auth.keytab: "/etc/drill/conf/drill.keytab",
      user.encryption.sasl.enabled: true
          }
}
```

Connection URL Examples

The following five examples show the JDBC connection URL that the embedded JDBC client uses for Kerberos authentication. The first section, Example of a Simple Connection URL, includes a simple connection string and the second section, Examples of Connection URLs Used with Previously Generated TGTs, includes examples to use with previously generated TGTs.

Example of a Simple Connection URL

Example 1: TGT for Client Credentials

The simplest way to connect using Kerberos is to generate a TGT on the client side. Only specify the service principal in the JDBC connection string for the Drillbit the user wants to connect to.

```
jdbc:drill:drillbit=10.10.10.10;principal=<principal for host 10.10.10.10>
```

In this example, the Drill client uses the:

- Default `service_name`, which is **`drill`**.
- `service_host` from the Drillbit name provided in the connection URL, which is **`10.10.10.10`**.

The service principal format is `<primary>/<instance>@<realm from TGT>`. The service principal is **`principal for host 10.10.10.10`**.

Examples of Connection URLs Used with Previously Generated TGTs

If you do not provide a service principal in the connection string when using Kerberos authentication, then use the `service_name` or `service_host` parameters. Since these parameters are optional, their default values will be used internally (if not provided) to create a valid principal.

Examples 2 through 4 show a valid connection string for Kerberos authentication if a client has previously generated a TGT. Realm information will be extracted from the TGT if it is not provided.

NOTE: For end-to-end authentication to function, it is assumed that the proper principal for the Drillbit service is configured in the KDC.

Example 2: Drillbit Provided by Direct Connection String and Configured with a Unique Service Principal

This type of connection string is used when:

- Each Drillbit in the cluster is configured with its own service principal.
- The instance component is the host address of the Drillbit.

  `jdbc:drill:drillbit=host1;auth=kerberos`

In this example, the Drill client uses the:

- Default `service_name`, which is **`drill`**.

- `service_host`, which is the Drillbit name provided in the connection URL (**`host1`**).

The internally created service principal will be **`drill/host1@<realm from TGT>`**.

Example 3: Drillbit Selected by ZooKeeper and Configured with Unique Service Principal

This type of connection string is used when the Drillbit is chosen by ZooKeeper instead of directly from the connection string.

```
jdbc:drill:zk=host01.aws.lab:5181;auth=kerberos;service_name=myDrill
```

In this example, the Drill client uses the:

- Provided `service_name`, which is **`myDrill`** as the primary name of the principal.
- `service_host` as the address of the Drillbit, which is chosen from the list of active drillbits that ZooKeeper provides (**`host01.aws.lab:5181`**).

The internally created service principal will be **`myDrill/<host address from zk>@<realm from TGT>`**.

Example 4: Drillbit Selected by Zookeeper and Configured with a Common Service Principal

This type of connection string is used when all Dillbits in a cluster use the same principal.

```
jdbc:drill:zk=host01.aws.lab:5181;auth=kerberos;service_name=myDrill;service
_host=myDrillCluster
```

In this example, the Drill client uses the:

- Provided `service_name`, which is **`myDrill`**.
- `service_host`, which is **`myDrillCluster`**.

The internally created service principal, which will be **`myDrill/myDrillCluster@<realm from TGT>`**.

Example 5: Keytab for Client Credentials

If a client chooses to provide its credentials in a keytab instead of a TGT, it must also provide a principal in the user parameter. In this case, realm information will be extracted from the `/etc/krb5.conf` file on the node if it is not provided in the connection URL. All other parameters can be used as shown in the preceding examples (1-4). This connection string is for the case when all Drillbits in a cluster use the same principal.

```
jdbc:drill:zk=host01.aws.lab:5181;auth=kerberos;service_name=myDrill;service
_host=myDrillCluster;keytab=<path to keytab file>;user=<client principal>
```

In this example, the Drill client:

- Will authenticate itself with the:
  - Keytab (**`path to keytab file`**) and
  - Principal provided in the user parameter (**`client principal`**)
- Uses the:
  - Provided `service_name`, which is **`myDrill`**.
  - `service_host`, which is **`myDrillCluster`**.

The internally created service principal will be **`myDrill/myDrillCluster@<realm from krb5.conf>`**.

last-updated: Jun 06, 2024

Plain Authentication

An administrator can configure Drill to use the Linux pluggable authentication module (PAM) for Plain (username and password) authentication. PAM provides an authentication module that interfaces with any installed PAM authentication entity, such as the local operating system password file (/etc/passwd) or LDAP.

NOTE: Starting in EEP 5.0, Drill supports form-based authentication between the web client and Drillbit. Form-based authentication is like Plain authentication in that a user is presented with a web form where s/he enters a username and password to access restricted web pages. Configuring Drill to Use libpam4j includes configuration details. When using form-based authentication, you can also configure Drill to use SPNEGO. See SPNEGO for HTTP Authentication.

When using PAM for authentication, each user with permission to run Drill queries must exist in the list of users that resides on each Drill node in the cluster. The username (including uid) and password for each user must be identical across all Drill nodes.

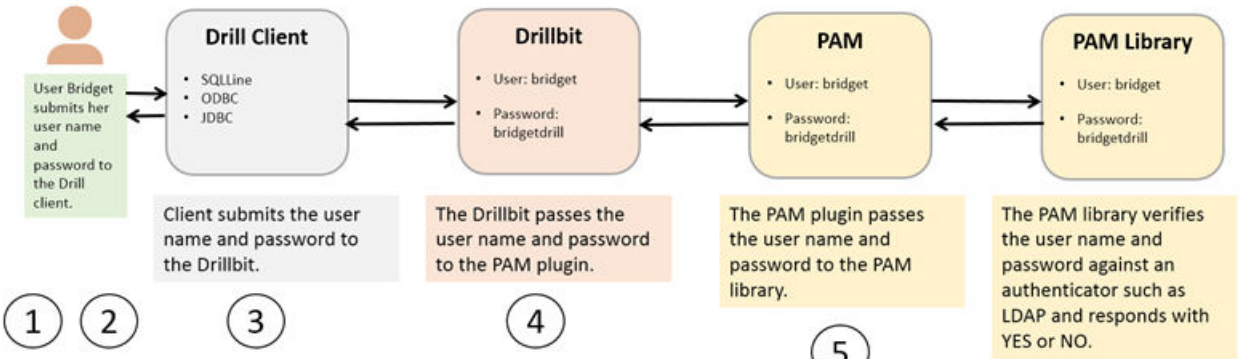
If you use PAM with /etc/passwd for authentication, verify that the users permitted to start the Drill process are part of the shadow user group on all nodes in the cluster. This enables Drill to read the /etc/shadow file for authentication.

NOTE: Plain authentication does not support SASL encryption. You can use SSL/TLS for encryption when Plain authentication is enabled. You can also enable user impersonation and create views to limit user access to data.

Authentication Process Overview

During the authentication process, the client passes a username and password to the Drillbit as part of the connection request, which then passes the credentials to PAM. If PAM authenticates the user, the connection request passes the authentication phase, and the connection is established. The user will be authorized to access Drill and issue queries against the filesystem or other storage plugins, such as Hive.

The following image illustrates the PAM user authentication process in Drill:



Plain (Username and Password) Authentication Process

If PAM cannot authenticate the user, the connection request does not pass the authentication phase and the user will not be authorized to access Drill. The connection is terminated as AUTH_FAILED.

For more PAM information (including a JPAM User Guide), see JPAM.

Configuring Plain Authentication in Drill

Drill supports the libjpam and libpam4j libraries. In Drill 1.12 and later, the libpam4j library is packaged with Drill. There is no download or external dependency required to use libpam4j. Using libpam4j is recommended for Drill 1.12 and later.

last-updated: Jun 06, 2024

NOTE: You can configure Drill to use multiple types of authenication mechanisms. For example, you can configure Drill to use Plain, Kerberos, and data-fabric-SASL; however, only SSL/TLS is supported for encryption when Plain authentication is configured with other authentication mechanisms.

The following sections provide information for configuring Drill to use libpam4j or libjpam, as well as instructions for connecting to Drill from SQLLine and BI tools when Plain authentication is enabled:

Configuring Drill to Use libpam4j
You can configure Drill to use libpam4j for Plain authentication between a client, such as ODBC, and the Drillbit.

Starting in EEP 5.0, you can configure Drill to use libpam4j for form-based authentication between a web client and Drillbit (web server). Form-based authentication is like Plain authentication in that a user is presented with a web form where s/he enters a username and password to access restricted web pages. When using form-based authentication, you can also configure Drill to use SPNEGO. See SPNEGO for HTTP Authentication.

Complete the following steps to configure Plain authentication (for JDBC/ODBC clients) and form-based authentication (for the web client) in Drill:

1. Add the following configurations to the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file:

```
drill.exec:{
   cluster-id:"drillbits1",

zk.connect:"<zk-node-hostname>:5181,<zk-node-hostname>:5181,<zk-node-host
name>:5181",
   security:{
      auth.mechanisms:[ "PLAIN"],
   },
   security.user.auth:{
      enabled:true,
      packages += "org.apache.drill.exec.rpc.user.security",
      impl:"pam4j",
      pam_profiles:[ "sudo", "login" ]
   },
   http.auth.mechanisms:[ "FORM" ]
}
```

2. (Optional) To add or remove different PAM profiles, add or delete the profile names in the `pam_profiles` array portion of the configuration:

```
pam_profiles: [ "sudo", "login" ]
```

3. Restart the Drillbit process on each Drill node, as shown:

```
/opt/mapr/drill/drill-<version>/bin/drillbit.sh restart
```

Configuring Drill to Use libjpam
You can configure Drill to use libjpam for Plain authentication between a client, such as ODBC, and the Drillbit.

To configure Drill to use libjpam, complete the following steps:

1. Copy the libjpam.so file from /opt/mapr/lib to a directory that does not contain other Hadoop components, for example /opt/pam/.

2. Add the following line to /opt/mapr/drill/drill-<version>/conf/drill-env.sh, including the directory where the libjpam.so file is located, as shown:

```
export
DRILLBIT_JAVA_OPTS="$DRILLBIT_JAVA_OPTS -Djava.library.path=<directory>"
Example: export
DRILLBIT_JAVA_OPTS="$DRILLBIT_JAVA_OPTS -Djava.library.path=/opt/pam/"
```

3. Add the following configuration to the drill.exec block in /opt/mapr/drill/drill-<version>/conf/drill-override.conf:

```
drill.exec: {
             cluster-id: "drillbits1",
             zk.connect:
"qa102-81.qa.lab:5181,qa102-82.qa.lab:5181,qa102-83.qa.lab:5181",
             impersonation: {
               enabled: true,
               max_chained_user_hops: 3
          },
             security: {
                auth.mechanisms : ["PLAIN"],
                 },
              security.user.auth: {
                enabled: true,
                packages += "org.apache.drill.exec.rpc.user.security",
                impl: "pam",
                pam_profiles: [ "sudo", "login", "mapr-admin" ]
        }
       }
```

4. (Optional) To add or remove different PAM profiles, add or delete the profile names in the pam_profiles array portion of the configuration:

```
pam_profiles: [ "sudo", "login" ]
```

5. Restart the Drillbit process on each Drill node, as shown:

```
/opt/mapr/drill/drill-<version>/bin/drillbit.sh restart
```

Connection URL for Plain Authentication using the Apache JDBC Driver to connect via SQLLine
When Plain authentication is enabled, each user that accesses the Drillbit process through a client, must provide username and password credentials for access.

Connecting to Drill from SQLLine

Include the `-n` and `-p` parameters with your username and password when launching SQLLine, as shown in the following example:

```
sqlline -u jdbc:drill:zk=10.10.11.112:5181 -n <username> -p <password>
```

Alternatively, you can launch SQLLine and then issue the `!connect` command to hide the password.

Complete the following steps to hide the password:

1. Run the sqlline script, as shown:

```
$ /etc/drill/bin/sqlline
```

2. At the prompt, enter the `!connect` command followed by

```
jdbc:drill:zk=zk=<zk name>[:<port>][,<zk name2>[:<port>]...]
```

, as shown:

```
`sqlline> !connect jdbc:drill:zk=localhost:5181 scan complete in 1385m`s
```

3. When prompted, enter a username and password; the password is hidden as it is typed, as shown:

```
Enter username for jdbc:drill:zk=localhost:5181: yourusername
Enter password for jdbc:drill:zk=localhost:5181: *************
```

Connecting to Drill from BI Tools

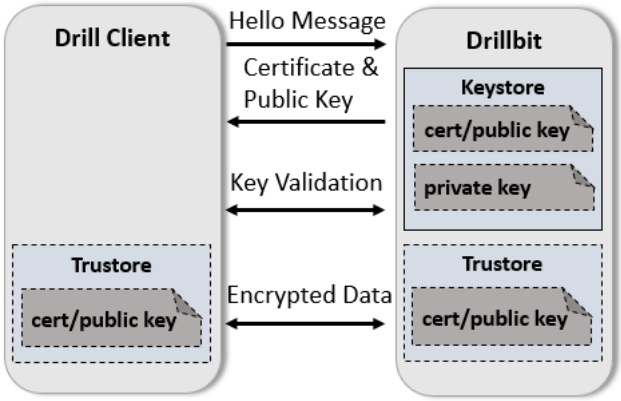
When you connect to Drill from a BI tool, such as Tableau, the ODBC driver prompts you for the authentication type, username, and password. For PAM, select **Basic Authentication** in the Authentication Type drop-down menu.

SSL/TLS for Encryption

You can enable SSL for Drill in a secure cluster. SSL (Secure Sockets Layer), more recently called TLS, is a security mechanism that encrypts data passed between the Drill client and Drillbit (server). SSL also provides one-way authentication through which the Drill client verifies the identity of the Drillbit.

Authentication occurs during the SSL handshake when the Drillbit (server) presents its certificate to the client, and the client checks if the certificate exists in its truststore or if the certificate is signed by a trusted CA (Certificate Authority) that exists in its truststore.

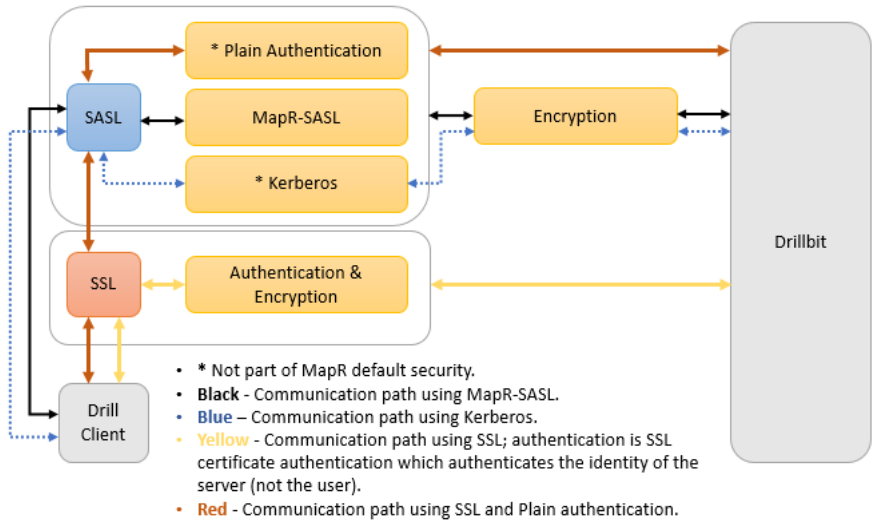
The following diagram depicts the communication between the Drill client and the Drillbit (server):



The SASL feature in Drill provides authentication and an option to encrypt data, however the encryption feature is not available when using Plain authentication. If you need to use Plain authentication (certain BI tools only use Plain authentication), you can enable SSL to encrypt data. Using SSL and SASL encryption together is strongly discouraged.

The following diagram depicts the SSL communication paths between the Drill client and Drillbit (server), including the scenario where Plain authentication is used:

last-updated: Jun 06, 2024



NOTE: The REST API supports HTTPS. SSL is not supported for communication between Drillbits.

The following sections provide information about how to use certificates in secure clusters, enabling and configuring SSL, connection parameters, and common SSL issues.

Related concepts

SSL Certificates on page 838
Describes how certificates are used to perform authentication and encryption for websites that use the HTTPS protocol.

SSL Certificates in Clusters

The Drill server requires an SSL certificate. The certificate can be self-signed or signed by a CA (Certificate Authority).

The sections below describe how to use SSL certificates in Data Fabric clusters.

SSL in a Cluster

By default, SSL is configured in a secure MapR cluster, but not enabled. In a secure cluster the keystore is configured for you. The security in a MapR cluster uses a self-signed certificate. If you have a certificate signed by a certificate authority, follow the instructions for Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster and then enable and configure SSL.

To use SSL, enable the SSL option and then modify any of the available configuration options as needed.

- To enable SSL for the ODBC/JDBC client to Drillbit communication path, you must enable SSL on the client side and Drillbit. See Drill Drivers for client instructions. See Configuring SSL/TLS for the Drillbit.
- To enable SSL for the Drill Web UI, see Configuring the Drill Web UI and Web API Security.

After you modify the configuration options, restart Drill, as shown:

```
$ maprcli node services -name drill-bits -action restart -nodes <node host
names separated by a space>
```

Configuring SSL/TLS

Enable SSL in `<DRILL_INSTALL_HOME>/conf/drill-override.conf`. You can use several configuration options to customize SSL/TLS.

last-updated: Jun 06, 2024

You must restart the Drillbit process on each node after you modify the configuration options, as shown:

```
$ maprcli node services -name drill-bits -action restart -nodes <node host
names separated by a space>
```

The following sections provide information and instructions for enabling and configuring SSL:

Enabling SSL

If SSL is enabled, all Drill clients, such as JDBC and ODBC, must connect to Drill servers using SSL. Enable SSL in the Drill startup configuration file, `drill-override.conf` located in `/opt/mapr/drill/drill-<version>/conf`.

To enable SSL for Drill, set the `drill.exec.security.user.encryption.ssl.enabled` option in `drill-override.conf` to `"true."`

Configuring SSL

You can customize SSL on a Drillbit through the SSL configuration options. You can set the options from the command line (using Java system properties) in the `drill-override.conf` file or in the property file to which the Hadoop parameter `hadoop.ssl.server.conf` points (recommended).

NOTE: Specifying values in `drill-override.conf` can expose the security parameters to end users. Administrators should set these values in the Hadoop security file and restrict permissions on that file.

If a parameter is specified in multiple places, the value in the Hadoop configuration takes precedence over the Drill configuration which takes precedence over the system property.

The Hadoop configuration is specified in the file pointed to by the `hadoop.ssl.server.conf` parameter in the Hadoop `core-site.xml` file. Typically, this parameter points to `$HADOOP_CONF/ssl-server.xml` which contains the property names to configure SSL. Both the `core-site.xml` file and the `ssl-server.xml` file must exist in the Drill classpath. The Drill SSL configuration picks up the Hadoop SSL configuration.

NOTE: Since the Drillbit implementation is based on JSSE, several standard parameters that apply to JSSE also apply to the Drillbit. However, you typically do not need to configure JSSE parameters.

The following are the SSL configuration options with their descriptions and default values.

drill.exec.security.user.encryption.ssl.enabled	*Hadoop Property Name:* N/A *System Property Name:* N/A *Description:* Enable or disable TLS for Drill client - Drill Server communication. You must set this option in `drill-override.conf`. *Allowed Values:* `true` or `false` *Drill Default:* `false`
drill.exec.ssl.protocol	*Hadoop Property Name:* N/A *System Property Name:* N/A *Description:* The version of the TLS protocol to use. *Allowed Values:* TLS, TLSV1, TLSv1.1, TLSv1.2 *Drill Default:* TLSv1.2 (recommended)
drill.exec.ssl.keyStoreType	*Hadoop Property Name:* ssl.server.keystore.type *System Property Name:* javax.net.ssl.keyStoreType *Description:* Format of the keystore file

last-updated: Jun 06, 2024

	Allowed Values: jks, jceks, pkcs12 *Drill Default:* jks
drill.exec.ssl.keyStorePath	*Hadoop Property Name:* ssl.server.keystore.location *System Property Name:* javax.net.ssl.keyStore *Description:* Location of the Java keystore file containing the Drillbit's own certificate and private key. On Windows, the specified pathname must use forward slashes,`/`, in place of backslashes. *Allowed Values:* Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.keyStorePassword	*Hadoop Property Name:* ssl.server.keystore.password *System Property Name:* javax.net.ssl.keyStorePassword *Description:* Password to access the private key from the keystore file. This password is used twice: To unlock the keystore file (store password), and to decrypt the private key stored in the keystore (key password) unless a key password is specified separately. *Allowed Values:* Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.keyPassword	*Hadoop Property Name:* ssl.server.keystore.keypassword *System Property Name:* Not Applicable *Description:* Password to access the private key from the keystore file. May be different from the keystore password. *Allowed Values:* Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.trustStoreType	*Hadoop Property Name:* ssl.server.truststore.type *System Property Name:* javax.net.ssl.trustStoreType *Description:* Format of the truststore file *Allowed Values:* jks, jceks, pkcs12 *Drill Default:* jks
drill.exec.ssl.trustStorePath	*Hadoop Property Name:* ssl.server.truststore.location *System Property Name:* javax.net.ssl.trustStore *Description:* Location of the Java keystore file containing the collection of CA certificates trusted by the Drill client. On Windows, the specified pathname must use forward slashes, `/`, in place of backslashes. **NOTE:** If the `trustStorePath` is not provided, Drill ignores the `trustStorePassword` parameter and gets the default Java truststore instead. This operation causes issues if the Java truststore has a non-default password. The Java APIs used to load the default keystore assume the default password. The only way to use the default keystore with a non-default password is to specify both the path and the password to the keystore. To work around this issue, pass the default Java truststore to the `trustStorePath` parameter.

last-updated: Jun 06, 2024

	Allowed Values: Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.trustStorePassword	*Hadoop Property Name:* ssl.server.truststore.password *System Property Name:* javax.net.ssl.trustStorePassword *Description:* Password to access the private key from the keystore file specified as the truststore. *Allowed Values:* Not Applicable *Drill Default:* Not Applicable
drill.exec.ssl.provider	*Hadoop Property Name:* Not Applicable *System Property Name:* Not Applicable *Description:* Changes the underlying implementation to the chosen value. *Allowed Values:* OpenSSL or JDK *Drill Default:* JDK
drill.exec.ssl.useHadoopConfig	*Hadoop Property Name:* Not Applicable *System Property Name:* Not Applicable *Description:* Use the setting in the Hadoop configuration file. The Hadoop configuration is specified in the file pointed to by the `hadoop.ssl.server.conf` parameter in the `core-site.xml` file. Typically, this parameter points to `$HADOOP_CONF/ssl-server.xml` which contains the property names to configure TLS. *Allowed Values:* `true` or `false` *Drill Default:* `true`

Configuring SSL on Drill on Yarn (DOY)

Starting with EEP 8.1.0, you can enable SSL on Drill on Yarn through SSL configuration options. In the `drill-on-yarn.conf` file, add the `drill.yarn.http.ssl-enabled` parameter. See Drill-on-YARN Limitations on page 3972 for additional information on related limitations.

drill.yarn.http.ssl-enabled	*Hadoop Property Name:* Not Applicable *System Property Name:* Not Applicable *Description:* Use the setting in the Hadoop configuration file with the required `drill.yarn.ssl.useHadoopConfig` parameter. *Allowed Values:* `true` or `false` *Drill Default:* `false`
drill.yarn.ssl.useHadoopConfig	*Hadoop Property Name:* Not Applicable *System Property Name:* Not Applicable *Description:* Use this setting in the Hadoop configuration file. The Hadoop configuration is specified in the file pointed to by the `hadoop.ssl.server.conf` parameter in the `core-site.xml` file. Typically, this parameter points to `$HADOOP_CONF/`

last-updated: Jun 06, 2024

`ssl-server.xml` which contains the property names for configuring the TLS.

Allowed Values: `true` or `false`

Drill Default: `false`

JDBC Connection Parameters

Use the SSL JDBC connection parameters and fully qualified host name to configure the JDBC connection string in SQLLine and connect to Drill.

The following table lists the parameters that you can include in the `jdbc` connection string using SQLLine:

NOTE: Examples are provided after the table. For additional instructions, see the Drill JDBC Driver documentation.

Parameter	Value	Required
enableTLS	true/false	[Optional] If true, TLS is enabled. If not set or set to false, TLS is not enabled.
trustStoreType	string	[Optional] Default: JKS The trustStore type. Allowed values are : JKS PKCS12 If the useSystemTrustStore option is set to true (on Windows only), the allowed values are: Windows-MY Windows-ROOT Import the certificate into the "Trusted Root Certificate Authorities" and set trustStoreType=Windows-ROOT. Also import the certificate into "Trusted Root Certificate Authorities" or "Personal" and set trustStoreType=Windows-MY.
trustStorePath	string	[Optional] Path to the truststore. If not provided the default Java truststore will be used. If this is not provided the trustStorePassword parameter will be ignored. Note that the order for looking for the default trustStore java-home/lib/security/jssecacerts then java-home/lib/security/cacerts
trustStorePassword	string	[Optional] Password to the truststore.

last-updated: Jun 06, 2024

disableHostVerification	true/false	[Optional] If true, we will not verify that the host in the certificate is the host we are connecting to. False by default (Hostname verification follows the specification in RFC2818).
disableCertificateVerification	true/false	[Optional] If true we will not validate the certificate against the truststore. False by default.
TLSProtocol	TLS, TLSV1, TLSv1.1, TLSv1.2, TLSv1.3	[Optional] Default: TLSv1.3 (recommended)
TLSHandshakeTimeout	Time in milliseconds	[Optional] Default: 10 seconds In some cases, the TLS handshake may fail and leave the client hanging. This option sets the time for the client to timeout.
TLSProvider	JDK/OPENSSL	[Optional] Default: JDK Changes the underlying implementation to the chosen value.
useSystemTrustStore	true/false	[Optional, Windows only] Default: false If provided, the client will read certificates from the Windows truststore. In this case, trustStorePath and trustStorePassword, if specified, will be ignored. The user should set the default provider in $JRE_HOME/lib/security/java.security to SunMSCAPI. The trustStoreType should be set to either Windows-MY or Windows-ROOT.

Examples

The following examples show you how to connect to Drill through SQLLine with the `jdbc` connection string when SSL is not enabled and when SSL is enabled with and without a truststore.

No SSL/TLS

```
./sqlline -u
"jdbc:drill:schema=dfs.work;drillbit=l
ocalhost:31010;enableTLS=false"
```

SSL/TLS Enabled - No truststore

The default JSSE truststore will be tried with default password; the provided password will be ignored. If the default truststore password has been changed, this gives an error. To use the default truststore with

last-updated: Jun 06, 2024

a different password, pass the path to the default truststore with the password.

```
./sqlline -u
"jdbc:drill:schema=dfs.work;drillbit=l
ocalhost:31010;enableTLS=true;trustSto
rePassword=drill123"
```

SSL/TLS enabled - With truststore

```
./sqlline -u
"jdbc:drill:schema=dfs.work;drillbit=l
ocalhost:31010;enableTLS=true;trustSto
rePath=~/ssl/
truststore.ks;trustStorePassword=drill
123"
```

ODBC Connection Parameters

Use the SSL ODBC connection parameters to configure a connection to Drill through an ODBC tool.

The following table lists the ODBC connection parameters:

NOTE: The Drill ODBC driver does not support password protected PEM/CRT files or multiple CRT certificates in a single PEM/CRT file. For additional instructions, see the Drill ODBC Driver documentation.

Name	Value	Required	Description
SSL	Clear (0)	No.	This option specifies whether the cliet uses an SSL encrypted connection to communicate with Drill. • Enabled(1):The client communicates with Drill using SSL. • Disabled(0):SS Lis disabled. SSL is configured independently of authentication. When authentication and SSL are both enabled, the driver performs the specified authentication method over an SSL connection.
TLSProtocol	Empty, which defaults to tlsv12.	No	This property specifies the TLS protocol version used. Accepted values are: • tlsv1 • tlsv11 • tlsv12

last-updated: Jun 06, 2024

TrustedCerts	The cacerts.pem file in the \lib subfolder within the Driver's installation directory. The exact file path varies depending on the version of the driver that is installed. For example, the path for the Windows driver is different from the path for the Mac OS driver.	No	The full path of the PEM file containing Trusted CA certificates, for verifying the server. If this option is not set, then the driver defaults to using the trusted CA certificates PEM file installed by the driver.
UseSystemTrustStore	Clear (0)	No	This option specifies whether to use a CA certificate from the system truststore, or from a specified PEM file. • Enabled (1): The driver verifies the connection using a certificate in the system truststore • Disabled (0): The driver verifies the connection using a specified PEM file. **Note:** This option is only available on Windows. If using this option, import the certificate into the "Trusted Root Certificate Authorities" certificate store.
DisableCertificateVerification	0	No	This property specifies that the driver verifies the host certificate against the truststore. Accepted values are: • 0: The driver verifies the certificate against the truststore. • 1: The driver does not verify the certificate against the truststore.
DisableHostVerification	0	No	This property specifies if the driver verifies that the host in the certificate is the host being connected to. Accepted values are: • 0: The driver verifies the certificate against the host being connected to. • 1: The driver does not verify the certificate against the host.

Avoiding Common SSL Issues

The following sections provide insight to some common error messages that you may encounter with SSL.

ERROR: No Cipher suites in common.

This is a general purpose error message that may have many reasons. The most common reason is that in order to use certain cipher suites, JSSE needs to use the private key stored in the Keystore. If this key is not accessible, JSSE filters out all cipher suites that need a private key. This effectively prunes out all available cipher suites so that no cipher suites match between the client and the server.

The private key from the keystore may be inaccessible for the following reasons:

- Missing Keystore file
- Invalid Keystore password
- Empty key password or a key password that is different from the keystore password

JSSE does not allow a key password that is null or an empty string even though it is possible to create a keystore with such a key password. Also, JSSE does not provide a system property to specify the key password. Drill provides a way to set the key password, but if you are using only system properties to configure JSSE, Drill will use the *keystore* password. If the keystore password is not the same as the key password, the key will again be inaccessible.

- Corrupt keystore

You can validate the keystore using keytool.

ERROR: SSL is enabled, but cannot be initialized due to the 'Cannot recover key' exception.

The key is protected with a password and the provided password is not correct.

ERROR: Client connection timeout.

A client connection can timeout because of networking issues or if there is a mismatch between the TLS/SSL configuration on the client and server.

Before trying to debug the TLS/SSL configuration, check if the server is reachable from the client.

If there is a mismatch between the TLS/SSL configuration, the TLS/SSL handshake between the client and server will fail. The server will silently drop the connection and the client will eventually time out. The handshake may fail due to many reasons, including:

1. The server is configured to enableTLS and the client is not (and vice versa).
   a. If the client is not configured to use TLS and the server is, the error message will be similar to the following:

```
Error: Failure in connecting to Drill:
org.apache.drill.exec.rpc.RpcException: HANDSHAKE_COMMUNICATION :
Channel closed /10.10.10.11:49907 <--> hostname/10.10.10.11:31010.
(state=,code=0)
java.sql.SQLNonTransientConnectionException: Failure in
connecting to Drill: org.apache.drill.exec.rpc.RpcException:
HANDSHAKE_COMMUNICATION : Channel closed /10.10.10.11:49907
<-->hostname/10.10.10.11:31010.
```

b. If the server is not configured to use TLS and the client tries to connect using TLS, the error message will be similar to the following:

```
Error: Failure in connecting to Drill:
org.apache.drill.exec.rpc.NonTransientRpcException: Connecting to the
server timed out. This is sometimes due to a mismatch in the SSL
configuration between client and server. [ Exception: Timeout waiting
for task.] (state=,code=0)
```

2. The server presents a certificate to the client containing a hostname that is not valid. When the client connects to a server, the hostname the client used to connect to the server must match the name of the host the certificate was assigned to. Certificates can contain wildcards for the hostname, so if you're connecting to a Drill cluster via ZooKeeper, it would be best to have a certificate that contains wildcards that cover all the hosts on which Drill might be running. It is also important to ensure that the DNS and the hostnames of the machines in the cluster are set up consistently so that the Drillbits are registered with ZooKeeper using the same name as the name assigned in the certificate. The error message in this case is the same as the previous case:

```
Error: Failure in connecting to Drill:
org.apache.drill.exec.rpc.NonTransientRpcException: Connecting to the
server timed out. This is sometimes due to a mismatch in the SSL
configuration between client and server. [ Exception: Timeout waiting
for task.] (state=,code=0)
```

Hostname verification can be turned off if there is no way to change the host configuration or the certificate. This is generally not recommended.

Security Between ZooKeeper and Drillbits

When Drill is installed on clusters with the default security enabled, authentication is enabled between the Drillbits and ZooKeeper. The ZooKeeper znode information is secured automatically through authentication and znode ACLs. Communication between the Drillbits and Zookeeper is not encrypted.

NOTE: If you installed Drill on a cluster that does not have the default security configuration, and you are configuring custom security, you must enable authentication and manually set ACLs on the znodes.

Drill uses ZooKeeper to store certain cluster-level configuration and query profile information in znodes. A znode is an internal data tree in ZooKeeper that stores coordination and execution related information. If information in the znodes is not properly secured, cluster privacy and/or security is compromised.

ZooKeeper uses ACLs to control access to znodes and secure the information they store. Starting in Drill 1.15, you can create a custom ACL (Access Control List) on the znodes to secure data. ACLs specify sets of ids and permissions that are associated with the ids.

Starting in Drill 1.15, ACLs in secure clusters are set to `[authid: all]`, which provides full access to the authenticated user that created the znode only. Discovery znodes (znodes with the list of Drillbits) have an additional ACL set to `[world:read]` making the list of Drillbits readable by any user.

NOTE: View the drill-override-example.conf file to see example ACL configurations.

Securing znodes

Complete the following steps to create a custom ACL and secure znodes:

1. Write a class that implements the `ZKACLProvider` interface. This class will contain the ACLs that need to be set on the znodes. You can use the ZKSecureACLProvider class as a sample reference.

2. Add the following dependency to the `pom` file of the project module created:

```
<groupId>org.apache.drill.exec</groupId>
<artifactId>drill-java-exec</artifactId>
```

3. Refer to the steps listed at https://drill.apache.org/docs/manually-adding-custom-functions-to-drill/ to create a JAR and then add the JAR to Drill's classpath.

4. In `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`, set `zk.acl_provider` to the `ZKACLProviderTemplate` type.

5. Restart Drill. When you restart Drill, the ACL, as mentioned in your custom class, is applied to the znode created when Drill starts.

NOTE: Existing ACLs for persistent znodes will not be affected if a Drillbit is restarted with a different ACL setting. ACLs are applied only at znode creation time. Drill does not recreate any znode that is already present. If you want to change an ACL for existing znodes, connect to the ZooKeeper server using zkCli and then use option a or b, as described:

- a) Shutdown Drillbits, delete the persistent znodes, change the ACL settings, and restart the Drillbit.
- b) Manually change the ACLs on the existing znodes to reflect the new ACL settings, using the `setAcl` command in the zkCli.

For either option to work, an authenticated connection between the zkCli and ZooKeeper Server must be established.

For additional information, refer to:

- ZooKeeper access control using ACLs
- ZooKeeper and SASL

Configuring Drill Web UI and Web API Security

The Drill web client and web API communicate with web browsers or web tools, like curl, through the HTTP or HTTPS. Drill uses HTTP by default.

Drill supports form-based (similar to Plain authentication) and SPNEGO authentication mechanisms to authenticate the communication between the web client and web browser or web tools. Drill supports SSL/TLS for encryption with form-based and SPNEGO authentication.

An administrator can configure security mechanisms and set up Drill Web UI administrators and administrator-user groups to control access to the Drill Web UI and Web API client applications. For example, limiting user access to Drill Web UI functionality, such as viewing or canceling queries submitted by other users.

NOTE:

- The Drill web server does not support data-fabric-SASL (tickets).
- With Drill Web UI security in place, users without administrator privileges must execute the SHOW SCHEMAS command in the Drill Web UI Query page to see storage plugin configuration information.

last-updated: Jun 06, 2024

Form-Based Authentication

In EEP 5.0 and later, Drill supports form-based authentication between the web client and Drillbit. Form-based authentication is like Plain Authentication in that a user is presented with a web form where s/he enters a username and password to access restricted web pages. Form-based authentication also uses the Linux PAM (Pluggable Authentication Module).

Configuring Drill to Use libpam4j provides configuration details. When using form-based authentication, you can also configure Drill to use SPNEGO for HTTP Authentication and SSL/TLS for encryption.

HTTPS Support

The Drill Web UI supports the HTTPS protocol for encryption. With the default security configuration, HTTPS is enabled for Drill and it uses SSL trust- and keystore, which comes with cluster installation.

To use custom certificates, see SSL Certificates in Secure and Unsecure MapR Clusters.

The following example shows the default HTTPS configuration in `<DRILL_INSTALL_HOME>/conf/drill-distrib.conf` for a secure cluster installation:

```
drill.exec: {
              http.ssl_enabled: true,
              ssl.useHadoopConfig: true
}
```

You can configure additional parameters:

Drill Property Name	Hadoop Property Name	System Property Name	Description
drill.exec.http.ssl_enabled:			Enable or disable communication. Y
drill.exec.ssl.keyStorePath	ssl.server.keystore.location	javax.net.ssl.keyStore	Location of the Ja own certificate ar pathname must u
drill.exec.ssl.keyStorePassword	ssl.server.keystore.password	javax.net.ssl.keyStorePassword	Password to acce This password is password), and to (key password) u
drill.exec.ssl.keyPassword	ssl.server.keystore.keypassword		Password to acce be different from
drill.exec.ssl.trustStorePath	ssl.server.truststore.location	javax.net.ssl.trustStore	Location of the Ja certificates truste pathname must u
drill.exec.ssl.trustStorePassword	ssl.server.truststore.password	javax.net.ssl.trustStorePassword	Password to acce specified as the t

last-updated: Jun 06, 2024

drill.exec.ssl.useHadoopConfig			Use the setting in hadoop configura the hadoop.ssl.se file. Typically, this ssl-server.xml wh TLS.  **NOTE:** Veri is located in symbolic lin for example `<DRILL_` .

Setting up Web UI Administrators and Administrator-User Groups
The `security.admin.user_groups` and `security.admin.users` options set the administrative users when authentication is enabled.

Users listed in `security.admin.users` and the users belonging to the groups listed in `security.admin.user_groups` get administrative privileges. By default, these options are set to the username and groups of the user who started the Drill process. You can modify these options from the Drill Web UI or using the ALTER SYSTEM command.

An administrative user that authenticates to a Drillbit through data-fabric-SASL, Kerberos, Plain mechanism or through the HTTPS web interface can modify the `security.admin.user_groups` and `security.admin.users` options. The administrator can add or remove user names or user groups.

The `security.admin.user_groups` and `security.admin.users` options allow a single user/group name or a comma separated list of user/group names. When you view these options in the Drill Web UI, dummy default strings appear until the user explicitly changes the values.

Authenticated administrative users can view the current administrative user and administrative user groups on the Drill Web UI landing page (https://<node-ip-address>:8047) in the *Encryption Info* section.

Drill REST API and Web UI

This topic provides information about the Drill REST API and Web UI, including permission requirements.

If Drill has authentication enabled, you must supply credentials when using the Drill REST API.

Although Drill (in HPE Ezmeral Data Fabric) does not support HTTP basic authentication, you can work around this if your HTTP client saves cookies between requests. As a workaround, save the authenticated cookie to a file and then use the cookie in subsequent requests, as shown in the following example:

```
//Log in and save the authenticated cookie to a file:

curl -X POST \
    -H "Content-Type: application/x-www-form-urlencoded" \
    -k -c cookies.txt -s \
    -d "j_username=DRILL_USER" \
    -d "j_password=DRILL_PASSWORD" \
    https://HOSTNAME:8047/j_security_check

//In subsequent requests, use the cookie from that request:

curl -kv \
       -b cookies.txt  \
       -X POST \
       -H "Content-Type: application/json" \
       -d @/tmp/hive-storage-plugin.json
       https://HOSTNAME:8047/storage/hive.json
```

NOTE: The session remains active for one hour. You can increase the session time through the `drill.exec.http.session_max_idle_secs` option in `drill-override.conf`:

```
drill.exec: {
  http: {
    session_max_idle_secs: 86400, # 24hr
  }
}
```

REST API Methods and Web UI Functions

The following table and subsections describe requests and privilege levels for accessing the REST API methods and corresponding Drill Web UI functions. Privileges in the table are listed as AMDIN, USER, and ALL. ALL indicates privileges given to both the user and administrator.

Path	Request Type	Output Type	Functionality	Privileges
/	GET	text/html	Returns Drillbit stats in a table in HTML format.	ALL
/stats.json	GET	application/json	Returns Drillbit stats such as ports and max direct memory in json format.	ALL
/status	GET	text/html	Returns Running!	ALL
/options.json	GET	application/json	Returns a list of options. Each option consists of name-value-type-kind (for example: (boot system datatype).	ALL
/options	GET	text/html	Returns an HTML table where each row is a form containing the option details and ability to modify the option values.	ALL
/option/{optionName}	POST	text/html	Updates the options and calls getSystemOptions to display list of options.	ADMIN
/storage.json	GET	application/json	Returns a list of storage plugin wrappers each containing name-config (instance of StoragePluginConfig) and enables the storage plugin configuration.	ADMIN
/storage	GET	text/html	Returns an HTML page with sections that contain: • a table where each row is a form containing the plugin button for update page link and a button to disable the plugin. • a table where each row is a form containing the plugin button for update page and a button to enable the plugin.	ADMIN
/storage/{name}.json	GET	application/json	Returns a plugin config wrapper for the requested web page.	ADMIN

last-updated: Jun 06, 2024

/storage/{name}	GET	text/html	Returns an HTML page that has an editable text box for configuration editing, followed by buttons for creating,updating, and deleting. Each of the buttons make calls that generate the new page again.	ADMIN
/storage/{name}/enable/{val}	GET	application/json	Updates the storage plugin status. Returns success or failure.	ADMIN
/storage/{name}.json	DELETE	application/json	Deletes the storage plugin. Returns success or failure.	ADMIN
/storage/{name}/delete	GET	application/json	Same as deletePluginJSON but a GET instead of a DELETE request.	ADMIN
/storage/{name}.json	POST	application/json	Creates or updates the storage plugin. Returns success or failure. Expects JSON input.	ADMIN
/storage/{name}	POST	application/json	Same as createOrUpdatePluginJSON expects JSON or FORM input.	ADMIN
/profiles.json	GET	application/json	Returns currently running and completed profiles from PStore. For each profile a queryId, startTime, foremanAddress, query, user, and state is returned. Each list (running and completed) is organized in reverse chronological order.	ADMIN, USER
/profiles	GET	text/html	Generates an HTML page from the data returned by getProfilesJSON with a hyperlink to a detailed query page.	ADMIN, USER
/profiles/{queryid}.json	GET	application/json	Returns the entire profile in JSON.	ADMIN, USER
/profiles/{queryid}	GET	text/html	Returns a complex profile page.	ADMIN, USER
/profiles/cancel/{queryid}	GET	text/html	Cancels the given query and sends a message.	ADMIN, USER
/query	GET	text/html	Gets the query input page.	ALL
/query.json	POST	application/json	Submits a query and waits until it is completed and then returns the results as one big JSON object.	ALL
/query	POST	text/html	Returns the results of submitQueryJSON in an HTML table.	ALL
/status/metrics	GET	application/json	Returns a page that fetches metric info from resource, status, and metrics.	ALL
/status/threads	GET	text/html	Returns a page that fetches metric information from resource, status, and threads.	ALL

last-updated: Jun 06, 2024

/login	GET	text/html	Returns an HTML log in page. If the user is already logged in, returns the home page. If the URL contains a redirect, sets the redirect URI for the session and forwards the user to the redirect page after the user is successfully logged in.	ALL
/login	POST	text/html	Returns a validation error for incorrect credentials.	ALL
/logout	GET	text/html	Ends a session.	ALL

GET /profiles.json

- ADMIN - gets all profiles on the system.
- USER - only the profiles of the queries the user has launched.

GET /profiles

- ADMIN - gets all profiles on the system.
- USER - only the profiles of the queries the user has launched.

GET /profiles/{queryid}.json

- ADMIN - return the profile.
- USER - if the query is launched the by the requesting user return it. Otherwise, return an error saying no such profile exists.

GET /profiles/{queryid}

- ADMIN - return the profile.
- USER - if the query is launched the by the requesting user return it. Otherwise, return an error saying no such profile exists

GET /profiles/cancel/{queryid}

- ADMIN - can cancel the query.
- USER - cancel the query only if the query is launched by the user requesting the cancellation.

Related concepts

Securing Drill on page 4016
An administrator can install Drill with the default security configuration or manually configure custom security for Drill.

More information

https://drill.apache.org/docs/rest-api/

SPNEGO for HTTP Authentication

Drill 1.13 and later supports the Simple and Protected GSS-API Negotiation mechanism (SPNEGO) to extend the Kerberos-based single sign-on authentication mechanism to HTTP. An administrator configures the web server (Drillbit) to use SPNEGO for authentication. Depending on the system, either the administrator or the user configures the client (web browser or web client tool) to use SPNEGO for authentication.

An administrator can configure both FORM (username and password) and SPNEGO authentication together, which provides the ability for clients with different security preferences to connect to the same

Drill cluster. When a client (a web browser or a web client tool, such as curl) requests access to a secured page from the web server (Drillbit), the SPNEGO mechanism uses tokens to perform a handshake that authenticates the client browser and the web server.

The Drill Web UI provides two possible log in options for a user depending on the configuration. If a user selects FORM, s/he must enter their username and password to access restricted pages in the Drill Web UI. The user is authenticated through PAM. If the user selects SPNEGO, the user is automatically logged in if they are an authenticated Kerberos user. If accessing a protected page directly, the user is redirected to the authentication log in page. If the client fails to authenticate using SPNEGO, an error page displays with an option to use FORM authentication, assuming FORM authentication is configured on the server side.

Browser Support

The following browsers were tested with Drill configured to use SPNEGO authentication:

- Firefox
- Chrome
- Safari
- Internet Explorer
- Web client tool, such as curl

Prerequisites

SPNEGO authentication for Drill requires the following:

- Drill 1.13 or later installed on each node.
- A working Kerberos infrastructure, which Drill does not provide.
- A Linux-based or Windows Active Directory (AD) Kerberos environment with secure clusters and a Drill server configured for Kerberos.
- Kerberos principal and keytab on each web server (Drillbit) that will use SPNEGO for authentication.
- Kerberos Ticket Granting Ticket on the client machine for the user accessing the Drillbit (web server).
- Drill web server configured for SPNEGO.

Configuring SPNEGO on the Web Server and Web Client

The following sections provide the steps that an administrator can follow to configure SPNEGO on the web server (Drillbit). An administrator or a user can follow the steps for configuring the web browser or client tool.

Configuring SPNEGO on the Drillbit (Web Server)
To configure SPNEGO on the web server, complete the following steps:

1. Generate a Kerberos principal on each web server that will receive inbound SPNEGO traffic. Each principal must have a corresponding keytab. The principal must have the following form:

```
"HTTP/<client-known-server-hostname@realm>"

   Example: "HTTP/example.QA.LAB@QA.LAB"
   //In this example, the client known server hostname is example.QA.LAB.
```

   NOTE: If HTTPS is enabled on the Drillbit (web server), the SPNEGO principal should also start with "HTTP/", not "HTTPS/" even though the URL includes HTTPS.

2. Update the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file on each Drillbit with the following server-side SPNEGO configurations:

   - To enable SPNEGO, add the following configuration to `drill-override.conf`:

```
impersonation: {
                     enabled: true,
                     max_chained_user_hops: 3
               },
               drill.exec.http: {
                     spnego.auth.principal:"HTTP/hostname@realm",
                     spnego.auth.keytab:"path/to/keytab",
                     auth.mechanisms: ["SPNEGO"]
               }
      }
      //The default authentication mechanism is "FORM".
```

   - To enable SPNEGO and FORM authentication, add the following configuration to `drill-override.conf`:

```
impersonation: {
                enabled: true,
                max_chained_user_hops: 3
             },
             security.user.auth: {
                     enabled: true,
                     packages +=
"org.apache.drill.exec.rpc.user.security",
                     impl: "pam4j",
                     pam_profiles: [ "sudo", "login" ]
              }
            drill.exec.http: {
                     spnego.auth.principal:"HTTP/hostname@realm",
                     spnego.auth.keytab:"path/to/keytab",
                     auth.mechanisms: ["SPNEGO", "FORM"]
            }
      }
```

3. (Optional) To configure the mapping from a Kerberos principal to a user account used by Drill, update the `drill.exec.security.auth.auth_to_local` property in the `drill-override.conf` file with custom rules, as described in Mapping from Kerberos Principal to OS user account.

   NOTE: Drill uses a Hadoop Kerberos name and rules to transform the client Kerberos principal to the principal Drill uses internally as the client's identity. By default, this mapping rule extracts the first portion from the provided principal. For example, if the principal format is Name1/Name2@realm, the default rule extracts only Name1 from the principal and stores Name1 as the client's identity on server side. Drill uses the short name, for example Name1, as the user account known to Drill. This user account name is used to determine if the authenticated user has administrative privileges.

Configuring SPNEGO on the Client

An administrator or user can configure SPNEGO on the client (web browser or client tools, such as curl). To configure SPNEGO on the client, a Kerberos Ticket Granting Ticket must exist for the user accessing the web server. The Kerberos Ticket Granting Ticket generated on the client side is used by the web client to get a service ticket from the KDC. This service ticket is used to generate a SPNEGO token, which is presented to the web server for authentication.

The client should use the same web server hostname (as configured in the server-side principal) to access the Drill Web Console. If the server hostname differs, SPNEGO authentication will fail. For example, if the server principal is `"HTTP/example.QA.LAB@QA.LAB"`, the client should use `http://example.QA.LAB:8047` as the Drill Web Console URL.

The following sections provide instructions for configuring the supported client-side browsers:

Firefox

To configure Firefox to use a negotiation dialog, such as SPNEGO to authenticate, complete the following steps:

1. Go to **About > Config**, and accept the warnings.
2. Navigate to the network settings.
3. Set `network.negotiate-auth.delegation-uris` to `"http://,https://"`.
4. Set `network.negotiate-auth.trusted-uris` to “http://,https://”.

Chrome

For MacOS or Linux, add the `--auth-server-whitelist` parameter to the `google-chrome` command. For example, to run Chrome from a Linux prompt, run the `google-chrome` command, as shown:

```
google-chrome --auth-server-whitelist = "hostname/domain"
  Example: google-chrome --auth-server-whitelist = "example.QA.LAB"
```

Safari

No configuration is required for Safari. Safari automatically authenticates using SPNEGO when requested by the server.

Internet Explorer

To configure Internet Explorer to use a negotiation dialog, such as SPNEGO to authenticate, complete the following steps:

last-updated: Jun 06, 2024

1. Go to **Tools > Options > Security > Local Intranet > Sites**, and select all options.
2. Select **Advanced**, and add one or both of the following URLs to server:
   - http://
   - https://

   NOTE: Make sure you use the hostname of the Drillbit in the URL.
3. Close the **Advanced** tab, and click **OK**.
4. Go to **Tools > Options > Advanced > Security** (in the checkbox list), and enable the **Integrated Windows Authentication** option.
5. Click **OK**.
6. Close and reopen IE. You can browse to your Spengo protected resource.

REST API

You can use CURL commands to authenticate using SPNEGO and access secure web resources over REST.

Issue the following `curl` command to log in using SPNEGO, and save the authenticated session cookie to a file, such as `cookie.txt`, as shown:

```
curl -v --negotiate -c cookie.txt -u : http://<hostname>:8047/spnegoLogin
```

Use the authenticated session cookie stored in the file, for example `cookie.txt`, to access the Drill Web Console pages, as shown in the following example:

```
curl -v --negotiate -b cookie.txt -u : http://<hostname>:8047/query
   Example: curl -v --negotiate -b cookie.txt -u : http://
example.QA.LAB:8047/query
```

Using ACEs on Views to Limit Data Access

Describes how to use access control expressions to limit data access for Views.

Apache Drill on page 3920 is a distributed SQL query layer that runs on the data platform. You can enable user impersonation and create views in Drill to control user access to data stored in the data platform at the row and column levels. Access to data is based on file permissions set on the data (source files) and on the view definition files.

In addition to standard POSIX permissions, ACEs (access control expressions) are supported to secure data in the distributed filesystem. ACEs are a flexible access control mechanism that applies to files, tables, and streams. Setting an ACE (access control expression) on a file modifies the file permission to honor the *ACE* setting. Drill honors *ACE* set on Drill view files and on the source files that views access.

Each Drill view created has an associated view definition file, with a `.view.drill` extension, on which you can set ACEs to secure the view.

Example

Frank creates a workspace in the dfs storage plugin configuration in Drill that points to his home directory in the distributed filesystem. He then uses Drill to create a table named “employees” that he and the HR group can access:

```
-rwxr----- frank:hr /user/frank/employees
```

last-updated: Jun 06, 2024

Joe, a member of the HR and MGR groups, creates a view named `emp_mgr_view` in his home directory to share a subset of the employees data with managers that belong to the MGR group:

```
-rwxr----- joe:mgr /user/joe/emp_mgr_view.drill.view
```

Managers in the MGR group have read permission on the `emp_mgr_view.drill.view` file so they can query the `emp_mgr_view` that Joe created and they can create new views from his view.

Setting *ACE* on the underlying data source (the “employees” table) or on the view file (`emp_mgr_view.drill.view`) that accesses the underlying data source resets the POSIX mode bits to match the permissions granted through *ACE* settings.

For example, if Frank issues the following command to apply an *ACE* to the “employees” table, a user must be a member of the EXEC group to read data in the “employees” table:

```
hadoop mfs -setace -R -readfile 'g:exec' employees
```

Anyone in the HR group that previously had access to the table can no longer access the table data unless they also belong to the EXEC group.

Running the `-getace` command on the table lists the *ACE* settings on the table:

```
hadoop mfs -getace /user/frank/employees
```

```
Path: /user/frank/employees
 readfile: g:exec
 writefile:
 executefile:
 readdir:
 addchild:
 deletechild:
 lookupdir:
 inherit: true
 mode: ---------
```

Similarly, if Joe issues the following command on the on the `emp_mgr_view.drill.view` file, only members of the HR group can read the file. Users that belong to the MGR group can no longer access the data through the view, unless they also belong to the HR group.

```
hadoop mfs -setace -R -readfile 'g:hr' emp_mgr_view.drill.view
```

Running the `-getace` command on view file shows the *ACE* settings on the file:

```
hadoop mfs -getace /user/joe/emp_mgr_view.drill.view
```

```
Path: /user/joe/emp_mgr_view.drill.view
 readfile: g:hr
 writefile:
  executefile:
  readdir:
  addchild:
  deletechild:
  lookupdir:
  inherit: true
  mode: ---------
```

You may also want to view another File ACE Example on page 1862.

Drill Drivers

HPE Ezmeral Data Fabric provides Drill ODBC and JDBC drivers that you can download and use to connect Drill to BI tools. The drivers are updated periodically to include support for new functionality in Drill.

The following table provides links to driver download sites and documentation:

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

Driver	Driver Download Site	Driver Documentation
Drill ODBC Driver	All versions of the Drill ODBC driver are located at https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR_Drill/.	• Information about the driver, including Drill driver version compatibility and important messages, is located at Drill ODBC Driver on page 4087. • Driver documentation, including installation and configuration instructions, is located in the Drill ODBC Driver PDF file. • How to Connect to Drill from Tableau on Windows on page 4089
Drill JDBC Driver	All versions of the Drill JDBC driver are located at https://package.ezmeral.hpe.com/tools/MapR-JDBC/MapR_Drill/.	• Information about the driver, including Drill driver version compatibility and important messages, is located at Drill JDBC Drivers on page 4075. • Driver documentation, including installation and configuration instructions, is located in the Drill JDBC Driver PDF file.

Drill JDBC Drivers

Download the Drill JDBC driver and use it on all platforms to connect BI tools, such as SQuirreL and Spotfire, to Drill. Drill also includes an embedded, open-source JDBC driver.

The downloadable Drill JDBC driver provides read-only access to Drill data sources and supports the security features described in Securing Drill.

Alternatively, you can use the open-source JDBC driver embedded in Drill; however, *the open-source JDBC driver is not tested on the MapR Data Platform*. The open-source driver supports Kerberos and Plain authentication mechanisms, but does not support the data-fabric-SASL authentication mechanism. After you install Drill from the `mapr-drill` package, you can find the open-source JDBC driver files in the following directories:

- `$DRILL_HOME/jars/jdbc-driver/drill-jdbc-all-<drill-version>.jar`
- `$DRILL_HOME/jars/drill-jdbc-<drill-version>.jar`

Drill JDBC Driver Download

Use the version of the driver that correlates with the version of the installed Drill server. Although older versions of the driver may connect to an upgraded version of Drill, the older drivers do not include all the server features available in the newer drivers.

NOTE: It is integral that you install and retain all files associated with the Drill JDBC driver as downloaded. Dependencies exist among driver files, and downloading and retaining all files allow for successful driver functionality and averts failures.

The following table provides links to the download locations for the Drill JDBC drivers that correlate with each of the Drill versions listed:

last-updated: Jun 06, 2024

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

Drill Version	JDBC Version
1.16.1.[200 or later]	1.6.11.1008
1.16.1.[0-199]	1.6.6.1008
1.16.0.x	1.6.8.1011
1.16.0.x	1.6.7.1010 **ATTENTION:** This driver supports JRE 8 only and includes updated driver classes. See Driver Class on page 4076.
1.15.0	1.6.0.1001
1.14.0	1.6.0.1001
1.13.0	1.5.9.1018
1.12.0	1.5.8.1017
1.11.0	1.5.6.1012
1.10.0	1.5.3.1006

Driver Class

IMPORTANT: The Drill JDBC Driver installation and configuration PDF document does not include the information provided in the following sections:

Driver Class

The *Registering the Driver Class* section of the Drill JDBC Driver documentation incorrectly lists the driver classes as `com.simba.drill.jdbc41.Driver` and `com.simba.drill.jdbc41.DataSource`.

- For driver version **1.6.6.1009 and earlier**, the correct driver classes are:
  - `com.mapr.drill.jdbc41.Driver`
  - `com.mapr.drill.jdbc41.DataSource`
- For driver version **1.6.7.1010**, the correct driver classes are:
  - `com.mapr.drill.jdbc.Driver`
  - `com.simba.drill.jdbc.DataSource`

JDBC Connection String

You can indicate the `schema` parameter in the connection string, as shown in the following example:

```
jdbc:drill:zk=10.10.100.30:5181,10.10.100.31:5181,10.10.100.32:5181/drill/
drillbits1;schema=hive
```

You can also include the authentication mechanism in the connection string using the `AuthMech` or `auth` parameter. For data-fabric-SASL, use `auth=MAPRSASL`.

- If using the data-fabric-SASL or Plain authentication mechanism, you must add the Drill JDBC JAR files and `/opt/mapr/lib/*` to the classpath of the third-party client tool, as shown in the following example for SQuirreL when the path to the driver is `C:\driver\MapRDrillJDBC41-1.5.6.1012:`

  ```
  -cp
  "%SQUIRREL_CP%;C:\driver\MapRDrillJDBC41-1.5.6.1012\*;C:\opt\mapr\lib\*"
  ```

  The driver JAR files should appear before `/opt/mapr/lib/*` in the classpath.

Using Data Fabric-SASL for Authentication on Windows

Drill is automatically configured with MapR security when you install Drill on a cluster configured with default security. To successfully connect to Drill from a Windows JDBC client, a user ticket must exist on the Windows client in the %TEMP% directory or in the location specified by the $MAPR_TICKETFILE_LOCATION environment variable.

The JDBC driver locates user tickets for the current Windows user in the default ticket location, %TEMP%, or in the location specified by the environment variable, $MAPR_TICKETFILE_LOCATION. See Tickets and Generating a MapR User Ticket for more information.

You can either copy a user ticket that was generated on the cluster into the default location (%TEMP%), or you can install the data-fabric client on the Windows client and then run the maprlogin command to generate the ticket on the Windows client.

NOTE: The JDBC user must be the same as the Windows user that created the ticket.

Example

If you want to connect to Drill as the mapr user, you must create a ticket for the mapr user, as shown:

```
$ maprlogin password -user mapr
[Password for user 'mapr' at cluster 'Cluster1':]
```

The credentials for the mapr user in Cluster1 are written to /tmp/maprticket_1000.

Next, place the ticket in the %TEMP% directory on the Windows client. For example, the default location for a Windows 10 user named Tabetha Stephens is shown:

```
'C:\Users\TABETH~1\AppData\Local\Temp/maprticket_Tabetha Stephens'
```

To override this location, set the "MAPR_TICKETFILE_LOCATION" global variable for the Windows user.

NOTE: Using the MAPR_TICKETFILE_LOCATION is recommended because the %TEMP% directory differs between Windows versions. You may also want to set the MAPR_TICKETFILE_LOCATION per user on the operating system to prevent all users from using the same user ticket on the client.

Avoiding Driver Conflicts

If you download and use the Drill JDBC driver, rename the embedded JDBC driver files to avoid any conflict between the downloaded driver and the open-source driver. The embedded JDBC driver files are in the following directories after you install Drill:

```
$DRILL_HOME/jars/jdbc-driver/drill-jdbc-all-1.10.0.jar
$DRILL_HOME/jars/drill-jdbc-1.10.0.jar
```

Changing the file extension to rename these files, as shown in the following example, prevents Drill or any other application, such as SQLLine, from picking up the embedded driver:

```
$DRILL_HOME/jars/jdbc-driver/drill-jdbc-all-1.10.0.jar.original
$DRILL_HOME/jars/drill-jdbc-1.10.0.jar.original
```

Connecting to Drill via the Drill Shell (SQLLine)

See Connecting to Drill via the Drill Shell (SQLLine) on page 4078.

Driver Limitations

When using data-fabric-SASL with JDBC or ODBC drivers, there is no way to specify the target cluster name as part of the connection parameters. Data Fabric-SASL reads the first entry in the `/opt/mapr/conf/mapr-clusters.conf` file and assumes it is the target cluster name.

For example, if the `mapr-clusters.conf` file has an entry for '`cluster1`' followed by an entry for '`cluster2`' and you want to connect to a node in '`cluster2`', authentication fails. As a workaround, manually switch the order of entries in the `mapr-clusters.conf` file.

Connecting to Drill via the Drill Shell (SQLLine)
SQLLine is a JDBC application that is packaged with Drill and serves as the Drill shell. When you issue queries from the SQLLine client, SQLLine passes the queries to the connected Drillbit (Drill node).

You can connect to Drill through Sqlline directly or through a connection-property file. To avoid exposing credentials, connect through the connection-property file.

A JDBC connection string supplies the connection information to a Drill node or ZooKeeper cluster. When you connect to a ZooKeeper cluster, ZooKeeper selects the Drillbit for SQLLine to connect to.

JDBC Connection String Example

Here is an example of a JDBC connection string that connects SQLLine to drillnode1:

```
jdbc:drill:drillbit=drillnode1:31010
```

The default port on a Drill node is 31010.

Connection Parameters

You can include SQLLine connection parameters in the connection string and run various shell commands, as described in Configuring the Drill Shell.

In the following example, `-u` is the connection parameter for the JDBC connection string, `-n` is the parameter for the username, and `-p` is the parameter for the password:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
"jdbc:drill:drillbit=drillnode1:31010" -n mapr -p mapr
```

Starting SQLLine

Start SQLLine from the Drill installation directory, as shown:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u
jdbc:drill:drillbit=drillnode1:31010
```

Configuration Options

You can also include configuration options, such as `schema`:

```
/opt/mapr/drill/drill-<version>/bin/sqlline -u "jdbc:drill:drillbit
drillnode1:31010;schema=dfs" -n <username> -p <password>
```

Schema

The `schema` is the name of a storage plugin configuration to use as the default for queries. If you indicate the schema in the connection URL, you do not have to run the `USE <schema>;` query to switch to the schema you want to use. All queries run against the schema indicated in the JDBC connection string.

Authentication

If authentication (Plain, MAPRSASL, or Kerberos) is enabled, include the `auth` option in the connection string. If Drill is installed on a cluster secured by default security, set `auth=MAPRSASL`.

For additional configuration options, refer to the *Driver Configuration Options* section in the JDBC Installation and Configuration Guide.

Connecting to a Specific Drill Node

Indicate which Drill node you want SQLLine to connect to in the JDBC connection string by using the following JDBC connection string format:

```
jdbc:drill:drillbit=<host>:<port>
```

Note that properties are case-sensitive. The `host` is the DNS or IP address of the server (Drill node). By default, the driver connects to port 31010.

Example

The following example shows how to run SQLLine with the JDBC connection string and includes the username, password, and auth parameters to authenticate to the server with Plain authentication:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline -u
"jdbc:drill:drillbit=<ip-address>:<por
t>;auth=PLAIN" -n <username> -p
<password>
```

If you installed Drill on a cluster with default security enabled, set the `auth` type to `maprsasl`:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline -u
"jdbc:drill:drillbit=<ip-address>:<por
t>;auth=MAPRSASL"
```

Connecting to ZooKeeper

When you include the ZooKeeper nodes in the JDBC connection string, ZooKeeper selects an available Drill node for SQLLine to use.

Indicate the ZooKeeper cluster you want SQLLine to connect to in the JDBC connection string, using the following JDBC connection string format:

```
jdbc:drill:zk=<zk-server-list>/drill/<clustername>
```

last-updated: Jun 06, 2024

The `zk-server-list` is a comma-separated list of the ZooKeeper nodes in the cluster. The `clustername` is the unique name of the Drillbit cluster that you want to connect to.

IMPORTANT: You can locate the name of the Drillbit cluster in `/opt/mapr/drill/drill-<version>/conf/drill-distrib.conf`. The default name of the Drillbit cluster is `drillbits1`. The name is set by the `cluster-id` property. If you have multiple Drill clusters, you might want to override the Drillbit cluster name in `drill-override.conf`. However, first back-up your storage plugin configurations, as they might reset to the defaults when you change the cluster name. Restart Drill after you edit `drill-override.conf`.

Note that properties are case-sensitive. The `host` is the DNS or IP address of the server (ZooKeeper node).

Example

The following example shows you how to configure the JDBC connection string to connect SQLLine to the ZooKeeper cluster:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-i
p>:<port>,=<node-ip>:<port>/drill/
drillbits1;auth=PLAIN
```

NOTE: The default port for ZooKeeper nodes in a data-fabric cluster is 5181.

If you installed Drill on a secure cluster, set the `auth` type to `maprsasl`:

```
/opt/mapr/drill/drill-<version>/bin/
sqlline
jdbc:drill:zk=<node-ip>:<port>,<node-i
p>:<port>,=<node-ip>:<port>/drill/
drillbits1;auth=MAPRSASL
```

Using a Connection-Property File with SQLLine

If you use a connection-property file, make sure you restrict user permission on the file to only those users you want to have access.

Complete the following steps to create a connection-property file and connect to Drill:

1. Create a connection-property file named `login.properties` with the following information:

```
url:<jdbc-connection-url>
user:<username>
password:<password>

//Example
cat login.properties
url:jdbc:drill:schema=dfs;drillbit=drill-lab-node01
user:drilluser
password:letsdrill
```

2. To connect to Drill, run SQLLine, as shown:

```
sqlline <sqlline args> <path/to/login.properties file>
```

last-updated: Jun 06, 2024

The following examples show you how to connect to Drill through the connection-property file and how to verify that log in details are safe:

Example 1: Connecting to Drill via the connection-property file

```
sqlline login.properties

Java HotSpot(TM) 64-Bit Server VM
warning: ignoring option
MaxPermSize=512M; support was removed
in 8.0
apache drill 1.16.0
"drill baby drill"
0: jdbc:drill:schema=dfs> !list
1 active connection:
 #0  open
jdbc:drill:schema=dfs;drillbit=drill-l
ab-node01
0: jdbc:drill:schema=dfs>!q
```

Example 2 : Submitting a query when connecting to Drill via the connection-property file

```
sqlline -q "SELECT version FROM
sys.version" login.properties
Java HotSpot(TM) 64-Bit Server VM
warning: ignoring option
MaxPermSize=512M; support was removed
in 8.0
apache drill 1.16.0
"the only truly happy people are
children, the creative minority and
drill users"
0: jdbc:drill:schema=dfs> select
version from sys.version
. . . . . . . . . . . . > +----------+
| version  |
+----------+
| 1.16.0   |
+----------+
1 row selected (0.295 seconds)
0: jdbc:drill:schema=dfs> Closing:
org.apache.drill.jdbc.impl.DrillConnec
tionImpl
$
```

Example 3: Use the properties command to connect to Drill via the connection-property file

```
Run sqlline from /opt/mapr/drill/
drill-<version>/bin sqlline

Java HotSpot(TM) 64-Bit Server VM
warning: ignoring option
MaxPermSize=512M; support was removed
in 8.0
apache drill 1.16.0
"a little sql for your nosql"

sqlline> !properties /home/drilluser/
login.properties
0: jdbc:drill:schema=dfs>
0: jdbc:drill:schema=dfs> !list
1 active connection:
 #0  open
jdbc:drill:schema=dfs;drillbit=drill-l
```

```
ab-node01
0: jdbc:drill:schema=dfs>
```

Example 4: Verify that Login Details are Safe

You can verify sqlline process information to confirm login details are not exposed to other users.

```
ps -ef | grep sqlline
drilluser     18938 21924 99 14:14
pts/0    00:00:03 /opt/

sqlline.SqlLine -d
org.apache.drill.jdbc.Driver --maxWidt
h=10000 --color=true login.properties
drilluser     20119  1691  0 14:14
pts/1    00:00:00 grep sqlline
```

How to Protect the Password

Use the `!connect` command to mask and protect the password, as shown in the following example:

```
sqlline> !connect
jdbc:drill:drillbit=ip-10-0-0-33.eu-west-2.compute.internal:31010

Enter username for
jdbc:drill:drillbit=ip-10-0-0-33.eu-west-2.compute.internal:31010: alice
Enter password for
jdbc:drill:drillbit=ip-10-0-0-33.eu-west-2.compute.internal:31010: ********
```

Start|Stop the Drill Service

You can start|stop|restart the Drillbit service on one or more nodes by using the Control System or the following command:

```
maprcli node services -name drill-bits -action start|restart|stop -nodes
<node host names separated by a space>
```

Use the host name if possible. Using host names instead of IP addresses is a best practice.

Drill Log Files

You can access the Drill log files in `/opt/mapr/drill/drill-<version>/logs/drillbit.log`.

last-updated: Jun 06, 2024

Using the Drill JDBC Driver with SQuirreL
You can use the Drill JDBC driver with SQuirreL to connect to Drill and query the data sources configured in Drill.

To use the Drill JDBC Driver with SQuirreL, verify that your system meets the prerequisites and then download and configure the driver.

Prerequisites

Verify that the system meets the following prerequisites:

- Java Runtime Environment (JRE), version 7.0 or later, installed on each machine where you plan to use the JDBC driver.
- Drill installed in distributed mode on one or multiple nodes in a cluster with data sources configured. See Connecting Drill to Data Sources.
- Verify that the system can resolve the hostnames of the ZooKeeper nodes of the Drill cluster. You can do this by configuring DNS for all of the systems. Alternatively, you can edit the hosts file to include the hostnames and IP addresses of all the ZooKeeper nodes used with the Drill cluster.
  - For Windows, create the entry in the `%WINDIR%\system32\drivers\etc\hosts`.
  - For Linux and Mac, create the entry in `/etc/hosts`.

    Example: `127.0.1.1 maprdemo`

Downloading and Configuring the Driver
This topic provides instructions for downloading and configuring the Drill JDBC driver for SQuirreL.

About this task

When you configure the driver, you define the driver and create an alias. The alias is a specific instance of the driver configuration. SQuirreL uses the driver definition and alias to connect to Drill so you can access data sources that you have registered with Drill. When you create the alias, you provide a connection URL that includes the name of the Drill directory stored in ZooKeeper and the cluster ID. The URL has the following format:

```
jdbc:drill:zk=<zookeeper_quorum>/<drill_directory_in_zookeeper>/<cluster_ID>
```

The following example shows a URL for Drill installed on a single node:

```
jdbc:drill:zk=10.10.100.56:5181/drill/demo_mapr_com-drillbits
jdbc:drill:zk=10.10.100.24:2181/drill/drillbits1
```

The following example shows a URL for Drill installed in distributed mode with a connection to a ZooKeeper quorum:

```
jdbc:drill:zk=10.10.100.30:5181,10.10.100.31:5181,10.10.100.32:5181/drill/
drillbits1
```

NOTE:

- The ZooKeeper port is 2181. In a data-fabric cluster, the ZooKeeper port is 5181.
- The Drill directory stored in ZooKeeper is `/drill`.
- The Drill default cluster ID is `drillbits1`. To determine the cluster ID, check the following file:

  ```
  <drill-installation>/conf/drill-override.conf
  ```

  For example:

  ```
  ... drill.exec: { cluster-id: "docs41cluster-drillbits", zk.connect:
  "centos23.lab:5181,centos28.lab:5181,centos29.lab:5181" } ...
  ```

To use the Drill JDBC driver with SQuirreL, complete the following steps:

Procedure

1. Download the latest Drill JDBC Driver and then unzip the file. The Drill JDBC Driver JAR files must exist in a directory on your machine before you can configure the driver in the SQuirreL client.
2. *If using the data-fabric-SASL or Plain authentication mechanism*, add the Drill JDBC JAR files and /opt/mapr/lib/* to Squirrel's classpath, as shown in the following example when the path to the driver is C:\driver\MapRDrillJDBC41-1.5.6.1012:

   ```
   -cp
   "%SQUIRREL_CP%;C:\driver\MapRDrillJDBC41-1.5.6.1012\*;C:\opt\mapr\lib\*"
   ```

   NOTE: The driver JAR files should appear before /opt/mapr/lib/* in the classpath.
3. Define the driver.
   a) Open the SQuirreL client.
   b) In the SQuirreL toolbar, select **Drivers > New Driver**. The Add Driver dialog appears.
   c) Enter the following information:
      - **Name** - Name for the Drill JDBC Driver
      - **Example URL** - `jdbc:drill:zk=<zookeeper_quorum>`

        Example: `jdbc:drill:zk=maprdemo:5181`
      - **Website URL** - `jdbc:drill:zk=<zookeeper_quorum>`

        Example: `jdbc:drill:zk=maprdemo:5181`

        Example: `jdbc:drill:zk=10.10.100.113:5181,10.10.100.115:5181`
   d) Select **Extra Class Path**, and click **Add**.
   e) Navigate to the directory that contains the JDBC JAR files.
   f) Select all of the files in the directory, and click **Choose**.

g) In the Class Name drop-down field, select the driver class. For driver version 1.6.6.1009 and earlier, select **com.mapr.drill.jdbc41.Driver** or type **com.mapr.drill.jdbc41.Driver** in the field if the option does not appear. For driver version 1.6.7.1010, select **com.mapr.drill.jdbc.Driver** or type **com.mapr.drill.jdbc.Driver** in the field if the option does not appear.

h) Click **Ok**. The SQuirreL client displays a message stating that the driver registration is successful, and you can see the driver in the Drivers panel.

4. Create a database alias.

a) Select the **Aliases** tab.

b) In the SQuirreL toolbar, select **Aliases > New Alias**. The Add Alias dialog box appears.

c) Enter the following information and click **Ok**.

- **Alias Name** - A unique name for the Drill JDBC Driver alias
- **Driver** - Select the Drill JDBC Driver
- **URL** - Enter the connection URL with the name of the Drill directory stored in ZooKeeper and the cluster ID.
- **User Name** - admin
- **Password** - admin

The *Connect to:* dialog appears.

d) Click **Connect**. SQuirreL displays a message stating that the connection is successful.

e) Click **Ok**. SQuirrel is connected to Drill through the Drill JDBC driver. You can run your queries.

Running a Drill Query from SQuirreL

Query sample data in Drill to verify that the SQuirreL client is successfully connected to the cluster through the Drill JDBC driver.

About this task

Run a test query on sample data to test the Drill connection.

To query sample data with Squirrel, complete the following steps:

Procedure

1. Click the **SQL** tab.

2. Enter the following query in the query box: `SELECT * FROM cp.`employee.json`;`

3. Press **Ctrl+Enter** to run the query. The query results display.

Results

You have successfully run a Drill query from the SQuirreL client!

Java Sample Code

To use the Drill JDBC driver in an application, you must include all of the JAR files from the ZIP archive in the classpath for the Java project.

The following Java code demonstrates how to use the JDBC API to:

- Register the driver for Drill
- Establish a connection to a Drill server

last-updated: Jun 06, 2024

- Query the database
- Parse a result set
- Handle exceptions
- Clean up to avoid memory leakage

```
// java.sql packages are required
import java.sql.*;
class DrillJDBCExample {
     // Define a string as the fully qualified class name
     // (FQCN) of the desired JDBC driver
       private static final String JDBC_DRIVER =
       "com.mapr.drill.jdbc.Driver";
     // Define a string as the connection URL
        private static final String CONNECTION_URL =
        "jdbc:drill:drillbit=192.168.1.1:31010";

            public static void main(String[] args) {
                Connection con = null;
                Statement stmt = null;
                ResultSet rs = null;
    // Define a plain query
       String query = "SELECT first_name, last_name, emp_id
       FROM `hive`.`default`.`emp`";

                try {

                    // Register the driver using the class name
                    Class.forName(JDBC_DRIVER);
                    // Establish a connection using the connection
                    // URL
                    con = DriverManager.getConnection(CONNECTION_
                    URL);
                    // Create a Statement object for sending SQL
                    // statements to the database
                    stmt = con.createStatement();

                    // Execute the SQL statement
                    rs = stmt.executeQuery(query);
                    // Display a header line for output appearing in
                    // the Console View
                    System.out.printf("%20s%20s%20s\r\n", "FIRST
                    NAME", "LAST NAME" , "EMPLOYEE ID");

                    // Step through each row in the result set
                    // returned from the database
                    while(rs.next()) {
                        // Retrieve values from the row where the

                        // cursor is currently positioned using
                        // column names
                        String FirstName = rs.getString("first_
                        name");
                        String LastName = rs.getString("last_name");
                        String EmployeeID = rs.getString("emp_id");

                    // Display values in columns 20 characters
                    // wide in the Console View using the
                    // Formatter
                    System.out.printf("%20s%20s%20s\r\n",
                    FirstName, LastName, EmployeeID);
```

last-updated: Jun 06, 2024

```
                    }
                } catch (SQLException se) {
                    // Handle errors encountered during interaction
                    // with the data source
                } catch (Exception e) {
                    // Handle other errors
                } finally {
                    // Perform clean up
                try {
                    if (rs != null) {
                        rs.close();
                    }
                } catch (SQLException se1) {
                    // Log this
                }
                try {
                    if (stmt != null) {
                        stmt.close();
                }
                } catch (SQLException se2) {
                    // Log this
                }
                try {
                    if (con != null) {
                        con.close();
                    }
                } catch (SQLException se3) {
                    // Log this
                } // End try
            } // End try
        } // End main
    } // End DrillJDBCExample
```

Drill ODBC Driver

HPE Ezmeral Data Fabric provides a Drill ODBC driver that you can download and use on all platforms to connect BI tools, such as Tableau, to Drill.

Use the version of the driver that correlates with the version of the installed Drill server. Although older versions of the driver may be able to connect to an upgraded version of Drill, the older drivers do not include all the server features available in the newer drivers.

The following table provides links to the download locations for the Drill ODBC drivers that correlate with each of the Drill versions listed:

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

Drill Version	ODBC Version
1.16.0.100 - 1.20.3.100	1.5.1.1002
1.16.0, 1.16.1.0	1.3.22.1055
1.15.0	1.3.22.1055
1.14.0	1.3.22.1055
1.13.0	1.3.16.1049
1.12.0	1.3.15.1048
1.11.0	1.3.15.1046
1.10.0	1.3.8.1030

last-updated: Jun 06, 2024

IMPORTANT:

- Detailed documentation for the Drill ODBC driver is available at Drill ODBC Driver.
- The 32-bit version of the Drill ODBC driver does not support MapR-SASL. MapR-SASL is only supported in the 64-bit Drill ODBC driver.
- The Drill ODBC driver does not support MapR-SASL for ZooKeeper connections. The Drill ODBC driver only supports MapR-SASL when connecting directly to Drillbits (Drill nodes).
- If you plan to use MapR-SASL for authentication on Windows, review Using MapR-SASL for Authentication on Windows on page 4088 for additional information and instructions.

Using MapR-SASL for Authentication on Windows

Drill is automatically configured with default security when you install Drill 1.11 and later on a secure (version 6.x or later) cluster configured with the default security. To successfully connect to Drill from a Windows ODBC client, the data-fabric client must be installed and a `mapr` user ticket must exist on the Windows client in the %TEMP% directory or in the location specified by the $MAPR_TICKETFILE_LOCATION environment variable.

The ODBC driver locates user tickets for the current Windows user in the default ticket location, %TEMP%, or in the location specified by the environment variable, $MAPR_TICKETFILE_LOCATION. See Tickets and Generating a MapR User Ticket for more information.

You can either copy a user ticket that was generated on the cluster into the default location (%TEMP%), or you can run the `maprlogin` command to generate the ticket on the Windows client.

If you copy a user ticket that was generated on the cluster, you must copy the `mapr-clusters.conf` file to the client machine. Copy the file from `/opt/mapr/conf/mapr-clusters.conf` to `C:/opt/mapr/conf/mapr-clusters.conf` on the client machine. Verify that the cluster to which the client is connecting is listed as the first entry in the `mapr-clusters.conf` file. Also, if the cluster is secure, verify that `secure=true` for the cluster entry in the file.

NOTE: The ODBC user must be the same as the Windows user that created the ticket.

Example

If you want to connect to Drill as the `mapr` user, you must create a ticket for the `mapr` user, as shown:

```
$ maprlogin password -user mapr
[Password for user 'mapr' at cluster 'Cluster1':]
```

The credentials for the `mapr` user in Cluster1 are written to `/tmp/maprticket_1000`.

Next, place the ticket in the %TEMP% directory on the Windows client. For example, the default location for a Windows 10 user named Tabetha Stephens is shown:

```
'C:\Users\TABETH~1\AppData\Local\Temp/maprticket_Tabetha Stephens'
```

To override this location, set the "MAPR_TICKETFILE_LOCATION" global variable for the Windows user.

NOTE: Using the MAPR_TICKETFILE_LOCATION is recommended because the %TEMP% directory differs between Windows versions. You may also want to set the MAPR_TICKETFILE_LOCATION per user on the operating system to prevent all users from using the same user ticket on the client.

last-updated: Jun 06, 2024

Driver Limitations

When using MapR-SASL with JDBC or ODBC drivers, there is no way to specify the target cluster name as part of the connection parameters. MapR-SASL reads the first entry in the `/opt/mapr/conf/mapr-clusters.conf` file and assumes it is the target cluster name.

For example, if the `mapr-clusters.conf` file has an entry for '`cluster1`' followed by an entry for '`cluster2`' and you want to connect to a node in '`cluster2`', authentication fails. As a workaround, manually switch the order of entries in the `mapr-clusters.conf` file.

Driver Issues

The following errors can occur in RHEL 8, Rocky Linux 8, CentOS, and CentOS 8 due to an incompatibility between the bundled `libcrypto.so` ODBC driver library and the `libk5crypto.so` system library:

- ```
  SQLDriverConnect = [iODBC][Driver Manager]/lib64/libk5crypto.so.3: \
  undefined symbol: EVP_KDF_ctrl, version OPENSSL_1_1_1b (0) SQLSTATE=00000
  ```

- ```
  [unixODBC][Driver Manager]Can't open lib '/opt/mapr/drill/lib/64/
  libdrillodbc_sb64.so':\
  file not found
  ```

Use either of the following methods to resolve the issue:

- Remove the bundled crypto library from the ODBC driver RPATH:

  ```
  rm /opt/mapr/drill/lib/64/ThirdParty/libcrypto.so.1.1
  ```

- Make the dynamic linker load the system version of the crypto library with a higher priority than the bundled ODBC library. How this is done depends on the version of the dynamic linker.

How to Connect to Drill from Tableau on Windows

Provides instructions for using the Drill ODBC driver to connect Tableau on a Windows PC to Drill on an HPE Ezmeral Data Fabric node.

The instructions in this document were created using the following environment:

- PC running Windows 10 (64-bit system)
- Secure HPE Ezmeral Data Fabric 7.0.0 node (non-FIPS compliant)
- Drill 1.16.1.400 (EEP 8.1.0) installed on the HPE Ezmeral Data Fabric node
- Tableau version 2021.4.3 installed on the Windows PC

This document walks you through the steps required to:

- Download, install, and configure JDK 11
- Install the Data Fabric 7.0.0 client on a Windows 64-bit computer (Required to access Drill on the HPE Ezmeral Data Fabric) node
- Download and install the Drill ODBC driver (v1.3.22.1055) and configure the DSN
- Connect to Tableau (version 2021.4.3)
- Run a couple of queries to test the Tableau connection to Drill

Download and Install JDK 11

Complete the steps in the following sections to download and install JDK 11. Once you have it installed, set `JAVA_HOME`.

Download JDK 11

Downloading JDK requires an Oracle account. You can create an account before completing the steps listed in this section, or you can follow the steps listed, create your account in step 4 and then repeat steps 1 - 4 again, but instead of creating an account in step 4, entering your credentials.

To download JDK 11:

1. Go to https://www.oracle.com/java/technologies/downloads/#java11.
2. Scroll down to the **Java SE Development Kit 11.0.14** section and select the **Windows** tab.
3. Click **jdk-11.0.14_windows-x64_bin.exe** to download.
4. Accept the license agreement and click the download button. An Oracle account log in window appears. Enter your Oracle account credentials or click Create Account. If you enter your credentials and click Sign in… the download begins. If you create an account, complete steps 1 - 4 again to get the download after you create your account.

Install JDK 11

Click the downloaded `jdk-11.0.14_windows-x64_bin.exe` file. An installation wizard walks you through the installation process. Once installation completes, set the `JAVA_HOME` environment variable.

Set JAVA_HOME

To set `JAVA_HOME`:

1. In Windows, go to **View advanced system settings**. The System Properties window appears.
2. Select the **Advanced** tab.
3. Click **Environment Variables**.
4. Click **New**. The New System Variable window opens.
5. Enter `JAVA_HOME` as the variable name.
6. Enter `C:\PROGRA~1\Java\jdk-11.0.14` as the Variable value. If your JDK version is different, replace `jdk-11.0.14` with your version. Currently, Data Fabric 7.0.0 supports JDK 11.
7. In the System Variables section, select **Path** and then click **Edit**.
8. Verify that `%JAVA_HOME%\bin` is listed. If it is not listed, add it.
9. Click **OK** on each system screen until they all close. To verify that JDK was installed, open the Windows command prompt and run:

```
C:\Users\myname> java -version

//The system should return the following:
java version "11.0.14" 2022-01-18 LTS
Java(TM) SE Runtime Environment 18.9 (build 11.0.14+8-LTS-263)
Java HotSpot(TM) 64-Bit Server VM 18.9 (build 11.0.14+8-LTS-263, mixed
mode)
```

last-updated: Jun 06, 2024

Install the HPE Ezmeral Data Fabric Client on Windows

The HPE Ezmeral Data Fabric client is required to connect to the HPE Ezmeral Data Fabric cluster node running Drill. Note that when you download the client, the client package name is `mapr-client`.

To install the Data Fabric client on your Windows PC, download the client package for Windows and then complete the installation and configuration steps.

1. Create an `\opt\mapr` directory on your `c:` drive. You can do this using Windows Explorer, or you can open the Windows command prompt and type the following in the prompt:

   ```
   mkdir c:\opt\mapr
   ```

2. Add the `MAPR_HOME` environment variable:
   a. In Windows, go to **View advanced system settings**. The System Properties window appears.
   b. Select the **Advanced** tab.
   c. Click **Environment Variables**.
   d. Click **New**. The New System Variable window opens.
   e. Enter `MAPR_HOME` as the variable name.
   f. Enter `MAPR_HOME=C:\opt\mapr` as the variable value.
   g. Click **OK**.
   h. In the System Variables section, double-click the **Path** variable. The Edit Environment Variable window opens.
   i. Verify that the following variables appear in the list:

      ```
      %JAVA_HOME%\bin
      %MAPR_HOME%\bin
      ```

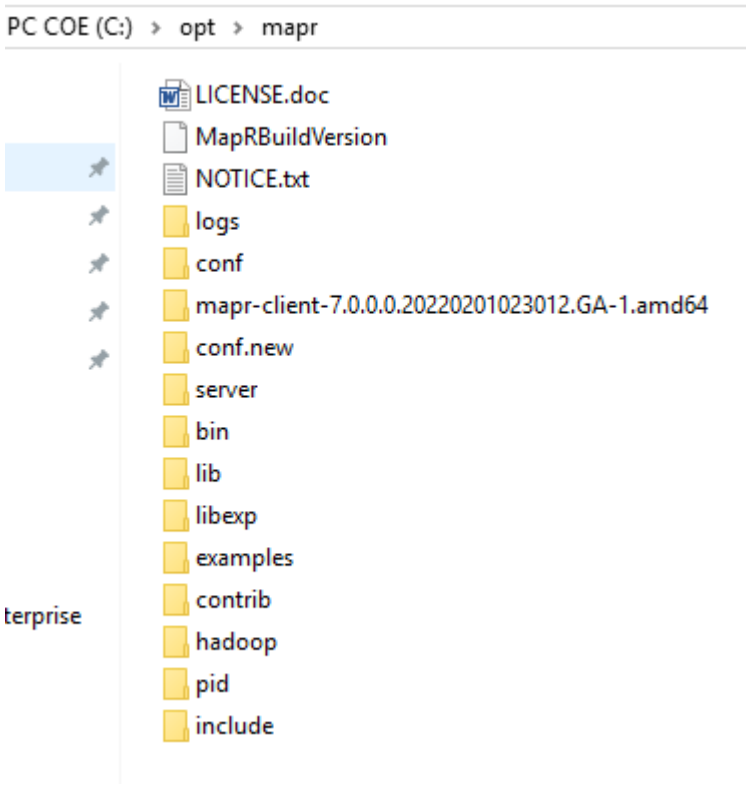
   j. Click **New** and add `%MAPR_HOME%\hadoop\hadoop-2.7.6\bin`. You should now see the following environment variables in the list:

      ```
      %JAVA_HOME%\bin
      %MAPR_HOME%\bin
      %MAPR_HOME%\hadoop\hadoop-2.7.6\bin
      ```

   k. Click **OK** on all screens to exit the environment variables windows.

3. Download the `mapr-client` package:
   a. Go to `https://package.ezmeral.hpe.com/releases/v7.0.0/windows/<package_name>`.
   b. Click on the `mapr-client-7.0.0.0` Windows client package to download it.
   c. Right-click on the downloaded file and select **Extract All…**. Extract all to the `C:\opt\mapr\` folder. Once extracted, you should see several files and folders listed in `C:\opt\mapr`, as shown in the following image:

last-updated: Jun 06, 2024



4. If your Windows command prompt is open, close it and reopen it.
5. Go to the `C:/opt/mapr` directory by running the following command:

   ```
   cd /opt/mapr
   ```

6. Run the configuration script. These instructions assume that the cluster you will be connecting to is secure. To run the configuration script, run the following command in the Windows command prompt:

   ```
   server\configure.bat -N <cluster_name> -c -secure -C
   <node-ip-address>:7222
   ```

last-updated: Jun 06, 2024

NOTE:

- `-N` specifies the cluster name.

  TIP: If you do not know the cluster name, you can use Putty or a similar tool to access the node in the cluster that you want to connect the client to and get the cluster name from the `mapr-clusters.conf` file. When you access the node, go to `/opt/mapr/conf` and then `cat` the `mapr-clusters.conf` file, for example:

  ```
  cd /opt/mapr/conf
  cat mapr-clusters.conf

  //You will see something like the following example returned
  where myCluster is the cluster name:
   myCluster secure=true 10.10.10.279:7222
  ```

- `-c` (lowercase) specifies a client configuration.
- `-secure` indicates connecting to a secure cluster.
- `-C` (uppercase) specifies the CLDB node(s).
- 7222 is the default port for the CLDB node.

7. Copy the `ssl_truststore` and `ssl-client.xml` files from the `/opt/mapr/conf` directory on the cluster node to the `C:\opt\mapr\conf` directory on the Windows client. Using a tool like WinSCP is useful for this.
8. On the Windows PC, run the following command to create a ticket:

   NOTE: When you connect to Drill, you will authenticate to Drill with the username and password that you use in this step.

   ```
   maprlogin password -user <DataFabricUserName>
   ```

   This command creates a ticket for `<DataFabricUserName>`, usually found in:

   ```
   C:\Users\<WindowsUserName>\AppData\Local\Temp\maprticket_<WindowsUserName
   >
   ```

9. In Windows, create a new environment variable named `MAPR_TICKETFILE_LOCATION` and set the variable value to `C:\Users\<WindowsUserName>\AppData\Local\Temp\maprticket_<WindowsUserName>`.
10. From the Windows command prompt, run a `hadoop` command to validate that the client is connected to the cluster node:
    a. Go to the `hadoop-2.7.6` directory:

    ```
    cd /opt/mapr/hadoop/hadoop-2.7.6
    ```

b. Run the following `hadoop` command:

```
hadoop fs -ls /

//Note that the / indicates a directory path.
```

The command should return results similar to the following:

```
Found 5 items
drwxr-xr-x   - uid_5000 gid_5000          4 2022-02-07 06:22 /apps
drwxr-xr-x   - uid_5000 gid_5000          0 2022-02-07 06:10 /opt
drwxrwxrwx   - uid_5000 gid_5000          0 2022-02-07 06:08 /tmp
drwxr-xr-x   - uid_5000 gid_5000          1 2022-02-07 06:11 /user
drwxr-xr-x   - uid_5000 gid_5000          2 2022-02-07 06:11 /var
```

Download the Drill ODBC Driver

To download the Drill ODBC driver:

1. Go to https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR_Drill/MapRDrill_odbc_v1.3.22.1055/.
2. Click `MapRDrill 1.3 64-bit.msi` to download the Windows 64-bit driver.
3. Click the downloaded file and follow the setup wizard to install the driver.
4. If you received a license file through email, copy the license file into the `\lib` sub-folder of the installation folder. You must have administrator privileges to change the contents of this folder.

Configure the DSN

To create a Data Source Name on Windows:

1. In Windows, go to **ODBC Data Sources**. The ODBC Data Source Administrator (64-bit) window opens.
2. In the ODBC Data Source Administrator, click the **Drivers** tab and then scroll down to verify that the **MapR Drill ODBC Driver** appears in the list of ODBC drivers installed on your system.
3. click the **System DSN** tab.
4. Click **Add**.
5. In the Create New Data Source dialog box, select **MapR Drill ODBC Driver** and then click **Finish**. The Drill ODBC Driver DSN Setup dialog box opens.
6. In the Data Source Name field, type a name for your DSN.
7. To connect to the Drill node, select **Direct to Drillbit** and then type the IP address or host name of the Drill server in the field beside the Direct to Drillbit option and the port on which the Drill server is listening. The port is typically 31010, for example: `10.10.10.279:31010`.
8. In the Authentication Type drop-down, select **MapRSASL**.
9. To test the connection, click **Test**. A successful connection returns a success message. If the connection fails, verify that the settings in the MapR Drill ODBC Driver DSN Setup dialog box are correct.
10. Click **OK** to exit the windows.

Connect Tableau to the Drill ODBC Driver (DSN)

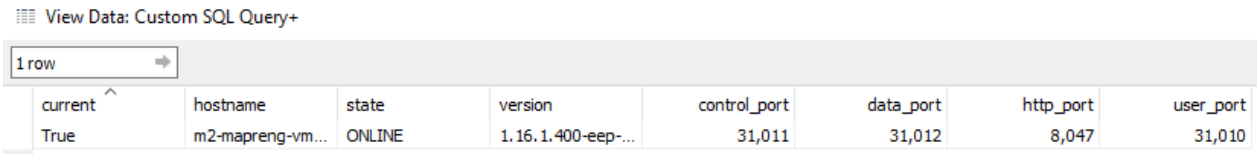
Note that version 2021.4.3 of Tableau was used to create these instructions.

To connect Tableau to the Drill ODBC driver (DSN):

1. Open Tableau.
2. Select **Connect To Server > More > Other Database (ODBC)**. The Other Database (ODBC) window opens.
3. In the DSN drop-down, select the DSN you created (when you completed the steps in the *Configure the DSN* section).
4. Click **Connect**.
5. Enter your credentials to authenticate and then click **Sign in...**. Use the same credentials you used when you created a ticket for the mapr-client.
6. To verify that Tableau is connected to the Drill node, run a couple of test queries:
   a. Double-click **New Custom SQL**.
   b. In the Edit Custom SQL box, enter the following query and then click **Preview Results...**:

```
SELECT * FROM sys.drillbits
```

The query should return results similar to the following:



View Data: Custom SQL Query+

1 row

current	hostname	state	version	control_port	data_port	http_port	user_port
True	m2-mapreng-vm...	ONLINE	1.16.1.400-eep-...	31,011	31,012	8,047	31,010

   c. Close the View Data: Custom SQL Query + box.
   d. In the Edit Custom SQL box, enter the following query and then click **Preview Results...**:

```
SELECT * FROM cp.`employee.json` LIMIT 3
```

This query runs against a sample file (`employee.json`) included in Drill's classpath. The query should return the following results:

View Data: Custom SQL Query+

3 rows

birth_date	education_level	first_name	full_name	gender	hire_date	last_name	management_role	marital_status	position_title	department_id	employee_id	position_id	salary	store_id	supervisor_id

1915-07-03	Graduate Degree	Derrick	Derrick Whelply	M	1994-12-01 00:...	Whelply	Senior Managem...	M	VP Country Man...	1	2	2	40,000.00	0	1
1969-06-20	Graduate Degree	Michael	Michael Spence	M	1998-01-01 00:...	Spence	Senior Managem...	S	VP Country Man...	1	4	2	40,000.00	0	1

Drill Configuration Files

The Drill installation includes configuration files with start-up options that you can modify prior to starting Drill.

The configuration files reside in a HOCON configuration file format, which is a hybrid between a properties file and a JSON file. The files have a nested relationship and a hierarchical structure, where one file overrides another. You can locate the files in the /opt/mapr/drill/drill-<version>/conf directory.

The configuration files are listed below in their hierarchical order. The drill-distrib.conf file overrides the drill-module.conf file, and the drill-override.conf file overrides the drill-distrib.conf file.

- drill-override.conf

- drill-distrib.conf
- drill-module.conf

Environment variables are also overridden in the same way, in the order listed below:

- drill-env.sh (or explicitly defined in environment)
- distrib-env.sh
- drill-config.sh

The following table lists the configuration files with their descriptions:

File Name	Description	Default Configuration with Secure Installation
drill-distrib.conf	Contains distribution-specific configurations for Drill. Automatically updated by configure.sh when you configure the cluster.	• Enables authentication, impersonation, and encryption with HPE Ezmeral Data Fabric-SASL as the default mechanism. • Enables TLS for the HTTPS channel. **NOTE:** By default, HTTPS uses the SSL certificate provided by the cluster installation; however, an administrator can specify a certificate in a keystore. • Enables the inbound impersonation policy for administrators to impersonate any other user.
distrib-env.sh	Contains distribution-specific defaults for various environment variables.	• Enables authentication between the Drillbits and ZooKeeper. • Configures the location of the default security configuration file, mapr.login.conf, used by Drill.
drill-env.sh	The drill-env.sh file contains the cluster admininstrator-specific environment variables that can differ from the defaults. You can modify this file to override the default values of system properties defined in the distrib-env.sh file or to define a new system property. For example, you can configure the amount of heap and direct memory allocated to Drill. See Configuring Drill Memory on page 3976.	Empty upon installation.

drill-override.conf	Use the drill-override.conf file to override the default values obtained from drill-module.conf and drill-distrib.conf. A cluster administrator can update this file to configure a Drillbit as required (different from default installation)	When you first install Drill, drill-override.conf contains ZooKeeper and Drillbit configuration information; however, after you run configure.sh -R, the entries are removed and the file does not contain any configurations.

Mask Sensitive Data in Query Logs and Profiles
Starting in Drill 1.20.2 (EEP 9.0.0 installed on Core 7.1.0), you can define a set of rules in a JSON file to mask sensitive data in Drill query logs and query profiles.

Masking Data in Query Logs

Drill includes the following Logback encoder and layout classes that enable you to configure Drill logs such that data in the final message is masked:

- `org.apache.drill.logback.MaskingPatternEncoder`
- `org.apache.drill.logback.MaskingPatternLayout`

The Drill encoder and layout provide the same functions as the following encoder and layout:

- `ch.qos.logback.classic.encoder.PatternLayoutEncoder`
- `ch.qos.logback.classic.PatternLayout`

The following examples demonstrate how to configure the Drill masking pattern encoder and layout in the `/opt/mapr/drill/drill-<version>/conf/logback.xml` file:

Masking Pattern Encoder Example

```
<configuration>
  <appender name="STDOUT"
class="ch.qos.logback.core.ConsoleAppe
nder">
    <encoder
class="org.apache.drill.logback.Maskin
gPatternEncoder">
      <rulesConfig>$
{pathToJsonConfig}</rulesConfig>
      <pattern>%d{HH:mm:ss.SSS}
[%thread] %-5level %logger{36} -
%msg%n</pattern>
    </encoder>
  </appender>

  <root>
    <level value="error" />
    <appender-ref ref="STDOUT" />
  </root>
</configuration>
```

Masking Pattern Layout Example

```
<configuration>
  <appender name="STDOUT"
class="ch.qos.logback.core.ConsoleAppe
nder">
    <encoder
class="ch.qos.logback.core.encoder.Lay
outWrappingEncoder">
      <layout
```

```
class="org.apache.drill.logback.MaskingPatternLayout">
        <rulesConfig>${pathToJsonConfig}</rulesConfig>
        <pattern>%d{HH:mm:ss.SSS} [%thread] %-5level %logger{36} - %msg%n</pattern>
      </layout>
    </encoder>
  </appender>

  <root>
    <level value="error" />
    <appender-ref ref="STDOUT" />
  </root>
</configuration>
```

Both examples include the `rulesConfig` parameter. The `rulesConfig` parameter is where you include the path to a JSON file that defines the masking rules. Enter the absolute path to the JSON file; do not use a relative path.

For information about how to define masking rules in a JSON file, see Configuring Masking Rules in a JSON File on page 4098.

Masking Data in Query Profiles

You can define rules that mask the following information in query profiles:

- Query plan text
- Queries
- Errors
- Verbose errors

To mask data in query profiles, define the masking rules in a JSON file and then set the `drill.exec.query_profile.masking_rules.config_path` parameter in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` or `/opt/mapr/drill/drill-<version>/conf/drill-distrib.conf` file to point to the JSON file.

For information about how to define masking rules in a JSON file, see Configuring Masking Rules in a JSON File on page 4098. For more information about Drill configuration files, see Drill Configuration Files on page 4095.

Configuring Masking Rules in a JSON File

The JSON file that defines the masking rules must include an array of objects with the following fields:

- search
- replace
- description

Use these fields to define the rules, as shown in the following examples:

```
[
  {
    "search": "([\\w\\d]+\\.)+(com)",
    "replace": "secret.domain.com",
```

```
    "description": "Mask domain names"
  },
  {
    "search": "MagicCompany",
    "replace": "TopSecretCompany",
    "description": "Mask company name"
  }
]
```

The following table describes each of the fields that define the masking rules:

Field	Required	Description	Default
search	Yes	Defines the string or regex pattern to mask. If entering a regex pattern, use the correct escaping. Drill does not apply the rule when this field is empty, null, or omitted.	-
replace	No	Defines the string that you want to mask the search string or regex pattern with. If you want to remove the search string or regex pattern, use "" to leave the space empty.	""
description	No	An optional field used to describe the search and replace rules. The description is not returned in the logs or query profiles.	Empty

Monitoring Drill Metrics

You can monitor Drill metrics and logs using the Kibana and Grafana interfaces that are available through MapR Monitoring. The Kibana interface is a log monitoring tool. The Grafana interface is a metrics monitoring tool where you can view system-level metrics for Drill.

Drill uses JMX (Java Management Extensions) to monitor queries at runtime. JMX provides the architecture to dynamically manage and monitor applications. JMX collects Drill system-level metrics that you can access through Grafana or through the Metrics page in the Drill Web Console.

You must install a specific set of services on cluster nodes to use the Kibana and Grafana monitoring tools. You can install the services using the MapR installer, or you can install these services manually. If you install the monitoring services in a cluster running Drill, you must restart Drill in order for Drill to communicate with JMX. However, if you install Drill after the monitoring services are installed, you must run the `configure.sh` command and restart the Drillbit service in order for the monitoring services to recognize that a new application is running in the cluster.

The following table lists the predefined Drill system-level metrics that you can view in Grafana:

Metric	Description
mapr.drill.allocator_root_used	The amount of memory used by the internal memory allocator. Measured in bytes.
mapr.drill.queries_running	The number of queries running for which the Drillbit is the foreman.
mapr.drill.queries_completed	The number of completed, cancelled, or failed queries for which the Drillbit was the foreman.
mapr.drill.fragments_running	The number of query fragments currently running in the Drillbit.
mapr.drill.allocator_root_peak	The peak amount of memory used by the internal memory allocator. Measured in bytes.
mapr.drill.heap_used	The amount of heap memory used by the JVM. Measured in bytes.
mapr.drill.non_heap_used	The amount of non-heap memory used by the JVM. Measured in bytes.

mapr.drill.count	The number of live daemon and non-daemon threads.
mapr.drill.fd_usage	The ratio of used file descriptors to total file descriptors.
mapr.drill.runnable_count	The number of threads executing in the JVM. This metric is useful for debugging Drill issues.
mapr.drill.waiting_count	The number of threads waiting to be executed. This may occur when a thread waits on another thread to perform an action before proceeding. This metric is useful for debugging Drill issues.
mapr.drill.blocked_count	The number of blocked threads waiting for a monitor lock. This metric is useful for debugging Drill issues.

Optimizing Queries with Indexes

HPE Ezmeral Data Fabric Database provides a highly scalable key-value database platform on which you can run SQL queries using Drill. As of the 6.0 release of the MapR Data Platform, HPE Ezmeral Data Fabric Database natively supports indexes on secondary fields in JSON tables.

NOTE: HPE Ezmeral Data Fabric Database does not support indexes on binary tables.

An index is a special table that stores a subset of document fields from a JSON table. The primary field in a JSON table is the `_id` field (unique key field). By default, HPE Ezmeral Data Fabric Database sorts the JSON table by the `_id` field. All other fields in the JSON table are secondary fields. You can create indexes on the secondary fields in a JSON table to eliminate full tables scans and significanlty improve query performance. See HPE Ezmeral Data Fabric Database as a Document Database and Secondary Index Concepts for more information.

Benefits of Indexes

Well-designed indexes can optimize access to data stored in HPE Ezmeral Data Fabric Database JSON tables and improve performance for high read operations, fast integrated analytics, and complex operational analytics. See Secondary Indexes for more information about the benefits of indexes.

Types of Queries that Benefit from Indexes

Indexes primarily benefit queries with filters in the WHERE clause and queries with an ORDER BY clause for sorting, as described in the following table:

Query Type	Description
Equality	Equality queries contain equality conditions, such as a=1 and can also include IN. See Equality Queries.
Range	Range queries contain range conditions, such as <=, >=, and the LIKE pattern matching condition. See Range Queries. **NOTE:** The LIKE operator only works on fields that have varchar data types. To use the LIKE operator in queries, use the CAST function to explicitly cast fields to varchar. To use indexes for such queries, create indexes on the cast expressions, as explained in Using Casts in Secondary Indexes.
ORDER BY	ORDER BY queries specify a sort order. If the ordering and sorting of the index key list match the ordering specified in a query, the optimizer in Drill does not have to sort the data after the index scan. See ORDER BY Queries.

last-updated: Jun 06, 2024

Multi-index	Multi-index queries contain conditions on multiple fields. Drill can scan multiple indexes and use the intersection of the matching documents to optimize these queries. Multi-index queries are an alternative to using composite key indexes. See Multi-Index Queries.

Drill can create index plans for queries with and without filters in the WHERE clause. For example, Drill can create an index plan for an ORDER BY query that does not have filters.

Drill 1.12 and later also supports the following types of queries without filters :

- GROUP BY
- JOIN
- DISTINCT

See Index Planning in Drill for more information.

Types of Indexes Supported by HPE Ezmeral Data Fabric Database

HPE Ezmeral Data Fabric Database supports several types of indexes on JSON tables including simple, composite, hashed, covering, and indexes with the CAST function.

NOTE: HPE Ezmeral Data Fabric Database enforces certain restrictions on indexes, such as a limit of 32 KB on the collective size of all indexed keys for each index. See Restrictions on Secondary Indexes for a full list of restrictions and Data Types Supported for Secondary Indexes.

The following table lists the supported index types with brief descriptions and links to topics that provide more information:

Index Type	Description
Simple	Simple indexes are indexes with a single indexed field (or key). See Simple Indexes.
Composite	Composite indexes are indexes that have more than one indexed field (or key). See Composite Indexes.
Hashed	Hashed indexes are indexes that distribute keys across logical partitions to avoid the creation of hot spots when HPE Ezmeral Data Fabric Database updates the index with new keys from the JSON table. See Hashed Indexes.
Covering	A covering index is an index that allows HPE Ezmeral Data Fabric Database to process a query using only the secondary indexes. HPE Ezmeral Data Fabric Database does not have to read data in the JSON table. See Covering Indexes on page 698.
Indexes with the CAST function	Indexes with the CAST function convert the indexed field to the data type specified by the CAST function and store the results. See Using Casts in Secondary Indexes.

Steps Required to Use Indexes

To use the index functionality with Drill, complete the following steps:

1. Install the latest version of the required data-fabric software on the cluster. See Preparing Clusters for Querying using Secondary Indexes on JSON Tables and Installing Drill.
2. Evaluate your queries and design indexes that support the queries. See Understanding the Secondary Index Workflow and Designing Secondary Indexes.

last-updated: Jun 06, 2024

3. Create indexes on JSON tables in HPE Ezmeral Data Fabric Database. See Adding Secondary Indexes on JSON Tables and Managing Secondary Indexes.

   NOTE: The user that creates indexes on a JSON table must have created the table or have the `indexperm` permission in addition to `readAce` on the volume and `lookupdir` on directories in the table path. If you do not have these permissions, consult with your system administrator.

4. Issue queries.

5. Verify that Drill uses the available indexes. See Determining Index Use and Troubleshooting Indexes.

Additional Information

- To see how Drill selects a query plan, see Selection and Execution of Secondary Indexes.
- To learn about the index planning and execution configuration options available in Drill, see Index Planning and Execution Configuration Options.
- For information about index architecture, see Implementation of Secondary Indexes.

Index Planning in Drill

Index planning reduces the I/O operation costs associated with full table scans. If an index is available, Drill can use the index to improve query performance.

Drill can use indexes to create query plans for queries that filter on indexed fields or fields included in an index. Fields in COUNT, COUNT DISTINCT, JOIN, GROUP BY, and ORDER BY also determine index use. Drill can create index-based query plans for queries with and without filters (WHERE clause).

NOTE: In Drill 1.11 and earlier, if a query does not have a filter, the query must have an ORDER BY clause.

Drill can create index plans for queries with an ORDER BY clause whether or not the query contains a filter, as shown in the following example:

```
SELECT L_LINENUMBER FROM lineitem ORDER BY L_LINENUMBER;
```

NOTE: In this example, L_LINENUMBER is an indexed field in the index selected for the query plan.

In Drill 1.12 and later, Drill can also create index-based query plans for the following types of queries when they do not have filters (WHERE clause):

- **GROUP BY** queries, as shown in the following example where L_COMMITDate is an indexed field in the index selected for the query plan:

  ```
  SELECT L_COMMITDate FROM lineitem GROUP BY L_COMMITDate;
  ```

- **JOIN** queries, as shown in the following example where L_ORDERKEY and O_ORDERKEY are indexed fields and L_LINESTATUS is an included field in the index selected for the query plan:

  ```
  SELECT L.L_LINESTATUS FROM lineitem L, orders O WHERE
  L.L_ORDERKEY=O.O_ORDERKEY;
  ```

  NOTE: If the planner picks two indexes, one for lineitem and one for orders, a sort merge join is used instead of a hash join.

last-updated: Jun 06, 2024

- Queries with **DISTINCT** projections, as shown in the following examples where L_LINENUMBER is an indexed field in the index selected for the query plan:

```
SELECT DISTINCT L_LINENUMBER FROM lineitem;
SELECT COUNT(DISTINCT L_LINENUMBER) FROM lineitem;
```

Drill can use indexes for queries that GROUP BY or ORDER BY the leading fields in an index. Drill does not use indexes for queries that GROUP BY or ORDER BY the trailing or included fields in an index.

When a query contains GROUP BY and ORDER BY operations on the leading indexed column, Drill can use the sort order of the index to create index-based query plans that use streaming aggregates and merge joins to improve query performance.

You can run the EXPLAIN PLAN FOR command with a query to see the query plan that Drill creates. See Covering and Non-Covering Queries for more information about index planning in Drill.

Index Planning and Execution Configuration Options
The 1.11 release of Drill introduces options that affect how Drill uses indexes when planning and executing queries. You can set the query planning and execution options, at the system or session level, using the ALTER SYSTEM|SESSION SET commands, as shown:

```
ALTER SYSTEM SET `planner.enable_index_planning` = true
ALTER SESSION SET `planner.enable_index_planning` = false
```

Options set at the session level only apply to queries that you run during the current Drill connection. Options set at the system level affect the entire system and persist between restarts. Session level settings override system level settings. Typically, you set the options at the session level unless you want the setting to persist across all sessions.

The following table lists the index planning and execution options that you can enable, disable, or modify:

NOTE: The planning option names are prefaced by planner, for example `planner.enable_index_planning`. The execution options are prefaced by exec, for example `exec.query.rowkeyjoin_batchsize`.

Option	Description	Default Value	Possible Values
planner.enable_index_planning	Enables or disables index planning	true	true|false
planner.index.force_sort_noncovering	Forces Drill to sort for non-covering indexes. If the query has an ORDER-BY on index columns and a non-covering index is chosen, by default Drill leverages the sortedness of the index columns and does not sort. Fast changing primary table data may produce a partial sort. This option forces a sort within Drill. **NOTE:** (Drill 1.11 only) You must enable this option for Drill to return the results of a non-covering query in sorted order.	false	true|false

last-updated: Jun 06, 2024

planner.enable_rowkeyjoin_conversion	Introduced in Drill 1.13. Drill can push down the rowkey filter to HPE Ezmeral Data Fabric Database during runtime. For a query to qualify for runtime filter pushdown, the join condition must filter on a rowkey. A rowkey is the value of the _id field in a JSON document, for example: `SELECT t.mscIdentities FROM dfs.root.`/user/mapr/MixTable` t WHERE t.row_key IN (SELECT max(convert_fromutf8(i.KeyA.ENTRY_KEY)) FROM dfs.root.`/user/mapr/TableIMSI` i WHERE i.row_key='460021050005636')` Drill evaluates the results of the subquery at runtime. The subquery yields a list of rowkeys from the TableIMSI table. Drill pushes down the list of rowkeys to HPE Ezmeral Data Fabric Database. HPE Ezmeral Data Fabric Database uses the rowkeys to locate the corresponding documents in the MixTable table and sends the results to Drill. **NOTE:** Currently, Drill does not support runtime filters for queries with equality conditions. The query planner in Drill converts an equality condition to a left join. As a workaround, use the IN operator instead of the equality (=) operator for queries in which you want Drill to push down the rowkey filter to HPE Ezmeral Data Fabric Database. Drill does not perform runtime filter pushdown for queries that filter on rowkeys in small fact tables when the rowcount is generated from the right side of the join.	true	true|false
planner.rowkeyjoin_conversion_selectivity_threshold	Introduced in Drill 1.13. Sets the selectivity (as a percentage) under which Drill uses a rowkey join for eligible queries.	0.01	Range: 0.0-1.0
planner.rowkeyjoin_conversion_using_hashjoin	Introduced in Drill 1.13. When enabled, Drill uses the hash join operator instead of a rowkey join.	false	true|false
planner.index.covering_selectivity_threshold	For covering indexes, this option specifies the filter selectivity that corresponds to the leading prefix of the index below which the index is considered for planning. For example, for the filter ‘a > 10 AND b < 20’ if an index has indexed fields (a, b, c) and the combined selectivity of the above condition is less than the threshold, the index is considered for the query plan.	0.75	0 - 1.0
planner.index.noncovering_selectivity_threshold	For non-covering indexes, this option specifies the filter selectivity that corresponds to the leading prefix of the index below which the index is considered for planning.	0.025	0 - 1.0
planner.index.max_chosen_indexes_per_table	The maximum number of “chosen” indexes for a table after index costing and ranking.	5	0 - 100
planner.index.rowkeyjoin_cost_factor	The cost factor that provides some control over the I/O cost for non-covering indexes when the rowkey join back to the primary table causes random I/O from the primary table.	0.1	0 - max_double
planner.enable_statistics	Enable or disable statistics for the filter conditions on indexed columns.	true	true|false
exec.query.rowkeyjoin_batchsize	For batch GET operations, this option specifies the batch size in terms of the number of rowkeys. Used for non-covering index plans when doing joins back to primary table.	128	0 - Long.MAX_VALUE

last-updated: Jun 06, 2024

exec.query.progress.update	Enable or disable updating transient query state in ZooKeeper. Disable this option for short running operational queries. When disabled, you do not see the query state , such as STARTING and RUNNING in the Drill Web Console.	true	true|false
exec.udf.use_dynamic	Enable or disable using dynamic UDFs for the queries. Disable this option for operational queries. When disabled, you cannot use dynamic UDFs for queries.	true	true|false
exec.query_profile.save	Enable or disable saving query profiles for the queries. Disable this option for operational queries. When disabled, Drill does not save query profiles and they are not available for analysis or debugging.	true	true|false
planner.use_simple_optimizer	Enable or disable using simple optimizer for queries. Simple optimizer applies fewer rules to reduce planning time and is meant to be used only for simple operational queries that use limit, sort, and filter. This optimizer applies rules for leveraging secondary indexes when index planning is enabled. Enable this option for operational queries.	false	true|false

Index Planning and Execution Options for Operational Queries

The following table lists the index planning and execution options for operational queries that you can enable, disable, or modify:

Option	Description	Default Value	Possible Values
exec.query.progress.update	Enable or disable updating transient query state in ZooKeeper. Disable this option for short running operational queries. When disabled, you do not see the query state , such as STARTING and RUNNING in the Drill Web Console.	true	true|false
exec.udf.use_dynamic	Enable or disable using dynamic UDFs for the queries. Disable this option for operational queries. When disabled, you cannot use dynamic UDFs for queries.	true	true|false
exec.query_profile.save	Enable or disable saving query profiles for the queries. Disable this option for operational queries. When disabled, Drill does not save query profiles and they are not available for analysis or debugging.	true	true|false
planner.use_simple_optimizer	Enable or disable using simple optimizer for queries. Simple optimizer applies fewer rules to reduce planning time and is meant to be used only for simple operational queries that use limit, sort, and filter. This optimizer applies rules for leveraging secondary indexes when index planning is enabled. Enable this option for operational queries.	false	true|false

last-updated: Jun 06, 2024

Covering and Non-Covering Queries

Drill uses a cost-based approach to determine an optimal query plan. When queries are eligible for index planning, the queries are either covering or non-covering.

For covering queries, only the index is needed to process the query. Drill creates an index-based query plan that includes an index scan. Covering queries avoid the overhead of fetching data from the primary table.

For non-covering queries, the index only contains a subset of the data required to process the query. Drill creates a query plan that includes an index scan and a join back to the primary table. In some scenarios, a full table scan is more cost efficient than an index scan and Drill will not create an index plan.

NOTE: (Drill 1.11 only) You must enable the `planner.index.force_sort_noncovering` option for Drill to return the results of a non-covering query in sorted order. See Index Planning and Execution Configuration Options

.

Indexes for covering and non-covering queries can contain indexed fields, or a combination of indexed and included fields. HPE Ezmeral Data Fabric Database stores included fields in the index. Each field added to the index increases the storage requirement for the index. As the storage size increases, the cost of reading the index also increases. Likewise, for the cost of adding and updating documents. Consider the impact on storage and updates when adding included fields to an index.

- For information about how Drill selects a query plan, see Selection and Execution of Secondary Indexes.
- For information about the types of queries that qualify for index-based plans, see Queries that Benefit from Secondary Indexes.
- For index concepts, see Secondary Index Concepts.

Covering and Non-Covering Query Examples

A query can be covering or non-covering based on the fields referenced in the query and the fields on which an index is created and/or includes.

The following query examples use an index, *l_comp_1*, created on a table, *lineitem*.

The *l_comp_1* index was created using the `maprcli table index add` command, as shown:

```
maprcli table index add -path /drill/testdata/tpch/sf1/
maprdb/json/range/lineitem -index l_comp_1 -indexedfields
L_LINENUMBER,L_ORDERKEY -includedfields L_LINESTATUS,L_QUANTITY
```

Covering Query Example

The following query references the L_LINESTATUS, L_QUANTITY, L_LINENUMBER, and L_ORDERKEY fields in the *lineitem* table:

```
SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE L_LINENUMBER = 1 AND
L_ORDERKEY BETWEEN 40 AND 75;
```

Because the *l_comp_1* index includes all fields referenced in the query, Drill creates a query plan that uses the index only.

Running the EXPLAIN PLAN FOR command with the query shows that Drill created a query plan that only uses the index to process the query:

```
EXPLAIN PLAN FOR SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75;
```

last-updated: Jun 06, 2024

```
00-00    Screen
00-01      Project(L_LINESTATUS=[$0], L_QUANTITY=[$1])
00-02        Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
indexName=l_comp_1], columns=[`L_LINESTATUS`, `L_QUANTITY`]]])
```

Reading the query plan, you can see that the plan includes an index scan, as indicated by *groupscan=[JsonTableGroupScan* and *indexName*. Drill and HPE Ezmeral Data Fabric Database can process this query using only the index.

Non-Covering Query Example

The following query references the L_RETURNFLAG, L_LINESTATUS, L_QUANTITY L_LINENUMBER, and L_ORDERKEY fields in the *lineitem* table:

```
SELECT L_RETURNFLAG, L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75;
```

Because the *l_comp_1* index does not include the L_RETURNFLAG field, Drill creates a query plan that uses the index, but also includes a join on the primary table.

Running the EXPLAIN PLAN FOR command with the query shows that Drill includes an index scan and a table scan:

```
EXPLAIN PLAN FOR SELECT L_RETURNFLAG, L_LINESTATUS, L_QUANTITY FROM
lineitem WHERE L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75;

00-00    Screen
00-01      Project(L_RETURNFLAG=[$0], L_LINESTATUS=[$1], L_QUANTITY=[$2])
00-02        Project(L_RETURNFLAG=[$2], L_LINESTATUS=[$3], L_QUANTITY=[$4])
00-03          Project(L_LINENUMBER=[$0], L_ORDERKEY=[$1],
L_RETURNFLAG=[$2], L_LINESTATUS=[$3], L_QUANTITY=[$4])
00-04            RowKeyJoin(condition=[=($5, $6)], joinType=[inner])
00-06              Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[RestrictedJsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75}))],
columns=[`L_LINENUMBER`, `L_ORDERKEY`, `L_RETURNFLAG`, `L_LINESTATUS`,
`L_QUANTITY`, `_id`], rowcount=60012.15000000001]])
00-05              Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
indexName=l_comp_1], columns=[`_id`]]])
```

Reading the query plan, you can see that the plan includes an index scan, as indicated by the *groupscan=[JsonTableGroupScan* and *indexName*, and also a scan on the primary table, as indicated by the *groupscan=[RestrictedJsonTableGroupScan* and the *RowKeyJoin*. To process this query, Drill and HPE Ezmeral Data Fabric Database can use the index, but HPE Ezmeral Data Fabric Database must also use the rowkey to perform a join on the primary table to fetch data in the L_RETURNFLAG field.

If this query ran on a regular basis, you could remove the *l_comp_1* index and create a new index that includes all fields referenced in the query, including the L_RETURNFLAG field, to improve query performance. However, running a query only once or a few times may not justify the overhead of removing the old index and creating a new index.

Non-Hashed and Hashed Indexes

You can create non-hashed and hashed indexes for queries on JSON tables in HPE Ezmeral Data Fabric Database.

Non-hashed indexes support conditional queries with an ORDER BY clause because HPE Ezmeral Data Fabric Database sorts the data in non-hashed indexes. When processing ORDER BY queries, Drill does not have to perform sort operations on the data.

Hashed indexes support the same conditional queries as non-hashed indexes, but they do not have a guaranteed sort order. Hashed indexes enable HPE Ezmeral Data Fabric Database to evenly distribute new writes on an index across logical partitions to avoid hot spotting. Drill must perform a sort for ORDER BY queries that use hashed indexes. Sorting the data can increase the CPU costs and negatively impact performance. See Hashed Indexes for additional information.

If you notice performance issues with ORDER BY queries that use hashed indexes, review the query plans to see if the plans include sort and merge operations. If this is the case, create non-hashed indexes to support the queries and achieve the best performance.

Examples of Hashed and Non-Hashed Index Plans for an ORDER BY Query

The examples here show the difference between a hashed and non-hashed index plan for the following query on the lineitem table that contains the ORDER BY clause:

```
SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE L_LINENUMBER = 1 AND
L_ORDERKEY BETWEEN 40 AND 75 ORDER BY L_LINENUMBER;
```

Hashed Index Plan Example

A hashed index, *l_hash_comp_1*, was created using the *maprcli table index add* command on a table, *lineitem*, as shown:

```
maprcli table index add -path /drill/testdata/tpch/sf1/
maprdb/json/hash/lineitem -index l_hash_comp_1 -indexedfields
L_LINENUMBER,L_ORDERKEY -includedfields L_LINESTATUS,L_QUANTITY -hashed true
```

Running the example query with the EXPLAIN PLAN FOR command shows that Drill produces an index plan with sort and merge operations to process the query when using the hashed index, as follows:

```
EXPLAIN PLAN FOR SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75 ORDER BY L_LINENUMBER;

00-00    Screen
00-01      Project(L_LINESTATUS=[$0], L_QUANTITY=[$1])
00-02        SingleMergeExchange(sort0=[2])
01-01          SelectionVectorRemover
01-02            Sort(sort0=[$2], dir0=[ASC])
01-03              Project(L_LINESTATUS=[$2], L_QUANTITY=[$3],
L_LINENUMBER=[$0])
01-04                Scan(table=[[si, tpch_sf1_maprdb_hash,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/hash/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
indexName=l_hash_comp_1], columns=[`L_LINENUMBER`, `L_ORDERKEY`,
`L_LINESTATUS`, `L_QUANTITY`]]])
```

Reading the query plan, you can see that Drill uses the hashed index in the plan, as indicated by *indexName=l_hash_comp_1*. To process the query, HPE Ezmeral Data Fabric Database can use the index, but Drill must sort and merge the data, as indicated by the *Sort* and *SingleMergeExchange* operations in the query plan.

last-updated: Jun 06, 2024

Using the hashed index plan for this ORDER BY query requires additional processing and negatively impacts performance.

Non-Hashed Index Plan Example

A non-hashed index, *l_comp_1*, was created using the `maprcli table index add` command on a table, *lineitem*, as shown:

```
maprcli table index add -path /drill/testdata/tpch/sf1/
maprdb/json/range/lineitem -index l_comp_1 -indexedfields
L_LINENUMBER,L_ORDERKEY -includedfields L_LINESTATUS,L_QUANTITY
```

Running the example query with the EXPLAIN PLAN FOR command shows that Drill produces an index plan without the additional sort and merge operations when using the non-hashed index to process the query, as follows:

```
EXPLAIN PLAN FOR SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE
L_LINENUMBER = 1 AND L_ORDERKEY BETWEEN 40 AND 75 ORDER BY L_LINENUMBER;

00-00    Screen
00-01      Project(L_LINESTATUS=[$0], L_QUANTITY=[$1])
00-02        Project(L_LINESTATUS=[$2], L_QUANTITY=[$3], L_LINENUMBER=[$0])
00-03          Scan(table=[[si, tpch_sf1_maprdb_range,
lineitem]], groupscan=[JsonTableGroupScan [ScanSpec=JsonScanSpec
[tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/json/range/lineitem,
condition=(((L_LINENUMBER = {"$numberLong":1}) and (L_ORDERKEY
>= {"$numberLong":40})) and (L_ORDERKEY <= {"$numberLong":75})),
indexName=l_comp_1], columns=[`L_LINENUMBER`, `L_ORDERKEY`, `L_LINESTATUS`,
`L_QUANTITY`]]])
```

Reading the query plan, you can see that Drill uses the non-hashed index plan, as indicated by *indexName=l_comp_1*. To process the query, HPE Ezmeral Data Fabric Database uses the index and Drill does not have to perform sort and merge operations on the data, as indicated by the absence of the Sort and SingleMergeExchange operations in the query plan. HPE Ezmeral Data Fabric Database sorted the data in the index when the index was created.

Writing Drill Queries that Leverage Indexes on Array Fields

Starting in EEP 6.0, the query planner in Drill can leverage indexes created on MapR Database JSON document fields with array data types, such as `"NUMBERS": [1, 2, 3, 4, 5]` and `"ADDRESSES": [{"CITY" : "SAN JOSE"}, {"CITY" : "PALO ALTO"}]`.

See JSON Document Data Types and Data Types and Secondary Index Fields for definitions and detailed examples.

If you want the query planner in Drill to leverage an index created on a field with an array data type, you must write the Drill query such that it includes specific SQL syntax, as shown in bold in the following example:

```
SELECT NAME, PHONE
FROM CUSTOMERS
WHERE _id IN ( SELECT _id
               FROM ( SELECT _id, FLATTEN(ADDRESSES) as f
          FROM CUSTOMERS) as t
               WHERE t.f.CITY = 'SAN JOSE' and t.f.STATE = 'CA')
;
```

The specific SQL syntax indicates (to the query planner in Drill) that the query is eligible for an index-based query plan.

The FLATTEN function separates elements in an array into individual records in a table. For example, if an array consists of five elements, FLATTEN separates each element into a single row, creating a table with five rows.

last-updated: Jun 06, 2024

The IN operator prevents Drill from returning duplicate rows. For example, when an array is flattened into a table, duplicate values may exist for a particular _id (rowkey). Using IN prevents Drill from returning rows with duplicate values.

Example

Suppose a JSON primary table named CUSTOMERS exists in MapR Database with the following data:

```
{ "_id": "001",
 "NAME": "ALICE",
 "PHONE": "408-555-1212",
 "ADDRESSES": [{"CITY" : "SAN JOSE" , "ZIPCODE" : 95124, "STATE" :
"CA", "UNITS" : [{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR":
7}]}, {"CITY" : "PALO ALTO", "ZIPCODE" : 94020, "STATE" : "CA",
"UNITS" : [{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR": 7}]},
{"CITY" : "SANTA CLARA", "ZIPCODE" : 95050, "STATE" : "CA", "UNITS" :
[{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR": 7}]}],
  "QTY": [11, 25, 16, 2, 10, 39, 5, 8, 7, 11]
}
{ "_id": "002",
 "NAME": "BOB",
 "PHONE": "408-555-1313",
 "ADDRESSES": [{"CITY" : "SAN JOSE" , "ZIPCODE" : 95132, "STATE" :
"CA", "UNITS" : [{"UNIT_NO":838, "FLOOR": 8}, {"UNIT_NO":888, "FLOOR":
8}]}, {"CITY" : "SAN JOSE", "ZIPCODE" : 95127, "STATE" : "CA", "UNITS" :
[{"UNIT_NO":555, "FLOOR": 5}, {"UNIT_NO":777, "FLOOR": 7}]}, {"CITY" :
"SAN RAMON", "ZIPCODE" : 94582, "STATE" : "CA", "UNITS" : [{"UNIT_NO":123,
"FLOOR": 1}, {"UNIT_NO":124, "FLOOR": 1}]}],
 "QTY": [2, 8, 1, 4, 3, 10, 2, 23]
}
{ "_id": "003",
 "NAME": "CHRIS",
 "PHONE": "408-555-1414",
 "ADDRESSES": [{"CITY" : "MOUNTAIN VIEW", "ZIPCODE" : 94043, "STATE" :
"CA", "UNITS" : [{"UNIT_NO":922, "FLOOR": 9}, {"UNIT_NO":958, "FLOOR":
9}]}, {"CITY" : "PALO ALTO", "ZIPCODE" : 94020, "STATE" : "CA", "UNITS" :
[{"UNIT_NO":666, "FLOOR": 6}, {"UNIT_NO":728, "FLOOR": 7}]}, {"CITY" :
"SUNNYVALE", "ZIPCODE" : 94086, "STATE" : "CA", "UNITS" : [{"UNIT_NO":226,
"FLOOR": 2}, {"UNIT_NO":333, "FLOOR": 3}]}],
 "QTY": [56, 19, 45, 25, 4, 77, 110, 3, 2, 1]
}
```

NOTE: The QTY field is an array. The ADDRESSES field is an array of maps.

The following query on the CUSTOMERS table returns the result of flattening the “ADDRESSES" array field into a column aliased as “f" where each element in the array is flattened into individual rows:

NOTE: In the results, notice that Bob has two addresses where the “CITY" is “SAN JOSE". Later in this example, you will see that using the IN operator prevents the query from returning duplicate rows.

```
SELECT NAME, PHONE, f FROM (SELECT NAME, PHONE, FLATTEN(ADDRESSES) AS f
FROM CUSTOMERS);

+---------+--------------+-------------------------------------------------------------------

| NAME    | PHONE        |
f
                                       |
+---------+--------------+-------------------------------------------------------------------

| ALICE   | 408-555-1212 | {"CITY":"SAN JOSE","STATE":"CA","UNITS":
[{"FLOOR":5,"UNIT_NO":555},
```

last-updated: Jun 06, 2024

                 |
+---------+--------------+-----------------------------------------------------------------
```

The following query returns the results of filter conditions on the fields “CITY" and “STATE" if the CITY is SAN JOSE and STATE is CA.

```
SELECT NAME, PHONE, f FROM (SELECT NAME, PHONE, FLATTEN(ADDRESSES) AS f
FROM CUSTOMERS) AS t WHERE t.f.CITY = 'SAN JOSE' and t.f.STATE = 'CA';

+-------+--------------+-----------------------------------------------------------------

| NAME  | PHONE        |
f

|
+-------+--------------+-----------------------------------------------------------------

| ALICE | 408-555-1212 | {"CITY":"SAN JOSE","STATE":"CA","UNITS":
[{"FLOOR":5,"UNIT_NO":555},
{"FLOOR":7,"UNIT_NO":777}],"ZIPCODE":95124}
                            |
| BOB   | 408-555-1313 | {"CITY":"SAN JOSE","STATE":"CA","UNITS":
[{"FLOOR":8,"UNIT_NO":838},
{"FLOOR":8,"UNIT_NO":888}],"ZIPCODE":95132}
                          |
| BOB   | 408-555-1313 | {"CITY":"SAN JOSE","STATE":"CA","UNITS":
[{"FLOOR":5,"UNIT_NO":555},
{"FLOOR":7,"UNIT_NO":777}],"ZIPCODE":95127}
```

last-updated: Jun 06, 2024

```
         |
+-------+-------------+-------------------------------------------------------------
```

Suppose a composite index exists on `ADDRESSES[].CITY` and `ADDRESSES[].STATE`with "NAME" as an included field. For the query planner to use the index, you must write the query using the specific SQL syntax that indicates that the query is eligible for an index-based query plan, as shown:

```
SELECT NAME, PHONE
FROM CUSTOMERS
WHERE _id IN ( SELECT _id
               FROM ( SELECT _id, FLATTEN(ADDRESSES) as f
           FROM CUSTOMERS) as t
               WHERE t.f.CITY = 'SAN JOSE' and t.f.STATE = 'CA');

//Issuing this query against the data in the CUSTOMERS table returns the
following results:
+--------+---------------+
|  NAME  |     PHONE     |
+--------+---------------+
| ALICE  | 408-555-1212  |
| BOB    | 408-555-1313  |
+--------+---------------+
```

NOTE: Although Bob has two addresses where the "CITY" is "SAN JOSE", the query returns only one result. The IN operator prevents the query from returning duplicate rows.

The following list summarizes key points about this query:

- The innermost subquery projects on the _id field (rowkey) and includes the FLATTEN function to separate the array elements in the “ADDRESSES” field. The field “ADDRESSES” is flattened into a table aliased as “t”, in a column aliased as “f”.
- The query uses the IN operator to ensure that the results returned contain unique values only; no duplicates. DISTINCT on the subquery to the right of IN is implicit. The SQL query pattern indicates to the query planner that the query is eligible for an index-based query plan.
- The query projects on column “NAME” and “PHONE”. “PHONE” requires a join back to the primary table on the _id field (rowkey) because it is not included in the composite index.
- The query planner recognizes that t.f.CITY references t.ADDRESSES[].CITY and t.f.STATE references t.ADDRESSES[].STATE and creates an index-based query plan.
- The index table in MapR Database is already flattened for the array field, “ADDRESSES”. Flatten is not evaluated in Drill. Drill pushes the filter conditions on the array field into MapR Database.

Filter Conditions on Various Types of Array Fields

The following table shows examples of filter conditions on various types of array fields and includes the MapR Database notation for the array field with the filter condition, as well as the SQL syntax for writing queries against the array fields.

NOTE: The queries in the table are written against the CUSTOMERS data used in the previous example.

Filter condition on …	Example using MapR Database notation (not SQL notation)	SQL

Performance Considerations

When writing queries that leverage indexes on array fields, consider the following points about performance:

- Query patterns that match those described previously in this document are pushed down to MapR Database. Drill does not evaluate the filter conditions, which adds considerable performance benefits even when the query planner does not select an index-based query plan.
- Deduplication on the _id is an extra operation (compared to regular, non-complex, indexes) that requires the overhead of hash aggregation.
- Try to avoid array columns in included fields within an index table, as they add a significant amount of storage overhead. However, this may result in the query planner selecting non-covering plans.
- Indexes with deeply nested array elements, such as `a[].b[].c[]...x.y`, can add to the MapR Database storage overhead and can potentially make Drill queries longer and more complex.

Limitations

Drill queries that leverage indexes on array fields have the following limitations:

- Only queries with patterns similar to those described previously in this document are eligible for index planning, assuming that the index is defined on an array field.
- The following conditions do not produce a covering index plan:
  - Pushdown conditions on indexed fields and included fields on same array element. For example, if an index has indexed fields a[].b and included fields a[].c, elementAND(a[], b > 10, c > 20) does not produce a covering index plan.
  - Pushdown conditions on scalar indexed fields and included fields containing an array element. For example, an index with indexed field m and included fields a[].b, m = 10 AND a[].b > 20 does not produce a covering index plan.
- For included array fields, the element must be provided without the [] for the query planner to pick covering plans. For example, `a` and not `a[]`. Note that MapR Database considers both a and a[] syntaxes as equivalent for included fields.
- Index planning is disabled for queries with multi-level flattens and intermediate filters that reference multi-level flattens. A filter can reference the root level flatten, but not the intermediate flattens.

last-updated: Jun 06, 2024

Determining Index Use

Evaluate the query plan to analyze query performance and determine if Drill uses indexes. You can view query plans in the Drill Web Console or through the command line using the EXPLAIN command. You can also disable the indexing option in Drill and compare an index-based plan to a full table scan plan.

Drill leverages indexes during the physical planning phase of the query. Drill estimates the cost of an index-based plan and a plan that includes a full table scan. See Selection and Execution of Secondary Indexes for information about how Drill selects a query plan. In cases where Drill does not select the index-based plan and instead selects a full table scan plan, you may want to remove the indexes to free up storage space and eliminate the overhead of the indexes.

The following example shows you how to determine if Drill selected an index-based plan for a query through the query profile in the Drill Web Console and the EXPLAIN PLAN FOR output.

Example

The subsequent sections assume that an index exists on a table named "lineitem." The index, l_single_c_5, is a single field index created on the L_QUANTITY field. The index also covers the L_SUPPKEY, L_DISCOUNT, L_SHIPDate, and L_SHIPMODE fields. If a query contains fields covered by the index, the query is a covering query. If a query contains fields not covered by the index, the query is non-covering and requires a lookup back into the primary table to retrieve data.

The following list summarizes the assumptions:

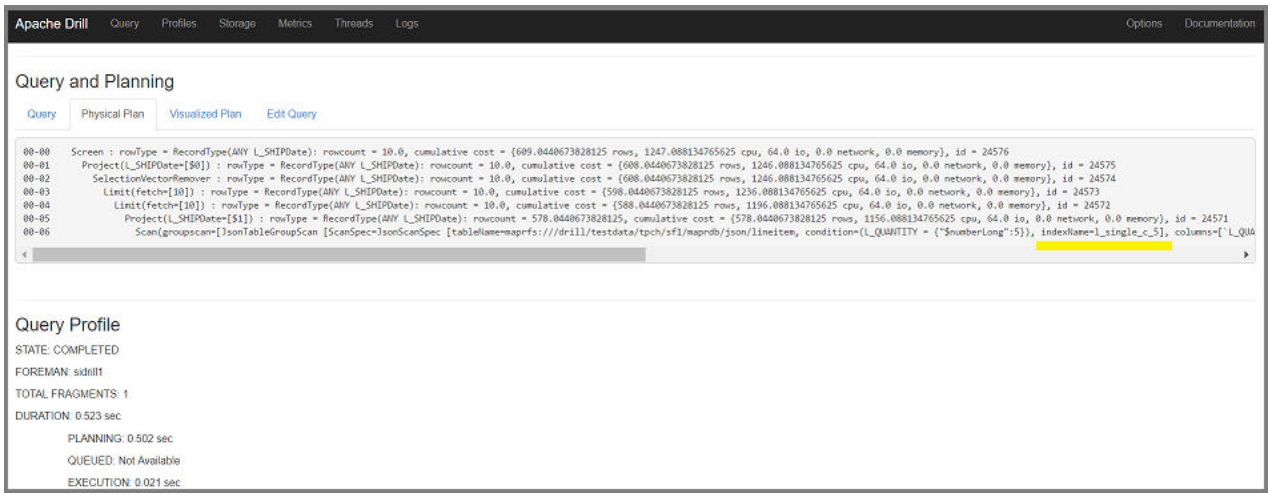
- **Table name:** lineitem
- **Index name:** l_single_c_5
- **Indexed field:** L_QUANTITY
- **Included fields:** L_SUPPKEY, L_DISCOUNT, L_SHIPDate, L_SHIPMODE

Query Profile

View the query plan on the **Profiles** tab in the Drill Web Console. See Starting the Web Console. Select the query you want to evaluate and then select the **Physical Plan** tab. You can see the physical plan that Drill used to execute the query.

The following image shows the physical plan that Drill used to execute this simple equality query:

```
SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5;
```



last-updated: Jun 06, 2024

In the plan, you can see that Drill scanned the index, l_single_c_5, instead of the primary table. The query was completely covered by the index because the index contains all fields referenced in the query and the query filtered on the indexed field.

EXPLAIN PLAN

Alternatively, you can issue the EXPLAIN command to see how Drill executes a query. To see the chosen physical execution plan for a query without running the query, issue the EXPLAIN PLAN FOR command. This command shows you if Drill plans to use the index when executing the query.

The following image shows the physical plan that Drill plans to use to execute this simple equality query:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+------+------+
| text | json |
+------+------+
| 00-00    Screen
00-01      Project(L_SHIPDate=[$0])
00-02        SelectionVectorRemover
00-03          Limit(fetch=[10])
00-04            Limit(fetch=[10])
00-05              Project(L_SHIPDate=[$1])
00-06                Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5}),
indexName=l_single_c_5], columns=[`L_QUANTITY`, `L_SHIPDate`]]])
```

In the plan, you can see that Drill plans to use the index, l_single_c_5, instead of performing a full table scan. The query is completely covered by the index because the index contains all fields referenced in the query and the query filters on the indexed field.

Compare Plans

If you want to compare an index-based plan against a plan with a full table scan, disable the planner.enable_index_planning option in Drill, and run the EXPLAIN PLAN FOR command for the query. Running this command with the planner.enable_index_planning option disabled forces Drill to generate a plan that includes a full table scan. You can compare the full table scan plan against the index-based plan to compare the costs and resource consumption of each plan.

You can see in the following query, with the indexing feature turned on, Drill generated a plan using the index:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+------+------+
| text | json |
+------+------+
| 00-00    Screen
00-01      Project(L_SHIPDate=[$0])
00-02        SelectionVectorRemover
00-03          Limit(fetch=[10])
00-04            Limit(fetch=[10])
00-05              Project(L_SHIPDate=[$1])
00-06                Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5}),
indexName=l_single_c_5], columns=[`L_QUANTITY`, `L_SHIPDate`]]])
```

last-updated: Jun 06, 2024

If you turn the option off, as shown:

```
ALTER SESSION SET planner.enable_index_planning = false
```

You can run the EXPLAIN PLAN FOR command again to see the plan with a full table scan included:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+------+------+
| text | json |
+------+------+
| 00-00    Screen
00-01      Project(L_SHIPDate=[$0])
00-02        SelectionVectorRemover
00-03          Limit(fetch=[10])
00-04            UnionExchange
01-01              SelectionVectorRemover
01-02                Limit(fetch=[10])
01-03                  Project(L_SHIPDate=[$1])
01-04                    Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5})],
columns=[`L_QUANTITY`, `L_SHIPDate`]]])
 |
```

NOTE: To see the cost of each plan, go to the Drill Web Console and view the query profile for each EXPLAIN PLAN FOR command that you issue through the command line.

Drill Limitations

Provides information about Drill limitations and solutions where applicable.

Max Drill Query Size Depends on ZooKeeper jute.maxbuffer Value

Issue	Drill cannot run a query that exceeds the ZooKeeper `jute.maxbuffer` value of 1 MB.
Solution	For the ZooKeeper `jute.maxbuffer` property, follow the recommendations in the ZooKeeper documentation. **CAUTION:** The `jute.maxbuffer` property is marked as an unsafe option. Do not change it to a higher value to run larger queries. For additional details about why this property is unsafe, see the Apache Zookeeper documentation: https://zookeeper.apache.org/doc/r3.6.2/zookeeperAdmin.html The following error indicates that the query is too large. To resolve this error, rewrite the query to fit within the `jute.maxbuffer` limit: `Query execution error. Details: EXECUTION_ERROR ERROR: Failed to persist query info. Query length is too big.`

In Drill EEP version 8.1.0 and earlier and EEP version 9.1.1 and earlier, the following type of error may also indicate that the query is too large:

```
Query execution
error. Details: SYSTEM
ERROR: ConnectionLossException:
KeeperErrorCode =
ConnectionLoss for /drill/running/
1bb44a40-c715-7b38-c310-05de39dfb3e7
```

In Drill EEP version 8.1.1, this error could indicate that the `jute.maxbuffer` value set for the Drillbit does not correspond with the ZooKeeper `jute.maxbuffer` value.

To change the value of `jute.maxbuffer` in Drill, add the `-Djute.maxbuffer` Java property to `DRILL_JAVA_OPTS` in `<drill_home>/conf/drill-env.sh`, as shown in the following example:

```
export
DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Dju
te.maxbuffer=900000
```

If you change the `jute.maxbuffer` value, you must update the system property on all servers (ZooKeeper nodes) and clients (Drillbit nodes) to have the same value. Failure to change the value on all servers and clients can result in further errors.

Working with subqueries

- The SELECT list in a scalar subquery can only contain one item/column.
- Correlated subqueries should return exactly one row.
- The WHERE clause of a subquery should not refer to more than one column of the table in the outer query.

Queries on JSON Files and Tables in HPE Ezmeral Data Fabric Return an OutOfMemoryException

An architectural limitation in Apache Drill can cause an overconsumption of memory when Drill queries files or tables with a certain JSON structure, resulting in an OutOfMemoryException.

Drill may return an OutOfMemoryException for queries that run against JSON files stored in HPE Ezmeral Data Fabric Database and HPE Ezmeral Data Fabric File Store that have many key-value pairs if the queries include the key-value pairs.

For example, the following JSON files could cause Drill to return an OutOfMemoryException when queries that include the key-value pairs run against the files:

JSON file with objects that have many key-value pairs

```
{
    "context" : {
        "1": "a",
        "2": "b",
        "3": "c",
        ... // many key-value pairs;
not showing 9996 of them
        "10000": "d"
```

last-updated: Jun 06, 2024

```
    }
}
{
    "context" : {
        "10001": "b"
        ... //many key-value pairs;
not showing 19998 of them
        "30000": "z"
    }
}
{
    "context" : {
        "3": "c"
    }
}
{
    "context" : {

    }
}
{
    "context" : {
        "5": "e"
    }
}
```

JSON file with thousands of objects, each having a unique key

```
{
    "context" : {
        "1": "a"
    }
}
{
    "context" : {
        "2": "b"
    }
}
{
    "context" : {
        "3": "c"
    }
}
{
    "context" : {
        "4": "d"
    }
}
{
    "context" : {
        "5": "e"
    }
}
```

In this scenario, if a JSON file contains thousands of objects with unique keys (in 30,000+ documents), the following query would cause an OutOfMemoryException:

```
SELECT context FROM
maprfs.`folderWithJSONDocuments`;
```

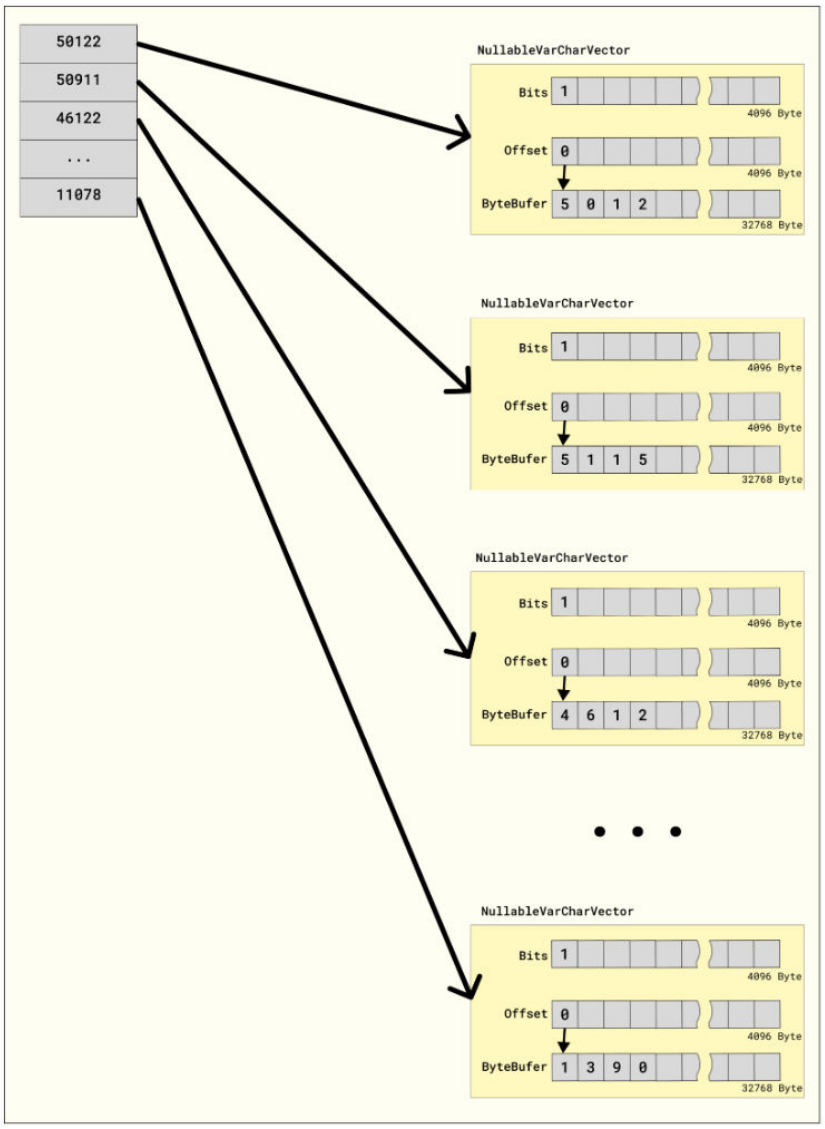
Issue Cause

Drill was designed to run queries against massive amounts of data. To successfully run such queries, Drill has a columnar execution engine that works with vectors. Drill creates a separate vector for each unique key and then allocates memory to each vector. Each vector stores about 1,024 values, which varies slightly depending on the data type of the value.

In the following illustration, each key has a VARCHAR value and Drill creates a NullableVarCharVector for each unique key:

JSON

```
{
  "context" : {
    "50122": "5012",
    "50911": "5115",
    "46122": "4612",
    ...
    "11078": "1390"
  }
}
```



Drill allocates 40960 bytes of direct memory to each NullableVarCharVector. You can see how Drill fills each vector with 7 bytes (2 bytes for a single CHAR string, like "a" and 5 bytes for internally used values).

In cases where Drill is querying thousands upon thousands of JSON files, this works well. However, in cases where Drill queries a single file, a memory issue occurs because each key-value pair in the JSON file may consume more than 1000x more memory than is required for the corresponding value. Each vector unnecessarily holds memory for several values, resulting in failed queries due to a memory shortage.

Refer to Value Vectors for more information about vectors in Drill.

Issue Resolution

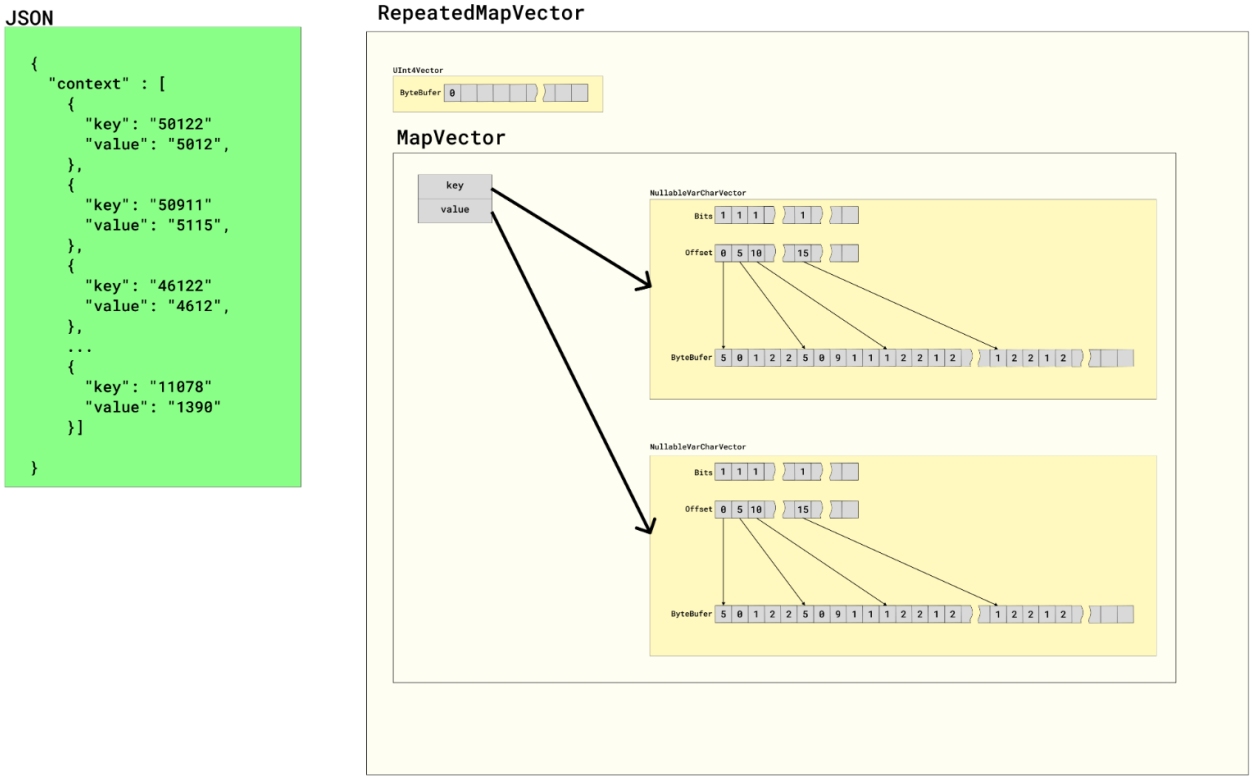
last-updated: Jun 06, 2024

To resolve or prevent this issue, change the format of the key-value pairs in the JSON file from an object to an array of objects, as shown in the following example:

```
{
  "context" : [
    {
      "key": "1",
      "value": "a"
    },
    {
      "key": "2",
      "value": "b"
    },
    {
      "key": "3",
      "value": "c"
    },
    ...,
    {
      "key": "100000",
      "value": "z"
    }
  ]
}
```

When a JSON file has an array of objects, Drill only creates two NullableVarCharVectors – one for the "key" and one for the "value". With this structure, only two vectors need to hold memory.

In the following illustration, you can see how Drill fills two vectors with many values versus filling thousands of vectors with only a few values:



last-updated: Jun 06, 2024

Unequal JOIN Support

By default, unequal joins are disabled in Drill because Drill does not have optimized JOIN operators to process these types of queries. An unequal join contains a condition with an inequality comparison between columns. An unequal join uses operators, such as <>, <, >, <=, or >= to establish the relationship between the joined columns. For example:

```
SELECT *
  FROM table1
  JOIN table2
  ON table1.column_name <= table2.column_name;
```

By default, if you run a query with an unequal join, the query fails and Drill returns the following error:

```
Error: UNSUPPORTED_OPERATION ERROR: This query cannot be planned possibly
due to either a cartesian join or an inequality join.
If a cartesian or inequality join is used intentionally, set the option
'planner.enable_nljoin_for_scalar_only' to false and try again.
```

Although Drill does not have optimized JOIN operators, Drill can process these types of queries in a non-efficient way using a nested loop join operator. To enable this, set the `planner.enable_nljoin_for_scalar_only` option to `false`. Drill can then execute `LEFT` and `INNER` joins; however, `RIGHT` joins will still fail with the error message shown.

Even when `planner.enable_nljoin_for_scalar_only` is disabled, Drill may still return an `UNSUPPORTED_OPERATION ERROR` for `LEFT` joins due to the join optimizations in Drill. If Drill detects that the right input is larger than the left, Drill optimizes the join such that the left and right inputs are flipped and the `LEFT` join type will be changed to `RIGHT`. If the query contains non-equi joins, after such optimizations, the query will fail because the nested loop join operator does not allow `RIGHT` joins.

Using the following query as an example:

```
SELECT *
  FROM table1
  LEFT JOIN table2
  ON table1.column_name <= table2.column_name;
```

If `table1` is smaller than `table2` or even empty, Drill applies a join optimization on the query and the query fails with the following error:

```
Error: UNSUPPORTED_OPERATION ERROR: This query cannot be planned possibly
due to either a cartesian join or an inequality join.
If a cartesian or inequality join is used intentionally, set the option
'planner.enable_nljoin_for_scalar_only' to false and try again.
```

The same optimization can make a RIGHT join executable when the left input is smaller than the right. In this case, the left and right inputs will be flipped and the RIGHT join type will be changed to LEFT. The nested loop operator supports LEFT joins. This is how Drill executes a query with a RIGHT join and no errors.

To avoid non-equi join errors, disable the join optimization by setting the `planner.enable_join_optimization` option to `false`.

IMPORTANT: Join optimizations improve query performance. If you disable the `planner.enable_join_optimization` option, it disables optimizations for all join types. If you need to disable this option for non-equi joins, only disable the `planner.enable_join_optimization` option at the session level using the ALTER SESSION SET command or through the Drill Web UI.

last-updated: Jun 06, 2024

Vulnerability Reports
Provides vulnerability information in relation to Drill.

CVE-2022-42889	This vulnerability *does not* impact Drill. The `commons-text` in Drill is only used for the following `StringDistanceFunctions` that involve classes from a similarity package: • cosine_distance • fuzzy_score • hamming_distance • jaccard_distance • jaro_distance • levenshtein_distance • longest_common_substring_distance

Drill *does not* use `StringSubstitutor`, which is what produces the vulnerability.

Hadoop

Starting from release 6.2.0, Hadoop (YARN) is decoupled from the core platform and exists as an ecosystem component as part of EEP. This is an essential requirement to support multi-tenant computer clusters for the HPE Ezmeral Data Fabric. For more information about YARN, see YARN on page 4720.

HBase

Apache HBase™ is the Hadoop database, a distributed, scalable, big data store. You can use Apache HBase when you need random, realtime read-write access to your Big Data. This section describes how to use HBase with the MapR Platform, but does not duplicate Apache documentation.

The goal of Apache HBase is to host very large tables – billions of rows with millions of columns – atop clusters of commodity hardware. Apache HBase is an open-source, distributed, versioned, column-oriented store modeled after Google's Bigtable: A Distributed Storage System for Structured Data by Chang et al. Just as Bigtable leverages the distributed data storage provided by the Google File System, Apache HBase provides Bigtable-like capabilities on top of Hadoop and Hadoop-compatible filesystems, such as the file system.

Installing Apache HBase on a MapR cluster involves storing all HBase components in a single volume mapped to directory `/hbase` in the cluster. Tables are stored in a flat namespace, not grouped logically with related files. Because all Apache HBase data resides in one volume, only one set of storage policies can be applied to the entire Apache HBase datastore. Mirrors and snapshots of the HBase volume do not provide functional replication of the datastore. Despite this limitation, mirrors can be used to back up HLogs and HFiles in order to provide a recovery point for Apache HBase data.

This section documents how to work with HBase on the MapR Converged Data Platform. You can refer also to documentation available from the Apache HBase project.

NOTE: The HPE Ezmeral Data Fabric Database provides native storage for table data, compatible with the HBase API. For new applications, consider using HPE Ezmeral Data Fabric Database binary tables for increased performance, more versatile table operations, and easier cluster administration.

Configuring HBase
Configure MapR-SASL Security (Authentication and Encryption) for HBase
This section describes the manual method for configuring security in HBase.

Starting with EEP 6.3.0, HBase services are secured by default with MapR-SASL. After installing HBase, you configure it by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option. There are two methods to configure HBase to be secure by default:

- Automatic Method
- Manual Method

Automatic Method

If you installed HBase by using the MapR Installer, the MapR Installer configures HBase daemons during installation. Additional configuration is not required.

Manual Method

After a new manual installation, to generate a valid default ecosystem configuration, run:

```
$MAPR_HOME/server/configure.sh -R
```

Four HBase services require configuration:

- HBase Master
- HBase RegionServer
- HBase Thrift
- HBase REST

Each service can be configured for authentication and encryption, as shown later on this page:

HBase Master and RegionServer

The Master and RegionServer services require the same configuration for security.

Authentication

To enable MapR-SASL authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

Encryption

To enable MapR-SASL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rpc.protection</name>
  <value>privacy</value>
</property>
```

Possible values for the `hbase.rpc.protection` property are:

- `authentication (auth)`
- `integrity (auth-int)`

- `privacy (auth-conf)`

The best practice is to spell out the values (authentication/integrity/privacy). The abbreviated values (in parentheses) can work, but using them is not recommended. Encryption is enabled only for the highest level of security (`privacy`).

HBase Thrift

It is possible to configure the HBase Thrift service to work over sockets or over the HTTP protocol. For authentication purposes, configuration is the same for both cases. For encryption, configuration is different for each case. Note that starting with the EEP6.3.0 property, `hbase.thrift.security.authentication` is no longer used to configure HBase Thrift for authentication.

Authentication

HBase Thrift relies on the same property used for Master and RegionServer. To enable authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

Encryption for Thrift over Sockets

To enable encryption with MapR-SASL for Thrift over sockets, make sure that the `hbase.regionserver.thrift.http` property is set to `false` and the following property is present in the `hbase-site.xml` file:

```
<property>
  <name>hbase.thrift.security.qop</name>
  <value>auth-conf</value>
</property>
```

Possible values for `hbase.thrift.security.qop` are:

- `auth`
- `auth-int`
- `auth-conf`

Encryption is enabled only for the highest level of security (`auth-conf`).

Encryption for Thrift over HTTP

To enable Thrift to work over the HTTP protocol, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
```

To enable Thrift over HTTP encryption through SSL, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.thrift.ssl.enabled</name>
```

```
  <value>true</value>
</property>
```

HBase REST

Authentication

To enable HBase REST authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rest.authentication.type</name>

<value>org.apache.hadoop.security.authentication.server.MultiMechsAuthentica
tionHandler</value>
</property>
```

With the MultiMechsAuthenticationHandler, MapR-SASL, Kerberos, and PAM authentication headers are supported. A custom AuthenticationHandler could be implemented and specified with the full class name in this property.

Encryption

To enable HBase REST SSL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rest.ssl.enabled</name>
  <value>true</value>
</property>
```

HBase Services Web UIs

Web UIs are available for each HBase service. The Web UIs run simultaneously with the service and within the same process. Security for these UIs must be configured too.

Authentication

To enable HBase Web UI authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

Authentication is implemented through the MultiMechsAuthenticationHandler and therefore supports MapR-SASL, Kerberos, and PAM authentication headers.

Encryption

To enable HBase Web UI SSL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.ssl.enabled</name>
  <value>true</value>
</property>
```

Configure HBase to use Kerberos

HBase supports MapR-SASL and Kerberos security, and can run securely independently of the security status of your HPE Ezmeral Data Fabric cluster.

last-updated: Jun 06, 2024

Procedure

To configure HBase to use Kerberos, perform the following steps:

1. Install the `mapr-hbase-master` and `mapr-hbase-regionserver` packages on the cluster.
2. On all HBase nodes, perform the following steps:
   a) Install the `krb5` packages and configure the Kerberos client as per the configuration for your environment.
   b) Set up the HBase Kerberos principal `mapr/<fqdn>@<realm>`. Each node requires a unique keytab file and Kerberos identity.
   c) Create an `hbase.keytab` file with the HBase Kerberos principal with the same process used to generate the CLDB keytab.
   d) Copy the `hbase.keytab` file to the `/opt/mapr/conf` directory.
   e) Use the `chown` command to change the keytab file's ownership to `mapr:mapr`.
   f) Use the `chmod` command to set the file's permissions to `600`.
   g) Update the `hbase-site.xml` file by adding the following section:

```
<property>
   <name>hbase.security.authentication</name>
   <value>kerberos</value>
 </property>
 <property>
  <name>hbase.security.authorization</name>
   <value>true</value>
 </property>
 <property>
   <name>hbase.regionserver.kerberos.principal</name>
   <value>mapr/_HOST@<KERBEROS_REALM></value>
 </property>
 <property>
   <name>hbase.master.kerberos.principal</name>
  <value>mapr/_HOST@<KERBEROS_REALM></value>
 </property>
```

   h) On a HPE Ezmeral Data Fabric cluster with security features enabled, replace the `${SIMPLE_LOGIN_OPTS}` value of the `MAPR_HBASE_SERVER_OPTS` property with `${KERBEROS_LOGIN_OPTS}` and the value of the `MAPR_HBASE_CLIENT_OPTS` property with `${HYBRID_LOGIN_OPTS}`. Also remove the `-Dzookeeper.sasl.client=false` option from the definition of `MAPR_HBASE_CLIENT_OPTS`.

      These properties are located in the `/opt/mapr/conf/env.sh` file.

   i) On a HPE Ezmeral Data Fabric cluster with security features disabled, replace the `${SIMPLE_LOGIN_OPTS}` value of the `MAPR_HBASE_SERVER_OPTS` and `MAPR_HBASE_CLIENT_OPTS` properties in the `/opt/mapr/conf/env.sh` file with `${KERBEROS_LOGIN_OPTS}`.

last-updated: Jun 06, 2024

3. On all HBase regionserver nodes, update the `hbase-site.xml` file by adding the following section:

```
<property>
   <name>hbase.regionserver.keytab.file</name>
   <value>/opt/mapr/conf/hbase.keytab</value>
 </property>
 <property>
   <name>hbase.coprocessor.region.classes</name>
   <value>
org.apache.hadoop.hbase.security.token.TokenProvider,org.apache.hadoop.hb
ase.security.access.AccessController</value>
 </property>
```

4. On the HBase master node, update the `hbase-site.xml` file by adding the following section:

```
<property>
  <name>hbase.master.keytab.file</name>
  <value>/opt/mapr/conf/hbase.keytab</value>
</property>
<property>
  <name>hbase.coprocessor.master.classes</name>
  <value>org.apache.hadoop.hbase.security.access.AccessController</value>
</property>
```

5. Restart the HBase master and regionserver nodes.

Enable Impersonation for HBase

About this task

HBase can be configured to offer impersonation, with or without Kerberos. This means that users can send commands to HBase through Hue without losing the fact that they will be run under their own credentials, instead of the `hue` user.

For instructions, see Enable Impersonation for HBase Thrift1 Gateway.

Configure HBase ACLs
HBase supports Access Control Lists (ACLs) to limit the privileges of users on the system. Before you can use ACLs, you need to perform the steps to enable ACLs.

HBase ACLs support the following privileges:

- `Read`
- `Write`
- `Execute`
- `Create tables`
- `Administrator`

The possible scopes are:

- `Superuser`
- `Global`
- `Namespace`

- `Table`
- `ColumnFamily`
- `Cell`

For information about each scope, see Understanding Access Levels.

Once you enable the use of ACLs, you can grant and remove privileges from users by using the `grant` and `revoke` commands from the HBase shell. The following example grants user `jfoo` read privileges from column family `cf1` of table `mytable`:

```
hbase(main):001:0> grant 'jfoo' 'R' 'mytable','cf1'
```

This example removes user `kbar`'s administrative privileges on the cluster:

```
hbase(main):001:0> revoke 'kbar' 'A'
```

Enable HBase Access Control
The following steps explain how to enable HBase ACLs.

Procedure

1. On the HBase Region Server, edit the `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` file, and add the following section:

```
<property>
    <name>hbase.coprocessor.region.classes</name>

<value>org.apache.hadoop.hbase.security.token.TokenProvider,org.apache.ha
doop.hbase.security.access.AccessController</value>
</property>
<property>
    <name>hbase.superuser</name>
    <value><admin1>,<admin2>,@<group1>,...</value> <!-- group names are
prefixed with '@' -->
  </property>
```

2. On the HBase Master, edit the `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` file, and add the following section:

```
<property>
    <name>hbase.coprocessor.master.classes</name>
    <value>org.apache.hadoop.hbase.security.access.AccessController</
value>
</property>
<property>
    <name>hbase.superuser</name>
    <value><admin1>,<admin2>,@<group1>,...</value> <!-- group names are
prefixed with '@' -->
  </property>
```

3. Restart HBase on every node.

Set Up Compression with HBase
Using compression with HBase reduces the number of bytes transmitted over the network and stored on disk. These benefits often outweigh the performance cost of compressing the data on every write and uncompressing it on every read.

last-updated: Jun 06, 2024

GZip Compression

GZip compression is included with most Linux distributions and works natively with HBase. To use GZip compression, specify it in the per-column family compression flag while creating tables in HBase shell. For example:

```
create 'mytable', {NAME=>'colfam', COMPRESSION=>'gz'}
```

LZ4 Compression

The LZ4 algorithm gives a slightly worse compression ratio than the LZO algorithm – which in turn is worse than algorithms like DEFLATE. However, compression speeds are similar to LZO and several times faster than DEFLATE, while decompression speeds can be significantly higher than LZO. Here is an example of configuring LZ4 compression:

```
create 'mytable1', {NAME=>'colfam', COMPRESSION=>'lz4'}
```

Snappy Compression

The Snappy compression algorithm is optimized for speed over compression. Snappy compression is included in the core MapR installation, and no additional configuration is required.

Configure the Default Database for HBase Clients

For HBase version 1.1 and later, a default database configuration determines whether clients connect to HBase tables or HPE Ezmeral Data Fabric Database tables. You can change the default setting for all HBase clients, or you can set the database for a particular job. This setting is ignored for HBase 0.98.12 client connections.

Set the Default Database using configure.sh

About this task

`configure.sh` automatically sets the default database for a node based on the presence of the following `mapr` packages:

- `mapr-hbase-master`
- `mapr-hbase-regionserver`

`configure.sh` also provides a parameter that you can use to set the default database. To explicitly set the default database to either `maprdb` or `hbase`, run `configure.sh` with the `-defaultdb` parameter. For example:

```
configure.sh -R -defaultdb maprdb
```

The following table describes the effect of various `configure.sh` commands on the default database setting:

Table

If ...	And you run `configure.sh` with the following `-defaultdb` parameter ...		
	No `-defaultdb` parameter specified	`-defaultdb hbase`	`-defaultdb maprdb`
`hbasemaster` or `hbaseregionserver` is installed on a node	The default database is set to `hbase`.	The default database is set to `hbase`	The default database is set to `hbase`, and the `maprdb` setting is ignored.

last-updated: Jun 06, 2024

Table (Continued)

If ...	And you run `configure.sh` with the following `-defaultdb` parameter ...		
	No `-defaultdb` parameter specified	`-defaultdb hbase`	`-defaultdb maprdb`
`hbasemaster` and `hbaseregionserver` are NOT installed on a node	The default database is set to `maprdb`.	The default database is set to `hbase`. However, this configuration does not work because HBase is not running.	The default database is set to `maprdb`.

For more information about `configure.sh`, see configure.sh on page 2821.

Set the Default Database using hbase-site.xml

About this task

You can configure the `mapr.hbase.default.db` property in the `hbase-site.xml` to override the default database that is set for the cluster:

Procedure

1. In the `hbase-site.xml`, edit the default value of `mapr.hbase.default.db`, and set it to either `hbase` or `maprdb`.

   For example:

   ```
   <property>
       <name>mapr.hbase.default.db</name>
       <value>hbase</value>
   </property>
   ```

2. Copy the property to the `hbase-site.xml` on each node that runs HBase, including any HBase client nodes.

Set the Database Type in the Job Configuration

Procedure

To set the database type in the job configuration you can add the following code:

- To connect to HPE Ezmeral Data Fabric Database tables:

  ```
  Configuration conf = HBaseConfiguration.create();
  conf.set("mapr.hbase.default.db", "maprdb");
  Connection connection = ConnectionFactory.createConnection(conf);
  Table table = connection.getTable(<TABLE_NAME>);
  ```

- To connect to HBase tables:

  ```
  Configuration conf = HBaseConfiguration.create();
  conf.set("mapr.hbase.default.db","hbase");
  Connection connection = ConnectionFactory.createConnection(conf);
  Table table = connection.getTable(<TABLE_NAME>);
  ```

HBase Configuration Properties

This section describes and shows examples of the configuration properties used in the `hbase-site.xml` file.

Basic Properties

Hbase.rootdir

Description: Specifies where the HBase data is stored. If not specified, by default HBase uses the `/tmp/` local folder. It is possible to use the local file system or a remote file system instance.

Example:

```
<property>
    <name>hbase.rootdir</name>
    <value>maprfs:///hbase</value>
</property>
```

HBase.cluster.distributed

Description: The mode the cluster will be in. Possible values are false for standalone mode and true for distributed mode. If false, startup runs all HBase and ZooKeeper daemons together in the one JVM.
Default: `false`.

Example:

```
<property>
    <name>hbase.cluster.distributed</
name>
    <value>true</value>
</property>
```

Hbase.zookeeper.quorum

Description: Comma-separated list of servers in the ZooKeeper ensemble. For example, `host1.mydomain.com,host2.mydomain.com,host3.mydomain.com`. By default this property is set to localhost for local and pseudo-distributed modes of operation. For a fully-distributed setup, this property should be set to a full list of ZooKeeper ensemble servers. If HBASE_MANAGES_ZK is set in `hbase-env.sh`, this is the list of servers that HBase will start or stop ZooKeeper on as part of cluster start or stop. Client-side, we will take this list of ensemble members and put it together with the `hbase.zookeeper.property.clientPort config.` and pass it into the Zookeeper constructor as the `connectString` parameter. Port could be specified together with hosts. In this case, the `hbase.zookeeper.property.clientPort` configuration is useless.

Example:

```
<property>
    <name>hbase.zookeeper.quorum</
name>
    <value>node11.cluster.com:5181</
value>
</property>
```

Dfs.support.append

Description: Specifies whether DFS allows appends to files.

Example:

```
<property>
    <name>dfs.support.append</name>
    <value>true</value>
</property>
```

Hbase.fsutil.maprfs.impl

Description: Specifies the FSUtil class (the utility methods for interacting with the underlying file system) used in HBase.

Example:

```
<property>
    <name>hbase.fsutil.maprfs.impl</
name>

<value>org.apache.hadoop.hbase.util.FS
MapRUtils</value>
</property>
```

Hbase.regionserver.handler.count

Description: Sets the count of RPC Listener instances spun up on RegionServers. The same property is used by the Master for a count of master handlers. Too many handlers can be counter-productive. Make it a multiple of the CPU count. If mostly read-only, handlers count close to CPU count does well. Start with twice the CPU count and tune from there.
Default: 30.

Example:

```
<property>

<name>hbase.regionserver.handler.count
</name>
    <value>30</value>
</property>
```

Fs.mapr.threads

Description: Controls currency in the HPE Ezmeral Data Fabric Database client.

Example:

```
<property>
    <name>fs.mapr.threads</name>
    <value>64</value>
</property>
```

Mapr.hbase.default.db

Description: Specifies whether to use HBase or the HPE Ezmeral Data Fabric Database client. Possible values are `hbase` and `maprdb`.

Example:

```
<property>
    <name>mapr.hbase.default.db</name>
    <value>hbase</value>
</property>
```

Security Properties

To support authorization, four properties must be enabled:

- `hbase.security.authorization`
- `hbase.security.exec.permission.checks`
- `hbase.coprocessor.master.classes`
- `hbase.coprocessor.region.classes`

If any one of them is missing, authorization will not be fully supported.

Hbase.security.authorizaation

Description: Specifies whether authorization is enabled or not.

Example:

```
<property>

<name>hbase.security.authorization</
name>
    <value>true</value>
</property>
```

Hbase.security.exec.permission.checks

Description: Without this option, all users continue to have access to execute endpoint coprocessors. This option is not enabled when you enable HBase Secure Authorization for backward compatibility.

Example:

```
<property>

<name>hbase.security.exec.permission.c
hecks</name>
    <value>true</value>
</property>
```

hbase.coprocessor.master.classes

Description: A comma-separated list of coprocessors that are loaded by the master (MasterObserver coprocessors). The AccessController has to be active to support authorization.

Example:

```
<property>

<name>hbase.coprocessor.master.classes
</name>

<value>org.apache.hadoop.hbase.securit
y.access.
    AccessController</value>
</property>
```

Hbase.coprocessor.region.classes

Description: A comma-separated list of RegionObserver and Endpoint coprocessors. TokenProvider and AccessController must be active to support authorization.

last-updated: Jun 06, 2024

Example:

```
<property>

<name>hbase.coprocessor.region.classes
</name>

<value>org.apache.hadoop.hbase.securit
y.token.TokenProvider.

org.apache.hadoop.hbase.security.acces
s.AccessController</value>
</property>
```

Authentication and Encryption Properties

hbase.security.authentication

Description: Defines whether to use SASL mechanisms in HBase to authenticate RPC connections from clients to HBase Master and RegionServer. Also defines whether to support authentication for HBaseThrift. Specifying `maprsasl` enables authentication for HBaseThrift over http.

Example:

```
<property>

<name>hbase.security.authentication</
name>
    <value>maprsasl</value>
</property>
```

hbase.security.token.authentication.method

Description: Enables SCRAM as a token authentication method. For FIPS-enabled nodes, running `/opt/mapr/server/configure.sh` automatically adds this property to `hbase-site.xml`. In clusters with a mix of FIPS and non-FIPS nodes, you must manually add this property to non-FIPS nodes.

Example:

```
<property>

<name>hbase.security.token.authenticat
ion.method</name>
  <value>SCRAM-SHA-256</value>
</property>
```

hbase.rpc.protection

Description: Enables or disables transport security encryption. To support encryption, the auth-conf (privacy) value must be specified. Possible values are:

- `auth` or `authentication`
- `auth-int` or `integrity`
- `auth-conf` or `privacy`

last-updated: Jun 06, 2024

Example:

```
<property>
    <name>hbase.rpc.protection</name>
    <value>auth-conf</value>
</property>
```

hbase.ssl.enabled

Description: Enables or disables SSL encryption for HBase WebUIs.

Example:

```
<property>
    <name>hbase.ssl.enabled</name>
    <value>true</value>
</property>
```

hbase.thrift.ssl.enabled

Description: Enables or disables SSL encryption for HBaseThrift. Works only for HBaseThrift over http (the `hbase.regionserver.thrift.http` property must be set to `true`).

Example:

```
<property>
    <name>hbase.thrift.ssl.enabled</
name>
    <value>true</value>
</property>
```

Hbase.thrift.security.qop

Description: Enables or disables transport security encryption for HBaseThrift. Use the `auth-conf` value to support encryption. This property works only for HBaseThrift over sockets (the `hbase.regionserver.thrift.http` property must be set to `false`). Possible values are:

- `auth`
- `auth-int`
- `auth-conf`

Example:

```
<property>
    <name>hbase.thrift.security.qop</
name>
    <value>auth-conf</value>
</property>
```

hbase.rest.authentication.type

Description: Defines the AuthenticationHandler to use during user-to-HBaseRest authentication. The `MultiMechsAuthenticationHandler` supports PAM, MapR SASL, and Kerberos authentication. If this property is not specified, authentication for HBaseRest is disabled.

last-updated: Jun 06, 2024

Example:

```
<property>

<name>hbase.rest.authentication.type</
name>

<value>org.apache.hadoop.security.auth
entication.server.
    MultiMechsAuthenticationHandler</
value>
</property>
```

hbase.rest.ssl.enabled

Description: Enables or disables SSL encryption (from client to server and vice versa) for the HBaseRest service.

Example:

```
<property>
    <name>hbase.rest.ssl.enabled</
name>
    <value>true</value>
</property>
```

Impersonation Properties

hbase.thrift.support.proxyuser

Description: Enables or disables impersonation for HBaseThrift. Works only for thrift over http (the `hbase.regionserver.thrift.http` property must be set to `true`).

Example:

```
<property>

<name>hbase.thrift.support.proxyuser</
name>
    <value>true</value>
</property>
```

hbase.rest.support.proxyuser

Description: Enables or disables impersonation for HBaseRest.

Example:

```
<property>

<name>hbase.rest.support.proxyuser</
name>
    <value>true</value>
</property>
```

hbase.regionserver.thrift.http

Description: Defines whether to use HBaseThrift over http (if `true` is specified) or over sockets. Used to support impersonation for thrift over http.

last-updated: Jun 06, 2024

Example:

```
<property>

<name>hbase.regionserver.thrift.http</
name>
    <value>true</value>
</property>
```

Using HBase

This section includes the following topics about working with HBase:

Getting Started in HBase

About this task

In this section, we'll create an HBase table on the cluster, enter some data, query the table, then clean up the data and exit.

HBase tables are organized by column, rather than by row. Furthermore, the columns are organized in groups called *column families*. When creating an HBase table, you must define the column families before inserting any data. Column families should not be changed often, nor should there be too many of them, so it is important to think carefully about what column families will be useful for your particular data. Each column family, however, can contain a very large number of columns. Columns are named using the format `family:qualifier`.

Unlike columns in a relational database, which reserve empty space for columns with no values, HBase columns simply don't exist for rows where they have no values. This not only saves space, but means that different rows need not have the same columns; you can use whatever columns you need for your data on a per-row basis.

Procedure

1. Start the HBase shell by typing the following command:

   ```
   hbase shell
   ```

2. Create a table called `weblog` with one column family named `stats`:

   ```
   create 'weblog', 'stats'
   ```

3. Verify the table creation by listing everything:

   ```
   list
   ```

last-updated: Jun 06, 2024

4. Add a test value to the `daily` column in the `stats` column family for row 1:

```
put 'weblog', 'row1', 'stats:daily', 'test-daily-value'
```

5. Add a test value to the `weekly` column in the `stats` column family for row 1:

```
put 'weblog', 'row1', 'stats:weekly', 'test-weekly-value'
```

6. Add a test value to the `weekly` column in the `stats` column family for row 2:

```
put 'weblog', 'row2', 'stats:weekly', 'test-weekly-value'
```

7. Type `scan 'weblog'` to display the contents of the table. Sample output:

```
ROW                   COLUMN+CELL
 row1                 column=stats:daily, timestamp=1321296699190,
value=test-daily-value
 row1                 column=stats:weekly, timestamp=1321296715892,
value=test-weekly-value
 row2                 column=stats:weekly, timestamp=1321296787444,
value=test-weekly-value
2 row(s) in 0.0440 seconds
```

8. Type `get 'weblog', 'row1'` to display the contents of row 1. Sample output:

```
COLUMN                CELL
 stats:daily          timestamp=1321296699190, value=test-daily-value
 stats:weekly         timestamp=1321296715892, value=test-weekly-value
2 row(s) in 0.0330 seconds
```

9. Type `disable 'weblog'` to disable the table.

10. Type `drop 'weblog'` to drop the table and delete all data.

11. Type `exit` to exit the HBase shell.

Running MapReduce Jobs with HBase

About this task

To run MapReduce applications with data stored in HBase, use a command such as the following to export table data to the HPE Ezmeral Data Fabric file system:

```
$ hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/
hbase-server-1.1.13.0-mapr-1912.jar export t1 /user/mapr/t1
```

or

```
$  hbase org.apache.hadoop.hbase.mapreduce.Export t1 /user/mapr/t4
```

The result is the same because of the tools included in the hbase-server.jar file:

```
$ hadoop fs -ls /user/mapr/t1/
Found 2 items
-rwxr-xr-x   3 mapr mapr          0 2019-11-11 15:00 /user/mapr/t1/_SUCCESS
-rw-r--r--   3 mapr mapr        249 2019-11-11 15:00 /user/mapr/t1/
```

```
part-m-00000
$ hadoop fs -ls /user/mapr/t4/
Found 2 items
-rwxr-xr-x   3 mapr mapr          0 2019-11-11 15:09 /user/mapr/t4/_SUCCESS
-rw-r--r--   3 mapr mapr        249 2019-11-11 15:09 /user/mapr/t4/
part-m-00000
$
```

Following is an example of the full output:

```
$ hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/
hbase-server-1.1.13.0-mapr-1912.jar export t1 /user/mapr/t1

The following table shows the tools included in the hbase-server.jar:

Name[1]	Class[2]	Description
rowcounter	RowCounter	Count rows in HBase table
CellCounter	CellCounter	Count cells in HBase table
export	Export	Write table data to HPE Ezmeral Data Fabric file system
import	Import	Import data written by Export
importtsv	ImportTsv	Import data in TSV format

Name[1]	Class[2]	Description
completebulkload	LoadIncrementalHFiles	Complete a bulk data load
copytable	CopyTable	Export a table from local cluster to peer cluster
verifyrep	VerifyReplication	Compare the data from tables in two different clusters **NOTE:** This function does not work for incrementColumnValues cells since the timestamp is changed after being appended to the log.
WALPlayer	WALPlayer	Replay WAL files
exportsnapshot	ExportSnapshot	Export the specific snapshot to a given file system

[1] Class is used for `hbase.org.apache.hadoop.hbase.mapreduce.<class>....`

[2] Name is used for `hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/hbase-server-1.1.13.0-mapr-1912.jar <name>...`

Using the libhbase Library

libhbase is a JNI-based, thread-safe C library that implements a native HBase client. You can use libhbase to build applications that access HBase.

This page contains the following topics:

- Installing libhbase
- Upgrading libhbase
- Building applications with libhbase
- Configuring the application environment
- Running a libhbase performance test

For examples that show how to use the APIs, see the sample source file.

Installing libhbase

Install libhbase on the nodes from which you will build and run the application.

Complete the following steps to install libhbase from a repository:

1. Configure the repository to point to http://package.ezmeral.hpe.com/releases/MEP/MEP-6.3.0/.

   IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

2. Based on your operating system, run one of the following commands to install the package:
   - On Red Hat /Centos: `yum install mapr-libhbase`
   - On SLES: `zypper install mapr-libhbase`
   - On Ubuntu: `apt-get install mapr-libhbase`

Once the installation completes, the libhbase installation includes the following directories under `/opt/mapr/libhbase/libhbase-<version>`:

```
/
+---bin/
+---conf/
+---include/
|   +--hbase/
+---lib/
|   +---native/
+---src
    +---examples/
    |   +---async/
    +---test/
        +---native/
            +---common/
```

NOTE: The `include` folder contains the headers required to build applications. The `lib/native` directory contains shared libraries.

Upgrading libhbase

To upgrade to a more recent version of libhbase:

1. Install the new version.
2. Re-configure the application environment to refer to the new libraries.

Building Applications with libhbase

libhbase should be installed on each node that builds the application.

Note the following items when you build applications with libhbase:

- The headers required to build applications are located under `/opt/mapr/libhbase/libhbase-<version>/include`.
- libhbase shared library is located in the following directory: `/opt/mapr/libhbase/libhbase-<version>/lib/native`.
- Since libhbase uses JNI, you must also link your application against libjvm. In general, the libjvm library is located within the JDK/JRE installation directory.

For example, the following command builds the `hello_hbase` application with the `hello_hbase.c` source code:

```
gcc -o hello_hbase hello_hbase.c -I/opt/mapr/
libhbase/libhbase-0.98.7/include -L/opt/mapr/libhbase/libhbase-0.98.7/lib/
native -lhbase -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

Configuring the Application Environment

Complete the following steps to configure the node from which you run the application:

- Verify that libhbase is installed on the node.
- Verify that both the libhbase and libjvm shared libraries are in the application's library search path. The libhbase shared library is located under `/opt/mapr/libhbase/libhbase-<version>/lib/native`. In general, the libjvm library is located within the JDK/JRE installation directory.

last-updated: Jun 06, 2024

- Specify any JARs required by the application with one of the following environment variables: `CLASSPATH` or `HBASE_LIB_DIR`.
- Specify custom JVM options, such as `-Xmx`, using the environment variable `LIBHBASE_OPTS`.

Running a libhbase Performance Test

libhbase 0.98.7 includes a performance test that supports sequential/random gets and puts. In libhbase 0.98.9, the performance test utility also includes support for Zipfian, support for uniform random key generation, and it test for scans. You can run the test using this shell script.

HBase Client and HPE Ezmeral Data Fabric Database Binary Tables

HPE Ezmeral Data Fabric 6.0.x and 6.1 provide Apache HBase-compatible APIs and client interfaces but do not support HBase as an ecosystem component. HPE Ezmeral Data Fabric Database binary tables provide native storage for table data and include high performance and availability, versatile table operations, and streamlined cluster administration. The following APIs and tools are available for HPE Ezmeral Data Fabric Database binary tables:

HBase Client	• After installing the HBase Client, you can use HBase Shell commands to manipulate HPE Ezmeral Data Fabric Database binary tables on a remote machine. See Installing HBase on a Client Node on page 245 and HPE Ezmeral Data Fabric Database HBase Shell (Binary Tables) on page 5509. • HPE Ezmeral Data Fabric Database supports binary tables through the libMapRClient (a library of C APIs) and Apache HBase Java APIs. See Developing Applications for Binary Tables on page 3237.
HBase REST Gateway	• The HBase REST Gateway allows users to manipulate HPE Ezmeral Data Fabric Database binary tables through the HBase REST API. See Installing the HBase REST Gateway on page 247.
HBase Thrift Gateway	• The HBase Thrift Gateway allows users to manipulate HPE Ezmeral Data Fabric Database binary tables through the HBase Thrift API. See Installing the HBase Thrift Gateway on page 247.

Using the HBase Thrift Gateway

HBase Thrift Gateway includes an API and a service that accepts Thrift requests to connect to HPE Ezmeral Data Fabric Database and HBase tables. The HBase Thrift Gateway is installed as a service that is managed by Warden. When `mapr-hbasethrift` is installed, the `warden.hbasethrift.conf` file is added to the `/opt/mapr/conf/conf.d` directory.

NOTE: MapR SASL authentication, encryption, and impersonation for HBase Thrift Gateway are enabled by default on secure clusters.

Starting the HBase Thrift Service

About this task

To start the HBase thrift service, enter the following command with the name of the host where hbasethrift is running:

```
maprcli node services -name hbasethrift -action start -nodes <node_hostname>
```

Configure Kerberos for HBase Thrift Gateway

About this task

Procedure

1. Add the following to the `hbase-site.xml` file for every Thrift gateway:

```
<property>
    <name>hbase.thrift.keytab.file</name>
    <value>$KEYTAB</value>
</property>
<property>
    <name>hbase.thrift.kerberos.principal</name>
    <value>$USER/_HOST@HADOOP.LOCALDOMAIN</value>
    <!-- This may need to be HTTP/_HOST@<REALM> and _HOST may not work.
You may have to put the concrete full hostname. -->
</property>
<property>
   <name>hbase.thrift.security.qop</name>
   <value>auth-conf</value>
</property>
<!-- Add these if you need to configure a different DNS interface from
the default -->
<property>
    <name>hbase.thrift.dns.interface</name>
    <value>default</value>
</property>
<property>
    <name>hbase.thrift.dns.nameserver</name>
    <value>default</value>
</property>
```

   Substitute the appropriate credential and keytab for $USER and $KEYTAB respectively.

2. If you are running HBase Thrift in HTTP mode, you must add additional properties to the `hbase-site.xml` to enable HTTP connections through Kerberos. This is required if you enabled the following property in the `hbase-site.xml`:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
```

   Add the following properties to enable HTTP connections through Kerberos:

```
<property>
    <name>hbase.thrift.spnego.principal</name>
    <value>HTTP/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
<property>
    <name>hbase.thrift.spnego.keytab.file</name>
    <value>$KEYTAB</value>
</property>
```

3. To use HPE Ezmeral Data Fabric Database tables without the full path, add the following property to the `core-site.xml` file:

```
<property>
    <name>hbase.table.namespace.mappings</name>
    <value>*:/</value>
</property>
```

   Add this property ONLY if you are working with HPE Ezmeral Data Fabric Database tables. Working with HBase tables is not possible when this property is present. For more information, see Considerations for Upgrading to HBase 1.1.13 on page 350. For more information about mapping tables, see Mapping to HBase Table Namespaces on page 465.

Results

The Thrift gateway authenticates with HBase using the supplied credential. No authentication is performed by the Thrift gateway itself. All client access via the Thrift gateway uses the Thrift gateway's credential and has its privilege.

Enable Impersonation for HBase Thrift Gateway

About this task

To configure the Thrift gateway to authenticate to HBase on the client's behalf, and to access HBase using a proxy user:

Procedure

1. To allow proxy users, add the following to the `hbase-site.xml` file for every HBase node:

```
<property>
    <name>hadoop.proxyuser.$USER.groups</name>
    <value>$GROUPS</value>
</property>
<property>
    <name>hadoop.proxyuser.$USER.hosts</name>
    <value>$GROUPS</value>
</property>
```

last-updated: Jun 06, 2024

2. To enable the doAs feature, add the following to the `hbase-site.xml` file for every Thrift gateway:

```
<property>
    <name>hbase.regionserver.thrift.http</name>
    <value>true</value>
</property>
<property>
    <name>hbase.thrift.support.proxyuser</name>
    <value>true/value>
</property>
```

3. Restart the Thrift gateway processes for the changes to take effect. If a node is running Thrift, the output of the `jps` command will list a `ThriftServer` process.
   - To restart Thrift on a node, use the following `maprcli` command:

```
maprcli node services -name hbasethrift -action restart -nodes
<node_hostname>
```

Using the HBase REST Gateway

HBase REST Gateway includes an API and a service that accepts REST requests to connect to HPE Ezmeral Data Fabric Database and HBase tables. Starting in version 0.98.9, the HBase REST Gateway is installed as a service that is managed by Warden. When mapr-hbase-rest is installed, the `warden.hbase-rest.conf` file is added to the `/opt/mapr/conf/conf.d` directory.

NOTE: PAM authentication, encryption, and impersonation for HBase REST are enabled by default on secure clusters.

Starting the HBase REST Service

About this task

To start the HBase REST service, enter the following command with the name of the host where hbaserest is running:

```
maprcli node services -name hbaserest -action start -nodes <node_hostname>
```

Configure Kerberos for HBase REST Gateway

About this task

Procedure

1. Add the following to the `hbase-site.xml` file for every REST Gateway:

```
<property>
    <name>hbase.rest.keytab.file</name>
    <value>$KEYTAB</value>
</property>
<property>
    <name>hbase.rest.kerberos.principal</name>
    <value>$USER/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
```

   Substitute the appropriate credential and keytab for $USER and $KEYTAB respectively.

   The REST Gateway will authenticate with HBase using the supplied credential.

last-updated: Jun 06, 2024

2. To enable REST Gateway Kerberos authentication for client access, add the following to the `hbase-site.xml` file for every REST Gateway:

```
<property>
    <name>hbase.rest.authentication.type</name>
    <value>kerberos</value>
</property>
<property>
    <name>hbase.rest.authentication.kerberos.principal</name>
    <value>HTTP/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
<property>
    <name>hbase.rest.authentication.kerberos.keytab</name>
    <value>$KEYTAB</value>
</property>
<!-- Add these if you need to configure a different DNS interface from
the default -->
<property>
    <name>hbase.rest.dns.interface</name>
    <value>default</value>
</property>
<property>
    <name>hbase.rest.dns.nameserver</name>
    <value>default</value>
</property>
```

   Substitute the keytab for HTTP for $KEYTAB.

Enable Impersonation for HBase REST Gateway

About this task

To enable HBase REST Gateway impersonation, configure all HBase servers to allow proxy users, then configure every REST Gateway to enable impersonation.

Procedure

- To enable REST Gateway impersonation, add the following to the `hbase-site.xml` file for every REST gateway:

```
<property>
    <name>hbase.rest.support.proxyuser</name>
    <value>true</value>
</property>
```

HBase REST Gateway and HBase Thrift Gateway Secured By Default to Use SSL
Starting in EEP 6.0.0, HBase REST and HBase Thrift use SSL by default on secured clusters.

1. On a secure cluster, by default, HBase REST and HBase Thrift read the `ssl-client.xml` file and configure SSL using this file.

2. To enable HBase REST and Thrift encryption, use the following properties. Note that SSL for Thrift is enabled only when the `hbase.regionserver.thrift.http` property is `true`:

   Enabling HBase REST encryption

   ```
   <property>
     <name>hbase.rest.ssl.enabled</name>
     <value>true</value>
   </property>
   ```

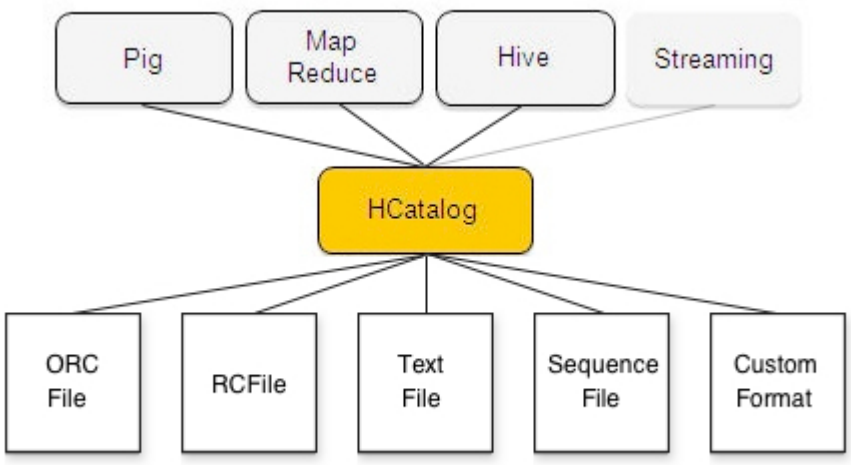
   Enabling HBase Thrift encryption

   ```
   <property>
     <name>hbase.thrift.ssl.enabled</name>
     <value>true</value>
   </property>
   ```

HCatalog

HCatalog is a table and storage management layer for Hadoop that enables users with different data processing tools — Pig, MapReduce — to more easily read and write data on the grid. HCatalog's table abstraction presents users with a relational view of data in the Hadoop distributed filesystem (HDFS) and ensures that users need not worry about where or in what format their data is stored — RCFile format, text files, SequenceFiles, or ORC files.

HCatalog supports reading and writing files in any format for which a SerDe (serializer-deserializer) can be written. By default, HCatalog supports RCFile, CSV, JSON, and SequenceFile, and ORC file formats. To use a custom format, you must provide the InputFormat, OutputFormat, and SerDe.



HCatalog is also automatically installed and upgraded along with Hive. For information about using HCatalog with Hive, see Hive and WebHCat Integration and Hive and HCatalog Integration.

Hive

Apache Hive™ is a data warehouse system for Hadoop that facilitates easy data summarization, ad-hoc queries, and the analysis of large datasets stored in Hadoop-compatible file systems, such as HPE Ezmeral Data Fabric. Hive provides a mechanism to project structure onto this data and query the data using a SQL-like language called HiveQL. At the same time this language also allows traditional map/reduce programmers to plug in their custom mappers and reducers when it is inconvenient or inefficient to express this logic in HiveQL.

You can refer also to documentation available from the Apache Hive project.

Hive components include the following:

- Hive Metastore
- HiveServer2
- HCatalog
- WebHCat
- Hive CLI
- Beeline

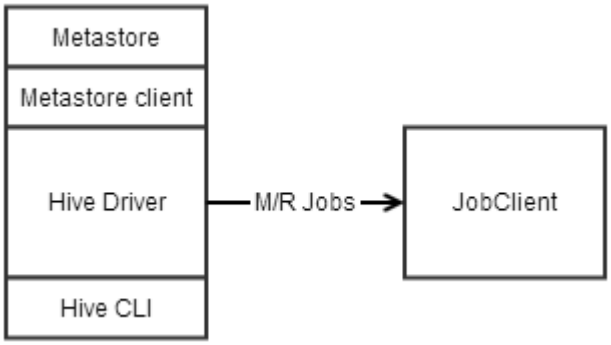
NOTE: If you installed Hive using the installer with the "Enable Security" check box selected, Hive is secured and no further configuration is required. However, if you installed Hive manually and wish to enable security for Hive, see Hive Security Configuration Options on page 4174 for information.

The following examples show how these components communicate with each other and when you might want to configure security features such as authentication and encryption:

last-updated: Jun 06, 2024

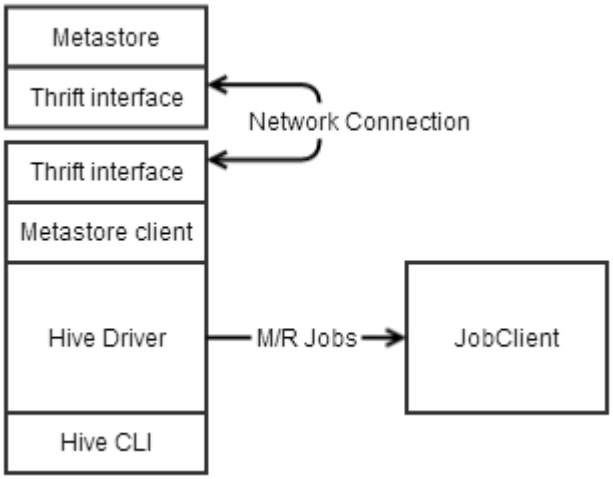
Case 1: Jobs Submitted by the Hive CLI, Embedded Metastore

In this case, all the information needed by Hive is contained within a single process, and no security is needed beyond that already provided by the JobClient's communications.



Case 2: Jobs Submitted by the Hive CLI, Remote Metastore

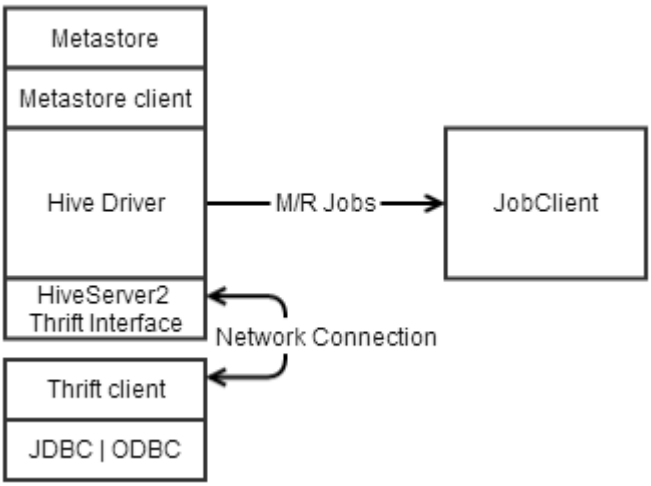
In this case, Hive needs to access a metastore remote to Hive's process using a Thrift interface. This communication can be left secured with Kerberos, or secured with data-fabric SASL.



Case 3: Jobs Submitted by HiveServer2, Embedded Metastore

In this case, JDBC or ODBC on a user's machine sends queries to HiveServer2, which submits the queries to the driver for parsing. The communication between JDBC and HiveServer2 can be secured with username and password with SSL, data-fabric SASL, or with Kerberos. Either approach offers authentication and encryption. JDBC/ODBC can also be configured to use username and password without SSL, which offers authentication *only*.

To use SSL from a client machine the `ssl_truststore` file must be copied from the cluster to the client.



Case 4: Jobs Submitted by HiveServer2, Remote Metastore

In this case, JDBC or ODBC on a user's machine sends queries to HiveServer2, which submits the queries to the driver, which runs the query and returns the results. The metastore is remote. In this case, there are two communications links to secure: the Thrift interface between the metastore client and server, and the Thrift interface between the client JDBC/ODBC and HiveServer2. The security arrangements for these links are identical to Cases 2 and 3.

Getting Started with Hive

About this task

In this tutorial, you'll create a Hive table, load data from a tab-delimited text file, and run a couple of basic queries against the table. For details on setting up HiveServer2 and starting BeeLine, see Using JDBC or Beeline to Connect to HiveServer2 on page 4270.

NOTE: If you are using HiveServer2, you will use the BeeLine CLI instead of the Hive shell, as shown below.

Take a look at the source data

About this task

First, take a look at the contents of the file using the terminal:

Procedure

1. Save the following data to a text file named `sample-table.txt`:

   The `sample-table.txt` table columns are delimited by tabs:

   ```
   1320352532    1001    http://www.mapr.com/doc    http://www.mapr.com
   192.168.10.1
   1320352533    1002    http://www.mapr.com    http://www.example.com
   192.168.10.10
   1320352546    1001    http://www.mapr.com    http://www.mapr.com/doc
   192.168.10.1
   ```

   If you are working on the MapR Virtual Machine, we'll be loading the file from the MapR Virtual Machine's local filesystem (not the cluster storage layer), so save the file in the MapR Home directory (for example, `/home/mapr`).

last-updated: Jun 06, 2024

2. Make sure you are in the Home directory where you saved `sample-table.txt` (type `cd ~` if you are not sure).
3. Type `cat sample-table.txt` to display the following output.

Results

```
mapr@mapr-desktop:~$ cat sample-table.txt
1320352532    1001    http://www.mapr.com/doc    http://www.mapr.com
192.168.10.1
1320352533    1002    http://www.mapr.com    http://www.example.com
192.168.10.10
1320352546    1001    http://www.mapr.com    http://www.mapr.com/doc
192.168.10.1
```

Notice that the file consists of only three lines, each of which contains a row of data fields separated by the TAB character. The data in the file represents a web log.

Create a table in Hive and load the source data:

Procedure

1. Type the following command to start the Hive shell, using tab-completion to expand the `<version>`:

   ```
   /opt/mapr/hive/hive-<version>/bin/hive
   ```

2. At the `hive>` prompt, type the following command to create the table:

   ```
   CREATE TABLE web_log(viewTime INT, userid BIGINT, url STRING, referrer
   STRING, ip STRING) ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t';
   ```

3. Type the following command to load the data from `sample-table.txt` into the table:

   ```
   LOAD DATA LOCAL INPATH '/home/mapr/sample-table.txt' INTO TABLE web_log;
   ```

Run basic queries against the table

Procedure

- Try the simplest query, one that displays all the data in the table:

  ```
  SELECT web_log.* FROM web_log;
  ```

  This query would be inadvisable with a large table, but with the small sample table it returns very quickly.

- Try a simple SELECT to extract only data that matches a desired string:

  ```
  SELECT web_log.* FROM web_log WHERE web_log.url LIKE '%doc';
  ```

  This query launches a MapReduce application to filter the data.

Configuring Hive

This section contains the following topics:

last-updated: Jun 06, 2024

Configure Hive Directories

You can configure the following Hive directories:

- Hive Scratch Directory
- Hive Warehouse Directory
- Hive Error Logs Directory

Hive Scratch Directory

In Hive 1.0, HPE Ezmeral Data Fabric configures the Hive scratch directory to be `/user/<user.name>/tmp/hive/<user.name>`. In Hive 0.13, the default scratch directory is /user/<user.name>/tmp/hive. The hive user must have write access to the /user folder.

To modify this parameter, perform one of the following operations:

- Set this parameter in the `hive-site.xml`.Copy the hive.exec.scratchdir property elements from the $HIVE_HOME/conf/hive-default.xml.template file and paste them into an XML configuration element in the $HIVE_HOME/conf/hive-site.xml file. Then, modify the value elements for these directories in the hive-site.xml file.
- Set this parameter from the Hive shell. Example:

```
hive> set hive.exec.scratchdir=/myvolume/tmp
```

NOTE: You will see better performance when queries import data from a table that is in the same Data Fabric volume as Hive scratch directory.

How Hive Handles Scratch Directories on HPE Ezmeral Data Fabric

When a query requires Hive to query existing tables and create data for new tables, Hive uses the following workflow:

1. Create the query scratch directory `hive_<timestamp>_<randomnumber>` under the Hive scratch directory.
2. Create the following directories as subdirectories of the scratch directory:
   a. Final query output directory. This directory's name takes the form `-ext-<number>`.
   b. An output directory for each MapReduce application. These directories' names take the form `-mr-<number>`.
3. Hive executes the tasks, including MapReduce applications and loading data to the query output directory.
4. Hive loads the data from output directory into a table. By default, the table's directory is in the `/user/hive/warehouse` directory. You can configure this location with the `hive.metastore.warehouse.dir` parameter in `hive-site.xml`, unless the table DDL specifies a custom location. Hive renames the output directory to the table directory in order to load the output data to the table.
5. The scratch directories are automatically deleted after the query completes successfully.

HPE Ezmeral Data Fabric uses Administering Volumes on page 1169, which are logical units that enable you to apply policies to a set of files, directories, and sub-volumes. When the output directory and the table directory are in different volumes, this workflow involves moving data across volumes. Moving data

across volumes is slower than moving data within a volume. Therefore, HPE Ezmeral Data Fabric sets `hive.optimize.insert.dest.volume` to `true` to automatically create a scratch directory in the same volume as the target table.

Hive Warehouse Directory

Hive tables are stored in the Hive warehouse directory. By default, HPE Ezmeral Data Fabric configures the Hive warehouse directory to be `/user/hive/warehouse` under the root volume. This default is defined in the `$HIVE_HOME/conf/hive-default.xml.template` file.

To modify this parameter, perform one of the following operations:

- Set this parameter in the `hive-site.xml`. Copy the hive.metastore.warehouse.dir property elements from the $HIVE_HOME/conf/hive-default.xml.template file and paste them into an XML configuration element in the $HIVE_HOME/conf/hive-site.xml file. Then, modify the value elements for these directories in the hive-site.xml file.
- Set this parameter from the Hive shell. Example:

```
hive> set hive.metastore.warehouse.dir=/myvolume/mydirectory
```

NOTE: You will see better performance when queries move data between tables in the same volume.

Hive Error Logs Directory

The log files are stored in `/opt/mapr/hive/hive-<version>/logs/<user>` by default.

To modify the log location:

1. Configure `hive.log.dir` in `$HIVE_HOME/conf/hive-log4j.properties` file. Example:

```
hive.log.dir=<other_location>
```

2. Set the sticky bit on the new directory. Example:

```
chmod 1777 <other_location>
```

Configuring Hive Client on a Data Fabric Client Node

This topic describes how to configure the Hive client on a Data Fabric client node.
Configuring Hive Client for EEP 9.0.0 and Later

About this task

To use the Hive client with secure clusters for EEP 9.0.0 and later, perform the following steps:

Procedure

1. Install the Data Fabric client. See Installing the Data Fabric Client on Red Hat and Oracle Linux (Non-FIPS) on page 405.
2. Copy `maprtrustcreds.jceks` from the `MAPR_HOME/conf` directory on the cluster to the `MAPR_HOME/conf` directory on the Data Fabric client.

Configuring `MSCK REPAIR TABLE`

This section guides you through configuring `MSCK REPAIR TABLE` command to compare and update the partitions in Hive Metastore and file systems.

Use the `MSCK REPAIR TABLE` command to manually update (ADD, DROP, SYNC) the partitions on Hive metastore with respect to file systems like HDFS, Amazon S3, filesystem, and others.

For example: You specify the location of filesystem when you create a Hive table. When you add or delete the partitions to or from the filesystem, the partitions in filesystem and Hive metastore becomes inconsistent.

Run `MSCK REPAIR TABLE` command to compare the partitions in filesystem and the partitions in Hive metastore and update the partitions in Hive metastore.

```
MSCK [REPAIR] TABLE <table name> [ADD/DROP/SYNC PARTITIONS];
```

Configure the Hive Metastore with the following Hive property:

Property	Default	Description
hive.msck.repair.batch.max.retries	0	Maximum number of retries for the msck repair command when adding unknown partitions. If the value is greater than zero it will retry adding unknown partitions until the maximum number of attempts is reached or batch size is reduced to 0, whichever is earlier. In each retry attempt, it will reduce the batch size by a factor of 2 until it reaches zero. If the value is set to zero it will retry until the batch size becomes zero as described above.

Configuring Database for Hive Metastore

The metadata for Hive tables and partitions are stored in the Hive Metastore. By default, the Hive Metastore stores all Hive metadata in an embedded Apache Derby database in the file system. The following sections describe how to configure other DBs for Hive Metastore.

CAUTION: Do not use `datanucleus.schema.autoCreateAll` for populating underlying databases. For more details, see prohibited usage of `datanucleus.schema.autoCreateAll` property .

Use MySQL for the Hive Metastore
The metadata for Hive tables and partitions are stored in the Hive Metastore. By default, the Hive Metastore stores all Hive metadata in an embedded Apache Derby database in the HPE Ezmeral Data Fabric file system. Derby only allows one connection at a time; if you want multiple concurrent Hive sessions, you can use MySQL for the Hive Metastore.

Prerequisites
Review the following prerequisites before you begin:

- Verify that MySQL (version 5.6.17 or later) is installed on the machine that will host the Hive metastore, and also verify that you can connect to the MySQL server from the Hive machine. You can run the Hive metastore on any machine that is accessible from Hive. You can test this with the following command:

  ```
  mysql -h <hostname> -u <user>
  ```

- The database administrator must create a database for the Hive metastore data, and the username specified in `javax.jdo.option.ConnectionUserName` must have permissions to access it. The database can be specified using the `ConnectionURL` parameter. The tables and schemas are created automatically when the metastore is first started.

TIP: In MapR 6.1.0 and earlier releases, the following steps can be used interchangeably for MariaDB.

About this task
Complete the following steps to configure Hive to use MySQL for the Hive Metastore:

IMPORTANT: For MySQL 8, set the `javax.jdo.option.ConnectionDriverName` property to `com.mysql.cj.jdbc.Driver`. The `com.mysql.jdbc.Driver` is deprecated. The new driver class is `com.mysql.cj.jdbc.Driver`. However, the driver is automatically registered via the Service Provider Interface, so manual loading of the driver class is generally unnecessary.

Procedure

1. Update the `hive-site.xml` in the Hive configuration directory (`/opt/mapr/hive/hive-<version>/conf`) with the following contents:

```
<configuration>

 <property>
    <name>javax.jdo.option.ConnectionURL</name>
    <value>jdbc:mysql://localhost:3306/hive?
createDatabaseIfNotExist=true</value>
    <description>JDBC connect string for a JDBC metastore</description>
</property>

 <property>
    <name>javax.jdo.option.ConnectionDriverName</name>
    <value>com.mysql.jdbc.Driver</value>
    <description>Driver class name for a JDBC metastore</description>
 </property>

 <property>
    <name>javax.jdo.option.ConnectionUserName</name>
    <value>root</value>
    <description>username to use against metastore database</description>
 </property>

 <property>
    <name>javax.jdo.option.ConnectionPassword</name>
    <value><fill in with password></value>
    <description>password to use against metastore database</description>
 </property>

 <property>
    <name>hive.metastore.uris</name>
    <value>thrift://localhost:9083</value>
 </property>

</configuration>
```

2. Run the `schematool` command as an initialization step.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

3. To connect to an existing MySQL metastore, make sure the `ConnectionURL` parameter and the `Thrift URIs` parameters in `hive-site.xml` point to the metastore's host and port.

4. To set a specific port for Thrift URIs, add the command `export METASTORE_PORT=<port>` into the file `hive-env.sh` (if `hive-env.sh` does not exist, create it in the Hive configuration directory). Example:

   ```
   export METASTORE_PORT=9083
   ```

5. Start the Hive Metastore service using one of the following commands:

   If you want the Hive Metastore to be managed by Warden, the maprcli, and the Control System:

   ```
   maprcli node services -name hivemeta -action start -nodes <space
   delimited list of nodes>
   ```

   If you want the Hive Metastore to be managed with standard hive commands:

   ```
   /opt/mapr/hive/hive-<version>/bin/hive --service metastore --start
   ```

   You can use also use `nohup hive --service metastore` to run the Metastore in the background.

   WARNING: If you have not configured a MySQL Metastore, do not run the Hive shell from an NFS mount location. If you try to do this, Hive will fail. The same problem will occur if you use the `hive-site.xml` file to configure the Metastore on an NFS mount location. Avoid both of these configurations.

Configuring a Remote MySQL Database for the Hive Metastore

About this task

After installing MySQL, perform the following steps to configure Hive Metastore on MySQL

Procedure

1. Install the MySQL connector. To install:

   - **MySQL connector on a RHEL 6+ system**

     On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file to the `/opt/mapr/hive/hive-<version>/lib/` directory.

     ```
     $ sudo yum install
     mysql-connector-java
     $ ln -s /usr/share/
     java/mysql-connector-java.jar /opt/
     mapr/hive/hive-<version>/lib/
     mysql-connector-java.jar
     ```

   - **MySQL connector on a SLES system**

     On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file to the `/opt/mapr/hive/hive-<version>/lib/` directory.

     ```
     $ sudo zypper install
     mysql-connector-java
     $ ln -s /usr/share/
     java/mysql-connector-java.jar /opt/
     mapr/hive/hive-<version>/lib/
     mysql-connector-java.jar
     ```

last-updated: Jun 06, 2024

- **MySQL connector on a Debian/Ubuntu system**

  On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file into the `/opt/mapr/hive/hive-<version>/lib/` directory.

  ```
  $ sudo apt-get install
  libmysql-java
  $ ln -s /usr/
  share/java/libmysql-java.jar /opt/
  mapr/hive/hive-<version>/lib/
  mysql-connector-java.jar
  ```

2. Create the database and an associated user. The following commands are for a Hive Metastore with hostname `metastorehost` to create a MySQL user with name `hive` and password `mypassword`:

   ```
   $ mysql -u root -p

   mysql> CREATE DATABASE metastore;
   mysql> CREATE USER 'hive'@'metastorehost' IDENTIFIED BY 'mypassword';
   ...
   mysql> REVOKE ALL PRIVILEGES, GRANT OPTION FROM 'hive'@'metastorehost';
   mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'hive'@'metastorehost';
   mysql> FLUSH PRIVILEGES;
   mysql> quit;
   ```

last-updated: Jun 06, 2024

3. Configure the Metastore service to communicate with the MySQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive//hive-<version>/conf/hive-site.xml` file.

   Suppose a MySQL database running on `myhost` and the user account `hive` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mysql://myhost/metastore</value>
  <description>the URL of the MySQL database</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.mysql.jdbc.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hive</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

   NOTE: Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

4. Run `schemaTool` to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

Configuring a Remote PostgreSQL Database for the Hive Metastore

Before you can run the Hive metastore with a remote PostgreSQL database, you must configure a JDBC driver to the remote PostgreSQL database, set up the initial database schema, and configure the PostgreSQL user account for the Hive user.

After installing PostgreSQL, perform the following steps to configure Hive Metastore on PostgreSQL.

Installing and Configuring PostgreSQL for the Hive Metastore

1. Download the PostgreSQL JDBC driver.

   Refer to the official PostgreSQL JDBC Driver website to download the JDBC driver and get information about the latest updates. Determine the appropriate database version and get the released drivers and JAR file.

2. Run the following commands using `sudo`:

a. Move the JAR into the Java `share` directory:

```
sudo mv <postgresql-jdbc.jar> /usr/share/java/postgresql-jdbc.jar
```

b. Change the access mode of the JAR file to 644:

```
sudo chmod 644 /usr/share/java/postgresql-jdbc.jar
```

c. Create symbolic link to the `/usr/lib/hive/lib/ directory`, for example:

```
sudo ln -s /usr/share/java/postgresql-jdbc.jar /opt/mapr/hive/
hive-<version>/lib/postgresql-jdbc.jar
```

3. Create the Metastore database and user accounts:

```
$ sudo -u postgres psql

postgres=# CREATE USER hiveuser WITH PASSWORD 'mypassword';
postgres=# CREATE DATABASE metastore;
```

To verify the connection from the Metastore service host, run the following command:

```
psql -h myhost -U hiveuser -d metastore
metastore=#
```

4. Configure the Metastore service to communicate with the PostgreSQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive//hive-<version>/conf/hive-site.xml` file. Suppose a PostgreSQL database running on host `myhost` under the user account `hive` with the password `mypassword`, set the following configuration properties in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:postgresql://myhost/metastore</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>org.postgresql.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
  </property>
```

NOTE: Though you can use the same `hive-site.xml` properties on all the hosts (client, metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all of the hosts; the other properties are only needed on the Metastore host.

5. Run `schemaTool` to create the initial DB structure:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType postgres -initSchema
```

Configuring a Remote Oracle Database for the Hive Metastore

About this task

After installing Oracle, perform the following steps to configure Hive Metastore on Oracle.

Procedure

1. Install the Oracle JDBC Driver.
   a) Download the Oracle JDBC Driver (`ojdbc6.jar`) from the Oracle website.
   b) Move the `ojdbc6.jar` file to `/opt/mapr/hive/hive-<version>/lib/` directory

2. Create the Metastore database and user account.

   Connect to your Oracle database as administrator, create the user that will use the Hive Metastore, and create the Metastore schema. For example:

   ```
   $ sqlplus "sys as sysdba"
   SQL> create user hiveuser identified by mypassword;
   SQL> grant connect to hiveuser;
   SQL> grant all privileges to hiveuser;
   SQL>CREATE DATABASE metastore
   ```

3. Configure the Metastore service to communicate with the Oracle database by setting the necessary properties (shown below) in the `/opt/mapr/hive//hive-<version>/conf/hive-site.xml` file.

   Suppose an Oracle database running on `myhost` and the user account `hiveuser` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

   ```
   <property>
     <name>javax.jdo.option.ConnectionURL</name>
     <value>jdbc:oracle:thin:@//myhost/metastore</value>
   </property>

   <property>
     <name>javax.jdo.option.ConnectionDriverName</name>
     <value>oracle.jdbc.OracleDriver</value>
   </property>

   <property>
     <name>javax.jdo.option.ConnectionUserName</name>
     <value>hiveuser</value>
   </property>

   <property>
     <name>javax.jdo.option.ConnectionPassword</name>
     <value>mypassword</value>
   </property>

   <property>
     <name>hive.metastore.uris</name>
     <value>thrift://<n.n.n.n>:9083</value>
     <description>IP address (or fully-qualified domain name) and port of
   the metastore host</description>
   </property>
   ```

   NOTE: Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

4. Run `schemaTool` to create the initial DB structure.

   ```
   /opt/mapr/hive/hive-<version>/bin/schematool -dbType oracle -initSchema
   ```

Configuring an Oracle Schema

You must create schemas for Oracle databases manually.

About this task

Use `schematool` to view and create relational database management system (RDBMS) schemas.

last-updated: Jun 06, 2024

See Apache Hive documentation for the detailed steps.

Configuring a Remote MS SQL SERVER Database for the Hive Metastore

About this task

After installing MS SQL, perform the following steps to configure Hive Metastore on MS SQL.

Procedure

1. Create `hiveuser` and Metastore schema.

```
1>CREATE DATABASE metastore;
2>GO
1>CREATE LOGIN <hiveuser> with password='<mypassword>;
2>CREATE USER <hiveuser> for login <hiveuser>;
3>GRANT <PRIVILEGES> to <hiveuser>;
4>GO
```

2. Download JDBC Driver from here, untar the file, and follow instructions in the `install.txt` file to install the driver.

3. Copy the JAR file to `/opt/mapr/hive/hive-version>/lib/` directory.

   - For Java 7

```
cp ~/sqljdbc_6.0/enu/jre7/sqljdbc41.jar /opt/mapr/hive/
hive-<version>/lib/
```

   - For Java 8

```
cp ~/sqljdbc_6.0/enu/jre8/sqljdbc42.jar /opt/mapr/hive/
hive-<version>/lib/
```

4. Configure the Metastore service to communicate with the MS SQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive//hive-<version>/conf/hive-site.xml` file.

   Suppose an MS SQL database running on `myhost` and the user account `hiveuser` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:sqlserver://<SERVER_NAME>:1433;DatabaseName=metastore;</
value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.microsoft.sqlserver.jdbc.SQLServerDriver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
  </property>
```

   NOTE: Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

5. Run `schemaTool` to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mssql -initSchema
```

Configuring MariaDB for the Hive Metastore

Installing MariaDB

To install MariaDB, use the MariaDB Repository Configuration Tool. See MariaDB Downloads.

Configuring Repositories

The following steps describe how to configure a repository and install the latest available stable version of MariaDB for different operating systems.

1. Configure a repository for MariaDB:

- **Red Hat / CentOS and SLES**

  Copy and paste the following custom MariaDB repository entry into a file under `/etc/yum.repos.d/`. You can name the file `MariaDB.repo` or something similar:

  ```
  # MariaDB 10.4 RedHat repository list
  # http://downloads.mariadb.org/mariadb/repositories/
  [mariadb]
  name = MariaDB
  baseurl = http://yum.mariadb.org/10.4/rhel7-amd64
  gpgkey=https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
  gpgcheck=1
  ```

- **Ubuntu**

  You can also create a custom MariaDB `sources.list` file. To do so, after importing the signing key as outlined above, copy and paste the following into a file under `/etc/apt/sources.list.d/`. You can name the file `MariaDB.list` or something similar. Or you can add it to the bottom of your `/etc/apt/sources.list` file:

  ```
  # MariaDB 10.4 repository list - created 2020-04-17 08:34 UTC
  # http://downloads.mariadb.org/mariadb/repositories/
  deb [arch=amd64,arm64,ppc64el] http://mirror.mephi.ru/mariadb/repo/
  10.4/ubuntu bionic main
  deb-src http://mirror.mephi.ru/mariadb/repo/10.4/ubuntu bionic main
  ```

2. After the `sources.list` file is in place, install MariaDB:

   - **Red Hat / CentOS**

     ```
     sudo yum clean all && sudo yum install mariadb-server mariadb-client
     ```

   - **SLES**

     ```
     sudo zypper update && sudo zypper install mariadb
     ```

   - **Ubuntu**

     ```
     sudo apt update && sudo apt install mariadb-server
     ```

3. Start the MariaDB server:

   - **Red Hat / CentOS and Ubuntu**

     ```
     sudo service mariadb start
     ```

   - **SLES**

     ```
     sudo systemctl start mariadb
     ```

4. In the command line, run the `mysql_secure_installation` shell script:

```
sudo mysql_secure_installation
Enter current password for root (enter for none): press Enter
Set root password? Y
New password: Type new root password
Re-enter new password: Confirm the password
Remove anonymous users? Y
Disallow root login remotely? Y
Remove test database and access to it? Y
Reload privilege tables now? Y
```

Configuring a JDBC Driver for MariaDB

Before you can run the Hive Metastore with a MariaDB database, you must:

- Configure a JDBC driver for the MariaDB database.
- Set up the initial database schema.
- Configure the MariaDB user account for the Hive user.

Use the following steps:

1. Install the MariaDB Connector/J manually with a `.jar` file. The MariaDB Connector/J can also be installed by manually installing a `.jar` file to a directory in your CLASSPATH. Download the MariaDB Connector/J `.jar` files from the following URL: https://downloads.mariadb.com/Connectors/java/connector-java-2.5.4/.

2. Copy the `.jar` files to the `/opt/mapr/hive/hive-<version>/lib/` directory:

```
cp mariadb-java-client-2.5.4-sources.jar /opt/mapr/hive-<version>/lib/
cp mariadb-java-client-2.5.4.jar /opt/mapr/hive/hive-<version>/lib/
cp mariadb-java-client-2.5.4-javadoc.jar /opt/mapr/hive/
hive-<version>/lib/
```

3. Restart Hive services:

```
maprcli node services -name hivemeta -action restart -nodes 'hostname -f'
maprcli node services -name hs2 -action restart -nodes 'hostname -f'
```

4. Create the Hive Metastore database and user accounts:

```
$ mysql -u root -p <password>

MariaDB [(none)]> CREATE USER hiveuser IDENTIFIED BY PASSWORD 'password';
MariaDB [(none)]> CREATE DATABASE metastore;
MariaDB [(none)]> REVOKE ALL PRIVILEGES, GRANT OPTION FROM
'hiveuser'@'metastorehost';
MariaDB [(none)]> GRANT ALL PRIVILEGES ON metastore.* TO
'hiveuser'@'metastorehost';
MariaDB [(none)]> FLUSH PRIVILEGES;
MariaDB [(none)]> quit;
```

Configuring the Hive Metastore on MariaDB

Use these steps:

1. In the Hive configuration directory (`/opt/mapr/hive/hive-<version>/conf`), update the `hive-site.xml` file with the following properties. Beginning with EEP 7.0.0, you must use the MySQL driver with MariaDB:

```
<property>
    <description>the URL of the MariaDB database</description>
    <name>javax.jdo.option.ConnectionURL</name>
    <value>jdbc:mysql://<hostname>:3306/metastore</value>
</property>
<property>
    <name>javax.jdo.option.ConnectionDriverName</name>
    <value>com.mysql.jdbc.Driver</value>
</property>
<property>
    <name>javax.jdo.option.ConnectionUserName</name>
    <value><hiveuser></value>
</property>
<property>
    <name>javax.jdo.option.ConnectionPassword</name>
    <value><fill in with password></value>
</property>
<property>
    <description>IP address (or FQDN) and port of the metastore host</
description>
    <name>hive.metastore.uris</name>
    <value>thrift://<hostname>:9083</value>
</property>
```

2. Run the `schematool` command as an initialization step:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

User Impersonation for Hive

User impersonation enables Hive to submit jobs as a particular user. Without impersonation, Hive submits queries and hadoop commands as the user that started HiveServer2 and Hive Metastore. On a MapR cluster, this user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable.

NOTE: Impersonation is enabled by default.

Enable User Impersonation
On non-secure clusters

Procedure

1. Set the following properties in the `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where HiveServer2 is installed:

```
<property>
  <name>hive.server2.enable.doAs</name>
  <value>true</value>
  <description>Set this property to enable impersonation in Hive Server
2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

2. Set the following property `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where Hive Metastore is installed:

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

On secure (MAPR-SASL and Kerberos) clusters

Procedure

1. Set the following properties in the `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where HiveServer2 is installed:

```
<property>
  <name>hive.server2.enable.doAs</name>
  <value>true</value>
  <description>Set this property to enable impersonation in Hive Server
2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>false</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

2. Set the following property `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where Hive Metastore is installed:

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>false</value>
  <description>Set this property to enable Hive Metastore service
impersonation in non-secure mode. In non-secure mode, setting this
property to true will cause the metastore to execute DFS operations
using the client's reported user and group permissions. Note that this
property must be set on both the client and server sides. If the client
sets it to true and the server sets it to false, the client setting will
be ignored.</description>
</property>
```

NOTE: The `hive.metastore.execute.setugi` property is set to false automatically after `/opt/mapr/server/configure.sh -R` is running.

On both secure and non-secure clusters

Procedure

On nodes where the **Resource Manager** and the **Node Manager** are installed, set the following properties in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file:

```
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value>
  <description>Allow the superuser mapr to impersonate any member of any
group</description>
</property>
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value>*</value>
  <description>The superuser can connect from any host to impersonate a
```

last-updated: Jun 06, 2024

```
user</description>
</property>
```

Results

WARNING: The impersonated user must have write permissions to `/user/hive/warehouse` and `/user/mapr-user/tmp/hive` directories.

Verify that User Impersonation is Enabled

About this task

To verify that Hive queries do not run as the `mapr` user, connect to HiveServer2 as a user other than `mapr`. Then run queries and verify that queries were run as the user that connected to HiveServer2.

To verify that hadoop commands submitted by Hive do not run as the `mapr` user, start the shell or connect to HiveServer2 as a user other than `mapr`. Then create some tables, and verify that the tables in `/user/hive/warehouse` are created under the user that started the shell or the user connected to HiveServer2.

Example: Hive Impersonation

The following examples illustrate Hive impersonation:

Example 1

1. Log in as a non-`mapr` user and generate a MapR ticket:

```
$ su mapruser1
$ maprlogin password
```

2. Connect to HiveServer2:

```
$ hive --service beeline
Beeline version 2.3.3-mapr-SNAPSHOT by Apache Hive
beeline> !connect jdbc:hive2://node4.cluster.com:10000/
default;ssl=true;auth=maprsasl
Connecting to jdbc:hive2://node4.cluster.com:10000/
default;ssl=true;auth=maprsasl
Connected to: Apache Hive (version 2.3.3-mapr-SNAPSHOT)
Driver: Hive JDBC (version 2.3.3-mapr-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

3. Create a table, and upload data:

```
0: jdbc:hive2://node4.cluster.com:10000/defau> create table
impersonation_example_first (id int, username string);
0: jdbc:hive2://node4.cluster.com:10000/defau> insert into
impersonation_example_first values (1, 'mapruser1');
```

4. To check that impersonation works, use the following commands to check the `/warehouse` directory of the MapR file system:

```
$ hadoop fs -ls /user/hive/warehouse
Found 1 items
drwxr-xr-x   - mapruser1 mapruser1          1 2019-05-22 14:40
/user/hive/warehouse/impersonation_example_first

$ hadoop fs -ls /user/hive/warehouse/impersonation_example_first
Found 1 items
-rwxrwxrwx   3 mapruser1 mapruser1         12 2019-10-15 07:21
/user/hive/warehouse/impersonation_example_first/000000_0
```

Example 2

1. Generate a MapR ticket for a non-`mapr` user.
2. Connect through JDBC using the `hive.server2.proxy.user` option with a non-`mapr` user name as an argument:

```
$ hive --service beeline
beeline> !connect
jdbc:hive2://node4.cluster.com:10000/
default;auth=maprsasl;ssl=true;hive.server2.proxy.user=mapruser1
Connecting to
jdbc:hive2://node4.cluster.com:10000/
default;auth=maprsasl;ssl=true;hive.server2.proxy.user=mapruser1
Client: auth-conf,auth-int,auth.Using Server one
Connected to: Apache Hive (version 2.3.3-mapr-SNAPSHOT)
Driver: Hive JDBC (version 2.3.3-mapr-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

3. Create a table and upload data:

```
0: jdbc:hive2://node4.cluster.com:10000/default> create table
impersonation_example_second (id int);
0: jdbc:hive2://node4.cluster.com:10000/default> insert into table
impersonation_example_second values (1), (2), (3), (5);
```

4. Check the owner of the table and data:

```
$ hadoop fs -ls /user/hive/warehouse/impersonation_example_second
Found 1 items
drwxrwxrwx   - mapruser1 mapruser1          1 2019-05-23 12:29
/user/hive/warehouse/impersonation_example_second

$ hadoop fs -ls /user/hive/warehouse/impersonation_example_second
Found 1 items
-rwxrwxrwx   3 mapruser1 mapruser1          8 2019-05-23 12:29
/user/hive/warehouse/impersonation_example_second/000000_0
```

Hive Security

You can configure the following features for Hive security:

last-updated: Jun 06, 2024

Hive Security Configuration Options
This section describes changes made in Hive default configuration. It shows how to configure Hive after manual installation.

Unlike the previous releases, starting in EEP 4.0, Hive should be configured by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option after installing Hive. Hive demons will not start automatically if Hive is not configured correctly. The security configuration are described in the following sections:

1. Automatic
2. Manual
3. Custom

NOTE: Do not use ecosystem `$HIVE_HOME/bin/configure.sh` script for Hive configuration. Every configuration of Hive should be done via the `$MAPR_HOME/server/configure.sh` utility by running it with the `-R` option. The core `$MAPR_HOME/server/configure.sh` utility invokes the ecosystem `configure.sh` script automatically with appropriate security option.

Automatic

If you installed Hive using the MapR Installer, the MapR Installer configures Hive daemons during installation. Additional configuration is not required.

Manual

After a new manual installation, to generate a valid default ecosystem configuration, run:

```
$MAPR_HOME/server/configure.sh -R
```

Table

Node, Package	Hive	HiveServer2	Hive Metastore	WebHCat
Node 1	X	X		
Node 2	X		X	
Node 3	X			X

- After a manual installation, run the following command on Node 1, Node 2, and Node 3:

  ```
  $MAPR_HOME/server/configure.sh -R
  ```

As a result:

- All Hive daemons are configured to support MapR-SASL. If the `hive.metastore.sasl.enabled` property is enabled in the `hive-site.xml` file, its value is set to `true`. If the property is not present, it is added in the `configuration` section as follows:

  ```
  <property>
     <name>hive.metastore.sasl.enabled</name>
     <value>true</value>
  </property>
  ```

- HiveServer2 is configured to support encryption between Hiveserver2 and Hive clients. If the `hive.server2.thrift.sasl.qop` property is available in the `hive-site.xml` file, its value is set to `auth-conf`. If the property is not present, it is added in the configuration section as follows:

```
<property>
   <name>hive.server2.thrift.sasl.qop</name>
   <value>auth-conf</value>
</property>
```

- The `configure.sh` script creates a backup folder for the current Hive configuration before it changes the configuration. All configuration properties including `*.conf`, `*.properties`, and `*.xml` are saved in the backup folder.

```
$HIVE_HOME/conf.YYYYMMDD_HHMMS
```

- 644 Unix permissions are applied to all configuration files. Each run of `configure.sh` with the `-R` option overwrites permissions of the configuration files to 644.
- The Hive default ports listed below are verified as available. If a port is not available, the `configure.sh` script generates an error message during configuration.

Hive default ports are as follows:

Role	Default Port
Hive Metastore	9083
HiveServer2	10000
HiveWebHCat	50111

Custom

For PAM, LDAP, and Kerberos custom configurations, run `configure.sh` with the `-R` option:

```
$MAPR_HOME/server/configure.sh -R
```

The `hive-site.xml` file is not changed. However, Warden files are copied and a `HIVE_HOME/conf` backup folder is created.

Preventing a Non-Administrative User from Installing Hooks

For a fresh install of EEP 6.1, a non-administrative user is prevented from installing hooks by default. For a minor version update (for example, EEP 6.0.0 to EEP 6.1.0 or EEP 5.0.1 to EEP 5.0.2), you need to modify the Hive configuration to prevent a malicious user from using Hive hooks to install malware on your MapR cluster.

About this task

In general, a hook is a mechanism for intercepting events, messages, or function calls during processing. Hive hooks are a mechanism to tie into the internal workings of Hive without the need of re-compiling Hive. Hive hooks, in this sense, provide the ability to extend and integrate external functionality with Hive.

Any user using beeline can install Java code as a Hive hook. On the MapR platform, these hooks run as the `mapr` user, which could represent a security vulnerability. To prevent a malicious user from using Hive hooks to install malware on a MapR cluster, the cluster admin should add the following properties to the default value of `hive.conf.restricted.list` in the `hive-site.xml` file, and then restart HiveServer 2 (HS2):

- `hive.exec.pre.hooks`

- `hive.exec.post.hooks`
- `hive.exec.failure.hooks`
- `hive.exec.query.redactor.hooks`

Adding the properties prevents a non-admin user from installing hooks into Hive.

Procedure

1. Add all hook-related properties to the default value of `hive.conf.restricted.list` in the `hive-site.xml` file:

   Hive 2.3

   - `hive.exec.pre.hooks`
   - `hive.exec.post.hooks`
   - `hive.exec.failure.hooks`
   - `hive.exec.query.redactor.hooks`
   - `hive.semantic.analyzer.hook`
   - `hive.query.lifetime.hooks`
   - `hive.exec.driver.run.hooks`
   - `hive.server2.session.hook`

   Hive 2.1

   - `hive.exec.pre.hooks`
   - `hive.exec.post.hooks`
   - `hive.exec.failure.hooks`
   - `hive.exec.query.redactor.hooks`
   - `hive.semantic.analyzer.hook`
   - `hive.exec.driver.run.hooks`
   - `hive.server2.session.hook`

2. Make sure `hive.conf.restricted.list` configuration parameter already has a default value which contains:

   Hive 2.3

   ```
   hive.security.authenticator.manager
   hive.security.authorization.manager
   Hive.security.metastore.authorizatio
   n.manager
   hive.security.metastore.authenticato
   r.manager
   Hive.users.in.admin.role,hive.server
   2.xsrf.filter.enabled
   hive.security.authorization.enabled
   hive.server2.authentication.ldap.bas
   eDN
   hive.server2.authentication.ldap.url
   hive.server2.authentication.ldap.Dom
   ain
   ```

last-updated: Jun 06, 2024

```
hive.server2.authentication.ldap.gro
upDNPattern
hive.server2.authentication.ldap.gro
upFilter
hive.server2.authentication.ldap.use
rDNPattern
hive.server2.authentication.ldap.use
rFilter
hive.server2.authentication.ldap.gro
upMembershipKey
hive.server2.authentication.ldap.use
rMembershipKey
hive.server2.authentication.ldap.gro
upClassKey
hive.server2.authentication.ldap.cus
tomLDAPQuery
```

Hive 2.1

```
hive.security.authenticator.manager
hive.security.authorization.manager
hive.users.in.admin.role
hive.server2.xsrf.filter.enabled
```

3. Add the default values already present in `hive.conf.restricted.list` to the `hive-site.xml` file:

Hive 2.3

```
<property>
  <name>hive.conf.restricted.list</
name>
  <value>

hive.security.authenticator.manager,

hive.security.authorization.manager,

hive.security.metastore.authorizatio
n.manager,

hive.security.metastore.authenticato
r.manager,

hive.users.in.admin.role,hive.server
2.xsrf.filter.enabled,

hive.security.authorization.enabled,

hive.server2.authentication.ldap.bas
eDN,

hive.server2.authentication.ldap.url
,

hive.server2.authentication.ldap.Dom
ain,

hive.server2.authentication.ldap.gro
upDNPattern,

hive.server2.authentication.ldap.gro
```

```
upFilter,

hive.server2.authentication.ldap.use
rDNPattern,

hive.server2.authentication.ldap.use
rFilter,

hive.server2.authentication.ldap.gro
upMembershipKey,

hive.server2.authentication.ldap.use
rMembershipKey,

hive.server2.authentication.ldap.gro
upClassKey,

hive.server2.authentication.ldap.cus
tomLDAPQuery,
     hive.exec.pre.hooks,
     hive.exec.post.hooks,
     hive.exec.failure.hooks,
     hive.exec.query.redactor.hooks,
     hive.semantic.analyzer.hook,
     hive.query.lifetime.hooks,
     hive.exec.driver.run.hooks,
     hive.server2.session.hook,
  </value>
</property>
```

Hive 2.1

```
<property>
  <name>hive.conf.restricted.list</
name>
  <value>

hive.security.authenticator.manager,

hive.security.authorization.manager,
     hive.users.in.admin.role,

hive.server2.xsrf.filter.enabled,
     hive.exec.pre.hooks,
     hive.exec.post.hooks,
     hive.exec.failure.hooks,
     hive.exec.query.redactor.hooks,
     hive.semantic.analyzer.hook,
     hive.exec.driver.run.hooks,
     hive.server2.session.hook,
  </value>
</property>
```

NOTE: Values of the `hive.conf.restricted.list` are split into separate lines for better readability. In the actual `hive-site.xml` file, no spaces or newlines exist between the commas.

Configuring Security Headers for Web Servers

This section describes how to configure response headers for REST API servers used in Hive WebHCat and the HiveServer2 web UI.

last-updated: Jun 06, 2024

About the Headers File

The XML file with security headers is located at:

```
/opt/mapr/hive/hive-<version>/conf/headres.xml
```

The `headres.xml` file contains the following headers:

```
<?xml version="1.0" encoding="utf-8" ?>
<!DOCTYPE properties SYSTEM "http://java.sun.com/dtd/properties.dtd">
<properties>
  <entry key="X-Content-Type-Options">nosniff</entry>
  <entry key="X-XSS-Protection">1; mode=block</entry>
  <entry key="Strict-Transport-Security">max-age=31536000;
includeSubDomains</entry>
  <entry key="Content-Security-Policy">default-src https:</entry>
</properties>
```

This table describes each header:

Header	Description	Default Value
X-XSS-Protection	Stops pages from loading when reflected cross-site scripting (XSS) is detected. Supported by IE, Chrome, and Safari.	`1: mode=block`
X-Content-Type-Options	Indicates that the MIME types advertised in the `Content-Type` headers should not be changed and should be followed.	`nosniff`
Strict-Transport-Security	Tells all browsers that the website should only be accessed using HTTPS instead of using HTTP.	`max-age=31536000;includeSubDomains`
Content-Security-Policy	Allows web-site administrators to control resources the user agent is allowed to load for a given page. This helps guard against cross-site scripting attacks (XSS).	`default-src https:`

Configuring Security Headers for WebHCat

To enable security headers for WebHCat, add the following to the `webhcat-site.xml` file, and replace `<version>` with your Hive version:

```
<property>
<name>templeton.jetty.response.headers.file</name>
<value>/opt/mapr/hive/hive-<version>/conf/headers.xml</value>
</property>
```

After configuring and restarting WebHCat, you should see security headers in the server response. For example:

```
< HTTP/1.1 200 OK
< Date: Thu, 03 Oct 2019 11:35:39 GMT
< Set-Cookie:
hadoop.auth="u=mapr&p=mapr&t=multiauth&e=1570138539451&s=CpX+tI7sScnnSUZpA1K
df+7hamM="; Path=/; Domain=.cluster.com; Expires=Thu, 03-Oct-2019 21:35:39
GMT; Secure; HttpOnly
< Content-Security-Policy: default-src https:
< X-XSS-Protection: 1; mode=block
< X-Content-Type-Options: nosniff
< Strict-Transport-Security: max-age=31536000
< Content-Type: application/json
```

last-updated: Jun 06, 2024

```
< Transfer-Encoding: chunked
< Server: Jetty(9.4.19.v20190610)
```

Configuring Security Headers for HiveServer2 Web UI

To enable security headers for the Hiveserver2 Web UI, add the following to the `hive-site.xml` file, replacing `<version>` with your Hive version:

```
<property>
    <name>hive.server2.webui.jetty.response.headers.file</name>
    <value>/opt/mapr/hive/hive-<version>/conf/headers.xml</value>
</property>
```

Then restart HiveServer2.

Configuring Custom Headers

To configure custom headers for web servers, edit the `headers.xml` file, and add `Custom-header` as follows:

```
<entry key="Custom-header">custom-value</entry>
```

Security Headers Auto-Configuration

If you install Hive on a secure cluster (MapR SASL or Kerberos) and run the following command after Hive installation, Hive automatically configures itself to enable security headers, and no additional action is needed:

```
/opt/mapr/server/configure.sh -R
```

Hive Authentication
The authentication method that you configure for the Hive Metastore, HiveServer2, and WebHcat determines how these Hive components access and connect to each other.

Clients of these components may require additional configuration and specific connection strings based on the selected authentication method.

To enable and use authentication for Hive, complete the following steps:

1. Determine which authentication methods are supported for each component and its clients.
2. Configure authentication for Hive components and their clients. See the following topics:
   - Authentication for Hive Metastore
   - Authentication for HiveServer2
   - Authentication for WebHCat
3. Determine how clients connect to each component. See Connecting to Hive.

Hive Metastore Authentication Support

The following table describes the different supported authentication methods for Hive Metastore and how it impacts the authentication options for its clients:

MapR Cluster	Hive Metastore (Remote) Authentication	HiveServer 2 Authentication Options	WebHCat Authentication Options
Secure	NONE	• NONE • KERBEROS • LDAP • PAM • CUSTOM • MAPRSASL • NOSASL	PAM
Secure	KERBEROS	KERBEROS	KERBEROS with SPNEGO
Secure	MAPRSASL (default)*	MAPRSASL (default)*	PAM
Not Secure	NONE	NONE	Simple authentication with <user.name> only
*As of Hive 0.13-1504 and Hive 1.0-1504, Hive Metastore supports MapR-SASL and MapR-SASL is enabled by default when the MapR cluster is secure.			

HiveServer2 Authentication Support

The following table describes the different supported authentication option for HiveServer2 based on the authentication method configured for Hive Metastore:

MapR Cluster	Hive Metastore (Remote) Authentication	HiveServer 2 Authentication Options
Secure	NONE	NONE
Secure	NONE	KERBEROS
Secure	NONE	LDAP
Secure	NONE	PAM (default)*
Secure	NONE	CUSTOM
Secure	NONE	MAPRSASL*
Secure	KERBEROS	KERBEROS
Secure	MAPRSASL (default)*	MAPRSASL*
Not Secure	NONE	NONE
*As of Hive 0.13-1510, Hive 1.0-1510, and Hive 1.2.1-1510, PAM and MapR-SASL are enabled by default when the cluster is secure. In Hive 0.13-1508 and Hive 1.0-1508, PAM is enabled by default when the cluster is secure. In Hive 0.13-1504 and Hive 1.0-1504, MapR-SASL is supported and enabled by default when the MapR cluster is secure.		

Clients of HiveServer2 authenticate with the same authentication method that is configured for HiveServer2. Clients of HiveServer 2 include ODBC, JDBC, and Beeline.

NOTE: Connections to HiveServer2 using ODBC do not support MapR-SASL.

last-updated: Jun 06, 2024

WebHCat Authentication Support

The following table describes the different authentication options for WebHCat based on the authentication method configured for Hive Metastore :

MapR Cluster	Hive Metastore (Remote) Authentication	WebHCat Authentication
Secure	KERBEROS	KERBEROS with SPNEGO
Secure	KERBEROS	PAM
Secure	MAPRSASL (default)*	PAM
Not Secure	NONE	Simple authentication with user.name only
*As of Hive 0.13-1504 and Hive 1.0-1504, Hive Metastore supports MapR-SASL and MapR-SASL is enabled by default when the MapR cluster is secure.		

Clients of WebHCat authenticate with the same authentication method that is configured for WebHCat. Web browsers are clients of WebHCat.

Description of Security Values

The following table describes the different security values:

Authentication Options	Description
NONE	No authentication check
LDAP	LDAP/AD based authentication
KERBEROS	Kerberos/GSSAPI authentication
CUSTOM	Custom authentication provider (use with property `hive.server2.custom.authentication.class`)
PAM	Pluggable authentication module
NOSASL	Raw transport
MAPRSASL	MapR SASL security

Authentication for Hive Metastore

You can configure authentication for in-bound client connections to the Hive Metastore when the metastore is remote, not embedded. Clients of Hive Metastore include the HiveCLI, HCatalog, HiveServer2, and WebHCat.

Hive Metastore supports the following authentication methods:

- MapR-SASL authentication
- Kerberos Authentication

MapR-SASL Authentication

MapR-SASL is available starting with the 1504 release of Hive 0.13 and Hive 1.0 and it is the default authentication method when the cluster is secure.

last-updated: Jun 06, 2024

Kerberos Authentication

When the cluster is secure, you can configure Hive Metastore to use Kerberos authentication. You must also configure Hive Metastore clients to use Kerberos when authenticating with Hive Metastore.

Configuring Hive Metastore Authentication

This section describes how to configure the `hive.metastore.authentication` property for secured and unsecured clusters. It describes cases when the property must be configured explicitly and when it can be omitted from `hive-site.xml`.

Hive Metastore supports two types of authentication: `MAPRSASL` and `KERBEROS`. At startup, Hive Metastore reads the system property `metastore.auth`. If `metastore.auth` is equal to null, then the authentication type is `NONE`. Otherwise, Hive Metastore takes the value of the system property `metastore.auth` and assigns it to the Hive Metastore configuration property `hive.metastore.authentication`.

You do not need to set up the `metastore.auth` system property manually. If a cluster is secured, Hive assigns the `MAPRSASL` value to the `metastore.auth` property. If a cluster is not secured, Hive assigns the `NONE` value to the `metastore.auth` property.

To enable Kerberos authentication, set the value of `hive.metastore.authentication` directly in `hive-site.xml`, as shown in the following table:

Table

Security	Value of `hive.metastore.authentication`	Notes
No security	`NONE`	The value is set automatically. You do not need to make an entry in `hive-site.xml`.
MapR SASL security	`MAPRSASL`	The value is set automatically. You do not need to make an entry in `hive-site.xml`.

Kerberos security	`KERBEROS`	You must make the following entry in `hive-site.xml`:
		`<property>`
		`<name>hive.metastore.authentication</name>`
		`<value>KERBEROS</value>`
		`</property>`

Configure Hive Metastore to use MapR-SASL

About this task

Procedure

Edit the `/opt/mapr/conf/env.sh` file and set the following properties:

```
MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"
MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab"
```

Configuring Hive Metastore Clients to use MapR-SASL

About this task

The Hive metastore clients are configured to use MapR-SASL when authenticating with Hive Metastore.

last-updated: Jun 06, 2024

NOTE: Hive Metastore clients must provide a valid MapR ticket to connect to the Hive Metastore. See Connecting to Hive on page 4269 for details.

Procedure

1. Ensure that the cluster is secure.
2. Edit the `/opt/mapr/conf/env.sh` file and set the following property:

```
MAPR_HIVE_LOGIN _OPTS="-Dhadoop.login=maprsasl"
```

Configure Hive Metastore to use Kerberos

About this task
Enabling Hive Metastore to use Kerberos authentication requires a kerberos principal, kerberos keytab, and the following configurations.

Complete the following steps on each node where a Hive Metastore is installed:

Procedure

1. Create a Kerberos server identity and add it to a keytab file. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file:

   NOTE: MapR clusters do not provide Kerberos infrastructure. The tips in this step assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

```
# kadmin
    : addprinc -randkey username/<FQDN@REALM>
    : ktadd -k /opt/mapr/conf/hive.keytab username/<FQDN@REALM>
```

   The `hive.keytab` file must be owned and readable only by the `mapr` user.

2. Configure the following properties in the following file:

```
/opt/mapr/hive/hive-<version>/conf/hive-site.xml
```

Property	Value
`hive.metastore.kerberos.keytab.file`	The Keytab file that contains the HiveMetastore principal.
`hive.metastore.kerberos.principal`	<The HiveMetastore principal. For example, mapr/<FQDN@REALM>.>

```
<property>
  <name>hive.metastore.kerberos.keytab.file</name>
  <value>/opt/mapr/conf/metastore.keytab</value>
  <description>The path to the Kerberos Keytab file
containing the metastore thrift server's service principal.</
description>
</property>
<property>
  <name>hive.metastore.kerberos.principal</name>
  <value>mapr/<FQDN@REALM></value>
```

```
  <description>The service principal for the metastore thrift server.
The special string _HOST will be replaced automatically with the correct
hostname.</description>
</property>
```

3. Configure the following properties in `/opt/mapr/conf/env.sh` on each node where the Hive Metastore is installed:
   - Set MAPR_HIVE_LOGIN _OPTS to

     ```
     "-Dhadoop.login=hybrid"
     ```

   - Set MAPR_HIVE_SERVER_LOGIN_OPTS to

     ```
     "-Dhadoop.login=hybrid"
     ```

Configure Hive Metastore Clients to use Kerberos

When the Hive Metastore is configured to use Kerberos authentication, you must also configure Hive Metastore Clients to use Kerberos when authenticating with Hive Metastore.

About this task

Complete the following steps on each node where a Hive Metastore client is installed:

Procedure

1. Configure MAPR_HIVE_LOGIN _OPTS to `" -Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.
2. Configure the following property in `hive-site.xml`:

Property	Value
`hive.metastore.kerberos.principal`	The HiveMetastore principal. For example, mapr/<FQDN@REALM>.

```
<property>
  <name>hive.metastore.kerberos.principal</name>
  <value>mapr/<FQDN@REALM></value>
  <description>The service principal for the metastore thrift server.
The special string _HOST will be replaced automatically with the correct
hostname.</description>
</property>
```

What to do next

See Connecting to Hive on page 4269 for details on how to connect to HiveMetastore once the server and client node are configured to use Kerberos.

NOTE: The MAPR_HIVE_LOGIN_OPTS and MAPR_HIVE_SERVER_LOGIN_OPTS were added in 1504 release of Hive 0.13 and Hive 1.0. If you have Hive 0.13 from a prior release, you do not need to configure these properties. Instead, set MAPR_ECOSYSTEM_LOGIN_OPTS and MAPR_ECOSYSTEM_SERVER_LOGIN_OPTS to `"-Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.

Authentication for HiveServer2

last-updated: Jun 06, 2024

You can configure authentication for in-bound client connection to HiveServer2. Clients of HiveServer 2 include beeline and odbc/jdbc client applications.

Credentials are submitted from the HiveServer2 clients to HiveServer2 as plain text. To secure the credential transmission, MapR supports SSL encryption for HiveServer2. For information about how to configure encryption, see Hive Encryption.

HiveServer2 supports the following authentication methods:

Configure MapR-SASL Authentication for HiveServer 2

About this task

MapR-SASL is available starting with the 1504 release of Hive 0.13 and Hive 1.0. However, the configuration requirements for MapR-SASL differ based on the version of Hive that you have installed:

- As of Hive 0.13-1501, Hive 1.0-1510, and Hive 1.2-1510, MapR-SASL and PAM are enabled by default on a secure cluster; no configuration is required. Complete the steps below if you want HiveServer2 to only accept MapR-SASL authentication.
- In Hive 0.13-1508 and Hive 1.0-1508, MapR-SASL is not the default and must be configured.
- In Hive 0.13-1504 and Hive 1.0-1504, MapR-SASL is the default authentication method when the cluster is secure. No configuration is required.

Procedure

1. Configure the following property in hive-site.xml on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	MAPRSASL

```
<property> <name>hive.server2.authentication</name> <value>MAPRSASL</
value></property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of
    nodes>
```

Configure HiveServer2 to use LDAP Authentication

Procedure

1. Configure the following properties in the `hive-site.xml` file on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	LDAP
hive.server2.authentication.ldap.url	The access URL for your LDAP server
hive.server2.authentication.ldap.baseDN	The base LDAP DN for your LDAP server. For example, `ou=People,dc=mycompany,dc=com`.

last-updated: Jun 06, 2024

Property	Value
hive.server2.authentication.ldap.userDNPattern	User DN Pattern - A DN pattern that can be used to directly login users to the LDAP database. This pattern is used for creating a DN string for "direct" user authentication, where the pattern is relative to the base DN in `ldapUrl`.

```
<property>
  <name>hive.server2.authentication</name>
  <value>LDAP</value>
</property>
<property>
  <name>hive.server2.authentication.ldap.url</name>
  <value><LDAP URL></value>
</property>
<property>
  <name>hive.server2.authentication.ldap.baseDN</name>
  <value><LDAP Base DN></value>
</property>
```

For generic LDAP servers, you must use:

a. `hive.server2.authentication.ldap.baseDN`

b. `hive.server2.authentication.ldap.userDNPattern`

However, Active Directory (AD) does not require the above two options, they can be replaced by the following property:

- hive.server2.authentication.ldap.Domain

Property	Value
hive.server2.authentication.ldap.Domain	The active directory domain for your environment.

```
<property>
  <name>hive.server2.authentication.ldap.Domain</name>
  <value><AD Domain Name></value>
</property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer2 to use PAM Authentication

About this task

You can configure HiveServer2 to use Pluggable Access Modules (PAM). The configuration requirements for PAM differ based on the version of Hive that you have installed.

Hive Version	Default Configuration	Configuration Requirement

last-updated: Jun 06, 2024

Hive 2.3	1904	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1901	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1808	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
Hive 2.1	1904	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1901	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1808	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1803	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.

Configure HiveServer2 to explicitly use PAM Authentication

Procedure

1. In the `hive-site.xml` on each HiveServer2 node, set the `hive.server2.authentication` property to PAM:

```
<property>
  <name>hive.server2.authentication</name>
  <value>PAM</value>
</property>
```

2. Restart HiveServer2 to apply these changes:

```
maprcli node services -name hs2 -action restart -nodes <comma-separated
list of nodes>
```

Configure HiveServer 2 to use Custom Authentication

Procedure

1. Create a custom Authenticator class derived from the following interface:

```
public interface PasswdAuthenticationProvider {
  /**
   * The Authenticate method is called by the HiveServer2 authentication
layer
   * to authenticate users for their requests.
   * If a user is to be granted, return nothing/throw nothing.
   * When a user is to be disallowed, throw an appropriate {@link
AuthenticationException}.
   *
   * For an example implementation, see {@link
LdapAuthenticationProviderImpl}.
   *
   * @param user - The username received over the connection request
   * @param password - The password received over the connection request
   * @throws AuthenticationException - When a user is found to be
   * invalid by the implementation
   */
  void Authenticate(String user, String password) throws
AuthenticationException;
}
```

   The SampleAuthenticator.java on page 4189 code has an example implementation that has stored usernames and passwords.

2. Configure the following properties in the `hive-site.xml` file on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	CUSTOM
hive.server2.custom.authentication.class	The authentication class name. For example, hive.server2.custom.authentication.class

```
<property>
<name>hive.server2.authentication</name>
<value>CUSTOM</value>
</property>

<property>
<name>hive.server2.custom.authentication.class</name>
<value>hive.test.SampleAuthenticator</value>
</property>
```

3. Restart Hiveserver2 to apply the changes:

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

SampleAuthenticator.java

```
package hive.test;

import java.util.Hashtable;
import javax.security.sasl.AuthenticationException;
import org.apache.hive.service.auth.PasswdAuthenticationProvider;
```

last-updated: Jun 06, 2024

```
/*
 javac -cp $HIVE_HOME/lib/hive-service-0.11-mapr.jar
SampleAuthenticator.java -d .
 jar cf sampleauth.jar hive
 cp sampleauth.jar $HIVE_HOME/lib/.
*/

public class SampleAuthenticator implements PasswdAuthenticationProvider {

  Hashtable<String, String> store = null;

  public SampleAuthenticator () {
    store = new Hashtable<String, String>();
    store.put("user1", "passwd1");
    store.put("user2", "passwd2");
  }

  @Override
  public void Authenticate(String user, String  password)
      throws AuthenticationException {

    String storedPasswd = store.get(user);

    if (storedPasswd != null && storedPasswd.equals(password))
      return;

    throw new AuthenticationException("SampleAuthenticator: Error
validating user");
  }

}
```

Configure HiveServer 2 to use Kerberos

About this task

NOTE: You can configure HiveServer2 to use Kerberos authentication. MapR clusters do not provide Kerberos infrastructure. The tips in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

Enabling HiveServer to use Kerberos authentication requires following steps on each node where HiveServer 2 is installed:

Procedure

1. Create a Kerberos Identity and keytab. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file: The `hive.keytab` file must be owned and readable only by the `mapr` user.

   ```
   # kadmin
       : addprinc -randkey username/<FQDN@REALM>
       : ktadd -k /opt/mapr/conf/hive.keytab username/<FQDN@REALM>
   ```

2. Configure the following properties in hive-site.xml on each node where hiveserver2 is installed:

Property	Value
hive.server2.authentication	KERBEROS

last-updated: Jun 06, 2024

Property	Value
hive.server2.authentication.kerberos.principal	<HiveServer2 Principle. For example, mapr/FQDN@REALM>
hive.server2.authentication.kerberos.keytab	<The keytab file for the HiverServer2 principle. For example, /opt/mapr/conf/hive.keytab>

```
<property>
  <name>hive.server2.authentication</name>
  <value>KERBEROS</value>
  <description>authenticationtype</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.principal</name>
  <value>mapr/FQDN@REALM</value>
  <description>HiveServer2 principal. If _HOST is used as the FQDN
portion, it will be replaced with the actual hostname of the running
instance.</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.keytab</name>
  <value>/opt/mapr/conf/hive.keytab</value>
  <description>Keytab file for HiveServer2 principal</description>
</property>
```

3. Reconfigure the following options in `env.sh` (`/opt/mapr/conf/env.sh`) on each node where hiveserver2 is installed:

   NOTE: These configurations are listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the changes in the `/opt/mapr/conf/env_override.sh` file. For more information, see About env_override.sh on page 3077.

Existing Configuration	Required Configuration

`MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab" MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"`	`MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=hybrid"`
	
	`MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"`

4. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer 2 Clients to use Kerberos

About this task

When HiveServer 2 is configured to use Kerberos authentication, you must also configure HiveServer2 clients to use Kerberos.

On each node where HiveServer2 clients (not including Beeline) are installed, reconfigure the following option in `env.sh` (`/opt/mapr/conf/env.sh`) file:

last-updated: Jun 06, 2024

Existing Configuration	Required Configuration
`MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"`	`MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"`

NOTE: This configuration is listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the change in the `/opt/mapr/conf/env_override.sh` file. For more information, see About env_override.sh on page 3077.

On each node where Beeline is installed, reconfigure the following option in `beeline.sh` (`$hive_home/bin/ext/beeline.sh`) file:

Existing Configuration	Required Configuration
`HADOOP_OPTS="$HADOOP_OPTS${MAPR_HIVE_LOGIN_OPTS}"`	`HADOOP_OPTS="$HADOOP_OPTS${KERBEROS_LOGIN_OPTS}"`

For more information, see Connecting to Hive on page 4269.

NOTE: The MAPR_HIVE_LOGIN_OPTS and MAPR_HIVE_SERVER_LOGIN_OPTS were added in 1504 release of Hive 0.13 and Hive 1.0. If you have Hive 0.13 from a prior release, you do not need to configure these properties. Instead, set MAPR_ECOSYSTEM_LOGIN_OPTS and MAPR_ECOSYSTEM_SERVER_LOGIN_OPTS to `"-Dhadoop.login=hybrid"` in /opt/mapr/conf/env.sh.

Configure HiveServer2 Web UI to use PAM Authentication

About this task

You can configure HiveServer2 web UI to use Pluggable Access Modules (PAM) authentication. The following Hive properties are added to enable PAM authentication for the HiveServer2 web UI:

```
hive.server2.webui.use.pam
Default value: false
Description: If true, the HiveServer2 WebUI will be secured with PAM
```

```
hive.server2.webui.pam.authenticator
Default value: org.apache.hive.http.security.PamAuthenticator
Description: Class for PAM authentication
```

Modifying the hive-site.xml file:

Procedure

Configure the following properties in the hive-site.xml file to enable authentication on each node where HiveServer2 is installed:

```
<!-- HS2 web UI PAM -->
<property>
  <name>hive.server2.webui.use.pam</name>
  <value>true</value>
</property>

<!-- HS2 web UI SSL -->
<property>
  <name>hive.server2.webui.use.ssl</name>
```

last-updated: Jun 06, 2024

```
  <value>true</value>
</property>

<property>
  <name>hive.server2.webui.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
</property>

<property>
  <name>hive.server2.webui.keystore.password</name>
  <value><ssl-keystore-password></value>
</property>
```

NOTE: After running `/opt/mapr/server/configure.sh -R`, all properties needed for HiveServer2 Web UI to use PAM authentication is added automatically to hive-site.xml on the Mapr-SASL secure cluster. Connections to HiveServer2 using ODBC do not support MapR-SASL.

Authentication for WebHCat

You can configure authentication for in-bound client connections to WebHCat. Clients of WebHCat include web browsers. WebHCat is a client of Hive Metastore.

WebHCat supports the following authentication methods:

Configure Kerberos Authentication for WebHCat

About this task

When security features are enabled on your MapR cluster and Kerberos is in use, communications between WebHCat and its clients can use Kerberos with SPNEGO.

To enable WebHCat to use Kerberos, complete the following steps on the node where WebHCat is installed.

Procedure

1. Create the principal `HTTP/<FQDN@REALM>` for WebHCat and add the principal to the keytab file. For example:

   ```
   kadmin: addprinc -randkey HTTP/<FQDN@REALM>
   kadmin: xst -k /opt/mapr/HTTP.keytab HTTP/<FQDN>
   ```

2. Verify the following:
   - The principal was added to the `/opt/mapr/conf/HTTP.keytab` file and that the file is only readable by the `mapr` user. For example: chown mapr /opt/mapr/conf/HTTP.keytab
   - The node where the WebHCat server is running has an HTTP user with a valid `maprlogin` password.

last-updated: Jun 06, 2024

3. Add the following section to the `/opt/mapr/hive/hive-<version>/hcatalog/etc/webhcat/webhcat-site.xml` file:

```
<property>
    <name>templeton.kerberos.secret</name>
    <value>secret value</value>
</property>
<property>
    <name>templeton.kerberos.principal</name>
    <value>HTTP/<FQDN@REALM></value>
</property>
<property>
    <name>templeton.kerberos.keytab</name>
    <value>/opt/mapr/conf/HTTP.keytab</value>
</property>
```

4. Add the following section to the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file:

```
<property>
      <name>hadoop.proxyuser.HTTP.groups</name>
      <value>*</value>
      <description>Allow the superuser mapr to impersonate any member of
any group</description>
</property>
<property>
      <name>hadoop.proxyuser.HTTP.hosts</name>
      <value>*</value>
      <description>The superuser can connect from any host to
impersonate a user</description>
</property>
```

5. Start WebHCat. See Managing the WebHCat Server.

6. To test if the connection is working, generate a Kerberos ticket with the `kinit` utility and then run the following command:

```
curl --negotiate -i -u : 'http://<FQDN>:50111/templeton/v1/ddl/
database/'
```

Configure Simple Authentication for WebHCat
: When the MapR cluster is not secure, simple authentication is enabled for WebHCat. No configuration is required.

Configure PAM Authentication for WebHCat
: When the MapR cluster is secure, username and password authentication is enabled for WebHCat. No configuration is required.

Configuring Hive for SCRAM Token Authentication

This topic describes the manual and automatic options to configure Hive for SCRAM token authentication.

Starting from EEP 8.1.0, Hive supports SCRAM token and SCRAM-SHA-256 authentication in HPE Ezmeral Data Fabric.

Table

#	Property	Data Type	Default value	Description

Table (Continued)

1	hive.delegation.token.authentication	String	DIGEST	Delegation token authentication method. Possible values are DIGEST, SCRAM

To connect to HiveServer2 on EEP 8.1.0 from Hive client on EEP 8.0.x, set `hive.delegation.token.authentication` property in HPE Ezmeral Data Fabric.

Manually Configuring SCRAM Token Authentication

To configure SCRAM token and SCRAM-SHA-256 authentication, set the following property on `HIVE_HOME/conf/hive-site.xml` file:

```
<property>
    <name>hive.delegation.token.authentication</name>
    <value>SCRAM</value>
</property>
```

The default value for `hive.delegation.token.authentication` is DIGEST.

To use `hive.delegation.token.authentication` for Hive, configure Hadoop for SCRAM:

- Set the value of `hadoop.security.token.authentication.method` property to `SCRAM-SHA-256` in `yarn-site.xml` file.
- Set `scram.password` property and ensure encrypted password file is available in file system.

To learn more, see Hadoop documentation.

Auto Configuring SCRAM Token Authentication

Execute `MAPR_HOME/server/configure.sh -R` script on a newly installed Data-Fabric SASL or KERBEROS secured cluster to automatically configure the following authentications:

1. For a FIPS enabled cluster, Hive configures `hive.delegation.token.authentication=SCRAM` authentication.
2. For a non-FIPS cluster if you configure Hadoop with `hadoop.security.token.authentication.method=SCRAM` authentication, Hive configures the SCRAM authentication.
3. For other clusters, Hive configures `hive.delegation.token.authentication=DIGEST` authentication.

For non-secure clusters, Hive configures `hive.delegation.token.authentication=DIGEST` authentication.

You can see `hive.delegation.token.authentication` property in `HIVE_HOME/conf/hive-site.xml` when you execute `configure.sh` command on newly installed cluster.

When you upgrade Hive, the upgrade does not update the value of the set `hive.delegation.token.authentication` property.

Manually set the value of `hive.delegation.token.authentication` property when you change the cluster settings from FIPS to non-FIPS or from non-FIPS to FIPS.

Hive Encryption
When you configure encryption, the thrift messages sent between the Hive Metastore, HiveServer 2, and HiveServer2 clients are encrypted.

When you configure encryption, the thrift messages sent between the Hive Metastore, HiveServer 2, and HiveServer2 clients are encrypted.

Encryption is supported when HiveServer2 has no authentication or when it is configured to use MapR-SASL or Kerberos authentication.

This section contains the following topics:

Configure Encryption with MapR-SASL or Kerberos Authentication

About this task
Complete the following steps on each node where HiveServer2 is installed:

Procedure

1. In `hive-site.xml` file, set the following property:

Property	Value
`hive.server2.thrift.sasl.qop`	`auth-conf`

NOTE: As of Hive 0.13-1504 and Hive 1.0-1504, `hive.server2.thrift.sasl.qop` is set to `auth-conf` by default on secure clusters.

```
<property>
  <name>hive.server2.thrift.sasl.qop</name>
  <value>auth-conf</value>
  <description>Sasl QOP value; one of 'auth', 'auth-int' and
'auth-conf'</description>
</property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure Encryption without Authentication

About this task
Complete the following steps on each node where HiveServer2 is installed:

Procedure

1. In `hive-site.xml` file, set the following properties:

Property	Value
`hive.server2.use.SSL`	`true`
`hive.server2.ssl.keystore`	<path to keystore file>
`hive.server2.ssl.keystore.password`	<password>

WARNING: If you specify the password in the `hive-site.xml` file, protect the file with the appropriate file permissions. HiveServer2 automatically prompts for the keystore password during startup when no password is stored in the `hive-site.xml` file.

```
<property>
  <name>hive.server2.use.ssl</name>
  <value>true</value>
  <description>enable/disable SSL communication</description>
</property>
<property>
  <name>hive.server2.ssl.keystore</name>
  <value><path-to-keystore-file></value>
  <description>path to keystore file</description>
</property>

<property>
  <name>hive.server2.ssl.keystore.password</name>
  <value><password></value>
  <description>keystore password</description>
</property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer2 Clients to use Encryption

Based on the encryption method, the requirements for clients to connect to HiveServer2 differ.

- When HiveServer2 uses encryption with MapR-SASL or Kerberos authentication, the client must specify the same sasl qop value that is set for HiveServer2 (auth-conf is the default, recommended option).
- When HiveServer2 uses SSL encryption without authentication, the client must specify a truststore. The `ssl_truststore` file must be copied from the cluster to the client. Specifying a truststore password is optional.

For details, see Connecting to Hive on page 4269.

Configure the TLS (SSL) Protocol Version in Hive

Beginning with EEPs 6.3.1 and 7.0.0, the default protocol version for TLS (SSL) is `TLSv1.2`, but you can use the `hive.ssl.protocol.version` property to set a custom value for TLS (SSL).

Setting the TLS (SSL) Protocol Version

To enable the direct configuration of the TLS (SSL) version, Hive provides the following property:

Property	Type	Default Value	Description
`hive.ssl.protocol.version`	`String`	`TLSv1.2`	SSL protocol versions for all Hive servers.

To set a custom value for the TLS (SSL) protocol version in Hive:

1. Add the following to the `hive-site.xml` file:

```
<property>
<name>hive.ssl.protocol.version</name>
```

last-updated: Jun 06, 2024

```
<value><custom_value></value>
</property>
```

In this example, `<custom_value>` can be one of the following:

- `SSLv2`
- `SSLv3`
- `SSLv2Hello`
- `TLSv1`
- `TLSv1.1`
- `TLSv1.2`

For more information, see the following table:

#	Algorithm Name (TLS/SSL Version)	Description
1	`Default`	Use the default algorithm.
2	`SSL`	Supports some versions of SSL; may support other versions.
3	`SSLv2`	Supports SSL version 2 or later; may support other versions.
4	`SSLv3`	Supports SSL version 3; may support other versions.
5	`TLS`	Supports some versions of TLS; may support other versions.
6	`TLSv1`	Supports RFC 2246: TLS version 1.0; may support other versions.
7	`TLSv1.1`	Supports RFC 4346: TLS version 1.1; may support other versions.
8	`TLSv1.2`	Supports RFC 5246: TLS version 1.2; may support other versions.

2. Restart all Hive services.

Special Considerations for Protocol Versions

Note these special considerations for the protocol versions:

- When `hive.ssl.protocol.version` is set to `TLSv1.2`, the protocol supports TLS 1.2. When `hive.ssl.protocol.version` is set to `TLSv1`, the protocol supports TLS versions up to TLS 1.0 (but not TLS 1.1 and 1.2). When `hive.ssl.protocol.version` is set to `TLSv1.1`, the protocol supports versions up to TLS 1.1 (but not TLS 1.2).
- `SSLv2Hello` is not a real encryption protocol. It merely enables clients to find out which encryption protocols are supported by the server to which they connect. As long as `SSLv2Hello` is used only by clients and servers to negotiate a safe protocol, such as `TLSv1.1` or `TLSv1.2`, it does not pose a security risk.

- Hive has a property called `hive.ssl.protocol.blacklist` with a default value of `SSLv2,SSLv3,SSLv2Hello,TLSv1,TLSv1.1`. If you want to enable `TLSv1.1`, for example, you must remove it from the blacklist above. For example:

```
<property>
<name>hive.ssl.protocol.blacklist</name>
<value>SSLv2,SSLv3,SSLv2Hello,TLSv1</value>
</property>

<property>
<name>hive.ssl.protocol.version</name>
<value>TLSv1.1</value>
</property>
```

- If you use the TLS (SSL) protocol version from the blacklist, you will get the following exception when connecting to Hiveserver2 via JDBC:

```
Unknown HS2 problem when communicating with Thrift server.
Error: Could not open client transport with JDBC
Uri: jdbc:hive2://<hostname>:10000/default;auth=maprsasl;ssl=true:
javax.net.ssl.SSLHandshakeException: Received fatal alert:
handshake_failure (state=08S01,code=0)
```

- Empty values are allowed for `hive.ssl.protocol.version`. Hive uses the default value in that case. The same is true for `hive.ssl.protocol.blacklist`.

- The `hive.ssl.protocol.version` property is out of scope for a secure-by-default configuration. This means that it will not appear in the `hive-site.xml` after you use the Hive `configure.sh` script. Nevertheless, the default value of `hive.ssl.protocol.version` is still `TLSv1.2`, and you do not need to set it explicitly.

Hive Password Encryption
EEP 4.0 introduces default configuration for Hive Metastore password encryption using the Data Fabric Installer. The password is stored in the `hive-site.xml` file.

EEP 4.0 introduces default configuration for Hive Metastore password encryption using the Data Fabric Installer. The password is stored in the `hive-site.xml` file.

NOTE: For Hive-2.1 (EEP-5.0.0 and later) and Hive-2.3 (EEP-6.0.0 and later) installed using the Data Fabric Installer, `javax.jdo.option.ConnectionPassword` is automatically encrypted.

```
<property>
  <name>javax.jdo.option.ConnectionPassword<name>
  <value>{password}<value>
<property>
```

The `hadoop.security.credential.provider.path` configuration property replaces the `javax.jdo.option.ConnectionPassword` property in the `hive-site.xml` file that contains the path to the keystore file created by the Hadoop Crediential Provider. Credential providers store and protect passwords out of clear text for the underlying database. By default, the Data Fabric Installer creates the keystore file in the Data Fabric file system. `/user/${MAPR_USER}/hivemetastore.jceks`.

NOTE: Starting from Hive-2.3 EEP 6.0.0, SSL keystore passwords, `hive.server2.webui.keystore.password`, `hive.server2.keystore.password`, and `templeton.keystore.password`, are automatically read from the `/opt/mapr/conf/ssl-client.xml` file without any additional steps from your side. But you can still encrypt them manually and store them in the `*jceks` files.

Reset Data Fabric Installer Default Configuration

To remove changes made by the Data Fabric Installer and reset Hive to its default setting:

1. Open the `hive-site.xml` file.
2. Delete the `hadoop.security.credential.provider.path` property.
3. Add the `javax.jdo.option.ConnectionPassword` property.
4. Save and close the `hive-site.xml` file.

Manual Password Encryption

NOTE: For any user to use Hive, the keystore file requires read permission (644). To limit keystore file access to a smaller number of Hive users, modify permissions as necessary.

ATTENTION: When you wish to run the `hadoop credential` command for provisioning a password or secret to a particular credential store provider, use the `-provider` command line option to explicitly indicate which provider store to use. If a path of multiple providers is given, the first non-transient provider will be used. Note that this provider may or may not be the one that you intended to use.

To encrypt a password manually:

1. Create the keystore file using the Hadoop Credential Provider as follows:

   ```
   hadoop credential create javax.jdo.option.ConnectionPassword -provider
   <path-to-keystore>
   ```

   Where `<path-to-keystore>` is `jceks://<file-system-name>/<path-to-keystore>`.

   For example, `jceks://maprfs/user/mapr/hivemetastore.jceks`

   NOTE: On running the command, you are prompted to enter and re-enter the password to encrypt. Once you provide the password and confirm the password, the `javax.jdo.option.ConnectionPassword` is created and the `org.apache.hadoop.security.alias.JavaKeyStoreProvider` is updated.

2. Delete the `javax.jdo.option.ConnectionPassword` property in the `hive-site.xml` file:

   ```
   <property>
     <name>javax.jdo.option.ConnectionPassword</name>
     <value>{yourpassword}</value>
   </property>
   ```

3. Add the `hadoop.security.credential.provider.path` property to the `/opt/mapr/hive/<hive-release-version>/conf/hive-site.xml` file:

   ```
   <property>
     <name>hadoop.security.credential.provider.path</name>
     <value>jceks://maprfs/user/mapr/hivemetastore.jceks</value>
     <description>specify password to use against metastore database here</
   description>
   </property>
   ```

4. Restart the Hive services to update the configuration:

```
maprcli node services -name hivemeta -action restart -nodes `hostname -f`
maprcli node services -name hs2 -action restart -nodes `hostname -f`
maprcli node services -name hcat -action restart -nodes `hostname -f`
```

Encrypt the Oozie Database Password

Follow the steps given below to encrypt the Oozie database password:

1. Configure Oozie to use a MySQL database as described in Configure a MySQL Data Store for Oozie.
2. Optionally, export the Hadoop credential store password as a system variable:`$ export HADOOP_CREDSTORE_PASSWORD=password`.
3. Add `oozie.service.jpaservice.jdbc.password` to the `jceks` keystore:

```
$ hadoop credential create
oozie.service.jpaservice.jdbc.password -provider jceks://path/to/
oozie.jceks
Enter the password:
Enter the password again:
oozie.service.jpaservice.jdbc.password has been successfully created.
org.apache.hadoop.security.alias.JavaKeyStoreProvider has been updated.
```

4. Verify that the MySQL password was added:

```
Keystore type: JCEKS
Keystore provider: SunJCE

Your keystore contains 1 entry

Alias name: oozie.service.jpaservice.jdbc.password
Creation date: Apr 11, 2018
Entry type: SecretKeyEntry
```

5. Once the `jceks` file is created, add the `hadoop.security.credential.provider.path` property to the `oozie-site.xml` file with the path to the `jceks` file. The `jceks` path location can be `maprfs` or a local file (`local-fs`).

```
<property>
   <name>hadoop.security.credential.provider.path</name>
   <value>jceks://path/to/oozie.jceks</value>
</property>
```

6. Update the `password` property to use `*****` instead of a word-readable password:

```
<property>
  <name>oozie.service.JPAService.jdbc.password</name>
  <value>*****</value>
</property>
```

Hive Authorization
MapR Data Platform has built-in platform authorization that protects all data regardless of the execution engine. This topic describes alternative authorization modes you can choose to implement.

For more information, refer to Authorization in Data Fabric on page 837.

In addition to the centralized authorization provided by the MapR Data Platform, you can use several authorization modes for Hive. The use cases and trade-offs for these authorization modes are described in the sections below.

Understanding Hive Authorization Use Cases

Table Storage Layer and SQL Query Engine are the two primary use cases for client-based authorization protection, delivered as part of the open source project.

Use Case 1: Table Storage Layer

This is the use case for Hive HCatalog API users.

In this case, Hive provides a table abstraction and metadata for files on storage (typically MapR filesystem). You have direct access to MapR filesystem and the metastore server (which provides an API for metadata access).

MapR filesystem access is authorized through the use of MapR filesystem permissions. You need to authorize metadata access using Hive configuration.

Use Case 2: SQL Query Engine

This is one of the most common use cases of Hive. This is the "Hive view" of SQL users and BI tools. This use case has the following two subcategories:

- Hive command line users - You have direct access to MapR filesystem and the Hive metastore, which makes this use case similar to use case 1.
- ODBC/JDBC and other HiveServer2 API users (Beeline CLI is an example) - You have all data or metadata access through HiveServer2. You do not have direct access to MapR filesystem or the metastore.

Understanding Hive Authorization Modes

Different modes of Hive authorization are available to satisfy different use cases.

Secure by Default Configuration (Storage Based Authorization in the Metastore Server)

Hive default security configuration is the storage based authorization in the Metastore server. Managed by mapr-tickets and impersonation level, Hive configurations control the data access and MapR filesystem permissions act as one source of truth for the table storage access. By enabling storage based authorization in the metastore server, you can use this single source for truth and have a consistent data and metadata authorization policy.

For use cases where the users have direct access to the data, Hive configurations do not control the data access. The MapR filesystem permissions act as the one source of truth for table storage access. To control metadata access on the metadata objects such as databases, tables, and partitions, MapR filesystem checks if you have permission to access the corresponding directories on the filesystem.

You can also protect access through HiveServer2 (use case 2.2) by ensuring that the queries run as the end user. The `hive.server2.enable.doAs` option should be `true` in the HiveServer2 configuration, this is a default value.

For more information, see Hive Security Configuration Options on page 4174.

SQL Standards Based Authorization in HiveServer2

Although storage based authorization provides access control at the level of databases, tables, and partitions, it can only control authorization at finer levels such as columns and views for MapR Database tables and not for files because the access control provided by the filesystem is at the level of directory and files. SQL standards authorization makes authorization possible for files BUT at the expense of not being able to enforce that access from any other tool.

For enabling SQL standards based authorization, refer to SQL Standards-Based Hive Authorization on page 4203.

Legacy Hive Authorization

Old default authorization is the authorization mode that has been available in earlier versions of Hive. However, this mode does not have a complete access control model, leaving many security gaps unaddressed.

For example, the permissions needed to grant privileges for a user are not defined, and any user can grant themselves access to a table or database.

This model is similar to the SQL standards based authorization mode, in that it provides grant or revoke statement-based access control. However, the access control policy is different from SQL standards based authorization, and they are not compatible. Use of this mode is also supported for Hive command line users. However, for reasons mentioned under the discussion of SQL standards based authorization, it is not a secure mode of authorization for the Hive command line.

Related Links

For information related to Hive authorization modes, see:

- Storage Based Authorization in the Metastore Server
- HCatalog Authorization
- SQL Standard Based Hive Authorization
- Hive deprecated authorization mode / Legacy Mode
- Hive security design document
- Hive security document

SQL Standards-Based Hive Authorization

Using EEP 6.0.0 and later, you can configure SQL standards-based authorization to enable fine grained access control with SQL commands.

The SQL standards-based authorization mode can be used in conjunction with storage-based authorization on the Metastore server. Like the current default authorization in Hive, SQL standards-based authorization is also enforced at query compilation time. To provide security through this option, the client must be secured. You can do this by allowing users access only through HiveServer2, and by restricting the user code and non-SQL commands that can be run. The checks will happen against the user who submits the request, but the query will run as the Hive server user. The directories and files for input data would have read access for this Hive server user. For users who do not need to protect against malicious users, this could potentially be supported through the Hive command line as well.

1. Add the following properties to `hive-site.xml`:

```
<!-- SQL standard based authorization -->
<property>
  <name>hive.server2.enable.doAs</name>
  <value>false</value>
</property>
<property>
  <name>hive.users.in.admin.role</name>
  <value>mapr</value>
</property>
<property>
  <name>hive.security.metastore.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.MetaStoreAuthzAPI
AuthorizerEmbedOnly</value>
</property>
<property>
  <name>hive.security.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQL
StdConfOnlyAuthorizerFactory</value>
</property>
```

2. Create a `hiveserver2-site.xml` configuration file:

```
touch /opt/mapr/hive/hive-<version>/conf/hiveserver2-site.xml
```

   Add the following properties to the `hiveserver2-site.xml` file:

```
<configuration>
<property>
  <name>hive.security.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQL
StdHiveAuthorizerFactory</value>
</property>
<property>
  <name>hive.security.authorization.enabled</name>
  <value>true</value>
</property>
<property>
  <name>hive.security.authenticator.manager</name>

<value>org.apache.hadoop.hive.ql.security.SessionStateUserAuthenticator</
value>
</property>
<property>
  <name>hive.metastore.uris</name>
  <value></value>
</property>
</configuration>
```

3. Change the owner of the `hiveserver2-site.xml` file to `mapr`, and restart Hive services:

```
chown mapr:mapr /opt/mapr/hive/hive-<version>/conf/hiveserver2-site.xml

maprcli node services -name hs2 -action restart -nodes `hostname -f`
maprcli node services -name hivemeta -action restart -nodes `hostname -f`
```

last-updated: Jun 06, 2024

If you are a database administrator and want to run commands such as `create role` and `drop role` or access objects without being given explicit access, you must run the `set role` command.

1. Create a test role:

```
hive> set role admin;
OK
Time taken: 0.02 seconds

hive> create role example_role;
OK
Time taken: 0.099 seconds

hive> show roles;
OK
admin
public
role1
example_role
Time taken: 0.02 seconds, Fetched: 3 row(s)
```

2. Grant access:

```
hive> GRANT example_role to USER testuser;
OK
Time taken: 0.058 seconds

hive> GRANT SELECT  on table eg_test to role example_role;
OK
Time taken: 0.146 seconds
```

3. Using the test role, check access:

```
sudo -u mapruser1 hive
```

   If there is an access violation, correct it. The following is an example of an access violation error:

```
hive> insert into table eg_test values (4), (5), (6);
FAILED: RuntimeException Cannot create staging directory
'maprfs:///user/hive/warehouse/
eg_test/.hive-staging_hive_2018-06-08_10-24-11_566_5325052587659005252-1'
:
User mapruser1(user id 5001) has been denied access to
create .hive-staging_hive_2018-06-08_10-24-11_566_5325052587659005252-1
```

   You can apply access restrictions to all actions except for READ access.

   The following are examples of permitted access operations:

   - Select:

```
hive> select count (*) from eg_test;
OK
3
Time taken: 2.491 seconds, Fetched: 1 row(s)
```

- Describe:

```
hive> describe extended eg_test;
OK
id                      int

Detailed Table Information
Table(tableName:eg_test, dbName:default, owner:mapr,
createTime:1528453013, lastAccessTime:0, retention:0,
sd:StorageDescriptor(cols:[FieldSchema(name:id, type:int,
comment:null)],
location:maprfs:/user/hive/warehouse/eg_test,
inputFormat:org.apache.hadoop.mapred.TextInputFormat,
outputFormat:org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat
,
compressed:false, numBuckets:-1, serdeInfo:SerDeInfo(name:null,
serializationLib:org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe,
parameters:{serialization.format=1}), bucketCols:[], sortCols:[],

viewExpandedText:null, tableType:MANAGED_TABLE, rewriteEnabled:false)
Time taken: 0.12 seconds, Fetched: 3 row(s)
```

- Show columns:

```
hive> SHOW COLUMNS from eg_test;
OK
id
Time taken: 0.049 seconds, Fetched: 1 row(s)
```

NOTE: For more information about privileges required for Hive operations, see the open source documentation.

Configure Hive Metastore to use Storage-Based Authorization

Describes how to enable storage-based authorization (SBA) for the Hive Metastore server.

Storage-based authorization controls access to the data using HDFS permissions (HDFS ACL). To control access to metadata objects, such as databases, tables, and partitions, it checks if you have permission on the corresponding directories on the file system.

To enable storage-based authorization for the Hive Metastore server, set these properties in `hive-site.xml`:

Property	Value	Description
`hive.metastore.pre.event.listeners`	`org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEventListener*`	Turns on Metastore security. A MetaStorePreEventListener that performs authorization or authentication checks on the metastore side. Note that this can only perform authorizaiton checks on defined metastore PreEventContexts, such as the adding, dropping, and altering of databases, tables, and partitions.

Property	Value	Description
`hive.security.metastore.authorization.manager`	`org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthorizationProvider*` Note: • The `StorageBasedAuthorizationProvider` setting first appeared on the Metastore side only in Hive 0.10.0. With Hive 0.12.0 and later, it can also run on the client side. • Starting from EEP 6.1.0, `hive.security.metastore.authorization.manager` is set to the `StorageBasedAuthorizationProvider` value by default.	`StorageBasedAuthorizationProvider` - Specifies use of an HDFS permission-based model (recommended) for the Metastore-side authorization provider. `DefaultHiveMetastoreAuthorizationProvider` - This default implements the standard Hive grant/revoke model.
`hive.security.metastore.authenticator.manager`	`org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticator` (default)	Authentication manager class name to be used in the metastore for authentication. The user-defined authenticator should implement the `org.apache.hadoop.hive.ql.security.HiveAuthenticationProvider` interface.
`hive.security.metastore.authorization.auth.reads`	true (default)	Default value (does not appear in `hive-site.xml` file). Set to `true`, Metastore authorization also performs a read authorization check (first supported in Hive 0.14.0).
`hive.server2.enable.doAs`	`true` (default)	Use for protected access through HiveServer2.

* In secure clusters, the Data Fabric "secure-by-default" configuration implicitly configures these properties in the `hive-site.xml` file.

SBA configuration example in hive-site.xml File

```
<property>
    <name>hive.security.metastore.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthoriz
ationProvider</value>
 </property>

<property>
    <name>hive.security.metastore.authenticator.manager</name>

<value>org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticato
r
    </value>
</property>

<property>
    <name>hive.security.metastore.authorization.auth.reads</name>
    <value>true</value>
</property>

<property>
```

last-updated: Jun 06, 2024

```
    <name>hive.server2.enable.doAs</name>
    <value>true</value>
</property>

<property>
    <name>hive.metastore.pre.event.listeners</name>

<value>org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEven
tListener</value>
</property>
```

If you use storage-based authorization, you still need to use one of the following authorization models to protect actions within the HiveServer2:

- Configuring Fallback Hive Authorizer on page 4208
- SQL Standards-Based Hive Authorization on page 4203

Fallback Hive Authorizer
Fallback Hive Authorizer is used by Hive DDL (Data Definition Language) tasks for access control and for checking authorization from `Driver.doAuthorization()`.

It is designed to prevent CVE-2018-11777.

In addition to the centralized authorization provided by the MapR Data Platform, you can use several authorization modes for Hive. The use cases and trade-offs for these authorization modes are described in the sections below.

Configuring Fallback Hive Authorizer

You can enable protection of actions within the HiveServer2 instance by using the Fallback Authorizer.

About this task
Use the Fallback Authorizer when you want to protect access for Hive clients (JDBC/ODBC, Beeline CLI, and other HiveServer2 API users).

To enable Fallback Authorization for Hive clients, set these properties in the `hive-site.xml` file:

Property	Value	Description
`hive.security.authorization.enabled`	`true*`	Enable or disable the Hive client authorization.
`hive.security.authorization.manager`	`org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.FallbackHiveAuthorizerFactory*`	Class name for the Hive client authorization manager.
`hive.users.in.admin.role`	`mapr*`	Comma-separated list of users who need to be added to the `admin` role. Note that a user who belongs to the `admin` role needs to run the `set role` command before getting the privileges of the `admin` role, as the `admin` role is not in `current roles` by default.

* In secure clusters, the MapR "Secure-by-Default" configuration implicitly configures the Fallback Authorizer in the `hive-site.xml` file.

Fall Back Authorizer applies the following restrictions:

- Allows `set` only for selected allowlist parameters.
- Disallows dfs commands except for `admin`.

last-updated: Jun 06, 2024

- Disallows local file location in SQL statements except for `admin`.
- Disallows `ADD JAR`, `COMPILE`, and `TRANSFORM` statements.

Fallback Authorization Configuration Example in hive-site.xml File

```
<property>
    <name>hive.security.authorization.enabled</name>
    <value>true</value>
</property>

<property>
    <name>hive.security.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.Fall
backHiveAuthorizerFactory</value>
</property>

<property>
    <name>hive.users.in.admin.role</name>
    <value>mapr</value>
 </property>
```

Action Restrictions with Fallback Hive Authorizer

After enabling Fallback Hive Authorizer, you can perform action restriction operations.

Procedure

- Disallow local file location in SQL statements for all except the administrator.
- Allow `set` for selected white list parameters.
- Disallow `dfs` commands for all except the administrator.
- Disallow `ADD JAR` statements for all except the administrator.
- Disallow `COMPILE` statements for all except the administrator.
- Disallow `TRANSFORM` statements.

Using a White List with Fallback Hive Authorizer

You can add an exception to Fallback Hive Authorizer restrictions using the `hive.security.authorization.sqlstd.confwhitelist.append` property.

About this task

The `hive.security.authorization.sqlstd.confwhitelist` property is list of comma-separated Java regexes that you can append to. Appending to this list instead of updating the original list means that you can append to the default set by SQL-standard authorization instead of replacing it entirely.

You can modify the configurations parameters that match these regexes when SQL-standard authorization is enabled.

To get the default value, use the `set <param>` command. The `hive.conf.restricted.list` checks are still enforced after the white-list check.

An example of a white-list configuration is as follows:

```
<property>
  <name>hive.security.authorization.sqlstd.confwhitelist.append</name>
```

```
  <value>hive.reloadable.aux.jars.path</value>
</property>
```

Procedure

- After adding this configuration to the `hive-site.xml` file, execute the following command:

```
set hive.reloadable.aux.jars.path=/path/to/jar
```

Considerations for Hive on JDK 17

Considerations for Hive on JDK 17

When configured correctly, Hive works on JDK 17, but it is still possible to encounter an error such as:

```
Caused by: java.lang.reflect.InaccessibleObjectException: <detailed
description>: module java.base does not "opens <module name>" to unnamed
module
```

Here is an example of the error:

```
Caused by: java.lang.reflect.InaccessibleObjectException: Unable to make
field private final int java.time.LocalDate.year accessible: module
java.base does not "opens java.time" to unnamed module
```

To fix the issue, you must add the following fix:

```
--add-opens java.base/<module name>=ALL-UNNAMED
```

For example:

```
--add-opens java.base/java.time=ALL-UNNAMED
```

You must add the fix in two places:

- `HADOOP_OPTS` variable in the `hive-env.sh` conf file
- `mapreduce.map.java.opts, mapreduce.reduce.java.opts, yarn.app.mapreduce.am.command-opts` properties of the `hive-site.xml conf` file

Here is an example of making the fix:

1. Add the following entry to the `hive-env.sh` file:

```
export HADOOP_OPTS="-XX:+IgnoreUnrecognizedVMOptions --add-opens
java.base/java.time=ALL-UNNAMED"
```

2. Add the following properties to the `hive-site.xml` file:

```
<property>
    <name>mapreduce.map.java.opts</name>
    <value>-Xmx900m --add-opens
java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC --add-opens
java.base/java.net=ALL-UNNAMED --add-opens
java.base/java.nio=ALL-UNNAMED --add-opens java.base/
java.util=ALL-UNNAMED --add-opens java.base/
java.util.concurrent.atomic=ALL-UNNAMED --add-opens java.base/
java.util.regex=ALL-UNNAMED --add-opens java.base/java.time=ALL-UNNAMED</
value>
</property>
<property>
    <name>mapreduce.reduce.java.opts</name>
    <value>-Xmx2560m --add-opens
java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC --add-opens
java.base/java.net=ALL-UNNAMED --add-opens
java.base/java.nio=ALL-UNNAMED --add-opens java.base/
java.util=ALL-UNNAMED --add-opens java.base/
java.util.concurrent.atomic=ALL-UNNAMED --add-opens java.base/
java.util.regex=ALL-UNNAMED --add-opens java.base/java.time=ALL-UNNAMED</
value>
</property>
<property>
    <name>yarn.app.mapreduce.am.command-opts</name>
    <value>-Xmx2560m --add-opens
java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC --add-opens
java.base/java.net=ALL-UNNAMED --add-opens
java.base/java.nio=ALL-UNNAMED --add-opens java.base/
java.util=ALL-UNNAMED --add-opens java.base/
java.util.concurrent.atomic=ALL-UNNAMED --add-opens java.base/
java.util.regex=ALL-UNNAMED --add-opens java.base/java.time=ALL-UNNAMED</
value>
</property>
```

Integrating Hive

Hive and HPE Ezmeral Data Fabric Database Integration

You can create HPE Ezmeral Data Fabric Database binary tables from Hive that can be accessed by both Hive and HPE Ezmeral Data Fabric Database. You can run Hive queries on HPE Ezmeral Data Fabric Database binary tables, convert existing HPE Ezmeral Data Fabric Database binary tables into Hive-HPE Ezmeral Data Fabric Database tables, and run Hive queries on those tables as well.

Install and Configure Hive

Procedure

1. Install and configure Hive if it is not already installed. See Installing Hive on page 248 for details.

2. Execute the `jps` command and ensure that all relevant Hadoop, MapR, and Zookeeper processes are running. Example:

```
$ jps
1549 jenkins.war
15051 QuorumPeerMain
30935 Jps
15551 CommandServer
15293 ResourceManager
15328 NodeManager
15131 WardenMain
```

3. Open the `hive-site.xml` file with your favorite editor, or create a `hive-site.xml` file if it doesn't already exist:

```
$ cd $HIVE_HOME
$ vi conf/hive-site.xml
```

4. Copy the following XML code and paste it into the `hive-site.xml` file.

   NOTE: If you already have an existing `hive-site.xml` file with a `configuration` element block, just copy the `property` element block code below and paste it inside the `configuration` element block in the `hive-site.xml` file. Be sure to use the correct values for the paths to your auxiliary JARs and ZooKeeper IP numbers.

   Example configuration:

```
configuration>

<property>
  <name>hive.aux.jars.path</name>
  <value>file:///opt/mapr/hive/hive-<version>/lib/
hive-hbase-handler-<version>-mapr.jar,
file:///opt/mapr/hbase/hbase-<version>/lib/
hbase-client-<version>-mapr.jar, file:///opt/mapr/hbase/
hbase-<version>/lib/hbase-server-<version>-mapr.jar,file:///opt/mapr/
hbase/hbase-<version>/lib/hbase-protocol-<version>-mapr.jar,file:///opt/
mapr/zookeeper/zookeeper-<version>/zookeeper-<version>.jar</value>
  <description>A comma separated list (with no spaces)
of the jar files required for Hive-HBase integration</description>
</property>

<property>
  <name>hbase.zookeeper.quorum</name>
  <value>xx.xx.x.xxx,xx.xx.x.xxx,xx.xx.x.xxx</value>
  <description>A comma separated list (with no spaces) of
the IP addresses of all ZooKeeper servers in the cluster.</description>
</property>

<property>
  <name>hbase.zookeeper.property.clientPort</name>
  <value>5181</value>
  <description>The Zookeeper
client port. The MapR default clientPort is 5181.</description>
</property>

</configuration>
```

5. Save and close the `hive-site.xml` file.

Results
If you have successfully completed all of the steps in this section, you're ready to begin the tutorial in the next section.
Getting Started with Hive and HPE Ezmeral Data Fabric Database Binary Integration

In this tutorial we will:

- Create a Hive table
- Populate the Hive table with data from a text file
- Query the Hive table
- Create a Hive-HPE Ezmeral Data Fabric Database table
- Introspect the Hive-HPE Ezmeral Data Fabric Database table from the HBase shell
- Populate the Hive-HPE Ezmeral Data Fabric Database table with data from the Hive table
- Query the Hive-HPE Ezmeral Data Fabric Database table from Hive
- Convert an existing HPE Ezmeral Data Fabric Database table into a Hive-MapR table

Be sure that you have successfully completed all of the steps in Installing Hive on page 248 and review the HPE Ezmeral Data Fabric Database topics before beginning this Getting Started tutorial.

This Getting Started tutorial is based on the Hive-HBase Integration section of the Apache Hive Wiki. However, please note that there are some significant differences.

Create a Hive table with two columns

Change to your Hive installation directory if you're not already there and start Hive:

```
$ cd $HIVE_HOME
$ bin/hive
```

Execute the CREATE TABLE command to create the Hive pokes table

```
hive> CREATE TABLE pokes (foo INT, bar STRING);
```

To see if the pokes table has been created successfully, execute the `SHOW TABLES` command

```
hive> SHOW TABLES;
OK
pokes
Time taken: 0.74 seconds
```

The `pokes` table appears in the list of tables. **Populate the Hive pokes table with data:**

The `kv1.txt` file is provided in the `$HIVE_HOME/examples/files` directory. Execute the LOAD DATA LOCAL INPATH command to populate the Hive `pokes` table with data from the `kv1.txt` file.

```
hive> LOAD DATA LOCAL INPATH './examples/files/kv1.txt' OVERWRITE INTO
TABLE pokes;
```

A message appears confirming that the table was created successfully, and the Hive prompt reappears:

```
Copying data from file:
...
OK
```

```
Time taken: 0.278 seconds
hive>
```

Execute a SELECT query on the Hive pokes table

```
hive> SELECT * FROM pokes WHERE foo = 98;
```

The SELECT statement executes, runs a MapReduce application, and prints the application output:

```
OK
98      val_98
98      val_98
Time taken: 18.059 seconds
```

The output of the SELECT command displays two identical rows because there are two identical rows in the Hive `pokes` table with a key of 98.

WARNING:

Hive tables can have multiple identical keys. As we will see shortly, HPE Ezmeral Data Fabric Database tables cannot have multiple identical keys, only unique keys.

Create a Hive-HPE Ezmeral Data Fabric Database table

Enter these four lines of code at the Hive prompt:

```
hive> CREATE TABLE mapr_table_1(key int, value string)
    > STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
    > WITH SERDEPROPERTIES ("hbase.columns.mapping" = ":key,cf1:val")
    > TBLPROPERTIES ("hbase.table.name" = "/user/mapr/xyz");
```

After a brief delay, a message appears confirming that the table was created successfully:

```
OK
Time taken: 5.195 seconds
```

Note: The TBLPROPERTIES command is not required, but those new to Hive-HPE Ezmeral Data Fabric Database integration may find it easier to understand what's going on if Hive and HPE Ezmeral Data Fabric Database use different names for the same table.

In this example, Hive will recognize this table as "mapr_table_1" and HPE Ezmeral Data Fabric Database will recognize this table as "xyz".

Start the HBase shell

Keeping the Hive terminal session open, start a new terminal session for HBase, then start the HBase shell:

```
$ cd $HBASE_HOME
$ bin/hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
Version 0.90.4, rUnknown, Wed Nov  9 17:35:00 PST 2011

hbase(main):001:0>
```

Execute the `list` command to see a list of HBase tables

```
hbase(main):001:0> list
TABLE
```

```
/user/mapr/xyz
1 row(s) in 0.8260 seconds
```

HBase recognizes the Hive-HPE Ezmeral Data Fabric Database table named `xyz` in directory `/user/mapr`. This is the same table known to Hive as `mapr_table_1`.

Display the description of the `/user/mapr/xyz` table in the HBase shell

```
hbase(main):004:0> describe "/user/mapr/xyz"
DESCRIPTION                                             ENABLED
 {NAME => '/user/mapr/xyz', FAMILIES => [{NAME => 'cf1', DATA_B true
 LOCK_ENCODING => 'NONE', BLOOMFILTER => 'NONE', REP
 LICATION_SCOPE => '0', VERSIONS => '3', MIN_VERSION
 S => '0', TTL => '2147483647', KEEP_DELETED_CELLS =
 > 'false', BLOCKSIZE => '65536', IN_MEMORY => 'fals
 e', ENCODE_ON_DISK => 'true', BLOCKCACHE => 'true'}
 ]}
1 row(s) in 0.0240 seconds
```

From the Hive prompt, insert data from the Hive table `pokes` into the Hive-HPE Ezmeral Data Fabric Database table `mapr_table_1`

```
hive> INSERT OVERWRITE TABLE mapr_table_1 SELECT * FROM pokes WHERE foo=98;
...
2 Rows loaded to mapr_table_1
OK
Time taken: 13.384 seconds
```

Query `mapr_table_1` to see the data we have inserted into the Hive-HPE Ezmeral Data Fabric Database table

```
hive> SELECT * FROM mapr_table_1;
OK
98      val_98
Time taken: 0.56 seconds
```

Even though we loaded two rows from the Hive `pokes` table that had the same key of 98, only one row was actually inserted into `mapr_table_1`. This is because `mapr_table_1` is a HPE Ezmeral Data Fabric Database table, and although Hive tables support duplicate keys, HPE Ezmeral Data Fabric Database tables only support unique keys. HPE Ezmeral Data Fabric Database tables arbitrarily retain only one key, and silently discard all of the data associated with duplicate keys.

Convert a pre-existing HPE Ezmeral Data Fabric Database table to a Hive-HPE Ezmeral Data Fabric Database table

To convert a pre-existing HPE Ezmeral Data Fabric Database table to a Hive-HPE Ezmeral Data Fabric Database table, enter the following four commands at the Hive prompt.

Note that in this example the existing HPE Ezmeral Data Fabric Database table is `my_mapr_table` in directory `/user/mapr`.

```
hive> CREATE EXTERNAL TABLE mapr_table_2(key int, value string)
    > STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
    > WITH SERDEPROPERTIES ("hbase.columns.mapping" = "cf1:val")
    > TBLPROPERTIES("hbase.table.name" = "/user/mapr/my_mapr_table");
```

Now we can run a Hive query against the pre-existing HPE Ezmeral Data Fabric Database table `/user/mapr/my_mapr_table` that Hive sees as `mapr_table_2`:

```
hive> SELECT * FROM mapr_table_2 WHERE key > 400 AND key < 410;
Total MapReduce jobs = 1
Launching Job 1 out of 1
Number of reduce tasks is set to 0 since there's no reduce operator
...
OK
401     val_401
402     val_402
403     val_403
404     val_404
406     val_406
407     val_407
409     val_409
Time taken: 9.452 seconds
```

Optimizing HPE Ezmeral Data Fabric Database Tables Search by ID

Starting from the 1904 release (EEP 6.0.2, EEP 6.1.1, and EEP 6.2.0), search by ID is supported with Hive HPE Ezmeral Data Fabric Database JSON tables.

About this task

Property of Optimization

Prerequisites

The property name is `hive.mapr.db.json.fetch.by.id.task.conversion` and the value has a boolean type and by default is set to `true`, which means it is enabled.

Procedure

- To disable optimization, set `hive.mapr.db.json.fetch.by.id.task.conversion` to `false`.

Conditions for Optimization

Procedure

- This optimizer is designed for queries such as:

```
SELECT *
FROM <mapr_db_json_table>
WHERE _id = <constant_string_value>;
```

or:

```
SELECT *
FROM <mapr_db_json_table>
WHERE _id = <constant_string_value> AND (<condition_1>) AND
(<condition_2>) ... AND (<condition_N>);
```

or:

```
SELECT *
FROM <mapr_db_json_table>
WHERE <Constant false operator>
```

last-updated: Jun 06, 2024

where `_id` is a key column of HPE Ezmeral Data Fabric Database JSON table. It provides usage of the `findById()` method of the HPE Ezmeral Data Fabric Database JSON table. The following functionality is not supported:

- joins
- group by
- distinct
- lateral view
- subquery
- create table as select (CTAS) or insert
- analyze
- single source

The predicate is not actually a part of the filter, so it is ignored by push down:

```
SELECT * FROM t WHERE (CASE WHEN _id = 'value_a' THEN 2 ELSE 4 END) > 3;
```

Using Optimization

Procedure

1. Consider the following HPE Ezmeral Data Fabric Database JSON table:

```
CREATE TABLE t(doc_id string, col1 string, col2 string)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/user/mapr/
db_json_table","maprdb.column.id" = "doc_id");
```

2. Run the `EXPLAIN` command:

```
EXPLAIN SELECT col1 FROM t WHERE doc_id='id_004';
```

last-updated: Jun 06, 2024

3. The following output is produced:

```
STAGE DEPENDENCIES:
 Stage-0 is a root stage

STAGE PLANS:
 Stage: Stage-0
  MapR DB JSON Fetch By Id Operator
  limit: -1
  Processor Tree:
  TableScan
  alias: t_small
  filterExpr: (doc_id = 'id_004') (type: boolean)
  Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
stats: NONE
  Filter Operator
   predicate: (doc_id = 'id_004') (type: boolean)
   Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
stats: NONE
   Select Operator
   expressions: col1 (type: string)
   outputColumnNames: _col0
   Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
stats: NONE
   ListSink
```

An important part of a query plan is that it shows if optimization is available for the query:

```
STAGE PLANS:
Stage: Stage-0
MapR DB JSON Fetch By Id Operator
```

Connecting Using Hive HPE Ezmeral Data Fabric Database JSON Connector

This section describes the Hive connector for HPE Ezmeral Data Fabric Database JSON table.

About this task

The Hive connector supports the creation of HPE Ezmeral Data Fabric Database based Hive tables. You can create a JSON table on HPE Ezmeral Data Fabric Database and load CSV data and/or JSON files to HPE Ezmeral Data Fabric Database using the connector. HPE Ezmeral Data Fabric Database based Hive tables can be:

- Queried just like file system based Hive tables.
- Combined with file system based Hive tables in joins and sub-queries.

NOTE: If you use Drill to query Hive tables based on MapR Database tables, you can enable the native Drill reader, which can improve query performance.

The following table lists the Hive data type and the corresponding (supported) HPE Ezmeral Data Fabric Database OJAI type:

Hive Type	HPE Ezmeral Data Fabric Database OJAI Type
BOOLEAN	BOOLEAN
BINARY	BINARY
TINYINT	BYTE
DATE	DATE

last-updated: Jun 06, 2024

Hive Type	HPE Ezmeral Data Fabric Database OJAI Type
DOUBLE	DOUBLE
FLOAT	FLOAT
INT	INT
BIGINT	LONG
SMALLINT	SHORT
STRING	STRING
TIMESTAMP	TIMESTAMP

The Hive connector for HPE Ezmeral Data Fabric Database JSON table also supports the use of the following complex data types:

- map
- array
- struct

NOTE: The HPE Ezmeral Data Fabric Database JSON tables do not support ACID transactions, bucketing, and alteration.

Creating a HPE Ezmeral Data Fabric Database JSON Table and Hive Table Using Hive

Procedure

- To create a table, run the command similar to the following:

  NOTE: The required properties are shown in bold.

```
CREATE TABLE primitive_types (
 id string,
 bo boolean,
 d double,
 da date,
 f double,
 i int,
 s string,
 ts timestamp)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/tbl","maprdb.column.id" = "id");
```

  Here:

  - The `maprdb.table.name`, `maprdb.column.id` and `STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'` are mandatory properties.
  - The value for `maprdb.column.id` column should be of type string or binary.

  To create a Hive table that exists on HPE Ezmeral Data Fabric Database, specify `EXTERNAL` in the table DDL. If the table created is EXTERNAL, when the table is dropped, only its metadata is deleted; the underlying HPE Ezmeral Data Fabric Database data remains intact. On the other hand, if the table is not EXTERNAL, dropping the table deletes both the metadata associated with the table and the underlying HPE Ezmeral Data Fabric Database data.

last-updated: Jun 06, 2024

For example, suppose a JSON table named `/apps/my_users` with the following values:

```
{"_id":"001","first_name":"John","last_name":"Doe","age":34}
{"_id":"002","first_name":"Jack","last_name":"Smith","age":26}
```

To create a Hive table over existing HPE Ezmeral Data Fabric Database JSON table:

```
CREATE EXTERNAL TABLE primitive_types (
 user_id string,
 first_name string,
 last_name string,
 age int)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/apps/my_users","maprdb.column.id" =
"user_id");
```

Now, because table `primitive_types` points to HPE Ezmeral Data Fabric Database table, you can perform ETL query similar to file system based Hive tables:

```
SELECT COUNT(*) FROM test_external;
SELECT MAX(age) AS label FROM test_external;
...
```

Loading CSV Data to HPE Ezmeral Data Fabric Database JSON Table

Procedure

1. Create intermediate table.
   For example:
   ```
   CREATE TABLE stage(id STRING, name STRING, age INT) ROW FORMAT DELIMITED
   FIELDS TERMINATED BY ',';
   ```
2. Load data to table.
   For example:
   ```
   LOAD DATA INPATH '/data' into table stage;
   ```
3. Create HPE Ezmeral Data Fabric Database table in Hive.
   For example:
   ```
   CREATE TABLE users(id STRING, name STRING, age INT)
   STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
   TBLPROPERTIES("maprdb.table.name" = "/users","maprdb.column.id" = "id");
   ```
4. Insert data through stage table.
   For example:
   ```
   INSERT INTO TABLE users select id, name, age from stage;
   ```

Loading JSON Files to HPE Ezmeral Data Fabric Database JSON Table

Procedure

1. Add SerDe JAR for JSON.
   For example:

   ```
   add jar /opt/mapr/hive/hive-<version>/hcatalog/share/hcatalog/
   hive-hcatalog-core-<version>-mapr.jar
   ```

2. Create intermediate table.
   For example:

   ```
   CREATE EXTERNAL TABLE stage(id string, name string, age int)
   ROW FORMAT SERDE 'org.apache.hive.hcatalog.data.JsonSerDe'
   STORED AS TEXTFILE;
   ```

3. Load data in stage table.
   For example:

   ```
   LOAD DATA INPATH '/data' into table stage;
   ```

   NOTE: If there is a key in the JSON file that starts with "_" (for example, "_id"), then treat the names as literals upon creating the schema and query using the same literal syntax. For example, specify `` `_id` string `` without any special serde properties. Then in the query, use `` select `_id` from sometable; ``. Alternatively, you can use 'org.openx.data.jsonserde.JsonSerDe' and add WITH SERDEPROPERTIES ("mapping.id" = "_id") to your table definition.

4. Create HPE Ezmeral Data Fabric Database table in Hive.
   For example:

   ```
   CREATE TABLE users(id STRING, name STRING, age INT)
   STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
   TBLPROPERTIES("maprdb.table.name" = "/users","maprdb.column.id" = "id");
   ```

5. Insert data through stage table.
   For example:

   ```
   INSERT INTO TABLE users select id, name, age from stage;
   ```

   If there is a key in your JSON file that starts with "_" (for example, "_id"), treat the names as literals upon creating the schema and also query using the same literal syntax. In the above example, it would look like `` `_id` string `` without any special serde properties for it. Then, use again in query as shown below:

   ```
   select `_id`  from sometable;
   ```

   Alternatively, use `org.openx.data.jsonserde.JsonSerDe` and add `WITH SERDEPROPERTIES ("mapping.id" = "_id" )` to your table definition.

Example

Refer to Hive MapR Database JSON Connector Tutorial for a connector example.

Understanding the UPDATE Statement

last-updated: Jun 06, 2024

Starting with EEP 6.0.0 (Hive 2.3), EEP 5.0.1 (Hive 2.1), EEP 4.1.2, and EEP 3.0.4, the UPDATE statement is supported with Hive HPE Ezmeral Data Fabric Database JSON tables.

You can use the UPDATE statement to update primitive, complex, and complex nested data types in HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

Updating Primitive Data Types

This section describes how to use the UPDATE statement to update primitive data types in HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

Procedure

1. Create a HPE Ezmeral Data Fabric Database JSON table and a Hive table:

```
CREATE TABLE simple_types_update (
>>>>>>> Incorporated edit comments
  doc_id string,
  bo boolean,
  d double,
  da date,
  f float,
  i int,
  s string,
  ts timestamp,
  ti tinyint,
  bi bigint,
  si smallint,
  bin binary)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/
simple_types_update","maprdb.column.id" = "doc_id");
```

2. Insert data into the table:

```
INSERT INTO TABLE simple_types_update VALUES ('1', true, 124.14,
'2017-11-29', 9192.12,
214566190, 'text', '2017-03-17 00:14:13', 125, 9223372036854775806,
23434, "binary string");
```

3. Run the UPDATE command on the table:

```
UPDATE simple_types_update
SET da = '2018-12-11',
bo = FALSE,
f = 91.777
WHERE doc_id = '1';
```

4. Verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables.
   - Verifying Hive table data:

```
hive> SELECT * FROM simple_types_update;

1    false    124.14    2018-12-11    91.777    214566190    text
2017-03-17 00:14:13    125    9223372036854775806    23434    binary
string
```

- Verifying HPE Ezmeral Data Fabric Database JSON table data:

```
find '/simple_types_update'

{"_id":"1","bi":{"$numberLong":9223372036854775806},"bin":
{"$binary":"YmluYXJ5IHN0cmluZwAAAAAAAA=="},
 "bo":false,"d":124.14,"da":{"$dateDay":"2018-12-11"},
 "f":{"$numberFloat":91.777},"i":{"$numberInt":214566190},
 "s":"text","si":{"$numberShort":23434},"ti":{"$numberByte":125},"ts":
{"$date":"2017-03-17T00:14:13.000Z"}}
```

Updating Complex Data Types

This section describes how to use the UPDATE statement to update complex data types in HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

Procedure

1. Create a HPE Ezmeral Data Fabric Database JSON table and a Hive table:

```
CREATE TABLE complex_types_update (
  doc_id string,
  info MAP<STRING, INT>,
  pets ARRAY<STRING>,
  user_info STRUCT<name:STRING, surname:STRING, age:INT, gender:STRING>)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/
complex_types_update","maprdb.column.id" = "doc_id");
```

2. Insert data into the table:

```
INSERT INTO TABLE complex_types_update SELECT '1', map('age', 28),
array('Cat', 'Cat', 'Cat'),
named_struct('name', 'Santa', 'surname', 'Claus','age', 1000,'gender',
'MALE');
```

3. Run the UPDATE command on the table:

```
UPDATE complex_types_update SET
info = map('year', 32),
pets = array('Dog', 'Cat', 'Pig'),
user_info = named_struct('name', 'Vasco', 'surname', 'da Gama','age',
558,'gender', 'MALE')
WHERE doc_id = '1';
```

4. Verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables.
   - Verifying Hive table data:

```
hive> SELECT * FROM complex_types_update;

1    {"year":32}    ["Dog","Cat","Pig"]
{"name":"Vasco","surname":"da Gama","age":558,"gender":"MALE"}
```

- Verifying HPE Ezmeral Data Fabric Database JSON table data:

```
find '/complex_types_update'

{"_id":"1","info":{"year":{"$numberInt":32}},"pets":
["Dog","Cat","Pig"],"user_info":{"age":{"$numberInt":558},
 "gender":"MALE","name":"Vasco","surname":"da Gama"}}
```

Updating Complex Nested Data Types

This section describes how to use the `UPDATE` statement to update complex nested data types in HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

Procedure

1. Create a HPE Ezmeral Data Fabric Database JSON table and a Hive table using Hive:

```
CREATE TABLE complex_nested_data_type_update
(
          entry STRING,
          num INT,
          postal_addresses MAP <STRING,
          struct
<USER_ID:STRING,ADDRESS:STRING,ZIP:STRING,COUNTRY:STRING>>
)
stored BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
tblproperties
(
           "maprdb.table.name" = "/complex_nested_data_type_update",
           "maprdb.column.id" = "entry"
);
```

2. Insert data into the table:

```
INSERT INTO TABLE complex_nested_data_type_update
SELECT '001', '1',
MAP ( 'Bill',
Named_struct ('user_id', '1', 'address', '3205 Woodlake ct', 'zip',
'45040', 'country', 'USA'));
```

3. Run the UPDATE command on the table by updating the `COUNTRY` value in `map(struct)`:

```
UPDATE complex_nested_data_type_update
SET postal_addresses = MAP ('Bill',
Named_struct ('user_id', '1', 'address', '3205 Woodlake ct', 'zip',
'45040', 'country', 'Hun'))
WHERE entry = '001';
```

4. Verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables.
   - Verifying Hive table data:

```
hive> SELECT * FROM complex_nested_data_type_update;

001    1    {"Bill":{"user_id":"1","address":"3205 Woodlake
ct","zip":"45040","country":"Hun"}}
```

- Verifying HPE Ezmeral Data Fabric Database JSON table data:

```
find '/complex_nested_data_type_update'
{"_id":"001","num":{"$numberInt":1},"postal_addresses":{"Bill":
{"address":"3205 Woodlake
ct","country":"Hun","user_id":"1","zip":"45040"}}}
```

UPDATE Statement Limitations

This section describes the features that the UPDATE statement does not support.

The UPDATE statement has the following known limitations:

- The UPDATE statement is fully supported only for primitive data types (see Connecting to HPE Ezmeral Data Fabric Database).
- The UPDATE statement is partly supported for complex data types; you can replace only the whole value of a complex type with new a value.
- You cannot update the `maprdb.column.id` value.

Understanding the INSERT INTO Statement

This section describes how to use the `INSERT INTO` statement to insert or overwrite rows in nested HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

- Single-row insert on page 4225
- Multiple-row insert on page 4227
- Overwriting data on page 4230

NOTE: The output shown in these examples is for illustration only; actual Hive CLI output varies, depending on your specific situation.

Single-row insert

You can use the `INSERT INTO` statement to insert a single table row into a nested HPE Ezmeral Data Fabric Database table using one of two methods.

For example, imagine that you have the following Hive HPE Ezmeral Data Fabric Database JSON table, `nested_data_insert`:

```
 CREATE TABLE nested_data_insert
 (
    entry STRING,
    num INT,
    postal_addresses MAP <STRING,
    struct <USER_ID:STRING,ADDRESS:STRING,ZIP:STRING,COUNTRY:STRING>>
 )
 stored BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
tblproperties
 (
    "maprdb.table.name" = "/nested_data_insert",
    "maprdb.column.id" = "entry"
 );
```

- You can insert the new row into your table by using a dummy table:

```
WITH dummy_table AS
  (SELECT '001' AS KEY,
          '1' AS num,
          MAP ('Adam',
               Named_struct ('user_id', '1', 'address', '3205 Woodlake
ct', 'zip', '45040', 'country', 'Usa'),
               'Wilfred',
               Named_struct ('user_id', '2', 'address', '777 Brockton
Avenue', 'zip', '34000', 'country', 'Ita')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

- Alternatively, you can insert the new row into your table by using a `SELECT` statement:

```
INSERT INTO TABLE nested_data_insert
SELECT '002',
       '2',
       MAP ('Bill',
            Named_struct ('user_id', '1', 'address', '328 Virginia Ave',
'zip', '54956', 'country', 'Bol'),
            'Stiv',
            Named_struct ('user_id', '2', 'address', 'Schererville',
'zip', '46375', 'country', 'Efi'));
```

After you insert data, you should verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables:

- Verify the insertion into the Hive table by using the `SELECT * FROM` syntax.

```
SELECT * FROM nested_data_insert;
```

Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	1	Adam	1	3205 Woodlake ct	45040	Usa
		Wilfred	2	777 Brockton Avenue	34000	Ita
002	2	Bill	1	328 Virginia Ave	54956	Bol
		Stiv	2	Schererville	46375	Efi

last-updated: Jun 06, 2024

- Verify the insertion into the HPE Ezmeral Data Fabric Database JSON table data using the `find` statement:

```
find '/nested_data_insert'

{
  "Adam": {
      "user_id": "1",
      "address": "3205 Woodlake ct",
      "zip": "45040",
      "country": "Usa"
           },
  "Wilfred": {
      "user_id": "2",
      "address": "777 Brockton Avenue",
      "zip": "34000",
      "country": "Ita"
           }
       }
{
   "Bill": {
      "user_id": "1",
      "address": "328 Virginia Ave",
      "zip": "54956",
      "country": "Bol"
       },
   "Stiv": {
      "user_id": "2",
      "address": "Schererville",
      "zip": "46375",
      "country": "Efi"
       }
}
```

Multiple-row insert

Now imagine that you want to insert three rows of data into `nested_data_insert`.

- You can insert the new rows into your table by using a dummy table:

```
WITH dummy_table AS
  (SELECT '003' AS KEY,
          '3' AS num,
          MAP ('Rony',
               Named_struct ('user_id', '1', 'address', '4333 Backer
str', 'zip', '12311', 'country', 'Hun')) AS postal_addresses
   UNION ALL SELECT '004' AS KEY,
                    '4' AS num,
                    MAP ('Ivan',
                         Named_struct ('user_id', '1', 'address', '833
Bridle Avenue', 'zip', '95111', 'country', 'CA')) AS postal_addresses
   UNION ALL SELECT '005' AS KEY,
                    '5' AS num,
                    MAP ('Ivan',
                         Named_struct ('user_id', '1', 'address', '664
Devon Ave', 'zip', '92021', 'country', 'Tog')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

- Alternatively, you can insert the new rows into your table by using a `SELECT` statement:

```
INSERT INTO TABLE nested_data_insert
SELECT '006',
       '6',
       MAP ('Rony',
            Named_struct ('user_id', '1', 'address', '150 National City',
'zip', '91950', 'country', 'Hun'))
UNION ALL
SELECT '007',
       '7',
       MAP ('Tomason',
            Named_struct ('user_id', '1', 'address', '272 Ocean Circle' ,
'zip', '92801', 'country', 'CA'))
UNION ALL
SELECT '008',
       '8',
       MAP ('Davin',
            Named_struct ('user_id', '1', 'address', '81 Augusta Ave',
'zip', '93905', 'country', 'CA'));
```

After you insert data, you should verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables:

- Verify the insertion into the Hive table by using the `SELECT * FROM` syntax.

```
SELECT * FROM nested_data_insert WHERE entry > '002' ;
```

Sample output:

Table

		postal_address				
entry	**num**		**USER_ID**	**ADDRESS**	**ZIP**	**COUNTRY**
003	3	Rony	1	4333 Backer str	12311	Hun
004	4	Ivan	1	833 Bridle Avenue	95111	CA
005	5	Ivan	1	664 Devon Ave.	92021	Tog
006	6	Rony	1	150 National City	91950	Hun
007	7	Tomason	1	272 Ocean Circle	92801	CA
008	8	Davin	1	81 Augusta Ave	93905	CA

- Verify the insertion into the HPE Ezmeral Data Fabric Database JSON table data using the `find` statement:

```
find '/nested_data_insert'

{
   "_id": "003",
   "num": {
     "$numberInt": 3
          },
   "postal_addresses": {
        "Rony": {
             "address": "4333 Backer str",
             "country": "Hun",
             "user_id": "1",
             "zip": "12311"
             }
         }
      }
{
   "_id": "004",
   "num": {
       "$numberInt": 4
          },
   "postal_addresses": {
          "Ivan": {
              "address": "833 Bridle Avenue",
              "country": "CA",
              "user_id": "1",
              "zip": "95111"
            }
      }
 }
 {
   "_id": "005",
   "num": {
           "$numberInt": 5
          },
   "postal_addresses": {
           "Ivan": {
               "address": "664 Devon Ave",
               "country": "Tog",
               "user_id": "1",
                "zip": "92021"
          }
      }
    }
{
     "_id": "006",
     "num": {
           "$numberInt": 6
            },
     "postal_addresses": {
          "Rony": {
             "address": "150 National City",
             "country": "Hun",
             "user_id": "1",
             "zip": "91950"
           }
       }
    }
{
    "_id": "007",
```

last-updated: Jun 06, 2024

```
    "num": {
         "$numberInt": 7
           },
    "postal_addresses": {
          "Tomason": {
              "address": "272 Ocean Circle",
              "country": "CA",
              "user_id": "1",
              "zip": "92801"
           }
       }
    }
{
    "_id": "008",
    "num": {
         "$numberInt": 8
           },
    "postal_addresses": {
           "Davin": {
                "address": "81 Augusta Ave",
                "country": "CA",
                "user_id": "1",
                "zip": "93905"
            }
         }
}
```

Overwriting data

Still using sample table `nested_data_insert`, you can use the INSERT statement on a dummy table to overwrite one or more complete rows.

For example, to overwrite the first row in `nested_data_insert (001)` with new values, use the following syntax:

```
WITH dummy_table AS
(SELECT '001' AS KEY,
'1' AS num,
MAP ('newAdam',
Named_struct ('user_id', '1', 'address', 'newAdress', 'zip', 'newZip',
'country', 'newCountry')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

After you overwrite data, you should verify that the data is changed in both Hive and HPE Ezmeral Data Fabric Database JSON tables:

- Verify the data into the Hive table by using the `SELECT * FROM` syntax.

  ```
  hive> SELECT * FROM nested_data_insert WHERE entry = '001';
  ```

  Sample output:

Table

		postal_address				
entry	**num**		**USER_ID**	**ADDRESS**	**ZIP**	**COUNTRY**
001	1	newAdam	1	newAddress	newZip	newCountry

last-updated: Jun 06, 2024

- Verify the data in the HPE Ezmeral Data Fabric Database JSON table data using the `findbyid` statement:

```
findbyid '/nested_data_insert' --id 001

{
   "_id": "001",
   "num": {
   "$numberInt": 1
           },
   "postal_addresses": {
        "newAdam": {
              "address": "newAdress",
              "country": "newCountry",
              "user_id": "1",
              "zip": "newZip"
           }
       }
}
```

For another example, imagine that you want to overwrite `003` and `004` rows in `nested_data_insert` with new values:

```
WITH dummy_table AS (
SELECT '003' AS KEY,
'3' AS num,
MAP ('newName1',
Named_struct ('user_id', '1', 'address', 'newAdress1', 'zip', 'newZip1',
'country', 'newCountry1')) AS postal_addresses
UNION ALL
SELECT '004' AS KEY,
'4' AS num,
MAP ('newName2',
Named_struct ('user_id', '1', 'address', 'newAdress2', 'zip', 'newZip2',
'country', 'newCountry2')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT * FROM dummy_table;
```

After you overwrite the data, you should verify that the data is changed in both Hive and HPE Ezmeral Data Fabric Database JSON tables.

- Verify the data in the Hive table by using the `SELECT * FROM` syntax.

```
hive> SELECT * FROM nested_data_insert WHERE entry IN ('003', '004');
```

Sample output:

Table

		postal_address				
entry	**num**		**USER_ID**	**ADDRESS**	**ZIP**	**COUNTRY**
003	3	newName1	1	newAddress1	newZip1	newCountry1
004	4	newName2	1	newAddress2	newZip2	newCountry2

Verify the data in the HPE Ezmeral Data Fabric Database JSON table data using the `findbyid` statement:

```
findbyid '/nested_data_insert' --id 003
{
```

```
  "_id": "003",
  "num": {
       "$numberInt": 3
          },
  "postal_addresses": {
  "newName1": {
       "address": "newAdress1",
       "country": "newCountry1",
       "user_id": "1",
       "zip": "newZip1"
          }
        }
    }
findbyid '/nested_data_insert' --id 004
     {
       "_id": "004",
       "num": {
          "$numberInt": 4
          },
       "postal_addresses": {
           "newName2": {
              "address": "newAdress2",
              "country": "newCountry2",
              "user_id": "1",
              "zip": "newZip2"
           }
        }
    }
```

WARNING: If you exclude columns both from the SELECT statement in your INSERT statement and from the table schema, the value of this column changes to NULL.

Finally, imagine that you want to overwrite the first row in `nested_data_insert (001)` with new values and overwrite the `num` column to `NULL`:

```
WITH dummy_table AS
(SELECT '001' AS KEY,
MAP ('newAdam',
Named_struct ('user_id', '1', 'address', 'newAdress', 'zip', 'newZip',
'country', 'newCountry')) AS postal_addresses)
INSERT INTO nested_data_insert (entry, postal_addresses)
SELECT * FROM dummy_table;
```

After you overwrite data, you should verify that the data is changed in both Hive and HPE Ezmeral Data Fabric Database JSON tables.

- Verify the data in the Hive table by using the `SELECT * FROM` syntax.

```
hive> SELECT * FROM nested_data_insert WHERE entry = '001';
```

Sample output:

Table

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	NULL	newAdam	1	newAddress	newZip	newCountry

last-updated: Jun 06, 2024

- Verify the data in the HPE Ezmeral Data Fabric Database JSON table (`num` row is not present):

```
findbyid '/nested_data_insert' --id 001

{
   "_id": "001",
   "postal_addresses": {
   "newAdam": {
         "address": "newAdress",
         "country": "newCountry",
         "user_id": "1",
         "zip": "newZip"
        }
     }
}
```

Understanding the MERGE Statement

You can use the `MERGE` statement to perform record-level `INSERT` and `UPDATE` operations efficiently within Hive tables.

The `MERGE` statement can be a key tool of MapR-cluster data management. It is based on ANSI-standard SQL.

The following scenarios can help you understand how to use the `MERGE` statement:

- Simple merge.maprdb.column.id is the join key on page 4233
- Simple merge.maprdb.column.id is not the join key on page 4234
- DELETE syntax in the MERGE statement on page 4234
- Multiple source rows match a given target row (cardinality violation) on page 4235
- Merge on mixed data types on page 4236
- Merge into external HPE Ezmeral Data Fabric Database JSON tables on page 4237
- Merge into partitioned HPE Ezmeral Data Fabric Database JSON tables on page 4237
- Merge into temporary HPE Ezmeral Data Fabric Database JSON tables on page 4237

Simple `merge.maprdb.column.id` is the join key

Consider merging the following example source and target tables:

Table

id	first_name	last_name	age
001	Dorothi	Hogward	7777
002	Alex	Bowee	7777
088	Robert	Dowson	25

Table

id	first_name	last_name	age
001	John	Smith	45
002	Michael	Watson	27
003	Den	Brown	33

You can use the following SQL-standard MERGE statement:

```
MERGE into customer_db_json_target trg
USING customer_source src
ON src.id = trg.id
WHEN MATCHED THEN UPDATE SET age = src.age
WHEN NOT MATCHED THEN
INSERT VALUES (src.id, src.first_name, src.last_name, src.age);
```

The result is:

id	first_name	last_name	age
001	John	Smith	7777
002	Michael	Watson	7777
003	Den	Brown	33
088	Robert	Dowson	25

NOTE: The age column is updated and a new `id` column is inserted.

Simple `merge.maprdb.column.id` is not the join key

Merging when `merge.maprdb.column` is not the join key is not recommended.

DELETE syntax in the MERGE statement

This section describes how to use the `DELETE` syntax in the `MERGE` statement for HPE Ezmeral Data Fabric Database JSON tables. Included are examples of usage and limitations.

Consider two tables: `tgt` which is the target table of the `MERGE` statement, and `src`, which is the source table from which data will be taken. Both tables use `MapRDBJsonStorageHandler` to store data. The following table shows the initial contents of the `tgt` table:

Table

id	Value
1	AAA
2	BBB
3	CCC
4	DDD
5	EEE

The following table shows the initial contents of the `src` table:

Table

id	Value
1	AAA
222	BBB---
3	CCC
444	DDD---
5	EEE

last-updated: Jun 06, 2024

The following merge statement contains a `WHEN MATCHED THEN DELETE` clause. It means that if the `id` from the `tgt` table equals the `id` from the `src` table, the row is removed from the `tgt` table. When the value of `id` does not match, a new row is inserted into the `tgt` table:

```
MERGE INTO tgt
USING src ON tgt.id=src.id
WHEN MATCHED THEN DELETE
WHEN NOT MATCHED THEN INSERT VALUES (src.id, src.value);
```

The following table shows the result of the merge:

Table

id	Value
2	BBB
222	BBB---
4	DDD
444	DDD---

Here we removed rows with `id` 1, 3, and 5 from the `tgt` table because they existed in the `src` table, and they matched values from the `tgt` table. We did not touch rows with `id` 2 and 4, because there were no such values in the `src` table. We inserted new rows with `id` values 222 and 444 because they existed in the `src` table and did not exist in the `tgt` table.

Limitations

The preceding solution has three limitations:

1. Subqueries are not supported as a source when `DELETE` is used.
2. The source table should be a HPE Ezmeral Data Fabric Database JSON table when deletion is used in a `MERGE` operator.
3. The `DELETE` operator is not supported with additional conditions after `WHEN MATCHED`. Use either a single `UPDATE` or `DELETE`.

Limitation #3 means that queries like the following are not supported:

```
MERGE INTO tgt
USING src
ON tgt._id = src._id
WHEN MATCHED AND [boolean expression1] THEN DELETE
WHEN MATCHED AND [boolean expression2] THEN UPDATE
WHEN NOT MATCHED THEN INSERT
```

Multiple source rows match a given target row (cardinality violation)

Consider merging the two tables `customer_db_json` and `customer_new`:

Table

id	first_name	last_name	age
001	John	Smith	45
002	Michael	Watson	27
003	Den	Brown	33

And:

last-updated: Jun 06, 2024

Table

id	first_name	last_name	age
001	Dorothi	Hogward	77
001	Dorothi	Hogward	77
088	Robert	Dowson	25

To MERGE `customer_new` and `customer_db_json`:

```
MERGE INTO customer_db_json trg
USING customer_new src ON src.id = trg.id
WHEN MATCHED THEN UPDATE
SET first_name = src.first_name,
last_name = src.last_name
WHEN NOT MATCHED THEN INSERT VALUES
(src.id, src.first_name, src.last_name, src.age);
```

This example causes an exception because of duplicate values in the `id` column in the `customer_new` table:

```
Caused by: org.apache.hadoop.hive.ql.metadata.HiveException: Error
evaluating cardinality_violation(_col0)
```

To avoid cardinality violation, set `hive.merge.cardinality.check=false`, but in this case the result is unpredictable because there is no rule that defines the order of duplicated data that will be inserted by using the MERGE statement.

Merge on mixed data types

The merge operation also supports mixed data types, such as arrays, maps, and structures.

Consider two tables `mixed_types_source` and `mixed_types_target`:

Table

doc_id	user_info
1	{"name":"Brandon","surname":"Lee","age":31,"gender":"MALE"}
2	{"name":"Johnson","surname":"Fall","age":23,"gender":"MALE"}
3	{"name":"Mary","surname":"Dowson","age":11,"gender":"FEMALE"}
4	{"name":"Paul","surname":"Rodgers","age":41,"gender":"MALE"}

And:

Table

id	user_info
1	{"name":"Lexx","surname":"Comfuzer","age":31,"gender":"MALE"}

To merge `mixed_types_source` and `mixed_types_target`:

```
MERGE INTO mixed_types_target trg
USING mixed_types_source src
ON src.doc_id = old.doc_id
WHEN MATCHED THEN UPDATE
SET user_info = src.user_info
```

```
WHEN NOT MATCHED THEN INSERT VALUES
(src.doc_id, src.user_info);
```

The result is:

Table

id	first_name
1	{"name":"Brandon","surname":"Lee","age":31,"gender":"MALE"}
2	{"name":"Johnson","surname":"Fall","age":23,"gender":"MALE"}
3	{"name":"Mary","surname":"Dowson","age":11,"gender":"FEMALE"}
4	{"name":"Paul","surname":"Rodgers","age":41,"gender":"MALE"}

Note that you cannot update only a part of a complex structure field. For example, suppose you have a structure stored as one field in a Hive table:

```
{"name":"Johnson","surname":"Fall","age":23,"gender":"MALE"}
```

You cannot update only the age field in the structure. You can only replace all values of the structure with new ones. For details, see Understanding the UPDATE Statement on page 4221.

Merge into external HPE Ezmeral Data Fabric Database JSON tables

The MERGE operator is also available for external HPE Ezmeral Data Fabric Database JSON tables. You can use the MERGE statement to insert and update values in external MapR database JSON table targets.

Merge into partitioned HPE Ezmeral Data Fabric Database JSON tables

Partitioned HPE Ezmeral Data Fabric Database JSON tables are not supported.

Merge into temporary HPE Ezmeral Data Fabric Database JSON tables

The MERGE operator is also available for temporary HPE Ezmeral Data Fabric Database JSON tables. Use temporary tables as target tables for merge. No additional syntax is needed.

Understanding the DELETE FROM Operation

In EEP 6.3.1 and later, you can use the DELETE FROM operation with HPE Ezmeral Data Fabric Database JSON tables.

Delete All Data from a Table

To delete all data from a HPE Ezmeral Data Fabric DatabaseJSON table use the following operator:

```
DELETE FROM <table_name>;
```

Example. In this example we create a table, insert data, and delete all rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

last-updated: Jun 06, 2024

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query gives an empty set. Deletions are supported only for HPE Ezmeral Data Fabric Database JSON tables and transactional tables.

```
DELETE FROM customer;
SELECT doc_id, first_name, last_name FROM customer;
```

Example. In this example, we try to delete data from a non-transactional and non-MapR Database JSON table:

```
DROP TABLE IF EXISTS simple_data;
CREATE TABLE simple_data (id INT);
INSERT INTO TABLE simple_data VALUES (1), (2), (3);
DELETE FROM simple_data;
```

The result is:

```
FAILED: SemanticException Operation is not supported. Table is nor ACID
neither MapRDbJSON
```

Delete a Single Row from a Table

To delete a single row from a HPE Ezmeral Data Fabric Database JSON table, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> = <value>;
```

Where:

`<table_name>` is the HPE Ezmeral Data Fabric Database JSON table.

`<id>` is a key column of the MapR Database JSON table. It corresponds to the `maprdb.column.id` property.

`<value>` is the value to be deleted.

Example. In this example, we create a table, insert data, and delete a single row:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes a single row using the `WHERE` clause:

```
DELETE FROM customer WHERE doc_id = "002";
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
003	Robby	Smart

Note. Deletions are supported only for key columns of HPE Ezmeral Data Fabric Database JSON tables.

Example. In this example, we try to use a column other than a key column of the MapR Database JSON table in deletion.

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Column `first_name` is not the key column of the table.

```
DELETE FROM customer WHERE first_name = "Max";
```

The result is:

```
FAILED: SemanticException Deletion over column first_name is forbidden. Use
only key column of MapR Db Json table: doc_id
```

Delete Several Rows from a Table

To delete several rows from a table, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> IN (<value1>, <value2>, ...);
```

Where:

`<table_name>` is the HPE Ezmeral Data Fabric Database JSON table.

`<id>` is a key column of the MapR Database JSON table. It corresponds to the `maprdb.column.id` property.

`<value1>, <value2>,` are values to be deleted.

Example. In this example, we create a table, insert data, and delete several rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes several rows using the `WHERE ... IN` clause:

```
DELETE FROM customer WHERE doc_id IN ("001", "002");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
003	Robby	Smart

Delete All Rows in a Table Except Listed Rows

To delete all rows from a table except a listed row, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> NOT IN (<value1>, <value2>, ...);
```

Where:

`<table_name>` is the HPE Ezmeral Data Fabric Database JSON table.

`<id>` is a key column of the MapR Database JSON table. It corresponds to the `maprdb.column.id` property.

`<value1>, <value2>,` are values to be preserved.

Example. In this example, we create a table, insert data, and delete all rows except the listed rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer","maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes all rows except the listed rows:

```
DELETE FROM customer WHERE doc_id NOT IN ("003");
SELECT doc_id, first_name, last_name FROM customer;
```

last-updated: Jun 06, 2024

Table

doc_id	first_name	last_name
003	Robby	Smart

Limitations of the DELETE FROM Operation

The following are three limitations of the current implementation:

- The current implementation does not support arbitrary conditions in the `WHERE` clause of the `DELETE` statement even if a key column is used.

  Example. In this example, `DELETE FROM` is used with an arbitrary condition:

  ```
  DELETE FROM customer WHERE doc_id == "003" OR doc_id <> "005";
  ```

  The result is:

  ```
  FAILED:
          SemanticException This condition is not supported for MapR Db
  Json deletions. Supported
          WHERE clauses are: <id> = value, <id> IN (value1, value2, ...),
  <id> NOT IN (value1, value2,
          ...)
  ```

- The current implementation does not support subqueries in the `WHERE` clause.
- The current implementation does not support deletions in the `MERGE` statement.

Hive and HBase Integration

You can create HBase tables from Hive that can be accessed by both Hive and HBase. This allows you to run Hive queries on HBase tables. You can also convert existing HBase tables into Hive-HBase tables and run Hive queries on those tables as well.

Install and Configure Hive and HBase

Procedure

1. Install and configure Hive if it is not already installed. See Installing Hive on page 248.
2. Install and configure HBase if it is not already installed. See Installing HBase on page 243.
3. Run the `jps` command, and ensure that all relevant Hadoop, HBase and Zookeeper processes are running:

   ```
   $ jps
   21985 HRegionServer
   1549 jenkins.war
   15051 QuorumPeerMain
   30935 Jps
   15551 CommandServer
   15698 HMaster
   15293 ResourceManager
   15328 NodeManager
   15131 WardenMain
   ```

Getting Started with Hive-HBase Integration

In this tutorial you will:

- Create a Hive table
- Populate the Hive table with data from a text file
- Query the Hive table
- Create a Hive-HBase table
- Introspect the Hive-HBase table from HBase
- Populate the Hive-Hbase table with data from the Hive table
- Query the Hive-HBase table from Hive
- Convert an existing HBase table into a Hive-HBase table

Be sure that you have successfully completed all the steps in the Install and Configure Hive and HBase section before beginning this Getting Started tutorial. This Getting Started tutorial closely parallels the Hive-HBase Integration section of the Apache Hive Wiki, and thanks to Samuel Guo and other contributors to that effort.

Create a Hive table with two columns:

Change to your Hive installation directory if you're not already there and start Hive:

```
$ cd $HIVE_HOME
$ bin/hive
```

Execute the CREATE TABLE command to create the Hive pokes table:

```
hive> CREATE TABLE pokes (foo INT, bar STRING);
```

To see if the pokes table has been created successfully, execute the SHOW TABLES command:

```
hive> SHOW TABLES;
OK
pokes
Time taken: 0.74 seconds
```

The `pokes` table appears in the list of tables.

Populate the Hive pokes table with data

Execute the LOAD DATA LOCAL INPATH command to populate the Hive `pokes` table with data from the `kv1.txt` file.

The `kv1.txt` file is provided in the `$HIVE_HOME/examples` directory.

```
hive> LOAD DATA LOCAL INPATH './examples/files/kv1.txt' OVERWRITE INTO
TABLE pokes;
```

A message appears confirming that the table was created successfully, and the Hive prompt reappears:

```
Copying data from file:
...
OK
Time taken: 0.278 seconds
hive>
```

Execute a SELECT query on the Hive pokes table:

```
hive> SELECT * FROM pokes WHERE foo = 98;
```

The SELECT statement executes, runs a MapReduce application, and prints the job output:

```
OK
98      val_98
98      val_98
Time taken: 18.059 seconds
```

The output of the SELECT command displays two identical rows because there are two identical rows in the Hive `pokes` table with a key of 98. Note: This is a good illustration of the concept that Hive tables can have multiple identical keys. As we will see shortly, HBase tables cannot have multiple identical keys, only unique keys.

To create a Hive-HBase table, enter these four lines of code at the Hive prompt:

```
hive> CREATE TABLE hbase_table_1(key int, value string)
    > STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
    > WITH SERDEPROPERTIES ("hbase.columns.mapping" = ":key,cf1:val")
    > TBLPROPERTIES ("hbase.table.name" = "xyz");
```

After a brief delay, a message appears confirming that the table was created successfully:

```
OK
Time taken: 5.195 seconds
```

Note: The TBLPROPERTIES command is not required, but those new to Hive-HBase integration may find it easier to understand what's going on if Hive and HBase use different names for the same table.

In this example, Hive will recognize this table as "hbase_table_1" and HBase will recognize this table as "xyz".

Start the HBase shell:

Keeping the Hive terminal session open, start a new terminal session for HBase, then start the HBase shell:

```
$ cd $HBASE_HOME
$ bin/hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
Version 0.90.4, rUnknown, Wed Nov  9 17:35:00 PST 2011

hbase(main):001:0>
```

Execute the list command to see a list of HBase tables:

```
hbase(main):001:0> list
TABLE
xyz
1 row(s) in 0.8260 seconds
```

HBase recognizes the Hive-HBase table named `xyz`. This is the same table known to Hive as `hbase_table_1`.

Display the description of the xyz table in the HBase shell:

```
hbase(main):004:0> describe "xyz"
DESCRIPTION
```

```
      ENABLED
 {NAME => 'xyz', FAMILIES => [{NAME => 'cf1', BLOOMFILTER => 'NONE',
REPLICATI true
 ON_SCOPE => '0', COMPRESSION => 'NONE', VERSIONS => '3', TTL =>
'2147483647', BL
 OCKSIZE => '65536', IN_MEMORY => 'false', BLOCKCACHE => 'true'}]}
1 row(s) in 0.0190 seconds
```

From the Hive prompt, insert data from the Hive table pokes into the Hive-HBase table hbase_table_1

```
hive> INSERT OVERWRITE TABLE hbase_table_1 SELECT * FROM pokes WHERE foo=98;
...
2 Rows loaded to hbase_table_1
OK
Time taken: 13.384 seconds
```

Query hbase_table_1 to see the data we have inserted into the Hive-HBase table:

```
hive> SELECT * FROM hbase_table_1;
OK
98      val_98
Time taken: 0.56 seconds
```

Even though we loaded two rows from the Hive `pokes` table that had the same key of 98, only one row was actually inserted into `hbase_table_1`. This is because `hbase_table_1` is an HBASE table, and although Hive tables support duplicate keys, HBase tables only support unique keys. HBase tables arbitrarily retain only one key, and will silently discard all the data associated with duplicate keys.

Convert a pre-existing HBase table to a Hive-HBase table

To convert a pre-existing HBase table to a Hive-HBase table, enter the following four commands at the Hive prompt.

Note that in this example the existing HBase table is `my_hbase_table`.

```
hive> CREATE EXTERNAL TABLE hbase_table_2(key int, value string)
    > STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
    > WITH SERDEPROPERTIES ("hbase.columns.mapping" = "cf1:val")
    > TBLPROPERTIES("hbase.table.name" = "my_hbase_table");
```

Now we can run a Hive query against the pre-existing HBase table `my_hbase_table` that Hive sees as `hbase_table_2`:

```
hive> SELECT * FROM hbase_table_2 WHERE key > 400 AND key < 410;
Total MapReduce jobs = 1
Launching Job 1 out of 1
Number of reduce tasks is set to 0 since there's no reduce operator
...
OK
401     val_401
402     val_402
403     val_403
404     val_404
406     val_406
407     val_407
409     val_409
Time taken: 9.452 seconds
```

Hive and HPL/SQL Integration

Note: This feature is presented as a developer preview. Developer previews are not tested for production environments, and should be used with caution.

HPL/SQL includes a Hive UDF function that allows you to execute HPL/SQL scripts (user-defined functions written in HPL/SQL language) in Hive queries.

HPL/SQL uses the `hplsql_locals.sql` file to parse a prepared procedure that can be used in the Hive query. If you want to add and use multiple functions, you should add each function to the `hplsql_locals.sql` file.

For example, to call the `hello` function from a Hive query, you can add a `hello` function to the `hplsql_locals.sql` file:

```
CREATE FUNCTION hello(text STRING)
 RETURNS STRING
BEGIN
 RETURN 'Hello, ' || text || '!';
END;
```

There are two possible ways to run the HPL/SQL `hello` function:

Running HPL/SQL from Hive CLI/Hive Beeline

The `hplsql_locals.sql` file must be located in the directory where the Hive CLI is started or in the `/opt/mapr/hive/hive-<version>/bin` directory if you are using Beeline. After adding the `hello` function to the `hplsql_locals.sql` file, register the HPL/SQL UDF in Hive as follows:

```
CREATE TEMPORARY FUNCTION hplsql AS 'org.apache.hive.hplsql.Udf';
```

To use the `hello` function written in HPL/SQL language in Hive, use a query such as the following:

```
SELECT hplsql('hello(:1)', name) FROM users;
```

Running HPL/SQL from the HPL/SQL CLI

When you run HPL/SQL scripts using the HPL/SQL CLI, you can use user-defined functions the same way you use built-in functions:

```
hplsql -e "SELECT hello(name) FROM users;"
```

The HPL/SQL CLI automatically connects to HiveServer2 using the configuration from the `hplsql-site.xml` file, registers the Hive UDF, and modifies the function call in the SQL statements. But you must ensure that the `hplsql_locals.sql` file containing the user-defined functions is located in the `/opt/mapr/hive/hive-<version>/bin` directory, where HiveServer2 can parse it.

For more information, see User-Defined Functions and Stored Procedures.

Hive and HCatalog Integration

The HCatalog on page 4150 library provides applications with a table view of the file system layer in your cluster, expanding your application's options from read/write data streams to add table operations such as get row and store row. The HCatalog library stores the metadata required for its operations in the Hive Metastore.

The `hcat` utility can execute any of the data definition language (DDL) commands available in Hive that do not involve launching a MapReduce application. Internally, the `hcat` utility passes DDL commands to the `hive` program. Data stored in the MapR filesystem is serialized and deserialized through

`InputStorageFormats` and `OutputStorageFormats` objects for records. Fields within a record are parsed with `SerDes`.

WARNING:

The `hive-json-serde-0.2.jar` JSON serializer/deserializer has not implemented a `serialize()` method and as a result does not function.

The WebHCat server provides a REST-like web API for HCatalog. For more information about using WebHCat, see Hive and WebHCat Integration on page 4248.

This section contains the following topics:

Accessing HCatalog Tables from Hive

About this task
To access tables created in HCatalog in Hive, use the following command to append paths to your `HADOOP_CLASSPATH` environment variable:

```
export HADOOP_CLASSPATH=${HADOOP_CLASSPATH}:$HCAT_HOME/share/hcatalog/
storage-handlers/hbase/lib/hbase-storage-handler-<version>.jar:$HCAT_HOME/
share/hcatalog/hcatalog-core-<version>-mapr.jar:$HCAT_HOME/share/hcatalog/
hcatalog-pig-adapter-<version>-mapr.jar:$HCAT_HOME/share/hcatalog/
hcatalog-server-extensions-<version>-mapr.jar
```

Loading and Retrieving Data from Pig

About this task
To use the HCatalog library `HCatLoader` and `HCatStorer` to load and retrieve data from Pig:

Procedure

1. Create a table with the `hcat` utility.

   ```
   hcat -e "create table hcatpig(key int, value string)"
   ```

2. Verify that the table and table definition both exist.

   ```
   hcat -e "describe formatted hcatpig"
   ```

3. Load data into the table from Pig: Copy the `$HIVE_HOME/examples/files/kv1.txt` file into the MapRFS file system, then start Pig and load the file with the following commands:

   ```
   pig -useHCatalog -Dfs.default.name=maprfs://CLDB_Host:7222/
   grunt> A = LOAD 'kv1.txt' using PigStorage('\u0001') AS(key:INT,
   value:chararray);
   grunt> STORE A INTO 'hcatpig' USING
   org.apache.hive.hcatalog.pig.HCatStorer();
   ```

4. Retrieve data from the `hcatpig` table with the following Pig commands: Another way to verify that the data is loaded into the `hcatpig` table is by looking at the contents of `maprfs://user/hive/warehouse/hcatpig/`. HCatalog tables are also accessible from the Hive CLI. All Hive queries work on HCatalog tables.

```
B = LOAD 'default.hcatpig' USING
org.apache.hive.hcatalog.pig.HCatLoader();
dump B; // this should display the records in kv1.txt
```

Running MapReduce Applications

About this task
This example uses a sample MapReduce program named `HCatalogMRTest.java`.

Procedure

1. From the command line, issue the following commands to define the environment:

```
export LIB_JARS=
$HCAT_HOME/share/hcatalog/hcatalog-core-<version>-mapr.jar,
$HIVE_HOME/lib/hive-metastore-<version>-mapr.jar,
$HIVE_HOME/lib/libthrift-<version>.jar,
$HIVE_HOME/lib/hive-exec-<version>-mapr.jar,
$HIVE_HOME/lib/libfb303-<version>.jar,
$HIVE_HOME/lib/jdo2-api-<version>-ec.jar,
$HIVE_HOME/lib/slf4j-api-<version>.jar

export HADOOP_CLASSPATH=
$HCAT_HOME/share/hcatalog/hcatalog-core-<version>-mapr.jar:
$HIVE_HOME/lib/hive-metastore-<version>-mapr.jar:
$HIVE_HOME/lib/libthrift-<version>.jar:
$HIVE_HOME/lib/hive-exec-<version>-mapr.jar:
$HIVE_HOME/lib/libfb303-<version>.jar:
$HIVE_HOME/lib/jdo2-api-<version>-ec.jar:
$HIVE_HOME/conf:
$HADOOP_HOME/conf:
$HIVE_HOME/lib/slf4j-api-<version>.jar
```

2. Compile `HCatalogMRTest.java`:

```
javac -cp `hadoop classpath`:${HCAT_HOME}/share/hcatalog/
hcatalog-core-<version>-mapr.jar HCatalogMRTest.java -d .
```

3. Create a JAR file:

```
jar -cf hcatmrtest.jar org
```

4. Create an output table:

```
hcat -e "create table hcatpigoutput(key int, value int)"
```

5. Run the job: At the end of the job, the file `hcatpigoutput` should have entries in the form `key, count`.

```
hadoop --config $HADOOP_HOME/conf jar ./hcatmrtest.jar
org.myorg.HCatalogMRTest -libjars $LIB_JARS hcatpig hcatpigoutput
```

Running Non-MapReduce Applications

About this task
This example uses a sample MapReduce program named `TestReaderWriter.java`.

Procedure

1. Add the following JAR files to your `$HADOOP_CLASSPATH` environment variable with the following command:

```
export HADOOP_CLASSPATH=$HADOOP_CLASSPATH:/opt/
mapr/hive/hive-<version>/lib/antlr-runtime-3.4.jar:/opt/mapr/hive/
hive-<version>/lib/hive-cli-<veresion>-mapr.jar
```

2. Compile the test program with the following command:

```
javac -cp `hadoop classpath`:${HCAT_HOME}/share/hcatalog/
hcatalog-core-<version>-mapr.jar TestReaderWriter.java -d <directory>
```

3. Create a JAR file with the following command:

```
jar -cf hcatrwtest.jar org
```

4. Run the job with the following command:

```
hadoop jar /root/<username>/hcatalog/hcatrwtest.jar
org.apache.hive.catalog.data.TestReaderWriter -libjars $LIB_JARS
```

Results
The last command should result in a table named `mytbl` that is populated with data.

Hive and WebHCat Integration

The WebHCat server provides a REST-like web API for HCatalog. Applications make HTTP requests to run Pig, Hive, and HCatalog DDL from within applications.

This topic contains the following sections:

Configuring the WebHCat Server

About this task
The properties to configure WebHCat are in the following file:

```
/opt/mapr/hive/hive-<version>/hcatalog/etc/webhcat/webhcat-site.xml
```

When you set up WebHCat, you can configure file system and Zookeeper as storage.

Procedure

1. To configure storage for WebHCat, add the MapRFS location property.

```
<property> <name>templeton.storage.class</name>
<value>org.apache.hive.hcatalog.templeton.tool.HDFSStorage</value> </
property> <property> <name>templeton.storage.root</name> <value>/user/
mapr/webhcat</value> <description>The path to the directory to use for
storage</description> </property>
```

2. To configure WebHCat for Pig:
   a) Compress the Pig installation, then move the compressed file to the MapRFS layer.

```
# cd /opt/mapr/pig
# tar -czvf /tmp/pig-<version>.tar.gz pig-<version>/
# hadoop fs -mkdir /user/mapr/webhcat
# hadoop fs -put /tmp/pig-<version>.tar.gz /user/mapr/webhcat/
```

   b) Set the value of the `templeton.pig.archive` property to the location of the compressed file.

```
<property> <name>templeton.pig.archive</name> <value>maprfs:///user/
mapr/webhcat/pig-<version>.tar.gz</value> </property>
```

   c) Set the value of the `templeton.pig.path` property to the path inside the compressed Pig file where the Pig binary is located.

```
<property>
    <name>templeton.pig.path</name>
    <value>pig-<version>.tar.gz/pig-<version>/bin/pig</value>
</property>
```

3. To configure WebHCat for Hive:
   a) Compress the Hive installation, then move the compressed file to the file system layer.

```
# cd /opt/mapr/hive
# tar -czvf /tmp/hive-<version>.tar.gz hive-<version>/
# hadoop fs -mkdir /user/mapr/webhcat
# hadoop fs -put /tmp/hive-<version>.tar.gz /user/mapr/webhcat
```

   b) Set the value of the `templeton.hive.archive` property to the location of the compressed file.

```
<property> <name>templeton.hive.archive</name> <value>maprfs:///user/
mapr/webhcat/hive-<version>.tar.gz</value> </property>
```

   c) Set the value of the `templeton.hive.path` property to the path inside the compressed Hive file where the Hive binary is located.

```
<property>
     <name>templeton.hive.path</name>
     <value>hive-<version>.tar.gz/hive-<version>/bin/hive</value>
</property>
```

4. To Configure WebHCat for streaming:

last-updated: Jun 06, 2024

a) Copy the Streaming JAR to the file system layer.

```
# hadoop fs -put
/opt/mapr/hadoop/hadoop-<version>/contrib/streaming/
hadoop-<version>-dev-streaming.jar /user/mapr/webhcat
```

b) Set the `templeton.streaming.jar` property to the location of the streaming JAR.

```
<property> <name>templeton.streaming.jar</name> <value>maprfs:///user/
mapr/webhcat/hadoop-<version>-dev-streaming.jar</value> </property>
```

Configure WebHCat Server to use SSL Encryption

About this task

You can configure WebHCat REST-API to use SSL (Secure Sockets Layer) encryption. The following WebHCat properties are added to enable SSL:

```
templeton.use.ssl
Default value: false
Description: Set this to true for using SSL encryption for  WebHCat server

templeton.keystore.path
Default value: <empty string>
Description: SSL certificate keystore location for WebHCat server

templeton.keystore.password
Default value: <empty string>
Description: SSL certificate keystore password for WebHCat server

templeton.ssl.protocol.blacklist
Default value: SSLv2,SSLv3
Description: SSL Versions to disable for WebHCat server

templeton.host
Default value: 0.0.0.0
Description: The host address the WebHCat server will listen on
```

Modifying the `webhcat-site.xml` file:

Procedure

Configure the following properties in the `webhcat-site.xml` file to enable SSL encryption on each node where HWebHCat is installed:

```
<!-- WebHCat SSL -->
<property>
  <name>templeton.use.ssl</name>
  <value>true</value>
</property>

<property>
  <name>templeton.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
</property>

<property>
  <name>htempleton.keystore.password</name>
```

last-updated: Jun 06, 2024

```
  <value><ssl-keystore-password></value>
</property>
```

NOTE: After running `/opt/mapr/server/configure.sh -R`, all properties needed to enable SSL encryption for WebHCat are added automatically to `webhcat-site.xml` on the Mapr-SASL secure cluster.

To check status of WebHCat server configured for SSL encryption, use following command:

```
curl -k 'https://<user>:<password>@<host>:50111/templeton/v1/status'
```

Requirements for Using Automatically Generated PEM Files
To use automatically generated PEM files for the WebHCat REST API on a MapR-SASL cluster, you need to have a cluster with a host name that consists at least of three parts: administrator user name and password, and WebHCat REST API host.

About this task
Check the status of the WebHCat REST API to make sure you have a cluster with a host name that consists of the administrator user name and password, and WebHCat REST API host service:

```
curl  --cacert /opt/mapr/conf/ssl_truststore.pem  -u
<cluster_admin_user>:<cluster_admin_password>
"https://<myhost.mapr.com>:50111/templeton/v1/status" -v
```

Results

The sample output for this example is as follows:

```
* TCP_NODELAY set
* Connected to c74v610.mapr.com (192.168.122.254) port 50111 (#0)
* Cipher selection: ALL:!EXPORT:!EXPORT40:!EXPORT56:!aNULL:!LOW:!
RC4:@STRENGTH
* successfully set certificate verify locations:
CAfile: /opt/mapr/conf/ssl_truststore.pem
CApath: none
* (303) (OUT), TLS Unknown, Certificate Status (22):
* (303) (OUT), TLS handshake, Client hello (1):
* (303) (IN), TLS handshake, Server hello (2):
* (303) (IN), TLS handshake, Certificate (11):
* (303) (IN), TLS handshake, Server key exchange (12):
* (303) (IN), TLS handshake, Server finished (14):
* (303) (OUT), TLS handshake, Client key exchange (16):
* (303) (OUT), TLS change cipher, Client hello (1):
* (303) (OUT), TLS handshake, Finished (20):
* (303) (IN), TLS change cipher, Client hello (1):
* (303) (IN), TLS handshake, Finished (20):
* SSL connection using unknown / ECDHE-RSA-AES256-GCM-SHA384
* Server certificate:
*  subject: CN=*.mapr.com
*  start date: May 10 15:18:03 2018 GMT
*  expire date: Apr 16 15:18:03 2118 GMT
*  common name: *.mapr.com (matched)
*  issuer: CN=*.mapr.com
*  SSL certificate verify ok.
* Server auth using Basic with user 'mapr'
> GET /templeton/v1/status HTTP/1.1
> Host: c74v610.mapr.com:50111
> Authorization: Basic bWFwcjptYXBy
> User-Agent: curl/7.59.0
```

```

```

Managing the WebHCat Server

About this task

As of Hive 0.13-1504 and Hive 1.0-1504, WebHCat is managed by Warden. Therefore, you can start and stop WebHCat using maprcli and the Control System.

Starting the WebHCat Server

About this task

Applies to versions prior to Hive 0.13-1504 and Hive 1.0-1504:

```
# ./webhcat_server.sh start
```

Starting WebHCat Using the maprcli

Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprcli node services command:

```
maprcli node services -name hcat -action start -nodes <space delimited
list of nodes>
```

Stopping WebHCat Using the maprcli

Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprcli node services command:

```
maprcli node services -name hcat -action stop -nodes <space delimited
list of nodes>
```

Starting or Stopping WebHCat Using the Control System

Procedure

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **WebHcat** to open the Nodes screen displaying all the nodes on which Hive Metastore is configured.

last-updated: Jun 06, 2024

3. On the Nodes screen, click the hostname of each node to display its Node Properties screen.
4. On each Node Properties screen, use the **Stop/Start** button in the WebHcat row under Manage Node Services to start WebHcat.

Checking the Error Logs

About this task

Go to the following folder:

```
/opt/mapr/hive/hive-<version>/logs/<user.name>/webhcat
```

NOTE: If you are running a Hive 0.13 version prior Hive 0.13-1504, go to the /tmp/<user.name>/webhcat folder to view the error logs.

Verifying the Server's Status

About this task

In a web browser, navigate to:

```
http://hostname:50111/templeton/v1/status?user.name=root
```

A healthy server will return the string `{"status":"ok","version":"v1"}`. You can change the port number from the default value of 50111 by editing the `webhcat-site.xml` file.

Running Jobs on the WebHCat Server

About this task

REST Calls in WebHCat

The base URI for REST calls in WebHCat is `http://<host>:<port>/templeton/v1/`. The following table lists elements appended to the base URI and DDL commands.

URI	Description
Server Information	
/status	Shows WebHCat server status.
/version	Shows WebHCat server version.
DDL Commands	
/ddl/database	List existing databases.
/ddl/database/<mydatabase>	Shows properties for the database named *mydatabase*.
/ddl/database/<mydatabase>/table	Shows tables in the database named *mydatabase*.
/ddl/database/<mydatabase>/table/<mytable>	Shows the table definition for the table named *mytable* in the database named *mydatabase*.
/ddl/database/<mydatabase>/table/<mytable>/property	Shows the table properties for the table named *mytable* in the database named *mydatabase*.

Launching a MapReduce Job with WebHCat

About this task

WebHCat launches two jobs for each MapReduce job. The first job, `TempletonControllerJob`, has one map task. The map task launches the actual job from the REST API call. Check the status of both jobs and the output directory contents.

Procedure

1. Copy the MapReduce example job to the MapRFS layer:

```
hadoop fs -put /opt/mapr/hadoop/hadoop-<version>/
hadoop-<version>-dev-examples.jar /user/mapr/webhcat/examples.jar
```

2. Use the `curl` utility to launch the job:

```
curl -s -d jar=examples.jar -d class="terasort" -d
arg=teragen.test -d arg=whop3 'http://localhost:50111/templeton/v1/
mapreduce/jar?user.name=<username>'
```

Launching a Streaming MapReduce Job with WebHCat

Procedure

1. Use the `curl` utility to launch the job:

```
curl -s -d arg=teragen.test -d output=mycounts -d mapper=/bin/cat -d
reducer="/usr/bin/wc -w" 'http://localhost:50111/templeton/v1/mapreduce/
streaming?user.name=<username>'
```

2. Check the job status for both WebHCat jobs at the jobtracker page in the Control System.

Launching a Pig Job with WebHCat

Procedure

1. Copy a data file into MapRFS:

```
hadoop fs -put $HIVE_HOME/examples/files/kv1.txt /user/<user name>/
```

2. Create a `test.pig` file with the following contents:

```
A = LOAD 'kv1.txt' using PigStorage('\u0001') AS(key:INT,
value:chararray);
STORE A INTO 'pig.output';
```

3. Copy the `test.pig` file into MapR filesystem:

```
hadoop fs -put test.pig /user/<user name>/
```

4. Run the Pig REST API command:

```
curl -s -d file=test1.pig -d arg=-v 'http://localhost:50111/templeton/v1/
pig?user.name=<username>'
```

5. Monitor the contents of the `pig.output` directory.

last-updated: Jun 06, 2024

6. Check the JobTracker page for two jobs: `TempletonControllerJob` and `PigLatin`.

Launching a Hive Job with WebHCat

Procedure

1. Create a table:

```
curl -s -d execute="create+external+table+ext3(t+TIMESTAMP)+location /
user/<user name>/ext3'" 'http://localhost:50111/templeton/v1/hive?
user.name=<username>'
```

2. Load data into the table:

```
curl -s -d execute="insert+overwrite+table+ext3+select+*+from+datetable"
'http://localhost:50111/templeton/v1/hive?user.name=<username>'
```

3. List the tables:

```
curl -s -d execute="show+tables" -d statusdir='hive.output' 'http://
localhost:50111/templeton/v1/hive?user.name=<username>'
```

   The list of tables is in `hive.output/stdout`.

The Job Queue

About this task

To show HCatalog jobs for a particular user, navigate to the following address:

```
http://<hostname>:<port>/templeton/v1/queue/?user.name=<username>
```

The default port for HCatalog is 50111.

Hive and Tez Integration
You can use Tez, instead of MapReduce, for generic data processing tasks. Tez significantly increases the processing speed. Tez, working with Hive, provides lower latency for interactive queries and higher throughput for batch queries.
Configuring Hive and Tez

About this task

To configure Hive on Tez, repeat the following steps on each node where you want to configure Hive on Tez. Tez mode for MR jobs is not compatible with all MR jobs, so do not set up the whole cluster to work on Tez.

There is a known issue related to the incomplete removal of previously installed Tez packages. The issue affects platforms on which Tez was installed but later removed using `sudo apt-get remove mapr-tez`. Because of Ubuntu-specific behavior and Tez source-code issues, the `remove` command removes Tez only partially in some installations. If this happens, an error is generated when you try to re-install Tez on Ubuntu, as described following in step 1. If you believe your installation might have this issue, you can prevent the error. Before performing the following steps, use the `purge` command to completely remove all previously installed Tez packages.

Procedure

1. Install Tez if it is already not installed. To install Tez, run the following command:

On CentOS / RedHat	`yum install mapr-tez`
On SLES	`zypper install mapr-tez`
On Ubuntu	`apt-get install mapr-tez`

   NOTE: Repeat this step on each node where you want Hive on Tez to be configured.

2. Create the `/apps/tez` directory on MapR filesystem.
   To create, run the following commands:

```
hadoop fs -mkdir /apps
hadoop fs -mkdir /apps/tez
```

3. Upload the Tez libraries to the `/tez` directory on the MapR file system.
   To upload, run the following commands:

```
hadoop fs -put /opt/mapr/tez/tez-<version> /apps/tez
hadoop fs -chmod -R 755 /apps/tez
```

4. Verify the upload.
   To verify, run the following command:

```
hadoop fs -ls /apps/tez/tez-<version>
```

5. Set the Tez environment variables. To set, open the `/opt/mapr/hive/hive-<version>/conf/hive-env.sh` file, add the following lines, and save the file:

```
export TEZ_CONF_DIR=/opt/mapr/tez/tez-<version>/conf
export TEZ_JARS=/opt/mapr/tez/tez-<version>/*:/opt/mapr/tez/
tez-<version>/lib/*
export HADOOP_CLASSPATH=$TEZ_CONF_DIR:$TEZ_JARS:$HADOOP_CLASSPATH
```

   NOTE: Repeat this step on each node where you want Hive on Tez to be configured.

6. Configure Hive for Tez engine. To configure, open the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file, add the following lines, and save the file.

```
<property>
