About Release 7.7.0

This site contains documentation for HPE Ezmeral Data Fabric release 7.7.0, including installation, configuration, administration, and reference content, as well as content for the associated ecosystem components and drivers.

CAUTION: New installations of release 7.6.0 are no longer recommended. Because of known issues with release 7.6.0, Hewlett Packard Enterprise recommends installing release 7.6.1 or later. See Deprecation of Release 7.6.0 on page 70.

Related concepts

Products Covered in the HPE Ezmeral Data Fabric Documentation on page 5575
This section lists the products covered in the HPE Ezmeral Data Fabric documentation portal and provides links to the related product documentation.

Release 7.7 Release Notes

These notes contain information about release 7.7 of the HPE Ezmeral Data Fabric.

What's New in Release 7.7

Describes the new features in release 7.7 and provides links to more information.

IMPORTANT: To view information for the as-a-service Data Fabric platform, see this website.

New Features

The following table shows the new features and capabilities that distinguish release 7.7.0 from the previous release (7.6.1). Most features require you to use the Data Fabric UI. With release 7.3.0 and later, you can use the Data Fabric UI on customer-managed clusters. To understand the limitations and benefits of doing so, see Data Fabric UI on page 820.

New Feature or Capability	Supported on		See for more information . . .
	DF SaaS?	Customer Managed?	
Add nodes by using the Data Fabric UI	Yes	No	Adding Nodes**
Node detail support	Yes	Yes	Viewing Node Information**
User behavior tracking*	Yes	Yes	Configuring Data Fabric to Track User Behavior on page 1772 update_insights.sh
Unified security policy for buckets	Yes	Yes	Administering Bucket Policies**
RHEL 9 and Ubuntu 22.04 Support	Yes	Yes	Operating System Support Matrix (as a service)** Operating System Support Matrix on page 5719 (customer-managed)
AWS Security Token Service (STS) support	Yes	Yes	Integrating the AWS Security Token Service (STS) with Data Fabric** Configuring STS for Data Fabric** clustergroup addexternal on page 2082

last-updated: Jun 06, 2024

New Feature or Capability	Supported on		See for more information . . .
	DF SaaS?	Customer Managed?	
CSI driver update	Yes	Yes	Container Storage Interface (CSI) Storage Plugin Release 1.2.x (FUSE POSIX) Container Storage Interface (CSI) Storage Plugin Release 1.0 (Loopback NFS) Example: Mounting a PersistentVolume for Static Provisioning Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin
Incremented the NFS Ganesha version	Yes	Yes	Accessing Data with NFS v4
Import a GCP S3 server into the global namespace	Yes	Yes	Working with External S3 Object Store** Viewing Object Store Details**
User group management features	Yes	Yes	Assigning a Role to a Group ** Viewing a List of Groups** Viewing a List of Users** Assigning a Role to a User**
New lifecycle dates for core 7.x releases	Yes	Yes	Core Support and Lifecycle Status
EEP 9.1.2 support for core 7.1.0	No	Yes	EEP Support and Lifecycle Status
Download fabric installation logs	Yes*	No	Downloading Installation Logs**
Enable IPv6 during fabric creation***	Yes	No	On-Premises Fabric Configuration Parameters**
Reinitiate a failed fabric deployment from the seed node UI	Yes	No	Troubleshoot Fabric Creation**

*This initial release of the user behavior tracking feature is provided as a preview with basic functionality.

**Indicates a link to the Data Fabric as-a-service documentation.

***HPE Ezmeral Ecosystem Pack (EEP) components do not support IPv6.

New Key for Signature Verification for Data Fabric Files

Release 7.6.1 implemented a new key for `.rpm`, `.tar.gz`, `.zip`, and `.tgz` files for the following Data Fabric products:

- HPE Ezmeral Data Fabric core 7.6.1 and later
- HPE Ezmeral Data Fabric clients
- HPE Ezmeral Ecosystem Pack (EEP) 9.2.1 and later
- Installer 1.18.0.5 and later

Before you install these products, you must import the HPE GPG public keys. This is a one-time operation on each node where packages are installed. Importing the keys allows you to, optionally, verify the GPG and RPM signatures for the products. A verified GPG or RPM signature attests that the product you received has been signed with digital private keys held only by HPE. Successful signature verification also ensures that the file has not been altered after it was signed and released by HPE.

last-updated: Jun 06, 2024

For more information, see HPE GPG Public Keys for GPG or RPM Signature Verification.

Product Name Change: HPE Ezmeral Data Fabric – Customer Managed

With release 7.3.0, the user-managed version of the platform changed its name to HPE Ezmeral Data Fabric – Customer Managed. "HPE Ezmeral Data Fabric" now refers to the as-a-service version of the platform, described later on this page. Documentation for the customer-managed platform remains on the website you are currently using.

New SaaS-Based HPE Ezmeral Data Fabric

Release 7.3.0 introduced a new HPE Ezmeral Data Fabric that can be used "as-a-service" and provides consumption-based pricing. Documentation for the new platform has its own website. For more information, see:

HPE Ezmeral Data Fabric Documentation

The new as-a-service HPE Ezmeral Data Fabric leverages the strengths of its predecessor, the HPE Ezmeral Data Fabric – Customer Managed platform. The as-a-service platform improves on its predecessor in many ways. The following table compares the platforms:

Feature	HPE Ezmeral Data Fabric	HPE Ezmeral Data Fabric – Customer Managed
Distributed File System	Yes	Yes
Global Namespace (GNS)	Yes	No
Object Support	Yes	Yes
Table Support	Yes	Yes
Event Stream Support	Yes	Yes
NFSv4 Support*	Yes	Yes
Container Storage Interface (CSI) Support	Yes	Yes
Database Support	Yes	Yes
Client Support	Yes	Yes
Single Sign-On (SSO) Support	Yes	Yes
Platform Management	Managed by HPE	User managed
Billing and Licensing	Consumption-only and some form of term (term-only not supported)	Consumption and Term
Air-Gap Support	Yes	Yes
Graphical User Interface	Data Fabric UI or Control System	Data Fabric UI or Control System
`maprcli` Command Line	Yes	Yes
Scale (number of nodes per fabric / cluster)	See note **	Thousands of nodes
EEP (HPE Ezmeral Ecosystem Pack)	No	Yes
OpenTelemetry (OTel)	Yes	Yes

*NFSv3 is not supported.

**For cloud deployments, the nodes and instances are predetermined based on the storage tier that you select during installation. While new fabrics can be added at any time, adding nodes after fabric creation is

last-updated: Jun 06, 2024

not currently supported for cloud deployments. For on-premises deployments, you determine the number of nodes at create time. You can add nodes later by using the steps in Adding Nodes.

New Repository for Data Fabric Software

On August 1, 2023, Hewlett Packard Enterprise introduced a new download repository for the HPE Ezmeral Data Fabric core and ecosystem software packages. https://package.ezmeral.hpe.com/ is the new repository for HPE Ezmeral Data Fabric downloads. For all Data Fabric releases, https://package.ezmeral.hpe.com/ replaces two older repositories:

Description	URL	Authentication Required?
New repository	https://package.ezmeral.hpe.com/	Yes
Old repositories	https://package.mapr.com/ https://package.mapr.hpe.com	Yes[1]

[1]Beginning October 2023, the old repositories are redirected to the new repository URL, which requires authentication.

The new repository requires you to provide the email and token for your HPE Passport account. Software that points to the old repositories must be updated to include your HPE Passport email and token. For more information about using the new repository, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

If you plan to use the Data Fabric Installer, you must update the Installer to the most current 1.18.0.3 version or later. Earlier versions of the Installer will not work with the new repository. See Updating the Installer on page 5595.

HPE Ezmeral Ecosystem Pack (EEP) Support

Release 7.7.0 requires EEP 9.2.2 or later. EEP 9.2.2 is new for this release and delivers updates to various ecosystem components but no new components. EEP 9.2.2 can be used with releases:

- 7.7.0
- 7.6.1
- 7.5.0
- 7.4.0
- 7.3.0*
- 7.2.0*

*Requires a patch. See EEP Support and Lifecycle Status on page 5728.

For more information about new features delivered as part of the Ecosystem Pack, see What's New in EEP 9.2.2 on page 6120. For reference information, see EEP 9.2.2 Reference Information on page 6120.

For information about the EEPs that can be used with different versions of core releases, see EEP Support and Lifecycle Status on page 5728.

SSO Support for Keycloak

HPE Ezmeral Data Fabric release 7.7.0 supports SSO when configured with the Keycloak identity and access management (IAM) solution. Other IAM solutions are not currently supported.

Configuring SSO is optional. If you do not configure SSO, you must use Data Fabric user names and passwords for access to the fabric. While SSO is supported for Data Fabric core, it is not currently supported for ecosystem components or the Installer.

Beginning with release 7.5.0, Keycloak is preconfigured and preinstalled if you:

- Install the `mapr-keycloak` package as part of cluster creation
- Specify the `-keycloak` option when you run the configure.sh on page 2821 script

For more information, see Configuring SSO on page 1029.

Data Access Gateway 6.3 Support

For the gateway to lightweight client applications, release 7.7.0 requires Data Access Gateway 6.3. Data Access Gateway 6.3 can only be used with core 7.7.0, 7.6.1, 7.5.0, 7.4.0, 7.3.0, and 7.2.0 with some restrictions.

CAUTION: Streams users who upgrade from release 7.1.0 (DAG 5.0) or release 7.2.0 (DAG 5.1) to one of the following releases will not be able to access topics configured using the pre-DAG 6.0 mapping rules:

- 7.7.0 (DAG 6.3)
- 7.6.1 (DAG 6.2)
- 7.5.0 (DAG 6.2)
- 7.4.0 (DAG 6.1)
- 7.3.0 (DAG 6.0)

For more information, see Understanding the HPE Ezmeral Data Fabric Data Access Gateway on page 1024 and the Data Access Gateway 6.3 Release Notes on page 5839.

JDK 17 Support

As indicated in the Java Support Matrix on page 5764, release 7.7.0 can be used in JDK 11 or in JDK 17 installations. EEP 9.2.2 can also be used in JDK 11 or JDK 17 installations. However, the Installer is supported only on JDK 11, and if new cluster nodes require a JDK at installation time, the Installer can only install JDK 11.

Installation Notes (Release 7.7)

Describes considerations for installing release 7.7

Note these considerations for new installations of release 7.7, which can be installed using manual steps or by using the Installer:

Installer and the New Repository

Installer users on all releases should update to Installer 1.18.0.6. Installer 1.18.0.6 supports the new https://package.ezmeral.hpe.com/ repository described in What's New in Release 7.7 on page 30. Using the new repository requires an HPE Passport user name and token. When installing the `mapr-setup.sh` script for Installer 1.18.0.6, you can specify your Passport credentials. See Installer on page 5579 and Updating the Installer on page 5595.

Considerations for Using the Installer

Before using the Installer with release 7.7, review these considerations:

last-updated: Jun 06, 2024

- Only Installer 1.18.0.6 can be used to install release 7.7.0. For more info, see Installer Updates on page 5674.
- Installer 1.18.0.6 is not supported for use with JRE 17 or JDK 17 and will not install JDK 17.
- Installer 1.18.0.6 does not contain user interface controls for configuring IPv6. However, you can configure IPv6 support by passing the `config.ipv6_support=true` Stanza option.

  IMPORTANT: HPE Ezmeral Ecosystem Pack (EEP) components do not support IPv6.
- For releases 7.0.0 and later, Installer 1.18.0.6 enforces security by default. You cannot install a non-secure cluster by using Installer 1.18.0.6, though it is still possible to install a nonsecure cluster by using Stanzas.
- You can use Installer 1.18.0.6 to install Zeppelin, but the Installer does not configure Zeppelin. All configuration and integration tasks must be done manually. See Zeppelin on page 4736.
- The Installer is not FIPS compliant and is not supported to run on a FIPS-enabled node. However, you can use the Installer to install a FIPS-compliant cluster. To do this, the Installer node must be installed on a non-FIPS node, and the cluster to be installed cannot include the Installer node as part of the cluster.
- You can use Installer 1.18.0.6 to install a FIPS-enabled cluster only if all the nodes to be installed are FIPS-enabled. Using the Installer to install a mix of FIPS-enabled and non-FIPS-enabled nodes is not supported.
- For a list of the operating systems that support Installer 1.18.0.6, see Installer Support Matrix on page 5770.
- For a list of known issues that affect Installer 1.18.0.6 and other Installer versions, see Installer Known Issues on page 5641.

EEP 9.2.2 and Release 7.7.0

EEP 9.2.2 can be used with releases 7.7.0, 7.6.1, 7.5.0, 7.4.0, 7.3.0 (with a patch), and 7.2.0 (with a patch). For more information about EEP compatibility, see EEP Support and Lifecycle Status on page 5728 and What's New in EEP 9.2.2 on page 6120.

32-GB Minimum Memory for Production Nodes

Minimum memory requirements for production nodes have changed. Production nodes require at least 32 GB of memory per node. For more information, see Memory and Disk Space on page 168.

Ubuntu 22.04 Dependency

Release 7.7.0 of the HPE Ezmeral Data Fabric has a dependency on the `libssl1.1` package, which is not included in Ubuntu 22.04. As a result, you must apply the package manually to Ubuntu 22.04 nodes before installing Data Fabric software.

NOTE: The following steps are required for cluster nodes but are not required for client nodes.

1. Download the `libssl1.1` package:

```
wget http://archive.ubuntu.com/ubuntu/pool/main/o/openssl/
libssl1.1_1.1.0g-2ubuntu4_amd64.deb
```

last-updated: Jun 06, 2024

2. Use the following command to install the package:

```
sudo dpkg -i libssl1.1_1.1.0g-2ubuntu4_amd64.deb
```

Installing Ranger by Using the Installer

Installer 1.18.0.6 cannot perform all of the installation tasks needed to install and configure Ranger. Some configuration steps must be completed manually after using the Installer. See Installing Ranger Using the Installer on page 5617.

Installing Tez by Using the Installer

In EEPs 9.0.0 and later, the Installer can install Tez, but the Tez user interface (UI) will not work because EEPs 9.0.0 and later include the YARN Application Timeline Service (ATS) version 2 by default. ATSv2 does not support the Tez UI. However, you can configure ATS version 1.0 or 1.5 to work with Hadoop 3, thereby enabling Tez. To enable the Tez UI, follow the steps in Configuring ATS 1.0 or 1.5 for Hadoop 3.3 on page 4731.

Installing the YARN ATS by Using the Installer

The Installer **Select Services** page does not provide a dedicated option for selecting and installing the YARN ATS (`mapr-timelineserver`). To install the ATS, you must install Tez. Because the `mapr-timelineserver` has a dependency on HBase, installing Tez by using the Installer automatically installs `mapr-hbase` and the `mapr-timelineserver`.

Monitoring Components Support for FIPS

The Spyglass logging components (Elasticsearch, Fluentd, and Kibana) are NOT supported in FIPs mode. Spyglass metrics components (Collectd, Open TSDB, and Grafana) work in FIPS mode even through Grafana is written in Go and is not FIPS compliant.

Licensing Changes for FIPS

To support FIPS clusters, the license file now contains two identical licenses. One is signed with a SHA-1 signature for non-FIPS clusters. The other is signed with a SHA256 signature for FIPS clusters. This enables MCS or maprcli commands to verify the signature regardless of support for FIPS compliance. User-visible changes are minimal, since MCS and the `maprcli license list` command show only the license that is currently applied.

Installing HttpFS

Beginning with release 7.1.0 and EEP 9.0.0, HttpFS is included with Hadoop and YARN. To install HttpFS, see Installing Hadoop and YARN on page 241.

Manual Installations and FIPS

There are no changes to the procedure for manual package installation. The steps are the same as described in Installing without the Installer on page 179.

Installers continue to use the `${MAPR_HOME}/server/configure.sh` script to configure both FIPS and non-FIPS nodes after the data-fabric packages are successfully installed. There are no customer-visible changes to the existing manual setup procedure to enable FIPS mode using the `${MAPR_HOME}/server/configure.sh` script:

- FIPS mode is automatically enabled only if the local operating system is FIPS enabled. The `configure.sh` script uses the `sysctl crypto.fips_enabled` command to detect if the operating system is in FIPS mode.

- FIPS mode implies secure mode as well. Thus, on a FIPS enabled node, `-secure` is the default, whereas in a regular, non-FIPS enabled node, `-unsecure` is the default for releases 7.2.0 and earlier.
- If the local operating system is not FIPS-enabled, the `configure.sh` script proceeds to perform regular, non-FIPS configuration.

Other than the change in the default `-secure` setting, system configuration for a machine running a FIPS enabled operating system looks the same as that on a regular machine running an operating system that is not FIPS-enabled.

It is important to note that nonsecure algorithms such as MD-5 and DES are disabled in FIPS. Therefore, legacy applications that use these algorithms will no longer run on FIPS-enabled nodes. So, while FIPS adds additional security, it also causes nonsecure legacy applications to fail unless they are upgraded. This is an important distinction between FIPS and non-FIPS mode.

Log Monitoring and FIPS

Log monitoring is not supported in installations with FIPS-enabled nodes in EEPs 8.1.0 and later.

Upgrade Notes (Release 7.7)

Describes the high-level steps and considerations for upgrading to release 7.7.0.

Upgrading to Release 7.7.0 (High-Level Steps)

Depending on your current Data Fabric release, upgrading to release 7.7.0 can require different combinations of procedures. Upgrading to release 7.7.0 can require an OS upgrade and requires a JDK upgrade if your cluster is running release 6.1.x or earlier. The following table summarizes the high-level upgrade steps. Before beginning the upgrade, be sure to review the upgrade considerations later on this page.

If your cluster is running one of these releases	Use these steps to upgrade to release 7.7.0	See for more information
7.6.1 7.5.0 7.4.0 7.3.0 7.2.0 7.1.0 7.0.0 6.2.0 6.1.1 6.1.0	**1.** Upgrade your OS to an OS that is supported by your current release and release 7.7.0. For example: • RHEL 8.2, 8.4, 8.6*, or 8.8 • Ubuntu 18.04, or 20.04** • SLES 15 SP2 or SP3 You can skip the OS upgrade if the Operating System Support Matrix on page 5719 shows that your current OS is supported on release 7.7.0. **2.** Install Java JDK 11 or JDK 17 or the equivalent. **3.** Upgrade from your current release to release 7.7.0 using one of the upgrade workflows. **4.** Upgrade your EEP components after upgrading core, as indicated in the workflow.	• Upgrading Ecosystem Packs on page 346 • Java on page 172 • Java Support Matrix on page 5764 • Upgrading Your Linux Operating System on page 314 • Operating System Support Matrix on page 5719 • Upgrade Workflows (Releases 6.x or 7.x to 7.7.0) on page 301

*Release 7.7.0 can be used with odd-numbered RHEL releases 8.1, 8.3, and 8.5, but Red Hat recommends upgrading from RHEL 7.x to even-numbered RHEL releases. For more information, see this article.

last-updated: Jun 06, 2024

**See the upgrade consideration for Ubuntu later on this page.

Professional Support for Upgrades
Upgrading can be time-consuming and complicated. Consider engaging HPE professional support services to assist in planning and executing your upgrade. For more information, contact your support representative. See Contact HPE on page 6283.

Release 7.7.0 Requires EEP 9.2.2

Release 7.7.0 requires EEP 9.2.2 or later. For more information about these EEPs, see What's New in EEP 9.2.2 on page 6120 and EEP 9.2.2 Reference Information on page 6120.

Upgrades to RHEL 9 and Ubuntu 22.04

Release 7.7.0 can be installed on nodes running RHEL 9 and Ubuntu 22.04, but upgrading an older Data Fabric release to release 7.7.0 on RHEL 9 or Ubuntu 22.04 is currently not supported.

Upgrades Using the Installer

Note these considerations for using the Installer to upgrade to release 7.7.0:

- Only Installer 1.18.0.6 can be used to upgrade to release 7.7.0. For more info, see Installer Updates on page 5674.
- Installer 1.18.0.6 only supports core upgrades from the following releases to release 7.7.0:
  - 7.6.1
  - 7.5.0
  - 7.4.0
  - 7.3.0
  - 7.2.0
  - 7.1.0

  Other core upgrades must be performed using manual steps. See Upgrading Core With the Installer on page 320 and Upgrading the Ecosystem Pack Without the Installer on page 366. All EEP upgrades are supported.
- Installer 1.18.0.6 is not supported for use with JRE 17 or JDK 17 and will not install JDK 17.
- Installer 1.18.0.6 cannot be used with older versions of Ubuntu. For more information, see Installer Updates on page 5674 and Selecting an Installer Version to Use on page 5587.
- For releases 7.0.0 and later, Installer 1.18.0.6 enforces security by default. You cannot install a non-secure cluster by using Installer 1.18.0.6, though it is still possible to install a nonsecure cluster by using Stanzas.
- You cannot use Installer 1.18.0.6 to install Zeppelin. You must install Zeppelin by using the manual steps. See Installing Zeppelin on page 270.
- The Installer is not FIPS compliant and is not supported to run on a FIPS-enabled node. However, you can use the Installer to install a FIPS-compliant cluster. To do this, the Installer node must be installed on a non-FIPS node, and the cluster to be installed cannot include the Installer node as part of the cluster.

- You can use Installer 1.18.0.6 to install a FIPS-enabled cluster only if all the nodes to be installed are FIPS-enabled. Using the Installer to install a mix of FIPS-enabled and non-FIPS-enabled nodes is not supported.
- For a list of the operating systems that support Installer 1.18.0.6, see Installer Support Matrix on page 5770.
- For a list of known issues that affect Installer 1.18.0.6 and other Installer versions, see Installer Known Issues on page 5641.

Online Versus Offline Upgrades

You can upgrade core software using a "rolling upgrade" process that transitions the cluster to release 7.7.0 one node at a time. Except for the node being upgraded, the cluster remains online during this process.

IMPORTANT: You cannot upgrade EEP components using an online or "rolling upgrade" process. EEP upgrades are always an offline process.

If you are upgrading from one of the following releases to 7.7.0, EEP 9.2.2 can be used as a bridging EEP:

- 7.6.1
- 7.5.0
- 7.4.0
- 7.3.0
- 7.2.0

A bridging EEP is an EEP that is supported on both the release you are currently running and the release to which you want to upgrade. EEP 9.2.2 can be installed on releases 7.2.0 through 7.7.0.

EEP Support and Lifecycle Status on page 5728 shows the EEPs that are supported for each core version.

If you are upgrading from release 6.1.x, 6.2.0, 7.0.0, or 7.1.0 to release 7.7.0, no bridging EEP is available. However, you can upgrade core directly to release 7.7.0. You do not need to upgrade to another release first.

CAUTION: Before upgrading directly from release 6.1.x or later to 7.7.0, be sure to review the COMSECURE-615 known issue in Known Issues (Release 7.7) on page 44.

Data Access Gateway 6.x and Streams Upgrade Consideration

For the gateway to lightweight client applications, release 7.7.0 requires Data Access Gateway 6.3. Data Access Gateway 6.3 can only be used with core 7.7.0, 7.6.1, 7.5.0, 7.4.0, 7.3.0, and 7.2.0 with some restrictions.

last-updated: Jun 06, 2024

CAUTION: Streams users who upgrade from release 7.1.0 (DAG 5.0) or release 7.2.0 (DAG 5.1) to any of the following releases will not be able to access topics configured using the pre-DAG 6.0 mapping rules:

- Release 7.7.0 (DAG 6.3)
- Release 7.6.1 (DAG 6.2)
- Release 7.5.0 (DAG 6.2)
- Release 7.4.0 (DAG 6.1)
- Release 7.3.0 (DAG 6.0)

For more information, see Understanding the HPE Ezmeral Data Fabric Data Access Gateway on page 1024 and the Data Access Gateway 6.2 Release Notes on page 5840.

32-GB Minimum Memory for Production Nodes

Minimum memory requirements for production nodes have changed. Production nodes require at least 32 GB of memory per node. For more information, see Memory and Disk Space on page 168.

Upgrading the Object Store

Upgrades from release 7.0.0 to 7.1.0 or later remove the Object Store configuration files in `/opt/mapr/conf`. This can prevent the Object Store from starting after the upgrade. To address this issue, the following upgrade pages instruct you to make a copy of certain files before upgrading and then restore the files to all nodes running the MOSS server after the upgrade:

- Preparing to Upgrade Core on page 315
- Installing Additional Core Features on page 345

Upgrades to CentOS Not Supported

Release 7.7.0 is not supported for use with CentOS. CentOS Linux 8 has reached End of Life (EOL) status. For more information, see this page.

Upgrades From Non-FIPS Mode to FIPS Mode Not Supported

Only new installations of FIPS clusters are currently supported. You cannot use the Installer or manual steps to upgrade a non-FIPS-compliant cluster to a FIPS-compliant cluster.

Upgrading from Ubuntu 16.0.4 to Release 7.7.0

Upgrading from Ubuntu 16.04 to release 7.7.0 requires a slightly different set of upgrade steps because:

- Release 7.7.0 cannot be used with Ubuntu 16.04.
- EEP 8.0.0 and later are not supported on Ubuntu 16.04.
- Installer 1.17.0.0 and later cannot be used with Ubuntu 16.04.

To perform the upgrade:

1. Upgrade your OS to Ubuntu 18.04 or 20.04. See Upgrading Your Linux Operating System on page 314.
2. If you are using the Installer, update it to the latest version. See Updating the Installer on page 5595.

3. Upgrade to EEP 9.2.2 and release 7.7.0 using the preceding high-level steps.

Note that even though Release 7.7.0 can be installed on nodes running Ubuntu 22.04, upgrading an older Data Fabric release to release 7.7.0 on Ubuntu 22.04 is currently not supported.

For a list of the operating systems on which you can install different versions of core, see Operating System Support Matrix on page 5719.

SLES Upgrades Require the Option to Address a Package Vendor Change

In releases 7.0.0 and later, the vendor for core packages changed to "Hewlett Packard Enterprise." In earlier releases, the vendor was "MapR Technologies Inc." This change can affect SLES upgrades.

For a manual upgrade from release 6.2.0 to releases 7.0.0 or later on SLES SP2, the `zypper update` command can fail because of a vendor mismatch in the RPM provider. Zypper returns an error saying that the vendor for the package you are trying to upgrade has changed.

To avoid this error, add the `--allow-vendor-change` option to the `zypper update` command. For an example, see Offline and Manual Upgrade Procedure on page 325.

Upgrades and Clear-Text Passwords

Upgrades from releases 6.1.x or 6.2.0 to releases 7.1.0 and later leave the clear-text passwords in the `ssl-server.xml` and `ssl-client.xml` configuration files unchanged. However, after applications are tested and the upgrade is known to be successful, the cluster administrator can remove the clear-text passwords. For more information, see Removing Clear-Text Passwords After Upgrade on page 1815.

`configure.sh -R` Behavior in Release 7.0.0 or Later

The following changes to `configure.sh -R` behavior occur when you upgrade from a release earlier than 7.0.0 to releases 7.0.0 or later:

- `mrhsm` configuration files are automatically upgraded to support the new PKCS#11 file-store feature.
- If the legacy `cldb.key` and/or `dare.master.key` exist in the `${MAPR_HOME}/conf/` directory, software automatically enables the PKCS#11 file store and imports these keys into the `${MAPR_HOME}/conf/tokens` directory. Since, these legacy keys are no longer needed, it is a best practice to move them to a safe place to increase security. It is optional to copy over the `${MAPR_HOME}/conf/tokens` to other nodes, as every occurrence imports the same keys during an upgrade:
  - By default, data-fabric software initializes `mrhsm` using the same default hsm label and so pin as when you do a new release 7.0.0 installation if `mrhsm` has not already been initialized. You can change these default values by specifying `-hsmlabel <label> -hsmsopin <so-pin>` options.
  - If `mrhsm` has already been initialized to use KMIP, you need to specify the `-hsmsopin <so-pin>` option to enable the file store correctly.

Hadoop and YARN Are Provided as Ecosystem Components

Beginning with core 6.2.0 and EEP 7.0.0, Hadoop and YARN services are no longer included in the repository for core packages. They are provided as ecosystem components in the EEP repository. If you are upgrading and need Hadoop and YARN services, you must install the packages as ecosystem components after upgrading. For more information, see Installing Hadoop and YARN on page 241.

Regenerating the mapruserticket File

Changes to the `CanImpersonate` parameter of the `mapruserticket` file in release 6.1.0 require users who upgrade manually to regenerate the file before restarting Warden. See Step 1: Restart and Check Cluster Services on page 333.

The file needs to be regenerated to ensure that impersonation works correctly for non-`mapr` users. Prior to release 6.1.0, all `mapruserticket` files were generated with `CanImpersonate = false`. Releases 6.1.0 and later enforce the `CanImpersonate` parameter and set the parameter to `true` for freshly installed clusters. For upgraded clusters, if `CanImpersonate` is not set to `true`, some services will not be able to impersonate.

Operational Changes (Release 7.7)

Lists the functional changes made to existing commands in HPE Ezmeral Data Fabric release 7.7.0.

New Key for Signature Verification for Data Fabric Files

Release 7.6.1 implemented a new key for `.rpm`, `.tar.gz`, `.zip`, and `.tgz` files for the following Data Fabric products:

- HPE Ezmeral Data Fabric core 7.6.1 and later
- HPE Ezmeral Data Fabric clients
- HPE Ezmeral Ecosystem Pack (EEP) 9.2.1 and later
- Installer 1.18.0.5 and later

Before you install these products, you must import the HPE GPG public keys. This is a one-time operation on each node where packages are installed. Importing the keys allows you to, optionally, verify the GPG and RPM signatures for the products. A verified GPG or RPM signature attests that the product you received has been signed with digital private keys held only by HPE. Successful signature verification also ensures that the file has not been altered after it was signed and released by HPE.

For more information, see HPE GPG Public Keys for GPG or RPM Signature Verification.

Repository Changes

Recent changes to the download repository for HPE Ezmeral Data Fabric core and ecosystem packages might affect your ability to install or upgrade software. For more inforrmation, see What's New in Release 7.7 on page 30.

32-GB Minimum Memory Requirement for Production Nodes

Minimum memory requirements for production nodes changed for releases 7.0.0 and later. Production nodes require at least 32 GB of memory per node. For more information, see Memory and Disk Space on page 168.

Nonsecure Configurations

Beginning with release 7.3.0, the configure.sh on page 2821 script no longer supports the `-unsecure` parameter. By default, `configure.sh` implements the `-S` or `-secure` parameter even if the parameter is not specified.

This change builds on security enhancements introduced in earlier releases. Releases 7.0.0 and later installations are secure by default. Also, Installer 1.18 automatically configures a secure cluster and does not provide an option to configure a non-secure cluster. Nonsecure installations have not been validated for use with releases 7.0.0 or later.

Using Custom Certificates with Object Store

Default installations of the HPE Ezmeral Data Fabric use encrypted, self-signed certificates to enable SSL communication. If your environment does not permit self-signed certificates, or if you prefer to generate your own certificates rather than use the default certificates, Data Fabric supports an option to generate your own certificates. See Using Custom Signed Certificates with Object Store on page 589.

Key Store and Trust Store Changes in Release 7.0.0 and Later

Releases 7.0.0 and later support FIPS installations, adding new security files and subdirectories. For Java applications, release 7.0.0 added the Bouncy Castle BCFKS key and trust stores. For non-Java applications, the existing PKCS#12 key and trust stores, as well as PEM files are used. Because of the security changes, the list of files that you must copy to enable security on all nodes is longer. For more information, see these topics:

- Security Files and Subdirectories on page 882
- Enabling Security on page 1776
- Understanding the Key Store and Trust Store Files on page 1793

Changes to Cross-Cluster Configuration

Note these operational changes:

- Running `configure-crosscluster.sh` in releases 7.0.0 and later requires you to specify two additional parameters:
  - `localtruststorepassword`
  - `remotetruststorepassword`
- The `configure-crosscluster.sh` script now returns an error if it is run by a user other than the cluster owner. For example, you cannot run the script as the `root` user.
- In releases 7.0.0 and later, cross-cluster configuration using the basic `configure-cross.cluster.sh` script options is supported if nodes in the local and remote clusters are either all non-FIPS nodes or all FIPS nodes. See Configuring Cross-Cluster Security for a Mixed (FIPS and Non-FIPS) Configuration on page 1958 for the manual steps to configure mixed clusters consisting of FIPS and non-FIPS nodes using the `-localhosts` and `-remotehosts` options.

For more information, see configure-crosscluster.sh on page 2835.

About ssl-server.xml and ssl-client.xml in Releases 7.0.0 and Later

The Hadoop configuration files (`ssl-server.xml` and `ssl-client.xml`) contain SSL configuration information for the client and server in XML format. This section describes some changes in the use of these files in releases 7.0.0 and later.

Clear-Text Passwords Are Removed from ssl-server.xml and ssl-client.xml

In release 6.2.0 and earlier releases of the HPE Ezmeral Data Fabric, key and trust store passwords are stored in clear text in the `ssl-server.xml` and `ssl-client.xml` configuration files, and the passwords are the same for both key and trust stores.

Beginning with release 7.0.0, clear-text passwords are removed from the Hadoop `ssl-server.xml` and `ssl-client.xml` configuration files. And distinct passwords are generated – one for the key store and one for the trust store. See Key and Trust Store Password Protection on page 1809.

For Java applications, key and trust store passwords are now protected in credential stores accessible through the Hadoop Credential Provider API. For non-Java applications key store passwords are stored in

`maprkeycreds.conf`, and trust store passwords are stored in `maprtrustcreds.conf`. See Application Development with Encrypted Key and Trust Stores on page 1823.

For information about what happens to the clear-text passwords during an upgrade, see the Upgrade Notes (Release 7.7) on page 37 and Removing Clear-Text Passwords After Upgrade on page 1815.

Do Not Copy These Files When FIPS-Enabled Nodes Are Present

In a cluster with FIPS-enabled nodes, the following files must not be copied to other nodes during security configuration:

- `ssl-client.xml`
- `ssl-server.xml`
- `ssl_keystore` (symlink)
- `ssl_truststore` (symlink)
- `ssl_userkeystore` (symlink)
- `ssl_usertruststore` (symlink)

In releases 7.0.0 and later, it is a best practice to avoid copying the `ssl-client.xml` and `ssl-server.xml` files regardless of the FIPS configuration. In particular, when adding a non-FIPS node to a FIPS cluster, you must not copy the Hadoop `ssl*.xml` files to the other nodes in the cluster. To determine whether a node is FIPS enabled, `manageSSLKeys.sh` reads the trust store type from `ssl-client.xml` when running in standalone mode instead of indirectly through `configure.sh`. Copying the Hadoop `ssl*.xml` files that are set to the BCFKS store type from a FIPS to a non-FIPS node then causes commands such as `manageSSLKeys.sh convert` to fail.

In a FIPS-enabled node, symlink files are provided for the `.bcfks` versions of the key store, user keystore, truststore, and user trust store. These files must not be copied. Copying the files can result in errors later when you run `configure.sh`.

For more information about the files to copy when you enable security, see Enabling Security on page 1776.

Known Issues (Release 7.7)

You might encounter the following known issues after upgrading to release 7.7. This list is current as of the release date.

IMPORTANT: The "Support notices of known issues" tool is no longer available, but you can obtain the same information by logging on to the HPE Support Center. See Support Articles in the HPE Support Center on page 6197.

Where available, the workaround for an issue is also documented. HPE regularly releases maintenance releases and patches to fix issues. We recommend checking the release notes for any subsequent maintenance releases to see if one or more of these issues are fixed.

Client Libraries

MFS-18249	The FUSE-based POSIX client remains in a dead/inactive state when the ticket expires. **Workaround:** To generate a new ticket, manually update the JWT access and refresh tokens.
MFS-18258	When you add a new cluster to a cluster group, the FUSE-based POSIX client and the loopbacknfs POSIX client take about five mintues to load or list the newly added cluster.

Workaround: None.

Data Fabric UI

Sign-in Issues

DFUI-160

If you sign in to the Data Fabric UI as an SSO user but you do not have fabric-level login permission, a sign-in page for the "Managed Control System" (MCS) is displayed. The "Managed Control System" sign-in is not usable for the consumption-based HPE Ezmeral Data Fabric.

Workaround: Use one of the following workarounds:

- Edit the MCS URL, and retry logging in. For example, change the boldface characters in the following URL:

  ```
  https;//
  <host-name>:8443/app/mcs/#/app/
  overview
  ```

  To this:

  ```
  https;//<host-name>:8443/app/dfui
  ```

- Try signing in as a user who has fabric-level login permission.
- Dismiss the MCS page, clear your browser cache, and retry signing in.

DFUI-437

If you sign in to the Data Fabric UI as a non-SSO user and then sign out and try to sign in as an SSO user, a sign-in page for the "Managed Control System" (MCS) is displayed. The "Managed Control System" sign-in is not usable for the consumption-based HPE Ezmeral Data Fabric.

Workaround: Use one of the following workarounds:

- Edit the MCS URL, and retry logging in. For example, change the boldface characters in the following URL:

  ```
  https;//
  <host-name>:8443/app/mcs/#/app/
  overview
  ```

  To this:

  ```
  https;//<host-name>:8443/app/dfui
  ```

- Dismiss the "Managed Control System" sign-in screen, and retry signing in as a non-SSO user.
- Dismiss the MCS page, clear your browser cache, and retry signing in.

DFUI-811

If you launch the Data Fabric UI and then sign out and wait for 5-10 minutes and then attempt to sign in, a

	sign-in page for the "Managed Control System" (MCS) is displayed. **Workaround:** See the workaround for DFUI-437.
DFUI-826	In a cloud fabric, an empty page is displayed after a session expires and you subsequently click on a fabric name. The browser can display the following URL: `https://<hostname>:8443/oath/login` **Workaround:** None.
DFUI-874	Sometimes when you attempt to sign in to the Data Fabric UI, the "Managed Control System" (MCS) is displayed, or the Object Store UI is displayed. **Workaround:** See the workaround for DFUI-437.
DFUI-897	A user with no assigned role cannot sign in to the Data Fabric UI. **Workaround:** Using your SSO provider software, assign a role to the user, and retry the sign-in operation.
DFUI-902	Incorrect resource data is displayed when an LDAP user signs in to the Data Fabric UI without any SSO roles. **Workaround:** See the workaround for DFUI-897
DFUI-1123	Attempting to sign in to the Data Fabric UI as a group results in a login error message in the browser. For example: `https://<hostname>:8443/login?error` **Workaround:** None.
DFUI-1135	The Data Fabric UI does not allow an SSO user to log in after an unsuccessful login attempt. **Workaround:** None.

Mirroring Issues

DFUI-1227	If you create a mirror volume with a security policy, an error is generated when you try to remove the security policy. **Workaround:** None.
DFUI-1229	Data aces on a mirror volume cannot be edited. **Workaround:** None.

Display Issues

DFUI-1186	After you complete the SSO setup for a new fabric, fabric resources such as volumes and mirrors are not immediately displayed in the Data Fabric UI. **Workaround:** Wait at least 20 minutes or more for the Data Fabric UI to display the fabric details.
DFUI-1221	If a fabric includes a large number of resources, loading the resources to display in the **Resources** card on the home page can take a long time. **Workaround:** None.

last-updated: Jun 06, 2024

DFUI-2102	When you create a table replica on a primary cluster with the source table on a secondary cluster, the replication operation times out. However, the table replica is successfully created on the primary cluster. The table replica appears in the **Replication** tab, but does not appear in the Data Fabric UI **Graph** or **Table** view for the primary cluster. This behavior is the same for both a source table on the primary cluster and the replica on the secondary cluster. **Workaround:** None.
DFUI-2099	When you delete a table replica from the Data Fabric UI **Home** page, the table replica remains listed in the **Replication** tab. When you select the table on the **Replication** tab, a message returns stating that the requested file does not exist. **Workaround:** None.
DFUI-2515	On a fabric with hundreds of resources (volumes, buckets, topics, tables), loading resources into the resource table can take a long time. During resource loading, the resource table might display a blank page or partial information. Also, browser and DFUI controls might be unresponsive. **Workaround:** None.

External S3

DFUI-2157	Editing buckets on external S3 servers is not supported. **Workaround:** None.
MFS-18893	s3cmd cp throws error while copy large or jumbo object from Data Fabric to external S3 buckets or across external S3 buckets, even if object is copied successfully . **Workaround:** None.
MFS-18905	The copy object operation fails intermittently when copying an object by using AWS CLI across S3 buckets on various cloud providers to Data Fabric and vice-versa. **Workaround:** None.

Installation or Fabric Creation

EZINDFAAS-819	Release 7.7.0 added support for the following new Asia Pacific regions for AWS fabrics: • Hyderabad • Mumbai • Sydney • Singapore • Melbourne

last-updated: Jun 06, 2024

However, you cannot deploy an AWS fabric in the Melbourne region because the default instance type (m6i.4xlarge) is not available in that region.

Workaround: If possible, deploy the AWS fabric in a different region.

MFS-18734

Release 7.7.0 of the HPE Ezmeral Data Fabric has a dependency on the `libssl1.1` package, which is not included in Ubuntu 22.04. As a result, you must apply the package manually to Ubuntu 22.04 nodes before installing Data Fabric software.

Workaround: On every node in the fabric or cluster:

NOTE: The following steps are required for cluster nodes but are not required for client nodes.

1. Download the `libssl1.1` package:

```
wget http://archive.ubuntu.com/
ubuntu/pool/main/o/openssl/
libssl1.1_1.1.0g-2ubuntu4_amd64.deb
```

2. Use the following command to install the package:

```
sudo dpkg -i
libssl1.1_1.1.0g-2ubuntu4_amd64.deb
```

MFS-18437

Fabric creation can fail if host-name resolution takes more than 200 ms.

Workaround: Check your host-name resolution time, and take steps to improve it. See Troubleshooting Seed Node Installation. Then retry fabric deployment.

DFUI-565, EZINDFAAS-169

Installation or fabric creation can fail if a proxy is used for internet traffic with the HPE Ezmeral Data Fabric.

Workaround: Export the following proxy settings, and retry the operation:

```
# cat /etc/environment
export http_proxy=http://
<proxy_server_hostname_or_IP>:<proxy_p
ort>
export https_proxy=http://
<proxy_server_hostname_or_IP>:<proxy_p
ort>
export HTTP_PROXY=http://
<proxy_server_hostname_or_IP>:<proxy_p
ort>
export HTTPS_PROXY=http://
<proxy_server_hostname_or_IP>:<proxy_p
ort>
```

last-updated: Jun 06, 2024

NFSv4

MFS-18264

Attempts to mount the NFS4 server fail and return the following error:

```
Mount.nfs4: Stale file handle
```

Workaround:

1. Update the EXPORT section of `/opt/mapr/conf/nfs4server.conf` as follows:

```
EXPORT
{
  # Export Id (mandatory,
each EXPORT must have a unique
Export_Id)
  Export_Id = 30;

  # Exported path (mandatory)
  Path = /mapr/clustername; <--
here instead of mapr please use /
mapr/clustername

  # Pseudo Path (required for NFS
v4)
  Pseudo = /mapr;

  Squash = No_Root_Squash;

  # Required for access (default
is None)
  # Could use CLIENT blocks instead
  Access_Type = RW;

  # Security type
(krb5,krb5i,krb5p)
  SecType = sys;

  # Exporting FSAL
  FSAL {
    Name = MAPR;
  }

  #SuperUser_Uid = 0;
}
```

   For more information about the `/opt/mapr/conf/nfs4server.conf` file, see Configuring NFSv4 Server.

2. Restart the NFSv4 server:

```
maprcli node services -nodes <node
names> -nfs4 restart
```

   For more information about starting or restarting NFSv4, see Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4.

last-updated: Jun 06, 2024

Object Store

MFS-17233

On cloud (AWS, Azure, or GCP) fabrics, if an instance is rebooted, the public IP addresses can change. If this happens, the MOSS certificates must be regenerated to include the new IP addresses, and the changes must be propagated to all fabric nodes.

Workaround: To regenerate the MOSS certificates:

1. Identify the new external IP address for each cloud instance.
2. On each cloud instance:
   a. Log on as a `sudo` user.
   b. Update the certificate using the following `manageSSLKeys.sh` command:

```
/opt/mapr/server/
manageSSLKeys.sh
createusercert -u
moss -ug mapr:mapr -k
<ssl_keystore_password> -p
<ssl_truststore_password> -ips
"<new external ip
of the instance>" -a moss -w
```

   c. Restart the MOSS service:

```
maprcli node services -nodes
'hostname -f' -name
s3server -action restart -json
```

NOTE: You can obtain the `ssl_keystore_password` and `ssl_truststore_password` from the node where the `configure.sh -secure -genkeys` command was issued. In the `/opt/mapr/conf/store-passwords.txt` file, the passwords are listed under keys as `ssl.server.keystore.keypassword` and `ssl.server.truststore.password`.

Use the following commands to ensure correct file ownership:

```
chown mapr:mapr /opt/mapr/
conf/ssl_usertruststore.p12
chmod 0444 /opt/mapr/conf/
ssl_usertruststore.p12"
chown mapr:mapr /opt/mapr/
conf/ssl_userkeystore.p12
chmod 0400 /opt/mapr/conf/
ssl_userkeystore.p12"
```

DFUI-519

An SSO user is unable to create buckets on the Data Fabric UI and the Object Store. This is applicable

	to an SSO user with any role such as infrastructure administrator, fabric manager or developer. **Workaround:** Create an IAM policy with all permissions in the user account. This has to be done via minIO client or the Object Store UI. Assign the IAM policy to the SSO user. Login to the Data Fabric UI and create a bucket/view bucket.
DFUI-577	Downloading a large file (1 GB or larger) can fail with the following error: `Unable to download file "<filename>": Request failed with status code 500` **Workaround:** Instead of using the Data Fabric UI to download a large file, use a MinIO Client (mc) command. For more information about mc commands, see MinIO Client (mc) Commands.
MFS-18250	The S3 server crashes when you copy a jumbo object (object size>256 MB) from one bucket to another bucket across fabrics using aws s3 cli. **Workaround:** Set the 'max_concurrent_requests' parameter value to 1 on the AWS configuration file.

Online Help

DFUI-459	If a proxy is used for internet traffic with the HPE Ezmeral Data Fabric, online help screens can time out or fail to fetch help content. **Workaround:** Add the following proxy servers to the `/opt/mapr/apiserver/conf/properties.cfg` file: • `http.proxy=<proxyServer>:<proxyPort>` • `https.proxy=<proxyServer>:<proxyPort>`

Security Policies

MFS-18154	A security policy created on a cloud-based primary fabric (such as AWS) is not replicated on to a secondary fabric created on another cloud provider (such as GCP). **Workaround:** None.

Topics

DFUI-637	Non-LDAP SSO user authenticating to Keycloak cannot create topic on the Data Fabric UI. **Workaround:** None.
DFUI-639	A non-LDAP SSO user authenticating to Keycloak cannot create a volume or stream using the Data Fabric UI. **Workaround:** None. Non-LDAP and SSO local users are not currently supported.

last-updated: Jun 06, 2024

Upgrade

COMSECURE-615

Upgrading directly from release 6.1.x to release 7.x.x can fail because the upgrade process reads password information from the default Hadoop `ssl-server.xml` and `ssl-client.xml` files rather than the original `.xml` files. Note that upgrades from release 6.2.0 to 7.x.x are not affected by this issue.

The issue does not occur, and the upgrade succeeds, if either of the following conditions is true:

- The existing password is `mapr123` (the default value) when the EEP upgrade is initiated.
- You upgrade the cluster first to release 6.2.0 and then subsequently to release 7.x.x.

Understanding the Upgrade Process and Workaround: The workaround in this section modifies the release 6.1.x-to-7.x.x upgrade so that it works like the 6.2.0-to-7.x.x upgrade.

Upgrading to core 7.x.x requires installing the `mapr-hadoop-util` package. Before the upgrade, Hadoop files are stored in a subdirectory such as `hadoop-2.7.0`. Installation of the `mapr-hadoop-util` package:

- Creates a subdirectory to preserve the original `.xml` files. This subdirectory has the same name as the original Hadoop directory and a timestamp suffix (for example, `hadoop-2.7.0.20210324131839.GA`).
- Creates a subdirectory for the new Hadoop version (`hadoop-2.7.6`).
- Deletes the original `hadoop-2.7.0` directory.

During the upgrade, a special file called `/opt/mapr/hadoop/prior_hadoop_dir` needs to be created to store the location of the prior Hadoop directory. The `configure.sh` script uses this location to copy the `ssl-server.xml` and `ssl-client.xml` files to the new `hadoop-2.7.6` subdirectory.

In a release 6.1.x-to-7.x.x upgrade, the `prior_hadoop_dir` file does not get created, and `configure.sh` uses the default `ssl-server.xml` and `ssl-client.xml` files provided with Hadoop 2.7.6. In this scenario, any customization in the original `.xml` files is not applied.

The following workaround restores the missing `prior_hadoop_dir` file. With the file restored, `configure.sh -R` consumes the `prior_hadoop_dir` file and copies the the original `ssl-server.xml` and `ssl-client.xml` files into the `hadoop-2.7.6` directory, replacing the files that contain the default `mapr123` password.

Workaround: After upgrading the ecosystem packages, *but before running* `configure.sh -R`:

last-updated: Jun 06, 2024

1. Create a file named `prior_hadoop_dir` that contains the Hadoop directory path. For example:

   ```
   # cat /opt/mapr/hadoop/
   prior_hadoop_dir
   /opt/mapr/hadoop/
   hadoop-2.7.0.20210324131839.GA
   ```

   If multiple directories are present, specify the directory with the most recent timestamp.

2. Run the `configure.sh -R` command as instructed to complete the EEP upgrade.

EZINDFAAS-793

In an AWS deployment, after an upgrade from release 7.6.1 to 7.7.0, SSO authentication can be disabled. This can be caused by a missing Keycloak certificate. To communicate with Keycloak, the API server needs the Keycloak certificate to be part of the local `ssl_truststore`.

Workaround: Use the following steps to restore the missing certificate:

last-updated: Jun 06, 2024

1. Run the following command to identify the node where the Keycloak service is running:

```
maprcli node list -columns svc,ip
hostname

service

ip-<IP_address>.us-west-1.compute.i
nternal
keycloak,s3server,cldb,ezotelcol,ho
ststats,collectd,data-access-gatewa
y,fileserver,mastgateway,opentsdb,g
ateway,apiserver,posixclientbasic

ip-<IP_address>.us-west-1.compute.i
nternal
s3server,ezotelcol,hoststats,collec
td,data-access-gateway,fileserver,m
astgateway,opentsdb,gateway,apiserv
er
ip-<IP_address>.us-west-1.compute.i
nternal
s3server,ezotelcol,hoststats,collec
td,data-access-gateway,fileserver,m
astgateway,opentsdb,gateway,apiserv
er
ip-<IP_address>.us-west-1.compute.i
nternal
s3server,ezotelcol,hoststats,collec
td,data-access-gateway,fileserver,m
astgateway,opentsdb,gateway,apiserv
er

ip-<IP_address>.us-west-1.compute.i
nternal
s3server,ezotelcol,hoststats,collec
td,data-access-gateway,fileserver,m
astgateway,opentsdb,gateway,apiserv
er
```

2. Run the following command to identify the primary CLDB node:

```
maprcli dump cldbstate -json
{
    "timestamp":1713419661362,
    "timeofday":"2024-04-18
05:54:21.362 GMT+0000 AM",
    "status":"OK",
    "total":3,
    "data":[
        {
            "ip":"<IP_address>",

"state":"CLDB_IS_MASTER_READ_WRITE"
,

"stateDuration":"00:47:57",

"mode":"MASTER_READ_WRITE",
            "desc":"kvstore tables
loading complete, cldb running as
master",
            "s3Info":{

"s3State":"S3_SERVER_MASTER",

"s3StateDuration":"00:43:26",
                "s3desc":"s3server
running as master"
            }
        },
        {
            "ip":"10.0.14.66",
            "error":"Couldn't
connect to the CLDB service"
        },
        {
            "ip":"10.0.2.60",
            "error":"Couldn't
connect to the CLDB service"
        }
    ]
}
```

3. Log in to the node where the Keycloak service is running.

4. From the node where Keycloak is running, copy the `/opt/mapr/keycloak-ha/conf/<FQDN>.crt` to all API Server nodes.

5. Log in to the primary CLDB node.

6. Use the following command to extract the `ssl_truststore` password:

```
truststore_password='cat /opt/mapr/
conf/store-passwords.txt | sed -n
'3p' | awk -F '=' '{print $2}''
```

last-updated: Jun 06, 2024

7. Use the following steps to import the certificate for the Keycloak service into the `ssl_truststore`:
   a. Check for the `ssocert` alias name. If it does not exist, import it:

```
keytool -list -v  -keystore /op
t/mapr/conf/
ssl_truststore -storepass
<<truststore_password>>  |
grep -i alias
Alias name: secure-cluster1
Alias name:
secure-cluster1-root-ca-chain
Alias name:
secure-cluster1-root-signing-ca
```

b. Use the `keytool` utility to import the Keycloak certficate:

```
keytool -import -alias
ssocert -file
<keycloak-host-FQDN>.crt -keyst
ore /opt/mapr/conf/
ssl_truststore -storepass
<<truststorepassword>>

Trust this certificate? [no]:
yes
Certificate was added to
keystore
[root@m2-hux68k-s01-n1 conf]#
```

c. Verify that the certificate was imported into the ssl_trustore:

```
keytool -list -v  -keystore /op
t/mapr/conf/
ssl_truststore -storepass
<<truststore>>  | grep -i alias
Alias name: secure-cluster1
Alias name:
secure-cluster1-root-ca-chain
Alias name:
secure-cluster1-root-signing-ca
Alias name: ssocert
```

8. Restart the API Server:

```
maprcli node services -name
apiserver -action restart -nodes
'hostname' -json
{
        "timestamp":1713503304969,
        "timeofday":"2024-04-18
10:08:24.969 GMT-0700 PM",
        "status":"OK",
        "total":0,
        "data":[

        ]
}
```

9. Open an incognito browser, and navigate to the Data Fabric UI URL:

```
https://<FQDN>:8443/app/dfui
```

   You should be redirected to the SSO authentication page.

EZINDFAAS-811

Upgrading from release 7.6.1 to 7.7.0 fails if you initiate the upgrade from a Data Fabric UI URL that is not the URL provided by the seed node when you created the fabric. The seed node indicates the API server node that is the primary installer host.

Workaround: Use either of the following workarounds:

- Initiate the upgrade from the Data Fabric UI URL provided by the seed node when the fabric was created. This URL uses the API server node with the running installer service.
- If you must use an API server node other than the primary installer host:
  1. Copy the `.pem` file from the `/infrastructure/terraform/` directory of the primary installer host to the `/tmp` directory of the secondary installer host where you want to initiate the upgrade.
  2. Restart the installer service on the secondary installer host:

     ```
     sudo service mapr-installer
     restart
     ```

  3. Initiate the upgrade as described in Upgrading a Data Fabric.

MFS-17624

An upgrade from release 7.5.0 or earlier to 7.6.0 or later can terminate with a fatal error detected by the Java Runtime Environment.

Workaround: None.

last-updated: Jun 06, 2024

MFS-18920	Upgrading from release 7.5.0 to 7.7.0 can change the valid duration of the JWT access token. Normally the token should be valid for two hours. After an upgrade operation, the valid duration can change from 2 hours to 20 minutes. When this happens, exporting the MAPR_JWT_TOKEN_LOCATION, MAPR_JWT_REFRESH_TOKEN_LOCATION variables does not correct the issue. **Workaround:** After upgrading, manually reset the valid duration of the JWT access token by using the steps in Access and Refresh Tokens.
DFUI-2163	SSO authentication is not enabled for Data Fabric UI, after upgrading from HPE Ezmeral Data Fabric release version 7.5 to release version 7.6. **Workaround:** Restart the API server after upgrade.

Volumes

DFUI-638	Non-LDAP SSO user authenticating to Keycloak cannot create volume on the Data Fabric UI. **Workaround:** Create a volume via the Data Fabric minIO client.

Resolved Issues (Release 7.7)

Lists the issues that were resolved in HPE Ezmeral Data Fabric releases 7.7.

This page lists the issues that are resolved in releases 7.7. An asterisk (*) indicates an issue that was reported by a customer.

Control System

For resolved issues related to the Control System, see Control System Release Notes on page 6161.

Core

Identifier	Description
CORE-885*	EERROR base.CommandOutput: JSON Parsing Exceptionorg.json.JSONException: Names must be non-nullDATA: {
CORE-909*	maprcli command returning conflicting information.
CORE-922*	Uninstalling/Rollback from 7.0.0.15 to 7.0 doesn't rollback the zookeeper-jute EBF jar causing zookeeper start-up fail
CORE-951*	Jackson-databind related vulnerabilities in Core 6.1.0
CORE-957*	Jackson databind Vulnerabilities reported in Mapr Client in EDF 6.1.0
CORE-966*	Alarms missing from INFO ,ERROR ,WARN group
CORE-849	[RHEL 9.0] nothing provides redhat-lsb-core needed by mapr-core

Data Fabric UI

Identifier	Description
DFUI-1090	Security: Vulnerable version of jettison@1.5.2 reported as part of the com.mapr.admin:mapr-apiserver@7.3.0.0-map
DFUI-1214	display proper error message when infra admin tries to upload object to others buckets
DFUI-1362	Security:: Burp Security Scanner reported Client-side desync vulnerability as part of DFUI Web portal's login
DFUI-1723	Table -> settings tab -> access control (form issues)
DFUI-1766	BinaryTable: Duplicate col names in a col family should be handled with an error message
DFUI-1793	Binary Table: When selected ACE type is Public the name field should be disabled.
DFUI-2066	File upload field doesn't reset value if selected file is removed
DFUI-2089	SSO:: DFUI::ClusterGroup:: SSO Authentication not enabled for Non-Primary cluster's DFUI
DFUI-2101	SSO Authentication not enabled on some of the API Servers automatically in Cluster
DFUI-2103	The column permissions page has weird behaviour when there are multiple cols with multiple user access info
DFUI-2104	Unable to see fabric delete status in dfui of seed node even it is deleted already
DFUI-2113	Binary Table: Reenabling Version on ColFam op does not work
DFUI-2114	Binary Table: An extra row is created in edit page when a certain Perm field is not enabled on CF
DFUI-2115	Binary Table: In Column Perm when a user added does not exist the page is stuck
DFUI-2119	Binary Table: Fabric User is not able to add Access Control for table on the secondary cluster
DFUI-2120	Binary Table: Not able to add Group Ace on the Column As fabric User on the secondary Cluster table
DFUI-2124	adding table replica shows timeout error
DFUI-2125	Replica pause/delete/resume status not reflected immediately
DFUI-2127	Binary Table:When 'Public' is added to the table 'Access Control' all CF and replication op buttons disappear
DFUI-2136	Not showing any bucket details on external s3 bucket overview tab
DFUI-2139	Additional space in MAPR_JWT_TOKEN_LOCATION export path giving not a valid identifier error
DFUI-2161	DFUI -> Have space or comma between IPV4 and IPV6 address for the node ip addresses view all
DFUI-2162	resource graph is not visible properly when we expand child nodes
DFUI-2167	Dfaas install UI is missing on "show more logs" hyperlink , which shows more descriptive error incase of install failures
DFUI-2171	Irrelevant error displayed when infra admin upload object into bucket

last-updated: Jun 06, 2024

Identifier	Description
DFUI-2174	policy created from secondary fabric df ui will appear instantly in the UI but they cant use immediatly
DFUI-2175	Incorrect environment variables name is used in export command guide on Client Library side drawer
DFUI-2178	create fabric is showing wrong state
DFUI-2183	seed node ui delete progress shows forever
DFUI-2186	Security:: DFUI :: CSP: style-src unsafe-inline header in https://<FQDN>:8443/app/dfui url get
DFUI-2208	ips text is overlapping on node ip adress window on 10 node cluster
DFUI-2219	Security: CVE :: Vulnerable versions of jboss-logging 3.3.2.Final, jcip-annotations 1.0-1 reported as part of the mapr-apiserver of 7.3.0
DFUI-2220	Failed to download JWT Keys from UI
DFUI-2250	Incorrect services state show on df ui
DFUI-2269	Security::GoogleCloudProvider credentials are been hardcoded in source df-ui/src/test/resources/gcpkey.json
DFUI-2270	Security:: AWS Access credentials are been hardcoded in the dfui source code
DFUI-2271	Security:: Azure Cloud Provider access details are hardcoded in plain text
DFUI-2275	Global namespace table: issues with scrolling
DFUI-2475	OPAL UI: Unable to edit unversioned bucket
DFUI-2480	Security: Vulnerable version of hazelcast 5.2.1 is reported as part of the security scan against mapr-apiserver-7.7.0.0.20240327004815-1.noarch.rpm
DFUI-2481	DFUI:: Client Library version not displayed as part of the client library download panel.
DFUI-2483	Mask creds from create fabric payload in apiserver.logs
DFUI-2491	Not able to deploy fabric on AWS using seed node
DFUI-2492	reinitiate fabric disappearing on page refresh
DFUI-2494	Don't display existing working fabric nodes on add node frame
DFUI-2498	List bucket action was not there
DFUI-2499	DF UI not retained sso after scaling fabric
DFUI-2500	add all supported actions in the bucket policy actions
DFUI-2502	DF UI -> IF fabric create fails no way to figure out what the error is unless you get to logs on node
DFUI-2506	DF UI -> storage_size is not being passed properly and fabric creation fails -> Passed as "N/A"
DFUI-2507	Download logs not showing error message when not able to download logs
DFUI-2514	getting error "tier offload not enabled for given volume" in browser console when accessing standared volume
DFUI-767	Lack of place for import action buttons

last-updated: Jun 06, 2024

Installation

Identifier	Description
EZINDFAAS-311	Security:: 7.4 Installer:: bundled with vulnerable version of "hibernate-validator-version 5.1.3.Final"
EZINDFAAS-313	Security:: 7.4 Installer:: Vulnerable version of jboss.logging bundled with installer.
EZINDFAAS-316	Security::7.4 installer :: vulnerable version of openssl 1.1.1s reported by STROSS
EZINDFAAS-317	Security:: Installer 7.4:: Security vulnerability reported by stross for " py 1.10.0" as part of mapr-installer-1.18.0.202305151707.rpm
EZINDFAAS-322	Security: Installer 7.4 : STROSS Scan reported urllib3 1.25.3 as critical vulnerable as part of mapr-installer-1.18.0.202305151707.rpm.tgz
EZINDFAAS-323	Security:: 7.4 Installer:: STROSS Scan reported vulnerable version of wheel 0.34.2 as part mapr-installer-1.18.0.202305151707.rpm.tgz
EZINDFAAS-341	SSO-CentralAuthorisation:: Cluster Deployed from Seed Node/installer, should be enabled with PBS-Master
EZINDFAAS-637	delete fabric option doesnt remove data_fabric.conf file created under /etc/apt/auth.conf.d/
EZINDFAAS-638	DFaaS Installer's Deployment log contains VPC,Subnet ID details in plain text during EDF deployment on AWS
EZINDFAAS-640	GCP :: GCP creds file upload as part of Cluster Deployment stored in plain text on disk without encryption
EZINDFAAS-642	fabric upgrade getting failed intermittently from 750 to 760
EZINDFAAS-643	Deployment Error details thrown by Seed Installer's DFUI throws "Sensitive information without Sanitation"
EZINDFAAS-644	list deployments is not able to update correct status to completion
EZINDFAAS-649	remove fabric is failing from seed node
EZINDFAAS-675	Security:: 7.3.0 DF Installer bundled with vulnerable version of woodstox-core 6.2.1
EZINDFAAS-677	Confusing listdeployments API response in case of reinitiate failed installation
EZINDFAAS-679	Failed remove a fabric which we tried to give non-existing hostname
EZINDFAAS-681	EZINDFAAS => Onprem remove fabric fails -> No such file or directory: '/opt/mapr/installer/ezdfaas/logs/delete-cluster_24_02_19_22_49_52.log'
EZINDFAAS-684	EZINDFAAS -> Onprem installation is done, it failed to update the state
EZINDFAAS-724	EZINDFAAS -> Fabric creation -> doesn't complete and in loop
EZINDFAAS-754	"Failed to upload latest infra state from host " after scaling
EZINDFAAS-755	EZDFAAS -> Logging for tracking purpose -> GCP instances and disks not deleted
EZINDFAAS-756	Formatting required in the json output of the maprcli command : installer clusterstatus -c %s -json -n . Current output is not properly formatted and hence not accessible as a json through code.
EZINDFAAS-761	DFaaS Installer:: DFaaS Cluster Deployment from DFUI Error Message shows securitygroup name,accesskeypair,instances names etc name etc when ever ClusterCreation fails.
EZINDFAAS-763	Unable to scale the fabric
EZINDFAAS-764	Keycloak is not coming up after installing 3 node fabric through installer
EZINDFAAS-766	DFaaS Installer: Deletion of Failed fabric shows deletion successful eventhough node login details were provided wrongly.
EZINDFAAS-767	GCP fabric create is failing bcoz of cloud creds access check added is failing

last-updated: Jun 06, 2024

Identifier	Description
EZINDFAAS-768	EZINDFAAS -> AWS/Azure resources not getting deleted from Cloud providers
EZINDFAAS-770	Mismatch progress status observed in fabric scaling
EZINDFAAS-771	EZINDFAAS > Tracking purpose -> For GCP VMs and Disks not getting deleted after fabric is removed and for Azure disks not deleted
EZINDFAAS-774	EZINDFAAS -> Azure fabric create automation failing -> Azure CREDENTIALS WERE NOT VERIFIED
EZINDFAAS-778	EZINDFAAS -> Automated GCP create fabric failing -> ERROR: Error creating and activating swap file on the root device.
EZINDFAAS-779	EZINDFAAS -> Automated AWS fabric creation failing with error -> Installing hashicorp/aws v5.44.0...\n\nError: Failed to install provider\n\nError while installing hashicorp/aws v5.44.0: context canceled\n\nProvider installation was canceled
EZINDFAAS-780	No hosts data returned in clusterscalestatus output
EZINDFAAS-781	Scale fabric is failing because of setup script download failure
EZINDFAAS-783	EZINDFAAS -> On created On prem fabric - > maprlogin password for ticket generation -> java.lang.NoClassDefFoundError: com/mapr/security/MaprSecurityException
EZINDFAAS-785	API installer logs, the first letter of the properties "installer_logs" and "archive_installer" are ignored.
EZINDFAAS-787	The Installer log file name is wrong inside the installer log info
EZINDFAAS-788	installer/clusterscalestatus response contains unescaped quotes
EZINDFAAS-789	Azure/AWS/GCP resources are not getting cleaned up after DFAAS test
EZINDFAAS-792	incorrect scalling nodes displayed in ui
EZINDFAAS-794	Unable to Scale the 3node fabric
EZINDFAAS-801	DFaaS: Cluster Deployment on AWS failed with error "Error: Invalid value for variable on variables.tf line 60: 60:"
EZINDFAAS-802	Keycloak is not coming up on onprem multinode fabric installed through seed container
EZINDFAAS-803	"Scale complete state" returning "True" before adding all nodes for scaling
EZINDFAAS-804	Installer picking incorrect hostnames when we trigger scaling from DFUI
EZINDFAAS-806	Confusing listdeployments and clusterstatus output at the beginning of installation phase of reinitiate failed fabric deploy
EZINDFAAS-807	Unable to get the "check for update" status of a fabric
EZINDFAAS-810	remove_cluster stuck on dfui side for a few minutes if fast_credential_check failed
EZINDFAAS-812	Whitelist port 7443 by default on cloud deployments

Packages and Dependencies for Data Fabric Software

This section describes package and dependency details for the Release 7.7 core and ecosystem components.

For downloadable packages, see these links:

- Core Packages
- EEP Packages
- Installer Packages

For core package dependencies for the supported OS distributions, see:

- Package Dependencies on page 103

For Installer package dependencies, see:

- Installer Prerequisites and Guidelines

Patches and Patch Documentation

Describes important considerations for patches and patch documentation.

Whenever possible, keep your software up to date by applying the latest patches available on the Support Portal. This practice can help you to resolve issues and minimize downtime.

Some patches enable new features or behaviors that are described in the documentation. However, the data-fabric documentation does not typically include patch numbers or identify the features or behaviors that are delivered by specific patches. If you see a fix or feature in the documentation that is not available on your platform, you might need to apply a patch in order to use the fix or feature.

To understand which patches apply to your platform, contact your support representative.

IMPORTANT: The "Support notices of known issues" tool is no longer available, but you can obtain the same information by logging on to the HPE Support Center. See Support Articles in the HPE Support Center on page 6197.

To download patches, see Downloading a Patch on page 473.

For information about applying a patch, see Applying a Patch on page 473.

Deprecation of Release 7.6.0

Describes how HPE Ezmeral Data Fabric release 7.6.1 replaces release 7.6.0.

CAUTION: New installations of release 7.6.0 are no longer recommended. Because of known issues with release 7.6.0, Hewlett Packard Enterprise recommends installing release 7.6.1 or later. If you installed release 7.6.0, Hewlett Packard Enterprise recommends applying the 7.6.1 patch release. EEP updates are not required. EEP 9.2.1 can be used with release 7.6.1.

If you need to upgrade from an earlier release, upgrade to release 7.6.1 or a 7.x release other than 7.6.0.

Release 7.6.1 Replaces 7.6.0

Release 7.6.0 is deprecated. Release 7.6.1 is a patch release that replaces release 7.6.0. Release 7.6.1 is identical to release 7.6.0 but includes fixes for the following issues:

- MFS-18300 – Disksetup fails on non-CLDB nodes as MFS fails to establish binding with CLDB
- MFS-18155 – NFS registers multiple times

- EZINDFAAS-649 – Remove fabric failing from seed node
- DFUI-2175 – Incorrect environment variables name is used in export command guide of client library side drawer

Development Environment for HPE Ezmeral Data Fabric

The Development Environment for HPE Ezmeral Data Fabric is a Docker container that enables you to create a single-node cluster. The container is lightweight and designed to run on your laptop. It requires no additional configuration for you to connect clients – also running on your laptop – to the cluster.

The Data Fabric cluster created by the Docker image includes the following components:

- Core 7.7.0:
  - HPE Ezmeral Data Fabric File Store on page 488
  - HPE Ezmeral Data Fabric Database on page 631
  - HPE Ezmeral Data Fabric Streams on page 766
  - HPE Ezmeral Data Fabric Control System on page 819
  - NFS for the HPE Ezmeral Data Fabric
- Apache Drill 1.20.3.200
- Apache Spark 3.3.3.0

Examples in this section show Mac OS X and Linux support for the container, but you can run the container on any operating system that supports Docker containers.

After you deploy the container, the environment inside the container runs Ubuntu 20 and JDK 11. By default, the Data Fabric cluster is configured as secure.

The Development Environment for HPE Ezmeral Data Fabric is provided *as is* for development purposes. HPE technical support is not available for this product. However, users may post questions or comments on the Ezmeral Data Fabric Community.

Prerequisites to Running the Development Environment for HPE Ezmeral Data Fabric

To run the Development Environment for HPE Ezmeral Data Fabric, you must first install the Data Fabric client and Docker software.

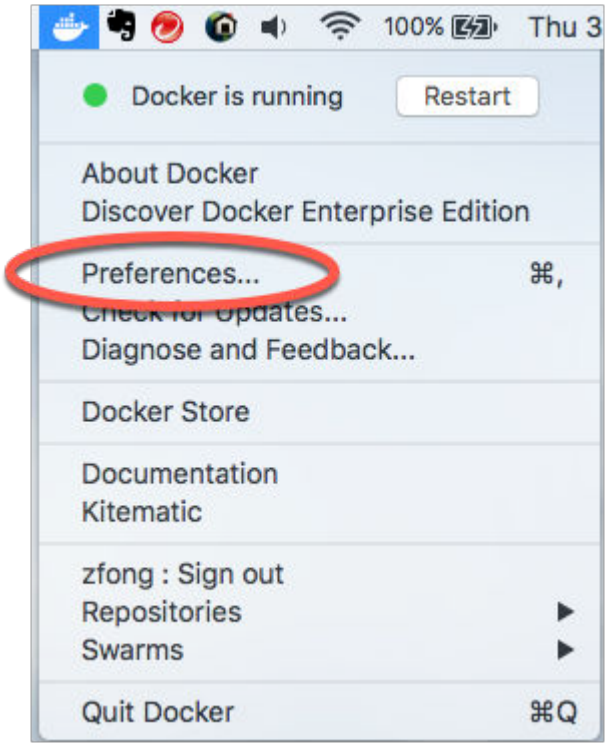
About this task

The instructions in this topic are specific to Mac OS X. The container is supported on all operating systems that support Docker containers.

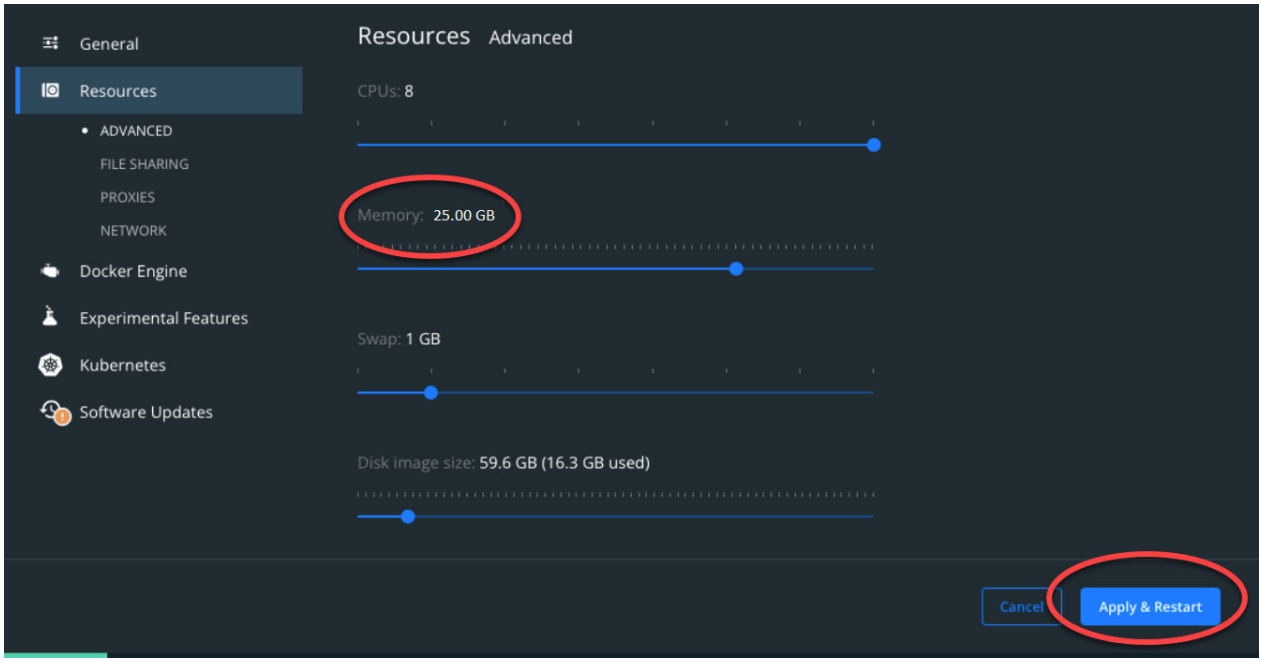
Procedure

1. **Optional:** If you intend to access the container using a client, install a Data Fabric client. For client-installation instructions, see Setting Up Clients and Services on page 400. For example, to install the client on your Mac laptop, see Installing the Data Fabric Client on Mac OS X (Non-FIPS) on page 412. You do not need to perform step 1 if you do not need client access.
2. Install Docker on your laptop:
   a) Download the software for Mac from https://www.docker.com/docker-mac, or follow the instructions for the appropriate Linux distribution.
   b) Install the software.

c) On a Mac, verify that Docker is running with at least 25 GB of memory by clicking **Docker->Preferences->Advanced**:



3. Modify the memory settings, if needed, and restart Docker. For release 7.1.0 and later, at least 25 GB of memory is recommended.



Running the Development Environment Script

Describes how to run the setup script that downloads the Docker image and launches the Docker container.

last-updated: Jun 06, 2024

About this task

The development environment script, `mapr_devsandbox_container_setup.sh`, downloads the Docker image associated with the container and launches the container image that starts the HPE Ezmeral Data Fabric cluster. It also performs the configuration steps needed to connect local HPE Ezmeral Data Fabric clients to the HPE Ezmeral Data Fabric cluster running in the container.

Procedure

1. Download mapr_devsandbox_container_setup.sh from GitHub.
2. **Optional:** Use a `docker pull` command to pre-download a copy of the image:

   ```
   docker pull maprtech/dev-sandbox-container:latest
   ```

   Pre-downloading is optional, but it makes the script run faster and prevents download issues when you run the script. The script checks to see if the image is already present on your system. If the image is present, the script uses the image. If it is not present, the script tries to download it.
3. Modify the script so it is executable:

   ```
   chmod +x mapr_devsandbox_container_setup.sh
   ```

4. Run the script. The following command uses the default values for the host network interface and image. By default, the script runs the latest version of the container, `maprtech/dev-sandbox-container:latest`, and uses host network interface `en0`:

   ```
   ./mapr_devsandbox_container_setup.sh
   ```

   To run an earlier version, replace `latest` with the tag corresponding to the version you want to use, and pass that as an argument to the script. The following example runs the 6.2.0 version:

   ```
   ./mapr_devsandbox_container_setup.sh -image maprtech/
   dev-sandbox-container:6.2.0.0_7.0.0_ubuntu18
   ```

   For a list of available tags, see https://hub.docker.com/r/maprtech/dev-sandbox-container/tags/.

   To use a host network interface other than `en0` for the container, run this command:

   ```
   $./mapr_devsandbox_container_setup.sh -nwinterface enp4s0
   ```

   If you want to use a non-default image and a different interface, run a command like this:

   ```
   $./mapr_devsandbox_container_setup.sh -nwinterface enp4s0 -image
   maprtech/dev-sandbox-container:7.1.0.0_9.0.0_ubuntu18
   ```

   In the preceding command, `enp4s0` is an example of a host network interface name that is likely different in your environment.

   NOTE: The script can take 5-10 minutes to run the first time you run it. It requires downloading the Docker image from the Docker repository.
5. When the Docker image is running, you see the following output:

   ```
   latest: Pulling from maprtech/dev-sandbox-container
   Digest:
   sha256:7d93044364d2961de7d4087562b1c03d2610c93229c85b54ebd0528b29046cf2
   ```

last-updated: Jun 06, 2024

```
Status: Image is up to date for maprtech/dev-sandbox-container:latest
docker.io/maprtech/dev-sandbox-container:latest
Developer Sandbox Container 447b55b4d6fb is running..
services required for Ezmeral Data fabric are coming up
services required for Ezmeral Data fabric are coming up
services required for Ezmeral Data fabric are coming up
services required for Ezmeral Data fabric are coming up

Docker Container is up and running....
Mac Client has been configured with the docker container.

Please login to the container using (root password mapr): ssh
root@localhost -p 2222
Login to MCS at https://localhost:8443
```

NOTE: Use this format to access MCS or the Data Fabric UI:

- To access MCS: `https://<IP address>:8443/app/mcs`
- To access the Data Fabric UI: `https://<IP address>:8443/app/dfui`

6. Log in to the Docker container:

```
ssh root@localhost -p 2222
```

7. Wait for the `AdminApplication` java process to start by viewing the output from `jps`:

```
root@maprdemo:~# jps
3472 WardenMain
28369 Jps
5105 CLDB
13810 RunJar
28259 FsShell
13235 AdminApplication
3232 QuorumPeerManager
12280 Drillbit
14122 RunJar
```

8. Generate a user ticket:

```
# maprlogin password
[Password for user 'root' at cluster 'maprdemo.mapr.io': ]
MapR credentials of user 'root' for cluster 'maprdemo.mapr.io' are
written to '/tmp/maprticket_0'
```

9. When `AdminApplication` is running, you can access the Control System in your browser by using the following URL:

```
https://localhost:8443
```

10. After all cluster services are running, you can access the file system by using POSIX commands, with `/mapr` as your mount point. The following steps show how to determine that all services are running:

a) Determine the id of your Docker container by examining the output from the following command:

```
docker ps
```

b) Examine the contents of the Docker logs by using the container id from Step a:

```
docker logs ca2c94d9e822
```

c) It can take a few minutes for all services to initialize, depending on the load in your environment. A message similar to the following in your log output indicates that all services are running:

```
This container IP : 172.17.0.2
```

d) Log in to the container using the command from Step 5.

e) Run the following command to access the HPE Ezmeral Data Fabric file system using `ls`:

```
root@maprdemo:~# ls /mapr
```

What to do next

NOTE: Whenever you change your network environment, you must reconfigure your container. Rerun the `mapr_devsandbox_container_setup.sh` script, and select option 2 when the script shows the following prompt:

```
MapR sandbox container is already running.
1. Kill the earlier run and start a fresh instance
2. Reconfigure the client and the running container for any network
changes
Please enter choice 1 or 2 :
```

Connecting Clients to the Development Environment for HPE Ezmeral Data Fabric

You can access the Data Fabric cluster running in the development-environment container from your laptop. Simply issue client commands from your laptop.

Setting up New Users

The Container for Developers is set up with only users `mapr` and `root`. If you want to connect clients as some other user, you must add your user name and group to the container.

For example, if running the `id` command on your laptop returns the following:

```
uid=5001(mapruser) gid=5000(maprgroup)
```

Then, run the following commands to add your user name and group to the container:

```
ssh root@localhost -p 2222
groupadd -g 5000 maprgroup
useradd -m -u 5001 -gmaprgroup mapruser
```

last-updated: Jun 06, 2024

Accessing the File System

The following command lists the files in the file system on the cluster:

```
/opt/mapr/bin/hadoop fs -ls /
```

Accessing HPE Ezmeral Data Fabric Database

To access the HPE Ezmeral Data Fabric Database, use HPE Ezmeral Data Fabric Database shell:

```
/opt/mapr/bin/mapr dbshell
```

In the HPE Ezmeral Data Fabric Database shell, you can create a table, insert into the table, and read from the table:

```
create /tmp/t1
insert /tmp/t1 --v '{"a":"ABC"}' --id "ID1"
find /tmp/t1
```

Accessing Drill

The Data Fabric client that you downloaded in the Prerequisites to Running the Development Environment for HPE Ezmeral Data Fabric on page 71 topic includes a minimum set of clients. To run other clients, you must first copy the client software to your laptop.

The following example shows how to do this for Apache Drill 1.20.x:

1. Determine your Docker `<container-id>` by examining the output of the `docker ps` command
2. Copy Drill from your container to your laptop specifying the `<container-id>`:

   ```
   docker cp <container-id>:/opt/mapr/drill /opt/mapr/drill
   ```

3. Connect to Drill as user `mapr` through JDBC by running `sqlline`:

   ```
   /opt/mapr/drill/drill-1.20.3/bin/sqlline -u
   "jdbc:drill:drillbit=localhost" -n mapr
   ```

   NOTE: If you are using a different version of Drill, replace the version string with your version.

4. Run a SQL query in `sqlline`:

   ```
   select * from cp.'employee.json' limit 10;
   ```

Demo Applications

Sample applications are available at https://github.com/mapr-demos/mapr-db-720-getting-started. The applications show you how to access an HPE Ezmeral Data Fabric Database JSON table using the following programming interfaces:

- Drill JDBC
- OJAI
- Understanding the HPE Ezmeral Data Fabric Database OJAI Connector for Spark on page 4633

See the README file in the GitHub repository for detailed steps to create the data used in the applications and how to run the applications.

Troubleshooting the Development Environment for HPE Ezmeral Data Fabric

This section describes problems you might encounter when deploying, running, and accessing the Development Environment for HPE Ezmeral Data Fabric. It also includes steps to troubleshoot and resolve the problems.

Cluster Does Not Come Up

Problem	The cluster does not come up, and `maprcli dump cldbstate -json` might return an error saying that CID1 is waiting to become master.
Possible Cause	Stale processes. The error can be seen on Linux nodes if any `mapr-` processes are running when you run the `mapr_dev_sandbox_container.sh` script.
Solution	Before running the `mapr_dev_sandbox_container.sh` script, kill any running `mapr-` processes.

MAPR_EXTERNAL Error

Problem	Running `maprcli` commands can return an error such as `MAPR_EXTERNAL: Empty string found` in the output of line 1 on the Docker container.
Possible Cause	The default host network interface of `en()` doesn't exist on the node where the script is run.
Solution	Specify a host network interface other than `en()` by using the `-nwinterface` option as described in Running the Development Environment Script on page 72.

Docker Login Problems

Problem	Attempting to log in to your Docker container returns the following error:
	`@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@`
	`@    WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED!    @`
	`@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@`

Possible Cause	You have an old ssh key in your `.ssh/known_hosts` file.
Solution	Replace the old ssh key with the correct key: `ssh-keygen -R [localhost]:2222`

Docker Failures

Problem	Docker fails to run the container.

Possible Cause

Docker encounters problems starting ZooKeeper or Warden.

Solution

1. Determine your Docker `<container-id>` by examining the output of the `docker ps` command.
2. Examine the Docker log files by running:

   ```
   docker logs <container-id>
   ```

3. Examine the HPE Ezmeral Data Fabric log files specified in the output for further diagnostics. You need to log in to the container to see those files.

Problem

Docker completes its startup as shown by the following output from Docker logs:

```
This container IP : 172.17.0.2
```

But Docker is killed before the cluster processes are running.

Possible Cause

You have not allocated enough memory to Docker.

Solution

Make sure you have configured Docker with at least 25 GB of memory as described at Step 2c at Prerequisites to Running the Development Environment for HPE Ezmeral Data Fabric.

Connection Problems

Problem

Unable to connect to Control System in your browser.

Possible Cause	Solution
The `AdminApplication` process is not running yet.	Run `jps` and wait for `AdminApplication` to appear in the list of running java processes.
You are accessing an older, cached copy of the Control System URL.	Clear your browser cache and retry connecting to the URL.

Unable to Access HPE Ezmeral Data Fabric Database Table

Problem

You cannot access a HPE Ezmeral Data Fabric Database table.

Possible Cause

You do not have permissions on the volume where the table is stored.

Solution

When creating a volume, make sure you set up the user access controls appropriately. See Creating a Volume on page 1177 for details.

Unable to run OJAI Queries Due to Query Service Errors

Problem

When running an OJAI query, you encounter an error indicating that the Query Service is not enabled.

Possible Cause	The Container for Developers is setup with only users `mapr` and `root`. You are running as some other user and your query requires the OJAI Distributed Query Service on page 640.
Solution	Add your user name and group to the container by following the instructions at Setting up New Users on page 75.

7.7.0 Installation

This section contains information about installing and upgrading HPE Ezmeral Data Fabric software. It also contains information about how to migrate data and applications from an Apache Hadoop cluster to a HPE Ezmeral Data Fabric cluster.

The topics in this section assume that you are planning, installing, or upgrading a single cluster. If your environment requires multiple clusters, you must repeat each documented procedure for each cluster.

Planning the Cluster

Describes information and factors used in planning your cluster.

A data-fabric installation is usually a large-scale set of individual servers, called *nodes*, collectively called a *cluster*. In a typical cluster, most nodes are dedicated to data processing and storage, and a smaller number of nodes run other services that provide cluster coordination and management.

The first step in deploying data-fabric is planning the servers that will form the cluster, and selecting the services that will run on each node. To determine whether a server is capable of contributing to the cluster, it may be necessary to check the requirements in Preparing Each Node. Each node in the cluster must be carefully checked against these requirements; unsuitability of a node is one of the most common reasons for installation failure.

For an excellent introduction to planning a data-fabric cluster, see this tech talk.

The objective of a cluster plan is to detail each node's set of services.

Select Services

This section describes some of the services that can be run on a node.

Every installation requires services to manage jobs and applications. **ResourceManager** and **NodeManager** manage MapReduce version 2 and other applications that can run on YARN. In addition, HPE Ezmeral Data Fabric requires the **ZooKeeper** service to coordinate the cluster, and at least one node must run the **CLDB** service. The **WebServer** service is required if you want to use the browser-based Control System.

After you install HPE Ezmeral Data Fabric core, you can install ecosystem components that belong to an Ecosystem Pack (EEP). An EEP provides a set of ecosystem components that work together. When a newer version or a revision to a component becomes available, the EEP version is updated to reflect the fact that an update was made. For more information about the ecosystem components available in each EEP and a list of EEPs supported by your HPE Ezmeral Data Fabric cluster version, see Ecosystem Packs (EEPs).

The following table shows some of the services that can be run on a node:

Service Category	Service	Description
Management	**Warden**	Warden runs on every node, coordinating the node's contribution to the cluster. Warden is also responsible for managing the service state and its resource allocations on that node.
YARN	**NodeManager**	Hadoop YARN NodeManager service. The NodeManager manages node resources and monitors the health of the node. It works with the ResourceManager to manage YARN containers that run on the node.
HPE Ezmeral Data Fabric Core	**FileServer**	FileServer is the HPE Ezmeral Data Fabric service that manages disk storage for file system and HPE Ezmeral Data Fabric Database on each node.
HPE Ezmeral Data Fabric Core	**CLDB**	Maintains the *container location database (CLDB)* (CLDB) service. The CLDB service coordinates data storage services among file system file server nodes, and access across HPE Ezmeral Data Fabric NFS gateways, and HPE Ezmeral Data Fabric clients.
HPE Ezmeral Data Fabric Core	**NFS**	Provides read-write HPE Ezmeral Data Fabric Direct Access NFS™ access to the cluster, with full support for concurrent read and write access.
Storage	**MapR HBase Client**	Provides access to HPE Ezmeral Data Fabric Database binary tables via HBase APIs. Required on all nodes that will access table data in file system, typically all edge nodes for accessing table data. HBase API can also be accessed through the HBase Thrift and Rest Gateways.
YARN	**ResourceManager**	Hadoop YARN ResourceManager service. The ResourceManager manages cluster resources, and tracks resource usage and node health.
Management	**ZooKeeper**	Internal service. Enables high availability (HA) and fault tolerance for HPE Ezmeral Data Fabric clusters by providing coordination.
YARN	**HistoryServer**	Archives MapReduce application metrics and metadata.
Management	**Web Server**	Contains static Control System user interface pages.
Management	**Apiserver**	Allows you to perform cluster administration programmatically, and supports the Control System (see Setting Up the Control System on page 454).

last-updated: Jun 06, 2024

Service Category	Service	Description
OJAI Distributed Query Service	**Drill**	Provides the distributed query service powered by Apache Drill for HPE Ezmeral Data Fabric Database JSON. Supports the following functionality: • Advanced secondary index selection • Sorts on large data sets • Parallel query execution See OJAI Distributed Query Service on page 640 for more details about the service.
Application	**Hue**	Hue is the Hadoop User Interface that interacts with Apache Hadoop and its ecosystem components, such as Hive, Pig, and Oozie. It also provides interactive notebook access to Spark through Livy.
Application	**Hive**	Hive is a data warehouse engine that supports SQL-like adhoc querying and data summarization.
Application	**HCatalog**	HCatalog provides applications with a table view of the file system layer of the cluster, expanding your options from read/write data streams to add-[Hive]-table operations such as get row and store row.
Application	**Cascading**	Cascading on page 3919 is an application framework for analyzing and managing big data.
Application	**Spark**	Spark is a processing engine for large datasets. While it can be deployed locally or standalone, the recommended deployment is on YARN. The application timeline server component provides a historical view of query details.
Application	**Airflow**	Apache Airflow is a tool that helps you to author, schedule, or monitor workflows or data pipelines.
Application	**Ranger**	Apache Ranger on page 4583 is a framework to enable, monitor and manage data security across the Hadoop platform in the HPE Ezmeral Data Fabric. Ranger provides centralized security administration and fine-grain access control for user access within Apache Hadoop, Apache Hive, Apache HBase, and other Apache components.

last-updated: Jun 06, 2024

Service Category	Service	Description
Application	**NiFi**	Apache NiFi on page 4573 is a dataflow system based on the concepts of flow-based programming. Apache NiFi supports powerful and scalable directed graphs of data routing, transformation, and system mediation logic. NiFi has a web-based user interface for the design, control, feedback, and monitoring of dataflows.
Application	**OTel**	OTel on page 4582 is an observability framework that allows you to instrument, generate, collect, and export telemetry data.
Application	**Zeppelin**	Apache Zeppelin on page 4736 is an open source, Web-based data-science notebook. You can use it with Data Fabric components to conduct data discovery, ETL, machine learning, and data visualization.

Cluster Design Objectives

This section describes some of the work that your cluster performs, and identifies key design considerations.

Begin by understanding the work that the cluster performs. Establish metrics for data storage capacity and throughput. Then characterize the data processing that will typically be performed.

Data Workload

While the Data Fabric is relatively easy to install and administer, designing and tuning a large production MapReduce cluster is a complex task that begins with understanding your data needs. Consider the kind of data processing that will occur and estimate the storage capacity and throughput speed required. Data movement, independent of MapReduce operations, is also a consideration. Plan for how data will arrive at the cluster, and how it will be made useful elsewhere.

Network bandwidth and disk I/O speeds are related; either can become a bottleneck. CPU-intensive workloads reduce the relative importance of disk or network speed. If the cluster will be performing a large number of big reduces, network bandwidth is important, suggesting that the hardware plan include multiple NICs per node. Data Fabric core can natively take advantage of multiple NICs and distribute workload across them. In general, the more network bandwidth, the faster things will run.

Running NFS on multiple data nodes can improve data transfer performance and make direct loading and unloading of data possible, but multiple NFS instances requires an Converged Enterprise Edition, Hadoop module license. For more information about NFS, see Managing the HPE Ezmeral Data Fabric NFS Service on page 1549.

Plan which nodes will provide NFS access according to your anticipated traffic. For instance, if you need 5Gb/s of write throughput and 5Gb/s of read throughput, the following node configurations would be suitable:

- 12 NFS nodes with a single 1GbE connection each
- 6 NFS nodes with dual 1GbE connections each
- 4 NFS nodes with quadruple 1GbE connections each

last-updated: Jun 06, 2024

When you set up NFS on all of the file server nodes, you enable a self-mounted NFS point for each node. A cluster made up of nodes with self-mounted NFS points enable you to run native applications as tasks. You can use round-robin DNS or a hardware load balancer to mount NFS on one or more dedicated gateways outside the cluster to allow controlled access.

High Availability

A properly licensed and configured Data Fabric cluster provides automatic failover for continuity throughout the Data Fabric core stack. Configuring a cluster for HA involves redundant instances of specific services, as well as a correct configuration of the Data Fabric NFS service. HA features are not available with the Converged Community Edition.

The following table describes redundant services used for HA:

Service	Strategy	Min. instances
CLDB	Primary/secondary--two instances in case one fails.	2
ZooKeeper	A majority of ZK nodes (a *quorum*) must be up.	3
ResourceManager	One active and one or more standby instances. If the active one fails, one standby instance takes over. This is configured automatically using Zero Configuration.	2
NFS	The more redundant NFS services, the better.	2
OpenTSDB	At least one instance should be up.	3
Elasticsearch	At least two instances should be up.	3

NOTE: You should use an odd number of ZooKeeper instances. Setting up more than 5 ZooKeeper instances is not usually needed.

For a high availability cluster, use five (5) ZooKeepers, so that the cluster can tolerate two (2) ZooKeeper nodes failing and still maintain a quorum. See Example Cluster Designs on page 91.

On a large cluster, you may choose to have extra nodes available in preparation for failover events. In this case, you keep spare, unused nodes ready to replace nodes running control services, such as CLDB or ZooKeeper in case of a hardware failure.

Virtual IP Addresses

You can use virtual IP addresses (VIPs) for load balancing or failover with the Converged Enterprise Edition, Hadoop module. VIPs provide multiple addresses that can be leveraged for round-robin DNS, allowing client connections to be distributed among a pool of NFS nodes. VIPs also enable high availability (HA) NFS. In a HA NFS system, when an NFS node fails, data requests are satisfied by other NFS nodes in the pool. Use a minimum of one VIP per NFS node per NIC that clients will use to connect to the NFS server. If you have four nodes with four NICs each, with each NIC connected to an individual IP subnet, use a minimum of 16 VIPs and direct clients to the VIPs in round-robin fashion. The VIPs should be in the same IP subnet as the interfaces to which they will be assigned. See Managing VIPs for NFS on page 1550 for NFS for details on enabling VIPs for your cluster.

If you plan to use VIPs on your cluster's NFS nodes, consider the following tips:

- Set up NFS on at least three nodes if possible.
- All NFS nodes must be accessible over the network from the machines where you want to mount them.

last-updated: Jun 06, 2024

- To serve a large number of clients, set up dedicated NFS nodes and load-balance between them. If the cluster is behind a firewall, you can provide access through the firewall through a load balancer instead of direct access to each NFS node. You can run NFS on all nodes in the cluster, if needed.
- To provide maximum bandwidth to a specific client, install the NFS service directly on the client machine. The NFS gateway on the client manages how data is sent in or read back from the cluster, using all its network interfaces (that are on the same subnet as the cluster nodes) to transfer data via Data Fabric APIs, balancing operations among nodes as needed.
- Use VIPs to provide High Availability (HA) and failover.

Minimum Cluster Size

Provides considerations for smaller clusters.

Three-Node Minimum Cluster

All Data Fabric production clusters must have a minimum of three (3) data nodes except for HPE Ezmeral Data Fabric Edge on page 6195. A three-node cluster provides minimal fault tolerance, does not support erasure coding, and can have disk-balancing issues. However, three nodes are cost effective for some applications and fully support data replication, which can mitigate some small-cluster weaknesses.

More Nodes Are Better

In general, it is better to have more nodes. Larger clusters recover faster from disk failures because more nodes are available to contribute. To maximize fault tolerance in the design of your cluster, see Example Cluster Designs on page 91.

A data node is defined as a node running a FileServer process that is responsible for storing data on behalf of the entire cluster. Having additional nodes deployed with control-only services such as CLDB and ZooKeeper is recommended, but they do not count toward the minimum node total because they do not contribute to the overall availability of data.

Considerations for Clusters Smaller Than 10 Nodes

Note these special considerations for clusters of 10 nodes or fewer:

- Erasure coding and rolling updates are not supported for clusters of four nodes or fewer.
- Erasure coding is not recommended for five- and six-node clusters. See the *Important* note in Erasure Coding Scheme for Data Protection and Recovery on page 1244.
- Dedicated control nodes are not needed on clusters with fewer than 10 data nodes.
- As the cluster size is reduced, each individual node has a larger proportional impact on cluster performance. As cluster size drops below 10 nodes, especially during times of failure recovery, clusters can begin to exhibit variable performance depending on the workload, network and storage I/O speed, and the amount of data being re-replicated.
- For information about fault tolerance, see Priority 1 - Maximize Fault Tolerance on page 92 and Cluster Design Objectives on page 82.

For hardware and configuration best practices, see Cluster Hardware on page 84.

Cluster Hardware

Describes important hardware-architecture considerations for your cluster.

When planning the hardware architecture for the cluster, make sure all hardware meets the node requirements listed in Preparing Each Node.

last-updated: Jun 06, 2024

The architecture of the cluster hardware is an important consideration when planning a deployment. Among the considerations are anticipated data storage and network bandwidth needs, including intermediate data generated when jobs and applications are executed. The type of workload also is important. Consider whether the planned cluster usage will be CPU-intensive, I/O-intensive, or memory-intensive. Think about how data will be loaded into and out of the cluster, and how much data is likely to be transmitted over the network.

Planning a cluster often involves tuning key ratios, such as:

- Disk I/O speed to CPU processing power
- Storage capacity to network speed
- Number of nodes to network speed

Typically, the CPU is less of a bottleneck than network bandwidth and disk I/O. To the extent possible, balance network and disk transfer rates to meet the anticipated data rates using multiple NICs per node. It is not necessary to bond or trunk the NICs together. The HPE Ezmeral Data Fabric can take advantage of multiple NICs transparently. Each node should provide raw disks to the data-fabric, with no RAID or logical volume manager, as the data-fabric takes care of formatting and data protection.

The following example architecture provides specifications for a recommended standard data-fabric Hadoop compute/storage node for general purposes. This configuration is highly scalable in a typical data center environment. The HPE Ezmeral Data Fabric can make effective use of more drives per node than standard Hadoop, so each node should present enough faceplate area to allow a large number of drives.

Standard Compute/Storage Node

- Dual CPU socket system board
- 2x8 core CPU, 32 cores with HT enabled
- 8x8GB DIMMs, 64GB RAM (DIMM count must be multiple of CPU memory channels)
- 12x2TB SATA drives
- 10GbE network interface
- OS using entire single drive, not shared as data drive

Best Practices

Hardware recommendations and cluster configuration vary by use case. For example, is the application an HPE Ezmeral Data Fabric Database application? Is the application latency-sensitive?

The following recommendations apply in most cases:

Disk Drives	• Drives should be JBOD, using single-drive RAID0 volumes to take advantage of the controller cache. • SSDs are recommended when using HPE Ezmeral Data Fabric Database JSON with secondary indexes. HDDs can be used with secondary indexes only if the performance requirements are thoroughly understood. Performance can be substantially impaired on HDDs because of high levels of disordered I/O requests. SSDs are not needed for using HPE Ezmeral Data Fabric Streams.

last-updated: Jun 06, 2024

	• SAS drives can provide better I/O latency; SSDs provide even lower latency. • Match aggregate drive throughput to network throughput.
Cluster Size	• In general, it is better to have more nodes. Larger clusters recover faster from disk failures because more nodes are available to contribute. For information about fault tolerance, see Example Cluster Designs on page 91. • For smaller clusters, all nodes are likely to fit on a single non-blocking switch. Larger clusters require a well-designed Spine/Leaf fabric that can scale.
Operating System and Server Configuration	• Red Hat Enterprise Linux, SUSE Linux Enterprise Server, Ubuntu, Rocky, and Oracle Enterprise Linux are supported as described in Operating System Support Matrix on page 5719. • Install the minimal server configuration. Use a product like Cobbler to PXE boot and install a consistent OS image. • Install the full JDK (11 or 17). See Java Support Matrix on page 5764. • For best performance, avoid deploying a data-fabric cluster on virtual machines. However, VMs are supported for use as clients or edge nodes.
Memory, CPUs, Number of Cores	• Make sure the DIMM count is an exact multiple of the number of memory channels the selected CPU provides. • Use CPUs with as many cores as you can. Having more cores is more important than having a slightly higher clock speed. • HPE Ezmeral Data Fabric Database benefits from lots of RAM: 256GB per node or more. • File-system-only nodes can have fewer, faster cores: 6 cores for the first 10GbE of network bandwidth, and an additional 2 cores for each additional 10GbE. For example, dual 25GbE (50GbE) file-system-only nodes perform best with at least 6+(4*2)=14 cores. • File-system-only nodes should have hyperthreading disabled.

Service Layout in a Cluster

Provides an overview of segregating services on different nodes.

How you assign services to nodes depends on the scale of your cluster and the data-fabric license level. For a single-node cluster – which must not be used in a production environment (see Minimum Cluster Size on page 84) – no decisions are involved. All of the services you are using run on the single node.

On medium clusters, the performance demands of the CLDB and ZooKeeper services require them to be assigned to separate nodes to optimize performance. On large clusters, good cluster performance requires that these services run on separate nodes.

last-updated: Jun 06, 2024

The cluster is flexible and elastic. Nodes play different roles over the lifecycle of a cluster. The basic requirements of a node are not different for management or for data nodes.

As the cluster grows, it becomes advantageous to locate control services (such as ZooKeeper and CLDB) on nodes that do not run compute services. The Data Fabric Converged Community Edition does not include HA capabilities, which restricts the number of instances that certain services can run. The number of nodes and the services they run evolve over the life cycle of the cluster.

To provide a high-availability, high-performance cluster, the data-fabric software architecture allows virtually any service to run on any node, or nodes. The following guidelines help you to plan your cluster service layout.

NOTE: It is possible to install data-fabric software on a one- or two-node demo cluster. Production clusters can harness hundreds of nodes, but five- or ten-node production clusters are appropriate for some applications.

Node Types

Depending on the size of your cluster, nodes may or may not perform specialized work.

In a production data-fabric cluster, some nodes are typically dedicated to cluster coordination and management, and other nodes are tasked with data storage and processing duties. An edge node provides user access to the cluster, concentrating open user privileges on a single host. In smaller clusters, the work is not so specialized, and a single node may perform data processing as well as management.

Nodes Running ZooKeeper and CLDB

High latency on a ZooKeeper node can lead to an increased incidence of ZooKeeper quorum failures. A ZooKeeper quorum failure occurs when the cluster finds too few copies of the ZooKeeper service running. If the ZooKeeper node is running other services, competition for computing resources can lead to increased latency for that node. If your cluster experiences issues relating to ZooKeeper quorum failures, consider reducing or eliminating the number of other services running on the ZooKeeper node.

Nodes for Data Storage and Processing

Most nodes in a production cluster are data nodes. FileServer and NodeManager run on data nodes. Data nodes can be added or removed from the cluster as requirements change over time.

Edge Nodes

So-called Edge nodes provide a common user access point for the data-fabric webserver and other client tools. Edge nodes may or may not be part of the cluster, as long as the edge node can reach cluster nodes. Nodes on the same network can run client services and other services, but edge nodes and client nodes may not host data-fabric monitoring components.

Related concepts

HPE Ezmeral Data Fabric Monitoring Architecture on page 1696
HPE Ezmeral Data Fabric Monitoring integrates with open-source components to collect, aggregate, store, and visualize metrics and logs.

Service Layout Guidelines for Large Clusters

Describes how to install and segregate services on large clusters.

General Guidelines

The following are guidelines for installing services on large clusters:

- **ResourceManager**: Run the ResourceManager services on dedicated nodes for clusters with over 250 nodes.

last-updated: Jun 06, 2024

- **Elasticsearch:** Elasticsearch consumes significant CPU, disk, and memory resources. Review the following guidelines:
  - Whenever possible, Elasticsearch should have a dedicated disk for its index directory.
  - Depending on the number of indexed logs, you may want to run the Elasticsearch service on five or more dedicated nodes.
  - On production clusters, consider increasing Elasticsearch's memory allocation. After you install Data Fabric Monitoring, see Configure the Elasticsearch Service Heap Size on page 1764.
  - On clusters with high-density racks, run one or more Elasticsearch services on each rack. Also, configure Fluentd to write logs to Elasticsearch services that reside on the same rack as the Fluentd services. After you install Data Fabric Monitoring, see Configure Fluentd Services to Write to Elasticsearch Nodes on the Same Rack on page 1765.
- **OpenTSDB:** Run the OpenTSDB service on five or more nodes for clusters over 100 nodes.

Services to Separate on Large Clusters

The following are guidelines about which services to separate on large clusters:

- **ResourceManager on ZooKeeper nodes:** Avoid running the ResourceManager service on nodes that are running the ZooKeeper service. On large clusters, the ResourceManager service can consume significant resources.
- **Monitoring Services on CLDB Nodes**: Avoid running the OpenTSDB, Elasticsearch, Kibana, or Grafana services on nodes that are running the CLDB service.

Service Layout Guidelines for Replication

Based on the use case, replicating HPE Ezmeral Data Fabric Database tables and HPE Ezmeral Data Fabric Streams may require the installation of Data Fabric Gateways and the HBase client on one or more nodes.

Guidelines for Installing Gateways

When you configure replication for HPE Ezmeral Data Fabric Database tables or HPE Ezmeral Data Fabric Streams, data-fabric gateways provide one-way communication between a source data-fabric cluster and a destination cluster. It is recommended to install at least three gateways on the destination cluster. Installing two or more gateways on a destination cluster allows for replication failover in the event that one gateway is unavailable. Installing three gateways on a large cluster enables better throughput for data replication. Installing more than three gateways can improve availability but is not likely to improve replication performance.

Guidelines for Installing HBase Client

When you configure replication for HPE Ezmeral Data Fabric Database tables, the HBase client is not required by default. However, you must install the HBase client to replicate HPE Ezmeral Data Fabric Database tables in the following situations:

- You plan to perform autosetup table replication using the HPE Ezmeral Data Fabric Database C API. In this case, you must install the HBase Client on the node where the C application will run.
- You plan to perform autosetup table replication using the `maprcli table replica autosetup` command without direct copy. In this case, you must install the HBase Client on the node where you submit the `maprcli table replica autosetup` command. For more information about autosetup table replication, see Replica Autosetup for HPE Ezmeral Data Fabric Database Tables on page 763.

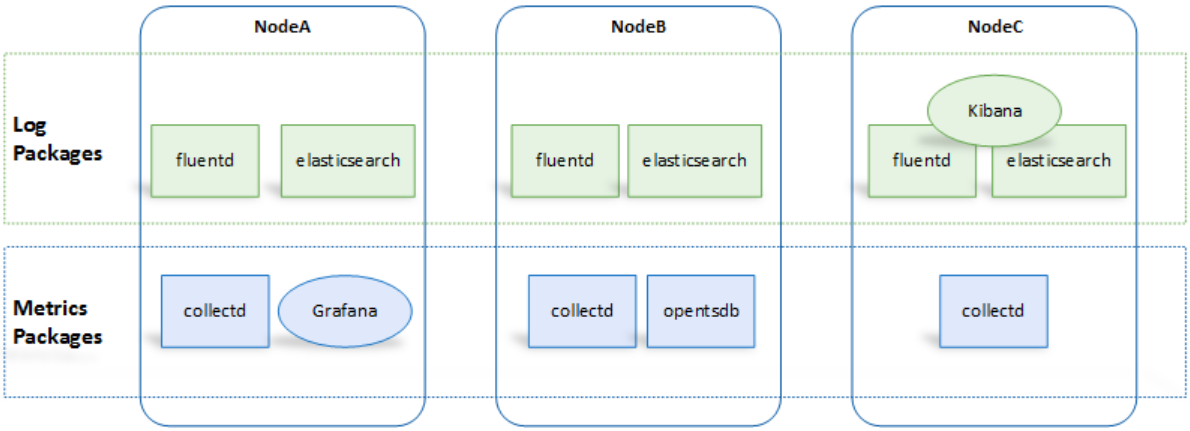
Data Fabric Monitoring Storage Options

Describes various storage options for Data Fabric Monitoring. The Control System relies on Data Fabric monitoring components to display metrics, but can function without the monitoring components. Using Data Fabric monitoring to store logs is optional.

The following installation options are available for metric storage with OpenTSDB and log storage with Elasticsearch. You can store logs and metrics on a non-Data Fabric cluster but this scenario is not supported by Data Fabric.

Store Metrics and Logs on the Monitored Cluster

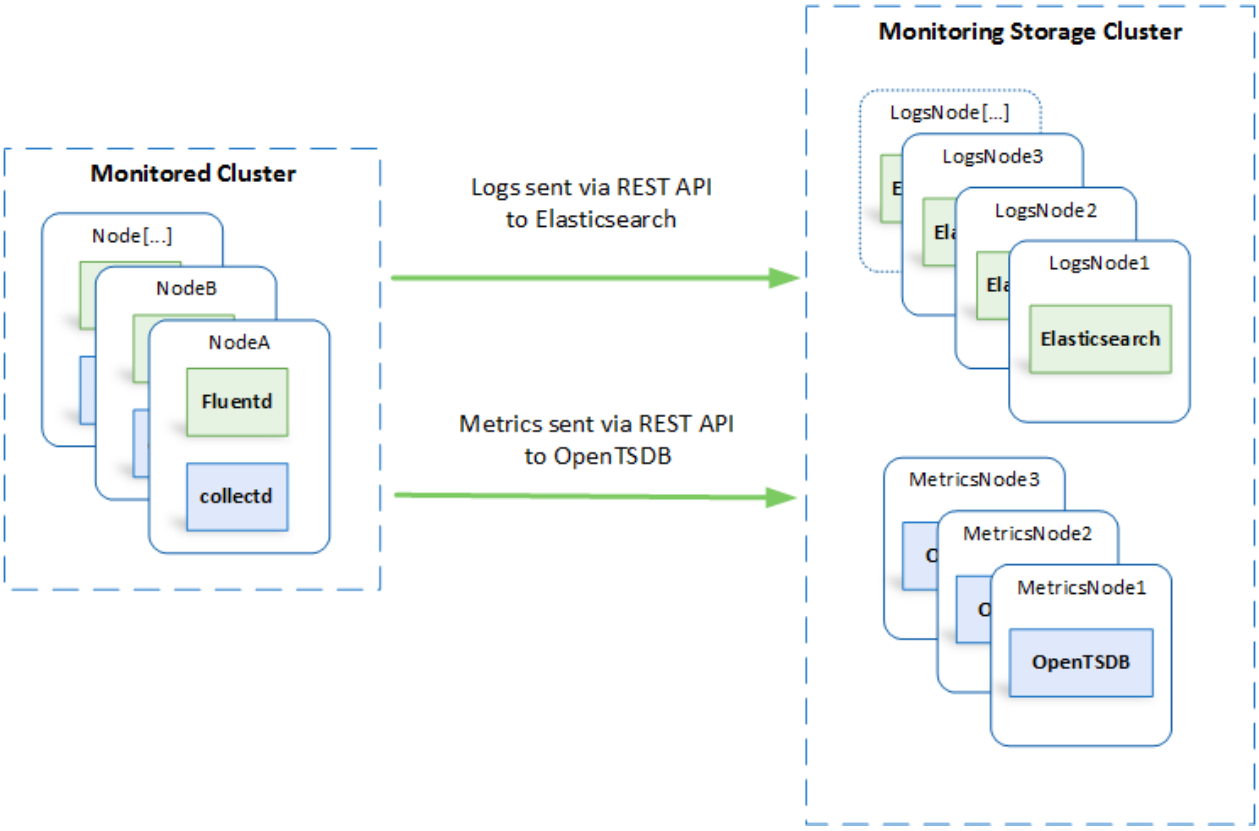
You can store metrics and logs on the nodes in the same Data Fabric cluster that you want to monitor. Note that installing Grafana is optional.



Store Metrics and Logs on a Storage Cluster

You can store metrics and logs for the Data Fabric cluster that you want to monitor, on nodes in a different Data Fabric cluster.

last-updated: Jun 06, 2024

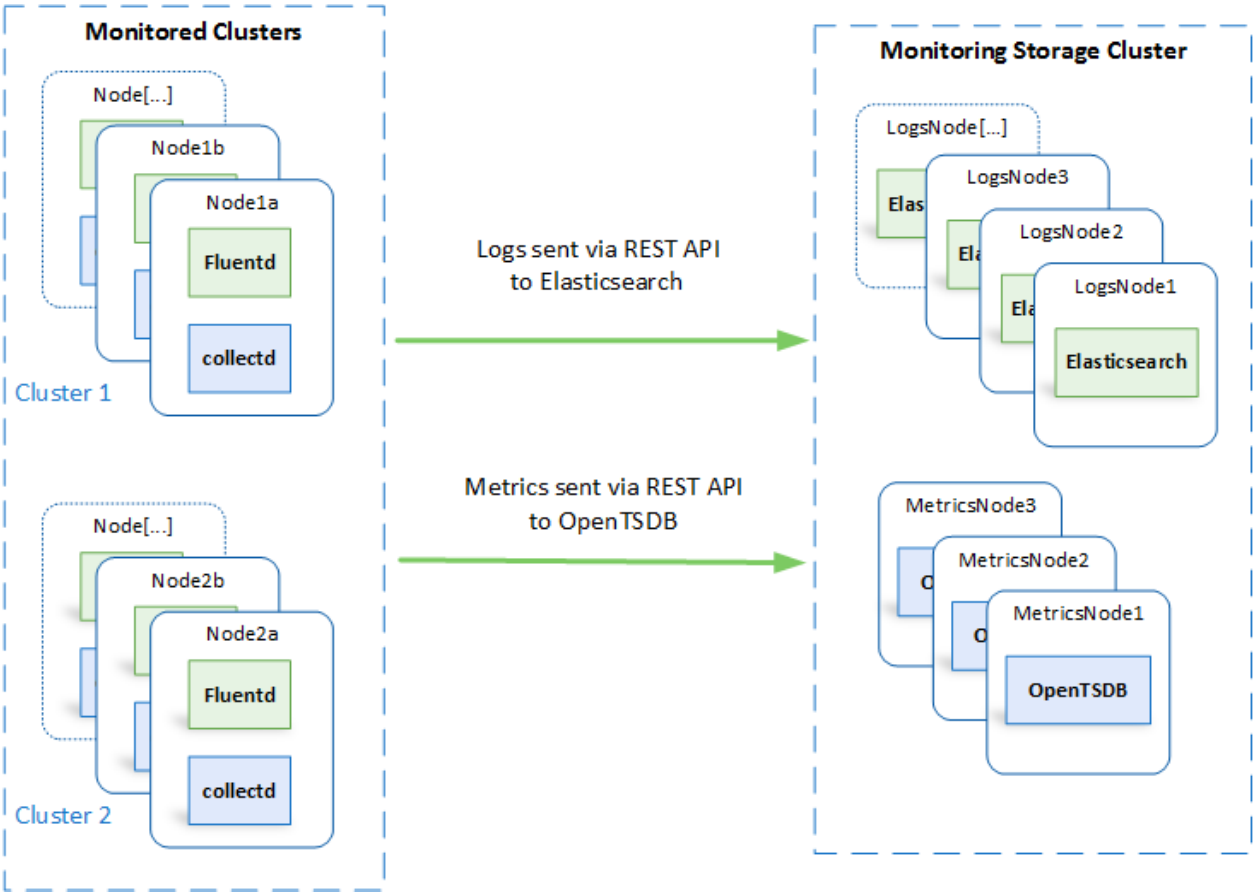


In this case, Kibana and Grafana can be installed on either cluster.

Use a Single Cluster to Store Monitoring Data for Multiple Clusters

You can store metrics and logs for more than one Data Fabric cluster on a shared set of nodes. With this option, a single dashboard can monitor multiple clusters.

last-updated: Jun 06, 2024



In this case, Kibana and Grafana can be installed on any of these clusters.

Example Cluster Designs
Describes how to design a Data Fabric cluster for maximum availability, fault-tolerance, and performance.

The topic includes example cluster designs for 6-node, 12-node, and 50-node clusters:

- Example 1: 6-Node Cluster (Single Rack) on page 95
- Example 2: 12-Node Cluster (3 Racks) on page 95
- Example 3: 50-Node Cluster (5 Racks) on page 96

Design Priorities

Building a cluster requires you to make decisions – and sometimes tradeoffs – that take into account cluster attributes such as:

- Performance
- Fault-tolerance
- Cost
- Ease of use
- Supportability
- Reliability

The following priorities and best practices can help you plan a durable cluster that includes all or most of these cluster attributes. The priorities are listed in order of importance:

Priority 1 - Maximize Fault Tolerance

Follow these best practices to ensure that your Data Fabric cluster can tolerate failures:

- Ensure an odd number of ZooKeeper services. ZooKeeper fault tolerance depends on a quorum of ZooKeeper services being available. At least three ZooKeeper services are recommended. For a higher level of fault tolerance, use five ZooKeeper services. With five ZooKeepers, the quorum is maintained even if two services are lost.
- For other services, it makes sense for them to be at least as reliable as ZooKeeper. Generally, this means at least two instances of the service for three ZooKeepers and three instances for five ZooKeepers.
- Include enough CLDBs to be as reliable as ZooKeeper. Because CLDBs use a primary-secondary configuration, a Data Fabric cluster can function with an odd or even number of CLDBs. The recommended minimum number of active CLDBs is two. To tolerate failures, more CLDBs are needed:
  - If you have three ZooKeepers, configure at least three CLDBs.
  - If you have five ZooKeepers, configure at least four CLDBs. With four CLDBs, the cluster can tolerate two CLDB failures and still provide optimal performance. Adding a fifth CLDB does not increase failure tolerance in this configuration.
- Include enough Resource Manager processes to be as reliable as ZooKeeper. Only one Resource Manager is active at a time:
  - If you have three ZooKeepers, you need at least two Resource Managers.
  - If you have five ZooKeepers, you need at least three Resource Managers. Three Resource Managers can survive the loss of two ZooKeepers.
- For most Data Fabric clusters, the recommended configuration is:
  - Three (3) ZooKeepers
  - Three (3) CLDBs
  - Two or three (2-3) Resource Managers

  For larger clusters, increase the number of CLDBs or ZooKeepers for better performance or higher reliability. Table 1 shows the number of failures tolerated by various combinations of ZooKeeper, CLDB, and Resource Manager services.

Table

ZooKeepers	CLDBs	Resource Managers	ZK/CLDB/RM Failures Tolerated
3	2[1]	2	1
3	3	2	1

last-updated: Jun 06, 2024

Table (Continued)

ZooKeepers	CLDBs	Resource Managers	ZK/CLDB/RM Failures Tolerated
5	4	3	2
5	5[2]	3	2

[1] For optimal failure handling, the minimum number of CLDBs is three; hence, three or more CLDBs are recommended. With two CLDBs, the failure of one does not result in an outage, but recovery can take longer than with three CLDBs.

[2] Using five CLDBs does not improve fault-tolerance significantly when compared with four CLDBs. However, it can be convenient to have the same number of CLDBs as ZooKeepers.

Priority 2 - Minimize Resource Contention

Every service on a node represents a tax on the resources provided by that node. Spreading services evenly across nodes maximizes performance and helps to keep failures isolated to failure domains. Because of power and networking considerations, a rack is usually the most common failure domain.

Follow these best practices to avoid performance bottlenecks:

- Spread like services across racks as much as possible. While not necessary, it is also convenient to put them in the same position, if possible.
- To maximize availability, use three or more racks even for small clusters. Using two racks is not recommended. If a cluster has three ZooKeepers, using two racks means one of the racks will host two ZooKeepers. In this scenario, a loss of a rack having two ZooKeepers can jeopardize the cluster.
  - For services that are replicated, make sure the replicas are in different racks.
  - Put the Resource Manager and CLDB services on separate nodes, if possible.
  - Put the ZooKeeper and CLDB services on separate nodes, if possible.
- Some administrators find it convenient to put web-oriented services together on nodes with lower IP addresses in a rack. This is not required.
- Avoid putting multiple resource-heavy services on the same node.
- Spread the following resources across all data nodes:
  - Clients
  - Drill
  - NFS

Priority 3 - Promote High Availability

Whenever possible, configure high availability (HA) for all services, not just for services that provide HA by default. CLDB, ZooKeeper, Resource Manager, and Drill provide HA by default. Some services are inherently stateless. If possible, configure multiple instances of these services:

- Kafka REST
- HBase Thrift
- HBase REST
- HTTPFS

last-updated: Jun 06, 2024

- HiveServer 2 (HS2)
- Hue
- Kafka Connect
- Data Fabric Data Access Gateway
- Data Fabric Gateway
- Keycloak
- OpenTSDB
- WebHCat
- WebServer

Priority 4 - Use Dedicated Nodes for Key Services on Large Clusters (50-100 Nodes)

Large clusters increase CLDB and Resource Manager workloads significantly. In clusters of 50 or more nodes:

- Use dedicated nodes for CLDB, ZooKeeper, and Resource Manager.

  NOTE: Dedicated nodes have the benefit of supporting fast fail-over for file-server operations.

- If fast fail-over is not critical and you need to minimize hardware costs, you may combine the CLDB and ZooKeeper nodes. For example, a large cluster might include 3 to 9 such combined nodes.
- If necessary, review and adjust the hardware composition of CLDB, ZooKeeper, and Resource Manager nodes. Once you have chosen to use dedicated nodes for these services, you might determine that they do not need to be identical to other cluster nodes. For example, dedicated CLDB and ZooKeeper nodes probably do not need as much storage as other cluster nodes.
- Avoid configuring Drill on CLDB or ZooKeeper nodes.

Example Clusters

The following examples are reasonable implementations of the design priorities introduced earlier in this section. Other designs are possible and might satisfy your unique environment and workloads.

- Example 1: 6-Node Cluster (Single Rack) on page 95
- Example 2: 12-Node Cluster (3 Racks) on page 95
- Example 3: 50-Node Cluster (5 Racks) on page 96

Each example includes tables for core components and Hadoop and ecosystem components. Because some services have specific database requirements, the examples also allocate nodes for dedicated MySQL or PostgreSQL instances.

IMPORTANT: The examples do not include all possible EEP components. For a complete list of the Data Fabric ecosystem components included in each EEP, see EEP Components and OS Support on page 5734. For a complete list of Apache projects, see the Apache Projects Directory.

last-updated: Jun 06, 2024

Example 1: 6-Node Cluster (Single Rack)

Example 1 shows a 6-node cluster contained in a single rack. When only a single rack is available, this example can work for small clusters. However, the recommended best practice for all clusters, regardless of size, is to use three or more racks, if possible.

Example 1a. Core Components for 6-Node Cluster

			Core

Example 3 Footnotes

* The Keycloak binary is installed on all nodes, but the service is started on only one node.

** Denotes a service that is lightweight and stateless. For greater performance, consider running these services on all nodes and adding a load balancer to distribute network traffic.

*** The *Total* column shows the total number of Core, Hadoop, and Ecosystem components installed on each host node for the example cluster.

Plan Initial Volumes
Describes why it is important to define volumes.

Data Fabric manages the data in a cluster in a set of *volumes*. Volumes can be mounted in the Linux filesystem in a hierarchical directory structure, but volumes do not contain other volumes. Each volume has its own policies and other settings, so it is important to define a number of volumes in order to segregate and classify your data.

Plan to define volumes for each user, for each project, and so on. For streaming data, you might plan to create a new volume to store new data every day or week or month. The more volume granularity, the easier it is to specify backup or other policies for subsets of the data. For more information on volumes, see Managing Data with Volumes.

Security Considerations

Planning for security will help you identify security shortcomings and address them before you go into production.

HPE Ezmeral Data Fabric releases provide security by default. If your cluster is not already secure, the Data Fabric Converged Data Platform supports many different levels of security. For more information, see Getting Started with HPE Ezmeral Data Fabric Security on page 1776.

Before installing data-fabric software using the published packages, make sure that you have reviewed the list of known vulnerabilities in Security Vulnerabilities on page 6184. If a vulnerability applies to your release, contact your data-fabric support representative for a fix, and apply the fix immediately, if applicable.

If the cluster you are planning to install must communicate with other clusters, the clusters should have similar security attributes. Mixing secure and nonsecure clusters is not recommended. For more information, see Setting Up Cross-Cluster Security on page 1948.

User Accounts

This section identifies how to organize authorized users of the cluster.

Part of the cluster plan is a list of authorized users of the cluster. It is preferable to give each user an account, because account-sharing makes administration less secure. Any user of the cluster must be established with the **same Linux UID and GID on every node in the cluster**. Central directory services, such as LDAP, AD, and IPA are often used to simplify user maintenance.

Next Step

After you have a complete cluster plan, you are ready to prepare each node.

It is important to begin installation with a complete Cluster Plan, but plans should not be immutable. Cluster services often change over time, particularly as clusters scale up by adding nodes. Balancing resources to maximize utilization is the goal, and it will require flexibility.

The next step is to prepare each node. Most installation difficulties are traced back to nodes that are not qualified to contribute to the cluster, or which have not been properly prepared. For large clusters, it can save time and trouble to use a configuration management tool such as Puppet or Chef.

Proceed to Preparing Each Node and assess each node.

last-updated: Jun 06, 2024

Installing Core and Ecosystem Components

Describes how to install HPE Ezmeral Data Fabric software and ecosystem components with or without the Installer.

This section assumes that you have already reviewed Planning the Cluster on page 79.

You can use either the Installer script or perform a manual installation. The Installer script takes care of using the right repositories for your Linux version, and there is nothing that you have to worry about. Hewlett Packard Enterprise recommends that you use the Installer script. The technically inclined can perform a manual installation.

Data Fabric Repositories and Packages

Describes the repositories for Data Fabric software and the ecosystem components.

Protected Internet Repository

The internet repository for Data Fabric core and ecosystem packages is now more secure. In August of 2023, the repository moved to a new location that requires authentication with an HPE Passport account:

https://package.ezmeral.hpe.com/

What's New in Release 7.7 on page 30 describes the repository change in more detail.

Because the new repository requires authentication, there are some new considerations for using it. See Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

Repositories for Core Software

HPE hosts `rpm` and `deb` repositories for installing the Data Fabric core software using Linux package-management tools. For every release of the core software, a repository is created for each supported platform.

Platform-specific installation repositories are hosted at: https://package.ezmeral.hpe.com/releases/v7.x.x/<platform>.

To set up the repositories, see Step 3: Prepare Packages and Repositories on page 182.

Repositories for Ecosystem Packs

An Ecosystem Pack (EEP) provides a set of ecosystem components that work together. HPE hosts `rpm` and `deb` repositories for easy installation of the ecosystem components.

These platform-specific repositories are hosted at the following location:

- https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/<platform>

For more information about the Ecosystem Packs (EEPs), see Ecosystem Packs on page 3893.

GitHub Repositories for Source Code

HPE releases the source code for ecosystem components to GitHub, including all patches that HPE has applied to the components. Source code projects for all releases since March 2013 are available at https://github.com/mapr. For example, the GitHub location for Airflow is https://github.com/mapr/airflow.

Maven Repositories for Application Developers

HPE hosts a Maven repository where application developers can download dependencies on Data Fabricsoftware or Hadoop ecosystem components. Maven artifacts for all releases since March 2013 are available at Maven Artifacts for the HPE Ezmeral Data Fabric on page 4745.

last-updated: Jun 06, 2024

Other Scripts and Tools

Other Data Fabric scripts and tools can be found in the following locations:

- https://package.ezmeral.hpe.com/scripts/
- https://package.ezmeral.hpe.com/tools/

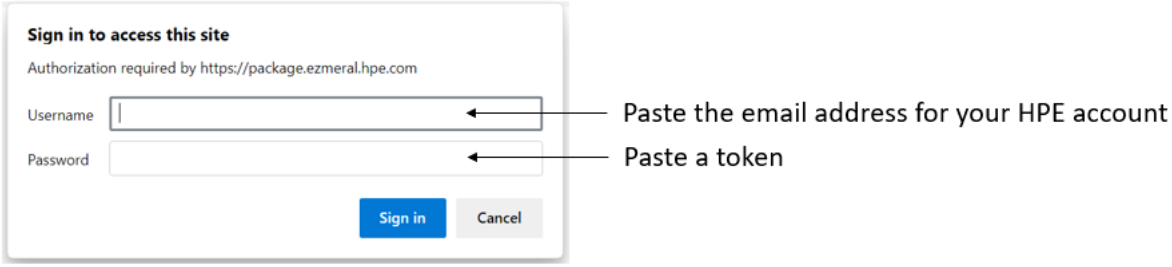
Using the HPE Ezmeral Token-Authenticated Internet Repository

Describes special considerations for using the token-authenticated internet repository for Data Fabric software and the ecosystem components.

Accessing the Token-Authenticated Repository

Using a browser to access the new token-authenticated package repository requires you to supply the email address associated with your HPE account and a token. Use these steps:

1. Navigate to the repository at https://package.ezmeral.hpe.com/.
   The authorization dialog box is displayed:



2. In the **Username** field, paste the email address for your HPE Passport account. To obtain an HPE Passport Account, see Obtaining an HPE Passport Account on page 103.
3. In the **Password** field, paste a token. To obtain a token, see Obtaining a Token on page 103.
4. Click **Sign in**.

What To Do If Your Installation Points to the Old Repositories

On October 2, 2023, the following Internet repositories were redirected to point to the new repository URL:

- https://package.mapr.com/
- https://package.mapr.hpe.com/

If your currently installed Data Fabric software points to one of these older repositories, you must make some changes to enable your installation to work with the new token-authenticated repository:

https://package.ezmeral.hpe.com/

You need to do the following:

- Obtain an HPE account (if you don't already have one)
- Obtain a token for your HPE account
- Update the Installer to the most current 1.18.0.3 version or later (if your installation uses the Installer)
- Update any installation or upgrade files that point to the Internet repository (see the following considerations)
- Reconfigure clients that point to the Internet repository (see the following considerations)

- Update any scripts that point to the Internet repository (see the following considerations)

Format for Passing an HPE User Name and Token to the Repository

Any files or scripts that point to the new Data Fabric internet repository must include the email address and token associated with a valid HPE account expressed in the following format:

`https://<email-address>:<token>@package.ezmeral.hpe.com/`

Examples for Accessing the Repository

In examples that require you to run Linux commands that point to the repository, this guide shows the format that is needed for including the user name and password. For example, to use a `wget` command with the new repository, you must add the email address and token as follows:

```
wget --user=jane.smith@company.com --password=<token> https://
package.ezmeral.hpe.com/releases/installer/mapr-setup.sh -P /tmp
```

Depending on the Linux distribution, other formats might be needed.

Obtaining an HPE Passport Account

An HPE Passport account is required to obtain support for Data Fabric products and gives you access to important HPE services.

To obtain an HPE Passport account, visit the MY HPE SOFTWARE CENTER and click **Sign In** to create a new account.

When you fill in information about your account, be sure to complete ALL of the fields (even fields that are not required). Leaving some fields blank can cause issues when you later try to access HPE repositories.

Obtaining a Token

A token associated with your HPE Passport account is required to obtain access to the HPE Ezmeral internet repositories.

You can create a new token at any time by using the following steps. A token created in this way does not expire. The token remains valid even after you create a new token.

To create a token for your HPE Passport account:

1. Visit the HPE Support Center User Token page.
2. Sign in if needed using your HPE Passport user ID and password.

Package Dependencies

Lists the interdependencies between packages across all the supported Operating Systems

Package Dependencies for Red Hat Enterprise Linux

Lists the dependencies for Red Hat Enterprise Linux (RHEL) 8.8.

Preparing Each Node

Defines minimum requirements for each node in your cluster.

Every node contributes to the cluster, so each node must be able to run HPE Ezmeral Data Fabric and Hadoop software. Nodes must meet minimum requirements for operating system, memory and disk resources, and installed software, such as Java. *Including unsuitable nodes in a cluster is a major source of installation difficulty.*

last-updated: Jun 06, 2024

Table

Component	Requirements
CPU	64-bit x86
CPU Cores	Minimum of 16 per CPU (see also Cluster Hardware on page 84)
OS	RHEL, Oracle Linux, Rocky, SLES, or Ubuntu
Memory	32 GB minimum for nodes in production
Disk	Raw, unformatted drives and no partitions
DNS	Hostname, reaches all other nodes
Users	Common users across all nodes; passwordless ssh (optional)
Java	Must run Java 11 or 17 (see the Java Support Matrix on page 5764)
Other	NTP, Syslog, PAM

TIP: For enhanced node performance and reliability, always set the MAPR_SUBNETS enivronment variable.

Use the subsequent sections as a checklist to make each candidate node suitable for its assigned roles. Install Data Fabric software on each node that you identify as meeting the minimum requirements.

CPU and Operating System

Describes how to check whether your processor and operating system are supported by data-fabric software.

Processor is 64-bit

To determine the processor type, run

```
$ uname -m
x86_64
```

If the output includes "x86_64," the processor is 64-bit. If it includes "i386," "i486," "i586," or "i686," it is a 32-bit processor, which is not supported by data-fabric software.

If the results are "unknown," or none of the above, use one of the following commands.

```
$ uname -a
Linux mach-name 2.6.35-22-server #33-Ubuntu SMP Sun Sep 19 20:48:58 UTC
2012 x86_64 GNU/Linux
```

In the `cpuinfo` file, the flag 'lm' (for "long-mode") indicates a 64-bit processor.

```
$ grep flags /proc/cpuinfo
flags               : fpu vme de pse tsc msr pae mce cx8 apic sep mtrr pge
mca cmov pat pse36 clflush dts acpi mmx fxsr sse sse2 ss syscall nx rdtscp
lm constant_tsc up arch_perfmon pebs bts rep_good xtopology tsc_reliable
nonstop_tsc aperfmperf pni pclmulqdq ssse3 cx16 sse4_1 sse4_2 popcnt aes
hypervisor lahf_lm ida arat
```

Supported Operating Systems

For the supported operating systems, see Operating System Support Matrix on page 5719.

To determine the name and version of the installed operating system, run the `lsb_release -a` command.

There is no problem if the `lsb_release` command reports "No LSB modules are available."

```
$ lsb_release -a
No LSB modules are available.
Distributor ID: Ubuntu
Description:    Ubuntu 10.10
Release:        10.10
Codename:       maverick
```

If the `lsb_release` command is not found, try one of the following alternatives:

```
$ cat /proc/version
Linux version 2.6.35-22-server (build@allspice) (gcc version 4.4.5 (Ubuntu/
Linaro 4.4.4-14ubuntu4) ) #33-Ubuntu SMP Sun Sep 19 20:48:58 UTC 2012
```

```
$ cat /etc/*-release
DISTRIB_ID=Ubuntu
DISTRIB_RELEASE=10.10
DISTRIB_CODENAME=maverick
DISTRIB_DESCRIPTION="Ubuntu 10.10"
```

If you determine that the node is running an older version of a supported OS, upgrade to at least a supported version, and test the upgrade before proceeding. If you find a different Linux distribution, such as Fedora or Gentoo, you must reformat and install a supported distribution on the node.

Memory and Disk Space
Describes required and recommended memory, storage, and disk capacities for each node.

Minimum Memory

For a production environment, Hewlett Packard Enterprise recommends at least 32 GB of memory per node. The absolute memory requirement for each node is determined by the data-fabric services that are configured to run on the node. For each configured service, you can adjust the minimum and maximum memory or use the default values, depending on your performance and functionality requirements (see Allocating Memory for Nodes on page 1127). Typical HPE Ezmeral Data Fabric production nodes have 128 GB or more. Development nodes often use considerably less than 32 GB.

Run `free -g` to display total and available memory in gigabytes.

```
$ free -g
             total       used       free     shared    buffers
cached
Mem:             3          2          1          0
0          1
-/+ buffers/cache:          0          2
Swap:            2          0          2
```

If the `free` command is not found, you can use other options such as `grep MemTotal: /proc/meminfo`, `vmstat -s -SM`, `top`, or various GUI system-information tools.

HPE does not recommend using the `numad` service, since it has not been tested and validated with HPE Ezmeral Data Fabric. Using the `numad` service can cause artificial memory constraints to be set, which can lead to performance degradation under load. To stop and disable the `numad` service:

1. Stop the service: `systemctl stop numad`.
2. Set the numad service *not* to start on reboot: `systemctl disable numad`

HPE does not recommend using *always overcommit* as it can lead to the kernel memory manager stopping processes to free memory, resulting in stopped HPE Ezmeral Data Fabric processes and system instability. Leave `vm.overcommit_memory` at its default value of 0, do not change the value to 1 or 2.

You can explore the functionality of HPE Ezmeral Data Fabric on non-production equipment, but under the demands of a production environment, memory needs to be balanced against disks, network, and CPU.

Storage

For data disks, Installer versions 1.12.0.0 and later require a minimum disk size that is equal to the physical memory on the node. If a data disk does not meet the minimum disk size requirement, a verification error is generated.

To display the currently available disks, use a command such as the following:

```
ls -l /dev/sd*
brw-rw---- 1 root 1000 8,  0 Sep 14 23:49 /dev/sda
brw-rw---- 1 root disk 8,  1 Sep 14 23:49 /dev/sda1
brw-rw---- 1 root disk 8,  2 Sep 14 23:49 /dev/sda2
brw-rw---- 1 root mapr 8, 16 Sep 20 11:44 /dev/sdb
brw-rw---- 1 root mapr 8, 32 Sep 20 11:44 /dev/sdc
brw-rw---- 1 root mapr 8, 48 Sep 20 11:44 /dev/sdd
```

To check the available disk space:

```
df /dev/sda
Filesystem     1K-blocks  Used Available Use% Mounted on
devtmpfs        12225720     0  12225720   0% /dev
```

HPE Ezmeral Data Fabric software works with raw unformatted devices and partitions. For optimized performance and high reliability, HPE recommends using raw unformatted devices. For data nodes, allocate at least three unmounted physical drives or partitions for data-fabric storage. Data Fabric software uses disk spindles in parallel for faster read/write bandwidth and therefore groups disks into sets of three.

Minimum Disk Allocation: HPE Ezmeral Data Fabric software requires a minimum of one disk or partition for data-fabric data. However, file contention for a shared disk decreases performance. In a typical production environment, multiple physical disks on each node are dedicated to the distributed file system, which results in much better performance.

Maximum Disk Allocation: If you are planning to install multiple instances of file system, the number of disks supported on a node can vary based on the number of instances you plan to install. For example, a single node with four instances of the data-fabric FileServer can support up to 360 disks.

Drive Configuration

Do not use RAID or Logical Volume Management with disks that are added to a data-fabric node. While HPE Ezmeral Data Fabric supports these technologies, using them incurs additional setup overhead and can affect your cluster's performance. Due to the possible formatting requirements that are associated with changes to the drive settings, configure the drive settings prior to installing data-fabric.

If you have a RAID controller, disable it, and let the system run in Host Bus Adapter (HBA) mode. For systems that do not support HBA, and have LSI MegaRAID controllers, configure the following drive-group settings for optimal performance:

Property (The actual name depends on the version)	Recommended Setting
RAID Level	RAID0
Stripe Size	>=256K
Cache Policy or I/O Policy	Cached IO or Cached

last-updated: Jun 06, 2024

Property (The actual name depends on the version)	Recommended Setting
Read Policy	Always Read Ahead or Read Ahead
Write Policy	Write-Through
Disk Cache Policy or Drive Cache	Disabled

Enabling the Disk Cache policy can improve performance. However, enabling the Disk Cache policy is not recommended because it increases the risk of data loss if the node loses power before the disk cache is committed to disk.

 **ATTENTION:** Disable write caching on all data-fabric disks if the disks are not battery backed.

Minimum Disk Space

OS Partition. Provide at least 10 GB of free disk space on the operating system partition. Provide 10 GB of free disk space in the `/tmp` directory and 128 GB of free disk space in the `/opt` directory. Services, such as ResourceManager and NodeManager, use the `/tmp` directory. Files, such as logs and cores, use the `/opt` directory.

File System. Provide the higher of 8 GB of free disk space or the memory allocated to the data-fabric file system. Note that the disk space should be greater than the memory allocated to the data-fabric file system. If you are using virtual disks, ensure that the virtual disks are thick-provisioned, to avoid the possibility of the virtual disk capacity being greater than actual physical disk capacity. A thin-provisioned virtual disk attempts to write past the end of the physical disk when the physical disk is full. Attempting to write past the end of physical disks could repeat across all thin-provisioned virtual disks at the same time if the thin-provisioned virtual disks are configured in a similar manner.

Swap Space. For production systems, provide at least 4 GB of swap space. If you believe more swap space is needed, consult the swap-space recommendation of your OS vendor. The amount of swap space that a production system needs can vary greatly depending on the application, workload, and amount of RAM in the system. Note that the Installer generates a warning if your swap space is either less than 10% of main memory, or less than 2 GB.

ZooKeeper. On ZooKeeper nodes, dedicate a partition, if practicable, for the `/opt/mapr/zkdata` directory to avoid other processes filling that partition with writes and to reduce the possibility of errors due to a full `/opt/mapr/zkdata` directory. This directory is used to store snapshots that are up to 64 MB. Since the four most recent snapshots are retained, reserve at least 500 MB for this partition. Do not share the physical disk where `/opt/mapr/zkdata` resides with any data-fabric file system data partitions to avoid I/O conflicts that might lead to ZooKeeper service failures.

Virtual Memory (swappiness)

Swappiness is a setting that controls how often the kernel copies the contents of RAM to swap. By setting `vm.swappiness` to the right value, you can prevent the system from swapping processes too frequently, but still allow for emergency swapping (instead of killing processes). For all Linux distributions, the HPE recommendation is to set `vm.swappiness` to 1.

To check the current value for `vm.swappiness` run:

```
cat /proc/sys/vm/swappiness
```

To change the value, run:

```
sudo sysctl vm.swappiness=1
```

The value of `vm.swappiness` can revert to a system default setting if you reboot the node. To make this setting permanent, enter `vm.swappiness=1` in `/etc/sysctl.conf` and save it.

last-updated: Jun 06, 2024

Connectivity

This section describes and helps you troubleshoot connectivity requirements.

Fully Qualified Domain Names (FQDNs)

When you install a HPE Ezmeral Data Fabric cluster and you specify the host names using the HPE Ezmeral Data Fabric installer or the `configure.sh` script, use fully qualified domain names (FQDNs). **Do not use an alias or IP address to specify the host names.** Using an IP address can prevent services such as the timeline service from verifying security certificates. In addition, monitoring services can fail after installation because of connection requests that are rejected. These issues can be difficult to troubleshoot and can be prevented by using FQDNs.

It is important to use FQDNs when configuring a secure cluster. However, the practice also applies to non-secure clusters that might later be upgraded to be secure. The same connectivity issues can be encountered when a non-secure cluster is upgraded to a secure cluster. If your cluster is non-secure and will not be secured, or if you are not concerned about connection issues for the monitoring services, you may use IP addresses to specify the host names.

Unique Hostnames

Each node in the cluster must be accessible via DNS. More specifically, each node in the cluster must have a unique hostname, resolvable forward and backward with every other node with both normal and reverse DNS name lookup.

Run `hostname -f` to check the node's hostname. For example:

```
$ hostname -f
node125.corp.example.com
```

If `hostname -f` returns a name, run `getent hosts 'hostname'` to return the node's IP address and fully-qualified domain name (FQDN).

```
$ getent hosts 'hostname'
10.250.1.53     node125.corp.example.com
```

To troubleshoot hostname problems, edit the `/etc/hosts` file as `root`. A simple `/etc/hosts` might contain:

```
127.0.0.1     localhost
10.10.5.10    mapr-hadoopn.maprtech.prv mapr-hadoopn
```

A common problem is an incorrect loopback entry (127.0.x.x) that prevents the IP address from being assigned to the hostname. For example, on Ubuntu, the default `/etc/hosts` file might contain:

```
127.0.0.1     localhost
127.0.1.1     node125.corp.example.com
```

A loopback (`127.0.x.x`) entry with the node's hostname will confuse the installer and other programs. Edit the `/etc/hosts` file and delete any entries that associate the hostname with a loopback IP. Only associate the hostname with the actual IP address.

NOTE: For more information about Ubuntu's default `/etc/hosts` file, see https://bugs.launchpad.net/ubuntu/+source/cloud-init/+bug/871966.

Use the `ping` command to verify that each node can reach the others using each node's hostname. For more information, see the hosts(5) man page.

last-updated: Jun 06, 2024

Common Users

A user that accesses the cluster must have the same credentials and user ID (uid) on each node in the cluster. Every person or department that runs HPE Ezmeral Data Fabric jobs must have an account and must also belong to a common group ID (gid). The uid for each user, and the gid for each group, must be consistent across all nodes.

A `mapr` user must exist, and have the same UID across all the cluster nodes. The `mapr` user has full privileges to administer the cluster. If you create the `mapr` user before you install HPE Ezmeral Data Fabric, you can test for connectivity issues. If you do not create the `mapr` user, installing HPE Ezmeral Data Fabric automatically creates the user for you. The `mapr` user ID is automatically created on each node if you do not use a directory service, such as LDAP.

To create a group, add a user to the group, or create the `mapr` user, run the following command as root substituting a uid for *m* and a gid for *n*. (The error "cannot lock /etc/passwd" suggests that the command was not run as root.)

```
$ useradd mapr --gid n --uid m
```

Example: `$ groupadd -g 5000 mapr` `$ useradd -g 5000 -u 5000 mapr`

To verify that the users or groups were created, run `su mapr`. Verify that a home directory was created (usually `/home/mapr`) and that the users or groups have read-write access to it. The users or groups must have write access to the `/tmp` directory, or Warden will fail to start services.

Optional: Passwordless ssh

Setting up passwordless ssh is straightforward. On each webserver node, generate a key pair and append the key to an authorization file. Then copy this authorization file to each node, so that every node is available from the webserver node.

`su mapr` (if you are not already logged in as mapr) `ssh-keygen -t rsa -P '' -f ~/` *`filename`*

The `ssh-keygen` command creates *`filename`* , containing the private key, and *`filename`* `.pub`, containing the public key. For convenience, you may want to name the file for the hostname of the node. For example, on the node with hostname "node10.10.1.1,"

```
ssh-keygen -t rsa -P '' -f ~/node10.10.1.1
```

In this example, append the file `/home/mapr/node10.10.1.1.pub` to the `authorized_keys` file.

Append each webserver node's public key to a single file, using a command such as `cat` *`filename`* `.pub >> authorized_keys`. (The key file is simple text, so you can append the file in several ways, including a text editor.) When every webserver node's empty passphrase public key has been generated, and the public key file has been appended to the primary "authorized_keys" file, copy this primary keys file to each node as `~/.ssh/authorized_keys`, where ~ refers to the mapr user's home directory (typically `/home/mapr`).

Recommended: Setting the MAPR_SUBNETS Variable

For enhanced performance and reliability, always set the MAPR_SUBNETS enivronment variable.

Java

To run data-fabric software and Hadoop, you must install a supported Java Development Kit (JDK) on your node.

Java

HPE Ezmeral Data Fabric requires the Java Development Kit (JDK). Installing only the Java runtime environment (JRE) is not sufficient. Verify that one of the following JDK versions is installed on the node:

last-updated: Jun 06, 2024

Java Requirements for Data Fabric Core	• Oracle Java JDK 11* • OpenJDK 11* • Amazon Corretto 11* *Oracle Java JDK 17, OpenJDK 17, and Amazon Corretto 17 are supported for releases 7.2.0 and later. See the Java Support Matrix on page 5764. **NOTE:** Make sure you have the development kit installed. Some JRE packages include jdk in the name, but do not provide the required JDK software.
Installation Information	To install one of the supported Java JDK distributions, see: • Oracle Java JDK 11 • OpenJDK 11 • Amazon Corretto 11
Special Requirements for Using OpenJDK	If you use OpenJDK: • RedHat/CentOS must have `java-<version>-openjdk-devel` installed. • SLES nodes must have `java-<version>-openjdk-devel` installed. • Ubuntu nodes must have `openjdk-<version>-jdk` installed.

NOTE: The `openjdk-devel` and `openjdk-<version>-jdk` packages include the `jps` command that lists running Java processes and can show whether the CLDB has started. This command is not supported in the Sun Java JRE.

Related reference

Java Support Matrix on page 5764
Shows the Java Development Kit versions supported by different HPE Ezmeral Data Fabric releases.

Infrastructure

Identifies certain software and settings that contribute to your node's infrastructure.

Network Time

To keep all cluster nodes time-synchronized, Data Fabric requires software such as a Network Time Protocol (NTP) server (or chrony for RHEL 7) to be configured and running on every node. If server clocks in the cluster drift out of sync, serious problems will occur with certain Data Fabric services. Data Fabric raises a Time Skew alarm on any out-of-sync nodes. For more information about obtaining and installing NTP, see http://www.ntp.org/.

Advanced: It is recommended to install an internal time server with which the cluster nodes can sync directly. If internet connectivity is lost, the time on the cluster nodes stays in sync. For more details, refer to the preceding documentation link for NTP

System Locale

Ensure that your system locale is set to `en_us`. For more information about setting the system locale, see this website.

last-updated: Jun 06, 2024

Syslog

`Syslog` should be enabled on each node to preserve logs for killed processes or failed jobs. Modern versions such as `syslog-ng` and `rsyslog` are possible, making it more difficult to be sure that a `syslog` daemon is present. One of the following commands should suffice:

```
syslogd -v
service syslog status

rsyslogd -v
service rsyslog status
```

Default umask

To prevent significant installation problems, ensure that the default umask for the root user is set to 0022 on all Data Fabric nodes in the cluster. You can change the umask setting in the `/etc/profile` file, or in the `.cshrc` or `.login` file. The `root` user must have a 0022 umask because the Data Fabric `admin` user requires access to all files and directories under the `/opt/mapr` directory, even those initially created by root services.

ulimit

`ulimit` is a command that sets limits on a user's access to system-wide resources. Specifically, it provides control over the resources available to the shell and to processes started by it.

The `mapr-warden` script uses the `ulimit` command to set the maximum number of file descriptors (`nofile`) and processes (`nproc`) to 64000. Higher values are unlikely to result in an appreciable performance gain. Lower values, such as the default value of 1024, are likely to result in task failures.

WARNING: The Data Fabric recommended value is set automatically every time Warden is started.

Depending on your environment, you might want to set limits manually for service accounts used to run I/O-heavy operations rather than relying on Warden to set them automatically using `ulimit`.

PAM

Nodes that run the **Control System** can take advantage of Pluggable Authentication Modules (PAM) if found. Configuration files in the `/etc/pam.d/` directory are typically provided for each standard Linux command. Data Fabric can use, but does not require, its own profile.

Security - SELinux

Using SELinux is supported if the cluster admin follows some specific best practices. See SELinux Support on page 177.

TCP Retries

On each node, set TCP retries for `net.ipv4.tcp_retries2` to 5 so that Data Fabric can detect unreachable nodes with less latency.

NOTE: The installation automatically sets TCP retries for `net.ipv4.tcp_syn_retries` to 4 on each node.

1. Edit the file `/etc/sysctl.conf` and add the following line:

   ```
   net.ipv4.tcp_retries2=5
   ```

2. Save the file and run:

   ```
   sysctl -p
   ```

last-updated: Jun 06, 2024

NFS

Disable the stock Linux NFS server on nodes that will run the Data Fabric NFS server.

iptables/firewalld

Enabling `iptables` on a node can close ports that are used by Data Fabric. If you enable `iptables`, make sure that required ports remain open. Check your current `iptables` rules by using the following command:

```
$ service iptables status
```

In CentOS 7, `firewalld` replaces `iptables`. To check your current `iptables` rules, use this command:

```
systemctl status firewalld
```

To ensure that the required ports are available, disable `firewalld` by using this command:

```
systemctl disable firewalld
```

Transparent Huge Pages (THP)

For data-intensive workloads, Data Fabric recommends disabling the Transparent Huge Pages (THP) feature in the Linux kernel.

RHEL Example

```
$ echo never > /sys/kernel/mm/transparent_hugepage/enabled
```

CentOS 7 Example

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
```

Ubuntu Example

```
$ echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

Automated Configuration

Some users find tools such as `Ansible`, `Puppet`, or `Chef` useful to configure each node in a cluster. Make sure, however, that any configuration tool does not reset changes made when Data Fabric packages are later installed. Specifically, do not let automated configuration tools overwrite changes to the following files:

- `/etc/sudoers`
- `/etc/sysctl.conf`
- `/etc/sysctl.d/60-mapr_elasticsearch.conf`
- `/etc/sysctl.d/60-mapr_fluentd.conf` on page 1766
- `/etc/security/limits.conf`
- `/etc/udev/rules.d/99-mapr-disk.rules`

Setting Resource Limits on CentOS/RedHat/Oracle Linux
While you can use Warden to automatically set resource limits, you may want to set limits manually.

About this task

Rather than relying on Warden to set resource file-access limits automatically using `ulimit`, you can use the following procedure to set the limits manually.

Procedure

1. Edit `/etc/security/limits.conf` and add a line to set the resource limits. For example, set the resource limits to 65536.

   ```
   <MAPR_USER> - nofile 65536
   ```

2. Edit `/etc/security/limits.d/90-nproc.conf` to add a similar line.

   ```
   <MAPR_USER> - nproc 64000
   ```

3. Check that the `/etc/pam.d/su` file contains the following settings:

   ```
   #%PAM-1.0
   auth            sufficient      pam_rootok.so
   # Uncomment the following line to implicitly trust users in the "wheel"
   group.
   #auth           sufficient      pam_wheel.so trust use_uid
   # Uncomment the following line to require a user to be in the "wheel"
   group.
   #auth           required        pam_wheel.so use_uid
   auth            include         system-auth
   account         sufficient      pam_succeed_if.so uid = 0 use_uid quiet
   account         include         system-auth
   password        include         system-auth
   session         include         system-auth
   session         required        pam_limits.so
   session         optional        pam_xauth.so
   ```

4. Use `ulimit` to verify settings.

5. Reboot the system.

6. Run the following command as the `mapr` user (not root) at a command line: `ulimit -n`

Setting Resource Limits on Ubuntu
While you can use Warden to automatically set resource limits, you may want to set limits manually.

About this task

Rather than relying on Warden to set resource limits automatically using `ulimit`, you can use the following procedure to set the limits manually.

Procedure

1. Edit `/etc/security/limits.conf` and add a line to set the resource limits. For example, set the resource limits:

   ```
   <MAPR_USER> - nofile 65536
   <MAPR_USER> - nproc 64000
   ```

last-updated: Jun 06, 2024

2. Edit `/etc/pam.d/su` and uncomment the following line.

```
session required pam_limits.so
```

3. Edit the `/etc/pam.d/common-session*` files to make sure the following entry is present:

```
# end of pam-auth-update config
session       required       pam_limits.so
```

4. Use `ulimit` to verify settings.
5. Reboot the system.
6. Run the following command as the `mapr` user (not root) at a command line: `ulimit -n`

Setting Resource Limits on SLES

While you can use Warden to automatically set resource limits, you may want to set limits manually.

About this task

Rather than relying on Warden to set resource limits automatically using `ulimit`, you can use the following procedure to set the limits manually.

Procedure

1. Edit the `/etc/pam.d/common-session*` files to make sure the following entry is present:

```
# end of pam-auth-update config
session       required       pam_limits.so
```

2. Use `ulimit` to verify settings.
3. Reboot the system.
4. Run the following command as the `mapr` user (not root) at a command line: `ulimit -n`

SELinux Support

HPE Ezmeral Data Fabric supports SELinux for cluster administrators who observe specific installation and administrative procedures.

Before using the HPE Ezmeral Data Fabric with SELinux, note the following considerations and best practices:

- **Installation:** Hewlett Packard Enterprise recommends disabling SELinux before installing Data Fabric software. If you install the cluster by using the Installer, the Installer disables SELinux automatically. If you require the extra security provided by SELinux, you can enable SELinux and place it in enforcing mode after installation. Also, rules can be defined by observing regular operations while the cluster is running.
- **Known Issues:** For a list of known issues that you should be aware of when using SELinux with the HPE Ezmeral Data Fabric, see Known issues: Running HPE Ezmeral Data Fabric on nodes with SELinux in enforcing mode.
- **Warnings in the Audit Log:** While using the HPE Ezmeral Data Fabric, if you see warnings in the SELinux audit log (`/var/log/audit/`) related to Data Fabric services, the cluster admin can fix them by using `chcon` or similar tools.

last-updated: Jun 06, 2024

- **Cluster-Admin Use of systemctl:** The Data Fabric cluster admin (typically the `mapr` user) must be allowed to use `systemctl`. Without access to `systemctl`, Warden can fail to start cluster services.
- **System Administration:** SELinux introduces significant complexity and should be managed by an experienced system administrator. Managing SELinux is outside the scope of Data Fabric cluster-administration activities.
- **Utilities and Services That Must Not Be Blocked** The following inexhaustive list of utilities and services must remain unblocked at all times for the HPE Ezmeral Data Fabric to run successfully in an SELinux environment:
  - `bash`
  - `dmidecode`
  - `glibc`
  - `hdparm`
  - `initscripts`
  - `iputils`
  - `irqbalance`
  - `libgcc`
  - `libstdc++`
  - `lsof`
  - `net-tools`
  - `nfs-utils`
  - `nss`
  - `perl`
  - `python`
  - `redhat-lsb-core`
  - `rpcbind`
  - `shadow-utils`
  - `syslinux`
  - `userspace-rcu`

Installing with the Installer

The Installer automates the process of installing Data Fabric software and offers you a variety of options to complete the installation.

last-updated: Jun 06, 2024

Use this option . . .	When	See for more information
Installer web interface	You need a wizard-like tool to install Data Fabric software, and you want visual feedback about the installation process.	Installer on page 5579
Installer Stanzas	You need a script-based tool to install Data Fabric software, and you do not want to click through the menus and options provided by the web-based Installer.	Installer Stanzas on page 5700
Installer Containers	You want to use either the web-based Installer or Stanzas from a Docker container.	Installer Containers on page 5695

NOTE: If you do not want to use one of the Installer options, you still have the option to install the software manually. See Installing without the Installer on page 179.

Installing without the Installer

Describes how to install HPE Ezmeral Data Fabric software and ecosystem components manually.

These steps describe how to install a secure Data Fabric cluster.

After you have planned the cluster and prepared each node, you can install the Data Fabric distribution from the Data Fabric repository or package files. Installing the software requires that you perform certain steps on each node. You can install Data Fabric ecosystem components, such as Hive, after you bring up the cluster.

WARNING: Before you install, make sure that all nodes meet the requirements for installation. See Preparing Each Node on page 166 for more information. Failure to prepare nodes is the primary cause of installation problems. **You must also make sure that the package dependencies are installed. See Package Dependencies on page 103 and Installer Prerequisites and Guidelines on page 5581. These packages are downloaded for you when you use the Installer, but must be installed manually before you install without using the Installer.**

You must also have the following information from your cluster plan when you install:

- List of the hostnames and IP addresses for all nodes.
- List of the services that you want to run on each node. For an example, see Example Cluster Designs on page 91.
- List of all disks and partitions to use on each node.

NOTE: For information about repositories and packages for Data Fabric software and Hadoop Ecosystem tools, see Data Fabric Repositories and Packages on page 101.

To install Data Fabric software successfully, complete each step described in the following sections. To learn how HPE uses, shares, transfers, and manages personal information, see the HPE Privacy Statement.

Step 1: (Optional) Enable FIPS Mode
If your cluster must be FIPS-compliant, you must enable FIPS mode at the operating system level *before* installing data-fabric software. If FIPS compliance is not needed, you can skip this step.

This page describes how to enable FIPS mode for each of the operating systems where it is supported. For more information about FIPS, see FIPS Compliance for HPE Ezmeral Data Fabric on page 878 and this page.

When you enable FIPS mode at the operating system level, the HPE Ezmeral Data Fabric platform is automatically installed in FIPS mode with FIPS-compliant BCFKS key and trust stores.

All FIPS 140-2 Level 1 Linux operating system distributions supported by the HPE Ezmeral Data Fabric have a way of enabling FIPS mode at the operating system level. However, enabling FIPS mode at the operating system level covers only the use of FIPS-compliant system libraries (OpenSSL), and not the additional packages that use cryptography that are not part of the operating system – notably JDK 11.

Note these considerations:

- Enabling FIPS mode at the operating system level automatically causes FIPS-compliant mode to be enabled in the HPE Ezmeral Data Fabric.
- FIPS compliance is enforced on a per-node level. It is possible for some nodes in a cluster to run in FIPS mode while others run in non-FIPS-compliant mode. Different nodes running in mixed configuration can communicate with each other as long as the cryptographic algorithms used for securing network data are FIPS-compliant. The AES-256 GCM cryptographic algorithm and TLS 1.2 and 1.3 protocols used to secure network data in previous data-fabric releases are FIPS compliant.

Determining if the Operating System is FIPS-Enabled

If you don't know the current FIPS status for a node, you can use `maprcli` commands to determine whether FIPS mode is enabled at the operating system. See Determining if a Host Is in FIPS Mode on page 1806.

Enabling FIPS Mode in Red Hat Enterprise Linux 8

Setting the RHEL 8 operating system to FIPS mode automatically makes the FIPS 140-2 Level 1 certified RedHat OpenSSL 1.1.1 library available with all non-FIPS approved cryptographic algorithms disabled.

You can install the RHEL 8 operating system with FIPS mode enabled by adding the `fips=1` option to the kernel command line during system installation. This is the recommended way to enable FIPS mode, as opposed to enabling FIPS mode later, because this ensures the system generates all cryptographic keys with FIPS-approved algorithms.

Alternatively, you can switch an existing non-FIPS system to FIPS mode after installation. To do this, use the `fips-mode-setup -enable` command, and then reboot the system:

```
# fips-mode-setup --enable
Setting system policy to FIPS.
FIPS mode will be enabled.
Please reboot the system for the setting to take effect.
# reboot
```

After the reboot, check the current state of FIPS mode using the following command:

```
# fips-mode-setup --check
FIPS mode is enabled
```

Enabling FIPS Mode in Ubuntu 18.04

In Ubuntu 18.04, access to FIPS repositories is controlled by a token associated with an Ubuntu Advantage subscription. For detailed information about how to enable FIPS in Ubuntu, refer to the Ubuntu website. The following steps provide a summary:

1. Install the Ubuntu Advantage tools:

   ```
   # sudo apt update && sudo apt install ubuntu-advantage-tools
   ```

last-updated: Jun 06, 2024

2. 2. If you are not using the Ubuntu PRO images, you need to obtain the UA token from your Ubuntu One account under the **Your Paid Subscriptions** header, save it, and then attach it to the Ubuntu system:

```
# sudo ua attach <token>
```

3. Enable FIPS, including security updates, and verify the status:

```
# sudo ua enable fips-updates
# sudo ua status
```

To enable only validated FIPS without the security updates (not recommended), which results in updating only validated packages upon revalidation, use `sudo ua enable fips` instead of `sudo ua enable fips-updates`.

4. Reboot the system for the changes to take effect. After rebooting, verify that FIPS is enabled:

```
# cat /proc/sys/crypto/fips_enabled
1
```

Enabling FIPS Mode in SUSE Enterprise Linux 15 SP2

For detailed information about how to enable FIPS in SLES 15 SP 2, refer to the SLES 15 SP 2 online documentation. The following steps provide a summary:

1. Install the FIPS pattern:

```
$ sudo zypper in -t pattern fips
```

2. Assuming that the boot partition is not on a separate partition, edit `/etc/default/grub` to add `fips=1` to `GRUB_CMDLINE_LINUX_DEFAULT`. For example:

```
GRUB_CMDLINE_LINUX_DEFAULT="splash=silent mitigations=auto quiet fips=1"
```

3. Save your changes, and rebuild the grub partition:

```
$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
$ sudo mkinitrd
```

4. Reboot, and verify your changes:

```
$ sudo sysctl -a | grep fips
crypto.fips_enabled = 1
```

Step 2: Import the Package Key

Before you install Data Fabric packages, you must import the package key.

About this task

Data Fabric packages are cryptographically signed. Before you can install the packages, you must import the package key: `maprgpg.key`. The package key allows you to, optionally, verify the package signatures. For more information, see HPE GPG Public Keys for GPG or RPM Signature Verification.

For SLES only, you do not have to import the key because `zypper` allows package installation with or without the key.

last-updated: Jun 06, 2024

Procedure

- To import the package key, issue the command appropriate for your Linux distribution:

  IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

  - RHEL/Rocky/Oracle Linux

    ```
    wget --user=<email> --password=<token> -O /tmp/maprgpg.key -q https://
    package.ezmeral.hpe.com/releases/pub/maprgpg.key && rpm --import /tmp/
    maprgpg.key
    wget --user=<email> --password=<token> -O /tmp/hpeezdf.pub -q https://
    package.ezmeral.hpe.com/releases/pub/hpeezdf.pub && rpm --import /tmp/
    hpeezdf.pub && gpg --import /tmp/hpeezdf.pub
    ```

  - Ubuntu

    ```
    wget --user=<email> --password=<token> -O /tmp/maprgpg.key -q https://
    package.ezmeral.hpe.com/releases/pub/maprgpg.key && sudo apt-key
    add /tmp/maprgpg.key
    wget --user=<email> --password=<token> -O /tmp/gnugpg.key -q https://
    package.ezmeral.hpe.com/releases/pub/gnugpg.key && sudo apt-key
    add /tmp/gnugpg.key
    ```

Step 3: Prepare Packages and Repositories
To install services correctly, each node must have access to the package files.

The Data Fabric software distribution is separated into two repositories that contain the package files:

- **Data Fabric packages.** These provide core functionality for Data Fabric clusters, such as the file system.
- **Ecosystem packages.** These packages are not specific to HPE Ezmeral Data Fabric. Examples include the packages for Hive and Spark.

You can make packages available to each node, as described in subsequent sections, using the Data Fabric Internet repository, a local repository, or a local path with rpm or deb package files. For information about packages and repositories for Data Fabric software and Hadoop Ecosystem tools, see Data Fabric Repositories and Packages on page 101.

Using the Data Fabric Repository (Installation)
This section describes how to make packages available through the HPE Ezmeral Data Fabric repository.

The HPE Ezmeral Data Fabric repository on the internet provides all of the packages required to install a Data Fabric cluster using native tools such as:

- `yum` on RHEL, Oracle Linux, or CentOS
- `zypper` on SLES
- `apt-get` on Ubuntu

Installing from the internet repository is generally the easiest installation method, but requires the greatest amount of bandwidth. With this method, each node is connected to the internet to download the required packages.

Set up repositories by completing the steps for your RHEL/Oracle Linux/CentOS, SLES, or Ubuntu distribution.

Adding the Data Fabric Repository on RHEL, CentOS, or Oracle Linux
This section describes how to install the Data Fabric repository.

Procedure

1. Change to the `root` user or use `sudo`.
2. Create a text file called `maprtech.repo` in the `/etc/yum.repos.d/` directory with the following content, replacing `<version>` with the version of data-fabric software that you want to install: (For the correct paths for all past releases, see the Data Fabric Repositories and Packages on page 101.)

   IMPORTANT: To access the Data Fabric internet repository, you must specify the user name (email) and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

   ```
   [maprtech]
   name=HPE Ezmeral Data Fabric
   baseurl=https://package.ezmeral.hpe.com/releases/v<version>/redhat/
   username=<email-address>
   password=<token>
   enabled=1
   gpgcheck=1
   protect=1

   [maprecosystem]
   name=HPE Ezmeral Data Fabric
   baseurl=https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/redhat
   username=<email-address>
   password=<token>
   enabled=1
   gpgcheck=1
   protect=1
   ```

3. If your connection to the Internet is through a proxy server, you must set the `http_proxy` environment variable before installation: You should also set the value for the `http_proxy` environment variable by adding the following section to the `/etc/yum.conf` file:

   ```
   http_proxy=http://<host>:<port>
   export http_proxy
   ```

   ```
   proxy=http://<host>:<port>
   proxy_username=<username>
   proxy_password=<password>
   ```

4. If you are installing release 6.1.0 on RHEL or CentOS 8.x, enable the EPEL repository as described in Enable the EPEL Repository on CentOS 8.x, RHEL 8.x, or Oracle Linux 8.x on page 184. Starting in RHEL 8.x, a `mapr-core-internal` package dependency (`sdparm`) is deprecated and moved to EPEL, and installation cannot complete without enabling it.

Enable the EPEL Repository on CentOS 6.x, RHEL 6.x, or Oracle Linux 6.4 or higher
This section describes how to download and install the EPEL repository.

Procedure

1. Download the EPEL repository:

```
wget https://archives.fedoraproject.org/pub/archive/epel/6/x86_64/
epel-release-6-8.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-6*.rpm
```

Enable the EPEL Repository on CentOS 7.x, RHEL 7.x, or Oracle Linux 7.0/7.1

This section describes how to download and install the EPEL repository.

Procedure

1. Download the EPEL repository:

```
wget http://dl.fedoraproject.org/pub/epel/
epel-release-latest-7.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-latest-7*.rpm
```

Enable the EPEL Repository on CentOS 8.x, RHEL 8.x, or Oracle Linux 8.x

This section describes how to download and install the EPEL repository.

Procedure

1. Download the EPEL repository:

```
wget http://dl.fedoraproject.org/pub/epel/
epel-release-latest-8.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-latest-8*.rpm
```

Adding the Data Fabric Repository on SUSE

This section describes how to install the Data Fabric repository.

Prerequisites

To verify that a SUSE release is supported by the HPE Ezmeral Data Fabric, see Operating System Support Matrix on page 5719.

Procedure

1. Change to the `root` user or use `sudo`.

2. Use the following command to add the repository for Data Fabric packages, replacing `<version>` with the version of Data Fabric software that you want to install:

   IMPORTANT: For SUSE distributions, if your user name is an email address that includes special characters – such as the @ symbol – you must URL encode the special characters so that the correct email address is passed to the authentication protocols in the repository. For most email addresses, changing the @ symbol to %40 is sufficient. For example:

   Unencoded email address: `jane.smith@company.com`

   URL encoded email address: `jane.smith%40company.com`

   To encode other special characters, see "URL Encoded Emails" at HPE Software Delivery Repository.

   ```
   zypper ar https://<email>:<token>@package.ezmeral.hpe.com/releases/
   v<version>/suse/ maprtech
   ```

3. Use the following command to add the repository for ecosystem packages: (For the correct paths for all past releases, see the Data Fabric Repositories and Packages on page 101.)

   ```
   zypper ar https://<email>:<token>@package.ezmeral.hpe.com/releases/MEP/
   MEP-<version>/suse/ maprecosystem
   ```

4. If your connection to the Internet is through a proxy server, you must set the `http_proxy` environment variable before installation:

   ```
   http_proxy=http://<host>:<port>
                export http_proxy
   ```

5. Update the system package index by running the following command:

   ```
   zypper refresh
   ```

6. data-fabric packages require a compatibility package in order to install and run on SUSE. Execute the following command to install the SUSE compatibility package:

   ```
   zypper install mapr-compat-suse
   ```

Installing sshpass

About this task
Before installing a cluster on a SUSE image, you must run the following command to install sshpass:

```
zypper --non-interactive -q --no-gpg-checks -p http://download.opensuse.org/
distribution/leap/42.3/repo/oss/ install sshpass
```

Adding the Data Fabric Repository on Ubuntu
This section describes how to install the Data Fabric repository.

Procedure

1. Change to the `root` user or use `sudo`.

last-updated: Jun 06, 2024

2. Create the following file:

```
# cat /etc/apt/auth.conf.d/package.ezmeral.hpe.com.conf
machine package.ezmeral.hpe.com
login <HPE-Passport-email>
password <HPE-Passport-token>
```

3. Add the following lines to `/etc/apt/sources.list`, replacing `<version>` with the version of Data Fabric software that you want to install. See the Data Fabric Repositories and Packages on page 101 for the correct paths for all past releases.

   Release 7.0.0 (with EEP 8.1.0) and later

   IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

```
deb https://package.ezmeral.hpe.com/releases/v<version>/ubuntu/ binary
bionic
deb https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/ubuntu/
binary bionic
```

   Release 5.2.1 through 6.2.0

```
deb https://package.ezmeral.hpe.com/releases/v<version>/ubuntu/ binary
trusty
deb https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/ubuntu/
binary trusty
```

4. Update the package indexes:

```
apt-get update
```

5. If your connection to the Internet is through a proxy server, add the following lines to `/etc/apt/apt.conf`:

```
Acquire
{
  Retries "0";
  HTTP
  {
     Proxy "http://<user>:<password>@<host>:<port>";
  };
};
```

Using a Local Repository

This section describes how to make packages available through a local repository.

You can set up a local repository on each node to provide access to installation packages. With this method, nodes do not require internet connectivity. The package manager on each node installs from packages in the local repository. To set up a local repository, nodes need access to a running web server to download the packages.

Subsequent sections describe how to create a single repository that includes both data-fabric components and the Hadoop ecosystem components.

Creating a Local Repository on RHEL, CentOS, or Oracle Linux

This section describes how to create and use a local repository.

last-updated: Jun 06, 2024

Procedure

1. Log in as `root` on the node or use `sudo`.
2. Create the following directory if it does not exist: `/var/www/html/yum/base`
3. On a computer that is connected to the internet, download the following files, substituting the appropriate `<version>` number and `<datestamp>`: (See Data Fabric Repositories and Packages on page 101 for the correct paths for all past releases.)

   ```
   https://package.ezmeral.hpe.com/releases/v7.x.x/redhat/
   mapr-<version>GA.rpm.tgz
   https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/redhat/
   mapr-mep-<version>-<datestamp>.rpm.tgz
   ```

4. Copy the files to `/var/www/html/yum/base` on the node, and extract them there.

   ```
   tar -xvzf mapr-v<version>GA.rpm.tgz
   tar -xvzf mapr-mep-<version>-<datestamp>.rpm.tgz
   ```

5. Create the base repository headers: When finished, verify the content of the new `/var/www/html/yum/base/repodata` directory: `filelists.xml.gz, other.xml.gz, primary.xml.gz, repomd.xml`

   ```
   createrepo /var/www/html/yum/base
   ```

Add the repository on each node

Each node must contain your local repository.

About this task

Procedure

- Create a text file called `maprtech.repo` in the `/etc/yum.repos.d` directory with the following content. The following example uses a host running core 7.5.0 and EEP 9.2.0:

```
[MapR_Core]
name = MapR Core Components
async = 1
baseurl = http://<host>/yum/base/v7.5.0/redhat
enabled = 1
gpgcheck = 1
protect = 1

[MapR_Ecosystem]
name = MapR Ecosystem Components
async = 1
baseurl = http://<host>/yum/base/MEP/MEP-9.2.0/redhat
enabled = 1
gpgcheck = 1
protect = 1

[MapR_Installer]
name=MapR Installer Components
baseurl=http://<host>/yum/base/installer/redhat
gpgcheck=1
enabled=1
protected=1
```

The Installer Components entry is needed only for intallations that use the Installer. It is not needed for manual installations.

WARNING: The EPEL (Extra Packages for Enterprise Linux) repository contains dependencies for the `mapr-metrics` package on RedHat/CentOS/Oracle Linux. If your RedHat/CentOS/Oracle Linux cluster does not use the `mapr-metrics` service, you can skip EPEL configuration.

Enable the EPEL repository on CentOS 6.x, RHEL 6.x, or Oracle Linux 6.4 or higher

This section describes how to download and install the EPEL repository.

Procedure

1. On a computer that is connected to the internet, download the EPEL repository:

```
wget https://archives.fedoraproject.org/pub/archive/epel/6/x86_64/
epel-release-6-8.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-6*.rpm
```

Enable the EPEL repository on CentOS 7.x, RHEL 7.x, or Oracle Linux 7.0/7.1

This section describes how to download and install the EPEL repository.

Procedure

1. Download the EPEL repository:

```
wget http://dl.fedoraproject.org/pub/epel/
epel-release-latest-7.noarch.rpm
```

last-updated: Jun 06, 2024

2. Install the EPEL repository:

```
rpm -Uvh epel-release-7*.rpm
```

Enable the EPEL repository on CentOS 8.x, RHEL 8.x, or Oracle Linux 8.x

This section describes how to download and install the EPEL repository.

Procedure

1. Download the EPEL repository:

```
wget http://dl.fedoraproject.org/pub/epel/
epel-release-latest-8.noarch.rpm
```

2. Install the EPEL repository:

```
rpm -Uvh epel-release-8*.rpm
```

Creating a Local Repository on SUSE

This section describes how to create and use a local repository.

Procedure

1. Login as `root` on the node or use `sudo`.
2. Create the following directory if it does not exist: `/var/www/html/zypper/base`
3. On a computer that is connected to the Internet, download the following files, substituting the appropriate `<version>` and `<datestamp>`: (See Data Fabric Repositories and Packages on page 101 for the correct paths for all past releases.)

```
https://package.ezmeral.hpe.com/releases/v<version>/suse/
mapr-<version>GA.rpm.tgz
https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/suse/
mapr-mep-<version>-<datestamp>.rpm.tgz
```

4. Copy the files to `/var/www/html/zypper/base` on the node, and extract them there.

```
tar -xvzf mapr-<version>GA.rpm.tgz
tar -xvzf mapr-mep-<version>-<datestamp>.rpm.tgz
```

5. Create the base repository headers: When finished, verify the content of the new `/var/www/html/zypper/base/repodata` directory: `filelists.xml.gz, other.xml.gz, primary.xml.gz, repomd.xml`

```
createrepo /var/www/html/zypper/base
```

Add the repository on each node

Each node must contain your local repository.

Procedure

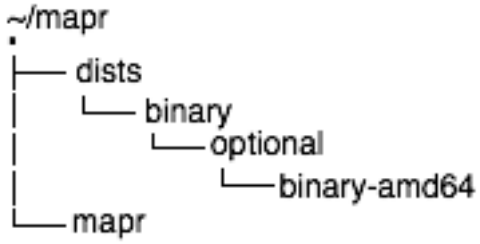
- Issue the following command to add the repository for data-fabric packages and the ecosystem packages, substituting the appropriate `<host>`:

```
zypper ar http://<host>/zypper/base/ maprtech
```

Creating a Local Repository on Ubuntu
This section describes how to create and use a local repository.

Procedure

1. Login as `root` on the machine where you will set up the repository.
2. Change to the directory `/root`, and create the following directories within it:



3. On a computer that is connected to the Internet, download the following files, substituting the appropriate `<version>` and `<datestamp>`: (See Data Fabric Repositories and Package Archives for the correct paths for all past releases.)

```
https://package.ezmeral.hpe.com/releases/v7.x.x/ubuntu/
mapr-<version>GA.deb.tgz
https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/ubuntu/
mapr-mep-<version>-<datestamp>.deb.tgz
```

4. Copy the files to `/root/mapr/mapr` on the node, and extract them there:

```
tar -xvzf mapr-<version>GA.deb.tgz
tar -xvzf mapr-mep-<version>-<datestamp>.deb.tgz
```

5. Navigate to the `/root/mapr/` directory.
6. Use `dpkg-scanpackages` to create `Packages.gz` in the `binary-amd64` directory:

```
dpkg-scanpackages . /dev/null | gzip -9c > ./dists/binary/optional/
binary-amd64/Packages.gz
```

7. Move the entire `/root/mapr/mapr` directory to the default directory served by the HTTP server (for example, `/var/www`), and make sure the HTTP server is running.

Add the Repository on Each Node
Each node must contain your local repository.

Procedure

1. On each node, use *one* of the following methods to add the repository:

last-updated: Jun 06, 2024

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102. If you added the `auth.conf.d` file as described in Adding the Data Fabric Repository on Ubuntu on page 185, you do not need to specify the email and token in the commands below.

- If you have installed the `software-properties-common` package, use the `add-apt-repository` utility to add the repository:

  Release 7.0.0 and later

EEP	`add-apt-repository 'deb https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/ubuntu binary bionic'`
Core	`add-apt-repository 'deb https://package.ezmeral.hpe.com/releases/v<version>/ubuntu binary bionic'`

  Releases 5.2.1 through 6.2.0

EEP	`add-apt-repository 'deb https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/ubuntu binary trusty'`
Core	`add-apt-repository 'deb https://package.ezmeral.hpe.com/releases/v<version>/ubuntu binary trusty'`

- If the `software-properties-common` package is not installed, create a file in `/etc/apt/sources.list.d` whose content is a single line as follows:

  Release 7.0.0 and later

EEP	`deb https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/ubuntu binary bionic`
Core	`deb https://package.ezmeral.hpe.com/releases/v<version>/ubuntu binary bionic`

  Releases 5.2.1 through 6.2.0

EEP	`deb https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/ubuntu binary trusty`
Core	`deb https://package.ezmeral.hpe.com/releases/v<version>/ubuntu binary trusty`

  NOTE: File names must end with `.list` and may only contain letters (a-z and A-Z), digits (0-9), underscore (_), hyphen (-), and period (.) characters.

2. On each node, update the package indexes (as `root` or with `sudo`). After performing these steps, you can use `apt-get` to install data-fabric software and Hadoop ecosystem components on each node from the local repository:

```
apt-get update
```

Using a Local Path with rpm or deb Package Files

This section describes how to make packages available through a local path.

About this task

You can download package files, store them locally, and then install data-fabric software from the files. This option is useful for clusters that are not connected to the internet.

last-updated: Jun 06, 2024

WARNING: In order for the installation to succeed, this method requires that you pre-install the data-fabric package dependencies on each node.

For a list of the dependency packages required for the data-fabric services that you are installing, see Packages and Dependencies for Data Fabric Software on page 70. Manually download the packages and install them.

To install data-fabric software from downloaded package files, complete the following steps:

Procedure

1. Using a machine connected to the internet, download the tarball for the core components and the ecosystem components, substituting the appropriate `<platform>`, `<version>`, and `<datestamp>`:
   - `https://package.ezmeral.hpe.com/releases/v7.x.x/<platform>/mapr-v<version>GA.rpm.tgz` (or `.deb.tgz`)
   - `https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/<platform>/mapr-mep-<version>-<datestamp>.rpm.tgz` (or `.deb.tgz`)

   IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

   For the correct paths for all past releases, see Data Fabric Repositories and Packages on page 101.

2. Extract the tarball to a local directory, either on each node or on a local network accessible by all nodes:

```
tar -xvzf mapr-<version>GA.rpm.tgz
tar -xvzf mapr-mep-<version>-<datestamp>.rpm.tgz
```

Step 4: Install Cluster Service Packages
The installation process varies based on the location of your packages and the configuration of your cluster.

Install services based on your cluster plan and service layout.

Before Installing Packages

Note these considerations:

- **Review security vulnerabilities:** Make sure that you have reviewed the list of known vulnerabilities in Security Vulnerabilities on page 6184. If a vulnerability applies to your release, contact your support representative for a fix. Apply the fix immediately, if applicable.

List of Packages by Node

The following table lists the core packages to install on cluster nodes:

On These Nodes	Install These Packages
On all [compute] cluster nodes	`mapr-fileserver` `mapr-s3server`

On designated cluster nodes	`mapr-cldb`
	`mapr-zookeeper`
	`mapr-mastgateway`
	`mapr-nfs` or `mapr-loopbacknfs`[1]
	`mapr-webserver`[2]
	`mapr-apiserver`[2]
	`mapr-gateway`

On client machines that run Hadoop commands that are not already part of the cluster	`mapr-client`

[1]See NFS Considerations on page 193.

[2]For special considerations related to the installation of the `mapr-webserver` and `mapr-apiserver` packages, see API Server and Web Server Packages for EEP 8.1.0 on page 6155.

WARNING: This table is a rough guide and does not include the additional non-data-fabric packages required for internal Package Dependencies on page 103 or Hadoop ecosystem components.

Install the packages based on a thorough plan. For example cluster designs, see Example Cluster Designs on page 91.

To install the HPE Ezmeral Data Fabric, select one of the installation methods in the subsequent topics, depending on your operating system.

NFS Considerations

When you install `mapr-nfs`, NFSv3 is installed. To install NFSv4, you must use the `mapr-nfs4server` package. NFS is not secure by default. If you wish to configure NFSv4 server to work with Kerberos servers, you must first install Active Directory and Kerberos servers. For more information, see Installing NFS for the HPE Ezmeral Data Fabric on page 401 and Configuring NFSv4 Server for Kerberos on page 1584.

Consider installing `mapr-loopbacknfs` if you need a secure POSIX client. Note that the Installer installs `mapr-loopbacknfs` on all nodes in the cluster when **Enable NFS** is not specified. For more information about `mapr-loopbacknfs`, see POSIX Clients on page 431.

Hadoop and YARN Packages

With Release 6.2.0, Hadoop and YARN packages moved into the MEP repository. For more information, see Installing Hadoop and YARN on page 241.

Installing from a Repository

Before installing from the repository, change to the `root` user or use `sudo`.

- On RedHat, CentOS, or Oracle Linux, use the `yum` command to install the services that you want to run on the node.

  Syntax and Example

  ```
  yum install <package_name> <package_name> <package_name>
  ```

  ```
  yum install mapr-fileserver mapr-webserver
  ```

last-updated: Jun 06, 2024

- On SLES, use the `zypper` command to install the services that you want to run on the node.

  Syntax and Example

  ```
  zypper install <package_name> <package_name> <package_name>
  ```

  ```
  zypper install mapr-fileserver mapr-webserver
  ```

- On Ubuntu, use the `apt-get` commands to update the Ubuntu package cache and install the services that you want to run on the node.

  1. Update the Ubuntu package cache:

     ```
     apt-get update
     ```

  2. Install the services:

     Syntax and Example

     ```
     apt-get install <package_name> <package_name> <package_name>
     ```

     ```
     apt-get install mapr-fileserver mapr-webserver
     ```

Installing from a Local Repository

Before installing from the repository, change to the `root` user or use `sudo`.

- On RedHat, CentOS, Oracle Linux, or SLES, use `rpm` command to install the appropriate packages for the node:

  1. Change the working directory to the location where the `rpm` package files are located.

  2. Install the services:

     Syntax and Example

     ```
     yum install <package_file> <package_file> <package_file>
     ```

     ```
     yum install /path/to/mapr-core-<version>.x86_64.rpm
     mapr-cldb-<version>.x86_64.rpm \
                  mapr-resourcemanager-<version>.x86_64.rpm
     mapr-webserver-<version>.x86_64.rpm \
     ```

     NOTE: Replace `<version>` with the exact version string found in the package filename.

- On Ubuntu, use the `dpkg` command to install the appropriate packages for the node.

  1. Change the working directory to the location where the `deb` package files are located.

last-updated: Jun 06, 2024

2. Install the services:

   Syntax and Example

```
dpkg -i <package_file> <package_file> <package_file>
```

```
dpkg -i mapr-core-<version>.x86_64.rpm mapr-cldb-<version>.x86_64.rpm \
              mapr-resourcemanager-<version>.x86_64.rpm
mapr-webserver-<version>.x86_64.rpm \
```

NOTE: Replace `<version>` with the exact version string found in the package filename.

Installing from Package Files

When you install from package files, you must manually pre-install any dependency packages in order for the installation to succeed. Most data-fabric packages depend on the package `mapr-core`. Similarly, many Hadoop ecosystem components have internal dependencies. For details, see Package Dependencies on page 103.

Step 5: Verify Installation Success
To confirm success, check each node.

To verify that the software was installed successfully, check the `/opt/mapr/roles` directory on each node. The software is installed in the `/opt/mapr` directory and a file is created in `/opt/mapr/roles` for every service that installs successfully. The following example shows the `/roles` directory with services that installed successfully:

Example

```
# ls -l /opt/mapr/roles
total 28
-rw-r--r-- 1 root root  90 Apr 19 09:29 apiserver
-rw-r--r-- 1 root root   0 Apr 11 21:31 cldb
-rw-r--r-- 1 root root   0 Apr 11 21:31 fileserver
-rw-r--r-- 1 root root   0 Apr 11 21:31 gateway
-rw-r--r-- 1 root root 110 Oct 23  2021 hadoop-client
-rw-r--r-- 1 root root 117 Oct 23  2021 hadoop-util
-rw-r--r-- 1 root root 110 Oct 23  2021 historyserver
-rw-r--r-- 1 root root   0 Apr 11 21:31 mastgateway
-rw-r--r-- 1 root root   0 Apr 11 21:31 nfs
-rw-r--r-- 1 root root 110 Oct 23  2021 nodemanager
-rw-r--r-- 1 root root 110 Oct 23  2021 resourcemanager
-rw-r--r-- 1 root root   0 Apr 22 03:15 s3server
-rw-r--r-- 1 root root 110 Oct 23  2021 timelineserver
-rw-r--r-- 1 root root   0 Apr 11 21:31 zookeeper
```

Step 6: Set Environment Variables
Before starting ZooKeeper or Warden, you must complete this step.

Set Environment Variables on page 3076 for the cluster. The `/opt/mapr/conf/env.sh` script looks for the directory where Java is installed and sets `JAVA_HOME` automatically. However, if you need to specify a different location for `JAVA_HOME`, edit `/opt/mapr/conf/env_override.sh`. This variable *must* be set before starting ZooKeeper or Warden. For more information, see About env_override.sh on page 3077.

Step 7: Configure Nodes
Connect nodes to the cluster, configure security, and arrange node storage.

You run the `configure.sh` script on a node to enable the node to communicate with the cluster. You must configure each node that is part of the cluster and each node that connects to the cluster as a client.

Perform the following operations to configure a node:

Operation	Description
Prepare to run configure.sh	This topic describes some information you will need to gather before running the `configure.sh` script.
Enabling the External Key Store (KMIP) Feature on page 197	These steps are required only if you want to enable an external key store during installation. For more information about the external key store (KMIP) feature, see External KMIP Keystore Overview on page 888.
Enabling Security on page 199	These steps configure your cluster for security, enabling security for authentication, authorization, and data. Data-at-rest (DARE) encryption can also be enabled during this task.
Configure storage	To configure storage on a node, you can manually run `disksetup`. You need to perform this step for nodes in the cluster that are installed with the `mapr-fileserver`. The steps you use to configure storage vary depending on whether or not DARE is enabled or disabled.

Preparing to Run configure.sh

Before you run `configure.sh`, collect the information that you need to run the script based on your requirements.

The `configure.sh` script can configure a node for the first time or update existing node configurations. Therefore, it has many configuration options that you can use.

- Note the hostnames of the CLDB and ZooKeeper nodes. Optionally, you can specify the ports for the CLDB and ZooKeeper nodes as well. The default CLDB port is 7222. The default ZooKeeper port is 5181.
- If a node in the cluster runs the HistoryServer, note the hostname for the HistoryServer. The HistoryServer node must be specified by using the `-HS` parameter.
- If one or more nodes in the cluster runs the ResourceManager, note the hostname or IP address for each ResourceManager node. Based on the version you install and your ResourceManager high availability requirements, you may need to specify the ResourceManager nodes using the `-RM` parameter. High availability for the ResourceManager is configured by default and does not need to be specified.
- If `mapr-fileserver` is installed on a node, you can use `configure.sh` with the `-F` option to format the disks and set up partitions. The `-F` option allows you to create a text file that lists the disks and partitions for use by the filesystem on the node. `configure.sh` passes the file to the `disksetup` utility. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate each partition with a space. For example:

  ```
  /dev/sdb
  /dev/sdc1 /dev/sdc2 /dev/sdc4
  /dev/sdd
  ```

  Or you can manually run `disksetup` after you run `configure.sh`. See Configuring Storage on page 215.
- For a cluster node that is on a VM, use the `--isvm` parameter when you run `configure.sh`, so that the script uses less memory.

last-updated: Jun 06, 2024

Enabling the External Key Store (KMIP) Feature

Enabling an external key store requires performing certain steps after installing data-fabric packages but before running `configure.sh`.

This page describes how to enable an external key store in the context of a manual installation of the HPE Ezmeral Data Fabric. If you do not need to enable an external key store, you may ignore this topic and proceed to Enabling Security on page 199.

Steps for Enabling an External Key Store

To enable the external key store (KMIP) feature, perform these steps:

1. Make sure that you have performed the following manual-installation steps:
   - Step 2: Import the Package Key on page 181
   - Step 3: Prepare Packages and Repositories on page 182
   - Step 4: Install Cluster Service Packages on page 192
   - Step 5: Verify Installation Success on page 195
   - Step 6: Set Environment Variables on page 195
2. Complete the vendor-specific HSM configuration (this can also be done before step 1). For more information, see Integration Guides on page 930.
3. Prepare the `/opt/mapr/server/configure.sh` command that you will run as part of Enabling Security on page 199. To enable the external key store, the command needs to include certain `-hsm` parameters. For more information about these parameters, see the "HSM Parameters" section in configure.sh on page 2821. For an example, see Example of configure.sh Command for Secure Cluster with DARE and KMIP Enabled on page 197 later on this page.

   The `-hsm` parameters you specify are passed to the `configure.sh` script, which sets up the filesystem to use the HSM and verify connectivity. Note that when it is used in this way, the `configure.sh` script acts as a front end to the various options in the `mrhsm` utility described in mrhsm Commands on page 905.
4. Perform the steps in the "Basic Procedure" for Enabling Security on page 199 using the `configure.sh` command that you created in step 3.

   At the end of the `configure.sh` script, if the configuration is correct, the HSM should be up and running. To check the HSM status, use the `mrhsm info` command.
5. In addition to copying various keystore and truststore files to all nodes in the cluster, as described in Enabling Security on page 199, for KMIP you must copy the contents of the `${MAPR_HOME}/conf/tokens` directory to all CLDB and ZooKeeper nodes in the cluster. Ensure that all the files in the `${MAPR_HOME}/conf/tokens` directory are owned by the `mapr` user and `mapr` group.
6. Proceed to Configuring Storage on page 215, and complete the remaining manual-installation steps.

Example of configure.sh Command for Secure Cluster with DARE and KMIP Enabled

The following example shows using `/opt/mapr/server/configure.sh` to enable security with data-at-rest-encryption (DARE) and HSM features enabled. **Bold-face** type indicates HSM options and messages:

```
/opt/mapr/server/configure.sh  -secure -genkeys -N test96.cluster.com -C
perfnode96.lab:7222
-Z perfnode96.lab:5181 -F disks.txt -dare -hsm -hsmip
```

```
10.10.30.129 -hsmlabel "SafeNet KeySecure"
-hsmsopin 12345678 -hsmclientcert /root/safenet-keysecure/

Enabling Security
Describes how to enable security for the cluster, platform, ecosystem components, and network-based connections.

About this task

The following steps enable:

- Security for the cluster nodes
- Wire-level encryption for the platform and ecosystem components
- Authentication for all network-based connections
- (Optional) Data-at-rest encryption on the cluster

These steps DO NOT enable security for client nodes. For client-installation information, see Setting Up Clients and Services on page 400.

Use *one* of the following procedures based on the composition of nodes in your cluster:

- Enabling Security When All Nodes Are Non-FIPS on page 199
- Enabling Security When All Nodes Are FIPS on page 203
- Enabling Security for a Mix of FIPS and Secure Non-FIPS Nodes on page 207

Enabling Security When All Nodes Are Non-FIPS

About this task

Use these steps to enable security for a cluster in which all nodes are non-FIPS-enabled nodes:

Procedure

1. If the cluster is running, shut it down.
2. If you are re-running the `configure.sh` script because of an invocation error from a previous run, remove the following files from `${MAPR_HOME}/conf` (if they are present) if you want to re-generate the CLDB key, server ticket, and certificates:
   - All key and trust stores. The files differ depending on whether the node is FIPS enabled. FIPS-enabled nodes use BCFKS key and trust stores, while secure non-FIPS nodes use JKS/JCEKS/P12 key and trust stores:
     - `maprkeycreds.jceks`
     - `maprtrustcreds.jceks`
     - `ssl_keystore, ssl_keystore.p12`
     - `ssl_truststore, ssl_truststore.p12`
     - `ssl_userkeystore`
     - `ssl_usertruststore`
   - All other files in `${MAPR_HOME}/conf` that are generated and configured on the first CLDB node:
     - All PEM files: `ssl_keystore-signed.pem` and `ssl_userkeystore-signed.pem`
     - All files in the `${MAPR_HOME}/conf/tokens` directory (but not the `tokens/` directory itself)

last-updated: Jun 06, 2024

- `maprserverticket`
- `mapruserticket`
- The `store-passwords.txt` file containing the clear-text passwords, if not already removed

For example:

```
cd /opt/mapr/conf
rm -rf cldb.key maprserverticket mapruserticket ssl-client.xml \
ssl_keystore ssl_truststore ssl-server.xml *.bcfks *.pem tokens/* \
store-passwords.txt
```

3. Run the `configure.sh` script with the `-secure -genkeys -dare` options on the first CLDB node in your cluster:

```
/opt/mapr/server/configure.sh -secure -dare -genkeys -Z
<Zookeeper_node_list> -C <CLDB_node_list> -N <cluster_name>
```

where both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]` and `-N <cluster_name>` specifies the cluster name. For the hostname, specify an FQDN as described in Connectivity on page 171. Do not specify an alias or IP address. The `-dare` option is required only if you wish to enable data-at-rest encryption at the cluster-level.

IMPORTANT: You must run `configure.sh` with the `-genkeys` option only *after* it is on one CLDB node. The resulting files should be generated only once and then copied to other nodes.

NOTE: The DARE master key is generated in the `tokens/` directory only if data at rest encryption is enabled on the cluster using the `-dare` option with `configure.sh`.

TIP: For a comprehensive listing of the Trust and Key Store files, see Understanding the Key Store and Trust Store Files on page 1793.

4. Copy files to the destination nodes as follows:
   - If your cluster consists of all secure non-FIPS-enabled nodes, use the following table as a guide to copy files to the destination nodes which are the nodes where the `-genkeys` option is not used to generate keys.

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper Nodes	• `conf/maprhsm.conf` • `conf/maprkeycreds.conf` • `conf/maprkeycreds.jceks` • `conf/maprserverticket` • `conf/maprtrustcreds.conf` • `conf/maprtrustcreds.jceks` • `conf/private.key`[1] • `conf/public.crt`[1] • `conf/ssl_keystore` • `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_keystore-signed.pem` • `conf/ssl_truststore` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/ssl_userkeystore` • `conf/ssl_userkeystore.p12` • `conf/ssl_userkeystore.pem` • `conf/ssl_userkeystore-signed.pem` • `conf/ssl_usertruststore` • `conf/ssl_usertruststore.p12` • `conf/ssl_usertruststore.pem` • `conf/tokens` (use a command such as `scp -r` to copy everything in this folder)

last-updated: Jun 06, 2024

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
All other cluster nodes, including MFS-only nodes	• conf/maprhsm.conf • conf/maprkeycreds.conf • conf/maprkeycreds.jceks • conf/maprserverticket • conf/maprtrustcreds.conf • conf/maprtrustcreds.jceks • conf/private.key[1] • conf/public.crt[1] • conf/ssl_keystore • conf/ssl_keystore.p12 • conf/ssl_keystore.pem • conf/ssl_keystore-signed.pem • conf/ssl_truststore • conf/ssl_truststore.p12 • conf/ssl_truststore.pem • conf/ssl_userkeystore • conf/ssl_userkeystore.p12 • conf/ssl_userkeystore.pem • conf/ssl_userkeystore-signed.pem • conf/ssl_usertruststore • conf/ssl_usertruststore.p12 • conf/ssl_usertruststore.pem

[1]If you are running Data Fabric 7.0.0.5 or later, the `private.key` and `public.crt` are not present and do not need to be copied to all other nodes. On Data Fabric 7.0.0.5, the `/opt/mapr/conf/ssl_usertruststore` performs this function and is present on all nodes.

5. Run `configure.sh` on each existing node in the cluster using the same arguments as in Step 3 but without the `-genkeys` option.

```
/opt/mapr/server/configure.sh -secure -dare -Z <Zookeeper_node_list> -C
<CLDB_node_list> -N <cluster_name>
```

The `-secure` option indicates that security must be enabled on the node where the command is run. The `-dare` option indicates that data at rest encryption must be enabled on the node and must be specified only if it was specified in Step 3.

last-updated: Jun 06, 2024

IMPORTANT:

- You must also do this on any nodes that you add to the cluster in the future.
- If you run `configure.sh -secure` on a node *before* you copy the necessary files to that node, the command fails.

6. Optionally, enable encrypted quorum ZooKeeper communication. See zoo.cfg on page 3002 for more information.

Enabling Security When All Nodes Are FIPS

About this task

Use these steps to enable security for a cluster in which all nodes are FIPS-enabled:

Procedure

1. If the cluster is running, shut it down.
2. If you are re-running the `configure.sh` script because of an invocation error from a previous run, remove the following files from `${MAPR_HOME}/conf` (if they are present) if you want to re-generate the CLDB key, server ticket, and certificates:
   - All key and trust stores. The files differ depending on whether the node is FIPS enabled. FIPS-enabled nodes use BCFKS key and trust stores, while secure non-FIPS nodes use JKS/JCEKS/P12 key and trust stores:
     - `maprkeycreds.bcfks`
     - `maprtrustcreds.bcfks`
     - `ssl_keystore (symlink), ssl_keystore.bcfks`
     - `ssl_truststore (symlink), ssl_truststore.bcfks`
     - `ssl_userkeystore (symlink), ssl_userkeystore.bcfks`
     - `ssl_usertruststore (symlink), ssl_usertruststore.bcfks`
   - All other files in `${MAPR_HOME}/conf` that are generated and configured on the first CLDB node:
     - All PEM files: `ssl_keystore-signed.pem` and `ssl_userkeystore-signed.pem`
     - All files in the `${MAPR_HOME}/conf/tokens` directory (but not the `tokens/` directory itself)
     - `maprserverticket`
     - `maprusertickt`
     - The `store-passwords.txt` file containing the clear-text passwords, if not already removed

   For example:

```
cd /opt/mapr/conf
rm -rf cldb.key maprserverticket maprusertickt ssl-client.xml \
ssl_keystore ssl_truststore ssl-server.xml *.bcfks *.pem tokens/* \
store-passwords.txt
```

3. Run the `configure.sh` script with the `-secure -genkeys -dare` options on the first CLDB node in your cluster:

   ```
   /opt/mapr/server/configure.sh -secure -dare -genkeys -Z
   <Zookeeper_node_list> -C <CLDB_node_list> -N <cluster_name>
   ```

   where both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]` and `-N <cluster_name>` specifies the cluster name. For the hostname, specify an FQDN as described in Connectivity on page 171. Do not specify an alias or IP address. The `-dare` option is required only if you wish to enable data at rest encryption at the cluster-level.

   IMPORTANT: You must run `configure.sh` with the `-genkeys` option only *once* on one CLDB node, since the resulting files should be generated only once and then copied to other nodes.

   NOTE: The DARE master key is generated in the `tokens/` directory only if data at rest encryption is enabled on the cluster using the `-dare` option with `configure.sh`.

   TIP: For a comprehensive listing of the Trust and Key Store files, see Understanding the Key Store and Trust Store Files on page 1793.

4. Copy files to the destination nodes as follows:

   - If your cluster consists of all FIPS-enabled nodes, use the following table as a guide to copy files to the destination nodes (the nodes where the `-genkeys` option is not used to generate keys):

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper Nodes	• `conf/maprhsm.conf` • `conf/maprkeycreds.bcfks` • `conf/maprkeycreds.conf` • `conf/maprserverticket` • `conf/maprtrustcreds.bcfks` • `conf/maprtrustcreds.conf` • `conf/private.key`[2] • `conf/public.crt`[2] • `conf/ssl_keystore.bcfks`[1] • `conf/ssl_keystore-signed.pem`[1] • `conf/ssl_keystore.p12`[1] • `conf/ssl_keystore.pem`[1] • `conf/ssl_truststore.bcfks`[1] • `conf/ssl_truststore.p12`[1] • `conf/ssl_truststore.pem`[1] • `conf/ssl_userkeystore.bcfks`[1] • `conf/ssl_userkeystore.pem`[1] • `conf/ssl_userkeystore-signed.pem`[1] • `conf/ssl_usertruststore.bcfks`[1] • `conf/ssl_usertruststore.pem`[1] • `conf/tokens` (use `scp -r` to copy everything in this folder)

last-updated: Jun 06, 2024

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
All other cluster nodes, including MFS-only nodes	• conf/maprhsm.conf • conf/maprkeycreds.bcfks • conf/maprkeycreds.conf • conf/maprserverticket • conf/maprtrustcreds.bcfks • conf/maprtrustcreds.conf • conf/private.key[2] • conf/public.crt[2] • conf/ssl_keystore.bcfks[1] • conf/ssl_keystore.p12[1] • conf/ssl_keystore.pem[1] • conf/ssl_keystore-signed.pem[1] • conf/ssl_truststore.bcfks[1] • conf/ssl_truststore.p12[1] • conf/ssl_truststore.pem[1] • conf/ssl_userkeystore.bcfks[1] • conf/ssl_userkeystore.p12[1] • conf/ssl_userkeystore.pem[1] • conf/ssl_userkeystore-signed.pem[1] • conf/ssl_usertruststore.bcfks[1] • conf/ssl_usertruststore.p12[1] • conf/ssl_usertruststore.pem[1]

[1]Do NOT copy the `ssl_` symlink files contained in the `conf/` directory. The symlinks are:

- `ssl_keystore` (symlink)
- `ssl_truststore` (symlink)
- `ssl_userkeystore` (symlink)
- `ssl_usertruststore` (symlink)

[2]If you are running Data Fabric 7.0.0.5 or later, the `private.key` and `public.crt` are not present and do not need to be copied to all other nodes. On Data Fabric 7.0.0.5, the `/opt/mapr/conf/ssl_usertruststore` performs this function and is present on all nodes.

last-updated: Jun 06, 2024

5. Run `configure.sh` on each existing node in the cluster using the same arguments as in Step 3 but without the `-genkeys` option.

   ```
   /opt/mapr/server/configure.sh -secure -dare -Z <Zookeeper_node_list> -C
   <CLDB_node_list> -N <cluster_name>
   ```

   The `-secure` option indicates that security must be enabled on the node where the command is run. The `-dare` option indicates that data at rest encryption must be enabled on the node and must be specified only if it was specified in Step 3.

   IMPORTANT:

   - You must also do this on any nodes that you add to the cluster in the future.
   - If you run `configure.sh -secure` on a node *before* you copy the necessary files to that node, the command fails.

6. Optionally, enable encrypted quorum ZooKeeper communication. See zoo.cfg on page 3002 for more information.

Enabling Security for a Mix of FIPS and Secure Non-FIPS Nodes

About this task

A mixed cluster is a cluster consisting of both FIPS-enabled and secure non-FIPS enabled nodes. Since the key and trust store formats are different between FIPS-enabled and secure non-FIPS enabled nodes, the BCFKS stores from FIPS-enabled nodes cannot be copied directly to secure non-FIPS enabled nodes, or vice versa. The Hadoop Credential stores also cannot be copied between FIPS-enabled and secure non-FIPS enabled nodes.

For a mixed configuration, you must:

- Generate the key and trust store, and user key and trust stores if required, on the secure non-FIPS node using the new `${MAPR_HOME}/server/manageSSLKeys.sh convert` utility:
  - After adding a FIPS-enabled node to a cluster consisting of only non-FIPS enabled nodes, generate the BCFKS key and trust stores on the non-FIPS enabled node. Copy them to the `${MAPR_HOME}/conf` directory of the FIPS-enabled node before running `configure.sh`.
  - After adding a secure non-FIPS enabled node to a cluster consisting of only FIPS-enabled nodes, copy the BCFKS key and trust stores from the FIPS-enabled node to a temporary location in the secure non-FIPS enabled node. Generate the JKS key and trust store on the secure non-FIPS enabled node.
- Run the `configure.sh` with the `-storepasswds` option on the node being configured to generate the credential stores.

Enabling Security for the First CLDB Node

About this task

The following steps describe how to enable security for the first CLDB node in the cluster. Note that the data-fabric core platform is installed as secure by default on FIPS-enabled hosts. Security is enabled even if the `-secure` flag is not specified to the `configure.sh` script.

Procedure

1. If the cluster is running, shut it down.

last-updated: Jun 06, 2024

2. If you are re-running the `configure.sh` script because of an invocation error from a previous run, remove the following files from `${MAPR_HOME}/conf` (if they are present) if you want to re-generate the CLDB key, server ticket, and certificates:
   - All key and trust stores. The files differ depending on whether the node is FIPS enabled. FIPS-enabled nodes use BCFKS key and trust stores, while secure non-FIPS nodes use JKS/JCEKS/P12 key and trust stores:

FIPS	Secure Non-FIPS
`maprkeycreds.bcfks`	`maprkeycreds.jceks`
`maprtrustcreds.bcfks`	`maprtrustcreds.jceks`
`ssl_keystore (symlink), ssl_keystore.bcfks`	`ssl_keystore, ssl_keystore.p12`
`ssl_truststore (symlink), ssl_truststore.bcfks`	`ssl_truststore, ssl_truststore.p12`
`ssl_userkeystore (symlink), ssl_userkeystore.bcfks`	`ssl_userkeystore`
`ssl_usertruststore (symlink), ssl_usertruststore.bcfks`	`ssl_usertruststore`

   - All other files in `${MAPR_HOME}/conf` that are generated and configured on the first CLDB node:
     - All PEM files: `ssl_keystore-signed.pem` and `ssl_userkeystore-signed.pem`
     - All files in the `${MAPR_HOME}/conf/tokens` directory (but not the `tokens/` directory itself)
     - `maprserverticket`
     - `maprusertic ket`
     - The `store-passwords.txt` file containing the clear-text passwords, if not already removed

   For example:

```
cd /opt/mapr/conf
rm -rf cldb.key maprserverticket maprusertic ket ssl-client.xml \
ssl_keystore ssl_truststore ssl-server.xml *.bcfks *.pem tokens/* \
store-passwords.txt
```

last-updated: Jun 06, 2024

3. Run the `configure.sh` script with the `-secure -genkeys -dare` options on the first CLDB node in your cluster:

```
/opt/mapr/server/configure.sh -secure -dare -genkeys -Z
<Zookeeper_node_list> -C <CLDB_node_list> -N <cluster_name>
```

   where both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]` and `-N <cluster_name>` specifies the cluster name. For the hostname, specify an FQDN as described in Connectivity on page 171. Do not specify an alias or IP address. The `-dare` option is required only if you wish to enable data at rest encryption at the cluster-level.

   IMPORTANT: You must run `configure.sh` with the `-genkeys` option only *once* on one CLDB node, since the resulting files should be generated only once and then copied to other nodes.

   NOTE: The DARE master key is generated in the `tokens/` directory only if data at rest encryption is enabled on the cluster using the `-dare` option with `configure.sh`.

Enabling Security for Additional Cluster Nodes

About this task

To enable security for additional cluster nodes, run `configure.sh` without the `-genkeys` option after copying the required files to the node. For a mixed configuration, first create the key and trust stores on the secure non-FIPS node using the `${MAPR_HOME}/server/manageSSLKeys.sh convert` utility. Then copy these stores to the key and trust stores of the additional cluster node:

- If you are connecting an additional secure non-FIPS cluster node to the first FIPS-enabled cluster node, copy the `ssl_keystore.bcfks` and `ssl_truststore.bcfks` from the `${MAPR_HOME}/conf` directory of the first FIPS-enabled cluster node to the node being configured. Then run the `manageSSLKeys.sh convert` utility from the secure non-FIPS node. Copy the converted JKS key and trust stores to the additional secure non-FIPS cluster node (or simply specify the destination key/trust store as `${MAPR_HOME}/conf/ssl_keystore` and `${MAPR_HOME}/conf/ssl_truststore` respectively in the `${MAPR_HOME}/server/manageSSLKeys.sh convert` utility).
- If you are connecting an additional FIPS-enabled cluster node to the first secure non-FIPS cluster node, copy the JKS `ssl_keystore` and `ssl_truststore` from the `${MAPR_HOME}/conf` directory of the first secure non-FIPS cluster node to a temporary directory of the first node. Then run the `manageSSLKeys.sh convert` utility from the first secure non-FIPS node. Copy the converted BCFKS key and trust stores to the `${MAPR_HOME}/conf` directory of the additional FIPS-enabled cluster node.

Adding a FIPS-Enabled Server to a FIPS Cluster

About this task

To connect a FIPS-enabled server to a cluster consisting of at least one FIPS-enabled node.

Procedure

1. Copy the following files from the existing FIPS-enabled server to the new FIPS server:

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper nodes	• `conf/ssl_keystore.bcfks` • `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.bcfks` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.bcfks` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.bcfks` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/tokens` (use `scp -r` to copy everything in this folder)
All other cluster nodes, including MFS-only nodes	• `conf/ssl_keystore.bcfks` • `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.bcfks` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreeds.bcfks` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.bcfks` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/ca` (use a command such as `scp -r` to copy everything in this folder)

CAUTION: Do NOT copy `conf/ssl_keystore` and `conf/ssl_truststore`. These are symbolic links to `ssl_keystore.bcfks` and `ssl_truststore.bcfks`, which will be generated by configure.sh.

last-updated: Jun 06, 2024

CAUTION: When adding a non-FIPS node to a FIPS cluster, DO NOT copy the Hadoop `ssl*.xml` files to the other cluster nodes. The `manageSSLKeys.sh` script (invoked by `configure.sh`) uses the store type to determine if FIPS is enabled and assumes the system is FIPS-enabled if the store type is BCFKS. Copying the Hadoop `ssl*` files that are set to the BCFKS store type from a FIPS node to a non-FIPS node causes the `configure.sh` script to fail.

2. Run `configure.sh` without the `-genkeys` option. For example, if the cluster name is `fips0.cluster.com` and the CLDB and ZooKeeper nodes are at `m2-mapreng-vm166250`, then the command is:

```
/opt/mapr/server/configure.sh -secure -N fips0.cluster.com \
    -C m2-mapreng-vm166250:7222
```

Adding a Secure Non-FIPS Server to a FIPS Cluster

About this task

Non-FIPS enabled nodes do not support the BCFKS trust store format. Copying the BCFKS trust store from a FIPS-enabled server to the non-FIPS enabled server that is being added will not work. Create the JKS trust store on the non-FIPS server by importing the same keys and certificates that are in the BCFKS key and trust stores on the existing FIPS-enabled server host. Different configuration procedures apply depending on whether you are configuring for the first cluster or for subsequent clusters.

Procedure

1. Copy the following files from an existing FIPS-enabled node in the cluster to the new non-FIPS node being added:

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper nodes	• `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/tokens` (use `scp -r` to copy everything in this folder)

last-updated: Jun 06, 2024

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
All other cluster nodes, including MFS-only nodes	• `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/ca` (use a command such as `scp -r` to copy everything in this folder)

CAUTION: When adding a non-FIPS node to a FIPS cluster, DO NOT copy the Hadoop `ssl*.xml` files to the other cluster nodes. The `manageSSLKeys.sh` script (invoked by `configure.sh`) uses the store type to determine if FIPS is enabled and assumes the system is FIPS-enabled if the store type is BCFKS. Copying the Hadoop `ssl*` files that are set to the BCFKS store type from a FIPS node to a non-FIPS node causes the `configure.sh` script to fail.

2. Copy the following key store, trust store, userkey store, and usertrust store files from the FIPS-enabled server to a temporary directory of the secure non-FIPS enabled server being added:
   - `${MAPR_HOME}/conf/ssl_keystore.bcfks`
   - `${MAPR_HOME}/conf/ssl_truststore.bcfks`
   - `${MAPR_HOME}/conf/ssl_userkeystore.bcfks`
   - `${MAPR_HOME}/conf/ssl_usertruststore.bcfks`
3. Run the `manageSSLKeys.sh convert` utility to convert the key and trust store (and userkey and usertruststore) from BCFKS format to JKS format. The destination key and trust store will be set to the same password as the source key/trust store. You can obtain the key and trust store passwords from the `store-passwords.txt` file. For example:

```
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType bcfks -dstType JKS \
    -p VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC \
    /tmp/ssl_keystore.bcfks /opt/mapr/conf/ssl_keystore
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType bcfks -dstType JKS \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /tmp/ssl_truststore.bcfks /opt/mapr/conf/ssl_truststore
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType bcfks -dstType JKS \
    -p VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC \
    /tmp/ssl_userkeystore.bcfks /opt/mapr/conf/ssl_userkeystore
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType bcfks -dstType JKS \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /tmp/ssl_usertruststore.bcfks /opt/mapr/conf/ssl_usertruststore
```

last-updated: Jun 06, 2024

4. Run the `configure.sh` script without the `-genkeys` option on the secure non-FIPS enabled server being added, using the `-storepasswds` option to specify the key and trust store passwords. Since the converted key and trust stores are set to the same password as the source, the passwords must be the same as the passwords you specified using the `-p` option in step 3. For example:

```
# /opt/mapr/server/configure.sh -secure \
    -N hpe186.cluster.com \
    -C m2-mapreng-vm167186:7222 \
    -Z m2-mapreng-vm167186:5181 \
    -storepasswds \
    VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC:1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA
```

Adding a FIPS Server to a Secure Non-FIPS Cluster

About this task

Use the following steps to connect a FIPS-enabled server to a cluster consisting of only secure non-FIPS enabled nodes:,

Procedure

1. Copy the following files from an existing secure non-FIPS node in the cluster to the FIPS-enabled server being added:

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper nodes	• `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/tokens` (use `scp -r` to copy everything in this folder)

last-updated: Jun 06, 2024

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
All other cluster nodes, including MFS-only nodes	• `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/ca` (use a command such as `scp -r` to copy everything in this folder)

CAUTION: When adding a non-FIPS node to a FIPS cluster, DO NOT copy the Hadoop `ssl*.xml` files to the other cluster nodes. The `manageSSLKeys.sh` script (invoked by `configure.sh`) uses the store type to determine if FIPS is enabled and assumes the system is FIPS-enabled if the store type is BCFKS. Copying the Hadoop `ssl*` files that are set to the BCFKS store type from a FIPS node to a non-FIPS node causes the `configure.sh` script to fail.

2. On the secure non-FIPS enabled server in the existing cluster, run the `manageSSLKeys.sh convert` utility to convert the key and trust store (and userkey and usertruststore) from JKS to BCFKS format. You can obtain the key and trust store passwords from the `store-passwords.txt` file. For example:

```
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType JKS -dstType bcfks \
    -p VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC \
    /opt/mapr/conf/ssl_keystore /tmp/ssl_keystore.bcfks
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType JKS -dstType bcfks \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /opt/mapr/conf/ssl_truststore /tmp/ssl_truststore.bcfks
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType JKS -dstType bcfks \
    -p VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC \
    /opt/mapr/conf/ssl_userkeystore /tmp/ssl_userkeystore.bcfks
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType JKS -dstType bcfks \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /opt/mapr/conf/ssl_usertruststore /tmp/ssl_usertruststore.bcfks
```

3. Copy the converted `.bcfks` files from the secure non-FIPS server to the FIPS server being added as follows:

Copy this converted file . . .	To this location on the FIPS server . . .
`ssl_keystore.bcfks`	`/opt/mapr/conf/ssl_keystore.bcfks`
`ssl_userkeystore.bcfks`	`/opt/mapr/conf/ssl_userkeystore.bcfks`
`ssl_truststore.bcfks`	`/opt/mapr/conf/ssl_truststore.bcfks`

last-updated: Jun 06, 2024

Copy this converted file . . .	To this location on the FIPS server . . .
`ssl_usertruststore.bcfks`	`/opt/mapr/conf/ssl_usertruststore.bcfks`

4. Run `configure.sh` without the `-genkeys` option on the FIPS enabled server being added, using the `-storepasswds` option to specify the key and trust store passwords. Since the converted BCFKS key and trust store is set to the same password as the source, the passwords must be the same as the passwords specified using the `-p` option in step 2. For example:

```
/opt/mapr/server/configure.sh -secure \
  -N hpe186.cluster.com \
  -C m2-mapreng-vm167186:7222 \
  -Z m2-mapreng-vm167186:5181 \
  -storepasswds \
VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC:1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA
```

Configuring Storage

This section describes how to format disks for cluster storage manually by using `disksetup`.

The disksetup utility formats disks for use by the data-fabric cluster. `disksetup` removes all data from the specified disks. Make sure you specify the disks correctly, and back up any data that you want to save. If you are re-using a node that was used previously in another cluster, it is important to format the disks to remove all data from the old cluster. For more information about the utility, see disksetup.

NOTE: The `disksetup` script assumes that you have free, unmounted physical partitions or hard disks for use by data-fabric software. To determine if a disk or partition is ready for use by data-fabric software, see Setting Up Disks for MapR.

disksetup and DARE

If data-at-rest-encryption (DARE) is enabled, you must use a different set of steps for configuring storage using `disksetup`. See the appropriate subtopic in this section.

Configuring Storage with DARE Disabled

This section describes how to format disks for cluster storage manually using `disksetup` with data-at-rest encryption (DARE) disabled.

Manually Running disksetup

You can create a text file that lists the disks and partitions for use by data-fabric software on a node. Each line should list either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate each partition with a space. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

In the following example, `/tmp/disklist` is a text file that lists the disks and partitions:

Example

```
/opt/mapr/server/disksetup /tmp/disklist
```

Configuring Storage with DARE Enabled

This section describes how to format disks for cluster storage manually using `disksetup` with data-at-rest encryption (DARE) enabled.

last-updated: Jun 06, 2024

Manually Running disksetup

You can create a text file that lists the disks and partitions for use by HPE Ezmeral Data Fabric software on a node. Each line should list either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate each partition with a space. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

In the following example, `/tmp/disklist` is a text file that lists the disks and partitions:

Example

```
/opt/mapr/server/disksetup /tmp/disklist
```

Using disksetup with DARE-Enabled Nodes

In a DARE-enabled cluster, you must use a different set of steps to run `disksetup`. `disksetup` will fail on some nodes if the DARE master key is not available. CLDB nodes have a local copy of the DARE master key, so `disksetup` works on CLDB nodes. Other nodes require a connection with a running CLDB node in order to run `disksetup`.

Use these steps to run `disksetup` on the CLDB nodes and then start the CLDB nodes so that you can then run `disksetup` on the remaining nodes and start those nodes:

1. Format the disks on the CLDB nodes (the nodes that contain the `dare.master.key`):

   ```
   /opt/mapr/server/disksetup /tmp/disklist
   ```

2. Start ZooKeeper and Warden so that other nodes can access the DARE master key on the CLDB nodes:
   a. Start ZooKeeper on all the ZooKeeper nodes:

      ```
      service mapr-zookeeper start
      ```

   b. Start Warden on the CLDB nodes:

      ```
      service mapr-warden start
      ```

3. Format the remaining node disks:

   ```
   /opt/mapr/server/disksetup /tmp/disklist
   ```

4. Start Warden on the remaining nodes:

   ```
   service mapr-warden start
   ```

Step 8: Bring up the Cluster

Before you can install monitoring or ecosystem components, you must enable the cluster by starting ZooKeeper and Warden and verifying the cluster installation status.

Bringing up the cluster involves starting ZooKeeper and Warden, installing an HPE Ezmeral Data Fabric license, and viewing the cluster installation status. Once these initial steps are done, the cluster is

functional, and you can use the Control System or the Command Line Interface (CLI) to examine nodes and activity on the cluster.

Starting ZooKeeper and Warden
Starting ZooKeeper and Warden brings up the cluster.

Depending on the options that you specified when running configure.sh on page 2821, Zookeeper and Warden might already be started.

NOTE: For a DARE-enabled cluster, you can skip this step because you already started the cluster in order to configure disk storage.

To check that Zookeeper is started, use this command on Zookeeper nodes:

```
systemctl status mapr-zookeeper
```

To check that Warden is started:

```
systemctl status mapr-warden
```

To start the cluster if Zookeeper and Warden are not started:

1. Start ZooKeeper on all nodes where it is installed, by issuing the following command:

   ```
   systemctl start mapr-zookeeper
   ```

2. Start Warden on all nodes:

   ```
   systemctl start mapr-warden
   ```

For clusters, ensure that Zookeeper has established a quorum. Use the nc command to check.

To install nc, use one of the following commands:

```
On RHEL: dnf install nmap-ncat
On SLES: zypper install netcat-openbsd
On Ubuntu: apt-get install netcat
```

To check for a quorum, run:

```
echo srvr | nc localhost 5181 | grep Mode
```

This command returns *leader* or *follower* if Zookeeper has established a quorum.

NOTE: For a single Zookeeper node (is not part of a cluster), the `nc` command always returns *standalone*.

Enabling the HPE Ezmeral Data Fabric Object Store
Some post-installation steps must be performed before you can use the HPE Ezmeral Data Fabric Object Store.

After applying the `mapr-s3server` package, you must perform post-installation steps to:

- Enable the Multithreaded Object Store Server (MOSS) to start in https mode.
- Enable user access to `mc` commands.
- Enable access to the Object Store through an application using the AWS S3 SDK.
- Enable CLI access to the Object Store.

- Gain access to the Object Store UI.

Post-Installation Steps

The following steps are needed if the cluster is running in secure mode:

1. If you did not do so as part of Enabling Security on page 1776, copy the following files to `/opt/mapr/conf` on all other nodes:
   - `/opt/mapr/conf/private.key`
   - `/opt/mapr/conf/ca/chain-ca.pem`

   NOTE: If you are running Data Fabric 7.0.0.5 or later, the `private.key` and `public.crt` are not present and do not need to be copied to all other nodes. On Data Fabric 7.0.0.5, the `/opt/mapr/conf/ssl_usertruststore` performs this function and is present on all nodes.
2. Copy `/opt/mapr/conf/ca/chain-ca.pem` to `~/.mc/certs/CAs/` on the node running mc.
3. On every node that runs an application using the AWS S3 SDK, add the `chain-ca.pem` to the Java `cacerts` truststore, as shown in the following example:

   ```
   ${JAVA_HOME}/bin/keytool -noprompt -importcert -file /opt/mapr/conf/ca/
   chain-ca.pem -alias maprca -keystore ${JAVA_HOME}/lib/security/
   cacerts -storepass <cacerts_truststore>
   ```

   Note:
   - The default password for `-storepass` is `changeit`.
   - The `{JAVA_HOME}` location can vary. For example, on RHEL 8.4, `{JAVA_HOME}` is located at: `/usr/lib/jvm/jre-11-openjdk-11.0.15.0.9-2.el8_5.x86_64`.
4. (Required if you want to access the Object Store from the CLI) Generate S3 keys (accessKey and secretKey) for the cluster administrator. The cluster administrator (typically the `mapr` user) must authenticate to the Object Store cluster and generate S3 keys on the *default* Object Store account.
   a. Use `maprlogin` to authenticate the cluster administrator.
   b. Run the `maprcli dump cldbstate -json` command to check the status of the S3 server module quorum. The dump output should indicate that the primary and secondary S3 server modules are running.
   c. Generate the keys, as shown in the following example:

      ```
      maprcli s3keys generate -domainname primary -accountname
      default -username mapr -json
      ```

      The primary domain is the only domain that exists in Object Store. Currently, you cannot create additional domains.
5. (Required if you upgraded from an earlier version of core to core 7.x) Restart the CLDB service on all nodes to activate the CLDB S3 modules:

   ```
   /opt/mapr/bin/maprcli node services -cldb restart -nodes <list node
   names separated by spaces>
   ```

   For additional information, see node services on page 2292.

last-updated: Jun 06, 2024

Log in to the Object Store UI

Log in to the Object Store UI at `https://<ip-address>:8443/app/mcs/opal/`. Before you log in to the Object Store UI, note the following Object Store login requirements for AD/LDAP users:

- All cluster nodes must be part of AD/LDAP. (Required for AD/LDAP users to log in to the Object Store UI.)
- The AD/LDAP user logging in to the Object Store must have log-in permission. You can set log-in permission from the Control System. Go to `https://<node-ip-address>:8443/app/mcs/#/overview` and select **Admin** > **User Settings**. Click the **Permissions** tab. Add the AD/LDAP user, and select the **Login** checkbox next to the username.

HTTPS Access to Object Store

You can use S3cmd or the AWS CLI to access Object Store over https. If you do not have S3cmd or the AWS CLI installed, you can download them:

- AWS CLI
- S3cmd

Before you run either command, you must first add the MOSS on page 6293 certificate with the java certificates, as shown in the following example:

```
${JAVA_HOME}/bin/keytool -noprompt -importcert -file /opt/mapr/conf/ca/
chain-ca.pem -alias mosscert -keystore ${JAVA_HOME}/lib/security/
cacerts -storepass changeit
```

The following sections provide command usage examples:

S3cmd

The following example shows how to access Object Store and create a bucket using the S3cmd:

```
s3cmd --ca-certs=/opt/mapr/conf/ca/
chain-ca.pem mb s3://bucketname
```

AWS

Before you use the aws command to access Object Store, verify that you have a recent version of `python3-urllib3`. (Version 1.22-1 was tested successfully.)

Also, you must either set an environment variable for the Object Store certificate, as shown:

```
export AWS_CA_BUNDLE=/opt/mapr/
conf/ca/chain-ca.pem
```

OR update `/root/.aws/config`, as shown:

```
[default]
region = us-east-1
ca_bundle = /opt/mapr/conf/ca/
chain-ca.pem
aws_access_key_id =
R2VPO2QR3CTDQ5SG4DJSKIZ2VX1X8HDOTO6NDC
HCM9NKASB03WJ
aws_secret_access_key =
1241TP3TOGWK8OGJJVR9N4D6P2M6BUIZLVQOT6
NHD4QH38QBU3HV2NXMHAIQNYJ2TQ
```

last-updated: Jun 06, 2024

The following example shows how to access Object Store and list buckets with the aws command:

```
aws s3api list-buckets --endpoint-url
https://
m2-sm2028-08-n4.mip.storage.hpecorp.ne
t:9000
```

HTTP Access to Object Store

To revert to http access, comment out the `moss.certs.dir=/opt/mapr/conf` line in the `/opt/mapr/conf/moss.conf` file.

Enabling S3 Virtual-Host-Style Requests

S3 REST requests can be made either in virtual host style or in path style. The host value of the HTTP request header indicates the request style:

Style	Example REST Request
Virtual Host	`host:<bucket_name>.mip.storage.hpecorp.net:9000`
Path	`host:mip.storage.hpecorp.net:9000`

However, the Amazon documentation indicates that path-style URLs will be discontinued in the future.

To enable the S3 server to work with virtual-host-style requests, use the steps below:

1. Install and configure a DNS server that maps the domain name of the S3 server to all the S3 servers in the cluster. For example:

   ```
   address=/mip.storage.hpecorp.net/10.163.161.175
   address=/mip.storage.hpecorp.net/10.163.163.164
   ```

2. Add the following command to `/opt/mapr/conf/env_override.sh`, and restart the S3 server on all nodes in the cluster:

   ```
   export MINIO_DOMAIN=<domain_name>
   ```

3. Use the `<domain_name>` during alias creation or as an endpoint URL in S3 requests wherever it is required:

   ```
   /opt/mapr/bin/mc alias set newmoss https://<domain_name>:9000
   <access_key> <secret_key>

   aws s3api put-object --bucket sbuck3 --body /root/1m --key
   f1 --endpoint-url https://<domain_name>:9000
   ```

Virtual host-style requests do not work when you use the host name during alias creation or as an endpoint URL. Do not add `MINIO_DOMAIN=<domain_name>` to `/opt/mapr/conf/env_override.sh` while using the complete host name during alias creation or as an endpoint.

Object Store Port

The default port for MOSS on page 6293 is 9000. The default port for S3 Gateway is also 9000. If you run S3 Gateway and Object Store in your cluster, change one of the ports to avoid conflicts. Change the MOSS port in `/opt/mapr/conf/moss.conf` by editing the `moss.port=<port_number>` option. Change the

S3 Gateway port in `/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json` by changing the `ports` option. For additional port information, see Ports Used by HPE Ezmeral Data Fabric Software on page 3079

Troubleshooting Installation
If you are having difficulty bringing up the cluster, you have a number of options.

Difficulty bringing up the cluster seems daunting, but most cluster problems are easily resolved. For the latest support tips, visit the Ezmeral Data Fabric Community.

- Can each node connect with the others? For a list of ports that must be open, see Ports Used by HPE Ezmeral Data Fabric Software on page 3079.
- Is the Warden service running on each node? On the node, run the following command as root:

  ```
  service mapr-warden status
     WARDEN running as process 18732
  ```

  If the Warden service is not running, check the Warden log file, `/opt/mapr/logs/warden.log`, for clues. To restart the Warden service:

  ```
  service mapr-warden start
  ```

- The ZooKeeper service is not running on one or more nodes:
  - Check the Warden log file for errors related to resources, such as low memory
  - Check the Warden log file for errors related to user permissions
  - Check for DNS and other connectivity issues between ZooKeeper nodes
- The `maprcli` program `/opt/mapr/bin/maprcli` won't run
  - Did you configure this node?
- Instance Mismatch Node Alarm is raised
  - Restart Warden to ensure that the number of file system instances is as configured.
- Permission errors appear in the log
  - Check that data-fabric changes to the following files have not been overwritten by automated configuration management tools:

`/etc/sudoers`	Allows the `mapr` user to invoke commands as root
`/etc/security/limits.conf`	Allows HPE Ezmeral Data Fabric services to increase limits on resources such as memory, file handles, threads and processes, and maximum priority level
`/etc/udev/rules.d/99-mapr-disk.rules`	Covers permissions and ownership of raw disk devices

Before contacting your HPE support representative, collect your cluster logs by using the mapr-support-collect script.

Installing the Cluster License
You must have a valid license to unlock the enterprise features of the HPE Ezmeral Data Fabric. You can obtain a trial license by contacting your HPE support representative.

For details, see Adding a License on page 1079.

Verifying the Cluster Installation Status

You can use the command line or the Control System to verify the status of your installation.

Using the CLI to Check the Cluster Installation Status

1. Log in to a cluster node.
2. Use the following command to list the HPE Ezmeral Data Fabric services:

```
maprcli service list
  logpath
displayname         name         state
  /opt/mapr/hbase/hbase-1.4.12/logs
HBaseRestServer     hbaserest    0
  /opt/mapr/hbase/hbase-1.4.12/logs
HBaseThriftServer   hbasethrift  0
  /opt/mapr/logs/mfs.log
FileServer          fileserver   0
  /opt/mapr/grafana/grafana-6.7.4/var/log/grafana
Grafana             grafana      0
  /opt/mapr/logs/cldb.log
CLDB                cldb         0
  /opt/mapr/logs/mastgateway.log
MASTGatewayService  mastgateway  0
  /opt/mapr/opentsdb/opentsdb-2.4.0/var/log/opentsdb
OpenTsdb            opentsdb     0
  /opt/mapr/logs/gateway.log
GatewayService      gateway      0
  /opt/mapr/logs/hoststats.log
HostStats           hoststats    0
  /opt/mapr/collectd/collectd-5.10.0/var/log/collectd
CollectD            collectd     0
  /opt/mapr/apiserver/logs/apiserver.log
APIServer           apiserver    0

maprcli license list
maprcli disk list -host <name or IP address>
```

3. Restart Warden on all remaining nodes using the following command:

```
service mapr-warden restart
```

   Warden is then responsible for starting the rest of the services configured on each node.

Using the Control System to Check the Cluster Installation Status

1. Log in to the Control System using the host name of the node where you installed the `mapr-webserver`. For more information, see Setting Up the Control System on page 454.

   NOTE: Because monitoring has not been installed yet and the Control System relies on monitoring for metrics collection, some Control System functions will not be available. You can still use the Control System to check the cluster services.

2. Click the **Nodes** tab to verify that all nodes are present and healthy (no alarms are present).
3. Click the **Services** tab to check for any stopped or failed services.

Step 9: Install Metrics Monitoring

Metrics monitoring is part of monitoring, which also includes log monitoring. Monitoring components are available as part of the Ecosystem Pack (EEP) that you selected for the cluster.

About this task

Complete these steps to install metrics monitoring as the `root` user or using `sudo`. Installing metrics monitoring components on a client node or edge node is not supported.

Procedure

1. For metrics monitoring, install the following packages:

Component	Requirements
collectd	Install the `mapr-collectd` package on each node in the HPE Ezmeral Data Fabric cluster.
OpenTSDB and AsyncHBase	Install the `mapr-opentsdb` on one or more nodes. To allow failover of metrics storage when one OpenTSDB node is unavailable, install OpenTSDB on at least three nodes in the cluster.  **NOTE:** `mapr-opentsdb` depends on `mapr-asynchbase`, and `mapr-asynchbase` is automatically installed on the node where you install `mapr-opentsdb`.
Grafana	Optional: Install the `mapr-grafana` package on at least one node in the HPE Ezmeral Data Fabric cluster. Grafana is optional for metrics monitoring in general.

On a three-node cluster, you could run the following commands to install metrics packages:

- For CentOS/RedHat:
  - Node A: `yum install mapr-collectd mapr-grafana`
  - Node B: `yum install mapr-collectd mapr-opentsdb`
  - Node C: `yum install mapr-collectd`
- For Ubuntu:
  - Node A: `apt-get install mapr-collectd mapr-grafana`
  - Node B: `apt-get install mapr-collectd mapr-opentsdb`
  - Node C: `apt-get install mapr-collectd`
- For SLES:
  - Node A: `zypper install mapr-collectd mapr-grafana`
  - Node B: `zypper install mapr-collectd mapr-opentsdb`
  - Node C: `zypper install mapr-collectd`

2. **Release 6.0.1 and later:** Configure a password for Grafana:

last-updated: Jun 06, 2024

- For a **secured cluster**, ensure that the `/opt/mapr/conf/ssl_truststore.pem` file is present in `/opt/mapr/conf` on the Grafana nodes. If the `/opt/mapr/conf/ssl_truststore.pem` file is not present, you must copy it from the CLDB primary node to `/opt/mapr/conf` on the Grafana nodes.

  NOTE: In a secure cluster, Grafana uses PAM to authenticate using the cluster administrator login ID (typically the `mapr` user ID) and password, so no additional information is needed.

3. On **every cluster node**, run `configure.sh` with the `-R` and `-OT` parameters, and other parameters, as needed, for the Grafana password. A Warden service must be running when you use `configure.sh -R -OT`.

```
/opt/mapr/server/configure.sh -R -OT <comma-separate list of OpenTSDB
nodes>
```

Parameter	Description
`-R`	After initial node configuration, specifies that `configure.sh` should use the previously configured ZooKeeper and CLDB nodes.
`-OT`	Specifies a comma-separated list of host names or IP addresses that identify the OpenTSDB nodes. The OpenTSDB nodes can be part of the current HPE Ezmeral Data Fabric cluster or part of a different HPE Ezmeral Data Fabric cluster. The list is in the following format: • `hostname/IP address[:port_no] [,hostname/IP address[:port_no]...]` **NOTE:** The default OpenTSDB port is 4242. If you want to use a different port, specify the port number when you list the OpenTSDB nodes.

For example, to configure monitoring components you can run one of the following commands:

- In this example, default ports are used for the OpenTSDB nodes.

```
/opt/mapr/server/configure.sh -R -OT NodeB
```

- In this example, non-default ports are specified for the OpenTSDB nodes:

```
/opt/mapr/server/configure.sh -R -OT NodeB:4040
```

After you run `configure.sh -R`, if errors are displayed see Troubleshoot Monitoring Installation Errors on page 229.

4. To start collecting metrics for the NodeManager and ResourceManager services, restart these services on each node where they are installed.

```
maprcli node services -name nodemanager -nodes <space separated list of
hostname/IPaddresses> -action restart
```

```
maprcli node services -name resourcemanager -nodes <space separated list
of hostname/IPaddresses> -action restart
```

Step 10: Install Log Monitoring

Installing the monitoring logging components is optional. The logging components enable the collection, storage, and visualization of core logs, system logs, and ecosystem component logs. Monitoring components are available as part of the Ecosystem Pack (EEP) that you selected for the cluster.

About this task

Complete the steps to install the logging components as the `root` user or using `sudo`. Installing logging components on a client node or edge node is not supported.

Procedure

1. For log monitoring, install the following packages:

Component	Requirements
fluentd	Install the `mapr-fluentd` package on each node in the cluster.
Elasticsearch	Install the `mapr-elasticsearch` package on at least three nodes in the cluster to allow failover of log storage if one Elasticsearch node is unavailable.
Kibana	Install the `mapr-kibana` package on at least one node in the cluster.

   For example, on a three-node cluster, you can run the following commands to install log packages:

   - For CentOS/RedHat:
     - Node A: `yum install mapr-fluentd mapr-elasticsearch`
     - Node B: `yum install mapr-fluentd mapr-elasticsearch`
     - Node C: `yum install mapr-fluentd mapr-elasticsearch mapr-kibana`
   - For Ubuntu:
     - Node A: `apt-get install mapr-fluentd mapr-elasticsearch`
     - Node B: `apt-get install mapr-fluentd mapr-elasticsearch`
     - Node C: `apt-get install mapr-fluentd mapr-elasticsearch mapr-kibana`
   - For SLES:
     - Node A: `zypper install mapr-fluentd mapr-elasticsearch`
     - Node B: `zypper install mapr-fluentd mapr-elasticsearch`
     - Node C: `zypper install mapr-fluentd mapr-elasticsearch mapr-kibana`

2. *For secure HPE Ezmeral Data Fabric clusters*, run `maprlogin print` to verify that you have a user ticket for the HPE Ezmeral Data Fabric user and the `root` user. These user tickets are required for a successful installation. If you need to generate a HPE Ezmeral Data Fabric user ticket, run `maprlogin password`. For more information, see Generating a HPE Ezmeral Data Fabric User Ticket on page 1831.

3. *For secure data-fabric clusters,* verify that the following keystore, truststore, and pem files are present on all nodes. If the files are not present, you must copy them from the security master node to all other nodes. If the `/opt/mapr/conf/ca` directory doesn't exist, you must create the directory:

last-updated: Jun 06, 2024

- `/opt/mapr/conf/ssl_userkeystore`
- `/opt/mapr/conf/ssl_userkeystore.csr`
- `/opt/mapr/conf/ssl_userkeystore.p12`
- `/opt/mapr/conf/ssl_userkeystore.pem`
- `/opt/mapr/conf/ssl_userkeystore-signed.pem`
- `/opt/mapr/conf/ssl_usertruststore`
- `/opt/mapr/conf/ssl_usertruststore.p12`
- `/opt/mapr/conf/ssl_usertruststore.pem`
- `/opt/mapr/conf/ca/root-ca.pem`
- `/opt/mapr/conf/ca/chain-ca.pem`
- `/opt/mapr/conf/ca/signing-ca.pem`

For more information about these files, see Understanding the Key Store and Trust Store Files on page 1793.

4. *For secure HPE Ezmeral Data Fabric clusters,* configure a password for the Elasticsearch `admin` user to enable authentication for the end user using Kibana to search the Elasticsearch log index. This password needs to be provided at the time of running `configure.sh`. If no password is specified, you will default to the pre-mep-5.0.0, default password of `admin`. Use *one* of the following methods to pass the password to Elasticsearch/Kibana:

   - On the nodes where Fluentd/Elasticsearch/Kibana is installed, export the password as an environment variable before calling `configure.sh`:

     ```
     export ES_ADMIN_PASSWORD="<newElasticsearchPassword>"
     ```

     Then run `configure.sh` as you normally would run it (go to step 5).

   - Add the following options to the `configure.sh` command in step 5. This method explicitly passes the password on the `configure.sh` command line:

     ```
     -EPelasticsearch '-password <newElasticsearchPassword>' -EPkibana
     '-password <newElasticsearchPassword>' -EPfluentd '-password
     <newElasticsearchPassword>'
     ```

     Example

     ```
     /opt/mapr/server/configure.sh -R -v -ES mfs74.qa.lab -ESDB /opt/
     mapr/es_db -OT mfs74.qa.lab -C mfs74.qa.lab -Z
     mfs74.qa.lab -EPelasticsearch '-password helloMapR' -EPkibana
     '-password helloMapR' -EPfluentd '-password helloMapR'
     ```

- Add the following options to the `configure.sh` command in step 5. This method explicitly passes the password on the `configure.sh` command line by specifying a file:

```
-EPelasticsearch '-password <name of local file containing new
password>'  -EPkibana '-password <name of local file containing new
password>' -EPfluentd '-password <name of local file containing new
password>'
```

Example

```
/opt/mapr/server/configure.sh -R -v -ES mfs74.qa.lab -ESDB /opt/
mapr/es_db -OT mfs74.qa.lab -C mfs74.qa.lab -Z
mfs74.qa.lab -EPelasticsearch '-password /tmp/es_password' -EPkibana
'-password /tmp/es_password' -EPfluentd '-password /tmp/es_password'
```

5. Run `configure.sh` on each node in the HPE Ezmeral Data Fabric cluster with the `-R` and `-ES` parameters, adding parameters to configure the Fluentd/Elasticsearch/Kibana password as needed. Optionally, you can include the `-ESDB` parameter to specify the location for writing index data. A Warden service must be running when you use `configure.sh -R`.

```
/opt/mapr/server/configure.sh -R -ES <comma-separate list of
Elasticsearch nodes> [-ESDB <filepath>]
```

Parameter	Description
`-ES`	Specifies a comma-separated list of host names or IP addresses that identify the Elasticsearch nodes. The Elasticsearch nodes can be part of the current HPE Ezmeral Data Fabric cluster or part of a different HPE Ezmeral Data Fabric cluster. The list is in the following format: • `hostname/IPaddress[:port_no] [,hostname/IPaddress[:port_no]...]` **NOTE:** The default Elasticsearch port is 9200. If you want to use a different port, specify the port number when you list the Elasticsearch nodes.

Parameter	Description
`-ESDB`	Specifies a non-default location for writing index data on Elasticsearch nodes. In order to configure an index location, you only need to include this parameter on Elasticsearch nodes. By default, the Elasticsearch index is written to `/opt/mapr/elasticsearch/elasticsearch-<version>/var/lib/MaprMonitoring/`. **NOTE:** Elasticsearch requires a lot of disk space. Therefore, a separate filesystem for the index is strongly recommended. It is not recommended to store index data under the `/` or the `/var` file system. Upgrading to a new version of monitoring removes the `/opt/mapr/elasticsearch/elasticsearch-<version>/var/lib/MaprMonitoring/` directory. If you want to retain Elasticsearch index data through an upgrade, you must use the `-ESDB` parameter to specify a separate filesystem or back up the default directory before upgrading. The Pre-Upgrade Steps for Monitoring on page 359 include this step.
`-OT`	Specifies a comma-separated list of host names or IP addresses that identify the OpenTSDB nodes. The OpenTSDB nodes can be part of the current HPE Ezmeral Data Fabric cluster or part of a different HPE Ezmeral Data Fabric cluster. Do not use this option when you configure a node for the first time. Use this option along with the `-R` parameter. A Warden service must be running when you use `configure.sh -R -OT`. The hostname list should use the following format: `hostname/IP address[:port_no] [,hostname/IP address[:port_no]...]` **NOTE:** The default OpenTSDB port is 4242. If you want to use a different port, specify the port number when you list the OpenTSDB nodes.
`-R`	After initial node configuration, specifies that `configure.sh` should use the previously configured ZooKeeper and CLDB nodes.

For example, to configure monitoring components you can run one of the following commands:

- In this example, a location is specified for the Elasticsearch index directory, and default ports are used for Elasticsearch nodes:

```
/opt/mapr/server/configure.sh -R -ES NodeA,NodeB,NodeC -ESDB /opt/mapr/myindexlocation
```

- In this example, non-default ports are specified for Elasticsearch, and the default location is used for the Elasticsearch index directory:

```
/opt/mapr/server/configure.sh -R -ES NodeA:9595,NodeB:9595,NodeC:9595
```

last-updated: Jun 06, 2024

After you run `configure.sh -R`, if errors are displayed see Troubleshoot Monitoring Installation Errors on page 229.

6. If you installed Kibana, perform the following steps:
   a) Use one of the following methods to load the Kibana URL:
      - From the Control System, select the **Kibana** view. After you select the **Kibana** view, you may also need to select the **Pop-out page into a tab** option.
      - From a web browser, launch the following URL: `https://<IPaddressOfKibanaNode>:5601`
   b) When the Kibana page loads, it displays a `Configure an index pattern` screen. Provide the following values:

      NOTE: The **Index contains time-based events** option is selected by default and should remain selected.

Field	Value
Index name or pattern	`mapr_monitoring-*`
Time-field	`@timestamp`

   c) Click **Create**.

Troubleshoot Monitoring Installation Errors

Review the following solutions to errors that you may encounter when you run `configure.sh` to configure monitoring.

Elasticsearch Errors

could not determine matching interface

Cause: The DNS is probably not setup correctly on this node.

Solution: Contact your DNS administrator or verify that `/etc/hosts` and `/etc/nssswitch.conf` are configured correctly. The `etc/hosts` file should list the host names and the hosts parameter in `/etc/nssswitch.conf` should be set to files dns.

Failed to create <esdb directory name>

Cause: There is not enough disk space, `configure.sh` was not run as the `root` user, or the index directory path is not valid.

Solution: Complete the following steps and then re-run `configure.sh`:

- Verify that there is enough disk space.
- Verify that the file system where the index directory will be created is not read-only. See Log Aggregation and Storage on page 1761 for more information on the index directory location.
- If you included the `-ESDB` parameter, verify that the index directory path uses a valid format: `/<existing_directory1>/<existing_directory2>/<new index directory>`.

Failed to resolve hostname

Cause: The DNS is probably not set up correctly on this node.

	Solution: Contact your DNS administrator or verify that `/etc/hosts` and `/etc/nssswitch.conf` are configured correctly. `/etc/hosts` should list the host names if the DNS database is not updated, and the hosts parameter in `/etc/nssswitch.conf` should be set to `files dns`

OpenTSDB Errors

Incompatible asynchbase jar found	**Cause:**The version of asynchbase installed on this node is not compatible with OpenTSDB. **Solution:**Install the correct asynchbase package on each OpenTSDB node. See the EEP release notes to determine the compatibility between package versions.
Failed to install asynchbase Jar file	**Cause:** There is not enough disk space, the file system is read-only, or `configure.sh` was not run as the root user. **Solution:** Complete the following steps and then re-run `configure.sh`: • Verify that you are logged in as the root user or using sudo. • Verify that there is enough disk space. • Verify that the file system containing the `/opt/mapr/opentsdb` directory is mounted as read/write.
Failed to create TSDB tables - need to rerun `configure.sh -R` or run `create_table.sh` as `$MAPR_USER`	**Cause:** On a secure cluster, this issue usually occurs when you run `configure.sh` to configure the nodes to use monitoring without first creating user tickets for the `root` user and the `$MAPR_USER`. **Solution:** Complete one or all of the following steps: • Verify that you have a user ticket for both root and the $MAPR_USER before running `configure.sh` or `create_table.sh`. Run `maprlogin print` to verify that you have a user ticket for the data-fabric user and the `root` user. If you need to generate a data-fabric user ticket, run `maprlogin password`. • Re-run `configure.sh`. For example, `configure.sh -R -OT <comma-separate list of OpenTSDB nodes> -ES <comma-separate list of Elasticsearch nodes>` • Run `${OTSDB_HOME}/share/opentsdb/tools/create_table.sh` to create OpenTSDB tables in the `mapr.monitoring` volume.

Fluentd Errors

fluentd service not enabled - missing clusterid	**Cause:** The data-fabric cluster was not up and running before `configure.sh` was run with the options to configure monitoring. **Solution:** Complete the following steps and then re-run `configure.sh`:

last-updated: Jun 06, 2024

	• Verify that the CLDB services is running. If not, start Warden with the following command: `service mapr-warden start`. • Verify that the `$MAPR_HOME/conf/clusterid` file exists.

Collectd Errors

collectd service not enabled - missing clusterid	**Cause:** The cluster was not up and running before `configure.sh` was run with the options to configure monitoring. **Solution:** Complete one or all of the following steps and then re-run `configure.sh`: • Verify that the CLDB services is running. If not, start Warden with the following command: `service mapr-warden start`. • Verify that the `$MAPR_HOME/conf/clusterid` file exists.

Grafana Errors

Failed to pick default data source host	**Cause:** The OpenTSDB nodes list defined by the `-OT` parameter was incorrect. **Solution:** Check the syntax and the validity of those nodes.
Failed to create scratch config file	**Cause:** There is not enough disk space, `configure.sh` was not run as the `root` user, or the file system was mounted as read-only. **Solution:** Complete one or all of the following steps and then re-run `configure.sh`: • Verify that you are logged in as the `root` user or using sudo. • Verify that there is enough disk space. • Verify that the file system containing `/opt/mapr/grafana` is mounted as read/write.
Failed to change the port	**Cause:** The `sed` utility failed to edit a port value in the temporary configuration file. This may occur due to issues with file system permissions, disk space, or file corruption. **Solution:** Complete the following steps and then re-run `configure.sh`: • Verify that the file system containing `/opt/mapr/grafana` is mounted as read/write. • Verify that there is enough disk space. • Re-install the monitoring packages.
Failed to configure ssl for grafana	**Cause:** The `sed` utility failed to edit a port value in the temporary configuration file. This can occur due to

last-updated: Jun 06, 2024

	issues with file system permissions, disk space, or file corruption. **Solution:** Complete the following steps and then re-run `configure.sh`: • Verify that the file system containing `/opt/mapr/grafana` is mounted as read/write. • Verify that there is enough disk space. • Re-install the monitoring packages.
ERROR: Failed to install grafana warden config file	**Cause:** There is not enough disk space, `configure.sh` was not run as the root user, or the file system containing `/opt/mapr/grafana` is mounted as read-only. **Solution:** Complete the following steps and then re-run `configure.sh`: • Verify that you are logged in as the `root` user or using sudo. • Verify that there is enough disk space. • Verify that the file system containing `/opt/mapr/grafana` is mounted as read/write.

Kibana Errors

Failed to configure elasticsearch server URL	**Cause:** There is not enough disk space, `configure.sh` was not run as the root user, or the file system containing `/opt/mapr/kibana` is mounted read-only. **Solution:** Complete the following steps and then re-run `configure.sh`: • Verify that you are logged in as the `root` user or using sudo. • Verify that there is enough disk space. • Verify that the file system containing `/opt/mapr/kibana` is mounted as read/write.
Failed to configure ssl for Kibana	**Cause:** There is not enough disk space or the root user does not have the required directory permissions to create the file in the `/opt/mapr/kibana/kibana-<version>/config` directory. **Solution:** Complete the following steps and then re-run `configure.sh`: • Verify that there is enough disk space. • Verify that the file system containing `/opt/mapr/kibana` is mounted as read/write.
Kibana logon unsuccessful because Searchguard "Service Unavailable"	**Cause:** On a slower server, Kibana logons sometimes do not succeed because the Searchguard configuration containing the user names and passwords has not finished loading. You might notice

an error like the following in the Elasticsearch `MapRMonitoring.log`:

```
[2018-06-30T07:47:15,062][ERROR]
[c.f.s.a.BackendRegistry  ] Not
yet initialized (you may
need to run sgadmin)
```

Solution: Try using the following command to restart Elasticsearch:

```
maprcli node services -name
elasticsearch -action restart -nodes $
(hostname -f)
```

Step 11: Install Ecosystem Components Manually

You can install one or more ecosystem components from any Ecosystem Pack (EEP) that is supported by the data-fabric cluster version. An EEP consists of a group of ecosystem components that work together.

Prerequisite: Set up the EEP Repository

Complete the following steps on each node in the cluster:

1. Verify that each node can access the ecosystem packages associated with the EEP version that you want to install. For information about how to set up the ecosystem repositories or to manually download each package, see Step 3: Prepare Packages and Repositories on page 182.
2. Update the repository cache to get the latest list of available packages:
   - On RedHat/CentOS:

     ```
     yum clean all
     ```

   - On SLES:

     ```
     zypper refresh
     ```

   - On Ubuntu:

     ```
     apt-get update
     ```

Manually Install Ecosystem Components

Review the Ecosystem Pack Release Notes to determine the list of ecosystem components available in the EEP that you have selected. Then, complete the installation steps for each component that you want to install.

NOTE:

- If you want to use the optional OJAI Distributed Query Service on page 640, you must install Drill. See Installing Drill on page 236.
- For special considerations related to the installation of the `mapr-apiserver` and `mapr-webserver` packages (for the control system) in releases 6.2.0 and later, see Setting Up the Control System on page 454.

Installing Airflow

This topic includes instructions for using package managers to download and install Apache Airflow from the EEP repository.

For instructions to set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

Installation on a Server Node or Edge Node

The Airflow client/server architecture requires you to install three packages on the server node or edge node:

- `mapr-airflow`
- `mapr-airflow-webserver`
- `mapr-airflow-scheduler`

The `mapr-airflow-webserver` and `mapr-airflow-scheduler` packages depend on `mapr-airflow`. The package manager automatically installs `mapr-airflow` when you install either `mapr-airflow-webserver` or `mapr-airflow-scheduler`. Execute the following commands as `root` or by using `sudo` on an HPE Ezmeral Data Fabric cluster.

1. On a node where you want to install Airflow, install `mapr-airflow`, `mapr-airflow-webserver`, and `mapr-airflow-scheduler`:
   - On Ubuntu:

     ```
     apt-get install mapr-airflow mapr-airflow-webserver
     mapr-airflow-scheduler
     ```

   - On RHEL/CentOS:

     ```
     yum install mapr-airflow mapr-airflow-webserver mapr-airflow-scheduler
     ```

   - On SLES:

     ```
     zypper install mapr-airflow mapr-airflow-webserver
     mapr-airflow-scheduler
     ```

   Note that installations on Oracle Enterprise Linux (OEL) must be done by the `root` user.

2. Run `configure.sh -R`.

   ```
   /opt/mapr/server/configure.sh -R
   ```

Installation on a Client Node

Airflow can be installed on a client node. The installation steps are the same as for a server node or edge node. However, after installation on a client node, you must manage all Airflow services manually. For example:

To manage the webserver:

```
/opt/mapr/airflow/airflow-<version>/bin/airflow.sh [start|stop] webserver
```

last-updated: Jun 06, 2024

To manage the scheduler:

```
/opt/mapr/airflow/airflow-<version>/bin/airflow.sh [start|stop] scheduler
```

Installation on a FIPS Node

Installing Airflow on a FIPS node requires some extra steps:

1. Install Airflow as described in Installation on a Server Node or Edge Node on page 234.
2. While logged on as the `root` user, run the repair tool:

   ```
   <airflow_home>/bin/repair_pip_depends.sh
   ```

3. Run the `configure.sh` script:

   ```
   /opt/mapr/server/configure.sh -R
   ```

4. Update the Airflow configuration to the FIPS support hash:

   ```
   Change "caching_hash_method = md5" to "caching_hash_method = sha256"
   ```

5. Restart Airflow services. See Starting, Stopping, and Restarting Airflow Services on page 3895.

Installing AsyncHBase Libraries

This topic includes instructions for using package managers to download and install AsyncHBase from the EEP repository.

Prerequisites

For instructions on setting up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

About this task

Execute the following commands as `root` or using `sudo`.

Procedure

1. Based on your operating system, run one of the following commands to install the package:

On Red Hat /Centos	`yum install mapr-asynchbase`
On SLES	`zypper install mapr-asynchbase`
On Ubuntu	`apt-get install mapr-asynchbase`

2. Run the `configure.sh` script with the following command to configure the AsyncHBase role for the node:

   ```
   /opt/mapr/server/configure.sh -R
   ```

last-updated: Jun 06, 2024

Results
After installing the `mapr-asynchbase` package, the AsyncHBase JAR file `asynchbase-<version>-mapr.jar` is in the `/opt/mapr/asynchbase/asynchbase-<version>` directory.

Installing Drill
This topic provides instructions for using package managers to download and install Drill.

You can install and run Drill on any number of nodes in your MapR cluster. You can install Drill to run under the Warden service or under YARN. Starting in MapR 6.0 and Drill 1.11, Drill is secured by default when you install Drill on a secure MapR 6.x cluster.

NOTE: See Component Versions for Released EEPs for version support in each EEP release.

MapR Default Security Configuration

Starting in Drill 1.11, Drill is automatically secured when you install Drill in a 6.x MapR cluster that was installed with the default MapR security configuration. The default security configuration uses MapR-SASL (mapr tickets) to provide authentication, authorization, and encryption for cluster security.

NOTE: The default security configuration does not support Drill-on-YARN.

The default MapR security configuration is not required. You can install Drill and configure custom security, or turn security off after installing with the default security configuration. See the *Drill Installation Security Scenarios* section below for more information. See Securing Drill.

Installing Drill Under Warden or YARN

You can install and run Drill under Warden or you can install and run Drill under YARN. If you are currently running Drill under Warden, you can upgrade Drill and continue to run Drill under Warden, or you can migrate Drill to run under YARN. See Migrate Drill to Run Under YARN for instructions.

When Warden manages the Drill cluster, you can use the MapR Control System for monitoring. YARN (Yet Another Resource Negotiator) is a cluster management tool that automates the resource sharing process in a cluster. When you launch Drill under YARN, YARN deploys (localizes) Drill onto each node. You can monitor the Drill cluster using the Drill-on-YARN Application Master web UI.

Drill Packages

You can use package managers to manually install the appropriate Drill package. The Drill packages provide the software needed to run Drill. MapR provides mapr-drill package and also a mapr-drill-yarn package.

Drill includes the Drill daemon, the core Drillbit service that runs on a node. Each node running the Drillbit service can receive, plan, and execute queries sent from a client. The software also includes the drill-shell command line interface, a pure-Java console-based utility, for connecting to a Drill cluster and executing SQL commands.

The following sections list the Drill packages and their descriptions:

mapr-drill	The mapr-drill package is required to run Drill under the MapR Warden service. This package installs or upgrades the Drill software in `/opt/mapr/drill` and integrates Drill with the MapR Warden service. You install this package on all nodes designated to run Drill.

NOTE: Verify that you get both the mapr-drill and mapr-drill-internal packages, especially if you install or upgrade through the URL or download through the MapR repositories. Also, verify that the packages have the same version. For example, if you install Drill 1.14, both packages should be version 1.14.

mapr-drill-yarn	The mapr-drill-yarn package is required to run Drill under YARN. This package installs the Drill software in `/opt/mapr/drill`. You install this package on the node that you designate as the Drill-on-YARN client. See Install Drill to Run Under YARN for details. YARN deploys Drill to every node included in the Drill cluster. Installing this package on every node is not required.

NOTE: If any users need to access SQLLine, you must install the mapr-drill-yarn package on every node where users expect access to SQLLine.

Drill and Query Services

To use the optional OJAI Distributed Query Service on page 640, you must install Drill and configure and register the service. See Configure the OJAI Distributed Query Service on page 241.

Drill Installation Security Scenarios

The following sections describe some manual installation scenarios for Drill with information about security configuration:

Installing or Upgrading Drill

You can install Drill on a MapR cluster with or without default security. After you install the Drill package, you must run the configuration script, configure.sh -R, to configure the Drill service on the nodes. When you run the configuration script, the script recognizes whether your MapR cluster is using the default security or not, and configures Drill accordingly.

In a secure cluster, an internal Drill configuration script automatically adds the security configuration to the `drill-distrib.conf` and `distrib-env.sh` files. See Securing Drill.

NOTE: You can override these default security settings in the `drill-override.conf` file, but doing so is not recommended or supported.

If your cluster is not using the default security, the internal Drill configuration script does not configure any security for Drill. Instead, it copies warden.drill-bits.conf to the conf.d directory.

Installing Drill with MapR and Configuring Custom Security

If you install MapR and Drill, and you want to manually secure the cluster and Drill instead of using the default security option, you must add a .customSecure file to the /opt/mapr/conf/ directory before you run configure.sh, as shown:

1. Run `/usr/bin/touch /opt/mapr/conf/.customSecure` to add the .customSecure file.
2. Run `configure.sh -R`.

The configuration script recognizes the .customSecure file which indicates not to configure the default security settings. At this point, you can manually configure security in drill-override.conf.

last-updated: Jun 06, 2024

Component and System Compatibility Matrix

See the Interoperability Matrix pages for information about the compatibility of Drill with operating systems and ecosystem projects.

Drill Storage and Format Plug-in Support Matrix

See the Drill Storage and Format Plugin Support Matrix page for a list of supported and unsupported data sources and formats in Drill on MapR.

Install Drill to Run Under Warden

Verify that your system meets the prerequisites listed below and then follow the instructions listed in Installing Drill to Run Under Warden to install the mapr-drill package on all nodes designated to run Drill under the MapR Warden service.

NOTE: See Component Versions for Released EEPs for version support in each EEP release.

Prerequisites

Before you install Drill, read Installing Drill, and verify that the system meets the following prerequisites:

- The MapR cluster is installed and running. Installing Drill first can result in configuration issues
- The EEP repository is configured. For instructions, see Step 9: Install Ecosystem Components Manually.

Refer to the Apache Drill Release Notes and Drill Release Notes for a list of known issues.

Hive and HBase Support

Installation of a supported version of Hive is optional. Support differs, depending on the Ecosystem Pack version that you install. See Component Versions for Released EEPs for version support in each EEP release.

NOTE: As of MapR 6.0, HBase is not supported.

Installing Drill to Run Under Warden

Explains how to manually install the latest version of Drill to run under the Data Fabric Warden service on the Data Fabric Converged Data Platform.

Prerequisites

NOTE: Starting in Drill 1.11, Drill is automatically secured when installed on a 6.x Data Fabric cluster with the default Data Fabric security configuration. The default security configuration uses Data Fabric security (mapr tickets) to provide authentication, authorization, and encryption for cluster security. See Securing Drill amd Component Versions for Released EEPs for more information.

Complete the following steps as `root` or using `sudo` to install Drill on a client or server node:

Procedure

1. To install Drill, issue the command appropriate for your system:

RedHat/CentOS	`yum install mapr-drill`
Ubuntu	`apt-get install mapr-drill`

last-updated: Jun 06, 2024

SLES	`zypper install mapr-drill`

NOTE: SLES is supported as of Drill 1.9.0-1703 and Drill 1.10.0-1703.

2. Run the configuration script to update the node configuration, as shown:

```
/opt/mapr/server/configure.sh -R
```

NOTE: See configure.sh for more information about the script.

3. Verify that Drill is configured and running on the node. You can use one of the following methods to verify that the Drillbit service is running on the node:
   - Issue the following command to verify the status of the Drillbit service from the command line:

     ```
     jps
     ```

   - Log in to the Control System at `https://<host_name>:8443` to verify the status of the Drillbit service.

     NOTE: You should see the Drillbit listed as a service running on the node.

4. Optionally, modify the Drill configuration. For example, you can change the log file directory, increase heap space and direct memory, or configure the file system as the persistent configuration storage. See Configuring Drill on page 3974.

   NOTE: You must restart the drillbit for the new configuration to take effect.

5. Repeat steps 1 through 3 on any other nodes designated to run Drill.

   NOTE:

   You can start|stop|restart the Drillbit service on one or more nodes using the Control System or the following command:

   ```
   $ maprcli node services -name drill-bits -action start|restart|
   stop -nodes <node host names separated by a space>
   ```

   Use the host name if possible. Using host names instead of IP addresses is a best practice.

   You can access the Drill log files in `/opt/mapr/drill/drill-<version>/logs/drillbit.log`.

Install Drill to Run Under YARN

You can install and configure Drill to run under YARN. See Drill-on-YARN Overview. If you are currently running Drill under Warden, back up the directory from your previous Drill installation, and migrate Drill to run under YARN. See Migrate Drill to Run Under YARN.

NOTE: Drill-on-YARN is an advanced feature used to manage a production Drill cluster. Only skilled Drill and MapR administrators, familiar with YARN, should configure Drill to run under YARN. If you are new to Drill, consider using Drill under Warden until you are familiar with Drill and the Drill cluster.

NOTE: The MapR default security feature introduced in MapR 6.0 is not supported with Drill-on-YARN.

last-updated: Jun 06, 2024

Verify that your system meets the prerequisites below and then follow the instructions in Installing Drill to Run Under YARN to install the mapr-drill-yarn package on the node designated as the Drill-on-YARN client to run Drill under YARN.

Prerequisites

Verify that your system meets the following prerequisites before you install Drill to run under YARN:

- The MapR cluster is installed and running. Installing Drill first can result in configuration issues
- You have planned the YARN cluster. See YARN on page 1019, Planning the Cluster on page 79, and Example Cluster Designs on page 91.
- - ResourceManager is installed on one node in the YARN cluster, and you have calculated disk requirements for the YARN ResourceManager.
  - NodeManager is installed on all nodes in the YARN cluster.
- You have designated one node to act as the Drill-on-YARN client. This is the node on which you install the mapr-drill-yarn package. The Drill-on-YARN client is a command-line program that starts, stops, and monitors the Drill cluster. The client provides the information that YARN needs to start the Application Master.
- Cluster resources can accommodate the Drill memory, CPU, and disk requirements.
- The EEP repository is configured. For instructions, see Step 8: Install Ecosystem Components Manually.

Hive and HBase Support

Installation of a supported version of Hive and HBase is optional. Support differs based on the EEP version that you install. See Component Versions for Released EEPs for version support in each EEP release.

Installing Drill to Run Under YARN

This topic includes instructions for using package managers to download and install Drill.

Prerequisites

Verify that the system meets the prerequisites. You must install the mapr-drill-yarn package on a node designated to run as the Drill-on-YARN client.

NOTE: The MapR default security feature introduced in MapR 6.0 is not supported with Drill-on-YARN.

Complete the following steps as `mapr` using `sudo` to install Drill on the node:

NOTE: If users need to access SQLLine, you must install the `mapr-drill-yarn` package on every node used to access SQLLine.

Procedure

1. To install Drill, issue the command appropriate for your system:

RedHat/CentOS	`yum install mapr-drill-yarn`
Ubuntu	`apt-get install mapr-drill-yarn`

last-updated: Jun 06, 2024

SLES	`zypper install mapr-drill-yarn`

NOTE:

- SLES is supported as of Drill 1.9.0-1703 and Drill 1.10.0-1703.
- Drill does not automatically start after you install the packages. Configuring Drill to Run Under YARN includes steps for starting Drill-on-YARN.

2. Configure Drill to run under YARN. See Configuring Drill to Run Under YARN.

ATTENTION: If you installed Drill-on-YARN 1.16.1.100 - 1.16.1.4 (the versions included in EEP 7.0.1 - EEP 8.1.0), the system fails to upload the Drill archive because the `/user/drill` directory does not exist. Resolve this issue before you follow the steps in Configuring Drill to Run Under YARN. To resolve the issue, follow the steps listed in the Drill 1.16.1.400-2201 (EEP 8.1.0) Release Notes.

Configure the OJAI Distributed Query Service

About this task

Use these steps to install and configure the OJAI Distributed Query Service on page 640:

Procedure

1. Using the EEP 4.0 or later repository, install Drill to run under Warden on all data nodes. See Install Drill to Run Under Warden on page 238.
2. Configure the query service by running the following configure.sh script command on the Drill nodes:

```
/opt/mapr/server/configure.sh -R -QS
```

3. Register the query service:

NOTE: In the following command `<clustername>` is the name of the cluster as specified in `/opt/mapr/conf/mapr-clusters.conf`.

```
maprcli cluster queryservice setconfig -enabled true -clusterid
<clustername>-drillbits -storageplugin dfs -znode /drill
```

Installing Hadoop and YARN

This topic describes how to use package managers to download and install Hadoop and YARN services from the EEP repository.

About the Hadoop and YARN Packages

Beginning with core 6.2.0 and EEP 7.0.0, Hadoop and YARN services are no longer included in the data-fabric repository for core packages. They are provided as ecosystem components in the EEP repository. For example:

Old location: `https://package.ezmeral.hpe.com/releases/v<version>/redhat/`

New location: `https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/redhat/`

In addition, some new packages have been added. The following table describes each package:

Package	Description
`mapr-hadoop-util`	This package is new for Release 6.2.0. This package contains the essential libraries to run `hadoop fs` and `hadoop mfs` shell commands, plus the minimal required Hadoop libraries for core to be able to function. On a data-fabric core node, `mapr-hadoop-util` is the minimal package you need to install for Hadoop shell commands, and for data-fabric operations, such as `maprlogin`, to work. `mapr-core` and `mapr-hadoop-client` automatically pull in `mapr-hadoop-util`, so you don't need to install it explicitly.
`mapr-hadoop-client`	This package is new for Release 6.2.0. This package contains the Hadoop job clients (MR and YARN). Clients can submit jobs to a server running `mapr-hadoop-core`. `mapr-hadoop-client` is sufficient to run all `hadoop mfs` and `hadoop fs` commands, and submit MapReduce jobs to whichever server is running `mapr-hadoop-core`.
`mapr-hadoop-core`	This package contains all the required libraries to run MapReduce jobs locally. Installing `mapr-hadoop-core` installs `mapr-hadoop-client` and `mapr-hadoop-util` as dependencies.
`mapr-nodemanager`	Installs the NodeManager service. This package installs `mapr-hadoop-core` as a dependency.
`mapr-resourcemanager`	Installs the ResourceManager service. This package installs `mapr-hadoop-core` as a dependency.
`mapr-historyserver`	Installs the HistoryServer service. This package installs `mapr-hadoop-core` as a dependency.
`mapr-timelineserver`	Installs the TimelineServer service.
`mapr-httpfs`	Installs the HttpFS service. Beginning with EEP 9.0.0, HttpFS is part of Hadoop.

Note that the `mapr-mapreduce2` package has been removed and is no longer available. `mapr-hadoop-core` obsoletes the `mapr-mapreduce2` package. All the contents of `mapr-mapreduce2` are now part of `mapr-hadoop-core`.

For package dependency information, see Package Dependencies on page 103.

Where to Install the Packages

Before installing Hadoop and YARN, you should plan which cluster nodes should run each service. The following table describes where to install the packages:

On these nodes	Install these packages
All nodes where you need access to the file system	`mapr-hadoop-util`

Designated nodes where Hadoop or YARN services are needed (install only the packages you need)	`mapr-nodemanager`
	`mapr-resourcemanager`
	`mapr-historyserver`
	`mapr-timelineserver`
	`mapr-httpfs`

Nodes where Hadoop or YARN services are installed	`mapr-hadoop-core`
Client nodes and nodes where applications will be launched	`mapr-hadoop-client`

Installing Hadoop and YARN Packages

The following steps use the operating-system package managers to download and install Hadoop and YARN packages from the EEP repository:

1. Change to the `root` user or use `sudo`:
   - On **RHEL, CentOS, or Oracle Linux,** use the `yum` command to install the services that you want to run on the node.

     Syntax

     ```
     yum install <package_name> <package_name> <package_name>
     ```

     Example

     ```
     yum install mapr-hadoop-util mapr-nodemanager mapr-httpfs
     ```

   - On **SLES**, use the `zypper` command to install the services that you want to run on the node. (SLES support might be limited; for more information, see Operating System Support Matrix on page 5719.)

     Syntax

     ```
     zypper install <package_name> <package_name> <package_name>
     ```

     Example

     ```
     zypper install mapr-hadoop-util mapr-nodemanager mapr-httpfs
     ```

   - On **Ubuntu**, use the `apt-get` commands to update the Ubuntu package cache and install the services that you want to run on the node.

     a. Update the Ubuntu package cache:

     ```
     apt-get update
     ```

     b. Install the services:

     Syntax

     ```
     apt-get install <package_name> <package_name> <package_name>
     ```

     Example

     ```
     apt-get install mapr-hadoop-util mapr-nodemanager mapr-httpfs
     ```

2. On each node, run `configure.sh` with the `-R` option. Include the `-TL` option if the timeline server is installed on the cluster. For example:

   ```
   configure.sh -R -HS <hostname> -TL <hostname>
   ```

Installing HBase

This topic includes instructions for using package managers to download and install HBase from the EEP repository.

Before installing HBase, you should plan which cluster nodes should run the HBase Master service, and which nodes should run the HBase RegionServer. At least one node (generally three nodes) should run the HBase Master. For example, install HBase Master on the ZooKeeper nodes. Only a few of the remaining nodes or all of the remaining nodes can run the HBase RegionServer.

The following procedures use the operating-system package managers to download and install from the EEP repository.

Install HBase on a Cluster Node
The following instructions use the package manager to download and install HBase from the EEP repository to a cluster node.

Prerequisites
For instructions on setting up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

About this task
Run the following commands as `root` or using `sudo`.

Procedure

1. On each planned HBase Master node, install `mapr-hbase-master`:
   - Ubuntu:
     ```
     apt-get install mapr-hbase-master
     ```
   - RedHat/CentOS:
     ```
     yum install mapr-hbase-master
     ```
   - SLES:
     ```
     zypper install mapr-hbase-master
     ```
2. On each planned HBase RegionServer node, install `mapr-hbase-regionserver`:
   - Ubuntu:
     ```
     apt-get install mapr-hbase-regionserver
     ```
   - RedHat/CentOS:
     ```
     yum install mapr-hbase-regionserver
     ```
   - SLES:
     ```
     zypper install mapr-hbase-regionserver
     ```
3. On all HBase nodes, run `configure.sh -R`:
   ```
   /opt/mapr/server/configure.sh -R
   ```

Installing HBase Client and Tools

MapR 6.0.x does not support HBase as an ecosystem component. Beginning with EEP 6.3.0, MapR 6.1 reintroduced HBase as an ecosystem component. With EEP 6.3.0 and later you can install the HBase Client and tools even if you decide not to install HBase as an ecosystem component. This topic describes the HBase Client and other tools that are available for use with the HPE Ezmeral Data Fabric Database.

Service	Description
HBase Client	After installing the HBase Client, you can use the HBase Shell to manipulate HPE Ezmeral Data Fabric Database tables. HPE Ezmeral Data Fabric Database also supports a number of HBase APIs for use with HPE Ezmeral Data Fabric Database binary tables. For information on installation and configuration, see Installing HBase on a Client Node on page 245. For more information about HPE Ezmeral Data Fabric Database tables and HBase APIs, see Developing Applications for Binary Tables on page 3237.
HBase Thrift Gateway	HBase Thrift Gateway includes an API and a service that accepts Thrift requests to connect to HPE Ezmeral Data Fabric Database tables. For information on installation and configuration, see Installing the HBase Thrift Gateway.
HBase REST Gateway	HBase REST Gateway includes an API and a service that accepts REST requests to connect to HPE Ezmeral Data Fabric Database tables. For information on installation and configuration, see Installing the HBase REST Gateway.
AsyncHBase Libraries	AsyncHBase library provides asynchronous Java APIs to access HPE Ezmeral Data Fabric Database tables. For information on installation and configuration, see Installing AsyncHBase Libraries on page 235.

Installing HBase on a Client Node

The following instructions use the package manager to download and install HBase from the EEP repository to a client node. When you install HBase on a client node, you can use the HBase shell from a machine outside the cluster.

Prerequisites

MapR 6.0.x does not support HBase as an ecosystem component. Beginning with EEP 6.3.0, MapR 6.1 reintroduced HBase as an ecosystem component. With EEP 6.3.0 and later you can install the HBase Client and tools even if you decide not to install HBase as an ecosystem component.

Before you being, verify the following prerequisites:

- The EEP repository is set up. For the steps to set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233
- The HPE Ezmeral Data Fabric client must be installed on the node where you install the HBase client.

  For HPE Ezmeral Data Fabric client setup instructions, see Setting Up the Client.
- You must know the IP addresses or hostnames of the ZooKeeper nodes on the cluster.

About this task

Run the following commands as `root` or using `sudo`.

Procedure

1. On the client computer, install `mapr-hbase`:

last-updated: Jun 06, 2024

CentOS or Red Hat	`yum install mapr-hbase`
Ubuntu	`apt-get install mapr-hbase`
SLES	`zypper install mapr-hbase`

2. On all HBase nodes, run configure.sh with a list of the CLDB nodes and ZooKeeper nodes in the cluster.

Configuring HBase on a Client Node
You can use a script to configure client nodes for use with HBase 1.1.13 or later on a secure or nonsecure MapR cluster.

You configure client nodes as part of a new installation or when you need to upgrade `mapr-hbase` on the client node from a previous HBase version (for example, HBase 1.1.8) to 1.1.13 or later.

Configuration Using the configure_client.sh Script

The `configure.sh` utility does not support the configuration of client nodes for HBase. However, you can use the following script to configure a client by specifying the ZooKeeper host name and port. The script supports secure (MapR-SASL) and nonsecure clusters, but does not support Kerberos (see Manual Configuration on page 246):

```
/opt/mapr/hbase/hbase-1.1.13/bin/configure_client.sh -zkServer <host>:<port>
```

Manual Configuration

To configure a client node manually for use with HBase 1.1.13 or later on a secure or nonsecure MapR cluster, do the following:

Desired Security	Do this . . .	Example

Nonsecure	1. Modify the `hbase.zookeeper.quorum` property to change the hostname and add the ZooKeeper port.	`<property>`
		`  <name>hbase.zookeeper.quorum</name>`
		`  <value><hostname>:5181</value>`
		`</property>`

Secure (MapR-SASL)	1. Modify the `hbase.zookeeper.quorum` property as shown in the nonsecure example.
	2. Add the properties shown in this example.
		`<property>`
		`  <name>hbase.security.authentication</name>`
		`  <value>maprsasl</value>`
		`</property>`
		`<property>`
		`  <name>hbase.rpc.protection</name>`
		`  <value>privacy</value>`
		`</property>`

last-updated: Jun 06, 2024

Desired Security	Do this . . .	Example

Secure (Kerberos)	1. Modify the `hbase.zookeeper.quorum` property as shown in the nonsecure example.
	2. Add the properties shown in this example.
		`<property>`
		`  <name>hbase.security.authentication</name>`
		`  <value>kerberos</value>`
		`  </property>`
		`  <property>`
		`  <name>hbase.rpc.protection</name>`
		`  <value>privacy</value>`
		`  </property>`
		`<property>`
		`  <name>hbase.master.kerberos.principal</name>`
		`  <value><username>/<fqdn>@<realm></value>`
		`</property>`
		`<property>`
		`  <name>hbase.regionserver.kerberos.principal</name>`
		`  <value><username>/<fqdn>@<realm></value>`
		`</property>`

Installing the HBase Thrift Gateway

About this task

The HBase Thrift Gateway can be installed on any node where the `mapr-client` package or the `mapr-core` package is installed.

Complete the following steps to install the HBase Thrift Gateway:

Procedure

1. Run the following command to install the HBase Thrift package:

On CentOS / Red Hat	`yum install mapr-hbasethrift`
Ubuntu	`apt-get install mapr-hbasethrift`
SLES	`zypper install mapr-hbasethrift`

2. Run configure.sh on the node where you installed the HBase Thrift package:

```
/opt/mapr/server/configure.sh -R
```

Results

After you install the HBase Thrift package and run `configure.sh -R`, Warden starts and monitors the service. Warden also displays the status of the HBase Thrift service on the MapR Control System user interface.

Installing the HBase REST Gateway

About this task

The HBase REST Gateway can be installed on any node where the `mapr-client` package or the `mapr-core` package is installed.

Complete the following steps to install the HBase REST Gateway:

last-updated: Jun 06, 2024

Procedure

1. Run the following command to install the HBase REST Gateway package:

On CentOS / Red Hat	`yum install mapr-hbase-rest`
Ubuntu	`apt-get install mapr-hbase-rest`
SLES	`zypper install mapr-hbase-rest`

2. Run configure.sh on the node where you installed the HBase REST Gateway package:

```
/opt/mapr/server/configure.sh -R
```

Results

After you install the HBase REST package and run `configure.sh -R`, Warden starts and monitors the service. Warden also displays the status of the HBase REST service on the MapR Control System user interface.

Installing Hive

This topic includes instructions for using package managers to download and install Hive from the EEP repository.

Prerequisites

To set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

You can install Hive on a node in the Data Fabric cluster or on a Data Fabric client node. Installation of HiveServer2 (HS2) on a client node is not supported by the Data Fabric platform. If you wish to install HS2 on a client node, note that one or more required JAR files may **not** be installed during the installation of `mapr-client`. Copy the following JAR file from a resource manager node to the Data Fabric client node:

```
/opt/mapr/hadoop/hadoop-<X.X.X>/share/hadoop/yarn/
hadoop-yarn-server-resourcemanager-<X.X.X>-mapr-<YYYY>.jar
```

Here:

X.X.X	Refers to the version (for example, hadoop-3.3.4)
YYYY	Refers to the release tag of ecosystem component (for example, 2210)

About the Hive Packages

For a list of fixes and new features, see the Hive Release Notes.

Hive is distributed as the following packages:

Package	Description
`mapr-hive`	The core Hive package.
`mapr-hiveserver2`	The Hive package that enables HiveServer2 to be managed by -Warden, allowing you to start and stop HiveServer2 using maprcli or the Data Fabric Control System. The `mapr-hive` package is a dependency and will be installed if you install `mapr-hiveserver2`. At installation time, Hiveserver2 is started automatically.

last-updated: Jun 06, 2024

Package	Description
`mapr-hivemetastore`	The Hive package that enables the Hive Metastore to be managed by Warden, allowing you to start and stop Hive Metastore using maprcli or the Data Fabric Control System. The `mapr-hive` package is a dependency and will be installed if you install `mapr-hivemetastore`. At installation time, the Hive Metastore is started automatically.
`mapr-hivewebhcat`	The Hive package that enables WebHCat to be managed by Warden, allowing you to start and stop WebHCat using maprcli or the Data Fabric Control System. The `mapr-hive` package is a dependency and will be installed if you install `mapr-hivewebhcat.` At installation time, the WebHCat is started automatically.

Make sure the environment variable `JAVA_HOME` is set correctly. For example:

```
# export JAVA_HOME=/usr/lib/jvm/java-7-sun
```

You can set these system variables by using the shell command line or by updating files such as `/etc/profile` or `~/.bash_profile`. See the Linux documentation for more details about setting system environment variables.

NOTE: The Data Fabric cluster must be up and running before installing Hive.

Considerations for Ubuntu

On Ubuntu, while configuring the new version of Hive, you could have an issue caused by an incomplete removal of previously installed Hive packages. To avoid this issue, use the `purge` command for complete removal of all previously installed Hive packages.

Installing the Hive Packages

Execute the following commands as `root` or using `sudo`.

1. On each planned Hive node, install Hive packages:
   - To install Hive:

On RHEL	`yum install mapr-hive`
On SLES	`zypper install mapr-hive`
On Ubuntu	`apt-get install mapr-hive`

   - To install Hive and HiveServer2:

On RHEL	`yum install mapr-hive mapr-hiveserver2`
On SLES	`zypper install mapr-hive mapr-hiveserver2`
On Ubuntu	`apt-get install mapr-hive mapr-hiveserver2`

last-updated: Jun 06, 2024

- To install Hive, HiveServer2, and HiveMetastore:

On RHEL	`yum install mapr-hive mapr-hiveserver2 mapr-hivemetastore`
On SLES	`zypper install mapr-hive mapr-hiveserver2 mapr-hivemetastore`
On Ubuntu	`apt-get install mapr-hive mapr-hiveserver2 mapr-hivemetastore`

- To install Hive, HiveServer2, HiveMetastore and WebHCat:

On RHEL	`yum install mapr-hive mapr-hiveserver2 mapr-hivemetastore mapr-hivewebhcat`
On SLES	`zypper install mapr-hive mapr-hiveserver2 mapr-hivemetastore mapr-hivewebhcat`
On Ubuntu	`apt-get install mapr-hive mapr-hiveserver2 mapr-hivemetastore mapr-hivewebhcat`

NOTE: Starting from EEP-5.0.2 and EEP-6.0.1+, you can use Apache Derby as the underlying database, but only for test purposes. To configure Hive on Derby DB, install all Hive packages (`mapr-hive`, `mapr-hiveserver2` `mapr-hivemetastore`, and `mapr-hivewebhcat`), and run the `configure.sh` command, as described in Step 3 in this procedure.

CAUTION: Do not use `datanucleus.schema.autoCreateAll` for populating underlying databases. For details, see prohibited usage of `datanucleus.schema.autoCreateAll` property .

2. Configure the database for Hive Metastore.
   See Configuring Database for Hive Metastore on page 4157.

3. Run `configure.sh` on page 2821 with the `-R` option.

```
/opt/mapr/server/configure.sh -R
```

Hive Executable
After Hive is installed, the executable is located at: `/opt/mapr/hive/hive-<version>/bin/hive`.

Considerations for JDK 17

See Considerations for Hive on JDK 17 on page 4210.

Considerations for Spark-Hive Compatibility

Some parquet files generated by the default Spark installation are not compatible with Hive.

If you are using Hive and Spark with the same dataset simultaneously, or if Hive needs to use data generated by Spark, do the following:

- If Spark has not yet generated the parquet files, set the `spark.sql.parquet.writeLegacyFormat` option to `true` in the Spark configuration.
- If Spark has already generated the parquet files without the compatibility option enabled, set the `spark.sql.parquet.writeLegacyFormat` option to `true` in the Spark configuration and regenerate the parquet files.

Hive can now work with the parquet files.

NOTE: See Spark Configuration in the Spark documentation for a detailed description of the configuration options.

Configuring Hive

See Hive User Impersonation for the steps to configure user impersonation for Hive and the Data Fabric cluster.

To configure Hive on Tez, see Configuring Hive and Tez on page 4255.

Installing Hue

This topic includes instructions for using package managers to download and install Hue from the EEP repository.

Prerequisites

To set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

NOTE: The Hue package, `mapr-hue`, can be installed on either a Data Fabric cluster node (recommended) or a Data Fabric client node. If you choose to install on a client node, keep in mind that Hue directories are owned by the user who installed Hue.

About this task

Execute the following commands as `root` or using `sudo`.

Procedure

1. Install the Hue packages.

   On Ubuntu:

   ```
   apt-get install mapr-hue
   ```

   On RHEL / CentOS:

   ```
   yum install mapr-hue
   ```

   On SLES:

   ```
   zypper install mapr-hue
   ```

2. If the node is a Data Fabric Client node, follow the additional instructions:

   a) To determine who the <INSTALL_USER> is, enter:

   ```
   logname
   ```

b) Set the following properties in `hue.ini` to that user.

```
server_user=<INSTALL_USER>
server_group=<INSTALL_USER>
default_user=<INSTALL_USER>
```

c) Change the `default_hdfs_superuser` property to the owner of `/var` on the cluster.

WARNING: The `<INSTALL_USER>` must exist on the cluster on *all* nodes. It must also be set as the proxy user in *all* configuration files listed in Configure Hue, depending on the Hue version you are installing.

3. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

What to do next

Installing Other Components

Based on your requirements, you may also want to install the following components on at least one node in the cluster.

Component	Description
HPE Ezmeral Data Fabric Database	Required for access to HPE Ezmeral Data Fabric Database tables
HttpFS	Required for viewing files in file system through Hue file browser
Spark	Required to process data using the Notebook UI.
Hive	Required to run queries with HiveServer2.

When you finish installing Hue, go to Configure Hue to learn how to configure Hue.

Installing Kafka Schema Registry

This topic includes instructions for using package managers to download and install the Kafka Schema Registry from a MapR repository.

Prerequisites

About this task

The Kafka Schema Registry is a service that provides a RESTful interface for storing and retrieving schemas. The Kafka Schema Registry can be installed on one or several nodes. You can install Kafka Schema Registry through the Installer or manually, using the instructions provided here. To install the `schema registry` package on a node, run the following commands as `root` or using `sudo`:

Procedure

1. Install the schema registry package:

   On Ubuntu:

   ```
   apt-get install mapr-schema-registry
   ```

   On RedHat/ CentOS:

   ```
   yum install mapr-schema-registry
   ```

   On SLES:

   ```
   zypper install mapr-schema-registry
   ```

2. Run `configure.sh -R`:

   ```
   /opt/mapr/server/configure.sh -R
   ```

   NOTE: Because the Kafka Schema Registry is managed by Warden, you don't have to restart Warden after installing the registry. Warden brings up the service after a few minutes.

What to do next

To manage and administer the Kafka Schema Registry, see Kafka Schema Registry on page 4543.

Installing KSQL

This topic describes how to use package managers to download and install KSQL from the EEP repository.

NOTE: You cannot upgrade from KSQL 4.1.1. You must uninstall version 4.1.1 and then install the newer version of KSQL.

Preparing for Installation

KSQL is included in EEP repositories beginning with EEP 6.0.0. To set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

The default KSQL configuration parameters are stored in `/opt/mapr/ksql/ksql-<version>/etc/ksql`.

KSQL Operational Modes

To install KSQL, you can use the Installer or the manual steps on this page. KSQL can be used in one of two modes:

Mode	Description
Interactive Mode	This mode is non-secure and allows developers to write KSQL queries interactively using the KSQL CLI.
Non-interactive Mode	This mode is more secure than the Interactive mode and is designed for KSQL query production deployment. Since the queries are known ahead of time, you can run non-interactive queries with more restrictive permissions.

The installation steps are the same for both modes. Run the following commands as `root` or using `sudo`.

Install KSQL in Interactive or Non-interactive Mode

You can install the `mapr-ksql` package on as many or as few nodes as you want. Installing on multiple nodes can increase availability of the service. Use these steps:

1. Install the `mapr-ksql` package:

   On Ubuntu:

   ```
   apt-get install mapr-ksql
   ```

   On RedHat/ CentOS:

   ```
   yum install mapr-ksql
   ```

   On SLES:

   ```
   zypper install mapr-ksql
   ```

2. On each node where you installed the package, run `configure.sh`:

   ```
   sudo /opt/mapr/server/configure.sh -R
   ```

Verify KSQL Installation

To confirm successful installation:

- Check for the presence of the KSQL home folder at `/opt/mapr/ksql/ksql-<version>`.
- Perform a test run:

  1. Start the KSQL server:

     ```
     maprcli node services -nodes <hostname> -name ksql -action restart
     ```

  2. Verify that KSQL is running by making a call to `http://localhost:8084/info`. For example:

     ```
     curl http://localhost:8084/info
     ```

  The expected response is:

  ```
  {"KsqlServerInfo":{"version":"(version)"}}
  ```

Configure KSQL

To configure KSQL, see KSQL Configuration on page 4443.

Installing Kafka Streams

Kafka Streams is a Java library and is part of the `mapr-kafka` package. Kafka Streams does not require special installation steps; however, you must install the `mapr-core` and `mapr-kafka` packages to use Kafka Streams.

Maven Dependency

To compile a Kafka Streams application, you must add the appropriate Maven dependency. Add a mapr maven repository and the Kafka Streams dependency to your `pom.xml` file to pull in the Maven artifacts.

- For Maven repository information and Kafka Streams dependency versions, see Maven Artifacts for the HPE Ezmeral Data Fabric on page 4745
- For more information about Maven artifacts and running a Kafka Streams Java application, see Running a Kafka Streams Java App on page 4456.

Example

The following `pom.xml` example may not correlate with the product versions you are installing.

```
<repository>
    <id>mapr-releases</id>
    <url>https://repository.mapr.com/maven/</url>
</repository>
<dependency>
    <groupId>org.apache.kafka</groupId>
    <artifactId>kafka-streams</artifactId>
    <version>2.6.1.300-eep-900</version>
</dependency>
<dependency>
    <groupId>org.apache.kafka</groupId>
    <artifactId>kafka-clients</artifactId>
    <version>2.6.1.300-eep-900</version>
</dependency>
```

Configure Kafka Streams

To configure Kafka Streams, see Kafka Streams Configuration on page 4455.

Installing HPE Ezmeral Data Fabric Streams Clients
This topic includes instructions for using package managers to download and install HPE Ezmeral Data Fabric Streams Clients from the EEP repository.

NOTE: The HPE Ezmeral Data Fabric Streams Java client is installed with the HPE Ezmeral Data Fabric Client on page 404.

Installing HPE Ezmeral Data Fabric Streams C Client
The HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams.

- For instructions on installing the MapR Client, see Installing the Data Fabric Client (Non-FIPS) on page 404
- For instructions on setting up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

Installation

As of MapR 6.0.1, the MapR C client is installed as part of the MapR Core installation and the mapr-client package installation. The MapR C client is available on Linux, Mac, and Windows operating systems.

NOTE: Specific installation is *not* required as of MapR 6.0.1!

For MapR 5.2.1 through MapR 6.0.0, the MapR C client must be installed. The MapR C client is available on Linux and Mac operating systems. As `root` or using `sudo`, install the `mapr-librdkafka` package on nodes where you want to run or build applications.

- On Ubuntu:

```
apt-get install mapr-librdkafka
```

last-updated: Jun 06, 2024

- On RedHat/CentOS:

```
yum install mapr-librdkafka
```

- On SLES:

```
zypper install mapr-librdkafka
```

- On Mac OS:
  1. Download the following TAR file: `https://package.ezmeral.hpe.com/releases/MEP/<MEP version>/<operating system>/<package>.tar.gz`
  2. Extract the TAR file under /opt/mapr:

```
tar -C /opt/mapr/ -zxf <librdkafka_tarFile_location>
```

NOTE: The `mapr-librdkafka` package pulls in the mapr-client as a dependency if the node does not have the `mapr-client` or `mapr-core` package installed.

Configuration

For MapR 6.0.1 and higher, use the following configuration instructions.

Linux	For Linux installations, add `/opt/mapr/lib` to the end of LD_LIBRARY_PATH. `export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib`
Mac	For Mac installations, add `/opt/mapr/lib` to the end of DYLD_LIBRARY_PATH. `export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib`
Windows	For Windows installations, no additional configuration is required. Link your application and run your programs against the HPE Ezmeral Data Fabric Client dynampic link libraries (dll) located at: `C:\opt\mapr\lib`. The corresponding librdkafka header is `C:\opt\mapr\include\librdkafka`.

ATTENTION: For MapR 6.0.0 and earlier, see Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586 for instructions on configuring the client.

Installing HPE Ezmeral Data Fabric Streams Python Client
The HPE Ezmeral Data Fabric Streams Python Client is a binding for librdkafka that is dependent on the HPE Ezmeral Data Fabric Streams C client (HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams).

Prerequisites

NOTE: As of MapR 5.2.1, you can create Python client applications for HPE Ezmeral Data Fabric Streams.

Verify that the following components are installed on the node:

- HPE Ezmeral Data Fabric Streams C Client (mapr-librdkafka)
- GNU Compiler Collection (GCC) is installed on the node.
- Python version 2.7.1 and above, up to Python version 3.6.x.
- Python pip
- python-devel (This is required for nodes with the Linux operating system.)

NOTE: For instructions on setting up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

IMPORTANT: Because the HPE Ezmeral Data Fabric Streams Python Client is dependent on the HPE Ezmeral Data Fabric Streams C Client, you must configure the HPE Ezmeral Data Fabric Streams C Client before using the HPE Ezmeral Data Fabric Streams Python Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.

Installation

NOTE: The Python client is available for Linux or Mac operating systems.

To install the HPE Ezmeral Data Fabric Streams Python Client using the Python Software Foundation, run the following command as `root` or using `sudo`:

- On Linux:

```
pip
install --global-option=build_ext --global-option="--library-dirs=/opt/
mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
mapr-streams-python
```

- On Mac:

```
pip
install --user --global-option=build_ext --global-option="--library-dirs=/
opt/mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
mapr-streams-python
```

NOTE: The referenced package works on nodes with the Linux or the Mac operating system. The Python Client for HPE Ezmeral Data Fabric Streams is *not* supported on Windows.

Alternatively, you can install the HPE Ezmeral Data Fabric Streams Python Client via the MapR package repository:

```
https://package.ezmeral.hpe.com/releases/MEP/<MEP version>/mac/
mapr-streams-python-<version>.tar.gz
```

Troubleshooting Mac OS Installation

If you install the HPE Ezmeral Data Fabric Streams Python Client on a Mac without the `--user` flag, you may encounter a "Not Permitted" error, signifying that you don't have permission to create a LICENSE file. The error will look similar to the following:

```
Copying LICENSE -> /System/Library/Frameworks/Python.framework/Versions/2.7/
                error: [Error 1] Operation not permitted:
                '/System/Library/Frameworks/Python.framework/Versions/2.7/
LICENSE'
```

To fix this issue, execute the following steps. These steps apply to users with a new Mac OS Sierra version 10.12.5.

1. Reboot your Mac while simultaneously holding the **Command** and **R** keys to go into Mac OS X Recovery mode.
2. Select **Utilities**, and then **Terminal**.
3. Type `csrutil disable`. A message will pop up, informing you that your System Integrity Protection (SIP) has been sucessfully disabled.
4. Reboot your Mac again.
5. Go into the Terminal and execute the following command as the `root` user:

   ```
   pip
   install --global-option=build_ext  --global-option="--library-dirs=/opt/
   mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
   mapr-streams-python
   ```

6. Once the script runs successfully, reboot your Mac while holding the **Command** and **R** keys. You will go into Mac OS X Recovery mode.
7. Select **Utilities**, and then **Terminal**.
8. Type `csruntil enable` to enable your SIP.

NOTE: To avoid this error, consider using a virtual Python environment or the `--user` flag.

Installing HPE Ezmeral Data Fabric Streams C#/.NET Client
The HPE Ezmeral Data Fabric Streams C#/.NET client is a binding for librdkafka that is dependent on the HPE Ezmeral Data Fabric Streams C client (HPE Ezmeral Data Fabric Streams C Client is a distribution of librdkafka that works with HPE Ezmeral Data Fabric Streams).

NOTE: As of MapR 6.0.1/ EEP 5.0, you can create C#/.NET client applications for HPE Ezmeral Data Fabric Streams.

Requirements

Verify that the following components are installed on the node:

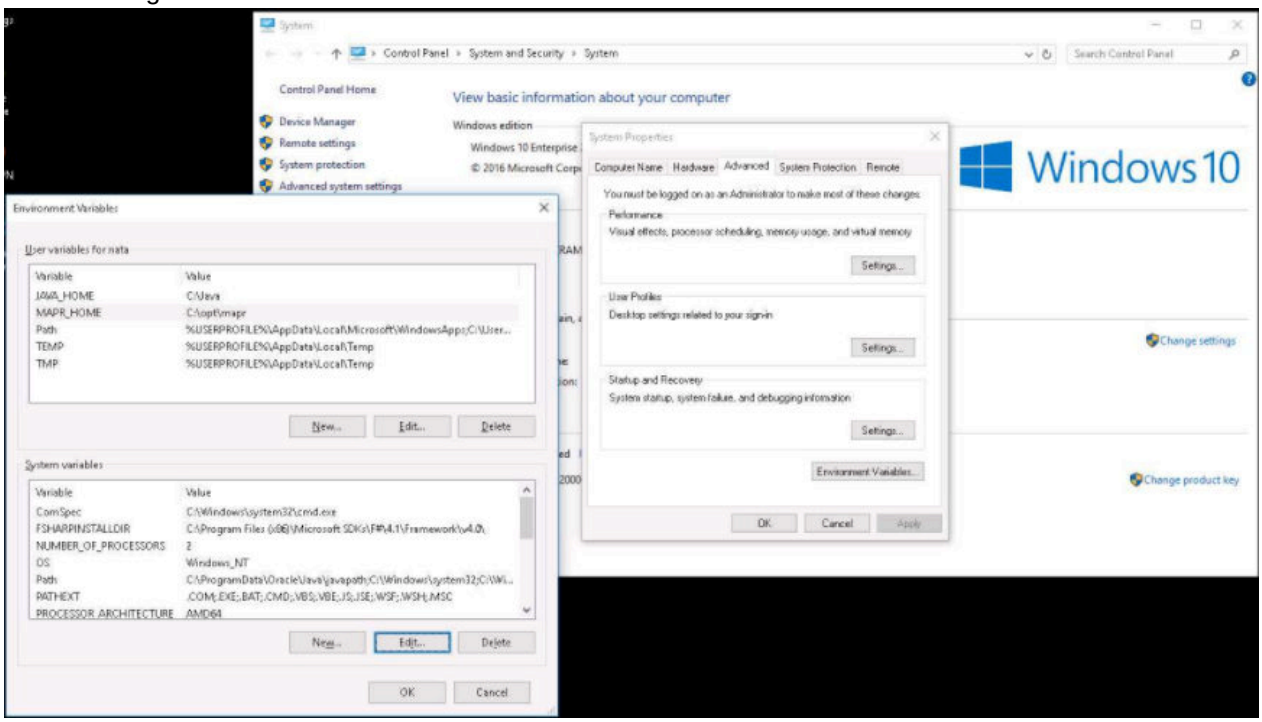
- MapR Client on Windows 7 (or higher) x64 operating systems
- MapR cluster version 6.0.1 or greater
- Java 8 SDK and set Java HOME
- HPE Ezmeral Data Fabric Streams C Client (mapr-librdkafka 0.11.3)

- HPE Ezmeral Data Fabric Streams C#/.NET Client (mapr-streams-dotnet)
- .NET SDK 4.5.x or 4.6.x or .NET Core SDK 1.1
- nuget.exe

For instructions on setting up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

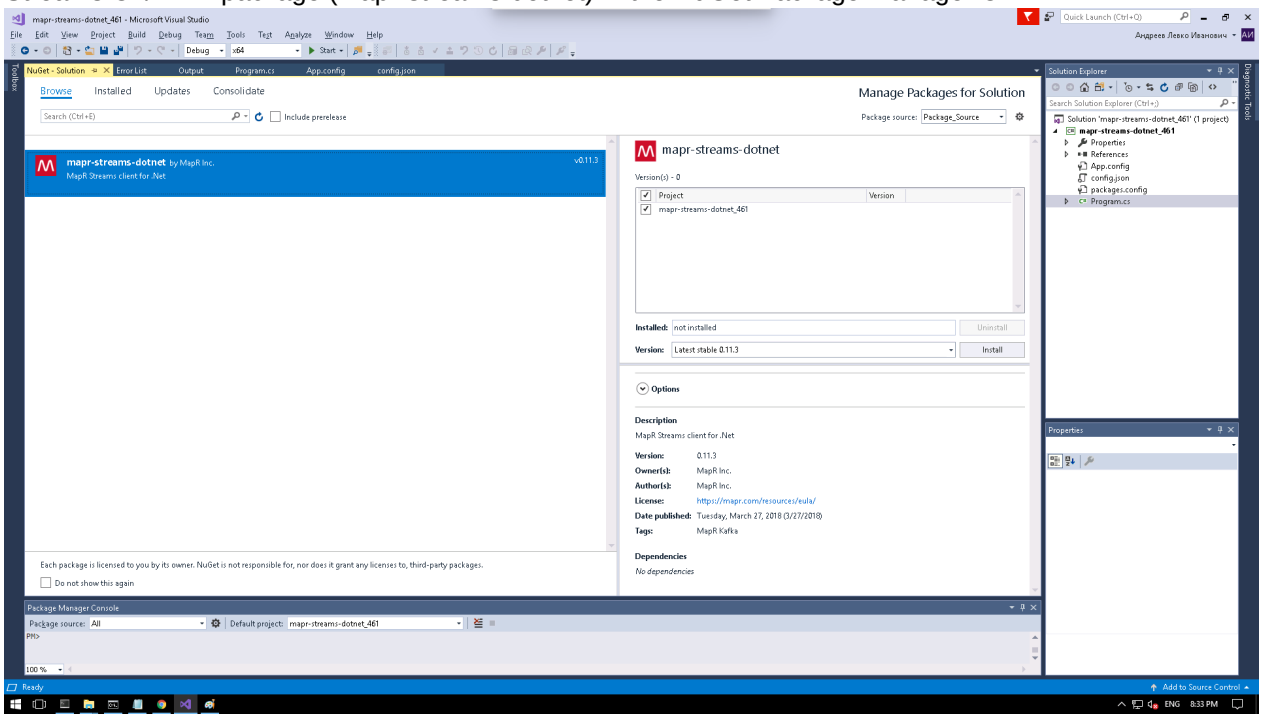
IMPORTANT: Because the HPE Ezmeral Data Fabric Streams C#/.NET Client is dependent on the HPE Ezmeral Data Fabric Streams C Client, you must configure the HPE Ezmeral Data Fabric Streams C Client before using the HPE Ezmeral Data Fabric Streams C#/.NET Client. See Configuring the HPE Ezmeral Data Fabric Streams C Client on page 3586.

The following screenshot shows the Environment Variables on Windows:



Installing on Windows

To install from the Visual Studio, search for the HPE Ezmeral Data Fabric Streams C#/.NET package (mapr-streams-dotnet) in the NuGet Package Manager UI.



To install from PowerShell:

1. Run the following command in the Package Manager Console:

```
Install-Package mapr-streams-dotnet -<version>
```

To add the package initial in .NET Core:

1. Create the application, for example: `dotnet new console`
2. Add the C#/.NET Client package, for example: `dotnet add package mapr-streams-dotnet`
3. Add a dependency in your **.csproj** file:

```
<ItemGroup>
<PackageReference Include="mapr-streams-dotnet" Version="<version
number>" />
</ItemGroup>
```

Installing HPE Ezmeral Data Fabric Streams Tools

This topic includes instructions for using package managers to download and install HPE Ezmeral Data Fabric Streams Tools from the EEP repository.

NOTE: For instructions on setting up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233

To install manually, first run the following commands as `root` or using `sudo`.

- On RedHat/Centos:

```
yum install <package_name>
```

- On Ubuntu:

```
apt-get install <package_name>
```

- On SLES:

```
zypper install <package_name>
```

After you install the Kafka tools, configure the Kafka components by running `configure.sh -R` on each node where you installed the Kafka tools:

```
/opt/mapr/server/configure.sh -R
```

Table

Package	Description
mapr-kafka	The core Kafka package. Required for HPE Ezmeral Data Fabric Streams and other Kafka components for HPE Ezmeral Data Fabric Streams.
mapr-ksql	The KSQL for HPE Ezmeral Data Fabric Streams package.
mapr-schema-registry	The Schema Registry for HPE Ezmeral Data Fabric Streams package.
mapr-kafka-rest	The Kafka REST Proxy for HPE Ezmeral Data Fabric Streams package.
mapr-kafka-connect-jdbc	The JDBC connect package for Kafka Connect for HPE Ezmeral Data Fabric Streams.
mapr-kafka-connect-hdfs	The HDFS connect package for Kafka Connect for HPE Ezmeral Data Fabric Streams.

Kafka REST Proxy for HPE Ezmeral Data Fabric Streams

The following packages are required for Kafka REST Proxy for HPE Ezmeral Data Fabric Streams:

- mapr-kafka
- mapr-kafka-rest
- mapr-client

NOTE: Before manually installing, verify that the **/opt/mapr/conf/daemon.conf** file exists and contains the mapr user and group.

NOTE: After installation, the Warden process automatically detects the configuration and starts the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams service on port 8082. This service is viewable on the Control System.

NOTE: The Kafka REST Proxy for HPE Ezmeral Data Fabric Streams service can be run on multiple cluster nodes simultaneously.

last-updated: Jun 06, 2024

Kafka Connect for HPE Ezmeral Data Fabric Streams

The following packages are required for Kafka Connect for HPE Ezmeral Data Fabric Streams:

- mapr-kafka
- mapr-kafka-connect-jdbc
- mapr-kafka-connect-hdfs

NOTE: The Kafka Connect for HPE Ezmeral Data Fabric Streams service can be run on multiple cluster nodes simultaneously.

Installing Data Access Gateway

This topic includes instructions for using package managers to download and install the Data Access Gateway from the EEP repository.

Prerequisites

To view the supported core and EEP versions for the Data Access Gateway, see the Data Access Gateway Support Matrix on page 5801.

To set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

The Data Access Gateway is included in EEP repositories beginning with EEP 5.0.0. The Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster. For EEP 6.0.0, the HPE Ezmeral Data Fabric Database JSON REST API and Python OJAI client use this service.

In the Installer, the gateway is not visible as a unique service but is installed when the HPE Ezmeral Data Fabric DataBase service is selected and can also be installed manually using this procedure. The gateway should be installed on at least two nodes, if possible, but not on CLDB or Zookeeper nodes. It is recommended to install the service on the same node as the gateway server.

About this task

Run the following commands as `root` or using `sudo`.

Procedure

1. Install the Data Access Gateway package:

   On Ubuntu:

   ```
   apt-get install mapr-data-access-gateway
   ```

   On RedHat/ CentOS:

   ```
   yum install mapr-data-access-gateway
   ```

   On SLES:

   ```
   zypper install mapr-data-access-gateway
   ```

2. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

NOTE: As the Data Access Gateway is managed by Warden, you don't have to restart Warden after installing the gateway. Warden brings up the service after a few minutes.

What to do next

To manage and administer the gateway, see Administering the Data Access Gateway on page 1961.

To learn more about the gateway, see Understanding the HPE Ezmeral Data Fabric Data Access Gateway on page 1024.

Installing Livy

This topic includes instructions for using package managers to download and install Livy from the EEP repository.

About this task

For instructions to set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

Run the following commands as `root` or using `sudo`:

Procedure

1. Install the mapr-livy package:

   RedHat/CentOS

   ```
   # yum install mapr-livy
   ```

   SLES

   ```
   # zypper install mapr-livy
   ```

   Ubuntu

   ```
   # apt-get install mapr-livy
   ```

2. Run the configure.sh script with the following command to configure the Livy role for the node:

   ```
   /opt/mapr/server/configure.sh -R
   ```

Installing NiFi

This topic includes instructions for using package managers to download and install Apache NiFi from the EEP repository.

For instructions to set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

Execute the following commands as `root` or by using `sudo` on an HPE Ezmeral Data Fabric cluster.

1. Install `mapr-nifi`.

On RHEL/ Centos	`yum install mapr-nifi`

last-updated: Jun 06, 2024

On Ubuntu	`apt-get install mapr-nifi`
On SLES	`zypper install mapr-nifi`

2. Run `configure.sh -R`.

```
/opt/mapr/server/configure.sh -R
```

3. To access, configure, and manage NiFi, see these topics:
   - Accessing NiFi UI on page 4574
   - NiFi Logs on page 4574
   - Configuring NiFi on page 4574
   - Starting, Stopping, and Restarting NiFi Services on page 4575

Installing OTel
This topic includes instructions for using package managers to download and install OTel from the EEP repository.

About this task

For instructions to set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

Run the following commands as `root` or using `sudo`:

Procedure

1. Install the mapr-ezotelcol package:

   RedHat/CentOS

```
# yum install mapr-ezotelcol
```

   SLES

```
# zypper install mapr-ezotelcol
```

   Ubuntu

```
# apt-get install mapr-ezotelcol
```

2. Run the configure.sh script with the following command to configure the OTel role for the node:

```
/opt/mapr/server/configure.sh -R
```

Installing Ranger
This topic includes instructions for using package managers to download and install Ranger from the EEP repository.

To set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

last-updated: Jun 06, 2024

Prerequisites for Installing Ranger

Ranger requires a database to store its internal data. Ranger uses MySQL as its default internal database, but Ranger also supports Oracle, PostgreSQL, MSSQL, and SQLA. Before Ranger installation and configuration, you must ensure that one of the supported databases is ready for Ranger to use. Perform these steps:

IMPORTANT: You can also provide the root credentials later while configuring the ranger. If you choose to provide the root credentials later, skip the following Step 1. and 2. See Configuring Ranger on page 4586 details.

1. Create a user for Ranger in the database. Note that the user name and password you specify in this step will be used for Ranger Admin configuration. The following example is for MySQL; the commands can be different for other databases:

```
mysql -uroot -p<root_password>

CREATE USER 'ranger_user_name'@'localhost' IDENTIFIED BY
'ranger_user_password';
GRANT ALL PRIVILEGES ON *.* TO 'ranger_user_name'@'localhost' WITH GRANT
OPTION;
GRANT ALL PRIVILEGES ON *.* TO 'ranger_user_name'@'localhost' IDENTIFIED
BY 'ranger_user_password' WITH GRANT OPTION;

CREATE USER 'ranger_user_name'@'%' IDENTIFIED BY 'ranger_user_password';
GRANT ALL PRIVILEGES ON *.* TO 'ranger_user_name'@'%' WITH GRANT OPTION;
GRANT ALL PRIVILEGES ON *.* TO 'ranger_user_name'@'%' IDENTIFIED BY
'ranger_user_password' WITH GRANT OPTION;

CREATE USER 'ranger_user_name'@'FQDN' IDENTIFIED BY
'ranger_user_password';
GRANT ALL PRIVILEGES ON *.* TO 'ranger_user_name'@'FQDN' WITH GRANT
OPTION;
GRANT ALL PRIVILEGES ON *.* TO 'ranger_user_name'@'FQDN' IDENTIFIED BY
'ranger_user_password' WITH GRANT OPTION;

FLUSH PRIVILEGES;
```

2. Ensure that the database for Ranger is created by its user. The database name that you specify in this step is used for Ranger Admin configuration:

```
mysql -uranger_user_name -p ranger_user_password
create database rangerdb;
```

3. **For SLES installations only:** Install the `insserv-compat` package before setting up Ranger services:

```
sudo zypper install insserv-compat
```

   Ranger uses System V initialization scripts to create the runtime directory. Installing `insserv-compat` ensures that the installation is compatible with the initialization scripts.

Installing Ranger

On each planned Ranger node, install `mapr-ranger`. Run the following commands as the cluster admin (typically the `mapr` user):

Ubuntu	`apt-get install mapr-ranger`

last-updated: Jun 06, 2024

RHEL	`yum install mapr-ranger`
SLES	`zypper install mapr-ranger`

Installing the Ranger Hive Plugin

You must install the Ranger Hive plugin only if you plan to restrict access to the HiveServer2 or Hive Metastore.

On each Hive node running HiveServer2 and Hive Metastore, if you are going to integrate Ranger with Hive Metastore, use the following command to install the `mapr-ranger-hive-plugin`:

Ubuntu	`apt-get install mapr-ranger-hive-plugin`
RHEL	`yum install mapr-ranger-hive-plugin`
SLES	`zypper install mapr-ranger-hive-plugin`

Installing the Ranger UserSync Service

The Ranger UserSync service is a helper service that obtains user information from Linux or LDAP and supplies the information to the Ranger Admin service. The Admin service leverages this information to create policies that apply to specific users of the platform.

You can choose to install the UserSync service on the same nodes where you install the Ranger Admin service, or you can install the service on nodes where the `mapr-ranger` package is not installed.

Run the following commands as the cluster admin (typically the `mapr` user):

Ubuntu	`apt-get install mapr-ranger-usersync`
RHEL	`yum install mapr-ranger-usersync`
SLES	`zypper install mapr-ranger-usersync`

NOTE: If you install `mapr-ranger-usersync` on a node where `mapr-ranger` is not installed, special configuration steps are required. See Configuring Ranger on page 4586.

Removing a Ranger Package

Before removing a Ranger package, you must disable the Ranger Hive plugin:

```
sudo bash /opt/mapr/ranger/ranger-<version>/ranger-hive-plugin/
disable-hive-plugin.sh
```

Post Installation Steps

To configure and start using Ranger, see Getting Started with Ranger on page 4584.

Related concepts

Installing Ranger Using the Installer on page 5617
Using the web-based Installer, you can install Apache Ranger and the Apache Ranger Hive plugin on the cluster.

Installing Spark Standalone

This topic describes how to use package managers to download and install Spark Standalone from the EEP repository.

Prerequisites

To set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

About this task

Spark is distributed as four separate packages:

Package	Description
`mapr-spark`	Install this package on any node where you want to install Spark. This package is dependent on the `mapr-client`, `mapr-hadoop-client`, `mapr-hadoop-util`, and `mapr-librdkafka` packages.
`mapr-spark-master`	Install this package on Spark master nodes. Spark master nodes must be able to communicate with Spark worker nodes over SSH without using passwords. This package is dependent on the `mapr-spark` and the `mapr-core` packages.
`mapr-spark-historyserver`	Install this optional package on Spark History Server nodes. This package is dependent on the `mapr-spark` and `mapr-core` packages.
`mapr-spark-thriftserver`	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the `mapr-spark` and `mapr-core` packages.

Run the following commands as `root` or using `sudo`.

Procedure

1. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory.

   ```
   hadoop fs -mkdir /apps/spark
   hadoop fs -chmod 777 /apps/spark
   ```

   NOTE: Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically.

2. Install Spark using the appropriate commands for your operating system:

   On CentOS 8.x / Red Hat 8.x

   ```
   dnf install
   mapr-spark mapr-spark-master
   mapr-spark-historyserver
   mapr-spark-thriftserver
   ```

   On Ubuntu

   ```
   apt-get install
   mapr-spark mapr-spark-master
   mapr-spark-historyserver
   mapr-spark-thriftserver
   ```

   On SLES

   ```
   zypper install
   mapr-spark mapr-spark-master
   ```

last-updated: Jun 06, 2024

```
mapr-spark-historyserver
mapr-spark-thriftserver
```

NOTE: The `mapr-spark-historyserver`, `mapr-spark-master`, and `mapr-spark-thriftserver` packages are optional.

Spark is installed into the `/opt/mapr/spark` directory.

3. For Spark 2.x:

   Copy the `/opt/mapr/spark/spark-<version>/conf/slaves.template` into `/opt/mapr/spark/spark-<version>/conf/slaves`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

   For Spark 3.x:

   Copy the `/opt/mapr/spark/spark-<version>/conf/workers.template` into `/opt/mapr/spark/spark-<version>/conf/workers`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

   For example:

   ```
   localhost
   worker-node-1
   worker-node-2
   ```

4. Set up passwordless ssh for the `mapr` user such that the Spark master node has access to all secondary nodes defined in the `conf/slaves` file for Spark 2.x and `conf/workers` file for Spark 3.x.

5. As the `mapr` user, start the worker nodes by running the following command in the master node. Since the Master daemon is managed by the Warden daemon, do not use the `start-all.sh` or `stop-all.sh` command.

   For Spark 2.x:

   ```
   /opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
   ```

   For Spark 3.x:

   ```
   /opt/mapr/spark/spark-<version>/sbin/start-workers.sh
   ```

6. If you want to integrate Spark with HPE Ezmeral Data Fabric Streams, install the Streams Client on each Spark node:

   - On Ubuntu:

     ```
     apt-get install mapr-kafka
     ```

   - On RedHat/CentOS:

     ```
     yum install mapr-kafka
     ```

7. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the HPE Ezmeral Data Fabric Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).

last-updated: Jun 06, 2024

8. After installing Spark Standalone but before running your Spark jobs, follow the steps outlined at Configuring Spark Standalone on page 4614.

Installing Spark on YARN

This topic describes how to use package managers to download and install Spark on YARN from the EEP repository.

Prerequisites

To set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

About this task

Spark is distributed as three separate packages:

Package	Description
`mapr-spark`	Install this package on any node where you want to install Spark. This package is dependent on the `mapr-client`, `mapr-hadoop-client`, `mapr-hadoop-util`, and `mapr-librdkafka` packages.
`mapr-spark-historyserver`	Install this optional package on Spark History Server nodes. This package is dependent on the `mapr-spark` and `mapr-core` packages.
`mapr-spark-thriftserver`	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the `mapr-spark` and `mapr-core` packages.

To install Spark on YARN (Hadoop 2), execute the following commands as `root` or using `sudo:`

Procedure

1. Verify that JDK 11 or later is installed on the node where you want to install Spark.
2. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory:

   ```
   hadoop fs -mkdir /apps/spark
   hadoop fs -chmod 777 /apps/spark
   ```

   NOTE: Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically when using the Installer. However, you must manually create this directory when performing a manual installation.

3. Install the packages:

   On Ubuntu

   ```
   apt-get install
   mapr-spark mapr-spark-historyserver
   mapr-spark-thriftserver
   ```

   On CentOS 8.x / Red Hat 8.x

   ```
   dnf install mapr-spark
   mapr-spark-historyserver
   mapr-spark-thriftserver
   ```

On SLES	`zypper install mapr-spark mapr-spark-historyserver mapr-spark-thriftserver`

NOTE: The `mapr-spark-historyserver` and `mapr-spark-thriftserver` packages are optional.

4. If you want to integrate Spark with HPE Ezmeral Data Fabric Streams, install the Streams Client on each Spark node:
   - **On Ubuntu:**
     ```
     apt-get install mapr-kafka
     ```
   - **On CentOS / Red Hat**:
     ```
     yum install mapr-kafka
     ```
5. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the data-fabric Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).

   For repository-specific information, see Maven Artifacts for the HPE Ezmeral Data Fabric on page 4745
6. After installing Spark on YARN but before running your Spark jobs, follow the steps outlined at Configuring Spark on YARN on page 4617.

Installing Spark on Mesos

This section includes instructions to download and install Apache Spark on Apache Mesos.

Prerequisites

The MapR distribution of Spark on Mesos is only certified on CentOS.

About this task

Spark 2.1.0 runs with Apache Mesos 1.0.0 or later. You do not need to apply any special patches of Mesos. If you are already running a Mesos cluster, you can skip this topic.

Procedure

Install Mesos following the instructions at Getting Started with Mesos.

NOTE: If you are building Mesos, execute the build steps as user 'mapr'. Also change the owner of the directory where you have unpacked the Mesos archive to user and group 'mapr'.

```
cd /path/to/mesos
sudo chown -R mapr:mapr /path/to/mesos
```

Installing Zeppelin

This topic includes instructions for using package managers to download and install Zeppelin 0.9 and later from the EEP repository.

About this task

For instructions to set up the EEP repository, see Step 11: Install Ecosystem Components Manually on page 233.

Run the following commands as `root` or using `sudo`:

Procedure

1. Install the `mapr-zeppelin` package:

   RHEL/CentOS

   ```
   # yum install mapr-zeppelin
   ```

   SLES

   ```
   # zypper install mapr-zeppelin
   ```

   Ubuntu

   ```
   # apt-get install mapr-zeppelin
   ```

2. Run the `configure.sh` script with the following command to configure the Zeppelin role for the node:

   ```
   /opt/mapr/server/configure.sh -R
   ```

Step 12: Run configure.sh
Run `configure.sh` with the `-R` option to complete the configuration of ecosystem components that were added manually.

After installing ecosystem components manually, you must run the `configure.sh` script with the `-R` option on each node in the cluster:

```
/opt/mapr/server/configure.sh -R
```

Configuring the Cluster

Describes post-installation configuration tasks for HPE Ezmeral Data Fabric clusters.

After installing HPE Ezmeral Data Fabric core and any desired ecosystem components, you might need to perform additional tasks to ready the cluster for production. To learn more about configuring clusters, see this course.

Configure the OJAI Distributed Query Service on page 241	If you want to use the optional OJAI Distributed Query Service on page 640, you must install Drill and configure and register the service.
Setting up Topology	The locations of nodes and racks in a cluster determine the location of replicated copies of data. Optimally defined cluster topology results in data being replicated to separate racks, providing continued data availability in the event of rack or node failure.
Setting Up Volumes	Keeping volume hierarchy efficient to maximize data availability. Without a volume structure in place, performance will be negatively affected. Referring to the volume plan created in Planning the Cluster, use the Control System or the `maprcli` command to create and mount distinct volumes to allow more granularity in specifying policy for subsets of data. If you do not set up volumes, and instead store all data in the single volume mounted at /, it creates problems in administering data policy later as data size grows.

last-updated: Jun 06, 2024

Designating NICs for HPE Ezmeral Data Fabric on page 1156	If multiple NICs are present on nodes, you can configure HPE Ezmeral Data Fabric to use one or more of them, depending on the cluster's need for bandwidth. See Cluster Design Objectives on page 82 for more information.
Setting up NFS	Access data on a licensed HPE Ezmeral Data Fabric cluster, mount the HPE Ezmeral Data Fabric cluster, and use standard shell scripting to read and write live data through NFS, which can be faster than using `hadoop fs` commands.
Configuring Authentication	If you use Kerberos, LDAP, or another authentication scheme, make sure PAM is configured correctly to grant HPE Ezmeral Data Fabric access.
Configuring Permissions	By default, users are able to log on to the Control System, but do not have permission to perform any actions. You can grant specific permissions to individual users and groups.
Setting Usage Quotas	You can set specific quotas for individual users and groups.
Configuring Alarm Notifications	If an alarm is raised on the cluster, HPE Ezmeral Data Fabric sends an email notification. For example, if a volume goes over its allotted quota, HPE Ezmeral Data Fabric raises an alarm and sends an email to the volume creator.
Setting Up the Client and MapR POSIX Client	You can access the cluster either by logging into a node on the cluster, or by installing HPE Ezmeral Data Fabric client software on a machine with access to the cluster's network.
Working with Mirror Volumes	To access multiple clusters or mirror data between clusters, work with mirror volumes.

Installing the HPE Ezmeral Data Fabric File Store

Describes how to install File Store software with or without the Installer.

The steps for installing the HPE Ezmeral Data Fabric File Store are the same as the steps for installing data-fabric software, with some exceptions as follows. File Store is a lightweight installation that includes the file system for data storage, support for mounting and accessing the cluster using NFS, and a range of optional clients.

This table shows the included features:

Included	Not Included
File system	Hadoop & YARN
NFS	MapReduce
Data Fabric, PACC, or POSIX clients (optional)	Database
Metrics and log monitoring (optional)	Streams
	Data-access gateway
	Ecosystem components

For more information about the File Store, see HPE Ezmeral Data Fabric File Store on page 488.

Before Installing the File Store Using the Installer

Regardless of the method you use to install the File Store, before installing, you should review the information in these topics:

- Data Fabric Repositories and Packages on page 101
- Preparing Each Node on page 166

last-updated: Jun 06, 2024

Installing the File Store Using the Installer

Use these steps to install the File Store using the web-based Installer:

1. Download the Installer. See Installer on page 5579.
2. On the **Version & Services** page of the Installer, specify these values:
   - **MapR Version:** 7.0.0 or later.
   - **Edition:** MapR Data Platform Enterprise Edition.
   - **Select Configuration Options:** Select security options as needed.
   - **License Option:** Apply the File Store license after the installation completes.
   - **EEP Version:** The EEP version is pre-selected.
   - **Auto-Provisioning Template:** MapR File System and Object Store (File Store). You do not need to select any services.
3. Click **Next** to advance through the menus.
4. On the **Monitoring** page, enable metrics collection with either the full or minimum configuration.
5. When the Installer indicates that the installation is complete, go to After Installing a File Store Cluster on page 274.

Installing the File Store without Using the Installer

Use the following information to install the File Store using manual steps.

You can use the manual installation steps described in Installing without the Installer on page 179 to install the release 7.0.0 or later packages. Perform all steps unless otherwise indicated. Note the following considerations for some steps:

Step 1	Follow the documented steps.
Step 2	A repository needs to be configured for the Metrics Monitoring components. These components are available in the EEP repository.
Step 3	Install these release 7.0.0 or later packages at a minimum: • `mapr-core` • `mapr-core-internal` • `mapr-apiserver` • `mapr-fileserver` • `mapr-librdkafka` • `mapr-cldb` • `mapr-nfs`[1] • `mapr-mastgateway` • `mapr-webserver` • `mapr-zookeeper`

last-updated: Jun 06, 2024

	• `mapr-zk-internal` For information about packages and dependencies, see Packages and Dependencies for Data Fabric Software on page 70.
Step 4	Follow the documented steps.
Step 5	Follow the documented steps.
Step 6	Follow the documented steps.
Step 7	Apply the File Store license.
Step 8	Complete the steps to install Metrics Monitoring.
Step 9	Installing Log Monitoring is optional.
Step 10	Skip this step. Except for the Metrics Monitoring components, you do not need to install any ecosystem components.
Step 11	Complete this step. Running `configure.sh` with the `-R` option is required.

[1]When you install `mapr-nfs`, NFSv3 is installed. To install NFSv4, you must use the `mapr-nfs4server` package. Neither NSFv3 nor NSFv4 provides security by default. You can configure NFSv4 server to work with Active Directory and Kerberos servers, but you must first install Active Directory and Kerberos servers. For more information, see Configuring NFSv4 Server for Kerberos on page 1584. NFSv3 does not support security. .

After Installing a File Store Cluster

After successfully installing the cluster, configure the cluster and set up clients using this information:

- Configuring the Cluster on page 271
- Setting Up Clients and Services on page 400

Installing HPE Ezmeral Data Fabric Object Store

Describes installation of the HPE Ezmeral Data Fabric Object Store software with or without the Installer.

Memory Requirement

Before installing the HPE Ezmeral Data Fabric Object Store, make sure each node in the cluster has the minimum memory recommended in Memory and Disk Space on page 168.

Installing the Package Manually

You install the HPE Ezmeral Data Fabric Object Store by applying the `mapr-s3server` package. The manual installation instructions for release 7.0.0 and later recommend installing this package on all cluster nodes. See Step 4: Install Cluster Service Packages on page 192.

Post-Installation Steps

Once the `mapr-s3server` package has been applied, several post-installation steps are necessary to start the object store server and enable `mc` commands. See Enabling the HPE Ezmeral Data Fabric Object Store on page 217.

last-updated: Jun 06, 2024

Metrics Monitoring and the Object Store

To take advantage of object-store features provided by the control system (MCS), you must install Metrics Monitoring on all clusters where the object store is installed. The manual installation procedure includes this step. See Step 9: Install Metrics Monitoring on page 222.

Gateway Node Installation

A gateway node is a node where no data-fabric software is installed. HPE does not recommend installation of the object store software on a gateway node. If gateway node installation is required, you must install the `mapr-core` and `mapr-core-internal` packages in addition to the `mapr-s3server` package. Note the following limitations for gateway node installations:

- Storage Recovery Metrics (SRM) will not work if a file server is not installed on the node running the multithreaded object store server (MOSS).
- Recovery and stats will not work on a gateway node.

Getting Started with the Object Store

See Getting Started with HPE Ezmeral Data Fabric Object Store on page 552.

Installing Kubernetes Interfaces for Data Fabric

This section describes how to plan for and install the Container Storage Interface (CSI) Storage Plugin and the Kubernetes Interfaces for Data Fabric FlexVolume Driver.

Getting Started with the Container Storage Interface (CSI) Storage Plugin

This section describes how to plan for, install, and upgrade the Container Storage Interface (CSI) Storage Plugin.

See Container Storage Interface (CSI) Storage Plugin Overview on page 805 for more information.

Planning for the Container Storage Interface (CSI) Storage Plugin
Includes information you should review before installing or using the Container Storage Interface (CSI) Storage Plugin.

For release notes information, see CSI Storage Plugin Release Notes on page 6165.

Downloads (CSI)
Lists the downloads for the Container Storage Interface (CSI) Storage Plugin.

Downloads for the Container Storage Interface (CSI) Storage Plugin are available at these locations:

Site	URL	Contents
Docker Hub	FUSE: • https://hub.docker.com/r/maprtech/csi-kdfplugin • https://hub.docker.com/r/maprtech/csi-kdfprovisioner • https://hub.docker.com/r/maprtech/csi-kdfdriver Loopback NFS:	Docker containers for the data-fabric installation files

Site	URL	Contents

GitHub Repository	https://github.com/mapr/mapr-csi	Data Fabric installation and example `.yaml` files: • A **deploy** folder that contains the latest CSI Plugin deployment `.yaml` files in `deploy/kubernetes/fuse` and `deploy/kubernetes/nfs` • An **examples** folder that contains example `.yaml` files • A **build** folder that contains the custom template to build CSI plugin container image

Prerequisites for Installing the Container Storage Interface (CSI) Storage Plugin
Lists the prerequisites for installing and using the Container Storage Interface (CSI) Storage Plugin.

Hardware and Software Requirements

To install and use the Container Storage Interface (CSI) Storage Plugin, you must have the following:

Component	Supported Versions
HPE Ezmeral Data Fabric File Store	6.1.0 or later. For additional version compatibility information, see CSI Version Compatibility on page 5763.
Ecosystem Pack (EEP)	Any EEP supported by data-fabric 6.1.0 or later. See EEP Support by MapR Core Version.
Kubernetes Software	1.17 and later*
OS (Kubernetes nodes)	All nodes in the Kubernetes cluster must use the same Linux OS. Configuration files are available to support: • CentOS • RHEL (use CentOS configuration file) • Ubuntu **NOTE:** Docker for Mac with Kubernetes is not supported as a development platform for containers that use data-fabric for Kubernetes.
CSI Driver	FUSE and Loopback NFS drivers (implementing the CSI spec with v1.3.0). The download location shows the latest version of the driver.
Sidecar Containers	The CSI plugin pod uses: • `csi-node-driver-registrar` — v1.3.0

last-updated: Jun 06, 2024

Component	Supported Versions
	• `livenessprobe` — v2.2.0 The CSI provisioner pod uses: • `csi-attacher` — v2.2.0 • `csi-provisioner` — v1.6.0 • `csi-snapshotter` — v3.0.2 • `snapshot-controller` — v3.0.2 • `livenessprobe` — v2.2.0 • `csi-resizer` — v0.5.0
POSIX License	The Basic POSIX client package is included by default when you install data-fabric for Kubernetes. The Platinum POSIX client can be enabled by specifying a parameter in the pod specification. To enable the Platinum POSIX client package, see Enabling the Platinum Posix Client for Kubernetes Interfaces for Data Fabric FlexVolume Driver on page 3885. For a comparison of the Basic and Platinum POSIX client packages, see Preparing for Installation (HPE Ezmeral Data Fabric POSIX Client) on page 432.

*Kubernetes alpha features are not supported.

Before You Install

Before installing the Container Storage Interface (CSI) Storage Plugin, note that the installation procedure assumes that the Kubernetes cluster is already installed and functioning normally. In addition:

1. Ensure that all Kubernetes nodes use the same Linux distribution.

   For example, all nodes can be CentOS nodes, or all nodes can be Ubuntu nodes. A cluster with a mixture of CentOS and Ubuntu nodes is not supported.

2. Configure your Kubernetes cluster to allow privileged pods by running the following commands:

   ```
   $ ./kube-apiserver ...  --allow-privileged=true …
   ```

   ```
   $ ./kubelet ...  --allow-privileged=true ...
   ```

3. Enable mount propagation to share volumes mounted by one container with other containers in the same pod and other pods on the same node.

   See Mount Propagation for more information.

last-updated: Jun 06, 2024

4. Apply CRDs to your Kubernetes cluster if they are not already present:

   Kubernetes 1.20 and Later

   ```
   kubectl apply -f https://
   raw.githubusercontent.com/kubernetes-csi/external-snapshotter/v4.2.1/
   client/config/crd/snapshot.storage.k8s.io_volumesnapshotclasses.yaml
   kubectl apply -f https://
   raw.githubusercontent.com/kubernetes-csi/external-snapshotter/v4.2.1/
   client/config/crd/snapshot.storage.k8s.io_volumesnapshotcontents.yaml
   kubectl apply -f
   https://raw.githubusercontent.com/kubernetes-csi/external-snapshotter/
   v4.2.1/client/config/crd/snapshot.storage.k8s.io_volumesnapshots.yaml
   ```

   Kubernetes 1.19 and Earlier

   ```
   kubectl apply -f https://raw.githubusercontent.com/
   kubernetes-csi/external-snapshotter/release-3.0/client/config/crd/
   snapshot.storage.k8s.io_volumesnapshotclasses.yaml
   kubectl apply -f https://raw.githubusercontent.com/
   kubernetes-csi/external-snapshotter/release-3.0/client/config/crd/
   snapshot.storage.k8s.io_volumesnapshotcontents.yaml
   kubectl apply -f https://raw.githubusercontent.com/
   kubernetes-csi/external-snapshotter/release-3.0/client/config/crd/
   snapshot.storage.k8s.io_volumesnapshots.yaml
   ```

   For more information see Snapshot Controller.

5. For OpenShift, install the SecurityContextConstraints by applying `deploy/openshift/csi-scc.yaml` in the `mapr-csi` GitHub repository:

   ```
   oc apply -f deploy/openshift/csi-scc.yaml
   ```

6. Create the state volume-mount path, and update the CSI driver `yaml`. In prior releases, the state of dynamically provisioned volumes and their snapshots was held in memory. The provisioner would lose this state if the controller pod was restarted or upgraded. After restarts, the provisioner would fail to take snapshots, restore snapshots, resize or clone previously created volumes.

   With the latest version of the CSI driver, the provisioner persists the encrypted state of the dynamically provisioned volumes and their snapshots in a volume on the data-fabric cluster. If the controller pod is restarted, the state is automatically recovered, and operations on previously created volumes work as intended.

   You can change the state volume-mount prefix by updating the `--statevolmountprefix=/path/to/dir` argument in the `mapr-kdfprovisioner` image of the CSI driver `yaml`.

   NOTE: The directory you specify needs to be read-writable for all users who provision volumes on the data-fabric cluster using CSI drivers:

   ```
   # Create state volume mount path
   hadoop fs -mkdir /apps/k8s
   hadoop fs -chmod 777 /apps/k8s

   # Update csi driver yaml
   --statevolmountprefix=/apps/k8s
   ```

last-updated: Jun 06, 2024

7. Understand the number of volume mounts per node that your application requires. The CSI driver default is 20 volume mounts per node. You can modify the number of volume mounts per node by adjusting the value of the `maxvolumepernode` parameter in the `csi-maprkdf-<version>.yaml` or `csi-maprnfskdf-<version>.yaml` file.

Installing, Uninstalling, and Upgrading the Container Storage Interface (CSI) Storage Plugin
This section describes the steps for installing, uninstalling, and upgrading the Container Storage Interface (CSI) Storage Plugin.

About this task
By default, the CSI Driver includes CentOS 8 as the base image. If you want to customize the installation, you can build your own container with a FUSE-based POSIX supported OS. See Building Your Own Container on page 280 for more information.
Installing the CSI Driver

Procedure

1. Download and install the CSI Driver custom resource definition on the Kubernetes cluster by running the following command:

   ```
   kubectl create -f csi-maprkdf-v<version>.yaml
   ```

   where `<version>` is the driver version being installed.

   FUSE

   ```
   kubectl create -f csi-maprkdf-v<version>.yaml
   ```

   Loopback NFS

   ```
   kubectl create -f csi-maprnfskdf-v<version>.yaml
   ```

   When you run the command to install the CSI Driver, the service accounts, rule-based access controls (RBAC), and the statefulset and daemonset are created on the pods on the Kubernetes cluster.

2. Verify the installation by running the following command.

   ```
   kubectl get pods --all-namespaces -o wide
   ```

What to do next
After installing, you can use the CSI Driver to statically and dynamically provision and mount a data-fabric volume. See Using the Container Storage Interface (CSI) Storage Plugin on page 3821 for more information.

Uninstalling the CSI Driver

Procedure

- To uninstall the CSI driver, run the following command:

  ```
  kubectl delete -f csi-maprkdf-v<version>.yaml
  ```

  where `<version>` is the driver version being installed.

  FUSE

  ```
  kubectl delete -f csi-maprkdf-v<version>.yaml
  ```

  Loopback NFS

  ```
  kubectl delete -f csi-maprnfskdf-v<version>.yaml
  ```

  When you run the command to uninstall, all the pods with the mount provisioned by CSI Driver are removed.

Upgrading the CSI Driver

About this task

Online upgrades for the CSI driver are not currently supported. To perform an offline upgrade, use the following steps:

Procedure

1. Shut down all application pods that have a persistent volume mounted in the HPE Ezmeral Data Fabric.
2. Reapply the new CSI driver `.yaml`, and wait for Kubernetes to restart all the CSI pods:

   ```
   kubectl apply -f csi-maprkdf-<version>.yaml
   ```

3. Restart application pods.

Building Your Own Container

Describes how to build a container using the Container Storage Interface (CSI) Storage Plugin template.

FUSE POSIX Example with CentOS 8 Image

The Container Storage Interface (CSI) Storage Plugin includes a template in the `build` directory to build your own container. The following template shows the Container Storage Interface (CSI) Storage Plugin build for FUSE POSIX with a CentOS 8 image. In the example, `<tag>` is the image version (available tags):

```
## FOR FUSE
# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved
# CentOS Package Build
FROM centos:centos8
LABEL mapr.os=centos8
ENV container docker
# Setup repos and dl prereqs + Mapr Core
COPY mapr.repo /etc/yum.repos.d/
RUN rpm --import http://dl.fedoraproject.org/pub/epel/RPM-GPG-KEY-EPEL-8; \
   rpm --import https://<EMAIL>:<TOKEN>@package.ezmeral.hpe.com/
```

```
releases/pub/maprgpg.key; \
   rpm --import https://<EMAIL>:<TOKEN>@package.ezmeral.hpe.com/
releases/pub/gnugpg.key; \{noformat}
   yum -y update && yum -y clean all; \
   yum -y install epel-release; \
   sed -i 's/^mirror/#mirror/g' /etc/yum.repos.d/epel.repo; \
   yum install -y mapr-client mapr-posix-client-basic
mapr-posix-client-platinum && \
   yum -y update && yum clean all && rm -rf /var/cache/yum; \
   mkdir -p /opt/mapr/lib/fusebasic /opt/mapr/lib/fuseplatinum; \
   cp /opt/mapr/lib/libMapRClient_c.so.1 /opt/mapr/lib/fusebasic/
libMapRClient_c.so.0; \
   rm -rf /opt/mapr/lib/libMapRClient_c.so.1
# Add Tini
ENV TINI_VERSION v0.18.0
ADD https://github.com/krallin/tini/releases/download/${TINI_VERSION}/tini /
tini
RUN chmod +x /tini
# Copy utils, driver and set entrypoint
COPY --from=docker.io/maprtech/csi-kdfdriver:<tag> \
    /go/src/plugin/bin/* /opt/mapr/bin/
RUN chmod +x /opt/mapr/bin/csi-kdfplugin; \
   chmod +x /opt/mapr/bin/start-fuse;
WORKDIR /opt/mapr
ENTRYPOINT ["/tini", "--", "bin/csi-kdfplugin"]
```

The template contains the information on the image for setting up the repository, deploying the (Basic, Container, or Platinum) POSIX client, information on the entry point, and Tini for POSIX process management. You can customize the template and build it by running the `docker-custom-build.sh` utility in the `build` directory or by running the `docker build` command with the custom image tag.

Loopback NFS Example with CentOS 8 Image

The following template shows the Container Storage Interface (CSI) Storage Plugin build for Loopback NFS with CentOS 8 image. In the example, `<tag>` is the image version (see available tags):

```
## FOR NFS

# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved

# CentOS Package Build
FROM centos:centos8
LABEL mapr.os=centos8
ENV container docker
# Setup repos and dl prereqs + Mapr Core
COPY mapr.repo /etc/yum.repos.d/
RUN rpm --import http://dl.fedoraproject.org/pub/epel/RPM-GPG-KEY-EPEL-8; \
    rpm --import https://<EMAIL>:<PASSWORD>@package.ezmeral.hpe.com/
releases/pub/maprgpg.key; \
    rpm --import https://<TOKEN>:<PASSWORD>@package.ezmeral.hpe.com/
releases/pub/gnugpg.key; \{noformat}
    yum -y update && yum -y clean all; \
    yum -y install epel-release; \
    sed -i 's/^mirror/#mirror/g' /etc/yum.repos.d/epel.repo; \
    sed -i 's/^#base/base/g' /etc/yum.repos.d/epel.repo; \
    yum install -y mapr-loopbacknfs; \
    yum clean all && rm -rf /var/cache/yum

# Add Tini
ENV TINI_VERSION v0.18.0
ADD https://github.com/krallin/tini/releases/download/${TINI_VERSION}/tini /
tini
```

```
RUN chmod +x /tini

# Copy utils, driver and set entrypoint
COPY --from=docker.io/maprtech/csi-nfsdriver:<tag> \
     /go/src/plugin/bin/* /opt/mapr/bin/
RUN chmod +x /opt/mapr/bin/csi-nfsplugin; \
    chmod +x /opt/mapr/bin/start-loopbacknfs;
WORKDIR /opt/mapr
ENTRYPOINT ["/tini", "--", "bin/csi-nfsplugin"]
```

Considerations for Using the Password Protected Repository

In the preceding examples, note that you must include your HPE Passport credentials to enable the `rpm --import <URL>` command to work. In addition, you must include the same credentials in your `maprtech.repo` file, as described in Adding the Data Fabric Repository on RHEL, CentOS, or Oracle Linux on page 183. For example:

```
[MapR_Core]
name = MapR Core Components
enabled = 1
baseurl = https://package.ezmeral.hpe.com/releases/v6.2.0/redhat/
username = <EMAIL>
password = <TOKEN>
protected = 1
gpgcheck = 1

[MapR_MEP]
name = MapR MEP Components
enabled = 1
baseurl = https://package.ezmeral.hpe.com/releases/MEP/MEP-7.1.0/redhat/
username = <EMAIL>
password = <TOKEN>
protected = 1
gpgcheck = 1
```

For more information about the new repository, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

Installing the HPE Ezmeral CSI Operator

Describes how to download and install the HPE Ezmeral CSI Operator for Kubernetes for deployment in Kubernetes and OpenShift environments.

Overview

The HPE Ezmeral CSI Operator for Kubernetes packages, deploys, and manages HPE Ezmeral CSI Drivers on Kubernetes and OpenShift. After installing the operator and creating a CSI Driver object, you can enable static and dynamic provisioning of persistent volumes on the HPE Ezmeral Data Fabric platform.

Installing the Operator in Kubernetes

To install the operator in a Kubernetes environment:

1. Install the Operator Lifecycle Manager (OLM) tool. The OLM allows you to manage the operators running on your cluster:

   ```
   $ curl -sL https://github.com/operator-framework/
   operator-lifecycle-manager/releases/download/v0.17.0/install.sh |
   bash -s v0.17.0
   ```

2. Install the HPE Ezmeral CSI Operator by running the following command:

```
$ kubectl create -f https://operatorhub.io/install/
hpe-ezmeral-csi-operator.yaml
```

   The operator is installed in the `my-hpe-ezmeral-csi-operator` namespace and is usable only from this namespace.

3. After installation, use the following command to watch the operator come up:

```
$ kubectl get csv -n my-hpe-ezmeral-csi-operator
```

4. To instantiate the driver object, create a file named `hpe-csi-operator.yaml`, and populate it according to the CSI Driver that is being deployed.

5. Create a CSI Driver object. The operator supports FUSE and Loopback NFS drivers. In the following examples, `<tag>` is the image tag:

   - **HPE Ezmeral CSI Driver (FUSE)**

```
apiVersion: ezmeral.hpe.com/v1
kind: HPEEzmeralCSIDriver
metadata:
  name: hpeezmeralcsidriver
  namespace: my-hpe-ezmeral-csi-operator
spec:
  controllerImage: maprtech/csi-kdfprovisioner:<tag>
  nodeImage: maprtech/csi-kdfplugin:<tag>
  pullPolicy: IfNotPresent
```

   - **HPE Ezmeral CSI Driver (Loopback NFS)**

```
apiVersion: ezmeral.hpe.com/v1
kind: HPEEzmeralNFSCSIDriver
metadata:
  name: hpeezmeralnfscsidriver
  namespace: my-hpe-ezmeral-csi-operator
spec:
  controllerImage: maprtech/csi-kdfprovisioner:<tag>
  nodeImage: maprtech/csi-nfsplugin:<tag>
  pullPolicy: IfNotPresent
```

6. Verify that the HPE Ezmeral CSI Operator and CSI Driver pods are running in the namespace:

```
$ kubectl get pods -n my-hpe-ezmeral-csi-operator
```

The CSI Driver is now ready to use. To use the CSI Driver to statically and dynamically provision and mount a data-fabric volume, see Using the Container Storage Interface (CSI) Storage Plugin on page 3821.

Installing the Operator in OpenShift

You can install the HPE Ezmeral CSI Operator in the OpenShift environment by using the OpenShift CLI or the web console.

Prerequisites for OpenShift Installation

The HPE Ezmeral CSI Driver needs to run in privileged mode and needs access to host ports in the host network and must be able to mount `hostPath` volumes. Hence, before deploying the HPE Ezmeral CSI Operator on OpenShift, you must create a set of security context constraints (SCCs) to allow the CSI Driver to run with these privileges:

```
curl -sL https://raw.githubusercontent.com/mapr/mapr-csi/master/deploy/
openshift/operator-scc.yaml > hpe-ezmeral-csi-scc.yaml
```

1. Change `my-hpe-ezmeral-csi-driver` to the name of the project (for example, `hpe-ezmeral-csi` below) where the CSI Operator is being deployed:

   ```
   oc new-project hpe-ezmeral-csi --display-name="HPE Ezmeral CSI Drivers
   for Kubernetes"
   sed -i  's/my-hpe-ezmeral-csi-driver/hpe-ezmeral-csi/g'
   hpe-ezmeral-csi-scc.yaml
   ```

2. Deploy the SCC:

   ```
   oc create -f hpe-ezmeral-csi-scc.yaml
   securitycontextconstraints.security.openshift.io/hpe-ezmeral-csi-scc
   created
   ```

Installing the Operator Using the OpenShift CLI

The following steps show an example of operator deployment using `oc`. This example assumes that the SCC has been applied to the project and has `kube:admin` privileges. The example deploys to the `hpe-ezmeral-csi` project, as described in the previous steps.

1. Create an operator group:

   ```
   apiVersion: operators.coreos.com/v1
   kind: OperatorGroup
   metadata:
     name: hpe-ezmeral-csi-operator
     namespace: hpe-ezmeral-csi
   spec:
     targetNamespaces:
     - hpe-ezmeral-csi
   ```

2. Create a subscription to the operator:

   ```
   apiVersion: operators.coreos.com/v1alpha1
   kind: Subscription
   metadata:
     name: hpe-ezmeral-csi-operator
     namespace: hpe-ezmeral-csi
   spec:
     channel: stable
     installPlanApproval: Automatic
     name: hpe-ezmeral-csi-operator
     source: certified-operators
     sourceNamespace: openshift-marketplace
   ```

   The operator is now installed on the OpenShift cluster. Creation of the subscription triggers the creation of the InstallPlan and CSV:

last-updated: Jun 06, 2024

3. Display information about the InstallPlan and CSV:

```
oc get installplan -n hpe-ezmeral-csi
NAME            CSV                                    APPROVAL    APPROVED
install-5lmzg   hpe-ezmeral-csi-operator.v<ver>   Automatic   true

oc get csv -n hpe-ezmeral-csi
NAME
DISPLAY                                                    VERSION
REPLACES   PHASE
hpe-ezmeral-csi-operator.v<ver>   HPE Ezmeral Data Fabric CSI Operator
for Kubernetes   <ver>                Succeeded
```

4. Create a CSI Driver object. The operator supports FUSE and Loopback NFS drivers:

   - **HPE Ezmeral CSI Driver (FUSE)**

```
apiVersion: ezmeral.hpe.com/v1
kind: HPEEzmeralCSIDriver
metadata:
  name: hpeezmeralcsidriver
  namespace: hpe-ezmeral-csi
spec:
  controllerImage: registry.connect.redhat.com/maprtech/
csi-kdfprovisioner:latest
  nodeImage: registry.connect.redhat.com/maprtech/csi-kdfplugin:latest
  pullPolicy: IfNotPresent
```

   - **HPE Ezmeral CSI Driver (LoopbackNFS)**

```
apiVersion: ezmeral.hpe.com/v1
kind: HPEEzmeralNFSCSIDriver
metadata:
  name: hpeezmeralnfscsidriver
  namespace: hpe-ezmeral-csi
spec:
  controllerImage: registry.connect.redhat.com/maprtech/
csi-kdfprovisioner:latest
  nodeImage: registry.connect.redhat.com/maprtech/csi-nfsplugin:latest
  pullPolicy: IfNotPresent
```

5. Verify that HPE Ezmeral CSI Operator and CSI Driver pods are running in the namespace:

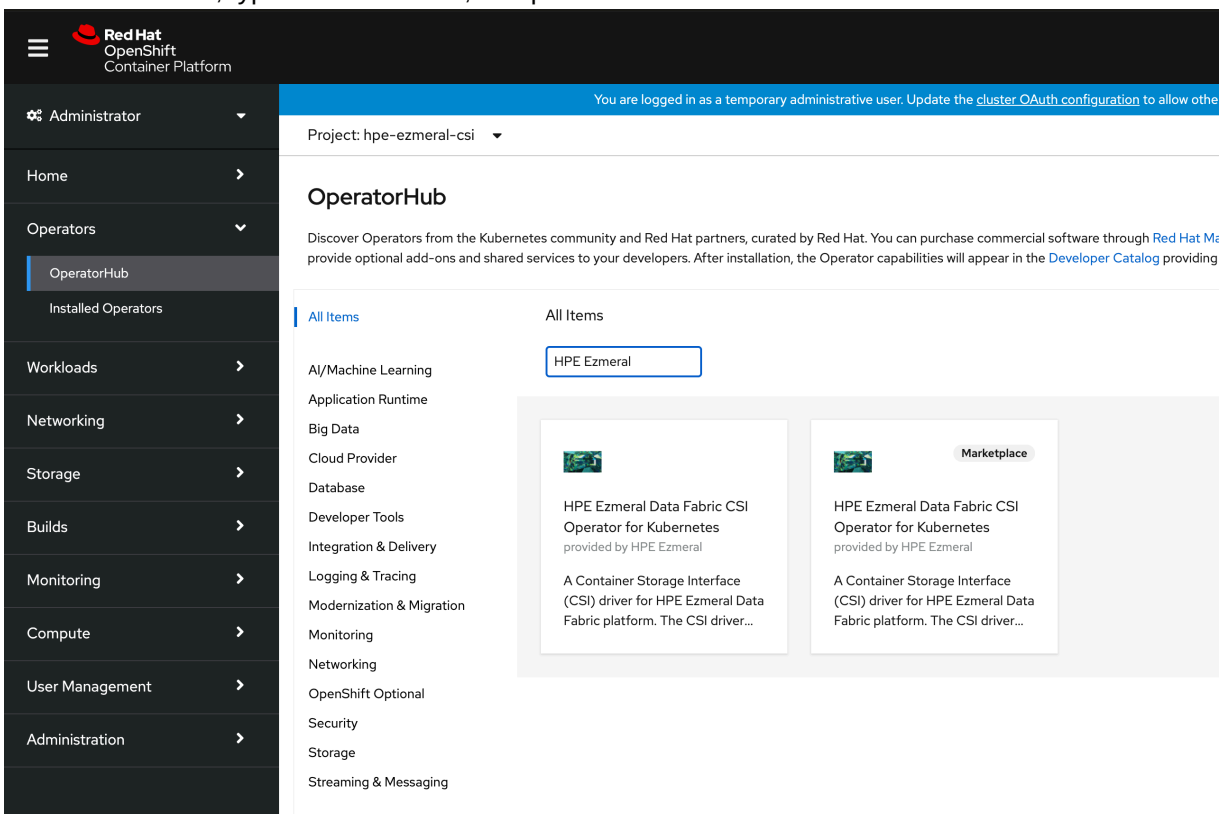
```
# oc get pods -n hpe-ezmeral-csi
NAME                                                READY   STATUS
RESTARTS   AGE
hpe-ezmeral-csi-controller-0                        7/7     Running
0          62s
hpe-ezmeral-csi-driver-operator-9dd887bf7-hdxc9     1/1     Running
0          4m6s
hpe-ezmeral-csi-node-79xw5                          3/3     Running
0          61s
hpe-ezmeral-csi-node-m2gpv                          3/3     Running
0          61s
hpe-ezmeral-csi-node-x25dr                          3/3     Running
0          61s
hpe-ezmeral-nfscsi-controller-0                     7/7     Running
0          29s
hpe-ezmeral-nfscsi-node-hhrhv                       3/3     Running
0          28s
hpe-ezmeral-nfscsi-node-jz5cx                       3/3     Running
0          28s
hpe-ezmeral-nfscsi-node-tvtgm                       3/3     Running
0          28s
```

Installing the Operator Using the OpenShift Web Console

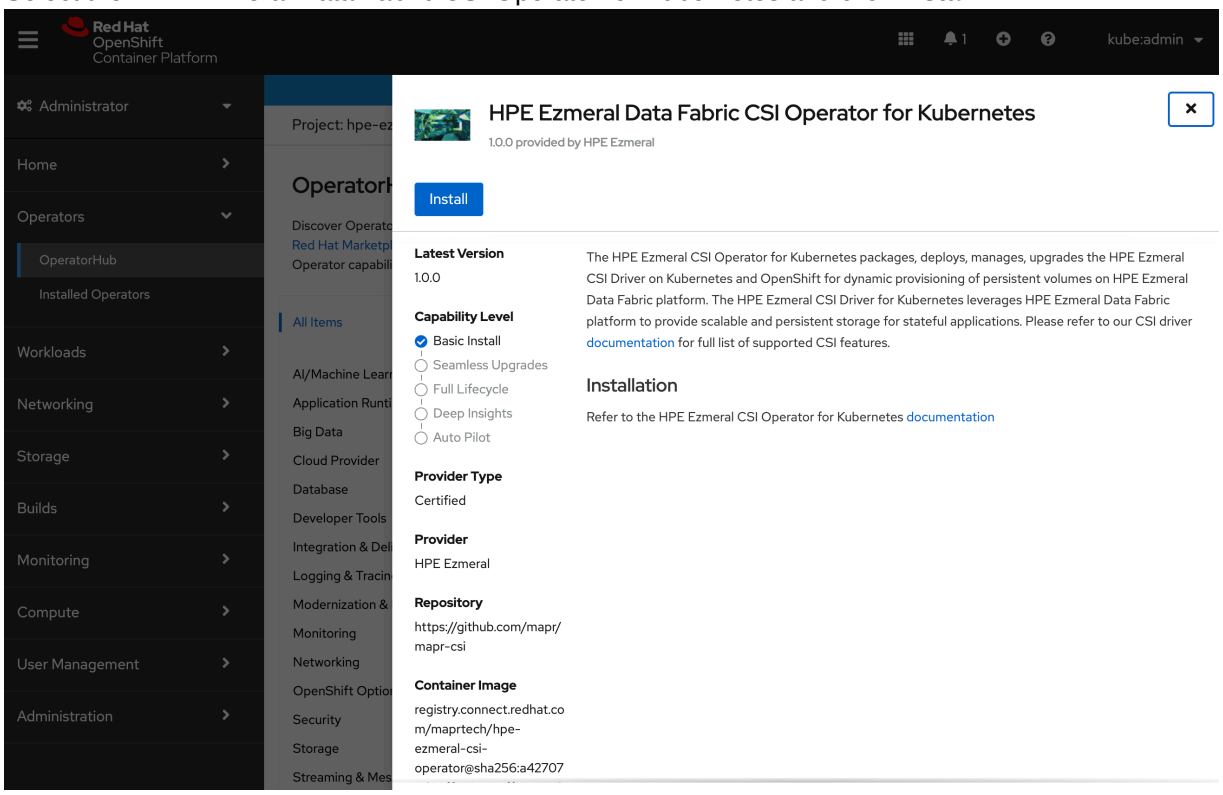
Use the following steps to install the operator using the web console:

1. Once the SCC has been applied to the project, log in to the OpenShift web console as `kube:admin`, and navigate to **Operators > OperatorHub**.

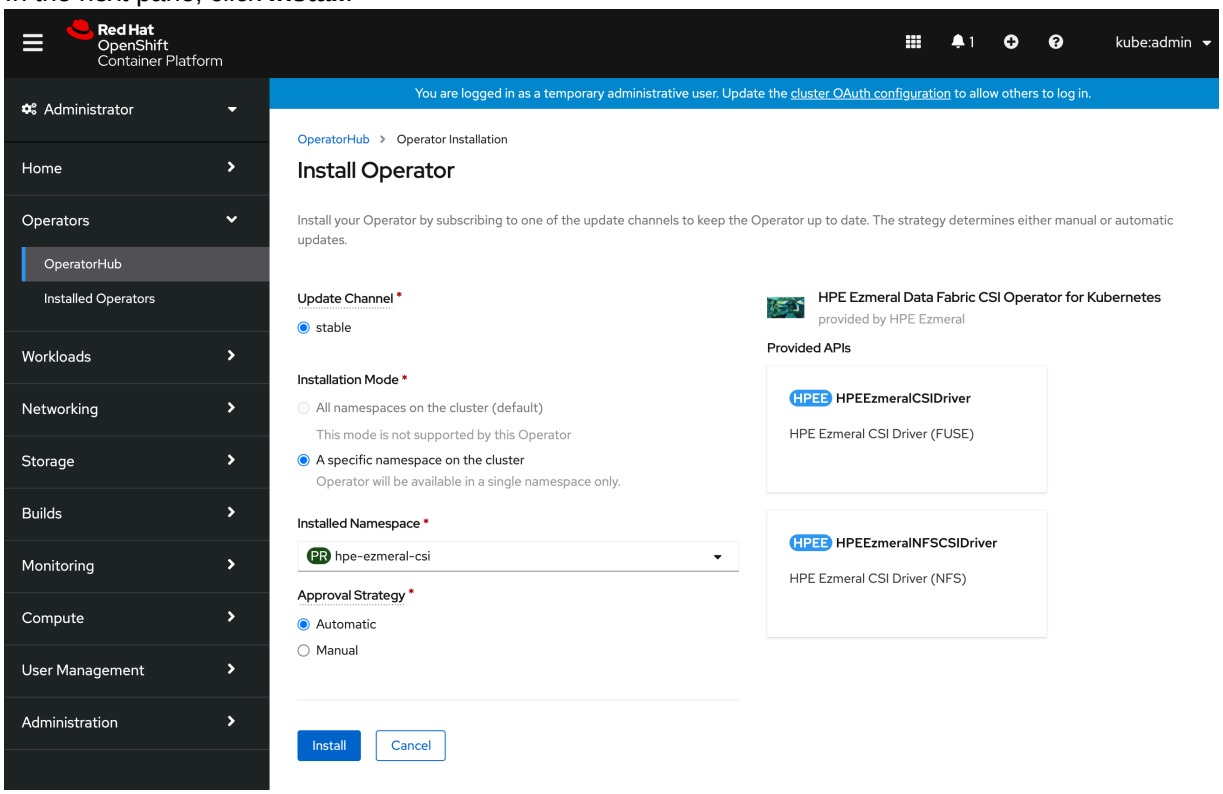
2. In the search field, type `HPE Ezmeral`, and press enter:



3. Select the HPE Ezmeral Data Fabric CSI Operator for Kubernetes and click **Install**:

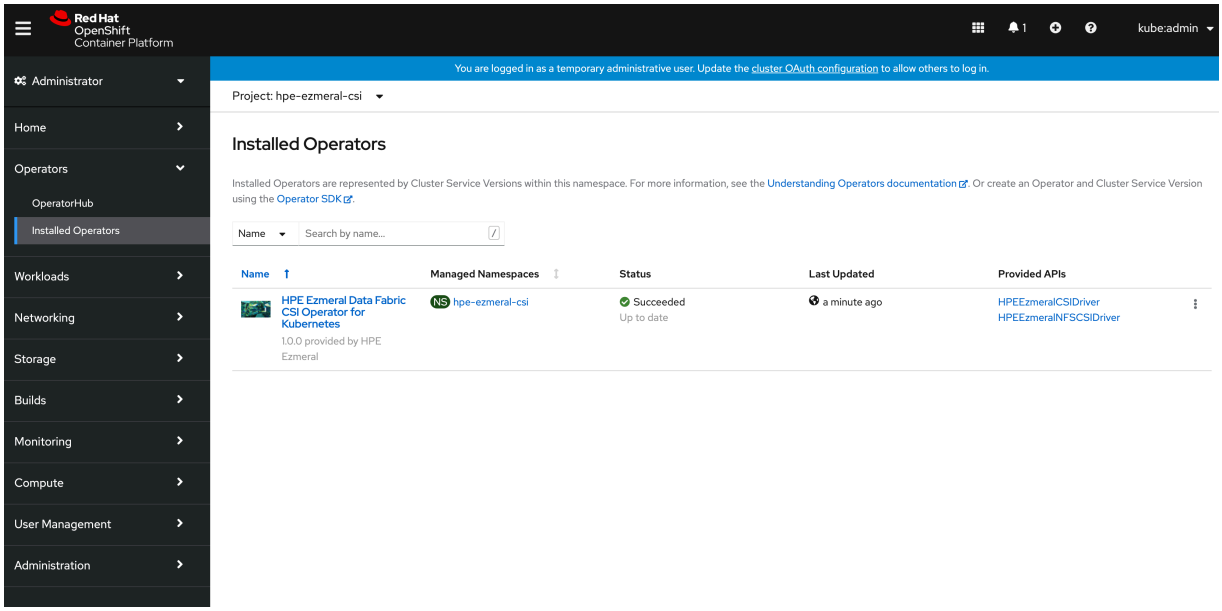


4. In the next pane, click **Install**:

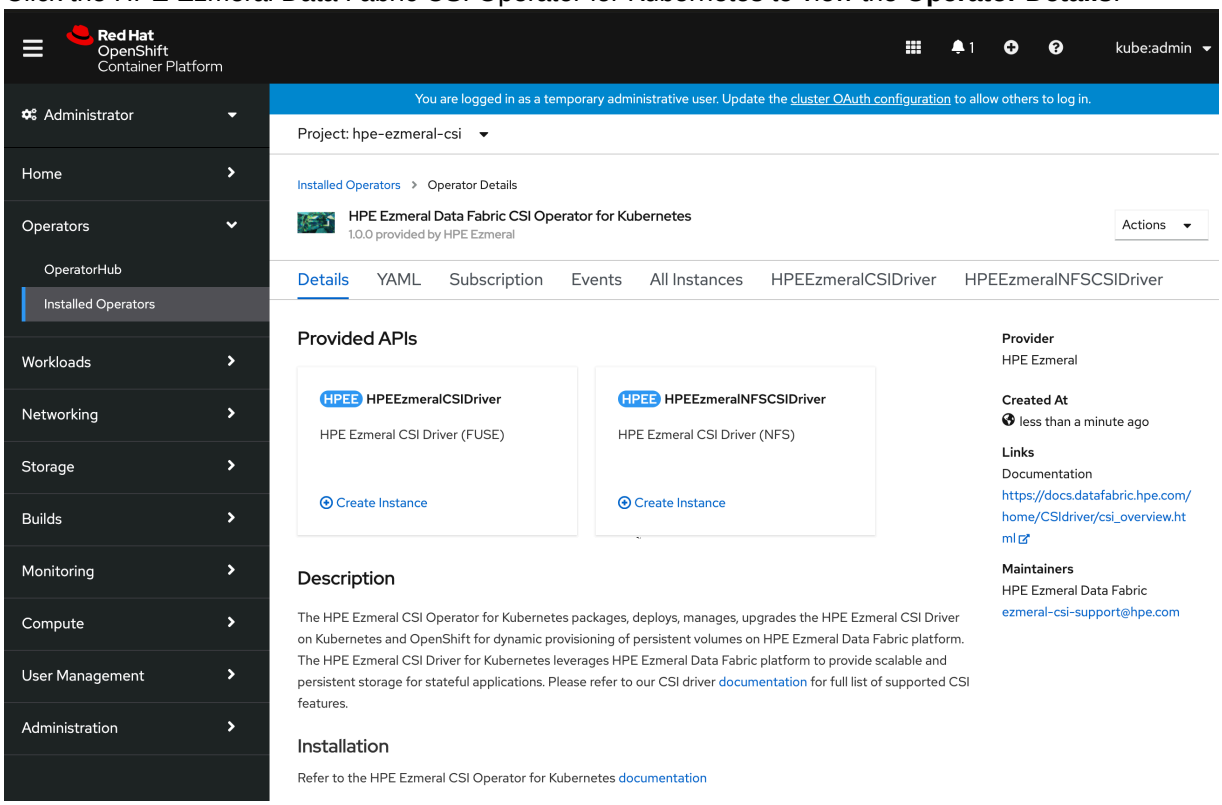


5. The HPE Ezmeral CSI Operator is now installed:

last-updated: Jun 06, 2024



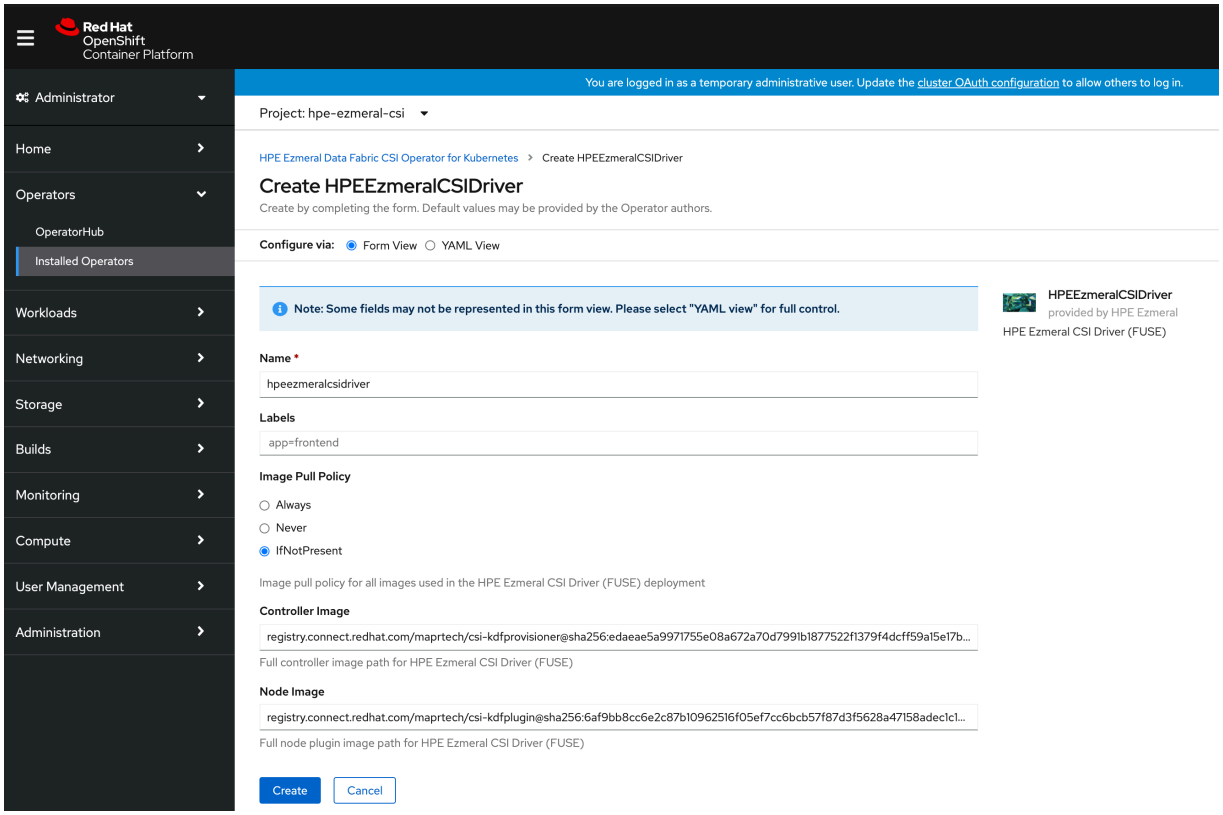
6. Click the HPE Ezmeral Data Fabric CSI Operator for Kubernetes to view the **Operator Details**:



7. To create the HPE Ezmeral CSI Driver (FUSE), click **Create Instance** under **HPEEzmeralCSIDriver**.

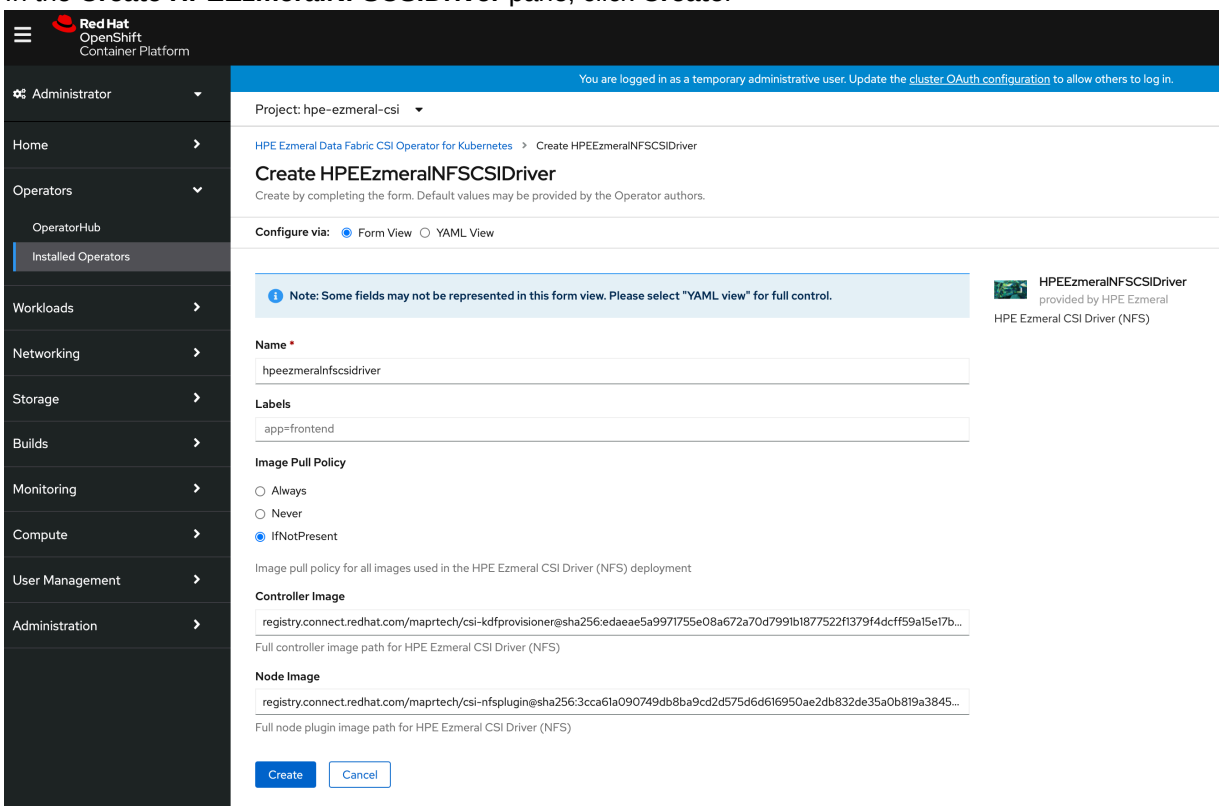
8. In the **Create HPEEzmeralCSIDriver** pane, click **Create**:

last-updated: Jun 06, 2024

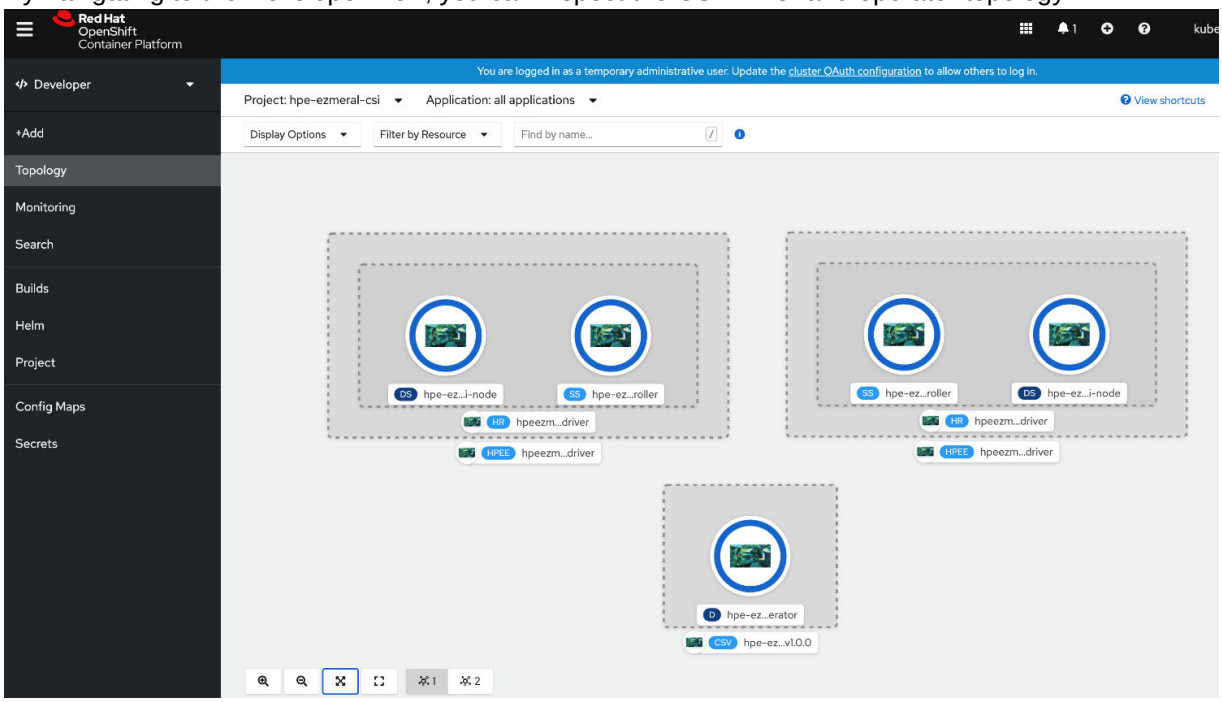


9. To create the HPE Ezmeral CSI Driver (NFS), click **Create Instance** under **HPEEzmeralNFSCSIDriver**.

10. In the **Create HPEEzmeralNFSCSIDriver** pane, click **Create**:



11. By navigating to the Developer view, you can inspect the CSI Driver and operator topology:



The CSI Driver is now ready for use. To use the CSI Driver to statically and dynamically provision and mount a data-fabric volume, see Using the Container Storage Interface (CSI) Storage Plugin on page 3821.

Migrating from Kubernetes Interfaces for Data Fabric FlexVolume Driver to Container Storage Interface (CSI) Storage Plugin
Describes how to migrate from the Kubernetes Interfaces for Data Fabric FlexVolume driver to the Container Storage Interface (CSI) Storage Plugin.

About this task

Installing both the CSI Driver and FlexVolume Driver on the same Kubernetes cluster can lead to an unstable Kubernetes environment. To migrate from the FlexVolume Driver to CSI Driver:

Procedure

1. Stop all the container workloads using the FlexVolume Driver and de-provision the FlexVolume Driver.
2. Uninstall the FlexVolume Driver.
3. Install the CSI Driver.

   For more information, see Installing, Uninstalling, and Upgrading the Container Storage Interface (CSI) Storage Plugin on page 279.
4. Modify the existing storage classes, PersistentVolumeClaims, PersistentVolumes, and Pod specifications to refer to the CSI Driver as the default Driver.
5. Resume the workloads you stopped (in step 1 above).

Getting Started with the MapR Data Fabric for Kubernetes FlexVolume Driver

Serves as a pointer on how to plan for, install, and upgrade data-fabric for Kubernetes.

For more information about the data-fabric for Kubernetes, see Kubernetes Interfaces for Data Fabric FlexVolume Driver Overview on page 809.

last-updated: Jun 06, 2024

Planning for the MapR Data Fabric for Kubernetes FlexVolume Driver
Points to information you should review before installing or using the data-fabric for Kubernetes FlexVolume driver.

For release note information, see MapR Data Fabric for Kubernetes Release Notes.

Prerequisites for Using the Kubernetes Interfaces for Data Fabric FlexVolume Driver

To use the *Kubernetes Interfaces for Data Fabric* FlexVolume driver, you must have the following software versions:

Component	Supported Versions
HPE Ezmeral Data Fabric File Store	5.2.2 or later
Ecosystem Pack (EEP)	Any EEP supported by MapR 5.2.2 or later. See EEP Support by MapR Core Version.
Kubernetes Software	1.9*
OS (Kubernetes nodes)	All nodes in the Kubernetes cluster must use the same Linux OS. Configuration files are available to support: • CentOS • Red Hat (use CentOS configuration file) • SLES (use CentOS configuration file) • Ubuntu **NOTE:** Docker for Mac with Kubernetes is not supported as a development platform for containers that use the MapR Data Fabric for Kubernetes.
Volume Plug-in	1.0 or later. The download location shows the available versions of the plug-in. Plug-ins are supported for: • CentOS • Ubuntu • Microsoft Azure AKS • Red Hat OpenShift** • Google Kubernetes Engine (GKE) **NOTE:** Amazon EKS is not currently supported.
Provisioner	1.0 or later. The download location shows the available versions of the provisioner.
POSIX License***	The Basic POSIX client package is included by default when you install the MapR Data Fabric for Kubernetes. The Platinum POSIX client can be enabled by specifying a parameter in the Pod spec. To enable the Platinum POSIX client package, see Enabling the Platinum Posix Client for Kubernetes Interfaces for Data Fabric FlexVolume Driver on page 3885. For a comparison of the Basic and Platinum POSIX client packages, see Preparing for Installation (HPE Ezmeral Data Fabric POSIX Client) on page 432.

*Kubernetes alpha features are not supported.

last-updated: Jun 06, 2024

**OpenShift Origin is supported because it supports Kubernetes 1.9. The OpenShift Container Platform (formerly known as OpenShift Enterprise) can be used only if it supports Kubernetes 1.9.

***Only the POSIX client is supported. NFSv3 is not supported.

Downloads (FlexVolume)

Downloads for the MapR Data Fabric for Kubernetes FlexVolume driver are available at these locations:

Site	URL	Content
MapR Software Downloads Site	https://package.ezmeral.hpe.com/tools/KubernetesDataFabric	MapR installation (`.yaml`) files
Docker Hub	https://hub.docker.com/r/maprtech/kdf-provisioner/ https://hub.docker.com/r/maprtech/kdf-plugin/	Docker containers for the MapR installation files
GitHub Repository	https://github.com/mapr/KubernetesDataFabric	Three types of resources: • A **build** folder that contains the Docker images used to build the data fabric • A **deploy** folder that contains the same files provided on the MapR Software Download site • An **examples** folder that contains example `.yaml` files

Installing the MapR Data Fabric for Kubernetes FlexVolume Driver
This section describes the steps you must take to prepare for installation and install the configuration files for the MapR Data Fabric for Kubernetes FlexVolume driver.

Installing HPE Ezmeral Data Fabric and Kubernetes Software on Separate Nodes

This section describes how to install the configuration files for the HPE Ezmeral Data Fabric for Kubernetes. In this configuration, Data Fabric and Kubernetes software must be installed on separate nodes.

To install the HPE Ezmeral Data Fabric for Kubernetes, you must download the configuration files and use the Kubernetes `kubectl` interface to install the namespace, RBAC, plug-in, and provisioner `.yaml` files.

Before Installation

Before installing the HPE Ezmeral Data Fabric for Kubernetes, note these preinstallation best practices:

- You must install the configuration files in the order shown in the steps below. Using a different installation order can cause problems.
- Ensure that all Kubernetes nodes use the same Linux distribution. For example, all nodes can be CentOS nodes, or all nodes can be Ubuntu nodes. But a cluster with a mixture of CentOS and Ubuntu nodes is not supported.
- This procedure does not allow you to install the HPE Ezmeral Data Fabric for Kubernetes on a Kubernetes node that is also a node in a Data Fabric cluster. If a Kubernetes node already has Data Fabric software installed, installing the HPE Ezmeral Data Fabric for Kubernetes can cause issues with the running Data Fabric cluster. See Installing HPE Ezmeral Data Fabric and Kubernetes Software on the Same Nodes on page 295.

- Do not install the Data Fabric client on a node where the volume plug-in configuration file is installed. The Data Fabric client can be installed on a node in the Kubernetes cluster, but it must be installed **before** the HPE Ezmeral Data Fabric for Kubernetes is installed on the same Kubernetes cluster.

Installation Steps

Use these steps to install the configuration files:

1. Download the following configuration (`.yaml`) files from `https://package.ezmeral.hpe.com/tools/KubernetesDataFabric/v<version>/` to a directory on a node in the Kubernetes cluster:

File	Description
`kdf-namespace.yaml`	Configuration file for the `mapr-system` namespace, under which all Data Fabric components are installed.
`kdf-rbac.yaml`	RBAC configuration file. This file enables the provisioner to call the Kubernetes APIs that it needs to function.
• `kdf-plugin-centos.yaml` • `kdf-plugin-ubuntu.yaml` • `kdf-plugin-azure.yaml`[1] • `kdf-plugin-openshift.yaml`[2] • `kdf-plugin-gke.yaml`[3]	Configuration files used to install the plug-in. Download the plug-in file that matches your environment. You can use the CentOS configuration file for RHEL, CentOS, or SLES Kubernetes hosts.
`kdf-provisioner.yaml`	Configuration file used to install the provisioner inside the Kubernetes cluster.

[1]Before installing the `kdf-plugin-azure.yaml`, see Azure AKS Considerations on page 297.

[2]To install the `kdf-plugin-openshift.yaml`, see OpenShift Considerations on page 298.

[3]To install the `kdf-plugin-gke.yaml`, see Google Kubernetes Engine (GKE) Considerations on page 298.

2. In Kubernetes, use the `kubectl create` command with the `-f` option to create the namespace for the plug-in and provisioner:

   NOTE: The examples in this procedure assume that you are running each `kubectl create` command from the directory containing the downloaded configuration files.

```
kubectl create -f kdf-namespace.yaml
```

3. In Kubernetes, use the `kubectl create` command with the `-f` option to install the RBAC file:

   NOTE: Do not apply the RBAC file in OpenShift environments. See OpenShift Considerations on page 298.

```
kubectl create -f kdf-rbac.yaml
```

4. In the plug-in configuration file that you downloaded in step 1, set the Kubernetes service location and the FlexVolume plug-in path. To specify the Kubernetes service location, specify the external location and port of your API server. You can find the correct values by doing a `kubectl config view` and looking at the current context and then looking at the cluster selected for that context. This information is used to look up tickets:

   ```
   - name : KUBERNETES_SERVICE_LOCATION
     value: "changeme!:6443"
   ```

   If your Kubernetes environment has a nonstandard location for FlexVolume plug-ins (for example, Azure environments sometimes use a nonstandard location), specify the FLEXVOLUME_PLUGIN_PATH by changing the directory in the `value:` field:

   ```
   - name : FLEXVOLUME_PLUGIN_PATH
     value: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec"
   ```

5. Use the `kubectl create` command with the `-f` option to install the plug-in. The plug-in that you specify in the `create` command depends on your operating system environment:

   NOTE: When you issue the `kubectl create -f` command, a daemon set copies the plug-in to every node in the Kubernetes cluster.

   ```
   kubectl create -f kdf-plugin-centos.yaml
   ```

   or

   ```
   kubectl create -f kdf-plugin-ubuntu.yaml
   ```

   or

   ```
   kubectl create -f kdf-plugin-azure.yaml
   ```

   or

   ```
   kubectl create -f kdf-plugin-openshift.yaml
   ```

   or

   ```
   kubectl create -f kdf-plugin-gke.yaml
   ```

6. In Kubernetes, use the `kubectl create` command with the `-f` option to install the provisioner on a single node of the Kubernetes cluster. Kubernetes determines the node on which to install the provisioner.

   ```
   kubectl create -f kdf-provisioner.yaml
   ```

7. To begin using the HPE Ezmeral Data Fabric for Kubernetes, see Kubernetes FlexVolume Driver Configuration on page 3869.

Installing HPE Ezmeral Data Fabric and Kubernetes Software on the Same Nodes

Note: This feature is presented as a developer preview. Developer previews are not tested for production environments, and should be used with caution.

This section describes how to install the configuration files for the HPE Ezmeral Data Fabric for Kubernetes. In this configuration, Data Fabric and Kubernetes software can coexist on the same nodes if certain version requirements are met.

IMPORTANT: Some versions of the HPE Ezmeral Data Fabric for Kubernetes do not support installing Data Fabric and Kubernetes software on the same nodes. To ensure that you are using a version that supports this feature, see the Kubernetes Interfaces for Data Fabric Release Notes on page 6165.

Before Installation

Before installing the HPE Ezmeral Data Fabric for Kubernetes, note these preinstallation requirements:

- This procedure assumes that the Kubernetes cluster is already installed and functioning normally.
- Ensure that all Kubernetes nodes use the same Linux distribution. For example, all nodes can be CentOS nodes, or all nodes can be Ubuntu nodes. But a cluster with a mixture of CentOS and Ubuntu nodes is not supported.
- This procedure requires stopping Warden and Zookeeper on all nodes in the Data Fabric cluster and then restarting Warden and Zookeeper on all nodes. The steps cannot be performed online one node at a time.
- Do not install the Data Fabric client on a node where the volume plug-in configuration file is installed. The Data Fabric client can be installed on a node in the Kubernetes cluster, but it must be installed **before** the HPE Ezmeral Data Fabric for Kubernetes is installed on the same Kubernetes cluster.

CAUTION: Do not try to install the volume plug-in without following the steps below. Doing so can cause Data Fabric libraries to be overwritten.

Install the MapR 6.0.1 or Later Cluster on the Kubernetes Nodes

Use any of the methods described in Installing with the Installer on page 178 to install a Data Fabric 6.0.1 or later cluster on the existing Kubernetes nodes.

Install the MapR Data Fabric for Kubernetes

Use these steps to install the HPE Ezmeral Data Fabric for Kubernetes on the Kubernetes cluster:

1. Stop all running jobs on the Data Fabric cluster.
2. Stop Warden on all Data Fabric cluster nodes by running the following command on each node:

   ```
   service mapr-warden stop
   ```

3. Stop Zookeeper on all Data Fabric Zookeeper nodes by running the following command on each node:

   ```
   service mapr-zookeeper stop
   ```

4. Deploy the HPE Ezmeral Data Fabric for Kubernetes components by using steps 1 through 6 of Installing HPE Ezmeral Data Fabric and Kubernetes Software on Separate Nodes on page 292.

last-updated: Jun 06, 2024

5. Configure the `MAPR_SUBNETS` environment variable to ensure that Data Fabric software does not use the `docker0` network interface on each node. See Designating NICs for HPE Ezmeral Data Fabric on page 1156.

   If `MAPR_SUBNETS` is not set, the CLDB uses all NICs present on the node. When Docker is installed on a node, the`docker0` bridge is created as a virtual NIC for use by the Docker containers. You must configure the `MAPR_SUBNETS` setting to include the physical NICs that you want the CLDB to use and *exclude* the `docker0` network interface. In this way, you can avoid issues with duplicate or non-routable IP addresses. For more information about `docker0`, see Docker container networking.

6. Start Zookeeper on all Data Fabric Zookeepr nodes by running the following command on each node:

   ```
   service mapr-zookeeper start
   ```

7. Start Warden on all Data Fabric cluster nodes by running the following command on each node:

   ```
   service mapr-warden start
   ```

Pod Security Policies and the HPE Ezmeral Data Fabric for Kubernetes

If your Kubernetes administrator has turned on Pod Security Policies, you must create a PSP for the HPE Ezmeral Data Fabric for Kubernetes. You should use your organization's best practices for writing a PSP, but you must enable several parameters in the PSP for your `maprkdf` service account:

```
volumes:
    - 'hostPath'
    - 'flexVolume'
allowedHostPaths:
    - pathPrefix: "/opt"
    - pathPrefix: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec/"
    - pathPrefix: "/etc/kubernetes"
    - pathPrefix: "/etc/localtime"
 allowedFlexVolumes:
    - driver: mapr.com/maprfs
```

Here is an example of a PSP that would work:

```
# Copyright (c) 2009 & onwards. MapR Tech, Inc., All rights reserved
apiVersion: extensions/v1beta1
kind: PodSecurityPolicy
metadata:
  name: mapr-kdf-psp
spec:
  volumes:
    - 'configMap'
    - 'emptyDir'
    - 'projected'
    - 'secret'
    - 'downwardAPI'
    - 'persistentVolumeClaim'
    - 'hostPath'
    - 'flexVolume'
  allowedHostPaths:
    - pathPrefix: "/opt"
    - pathPrefix: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec/"
    - pathPrefix: "/etc/kubernetes"
    - pathPrefix: "/etc/localtime"
  allowedFlexVolumes:
    - driver: mapr.com/maprfs
```

last-updated: Jun 06, 2024

```
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
    rule: 'RunAsAny'
  fsGroup:
    rule: 'RunAsAny'
```

You enable a PSP for a ServiceAccount as part of a ClusterRole that is bound to the ServiceAccount. See Using RBAC Authorization. For example, add the `mapr-kdf-psp` to a ClusterRole like this:

```
- apiGroups: ['extensions']
    resources: ['podsecuritypolicies']
    verbs:     ['use']
    resourceNames:
    - mapr-kdf-psp
```

Azure AKS Considerations

Microsoft Azure turns on PodSecurityPolicies by default. This means you must create RBAC and PodSecurityPolicies for both the plug-in and any containers that call the plug-in.

Here is an example of a PSP. It is recommended that you adapt this PSP to the security best practices of your organization:

```
apiVersion: extensions/v1beta1
kind: PodSecurityPolicy
metadata:
  name: mapr-kdf-psp
spec:
  volumes:
    - 'configMap'
    - 'emptyDir'
    - 'projected'
    - 'secret'
    - 'downwardAPI'
    - 'persistentVolumeClaim'
    - 'hostPath'
    - 'flexVolume'
  allowedHostPaths:
    - pathPrefix: "/opt"
    - pathPrefix: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec/"
    - pathPrefix: "/etc/kubernetes"
    - pathPrefix: "/etc/localtime"
  allowedFlexVolumes:
    - driver: mapr.com/maprfs
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
    rule: 'RunAsAny'
  fsGroup:
    rule: 'RunAsAny'
```

Azure uses a non-standard FlexVolume path: `/etc/kubernetes/volumeplugins`. This path has already been changed in `kdf-plugin-azure.yaml`.

You must set the KUBERNETES_SERVICE_LOCATION for Azure. You can find the correct value by connecting to your Azure cluster using the `kubectl` interface. Use the `kubectl config view` command, and find the server name and port for the current context.

last-updated: Jun 06, 2024

In Azure, the Kubelet process is running inside a *hypercube* container. The MapR plug-in must run inside that container. This means that the plug-in log is somewhat hidden. To view the plug-in log:

```
docker ps <to find the hyperkube container>
docker exec -it <hyperkube container ID> /bin/bash
cd /opt/mapr/logs
cat plugin plugin-k8s.log
```

OpenShift Considerations

For OpenShift environments, the installation steps are the same as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 292. However, you must not apply the RBAC file. Instead run the following commands:

```
oc create -f kdf-openshift-sa.yaml
oc create -f kdf-openshift-scc.yaml
oc adm policy add-scc-to-user maprkdf-scc
system:serviceaccount:mapr-system:maprkdf
oc create -f kdf-openshift-cr.yaml
oc adm policy add-cluster-role-to-user mapr:kdf
system:serviceaccount:mapr-system:maprkdf
```

All other installation steps are the same.

Google Kubernetes Engine (GKE) Considerations

To create a Google Kubernetes Engine (GKE) cluster, you must use Ubuntu node images instead of CentOS.

The high-level installation steps are as follows:

1. Create a cluster with Ubuntu nodes.
2. Follow the steps later on this page to create a PodSecurityPolicy (PSP).
3. Install the namespace, as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 292.
4. Install the PSP.
5. Install the RBAC file, as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 292.
6. Modify the service location in the plug-in, as described later on this page.
7. Install the `kdf-plugin-gke.yaml`, as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 292
8. Install the provisioner, as described in Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 292

Creating a PSP

GKE turns on PodSecurityPolicies by default. This means that you must create Role-Based Access Control (RBAC) and PodSecurityPolicies for both the plug-in and any containers that call the plug-in. Before you can edit RBAC and PSPs in GKE, you have to give your `kubectl id` sufficient permissions. Assuming you have already logged into Google Cloud and connected your cluster to `kubectl`, you need to execute the following command:

```
gcloud info | grep Account
```

last-updated: Jun 06, 2024

The command returns an email address. Copy the email address into the following command:

```
kubectl create clusterrolebinding
yourname-cluster-admin-binding --clusterrole=cluster-admin --user=myname@exa
mple.org
```

If this command is successful, you will have permissions to create a Pod security policy. Here is an example of a PSP. It is recommended that you adapt this PSP to the security best practices of your organization:

```
apiVersion: extensions/v1beta1
kind: PodSecurityPolicy
metadata:
  name: mapr-kdf-psp
spec:
  volumes:
    - 'configMap'
    - 'emptyDir'
    - 'projected'
    - 'secret'
    - 'downwardAPI'
    - 'persistentVolumeClaim'
    - 'hostPath'
    - 'flexVolume'
  allowedHostPaths:
    - pathPrefix: "/opt"
    - pathPrefix: "/usr/libexec/kubernetes/kubelet-plugins/volume/exec/"
    - pathPrefix: "/etc/kubernetes"
    - pathPrefix: "/etc/localtime"
  allowedFlexVolumes:
    - driver: mapr.com/maprfs
  runAsUser:
    rule: 'RunAsAny'
  seLinux:
    rule: 'RunAsAny'
  supplementalGroups:
    rule: 'RunAsAny'
  fsGroup:
    rule: 'RunAsAny'
```

Nonstandard FlexVolume Path and Service Location

GKE uses a non-standard FlexVolume path: `/home/kubernetes/flexvolume`. This path has already been changed in `kdf-plugin-gke.yaml`. However, you must set the KUBERNETES_SERVICE_LOCATION for GKE. To do this, you must edit the `kdf-plugin-gke.yaml` file to specify the service location. You can find the correct value by connecting to your GKE cluster using the `kubectl` interface. Use the `kubectl config view` command, and find the server name and port for the current context.

Upgrading the MapR Data Fabric for Kubernetes

This section describes how to upgrade the plug-in and dynamic provisioner, or upgrade Pods with attached volumes.

Upgrading the Plug-in and Provisioner

Before upgrading the plug-in, stop any Pods using the plug-in. You may want to quiesce any traffic hitting the Pod before shutdown. Failure to shut down the Pods before replacing the plug-in can lead to the Pod not being able to access its data until it is restarted.

last-updated: Jun 06, 2024

Removing the plug-in does not kill existing Pods. The Pods should only lose their mounted storage when a new version of the plug-in is installed and the libraries used to communicate with MapR software are deleted.

Upgrading the provisioner does not require stopping Pods, but dynamic provisioning (creating MapR volumes for new PersistentVolumeClaims) will be unavailable during the provisioner upgrade.

Use these steps to upgrade the plug-in:

1. Stop any Pods using the the plug-in to be upgraded. Before shutting down the Pod, you might want to quiesce any traffic hitting the Pod.

   NOTE: If any Pods that use the MapR Data Fabric for Kubernetes are not shut down during the plug-in upgrade, those Pods will have mount access removed and will need to be deleted and re-created as new Pods. If existing Pods need to be removed or are stuck in the Terminating state, you can delete them forcefully by using the `kubectl delete pod` command:

   ```
   kubectl delete pod <pod-name> -n
   <pod-namespace> --force --grace-period=0
   ```

2. Download the new plug-in. See Downloads (FlexVolume) on page 292.

3. Delete the old plug-in:

   ```
   kubectl delete -f kdf-<old_plugin>.yaml
   ```

4. Deploy the new plugin:

   ```
   kubectl create -f kdf-<new_plugin>.yaml
   ```

Upgrading Pods with Attached Volumes

Pods with mounted volumes can be patched in place. See Update API Objects in Place Using kubectl patch. Volumes will disappear only when the Pod is deleted. Patching a Pod does not affect the mount. When a Pod is deleted, a volume disappears. However, if you delete a Pod using a PersistentVolume and you leave the PVC alive, you can remount the PersistentVolumeClaim and its PersistentVolume with a new Pod. In this scenario, there is no disruption or need to recreate the PersistentVolume.

Upgrading Core or EEP Components

Depending on your current configuration, you may choose to upgrade the release version (core), ecosystem components, clients, or monitoring components.

Getting Started with Upgrades

Most upgrades involve moving from one version of core to another version and upgrading Ecosystem Pack (EEP) components at the same time. To learn about the different methods you can use to execute this kind of upgrade, see Upgrade Workflows (Releases 6.x or 7.x to 7.7.0) on page 301.

Upgrading an EEP

To upgrade an ecosystem component, you must upgrade the EEP to which it belongs. EEPs can be upgraded when you upgrade core or independently of a core upgrade. If your core release supports multiple EEP versions, you might be able to upgrade to a different EEP without upgrading core. See EEP Support and Lifecycle Status on page 5728.

last-updated: Jun 06, 2024

If a component is supported by your current EEP, you can add the component at any time by using manual steps or the **Incremental Install** function of the Installer. See Upgrading Ecosystem Packs on page 346.

Upgrading Data Fabric Clients

The Data Fabric client is a part of core. You upgrade client nodes after you upgrade the cluster nodes but before enabling new features. See Planning Upgrades to Data Fabric Clients on page 312.

Upgrading Monitoring

Monitoring components are available as part of the Ecosystem Pack (EEP) that you selected for the cluster. Once Monitoring is installed, you can upgrade Monitoring components as part of the EEP upgrade process. You can upgrade a EEP without having to upgrade core, provided the EEP you plan to upgrade to is supported by the current release. See Upgrading Ecosystem Packs on page 346.

Upgrade Workflows (Releases 6.x or 7.x to 7.7.0)

This section describes three common methods for upgrading from one core release to another. The workflows in this section introduce you to the high-level steps for each method and provide links to pages showing more detail.

Workflow: Manual Rolling Upgrade from Release 6.x or 7.x to 7.7.0

This page summarizes the steps for upgrading from release 6.1.x or 6.2.0 or 7.x to release 7.7.0 by using a manual rolling upgrade. In this workflow, the cluster to be upgraded is secure; after the upgrade, the cluster will continue to be secure.

Manual Rolling Upgrade Summary

In a manual rolling upgrade, you upgrade the software one node at a time so that the cluster as a whole remains operational throughout the process. The manual rolling upgrade requires you to:

1. Perform pre-upgrade checks.
2. Perform a rolling upgrade of core.
3. Verify that all use cases are functional on the cluster.
4. Upgrade the EEP to 9.2.2.
5. Merge custom configuration settings.
6. Enable 7.7.0 features.
7. Perform post-upgrade checks.

The workflow later in this section provides more detail to help you get started with a manual rolling upgrade.

Considerations for Manual Rolling Upgrades

Before performing a manual rolling upgrade, note these considerations:

- Rolling upgrades only upgrade core packages, not ecosystem components. A rolling upgrade of ecosystem components is not supported.
- If you choose to do a rolling upgrade on a cluster with core and ecosystem components, the ecosystem components will continue to work during the rolling upgrade as long as the ecosystem components are not updated. If you choose to upgrade core and ecosystem components together, the ecosystem components might not function properly during the upgrade process.

- After upgrading core to release 7.7.0, you must upgrade ecosystem components to EEP 9.2.2 or later, and this must be done before you enable 7.7.0 features.

Manual Rolling Upgrade Workflow

High-Level Steps	Detailed Information (review all items unless noted otherwise)
1. Understand Core/MEP Dependencies	• Operating System Support Matrix on page 5719 • EEP Support and Lifecycle Status on page 5728 • Component Versions for Released EEPs on page 5750
2. Plan for the Core Upgrade	• Upgrading and Your License on page 308 • Installation Notes (Release 7.7) on page 34 • Upgrade Notes (Release 7.7) on page 37 • Planning Your Core Upgrade on page 309
3. Plan for the EEP Upgrade	• Planning Ecosystem Pack (EEP) Upgrades on page 346
4. Perform Pre-Upgrade Steps for Core	• Preparing to Upgrade Core on page 315
5. Prepare to Upgrade EEP Components	• Preparing to Upgrade the Ecosystem Pack on page 347
6. Set up Repositories	• Setting Up Repositories on page 322
7. Perform the Manual Rolling Upgrade	• Manual Rolling Upgrade Description on page 327 • Manual Rolling Upgrade Procedure on page 329

last-updated: Jun 06, 2024

High-Level Steps	Detailed Information (review all items unless noted otherwise)
8. Upgrade the EEP Components	• Upgrading the Ecosystem Pack Without the Installer on page 366
9. Perform Post-Upgrade Steps for EEP	• Finishing the Ecosystem Pack Upgrade on page 386
10. Perform Post-Upgrade Steps for Core	• Restart and Check Cluster Services • Manually Update Configuration Files • Upgrade Clients • Enable New Features
11. Install Additional Core Features	• Installing Additional Core Features on page 345  **NOTE:** This page includes the steps to generate Object Store certificates by using `manageSSLKeys.sh`. The certificates must be generated after upgrading and running `configure.sh -R`. If you fail to generate the certificates, you will not be able to use the Object Store.
12. Secure the Upgraded Cluster	• Securing the Upgraded Cluster on page 346

Workflow: Offline Manual Upgrade from Release 6.x or 7.x to 7.7.0
This page summarizes the steps for upgrading from release 6.1.x or 6.2.0 or 7.x to 7.7.0 by using the offline manual upgrade. In this workflow, the cluster to be upgraded is secure; after the upgrade, the cluster will continue to be secure.

Offline Manual Upgrade Summary

In an offline manual upgrade, cluster processes and the jobs that depend on them are stopped on all nodes so that packages can be updated. The offline upgrade process is simpler than a rolling upgrade, and usually completes faster. The offline manual upgrade requires you to:

1. Perform pre-upgrade checks.
2. Shut down the cluster.
3. Upgrade core to release 7.7.0.
4. Upgrade the EEP to 9.2.2.
5. Merge custom configuration settings.
6. Start the cluster and perform post-upgrade checks.

7. Enable core 7.7.0 features.

The workflow later on this page provides more detail to help you get started with an offline manual upgrade.

Considerations for Offline Manual Upgrades

Before performing an offline manual upgrade, note the following considerations:

NOTE: After upgrading core to release 7.7.0, you must upgrade ecosystem components to an EEP that is compatible with 7.7.0. This must be done before you enable release 7.7.0 features. To determine the compatible EEPs, see EEP Support and Lifecycle Status on page 5728.

- The offline upgrade procedure requires an outage of the entire cluster. During the maintenance window, the administrator:
  - Stops all jobs on the cluster.
  - Stops all cluster services.
  - Upgrades packages on all nodes (which can be done in parallel).
  - Brings the cluster back online at once.

Offline Manual Upgrade Workflow

High-Level Steps	Detailed Information (review all items unless noted otherwise)

The certificates must be generated after upgrading and running `configure.sh -R`. If you fail to generate the certificates, you will not be able to use the Object Store.
12. Secure the Upgraded Cluster	• Securing the Upgraded Cluster on page 346

Workflow: Installer Upgrade from Release 6.x or 7.x to 7.7.0
This page summarizes the steps for upgrading from core 6.1.x or 6.2.0 or 7.x to 7.7.0 by using the Installer.

last-updated: Jun 06, 2024

NOTE: Nonsecure clusters are not supported in release 7.1.0 and later. In this workflow, if the cluster to be upgraded is nonsecure; after the upgrade, the cluster will continue to be nonsecure and must be secured by using the **Incremental Install** function of the Installer.

Installer Upgrade Summary

In an upgrade using the Installer, the Installer shuts down core on the entire cluster, upgrades and configures core, starts core, upgrades EEP components, and then starts the EEP components. Like the offline manual upgrade, the Installer upgrade is an *offline* upgrade. The Installer upgrade requires you to:

1. Plan for the upgrade.
2. Update the Installer to version 1.18.0.6.
3. Launch the Installer and select **Version Upgrade**.
4. Complete the upgrade through the Installer.
5. Manually merge custom configuration settings.
6. Perform post-upgrade checks.

The workflow later on this page provides more detail to help you get started with the Installer upgrade.

Considerations for Installer Upgrades

Before upgrading using the Installer, note these considerations:

- Upgrades using the Installer are supported only from release 6.1.x or later.
- Security settings cannot be changed during a version upgrade using the Installer.
- Before upgrading using the Installer, you must update the installer to version 1.18.0.6 or later.
- This procedure assumes that the cluster was originally installed using the Installer or an Installer Stanza. If the cluster was installed manually, you must use the manual steps to upgrade or use probe and import to generate the installer database.

12. Secure the Upgraded Cluster	• Securing the Upgraded Cluster on page 346

Upgrading Core

Describes the process of upgrading core.

Upgrading core typically includes upgrading:

- Core
- Ecosystem Components
- Data Fabric Clients

Upgrading core means you will need to upgrade to a Ecosystem Pack (EEP). For example, upgrading to release 7.2 requires you to upgrade to EEP 9.1.0 or later before you can enable release 7.2 features.

The steps for upgrading a EEP are in another section of this guide because EEPs can be upgraded independently of the core version. The following procedures prompt you when it is necessary to plan for or upgrade a EEP.

Upgrading core consists of the following steps:

1. Planning the Upgrade – Determine the upgrade method, when to upgrade, and whether ecosystem components or data-fabric clients need to be upgraded along with core.
2. Preparing to Upgrade – Prepare the cluster for upgrade while it is still operational. This includes pre-upgrade steps for core and ecosystem components.
3. Upgrading the Cluster
   - Upgrading with the Installer - Use a web interface that automates the upgrade of core and ecosystem components.
   - Upgrading without the Installer - Perform steps to upgrade core and manually upgrade each ecosystem component.
4. Finishing the Upgrade -Complete the post-upgrade steps for core and any ecosystem components that you upgraded.
5. Upgrading data-fabric clients – Perform steps to upgrade the data-fabric client.

NOTE: In this document, the *existing* version refers to the release version that you are upgrading *from* and the *new* version refers to the release version that you are upgrading to.

Instructions in the following sections guide you through each upgrade step:

Upgrading and Your License
You do not need a new license to upgrade an HPE Ezmeral Data Fabric cluster. However, it's a good idea to check your cluster license periodically and renew the license before it expires.

last-updated: Jun 06, 2024

Checking Your Cluster License

To view license information on your cluster, see Viewing the Licenses on the Cluster on page 1080.

For HPE Ezmeral Data Fabric licensing information, see Product Licensing on page 6199.

Related tasks

Core Upgrade Process

When you upgrade core, you will also upgrade a number of cluster components.

The following cluster components are upgraded with core:

- Storage Layer: file system fileserver and Container Location Database (CLDB) services
- Cluster Management Services: ZooKeeper and Warden
- NFS server
- Web server, including the Control System user interface and REST API to cluster services
- The `maprcli` commands for managing cluster services
- Any new features and performance enhancements introduced with the new version.

When you upgrade core, the following changes occur within the `/opt/mapr` directory:

- If required, additional folders are added.
- Product binaries are replaced by binaries associated with the new version.
- Existing configuration files remain in the active directory and default configuration files associated with the new version are installed in a new directory:

Default Configuration File Directories	Active Configuration File Directories
`/opt/mapr/conf.new`	`/opt/mapr/conf`
`/opt/mapr/conf/conf.d.new`	`/opt/mapr/conf/conf.d`

Shows the Hadoop RPC protocol version and compatible Data Fabric client versions for each release.

Planning Your Core Upgrade

Describes how to develop a successful plan for your upgrade process.

The key to a successful upgrade process is to plan the process ahead of time. This page helps you develop an upgrade process that fits the needs of your cluster and users.

Choosing a Cluster Upgrade Method

Supported upgrade methods are:

- Manual rolling upgrade

- Offline manual upgrade
- Offline upgrade using the Installer

Upgrade Workflows (Releases 6.x or 7.x to 7.7.0) on page 301 describes these methods in more detail. The method you choose affects the flow of events while upgrading packages on nodes and the duration of the maintenance window.

Offline Upgrade

The offline upgrade process is simpler than a rolling upgrade, and usually completes faster. In an offline upgrade, data-fabric software processes and the jobs that depend on them are stopped on all nodes so that packages can be updated. Offline upgrade is the default upgrade method when other methods cannot be used.

Offline Upgrade Paths without the Installer

You can perform an offline upgrade from the following core versions:

- Release 7.x
- Release 6.x
- Release 5.x
- Release 4.1
- Release 4.0.x
- Release 3.x

NOTE: After upgrading core to release 6.0 or later, you must upgrade ecosystem components to an EEP that is compatible with your core 6.0 or later release. To determine the compatible EEPs, see EEP Support and Lifecycle Status on page 5728. This must be done before you enable core features.

During the maintenance window, the administrator:

- Stops all jobs on the cluster.
- Stops all cluster services.
- Upgrades packages on all nodes (which can be done in parallel).
- Brings the cluster back online at once.

Rolling Upgrade

In a manual rolling upgrade, you upgrade the data-fabric software one node at a time so that the cluster as a whole remains operational throughout the process. The fileserver service on each node goes offline while packages are upgraded, but its absence is short enough that the cluster does not raise the data-under-replication alarm.

The following restrictions apply to rolling upgrades:

- In release 6.0 and later, only manual rolling upgrades are supported. Scripted rolling upgrades are not supported.
- Rolling upgrades only upgrade core packages, not ecosystem components. A rolling upgrade of ecosystem components is not supported.

last-updated: Jun 06, 2024

- If you choose to do a rolling upgrade on a cluster with core and ecosystem components, the ecosystem components will continue to work during the rolling upgrade as long as the ecosystem components are not updated. If you choose to upgrade core and ecosystem components together, the ecosystem components might not function properly during the upgrade process.
- The administrator should block off a maintenance window, during which only critical jobs are allowed to run and users expect longer-than-average run times.

Rolling Upgrade Paths

You can perform a manual rolling upgrade from only the following core versions:

- Release 5.2.x with EEP 3.0.1 or later
- Release 6.x with EEP 4.0.0 or later
- Release 7.x with EEP 8.1.0 or later

NOTE: After upgrading core, you must upgrade ecosystem components to EEP 4.0.0 or later, and this must be done before you enable release 6.x or later features. To determine the EEP required by your release, see EEP Support and Lifecycle Status on page 5728.

Updating the JDK

Check the JDK Support Matrix to verify that your JDK version is supported by the core version to which you are upgrading. Releases 6.0 and 6.1 require JDK 8. Release 6.2.0 and later require JDK 11 or JDK 17. For more information, see the JDK Support Matrix.

Planning for Security

Security is not enabled by default for upgrades. During an upgrade, the security attributes of your cluster are preserved unless you decide to change them. Note that if you have configured security on a release 5.2.x cluster, you cannot use the Installer or Stanzas to upgrade. You must upgrade manually. For information about custom security, see Customizing Security in HPE Ezmeral Data Fabric on page 1939.

Before upgrading core software, make sure that you have reviewed the list of known vulnerabilities in Security Vulnerabilities on page 6184. If a vulnerability applies to your release, contact your HPE support representative for a fix, and apply the fix immediately, if applicable.

Scheduling the Upgrade

Consider the following factors when scheduling the upgrade:

- When will preparation steps be performed? How much of the process can be performed before the maintenance window?
- What calendar time would minimize disruption in terms of workload, access to data, and other stakeholder needs?
- How many nodes need to be upgraded? How long will the upgrade process take for each node, and for the cluster as a whole?
- When should the cluster stop accepting new non-critical jobs?
- When (or will) existing jobs be terminated?
- How long will it take to clear the pipeline of current workload?
- Will other Hadoop ecosystem components (such as Hive) get upgraded during the same maintenance window?

last-updated: Jun 06, 2024

- When and how will stakeholders be notified?

Planning Upgrades to Data Fabric Clients

Determine if you need to upgrade data-fabric client nodes. You upgrade data-fabric client nodes after you upgrade the cluster nodes but before enabling new features.

Data Fabric Client Nodes

On each data-fabric client node, upgrade to the client version that is compatible with the operations that you want to perform on the cluster. The following table shows which supported client operations are available based on the client version and the cluster version.

POSIX Client Nodes

On POSIX client nodes, the only supported client operation is file system access. As of release 5.1, FUSE-based POSIX clients are available in addition to loopback NFS clients.

POSIX loopback NFS clients can be upgraded, or a fresh install can be performed.

See Upgrading the Data Fabric POSIX loopbacknfs Client on page 338 for more information.

NOTE: Basic and Platinum POSIX client packages are recommended for fresh installation and for all new clusters.

The following table shows which loopback NFS client versions are supported by which data-fabric clusters. For example, the release 6.0 cluster supports 4.0.2, 4.1, 5.0, 5.1, and 5.2 loopback NFS clients.

Table

	7.x Client	6.x Client
7.x Cluster	Yes	Yes
6.x Cluster	Yes	Yes

Determining Cross-Cluster Feature Support

HPE Ezmeral Data Fabric supports features that operate on more than one cluster. Before you upgrade, consider the impact of the following cross-cluster features:

Volume Mirroring	Volume mirroring works from a lower version to a higher version irrespective of the features that you enable on the higher version. For example, you can mirror volumes from a release 6.1 cluster to a release 6.2 cluster irrespective of whether or not you have enabled the new features present in the release 6.2 version. However, volume mirroring from a higher release version to a lower release version works only when you enable identical sets of features on both clusters. For example, you can mirror volumes from a release 6.2 cluster to a release 6.1 cluster only if you do not enable new features that are present on the release 6.2 cluster.
Table Replication	Table replication works between clusters of different versions as long as both versions support HPE Ezmeral Data Fabric Database table replication. For example, you can replicate HPE Ezmeral Data Fabric Database binary tables from a release 6.2 cluster to a release 6.0 cluster.

last-updated: Jun 06, 2024

NOTE: As of release 5.2, HPE Ezmeral Data Fabric Database JSON table replication is also supported. You cannot replicate HPE Ezmeral Data Fabric Database JSON tables to a cluster that runs a version prior to release 5.2.

Policy-Based Security	An upgraded data-fabric platform has all the policy-based security features set to the default values: • Upgraded volumes are not tagged with any security policies, and have the `enforcementMode` setting at its default (`PolicyAceAndDataAce`). Determination of access rights is based on the existing access determination algorithm: `Grant access if Permitted(mode bits) OR Permitted(ACE)` • Files and directories are not tagged with any security policies. • After enabling the policy-based security feature, use the `maprcli`, extended attribute commands, and other Java, C, and Hadoop APIs to tag volumes, files, and directories.

Planning for the Ecosystem Pack

To plan for the Ecosystem Pack (EEP), see Planning Ecosystem Pack Upgrades.

What's Next

Go to Preparing to Upgrade Core on page 315.

When Upgrading Core with the Installer Requires an OS Upgrade

Helps you decide if an OS upgrade is needed when you are using the Installer to upgrade to core 7.0.0 or later.

IMPORTANT: Installer 1.18.0.3 supports core upgrades only from release 7.3.0 to 7.4.0. All EEP upgrades are supported. The Installer cannot be used on some OS versions. For details, see Installer Support Matrix on page 5770. To upgrade core or EEP manually, see these topics:

- Upgrading Core Without the Installer on page 322
- Upgrading the Ecosystem Pack Without the Installer on page 366

OS Versions Supported by Core 7.x

Some upgrades to core 7.x require upgrading the cluster operating system. For supported OS versions, see Operating System Support Matrix on page 5719.

OS Upgrade Not Required

If the Linux OS for your cluster is supported for core 7.x, you do NOT need to upgrade the OS before you upgrade core. For example, if your cluster runs core 6.2.0 on Ubuntu 18.04 and you want to upgrade to core 7.x on 18.04, you can perform the upgrade entirely through the Installer by using the **Version Upgrade** feature. See Upgrading Core With the Installer on page 320.

last-updated: Jun 06, 2024

OS Upgrade Required

If the Linux OS for your cluster is not supported for core 7.x, you must upgrade the Linux OS before upgrading to core 7.x. Use the following steps. After upgrading the OS, you can use the Installer to complete the upgrade to core 7.x:

1. Make sure you are using the latest version of the Installer, which is required for core 7.x. For more information, see Selecting an Installer Version to Use on page 5587.
2. Apply the latest core patch on all nodes of the cluster to be upgraded. See Applying a Patch on page 473.
3. Shut down the cluster as described in one of these topics:
   - Shutting Down a Cluster on page 1101
   - Shutting Down a Cluster Using the Installer Shutdown Button on page 5633
4. On the *Installer node*, shut down the Installer (requires `root` authentication):

   ```
   systemctl stop mapr-installer
   ```

   For more information about the Installer, see Installer on page 5579.
5. On all cluster nodes, upgrade the OS to one of the supported versions mentioned earlier on this page. For upgrade information, see Upgrading Your Linux Operating System on page 314.
6. On the Installer node, check the Installer status to see if it is started:

   ```
   systemctl status mapr-installer
   ```

7. If the Installer isn't started, start it (requires `root` authentication):

   ```
   systemctl start mapr-installer
   ```

8. Continue with the upgrade workflow using the Installer. See Upgrading Core With the Installer on page 320.

Related concepts

Starting and Stopping the Installer on page 5670
Describes how and when you need to shut down and restart the Installer.

Upgrading Your Linux Operating System

Upgrading to a new release of the HPE Ezmeral Data Fabric sometimes requires you to upgrade your Linux operating system. This page has pointers to more information about OS upgrades.

For a list of the Linux operating systems on which you can install the HPE Ezmeral Data Fabric, see Operating System Support Matrix on page 5719. The links provided on this page are only suggestions. This information has not been validated by HPE and is not guaranteed to be appropriate for your installation.

Upgrading Red Hat Enterprise Linux Software

After Upgrading Your Linux Operating System

After upgrading your Linux operating system, HPE recommends that you run the `configure.sh` script with the `-R` option on each node in the cluster:

```
/opt/mapr/server/configure.sh -R
```

Then you can restart the Data Fabric services on each node.

Preparing to Upgrade Core

Complete these pre-upgrade steps for core.

Upgrade a test cluster before upgrading your production cluster. After you have planned your upgrade process, prepare the cluster for upgrade while your existing cluster is fully operational. Prepare to upgrade as described in this section to minimize downtime and eliminate unnecessary risk. Design and run health tests and back up critical data. Performing these tasks during upgrading reduces the number of times you have to touch each node, but increases down-time during upgrade.

Complete the following pre-upgrade steps:

1. Verify System Requirements for All Nodes

Verify that all nodes meet the following minimum requirements for the new version of core software:

- **Software dependencies.** Package dependencies in the HPE Ezmeral Data Fabric distribution can change from version to version. If the new HPE Ezmeral Data Fabric version has dependencies that were not present in the older version, you must address them on all nodes before upgrading your software. Installing dependency packages can be done while the cluster is operational. See Package Dependencies on page 103. If you are using a package manager, you can specify a repository that contains the dependency package(s), and allow the package manager to automatically install them when you upgrade the HPE Ezmeral Data Fabric packages. If you are installing from package files, you must pre-install dependencies on all nodes manually.
- **Hardware requirements.** The newer version of packages might have greater hardware requirements. Hardware requirements must be met before upgrading.
- **OS requirements.** HPE Ezmeral Data Fabric OS requirements do not change frequently. If the OS on a node doesn't meet the requirements for the newer HPE Ezmeral Data Fabric version, plan to decommission the node and re-deploy it with an updated OS after the upgrade. See Operating System Support Matrix on page 5719.

last-updated: Jun 06, 2024

- **Certificate requirements.** Recent versions of Safari and Chrome web browsers have removed support for older certificate cipher algorithms, including those used by some HPE Ezmeral Data Fabric versions. For more information about resolving this issue, see Unable to Establish a Secure Connection on page 6186.

2. Design Health Checks

Plan what kind of test jobs and scripts you will use to verify cluster health as part of the upgrade process. You will verify cluster health several times before, during, and after upgrade to ensure success at every step, and to isolate issues whenever they occur. Create both simple tests to verify that cluster services start and respond, as well as non-trivial tests that verify workload-specific aspects of your cluster.

Design Simple Tests

Here are a few examples of simple tests you can design to check node health:

- Use maprcli commands to see if any alerts exist and to verify that services are running as expected. For example:

```
# maprcli node list -columns svc
hostname
service                                                 ip
labnode55
nodemanager,cldb,fileserver,hoststats                   10.10.82.55
labnode56
nodemanager,fileserver,hoststats                        10.10.82.56
labnode57
fileserver,nodemanager,hoststats                        10.10.82.57
labnode58
fileserver,nodemanager,webserver,hoststats              10.10.82.58
                        ...lines deleted...
                        # maprcli alarm list
                        alarm state
description
                         entity    alarm name
alarm statechange time
                        1            One or more licenses is about to
expire within 25 days
CLUSTER   CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION   1366142919009
                        1            Can not determine if service: nfs is
running. Check logs at: /opt/mapr/logs/nfsserver.log         labnode58
NODE_ALARM_SERVICE_NFS_DOWN            1366194786905
```

  In this example, you can see that an alarm is raised indicating that HPE Ezmeral Data Fabric software expects an NFS server to be running on node `labnode58`, and the node list of running services confirms that the nfs service is not running on this node.

- Batch create a set of test files.
- Submit a MapReduce application.
- Run simple checks on installed Hadoop ecosystem components. For example, run a Hive query.

Design Non-trivial Tests

Appropriate non-trivial tests are specific to your particular cluster workload. You may have to work with users to define an appropriate set of tests. Run tests on the existing cluster to calibrate expectations for “healthy” task and job durations. On future iterations of the tests, inspect results for deviations. Some examples:

- Run performance benchmarks relevant to the cluster’s typical workload.

last-updated: Jun 06, 2024

- Run a suite of common jobs. Inspect for correct results and deviation from expected completion times.
- Test correct inter-operation of all components in the Hadoop stack and third-party tools.
- Confirm the integrity of critical data stored on the cluster.

3. Verify Cluster Health

Run the test you designed in step 2 to verify the cluster health prior to upgrade.

- Run the suite of simple tests to verify that basic features of the core are functioning correctly, and that any alarms are known and accounted for.
- Run the suite of non-trivial tests to verify that the cluster is running as expected for a typical workload, including integration with Hadoop ecosystem components and third-party tools.

Proceed with the upgrade only if the cluster is in an expected, healthy state.

4. Back Up Critical Data

Data in the cluster persists across upgrades from version to version. However, as a precaution, you might want to back up critical data before upgrading. If you deem it practical and necessary, you can do any of the following:

- Copy data out of the cluster using `distcp` to a separate, non-Hadoop datastore.
- Mirror critical volume(s) into a separate HPE Ezmeral Data Fabric cluster, creating a read-only copy of the data which can be accessed via the other cluster.

When services for the new version are activated, the file system will update data on disk automatically. The migration is transparent to users and administrators. Once the cluster is active with the new version, you cannot roll back.

5. Run Your Upgrade Plan on a Test Cluster

Before executing your upgrade plan on the production cluster, perform a complete *dry run* on a test cluster. You can perform the dry run on a smaller cluster than the production cluster, but make the dry run as similar to the real-world circumstances as possible. For example, install all Hadoop ecosystem components that are in use in production, and replicate data and jobs from the production cluster on the test cluster. The goals for the dry run are:

- Eliminate surprises. Get familiar with all upgrade operations you will perform as you upgrade the production cluster.
- Uncover any upgrade-related issues as early as possible so you can accommodate them in your upgrade plan. Look for issues in the upgrade process itself, as well as operational and integration issues that could arise after the upgrade.

6. Pause Cross-Cluster Operations

Complete the steps for each cross-cluster feature used by this cluster:

- **Volume Mirroring.** If volumes from another cluster are mirrored on this cluster, use one of the following options to stop the mirroring of volumes on this cluster:

Using the Control System	See Stopping the Mirror on page 1238.
Using a `maprcli` command	Run the `maprcli volume mirror stop` command on this cluster. See volume mirror stop on page 2675.

- **Table Replication.** If source tables on this cluster are replicated to tables on another cluster, pause the replication of tables on this cluster. Use one of the following options for each source table on this cluster:

Using the Control System	**1.** Log in to the Control System and go to the source table information page. **2.** On the Replications tab associated with the source table, select each replica and then click **Actions** > **Pause Replication** > **.**
Using a `maprcli` command	Run the `maprcli table replica pause` command. See table replica pause on page 2516.

NOTE: Once you have completed the core upgrade and the Post-Upgrade Steps for Core on page 332, you can resume cross-cluster operations.

7. Back up Configuration Files

If you plan to upgrade from release 7.0.0 to 7.1.0 or later, create a backup copy of the following files in the `/opt/mapr/conf` directory:

- `moss.conf`
- `s3cfg`
- `moss-core-site.xml`

After the upgrade, you must copy these files back to the `/opt/mapr/conf` directory on any node running the Multithreaded Object Store Server (MOSS). The copy operation can be done as a step in finishing the core upgrade. See Installing Additional Core Features on page 345.

If you are upgrading the FUSE-based POSIX client on Ubuntu, create a backup copy of your custom settings in the `fuse.conf` file in `/opt/mapr/conf` directory. If you do not create a backup copy, you might lose your custom settings for the POSIX client because the new `fuse.conf` file with default settings will overwrite your current `fuse.conf` file with custom settings.

If you are upgrading the FUSE-based POSIX client on other supported operating systems, during upgrade the software automatically sets up the `fuse.conf.backup` file in addition to the new `fuse.conf` file in the `/opt/mapr/conf` directory.

Consider creating the `env_override.sh` file to store custom settings for environmental variables. Upgrading to a new release causes the `env.sh` file to be replaced and removes any custom settings. Creating the `env_override.sh` file can simplify the management of environmental variables. For more information, see About env_override.sh on page 3077.

8. Migrate from MapReduce Version 1

MapReduce version 1 (MRv1) is deprecated for MapR 6.0 or later. If you were previously using MRv1, you must prepare your cluster to run MapReduce version 2 (MRv2) applications before upgrading to core 6.0 or later:

- Ensure that the MapReduce mode on your cluster is set to `yarn`. MRv2 is an application that runs on top of YARN.
- Uninstall all packages associated with MRv1.

For more information about how to prepare your cluster to run MRv2 applications, see Migrating from MapReduce Version 1 to MapReduce Version 2 on page 319.

last-updated: Jun 06, 2024

9. Migrate from Mahout and Storm

Mahout and Storm are not supported on core 6.0 or later. Before the upgrade, disable applications that use these components, and remove the Mahout and Storm packages. To view the ecosystem components supported on data-fabric releases, see Component Versions for Released EEPs.

Pig, Flume, Sqoop, and other components are not supported in EEP 8.1.0 and later. For more information, see Discontinued Ecosystem Components on page 5748.

10. Prepare to Upgrade the Ecosystem Pack

Complete the pre-upgrade steps in Preparing to Upgrade the Ecosystem Pack. Then return to this section.

What's Next

Go to Upgrading Core With the Installer on page 320 or Upgrading Core Without the Installer on page 322.

Migrating from MapReduce Version 1 to MapReduce Version 2
If you previously ran MRv1 jobs on your cluster, prepare your cluster to run YARN applications in Data Fabric 6.0 or later.

Configuring the MapReduce Mode

Client and cluster nodes submit MapReduce applications to the YARN framework (`yarn` mode) unless you configure them to use the classic framework (`classic` mode). Because MapReduce version 1 (MRv1) is deprecated for Data Fabric 6.0 and later, you can no longer submit MRv1 jobs using `classic` mode. If you previously configured your client and cluster nodes to use `classic` mode, you must prepare your cluster to run YARN applications in Data Fabric 6.0 or later. Before upgrading to Data Fabric 6.0 or later, ensure that the MapReduce mode is set to `yarn` in the environment variable, on client nodes, and on the cluster.

Configure the MapReduce mode for the following components:

Component	How to Change the Mode to `yarn`:
Environment Variable	Set the MapReduce mode in an environment variable: **1.** Open a terminal on the client node. **2.** Enter the following command on the shell: `export MAPR_MAPREDUCE_MODE=yarn`
Client	In the hadoop_version file on a Data Fabric client node, verify the MapReduce mode is set to `yarn`. **1.** Open the hadoop_version file in the following location: `/opt/mapr/conf/` **2.** If the default_mode parameter is set to `classic`, change it to `yarn`: `default_mode=yarn`.

Component	How to Change the Mode to `yarn`:
Cluster	Run the following command to display the cluster-wide mode: `maprcli cluster mapreduce get`. If the cluster is set to `classic` mode, use the command line or the Control System to set it back to the `yarn`default for all nodes in the cluster: • To set the cluster's MapReduce mode using `maprcli`: 1. Run the following command: `maprcli cluster mapreduce set -mode yarn`. • To set the cluster's MapReduce mode in the Control System: 1. Log in to the Control System. 2. Perform one of the following operations: • In the header area, click the link that contains the current MapReduce version. • In the **System Settings** view of the Navigation Pane, click **MapReduce Version.** 3. In the **Configure MapReduceMode** dialog, select the `yarn` option for the cluster. 4. Click **OK**.

Uninstalling MRv1 Packages

After verifying that the MapReduce mode is set to `yarn`, uninstall the packages associated with MRv1:

- `mapr-jobtracker`
- `mapr-tasktracker`
- `mapr-metrics`

The following table lists uninstall commands by operating system. Use these commands to uninstall the above packages:

Operating System	Uninstall Command
Ubuntu	`apt-get remove <package name>`
CentOS/RedHat:	`yum remove <package name>`
SLES	`zypper rm <package name>`

Upgrading Core With the Installer

If the cluster that you want to upgrade was installed using the Installer, use the Installer to upgrade core.

last-updated: Jun 06, 2024

Prerequisites

IMPORTANT: Installer 1.18.0.3 supports core upgrades only from release 7.3.0 to 7.4.0. All EEP upgrades are supported. To upgrade core or EEP manually, see these topics:

- Upgrading Core Without the Installer on page 322
- Upgrading the Ecosystem Pack Without the Installer on page 366

Before you begin, review Planning Your Core Upgrade on page 309, and verify that your cluster is prepared for an upgrade. In some cases, a maintenance update can be performed rather than a version upgrade. For more information, see Performing a Maintenance Update on page 5635

WARNING: The **Version Upgrade** operation is an *offline* operation. Service failures, job failures, or the loss of customized configuration files can occur if you do not perform the steps to prepare the cluster for an upgrade.

About this task

Procedure

1. Update the Installer. For more information, see Updating the Installer on page 5595.
   This step ensures that the Installer has access to the latest packages.
2. Halt jobs and applications. Stop accepting new jobs and applications, and stop YARN applications.

   ```
   # yarn application -list
   # yarn application -kill <ApplicationId>
   ```

   You might also need specific commands to terminate custom applications.
3. Launch the Installer URL (`https://<hostname/IPaddress>:9443`)
4. Select the **Version Upgrade** option to complete the upgrade through the Installer. The installer allows you to specify the core version, the Ecosystem Pack (EEP) version, and the components and services you want to install.

last-updated: Jun 06, 2024

NOTE:

- Incorporate a brief delay when you use the **Version Upgrade** screen. After specifying the core version, the EEP version, and the services you need, wait a minute or two before clicking **Next** to advance to the next screen. This delay gives the Installer time to process the selections that you made.
- Do not refresh the browser page during the upgrade sequence. Doing so can cause errors. For more information, see IN-1915 in MapR Installer Known Issues.
- If you upgrade a non-secure cluster to release 6.0.1 or later and metrics monitoring is enabled, the Installer asks you to specify a password for the Grafana administrator ID (`admin`). You must specify a password. For more information about Grafana password requirements, see Logging on to Grafana on page 1752.
- If the Installer indicates that the version upgrade failed, or if the following error message is displayed, use the **Import State** command to revert the cluster to the last known state. See Importing or Exporting the Cluster State on page 5634.

```
Custom secure cluster < MapR core 6.0.0 cannot be upgraded
```

5. Once the upgrade through the Installer is complete, perform the post-upgrade steps. See Finishing the Core Upgrade on page 332.

Upgrading Core Without the Installer
You can upgrade core without using the Installer.

First, you perform an offline or rolling upgrade of the data-fabric core manually. Next, you configure the new version to enable support of data-fabric core features. Finally, you upgrade ecosystem components manually.

Before upgrading, be sure to review the Upgrade Notes (Release 7.7) on page 37.

When upgrading, you can install packages from one of the following sources:

- Data-fabric Internet repository
- A local repository
- Individual package files

See the next topic to begin setting up repositories.

When you are finished upgrading core, follow the steps to upgrade the ecosystem components, as described in Upgrading the Ecosystem Pack Without the Installer on page 366.

Then proceed to Finishing the Core Upgrade on page 332.

Setting Up Repositories
This section describes how to set up internet and local repositories for each operating system.

Both internet repositories and local repositories can be set up. In addition, package files can be downloaded, stored locally, and then the software can be installed from the files. The following sections describes how to do both for each operating system.

Platform-specific upgrade repositories are hosted at: https://package.ezmeral.hpe.com/releases/v<version>/<platform>/mapr-v<version>GA-upgrade.<rpm/deb>.tgz.

See Data Fabric Repositories and Packages on page 101 for more information about repositories and packages.

Using the Data Fabric Repository (Upgrade)
It is usually easiest to install an HPE Ezmeral Data Fabric cluster from a Data Fabric repository.

The Data Fabric repository provides all of the packages required to install a cluster using native tools such as `yum` on RHEL, Oracle Linux, or CentOS, or `apt-get` on Ubuntu, or `zypper` on SUSE. Installing from the data-fabric repository is generally the easiest installation method, but requires the greatest amount of bandwidth. With this method, each node is connected to the internet to download the required packages.

When setting up a repository for the new version, leave in place the repository for the existing version because you might need to use it again.

Prepare packages and repositories on every node, or on a single node if keyless SSH is set up for the `root` user.

Set up repositories by completing the steps for your RHEL/Oracle Linux/CentOS, SUSE, or Ubuntu distribution. See these pages:

- Adding the Data Fabric Repository on RHEL, CentOS, or Oracle Linux on page 183
- Adding the Data Fabric Repository on SUSE on page 184
- Adding the Data Fabric Repository on Ubuntu on page 185

For information about repositories and packages for Data Fabric software and Hadoop Ecosystem tools, see Data Fabric Repositories and Packages on page 101.

Repositories for Core Software

HPE hosts `rpm` and `deb` repositories for installing the core software using Linux package management tools. For every release of the core software, a repository is created for each supported platform.

Platform-specific upgrade repositories are hosted at: https://package.ezmeral.hpe.com/releases/v<version>/<platform>/mapr-v<version>GA-upgrade.<rpm/deb>.tgz.

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

Repositories for Ecosystem Tools

HPE hosts `rpm` and `deb` repositories for installing ecosystem tools, such as Flume, Hive, Oozie, Pig, and Sqoop. At any given time, the recommended versions of ecosystem tools that work with the latest version of core software are available here.

These platform-specific repositories are hosted at the following locations:

- https://package.ezmeral.hpe.com/releases/MEP/MEP-<version>/<platform>

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

NOTE: The MEP-<version> directory can be represented by a 2-digit number or a 3-digit number (for example, MEP-2.0 or MEP-2.0.0). See Understanding Two-Digit and Three-Digit EEPs on page 5638.

Using a Local Repository
If you install a Data Fabric cluster from a local repository, you do not need an internet connection.

You can set up a local repository on each node to provide access to installation packages. With this method, nodes do not require internet connectivity. The package manager on each node installs from

packages in the local repository. To set up a local repository, nodes need access to a running web server to download the packages.

Set up repositories by completing the steps for your RHEL/Oracle Linux/CentOS, SUSE, or Ubuntu distribution. See these pages:

- Creating a Local Repository on RHEL, CentOS, or Oracle Linux on page 186
- Creating a Local Repository on SUSE on page 189
- Creating a Local Repository on Ubuntu on page 190

Platform-specific upgrade repositories are hosted at: https://package.ezmeral.hpe.com/releases/v<version>/<platform>/mapr-v<version>GA-upgrade.<rpm/deb>.tgz.

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

For more information about repositories and packages for data-fabric software and Hadoop Ecosystem tools, see Data Fabric Repositories and Packages on page 101.

Set Up Individual Package Files
This section describes how to upgrade Data Fabric software using individual package files.

About this task

You can download package files, store them locally, and then install Data Fabric from the files. This option is typically used to upgrade clusters that are not connected to the internet.

Platform-specific upgrade repositories are hosted at: https://package.ezmeral.hpe.com/releases/v<version>/<platform>/mapr-v<version>GA-upgrade.<rpm/deb>.tgz.

See Data Fabric Repositories and Packages on page 101 for more information about repositories and packages.

To upgrade Data Fabric using individual package files, you need to first pre-install the Data Fabric package dependencies on each node. See the Package Dependencies on page 103 for the dependency packages required for the cluster services that you are installing. Manually download the packages and install them.

Procedure

1. Using a machine connected to the internet, download the tarball for the Data Fabric components and the Hadoop ecosystem components, substituting the appropriate `<platform>`, `<version>`, and `<datestamp>`.

   For example:

   ```
   https://package.ezmeral.hpe.com/releases/v<version>/ubuntu/
   mapr-v<version>GA-upgrade.deb.tgz
   ```

2. Extract the tarball to a local directory, either on each node or on a local network accessible by all nodes:

   ```
   tar -xvzf <product_package>.tgz
   ```

Upgrading Core
The following topics describe offline and manual upgrades, and manual rolling upgrades.

NOTE: After completing your upgrade, see Post-Upgrade Steps for Core on page 332

last-updated: Jun 06, 2024

Offline and Manual Upgrade Procedure
The offline, manual upgrade procedure is suitable for upgrading small clusters. On large clusters, these steps are commonly performed on all nodes in parallel using scripts or remote management tools.

This procedure assumes that you have planned and prepared for the upgrade as described earlier. This procedure also assumes that the cluster meets prerequisites, including the correct JDK for the core version to which you are upgrading. For more information, see the JDK Support Matrix.

NOTE: An offline upgrade is performed as the `root` user or with sudo.

At the end of this procedure, you use `yum update` or `zypper update` on RHEL or SLES to upgrade the packages. Ignore any warnings that certain packages are not installed. Packages will be upgraded correctly, and no additional packages will be installed.

This procedure assumes that the cluster being upgraded is running release 6.1.x, 6.2.0, 7.0.0, 7.1.0, 7.2.0, 7.3.0, 7.4.0, 7.5.0, or 7.6.x:

1. Notify stakeholders of the impending upgrade, and stop accepting new jobs and applications. Terminate running jobs and applications by running `maprcli` commands on appropriate nodes in the cluster.

   For YARN applications, use the following commands:

   ```
   # yarn application -list
            # yarn application -kill <ApplicationId>
   ```

2. Disconnect NFS mounts. Unmount NFS for the HPE Ezmeral Data Fabric share from all clients connected to it, including other nodes in the cluster. This allows all processes accessing the cluster via NFS to disconnect gracefully.

   For example, if the cluster is mounted at `/mapr`, use this command:

   ```
   # umount /mapr
   ```

3. Display the services on each node in the cluster, and stop ecosystem component services on the nodes.

   ```
   # maprcli node list -columns hostname,csvc
   # maprcli node services -multi '[{ "name": "hue", "action": "stop"},
   { "name": "oozie", "action": "stop"}, { "name": "hs2", "action":
   "stop"}]' -nodes <hostnames>
   ```

4. If a POSIX client service is running, stop the service:
   - For the `mapr-loopbacknfs` service:

     ```
     service mapr-loopbacknfs stop
     ```

   - For the FUSE-based POSIX basic service:

     ```
     service mapr-posix-client-basic stop
     ```

   - For the FUSE-based POSIX platinum service:

     ```
     service mapr-posix-client-platinum stop
     ```

5. Determine where the CLDB and ZooKeeper services are installed.

6. Stop Warden on the CLDB nodes first, and then on all remaining nodes.
7. Stop ZooKeeper on all nodes where it is installed.
8. Ensure that no stale cluster processes are running. If so, stop the processes:

   ```
   ps -ef | grep mapr
   pkill -u mapr
   ```

9. Remove any existing patches:
   a. Run one of the following commands to determine if a patch is installed.
      - RHEL and SLES: `rpm -qa mapr-patch`
      - Ubuntu: `dpkg -l | grep mapr-patch`

      If the command displays no output, no patch is installed.
   b. If one or more patches are installed, run one of the following commands to remove the patches:
      - RHEL or SLES: `sudo rpm -e mapr-patch`
      - Ubuntu: `sudo apt-get -y remove mapr-patch`
10. Upgrade core packages by installing the appropriate package key.
    - RHEL: `sudo rpm --import https://package.ezmeral.hpe.com/releases/pub/maprgpg.key`
    - SLES: No package key needed.
    - Ubuntu: `wget -O - https://package.ezmeral.hpe.com/releases/pub/maprgpg.key | sudo apt-key add -`
11. Use the following command to view the Java alternatives menu, and set Java to JDK 11 or JDK 17:

    ```
    sudo update-alternatives --config java
    ```

12. Upgrade these core component and Hadoop common packages on all nodes where packages exist.

    Components to upgrade are:
    - `mapr-cldb`
    - `mapr-client`
    - `mapr-core`
    - `mapr-core-internal`
    - `mapr-fileserver`
    - `mapr-gateway`
    - `mapr-hadoop-client`
    - `mapr-hadoop-core`
    - `mapr-hadoop-util`

last-updated: Jun 06, 2024

- `mapr-historyserver`
- `mapr-keycloak` (for upgrades from release 7.5.0 or later)
- `mapr-nfs`
- `mapr-nodemanager`
- `mapr-resourcemanager`
- `mapr-webserver`
- `mapr-zookeeper`
- `mapr-zk-internal`

When using `yum update` or `zypper update`, do not use a wildcard such as `mapr-*` to upgrade all data-fabric packages, which could erroneously include Hadoop ecosystem components such as `mapr-hive` and `mapr-pig`.

- RHEL:

```
yum update mapr-cldb mapr-core mapr-core-internal mapr-gateway
mapr-fileserver mapr-hadoop-core mapr-historyserver mapr-nfs
mapr-nodemanager mapr-resourcemanager mapr-webserver mapr-zookeeper
mapr-zk-internal mapr-client mapr-hadoop-client mapr-hadoop-util
```

- SLES:

```
zypper update --allow-vendor-change mapr-cldb mapr-compat-suse
mapr-core mapr-core-internal mapr-gateway mapr-fileserver
mapr-hadoop-core mapr-historyserver mapr-mapreduce2 mapr-nfs
mapr-nodemanager mapr-resourcemanager mapr-webserver mapr-zookeeper
mapr-zk-internal mapr-client mapr-hadoop-client mapr-hadoop-util
```

- Ubuntu: First get a list of the data-fabric packages installed on the node, and then run `apt-get install` on the listed packages.

```
# dpkg --list | grep "mapr" | grep -P "^ii"| awk '{ print $2}'|tr "\n"
" "
# apt-get install <package-list>
```

13. Verify that packages were installed successfully on all nodes. Confirm that there were no errors during installation, and check that `/opt/mapr/MapRBuildVersion` contains the expected value.

    For example:

```
# cat /opt/mapr/MapRBuildVersion
7.7.0.0.2024xxxxxxxxx.GA
```

See Post-Upgrade Steps for Core on page 332

Manual Rolling Upgrade Description

In a manual rolling upgrade, you upgrade the Data Fabric software one node at a time so that the cluster as a whole remains operational throughout the process.

NOTE: Rolling upgrades to release 7.7.0 are supported only for clusters running release 6.1.x, 6.2.0, 7.0.0, 7.1.0, 7.2.0, 7.3.0, 7.4.0, 7.5.0, or 7.6.x.

last-updated: Jun 06, 2024

Before you Upgrade

Before you begin a manual rolling upgrade, perform the following steps:

- Determine the upgrade groups. To see a list of services on each node, run the following command:

```
maprcli node list -columns hostname,csvc
```

- If the cluster is secure, the cluster admin user must have a security ticket created before running the upgrade. Otherwise, some upgrade commands will not run.

Group Upgrade Order

Upgrade cluster nodes in groups based on the services running on each node. Upgrade groups of nodes in the following order:

Group	Nodes in this Group
1	Each node only has ZooKeeper. This establishes a stable ZooKeeper quorum on the new version, which remains active through the rest of the upgrade process.
2	Each node only has a Data Fabric gateway (`mapr-gateway-x.x.x`), or it has ZooKeeper.
3	Each node only has fileserver or it has fileserver, Data Fabric gateway, and ZooKeeper.
4	Each node only has NodeManager or it has NodeManager, fileserver, Data Fabric gateway, and ZooKeeper.
5	Each node only has ResourceManager or it has ResourceManager, NodeManager, fileserver, Data Fabric gateway, and ZooKeeper. When you upgrade nodes in this group, upgrade nodes with the standby ResourceManagers before you upgrade the node with the active ResourceManager.
6	Each node has ResourceManager, NodeManager, fileserver, Data Fabric gateway, and ZooKeeper.
7	Each node only has CLDB server or it has CLDB server, ResourceManager, NodeManager, fileserver, Data Fabric gateway, and ZooKeeper. When you upgrade nodes in this group, upgrade nodes with the secondary CLDB before you upgrade the node with the primary CLDB.

Package Upgrade Order

When you upgrade each node, upgrade existing packages in the following order:

- On all operating systems except SLES, upgrade the `mapr-core` package first. Subsequent packages can be done in any order.
- On SLES, upgrade the `mapr-compat-suse` package first and the `mapr-core` package second. Subsequent packages can be done in any order.

The following is a list of the primary packages:

- `mapr-cldb`
- `mapr-compat-suse` (if upgrading on SLES)

- `mapr-core-internal`
- `mapr-core`
- `mapr-fileserver`
- `mapr-gateway`
- `mapr-hadoop-core*`
- `mapr-historyserver*`
- `mapr-keycloak` (for upgrading from release 7.5.0 and later)
- `mapr-nfs`
- `mapr-nodemanager*`
- `mapr-resourcemanager*`
- `mapr-s3server`
- `mapr-webserver`
- `mapr-zk-internal`
- `mapr-zookeeper`

*In release 6.2.0 and later, these packages are part of the EEP and must be reinstalled. See Installing Hadoop and YARN on page 241.

What's Next
See Manual Rolling Upgrade Procedure on page 329
Manual Rolling Upgrade Procedure
Describes how to upgrade each node manually to the latest version of Data Fabric packages.

Complete the following upgrade steps for each node in each upgrade group for a cluster with a file system.

NOTE: For a cluster with EEP components, you must complete a separate, offline upgrade in addition to these upgrade steps. See Workflow: Offline Manual Upgrade from Release 6.x or 7.x to 7.7.0 on page 303.

This procedure assumes that the cluster being upgraded is running release 6.1.x, 6.2.0, 7.0.0, 7.1.0, 7.2.0, 7.3.0, 7.4.0, 7.5.0, or 7.6.x:

1. On all nodes in the cluster, install the latest core patch for the release that is currently installed. The latest core patch must be installed on all nodes before you start the rolling upgrade. For more information, see Applying a Patch on page 473.
2. Download the archive file from https://package.ezmeral.hpe.com/releases/.

   IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

3. Extract the archive file. When you upgrade each package, be sure to specify the full path to the files in this local directory:

```
tar -xzvf <archive file>
```

4. Stop the CLDB if it is running on the node, before putting that node into maintenance mode. Otherwise, the maintenance mode operation is not permitted:

```
maprcli node services -name cldb -action stop -nodes <hostname>
```

5. Set the node to maintenance mode:

```
sudo maprcli node maintenance -nodes <hostname> -timeoutminutes 30
```

6. Notify the CLDB that the node is going to be upgraded:

```
sudo maprcli notifyupgrade start -node <hostname>
```

7. Stop Warden:

```
sudo service mapr-warden stop
```

8. If ZooKeeper is installed on the node, stop ZooKeeper:

```
service mapr-zookeeper stop
```

9. Check to ensure that all services are stopped:

```
jps
46343 Jps
3607 -- process information unavailable
(Nothing running here)
```

10. Use the following command to view the Java alternatives menu, and set Java to JDK 11 or JDK 17:

```
sudo update-alternatives --config java
```

11. Remove any patches installed on the node.
    - RHEL, Rocky, or SLES: `sudo rpm -e mapr-patch`
    - Ubuntu: `sudo apt-get -y remove mapr-patch`
12. Upgrade each data-fabric package on the node based on the defined package upgrade order by running this command for each package:
    - RHEL or SLES: `yum upgrade <packagename>`
    - Ubuntu: `apt-get install --only-upgrade -o Dpkg::Options::="--force-overwrite" mapr-fileserver mapr-core mapr-cldb`

      NOTE: During the upgrade process on Ubuntu, the system displays *dpkg* warnings about overwriting. You can ignore these warnings.
13. Verify that the following packages are removed (these packages are obsolete in release 6.2 and later):

last-updated: Jun 06, 2024

- Remove `mapr-mapreduce2` if it is present
- Remove `mapr-hadoop-core` if you are upgrading a fileserver node that does not have the ResourceManager, NodeManager, or History Server. On such a node, only `mapr-hadoop-util` is needed after upgrading.

14. Run configure.sh with the `-disableSsl` option:

```
/opt/mapr/server/configure.sh -R -disableSsl
```

Disabling SSL prevents the upgraded node from attempting to use SSL with nodes that have not been upgraded. Release 6.2.0 and later nodes use SSL, but release 6.1.x nodes do not. After all the ZooKeeper nodes have been upgraded, the SSL feature can be turned on by stopping the cluster, running `configure.sh -R` on all nodes, and restarting the cluster.

15. Ensure that every node has the following files in the `/opt/mapr/conf` directory:
    - `maprserverticket`
    - `ssl_keystore`
    - `ssl_keystore.p12`
    - `ssl_keystore.pem`
    - `ssl_truststore`
    - `ssl_truststore.p12`
    - `ssl_truststore.pem`
16. If ZooKeeper is installed on the node, start ZooKeeper:

```
service mapr-zookeeper start
```

17. Start Warden:

```
sudo service mapr-warden start
```

18. Check that the CLDB is running:

```
maprcli node list
```

If output is displayed, the CLDB is running. If not, start the CLDB.

19. Exit maintenance mode on the node, and notify the CLDB about the upgraded version and about the finished status of the upgrade process:

```
sudo maprcli node maintenance -nodes <hostname> -timeoutminutes 0
sudo maprcli config save -values {mapr.targetversion:"'cat /opt/mapr/
MapRBuildVersion'"}
sudo maprcli notifyupgrade finish -node <hostname>
```

last-updated: Jun 06, 2024

20. Start ZooKeeper and Warden:

```
service mapr-zookeeper start
sudo service mapr-warden start
```

21. Wait for the containers to synchronize. Then run the following command, and check that there is no output:

```
/opt/mapr/server/mrconfig info containers resync local
```

No output signifies that the containers are synchronized.

To perform important post-upgrade tasks, such as updating configuration files and restarting the Control System API server, see Post-Upgrade Steps for Core on page 332 and Installing Additional Core Features on page 345.

Finishing the Core Upgrade
This section provides post-upgrade steps for core.

Post-Upgrade Steps for Core
After upgrading core, several manual steps are required.
Considerations for Upgrades Using the Installer
If you use the Installer to upgrade the cluster, some post-upgrade steps for core do not need to be performed. This page describes the post-upgrade steps that are performed by the Installer and the steps that you must perform manually.

This information is relevant to the workflow for Installer upgrades. The information on this page also applies to upgrades performed using Installer Stanzas.

Post-Upgrade Step for Core	Performed by Installer?	Notes
Step 1: Restart and Check Cluster Services on page 333	Yes, with exceptions. See the notes.	Usually, you do not need to perform this step. When you use the Installer to upgrade, the Installer runs `configure.sh` on each node, starts ZooKeeper and Warden, and sets the new cluster version. If the `env_override.sh` file is present, the Installer uses environment variables from the `env_override.sh` file. If you use the Installer to upgrade, you need to perform this step manually only if you make significant changes to configuration files *after* the upgrade (see Step 2: Manually Update Configuration Files on page 336).
Step 2: Manually Update Configuration Files on page 336	No	You might need to perform this step. The Installer uses default configuration-file settings and does NOT update configuration files. You must perform this step after upgrading using the Installer only if you have made configuration-file customizations that you want to migrate to the upgraded cluster. Depending on the customization, you might also need to restart services or even the full cluster after updating configuration files.
Step 3: Upgrade Clients on page 336	No	You need to perform this step. Enabling some new features, such as `mfs.feature.name.container.size.control` can cause client failures if the features are enabled before the clients are upgraded.

last-updated: Jun 06, 2024

Post-Upgrade Step for Core	Performed by Installer?	Notes
Step 4: Enable New Features on page 340	Yes	You do not need to perform this step. The Installer enables new features as part of a version upgrade.

Step 1: Restart and Check Cluster Services
After upgrading core using either a manual offline or rolling upgrade method (not upgrading with the Installer) and upgrading your ecosystem components, configure and restart the cluster and services.

About this task

NOTE: This task is applicable only to manual offline and rolling upgrade methods.

IMPORTANT: Before restarting cluster services, upgrade any existing ecosystem packages to versions compatible with the upgraded data-fabric release. For more information, see EEP Components and OS Support.

This procedure configures and restarts the cluster and services, including ecosystem components, remounts the NFS share, and checks that all packages have been upgraded on all nodes.

After finishing this procedure, run non-trivial health checks, such as performance benchmarks relevant to the cluster's typical workload or a suite of common jobs. It is a good idea to run these types of checks when the cluster is idle. In this procedure, you configure each node in the cluster without changing the list of services that will run on the node. If you want to change the list of services, do so after completing the upgrade. After you have upgraded packages on all nodes, perform this procedure on all nodes to restart the cluster. Upon completion of this procedure, core services are running on all nodes.

Procedure

1. Merge any custom edits that you made to your cluster environment variables into the new `/opt/mapr/conf/env_override.sh` file before restarting the cluster. This is because the upgrade process replaces your original `/opt/mapr/conf/env.sh` file with a new copy of `env.sh` that is appropriate for the data-fabric release to which you are upgrading. The new `env.sh` does not include any custom edits you might have made to the original `env.sh`. However, a backup of your original `env.sh` file is saved as `/opt/mapr/conf/env.sh<timestamp>`. Before restarting the cluster, you must add any custom entries from `/opt/mapr/conf/env.sh<timestamp>` into `/opt/mapr/conf/env_override.sh`, and copy the updated `env_override.sh` to all other nodes in the cluster. See About env_override.sh on page 3077.

2. On each node in the cluster, remove the `maprserticket` file. For manual upgrades, the file must be removed to ensure that impersonation works properly. The `maprserticket` file is re-created automatically when you restart Warden. For more information, see Upgrade Notes (Release 7.7) on page 37.
   ```
   # rm /opt/mapr/conf/maprserticket
   ```

3. If you are upgrading from core 6.1.x to core 7.x, create the `ssl_truststore.pem` and `ssl_keystore.pem` files. These files are used by the Data Access Gateway, Grafana, and Hue components. This step is necessary only for manual upgrades because upgrades performed with the Installer distribute the files automatically. Use these commands:

a) Use the `manageSSLKeys.sh` utility to generate the files:

```
/opt/mapr/server/manageSSLKeys.sh convert -N my.cluster.com /opt/mapr/
conf/ssl_truststore /opt/mapr/conf/ssl_truststore.pem

/opt/mapr/server/manageSSLKeys.sh convert -N my.cluster.com /opt/mapr/
conf/ssl_keystore /opt/mapr/conf/ssl_keystore.pem
```

b) Copy the generated `ssl_keystore.pem` and `ssl_truststore.pem` files to the `/opt/mapr/conf/` directory on all the nodes in the cluster.

4. Depending on the release from which you are upgrading, use one of the following commands to create the new userkeystores and usertruststores. You must run the command in order to enable log monitoring and the MCS and Object Store user interfaces. You run this command once on any node, and then copy the resulting files to all other nodes in the cluster:

   - To upgrade from core 6.2.0 to 7.0.0 or later:

     ```
     manageSSLKeys.sh createusercert -a moss -u *.$(hostname -d) -ug
     <cluster_admin_id>:<cluster_admin_group>
     ```

   - To upgrade from core 6.1.x to 7.0.0 or later:

     ```
     manageSSLKeys.sh createusercerts -ug
     <cluster_admin_id>:<cluster_admin_group> -N <cluster_name>
     ```

   For more information about the user certs, see:

   - Understanding the Key Store and Trust Store Files on page 1793
   - Step 10: Install Log Monitoring on page 225
   - manageSSLKeys.sh on page 2897

5. On each node in the cluster, run `configure.sh` with the `-R` option:
   ```
   # /opt/mapr/server/configure.sh -R -HS <hostname>
   ```

6. If ZooKeeper is installed on the node, start it:
   ```
   # service mapr-zookeeper start
   ```

7. Start Warden.
   ```
   # service mapr-warden start
   ```

8. Run a simple health-check targeting the file system and MapReduce services only. Address any issues or alerts that might have come up at this point.

9. Set the new cluster version in the `/opt/mapr/MapRBuildVersion` file by running the following command on any node in the cluster:
   ```
   # maprcli config save -values {mapr.targetversion:"`cat /opt/mapr/
   MapRBuildVersion`"}
   ```

10. Verify the new cluster version:

    For example:

    ```
    # maprcli config load -keys mapr.targetversion
    mapr.targetversion
    7.2.0.0.20230118195227.GA
    ```

11. Remount the data-fabric NFS share:

    The following example assumes that the cluster is mounted at `/mapr`:

    ```
    # mount -o hard,nolock <hostname>:/mapr /mapr
    ```

12. Run commands, as shown in the example, to check that the packages have been upgraded successfully:

    Check the following:

    - All expected nodes show up in a cluster node list, and the expected services are configured on each node.
    - A master CLDB is active, and all nodes return the same result.
    - Only one ZooKeeper service claims to be the ZooKeeper leader, and all other ZooKeepers are followers.

    For example:

    ```
    # maprcli node list -columns hostname,csvc
    hostname configuredservice ip
    centos55 nodemanager,cldb,fileserver,hoststats 10.10.82.55
    centos56 nodemanager,cldb,fileserver,hoststats 10.10.82.56

```

Step 2: Manually Update Configuration Files
After upgrading core using a manual offline or rolling upgrade method, update your configuration files.

NOTE: This task is applicable to all manual upgrade methods: offline and rolling upgrades.

IMPORTANT: After upgrading but before enabling new features, all nodes in your cluster must be upgraded, and all configuration files must be updated.

To manually update the configuration files:

1. On all nodes, manually merge new configuration settings from the `/opt/mapr/conf.new/warden.conf` file into the `/opt/mapr/conf/warden.conf` file.
2. For secure clusters: On all nodes, manually copy `/opt/mapr/conf.new/mapr.login.conf` to the `/opt/mapr/conf/` directory, and set the file permissions to 0644. This file contains Zookeeper security information.
3. On all nodes, manually merge new configuration settings from the files in the `/opt/mapr/conf/conf.d.new/` directory to the files in the `/opt/mapr/conf/conf.d/ directory`.
4. Manually merge the port and authentication configuration information in the `/opt/mapr/conf/web.conf` directory from the pre-6.0 release version to the `/opt/mapr/apiserver/conf/properties.cfg` file of the upgraded release version.

   For example, the following from the `/opt/mapr/conf/web.conf` file from the pre-6.0 version must be manually copied over to the `/opt/mapr/apiserver/conf/properties.cfg` file of the new version:

   ```
   # HTTPS Settings
   mapr.webui.https.port=8443
   mapr.rest.auth.methods=kerberos,basic // if kerberos auth
   ```

5. Manually merge new configuration settings in `/opt/mapr/conf/fuse.conf` file with custom settings in `/opt/mapr/conf/fuse.conf.backup` file and restart FUSE for the settings to take effect.

   After the upgrade, on all supported operating systems other than Ubuntu, the new `fuse.conf` file and a backup copy of the `fuse.conf` file from prior version named `fuse.conf.backup` are available in the `/opt/mapr/conf` directory. You can find the new parameters with default values in the new `fuse.conf` file and your custom settings from the prior version in the `fuse.conf.backup` file. On Ubuntu, you can find the new `fuse.conf` file in the `/opt/mapr/conf` directory and by default, there is no backup copy of the `fuse.conf` file from prior version unless you created one before upgrade.

Step 3: Upgrade Clients
After you upgrade your cluster, you may also need to upgrade your data-fabric client or POSIX client.

When you upgrade the cluster, consider if your data-fabric client or your POSIX client needs to be upgraded as well. See Planning Upgrades to Data Fabric Clients on page 312.

NOTE: Basic and Platinum POSIX client packages are recommended for fresh installation and for all new clusters.

Upgrading the Data Fabric Client

Depending on which Data Fabric client you want to update, you will either need to install and reconfigure or perform a package upgrade.

To get a newer version of the Windows or Mac OS X client, install the newer Data Fabric client and reconfigure it. To get a newer version of the Linux Data Fabric client, perform a package upgrade.

Upgrading the Data Fabric Client on a Linux Server

This section describes how to upgrade the Data Fabric client on a Linux Server.

About this task

To upgrade the Data Fabric client on an RHEL, SLES, or Ubuntu server, you must upgrade the `mapr-client` package. When you upgrade the Data Fabric client packages on the server, the configuration files in the `/opt/mapr/hadoop/hadoop-2.x.x` directory are automatically copied into the active directory associated with the Hadoop 3.x.x directory.

Procedure

1. Remove any currently installed client patches. For example:
   - **On RedHat and CentOS**

     ```
     yum remove mapr-patch-client-<version>
     ```

   - **On Ubuntu**

     ```
     apt-get remove mapr-patch-client-<version>
     ```

   - **On SLES**

     ```
     zypper remove mapr-patch-client-<version>
     ```

2. Configure the repository to point to the target release and operating system.
3. Run the following command to upgrade the client package:
   - On RedHat / CentOS: `yum update mapr-client`
   - On SLES: `zypper update mapr-client`
   - On Ubuntu: `apt-get install mapr-client`

Upgrading the loopbacknfs POSIX Client on a Linux Server on page 338
This section describes how to upgrade the loopbacknfs POSIX Client on a Linux server.

Upgrading the Data Fabric Client on Windows

This section describes how to upgrade the data-fabric client on Windows.

last-updated: Jun 06, 2024

About this task

When you upgrade the data-fabric client on Windows, you need to rename the existing client directory, install the new version, and then merge the configuration files.

Procedure

1. Rename the existing client installation directory. For example, you can rename `\opt\mapr` to `\opt_old\mapr.`
2. Complete the installation steps in Installing the Data Fabric Client on Windows (Non-FIPS) on page 415.
3. To retain existing configurations and accept new defaults, merge the contents of the directory in the previous installation with the directory in the new installation. For example:
   - Previous installation directory: `%MAPR_HOME%\hadoop\hadoop-2.x.x\etc\hadoop`
   - New installation directory: `%MAPR_HOME%\hadoop\hadoop-3.3.4\etc\hadoop`

Upgrading the Data Fabric Client in Mac OS X

This section describes how to upgrade the Data Fabric client on Mac OS X.

About this task

When you upgrade the data-fabric client on Mac OS X, you need to rename the existing client directory, install the new version, and then merge the configuration files.

Procedure

1. Rename the existing client installation directory. For example, you can rename `/opt/mapr` to `/opt_old/mapr.`
2. Complete the installation steps in Installing the Data Fabric Client on Mac OS X (Non-FIPS) on page 412.
3. To retain existing configurations and accept the new defaults, merge the contents of the following directories in the previous installation with the ones in the new installation:
   - `opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`
   - `opt/mapr/hadoop/hadoop-0.20.0/conf`

Upgrading the Data Fabric POSIX loopbacknfs Client

Perform a package upgrade to get a newer version of the data-fabric POSIX loopbacknfs Client.

To get a newer version of the POSIX loopback NFS client, perform a package upgrade. POSIX loopback NFS client can be upgraded or a fresh install can be performed.

NOTE: Basic and Platinum POSIX client packages are recommended for fresh installation and for all new clusters.

Upgrading the loopbacknfs POSIX Client on a Linux Server

This section describes how to upgrade the loopbacknfs POSIX Client on a Linux server.

About this task

To upgrade the loopbacknfs POSIX client on a RHEL, SLES, or Ubuntu server, you must upgrade the `mapr-loopbacknfs` package.

last-updated: Jun 06, 2024

Procedure

1. Stop the `mapr-loopbacknfs` service.

```
service mapr-loopbacknfs stop
```

2. Remove any currently installed client patches. For example:
   - On RedHat / CentOS: `yum remove mapr-patch-loopbacknfs`
   - On SLES: `zypper remove mapr-patch-loopbacknfs`
   - On Ubuntu: `apt-get remove mapr-patch-loopbacknfs`
3. Upgrade the `mapr-loopbacknfs` package.
   - On RedHat / CentOS: `yum update mapr-loopbacknfs`
   - On SLES: `zypper update mapr-loopbacknfs`
   - On Ubuntu: `apt-get install mapr-loopbacknfs`
4. Update the cluster configuration information in the `mapr-loopbacknfs.new` file.

```
vi /usr/local/mapr-loopbacknfs/initscripts/mapr-loopbacknfs.new
```

5. Copy `mapr-loopbacknfs.new` to the `mapr-loopbacknfs` script

```
cp
/usr/local/mapr-loopbacknfs/initscripts/mapr-loopbacknfs.new
/usr/local/mapr-loopbacknfs/initscripts/mapr-loopbacknfs
```

6. Start the loopbacknfs service.

```
service mapr-loopbacknfs start
```

7. Check the status of the loopbacknfs service.

```
service mapr-loopbacknfs status
```

Troubleshooting loopbacknfs POSIX Client Upgrades

If you are having difficulty upgrading the POSIX client, it might be due to a shared-memory-segment lock.

About this task

If the `mapr-loopbacknfs` service fails to start after an upgrade, use the following steps to determine if a shared-memory-segment lock was the cause of the failure:

Procedure

1. Open the `loopbacknfs.log` file. The loopbacknfs.log file is in the following directory: `/usr/local/mapr-loopbacknfs/logs/`
2. Check for the following string: `Create/Attach to shm failed`
3. If the string is present, perform the following steps:

last-updated: Jun 06, 2024

a) Run the following command to identify the `shmid` of the lock: `ipcs -m | grep 0x0000161c`

b) Run the following command to remove the lock:`ipcrm -m <shm id>`

c) Start the `mapr-loopbacknfs` service.

Upgrading the FUSE POSIX Client on a Linux Server

This section describes how to upgrade the FUSE POSIX client on a Linux server.

About this task

To upgrade the FUSE POSIX client on a RHEL, SLES, or Ubuntu server, you must upgrade the `mapr-posix-client-basic` or `mapr-posix-client-platinum` package.

Procedure

1. Stop the `mapr-posix-client-basic` or `mapr-posix-client-platinum` service. For example:

   ```
   service mapr-posix-client-basic stop
   ```

2. Remove any currently installed client patches. For example:
   - On RHEL / CentOS: `yum remove mapr-patch-posix-client-basic`
   - On SLES: `zypper remove mapr-patch-posix-client-basic`
   - On Ubuntu: `apt-get remove mapr-patch-posix-client-basic`
3. Upgrade the `mapr-posix-client-basic` or `mapr-posix-client-platinum` package:
   - On RHEL / CentOS: `yum update mapr-patch-posix-client-basic`
   - On SLES: `zypper update mapr-patch-posix-client-basic`
   - On Ubuntu: `apt-get install mapr-patch-posix-client-basic`
4. Update the cluster configuration information in the `/opt/mapr/conf/fuse.conf` file:

   ```
   vi /opt/mapr/conf/fuse.conf
   ```

5. Copy any new parameters from `fuse.conf.new` to the `/opt/mapr/conf/fuse.conf` file.
6. Start the FUSE POSIX service:

   ```
   service mapr-patch-posix-client-basic start
   ```

7. Check the status of the FUSE POSIX service:

   ```
   service mapr-patch-posix-client-basic status
   ```

Step 4: Enable New Features

Describes the new features to enable after upgrading core without the Installer using a manual offline or rolling upgrade method.

This task applies to all manual upgrade methods: offline, rolling, and manual rolling upgrades. After a successful manual upgrade, administrators have the option to enable new features that are not enabled by default. During a fresh install, these features are enabled automatically.

last-updated: Jun 06, 2024

Before Enabling New Features

Before enabling new features, review these important notes:

- You can obtain a list of features for your currently installed software by using the following command:

```
maprcli cluster feature list
```

- Before enabling new features, you must upgrade all nodes in the cluster and all clients that access the cluster.
- The `maprcli config save` command is no longer available for enabling features.

How to Enable New Features

You enable new features by using the `maprcli cluster feature enable` command. For more information about this command, see maprcli cluster commands.

Hewlett Packard Enterprise recommends that you enable *all* new features. Use the following command:

```
maprcli cluster feature enable -all
```

Feature Summary

The following table describes considerations for enabling some features. The table ia not a complete list of data-fabric features:

Feature	Feature Name	Available as of Release	Description
HPE Ezmeral Data Fabric Object Store	`cldb.objectstore.support`	7.0.0	Enables native object storage to store objects and metadata for optimized access. Provides access to data through multiple protocols, including the native S3 API, NFS, POSIX, and CSI. Object Store S3 protocols fully comply with AWS S3, including S3 Select features. For more information, see HPE Ezmeral Data Fabric Object Store on page 541.
Policy-Based Security	`mfs.feature.pbs`	6.2	Enables a feature that administrators can use to organize security controls into a manageable number of security policies. For more information, see Policy-Based Security on page 854.
Snapshot Restore	`mfs.feature.snapshot.restore.support`	6.2	Restores volume data from a snapshot.
Storage Labels	`cldb.lbs.support`	6.2	Enables usage of Storage Labels on a cluster upgraded to version 6.2.
Optimize Volumes for CLDB	`cldb.feature.optimize.volume.kvstores`	6.2	Enabling this tunable automatically optimizes the B-Tree of CLDB tables with a large number of volumes and read-write containers, and results in enhanced CLDB performance. For more information, see Optimizing CLDB Tables on page 829.

last-updated: Jun 06, 2024

Feature	Feature Name	Available as of Release	Description
Parallel Offload	`mfs.feature.container.sharding.support`	6.2	Enables the parallel offload feature to use multiple MAST Gateways, to offload a volume's data in parallel. For more information, see Enabling Tiering on page 1284.
Last Access Time	`mfs.feature.update.atime`	6.2	Enables the Last Access Time feature. For more information, see Tuning Last Access Time on page 531.
Data-at-Rest Encryption	`mfs.feature.dare`	6.1	Enables support for encrypting data at rest on the data-fabric cluster. See Enabling Encryption of Data at Rest on page 1799 for more information.
Data Tiering	`mfs.feature.storage.tiering.support`	6.1	Enables support for offloading data to different storage tiers. See Enabling Tiering on page 1284 for more information.
Name Container Threshold	`mfs.feature.name.container.size.control`	6.0.1	Enables support for setting a limit on the size of data stored in the name container for a volume.
Directcopy for Autosetup Replication, Change Data Capture and Secondary Index	`mfs.feature.db.streams.v6.support`	6.0	Enables the following: • HPE Ezmeral Data Fabric Database tables and HPE Ezmeral Data Fabric Streams to use the directcopy option with the autosetup replication feature. • HPE Ezmeral Data Fabric Database table Change Data Capture (CDC) feature. • HPE Ezmeral Data Fabric Database Secondary Index feature.
Enforce Guaranteed Minimum Replication	`mfs.feature.enforce.min.replication`	6.0	Enables support for enforcing minimum number of replicas for (read-write) volumes during write operations. **NOTE:** Do not enable this feature before upgrading all the nodes in the cluster. If you enable this feature before upgrading all the nodes, file system shuts down on the nodes that have not yet been upgraded.
CLDB Snapshot Improvements	`mfs.feature.snapshotdb.lite`	6.0	This feature stays disabled even after you enable it, till you perform a CLDB failover. The feature is enabled only after the CLDB failover is complete, after which you can experience significant performance improvements for snapshot create and delete operations.

Feature	Feature Name	Available as of Release	Description
External IPs for CLDB	`cldb.feature.external.ip`	6.0	Enables support for external IP addresses and port forwarding. Set the environment variables (as described here) before enabling this feature. After enabling this feature, perform a CLDB failover to allow file system to re-register.
Container Identity Reuse	`cldb.feature.cid.reuse`	5.2.1	Support for container identity reuse.
Fast inode Scan for Mirroring	`mfs.feature.fastinodescan.support`	5.2.1	Enables fast mirroring when there are large numbers of files with few changes.
Streams Connect Support	`mfs.feature.streams.connect.support`	5.2.1	Enables support for Kafka Connect in the distributed mode.
Extended Attributes	`mfs.feature.fileace.support`	5.2	Enables support for adding, retrieving, and removing extended attributes on files and directories.
Hardlinks	`mfs.feature.hardlinks.support`	5.2	Enables support for retrieving hard links on files.
Access Control Expressions for file system	`mfs.feature.fileace.support`	5.1	Enables the setting of Access Control Expressions on filesystem and whole volume data.
HPE Ezmeral Data Fabric Streams and HPE Ezmeral Data Fabric Database as a document database	`mfs.feature.db.json.support`	5.1	Enables the use of MapR Streams and HPE Ezmeral Data Fabric Database as a Document Database on page 642.
MapR Auditing	`mfs.feature.audit.support`	5.0	Logs audit records of cluster-administration operations and operations on directories, files, and tables.
MapR Volume Upgrade	`mfs.feature.volume.upgrade` `mfs.feature.rwmirror.support`	5.0	Enables support for promotable mirrors on both old-format and new-format volumes.
HPE Ezmeral Data Fabric Database Table Replication	`mfs.feature.db.repl.support`	4.1	Enables support for HPE Ezmeral Data Fabric Database table replication.
Promotable Mirror Volumes	`mfs.feature.rwmirror.support`	4.0.2	Enables support for promotable mirror volumes.

Feature	Feature Name	Available as of Release	Description
Reduce On-Disk Container Size	`cldb.reduce.container.size`	4.0.2	Reduces the space required on-disk for each container. The reduction of the on-disk container size takes effect after the CLDB service restarts or fails over. **NOTE:** After enabling this feature on a cluster with more than a million containers, it may take some time for the initial failover to complete, as the CLDB rewrites container location tables and storage pool container map tables. However, this delay does not reoccur with any subsequent failovers.
Bulk Loading of Data to HPE Ezmeral Data Fabric Database Tables	`mfs.feature.db.bulkload.support`	3.1.1	Enables support for bulk loading of data to HPE Ezmeral Data Fabric Database tables. Used when upgrading from MapR version 3.1 or earlier.

Access Control Expressions and Table Region Merges	`mfs.feature.db.ace.support`
	
	`mfs.feature.db.regionmerge.support`
	
	`mfs.feature.filecipherbit.support`
		3.1	The following features enable support for Managing Access Control Expressions on page 1855 (ACEs) and table region merge on page 2496. Used when upgrading from MapR version 3.0.x.
			
			`mfs.feature.db.ace.support`
			`mfs.feature.db.regionmerge.support`
			
			These features are automatically enabled with a fresh install or when you upgrade from a version earlier than 3.0.x.
			
			IMPORTANT: After enabling ACEs for HPE Ezmeral Data Fabric Database tables, table access is enforced by table ACEs instead of the filesystem. As a result, all newly created tables are owned by root and have their mode bits set to 777.
			
			The following feature enables encryption of network traffic to or from a file, directory, or HPE Ezmeral Data Fabric Database table. This feature is enabled after you enable security features on your cluster.
			
			`mfs.feature.filecipherbit.support`
			
			WARNING: Clusters with active security features experience job failures until this configuration value is set.

last-updated: Jun 06, 2024

Installing Additional Core Features

Some features can require additional configuration or the installation of additional packages after an upgrade to a new release.

Enabling the Control System After an Upgrade

Release 7.1.0 upgraded the `hazelcast.xml` file that the Control System uses to manage session information. After an upgrade to release 7.1.0 or later, if the upgraded file is not available, the Control System can fail to start. Use the following steps to avoid Control System startup issues after an upgrade:

1. Navigate to the `/opt/mapr/apiserver/conf/` directory:

   ```
   cd /opt/mapr/apiserver/conf/
   ```

2. Rename the current `hazelcast.xml` file as follows:

   ```
   mv hazelcast.xml hazelcast.xml.bkp
   ```

3. Copy the upgraded `hazelcast.xml` file from the `/conf.new` directory to the `/conf` directory:

   ```
   cp /opt/mapr/apiserver/conf.new/hazelcast.xml .
   ```

4. Restart the Control System API server:

   ```
   maprcli node services -name apiserver -action restart -nodes
   <apiserver_node_name>
   ```

Restoring Object Store Configuration Files

Upgrades from release 7.0.0 to 7.1.0 or later remove the Object Store configuration files in `/opt/mapr/conf`. This can prevent the Object Store from starting after the upgrade.

Preparing to Upgrade Core on page 315 instructed you to create a backup of these files:

- `moss.conf`
- `s3cfg`
- `moss-core-site.xml`

After upgrading, copy the backed-up files to `/opt/mapr/conf` on any node running the MOSS server.

Installing the HPE Ezmeral Data Fabric Object Store After an Upgrade

Release 7.0.0 added the HPE Ezmeral Data Fabric Object Store. If you upgraded from a release earlier than release 7.0.0, use the following steps to install the Object Store:

1. Install the `mapr-s3server` package on all cluster nodes. For more information about installing cluster service packages, see Step 4: Install Cluster Service Packages on page 192.

2. Enable Object Store support if it is not already enabled:

   ```
   maprcli cluster feature enable -name cldb.objectstore.support -force
   true -json
   ```

last-updated: Jun 06, 2024

3. Restart the CLDB services on the CLDB secondary nodes:

```
/opt/mapr/bin/maprcli node services -cldb restart -nodes node1 node2
node3
```

   For more information about node services, see node services on page 2292.

4. Generate the Object Store certificates by using the `manageSSLKeys.sh`:
   - After upgrading from core 6.2.0 to 7.0.0 or later:

```
manageSSLKeys.sh createusercert -a moss -u *.<domain_name> -ug
<cluster_admin_id>:<cluster_admin_group>
```

     In this command, `-u` specifies the domain name.

   - After upgrading from core 6.1.x to 7.0.0 or later:

```
manageSSLKeys.sh createusercerts -ug
<cluster_admin_id>:<cluster_admin_group> -N <cluster_name>
```

5. Complete all steps in Enabling the HPE Ezmeral Data Fabric Object Store on page 217.

Installing Monitoring After an Upgrade

Monitoring, also known as the Spyglass initiative, provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications. You can only install Monitoring after you upgrade ecosystem components.

- To install Monitoring without the Installer, see Step 9: Install Metrics Monitoring on page 222 and Step 10: Install Log Monitoring on page 225.

Securing the Upgraded Cluster

Nonsecure clusters can be secured after the upgrade process.

If your cluster was nonsecure before you upgraded it, the cluster will remain nonsecure after the upgrade. If you used the manual-rolling or offline-manual workflows to upgrade and you want to add security, see Getting Started with HPE Ezmeral Data Fabric Security on page 1776.

If you used the Installer workflow to upgrade, and you want to add security, see Using the Enable Secure Cluster Option on page 5611.

Upgrading Ecosystem Packs

Describes how to upgrade Ecosystem Packs (EEPs), either as part of a core upgrade or to take advantage of a new EEP for the current version of core.

An Ecosystem Pack (EEP) provides a set of ecosystem components that are fully tested by HPE to be interoperable except where noted. For more information about EEPs, see Ecosystem Packs.

Planning Ecosystem Pack (EEP) Upgrades

The set of ecosystem components that you run in the cluster must all belong to the same EEP.

As of release 5.2, you must install ecosystem components as part of an EEP. You will be offered packs to install that contain selected component versions. After upgrading, you may want to upgrade to a more recent EEP to get the latest patch releases or newer versions of ecosystem components.

Most core versions support multiple EEPs, but the set of ecosystem components that you run in the cluster must all belong to the same EEP. You cannot selectively upgrade components. When you upgrade an EEP, all components are replaced with the versions contained in the newly selected EEP.

To compare ecosystem component versions across EEPs, see Component Versions for Released EEPs.

For EEP lifecycle information, see EEP Support and Lifecycle Status on page 5728.

For details about the ecosystem components available in each EEP and the list of EEPs supported by your core version, see the EEP Release Notes on page 5804.

For API or behavioral changes associated with new ecosystem components, see the documentation for the individual component under Ecosystem Components.

Preparing to Upgrade the Ecosystem Pack
Complete these pre-upgrade steps for each ecosystem component in the EEP that you want to upgrade.

For the components provided in each EEP, see the EEP Release Notes on page 5804.

These steps are intended primarily for ecosystem-component upgrades performed manually (without the Installer). However, you need to perform some pre-upgrade steps even if you are upgrading using the Installer.

Stopping each service is optional if you are using the Installer because the Installer stops all services before upgrading. But the Installer does NOT back up configuration files.

IMPORTANT: Regardless of the upgrade method that you use, follow the pre-upgrade steps for backing up your configuration files before upgrading. The upgrade process replaces your current configuration files with new configuration files that contain default values for the release to which are upgrading. Any custom settings are lost and must be migrated manually as part of the post-upgrade steps.

Pre-Upgrade Steps for Airflow
Complete the following steps before you upgrade Airflow with or without the Installer.

About this task
Use these steps:

Procedure

1. Stop the `airflow-scheduler` and `airflow-webserver` services if they are installed:

   ```
   maprcli node services -name airflow-webserver -action stop -nodes <nodes
   list>
   maprcli node services -name airflow-scheduler -action stop -nodes <nodes
   list>
   ```

2. If necessary, back up the Airflow configuration file. If you made configuration changes that you want to carry over to the next version, you must back up the configuration file. Typically, the following configuration file contains changes:

   - `<airflow_home>/conf/airflow.cfg`

   To back up the configuration file, copy the file to a location outside the installation directory. After upgrading, you can reapply changes to the updated Airflow installation using the backup.

3. Back up the `/dags` directory if it is present under the `<airflow_home>` directory. To back up the `/dags` directory, copy the directory to a location outside the `<airflow_home>` directory. After upgrading, you can reapply changes to the updated Airflow installation using the backup.

   For more information about upgrading Airflow, see:

   - Upgrading Airflow to a newer version
   - Best Practices

last-updated: Jun 06, 2024

Pre-Upgrade Steps for Drill

Complete the following steps before you upgrade Drill with or without the Installer.

About this task

Starting in Drill 1.11, Drill is automatically secured when installed in a release 6.x cluster with the default MapR security configuration. The default security configuration uses data-fabric security (`mapr` tickets) to provide authentication, authorization, and encryption for cluster security. See Securing Drill for more information.

NOTE: The default security feature introduced in release 6.0 is not supported with Drill-on-YARN.

NOTE: See Component Versions for Released EEPs for version support in each EEP release.

Preserving Custom Security When Upgrading Core and Drill

You can perform a manual upgrade, for example from a secured release 5.2 cluster to 6.0, to preserve your security settings from 5.2. When you upgrade, a special file, /opt/mapr/conf/.upgrade_from, checks for security settings. If security is set, the same settings carry over to 6.x.

During a custom upgrade, Drill configurations are not carried over. You must either reconfigure all of your Drill settings, or save your previous settings and then override the default Drill settings. You can manually secure Drill either by copying over the old drill-override.conf file into /opt/mapr/drill/drill-<version>/conf or by updating the /opt/mapr/drill/drill-<version>/conf/drill-distrib.conf file with the security settings.

After you upgrade, you must run configure.sh -R to configure the cluster. When you run the configuration script, it adds a .customSecure file to the /opt/mapr/conf directory. This file calls the internal ecosystem scripts, but does not configure Drill.

If you decide you want to enable the default security option, you can do so by running configure.sh with the -secure and -forceSecurityDefaults flags, as shown:

```
/opt/mapr/server/configure.sh -forceSecurityDefaults [ -unsecure | -secure ]
 -C <CLDB_node> -Z <ZK_node>
```

Running configure.sh with these flags secures the cluster and supported ecosystem components. The internal Drill configuration script configures Drill security in the drill-distrib.conf and distrib-env.sh files. See Securing Drill.

Drill Management Service

Drill can run under the Warden service or under YARN. You can upgrade Drill and continue to run Drill under the Warden service. If you are currently running Drill under the Warden service, you can migrate Drill to run under YARN. If you want to migrate Drill to run under YARN, see Migrate Drill to Run Under YARN.

If you are upgrading Drill to run under Warden, Drill should preserve your storage plugin and configuration files when you upgrade. However, you should backup and restore your configuration files and UDF JAR files.

Pre-Upgrade Steps

Complete the following steps on Drill servers and clients before you upgrade Drill:

1. Optionally, back up storage plugin configurations:
   a. Open the Drill Web Console. The Drill node that you use to access the Web Console is a node that is currently running the Drillbit process.
   b. Click the **Storage** tab.
   c. Click **Update** next to a storage plugin.
   d. Copy the configuration to a text file, and save the file.

e. Repeat steps **c** and **d** for each storage plugin configuration that you want to save.

2. To stop the Drillbit service on all nodes, issue the following command:

```
maprcli node services -name drill-bits -action stop -nodes <node
hostnames separated by a space>
```

Pre-Upgrade Steps for Hadoop and YARN

Complete the following steps before you upgrade Hadoop and YARN with or without the Installer.

About this task

Before release 6.2.0 and EEP 7.0.0, Hadoop and YARN services were part of the Data Fabric repository for core packages. Upgrading Hadoop was not possible because releases 5.2.x, 6.0.x, and 6.1.x all used the same Hadoop version (version 2.7.0). Beginning with release 6.2.0 and EEP 7.0.0, Hadoop and YARN services were removed from Data Fabric core and delivered as ecosystem components in the EEP(MEP) repository. For more information, see Installing Hadoop and YARN on page 241.

Delivering Hadoop and YARN services in an EEP makes it possible to upgrade the packages independently of the HPE Ezmeral Data Fabric. Hadoop Protocol Versions on page 5766 shows the currently supported Hadoop versions. The following table describes the supported Hadoop upgrades:

If your current Hadoop version is	To upgrade, you must
2.7.4.0 or later	Upgrade to an EEP that provides a newer Hadoop version.  **IMPORTANT:** Rolling upgrades from Hadoop 2.x to Hadoop 3.x are not supported. Only offline upgrades to Hadoop 3.x are supported.
2.7.0	Upgrade to core 6.2.x and install Hadoop components from a EEP that is supported on core 6.2.x. See Upgrade Workflows (Releases 6.x or 7.x to 7.7.0) on page 301.

To prepare to upgrade Hadoop 2.7.4.0 or later:

1. Stop the following services if they are installed:

```
maprcli node services -name resourcemanager -action stop -nodes
<IP-address>
maprcli node services -name nodemanager -action stop -nodes <IP-address>
maprcli node services -name historyserver -action stop -nodes
<IP-address>
maprcli node services -name timelineserver -action stop -nodes
<IP-address>
```

You do not need to back up configuration files manually. Hadoop configuration files are automatically backed up to this directory: `/opt/mapr/hadoop/hadoop-<timestampversion>`

Pre-Upgrade Steps for HBase

Complete the following steps before you upgrade HBase with or without the Installer.

About this task

Procedure

1. **Upgrade your HBase Java applications.**
   Check your HBase applications for Java APIs that are no longer supported in HBase 1.1. See HBase Java API Support. Then, update the applications to use APIs supported by HBase 1.1 and recompile your applications with HBase 1.1.

2. **Take a snapshot of the HBase volume.** This step is applicable if you are upgrading with the MapR Installer or upgrading manually.
   The snapshot creates a backup of the volume data that you can use to recover your data in the event that corruption occurs during the upgrade process. For more information, see Creating Volume Snapshots on page 1270.

3. **Optional: Create a backup copy of any configuration files that contain customized values.** This step is applicable if you are upgrading with the MapR Installer or upgrading manually.
   The configuration files are located in `/opt/mapr/hbase/hbase-<version>/conf/`. Copy any that you want to back up to another location. If you plan to upgrade with the MapR installer, copy files to a location that is outside the MapR installation directory. After upgrading, you can reapply changes to the updated HBase installation using the backup.

Considerations for Upgrading to HBase 1.1.13
Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

Removing the Mappings Property

A release 6.0.x cluster installed using the Installer contains an `hbase.table.namespace.mappings` property in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file. For example:

```
<property>
   <name>hbase.table.namespace.mappings</name>
   <value>*:/</value>
</property>
```

Release 6.0.x clusters support HPE Ezmeral Data Fabric Database, but they do not support HBase. Therefore, if you upgrade the cluster manually from Release 6.0.x, you need to remove this property in order to support HBase connections to both HBase and HPE Ezmeral Data Fabric Database.

If you do not remove the property, you might see the following message:

```
This client is configured to use MapR tables only. HBase status is not
available. MapR cluster status
can be viewed using the 'maprcli dashboard info' command or the UI.
```

How HBase Configuration Files Are Preserved During an Upgrade

Starting with EEP 6.3.0, existing HBase configuration files are automatically saved during an upgrade. This table describes what happens to HBase configuration files during an upgrade.

When you upgrade from HBase Version	To Version	HBase Configuration Files
1.1.8	1.1.13	Are overwritten by new configuration files.
1.1.13	1.1.13 (with patches)[1]	Are saved (not overwritten).

[1]An upgrade from HBase 1.1.13 to HBase 1.1.13 is a valid upgrade path if patches have been added to HBase 1.1.13 and you want to apply the patches.

This example shows a listing of the configuration files that are saved after an upgrade from HBase 1.1.8 to HBase 1.1.13:

```
[mapr@node2 etc]$ ls /opt/mapr/hbase/
hbase-1.1.13 hbase-1.1.8.201904050941 hbaseversion

$ ls /opt/mapr/hbase/hbase-1.1.8.201904050941/conf/
hadoop-metrics2-hbase.properties hbase-env.sh hbase-policy.xml
hbase-site.xml log4j.properties regionservers
warden.hbaserest.conf warden.hbaserest.conf.template
warden.hbasethrift.conf warden.hbasethrift.conf.template
```

Applications and Security

Existing HBase applications might need to be modified to work properly with HBase 1.1.13 in a secure cluster:

HBase API Client	No changes
HBase REST	No changes if the old client used PAM (can now be changed to mapr-sasl header)
HBase Thrift over HTTP	No change if the old client used PAM (can now be changed to mapr-sasl header)
HBase Thrift over Socket	No changes

Configuring the Default Database for HBase Clients

EEP 6.3.0 introduced some minor changes to default database configuration. For details, see Configure the Default Database for HBase Clients on page 4131.

Pre-Upgrade Steps for HBase Client
Complete the following steps before you upgrade HBase Client with or without the Installer.

About this task
If you made configuration changes that you want to carry over to the next version of HBase Client, you need to back up configuration files.

Procedure

1. Copy the configuration files in `/opt/mapr/hbase/hbase-<version>/conf/` to a location outside the installation directory.
2. After upgrading, you can reapply changes to the updated HBase Client by merging the configuration files back into `/opt/mapr/hbase/hbase-<version>/conf/`. See Post-Upgrade Steps for HBase Client on page 389 for more information.

Related concepts

Considerations for Upgrading to HBase 1.1.13 on page 350
Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

Pre-Upgrade Steps for Hive
Complete the following steps before you upgrade Hive with or without the Installer.

About this task

Upgrades from Hive 2.x to 3.x require some additional pre-upgrade steps. If you are upgrading from Hive 2.x to 3.x, review and complete the pre-upgrade activities in the following topics before completing the steps on this page:

- Preparing to Upgrade from Hive 2.x to 3.x on page 352
- ACID Table Upgrade Routine on page 354

For this task, you need to back up the metastore database in case an error occurs during the Hive upgrade. You also need to back up configuration files if you made configuration changes that you want to carry over to the next version.

Procedure

1. Back up the metastore database.
   ```
   mysqldump -u<user> -p<passwd> <metastore_db_name> -r metastore-db-dump.sql
   ```
2. Copy the configuration files in `/opt/mapr/hive/hive-<version>/conf/` to a location outside the installation directory.
   After upgrading, you can reapply changes to the updated Hive installation using the backup.
3. Stop Hive services.
   ```
   maprcli node services -name hivemeta -action stop -nodes <list of hive
   nodes>
   maprcli node services -name hs2 -action stop -nodes <list of hive nodes>
   maprcli node services -name  hcat -action stop -nodes <list of hive
   nodes>
   ```

Preserving the Hive Configuration
Starting from EEP-6.0.0, preserving of user configuration logic is built into Hive.

Procedure

- For a minor version update (for example, `Hive-2.1-1803` to `Hive-2.1-1808`), user configuration from a previous version is copied to a folder with an old version timestamp and is also copied to a new version `conf` folder.
- For a major version update (for example, `Hive-2.1-1803` to `Hive-2.3-1808`), user configuration from a previous version is **only** copied to a folder with an old version timestamp.

Starting from EEP-5.0.2 and EEP-6.0.1, a logic of preserving user Warden files configuration for Hive Metastore, HiveServer2 and WebHCat are built into Hive.

Procedure

- For a minor version update (for example, `Hive-2.1-1808` to `Hive-2.1-1901`), user configuration of Warden files from a previous version is copied to a folder with an old version timestamp and is also preserved in the `MAPR_HOME/conf/conf.d/` folder.
- For a major version update (for example, `Hive-2.1-1808` to `Hive-2.3-1901`), user configuration from a previous version is **only** copied to a folder with an old version timestamp.

Preparing to Upgrade from Hive 2.x to 3.x
Upgrading from Hive 2.x to 3.x requires you to understand data migration, ACID table migration, permissions, folder structures, and artifact naming.

EEP 9.0.0 introduced Hive 3.1.3, while EEP 7.x and 8.x supported Hive 2.3. Any upgrades from EEP 7.x and 8.x to EEP 9.0.0 require a thorough review of the considerations in this topic. For information about the Hive versions in different EEPs, see Component Versions for Released EEPs on page 5750.

ACID Table Migration

In Hive 3.x, all data – including data in tables, partitions, and UDF functions – is supported as is in Hive 2.x, except for ACID (transactional) tables. ACID tables require some actions *before* you upgrade from Hive 2.x to 3.x.

Hive 3.x changed the on-disk layout of ACID tables. Any ACID table partition that had an Update, Delete, or Merge statement executed since the last major compaction must execute a major compaction before upgrading to Hive 3.x.

No more Update, Delete, or Merge statements may be executed against these tables after the start of major compaction. Not following this sequence can lead to data corruption. Tables and partitions that contain only results of Insert statements are fully compatible and do not need to be compacted.

For details, see ACID Table Upgrade Routine on page 354.

Permission Processing for New Tables

Hive 3.x dropped the following property:

```
hive.warehouse.subdir.inherit.perms
```

Instead of the Hive permission inheritance that was based on the `hive.warehouse.subdir.inherit.perms` parameter setting, Hive 3.x supports the data-fabric file-system access control model. In Hive 3x, a directory inherits permissions from the `Default` file-system value. All permissions-inheritance logic has been removed.

To summarize the new behavior:

- 777 - default warehouse directory
- 755 - child directories (no more inheritance)

Table permissions that remain from Hive 2.x are unchanged.

Folder Structure and Versioning

Unlike Hive 2.x, Hive-3.x has a three-digit version, which introduces a change in the `HIVE_HOME` pattern. For example:

Hive Version	HIVE_HOME Pattern
2.x	`/opt/mapr/hive/hive-2.3`
3.x	`/opt/mapr/hive/hive-3.1.3`

This change can affect any custom parsing utilities for `HIVE_HOME`.

Artifact Naming

Hive 3.x JAR artifacts use a four-digit version. For example:

```
hive-A.B.C.D.jar
```

where:

- A is the Major version

- `B` is the Minor version
- `C` is the Patch version
- `D` is the EBF/Release version

This change can affect dependency management in custom applications that refer to Hive 3.x.

ACID Table Upgrade Routine
Contains a procedure that must be followed if your installation of Hive 2.x includes ACID tables and you want to upgrade from Hive 2.x to 3.x. If Hive is upgraded from 2.x to 3.x without performing these steps, data in the ACID tables will be corrupted during the upgrade.

Prerequisites

The following steps assume:

- A cluster with release 7.0.0 and EEP 8.1.0.
- The cluster is running Hive 2.3 and Hadoop 2.7.
- Derby is *not* used as the Hive Metastore backend database.
- The Hive Upgrade ACID Tool JAR has been downloaded to the Hive 2.x installation node.

Considerations for Running the Tool

Note these considerations:

- You must run the Upgrade ACID Tool before upgrading any cluster package.
- You must run the Upgrade ACID Tool on a live cluster.
- Before running the Upgrade ACID Tool, stop the `hs2` service to ensure no access is permitted during the upgrade tool run.

ACID Table Upgrade Steps

Use these steps to run the tool:

1. Stop the `hs2` service:

```
$ maprcli node services -action stop -nodes `hostname -f` -name hs2;
```

2. Run the Upgrade ACID Tool. Modify the following paths in the run command to match the environment:

Path	Description
`/opt/mapr/hive/hive-<old_hive_version>`	Path to the Hive 2.x installation
`/opt/mapr/hadoop/hadoop-<old_hadoop_version>`	Path to the Hadoop 2.7 installation
`<path_to>/ hive-upgrade-acid-<new_hive_version>-eep-900.jar`	Path to the upgrade tool JAR file

Here is the command syntax:

```
$ java -cp /opt/mapr/lib/*:/opt/mapr/hive/
hive-<old_hive_version>/lib/*:/opt/mapr/hive/hive-<old_hive_version>/
conf/*:/opt/mapr/hadoop/hadoop-<old_hadoop_version>/lib/*:/opt/mapr/
hadoop/hadoop-<old_hadoop_version>/etc/hadoop/*:/opt/mapr/hadoop/
hadoop-<old_hadoop_version>/share/hadoop/yarn/sources/*:/opt/mapr/hadoop/
```

```
hadoop-<old_hadoop_version>/share/hadoop/mapreduce/*:/opt/mapr/hadoop/
hadoop-<old_hadoop_version>/share/hadoop/mapreduce/sources/*:/opt/mapr/
hadoop/hadoop-<old_hadoop_version>/share/hadoop/hdfs/*:/opt/mapr/hadoop/
hadoop-<old_hadoop_version>/share/hadoop/hdfs/sources/*:/home/mapr/
hive-upgrade-acid-<new_hive_version>-eep-900.jar
org.apache.hadoop.hive.upgrade.acid.UpgradeTool -preUpgrade -execute
```

If the path values are as follows:

Path	Description
`/opt/mapr/hive/hive-2.3`	Path to the Hive 2.x installation
`opt/mapr/hadoop/hadoop-2.7.6`	Path to the Hadoop 2.7 installation
`/home/mapr/hive-upgrade-acid-3.1.3.0-eep-900.jar`	Path to the upgrade tool JAR file

Here's an example:

```
$ java -cp /opt/mapr/lib/*:/opt/
mapr/hive/hive-2.3/lib/*:/opt/mapr/hive/hive-2.3/conf/*:/opt/mapr/hadoop/
hadoop-2.7.6/lib/*:/opt/mapr/hadoop/hadoop-2.7.6/etc/hadoop/*:/opt/
mapr/hadoop/hadoop-2.7.6/share/hadoop/yarn/sources/*:/opt/mapr/hadoop/
hadoop-2.7.6/share/hadoop/mapreduce/*:/opt/mapr/hadoop/hadoop-2.7.6/
share/hadoop/mapreduce/sources/*:/opt/mapr/hadoop/hadoop-2.7.6/share/
hadoop/hdfs/*:/opt/mapr/hadoop/hadoop-2.7.6/share/hadoop/hdfs/sources/*:/
home/mapr/acid-test/hive-upgrade-acid-3.1.3.0-eep-900.jar
org.apache.hadoop.hive.upgrade.acid.UpgradeTool -preUpgrade -execute
```

Note that the `-preUpgrade` and `-execute` flags are mandatory.

3. Continue the cluster and Hive upgrade procedures. At this point, the ACID tables are ready to use by Hive 3.x, and no further ACIDupgrade actions are required.

Troubleshooting

This section addresses common troubleshooting scenarios during the ACID table upgrade operation:

Problem

The Hive Upgrade ACID Tool finishes almost instantly with the following log messages (the example log is trimmed for readability):

```
INFO  [main] acid.UpgradeTool - No
compaction is necessary
INFO  [main] acid.UpgradeTool - No
acid conversion is necessary
INFO  [main] acid.UpgradeTool - No
managed table conversion is necessary
INFO  [main] acid.UpgradeTool - No
file renaming is necessary
```

Solution

These log messages are not necessarily a problem. It is possible that even though ACID tables are present, the upgrade tool decided these tables do not need any upgrade modifications.

last-updated: Jun 06, 2024

Problem

The Hive Upgrade ACID Tool fails with the following error:

```
java.lang.NoClassDefFoundError
```

Solution

Make sure all paths in the `run` command are specified correctly and exist in the file system.

Problem

The Hive Upgrade ACID Tool fails with the following error:

```
Error: Could not find or load main
class
org.apache.hadoop.hive.upgrade.acid.Up
gradeTool
```

Solution

Make sure that:

- The path to the upgrade tool JAR file is specified correctly.
- The JAR file is included in the classpath option.
- The JAR file exists within the specified path.

Problem

The Hive Upgrade ACID Tool fails with the following log messages (the example log is trimmed for readability):

```
ERROR [main] acid.UpgradeTool -
UpgradeTool failed
java.lang.NullPointerException
at
org.apache.hadoop.hive.ql.io.AcidUtils
.getChildState(AcidUtils.java)
at
org.apache.hadoop.hive.ql.io.AcidUtils
.getAcidState(AcidUtils.java)
```

Solution

Most likely the `run` command does not contain the `-execute` flag. Make sure that the `-execute` flag contains a preceding dash.

Problem

The Hive Upgrade ACID Tool fails with the following log messages (the example log is trimmed for readability):

```
WARN  rpcauth.RpcAuthRegistry - No
RpcAuthMethod registerd for
authentication method CUSTOM
ERROR acid.UpgradeTool - UpgradeTool
failed
java.lang.NullPointerException
at
org.apache.hadoop.hive.thrift.ThriftTr
ansportHelper.createMapRSaslTransport
(ThriftTransportHelper.java)
at
org.apache.hadoop.hive.thrift.HadoopTh
riftAuthBridge25Sasl$Client.createClie
ntTransport
(HadoopThriftAuthBridge25Sasl.java)
```

```
at
org.apache.hadoop.hive.metastore.HiveM
etaStoreClient.open
(HiveMetaStoreClient.java)
at
org.apache.hadoop.hive.metastore.HiveM
etaStoreClient.<init>(HiveMetaStoreCli
ent.java)
```

Solution

Most likely too many JARs were specified in the classpath. Do not use a command such as the following to collect JARs for the classpath in the upgrade utility `run` command. Use exactly the classpath values specified in the preceding template:

```
find /opt/mapr -iname "*.jar" | xargs
| tr -s ' ' ':'
```

Pre-Upgrade Steps for HttpFS

Complete the following steps before you upgrade HttpFS with or without the Installer.

About this task

IMPORTANT: If you are upgrading from EEP 8.x.x or a previous EEP to EEP 9.0.0 or later, note that EEP 9.0.0 introduced changes to the location of the `httpfs-site.xml` file and the name of the timeout property. For more information about these changes, see Network Timeout for HttpFS on page 4374.

Stop the HttpFS service using the following command:

```
maprcli node services -name httpfs -action stop -nodes <ip_address>
```

Preserving HttpFS Configuration

Preserving of user configuration logic is built into HttpFS.

Procedure

- User configuration from a previous version is copied to a folder with an old version timestamp and is also copied to a new version `conf` folder.

Pre-Upgrade Steps for Hue

Complete the following steps before you upgrade Hue with or without the Installer.

About this task

Procedure

1. Stop the Hue service:
   ```
   maprcli node services -name hue -action stop -nodes <ip_address>
   ```

2. Create a Hue database dump as a JSON object:

   For MySQL, PostgreSQL, or Oracle

   ```
   source /opt/mapr/hue/hue-<version>/bin/activate
   hue dumpdata > ~/dump-hue-<version>.json
   deactivate
   ```

   For SQLite

   ```
   cd /opt/mapr/hue/hue-<version>/desktop
   sqlite3 desktop.db .dump > ~/dump-hue-<version>-sqlite.bak
   ```

3. Copy the configuration properties from `/opt/mapr/hue/hue-<version>/desktop/conf/` to a location outside your installation directory.

   After upgrading, you can reapply changes to the updated Hue installation using the backup.

4. After upgrading on Ubuntu, remove the `mapr-hue-base` package:

   ```
   apt-get remove mapr-hue-base
   ```

Preserving Hue Configuration
Starting from EEP-6.0.0, preserving of user configuration logic is built into Hue.

Procedure

- For a major version update (for example, `Hue-3.2-1803` to `Hive-4.2-1808`), user configuration from a previous version is **only** copied to a folder with an old version timestamp (`/HUE_HOME/hue-3.12.0.201707281202`).

Pre-Upgrade Steps for Data Access Gateway
Complete the following steps before you upgrade the Data Access Gateway with or without the Installer.

Procedure

Stop the service:

```
maprcli node services -nodes <node name> -name data-access-gateway -action
stop
```

Pre-Upgrade Steps for Livy

About this task
Complete the following steps before you upgrade Livy with or without the Installer.

Use these steps:

1. Stop the Livy service if it is installed:

   ```
   maprcli node services -name livy -action stop -nodes <ip_address>
   ```

2. If necessary, back up configuration files:

   If you made configuration changes that you want to carry over to the next version, you need to back up the configuration files. Typically, the following configuration files contain changes:

   - `/opt/mapr/livy/livy-<version>/conf/livy.conf`

last-updated: Jun 06, 2024

- `/opt/mapr/livy/livy-<version>/conf/livy-env.sh`

To back up configuration files, copy the files to a location outside the installation directory. After upgrading, you can reapply changes to the updated Livy installation using the backup.

NOTE:

- Starting from EEP-6.0, for Livy upgrades, from Livy 0.3 and above, user configuration files are saved during upgrade.
- For Livy upgrades from `mapr-hue-livy 3.12`, user configuration files are NOT saved during the upgrade.
- For manual Livy upgrades from `mapr-hue-livy 3.12` on Ubuntu, you need to remove the old `mapr-hue livy` package manually.

Pre-Upgrade Steps for Monitoring

Complete the following steps before you upgrade Monitoring Components with or without the Installer.

About this task

During an upgrade using the Installer, a script backs up many of the configuration files. However, whether or not you are upgrading manually or by using the Installer, it is a best practice to back up the files manually. Manual backups can help in case an error occurs or the specific file you customized is not automatically backed up by the script.

Before performing the pre-upgrade steps, note these important considerations:

- The Monitoring upgrade is an offline upgrade and *not* a rolling upgrade.
- This upgrade procedure is customized for the Data Fabric implementation of the monitoring components. Because the Data Fabric implementation has a narrow focus and there are numerous components, the upgrade steps are simplified. Data Fabric upgrade documentation does *not* include all of the upgrade steps that are included in the vendor documentation for each component. Before starting the upgrade process, consider familiarizing yourself with the vendor-upgrade steps to determine if your environment requires extra measures to protect data and configurations.
  - Elasticsearch upgrade
  - Kibana upgrade
  - Search Guard upgrade
  - Grafana upgrade
- This upgrade sequence does not implement security in the Monitoring components. If the cluster you are upgrading is secure and you are upgrading to a new version of Elasticsearch, the security keys will be deleted when you upgrade the monitoring packages. You must regenerate the keys and copy them to the appropriate nodes after upgrading. The Post-Upgrade Steps for MapR Monitoring on page 394 provide links to the installation procedures containing this information.

Procedure

1. Before backing up configuration files, ensure that your Elasticsearch and Kibana indexes are not affected by the upgrade:

   NOTE: This step assumes that log monitoring is configured. You can skip this step if your cluster is not configured for log monitoring.

last-updated: Jun 06, 2024

a) If you are using Elasticsearch version 2.x, upgrade your Elasticsearch index to version 6. For upgrade information, see: https://www.elastic.co/guide/en/elasticsearch/reference/current/reindex-upgrade.html

You need to upgrade your Elasticsearch index if your cluster is running a EEP in the range 1.1 through 3.0.x. See the following table. EEPs 1.1 through 3.0.x use Elasticsearch version 2.3.3. If your cluster is running a EEP in the range 4.0.0 through 5.0.x, you are using Elasticsearch 5.4.1, and you do NOT need to upgrade the index. For more information about Elasticsearch / Search Guard version information, see this website.

Core	EEP	Elasticsearch Version	SearchGuard Version	Kibana Plugin Version
6.1.0	6.1.0	6.5.3.0	24.0	17
6.1.0	6.0.x	6.2.3	23.0	14
6.0.x	4.0.0 through 5.0.2	5.4.1	N/A	N/A
5.2.x	3.0.5 and earlier	2.3.3	N/A	N/A

For more information about the Monitoring component versions included in each EEP, see Component Versions for Released EEPs on page 5750.

b) Create a snapshot of the Kibana index to capture index information before the upgrade. This information will be restored after the upgrade. For snapshot information, see https://www.elastic.co/guide/en/elasticsearch/reference/5.6/modules-snapshots.html.

2. Before you upgrade metric monitoring components, create a backup of the configuration files to a location outside your installation directory. The following configuration file-lists include files that are commonly used for configuration and may not include every file that you may have customized.
   - Collectd configuration files:
     - /opt/mapr/conf/conf.d/warden.collectd.conf
     - /opt/mapr/collectd/collectd-<version>/etc/collectd.conf
     - /etc/logrotate.d/collectd
   - Grafana configuration files:
     - /opt/mapr/conf/conf.d/warden.grafana.conf
     - /opt/mapr/grafana/grafana-<version>/etc/grafana/grafana.ini
     - /opt/mapr/grafana/grafana- <version>/etc/grafana/ldap.toml
   - OpenTSDB configuration files:
     - /opt/mapr/conf/conf.d/warden.opentsdb.conf
     - /opt/mapr/opentsdb/opentsdb-<version>/etc/opentsdb/opentsdb.conf
     - /opt/mapr/opentsdb/opentsdb-<version>/etc/opentsdb/logback.xml
     - opt/mapr/opentsdb/opentsdb-<version>/bin/tsdb_cluster_mgmt.sh (This file is not automatically backed up.)
3. Before you upgrade log monitoring components, create a backup of the following files to a location outside your installation directory. The following configuration file lists include files that are commonly used for configuration and may not include every file that you may have customized.

last-updated: Jun 06, 2024

- Kibana configuration files:
  - /opt/mapr/conf/conf.d/warden.kibana.conf
  - /opt/mapr/kibana/kibana-<version>/etc/conf/kibana.js
- fluentd configuration files:
  - /opt/mapr/conf/conf.d/warden.fluentd.conf
  - /opt/mapr/fluentd/fluentd-<version>/etc/fluentd/fluentd.conf
  - /opt/mapr/fluentd/fluentd-<version>/etc/fluentd/es_config.conf
  - /opt/mapr/fluentd/fluentd-<version>/etc/fluentd/maprfs_config.conf
  - /opt/mapr/fluentd/fluentd-<version>/etc/fluentd/grok-patterns
  - /etc/logrotate/fluentd
- Elasticsearch configuration files:
  - /opt/mapr/conf/conf.d/warden.elasticsearch.conf
  - /opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/elasticsearch.yml
  - /opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/logging.yml
  - /opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/curator.yml
  - /opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/curator_actions/delete_indices.yml (This file is not automatically backed up.)
  - /opt/mapr/elasticsearch/elasticsearch-<version>/var/lib/MaprMonitoring/ (This directory is the default location for Elasticsearch index data. You must back up this directory unless you specified a non-default location using the `-ESDB` parameter with `configure.sh` during installation.)

4. Stop all monitoring services on the cluster.

a) To stop collectd, run the following command:

```
maprcli node services -name collectd -nodes <space separated list of
hostname/IPaddresses> -action stop
```

b) To stop Grafana, run the following command:

```
maprcli node services -name grafana -nodes <space separated list of
hostname/IPaddresses> -action stop
```

c) To stop OpenTSDB, run the following command:

```
maprcli node services -name opentsdb -nodes <space separated list of
hostname/IPaddresses> -action stop
```

d) To stop Kibana, run the following command:

```
maprcli node services -name kibana -nodes <space separated list of
hostname/IPaddresses> -action stop
```

e) To stop fluentd, run the following command:

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> -action stop
```

f) To stop Elasticsearch, run the following command:

```
maprcli node services -name elasticsearch -nodes <space separated
list of hostname/IPaddresses> -action stop
```

Pre-Upgrade Steps for HPE Ezmeral Data Fabric Streams Tools
Complete the following steps before you manually upgrade HPE Ezmeral Data Fabric Streams Tools.

Kafka REST

Run the following command to stop the Kafka REST service on each node:

```
maprcli node services -name kafka-rest -action stop -nodes <list of Kafka
REST service nodes>
```

To see how configuration files are saved during an upgrade, see Saving Kafka REST Configurations on page 4473.

Kafka Connect

Run the following command to stop the Kafka Connect service on each node:

```
maprcli node services -name kafka-connect -action stop -nodes <list of
Kafka Connect service nodes>
```

To see how configuration files are saved during an upgrade, see Saving Kafka Connect Configurations on page 4542.

Pre-Upgrade Steps for NiFi
Complete the following steps before you upgrade NiFi with or without the Installer.

About this task
Logic to preserve the user configuration is built into NiFi. During an upgrade, all files from the previous version directory, are automatically copied to a directory with the name of the previous version and timestamp. Configuration and user flows are automatically migrated to the new version. To begin the upgrade process:

Procedure

1. Stop the NiFi service using the following command:

   ```
   maprcli node services -name nifi -action stop -nodes <hostname>
   ```

2. **Optional:** Create a backup copy of any configuration files that contain customized values. This step is applicable if you are upgrading with the Installer or upgrading manually:
   a) Find the configuration files located in `/opt/mapr/nifi/nifi-<version>/conf/`.

   b) Copy any files that you want to back up to another location. If you plan to upgrade by using the Installer, copy files to a location that is outside the installation directory. After upgrading, you can reapply changes to the updated NiFi installation using the backup.

Pre-Upgrade Steps for Ranger

Complete the following steps before you upgrade Ranger with or without the Installer.

About this task

Use these steps:

Procedure

1. Stop the Ranger Admin and Ranger UserSync services if they are installed:

   ```
   maprcli node services -name ranger-admin -action stop -nodes <node list>
   maprcli node services -name ranger-usersync -action stop -nodes <node
   list>
   ```

2. If necessary, back up the Ranger configuration file. If you made configuration changes that you want to carry over to the next version, you need to back up the file. Typically, the following configuration files contain changes:

   - For services:
     - `<ranger_home>/ranger-admin/ews/webapp/WEB-INF/classes/conf/ranger-admin-site.xml`
     - `<ranger_home>/ranger-usersync/conf/ranger-ugsync-site.xml`
   - For plug-ins:
     - `<ranger_home>/ranger-<component_name>-plugin/install.properties`

   To back up a configuration file, copy the file to a location outside the installation directory. After upgrading, you can use the backup to reapply changes to the updated Ranger installation.

Pre-Upgrade Steps for Spark

Complete the following steps before you upgrade Spark with or without the Installer.

Pre-Upgrade Steps for Spark Standalone

About this task

Procedure

1. Copy configuration files from `/opt/mapr/spark/spark-<version>/conf` to a location outside of the data-fabric installation directory.

   For example, if Spark SQL is configured to work with Hive, copy the `/opt/mapr/spark/spark-<version>/conf/hive-site.xml` file to a backup directory.

2. Shut down the spark-master, spark-historyserver services (if the spark-historyserver is running).

   ```
   maprcli node services -nodes <node-ip> -name spark-master -action stop
   maprcli node services -nodes <node-ip> -name spark-historyserver -action
   stop
   ```

last-updated: Jun 06, 2024

3. As the `mapr` user, stop the secondary instances:

   For Spark 2.x:

   ```
   /opt/mapr/spark/spark-<version>/sbin/stop-slaves.sh
   ```

   For Sparx 3.x:

   ```
   /opt/mapr/spark/spark-<version>/sbin/stop-workers.sh
   ```

Pre-Upgrade Steps for Spark on YARN

Procedure

1. Copy configuration files from `/opt/mapr/spark/spark-<version>/conf` to a location outside of the installation directory.

   For example, if Spark SQL is configured to work with Hive, copy the `/opt/mapr/spark/spark-<version>/conf/hive-site.xml` file to a backup directory.

2. Shut down the spark-historyserver services (if the spark-historyserver is running):

   ```
   maprcli node services -nodes <node-ip> -name spark-historyserver -action stop
   ```

Preserving Spark Configuration

About this task
Starting from EEP 6.0.0, in case of a version update, configuration from a previously installed version of Spark is stored in a folder with an old version timestamp.
Pre-Upgrade Steps for Tez
Complete the following steps before you upgrade Tez with or without the Installer.

About this task

If you made any configuration changes that you want to carry over to the next version, you need to back up the configuration properties files:

Procedure

1. Locate the files in the `/opt/mapr/tez/tez-<version>/conf/` and `/opt/mapr/tez/tez-<version>/tomcat/apache-tomcat-<version>/webapps/tez-ui/config/` directories.

2. Copy the files to a location outside the installation directory.

3. Delete the old `/apps/tez` directory on the file system layer.

   ```
   hadoop fs -rm -r /apps/tez
   ```

   After upgrading, you can reapply changes to the updated Tez installation using the backup.

Preserving the Tez Configuration
Starting from EEP 6.0.0, Tez assists you in preserving the user configuration.

Procedure

- For a minor version update (for example, `Tez-0.8-1803` to `Tez-0.8-1808`), the user configuration from a previous version is copied to a folder with an old version timestamp and also copied to a new version `conf` folder.
- For a major version update (for example, `Tez-0.8-1803` to `Tez-0.9-1808`), the user configuration from a previous version is **only** copied to a folder with an old version timestamp.

CentOS and SLES OS	• For upgrades from EEP 3.x to EEP 6.0.0, no additional steps are needed to preserve the user configuration. • For upgrades from EEP 4.0.0/4.1.0 to EEP 6.0.0, preserving the user configuration works only for configuration files (such as `tez-site.xml` and `configs.js`), but the Tomcat service is still present from the previous Tez version. As a precondition for upgrade from EEP 4.0.0/4.1.0, manually stop the Tomcat service and remove the `tez-0.8/` directory. • For upgrades from EEP 4.1.1/5.0.0 to EEP 6.0.0, no additional steps are needed to preserve the user configuration.
Ubuntu	• For upgrades from EEP 3.x to EEP 6.0.0, no additional steps are needed to preserve the user configuration. • For upgrades from EEP 4.0.0/4.1.0 to EEP 6.0.0, preserving the user configuration works only for configuration files (such as `tez-site.xml` and `configs.js`), but the Tomcat service is still present from the previous Tez version. As a precondition for upgrade from EEP 4.0.0/4.1.0, manually stop the Tomcat service and remove the `tez-0.8/` directory. • For upgrades from EEP 4.1.1/5.0.0 to EEP 6.0.0, you need to preserve the user configuration manually.

Upgrading the Ecosystem Pack With the Installer

If the cluster that you want to upgrade was installed using the Installer, you can use the Installer to upgrade the Ecosystem Pack (EEP).

About this task

Procedure

1. Verify that all ecosystem components are prepared for an upgrade.

   WARNING: Service failures, job failures, or the loss of customized configuration files can occur if you do not perform the steps to prepare ecosystem components for an upgrade.

2. Update the Installer. For more information, see Updating the Installer on page 5595.

   This step ensures that the Installer has access to the latest packages.

last-updated: Jun 06, 2024

3. Halt jobs and applications. Stop accepting new jobs and applications, and stop YARN applications.

```
# yarn application -list
# yarn application -kill <ApplicationId>
```

   You might also need specific commands to terminate custom applications.

4. Launch the Installer URL (`https://<hostname/IPaddress>:9443`).

5. Select the **Incremental Install** option.

6. Select the **EEP Version** to which you want to upgrade, and complete the upgrade through the Installer.

7. Once the upgrade through the Installer is complete, perform the post-upgrade steps. See Finishing the Ecosystem Pack Upgrade.

Upgrading the Ecosystem Pack Without the Installer
After you upgrade core without using the Installer, you need to upgrade ecosystem components with manual steps. First, verify that your repository is configured to use an Ecosystem Pack (EEP) that is supported by your cluster version. Then, upgrade each component manually.

NOTE: If you installed the cluster with the Installer, do not use the following steps to upgrade your ecosystem components. Instead, see Upgrading Core With the Installer on page 320.

Prerequisite: Set up the EEP Repository

Complete the following steps on each node in the cluster when you upgrade without the Installer:

1. Verify that each node can access the ecosystem packages associated with the EEP version that you want to use. For information on how to setup the ecosystem repositories or to manually download each package, see Setting Up Repositories on page 322.

2. Update the repository cache to get the latest list of available packages:
   - On RHEL/CentOS:

```
# yum clean all
```

   - On SLES:

```
 # zypper refresh
```

   - On Ubuntu:

```
# apt-get update
```

Manually Upgrade Ecosystem Components

Review the EEP Release Notes on page 5804 to determine the list of ecosystem components available in the EEP that you have selected. Then, complete the manual upgrade steps for each component that you want to upgrade.

Upgrading Airflow
This section describes how to upgrade Airflow without the Installer.

Before upgrading, review the Apache Airflow upgrade documentation.

Use one of the following commands to upgrade all Airflow services using a package manager:

- On RHEL/CentOS:

```
yum update mapr-airflow mapr-airflow-scheduler mapr-airflow-webserver
```

- On Ubuntu:

```
apt-get install mapr-airflow mapr-airflow-scheduler mapr-airflow-webserver
```

- On SLES:

```
zypper update mapr-airflow mapr-airflow-scheduler mapr-airflow-webserver
```

Upgrading AsyncHBase Libraries
This section describes how to upgrade the AsyncHBase Libraries without the Installer.

About this task
To upgrade to a more recent version of the AsyncHBase library, install the new version. See Installing AsyncHBase Libraries.

NOTE: AsyncHBase 1.7 is binary compatible with AsyncHBase 1.6.

Upgrading Drill
This section describes how to upgrade Drill without the Installer.

Before you upgrade Drill, complete the pre-upgrade steps.

ATTENTION: Due to Drill version changes (3-digit to 4-digit), you cannot upgrade from Drill in EEP 7.0.0 (Drill 1.16.1) to Drill in EEP 7.0.1 (Drill 1.16.1.5) or later. You must perform a new installation of Drill. Alternatively, if you are running Drill on CentOS or RHEL, you can issue the following command as a workaround to upgrade Drill:

```
rpm -Uv --<old-package> <path/to/packages>/*.rpm
```

Complete the following steps on the Drill server and client nodes as root or using sudo to upgrade Drill without the Installer:

1. To eliminate cached packages and files, issue the following command:

```
yum clean all
```

2. To upgrade Drill, issue the command appropriate for your system on each Drill node:
   - RedHat/CentOS

```
yum update mapr-drill
```

   - Ubuntu

```
sudo apt-get install mapr-drill
```

last-updated: Jun 06, 2024

- SLES

```
zypper update mapr-drill
```

NOTE: SLES is supported as of Drill 1.9.0-1703 and Drill 1.10.0-1703.

3. Complete the post-upgrade steps for Drill.

Upgrading Hadoop and YARN
This section describes how to upgrade Hadoop and YARN without the Installer.

About this task

Procedure

Run the following command to upgrade Hadoop and YARN using a package manager:

IMPORTANT: Upgrade all Hadoop packages installed on the node, including role packages. For information about the packages, see Installing Hadoop and YARN on page 241.

- On RHEL/CentOS:

```
yum update <package_name> <package_name> <package_name> <package_name>
```

- On Ubuntu:

```
apt-get install <package_name> <package_name> <package_name>
<package_name>
```

- On SLES:

```
zypper update <package_name> <package_name> <package_name> <package_name>
```

Upgrading HBase
This section describes how to upgrade HBase without the Installer.

Upgrading an established deployment of HBase requires planning and consideration before beginning the upgrade process. Below are items to consider as you plan to upgrade:

- **Check for version interoperability and perform any required cluster upgrade first.** To see which versions of HBase are supported in each release, see the HBase Release Notes on page 5892 and Interoperability Matrices on page 5715. If you also plan to upgrade the core release as part of upgrading your HBase cluster, upgrade core first (see Upgrading Core on page 308). After successfully upgrading core, upgrade the HBase component.
- **Perform health checks.** Perform health checks and address any concerns before upgrading HBase. As a start, run `hbck` to check for any inconsistencies in HBase data. For usage details, refer to the Apache HBase Reference Guide.

```
hbase hbck
```

- **Review the cluster service layout.** While planning to upgrade, it is a good time to review your cluster service layout and determine if the right services are running on the right set of nodes. For example, as your cluster grows, you will tend to isolate cluster-management services from compute services on separate nodes. Review Planning the Cluster on page 79 and Installing HBase on page 243 for details on planning the service layout.
- **Consider migration of data, maintenance of HBase services, and any version-specific considerations that apply to you.** For details, refer to the Apache HBase Reference Guide.
- **Perform a test upgrade.** Because the upgrade process takes HBase services offline and requires careful planning, perform a test upgrade on a development cluster to make sure you understand the process. After you have experienced success on a dev cluster, proceed with your production cluster.

To upgrade, complete the upgrade steps for the version of HBase to which you want to upgrade.

Upgrade from HBase 1.1.8

About this task

Complete the following steps to upgrade HBase 1.1.8 to 1.1.13 or later:

Procedure

1. Ensure that you have completed the pre-upgrade steps.
2. Use the following commands to upgrade the packages:

   After configuring repositories so that the version you want to install is available, you can use a package manager to install from the repository. The upgrade process removes all but the following directories in the current HBase directory: `conf` and `logs`.

To upgrade with a package manager:

On RedHat and CentOS

To upgrade an HBase region server node:

```
yum update
mapr-hbase
mapr-hbase-regio
nserver
```

To upgrade an HBase master node:

```
yum update
mapr-hbase
mapr-hbase-maste
r
```

To upgrade an HBase client node:

```
yum update
mapr-hbase
```

On Ubuntu

To upgrade an HBase region server node:

```
apt-get install
mapr-hbase
mapr-hbase-regio
nserver
```

last-updated: Jun 06, 2024

On SLES	To upgrade an HBase master node:
	`apt-get install mapr-hbase mapr-hbase-master`
	To upgrade an HBase client node:
	`apt-get install mapr-hbase`

	To upgrade an HBase region server node:
	`zypper update mapr-hbase mapr-hbase-regionserver`
	To upgrade an HBase master node:
	`zypper update mapr-hbase mapr-hbase-master`
	To upgrade an HBase client node:
	`zypper update mapr-hbase`

If you have additional HBase services or libraries installed, you should also upgrade those packages to match the HBase version you are upgrading to.

- Upgrade HBase Thrift Gateway.
- Upgrade the AsynchHbase Libraries.
- To upgrade the libhbase libraries, see Using the libhbase Library on page 4143.

3. Migrate any custom configuration settings to the configuration files within the `conf` directory:

```
/opt/mapr/hbase/hbase-<version>/conf/
```

4. Run `configure.sh -R` on all of the upgraded HBase nodes:

```
$ /opt/mapr/server/configure.sh -R
```

5. Complete the post-upgrade steps.

Related concepts

Considerations for Upgrading to HBase 1.1.13 on page 350

last-updated: Jun 06, 2024

Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

Upgrading HBase Client and Tools
This section describes how to upgrade HBase Client and other tools without the Installer.

Note that release 6.0.x provides Apache HBase-compatible APIs and client interfaces but does not support HBase as an ecosystem component. MapR 6.1.0 supports HBase with EEP 6.3.0 and later.

Service	Description
HBase Client	Upgrading the HBase Client upgrades both the HBase Shell and the HBase APIs supported for use with HPE Ezmeral Data Fabric Database binary tables and HPE Ezmeral Data Fabric Database JSON tables.
HBase Thrift Gateway	HBase Thrift Gateway includes an API and a service that accepts Thrift requests to connect to HPE Ezmeral Data Fabric Database tables. See Upgrading HBase Thrift Gateway on page 371 for upgrade information.
HBase REST Gateway	HBase REST Gateway includes an API and a service that accepts REST requests to connect to HPE Ezmeral Data Fabric Database tables. See Upgrading HBase REST Gateway on page 371 for upgrade information.
AsyncHBase Libraries	AsyncHBase library provides asynchronous Java APIs to access HPE Ezmeral Data Fabric Database tables. See Upgrading AsyncHBase Libraries on page 367 for upgrade information.

Upgrading HBase Thrift Gateway

About this task
Complete the following steps to upgrade the HBase Thrift Gateway:

Procedure

1. Run the following command to upgrade the HBase Thrift package:

   On CentOS / Red Hat
   ```
   yum update mapr-hbasethrift
   mapr-hbase
   ```

   Ubuntu
   ```
   apt-get update mapr-hbasethrift
   mapr-hbase
   ```

   SLES
   ```
   zypper update mapr-hbasethrift
   mapr-hbase
   ```

2. Run the `configure.sh` script with the `-R` option on the node where you upgraded the HBase Thrift package:

   ```
   /opt/mapr/server/configure.sh -R
   ```

Upgrading HBase REST Gateway

About this task
Complete the following steps to upgrade the HBase REST Gateway:

Procedure

1. Run the following command to upgrade the HBase REST package:

On CentOS / Red Hat	`yum update mapr-hbase-rest mapr-hbase`
Ubuntu	`apt-get update mapr-hbase-rest mapr-hbase`
SLES	`zypper update mapr-hbase-rest mapr-hbase`

2. Run configure.sh on the node where you upgraded the HBase Thrift package:

```
/opt/mapr/server/configure.sh -R
```

Upgrading AsyncHBase Libraries
This section describes how to upgrade the AsyncHBase Libraries without the Installer.

About this task
To upgrade to a more recent version of the AsyncHBase library, install the new version. See Installing AsyncHBase Libraries.

NOTE: AsyncHBase 1.7 is binary compatible with AsyncHBase 1.6.

Upgrading Hive
This section describes how to upgrade Hive without the Installer.

About this task

Use one of the following methods to upgrade the Hive components on all nodes where Hive is installed.

Procedure

To:

- Upgrade with a package manager, install new packages from the repository:
  - On RedHat and CentOS:

```
yum update mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

  - On Ubuntu:

```
apt-get install mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

last-updated: Jun 06, 2024

- On SLES:

```
zypper update mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

- Manually remove a prior version and manually install the latest version in the repository, run the package manager twice, first to remove the old version, and again to install the new version.

  NOTE: In this case, configurations are not preserved automatically.

  - On RedHat and CentOS:

```
yum remove mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
yum install mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

  - On Ubuntu:

```
apt-get remove mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
apt-get install mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

  - On SLES:

```
zypper remove mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
zypper install mapr-hive mapr-hiveserver2 mapr-hivemetastore
mapr-hivewebhcat
```

What to do next
To apply custom configurations to the new version, migrate any custom configuration settings into the new default files in the `conf` directory. See Post-Upgrade Steps for Hive on page 389.
Upgrading from Hive 2.1 to Hive 2.3 with Oracle DB used in Metastore
This section describes how the different upgrade scenarios from Hive 2.1 to Hive 2.3.

Column type verification

You need to first check your current Oracle DB schema and understand your upgrade scenario.

All the examples below use the Oracle SQL*Plus tool to execute SQL statements. Use the `DESCRIBE <Table name>;` to command to check the Oracle table information for following Hive metastore tables:

- `COLUMNS_V2`
- `SD_PARAMS`
- `TABLE_PARAMS`
- `SERDE_PARAMS`

Table

Table	Column	Possible value of column type	
		Scenario I	Scenario II
(1)	(2)	(3)	(4)
COLUMNS_V2	TYPE_NAME	CLOB	VARCHAR2(4000)
SD_PARAMS	PARAM_VALUE	CLOB	VARCHAR2(4000)
TABLE_PARAMS	PARAM_VALUE	CLOB	VARCHAR2(4000)
SERDE_PARAMS	PARAM_VALUE	CLOB	VARCHAR2(4000)

If column TYPE_NAME in the COLUMNS_V2 table has VARCHAR2(4000) as the data type, then you have to perform upgrade scenario I. If column TYPE_NAME in the COLUMNS_V2 table has a data type CLOB, then you have to perform upgrade scenario II.

All columns types must belong to the same upgrade scenarios, in other words all your columns types must be VARCHAR2 or CLOB.

Use upgrade scenario I

Upgrading to Hive 2.3 (EEP 6.1.0 and above)

To upgrade from Hive-2.1 to Hive 2.3, first download Hive 2.3 from the EEP 6.1.0 package repository and perform the upgrade according to the common upgrade instructions.

Upgrading to Hive 2.3 (before EEP 6.1.0)

To upgrade Hive 2.1 to Hive 2.3 (before EEP 6.1.0), edit the `upgrade-2.1.0-to-2.2.0.oracle.sql` file:

```
nano $HIVE_HOME/scripts/metastore/upgrade/oracle/
upgrade-2.1.0-to-2.2.0.oracle.sql
```

Remove the `@039-HIVE-12274.oracle.sql;` line from the upgrade script and then perform the upgrade according to the common upgrade instructions.

Use upgrade scenario II

Upgrade to Hive 2.3 (EEP 6.1.0 and above)

last-updated: Jun 06, 2024

1. Replace the content of `@039-HIVE-12274.oracle.sql;` file to:

```
-- change PARAM_VALUE to CLOBs
ALTER TABLE COLUMNS_V2 ADD (TEMP CLOB);
UPDATE COLUMNS_V2 SET TEMP=TYPE_NAME;
ALTER TABLE COLUMNS_V2 DROP COLUMN TYPE_NAME;
ALTER TABLE COLUMNS_V2 RENAME COLUMN TEMP TO TYPE_NAME;

ALTER TABLE TABLE_PARAMS ADD (TEMP CLOB);
UPDATE TABLE_PARAMS SET TEMP=PARAM_VALUE, PARAM_VALUE=NULL;
ALTER TABLE TABLE_PARAMS DROP COLUMN PARAM_VALUE;
ALTER TABLE TABLE_PARAMS RENAME COLUMN TEMP TO PARAM_VALUE;

ALTER TABLE SERDE_PARAMS ADD (TEMP CLOB);
UPDATE SERDE_PARAMS SET TEMP=PARAM_VALUE, PARAM_VALUE=NULL;
ALTER TABLE SERDE_PARAMS DROP COLUMN PARAM_VALUE;
ALTER TABLE SERDE_PARAMS RENAME COLUMN TEMP TO PARAM_VALUE;

ALTER TABLE SD_PARAMS ADD (TEMP CLOB);
UPDATE SD_PARAMS SET TEMP=PARAM_VALUE, PARAM_VALUE=NULL;
ALTER TABLE SD_PARAMS DROP COLUMN PARAM_VALUE;
ALTER TABLE SD_PARAMS RENAME COLUMN TEMP TO PARAM_VALUE;

-- Expand the hive table name length to 256
ALTER TABLE TBLS MODIFY (TBL_NAME VARCHAR2(256));
ALTER TABLE NOTIFICATION_LOG MODIFY (TBL_NAME VARCHAR2(256));
ALTER TABLE PARTITION_EVENTS MODIFY (TBL_NAME VARCHAR2(256));
ALTER TABLE TAB_COL_STATS MODIFY (TABLE_NAME VARCHAR2(256));
ALTER TABLE PART_COL_STATS MODIFY (TABLE_NAME VARCHAR2(256));
ALTER TABLE COMPLETED_TXN_COMPONENTS MODIFY (CTC_TABLE VARCHAR2(256));

-- Expand the hive column name length to 767
ALTER TABLE COLUMNS_V2 MODIFY (COLUMN_NAME VARCHAR(767));
ALTER TABLE PART_COL_PRIVS MODIFY (COLUMN_NAME VARCHAR2(767));
ALTER TABLE TBL_COL_PRIVS MODIFY (COLUMN_NAME VARCHAR2(767));
ALTER TABLE SORT_COLS MODIFY (COLUMN_NAME VARCHAR2(767));
ALTER TABLE TAB_COL_STATS MODIFY (COLUMN_NAME VARCHAR2(767));
ALTER TABLE PART_COL_STATS MODIFY (COLUMN_NAME VARCHAR2(767));
```

2. Add the following line to the `$HIVE_HOME/scripts/metastore/upgrade/oracle/upgrade-2.1.0-to-2.2.0.oracle.sql` file after the `@038-HIVE-10562.oracle.sql;` line:

```
@039-HIVE-12274.oracle.sql;
```

3. Perform upgrade according to the common upgrade instructions.

Upgrade to Hive 2.3 (before EEP 6.1.0)

1. Replace the content of `@039-HIVE-12274.oracle.sql;` file to the same as in the previous scenario.

2. Make sure that the following line is present in the `$HIVE_HOME/scripts/metastore/upgrade/oracle/upgrade-2.1.0-to-2.2.0.oracle.sql` file:

```
@039-HIVE-12274.oracle.sql;
```

3. Perform upgrade according to the common upgrade instructions.

Upgrading HttpFS

This section describes how to upgrade HttpFS without the Installer.

To upgrade HttpFS:

IMPORTANT: If you are upgrading from EEP 8.x.x or a previous EEP to EEP 9.0.0 or later, note that EEP 9.0.0 introduced changes to the location of the `httpfs-site.xml` file and the name of the timeout property. For more information about these changes, see Network Timeout for HttpFS on page 4374.

1. Run one of the following commands to use a package manager to install the new packages from the repository:
   - On RHEL/CentOS:
     ```
     yum update mapr-httpfs
     ```
   - On Ubuntu:
     ```
     apt-get install mapr-httpfs
     ```
   - On SLES:
     ```
     zypper update mapr-httpfs
     ```
2. If you haven't already upgraded Hadoop, upgrade the following Hadoop packages:
   - `mapr-hadoop-util`
   - `mapr-hadoop-client`
   - `mapr-hadoop-core`

   See these topics:
   - Pre-Upgrade Steps for Hadoop and YARN on page 349
   - Upgrading Hadoop and YARN on page 368
   - Post-Upgrade Steps for Hadoop and YARN on page 388

Upgrading Hue

This section describes how to upgrade Hue without the Installer.

About this task

Execute the following commands as a user with admin permissions:

Procedure

1. Run one of the following commands to upgrade Hue using a package manager:
   - On Ubuntu:
     ```
     apt-get install mapr-hue
     ```

last-updated: Jun 06, 2024

- On RedHat/CentOS:

```
yum update mapr-hue
```

- On SLES:

```
zypper update mapr-hue
```

2. For EEP 4.0.0 and later, update Livy using the steps in Upgrading Livy on page 377. For EEP releases earlier than EEP 4.0.0, run one of the following commands to upgrade Hue-livy using a package manager:
   - On Ubuntu:

```
apt-get install mapr-hue-livy
```

   - On RedHat/CentOS:

```
yum update mapr-hue-livy
```

   - On SLES:

```
zypper update mapr-hue-livy
```

Upgrading the Data Access Gateway

This section describes how to upgrade the Data Access Gateway without the Installer.

About this task

Complete the following steps to upgrade the Data Access Gateway without the Installer.

1. Install the new package using the command that is appropriate for your distribution:

RedHat/CentOS	`yum update mapr-data-access-gateway`
Ubuntu	`apt-get install mapr-data-access-gateway`
SLES	`zypper update mapr-data-access-gateway`

2. On the CLDB master node, use the `manageSSLKeys.sh` script to generate the p12 keystore file, which enables OpenSSL communication channel for the gRPC service. For example:

```
/opt/mapr/server/manageSSLKeys.sh convert -k -N <cluster_name> /opt/mapr/
conf/ssl_keystore /opt/mapr/conf/ssl_keystore.pem
```

3. Copy the `/opt/mapr/conf/ssl_keystore.p12` and `/opt/mapr/conf/ssl_keystore.pem` files to all other nodes that contain the Data Access Gateway.

Upgrading Livy

About this task

This section describes how to upgrade Livy without the Installer.

Procedure

Run the following command to upgrade Livy using a package manager:

- On RHEL/CentOS:

```
yum update mapr-livy
```

- On Ubuntu:

```
 apt-get install mapr-livy
```

- On SLES:

```
zypper update mapr-livy
```

Upgrading Monitoring

Complete the following steps to upgrade Monitoring without the Installer.

About this task

NOTE: Before performing the following steps, make sure that you have completed the Pre-Upgrade Steps for Monitoring on page 359.

Execute the following commands as `root` or using `sudo`.

Procedure

1. Upgrade the following metric monitoring packages wherever they are installed on the cluster: `mapr-collectd`, `mapr-grafana`, and `mapr-opentsdb`.

   For example, on a three node cluster, you could run the following commands to upgrade metrics monitoring packages:

   - For CentOS/RedHat:
     - Node A:

```
yum upgrade mapr-collectd mapr-grafana
```

     - Node B:

```
yum upgrade mapr-collectd mapr-opentsdb
```

     - Node C:

```
yum upgrade mapr-collectd
```

   - For Ubuntu:

last-updated: Jun 06, 2024

- Node A:

```
apt-get install mapr-collectd mapr-grafana
```

- Node B:

```
apt-get install mapr-collectd mapr-opentsdb
```

- Node C:

```
apt-get install mapr-collectd
```

- For SLES:
  - Node A:

```
zypper update mapr-collectd mapr-grafana
```

  - Node B:

```
zypper update mapr-collectd mapr-opentsdb
```

  - Node C:

```
zypper update mapr-collectd
```

2. Upgrade the following log monitoring packages wherever they are installed on the cluster: `mapr-fluentd`, `mapr-elasticsearch`, and `mapr-kibana`.

   For example, on a three node cluster, you can run the following commands to upgrade log monitoring packages:

   - For CentOS/RedHat:
     - Node A:

```
yum upgrade mapr-fluentd mapr-elasticsearch
```

     - Node B:

```
yum upgrade mapr-fluentd mapr-elasticsearch
```

     - Node C:

```
yum upgrade mapr-fluentd mapr-elasticsearch mapr-kibana
```

   - For Ubuntu:
     - Node A:

```
apt-get install mapr-fluentd mapr-elasticsearch
```

- Node B:

```
apt-get install mapr-fluentd mapr-elasticsearch
```

- Node C:

```
apt-get install mapr-fluentd mapr-elasticsearch mapr-kibana
```

- For SLES:
  - Node A:

```
zypper update mapr-fluentd mapr-elasticsearch
```

  - Node B:

```
zypper update mapr-fluentd mapr-elasticsearch
```

  - Node C:

```
zypper update mapr-fluentd mapr-elasticsearch mapr-kibana
```

Reinstalling Monitoring Components After an Upgrade
During an upgrade from EEP 6.x to EEP 7.0.0 or EEP 7.0.1, some monitoring components do not get updated because of an error in the fourth digit of the package version. This page provides a workaround for the issue.

About this task
The issue (known issue ES-77 or FLUD-55) is fixed in EEP 7.1.0 and later.

This issue can occur during manual upgrades or upgrades performed using the Installer. The affected components can include any or all of the following:

- Elasticsearch
- Fluentd
- Grafana
- Kibana

Follow these steps to identify, remove, and reinstall the packages that were not upgraded:

Procedure

1. After upgrading, use one of the following commands to check the package versions of the installed monitoring components:

OS	Command
RHEL/CentOS	`yum list installed`
SLES	`zypper packages --installed-only`
Ubuntu	`apt list --installed`

2. Identify the packages that were not upgraded. The following table shows the desired versions for each package for EEPs 7.0.0 and 7.0.1. For more version information, see Component Versions for Released EEPs on page 5750.

Package	Desired Version	
	EEP 7.0.0	EEP 7.0.1
`mapr-elasticsearch`	6.8.8.0	6.8.8.0
`mapr-fluentd`	1.10.3.0	1.10.3.0
`mapr-grafana`	6.7.4.0	6.7.4.0
`mapr-kibana`	6.8.8.0	6.8.8.0

3. Before removing the packages that were not upgraded:
   a) Ensure that you have backed up any configuration files and indexes as described in Pre-Upgrade Steps for Monitoring on page 359. For Elasticsearch in particular, you must back up the default location for Elasticsearch index data unless you specified a non-default location using the `-ESDB` parameter with `configure.sh` during installation.

   b) Export or make backup copies of any custom dashboards you configured for Grafana or Kibana.

4. Manually uninstall the packages that were not upgraded by using one of the following commands. For example, to uninstall the Elasticsearch package:
   - RHEL/CentOS:
     - `yum remove mapr-elasticsearch`
   - SLES:
     - `zypper remove mapr-elasticsearch`
   - Ubuntu:
     - `apt remove mapr-elasticsearch --purge`

5. Install the desired packages for EEP 7.0.0 or EEP 7.0.1 using *one* of the following methods:
   - **Method 1 – Using the Installer**

     Using the Installer, perform an incremental installation. See Using the Incremental Install Function on page 5630.

   - **Method 2 – Manual Reinstall**

     For Grafana, reinstall the package and run `configure.sh` using the commands shown in Step 9: Install Metrics Monitoring on page 222.

     For Elasticsearch, Fluentd, and Kibana, reinstall the packages and run `configure.sh` using the commands shown in Step 10: Install Log Monitoring on page 225.

last-updated: Jun 06, 2024

Upgrading the HPE Ezmeral Data Fabric Streams Python Client

This section describes how to upgrade the HPE Ezmeral Data Fabric Streams Python Client without the Installer.

About this task

To install the HPE Ezmeral Data Fabric Streams Python Client using the Python Software Foundation, run the following command as `root` or using `sudo`:

```
pip
install -upgrade --global-option=build_ext --global-option="--library-dirs=/
opt/mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
mapr-streams-python
```

OR:

```
pip
install -U --global-option=build_ext --global-option="--library-dirs=/opt/
mapr/lib" --global-option="--include-dirs=/opt/mapr/include/"
mapr-streams-python
```

Alternatively, you can install the HPE Ezmeral Data Fabric Streams Python Client via the MapR package repository:

```
https://package.ezmeral.hpe.com/releases/MEP/<MEP version>/mac/
mapr-streams-python-<version>.tar.gz
```

IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

Upgrading HPE Ezmeral Data Fabric Streams Tools

Complete the following steps to upgrade HPE Ezmeral Data Fabric Streams Tools without the Installer.

About this task

If you are upgrading from Kafka 2.1.1 to 2.6.1, you may first want to review Changes in Kafka 2.6.1 on page 4463. To upgrade, run the following commands as `root` or using `sudo`:

Procedure

1. Stop the service using `maprcli node services -name <name_service> - action stop -nodes <space delimited list of Kafka tools server nodes>`:
2. Run one of the following commands to upgrade the Kafka REST Proxy for Streams:
   - On Ubuntu:

     ```
     apt-get install mapr-kafka-rest
     ```

   - On RedHat/CentOS:

     ```
     yum update mapr-kafka-rest
     ```

   - On SLES:

     ```
     zypper update mapr-kafka-rest
     ```

last-updated: Jun 06, 2024

3. Run one of the following commands to upgrade the Kafka Connect for HPE Ezmeral Data Fabric Streams - HDFS Connector:
   - On Ubuntu:
     ```
     apt-get install mapr-kafka-connect-hdfs
     ```
   - On RedHat/CentOS:
     ```
     yum update mapr-kafka-connect-hdfs
     ```
   - On SLES:
     ```
     zypper update mapr-kafka-connect-hdfs
     ```
4. Run one of the following commands to upgrade the Kafka Connect for HPE Ezmeral Data Fabric Streams - JDBC Connector:
   - On Ubuntu:
     ```
     apt-get install mapr-kafka-connect-jdbc
     ```
   - On RedHat/CentOS:
     ```
     yum update mapr-kafka-connect-jdbc
     ```
   - On SLES:
     ```
     zypper update mapr-kafka-connect-jdbc
     ```
5. Run `configure.sh -R` on each node where you installed Kafka components to complete the configuration: `/opt/mapr/server/configure.sh -R`

What to do next
Apply custom configurations to the new version by migrating any custom configuration settings into the new default files in the **conf** directory. See Post-Upgrade Steps for HPE Ezmeral Data Fabric Streams Tools on page 395 for more information.

Upgrading NiFi
This section describes how to upgrade NiFi without the Installer.

Run one of the following commands to upgrade NiFi using a package manager:

- On RHEL/CentOS:
  ```
  yum update mapr-nifi
  ```
- On Ubuntu:
  ```
  apt-get install mapr-nifi
  ```
- On SLES:
  ```
  zypper update mapr-nifi
  ```

Upgrading Ranger

This section describes how to upgrade Ranger without the Installer.

Before upgrading, review the Pre-Upgrade Steps for Ranger on page 363.

Upgrading from EEP 9.0.0

In EEP 9.0.0, the `mapr-ranger` package has both Admin and UserSync services. From EEP 9.1.0 and later, `mapr-ranger` has only an Admin service, and there is a new package for the UserSync service: `mapr-ranger-usersync`.

When you upgrade from EEP 9.0.0 to EEP 9.1.0 or later, all the packages are upgraded, but you must manually install `mapr-ranger-usersync` as a new package:

1. Upgrade all `mapr-ranger*` packages:
   - On RHEL/CentOS:
     ```
     yum update mapr-ranger*
     ```
   - On Ubuntu:
     ```
     apt-get install mapr-ranger*
     ```
   - On SLES:
     ```
     zypper update mapr-ranger*
     ```
2. Install the `mapr-ranger-usersync` package:
   - On RHEL/CentOS:
     ```
     yum install mapr-ranger-usersync
     ```
   - On Ubuntu:
     ```
     apt-get install mapr-ranger-usersync
     ```
   - On SLES:
     ```
     zypper install mapr-ranger-usersync
     ```

Upgrading Spark Standalone

This section describes how to upgrade Spark Standalone without the Installer.

About this task

Procedure

1. Install the Spark packages.
   - On Ubuntu:
     ```
     apt-get install mapr-spark mapr-spark-master mapr-spark-historyserver
     ```

last-updated: Jun 06, 2024

- On RedHat/CentOS:

```
yum update mapr-spark mapr-spark-master mapr-spark-historyserver
```

- On SLES:

```
zypper upgrade mapr-spark mapr-spark-master mapr-spark-historyserver
```

2. (Optional): Starting in the EEP 4.0 release, you can install the Spark Thrift Server package.

On Ubuntu	`apt-get insall mapr-spark-thriftserver`
On RedHat / CentOS	`yum install mapr-spark-thriftserver`
On SLES	`zypper install mapr-spark-thriftserver`

Upgrading Spark on YARN

This section describes how to upgrade Spark on YARN without the Installer.

About this task

The following instructions explain how to upgrade an existing installation of Spark. Spark will be installed in a new subdirectory under `/opt/mapr/spark`.

Procedure

1. Install the Spark packages.

   NOTE: You only need to upgrade the mapr-spark-historyserver if your previous installation included this package.

On Ubuntu	`apt-get install mapr-spark mapr-spark-historyserver`
On RedHat / CentOS	`yum update mapr-spark mapr-spark-historyserver`
On SLES	`zypper upgrade mapr-spark mapr-spark-historyserver`

2. (Optional): Starting in the EEP 4.0 release, you can install the Spark Thrift Server package.

On Ubuntu	`apt-get insall mapr-spark-thriftserver`
On RedHat / CentOS	`yum install mapr-spark-thriftserver`

last-updated: Jun 06, 2024

On SLES	`zypper install mapr-spark-thriftserver`

Upgrading Tez

This section describes how to upgrade Tez without the Installer.

About this task

Complete the following steps to upgrade Tez without the Installer.

Procedure

Use the following method to upgrade Tez on all the nodes where Tez is installed.

- Upgrade with a package manager, install new packages from the repository.

On RedHat and CentOS	`yum update mapr-tez`
On Ubuntu	`apt-get install mapr-tez`
On SLES	`zypper update mapr-tez`

What to do next

To apply custom configurations to the new version, migrate any custom configuration settings into the new default files in the `conf` directory. See Post-Upgrade Steps for Tez on page 398.

Finishing the Ecosystem Pack Upgrade

Complete the post-upgrade steps for each ecosystem component that was upgraded.

Post-Upgrade Steps for Airflow

Complete the following steps after you upgrade Airflow with or without the Installer.

About this task

Use these steps:

1. Run `configure.sh -R` to update the `airflow.cfg` file:

   ```
   /opt/mapr/server/configure.sh -R
   ```

2. Migrate any custom configuration settings (especially database-related settings) into the `<airflow_home>/conf/` directory. For example, if MySQL is used as the database, install the `mysqlclient` by using the following steps:

   a. Run `.<airflow_home>/build/env/bin/activate`

   b. Run `pip install mysqlclient==2.2.0`

   c. Run `deactivate`

3. For upgrades from an older version of Airflow to a newer version, run the Airflow database upgrade tool:

last-updated: Jun 06, 2024

a. Use the following command to migrate the database:

```
airflow db migrate
```

b. Create your default connections:

```
airflow connections create-default-connections
```

For more information about the upgrade tool, see Reference for Database Migrations in the Apache Airflow documentation.

4. Start the `airflow-scheduler` and `airflow-webserver` services:

```
maprcli node services -nodes <hostname> -name airflow-scheduler -action
restart
maprcli node services -nodes <hostname> -name airflow-webserver -action
restart
```

5. **Optional:** If using the default SequentialExecutor, create a user. For example:

```
airflow users create --username any_user --firstname any_user --lastname
any_user -p any_user --role Admin --email admin@example.org
```

Post-Upgrade Steps for Drill
Complete the following steps after you upgrade Drill with or without the Installer.

About this task

1. Configuration files from the previous installation now reside in `/opt/mapr/drill/OLD_DRILL_VERSIONS`. If you have made any changes to configuration files in the previous version, compare and restore your previous configurations in the `/opt/mapr/drill/drill-<version>/conf` directory. Also, copy over any UDF or custom storage or format plugin JAR files that you added to the previous Drill directory.

   NOTE: The `drill-override.conf` contains your ZooKeeper configuration and any other options specified in the file. The `drill-env.sh` file contains any options that you modified, such as Drill memory allocation. The `logback.xml` file contains changes you may have made to use Lilith.

2. Run `configure.sh` to refresh the node configuration.

```
$ /opt/mapr/server/configure.sh -R
```

NOTE: Drill should be configured and running on the node. You can use one of the following methods to verify that the Drillbit service is running on the node:

- Issue the following command to verify the status of the Drillbit service from the command line:

```
jps
```

- Log in to the Control System at `https://<host name>:8443` and click **Services** to verify the status of the Drillbit service.

You should see the Drillbit listed as a service running on the node.

3. Enter the following URL in a web browser to access the Drill Web Console and verify that your storage plugin configurations were preserved during the upgrade:

```
http://<IP address or host name>:8047/storage
```

If your storage plugins were not preserved, use the back up that you took before the upgrade to restore them.

NOTE: You can start/stop/restart the Drillbit service on one or more nodes using the Control System or the following command:

```
$ maprcli node services -name drill-bits -action start|restart|
stop -nodes <node host names separated by a space>
```

Use the host name if possible. Using host names instead of IP addresses is a best practice.

You can access the Drill log files in `/opt/mapr/drill/drill-<version>/logs/drillbit.log`.

Post-Upgrade Steps for Hadoop and YARN

Complete the following steps after you upgrade Hadoop and YARN with or without the Installer.

About this task

1. On each node, run `configure.sh` with the `-R` option. Include the `-TL` option if the timeline server is installed on the cluster. For example:

```
configure.sh -R -HS <hostname> -TL <hostname>
```

2. Optional: Transfer any custom configuration settings into the new default files in the configuration directory:

   New configuration directory: `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/`

   Backup configuration directory: `/opt/mapr/hadoop/hadoop-<timestampversion>/etc/hadoop/`

In the backup configuration directory, `<timestampversion>` is the version from packages that were installed before the upgrade. For example: `2.7.4.100.202101211026`.

Post-Upgrade Steps for HBase

Complete the following steps after you upgrade HBase without the Installer.

last-updated: Jun 06, 2024

About this task
If you upgrade using the Installer, running `configure.sh` is not necessary.

Procedure

Run `configure.sh -R`.

```
/opt/mapr/server/configure.sh -R
```

After you run the `configure.sh -R` command, the HBase Thrift, HBase REST, HBase Master, and HBase RegionServer services are started automatically.

Related concepts

Considerations for Upgrading to HBase 1.1.13 on page 350
Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

Post-Upgrade Steps for HBase Client
Complete the following steps after you upgrade HBase Client with or without the Installer.

About this task
Merge custom configuration files with the new default files (optional).

Procedure

1. If you backed up HBase Client configuration files into a location outside the installation directory before upgrading HBase Client, you must retrieve them if you want to save your custom configuration.
2. Merge HBase Client configuration files from with the new default files in `/opt/mapr/hbase/hbase-<version>/conf/`. Be sure not to simply copy over the configuration files: to avoid overwriting the default files, conduct a merge.

Related concepts

Considerations for Upgrading to HBase 1.1.13 on page 350
Before upgrading to HBase 1.1.13, familiarize yourself with aspects of the EEP 6.3.0 HBase implementation that can affect an upgrade.

Post-Upgrade Steps for Hive
Complete the following steps after you upgrade Hive with or without the Installer.

About this task

Procedure

1. If you are using the Ranger Hive plugin, re-run the script `enable-hive-plugin.sh`.
2. Migrate Hive Configuration.

   Migrate any custom configuration settings into the Hive 2.3 version in the `/opt/mapr/hive/hive-2.3/conf/` directory.
3. Update the Hive Metastore.

   For upgrades from the old version of Hive to the new version, run the `schematool` command with the `-upgradeSchema` option.

NOTE: If you encounter any issues running the `schematool` command, make sure you have finished all steps in Step 1: Restart and Check Cluster Services on page 333. In particular, ensure you have completed step 5:

- On each node in the cluster, run `configure.sh` with the `-R` option: `# /opt/mapr/server/configure.sh -R -HS <hostname>`

Afterward, re-run the `schematool` command.

NOTE: Review and, if necessary, perform the steps described in Troubleshooting Hive Upgrade Issues on page 390 before running this command.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType
<metastore_database> -upgradeSchema
```

For example, for upgrades from Hive 2.1 to 2.3 on MySQL, run the following command:

```
/opt/mapr/hive/hive-2.3/bin/schematool -dbType mysql -upgradeSchema
```

NOTE: If you encounter any issues related to running Hive on JDK 17, see Considerations for Hive on JDK 17 on page 4210.

4. Run `configure.sh -R`.

   ```
   /opt/mapr/server/configure.sh -R
   ```

   This step enables Warden to recognize the newly installed services.

5. Verify that the metastore database update completed successfully. You can use the following diagnostic tests:
   - Run the `show tables` command in Hive and make sure it returns a complete list of all your Hive tables.
   - Perform simple SELECT operations on Hive tables that existed before the upgrade.
   - Perform filtered SELECT operations on Hive tables that existed before the upgrade.

Troubleshooting Hive Upgrade Issues

This section describes how to troubleshoot inconsistencies in an underlying database after creating tables with the `datanucleus.schema.autoCreateAll` property.

Prerequisites

The `datanucleus.schema.autoCreateAll` property creates tables gradually. After creating tables using this property, if you upgrade to Hive 2.3 using `schematool`, the `schematool` command will not be able to verify all the necessary tables because all the necessary tables were not created by the `datanucleus.schema.autoCreateAll` property.

Procedure

1. Determine the version from which you are upgrading.
2. Start MySQL:

   ```
   mysql -u <user> -p <password>
   ```

3. Run the following commands in your MySQL command line.

Upgrade from Hive 1.2

```
USE metastore;
SOURCE /opt/mapr/hive/hive-2.1/
scripts/metastore/upgrade/mysql/
hive-schema
        -1.2.0.mysql.sql;
SOURCE /opt/mapr/hive/hive-2.1/
scripts/metastore/upgrade/mysql/
hive-txn-schema
        -0.13.0.mysql.sql;
```

Upgrade from Hive 1.0

```
USE metastore;
SOURCE /opt/mapr/hive/hive-2.1/
scripts/metastore/upgrade/mysql/
hive-schema-0.14.0.
mysql.sql;
```

Upgrade from Hive 0.13

```
USE metastore;
SOURCE /opt/mapr/hive/hive-2.1/
scripts/metastore/upgrade/mysql/
hive-schema-0.13.0.mysql.sql;
```

Results

Running SOURCE for the version before the upgrade makes the underlying database consistent for running `schematool` command with the `-upgradeSchema` option.

Post-Upgrade Steps for HttpFS

Complete the following steps after you upgrade HttpFS with or without the Installer.

Procedure

Run the `configure.sh` script after making configuration changes:

```
sudo bash /opt/mapr/server/configure.sh -R
```

IMPORTANT: If you are upgrading from EEP 8.x.x or a previous EEP to EEP 9.0.0 or later, note that EEP 9.0.0 introduced changes to the location of the `httpfs-site.xml` file and the name of the timeout property. For more information about these changes, see Network Timeout for HttpFS on page 4374.

Post-Upgrade Steps for Hue

Complete the following steps after you upgrade Hue with or without the Installer:

About this task

Procedure

1. To configure the Hue-livy package after upgrading, see Integrate Hue With Spark on page 4414.

2. Copy the changes that you made for required services in your existing `hue.ini` file into the latest version of the file:

```
/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini
```

NOTE: Hue 3.9 uses the old Query editor to work with Hive and Impala queries, and introduces new Spark Notebooks. Hue 3.10+ uses Notebooks as a replacement for the old Query editor for Hive and Impala. If you are upgrading to Hue 3.10+, and you want to have access to your saved queries in the old Hive or Impala Query editor, you need to configure Hue to use the old Query editor. To do this, set the `use_new_editor` property in the `hue.ini` file to `false`. For example:

```
[desktop]
...
  # Choose whether to show the new SQL editor.
  use_new_editor=false
```

3. If you use SQLite as the Hue database, load its backup:
   a) If the Hue node runs on Ubuntu, install sqlite3:

```
apt-get install sqlite3
```

   b) Run the following commands:

```
cd /opt/mapr/hue/hue-<new_version>/desktop
mv desktop.db desktop.db.old
sqlite3 desktop.db < ~/dump-hue-<old_version>-sqlite.bak
sqlite3 desktop.db
DELETE FROM django_content_type;
```

4. Update the old database schema so that it is compatible with the new upgraded version:
   a) For Hue 4.3+:

```
source /opt/mapr/hue/hue-<new_version>/bin/activate
hue migrate --run-syncdb --fake-initial
deactivate
```

   For example, run the following commands to update the database schema to make it compatible with Hue 4.3+:

```
source /opt/mapr/hue/hue-4.3.0/bin/activate
hue migrate --run-syncdb --fake-initial
deactivate
```

b) For Hue version up to Hue 4.2:

```
source /opt/mapr/hue/hue-<new_version>/bin/activate
hue syncdb --noinput
hue migrate --merge
deactivate
```

For example, run the following commands to update the database schema to make it compatible with Hue 4.2:

```
source /opt/mapr/hue/hue-4.2.0/bin/activate
hue syncdb --noinput
hue migrate --merge
deactivate
```

If you are using MySQL, PostgreSQL, or Oracle, and you have trouble with the database during the Hue upgrade, you can restore your data from the backup that you created during the Pre-Upgrade Steps for Hue:

```
source /opt/mapr/hue/hue-<new_version>/bin/activate
hue loaddata --ignorenonexistent ~/dump-hue-<old_version>.json
deactivate
```

5. **For upgrades performed without the Installer:** If you are using Hadoop MRv1, complete the following steps to establish communication between Hue and the JobTracker processes:
   a) Remove existing Hue plugins from the MapReduce lib directory:

```
rm /opt/mapr/hadoop/hadoop-0.20*/lib/hue-plugins-*.jar
```

   b) Copy new Hue plugins to the MapReduce lib directory:

```
cp /opt/mapr/hue/hue-<version>/desktop/libs/hadoop/java-lib/
hue-plugins-*.jar /opt/mapr/hadoop/hadoop-0.20*/lib/
```

   For example, run the following commands to copy the Hue plugin for Hue 3.10+:

```
cp /opt/mapr/hue/hue-3.10.0/desktop/libs/hadoop/java-lib/
hue-plugins-*.jar /opt/mapr/hadoop/hadoop-0.20*/lib/
```

   c) Restart the JobTracker services:

```
maprcli node services -jobtracker restart -nodes <ip_addresses>
```

6. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

If you do not complete this step, Hue may fail to start and the Control System may still display references to the Hue version that you upgraded from.

7. Restart the Hue service:

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

Post-Upgrade Steps for MapR Data Access Gateway

Complete the following steps after you upgrade the Data Access Gateway with or without the Installer.

Procedure

1. Run `configure.sh -R`:

   ```
   /opt/mapr/server/configure.sh -R
   ```

2. Restart the service:

   ```
   maprcli node services -nodes <node name> -name
   data-access-gateway -action restart
   ```

Post-Upgrade Steps for Livy

About this task

Complete the following steps after you upgrade Livy with or without the Installer.

Optional: Migrate Custom Configurations

Transfer any custom configuration settings into the new default files in the `conf` directory (`/opt/mapr/livy/livy-<version>/conf/`).

Post-Upgrade Steps for MapR Monitoring

Complete the following steps after you upgrade Monitoring Components with or without the Installer.

About this task

Procedure

1. After you upgrade monitoring components, add customized properties from the configuration files that you backed up before the upgrade to the files in the new installation directories.

   Backups of many of the Monitoring component configuration files are stored in the `/opt/mapr/<component>/<component>-<new_version>/etc` directory and its subdirectories. During the backup of a configuration file, the upgrade script appends the component version number to the filename. For example, the backup filename for `collectd.conf` is `collectd.conf-5.5.1`. Therefore, if you did not manually back up the configuration files before upgrading Monitoring components, you may be able to retrieve the configuration.

2. On each node in the cluster, run `configure.sh` with the `-R` option.

   ```
   /opt/mapr/server/configure.sh -R
   ```

3. If you created a snapshot of the Kibana index as described in Pre-Upgrade Steps for Monitoring on page 359, restore the snapshot to ensure that you have access to index information that was present before the upgrade. See https://www.elastic.co/guide/en/elasticsearch/reference/5.6/modules-snapshots.html.

4. If you need to configure the Monitoring components for security, follow the steps in the installation procedures to generate the necessary files and distribute them across the cluster:

   - Step 9: Install Metrics Monitoring on page 222
   - Step 10: Install Log Monitoring on page 225

Post-Upgrade Steps for HPE Ezmeral Data Fabric Streams Tools
Complete the following steps after manually upgrading HPE Ezmeral Data Fabric Streams Tools.

Kafka REST Proxy

The following post-upgrade steps are applicable when upgrading Kafka REST Proxy.

1. Review your configuration files and modify as needed:

```
/opt/mapr/kafka-rest-<version>/config
```

2. Run the `configure.sh` file. For example:

```
/opt/mapr/server/configure.sh -R
```

3. Start the Kafka REST service

```
maprcli node services -name kafka-rest -action start -nodes < list of
Kafka REST service nodes >
```

To see how configuration files are saved during an upgrade, see Saving Kafka REST Configurations on page 4473.

Kafka Connect

The following post-upgrade steps are applicable when upgrading Kafka Connect.

1. Review your configuration files and modify as needed:

```
/opt/mapr/kafka-<version>/config
```

2. Run the `configure.sh` file. For example:

```
/opt/mapr/server/configure.sh -R
```

3. Start the Kafka Connect service

```
maprcli node services -name kafka-connect -action start -nodes <list of
Kafka Connect service nodes>
```

To see how configuration files are saved during an upgrade, see Saving Kafka Connect Configurations on page 4542.

Post-Upgrade Steps for NiFi
Complete the following steps after you upgrade NiFi with or without the Installer.

About this task

Use these steps:

1. Run the `configure.sh -R` script after making configuration changes:

```
/opt/mapr/server/configure.sh -R
```

2. Start the NiFi services (if the services do not start automatically):

```
maprcli node services -nodes <hostname> -name nifi -action start
```

Post-Upgrade Steps for Ranger

Complete the following steps after you upgrade Ranger with or without the Installer.

About this task

Use one of the following procedures, depending on the EEP that you are upgrading:

Upgrading from EEP 9.1.0 or Later

1. **NOTE:** Upgrading Ranger to a new 3-digit version (such as version 2.3.0 to 2.4.0) does not overwrite new configurations.

   If you are upgrading Ranger to a new 3-digit version, first do the following:

   a. Repeat the steps in Configuring Ranger on page 4586.

   b. For any Ranger plugins, re-fill `install.properties` as described in Integrating HiveServer2 with Ranger on page 4596 and Integrating Yarn with Ranger on page 4599.

2. For each Ranger plugin, re-run `enable-<component>-plugin.sh`.

3. Run `configure.sh -R` so that services can be restarted and the changes can take effect:

```
/opt/mapr/server/configure.sh -R
```

Upgrading from EEP 9.0.0

In EEP 9.0.0, the `mapr-ranger` package has both Admin and UserSync services. From EEP 9.1.0 and later, `mapr-ranger` has only an Admin service, and there is a new package for the UserSync service: `mapr-ranger-usersync`.

When you upgrade from EEP 9.0.0 to EEP 9.1.0 or later, all the packages are upgraded, but you must manually install `mapr-ranger-usersync` as a new package. In this upgrade scenario, packaging does not back up the existing configuration for the UserSync service, so the following user tasks are required:

1. **NOTE:** Upgrading Ranger to a new 3-digit version (such as version 2.3.0 to 2.4.0) does not overwrite new configurations.

   If you are upgrading Ranger to a new 3-digit version, first do the following:

   a. Repeat the steps in Configuring Ranger on page 4586.

   b. For any Ranger plugins, re-fill `install.properties` as described in Integrating HiveServer2 with Ranger on page 4596 and Integrating Yarn with Ranger on page 4599.

2. For each Ranger plugin, re-run `enable-<component>-plugin.sh`.

3. In the UserSync `install.properties` file (`/opt/mapr/ranger/ranger-<version>/ranger-usersync/install.properties`), modify the following properties:

```
POLICY_MGR_URL = https://FQDN:<admin_port>
rangerUsersync_password=<usersync_password_specified_in_admin_install.properties>
```

last-updated: Jun 06, 2024

4. Run the setup script:

```
sudo /opt/mapr/ranger/ranger-<version>/ranger-usersync/setup.sh
```

5. Run the configuration script:

```
sudo /opt/mapr/server/configure.sh -R
```

6. Restart the services:

```
/opt/mapr/bin/maprcli node services -name ranger-admin -action
restart -nodes <hostname>
/opt/mapr/bin/maprcli node services -name ranger-usersync -action
restart -nodes <hostname>
```

NOTE: (RAN-259) During the upgrade within the same 3-digit version of Ranger, the `install.properties` files are preserved for both the services and the plugins. If a new property is introduced in a newer version, you might encounter the following error message while enabling a plugin or executing `setup.sh` files:

```
XmlConfigChanger$ValidationException: ERROR: configuration token
[<property_name>] is not defined
```

In this case, refer to the related release notes to see the details of the new property, and add the property to the corresponding `install.properties` file.

Post-Upgrade Steps for Spark

Complete the following steps after you upgrade Spark with or without the Installer.

Post-Upgrade Steps for Spark Standalone Mode

About this task

Procedure

1. (Optional) Migrate Custom Configurations.

   Migrate any custom configuration settings into the new default files in the conf directory (`/opt/mapr/spark/spark-<version>/conf`).

2. If Spark SQL is configured to work with Hive, copy the `hive-site.xml` file into the `conf` directory (`/opt/mapr/spark/spark-<version>/conf`).

3. Run the following commands to configure the secondary instances:

   a) For Spark 2.x:

   Copy the `/opt/mapr/spark/spark-<version>/conf/slaves.template` into `/opt/mapr/spark/spark-<version>/conf/slaves`.

   For Spark 3.x:

   Copy the `/opt/mapr/spark/spark-<version>/conf/workers.template` into `/opt/mapr/spark/spark-<version>/conf/workers`.

b) Add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.
For example:

```
localhost
worker-node-1
worker-node-2
```

4. Run configure.sh -R.
5. Restart all the spark secondary instances as the `mapr` user:
For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh spark://
<comma-separated list of spark master hostname: port>
```

For Spark 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-workers.sh spark://
<comma-separated list of spark master hostname: port>
```

6. Delete the old Spark directory from `/opt/mapr/spark`. For example, if you upgraded from Spark 2.1.0 to 2.3.1, you need to delete `/opt/mapr/spark/spark-2.1.0`.
Starting with the EEP 6.1.0 release, for Spark 2.2.1 and later versions, after an upgrade the old directory is automatically removed. Only the new directory and the directory with the timestamp is present.

Post-Upgrade Steps for Spark on YARN

Procedure

1. (Optional) Migrate Custom Configurations.
Migrate any custom configuration settings into the new default files in the conf directory (`/opt/mapr/spark/spark-<version>/conf`). Also, if you previously configured Spark to use the Spark JAR file from a location on the file system, you need to copy the latest JAR file to the file system and reconfigure the path to the JAR file in the `spark-defaults.conf` file. See Configure Spark JAR Location on page 4618.
2. If Spark SQL is configured to work with Hive, copy the `hive-site.xml` file into the conf directory (`/opt/mapr/spark/spark-<version>/conf`).
3. Run configure.sh -R.
4. Delete the old Spark directory from `/opt/mapr/spark`. For example, if you upgraded from Spark 2.1.0 to 2.3.1, you need to delete `/opt/mapr/spark/spark-2.1.0`.
Starting with the EEP 6.1.0 release, for Spark 2.2.1 and later versions, after an upgrade the old directory is automatically removed. Only the new directory and the directory with the timestamp is present.

Post-Upgrade Steps for Tez
Complete the following steps after you upgrade Tez with or without theInstaller.

About this task

After a minor version update, for example from `Tez-0.9-1808` to `Tez-0.9-1901`, no changes to the user configuration, `tez-site.xml` file, are applied. To apply the latest changes manually, see the Tez Release Notes on page 6107.

Procedure

1. (Optional) Migrate any custom configuration settings into the new default files in the `/opt/mapr/tez/tez-<old version>/conf/` directory.
2. Reconfigure the Hive-on-Tez User Interface. This is necessary because the old tomcat folder gets removed from the cluster during the upgrade procedure. For details, see Hive-on-Tez User Interface on page 4259.
3. If you are using the Installer, no additional steps are required. For manual installation, you need to configure Hive and Tez. See Configuring Hive and Tez on page 4255.

Preparing the Cluster for a Maintenance Update

This section identifies how to prepare for applying either a minor update or a patch.

Depending on the task you need to perform, see the following topics:

To prepare for a minor update of the core version:	Preparing to Upgrade Core on page 315
To prepare to apply a patch:	Verify Cluster Readiness for a Patch

For more information about maintenance updates, see Performing a Maintenance Update on page 5635.

Performing a Maintenance Update

Perform a maintenance update when you want to upgrade to a new patch version of core or apply a patch.

A maintenance update is an update to your installed software that does not require configuration-file changes. Performing a maintenance update has no effect on the ecosystem packages (EEP components). You perform a maintenance update when you want to do either or both of the following:

- **Update to a new patch version of core.** For example, you can perform a maintenance update to change your core version from release 6.1.0 to release 6.1.1. You cannot use a maintenance update to change your core version from a minor version, such as 6.1, to another minor version, such as 6.2. Instead, use the **Version Upgrade** button for minor-version upgrades. The **Version Upgrade** button also permits an upgrade to a patch version of core.
- **Apply a patch.** The **Maintenance Update** page is one of several installer screens that offer the **Patch file** option. See Applying a Patch Using the Installer on page 473.

You cannot perform a maintenance update if your current EEP version is incompatible with the selected core version. For example, you cannot do a maintenance update from release 6.1.0 and EEP 6.3.0 to release 6.1.1 because EEP 6.3.0 is not compatible with release 6.1.1. For EEP and core compatibility information, see EEP Support and Lifecycle Status on page 5728.

NOTE: The maintenance update is an offline update (not a rolling update).

You perform a maintenance update using the Installer. To perform a maintenance update:

1. Verify that your installed EEP is supported by the core version you plan to select for the maintenance update. To check your EEP version, see Checking the EEP Version on page 5598. For EEP and core compatibility information, see EEP Support and Lifecycle Status on page 5728.
2. Update the Installer to the latest supported version. See Updating the Installer on page 5595.

last-updated: Jun 06, 2024

3. Prepare the cluster for a maintenance update by referring to one or both of these topics:
   - Preparing to Upgrade Core on page 315
   - Verify Cluster Readiness for a Patch
4. Start the Installer. For more information, see Installer on page 5579.
5. Click the **Maintenance Update** button.
6. Change the core version, or install a core patch, or both.

   IMPORTANT: During patch-file installation, do not refresh the browser page while the patch file is being uploaded. Doing so can interrupt the upload process.
7. Click **Next** to complete the update.

Related concepts

Checking the EEP Version on page 5598
Some Installer operations require you to know the version of the currently installed Ecosystem Pack (EEP). You can check the EEP version easily from within the Installer user interface or derive the EEP version from your repository information.

Installer Updates on page 5674
Installer updates provide new features or bug fixes.

Related reference

EEP Support and Lifecycle Status on page 5728
This page shows the EEPs that are supported for different core releases and the current lifecycle status for each EEP.

Setting Up Clients and Services

Describes how to set up and use interfaces to an HPE Ezmeral Data Fabric cluster from a client computer.

HPE Ezmeral Data Fabric packages are contained in two different repositories:

- **Core packages**: Contains the API server, the webserver, CLDB, the core HPE Ezmeral Data Fabric package, file server, the NFS servers, the gateway, various POSIX and thin clients, and ZooKeeper. The latest versions of these packages are at https://package.ezmeral.hpe.com/releases/.
- **EEP (previously *MEP*) packages**: These are the ecosystem packages and contain Drill, Hadoop, Hive, Livy, Pig, Spark, Tez, and Yarn. Available versions of these packages are at https://package.ezmeral.hpe.com/releases/MEP/.

HPE Ezmeral Data Fabric provides many interfaces for working with a cluster from a client computer. These interfaces are listed later on this page.

Prerequisites for Linux Hosts

Before you can set up clients on Linux hosts, you must:

- Install the package key on the client machine. See Step 2: Import the Package Key on page 181.
- Set up repositories. See Using the Data Fabric Repository (Installation) on page 182.

After you have installed the package key and set up the repositories, use the steps in the following sections to install clients.

Direct Access NFS™

Describes how to configure Direct Access NFS to mount the file system to a local directory.

Use Direct Access NFS™ to mount the MapR filesystem locally as a directory on a Mac, Linux, or Windows computer.

See Managing the HPE Ezmeral Data Fabric NFS Service on page 1549 for more information.

Installing NFS for the HPE Ezmeral Data Fabric

Describes how to install the NFS service on a node.

About this task

The following sections describe how to install the NFSv3 server, NFSv4 server, and the NFS client.

Installing the NFSv3 Server

Procedure

- Install the NFSv3 server package.

  To install, run the following command:

RHEL or CentOS	`yum install mapr-nfs`
Ubuntu	`apt-get install mapr-nfs`
SLES	`zypper install mapr-nfs`

  If the NFS server is installed without fileserver on a node, the node will be placed in the `/nfsserver` topology. If the fileserver is installed at a later time, the node will be moved to the `/data` topology, which is the default for fileserver nodes.

Installing the NFSv4 Server

About this task

The NFSv4 server can be installed only on Data Fabric 6.1 or later clusters. NFSv4 and NFSv3 servers cannot run on the same node. If you have the NFS client running on an edge node, you can use that client to connect to the Data Fabric NFS server on clusters running either 5.2, where only NFSv3 server can be installed, or 6.1 or later, where NFSv4 or NFSv3 can be installed.

Procedure

1. On the host where you plan to install the NFSv4 server, download, if necessary, and install the `nfs-utils` package, if it is already not installed.

2. Ensure that `rpc.statd` is running on the node.
   To verify, run the following command:

   ```
   ps -ef| grep rpc.st
       rpcuser 18889 1 0 01:04 ? 00:00:00 /sbin/rpc.statd
       root 27016 6933 0 01:25 pts/0 00:00:00 grep color=auto rpc.st
   ```

   If it is not already running, run the following to start it:

   ```
   /sbin/rpc.statd
   ```

3. Install NFSv4 server package.
   To install, run the following command:

RHEL or CentOS	`yum install mapr-nfs4server`
Ubuntu	`apt-get install mapr-nfs4server`
SLES	`zypper install mapr-nfs4server`

   The `mapr-nfsganesha` package is also installed as a dependency package. If NFS server is installed without fileserver on a node, the node is in the `/nfsserver` topology. If fileserver is installed at a later time, the node is moved to the `/data` topology, which is the default for fileserver nodes.

4. Run the `configure.sh` on page 2821 utility with the `-u` and `-g` options to configure the services to run under user `mapr` and the group of the `mapr` user.

   IMPORTANT: This step is required only if you are configuring NFSv4 server to work with Kerberos.

Installing the NFS Client

Procedure

- To install the NFS client, run the following command:

RHEL or CentOS	`sudo yum install nfs-utils`
Ubuntu	`sudo apt-get install nfs-common`
SLES	`sudo zypper install nfs-client`

NOTE: NFSv3 clients cannot connect to the NFSv4 server because the NFSv4 server only supports v4 protocol.

last-updated: Jun 06, 2024

Mounting NFS on the Data Fabric File System on a Cluster Node

About this task

Refer to Accessing Data with NFS v4 on page 1567 and Mounting NFS for the HPE Ezmeral Data Fabric to file system on a Cluster Node on page 1559 for steps to mount NFS to a Data Fabric file system.

Before You Start Using Data Fabric NFS

Make sure the following conditions are met before using the Data Fabric NFS gateway:

- The stock Linux NFS service must not be running. Linux NFS and Data Fabric NFS cannot run concurrently.
- Data Fabric NFSv3 and NFSv4 should not be installed on the same node.
- The lock manager (nlockmgr) must be disabled.
- On Red Hat and CentOS v6.0 and higher, the `rpcbind` service must be running.

  You can use the command `ps ax | grep rpcbind` to check.
- On Red Hat and CentOS v5.x and lower, and on Ubuntu and SLES, the `portmapper` service must be running.

  You can use the command `ps ax | grep portmap` to check.
- The `mapr-nfs` package for NFSv3 or `mapr-nfs4server` package for NFSv4 must be present and installed.

  You can list the contents in the `/opt/mapr/roles` directory to check for `nfs` in the list.
- Make sure you have applied a Community Edition (M3) license or an Enterprise Edition (M5) license (paid or trial) to the cluster.

  See Adding a License.
- Make sure the Data Fabric NFS service is started.

  See Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv3 on page 1558 or Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4 on page 1591.
- Verify that the primary group of the user listed for `mapr.daemon.user` in the `/opt/mapr/conf/daemon.conf` file is `mapr.daemon.group`.

  Restart Warden after any changes to `daemon.conf`.

For information about mounting the cluster using:

- NFSv3, see Accessing Data with NFS v3 on page 1557.
- NFSv4, see Accessing Data with NFS v4 on page 1567.

For information on upgrading your cluster, see Upgrading Core on page 308.

WARNING: To preserve compatibility with 32-bit applications and system calls, MapR-NFS uses 32-bit inode numbers by default. On 64-bit clients, this default forces the client's 64-bit inode numbers to be hashed down to 32 bits. Hashing 64-bit inodes down to 32 bits can potentially cause inum conflicts. To change the default behavior to 64-bit inode numbers, set the value of the `Use32BitFileId` property to 0 in the `nfsserver.conf` file, then restart the NFS server.

last-updated: Jun 06, 2024

HPE Ezmeral Data Fabric Client

Describes how to install the HPE Ezmeral Data Fabric client to run Hadoop commands, jobs, and applications from a client machine.

You can use the client to:

- Submit MapReduce applications.
- Submit YARN applications.
- Run `hadoop fs` on page 5549, and `hadoop mfs` on page 5557 commands.

The method that you use to submit the Hadoop commands on Mac and Windows clients is different from the method that is used on Linux machines. For more information, see Running Hadoop Commands on a Mac and Windows Client.

Installing the Data Fabric Client (Non-FIPS)
This section describes how to prepare the client machine for the installation process in a non-FIPS environment.

In a FIPS or mixed FIPS/non-FIPs environment, special procedures are required to configure clients. If your environment is FIPS or mixed FIPS/non-FIPS, see Installing the Data Fabric Client (FIPS) on page 417.

CAUTION: Do not attempt to install Ecosystem Pack (EEP) service components on client machines. Client machines do not have the service-management framework required to host the service components.

Before you install the data-fabric client, perform the following steps:

- **Verify that the operating system on the machine where you plan to install the client is supported.** For a list of operating systems that are compatible with the data-fabric clients, see Client Support Matrix on page 5768.
- **Verify that the machine where you plan to install the client is not a cluster node.** The data-fabric client is intended for use on a computer that has no other data-fabric server software installed.
- **Ensure that the hostname of the machine is set to a fully qualified DNS name**. This is critical as else configure.sh will fail to generate SSL keys.
- **Obtain connectivity information and cluster setup requirements.** When you use `configure.sh` to configure the client, you will need to know the following details:
  - The cluster name. You will need the cluster name when you specify the `-N` parameter.
  - The IP addresses and ports of the CLDB nodes on the cluster. You will need this information when you specify the CLDB nodes with the `-C` parameter.
  - If one or more nodes in the cluster run the ResourceManager, you may need to specify the hostname or IP address for each ResourceManager nodes using the `-RM` parameter. If the cluster is configured to use zero-configuration failover, do not specify the ResourceManager nodes. If the cluster is not configured to use zero-configuration failover, specify each ResourceManager node.
  - Determine if the cluster is secure. If the cluster is secure, you will need to specify the `-secure` parameter when you run `configure.sh`.
  - If a node in the cluster runs the HistoryServer, note the hostname for the HistoryServer. You must specify each HistoryServer node using the `-HS` parameter.

- **Add the hostname mapping.** In the `/etc/hosts` file of the client machine, add a mapping between the CLDB nodes in the cluster and the IP addresses of those nodes.

  For example, add the IP address 10.10.82.22 and CLDB node name centos22 on the Mac OSX where you installed the client:

  ```
  127.0.0.1       localhost
  255.255.255.255 broadcasthost
  ::1             localhost
  fe80::1%lo0     localhost
  10.10.82.22     centos22
  ```

- **Configure repositories for the client.** The client nodes also need to have the data-fabric repositories configured in order to pull the client packages. See Data Fabric Repositories and Packages on page 101.

To install the client, obtain the data-fabric packages for your operating system at https://package.ezmeral.hpe.com/releases/ and complete the installation steps described in one of the subsequent topics.

Installing the Data Fabric Client on Red Hat and Oracle Linux (Non-FIPS)
This section describes how to install the Data Fabric client on Red Hat and Oracle Linux.

The following steps describe how to install a non-FIPS client for use with a secure non-FIPS cluster. If you need to install a FIPS or non-FIPS-enabled client for use with a cluster consisting of all FIPS nodes or a mix of FIPS and non-FIPS nodes, see the procedures in Installing the Data Fabric Client (FIPS) on page 417.

These steps assume that you have already set up a Data Fabric repository as described in Adding the Data Fabric Repository on RHEL, CentOS, or Oracle Linux on page 183.

1. Remove any previous Data Fabric software. You can use `rpm -qa | grep mapr` to get a list of installed Data Fabric packages, then type the packages separated by spaces after the `rpm -e` command:

   ```
   rpm -qa | grep mapr
   rpm -e mapr-fileserver mapr-core
   ```

2. Import the package keys to enable signature verification:

   ```
   wget --user=<email> --password=<token> -O /tmp/maprgpg.key -q https://
   package.ezmeral.hpe.com/releases/pub/maprgpg.key && rpm --import /tmp/
   maprgpg.key
   wget --user=<email> --password=<token> -O /tmp/hpeezdf.pub -q https://
   package.ezmeral.hpe.com/releases/pub/hpeezdf.pub && rpm --import /tmp/
   hpeezdf.pub && gpg --import /tmp/hpeezdf.pub
   ```

   Optionally, you may use commands to verify the signatures before installing the software. For more information, see HPE GPG Public Keys for GPG or RPM Signature Verification.

3. Install the client for your target architecture:

   ```
   yum install mapr-client.x86_64
   ```

4. To use this client with a secure cluster or clusters, copy the following files from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client.

   - `ssl_truststore`
   - `ssl_truststore.p12`

last-updated: Jun 06, 2024

- `ssl_truststore.pem`
- `maprtrustcreds.conf`
- `maprtrustcreds.jceks`
- `ssl_keystore-signed.pem`

If this client will connect to multiple clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool. You must perform the merging on the cluster. See Managing Secure Clusters on page 1947 for details on how to connect to a secure cluster.

5. Run `configure.sh` to configure the client. In the following examples, the `-N` parameter specifies the cluster name, the `-c` (lowercase) parameter specifies a client configuration, the `-secure` parameter is added if the cluster is secure, the `-C` (uppercase) parameter specifies the CLDB nodes, and the `-HS` parameter specifies the HistoryServer node. To ensure that the client can connect in the event of a CLDB node failure, all CLDB nodes are specified. For more information about the syntax, parameters, and behavior of `configure.sh`, see configure.sh.

   Secure cluster example

   ```
   /opt/mapr/server/configure.sh -N my.cluster.com -c -secure -C
   mynode01:7222,mynode02:7222,mynode03:7222 -HS mynode02
   ```

   Non-secure cluster example

   ```
   /opt/mapr/server/configure.sh -N my.cluster.com -c -C
   mynode01:7222,mynode02:7222,mynode03:7222 -HS mynode02
   ```

   NOTE:

   If the cluster was configured with a *cluster admin* `user:group` that is different from the default `mapr:mapr` value, you must include options to specify the cluster admin user and group information when you run `configure.sh` to configure the client.

   If the cluster-admin user ID is present on the client node, include these options:

   - `-u`
   - `-g`

   If the cluster-admin user ID is not present on the client node, include these options:

   - `-u`
   - `-g`
   - `--create-user | -a`
   - `-U`
   - `-G`

   The following table describes each option:

Option	Description
`-u`	The user name under which cluster services run.

Option	Description
`-g`	The group name under which cluster services run.
`--create-user | -a`	Creates a local user to run cluster services, using the specified user either from the `-u` parameter, or from the environment variable `$MAPR_USER`.
`-U`	The user ID to use when creating `$MAPR_USER` with the `--create-user` or `-a` option; corresponds to the `-u` or `--uid` option of the `useradd` command in Linux.
`-G`	The group ID to use when creating `$MAPR_USER` with the `-create-user` or `-a` option; corresponds to the `-g` or `-gid` option of the `useradd` command in Linux.

6. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

Related concepts

Managing Secure Clusters on page 1947
Provides procedures that will enable you to use MapR clusters securely.

Related tasks

Step 2: Import the Package Key on page 181
Before you install Data Fabric packages, you must import the package key.

Related reference

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Installing the Data Fabric Client on SLES (Non-FIPS)

This section describes how to install the Data Fabric Client on SLES.

1. Remove any previous data-fabric software. You can use `rpm -qa | grep mapr` to get a list of installed data-fabric packages:

   ```
   rpm -qa | grep mapr
   ```

   Then type the package names separated by spaces after the `zypper rm` command. For example:

   ```
   zypper rm mapr-fileserver mapr-core
   ```

2. Import the package keys to enable signature verification:

   ```
   wget --user=<email> --password=<token> -O /tmp/maprgpg.key -q https://
   package.ezmeral.hpe.com/releases/pub/maprgpg.key && rpm --import /tmp/
   maprgpg.key
   wget --user=<email> --password=<token> -O /tmp/hpeezdf.pub -q https://
   package.ezmeral.hpe.com/releases/pub/hpeezdf.pub && rpm --import /tmp/
   hpeezdf.pub && gpg --import /tmp/hpeezdf.pub
   ```

   Optionally, you may use commands to verify the signatures before installing the software. For more information, see HPE GPG Public Keys for GPG or RPM Signature Verification.

3. Run the following command to install the data-fabric client:

   ```
   zypper install mapr-client
   ```

4. To use this client with a secure cluster or clusters, copy the following files from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client:
   - `ssl_truststore`
   - `ssl_truststore.p12`
   - `ssl_truststore.pem`
   - `maprtrustcreds.conf`
   - `maprtrustcreds.jceks`
   - `ssl_keystore-signed.pem`

   If this client will connect to multiple clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool. You must perform the merging on the cluster. See Managing Secure Clusters on page 1947 for details on how to connect to a secure cluster.

5. Run `configure.sh` to configure the client. In the following examples, the `-N` parameter specifies the cluster name, the `-c` (lowercase) parameter specifies a client configuration, the `-secure` parameter is added if the cluster is secure, the `-C` (uppercase) parameter specifies the CLDB nodes, and the `-HS` parameter specifies the HistoryServer node. To ensure that the client can connect in the event of a CLDB node failure, all CLDB nodes are specified. For more information about the syntax, parameters, and behavior of `configure.sh`, see configure.sh.

   Secure cluster example

   ```
   /opt/mapr/server/configure.sh -N
   my.cluster.com -c -secure -C
   mynode01:7222,mynode02:7222,mynode03
   :7222 -HS mynode02
   ```

   NOTE:

   If the cluster was configured with a *cluster admin* `user:group` that is different from the default `mapr:mapr` value, you must include options to specify the cluster-admin user and group information when you run `configure.sh` to configure the client.

   If the cluster-admin user ID is present on the client node, include these options:
   - `-u`
   - `-g`

   If the cluster-admin user ID is not present on the client node, include these options:
   - `-u`
   - `-g`
   - `--create-user | -a`
   - `-U`
   - `-G`

   The following table describes each option:

last-updated: Jun 06, 2024

Option	Description
`-u`	The user name under which cluster services run.
`-g`	The group name under which cluster services run.
`--create-user | -a`	Creates a local user to run cluster services, using the specified user either from the `-u` parameter, or from the environment variable `$MAPR_USER`.
`-U`	The user ID to use when creating `$MAPR_USER` with the `--create-user` or `-a` option; corresponds to the `-u` or `--uid` option of the `useradd` command in Linux.
`-G`	The group ID to use when creating `$MAPR_USER` with the `-create-user` or `-a` option; corresponds to the `-g` or `-gid` option of the `useradd` command in Linux.

6. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

Related concepts

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Installing the Data Fabric Client on Ubuntu (Non-FIPS)

This section describes how to install the Data Fabric client on Ubuntu.

1. Remove any previous data-fabric client software. You can use `dpkg --list | grep mapr` to get a list of installed data-fabric packages. Then type the packages separated by spaces after the `dpkg -r` command. For example:

```
dpkg -r mapr-core mapr-fileserver
```

2. Update your Ubuntu repositories. For example:

```
apt-get update
```

3. Import the package keys to enable signature verification:

```
wget --user=<email> --password=<token> -O /tmp/maprgpg.key -q https://
package.ezmeral.hpe.com/releases/pub/maprgpg.key && rpm --import /tmp/
maprgpg.key
wget --user=<email> --password=<token> -O /tmp/hpeezdf.pub -q https://
package.ezmeral.hpe.com/releases/pub/hpeezdf.pub && rpm --import /tmp/
hpeezdf.pub && gpg --import /tmp/hpeezdf.pub
```

Optionally, you may use commands to verify the signatures before installing the software. For more information, see HPE GPG Public Keys for GPG or RPM Signature Verification.

4. Make sure the client is running JDK 11 or later:

```
$ echo $JAVA_HOME
/Library/Java/JavaVirtualMachines/jdk-11.0.1.jdk/Contents/Home
$ /Library/Java/JavaVirtualMachines/jdk-11.0.1.jdk/Contents/Home/bin/
java -version
openjdk version "11.0.1" 2018-10-16
OpenJDK Runtime Environment 18.9 (build 11.0.1+13)
OpenJDK 64-Bit Server VM 18.9 (build 11.0.1+13, mixed mode)
```

5. Run the following command to install the data-fabric client:

```
apt-get install mapr-client
```

6. To use this client with a secure cluster or clusters, copy the `ssl_truststore` and `ssl-client.xml` files from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client.

   If this client will connect to multiple clusters, you must merge the `ssl_truststore` files on the server by using the `/opt/mapr/server/manageSSLKeys.sh` tool, and then copy the merged file to `/opt/mapr/conf` on the client. For an example of merging the `ssl_truststore` files, see step 3 in Configuring Secure Clusters for Running Commands Remotely on page 1949.

7. Run `configure.sh` to configure the client. In the following examples:

`-N` (uppercase)	Specifies the cluster name
`-c` (lowercase)	Specifies a client configuration
`-secure`	Indicates that the cluster is secure
`-C` (uppercase)	Specifies the CLDB nodes
`-HS`	Specifies the HistoryServer node

   To ensure that the client can connect in the event of a CLDB node failure, all CLDB nodes are specified. For more information about the syntax, parameters, and behavior of `configure.sh`, see configure.sh.

   Secure cluster example

```
/opt/mapr/server/configure.sh -N my.cluster.com -c -secure -C
mynode01:7222,mynode02:7222,mynode03:7222 -HS mynode02
```

   Non-secure cluster example

```
/opt/mapr/server/configure.sh -N my.cluster.com -c -C
mynode01:7222,mynode02:7222,mynode03:7222 -HS mynode02
```

NOTE:

If the cluster was configured with a cluster-admin `user:group` that is different from the default `mapr:mapr` value, you must include options to specify the cluster-admin user and group information when you run `configure.sh` to configure the client.

If the cluster-admin user ID is present on the client node, include these options:

- `-u`
- `-g`

If the cluster-admin user ID is not present on the client node, include these options:

- `-u`
- `-g`
- `--create-user | -a`
- `-U`
- `-G`

8. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

Related concepts

Provides procedures that will enable you to use MapR clusters securely.

Related reference

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Installing OpenSSL 1.1.1 for the Mac Client

The LibreSSL version of OpenSSL that comes preinstalled on the macOS is not compatible with HPE Ezmeral Data Fabric release 7.0.0. Before running `configure.sh` to configure the Mac client, you must install the OpenSSL 1.1.1 package and add paths to the OpenSSL 1.1.1 command and dynamic libraries.

To install OpenSSL 1.1.1 on macOS:

1. Run the following `brew install` command:

```
brew install OpenSSL@1.1
```

2. Add the paths to the OpenSSL binary and library:

```
OPENSSL_INSTALLED_LOCATION=`brew --prefix openssl@1.1`
OPENSSL_LIBRARY_PATH=${OPENSSL_INSTALLED_LOCATION}/lib
OPENSSL_PATH=${OPENSSL_INSTALLED_LOCATION}/bin
export PATH=${OPENSSL_PATH}:${PATH}
LD_LIBRARY_PATH=${OPENSSL_LIBRARY_PATH}:${LD_LIBRARY_PATH}
```

3. Verify that the OpenSSL 1.1.1 binary is used. Issuing the following command should return `Open SSL 1.1.1x`:

   ```
   openssl version
   OpenSSL 1.1.1l  24 Aug 2021
   ```

   If the `openssl version` command returns `LibreSSL`, your configuration settings are incorrect:

   ```
   openssl version
   LibreSSL 2.8.3
   ```

4. Verify your OpenSSL dynamic library configuration by using the `verify_ossl` utility:

   ```
   % /opt/mapr/server/verify_ossl
   Verified that OpenSSL can be successfully loaded
   ```

5. If `verify_ossl` returns output like the following, then your LD_LIBRARY_PATH settings are incorrect:

   ```
   /opt/mapr/server/verify_ossl
   Unable to load OpenSSL from specified locations. Error:
   dlopen(libssl.1.1.dylib, 6): image not found
   Cannot load libssl, file not found in common locations, Exiting...
   Cannot Initialize OpenSSL
   ```

After you have verified that OpenSSL 1.1.1 is installed and that your OpenSSL configuration settings point to the OpenSSL 1.1.1 library, you can configure the Mac client. See Installing the Data Fabric Client on Mac OS X (Non-FIPS) on page 412.

Installing the Data Fabric Client on Mac OS X (Non-FIPS)
This section describes how to install the Data Fabric client on Mac OS X.

Limitation: Under OS X, the `getgroups` command returns a maximum of 16 groups for a user. If the Mac OS user for which you are installing the client attempts to read or write to a Data Fabric filesystem resource as a member of a group that was not included in the list of 16 groups returned by `getgroups`, file permission errors may result.

1. Install the OpenSSL 1.1.1 package and add paths to the OpenSSL 1.1.1 command and dynamic libraries, as described in Installing OpenSSL 1.1.1 for the Mac Client on page 411.

2. Install or update bash to ensure that the bash version is 4.0.0 or higher:

   ```
   brew install bash
   ```

3. Install or update `gnu-getopt`, which is needed to configure Hadoop later in this procedure:

   ```
   brew install gnu-getopt
   ```

4. Create the `/opt` directory: `sudo mkdir -p /opt`

5. Download the file for the version that you want to install:

   IMPORTANT: To access the Data Fabric internet repository, you must specify the user name (email) and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

   ```
   https://package.ezmeral.hpe.com/releases/<version>/mac/<mapr-client
   package name>
   ```

6. Open the **Terminal** application.

7. Import the package keys to enable signature verification:

   ```
   wget --user=<email> --password=<token> -O /tmp/maprgpg.key -q https://
   package.ezmeral.hpe.com/releases/pub/maprgpg.key && rpm --import /tmp/
   maprgpg.key
   wget --user=<email> --password=<token> -O /tmp/hpeezdf.pub -q https://
   package.ezmeral.hpe.com/releases/pub/hpeezdf.pub && rpm --import /tmp/
   hpeezdf.pub && gpg --import /tmp/hpeezdf.pub
   ```

   Optionally, you may use commands to verify the signatures before installing the software. For more information, see HPE GPG Public Keys for GPG or RPM Signature Verification.

8. Extract `mapr-client-<version>.tar.gz` into the `/opt` directory:

   ```
   sudo tar -C /opt -zxf mapr-client-<version>.tar.gz*
   ```

9. Make sure the client is running JDK 11 or later:

   ```
   $ echo $JAVA_HOME
   /Library/Java/JavaVirtualMachines/jdk-11.0.1.jdk/Contents/Home
   $ /Library/Java/JavaVirtualMachines/jdk-11.0.1.jdk/Contents/Home/bin/
   java -version
   openjdk version "11.0.1" 2018-10-16
   OpenJDK Runtime Environment 18.9 (build 11.0.1+13)
   OpenJDK 64-Bit Server VM 18.9 (build 11.0.1+13, mixed mode)
   ```

10. Before running `configure.sh`, make sure that `JAVA_HOME` is set correctly for the client in the following script: `/opt/mapr/conf/env.sh`

    For example:

    ```
    $ export JAVA_HOME=$(/usr/libexec/java_home)
    ```

11. To use this client with a secure cluster or clusters, copy the following files from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client:

    - `ssl_truststore`
    - `ssl-client.xml`
    - `maprtrustcreds.jceks`
    - `maprtrustcreds.conf`

    If this client will connect to multiple clusters, you must merge the `ssl_truststore` files on the server by using the `/opt/mapr/server/manageSSLKeys.sh` tool, and then copy the merged file

to `/opt/mapr/conf` on the client. For an example of merging the `ssl_truststore` files, see step 3 in Configuring Secure Clusters for Running Commands Remotely on page 1949.

12. Run `configure.sh` to configure the client. On the Mac client, you must run `configure.sh` from the `/usr/local/bin/bash` directory. In the following examples:

`-N` (uppercase)	Specifies the cluster name
`-c` (lowercase)	Specifies a client configuration
`-secure`	Indicates that the cluster is secure
`-C` (uppercase)	Specifies the CLDB nodes
`-HS`	Specifies the HistoryServer node

To ensure that the client can connect in the event of a CLDB node failure, all CLDB nodes are specified. For more information about the syntax, parameters, and behavior of `configure.sh`, see configure.sh.

Secure cluster example

```
sudo /usr/local/bin/bash /opt/mapr/server/configure.sh -N
my.cluster.com -c -secure -C mynode01:7222,mynode02:7222,mynode03:7222
```

Non-secure cluster example

```
sudo /usr/local/bin/bash /opt/mapr/server/configure.sh -N
my.cluster.com -c -C mynode01:7222,mynode02:7222,mynode03:7222 -HS nodeA
```

NOTE:

If the cluster was configured with a cluster-admin `user:group` that is different from the default `mapr:mapr` value, you must include options to specify the cluster-admin user and group information when you run `configure.sh` to configure the client.

If the cluster-admin user ID is present on the client node, include these options:

- `-u`
- `-g`

If the cluster-admin user ID is not present on the client node, include these options:

- `-u`
- `-g`
- `--create-user | -a`
- `-U`
- `-G`

13. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

14. Configure Hadoop to enable Hadoop jobs to run on the Mac OS client:

```
/opt/mapr/hadoop/hadoop-2.7.6/bin/configure.sh --unsecure -EC "-HS
centos.cluster.com --client"
```

For information about running Hadoop commands on Mac OS X, see Running Hadoop Commands on a Mac and Windows Client on page 449.

Related concepts

Managing Secure Clusters on page 1947
Provides procedures that will enable you to use MapR clusters securely.

Related reference

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Installing the Data Fabric Client on Windows (Non-FIPS)

Installing the HPE Ezmeral Data Fabric client makes it possible to access the file system from a Windows workstation.

NOTE: Be aware of special considerations for installing the Windows client in a Java 17 environment. See Considerations for Java 17 on page 5765.

Compatibility with Network Address Translation (NAT) Adapters

In VM environments, the data-fabric client on Windows works with a single NAT virtual adapter as long as it is the only virtual adapter configured for the VM. If you want to use more than one adapter, you must use other types of virtual adapters. If you use multiple NAT adapters in your VM environment, your jobs and file-system operations will fail.

Use these steps to install the client:

1. To use the client with Release 7.1.0, make sure that a supported distribution of Java 11 is installed on the Windows computer. See Java Support Matrix on page 5764. To check the Java version, use this command in the Windows command prompt:

```
java -version
```

2. Create the `\opt\mapr` directory on your `c:` drive (or on another hard drive of your choosing). You can use Windows Explorer, or type the following at the command prompt:

```
mkdir c:\opt\mapr
```

3. Add the following environment variables:

System Variable	Value
`JAVA_HOME`	`JAVA_HOME=C:\jdk-11` **NOTE:** The path that you set for the JAVA_HOME environment variable must not include spaces.
`MAPR_HOME`	`MAPR_HOME=C:\opt\mapr`

`PATH`	`%JAVA_HOME%\bin`
	`%MAPR_HOME%\bin`
	`%MAPR_HOME%\hadoop\hadoop-3.3.4\bin`

4. After adding environment variables, exit and reopen the command prompt.
5. Download the client package archive:

   IMPORTANT: To access the Data Fabric internet repository, you must specify the user name (email) and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

   a. Navigate to the Internet repository:

   ```
   https://package.ezmeral.hpe.com/releases/v<version>/windows/<package name>
   ```

   b. Download the `mapr-client-7.1.0.0` package to `C:\opt\mapr`.

   c. Extract the archive by right-clicking the file and selecting **Extract All...**.

   d. Specify `C:\opt\mapr\` as the folder where the files are extracted. If you extract the files to a subfolder of `C:\opt\mapr\`, such as `C:\opt\mapr\mapr-client-7.0.0.0.<timestamp>`, the `configure.bat` command can return errors.

6. At the command prompt, run `configure.bat` to configure the client.

   In the following examples:

   - `-N` specifies the cluster name.
   - `-c` (lowercase) specifies a client configuration.
   - `-secure` is added if the cluster is secure.
   - `-C` (uppercase) specifies the CLDB nodes.
   - `-HS` specifies the HistoryServer node.
   - 7222 is the default port for the CLDB node.

   To ensure that the client can connect in the event of a CLDB node failure, you can optionally specify all CLDB nodes. For details about the syntax, parameters, and behavior of configure.bat, see configure.sh.

   Secure cluster example

   ```
   server\configure.bat -N <cluster_name> -c -secure -C mynode01:7222,mynode02:7222,mynode03:7222
   ```

7. To use this client with a secure cluster or clusters, copy the following files from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client:

   - `ssl_truststore`
   - `ssl-client.xml`
   - `maprtrustcreds.jceks`
   - `maprtrustcreds.conf`

   If this client will connect to multiple clusters, you must merge the `ssl_truststore` files on the server by using the `/opt/mapr/server/manageSSLKeys.sh` tool, and then copy the merged file to

last-updated: Jun 06, 2024

`c:\opt\mapr\conf` on the client. For an example of merging the `ssl_truststore` files, see step 3 in Configuring Secure Clusters for Running Commands Remotely on page 1949.

For more information about connecting to a secure cluster, see Managing Secure Clusters on page 1947.

8. On the Windows computer, create a ticket:

```
maprlogin password -user <DataFabricUserName>
```

This command creates a ticket for `<DataFabricUserName>`, usually as:

```
C:\Users\<WindowsUserName>\AppData\Local\Temp\maprticket_<WindowsUserName
>
```

NOTE: If you intend to run MapReduce jobs as `<DataFabricUserName>`, set the `MAPR_TICKETFILE_LOCATION` system variable to `C:\Users\<WindowsUserName>\AppData\Local\Temp\maprticket_<DataFabricUserName>`.

9. Use the `hadoop fs -ls /` command to check for connectivity to the cluster. For example:

```
hadoop fs -ls /
22/02/01 15:59:26 INFO util.log: Logging initialized @2631ms to

Managing Secure Clusters on page 1947
Provides procedures that will enable you to use MapR clusters securely.

Installing the Data Fabric Client (FIPS)

This section describes how to prepare the client machine for the installation process in a FIPS environment.

In a FIPS or mixed FIPS/non-FIPs environment, special procedures are required to configure clients. If your environment is non-FIPS, see Installing the Data Fabric Client (Non-FIPS) on page 404.

Release 7.0.0 of the HPE Ezmeral Data Fabric introduced the use of the FIPS-approved BCFKS store type. Non-FIPS secure installations continue to use the JKS and PKCS#12 store types, so this results in some changes in the client-installation procedure to connect a secure non-FIPS-enabled cluster to a FIPS-enabled cluster. The protection of key and trust store passwords using the Hadoop Credential Provider API also necessitates changes in the client-installation procedure.

Preparing and Installing the Data Fabric Client on RHEL 8.x

The steps for preparing to install the client in a FIPS environment are the same as the steps documented for a non-FIPS environment. See Installing the Data Fabric Client (Non-FIPS) on page 404.

The first three steps in the client-installation procedure remain the same as the steps documented in Installing the Data Fabric Client on Red Hat and Oracle Linux (Non-FIPS) on page 405:

1. Remove any previous data-fabric software. You can use `rpm -qa | grep mapr` to get a list of installed data-fabric packages, then type the packages separated by spaces after the `rpm -e` command. For example:

   ```
   rpm -qa | grep mapr
   rpm -e mapr-fileserver mapr-core
   ```

2. Install the data-fabric package key. The package key must be installed before you can install data-fabric packages. For more information, see Step 2: Import the Package Key on page 181:

   IMPORTANT: To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see Using the HPE Ezmeral Token-Authenticated Internet Repository on page 102.

   ```
   wget --user=<email> --password=<token> -O /tmp/maprgpg.key -q https://
   package.ezmeral.hpe.com/releases/pub/maprgpg.key && rpm --import /tmp/
   maprgpg.key
   ```

3. Install the client. For example:

   ```
   yum install mapr-client
   ```

Configuring the Secure Data Fabric Client

After installation, the next step is different depending on whether the secure cluster that the client is connecting to is FIPS-enabled or not. In this definition, *server* refers to the FIPS-enabled host from which the trust stores are copied. A FIPS-enabled installation always implies a secure installation. Different configuration procedures are needed, depending on whether the server and client are FIPS-enabled. Possible scenarios are:

- Both server and client are FIPS-enabled.
- Client is secure but not FIPS-enabled, but server is FIPS-enabled.
- Client is FIPS-enabled, and server is secure but not FIPS-enabled.
- Both server and client are secure but not FIPS-enabled.

In all four scenarios, the procedure is different depending on whether the client is connecting to the first cluster or to subsequent clusters. Sub-topics in this section outline the steps for each of the combinations. In all cases, after copying the files from the server and performing any needed post-copy steps, you must run the `${MAPR_HOME/server/configure.sh` command with the `-c` (client configuration) option.

The general syntax is the same as described in Installing the Data Fabric Client on Red Hat and Oracle Linux (Non-FIPS) on page 405:

```
# /opt/mapr/server/configure.sh -secure -N <cluster-name> -c \
    -C <CLDB1>:<CLDB1-port>[,[CLDB2>:<CLDB1-port>,...] \
    -HS <history server node>
```

For example, if your cluster name is `fips0`, `fips1`, and `fips2`, and your CLDB nodes are `node1`, `node2`, and `node3`, and your History Server node is `node2`, then the command would be:

```
# /opt/mapr/server/configure.sh -secure -N fips0.cluster.com -c \
    -C node1:7222,node2:7222,node3:7222 -HS node2
```

The following sub-topics summarize the steps to connect to different combinations of FIPS-enabled and non-FIPS-enabled server and client nodes.

Configuring a FIPS-Enabled Client for a FIPS-Enabled Server

Describes client configuration when the client is FIPS and the server is FIPS.

Configuration for the First Cluster

To connect the FIPS-enabled client to a FIPS-enabled server for the first cluster, copy the following files from the FIPS-enabled server to the client:

- `${MAPR_HOME}/conf/ssl_truststore.bcfks`
- `${MAPR_HOME}/conf/maprtrustcreds.bcfks`

Then, run the `configure.sh` script with the `-c` (client only) option. For example, if the cluster name is `fips0.cluster.com` and the CLDB and Zookeeper nodes are at `m2-mapreng-vm166250`, then the command might be as follows:

```
/opt/mapr/server/configure.sh -secure -N fips0.cluster.com -c \
    -C m2-mapreng-vm166250:7222
```

The `${MAPR_HOME}/server/configure.sh` script makes the following changes:

- The `${MAPR_HOME}/conf/mapr-clusters.conf` is set to the specified cluster name and CLDB hosts.
- The symbolic link `${MAPR_HOME}/conf/ssl_truststore` is created to point to `${MAPR_HOME}/conf/ssl_truststore.bcfks`:

  ```
  # ls -l ssl_truststore
  lrwxrwxrwx 1 root root 35 Aug 17 16:52 ssl_truststore -> /opt/mapr/conf/
  ssl_truststore.bcfks
  ```

- • The `${MAPR_HOME}/hadoop/hadoop-${HADOOP_VERSION}/etc/hadoop/ssl-client.xml` is updated to have the same contents at the server; that is:
  - All password properties are removed.
  - The trust store type is set to `bcfks`.
- The `${MAPR_HOME}/hadoop/hadoop-${HADOOP_VERSION}/etc/hadoop/core-site.xml` is updated with the `hadoop.security.credential.provider.path` property with the provider path set to `localbcfks://file/opt/mapr/conf/maprtrustcreds.bcfks`. This enables commands such as `hadoop credential list` to work without specifying the provider path. This also allows the Hadoop `Configuration.getPassword()` API used by various components to retrieve the trust store credentials to work.

Configuration for Subsequent Clusters

If your client is connecting to a second or subsequent clusters, you need to merge the trust store contents from these clusters to your existing trust store. There are two ways to perform the configuration:

- **Merge the trust stores:** Copy the trust store from the FIPS-enabled server to the client, then merge the trust stores using the `manageSSLKeys.sh merge` command. Then, run the `configure.sh` command. In this method, you only need to copy a single trust store, but you need to specify the trust store password for the cluster you want to connect to at the client to complete the configuration.

- **Import certificates:** Copy the root CA and server certificates from the FIPS-enabled server to the client, then use the `manageSSLKeys.sh import` command to import the certificates to the existing client trust store. Then, run the `configure.sh` command. In this method, you need to copy multiple certificates, but you do not need the trust store password for the cluster you are connecting to.

The following sections describe these configuration methods:

Configuration by Merging Trust Stores

This is the first method described at the beginning of this section, where we copy the trust store from the FIPS-enabled server to the FIPS-enabled client and then merge the trust stores. Use these steps:

1. Copy the `${MAPR_HOME}/conf/ssl_truststore.bcfks` from the FIPS-enabled server node to some directory, such as `/tmp`.

2. Use the `merge` option in `manageSSLKeys.sh` to merge the trust stores. The command syntax is as follows. At least the first and second parameters are required:

```
/opt/mapr/server/manageSSLKeys.sh merge \
    <from-trust> <to-trust> <from-password> <to-password>
```

The following table describes each parameter:

Parameter	Description
`from-trust`	Full or relative path to the source trust store from which the certificates are retrieved. This is the trust store that is copied from the FIPS-enabled server in Step 1. This parameter is required.
`to-trust`	Full or relative path to the destination trust store which will contain the merged certificates. In this case, where you are configuring a connection to a second or subsequent cluster, this is the trust store in `${MAPR_HOME}/conf`. This parameter is required.
`from-password`	Password for the source trust store `from-trust`. You need to obtain the trust store password from the `store-passwords.txt` file in the FIPS-enabled server node that was created after a fresh installation. This parameter is optional. If not specified, it defaults to `mapr123`.
`to-password`	Password for the destination trust store `to-trust`. This is the password for the existing trust store on the client node. If not specified, it defaults to `mapr123`.

For example:

```
# /opt/mapr/server/manageSSLKeys.sh merge \
  /tmp/ssl_truststore.bcfks \
  /opt/mapr/conf/ssl_truststore.bcfks \
  qoaY9_ZkZkh8mOy_Fr2W50vaduhgAC72 \
  mapr123
Merging certificates from /tmp/ssl_truststore.bcfks into existing /opt/
mapr/conf/ssl_truststore.bcfks
# keytool -list -keystore /opt/mapr/conf/ssl_truststore.bcfks \
 -storepass mapr123 -storetype bcfks \
 -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
 -providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
 -providername BCFIPS
Keystore type: BCFKS
Keystore provider: BCFIPS

Configuration by Importing Certificates

This section describes the steps to configure the Ezmeral Data Fabric client by importing certificates from the server:

1. Copy the following files from the cluster that the client wants to connect from `${MAPR_HOME}/conf` on the server to a temporary directory, retaining the same directory structure:
   - The server certificate `ssl_keystore-signed.pem`
   - The root CA certificate in `ca/root-ca.pem`.

For example, on the FIPS-enabled client:

```
[root@m2-mapreng-vm166251 ~]# cd /tmp
[root@m2-mapreng-vm166251 ~]# mkdir -p fips0/ca
[root@m2-mapreng-vm166251 tmp]# cd /tmp/fips0
[root@m2-mapreng-vm166251 fips0]# scp root@fips0:/opt/mapr/conf/
ssl_keystore-signed.pem .
ssl_keystore-signed.pem                       100% 1261     1.6MB/s
00:00
[root@m2-mapreng-vm166251 fips0]# scp root@fips0:/opt/mapr/conf/ca/
root-ca.pem ca/.
root-ca.pem                                   100% 1062     1.3MB/s
00:00
[root@m2-mapreng-vm166251 fips0]# find . -print
.
./ca
./ca/root-ca.pem
./ssl_keystore-signed.pem
```

2. Run the `manageSSLKeys.sh` utility with the `importcertstotruststore` option to import the certificates to the trust store. The parameters are as follows:

Parameter	Description
`-N <cluster-name>`	The name of the cluster to which the client wants to connect.
`-p <password>`	Password for the client's trust store.
`-c <path-to-certs>`	Full or relative path name to the directory containing the certificates to be imported.

For example:

```
[root@m2-mapreng-vm166251 fips0]# /opt/mapr/server/manageSSLKeys.sh
importcertstotruststore -N fips0.cluster.com -p mapr123 -c /tmp/fips0
Adding root CA to trust store
```

3. Verify that the certificates have been successfully imported into the trust store. There should be two new aliases in the trust store for the new `fips0.cluster.com` cluster. For example:

```
# keytool -list \
-keystore /opt/mapr/conf/ssl_truststore.bcfks -storepass mapr123 \
-storetype bcfks \
-provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
-providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
-providername BCFIPS
Keystore type: BCFKS
Keystore provider: BCFIPS

Your keystore contains 6 entries

0:FE:00:E6:84:C8:37:16
```

4. Run `configure.sh` with the `-c` option. For example:

```
# /opt/mapr/server/configure.sh -secure -N fips0.cluster.com \
-c -C m2-mapreng-vm166250:7222
CLDB node list: m2-mapreng-vm166250:7222
Zookeeper node list:
External Zookeeper node list:
As cluster provided as input: fips0.cluster.com is not current cluster.
Only /opt/mapr/conf/mapr-clusters.conf will be updated
```

5. Remove the temporary directory containing the certificates. This is no longer needed since the certificates have been imported to the trust store:

```
# rm -rf /tmp/fips0
```

6. Verify your configuration in the same way as in the previous section:

```
# cat /opt/mapr/conf/mapr-clusters.conf
hpe186.cluster.com secure=true m2-mapreng-vm167186:7222
fips2.cluster.com secure=true m2-mapreng-vm166252:7222
fips0.cluster.com secure=true m2-mapreng-vm166250:7222
# maprlogin password -cluster fips0.cluster.com
[Password for user 'root' at cluster 'fips0.cluster.com': ]
MapR credentials of user 'root' for cluster 'fips0.cluster.com' are

Configuring a Secure Non-FIPS-Enabled Client for a FIPS-Enabled Server
Describes client configuration when the client is non-FIPS and the server is FIPS.

Non-FIPS enabled nodes do not support the BCFKS trust store format. Therefore, copying the BCFKS trust store from server to client does not work. You need to create the JKS trust store on the non-FIPS client by importing the same certificates that are in the BCFKS trust store on the FIPS-enabled server host. Different configuration procedures apply depending on whether you are configuring for the first cluster or for subsequent clusters.

Configuring the First Cluster

Use the following steps to configure a secure non-FIPS-enabled client to a FIPS-enabled server for the first cluster:

1. Copy the `${MAPR_HOME}/conf/ssl_truststore.bcfks` from the FIPS-enabled server to a temporary directory of the secure non-FIPS enabled client.

2. Run the `manageSSLKeys.sh convert` utility to convert the trust store from BCFKS format to JKS format. The destination trust store will be set to the same password as the source trust store. For example:

```
/opt/mapr/server/manageSSLKeys.sh convert \
    -srcType bcfks -dstType JKS \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /tmp/ssl_truststore.bcfks /opt/mapr/conf/ssl_truststore
```

3. On the secure non-FIPS enabled client, run the `configure.sh` script with the `-c` option, using the `-storepasswds` option to specify the trust store password, but without the key store password. Since the converted trust store is set to the same password as the source, the password must be the same as the one you specified using the `-p` option in Step 2. For example:

```
/opt/mapr/server/configure.sh -secure -N hpe186.cluster.com -C
m2-mapreng-vm167186:7222 -Z m2-mapreng-vm167186:5181 -c -storepasswds
:1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA
```

Configuring for Subsequent Clusters

If your secure non-FIPS enabled client is connecting to the second or subsequent clusters where the nodes are FIPS-enabled, you cannot use the procedure described for the FIPS client to FIPS server to merge the trust store contents from these clusters to your existing trust store, since the trust store type is different. You need to use the `keytool` utility to merge the trust stores. Use the following steps:

1. Copy the trust store from the FIPS server to the current node. For example:

```
# scp root@fips0:/opt/mapr/conf/ssl_truststore.bcfks /tmp/.
```

2. Run the `keytool` command to import the contents of the BCFKS trust store into the JKS trust store. You need the passwords for the BCFKS trust store on the remote node as well as the JKS trust store on the local node that you are importing to. For example:

```
# keytool -importkeystore -srckeystore ssl_truststore.bcfks \
-srcstorepass SPCs12NrH10F1tqD8p3C1_6r1vHB9AIx \
-srcstoretype bcfks \
-destkeystore /tmp/ssl_truststore \
-deststorepass j01Z8SdPV_r3N8bOnV1hzRwzCC_w8x4C \
-deststoretype jks \
-provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
-providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
-srcprovidername BCFIPS
Importing keystore ssl_truststore.bcfks to ssl_truststore...
Entry for alias fips0.cluster.com-root-signing-ca successfully imported.
Entry for alias fips0.cluster.com-root-ca-chain successfully imported.
Entry for alias fips0.cluster.com successfully imported.
Import command completed:  3 entries successfully imported, 0 entries
failed or cancelled
```

3. 3. Run the `configure.sh` command. For example:

```
# /opt/mapr/server/configure.sh -secure -N hpe186.cluster.com -c -C
m2-mapreng-vm166186:7222
```

Configuring a FIPS Client for a Secure Non-FIPS Server

Describes client configuration when the client is FIPS and the server is secure non-FIPS.

The steps to connect a FIPS-enabled client to a secure non-FIPS-enabled server are similar to the steps to connect a FIPS-enabled client to a secure non-FIPS-enabled server.

Configuring Connectivity for the First Cluster

Use these steps to configure connectivity for a FIPS-enabled client to a secure non-FIPS-enabled server:

1. On the secure non-FIPS-enabled server, run the `manageSSLKeys.sh convert` utility to convert the trust store from JKS to BCFKS format. For example:

```
/opt/mapr/server/manageSSLKeys.sh convert \
    -srcType JKS -dstType bcfks \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /opt/mapr/conf/ssl_truststore /tmp/ssl_truststore.bcfks
```

2. Copy the converted `ssl_truststore.bcfks` trust store from the secure non-FIPS server to the `/opt/mapr/conf/ssl_truststore.bcfks` of the FIPS client.

3. Run `configure.sh` with the `-c` option on the FIPS enabled client, using the `-storepasswds` option to specify the trust store password but without the key store password. Since the converted BCFKS trust store is set to the same password as the source, the password must be the same as the one you specified using the `-p` option in Step 2. For example:

```
/opt/mapr/server/configure.sh -secure -N hpe186.cluster.com -C
m2-mapreng-vm167186:7222 -Z m2-mapreng-vm167186:5181 -c -storepasswds
:1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA
```

After a successful run of `configure.sh`, the following files are created or updated:

- The BCFKS trust store credential file `${MAPR_HOME}/conf/maprtrustcreds.bcfks`:

```
[root@m2-mapreng-vm166251 ~]# hadoop credential list
Listing aliases for CredentialProvider:
localbcfks://file/opt/mapr/conf/maprtrustcreds.bcfks
ssl.client.truststore.password
```

- Symbolic links `${MAPR_HOME}/conf/ssl-client.xml` and `${MAPR_HOME}/conf/ssl-server.xml` are created to `${HADOOP_HOME}/etc/hadoop/ssl-client.xml` and `${HADOOP_HOME}/etc/hadoop/ssl-server.xml` respectively. The `ssl-server.xml` is not used for clients and is not modified by the `configure.sh` script.

- The Hadoop Credential Provider credential store `${MAPR_HOME}/conf/maprtrustcreds.bcfks` is created to store the trust store password specified in the `-storepasswds` option. The password for the trust store is set to the default of `mapr123`. To change the password, use the `manageSSLKeys.sh` script with the `createrandompassword` option to create a random password, or the `copywithconfiguredpassword` option to set a new user-selectable password.

Configuring Connectivity for Subsequent Clusters

The procedure of connecting a FIPS client to a secure non-FIPS server is similar to that of connecting a non-FIPS client to a FIPS server. Use the following steps:

1. Copy the trust store from the non-FIPS server to the current node. For example:

```
# scp root@hpe186:/opt/mapr/conf/ssl_truststore /tmp/.
```

2. Run the `keytool` command to import the contents of the BCFKS trust store into the JKS trust store. You need the passwords for the BCFKS trust store on the remote node, as well as the JKS trust store on the local node that you are importing to. For example:

```
# keytool -importkeystore \
-srckeystore /tmp/ssl_truststore \
-srcstorepass j01Z8SdPV_r3N8bOnV1hzRwzCC_w8x4C \
-srcstoretype jks \
-destkeystore ssl_truststore.bcfks \
-deststoretype bcfks \
-deststorepass SPCs12NrH10F1tqD8p3C1_6r1vHB9AIx \
-provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
-providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
-providername BCFIPS
Importing keystore ssl_truststore to ssl_truststore.bcfks...
Entry for alias hpe186.cluster.com successfully imported.
Entry for alias hpe186.cluster.com-root-signing-ca successfully imported.
Entry for alias hpe186.cluster.com-root-ca-chain successfully imported.
```

You can verify the contents of your merged trust store by using the `keytool` command:

```
# keytool -list -keystore ssl_truststore.bcfks \
-provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
-providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
-providername BCFIPS \
-storetype bcfks \
-storepass SPCs12NrH10F1tqD8p3C1_6r1vHB9AIx
Keystore type: BCFKS
Keystore provider: BCFIPS

```

3. Run the `configure.sh` command with the `-c` option, and specify the cluster you want to connect to in the `-N` option, with the CLDBs in the `-C` section. For example:

```
# /opt/mapr/server/configure.sh -secure -N hpe186.cluster.com -c -C
s1:7222
```

Configuring a Secure Non-FIPS Client for a Secure Non-FIPS Server
Describes client configuration when the client and server are non-FIPS.

No additional configuration is needed to configure a secure non-FIPS client for a secure non-FIPS server. Use the non-FIPS procedures documented for Installing the Data Fabric Client (Non-FIPS) on page 404.

Verifying the Client Configuration
Describes how to verify that clients installed in a FIPS or mixed FIPS/non-FIPS environment are configured correctly.

After running any pre-configuration steps and the `configure.sh` script with the `-c` (client only) option, your client should be successfully configured. The final step is to verify your client configuration. Most of these steps are the same as verification steps for release 6.2.0 and earlier client installations. An added step for FIPS clients is to verify the existence and functionality of the Hadoop Credential Provider store, in order to protect your trust store passwords.

Verifying the Trust Store Configuration

On FIPS-enabled clients, you can run the `keytool -list -keystore` command to view the entries in the trust store:

```
[root@m2-mapreng-vm166251 ~]# keytool -list -keystore /opt/mapr/conf/
ssl_truststore.bcfks -storepass mapr123 -storetype bcfks -provider
org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider -providerpath /opt
/mapr/lib/bc-fips-1.0.2.1.jar -providername BCFIPS
Keystore type: BCFKS
Keystore provider: BCFIPS

Your keystore contains 4 entries

E:00:E6:84:C8:37:16
```

Verifying the Hadoop Credential Provider Store

Beginning with release 7.0.0, passwords from `ssl-client.xml` are now stored in the Hadoop Credential Provider Store in `${MAPR_HOME}/conf/maprtrustcreds.bcfks` (for FIPS-enabled nodes) and `${MAPR_HOME}/conf/maprtrustcreds.jceks` (for secure non-FIPS nodes). You should also verify that the Hadoop Credential Provider trust store is correctly configured. The hadoop credential

list command for a client node should only contain a single entry for the password for the `ssl.client.truststore.password` property:

```
# hadoop credential list
Listing aliases for CredentialProvider: localbcfks://file/opt/mapr/conf/
maprtrustcreds.bcfks
ssl.client.truststore.password
```

Verifying Server Connectivity

You should also perform the regular verifications to confirm server connectivity to ensure that you can successfully obtain a MapR ticket using `maprlogin` and execute Hadoop commands, for example:

```
# maprlogin password
[Password for user 'root' at cluster 'fips0.cluster.com': ]
MapR credentials of user 'root' for cluster 'fips0.cluster.com' are written
to '/tmp/maprticket_0'
# hadoop fs -ls /
Found 5 items
drwxr-xr-x   - mapr mapr      3 2021-08-19 17:11 /apps
drwxr-xr-x   - mapr mapr      0 2021-08-19 17:13 /opt
drwxrwxrwx   - mapr mapr      0 2021-08-19 17:10 /tmp
drwxr-xr-x   - mapr mapr      1 2021-08-19 17:14 /user
drwxr-xr-x   - mapr mapr      2 2021-08-19 17:14 /var
```

If your client is connecting to multiple clusters, use the `hadoop fs -ls maprfs://<clustername>/` command to verify your configuration. For example:

```
# hadoop fs -ls maprfs://fips0.cluster.com/
Found 5 items
drwxr-xr-x   - mapr mapr   3 2021-08-30 09:23 maprfs://fips0.cluster.com/

user
drwxr-xr-x   - mapr mapr   2 2021-08-30 09:26 maprfs://
fips0.cluster.com/var
```

Configuring the Windows Client

You can use the data-fabric client on Windows.

This section describes how to configure the data-fabric client on Windows:

Configuring the Data Fabric Client User on Windows

Before you use the Windows Client, configure it with information from your cluster.

About this task

Before running applications on the Windows Client, configure the `core-site.xml` file with the UID, GID, and user name of the cluster user that will be used to access the non-secure cluster.

NOTE: If you are on a secure cluster, this configuration is not needed because on secure clusters, the username is available through the ticket.

Complete the following steps:

Procedure

1. Obtain the UID and GID that has been set up for your user account. To determine the correct UID and GID values for your username, log into a cluster node and type the `id` command. In the following example, the UID is 1000 and the GID is 2000:

   ```
   $ id
   uid=1000(juser) gid=2000(juser)
   groups=4(adm),20(dialout),24(cdrom),46(plugdev),105(lpadmin),119(admin),1
   22(sambashare),2000(juser)
   ```

2. Add the following parameters to the `core-site.xml` files that correspond to the version of the hadoop commands that you plan to run:

   ```
   <property>
     <name>hadoop.spoofed.user.uid</name>
     <value>{UID}</value>
   </property>
   <property>
     <name>hadoop.spoofed.user.gid</name>
     <value>{GID}</value>
   </property>
   <property>
     <name>hadoop.spoofed.user.username</name>
     <value>{id of user who has UID}</value>
   </property>
   ```

   WARNING: You must use the *numeric* values for `UID` and `GID`, not the text names.

   NOTE: When wire-level security is implemented on Windows, spoofing is not supported. This greatly increases the security of the cluster, but the `core-site.xml` file settings above then have no effect.

   For MapReduce version 2 or other applications that run on YARN, the `core-site.xml` file(s) that you need to edit is located at: `%MAPR_HOME%\hadoop\hadoop-3.x.x\etc\hadoop\core-site.xml`.

Configure the Windows Client to Submit MapReduce Applications
This section describes how to add a property that allows you to run MapReduce applications from a Windows client.

Procedure

- Before running any MapReduce applications from a Windows client, add the following property to the `mapred-site.xml` file:

  ```
  <property>
  <name>mapreduce.app-submission.cross-platform</name>
  <value>true</value>
  </property>
  ```

  The `mapred-site.xml` file for MapReduce applications is located in the following directory:

  ```
  %MAPR_HOME%\hadoop\hadoop-3.x.x\etc\hadoop\mapred-site.xml
  ```

Installing the Hadoop Client
Describes how to install the Hadoop client.

last-updated: Jun 06, 2024

Before release 6.2.0 and EEP 7.0.0, the Hadoop client was part of the data-fabric client (the `mapr-client` package). Beginning with release 6.2.0 and EEP 7.0.0, Hadoop and YARN services are removed from core and delivered as ecosystem components in the EEP repository. For more information about these services, see Installing Hadoop and YARN on page 241.

For Hadoop client-compatibility information, see Hadoop Client Compatibility on page 5767.

While the `mapr-hadoop-client` package is now included in the EEP repositories for RHEL, Ubuntu, and SLES, the Hadoop client is still part of the `mapr-client` zip file for Windows and Mac platforms. Delivering Hadoop and YARN services in an EEP makes it possible to install and upgrade the Hadoop client package independently of the data-fabric client. You can install the Hadoop client at the same time as the data-fabric client or later. Note that you must use `configure.sh` with the `-c` option to specify the client setup.

The Hadoop client depends on the `mapr-client` package and should be installed after the `mapr-client`. In the following example, the Hadoop client is installed with the `mapr-client`:

```
# yum install mapr-client mapr-hadoop-client
.....................
# /opt/mapr/server/configure.sh -N my.cluster.com -c -C
node1.cluster.com:7222 -HS node1.cluster.com
.....................
# hadoop fs -ls /
Found 5 items
drwxr-xr-x  - root root       2 2020-10-26 15:20 /apps
drwxr-xr-x  - root root       0 2020-10-26 15:23 /opt
drwsrwxrwx  - root root       2 2020-10-26 12:14 /tmp
drwxr-xr-x  - root root       2 2020-10-26 12:00 /user
drwxr-xr-x  - root root       1 2020-10-26 15:20 /var
```

The following example shows installing the Hadoop client on a client node where the `mapr-client` has already been installed:

```
# yum install mapr-hadoop-client
.....................
# /opt/mapr/server/configure.sh -R -c -HS node1.cluster.com
```

POSIX Clients

Describes how to install the POSIX loopback NFS, and the FUSE-based POSIX clients.

This section contains instructions for installing the data-fabric POSIX Clients. The data-fabric software provides a POSIX loopback NFS client package, and FUSE-based POSIX Basic and Platinum client packages. Each FUSE-based POSIX client package implies a specific data-fabric filesystem throughput optimization of n/G per second. These clients can be installed and used according to the same principles as the POSIX loopback NFS client.

Overview of loopback NFS and FUSE-based POSIX Clients

The NFS version 3.0 protocol does not have secure data transit, nor authentication capabilities to authenticate users who connect to the data-fabric NFS version 3.0 server. Any client and any user can connect to the data-fabric NFS server, remotely.

Loopback NFS tightens security and ensures that only authenticated users can access the NFS server. The loopback NFS client runs on the same node as the NFS server, and can connect to only that NFS server based on the ticket generated. Remote clients cannot access the server.

> **TIP:** For enhanced performance and reliability, use a FUSE-based POSIX client that works similar to the loopback NFS server in terms of security and authentication, and always set the MAPR_SUBNETS enivronment variable.

last-updated: Jun 06, 2024

NOTE: NFS version 4.0 has in-built security and authentication. Remote clients and users can access data-fabric NFS version 4.0 servers securely.

Installing the mapr-loopbacknfs Package

POSIX clients enable application servers, web servers, and other client nodes and applications to read and write directly and securely to a data-fabric cluster.

About this task

Consider installing `mapr-loopbacknfs` if you need a secure POSIX client. You can install the `mapr-loopbacknfs` client on any client node, even your laptop, if you have Linux installed. A client node must have a supported Linux OS distribution and must be outside the data-fabric cluster, not running `mapr-fileserver` or other Hadoop services. You cannot install the data-fabric POSIX client on a Windows or Mac OS X machine.

As a POSIX client, `mapr-loopbacknfs` can use any of the 10 POSIX connections provided by the Basic license. If you need more POSIX client connections, consider upgrading to a Platinum license, as described in Preparing for Installation (HPE Ezmeral Data Fabric POSIX Client) on page 432.

ATTENTION: Note that the Installer installs `mapr-loopbacknfs` on all nodes in the cluster when **Enable NFS** is not specified.

To install `mapr-loopbacknfs` on your machine, perform the following steps for your version of Linux, as the `root` user or using `sudo`. The package is installed to the `/usr/local/mapr-loopbacknfs` directory.

- **For CentOS, RHEL, or Oracle Linux**

```
[root@ip-<ip_address> ~] # yum install mapr-loopbacknfs
```

- **For SLES**

```
# zypper install mapr-compat-suse
```

```
# zypper install mapr-loopbacknfs
```

- **For Ubuntu**

```
# sudo apt-get install mapr-loopbacknfs
```

Installing FUSE-based POSIX Client Packages

Describes how to install a FUSE-based Basic or Platinum POSIX client package.

FUSE-based POSIX clients allow app servers, web servers, and other client nodes and apps to read and write data directly and securely to a data-fabric cluster like a Linux filesystem.

Preparing for Installation (HPE Ezmeral Data Fabric POSIX Client)

To install the HPE Ezmeral Data Fabric POSIX Client on a node, you must meet certain requirements.

The HPE Ezmeral Data Fabric POSIX client can be installed on any node if you have Linux installed. You cannot install the HPE Ezmeral Data Fabric POSIX client on a Windows or Mac OS X machine. The client requires Java 1.8 or later to be installed on your system.

POSIX Client Package Summary

Two separate POSIX client packages are provided, each with different performance tiers. Each package implies a specific file system throughput optimization of n/GB (bytes) per second where n=1 for Basic, and

last-updated: Jun 06, 2024

n=5 for Platinum POSIX client. These clients can be installed and used according to the same principles as the POSIX loopback NFS client. The following table lists the packages.

	Basic POSIX Client	Platinum POSIX Client
Name	HPE Ezmeral Data Fabric POSIX Client Basic	HPE Ezmeral Data Fabric POSIX Client Platinum
Number of Clients	Up to 10 free	Free
Performance	Up to 1GB (Byte)/sec	Up to 5GB (Byte)/sec (with HT disabled)
MapR Package	`mapr-posix-client-basic`	`mapr-posix-client-platinum`

Client-Side Hardware Requirements

To accommodate the POSIX client, your hardware should meet the following requirements:

	Basic	Platinum
Hyper-threading*	Off	Off
Physical CPU(s) (with HT disabled)	1	2
Core(s) per socket	8	8
Socket(s)	1	2
Processor speed	2.2 GHz	2.60 GHz
Memory Click Speed	>=1333 MHz	>=1666 MHz
NICs	10 Gbps (2 GB/sec)	40 Gbps (5 GB/sec)

* Disabling hyper-threading (HT) improves performance.

Linux Kernel Tuning Recommendations

If the client connects to the servers over a 40GigE switch, you should set the following parameters in `/etc/sysctl.conf` to 16 MB on all the nodes to achieve maximum throughput.

NOTE: This setting is not required, but if the network has a large capacity, this setting allows the OS to buffer large chunks of data for transmission, which improves throughput.

- `net.core.rmem.max`
- `net.core.rmem_default`
- `net.core.wmem_max`
- `net.core.wmem_default`
- `net.ipv4.tcp_rmem`
- `net.ipv4.tcp_wmem`
- `net.ipv4.tcp_mem`

Installing the FUSE-Based POSIX Client

Describes how to install the FUSE-based POSIX client package on your system.

last-updated: Jun 06, 2024

FUSE-based POSIX clients require the FUSE kernel module. Run the following command to load the kernel module:

```
modprobe fuse
```

You can install the FUSE-based POSIX client on any node, including cluster nodes.

To install the `mapr-posix-client-*` package on your machine, where `*` refers to the basic or the platinum client package, perform the following steps for your version of Linux, as the `root` user, or using `sudo`. The package is installed to the `/opt/mapr/bin/` directory.

1. Run the following command to install the POSIX client package on your machine:
   - **For CentOS, RHEL, or Oracle Linux**

     ```
     # yum install mapr-posix-client-*, where * is either the basic or the
     platinum package
     For example: yum install mapr-posix-client-basic
     ```

      **TROUBLE:** On Oracle Linux, you must also install the `compat-openssl10` package to get the POSIX client running:

     ```
     yum install compat-openssl10
     ```

   - **For SLES**

     ```
     # zypper install mapr-posix-client-*, where * is either the basic or
     the platinum package
     For example: zypper install mapr-posix-client-basic
     ```

   - **For Ubuntu**

     ```
     # sudo apt-get install mapr-posix-client-*, where * is either the
     basic or the platinum package
     For example: apt-get install mapr-posix-client-basic
     ```

2. To use this client with a secure cluster or clusters, copy the following files from the `/opt/mapr/conf` directory on the cluster to the `/opt/mapr/conf` directory on the client.
   - `maprtrustcreds.conf`
   - `maprtrustcreds.jceks`
   - `ssl_truststore`
   - `ssl_truststore.p12`
   - `ssl_truststore.pem`

   If this client will connect to multiple clusters, merge the `ssl_truststore` files with the `/opt/mapr/server/manageSSLKeys.sh` tool. You must perform the merging on the cluster. See Managing Secure Clusters on page 1947 for details on how to connect to a secure cluster.

3. Run `configure.sh` to set this node as a client node.

- **Secure cluster example**

  For a fresh installation of the POSIX client, run `configure.sh` with the `-secure` option:

  ```
  /opt/mapr/server/configure.sh -N <clustername> -C <CLDBhost> -Z
  <ZooKeeperhost> -c -secure
  ```

- **Non-secure cluster example**

  For a fresh installation of the POSIX client, run `configure.sh` without the `-secure` option:

  ```
  /opt/mapr/server/configure.sh -N <clustername> -C <CLDBhost> -Z
  <ZooKeeperhost> -c
  ```

- **Reinstalling the client**

  When reinstalling the POSIX client, run `configure.sh` with the `-R` option to reuse the existing configuration.

  ```
  /opt/mapr/server/configure.sh -c -R
  ```

  Do NOT add the `-secure` option when running configure.sh with the `-R` option.

4. At the end of the client installation, run the maprlogin password command to create a valid ticket to connect to the cluster.

To configure, start, and mount the client:

- Configure the POSIX client
- Start the POSIX client
- Mount the cluster

About the HPE Ezmeral Data Fabric Persistent Application Client Container (PACC)

This container gives you seamless access to HPE Ezmeral Data Fabric cluster services.

This topic introduces the Data Fabric Persistent Application Client Container (PACC), including its function, benefits, components, and applications.

The Data Fabric (PACC) is a Docker-based container image that includes a container-optimized Data Fabric client. The PACC provides seamless access to Data Fabric Converged Data Platform services, including the file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Streams. The PACC makes it fast and easy to run containerized applications that access data in the Data Fabric.

FUSE POSIX Client for File-Based Applications

To support persistent, file-based applications, the Data Fabric PACC includes a FUSE-Based POSIX Client, optimized for containers, that allows app servers, web servers, and other applications to read and write data directly to the Data Fabric file system. If your cluster has a Data Fabric POSIX Client for Containers license, the PACC can connect with Data Fabric 5.1 or later clusters.

Traditionally, all file data created by containers is lost when a container is terminated, which can happen during an application or hardware failure. By using the POSIX client within the PACC, applications can reliably persist file data directly to the Data Fabric file system, where it can be re-attached to the container in the event of application or hardware failures.

last-updated: Jun 06, 2024

Support for Microservice Applications

To support stateful microservice applications, the PACC also contains a container-optimized version of the Data Fabric client, which includes libraries for accessing HPE Ezmeral Data Fabric Database and HPE Ezmeral Data Fabric Streams.

Secure Access

The Data Fabric PACC is designed to provide access to a secure cluster for all Data Fabric Converged Platform data services. Users can pass a Data Fabric ticket file into the container at runtime. All data access, whether to the file system, HPE Ezmeral Data Fabric Database, or HPE Ezmeral Data Fabric Streams, is authorized and audited according to the authenticated identity of the ticket file.

PACC Contents

The PACC includes the following components:

- HPE Ezmeral Data Fabric Database Client[1]
- HPE Ezmeral Data Fabric Streams Client
- POSIX Client for Containers
- Hadoop Client with YARN[2]
- HBase Client[2]
- Hive Client[2]
- Pig Client[2]
- Python
- Java
- Curl, Wget, Openssl, NFS-common, etc

[1]The HPE Ezmeral Data Fabric Database client includes support for HPE Ezmeral Data Fabric Database binary tables and HPE Ezmeral Data Fabric Database JSON tables.

[2]Included only if specified and only in Data Fabric PACC images created using `mapr-setup.sh`.

Using the PACC

To get started with the Data Fabric PACC, you can take advantage of pre-built Docker images or create your own images to include site-specific environmental parameters:

To . . .	See this topic
See a list of the data-fabric pre-built Docker images	Extending a PACC on page 439
Create your own images containing data-fabric software	Creating a PACC Image Using mapr-setup.sh on page 440

Before Deploying the PACC

Perform a series of checks on the platform and cluster before deploying the PACC.

Before you deploy a PACC, or an application container based on the PACC, perform the following checks on the platform and cluster.

On the platform where you plan to deploy...	On the data-fabric cluster...

last-updated: Jun 06, 2024

• Verify that Docker 1.12.5 or later is installed and the Docker daemon is up and running. For download instructions, see this Docker website.
• Verify that you have sufficient disk space for use by the container.
  • 1 GB for the pre-built images
  • 1.5 GB for the user-created images
	• If you plan to connect to the data-fabric file system using the POSIX client, you *must* verify that you have a license for the POSIX Client for Containers. No license is required to connect to HPE Ezmeral Data Fabric Database or HPE Ezmeral Data Fabric Streams. To obtain the license, do one of the following:
	  • Clusters registered with the MapR Enterprise Trial license can connect unlimited POSIX Clients for Containers.
	  • For production use of the POSIX Client for Containers, contact your HPE sales representative.
	• Obtain the information that you will use to set up the container. You need to gather:
	  • The cluster name.
	  • The time zone of the container. If no time zone is specified, the container uses UTC as the default time zone.
	  • The IP addresses of the cluster nodes running the CLDB.
	  • A ticket if you need to connect to a secure cluster.

Leveraging File System Storage for Application Persistence

The data associated with containers is typically not persistent. If you specify a mount path using `MAPR_MOUNT_PATH`, any data written to the mounted directory will be persisted to the data-fabric file system. For example, you could create a symlink to the Apache log directory and persist all log files in the filesystem.

If you specify a mount path and if your hardware or application fails, re-launching the container in any location using the same Docker runtime environment variables will result in all pre-created data being available for use.

Security Considerations

You should be aware of security considerations for secure and non-secure clusters when using PACCs. See Security Considerations for the PACC on page 437.

Security Considerations for the PACC

This section describes key considerations for using Docker containers with secure and non-secure clusters.

Secure Clusters

Docker containers, like other virtualization technologies, allow client access from user identities that are not controlled by central IT. As a result, these technologies can be problematic when used with clusters that are not secure (where trust is based on trusting the client). Therefore, HPE suggests that you use secure clusters with PACCs.

PACCs, and applications built from them, are launched with a ticket that contains the application's identity from the perspective of the cluster. On secure clusters, the user identity, user ID (`UID`), and group ID (`GID`) are specified in the ticket and passed to the file system for cluster communication. The ticket ensures that operations, such as authorization and auditing, are performed as the authenticated user. A different ticket should be created for each container that is launched. The user's identity should be the identity of the user who accesses data.

last-updated: Jun 06, 2024

All access from Docker containers to the cluster requires a ticket be present inside the container. Users or administrators should generate a ticket for each container prior to launch, and pass the ticket into the container at runtime. The ticket *must* be generated for the user that your applications access the cluster as. You should create a container user with the same `MAPR_CONTAINER_USER`, `MAPR_CONTAINER_GROUP`, `MAPR_CONTAINER_GID`, and `MAPR_CONTAINER_UID` runtime environment variables.

Always use service or user tickets, not impersonation tickets. The ticket type and lifetime should consider the lifetime of the application being deployed. Use of impersonation tickets may allow rogue applications running in containers to impersonate arbitrary users (including `root` or `mapr`) and gain access to any data in the cluster.

The ticket file location in the container is set with the `MAPR_TICKETFILE_LOCATION` environment variable, which is set at runtime for the user specified in `MAPR_CONTAINER_USER`. The ticket file must always be stored in `/tmp`. For example: `/tmp/mapr_ticket`.

In case of loss or breach, you can revoke tickets.

Non-Secure Clusters

On non-secure clusters, you can restrict access by running the application inside the container as a user with appropriate privileges on the cluster. This is controlled using runtime environment variables.

NOTE: HPE recommends that you do not use either `mapr` or `root` users.

- **`MAPR_CONTAINER_USER`** and **`MAPR_CONTAINER_UID`** specify:
  - The default user invoked when starting the container
  - The user that the user application inside the container will run as
- **`MAPR_CONTAINER_GID`** represents the `GID` that the application inside the Docker container will run as
- **`MAPR_CONTAINER_GROUP`** represents the group that the application inside the Docker container will run as

Writing Applications to Use the PACC

This section describes a number of resources for developing applications to use the Persistent Application Container Client.

Developing applications to use the PACC is the same as developing applications on other data-fabric-supported platforms. To get started, see these topics:

- File Store and Apps
- HPE Ezmeral Data Fabric Database and Applications
- HPE Ezmeral Data Fabric Streams and Applications

To build a container for your application that can leverage HPE Ezmeral Data Fabric services, you will create a Dockerfile referencing the PACC which installs your application and its dependencies. You can then build and launch your application using the same runtime variables described later in this section.

Extending a PACC
You can use a PACC to create a new Docker image.

These pre-built Docker container base images – called Persistent Application Client Containers (PACCs) – are available in the maprtech/pacc public repository:

Table

PACC Repository and Tag	Container OS	Image
7.2.0	Ubuntu 20.04	`maprtech/pacc:7.2.0_9.1.0_ubuntu20_yarn_fuse_hbase_hive_spark_streams`
7.1.0	Ubuntu 20.04	`maprtech/pacc:7.1.0_9.0.0_ubuntu20_yarn_fuse_hbase_hive_spark_streams`
7.0.0	Ubuntu 20.04	`maprtech/pacc:7.0.0_8.1.0_ubuntu20_yarn_fuse_hbase_hive_spark_streams`
6.2.0	CentOS 8.x	`maprtech/pacc:6.2.0_7.0.0_centos8`
	CentOS 7.x	N/A
	Ubuntu 18.04	`maprtech/pacc:6.2.0_7.0.0_ubuntu18`
	Ubuntu 16.04	N/A
6.1.0	CentOS 8.x	N/A
	CentOS 7.x	`maprtech/pacc:6.1.0_6.0.0_centos7`
	Ubuntu 18.04	N/A
	Ubuntu 16.04	`maprtech/pacc:6.1.0_6.0.0_ubuntu16`
6.0.1	CentOS 8.x	N/A
	CentOS 7.x	`maprtech/pacc:6.0.1_5.0.0_centos7`
	Ubuntu 18.04	N/A
	Ubuntu 16.04	`maprtech/pacc:6.0.1_5.0.0_ubuntu16`
6.0.0	CentOS 8.x	N/A
	CentOS 7.x	`maprtech/pacc:6.0.0_4.0.0_centos7`
	Ubuntu 18.04	N/A
	Ubuntu 16.04	`maprtech/pacc:6.0.0_4.0.0_ubuntu16`

While you cannot modify a data-fabric Docker image directly, you can build a custom image that is based on a Persistent Application Client Container (PACC). The following example shows a custom Dockerfile that is used to create a new Docker image. In this example, an application has a JAR file that takes a producer as a parameter and runs a custom function.

last-updated: Jun 06, 2024

The example has two parts. In Part 1, the custom Dockerfile uses the Docker `FROM` command to download a PACC to a container on the user platform. A directory is created, and a JAR file is copied into the container so that it can be run in Java. The `CMD` command starts the application inside the container. In Part 2, the custom Dockerfile is built using the `docker build` command.

Part 1. Creating a Custom Dockerfile

```
FROM maprtech/pacc:5.2.0_2.0_centos6

# Copy jar to container
RUN mkdir -p /usr/share/mapr-apps/
COPY mapr-streams-examples-1.0-SNAPSHOT-jar-with-dependencies.jar /usr/
share/mapr-apps/mapr-app-001.jar

# Run producer application in container
CMD [ "java", "-cp", "$MAPR_CLASSPATH:/usr/share/mapr-apps/
mapr-app-001.jar", "com.mapr.examples.Run", "producer" ]
```

Part 2. Building a Custom Docker Image From the Dockerfile

```
docker build -t <new docker image> .
  Note: Above needs to be run in the same directory as Dockerfile
  Make sure the image is created and no issue building Docker image.
docker images -a
```

Creating a PACC Image Using mapr-setup.sh

This section describes how to download and run the `mapr-setup.sh` script to create a Persistent Application Container Client (PACC) image.

To create a PACC image using `mapr-setup.sh`:

1. Before using `mapr-setup.sh`, review these topics to understand important prerequisites and security considerations:
   - Before Deploying the PACC on page 436
   - Security Considerations for the PACC on page 437
2. Use the following steps to download the `mapr-setup.sh` script to a Linux or Mac OS X platform where Docker 1.12.5 or later is installed.

   NOTE: Running `mapr-setup.sh` on Windows is not supported.

   a. Change the file permissions so that you can run the script:

   ```
   chmod +x /tmp/mapr-setup.sh
   ```

3. Run the `mapr-setup.sh` script with the `docker client` command to create the Docker image:

   ```
   /tmp/mapr-setup.sh -R https://<email>:<token>@package.ezmeral.hpe.com/
   releases/ docker client
   ```

4. Answer the command-line prompts to provide the information needed to configure the image. The following table describes each prompt. If you press **Enter** without specifying a value, `mapr-setup.sh` uses the default value shown in the square brackets ([]):

Parameter	Notes
`Build MapR client image? (y/n) [y]`	Press y to continue or n to exit the script.

last-updated: Jun 06, 2024

`Image OS class (centos8, ubuntu18) [<local OS>]:`	Specify the base operating system on which to build the image. **NOTE:** SLES is not currently supported.
`Docker FROM base image name:tag [centos:centos8]:`	Specify the starting image used to create the new image. If necessary, you can enter your own tag and image name to choose a base image already created for your installation.
`MapR core version [6.x.x]:`	Specify the core version that matches the version of the data-fabric cluster you want to access using the PACC. For the supported core values, see Table 1 in Extending a PACC on page 439. If you want to install the Hadoop Client with YARN, you must select `5.2.1` or later.
`MapR EEP version [x.x.x]:`	Specify the EEP version that matches the EEP version of the data-fabric cluster you want to access using the PACC. Supported values are `2.0` or later. If you want to install the Hadoop Client with YARN, you must select EEP `3.0` or later. For more information about EEPs, see EEP Components and OS Support on page 5734.
`Install Hadoop YARN client (y/n) [n]:`	Choose whether to install the Hadoop Client with YARN. Note that the Hadoop Client with YARN requires core version 5.2.1 and EEP 3.0 or later. If you choose No, the script installs the POSIX (FUSE), HPE Ezmeral Data Fabric Database, and data-fabric streams clients. The script does not install the Hadoop Client with YARN and does not ask if you want to install the Hive, Pig, and streams clients.
`Add POSIX (FUSE) client to container? (y/n) [y]:`	Choose whether to install the POSIX (FUSE) client.
`Add HBase client to container? (y/n) [n]:`	Choose whether to install the HBase client.
`Add Hive client to container? (y/n) [n]:`	Choose whether to install the Hive client.
`Add Pig client to container? (y/n) [n]:`	Choose whether to install the Pig client.
`Add Spark client to container? (y/n) [n]:`	Choose whether to install the Spark client.
`Add MapR Streams clients to container? (y/n) [y]:`	Choose whether to install the streams clients.

`Install additional packages? (y/n) [n]:`
 	
`List of packages to be installed [python3 nano]: <space-separated-list-of-packages>`
	Specify a space-separated list of custom packages that will be installed during the build of the image. For example, if you answer `yes` and accept the default, the `python3` and `nano` packages are included in the container. The custom packages must be present in the default OS repository for the script to install them.

`MapR client image tag name [<name>]:`	Accept the software-provided name for the image, or provide your own name. This is the name you will use to run the image to create the PACC. The script automatically provides a name. For example: `maprtech/pacc:6.0.0_4.0.0_centos7_yarn_fuse_hbase_hive_pig_streams`
`Container network mode (bridge|host) [bridge]:`	Select the Docker network mode. For more information, see the Docker documentation.

last-updated: Jun 06, 2024

`Container memory: specify host XX[kmg] or 0 for no limit [0]:`	Specify the maximum amount of memory (in kilobytes, megabytes, or gigabytes) that Docker allows the container to access. For example: • 2g • 4096m • 0 Accepting the default (0), means there is no restriction on memory, and the container can use as much memory as the platform makes available.

5. Press **Enter** after the last prompt. The script creates the image and notifies you of successful creation. For example:

```
    Complete!

    ...Success

    Stopped service mapr-posix-client-container

    ...Success

     ---> 170362a5a82d
    Removing intermediate container 8f100b9d6d9b
    Step 7/8 : ENTRYPOINT /opt/mapr/installer/docker/mapr-setup.sh
container
     ---> Running in f98e5cde91ed
     ---> 7099a990a422
    Removing intermediate container f98e5cde91ed
    Step 8/8 : CMD start
     ---> Running in f6ae4139ab41
     ---> 01ca2ab6d0d3
    Removing intermediate container f6ae4139ab41
    Successfully built 01ca2ab6d0d3

    Edit '/root/thinclient/docker_images/client/mapr-docker-client.sh'
to set
       MAPR_CLUSTER and MAPR_CLDB_HOSTS and then execute it to start the
container
```

`mapr-setup.sh` creates the `mapr-docker-client.sh` sample-run file and displays the location of the file:

```
Edit '/root/thinclient/docker_images/client/mapr-docker-client.sh' to set
MAPR_CLUSTER and MAPR_CLDB_HOSTS and then execute it to start the
container
```

`mapr-docker-client.sh` contains environment variables for the image and makes it easy for you to start the container.

6. Edit the `mapr-docker-client.sh` script file. At a minimum, you must provide the `MAPR_CLUSTER` name and the `MAPR_CLDB_HOSTS` information. For example:

```
MAPR_CLUSTER=my.cluster.com
MAPR_CLDB_HOSTS=perfnode13[4-9].perf.lab
```

last-updated: Jun 06, 2024

NOTE: To specify multiple entries, you can use a comma-separated list of CLDB hosts or an expression like the expressions described in "What expressions can I use to specify multiple nodes?" in the Installer FAQ on page 5605.

You may wish to provide other values. You can:

- Specify a list of packages from the Docker hub to be installed inside the container during start-up by specifying `MAPR_ADDITIONAL_PACKAGES=<space-separated-list-of-packages>`.

  For example:

  ```
  MAPR_ADDITIONAL_PACKAGES=python3 nano
  ```

  Note the following considerations for this option:

  - The custom packages must be present on the Docker hub for the script to install them.
  - This option requires an Internet connection.
  - This option increases the startup time for the container.
- Start the FUSE client by specifying the `MAPR_MOUNT_PATH`.
- For a secure cluster, use a ticket by specifying a `MAPR_TICKETFILE_LOCATION`. For more information about security parameters, see Running the PACC Using Docker on page 444.
- For secure and non-secure clusters, follow security best practices by specifying these parameters:
  - `MAPR_CONTAINER_USER`
  - `MAPR_CONTAINER_GROUP`
  - `MAPR_CONTAINER_UID`
  - `MAPR_CONTAINER_GID`
- Set environment variables, such as `MAPR_CLASSPATH`, `MAPR_HOME`, `PATH`, and others.
- Set the container time zone by specifying `MAPR_TZ`. The default is UTC.
- Add the POSIX mount by uncommenting the `MAPR_MOUNT_PATH` parameter and specifying a mount path value. The `MAPR_MOUNT_PATH` parameter is commented out for Mac builds but not for Linux builds. If you uncomment the parameter, you can ignore the following error message:

  ```
  Started service mapr-posix-client-container [FAILED]
  ```

7. Run the `mapr-docker-client.sh` file to start the container:

```
./docker_images/client/mapr-docker-client.sh
```

   The script uses the current user name to create a user for cluster access. This user is created so that you can run your application as a data-fabric client user:

```
Testing for cluster user account...

Enter MapR cluster user name: robertjones

User 'robertjones' does not exist. Creating new cluster user account...

Enter 'robertjones' uid: 502
 Enter 'robertjones' group name: users
 Enter 'robertjones' password: <password>
...Success

Configuring MapR client ( -c -C perfnode134.perf.lab -N
my.cluster.com)...

create /opt/mapr/conf/conf.old
Configuring Hadoop-2.7.0 at /opt/mapr/hadoop/hadoop-2.7.0
Done configuring Hadoop
CLDB node list: perfnode134.perf.lab:7222
Zookeeper node list:
Node setup configuration: hbinternal
Log can be found at: /opt/mapr/logs/configure.log

...Success
```

   The successful completion of this step results in a user prompt that is inside the newly running container. Take care not to exit this prompt inadvertently, as doing so terminates the container.

8. Open a new session to the Docker host, and use the `docker ps` and `docker inspect` commands to inspect the container. Do not try to run the `docker ps` and `docker inspect` commands from the user prompt created in Step 7. You must open a new session to the Docker host to avoid terminating the container:

```
docker ps
docker inspect <container-run-ID>
```

Running the PACC Using Docker

This section describes and provides examples for using the `docker run` command to run a pre-built container image.

To run a pre-built container image, you:

1. Select a PACC or an application built from the PACC.

2. Determine if your cluster is secure by viewing the contents of the file `/opt/mapr/conf/mapr-clusters.conf`. For example, the following shows a non-secure cluster:

```
my.cluster.com secure=false ip-172-24-11-84
```

   If your cluster is secure, generate a service ticket by following the instructions in Generating a Service Ticket on page 1832.

3. Use the `docker run` command to run the container. You can run the command from a Linux prompt, Windows command line, or a Mac terminal.
4. Verify that the container was created and is connected to the cluster.

NOTE: You run user-created images from the `mapr-client.sh` script file. See Creating a PACC Image Using mapr-setup.sh on page 440.

Using the `docker run` Command

Here is the general syntax for the `docker run` command:

```
docker run -it -e MAPR_CLUSTER=<cluster-name> -e
MAPR_TZ=<time-zone> -e MAPR_CLDB_HOSTS=<cldb-list> -e
MAPR_CONTAINER_USER=<user-name> -e MAPR_CONTAINER_PASSWORD=<password> -e
MAPR_CONTAINER_UID=<uid> -e MAPR_CONTAINER_GID=<gid> -e
MAPR_CONTAINER_GROUP=<group-name> -e MAPR_TICKETFILE_LOCATION=/tmp/
mapr_ticket -v <ticket-file-host-location>:/tmp/mapr_ticket:ro -e
MAPR_MOUNT_PATH=<path_to_fuse_mount_point> --cap-add SYS_ADMIN --cap-add
SYS_RESOURCE --device /dev/fuse --security-opt apparmor:unconfined
<image-name>
```

The following table describes the keys and variables used in the syntax:

NOTE: Pay special attention to the mandatory parameters. If you neglect to specify all mandatory parameters, the `docker run` command will fail.

Key	Variable	Mandatory/Optional	Description
`MAPR_CLUSTER`	`<cluster-name>`	Mandatory	The name of the Data Fabric cluster to which the container will connect.
`MAPR_CLDB_HOSTS`	`<cldb-list>`	Mandatory	CLDB host IP addresses separated by a comma. For example: `(hostname[:port_no] [,hostname[:port_no]...])`
`MAPR_CONTAINER_USER`	`<user-name>`	Mandatory	The user that the user application inside the Docker container will run as. This configuration is functionally equivalent to the Docker native `-u` or `--user`. Do not use Docker `-u` or `--user`, as the container needs to start as the `root` user to bring up FUSE before switching to the MAPR_CONTAINER_USER. The user specified here is the user that all storage operations on the Data Fabric cluster will be performed as. Therefore, HPE recommends not using `root` or `mapr`. For secure clusters, this user must match the user in the ticket passed via MAPR_TICKETFILE_LOCATION. This user also owns the `/opt/mapr` directory tree.
`MAPR_CONTAINER_PASSWORD`	<password>	Optional	The password of the user running inside the container. If not specified, it defaults to the <user-name>.

Key	Variable	Mandatory/Optional	Description
`MAPR_TZ`	`<time-zone>`	Optional	The time zone inside the container. For a list of time-zone settings, see this website. The default is UTC.
`MAPR_CONTAINER_UID`	`<uid>`	Optional	The UID that the application inside the Docker container will run as. This is a companion to the MAPR_CONTAINER_USER option. If a UID is not provided, the default is UID 1000. Providing a UID is strongly recommended. For secure clusters, this UID must match the UID specified in the ticket file.
`MAPR_CONTAINER_GID`	`<gid>`	Optional	The GID that the application inside the Docker container will run as. This is a companion to the MAPR_CONTAINER_USER option. If a GID is not provided, the default is GID 1000. Providing a GID is strongly recommended. For secure clusters, this GID must match the GID specified in the ticket file.
`MAPR_CONTAINER_GROUP`	`<group-name>`	Optional	The group that the application inside the Docker container will run as. This is a companion to the MAPR_CONTAINER_USER option. If a group name is not provided, the default is `users`. Providing a group name is strongly recommended. For secure clusters, the group must match the group specified in the ticket file.
`MAPR_TICKETFILE_LOCATION`	`/tmp/mapr_ticket`	Optional (required only for a secure cluster)	The location inside the container where the ticket file resides. For more information about tickets, see Managing Tickets.
`MAPR_MOUNT_PATH`	`<path-to-fuse-mount-point>`	Optional (required only for FUSE client use)	The path to the FUSE mount point. If this parameter is not specified, the FUSE client is disabled.
`-v`	`<ticket-file-host-location>:/tmp/mapr_ticket:ro`	Optional (required only for a secure cluster)	The location of the ticket on the host where you are running the container, and the desired location of the ticket file in the Docker container. The `docker run` command maps the location on the host with the location inside the container. `ro` means read-only. `-v` refers to a volume mount. Make sure the owner and group on the host ticket file match the UID and GID specified in the ticket file.
`--cap-add`	`SYS_ADMIN`	Optional (required only for FUSE use)	A parameter that is needed for the FUSE process to start inside the container, as `root` access to the FUSE device is required.
`--cap-add`	`SYS_RESOURCE`	Optional (required only for FUSE use)	A parameter that is required for the FUSE process to start.
`--device`	`/dev/fuse`	Optional (required only for FUSE use)	A parameter that is required to mount the FUSE device.

last-updated: Jun 06, 2024

Key	Variable	Mandatory/Optional	Description
	`<image-name>`	Mandatory	The name of the container image to run. This is either the Persistent Application Client Container (PACC) or a custom application container built from the PACC.
`--security-opt`	`apparmor:unconfined`	Optional (required only on Ubuntu hosts)	A parameter that is required for FUSE on Ubuntu hosts. For more information, see Docker-16429.

Example `docker run` Commands

Here are four examples for using the `docker run` command:

- Secure Cluster with FUSE-Based POSIX Client
- Secure Cluster without FUSE-Based POSIX Client
- Non-Secure Cluster with FUSE-Based POSIX Client
- Non-Secure Cluster without FUSE-Based POSIX Client

The following command generates a service ticket on the cluster or a client that is valid for 30 days. (For more `maprlogin` command examples, see maprlogin Command Examples).

```
maprlogin generateticket -type service -cluster cluster1 -duration
30:0:0 -out /tmp/bobs_ticket -user bob
```

The ticket can be copied from `/tmp/bobs_ticket` to `/user/tickets/bobs_ticket` on the container host and used in the following `docker run` commands for secure clusters:

Secure Cluster with FUSE-Based POSIX Client

```
docker run -it -e MAPR_CLUSTER=cluster1 -e MAPR_CLDB_HOSTS=CLDB_1,CLDB_2 -e
MAPR_CONTAINER_USER=bob -e MAPR_TICKETFILE_LOCATION=/tmp/mapr_ticket -v  /
user/tickets/bobs_ticket:/tmp/mapr_ticket:ro -e MAPR_MOUNT_PATH=/
mapr --cap-add SYS_ADMIN --cap-add SYS_RESOURCE --device /dev/fuse maprtech/
pacc:5.2.1_3.0_centos7
```

Secure Cluster without FUSE-Based POSIX Client

```
docker run -it -e MAPR_CLUSTER=cluster1 -e MAPR_CLDB_HOSTS=CLDB_1,CLDB_2 -e
MAPR_CONTAINER_USER=bob -e MAPR_TICKETFILE_LOCATION=/tmp/mapr_ticket -v  /
user/tickets/bobs_ticket:/tmp/mapr_ticket:ro maprtech/pacc:5.2.1_3.0_centos7
```

Non-Secure Cluster with FUSE-Based POSIX Client

In a non-secure cluster, specifying the MAPR_CONTAINER_USER, MAPR_CONTAINER_GROUP, MAPR_CONTAINER_UID, and MAPR_CONTAINER_GID is strongly recommended, and these values must match the user credentials on the server:

```
docker run -it --cap-add SYS_ADMIN --cap-add SYS_RESOURCE --device /dev/
fuse -e MAPR_CLUSTER=cluster1 -e MAPR_CLDB_HOSTS=CLDB_1,CLDB_2 -e
MAPR_CONTAINER_USER=bob -e MAPR_CONTAINER_GROUP=dev -e
MAPR_CONTAINER_UID=10000 -e MAPR_CONTAINER_GID=10000 -e MAPR_MOUNT_PATH=/
mapr maprtech/pacc:5.2.1_3.0_centos7
```

Non-Secure Cluster without FUSE-Based POSIX Client

last-updated: Jun 06, 2024

In a non-secure cluster, specifying the MAPR_CONTAINER_USER, MAPR_CONTAINER_GROUP, MAPR_CONTAINER_UID, and MAPR_CONTAINER_GID is strongly recommended, and these values must match the user credentials on the server:

```
docker run -it -e MAPR_CLUSTER=cluster1 -e MAPR_CLDB_HOSTS=CLDB_1,CLDB_2 -e
MAPR_CONTAINER_USER=bob -e MAPR_CONTAINER_GROUP=dev -e
MAPR_CONTAINER_UID=10000 -e MAPR_CONTAINER_GID=10000 maprtech/
pacc:5.2.1_3.0_centos7
```

TIP:

To re-launch a container, you can use these Docker commands:

```
# docker ps -a
# docker start <container-run-ID>
```

Use `docker start -i` if you need to start with an interactive shell.

Verifying the Launch of the PACC

After running the `docker run` command, you should see the `Starting services` message. For example:

```
Starting services (mapr-posix-client-container)...
Started service mapr-posix-client-container
...Success
$
```

When the installation is successful, the client connects to the cluster, storage is mounted, and the FUSE POSIX client is started automatically. Use the `ls $MAPR_MOUNT_PATH` command to test the connection to the cluster. This command should return the cluster name. For example:

```
$ ls $MAPR_MOUNT_PATH
cluster1
```

To display some directories on the cluster, use this command:

```
$ ls $MAPR_MOUNT_PATH/cluster1
apps var user hbase opt tmp
```

PACC Sample Application
These examples demonstrate how to deploy and run a data-fabric application into a container.

For an example of deploying and running a data-fabric application into a container, see:

Getting Started with a Client Container (blog)

Data Fabric PACC Known Issues
This topic describes some known issues that you should be aware of while troubleshooting.

Issue	Description
DOC-148	On Mac OS X, using `mapr-setup.sh` to create a Docker image can generate the following error when the ping to a hostname fails: `ERROR: Hostname <hostname> cannot be resolved. Correct the problem and retry mapr-setup.sh` **Workaround:**

last-updated: Jun 06, 2024

Issue	Description
	To enable remote login on the Mac, select the **Remote Login** option in **System Preferences > Sharing**. Then retry the `mapr-setup.sh` command.

INF O-47	When running PACC or Zeppelin Docker images, starting or restarting the FUSE client incorrectly reports FAILED. Docker generates an error like the following:
	`mapr-posix-client-container [FAILED]`
	If you can access the data-fabric file system from your client, then ignore the error. You can also confirm a successful FUSE client start by checking `/opt/mapr/logs/posix-client-container.log`. The following shows a successful start:
	`Mon Oct 16 10:49:56 PDT 2017: Mounting posix-client-container / mapr --log_path /opt/mapr/logs --client_lib_path /tmp -o allow_other -o big_writes -o auto_unmount -o async_dio -o max_background=64 -o auto_inval_data at /mapr ...`
	`Starting fuse with 1 libraries`
	`Mon Oct 16 10:49:56 PDT 2017: Result:0`
	`Mon Oct 16 10:50:06 PDT 2017: Running /etc/init.d/mapr-posix-client-container status`
	`Mon Oct 16 10:50:06 PDT 2017: posix-client-container is mounted at /mapr.`
	The error is due to incorrect handling of a data-fabric script return exit code.

Running Hadoop Commands on a Mac and Windows Client

The location from which you run Hadoop commands depends on your machine.

When you run Hadoop commands on the Mac and Windows client, use the Hadoop 3 version to run MapReduce version 2 applications.

To run the..	Run the command from this location:
Hadoop 3 version of the command	On Windows: `%MAPR_HOME%\hadoop\hadoop-3.x.x\bin` On Mac: `/opt/mapr/hadoop/hadoop-3.x.x/bin`

On Linux installations, the installer creates symlinks to the Hadoop directories by default. On Mac, you can create the symlinks. Once the symlinks are created, you can specify the version of the Hadoop command as mentioned in the Hadoop command documentation.

IMPORTANT: For Windows:

- The user that runs Hadoop commands from the Hadoop 3 directory cannot have a space or a hyphen (-) in the user name.
- The native Hadoop library is not present on Windows. Therefore, the `hadoop fs -getmerge` command is not available.

Create Symlinks to Hadoop Directories for the Mac Client

Run Hadoop commands using the `hadoop3` keywords.

About this task

Use the following steps to create `hadoop3` symlinks in the `usr/local/bin` directory for a Data Fabric client on Mac OS X:

last-updated: Jun 06, 2024

Procedure

1. To create the symlinks, run the following commands as `root`:

   ```
   ln -s /opt/mapr/hadoop/hadoop-3.x.x/bin/hadoop /usr/local/bin/hadoop
   ```

   NOTE: In the preceding command, replace `hadoop-3.x.x` with the actual Hadoop 3 version that you installed.

2. Add the Hadoop binaries to the `PATH` environment variable. For example, add the following text to the user login shell script such as ~/.bashrc:

   ```
   export PATH=/opt/mapr/bin:/opt/mapr/hadoop/hadoop-3.x.x/bin:${PATH}
   ```

   NOTE: In the preceding text, replace `hadoop-3.x.x` with the actual Hadoop 3 version that you installed.

Results
Now, you can run hadoop commands by using the `hadoop` keywords.

Installing the MAST Gateway

Describes how to install the Automated Storage Tiering (MAST) Gateway service.

About this task

The MAST Gateway acts as the centralized entry point for all the operations that need to be performed on the tiered storage. The MAST Gateway can be installed (with or without file system) on specific hosts on the cluster with access to the 3rd party cloud storage (for cold tier operations) or on the edge node. Before you install the MAST Gateway, review the Pre-Installation Considerations on page 451.

What to do next
See Configuring the MAST Gateway Service on page 1634 after installing the MAST Gateway.

Installing the MAST Gateway Using the Installer

About this task
When you install release 6.1 or later using the Installer on page 5579, select the **MapR-XD: Cloud Scale Data Platform auto-provisioning template** to install the MAST Gateway automatically on all the nodes.

Installing the MAST Gateway from the Command-line

Procedure

- Run the following command on the node where you want to install the MAST Gateway:

CentOS	`yum install mapr-mastgateway`
Ubuntu	`apt-get install mapr-mastgateway`
SLES	`zypper install mapr-mastgateway`

last-updated: Jun 06, 2024

Installing Additional MAST Gateways from the Command-line

About this task

If you install a new MAST Gateway on a cluster already performing tiering operations (using other installed MAST Gateways), perform the following steps to force CLDB to rebalance utilization of all the MAST Gateways including the newly added MAST Gateway:

Procedure

1. Install the `mapr-mastgateway` package on the node.
2. Run `configure.sh` on page 2821 with the `-R` option to register the MAST Gateway with the CLDB.
   For example:

   ```
   /opt/mapr/server/configure.sh -R
   ```

   After this command runs, newly created volumes are assigned to this MAST Gateway.
3. Run the following command to force CLDB to reassign existing volumes to the least utilized MAST Gateways:

   ```
   /opt/mapr/server/mrconfig mastgateway refreshvolassignment <volume-name>
   ```

   You must run this command once for each volume to reassign. HPE recommends running this command for all volumes if MAST Gateway is either newly added to the cluster or permanently removed from the cluster. When this command runs, CLDB reassigns the volume tiering operation to the least utilized MAST Gateway, which might be the newly added MAST Gateway, to force rebalancing.

   For more information, see `mastgateway refreshvolassignment` on page 2950.

Pre-Installation Considerations

Lists the recommendations that you must follow before installing MAST Gateways.

By default, the MAST Gateway uses 16 threads for volume and file offload and recall operations and another 16 threads for handling internal operations and other operations such as reads (which triggers automatic recall requests), writes, etc. Each thread processes offload or recall of a container (associated with a volume). Each MAST Gateway can process one or more volumes (and associated containers) simultaneously depending on the number of threads available for processing the containers associated with the volumes. Each volume is assigned to a MAST Gateway for a tiering operation irrespective of the number of containers associated with the volume.

For example, suppose you have a volume with 5 containers. The MAST Gateway allocates 5 threads, one per container, to process the offload of that volume's data; the other 11 threads are available for other tiering-related operations on other tiering-enabled volumes. However, if you have a volume with 20 containers. The MAST Gateway allocates all 16 threads to process the offload of that volume's data and as threads are freed, other unprocessed containers associated with the volume are processed. Now, suppose that you have configured multiple MAST Gateways for the volume that has 20 containers. . Volume offload is then distributed among the multiple MAST gateways, leading to enhanced performance of the cluster. If you have multiple large volumes with multiple containers, MapR recommends more than one MAST Gateway to process all the containers associated with all the volumes.

If you have a limited number of nodes that can access the cold tier (because of controlled access to WAN, proxy setup, etc.), install and run MAST Gateway on only those nodes and set up proxy server parameters in the `mastgateway.conf` file. See step 5 in Configuring the MAST Gateway Service on page 1634 for more information on the configuration parameters to set for using a proxy server. On the other hand, if all the cluster nodes can access the tier, then consider the following before deploying the MAST Gateway:

last-updated: Jun 06, 2024

1. A single MAST Gateway can offload at around 300 MB/sec at full throttle. So, compute the minimum number of MAST Gateways based on network capacity of the connection to the tier.
2. If you expect many volume offloads and recall operations to get triggered at the same time, consider installing MAST Gateways on a few more nodes or adding more MAST Gateways at a later time. See Installing the MAST Gateway on page 450 for information.

In general, you must allocate at least 2GB of memory for the MAST Gateway operations. The memory consumption can increase during heavy load. See settings for configuring memory for MAST Gateway in Step 7 for Configuring the MAST Gateway Service on page 1634.

NOTE: Before installing MAST Gateways, you must ensure that the system time on all the cluster nodes is the same. If the system time on CLDB and file server nodes are different, the mtime rule for migrating data might not work as intended. If you see a time skew alarm in the cluster, resolve the alarm immediately to prevent catastrophic failures.

Supported Clients

To manually perform tiering-related operations on a volume, you can use the following:

- The maprcli command
- The REST API

To manually perform tiering-related operations on a file, you can use the following:

- The FUSE-based POSIX client client
- The loopbacknfs POSIX client client
- The NFS client
- The hadoop command
- The maprcli command
- The REST API

You must use clients from MapR v6.1 for accessing tiered volumes and performing tiering operations. You cannot use mixed mode clients to access and run tiering jobs on tiered volumes.

Enabling Soft Mount and Setting the Timeout

Describes how to enable soft mount, and set the RPC timeout for HPE Ezmeral Data Fabric components.

About this task

By default, all file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric-Streams operations never timeout as they wait (hard mount behavior) for the operation to succeed and/or the server to respond. You can configure a soft mount behavior by setting the values for the following parameters in the `core-site.xml` or `hbase-site.xml` file:

`fs.mapr.hardmount`	Specifies whether or not to enable hard mount. Value can be: • `true` - enable hard mount • `false` - disable hard mount The default value is `true`.

last-updated: Jun 06, 2024

`fs.mapr.rpc.timeout`	This parameter is valid for MapR 6.0.0 and earlier. Specifies the RPC timeout value in seconds. The default value is 300 seconds. The value cannot be less than 30 seconds. If the value is greater than 300 seconds, TCP keepalive probes are sent to prevent the TCP socket from timing out. If value is below 300 seconds, the RPCs will timeout after the specified time.
`streams.rpc.timeout.ms`	This parameter is new as of MapR 6.0.1. Specifies the RPC timeout value in milliseconds. The default value is 300000 milliseconds. The value cannot be lower than 30000 milliseconds. If the value is greater than 300000 milliseconds, TCP keepalive probes are sent to prevent the TCP socket from timing out. If value is below 30000 milliseconds, the RPCs will timeout after the specified time.

These parameter settings affect all clients.

NOTE: For HPE Ezmeral Data Fabric-Streams, these parameters can be set as configuration properties when constructing the Consumer or Producer Java object. For more information, see HPE Ezmeral Data Fabric-Streams.

Enabling Soft Mount

Procedure

1. Open the `core-site.xml` or `hbase-site.xml` file and add the parameter as follows:

```
<property>
  <name>fs.mapr.hardmount</name>
  <value>false</value>
  <description>enabling soft mount by setting value to false</
description>
</property>
```

2. Save and close the file.

Setting RPC Timeout

Procedure

1. Open the `core-site.xml` or `hbase-site.xml` file and add the parameter as follows:

   As of MapR 6.0.1:

```
<property>
  <name>streams.rpc.timeout.ms</name>
  <value>300000</value>
  <description>RPC timeout value</description>
</property>
```

   For MapR 6.0.0 and earlier:

```
<property>
  <name>fs.mapr.rpc.timeout</name>
  <value>30</value>
  <description>RPC timeout value</description>
</property>
```

last-updated: Jun 06, 2024

2. Save and close the file.

Troubleshooting

Describes changes to `core-site.xml` file to troubleshoot issues.

fs.mapr.bind.retries Parameter

If there are issues related to unavailability of port, set the value for `fs.mapr.bind.retries` configuration parameter in `core-site.xml` file to `true`. If `true`, the client tries to bind during client initialization for 5 minutes before failing. By default, the `fs.mapr.bind.retries` configuration parameter is set to `false`.

For example, your entry in `core-site.xml` file should look similar to the following:

```
<property>
  <name>fs.mapr.bind.retries</name>
  <value>true</value>
  <description>Bind during client initialization for 5 minutes</description>
</property>
```

fs.mapr.bailout.on.library.mismatch Parameter

When running any application with older versions of the MapR JARs, the system could hang if the older JARs link to the native library installed on cluster nodes that have been updated to a newer MapR version. The `fs.mapr.bailout.on.library.mismatch` parameter detects mismatched libraries, fails the job, and logs an error message. The parameter is enabled by default. You can disable the parameter on all the YARN nodes and resubmit the job for the job to continue to run. To disable the parameter, you must set it to `false` in the `core-site.xml` file.

For example, to disable, your entry in the `core-site.xml` file should look similar to the following:

```
<property>
  <name>fs.mapr.bailout.on.library.mismatch</name>
  <value>false</value>
  <description>Disabling to continue running jobs</description>
</property>
```

libMapRClient.so Binary

The `libMapRClient.so` binary is in `/opt/mapr/lib` directory and also bundled in `maprfs-XXX.jar` file. All the applications that include the JAR also have `libMapRClient.so` binary. If there are multiple `libMapRClient.so` on a machine and if you know the location of all the JARs, you can run the following commands to check the mapr version of a binary:

```
# jar tvf mapr-<XXX>.jar | grep libMapRClient.so
# jar xvf mapr-<XXX>.jar com/mapr/fs/native/Linux/x86_64/libMapRClient.so
# cd com/mapr/fs/native/Linux/x86_64/
# strings libMapRClient.so | grep mapr-version
# cd /opt/mapr/lib
# strings libMapRClient.so | grep mapr-version
```

This is useful in determining if there are old binaries installed on the system.

Setting Up the Control System

Describes how to configure and access the Control System.

The Control System allows you to manage the cluster (including nodes, volumes, users, and alarms) through a comprehensive graphical user interface with all the functionality of the command line or REST APIs.

Web Server and API Server Packages

Before installing the web server and API server, it is important to understand where the packages are located. If you want to use EEP 8.1.0, which can work with release 6.2.0 or release 7.0.0 and above, the web server (`mapr-webserver`) and API server (`mapr-apiserver`) packages that you must apply depend on the core release version. And the packages for release 7.0.0 and later, and the packages for release 6.2.0 reside in different locations. Use the following table to determine which packages to use:

For release	Use the web server and API server packages in the . . .
7.0.0 and later	Releases repository for core 7.x.x: `http://package.ezmeral.hpe.com/releases/v7.x.x/`
6.2.0	EEP repository for EEP 8.1.0: `http://package.ezmeral.hpe.com/releases/MEP/MEP-8.1.0/`

Installing the Web Server and API Server

In prior releases, the `mapr-webserver` package contained both the Control System UI static files and the server running the Java application. Starting from v6.0, the UI static files are in `mapr-webserver`. The `mapr-apiserver` runs the server that sends the queries. The apiserver allows you to perform cluster administration programmatically.

When you install `mapr-webserver`, the `mapr-apiserver` is automatically installed because of the dependency on the `mapr-apiserver` to perform the queries. If `mapr-webserver` is installed, you can use the graphical user interface to manage your cluster. You can also install the `mapr-apiserver` independently to run APIs or web clients that query or programmatically access file system, HPE Ezmeral Data Fabric Database, and other components; however, without the webserver, the Control System will not be available on this node to perform administrative tasks using the UI.

To install the webserver and/or apiserver, see Installing Core and Ecosystem Components on page 101.

- If you install using the Installer, by default, the installer selects one instance of the `mapr-webserver` and `mapr-apiserver` to install. You can specify additional webserver and/or apiserver instances to install in the *Configure Service Layout* page.
- If you install manually, run the appropriate command on the node to install the `mapr-webserver` and/or `mapr-apiserver` packages. For more information on the command to run, see Step 4: Install Cluster Service Packages on page 192. After you install the packages, run the following commands:
  - `/opt/mapr/server/configure.sh -R`
  - `maprcli node services -nodes <nodes> -name apiserver -action start`

For the purposes of high availability, the recommendation is to run at least 2 instances of the webserver and 2 instances of the apiserver.

Configuring Metrics and Logging to Enable Metrics Visualization

During installation using the Installer, you can configure metrics and logging using settings on the **Monitoring** page of the Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the panes on the Control System. If you

last-updated: Jun 06, 2024

did not install metrics collection or logging during your initial installation, you can add it later by selecting the feature during an Incremental Install.

Configuring SameSite Cookie Support

The SameSite attribute of the Set-Cookie HTTP response header allows you to declare if your cookie should be restricted to a first-party or same-site context.

Edit the following section in the `/opt/mapr/apiserver/conf/web.xml` file to set the SameSite cookie:

```
<session-config>
   <cookie-config>
     <http-only>true</http-only>
     <max-age>86400</max-age>
     <name>MAPR.APISERVER.JSESSIONID</name>
     <secure>true</secure>
     <comment>__SAME_SITE_LAX__</comment>
   </cookie-config>
   <session-timeout>30</session-timeout>
 </session-config>
```

Set it to one of the following values:

_SAME_SITE_STRICT_	Cookies will only be sent in a first-party context and not be sent along with requests initiated by third party websites.
_SAME_SITE_LAX_	Cookies are allowed to be sent with top-level navigations and will be sent along with GET request initiated by the third party website. This is the default value.
_SAME_SITE_NONE_	Cookies will be sent in all contexts, that is, sending cross-origin is allowed.

For more information, see SameSite cookies.

Browser Compatibility

The Control System is web-based, and works with the following browsers:

- Chrome 58 and later
- Safari 11.x for v6.0.1
- Safari 10.x for v6.0

  NOTE: Safari Private Window is not supported.

- Firefox 53 and later
- Microsoft Edge 15, 16, and 17

NOTE: If you encounter the following error on Firefox 79 and above:

```
Secure Connection Failed
Error code: SEC_ERROR_REUSED_ISSUER_AND_SERIAL
```

then delete the Control System certificates as described to resolve this error.

last-updated: Jun 06, 2024

Launching the Control System

To use the Control System, navigate to the host that is running the WebServer in the cluster. Control System access to the cluster is typically using HTTP on port 8080 or using HTTPS on port 8443. You should disable pop-up blockers in your browser to allow HPE Ezmeral Data Fabric to open help links in new browser tabs.

The first time you open the Control System using HTTPS from a new browser, the browser alerts you that the security certificate is unrecognized. This is normal behavior for a new connection. Add an exception in your browser to allow the connection to continue.

Configuring the Control System

Describes the configuration of Control System properties.

The Control System properties can be configured in the `/opt/mapr/apiserver/conf/properties.cfg` file. For example:

```
ojai.cache.size=64
mapr.webui.https.port=8443
doc.url=https://docs.datafabric.hpe.com/
proxy.zkservices=elasticsearch,opentsdb
activity.metrics.thread.pool.size=10
```

The properties are as follows:

activity.metrics.thread.pool.size

Default Value: 10

Description: Denotes the number of threads used to query table metrics.

authentication.pam.service

Default Value: `mapr-admin`

Description: The file to use for PAM authentication.

doc.url

Default Value: https://docs.datafabric.hpe.com/

Description: The URL to the HPE Ezmeral Data Fabric documentation.

log.sensitive.keys

Default Value: Not Applicable

Description: The properties to exclude from the logs. For example, to hide SMTP or LDAP passwords in the logs, specify the properties for the passwords as follows:

```
log.sensitive.keys=<mapr.smtp.sender.password>;<mapr.ldap.binddnpasswd>
```

If you do not specify this property, passwords are not hidden in the logs.

mapr.rest.auth.methods

Default Value: `basic`

Description: The authentication methods to use for HPE Ezmeral Data Fabric REST calls. Add `kerberos` to this setting to enable SPNEGO.

mapr.webui.http.port

Default Value: 8081

Description: The port to use to connect to the Control System.

mapr.webui.https.port

Default Value: 8443

Description: The port to use to securely connect to the Control System.

ojai.cache.size

Default Value: 64

last-updated: Jun 06, 2024

	Description: The size of the cache in MB that the OJAI controller uses.
proxy.zkservices	*Default Value:* `elasticsearch,opentsdb` *Description:* The proxy to use for ZooKeeper services
requestHeaderSize	*Default Value:* 8KB *Description:* The size of the request header.
ssl.exclude-ciphers	*Default Value:* `TLS_DHE.,TLS_EDH` *Description:* The encryption ciphers that should *not* be used for communication.
ssl.exclude-protocols	*Default Value:* `SSLv3,TLSv1,TLSv1.1` *Description:* The security protocols that should *not* be used for communication.
ssl.keystore	*Default Value:* `/opt/mapr/conf/ssl_keystore` *Description:* The path to the SSL keystore.
ssl.truststore	*Default Value:* `/opt/mapr/conf/ssl_truststore` *Description:* The path to the SSL truststore.

NOTE: You must restart the apiserver for the changes to take effect. For example, run the following command to restart the apiserver:

```
maprcli node services -action restart -name apiserver -nodes `hostname`
```

Configuring Authentication

Lists the authentication methods supported by the Control System and the apiserver.

Both the Control System and apiserver (that processes REST API calls) require one of the following method of authentication:

- Basic authentication (with a username and password) on secure and non-secure clusters. Refer to documentation for information on setting up username, password, and permissions for accessing the Control System and REST API calls.
- Simple and Protected GSSAPI Negotiation Mechanism (SPNEGO) on secure clusters to authenticate REST calls to the Control System and access the resources directly. Refer to documentation for information on configuring SPNEGO for the Control System and REST API calls.
- Pluggable Authentication Modules (PAM) for password verification. Refer to documentation for information on configuring PAM for the Control System and REST API calls.

For information on using the Control System, `maprcli` commands, and the REST APIs, refer to topics under 7.7.0 Administration on page 1026.

Managing Sessions

Describes how to configure session parameters for the Control System and REST clients.

About this task

You can enable session replication to avoid having the client re-authenticate when routed to a different apiserver.

Enabling Session Replication for the Control System

About this task

When a client establishes a connection with an apiserver (node on which the Control System is installed), the session information is returned in the response. If you have set up multiple apiservers, you can configure the system to store the session information in a database for resending with further requests. For example, in the event of a node failure, you can send the session information with further requests so that the client uses the same session and does not re-authenticate when routed to a different apiserver.

To configure the host for session replication, perform the following steps on all the nodes running the apiserver:

Procedure

1. Open the `/opt/mapr/apiserver/conf/hazelcast.xml` file and set the value for the `com.mapr.admin.lib.JsonDbMapStore` parameter to `true`.

   For example, your setting in the file for this parameter should look similar to the following (as shown in bold):

   ```
   <map-store enabled="true">
      <class-name>com.mapr.admin.lib.JsonDbMapStore</class-name>
   </map-store>
   ```

   By default, this is disabled (`false`) and the session information is not stored in the DB.

2. Specify the hostname of the apiservers (cluster of nodes) where the session information can be sent with the request.

   For example, to specify the list of apiservers, modify the following in the `/opt/mapr/apiserver/conf/hazelcast.xml` file:

   ```
   <network>
      <join>
         <multicast enabled="false"></multicast>
         <tcp-ip enabled="false">
            <member>hostname.example.com</member>
            <member>hostname.example.com</member>
         </tcp-ip>
      </join>
   </network>
   ```

   The default value for both `multicast` and `tcp-ip` is `false`. If you set the value for `multicast` to `true`, all apiservers on the cluster are automatically added to the list of apiservers where re-authentication is not required once a connection is established. This is not recommended. Instead, set the value for `tcp-ip` to `true` and explicitly specify the hostnames of the apiservers (cluster of nodes) where re-authentication is not required once a session is established.

   For example, your entry in the file should look similar to the following (as shown in bold):

   ```
   <network>
      <join>
         <multicast enabled="false"></multicast>
         <tcp-ip enabled="true">
            <member>abc.example.com</member>
            <member>xyz.example.com</member>
         </tcp-ip>
      </join>
   </network>
   ```

last-updated: Jun 06, 2024

3. Save and close the `/opt/mapr/apiserver/conf/hazelcast.xml` file.
4. Open the `/opt/mapr/apiserver/conf/web.xml` file and specify the domain name of the cluster to cache using the `cookie-domain` parameter.

   For example, your setting in the file should look similar to the following (as shown in bold):

   ```
   <init-param>
      <param-name>cookie-domain</param-name>
      <param-value>.example.com</param-value>
   </init-param
   ```

5. Save and close the `/opt/mapr/apiserver/conf/web.xml` file.
6. Restart the apiserver by running the following command:

   ```
   service mapr-apiserver start
   ```

Configuring Sessions for REST Clients

About this task

This section describes how to get a session cookie, which can be used on subsequent requests. This cookie, valid for up to 30 minutes by default, contains the session ID and can be used to verify the identity of further API calls.

To get and save a cookie, which you can then use with subsequent requests, for:

- Basic authentication, submit a request similar to the following:

  ```
  curl -X POST -c <cookiefile-location>  https://<webserver-host>:8443/
  login -d 'username=root&password=mapr'
  ```

- SPNEGO, submit a request similar to the following:

  ```
  curl --negotiate -u : -b <cookiefile-location> -c <cookiefile-location>
  https://&lt;web server node>:8443/rest/&lt;API call> -k -v
  ```

The contents of the cookie file may look similar to the following:

```
cat /tmp/cookiejar.txt
    # Netscape HTTP Cookie File
    # https://curl.haxx.se/docs/http-cookies.html
    # This file was generated by libcurl! Edit at your own risk.

    #HttpOnly_<webserver-hostname>  FALSE  /  TRUE   1509486224
MAPR.APISERVER.JSESSIONID  node014ukard563rhu1ns8umn2s6uft3709.node0
    #HttpOnly_<webserver-hostname>  FALSE  /  FALSE  0
MAPR.APISERVER.SESSIONID
```

Configuring Session Timeout

About this task

For a longer session, modify the value of the `session-timeout` parameter in the `/opt/mapr/apiserver/conf/web.xml` file. The value for this parameter is in minutes. The `session-timeout` parameter in the `web.xml` file is applicable for all clients. If no REST API calls are made for 30 minutes (default value) by a client, then the apiserver will terminate the session for that client.

IMPORTANT: The session-timeout parameter in the `web.xml` file is **NOT related** to the Session Rate setting in the Control System. The Session Rate setting in the Control System sets the idle timeout parameter for the **Control System ONLY**. If there is no activity on the Control System within this timeout period, the client sends a logout request to log out from the Control System.

Procedure

1. Open the `/opt/mapr/apiserver/conf/web.xml` file.
2. Change the value of the `session-timeout` parameter.

   For example, in the `/opt/mapr/apiserver/conf/web.xml` file, change the parameter shown in bold:

```
<session-config>
   <cookie-config>
      <http-only>true</http-only>
      <max-age>86400</max-age>
      <name>MAPR.APISERVER.JSESSIONID</name>
      <!-- <secure>true</secure> -->
   </cookie-config>
   <session-timeout>30</session-timeout>
</session-config>
```

Configuring Impersonation

Lists the process to permit the `mapr` user to impersonate other users.

Impersonation, also known as identity assertion, is one user (the `mapr` super user) accessing data and submitting jobs on behalf of another user.

NOTE: Only the `mapr` user can impersonate other users.

For secure clusters, to have a request processed as an impersonated user:

1. The user submitting the request must be the `mapr` user and the request should have the HTTP header X-MAPR-IMPERSONATED-USER, passed in the request.

   The value of the header is the username of the impersonated user.
2. The header must also include "`Authorization: Basic <base64_encoding_of_userID:pwd>`" for the apiserver to authorize the request.

   Here userID is `mapr` and the password is the PAM Linux password for `mapr` user on the node on which the apiserver is running.

For example:

```
curl -XPOST -H "Accept: application/json" -H  "X-MAPR-IMPERSONATED-USER:
m7user1" -H "Authorization: Basic bWFwcjptYXBy" -k https://10.20.30.40:8443/
rest/table/create?path=%2Ftmp%2FsrcC -v
```

For a non-secure cluster, data-fabric requires a file for the user to impersonate in the `/opt/mapr/conf/proxy` directory. The logged-in user is allowed to impersonate only if the `/opt/mapr/conf/proxy/<user_to_impersonate>` file is present. By default, this file is created during installation for the `mapr` user and the `root` user. If the file is not present, HTTP 403 is returned to the client if the client attempts to impersonate a user who does not have the file.

Migrating to the HPE Ezmeral Data Fabric

Provides instructions for migrating business-critical data and applications from an Apache Hadoop cluster to an HPE Ezmeral Data Fabric cluster.

This guide provides instructions for migrating business-critical data and applications from an Apache Hadoop cluster to an HPE Ezmeral Data Fabric cluster.

The data-fabricdistribution is 100% API-compatible with Apache Hadoop, and migration is a relatively straightforward process. The additional features available in the HPE Ezmeral Data Fabric provide new ways to interact with your data. In particular, the HPE Ezmeral Data Fabric provides a fully read/write storage layer that can be mounted as a filesystem via NFS, allowing existing processes, legacy workflows, and desktop applications full access to the entire cluster.

Migration consists of planning, deployment, and migration of components, applications, data, and nodes.

See the https://docs.datafabric.hpe.com/home/ReleaseNotes/c_relnotes_intro.html for up-to-date information about migration issues.

Planning and Initial Deployment

There are a number of considerations to take into account before migrating from Apache Hadoop to Data Fabric Hadoop.

The first phase of migration is planning. In this phase you will identify the requirements and goals of the migration, identify potential issues in the migration, and define a strategy.

The requirements and goals of the migration depend on a number of factors:

- Data migration: can you move your datasets individually, or must the data be moved all at once?
- Downtime: can you tolerate downtime, or is it important to complete the migration with no interruption in service?
- Customization: what custom patches or applications are running on the cluster?
- Storage: is there enough space to store the data during the migration?

The Data Fabric Hadoop distribution is 100% plug-and-play compatible with Apache Hadoop, so you do not need to make changes to your applications to run them on a Data Fabric cluster. Data Fabric Hadoop automatically configures compression and memory settings, task heap sizes, and local volumes for shuffle data.

Initial Deployment

The initial Data Fabric deployment phase consists of installing, configuring, and testing the Data Fabric cluster and any ecosystem components (such as Hive or Pig) on an initial set of nodes. Once you have the Data Fabric cluster deployed, you will be able to begin migrating data and applications.

To deploy the Data Fabric cluster on the selected nodes, see the Installing Core and Ecosystem Components on page 101

Component Migration

This section describes how to migrate customized components to Hadoop for the HPE Ezmeral Data Fabric.

Hadoop for the HPE Ezmeral Data Fabric features the complete Hadoop distribution including components such as Hive. There are a few things to know about migrating Hive, or about migrating custom components you have patched yourself.

Custom Components

If you have applied your own patches to a component and wish to continue to use that customized component with the Data Fabric distribution, you should keep the following considerations in mind:

- **Data Fabric libraries**: All Hadoop components must point to data-fabric software for the Hadoop libraries. Change any absolute paths. Do not hardcode `hdfs://` or `maprfs://` into your applications. This is also true of Hadoop ecosystem components that are not included in the Data Fabric Hadoop distribution (such as Cascading). For more information see Working with file system.
- **Component compatibility**: Before you commit to the migration of a customized component (for example, customized HBase), check the Data Fabric release notes to see if HPE has issued a patch that satisfies your business requirements. HPE publishes a list of Hadoop common patches and Data Fabric patches with each release and makes those patches available for HPE customers to take, build, and deploy.
- **ZooKeeper coordination service**: Certain components depend on ZooKeeper. When you migrate your customized component from the HDFS cluster to the Data Fabric cluster, make sure it points correctly to the Data Fabric ZooKeeper service.

Hive Migration

You can continue to use Hive tables in a Data Fabric cluster.

About this task

Hive facilitates the analysis of large datasets stored in the Hadoop file system by organizing that data into tables that can be queried and analyzed using a dialect of SQL called HiveQL. The schemas that define these tables and all other Hive metadata are stored in a centralized repository called the *metastore*.

If you would like to continue using Hive tables developed on an HDFS cluster in a Data Fabric cluster, you can import Hive metadata from the metastore to recreate those tables in Data Fabric. Depending on your needs, you can choose to import a subset of table schemas or the entire metastore in one go:

- **Importing table schemas into a Data Fabric cluster**: Use this procedure to import a subset of the Hive metastore from an HDFS cluster to a Data Fabric cluster. This method is preferred when you want to test a subset of applications using a smaller subset of data.
- **Importing an entire Hive metastore into a Data Fabric cluster**: Use the following procedure to import an entire Hive metastore from an HDFS cluster to a Data Fabric cluster. This method is preferred when you want to test all applications using a complete dataset. You will need to redirect all of links that formerly pointed to the HDFS (`hdfs://<namenode>:<port number>/<path>`) to point to file system (`maprfs:///<path>`).

  MySQL is a very popular choice for the Hive metastore and is used in the following example. If you are using another RDBMS, consult the relevant documentation.

Procedure

1. Ensure that both Hive and your database are installed on one of the nodes in the Data Fabric cluster. For step-by-step instructions on setting up a standalone MySQL metastore, see Using MySQL for the Hive Metastore.
2. On the HDFS cluster, back up the metastore to a file.

   ```
   mysqldump [options] \--databases db_name... > filename
   ```

3. Ensure that queries in the dumpfile point to the file system rather than HDFS. Search the dumpfile and edit all of the URIs that point to `hdfs://` so that they point to `maprfs:///` instead.

last-updated: Jun 06, 2024

4. Import the data from the dumpfile into the metastore running on the node in the Data Fabric cluster:

```
mysql [options] db_name < filename
```

What to do next

Using Hive with Data Fabric volumes

file system does not allow moving or renaming across volume boundaries. Be sure to set the Hive Scratch Directory and Hive Warehouse Directory in the same volume where the data for the Hive job resides before running the job. For more information, see How Hive Handles Scratch Directories on Data Fabric in Hive Directories.

HBase Migration

The HPE Ezmeral Data Fabric Hadoop distribution includes HBase, with a number of Data Fabric-exclusive enhancements.

HBase is the Hadoop database, which provides random, real-time read/write access to very large datasets. The Data Fabric Hadoop distribution includes HBase and is fully integrated with Data Fabric enhancements for speed, usability, and dependability. Data Fabric provides a volume (normally mounted at `/hbase`) to store HBase data.

- **HBase bulk load jobs**: If you are currently using HBase bulk load jobs to import data into the HDFS, make sure to load your data into a path under the `/hbase` volume.
- **Compression**: The HBase write-ahead log (WAL) writes many tiny records, and compressing it would cause massive CPU load. Before using HBase, turn off Data Fabric compression for directories in the HBase volume.

Migrating between Apache HBase and HPE Ezmeral Data Fabric Database Binary Tables

You can use the CopyTable tool to migrate data from an Apache HBase table to a HPE Ezmeral Data Fabric Database binary table.

HPE Ezmeral Data Fabric Database tables can be parsed by the Apache CopyTable tool (`org.apache.hadoop.hbase.mapreduce.CopyTable`).

Before You Start HBase Migration

Before migrating your tables to another platform, consider the following points:

- **Schema Changes**. Apache HBase and HPE Ezmeral Data Fabric Database binary tables have different limits on the number of column families. When you are migrating to HPE Ezmeral Data Fabric Database binary tables, you may be interested in changing your table's schema to take advantage of the increased availability of column families.
- **API Mappings**: When you are migrating from Apache HBase to HPE Ezmeral Data Fabric Database tables, examine your current HBase applications to verify the APIs and HBase Shell commands used are fully supported.
- **Namespace Mapping**: If the migration will take place over a period of time, be sure to plan your table namespace mappings in advance to ease the transition. See Mapping to HBase Table Namespaces on page 465 for more information.
- **Implementation Limitations**: HPE Ezmeral Data Fabric Database binary tables do not support HBase coprocessors. If your existing Apache HBase installation uses coprocessors, plan any necessary modifications in advance. HPE Ezmeral Data Fabric Database binary tables support a subset of the regular expressions supported in Apache HBase. Check your existing workflow and HBase applications to verify you are not using unsupported regular expressions.

When migrating to HPE Ezmeral Data Fabric Database binary tables, change your Apache HBase client to the Data Fabric client by installing the version of the `mapr-hbase` package that matches the version of Apache HBase on your source cluster.

See Installing without the Installer on page 179 for information about installation procedures, including setting up the proper repositories.

Mapping to HBase Table Namespaces
This section describes mapping table namespaces between Apache HBase tables and HPE Ezmeral Data Fabric Database binary tables.

The MapR implementations of the HBase Java API and libhbase differentiate between Apache HBase tables and HPE Ezmeral Data Fabric Database tables according to table names. In certain cases, such as migrating code from Apache HBase tables to HPE Ezmeral Data Fabric Database tables, users need to force the API they are using to access a HPE Ezmeral Data Fabric Database table, even though the table name could map to an Apache HBase table. The `hbase.table.namespace.mappings` property allows you to map Apache HBase table names to HPE Ezmeral Data Fabric Database tables. This property is typically set in the configuration file `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml`.

In general, if a table name includes a slash (`/`), the name is assumed to be a path to a HPE Ezmeral Data Fabric Database table, because slash is not a valid character for Apache HBase table names. In the case of "flat" table names without a slash, namespace conflict is possible, and you might need to use table mappings.

Table Mapping Naming Conventions

A table mapping takes the form *`name`*`:`*`map`*, where *`name`* is the table name to redirect and *`map`* is the modification made to the name. The value in *`name`* can be a literal string or contain the `*` wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

Mappings and Table Listing Behaviors

When you use the `list` command without specifying a directory, the command's behavior depends on two factors:

- Whether a table mapping exists
- Whether Apache HBase is installed and running

Here are three different scenarios and the resulting `list` command behavior for each.

- There is a table mapping for *, as in `*:/tables`. In this case, the `list` command lists the tables in the mapped directory.
- There is no mapping for *, and Apache HBase is installed and running. In this case, the `list` command lists the HBase tables.
- There is no mapping for *, and Apache HBase is not installed or is not running.
  - For HBase 0.98.12, the shell will try to connect to an HBase cluster but it will return an error instead.

- For HBase 1.1 or above, if the `mapr.hbase.default.db` property in the hbase-site.xml is set to `hbase`, the list command will return an error stating that HBase is not available. If the `mapr.hbase.default.db` property is set to `maprdb`, list command will list the HPE Ezmeral Data Fabric Database tables under the user's home directory.

Example 1: Map all HBase tables to HPE Ezmeral Data Fabric Database tables in a directory

In this example, any flat table name `foo` is treated as a HPE Ezmeral Data Fabric Database table in the directory `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>*:/tables_dir</value>
        </property>
```

Example 2: Map specific Apache HBase tables to specific HPE Ezmeral Data Fabric Database tables

In this example, the Apache HBase table name `mytable1` is treated as a HPE Ezmeral Data Fabric Database table at `/user/aaa/mytable1`. The Apache Hbase table name `mytable2` is treated as a HPE Ezmeral Data Fabric Database table at `/user/bbb/mytable2`. All other Apache HBase table names are treated as stock Apache HBase tables.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/</value>
        </property>
```

Example 3: Combination of specific table names and wildcards

Mappings are evaluated in order. In this example, the flat table name `mytable1` is treated as a HPE Ezmeral Data Fabric Database table at `/user/aaa/mytable1`. The flat table name `mytable2` is treated as a HPE Ezmeral Data Fabric Database table at `/user/bbb/mytable2`. Any other flat table name `foo` is treated as a HPE Ezmeral Data Fabric Database table at `/tables_dir/foo`.

```
<property>
        <name>hbase.table.namespace.mappings</name>
        <value>mytable1:/user/aaa/,mytable2:/user/bbb/,*:/tables_dir</value>
        </property>
```

Compression Mappings

HPE Ezmeral Data Fabric Database binary tables support the LZ4, LZF, and ZLIB compression algorithms.

When you create a HPE Ezmeral Data Fabric Database binary table with the Apache HBase API or the HBase shell and specify the LZ4, LZO, or SNAPPY compression algorithms, the table uses the LZ4 compression algorithm.

When you describe a HPE Ezmeral Data Fabric Database binary table's schema through the HBase API, the LZ4 and OLDLZF compression algorithms map to the LZ4 compression algorithm.

Copying Data

About this task

NOTE: The Apache CopyTable tool launches a MapReduce application. The nodes on your cluster must have the correct version of the `mapr-hbase` package installed. To ensure that your existing HBase applications and workflow work properly, install the `mapr-hbase` package that provides the same version number of HBase as your existing Apache HBase.

Launch the CopyTable tool with the following command, specifying the full destination path of the table with the `--new.name` parameter:

```
hbase org.apache.hadoop.hbase.mapreduce.CopyTable
-Dhbase.zookeeper.quorum=<ZooKeeper IP Address>
-Dhbase.zookeeper.property.clientPort=5181 --new.name=/user/john/foo/
mytable01
```

This example migrates the existing Apache HBase table `mytable01` to the HPE Ezmeral Data Fabric Database tables `/user/john/foo/mytable01`. On the node in the HPE Ezmeral Data Fabric cluster where you will launch the CopyTable tool, modify the value of the `hbase.zookeeper.quorum` property in the `hbase-site.xml` file to point at a ZooKeeper node in the source cluster. Alternately, you can specify the value for the `hbase.zookeeper.quorum` property from the command line. This example specifies the value in the command line.

Procedure

1. Create the destination table. This example uses the HBase shell. The maprcli and the Control System are also viable methods.

   ```
   [user@host]$ hbase shell
   HBase Shell; enter 'help<RETURN>' for list of supported commands.
   Type "exit<RETURN>" to leave the HBase Shell

   hbase(main):001:0> create '/user/john/foo/mytable01', 'usernames',
   'userpath'
   0 row(s) in 0.2040 seconds
   ```

2. Exit the HBase shell.

   ```
   hbase(main):002:0> exit
   [user@host]
   ```

3. From the command line, use the CopyTable tool to migrate data.

   ```
   [user@host] hbase
   org.apache.hadoop.hbase.mapreduce.CopyTable -Dhbase.zookeeper.quorum=zkno
   de1,zknode2,zknode3 --new.name=/user/john/foo/mytable01 mytable01
   ```

Verifying Migration

About this task

After copying data to the new tables, verify that the migration is complete and successful. In increasing order of complexity:

Procedure

1. Verify that the destination table exists. From the HBase shell, use the `list` command, or use the `hadoop fs -ls /user/john/foo` command from a Linux prompt:

   ```
   hbase(main):006:0> list '/user/john/foo'
   TABLE
   /user/john/foo/mytable01
   1 row(s) in 0.0770 seconds
   ```

last-updated: Jun 06, 2024

2. Check the number of rows in the source table against the destination table with the `count` command:

```
hbase(main):005:0> count '/user/john/foo/mytable01'
30 row(s) in 0.1240 seconds
```

3. Hash each table, then compare the hashes.

Decommissioning Apache HBase Nodes

About this task

To decommission nodes running Apache HBase, follow these steps for each node:

Procedure

1. From the HBase shell, disable the Region Load Balancer by setting the value of `balance_switch` to `false`:

```
hbase(main):001:0> balance_switch false
```

2. Leave the HBase shell by typing `exit`.
3. Run the *graceful stop* script to stop the HBase RegionServer:

WARNING: The `graceful_stop.sh` script does not look up the hostname for an IP number. Do not pass an IP number to the script. Check the list of RegionServers in the Apache HBase Master UI to determine the hostname for the node being decommissioned.

```
[user@host] cd /opt/mapr/hbase/hbase-<hbase-version>
./bin/graceful_stop.sh <hostname>
```

Application Migration

Before you migrate your applications to the MapR Hadoop distribution, consider testing your applications using a small subset of data.

About this task

In this phase, you will migrate your applications to the MapR cluster test environment. The goal of this phase is to get your applications running smoothly on the MapR cluster using a subset of data. Once you have confirmed that all applications and components are running as expected you can begin migrating your data.

Migrating your applications from HDFS to MapR is relatively easy. MapR Hadoop is 100% plug-and-play compatible with Apache Hadoop, so you do not need to make changes to your applications to run them on a MapR cluster.

Application Migration Guidelines Keep the following considerations in mind when you migrate your applications:

- **MapR Libraries**: Ensure that your applications can find the libraries/configs it is expecting. Make sure the java classpath includes the path to `maprfs.jar` and the `java.library.path` includes `libMapRClient.so`

- **MapR Storage**: Every application must point to file system (`maprfs:///`) rather than the HDFS (`hdfs://`). If your application uses fs.default.name then it will work automatically. If you have hardcoded HDFS links into your applications, you must redirect those links so they point to file system. Setting a default path of `maprfs:///` tells your applications to use the cluster specified in the first line of mapr-clusters.conf. You can also specify a specific cluster with `maprfs:///mapr/<cluster name>/`.
- **Permissions**: The distcp command does not copy permissions; permissions defined in HDFS do not transfer automatically to file system. MapR uses a combination of access control lists (ACLs) to specify cluster or volume-level permissions and file permissions to manage directory and file access. You must define these permissions in MapR when you migrate your customized components, applications, and data. For more information, see Managing Permissions.
- **Memory**: Remove explicit memory settings defined in your applications. If memory is set explicitly in the application, the jobs may fail after migration to MapR.

Generally, the best approach to migrating your applications to MapR is to import a small subset of data and test and tune your application using that data in a test environment before you import your production data.

The following procedure offers a simple roadmap for migrating and running your applications in a MapR cluster test environment.

Procedure

1. Copy over a small amount of data to the MapR cluster. Use the hadoop distcp hftp command to copy over a small number of files:

   ```
   $ hadoop distcp hftp://namenode1:50070/foo maprfs:///bar
   ```

   You must specify the namenode IP address, port number, and source directory on the HDFS cluster. For more information, see Copying Data from Apache Hadoop
2. Run the application.
3. Add more data and test again.
4. When the application is running to your satisfaction, use the same process to test and tune another application.

Data Migration

After you migrate your applications to the MapR cluster, you can copy your data from the Apache Hadoop HDFS to the MapR cluster.

Once you have installed and configured your MapR cluster in a test environment and migrated your applications to the MapR cluster you can begin to copy over your data from the Apache Hadoop HDFS to the MapR cluster.

Use any of the following methods to copy data from an HDFS cluster to a MapR cluster:

Method	Description
hdfs:// protocol	You can use the hadoop distcp command with the `hdfs://` protocol to copy data from an HDFS cluster into a MapR cluster. Use this method if the HDFS cluster and the MapR cluster use the same RPC protocol version. For all other scenarios, use the `webhdfs://` protocol or NFS gateway to copy data to a MapR cluster.

last-updated: Jun 06, 2024

Method	Description
webhdfs:// protocol	You can use the hadoop distcp command with the `webhdfs://` protocol to copy data from an HDFS cluster into a MapR cluster.
NFS	You can mount a MapR cluster to an HDFS cluster via NFS mount and then use the hadoop distcp command to copy data between the two clusters.

Using the hdfs:// Protocol

This section describes how to copy data from an HDFS cluster to a MapR cluster using the hdfs:// protocol.

About this task

Before you can copy data from an HDFS cluster to a MapR cluster using the `hdfs://` protocol, you must configure the MapR cluster to access the HDFS cluster. To do this, complete the steps listed in Configuring a MapR Cluster to Access an HDFS Cluster for the security scenario that best describes your HDFS and MapR clusters and then complete the steps listed under Verifying Access to an HDFS Cluster.

You also need the following information:

- `<NameNode>`: the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>`: the port for connecting to the NameNode in the HDFS cluster
- `<HDFS path>`: the path to the HDFS directory from which you plan to copy data
- `<MapR-FS path>`: the path in the MapR cluster to which you plan to copy HDFS data
- `<file>`: a file in the HDFS path

To copy data from HDFS to file system using the `hdfs://` protocol, complete the following steps:

Procedure

1. Run the following hadoop command to determine if the MapR cluster can read the contents of a file in a specified directory on the HDFS cluster:

   ```
   hadoop fs -cat <NameNode>:<NameNode port>/<HDFS path>/<file>
   ```

   For example:

   ```
   hadoop fs -cat hdfs://nn1:8020/user/sara/contents.xml
   ```

2. If the MapR cluster can read the contents of the file, run the distcp command to copy the data from the HDFS cluster to the MapR cluster:

   ```
   hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> maprfs://
   <MapR-FS path>
   ```

   For example:

   ```
   hadoop distcp hdfs://nn1:8020/user/sara maprfs:///user/sara
   ```

   Note the required triple slashes in `maprfs:///`

Using the webhdfs:// Protocol

This section describes how to copy data from an HDFS cluster to a MapR cluster using the webhdfs:// protocol.

About this task

Before you can copy data from an HDFS cluster to a MapR cluster using the `webhdfs://` protocol, you must configure the MapR cluster to access the HDFS cluster. To do this, complete the steps listed in Configuring a MapR Cluster to Access an HDFS Cluster for the security scenario that best describes your HDFS and MapR clusters and then complete the steps listed under Verifying Access to an HDFS Cluster.

To copy data from HDFS to file system using the `webhdfs://` protocol, complete the following steps:

Procedure

1. The HDFS cluster must have WebHDFS enabled. Verify that the following parameter exists in the `hdfs-site.xml` file and that the value is set to `true`.

   ```
   <property>
   <name>dfs.webhdfs.enabled</name>
   <value>true</value>
   </property>
   ```

   You also need the following information:

   - `<NameNode>`: the IP address or hostname of the NameNode in the HDFS cluster
   - `<NameNode HTTP Port>`: the HTTP port on the NameNode in the HDFS cluster
   - `<HDFS path>`: the path to the HDFS directory from which you plan to copy data
   - `<MapR-FS path>`: the path in the MapR cluster to which you plan to copy HDFS data

2. Run the following command from a node in the MapR cluster to copy data from HDFS to file system using `webhdfs://`:

   ```
   hadoop distcp webhdfs://<NameNode>:<NameNode HTTP Port>/<HDFS path>
   maprfs:///<MapR-FS path>
   ```

   For example:

   ```
   hadoop distcp webhdfs://nn2:50070/user/sara maprfs:///user/sara
   ```

   Note the required triple slashes in `maprfs:///`.

Using NFS

This section describes how to copy data from an HDFS cluster to a MapR cluster using NFS.

About this task

If NFS is installed on the MapR cluster, you can mount the MapR cluster to the HDFS cluster and then copy files from one cluster to the other using `hadoop distcp`. If you do not have NFS installed and a mount point configured, see Accessing Data with NFS and Setting Up MapR NFS.

To perform a copy using `distcp` via NFS, you need the following information:

- `<MapR NFS Server>`: the IP address or hostname of the NFS server in the MapR cluster

last-updated: Jun 06, 2024

- `<maprfs_nfs_mount>`: the NFS export mount point configured on the MapR cluster; default is /mapr
- `<hdfs_nfs_mount>`: the NFS mount point configured on the HDFS cluster
- `<NameNode>`: the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>`: the port on the NameNode in the HDFS cluster
- `<HDFS path>`: the path to the HDFS directory from which you plan to copy data
- `<MapR-FS path>`: the path in the MapR cluster to which you plan to copy HDFS data

To copy data from HDFS to file system using NFS, complete the following steps:

Procedure

1. Issue the following command to mount the MapR cluster to the HDFS NFS mount point:

   ```
   mount <MapR NFS Server>:/<maprfs_nfs_mount> /<hdfs_nfs_mount>
   ```

   For example:

   ```
   mount 10.10.100.175:/mapr /hdfsmount
   ```

2. Issue the following command to copy data from the HDFS cluster to the MapR cluster:

   ```
   hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> file:///
   <hdfs_nfs_mount>/<MapR-FS path>
   ```

   For example:

   ```
   hadoop distcp hdfs://nn1:8020/user/sara/file.txt file:///hdfsmount/user/
   sara
   ```

3. Issue the following command from the MapR cluster to verify that the file was copied to the MapR cluster:

   ```
   hadoop fs -ls /<MapR-FS path>
   ```

   For example:

   ```
   hadoop fs -ls /user/sara
   ```

Node Migration

You can add decommissioned HDFS data nodes to your HPE Ezmeral Data Fabric cluster.

Once you have loaded your data and tested and tuned your applications, you can add decommission HDFS data-nodes and add them to the Data Fabric cluster.

This is a three-step process:

- **Decommissioning nodes on an Apache Hadoop cluster**: The Hadoop decommission feature enables you to gracefully remove a set of existing data-nodes from a cluster while it is running, without data loss. For more information, see the Hadoop Wiki FAQ.
- **Meeting minimum hardware and software requirements**: Ensure that every data-node you want to add to the Data Fabric cluster meets the hardware, software, and configuration requirements.

- **Adding Nodes to a Data Fabric cluster**: You can add those data-nodes to the Data Fabric cluster. For more information, see Adding Nodes to a Cluster.

Applying a Patch

You can apply a patch by using the Installer, by using the command line (a manual process), or by using an Installer Stanza.

Downloading a Patch

Patches for the HPE Ezmeral Data Platform can be downloaded from a secure FTP server.

To download the latest patches for supported versions:

1. Navigate to the secure FTP server at https://sftp.mapr.com.
2. Log in using `maprpatches` for your **Login ID**. Leave the **Password** field blank.
3. Click **Login**.

IMPORTANT: The "Support notices of known issues" tool is no longer available, but you can obtain the same information by logging on to the HPE Support Center. See Support Articles in the HPE Support Center on page 6197.

Applying a Patch Using the Installer

The Installer automates much of the work involved in applying patches.

For clusters with many nodes, using the Installer can save you time and reduce the likelihood of errors when compared with other methods of applying patches. With the Installer, you can apply a patch during a:

- New installation of HPE Ezmeral Data Fabric software
- Maintenance update
- Version upgrade
- Incremental Install

NOTE: Applying a patch using the Installer is an offline update (not a rolling update). Also, you cannot use the Installer to apply a patch to an edge node or a client node.

To apply a patch using the Installer:

1. Obtain the patch from Support. See Applying a Patch on page 473.
2. Ensure that the cluster is ready for a patch update. For more information, see Verify Cluster Readiness for a Patch. Then return to this procedure.
3. Start the Installer. For more information, see Installer.
4. Select the **Patch file** option:

If . . .	Then . . .
Data Fabric software is not yet installed on the cluster (new installation)	Click the **Patch file** option under the **HPE Ezmeral Data Fabric Version** field on the **Version & Services** page.

last-updated: Jun 06, 2024

Data Fabric software is already installed (maintenance update or version upgrade)	Do one of the following: • Click the **Maintenance Update** button. If you are performing a maintenance update, the Patch file option appears on the **Maintenance Update** page. For more information, see Performing a Maintenance Update on page 5635. • Click the **Version Upgrade** button on the Installer page. If you are performing a version upgrade, the **Patch file** option appears under the **HPE Ezmeral Data Fabric version** on the **Upgrade Version & Services** page. • Click the **Incremental Install** button. The Patch file option appears on the **Version & Services** page.

The installer prompts you to select the patch.

5. Select the patch file, and click **Choose**. The installer verifies that the core version of the installed core (or the core version you are upgrading to) matches the core version of the patch file name. The installer also ensures that the patch file starts with *mapr-patch*, ends with *rpm* or *deb*, and does not include text such as *client* or *nfs* (to ensure that it is a core patch file). The installer does not ensure that the patch you are applying is a patch number higher than the one that is already installed (if a patch is already installed).

6. Make other installer selections as needed. The patch is uploaded and will be installed in the background after the installer has applied any core packages.

   NOTE: The next time you run the Installer on the cluster, the installer shows the updated patch version on the **Incremental Install** page or, if you enable patch installation, on the **Version Upgrade** or **Maintenance Update** page.

Applying a Patch Manually

HPE Ezmeral Data Fabric patches are version-specific and cumulative. Each patch contains the code fixes that were included in the previous patch for that release version.

Before applying a patch, note these considerations:

- For patch-download information, see Applying a Patch on page 473.
- The steps for patching the Control System are different from the steps for patching core. See Special Considerations for the Control System Patches on page 482.
- You can also apply a patch using the Installer. See Applying a Patch Using the Installer on page 473.
- A patch for a given software version can be removed, and an older patch for the same software version can be installed. However, rolling back a cluster from a newer release version to an older version is not supported.

- Different types of patches are available, and some patches can only be installed on specific nodes:

Patch Type	Install on These Nodes
`mapr-patch`	All control and data nodes
`mapr-patch-client`	HPE Ezmeral Data Fabric client nodes only
`mapr-patch-loopbacknfs`	Any node where POSIX is supported
`mapr-patch-nfs4server`	Any node where NFSv4 is supported
`mapr-patch-posix-client-basic`	Any node where FUSE POSIX is supported
`mapr-patch-posix-client-platinum`	Any node where FUSE POSIX is supported

Applying a patch is a three-step process:

1. Step 1: Verify Cluster Readiness for a Patch on page 475
2. Step 2: Apply the Patch to Data Nodes on page 477
3. Step 3: Apply the Patch to CLDB Nodes on page 478

When you apply a patch to the cluster, the patched files along with original files (non-patched) are copied to the `/opt/mapr/.patch` folder. In the `/opt/mapr/.patch` folder, the file ending with `.0` is the original file (non-patched) and the file ending with `.<patch_number>` is the patched version. Therefore, if there is a file under `/opt/mapr/.patch/lib/`, you can compare that with the corresponding file under `/opt/mapr/lib/` by using the `md5sum` command to verify that the patch was successfully deployed.

If you need more information or if you encounter any problems with patch installation, contact HPE Support.

Step 1: Verify Cluster Readiness for a Patch
Before you apply a patch, check that the cluster is ready for a patch to be applied. In addition to the prerequisites, consider verifying that the cluster utilizes best practices which will facilitate a more optimal patch installation.

Patch Install Prerequisites

Before you apply a patch on the cluster, verify that all CLDB nodes are running and that container 1 is fully replicated on each CLDB node.

Run `maprcli dump containerinfo -ids 1 -json`. In the output, all CLDBs should be listed under `ActiveServers` and each node should report a VALID state.

For example:

```
...
      "data":[
             {
                "ContainerId":1,
```

last-updated: Jun 06, 2024

```
                "Epoch":3,
                "Master":"<masterCLDB_IP>:5660--3-VALID",
                "ActiveServers":{
                  "IP:Port":[
                      "<masterCLDB_IP>:5660--3-VALID",
                      "<slaveCLDB_IP>:5660--3-VALID",
                      "<slaveCLDB_IP>:5660--3-VALID"
                   ]
              },
                  "InactiveServers":{
                   },
                  "UnusedServers":{
              },
...
```

NOTE: RESYNC state will display when container 1 is not fully replicated on that node. You must wait until each CLDB node has a VALID state for container 1 before proceeding with the patch installation.

For more information, see dump containerinfo on page 2144

Best Practices for Patch Installation

Failure to follow the best practices may, in some cases, impact the speed in which the patch installation completes. Check to see if your cluster abides by the following best practices:

The volume min replication setting should be greater than or equal to 2 for CLDB volume.

This ensures that container 1 always has at least two valid copies. Run the following command to list the current replication setting:

```
maprcli dump volumeinfo -volumename
mapr.cldb.internal -json
```

In the output, the "VolumeMinReplication" parameter lists the current replication setting for the named volume. For more information, see maprcli dump volumeinfo.

No under replicated volumes should exist on the cluster.

Run the following command to check for under-replicated volumes:

```
maprcli alarm list
```

For more information, see maprcli alarm list.

Each CLDB node should be configured to have a minimum of 3 disks in its storage pool.

Run the following command on each CLDB node to get a list of the disks configured for each storage pool:

```
mrconfig sp list [-v]
```

In this example output, there are three disks associated with SP1:

```
ListSPs resp: status 0:2 No. of SPs
(2), totalsize 4562260 MB, totalfree
4537550 MB
SP 0: name SP1, Online, size 2736933
MB, free 2724749 MB, path /dev/sdb,
log 200 MB, port 5660,
guid
a3055a6db41f285b005883bbd701c1e5,
clusterUuid -5009075714600063565-10036
```

last-updated: Jun 06, 2024

```
7519220387605,
disks /dev/sdb /dev/sdd /dev/sde
```

For more information, see mrconfig sp list.

Step 2: Apply the Patch to Data Nodes
When applying a patch manually, apply the patch to nodes dedicated to storing and processing data prior to applying the patch to nodes that run the CLDB. This includes nodes that run the Fileserver for storage and processing components such as the NodeManager and the HBase client.

About this task
Apply the patch either to one node at a time or to batches of nodes. If you apply the patch to all nodes in parallel, the cluster will go down, and data will be unavailable temporarily. For clusters with more than 100 data nodes, it is a best practice to apply the patch in batches. Wait a few minutes before proceeding to the next batch of nodes.

On each data node:

Procedure

1. Stop the Warden and ZooKeeper (if installed) services:
   a) To stop Warden, run the following command:
   ```
   sudo service mapr-warden stop
   ```
   b) If ZooKeeper is installed on the node, run this command:
   ```
   sudo service mapr-zookeeper stop
   ```
2. If a patch is already installed on the cluster, run one of the following commands to uninstall it:
   - On RHEL: `sudo rpm -e mapr-patch`
   - On SLES: `sudo zypper remove mapr-patch`
   - On Ubuntu: `sudo apt-get -y remove mapr-patch`
3. Install the patch using one of the following commands:
   - On RHEL: `sudo rpm -ivh mapr-patch-<new_patch_number>.rpm`
   - On SLES: `sudo zypper install mapr-patch-<new_patch_number>.rpm`
   - On Ubuntu: `sudo dpkg -i mapr-patch-<new_patch_number>.deb`
4. Start the Warden and ZooKeeper (if installed) services:
   a) If ZooKeeper is installed on the node, run this command to start ZooKeeper:
   ```
   sudo service mapr-zookeeper start
   ```
   b) To start Warden, run this command:
   ```
   sudo service mapr-warden start
   ```
5. To verify that the patch was installed successfully, run one of the following commands:

- On RHEL or SLES: `sudo rpm -ql mapr-patch-<new_patch_number>`
- On Ubuntu: `sudo dpkg -l | grep mapr-patch-<new_patch_number>`

Step 3: Apply the Patch to CLDB Nodes
When applying a patch manually, apply the patch to CLDB secondary nodes prior to applying the patch on the primary CLDB node. After you apply a patch to a CLDB node, you must verify that container 1 is fully replicated before proceeding to apply the patch to the next CLDB node.

About this task
For large clusters with many containers, when you do not patch CLDB nodes in the prescribed order, there may be a considerable delay before the cluster can process client operations. For smaller clusters, this is not critical as the cluster can generally start accepting client operations in about 5 minutes.

Complete the following steps on each CLDB secondary node and then on the CLDB primary node:

Procedure

1. Stop the Warden and ZooKeeper (if installed) services:
   a) To stop Warden, run the following command:
   ```
   sudo service mapr-warden stop
   ```
   b) If ZooKeeper is installed on the node, run this command:
   ```
   sudo service mapr-zookeeper stop
   ```
2. If there is already a patch installed on the cluster, run one of the following commands to uninstall it:
   - On CentOS/RedHat: `sudo rpm -e mapr-patch`
   - On SLES: `sudo zypper remove mapr-patch`
   - On Ubuntu: `sudo apt-get -y remove mapr-patch`
3. Install the patch using one of the following commands:
   - On CentOS/RedHat: `sudo rpm -ivh mapr-patch-<new_patch_number>.rpm`
   - On SLES: `sudo zypper install mapr-patch-<new_patch_number>.rpm`
   - On Ubuntu: `sudo dpkg -i mapr-patch<new_patch_number>.deb`
4. Start the Warden and ZooKeeper (if installed) services:
   a) If ZooKeeper is installed on the node, run this command to start ZooKeeper:
   ```
   sudo service mapr-zookeeper start
   ```
   b) To start Warden, run this command:
   ```
   sudo service mapr-warden start
   ```
5. To verify that the patch was installed successfully, run one of the following commands:
   - On CentOS/RedHat or SLES: `sudo rpm -ql mapr-patch-<new_patch_number>`

- On Ubuntu: `sudo dpkg -l | grep mapr-patch-<new_patch_number>`

6. Verify that the CLDB node that you patched is running and that container 1 on that node is fully replicated.

   Run `maprcli dump containerinfo -ids 1 -json`.

   In the output, the CLDB node that you just patched should be listed under ActiveServers, and should report a VALID state for container 1.

   For example:

```
...
      "data":[
             {
                "ContainerId":1,
                "Epoch":3,
                "Master":"<masterCLDB_IP>:5660--3-VALID",
                "ActiveServers":{
                  "IP:Port":[
                      "<masterCLDB_IP>:5660--3-VALID",
                      "<slaveCLDB_IP>:5660--3-VALID",
                      "<slaveCLDB_IP>:5660--3-VALID"
                   ]
              },
                  "InactiveServers":{
                   },
                  "UnusedServers":{
              },
...
```

   NOTE: The RESYNC state will display when container 1 is not fully replicated on that node. You must wait until the CLDB node that you just patched has a VALID state for container 1.

   For more information, see dump containerinfo on page 2144

Applying a Patch Using an Installer Stanza

Applying a patch using an Installer Stanza leverages the automation provided by the patch-install capability of the web-based Installer.

To apply a patch using an Installer Stanza, you specify a file name and directory in the `environment.patch_location` parameter in the Stanza (YAML) file. Then you issue the `install` command to run the Stanza.

NOTE: Applying a patch using the Installer is an offline update (not a rolling update).

For information about the `install` command, see Installing or Upgrading Core Using an Installer Stanza on page 5706. For information about the Stanza parameters, see Working with Installer Stanza Files on page 5700.

Rolling Back a Patch

Removing a previously installed patch is a manual process. You can revert to a previous version of the patch by first removing the current patch and then installing the previous version.

When no previous patch version is installed – for example, when you have installed a new release that has not yet been patched – you must use the `configure.sh -R` command and restart services after rolling back. Always test patch installs in a test environment before applying patches to production environments.

NOTE: Rolling back a cluster from a newer data-fabric software version to an older version is not supported. See Applying a Patch Manually on page 474.

Rolling Back to a Previous Patch

If a newly installed patch for a given software version delivers unexpected behavior, you can remove the patch or install an older patch for the same data-fabric software version. Use the following steps.

On each data node:

1. Stop the Warden and ZooKeeper (if installed) services:
   a. To stop Warden, run the following command:
   ```
   sudo service mapr-warden stop
   ```
   b. If ZooKeeper is installed on the node, run this command:
   ```
   sudo service mapr-zookeeper stop
   ```
2. If a patch is already installed on the cluster, run one of the following commands to uninstall it:
   - On CentOS/RHEL: `sudo rpm -e mapr-patch`
   - On SLES: `sudo zypper remove mapr-patch`
   - On Ubuntu: `sudo apt-get -y remove mapr-patch`
3. Install the desired older version of the patch using one of the following commands. To view the available patch versions, see Obtaining the Latest Patch Version on page 481 later on this page:
   - On CentOS/RHEL: `sudo rpm -ivh mapr-patch-<older_patch_number>.rpm`
   - On SLES: `sudo zypper install mapr-patch-<older_patch_number>.rpm`
   - On Ubuntu: `sudo dpkg -i mapr-patch-<older_patch_number>.deb`
4. Start the Warden and ZooKeeper (if installed) services:
   a. If ZooKeeper is installed on the node, run this command to start ZooKeeper:
   ```
   sudo service mapr-zookeeper start
   ```
   b. To start Warden, run this command:
   ```
   sudo service mapr-warden start
   ```

Rolling Back When When There Is No Previous Patch

If you install a new release and apply a patch but need to roll back the patch, use the following steps to roll back. On each node:

1. Stop the Warden and ZooKeeper (if installed) services:
   a. To stop Warden, run the following command:
   ```
   sudo service mapr-warden stop
   ```
   b. If ZooKeeper is installed on the node, run this command:
   ```
   sudo service mapr-zookeeper stop
   ```

last-updated: Jun 06, 2024

2. Uninstall the patch:
   - On CentOS/RHEL: `sudo rpm -e mapr-patch`
   - On SLES: `sudo zypper remove mapr-patch`
   - On Ubuntu: `sudo apt-get -y remove mapr-patch`
3. Run `configure.sh -R` to revert to the unpatched configuration.
4. Start the Warden and ZooKeeper (if installed) services:
   a. If ZooKeeper is installed on the node, run this command to start ZooKeeper:
   ```
   sudo service mapr-zookeeper start
   ```
   b. To start Warden, run this command:
   ```
   sudo service mapr-warden start
   ```

Obtaining the Latest Patch Version

The latest patch version (for example, version n) and the previous patch version (version `n-1`), are always available on sftp.mapr.com. To log in, specify `maprpatches` for the **Login ID**, and leave the **Password** field blank.

Getting Help with Patches

For technical assistance in removing a patch and restoring the functionality that existed before the patch was installed, open a case with HPE Support Center.

Applying a Patch for an Ecosystem Component

Patches for ecosystem components are handled differently from patches for Data Fabric core software.

About Patches for Ecosystem Components

Ecosystem components are updated as a package rather than a patch file. While core patches typically include a prefix such as `mapr-patch` or `mapr-patch-client`, ecosystem patches are delivered as a new package and do not use the core patch mechanism.

To identify an ecosystem patch package, look for the component name in the patch name. For example:

```
mapr-livy-0.7.0.304.202309110421-1.noarch.rpm
```

Then use the steps on this page to update the currently installed package. The steps on this page use the Livy component as an example.

Downloading a Patch for an Ecosystem Component

Patches for ecosystem components can be downloaded from the secure FTP server. To download a patch file for an ecosystem component:

1. Use the steps in Downloading a Patch on page 473 to sign in to the secure FTP server.
2. Navigate to the `/ecosystem/rpm/<component-name>/` or `/ecosystem/deb/<component-name>/` directory.
3. Click the patch to select it.

last-updated: Jun 06, 2024

4. Click **Download**.

Applying the Patch

To apply the patch:

1. On all nodes where the ecosystem component is running, stop the service for the component. For example:

   ```
   maprcli node services -name livy -action stop -nodes <ip_address>
   ```

2. Before upgrading, check to see if other actions are needed. For example, you might want to back up configuration files for a component before upgrading. For more information, review the pre-upgrade steps for the component in Preparing to Upgrade the Ecosystem Pack on page 347.

3. Use the following commands to upgrade the currently installed package for the component. For example:

   - On RHEL / CentOS or SLES:

     ```
     rpm -U <path to new package>
     ```

   - On Ubuntu:

     ```
     dpkg -i <path to new package>
     ```

4. Run `configure.sh` to update the configuration for the new package:

   ```
   $ /opt/mapr/server/configure.sh -R --noRecalcMem
   ```

5. On all nodes where the service is installed, start the service:

   ```
   maprcli node services -name livy -action start -nodes <ip_address>
   ```

Special Considerations for the Control System Patches

Patches for the Control System are handled differently from patches for cluster data nodes and CLDB nodes.

The Control System software is updated as a package rather than a patch file. While core patches typically include a prefix such as `mapr-patch` or `mapr-patch-client`, or `mapr-patch-posix-client-basic`, Control System software is updated as a new package and does not use the core patch mechanism.

To identify a Control System patch package, look for `mapr-apiserver` or `mapr-webserver` in the package name, and use these steps to update your currently installed packages:

1. Stop the `apiserver` service on all Control System nodes:

   ```
   $ maprcli node services -filter [csvc==apiserver] -name
   apiserver -action stop
   ```

2. Upgrade the existing `mapr-apiserver` and `mapr-webserver` packages. For example:

last-updated: Jun 06, 2024

- On CentOS/RedHat or SLES:

```
$ rpm -Uvh <path to new mapr-apiserver>
$ rpm -Uvh <path to new mapr-webserver>
```

- On Ubuntu:

```
$ dpkg -i <path to new mapr-apiserver>
$ dpkg -i <path to new mapr-webserver>
```

3. Run `configure.sh` to update the configuration for the new packages:

```
$ /opt/mapr/server/configure.sh -R --noRecalcMem
```

4. Start the `apiserver` service on all Control System nodes:

```
$ maprcli node services -filter [csvc==apiserver] -name
apiserver -action start
```

Special Considerations for FUSE POSIX Patches

Patches for some features, such as the FUSE POSIX client, can require post-installation steps.

When you install a FUSE POSIX patch, a new and backup copy of the `fuse.conf` file are created in the `/opt/mapr/conf` directory. These files are called:

- `fuse.conf.new`
- `fuse.conf.old`

You can find the new parameters in the `fuse.conf.new` file. If needed, you can copy the new parameters to your existing `fuse.conf` file and restart FUSE for the settings to take effect.

For FUSE POSIX configuration information, see Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client on page 1615.

Applying a Patch to a POSIX Client

This procedure enables you to apply a patch to any of the HPE Ezmeral Data Fabric POSIX clients, which include the loopbacknfs POSIX client, the FUSE-based POSIX basic client, and the FUSE-based POSIX platinum client.

1. Before applying a patch to a FUSE-based POSIX client, review Special Considerations for FUSE POSIX Patches on page 483.
2. Use one of the following commands to stop the POSIX client service:
   - For the `mapr-loopbacknfs` service:

```
service mapr-loopbacknfs stop
```

   - For the FUSE-based POSIX basic service:

```
service mapr-posix-client-basic stop
```

- For the FUSE-based POSIX platinum service:

```
service mapr-posix-client-platinum stop
```

3. Remove any currently installed client patches:

For the `mapr-loopbacknfs` service:	• On Red Hat / CentOS:
	`yum remove mapr-patch-loopbacknfs-<old_patch_number>.rpm`
	• On SLES:
	`zypper remove mapr-patch-loopbacknfs-<old_patch_number>.rpm`
	• On Ubuntu:
	`apt-get remove mapr-patch-loopbacknfs-<old_patch_number>.deb`

For the FUSE-based POSIX basic service:	• On Red Hat / CentOS:
	`yum remove mapr-patch-posix-client-basic-<old_patch_number>.rpm`
	• On SLES:
	`zypper remove mapr-patch-posix-client-basic-<old_patch_number>.rpm`
	• On Ubuntu:
	`apt-get remove mapr-patch-posix-client-basic-<old_patch_number>.deb`

For the FUSE-based POSIX platinum service:	• On Red Hat / CentOS:
	`yum remove mapr-patch-posix-client-platinum-<old_patch_number>.rpm`
	• On SLES:
	`zypper remove mapr-patch-posix-client-platinum-<old_patch_number>.rpm`

last-updated: Jun 06, 2024

	• On Ubuntu: `apt-get remove mapr-patch-posix-client-platinum-<old_patch_number>.deb`

4. Apply the new patch:

For the `mapr-loopbacknfs` service:	• On Red Hat / CentOS:
	`sudo rpm -i mapr-patch-loopbacknfs-<new_patch_number>.rpm`
	• On SLES:
	`sudo zypper install mapr-patch-loopbacknfs-<new_patch_number>.rpm`
	• On Ubuntu:
	`sudo dpkg -i mapr-patch-loopbacknfs-<new_patch_number>.deb`

For the FUSE-based POSIX basic service:	• On Red Hat / CentOS:
	`sudo rpm -i mapr-patch-posix-client-basic-<new_patch_number>.rpm`
	• On SLES:
	`sudo zypper install mapr-patch-posix-client-basic-<new_patch_number>.rpm`
	• On Ubuntu:
	`sudo dpkg -i mapr-patch-posix-client-basic-<new_patch_number>.deb`

For the FUSE-based POSIX platinum service:	• On Red Hat / CentOS: `sudo rpm -i mapr-patch-posix-client-platinum-<new_patch_number>.rpm`

last-updated: Jun 06, 2024

	• On SLES:
	`sudo zypper install mapr-patch-posix-client-platinum-<new_patch_number>.rpm`
	• On Ubuntu:
	`sudo dpkg -i mapr-patch-posix-client-platinum-<new_patch_number>.deb`

5. Use one of the following commands to restart the POSIX client service:
   - For the `mapr-loopbacknfs` service:
     ```
     service mapr-loopbacknfs start
     ```
   - For the FUSE-based POSIX basic service:
     ```
     service mapr-posix-client-basic start
     ```
   - For the FUSE-based POSIX platinum service:
     ```
     service mapr-posix-client-platinum start
     ```

7.7.0 Data Fabric

HPE Ezmeral Data Fabric is the industry-leading data platform for AI and analytics that solves enterprise business needs.

The HPE Ezmeral Data Fabric enables you to master critical data challenges, specifically:

- Speed up AI and analytics initiatives for more impact at production scale
- Accelerate time-to-value for hybrid cloud and multi-cloud strategies

last-updated: Jun 06, 2024

- Create highly reliable, scalable data fabric
- Use data streams for real-time edge analytics
- Implement Kubernetes containerization more effectively

The HPE Ezmeral Data Fabric allows you to address your critical data needs while providing industry-leading performance, data security, easy application development, and true scalability.

The HPE Ezmeral Data Fabric enables you to solve critical business needs:

Business Need	HPE Ezmeral Data Fabric Provides....	Typical Use Cases...
AI and Analytics	A data platform approach for a full range of AI, ML, Analytics with no silos, faster response, and mission-critical reliability at scale	• Contextual experiences • Recommendations • Churn detection • Real-time analytics • DWH offload • Operational data hub • Fraud detection • Security analytic
IOT and Edge Analytic	Seamless edge to on-prem or cloud data movement with analytics	• IoT Analytic • Edge to edge fabric • Anomaly detection • Preventative maintenance • Multi-cloud • Streaming analytic • Real-time response
Journey to Cloud	Easy data and application movement between on-prem and multiple clouds delivers lower TCO and higher flexibility	• Scale-out storage • Global repository, persistent data containers • High-performance file system • Multi-cloud choice • GDPR
Containers	Enable stateful applications in containers to use system-of-record data in a high-reliability platform	• Improve agility • Greater flexibility • Higher elasticity • Better utilization

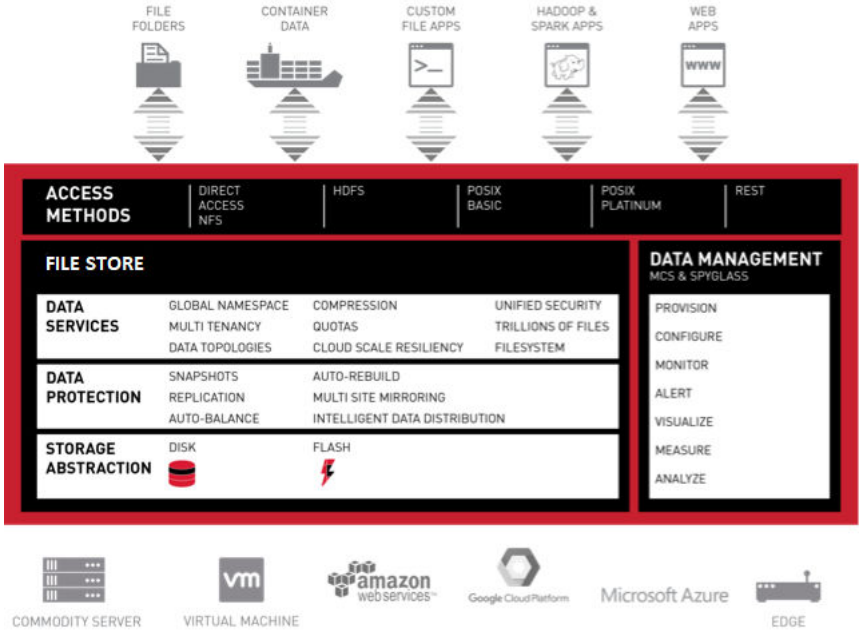
HPE Ezmeral Data Fabric File Store

HPE Ezmeral Data Fabric File Store is a distributed file system for data storage, data management, and data protection. File Store supports mounting and cluster access via NFS and FUSE-based POSIX clients (basic, platinum, or PACC) and also supports access and management via HDFS APIs.

File Store is the only cloud-scale data store that enables you to build a fabric of exabyte-scale. File Store supports trillions of files and hundreds of thousands of client nodes. And File Store runs on edge clusters, on-prem data centers, and the public cloud.

You can manage your clusters from the Managed Control System (web console) and monitor them using HPE Ezmeral Data Fabric Monitoring (Spyglass initiative).



1. Direct Access NFS
2. HDFS
3. FUSE-based POSIX Clients
4. REST API
5. Storage Abstraction
6. Data Protection

File System

Discusses the features of the Data Fabric distributed file system and compares it to the Hadoop Distributed File System (HDFS).

The Data Fabric distributed file system provides a unified data solution for structured data (tables) and unstructured data (files). The file system is fully compliant with POSIX and Hadoop and is case sensitive.

The Data Fabric file system is a random, read-write distributed file system that allows applications to concurrently read and write directly to disk. By contrast, the Hadoop Distributed File System (HDFS) has append-only writes and can only read from closed files. As HDFS is layered over the existing Linux file system, a large number of input/output (I/O) operations decrease cluster performance. The Data Fabric distributed file system also eliminates the Namenode associated with cluster failure in other Hadoop distributions, and enables special features for data management and high availability.

The storage system architecture used by the Data Fabric distributed file system is written in C/C++ and prevents locking contention, eliminating performance impact from Java garbage collection.

The following table highlights some of the features of the Data Fabric file system:

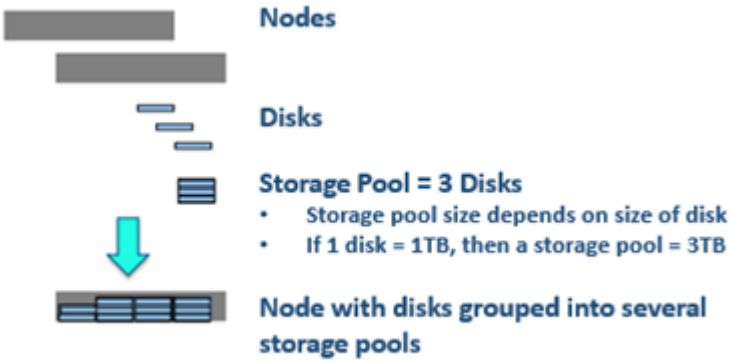
Feature	Description
Storage pools	A group of disks to which the Data Fabric file system writes data.
Containers	An abstract entity that stores files and directories in the Data Fabric file system. A container always belongs to exactly one volume, and can hold namespace information, file chunks, or table chunks for that volume.
CLDB	A service that tracks the location of every container.
Volumes	A management entity that stores and organizes containers. Used to distribute metadata, set permissions on data in the cluster, and for data backup. A volume consists of a single name container, and a number of data containers.
Direct Access NFS	Enables applications to read and write data directly on to the cluster.
POSIX Clients	The loopbacknfs and FUSE-based POSIX clients connect to one or more Data Fabric clusters, and allow app servers, web servers, and applications to write data directly and securely to the Data Fabric cluster.

last-updated: Jun 06, 2024

Storage Pools
Describes what storage pools are.

The file system storage architecture consists of multiple storage pools that reside on each node in a cluster. A storage pool is made up of one or more disks grouped by the data-fabric file system. The default number of disks in a storage pool is three. The containers that hold the data-fabric filesystem data are stored in, and replicated among the storage pools in the cluster.

The following image represents disks grouped together to create storage pools that reside on a node:



Write operations within a storage pool are striped across disks to improve write performance. Stripe width and depth are configurable with the disksetup script. As the data-fabric filesystem performs data replication, you do not need to configure RAID.

Containers and the CLDB
Describes what containers are, and the role of the Container Location Database (CLDB) in managing them.

The data-fabric file system stores data in abstract entities called containers that reside on storage pools. Each storage pool can store many containers. Blocks enable full read-write access to the data-fabric file system, with efficient snapshots.

An application can write, append, or update more than once in the data-fabric file system, and can also read a file as it is being written. In other Hadoop distributions, an application can only write once, and the application cannot read a file as it is written.

On average, a container size is 10-30 GB. The default container size is 32GB. Large number of containers allow for greater scaling and allocation of space in parallel, without bottlenecks.

Described from the physical layer:

- Files are divided into chunks.
- The chunks are assigned to containers.
- The containers are written to storage pools, which are made up of disks on the nodes in the cluster.

The following table compares the data-fabric file system storage architecture to the HDFS storage architecture:

Storage Architecture	HDFS	Data Fabric File System
Management layers	Files, directories and blocks, managed by Namenode.	Volume, which holds files and directories, made up of containers, which manage disk blocks and replication.
Size of file shard	64MB block	256MB chunk

last-updated: Jun 06, 2024

Storage Architecture	HDFS	Data Fabric File System
Unit of replication	64MB block	32GB container
Unit of file allocation	64MB block	8KB block

To preserve data, the data-fabric file system automatically replicates containers across various nodes on the cluster. Container replication creates multiple synchronized copies of the data across the cluster for failover. Container replication also helps localize operations, and ensures that read operations occur in parallel. When a disk or node failure brings a container's replication levels below a specified replication level, the data-fabric file system automatically re-replicates the container elsewhere in the cluster until the desired replication level is achieved. A container only occupies disk space when an application writes to it.

The CLDB (Container Location Database) maintains information about the location of every container in the cluster, defines the container precedence in the replication chain, and organizes container content updates across the replication chain. It runs as a system of independent servers, only one of which is a master at any time.

The data-fabric file system and other services (such as NFS Gateway and POSIX) send heartbeat (HB) messages to the master CLDB. The CLDB is registered with ZooKeeper, and the master CLDB to ZooKeeper connection is kept alive by sending a probe message every few seconds. The CLDB service tracks the location of every container, and uses these HB messages to determine the state of all containers on that node. The CLDB actively participates in the failover of a node in the event of a node failure.

Understanding Replication
Describes how replication works, and how to configure the replication factor.

Volumes are stored as pieces called containers that contain files, directories, and other data. By default, the maximum container size is 32 GB. The HPE Ezmeral Data Fabric administrator sets the maximum container size using the `cldb.container.sizemb` parameter (see the config commands). Containers are replicated to protect data. Normally, each container has three copies stored on separate nodes to provide uninterrupted access to all data, even if a node fails.

For each volume, you can specify a desired and minimum data replication factor, and a desired and minimum namespace (name container) replication factor.

When enabled, the CLDB manages the namespace container replication separate from the data container replication. Use this capability when you have low volume replication, but want to have higher namespace replication.

NOTE: The namespace container parameters, *nsreplication* or *nsminreplication*, must be the same or larger than the equivalent data replication parameter, *replication* or *minreplication*.

Data Replication

- The replication factor is the number of replicated copies that you need for normal operation and data protection. When the number of copies falls below the desired replication factor, but remains equal to or above the minimum replication factor, the CLDB actively creates additional copies of the container while trying to minimize the impact of making an additional copy of the container. Re-replication occurs after the timeout specified in the `cldb.fs.mark.rereplicate.sec` parameter (configurable using the configuration API). The minimum replication factor is 1 and the maximum is 6 (default: 3).
- The minimum value of the minimum replication factor is the smallest number of copies you need in order to adequately protect against data loss. When the replication factor falls below this

	minimum value, re-replication occurs aggressively if data is being actively written to the container. If the `enforceminreplicationforio` property is set to `true`, writes succeed only when the minimum replication factor requirements are met. If the `enforceminreplicationforio` property is set to `true` and the minimum number of copies are not available, the client is asked to retry. In the case of a: • Hard mount, the client might try for up to 10 minutes and then return an error • Soft mount, the client might return an error The minimum value of the minimum replication factor is 1 and the maximum value is 6 (default:2). In all cases, the minimum replication factor cannot be greater than the replication factor. When you increase the minimum replication factor, if the `enforceminreplicationforio` property (configurable at the volume level) is set to `true`, the requirement to maintain a minimum number of copies is not enforced during writes until new copies of all containers associated with the volume are created.
Name Container Replication	• The namespace replication factor is the number of namespace container replicated copies that you need for normal operation and data protection. When the number of copies falls below the desired replication factor, but remains equal to or above the minimum replication factor, the CLDB actively creates additional copies of the container while trying to minimize the impact of making an additional copy of the container. Re-replication occurs after the timeout specified in the `cldb.fs.mark.rereplicate.sec` parameter (configurable using the configuration API). The minimum replication factor is 1 and the maximum is 6 (default: 3). • The minimum value of the minimum namespace replication factor is the minimum number of namespace container replicated copies you want in order to adequately protect against data loss. When the replication factor falls below this minimum value, re-replication occurs aggressively if data is being actively written to the container. If the `enforcemineplicationforio` property (configurable at the volume level) is set to `true`, writes succeed only when this minimum value of the minimum replication factor requirements are met. If this property is set to `true` and minimum number of copies are not available, the client is asked to retry. In the case of a: • Hard mount, the client tries for up to 10 minutes and then return an error • Soft mount, the client returns an error The system does not wait for lost replicas to become available again. The minimum value

last-updated: Jun 06, 2024

of the muinimum replication factor is 1 and the maximum value is 6 (default: 2). In all cases, the minimum replication factor cannot be greater than the replication factor. When you increase the minimum replication factor, if the `enforceminreplicationforio` property is set to `true`, the presence of the minimum number of copies is not enforced during writes until new copies of all containers associated with the volume are created.

NOTE: The maximum replication setting of 6 does **not** apply for ***mapr.cldb.internal volume containers*** (CID-1). The number of CID-1 container replicas are always equivalent to the number of CLDB nodes in the cluster.

If any containers in the CLDB volume fall below the minimum value of the minimum replication factor, the cluster is inaccessible until aggressive re-replication restores the minimum level of replication. If a disk failure is detected, any data stored on the failed disk is re-replicated without regard to the timeout specified in the `cldb.fs.mark.rereplicate.sec` parameter.

If all copies of a container, which are neither under nor over replicated, are on the same rack, HPE Ezmeral Data Fabric automatically detects and distributes the copies, such that they are all not on the same rack, after 12 hours. If a container is under replicated and HPE Ezmeral Data Fabric is unable to find a different rack for the new copy, the creation of the copy is deferred. If another rack is unavailable for the new copy after 3 hours, HPE Ezmeral Data Fabric creates a copy of the container on the same rack and if this results in all copies of the container being on the same rack, HPE Ezmeral Data Fabric distributes the copies after 12 hours. Also, during replication, HPE Ezmeral Data Fabric tries to defer the scenarios where all copies end up on the same rack. As per deferring policy:

- If a container has copies less than the "minimum replication" but greater than 2 and if both copies end up on the same rack, then HPE Ezmeral Data Fabric tries to create the third copy on a different rack for up to 3 hours.
- If a container has copies more than the minimum but less than the desired and if all copies are on the same rack, then HPE Ezmeral Data Fabric tries to create the next copy on a different rack for up to 3 hours.

If you do not set the namespace (NS) replication and minimum namespace replication values explicitly, they assume the same values as (data) replication and minimum replication respectively. This means that all changes to (data) `replication` and `minreplication` parameters are also reflected in `nsreplication` and `nsminreplication`. If `nsreplication` or `nsminreplication` is modified or specified during creation, `nsreplication` and `nsminreplication` start assuming values different from `replication` and `minreplication`.

Table Replication vs Mirroring - Understanding the Differences

This section describes the advantages of both Table Replication and Mirroring, to let you determine the best option for your use case.

Advantages of Table Replication

1. Table replication replicates each table update instantaneously, in seconds (subject to compute and network resources). Mirroring has a much larger RTO (recovery time objective), in minutes.
2. Table replication also transmits lesser data because it just transmits the actual physical rows and nothing else.

3. In table replication, both the end points are READ-WRITE masters with the option of two-way multi-master replication.

4. Table replication proceeds from Source Table > Destination Gateway(s) > Destination Table, which provides reasonable isolation between the two end point clusters. The source table talks only to the Destination Gateway(s).

When using mirroring, avoid placing table replication sources in the mirror volume. Doing so, creates problems if the mirror is broken and promoted.

For tables and streams, table replication is usually the right choice. However, there are exemptions where mirroring is the best choice.

Advantages of Mirroring

1. Since a volume mirror represents a moment in time, there is a higher probability of recovering from a volume than from multiple tables.

2. You can retain old states of a mirror. If you have deleted a bunch of data in your tables and table replication has replicated those changes, then you can recover your data from a mirror.

3. Mirrors are helpful during development. Create a read-write mirror and use for development. Revert it to the last mirrored state and start over. The point is that you can revert the entire volume to a known state, as needed.

4. Use local mirror(s) to increase read throughput.

5. You can use mirrors to obtain traceability and reproducibility during data operations such as machine learning. You can have separate mirrors for different clusters, and operations on one mirror do not affect the other.

Understanding Topology
Provides an overview of how to define cluster topology.

The data-fabric software uses node topology to determine the location of replicated copies of data. Node topology describes the locations of nodes in a cluster. You can define the cluster topology by specifying a topology for each node in the cluster. Use topology to group nodes by rack or switch, to provide a hint as to how data should be replicated to protect against data loss or unavailability because of a switch or rack failure.

In a topology, data-fabric distributes container copies optimally among leaf nodes. For example, in a topology such as `europe/uk/london/DC2/room4/row22`, where `row22` contains multiple racks such as `row22/rack1`, `row22/rack2`, `row22/rack3`, and so on, data-fabric tries to ensure that all copies of the container do not end up on the same rack (for example, `rack1`). By setting each leaf value to correspond to a physical rack, you can ensure that replicated data is distributed across racks to improve fault tolerance.

Related concepts
Setting Up Node Topology on page 1112
Define node topologies for every node in the cluster.

Setting Up Volume Topology on page 1232
Specifies how to use volume topology to place volumes on specific racks, nodes, or groups of nodes.

Volumes, Snapshots, and Mirrors
Describes what Snapshots and Mirrors are, and the advantages of using them for replication.

Volumes are a management entity that logically organize a cluster's data. Since a container always belongs to exactly one volume, that container's replicas all belong to the same volume as well. Volumes do not have a fixed size and they do not occupy disk space until the data-fabric file system writes data to a container within the volume. A large volume may contain anywhere from 50-100 million containers.

The CLI and REST API provide functionality for volume management. Typical use cases include volumes for specific users, projects, development, and production environments. For example, if an administrator needs to organize data for a special project, the administrator can create a specific volume for the project. The HPE Ezmeral Data Fabric file system organizes all containers that store the project data within the project volume. A cluster can have many volumes.

The HPE Ezmeral Data Fabric file system creates a name container for each volume. The name container stores the volume's namespace and file chunk locations, along with inodes for the objects in the file system. The file system stores the metadata for files and directories in the name container, which is updated with each write operation.

The first 64KB of each file in a volume is written to the name container. Data beyond 64KB is written to data containers. Data containers are created only when the file or table data goes above 64KB. Each name or data container is associated with only one volume; volumes may have many associated data containers, but only one name container.

Local volumes are part of the cluster's global namespace, and are accessible on the path `/var/mapr/local/<host>`.

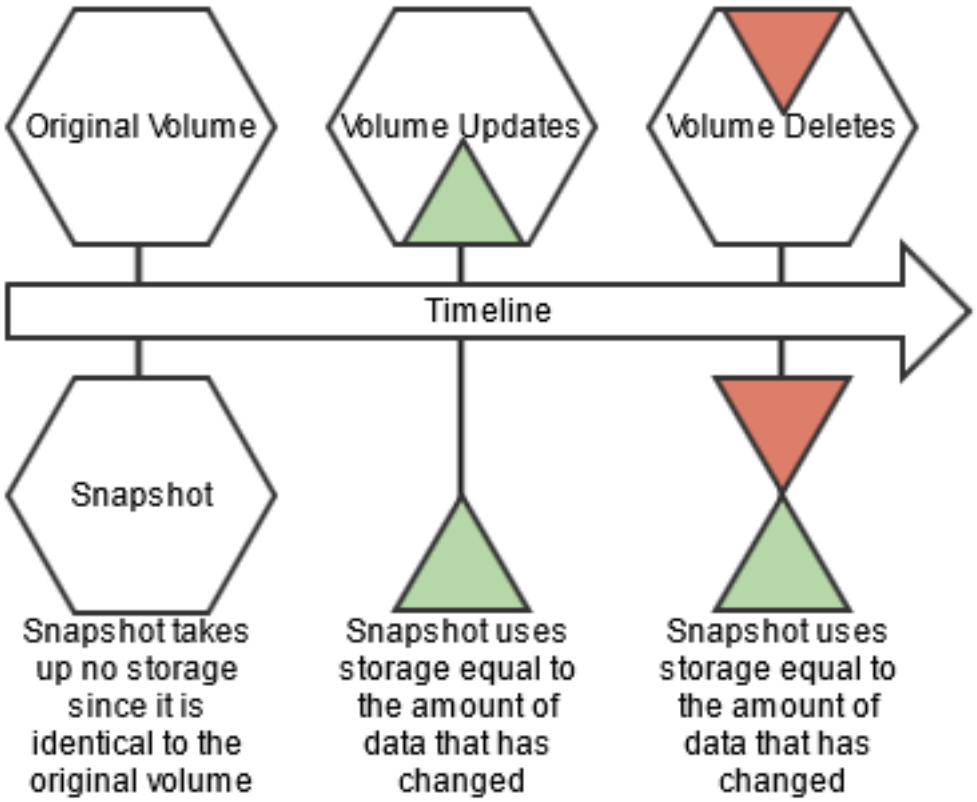
On a cluster with an Enterprise Edition or Enterprise Database Edition license, you can create a special type of volume called a mirror, a local or remote read-only copy of an entire volume. Mirrors are useful for load balancing or disaster recovery. You can also create a snapshot, an image of a volume at a specific point in time. Snapshots are useful for rollback to a known data set.

On a cluster, you can create a tenant share, or volume for tenant users. A tenant share is an isolated space where you can set different policies, quotas, and access privileges for specific users/hosts (referred to as tenants). This allows each tenant to own its own copy of storage space, users, data security, administration, and other such specifications. For more information, see Multitenancy on File System on page 533.

Snapshots

Snapshots enable you to roll back to a known good data set and recover data always in case of data corruption or accidental deletions, without the help of storage administrators. A snapshot is a read-only image of a volume that provides point-in-time recovery. Snapshots only store changes to the data present in the volume, and as a result make extremely efficient use of the cluster's disk resources. Snapshots preserve access to historical data, and protect the cluster from user and application errors. You can create a snapshot manually, or automate the process with a schedule. Snapshots are stored in the `.snapshots` directory. You can always view snapshots from this directory.

The following image represents a mirror volume, and a snapshot created from a source volume:



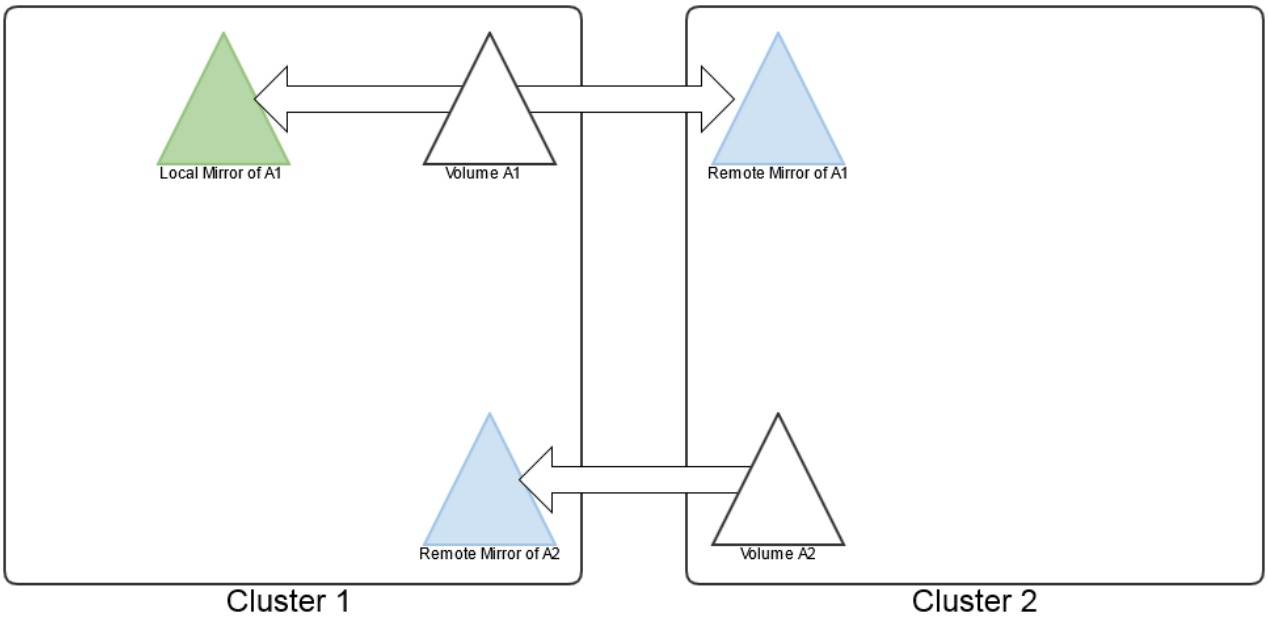
New write operations on a volume with a snapshot are redirected to preserve the original data. Snapshots only store the incremental changes in a volume’s data from the time the snapshot was created. The storage used by a volume's snapshots does not count against the volume's quota.

Mirror Volumes

Data Fabric provides built-in mirroring to set recovery time objectives and to automatically mirror data for backup. You can create local or remote mirror volumes to mirror data between clusters, data centers, or between on-premise and public cloud infrastructures.

Mirror volumes are read-only copies of a source volume. You can control the schedule for mirror refreshes from the Control System or with the command-line tools. You can create local (on the same cluster) or remote (on a different cluster) mirror volumes from the Control System, or from the command line.

last-updated: Jun 06, 2024



When you create a mirror volume, the HPE Ezmeral Data Fabric file system creates a temporary snapshot of the source volume. The mirroring process reads content from the snapshot into the mirror volume. The source volume remains available for read and write operations during the mirroring process. The initial mirroring operation copies the entire source volume. Subsequent mirroring operations only update the differences between the source volume and the mirror volume.

Mirror volumes can be promoted to read-write volumes. The main use case for this feature is to support disaster-recovery scenarios in which a read-only mirror needs to be promoted to a read-write volume so that it can become the primary volume for data storage. In addition, read-write volumes that were mirrored to other volumes can be made into mirrors (to establish a mirroring relationship in the other direction). You can also convert read-write volumes back to read-only mirrors.

Related concepts

Understanding Replication on page 492
Describes how replication works, and how to configure the replication factor.

Types of Volumes

Lists the various types of volumes.

This glossary explains the different types of volumes.

Term	Definition

NC Standard Volume	A non-convertible (NC) standard volume is a volume with read-write capabilities, created *before* data-fabric version 4.0.2. These volumes cannot be converted to standard mirror volumes. If this volume type is designated as a source volume when a mirror volume is created, the mirror volume will be a NC mirror volume.
	A NC standard volume is designated as type 0 in the output of the `volume info` command. For example:
	`maprcli volume info -name oldrw`
	lists
	`"mirrortype":0`

Term	Definition
Standard Volume	A standard volume is a read-write volume created as of data-fabric version 4.0.2. A standard volume can be converted from read-write to mirror (read-only). If a mirror is created from this type of volume, the mirror can be promoted to a read-write volume. A standard volume is designated as type `rw` on the command line. For example: `maprcli volume create -name volA -path / testvol -type rw`

NC Mirror Volume	A non-convertible read-only mirror volume is a volume created *before* data-fabric version 4.0.2. This volume type cannot be promoted to a read-write volume, and can only be created from a NC standard volume.
	A NC mirror volume is designated as type 1 in the output of the `volume info` command. For example:
	`maprcli volume info -name oldmirror`
	lists
	`"mirrortype":1`

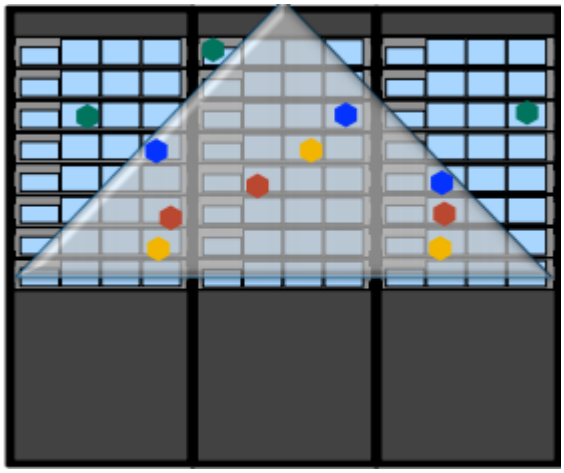
Standard Mirror	Standard mirror is a mirror volume that starts as a read-only volume, and can be promoted to a read-write volume. A standard mirror volume is designated as type `mirror` on the command line and can only use a standard volume as its source. For example: `maprcli volume create -name volB -path / mirvol -type mirror -source volA`

Volume Topology
Describes what volume topology is, and the topology of replicas and mirrors.

The topology describes the locations of nodes and racks in the cluster. Volume topology is based on node topology. You define volume topology after you define node topology. When you set up node topology, you can group nodes by rack or switch. file system uses node topology to determine where to replicate data for continuous access to the data in the event of a rack or node failure.

A volume's topology defines which racks or nodes a volume includes.

The following image represents a volume that spans a cluster:



last-updated: Jun 06, 2024

Topology of Local Volume Replicas

The primary copies for containers of local volumes are placed on the local node. The nodes for the replica copies for containers of local volumes are chosen in the following order:

1. Use a topology that is explicitly specified for replicas during volume creation or modification.
2. Use the relative path for replicas of local volumes if the configuration parameter specifies such a path.
3. Use the default volume topology.

See Setting the Topology for Local Volume Replicas on page 1233, Creating Replicas of Local Volumes in Custom Topology Using the CLI on page 1233, and Setting Default Volume Topology Using the CLI on page 1234.

Mirror Volume Topology

When the root volume on a cluster is mirrored, the source root volume contains a writable volume link, `.rw` that points to the read/write copies of all local volumes. In that case, the mount path `/` refers to one of the root volume's mirrors, and is read-only. The mount path `/.rw` refers to the source volume, and is read/write.

A mount path that consists entirely of mirrored volumes refers to a mirrored copy of the specified volume. When a mount path contains volumes that are not mirrored, the path refers to the target volume directly. In cases where a path refers to a mirrored copy, the `.rw` link is useful for navigating to the read/write source volume.

Sample Volume Topology with Mirrors

The following example shows a volume topology with mirrors:

For the four volumes `/`, `a`, `b`, and `c`, the following table indicates the volumes referred to by example mount paths for particular combinations of mirrored and not mirrored volumes in the path:

/	a	b	c	This Path	Refers To This Volume...	Which is...
Mirrored	Mirrored	Mirrored	Mirrored	`/a/b/c`	Mirror of c	Read-only
Mirrored	Mirrored	Mirrored	Mirrored	`/.rw/a/b/c`	c directly	Read/Write
Mirrored	Mirrored	*Not Mirrored*	Mirrored	`/a/b/c`	c directly	Read/Write

Authorization with Volumes: Intelligent Policy Management

Describes methods to manage volume permissions.

The data-fabric filesystem uses volumes as a unique management entity. A volume is a logical unit that you create to apply policies to a set of files, directories, tables, and sub-volumes. You can create volumes for each user, department, or project. Mirror volumes and volume snapshots provide data recovery and data protection functionality.

Volumes can enforce disk usage limits, set replication levels, establish ownership and control permissible actions, and measure the cost generated by different projects or departments. When you set policies on a volume, all files contained within the volume inherit the same policies set on the volume. Other Hadoop distributions require administrators to manage policies at the file level.

You can manage volume permissions through one of the following:

- Access Control Lists (ACLs) in the Control System or from the command line. ACLs can be used to control administrative access to volumes.
- Access Control Expressions (ACEs) in the Control System or from the command line. ACEs can be used to control data access using boolean expressions.

You can also set read, write, and execute permissions on a file or directory for users and groups with ACEs and standard UNIX commands, when that volume has been mounted through NFS, or using standard `hadoop fs` commands.

Mirror Volumes
Provides a synopsis of what mirror volumes are and the mirroring process.

Creating a mirror volume is similar to creating a normal read/write volume. However, when you create a mirror volume, you must specify a source volume from which the mirror retrieves content. This retrieval is called the mirroring operation. Like a normal volume, a mirror volume has a configurable replication factor. Only one copy of the data is transmitted from the source volume to the mirror volume. HPE Ezmeral Data Fabric volumes can only be mirrored and NOT replicated. However, the source and mirror volumes handle their own internal HPE Ezmeral Data Fabric filesystem replication (which is based on the replication factor) independently. file system internally replicates source and mirror volumes independently of each other.

NOTE: Volume mirroring from a lower HPE Ezmeral Data Fabric version to higher HPE Ezmeral Data Fabric version is supported. For example, you can mirror volumes from a HPE Ezmeral Data Fabric 4.0.1 cluster to a HPE Ezmeral Data Fabric 5.2 cluster. However, you cannot mirror volumes from a HPE Ezmeral Data Fabric 5.2 cluster to a HPE Ezmeral Data Fabric 4.0.1 cluster.

Mirroring Process

The HPE Ezmeral Data Fabric system creates a temporary snapshot of the source volume at the start of a mirroring operation. The mirroring process reads content from the snapshot into the mirror volume. The source volume remains available for read and write operations during the mirroring process.

If the mirroring operation is schedule-based, the snapshot expires according to the value of the schedule's **Retain For** parameter. Snapshots created during manual mirroring persist until they are deleted manually.

The mirroring process transmits only the differences between the source volume and the mirror. The initial mirroring operation copies the entire source volume, but subsequent mirroring operations can be extremely fast. If the fastinodescan feature is enabled, mirroring will proceed significantly faster when there are large number of files and few changes since the last mirroring operation. The fastinodescan feature is enabled by default for all new installations, but must be manually enabled if you are upgrading from pre-5.2.x versions. See the Upgrade Guide for information on enabling this feature. To determine whether the fastinodescan feature is enabled, run the following command:

```
/opt/mapr/bin/maprcli config load -json | grep
mfs.feature.fastinodescan.support
```

To use the fastinodescan feature on converted or promoted volumes, mirroring must be restarted from the source volume after converting volume from mirror to read-write and vice versa.

The mirroring operation never consumes all available network bandwidth, and throttles back when other processes need more network bandwidth. The server sending mirror data continuously monitors the total round-trip time between the data transmission and arrival, and uses this information to restrict itself to 30% of the available bandwidth (continuously calculated). If the network or servers anywhere along the entire path need more bandwidth, the sending server throttles back automatically. If more bandwidth opens up, the sender automatically increases how fast it sends data. Mirror throttling can be disabled so that all available bandwidth is devoted to mirror operations. See Disabling Mirror Throttling for details.

last-updated: Jun 06, 2024

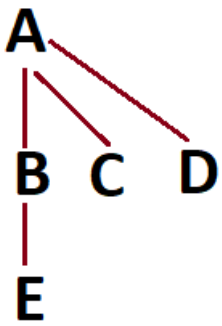
During the copy process, the mirror is a fully-consistent image of the source volume. Mirrors are atomically updated at the mirror destination. The mirror does not change until all bits are transferred, at which point all the new files, directories, blocks, etc., are atomically moved into their new positions in the mirror-volume. The previous mirror is left behind as a snapshot, which can be accessed from the .snapshot directory. These old snapshots can be deleted on a schedule.

Mirroring is extremely resilient. In the case of a network partition, where some or all of the machines that host the source volume cannot communicate with the machines that host the mirror volume, the mirroring operation periodically retries the connection. Once the network is restored, the mirroring operation resumes.

Altering Mirror Relationships

You can use the volume modify on page 2676 command to change mirror relationships. You can change the mirror relationship to any of the volumes (either `rw` or `mirror`) that have the same mirror root, as the mirrored volume.

For example, consider the mirror tree:



Volume E mirrors volume B. However, if volume B becomes unavailable, you can set either volume A, or volume C, or volume D as the source of mirroring for volume E, since volume B, volume C, and volume D have the same mirror data source volume, which is volume A.

Mirror Types
Explains the available mirror types.

You can check the status of your volumes in terms of their mirror type. The `maprcli volume info` command returns the following `mirrortype` values:

mirrortype	Description	Volume upgrade required (to support promotability)
0	Old-format volume, created in an earlier release and present in the cluster after an upgrade to Version 5.0	Yes, if the volume is intended for use as a read-write mirror.
1	An old-format mirror volume whose source volume is a type 0 volume (in any data-fabric version). These mirror volumes cannot be upgraded.	No, not allowed. The `maprcli volume upgradeformat` command returns an error for these volumes.
2	New-format mirror volume that may be promoted to read-write (no upgrade command required).	No, not needed. These volumes are already in the new format and are promotable.
3	New-format standard volume: either created new in 5.0 or upgraded in 5.0 via the maprcli volume promote command.	No, not needed. These volumes are already in the new format and are promotable.

last-updated: Jun 06, 2024

To check the mirror types for your volumes in Version 5.0, run the following command:

```
maprcli volume list -columns volumename,mirrortype -json
...
 {
   "volumename":"vol999",
   "mirrortype":0
  },
  {
   "volumename":"volume1",
   "mirrortype":3
  },
  {
   "volumename":"volume2",
   "mirrortype":3
  },
  {
   "volumename":"volume3",
   "mirrortype":2
  },
...
```

Local Mirroring
Describes the use of local mirror volumes. The local mirror volume and its source are present on the same cluster,

A *local mirror volume* is a mirror volume whose source is on the same cluster. Local mirror volumes are useful for load balancing or for providing a read-only copy of a data set.

You can locate your local mirror volumes in specific servers or on racks with particularly high bandwidth, mounted in a public directory separate from the source volume.

The most frequently accessed volumes in a cluster are likely to be the root volume and its immediate children. To load-balance read operations on these volumes, mirror the root volume (typically `mapr.cluster.root`, which is mounted at `/`). By mirroring these volumes, you can serve read requests from the mirrors, and distribute load across the nodes. Less-frequently accessed volumes that are lower in the hierarchy do not need mirror volumes. Since the mount paths for those volumes are not mirrored throughout, those volumes are writable.

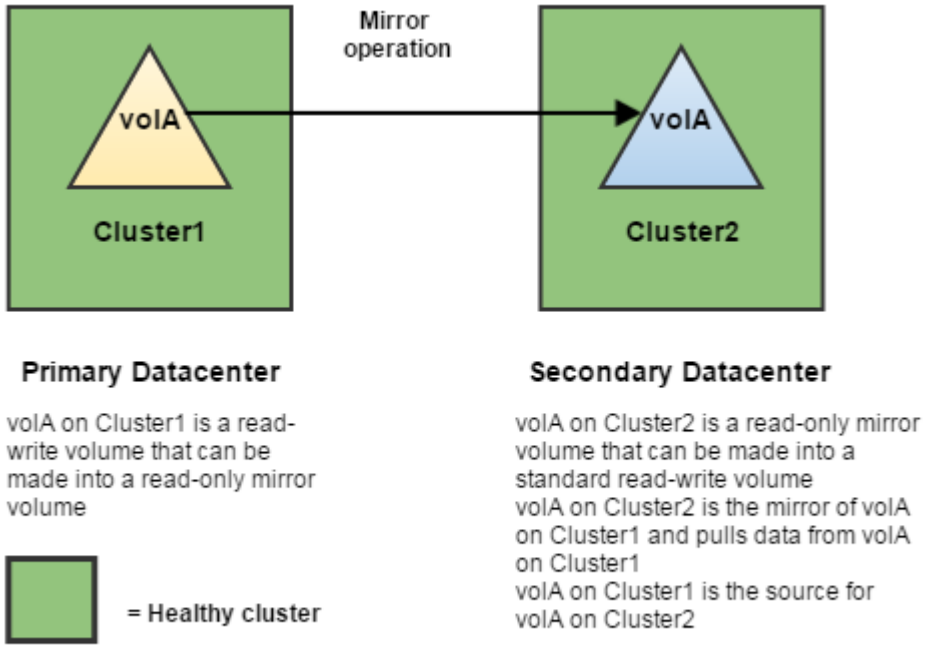
NOTE: If you are creating a local mirror of the root volume, root(`/`) points to the mirror volume, hence root is read-only. For read-write copy of root (`/`), you must use the special path, `/.rw`

Remote Mirroring
Describes the concept and purpose of remote mirror volumes.

A remote mirror volume is a mirror volume with a source in another cluster. You can use remote mirrors for offsite backup, for data transfer to remote facilities, and for load and latency balancing for large websites. By mirroring the cluster's root volume and all other volumes in the cluster, you can create an entire mirrored cluster that keeps in sync with the source cluster.

Backup mirrors for disaster recovery can be located on physical media outside the cluster, or in a remote cluster. If disaster strikes the source cluster, you can check the time of last successful synchronization to determine the freshness of the backup (see Mirror Status).

Once data volumes are created in a primary data center, the data-fabric administrator creates mirror volumes in a remote secondary data center. The following diagram illustrates the mirror relationship between these two volumes:



NOTE: When you use promotable mirrors, you must set up the volumes on the destination cluster in the same way as on the primary site. This means that volume names are the same and mount points are the same. If you use a hierarchical mounting structure (such as /A/B) on the primary site, you must recreate the same structure once you promote the mirror volumes at the secondary site.

Mirror Cascades
Describes what mirror cascades are, and their advantages.

In a cascade, one mirror synchronizes to the source volume, and each successive mirror uses a previous mirror as its source. Mirror cascades are useful for propagating data over a distance, then re-propagating the data locally instead of transferring the same data remotely again for each copy of the mirror. In the following example, the < character indicates a mirror's source:

```
/ < mirror1 < mirror2 < mirror3
```

A mirror cascade makes more efficient use of your cluster's network bandwidth, but synchronization can be slower to propagate through the chain. For cases where synchronization of mirrors is a higher priority than network bandwidth optimization, make each mirror read directly from the source volume:

```
mirror1 >   < mirror2
          /
mirror3 >   < mirror4
```

You can:

- Create a mirror cascade by setting the source volume of each mirror in the **Properties** tab of the Control System when creating a mirror volume.
- Break a mirror cascade made from existing mirror volumes by changing the source volume of each mirror in the **Properties** tab of the Control System when editing the mirror volume.

Promotable Mirrors
Explains the use of promotable mirrors for enhanced performance, data recovery, and business continuity.

In general, mirror volumes are created for the purpose of preventing or minimizing data loss. Data loss scenarios range from accidental overwrites to rack failures, to a disaster that destroys an entire data center. Mirror volumes are also used to improve performance or to make copies of data for use in other clusters without impacting production.

As of the 4.0.2 release, all new mirror volumes can be made into read-write volumes. In addition, read-write volumes that were mirrored to other volumes can be made into mirrors (to establish a mirroring relationship in the other direction). This functionality is useful in scenarios such as:

- Disaster recovery If a read-write volume with critical data goes down in a primary data center, a mirror volume in a remote data center can be made into a read-write volume in order to maintain business continuity. Later, if the primary data center comes back online, the original mirror relationship can be restored by making the new read-write volume back into a mirror volume.
- Running applications on a copy of production data
- Resynchronization (reestablishing a mirror relationship after it is broken)

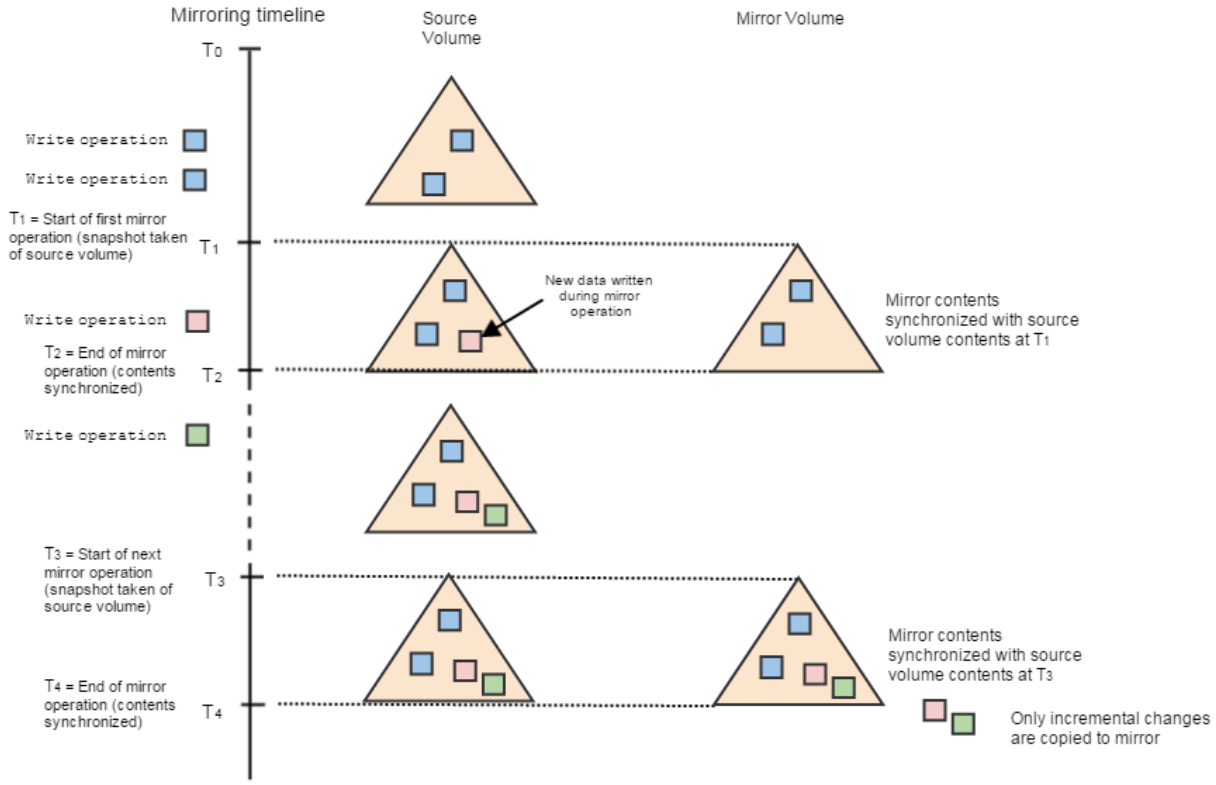
Refer to Using Promotable Mirrors for Disaster Recovery on page 1239 for details on using promotable mirrors.

Incorporating Mirror Volumes into a Disaster Recovery Plan
Lists the points to note when incorporating mirror volumes into a disaster recovery plan.

Mirroring critical data to a remote data center (with the ability to make mirror volumes into read-write volumes) addresses the following objectives:

- Recovery Point Objective (RPO) - the age of the files you need to recover (and how much data you can afford to lose)
- Recovery Time Objective (RTO) - how soon you need to have a working data center in order to maintain business continuity

In a typical scenario that employs remote mirrors, the contents of a source volume are mirrored to a mirror volume in a remote cluster at a frequency specified by the mirror schedule. At the start of each mirror operation, a snapshot is taken of the source volume's contents. The mirror operation takes some time to complete, and while the data is being copied from the snapshot to the mirror volume, more data is written to the source volume. This data will be captured during the next mirror operation. When each mirror operation completes, the contents of the mirror volume are identical to the contents of the source volume at the time of the snapshot. For subsequent mirror operations, only the incremental changes (additions and deletions) are copied to the mirror volume, which synchronizes its contents with the contents of the source volume at the time of the snapshot.



If the source cluster goes down, any data written to the source volume since the last successful mirror operation cannot be copied to the mirror. The amount of data lost depends on the number of write operations in the interval from the last successful mirror to the time the cluster goes down.

Factors that Affect RTO

Lists the factors that affect the Recovery Time Objective (RTO).

During a disaster, an administrator must first determine that the link between the primary data center and the secondary data center has failed. Next, the administrator begins the process of switching applications that were running on the primary data center over to the secondary data center. For write applications, the administrator begins converting mirror volumes to read-write volumes, starting with volumes that contain the most critical data. Note that read applications can run on read-only mirrors, but write applications can only run on read-write volumes.

To gauge how long it will take to switch applications from the primary data center to the secondary data center (and to set the RTO accordingly), consider these factors:

- Detection time (how long it takes to determine that the link is down between the two data centers)
- Switching time (how long it takes to switch applications from one data center to the other)
- Promotion time (how long it takes to change read-only mirror volumes to read-write volumes that can run write applications). Promotion time is based on the number of containers in a volume or across volumes.
- Whether mirror throttling is enabled (the default) or disabled (which speeds up the mirroring process)

Various factors affect the amount of data that can be recovered through the use of mirror volumes. To specify a realistic recovery point objective in your disaster recovery plan, take the following factors into account:

last-updated: Jun 06, 2024

- Mirror schedule (how often the mirror is synchronized with its source volume) - Note that the first mirror operation is a full synchronization between source and mirror volumes. Subsequent mirror operations are incremental - only the changes that occurred since the last mirror event need to be copied in order to synchronize the contents between the two volumes.
- Network link between the source volume and the mirror volume (consider the stability and quality of the link, as well as latency, throughput, and other activities across the link)

Data Tiering
Provides an overview of what tiering is, its various types, and how it works in the HPE Ezmeral Data Fabric.

The HPE Ezmeral Data Fabric provides rule-based automated tiering functionality that allows you to seamlessly integrate with:

- Low-cost storage as an additional storage tier in the Data Fabric cluster for storing file data that is less frequently accessed ("warm" data) in erasure-coded volume.
- 3rd party cloud object storage as an additional storage tier in the Data Fabric cluster to store file data that is rarely accessed or archived ("cold" data).

In this way, valuable on-premise storage resources can be used for more active or "hot" file data and applications, while "warm" and/or "cold" file data can be retained at minimum cost for compliance, historical, or other business reasons. The Data Fabric provides consistent and simplified access to and management of the data.

See also: Working with Tiered Volumes on page 1244

Where is data tiered?

For "warm" data, the Data Fabric allows you to offload data to specific nodes or low-cost hardware in a topology. The Data Fabric uses erasure coding to protect data on the low-cost hardware. Erasure coding also reduces the storage overhead in the range of 1.2x-1.5x. See Overview of Tiers on page 509 for more information on erasure coding.

For "cold" data, the Data Fabric allows you to easily offload your cluster data to public, private, and hybrid clouds. You can offload data to remote cloud from vendors such as Amazon AWS, Google Cloud Platform, Microsoft Azure, IBM Cleversafe, Hitachi HCP, and Minio. This allows you to tap into cloud-scale capacity.

NOTE: the Data Fabric supports tiering for only file and volume data; tiering of tables and streams is not supported.

The Data Fabric allows you to configure a volume at the time of volume creation for either warm or cold tier, but not both. If you do not know the type of tier to associate with the volume, you can still create a volume that is tiering-enabled and associate a specific tier later with the volume. However, volumes not enabled for tiering at the time of volume creation cannot be enabled for tiering after the volume is created. You cannot modify the type of tier associated with the volume after the volume is created.

When you create a volume and configure it for warm or cold tiering — associating a warm or cold tier, a storage policy (referred to as rule in the CLI), and an offload schedule — the Data Fabric automatically moves the data out of the volume and into the tier, and purges the data in the volume on the the Data Fabric cluster to release the disk space on the the Data Fabric cluster. However, for tiering-enabled volumes, the amount of hard quota you set is the total space allocated for the volume irrespective of the location (cluster or tier) of the volume data. Writes fail when volume disk space usage reaches the quota assigned for the volume whether or not volume data is local (on the cluster) or remote (on the tier). Also, if you want to recall volume data back to the the Data Fabric cluster, you must have the disk space in the volume equivalent to the amount of data being recalled from the tier. You can retrieve and view the disk space usage metric, including the amount of data offloaded to the tier, for a tiering-enabled volume using the Control System, the CLI, and REST API.

How frequently is data offloaded?

The Data Fabric automatically offloads data based on the criteria that you define in the storage policy for offloading data and at the frequency you specify in the schedule. The Data Fabric automatically offloads data in the volume at the frequency in the schedule only if data in the volume meets the criteria in the associated storage policy. If you do not specify a criteria, for volumes configured for:

- Erasure coding (warm tier), the Data Fabric applies a default criteria, which is a modification timestamp of 1 day, for offloading data.
- Remote archiving (cold tier), the Data Fabric does not associate a default criteria. You can use the Control System, CLI, and REST API to manually trigger an offload of volume data.

For more information, see Data Storage Policy on page 512. If you do not associate a schedule for offloading data, for volumes configured for:

- Erasure coding (warm tier), the Data Fabric automatically uses the default Automatic Tiering Scheduler, which uses internal policies to decide when to schedule the offload operation.
- Remote archiving (cold tier), the Data Fabric does not associate a default schedule. You can use the Control System, CLI, and REST API to manually trigger an offload of volume data.

Even when you manually trigger an offload, the Data Fabric offloads data only if the data meets the criteria defined in the storage policy. In addition, for warm-tier volumes, the Data Fabric offloads data only if the object (stripe) has data exceeding 90% of the object payload; if an object has data less than 90% of the object payload, the object is not offloaded and the metadata tables are not updated. For more information, see Data Offload and Purge on page 512.

What is the MAST Gateway?

The Data Fabric automated storage tiering (MAST) Gateway acts as the centralized entry point for all the tiering operations. CLDB assigns tiering-enabled volumes to MAST Gateways for processing all tiering operations for the volume. For more information, see Overview of MAST Gateway on page 510.

How is compressed and encrypted data transferred and stored?

Data is encrypted during transfer to ensure security of data if the cluster is a secure cluster and if wire-level security is enabled for the volume. In addition, stored data is encrypted if:

- The warm-tier volume is enabled for data-at-rest encryption (`dare`).
- The cold-tier volume is enabled for tier encryption (`tierencryption`).

Data in the volume is transferred and stored as-is, compressed or uncompressed, on the tier. You can set up replication, snapshots, and mirror volumes for tiering-enabled volumes. See Data Replication, Snapshots, Mirroring, Auditing, and Metrics Collection on page 516 for more information.

How are reads, writes, and deletes handled?

When a client tries to read offloaded data, the Data Fabric processes the read request of the warm-tiered and cold-tiered standard and mirror volume data differently. Similarly, when a client writes to a tiered volume, the Data Fabric processes appends and overwrites differently. See Data Reads, Writes, and Recalls on page 519 for more information.

Data, once offloaded, is purged on the the Data Fabric cluster to release the disk space. When you delete an entire file, part of a file, or a snapshot, corresponding objects are removed from the tier also. See Data Compaction on page 524 for more information.

last-updated: Jun 06, 2024

Enabling Tiering

To enable tiering, see Enabling Tiering on page 1284

.
Overview of Tiers
Describes what warm and cold tiers are.

Data fabric considers data that is active and frequently accessed as "hot" data and data that is rarely accessed as “warm” or “cold” data. The mechanism used to store "hot" data is referred to as the hot-tier (or the data fabric cluster), the mechanism used to store "warm" data is referred to as the EC-tier (or low-cost storage alternative on the data fabric cluster), and the mechanism to store "cold" data is referred to as the cold tier (or low-cost storage alternative on the cloud). Hot, warm, and cold data is identified based on the rules and policies set by the administrator.

Data starts off as hot when it is first written to local storage (on the data fabric cluster). It becomes warm or cold based on the rules and policies the administrator configures. Data can then be set up to be automatically offloaded using the data fabric automated storage tiering (MAST) Gateway service to the erasure coded volume on the low-cost storage alternative on the data fabric cluster (warm tier) or to the low-cost storage alternative on the 3rd party cloud object store (cold tier) like AWS S3.

Warm Tier

On the data fabric cluster, every volume enabled for erasure coding (or warm tiering) acts as a "front-end" volume and has a corresponding hidden erasure coded (or EC) volume in the specified topology (of the low-cost storage alternative). Erasure coding (EC) is a data protection technique where data is broken into many fragments (or *m* pieces) and encoded with some extra redundant fragments (or *n* pieces) to guard against disk failures. That is, for volumes configured for erasure coding, file data in the volume is broken into many fragments (or *m* pieces) and encoded with pre-configured number of redundant fragments (or *n* pieces). In the event of disk failure, any *m* piece can be used to get back the original file. See Erasure Coding Scheme for Data Protection and Recovery on page 1244 for more information.

Although you write to and read from the front-end volumes, the front-end volume is akin to a staging area, where volume’s data is held on demand. Data written to a volume is periodically moved to the back end erasure coded volume, releasing the disk space for the front-end volume on the filesystem and providing the space savings of erasure coded volumes. Data in the front-end volume is moved to the corresponding erasure coded volume based on an offload schedule. The front-end volume holds only small amount of required data, and data is shuffled between the front-end volume and the corresponding erasure coded volume as required. See Data Reads, Writes, and Recalls on page 519 for more information.

There is also a visible tier-volume on the data fabric cluster for storing the metadata associated with the volume. When you create a warm tier, the tier volume named `mapr.internal.tier.<tiername>` is by default created in the `/var/mapr/tier` path. When you create a warm-tier volume using the `ecenable` parameter or the Control System, a warm tier is automatically created and the corresponding tier volume named `mapr.internal.tier.autoec.<volName>.<creationTime>` is, by default, created in the `/var/mapr/autoectier` path.

last-updated: Jun 06, 2024

	While three-way replicated regular volumes require 3 times the amount of disk space of the regular volume, erasure coded volumes reduce the storage overhead in the range of 1.2x-1.5x. On the data fabric cluster, only the metadata of the volume in the namespace container is 3-way replicated. You can create one warm tier per volume using the Control System, the CLI, and REST API or create and associate multiple volumes with different erasure coding schemes with the same warm tier using the CLI and REST API (only). You cannot associate the same warm tier with multiple volumes using the Control System.
Cold Tier	On the data fabric cluster, every cold tier (referred to as remote target in the Control System) has a bucket on the 3rd party cloud store where volume data is offloaded based on the policy configured by the administrator. Volume data in 64KB data chunks is packed into 8MB sized objects and offloaded to the bucket on the tier and the corresponding volume metadata is stored in a visible tier-volume as HPE Ezmeral Data Fabric Database tables on the data fabric cluster. During writes and reads, volume data is recalled to the data fabric cluster if necessary. Data written to the volume is periodically moved to the remote target, releasing the disk space on the filesystem. See Data Reads, Writes, and Recalls on page 519 for more information. Data stored on the data fabric cluster requires 3 times the amount of disk space of the regular volume on premium hardware due to replication (default being 3). After offloading to the cloud, the space used by data (including data in the namespace container) in the volume on the data fabric cluster is freed and only the metadata of the volume in the namespace container is 3-way replicated on the data fabric cluster. There is also a visible tier-volume on the data fabric cluster for storing the metadata associated with the volume. When you create a cold tier, the tier volume named `mapr.internal.tier.<tierName>` is by default created in the `/var/mapr/tier` path. A directory/folder for the volumes associated with the tier, identifiable by `volumeid`, is created under the path after the first offload of data from the volume to the tier. You can create one tier per volume or create and associate multiple volumes with the same tier using the Control System, the CLI, and REST API.

See also: Managing Tiers on page 1284

Overview of MAST Gateway
Describes the role of the MAST Gateway for operations on tiered storage.

The MAST Gateway can be installed on specific hosts on the data fabric cluster with access to the tier. The MAST Gateway acts as the centralized entry point for all the operations that need to be performed on the tiered storage including the following:

Warm Tier	For volumes configured for warm tiering, the MAST Gateway:

- Identifies files in the volume that are ready to be offloaded, fetches data corresponding to these files from file system, and packs this data for offload. It:
  - Identifies and fetches the data to offload.

    It handles both compressed and uncompressed data. Compressed data from the file server is transferred and stored as-is on the warm tier.
  - Creates stripes based on the erasure coding scheme.

    For example, for an erasure coding scheme of 4+2, the stripe depth would be 6x4MB=24MB.
  - Manages statistics on the amount of data offloaded.
  - Prepares a corresponding metadata on the data fabric cluster for the data.

    The MAST Gateway stores the metadata in HPE Ezmeral Data Fabric Database tables in a separate volume associated with the tier.
- Tracks invalid data and deletes stripelets that are completely invalid.
- Fetches data from the tier.
- Recalls whole volume from the tier to the data fabric cluster.

Cold Tier

For volumes configured for cold tiering, the MAST Gateway:

- Identifies files in the volume that are ready to be offloaded, fetches data corresponding to these files from file system, and packs this data for offload. It:
  - Identifies and fetches the data to offload and creates objects (including creating new buckets) in the storage tier for the data.
  - Manages statistics on the amount of data offloaded.
  - Updates metadata references for remote access.
- Tracks invalid data and deletes objects that are completely invalid.
- Fetches data from the tier. It:
  - Handles both compressed and uncompressed data. If data on file server is compressed, the compressed data is not uncompressed/ re-compressed during offload or recall. Compressed data from the file server is transferred and stored as-is on the cold tier.
  - Ensures that data is decrypted, if it is encrypted, before forwarding it to file system.
- Recalls whole volume from the tier to the data fabric cluster.

last-updated: Jun 06, 2024

The MAST Gateway uses curl to transfer data to and from S3 cloud storage.

The MAST Gateway uses an exponential backoff retry mechanism. If curl fails to connect to the S3 destination even after a minute of trying, or if curl fails to fetch data from the S3 destination even after 5 minutes of being connected, the MAST Gateway declares a failure and reports it to the CLDB. The CLDB then reschedules the (vol) tasks after 30 minutes.

The MAST Gateway sends heartbeat messages to CLDB every 5 seconds. CLDB manages the discovery and a minimal global state of the MAST Gateway service. CLDB also manages the volumes and any policy configurations on the volumes. When a volume is assigned to a gateway, the volume remains assigned to the gateway across CLDB, Gateway, and cluster restarts. Volumes are assigned evenly to gateways and CLDB balances the gateway load. For more information, see Balancing Gateway Load on page 1640.

By default, the MAST Gateway uses 16 threads for volume and file offload and recall operations and another 16 threads for handling internal operations and other operations such as reads (which triggers automatic recall requests), writes, etc. Each thread processes uses the curl library to offload or recall a container (associated with a volume). Each MAST Gateway can process one or more volumes (and associated containers) simultaneously depending on the number of threads available for processing the containers associated with the volumes. Each volume is assigned to a MAST Gateway for a tiering operation irrespective of the number of containers associated with the volume.

When a MAST Gateway goes down during a volume-level offload, CLDB does not immediately reassign all the volumes assigned to that MAST Gateway to other gateways. CLDB waits for some time to allow the MAST Gateway to come back up and send heartbeat again; CLDB re-assigns volumes with pending tasks to other gateways if the MAST Gateway does not come back up again. All other volumes are redistributed when the gateway balancer runs again. On the other hand, if the MAST Gateway comes back up again, the volumes remain assigned to the MAST Gateway. The load on the MAST Gateways is rebalanced when the balancer runs again. See Balancing Gateway Load on page 1640 for more information. MAST Gateways use transactions to ensure that all the updates are consistent, and that any new gateway can pick up exactly from where the old gateway left.

If a MAST Gateway goes down during a file-level offload and if the offload was triggered using:

- The `hadoop` command, CLDB reassigns the volume to another MAST Gateway.
- The MapR CLI, REST API, or dot interface, CLDB does not reassign to another MAST Gateway.

See also: Managing the MAST Gateway on page 1634

Data Storage Policy
Provides an overview of creating storage policies and formulating rules to offload data.

You can configure a storage policy (or rules) for data at the volume level. The storage policy simplifies the lifecycle management of data in the volume including automated migration of files to low-cost storage alternatives. The policy can contain rules for files that have a well-defined lifecycle or for files you want to switch to different storage tiers during their lifecycle.

You can specify the rules, at the volume level, to selectively identify files to offload (such as file size, file owner, and file modification time), the schedule for offloading the data (for example, 2 months after file modification), and the settings for storing (such as the location and credentials for the tier) and recalling the offloaded data. You can configure one rule per volume using the CLI or REST API. You can also associate a schedule to automatically offload data at scheduled intervals based on the associated rules.

See Managing Storage Policies on page 1301 for more information.

Data Offload and Purge
Describes the process of offloading data to warm and cold tiers, and purging data from storage pools.

The MAST Gateway service drives the offload process. On volumes configured for warm or cold tiering, the CLDB notifies the MAST Gateway service to start the offload based on either of the following:

- The schedule set at the volume level for offload.

- The request triggered by the client (through the Control System, the CLI, or REST API).

The MAST Gateway service then scans the files in the volume and starts the offload by picking the files that meet the criteria in the rule associated with the volume.

Offloading Data to the Warm Tier

On volumes configured for warm tiering, the MAST Gateway service detects the files that meet the criteria in the configured rules, collects data to offload from the read-write containers of the front-end volume on the data fabric file system, and:

1. Creates objects based on the erasure coding scheme.

   For example, for an erasure coding scheme of 4 + 2 and stripe depth of 4 MB, which is the default, the object size is 4 x 4 MB = 16 MB and the stripe length is 6 x 4 MB = 24 MB. When offloading an individual file, the file must contain data exceeding 90% of the object size to qualify for offload. When offloading a volume, an object can contain multiple small files, and the per-file size requirement does not apply. Still, any objects that fall below the threshold are not offloaded.

   NOTE: Data is broken into many fragments (or *m* pieces) and encoded with some extra redundant fragments (or *n* pieces) to guard against disk failures.

2. Prepares a corresponding metadata on the data fabric cluster for the data.

   The MAST Gateway stores the metadata in HPE Ezmeral Data Fabric Database tables in a separate volume associated with the tier.

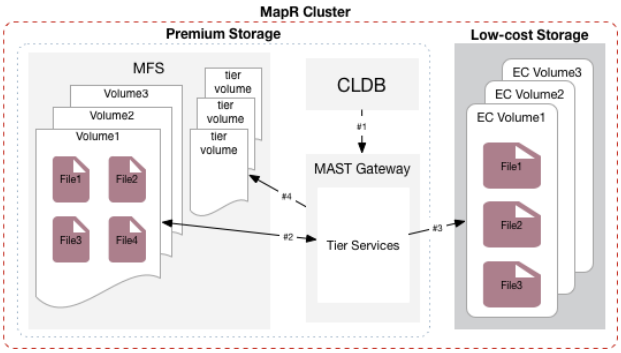
3. Offloads the objects to the tier.

   NOTE: If an object contains less than 90% of the object size, the object is not offloaded and the metadata table is not updated; the volume might have local data. However, the MAST Gateway will report successful job completion.

   Data is offloaded to the tier in the same state, compressed or uncompressed, as was stored in the front-end volume. If data encryption is enabled on the front-end volume (using the `dare` parameter), data is encrypted during and after offload to the erasure-coded volume.

The following illustration shows the CLDB notifying the MAST Gateway service to start the offload (#1) and the MAST Gateway fetching data from the front-end volume (#2), offloading the data to the associated erasure-coded volume (#3), and then writing metadata to the tier volume associated with the front-end volume (#4).

last-updated: Jun 06, 2024



As stated above, when offloading an individual file, it might not qualify for offload because objects that contain less than 90% of the object size do not qualify for an offload. For example, assume that you have a 13 MB file in a volume enabled for warm-tier erasure coding scheme 4 + 2. The object size for the volume is 16 MB (4 x 4 MB). Thus, an individual file of 13 MB is less than 90% of the object size. In this case, a 13 MB file does not qualify for file offload by itself.

Similarly, portions of a large file might not qualify for offload. For example, assume that you have a file in the volume enabled for warm-tier erasure coding scheme 4 + 2 is 20 MB. The object size for the volume is 16 MB (4 x 4 MB), and the individual file of 20 MB exceeds the upper limit of the object size. Portions of data in the file are offloaded, and up to 4 MB of file data might remain on the hot tier.

When offloading a volume, smaller files can be combined into an object for offload. Still, some portions of those files might not be placed in objects that exceed the 90% size threshold. Those portions of the file will not be offloaded.

Offloading Data to Cold Tier

On volumes configured for cold tiering, the MAST Gateway service detects the files that meet the criteria in the configured rules, collects data to offload from the read-write containers and snapshots for the volume on the Data Fabric file system, and:

1. Packs 64 k data chunks into 8 MB-sized objects.
2. Creates the bucket on the tier (or remote target) if the specified bucket is already not present on the tier.
3. Prepares corresponding metadata on the Data Fabric cluster for the data and creates the objects in the tier.

   The MAST Gateway stores the metadata in HPE Ezmeral Data Fabric Database tables in a separate volume associated with the tier.

last-updated: Jun 06, 2024

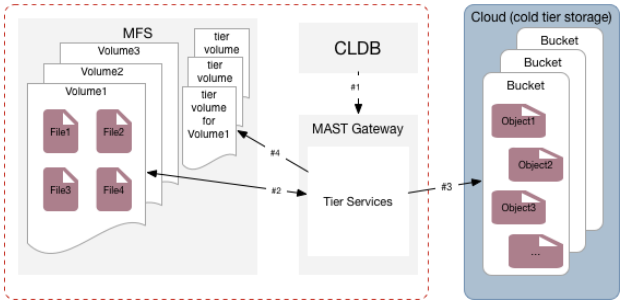
4. Offloads the data to the tier using libcurl.

   NOTE: Data is offloaded to the tier in the same state, compressed or uncompressed, it was stored on the file system. If data encryption is enabled at the volume level (using the `tierencryption` parameter), data is encrypted during and after offload. See `volume create` or `volume modify` for more information about the parameter.

   For the offloaded data, the unique object IDs are generated using a combination of cluster ID, volume ID, and a unique sequence of numbers. For example, the names of the objects in S3 can look similar to the following:

   ```
   0.b258a07.86e.1
   0.b258a07.86a.1
   0.b258a07.86c.1
   ```

   The following illustration shows the CLDB notifying the MAST Gateway service to start the offload (#1) and the MAST Gateway fetching data from the volume (#2), offloading the data to the third-party storage alternative (#3), and then writing metadata to the tier volume associated with the volume (#4).



The MAST Gateway service notifies the CLDB when the offload operation completes successfully. Entire volumes can be moved from "hot" to "warm" tier or "hot" to "cold" tier and vice-versa on demand by using CLIs. For each offloaded volume, the file system stores only the metadata for the offloaded data in a volume on the hot tier.

NOTE: If the offload fails, an alarm, VOLUME_ALARM_OFFLOAD_FAILURE, is raised. Check the log file for more information about the error. For log information, see Enabling Debug Logging for MAST Gateway on page 1642. For some errors, CLDB tries to offload the data again after a brief wait. For more information, see Retrying Failed Operation on page 1261.

See also: Offloading a Volume to a Tier on page 1255 and Offloading a File to a Tier Using the CLI and REST API on page 1340

Purging Data on file system

While offloading, metadata is written to the HPE Ezmeral Data Fabric Database table in a separate volume associated with the tier, and the data blocks are removed from the storage pool in the hot tier. An offload is considered successful only when data on all active replicas has been purged (or removed from the storage pool to release the disk space on the Data Fabric file system) in the hot tier. When you offload data at the file level, all data, including recalled data, is immediately purged from the hot tier. For more information, see Data Compaction on page 524.

Data Replication, Snapshots, Mirroring, Auditing, and Metrics Collection
Provides an overview of what Data Replication, Snapshots, Mirroring, Auditing, and Metrics Collection are.

Replication

Data from one of the replica containers is first offloaded and then the data in all the replica containers is purged. file system only stores the metadata after data is offloaded. The offload is considered successful only when data on all active replicas have been purged (or removed from the storage pool to release the disk space on the data-fabric filesystem). If, during the offload, the node on which one of the replicas reside is down, the data on that container is purged once the node comes back up.

In the tiering architecture, although data is moved to the storage tier, the namespace of the volume continues to be 3-way replicated. So, the metadata related to namespace container has 3x cost.

The offloaded replica containers are recalled if/when the whole volume is recalled. When a replica is reinstituted to the cluster as a result of a recall operation, a re-synchronization happens to bring all the replicas up to date from the designated master container.

NOTE: The offload and recall settings on the master container are applicable to the replica containers as well.

Snapshots

You can associate a snapshot schedule with tiering-enabled volumes. When the data in the volume is offloaded, associated snapshots are also offloaded and file system only stores the metadata. If the whole volume is recalled, the snapshots are also recalled to the data-fabric filesystem. When offloading recalled snapshots, the rules for data offload apply to snapshots as well.

NOTE: You may experience latencies when accessing snapshots associated with offloaded data.

Mirroring

You can create tiering-enabled source volumes and associate them with tiering-enabled mirror volumes. You cannot associate tiering-enabled mirror volumes with standard volumes that are not tiering-enabled and vice versa. Only homogeneous combination of mirror and standard volumes are supported; heterogeneous combination of mirror and standard volumes are **not** supported.

NOTE: Both mirror volume and source volume data can be set up to be offloaded to the same tier (that is the same cold tier) or different tiers (that is different cold tiers). Data Fabric does not require the source and mirror volume to be configured to use the same tier or have the same tier settings. Warm tier enabled volumes can have the same tier settings; however, the volume's tier only stores the meta data and data in each volume is offloaded to an associated back-end volume.

When a synchronization of the tiering-enabled mirror volume with the (local or remote) tiering-enabled source volume is triggered (either manually or automatically based on a schedule), the mirror volume synchronizes with the source volume if source volume data is local (and not yet tiered). On the other hand, if the source volume data is tiered, the tiering-enabled mirror volume synchronizes with the tiered data fetched by the MAST Gateway that is assigned to the source volume. Incremental changes in the mirror volume are offloaded based on the offload rules associated with the tiering-enabled mirror volume.

Using Tiering-Enabled Mirror Volumes for Disaster Recovery	You can create a secondary, cost optimized disaster recovery cluster for a primary three-way replicated cluster. To do this, create two clusters — a primary tiering-enabled cluster with no active schedule to automatically offload data and an associated secondary cluster where primary cluster data is mirrored and then aggressively offloaded to the tier. While the primary or source cluster continues to be three-way replicated, if the the secondary, disaster recovery cluster data is:

last-updated: Jun 06, 2024

- Erasure coded (warm tier), it provides space savings in the range of 1.2x-1.5x.
- On a third-party cloud storage (cold tier), it can be three-way replicated on a low-cost storage alternative.

In case of a disaster, you can recall data from the tier to the data-fabric cluster.

NOTE: If you promote a tiering-enabled mirror volume during an offload or recall operation of the data associated with the mirror volume, the offload or recall operation is aborted and the mirror volume is converted to a read-write volume; the `tierjobstatus` command for the offload or recall job shows AbortedInternal status.

Auditing

The data-fabric audit feature lets you log audit records of cluster-administration operations and operations on the data in the volume. Scheduled (and automatically triggered) tiering operations such as offload and compaction are not audited. However, if auditing is enabled at the cluster level, the manually triggered volume-level tiering operations such as offload, recall, abort, etc. are audited in the CLDB audit logs. For example, you can see a record similar to the following in the `/opt/mapr/logs/cldbaudit.log.json` file for `volume offload` on page 2698 command:

```
{"timestamp":
{"$date":"2018-06-07T15:34:28.580Z"},"resource":"vol1","operation":"volumeOf
fload","uid":0,"clientip":"10.20.30.40","status":0}
```

If auditing is enabled for data in the tiering-enabled volume and files within, file-level tiering operations such as offload, recall, etc. triggered using the REST API, hadoop, and dot-interface are audited in the FS audit logs (`/var/mapr/local/<hostname>/audit/5661/FSAudit.log-<*>.json` file).See Auditing Data Access Operations on page 849 for the list of file-level tiering operations that are audited. You can selectively enable or disable auditing of these operations. See Selective Auditing of File-System, Table, and Stream Operations Using the CLI on page 1061 for more information. For example, you can see records similar to the following in the `/var/mapr/local/<hostname>/audit/5661/FSAudit.log-<*>.json` file for `file offload` on page 2196 command:

```
/mapr123/Cloudpool19//var/mapr/local/abc.sj.us/audit/5660/
FSAudit.log-2018-09-12-001.json:1:{"timestamp":
{"$date":"2018-09-12T05:47:04.199Z"},"operation":"FILE_OFFLOAD","uid":0,"ipA
ddress":"10.20.35.45","srcFid":"3184.32.131270","volumeId":16558233,"status"
:0}
```

Both the `tier rule list` on page 2547 and `tier list` on page 2533 commands are audited in the `/opt/mapr/logs/cldbaudit.log.json` file as well as the `/opt/mapr/mapr-cli-audit-log/audit.log.json` file. The record in the audit log might look something similar to the following:

```
{"timestamp":
{"$date":"2018-06-13T09:15:24.004Z"},"resource":"cluster","operation":"offlo
adRuleList","uid":0,"clientip":"10.10.81.14","status":0}
{"timestamp":
{"$date":"2018-06-13T09:14:42.304Z"},"resource":"cluster","operation":"tierL
ist","uid":0,"clientip":"10.10.81.14","status":0}
```

When auditing operations like `tierjobstatus` and `tierjobabort`, the coalesce interval set at the volume level is not honored. You may see multiple records of the same operation from the same client in the log.

Read requests processed using cache-volumes or erasure-coded volumes are not audited because when the file is accessed, the request first goes to the front-end volume and the operation is audited there. The audit record contains the ID of the front-end volume (volid) and primary file ID (fid). However, the write to the cache-volume for a volume-level recall of data is audited in the audit logs on the file server hosting the cache-volume with the primary file ID (fid). The write to the cache-volume for a file-level recall of data is not audited.

In addition, you can enable auditing of offload and/or recall events at both the volume and file levels by enabling auditing for `filetieroffloadevent` and `filetierrecallevent` at the volume level. By default, auditing is disabled for `filetieroffloadevent` and `filetierrecallevent`. If you enable auditing for `filetieroffloadevent` and `filetierrecallevent` using the `dataauditops` parameter with the `volume create` on page 2588 or `volume modify` on page 2676 command, the following are audited in the FS audit log:

- For `filetieroffloadevent`, files offloaded by running the `file offload` on page 2196 command or (only) files purged on MapR filesystem after running `volume offload` on page 2698 command.
- For `filetierrecallevent`, files recalled by running the `file recall` on page 2197 or `volume recall` on page 2700 command.

For example, you can see a record similar to the following in the `/var/mapr/local/<hostname>/audit/5661/FSAudit.log-<*>.json` file if auditing is enabled at the volume-level for `filetieroffloadevent`:

```
abc.sj.us/audit/5661/FSAudit.log-2018-06-07-001.json:{"timestamp":
{"$date":"2018-06-07T07:27:58.810Z"},"operation":"FILE_TIER_OFFLOAD_EVENT","
uid":2000,"ipAddress":"1}
```

For more information:

- Auditing in Data Fabric on page 841
- Managing Auditing on page 1057

Collecting Metrics

If volume metrics collection is enabled on the tiering-enabled volume, metrics for all read and write operations on the tiered volume are logged in the metrics log. For example, you can see a record similar to the following in the metrics log file:

```
{"ts":1534960230000,"vid":248672388,"RDT":0.0,"RDL":0.0,"RDO":0.0,"WRT":3636
22.7,"WRL":7209.0,"WRO":2580.0}
{"ts":1534960250000,"vid":248672388,"RDT":363686.7,"RDL":2856.0,"RDO":2847.0
,"WRT":0.0,"WRL":0.0,"WRO":0.0}
```

Tiering-related operations do not generate metrics records. That is, volume and file level offload, recall, and abort operations are not logged in the metrics log. However, the volumes created to support tiering (such as the cache-volume, the metadata volume, and the erasure-coded volume) have metrics collection enabled and the metrics records for these volumes are logged with the ID of the associated parent or front-end volume. That is, read operations on the the cache-volume are logged with the ID of the associated front-end volume. For example, you can see records similar to the following in the metrics log file for the volume:

```
{"ts":1534968850000,"vid":209801522,"RDT":6328.5,"RDL":161.0,"RDO":158.0,"WR
T":0.0,"WRL":0.0,"WRO":0.0}
{"ts":1534968860000,"vid":209801522,"RDT":234669.7,"RDL":5241.0,"RDO":5143.0
,"WRT":0.0,"WRL":0.0,"WRO":0.0}
```

See Enabling Volume Metric Collection on page 1676 and Collecting Volume Metrics on page 1674 for more information.

Data Reads, Writes, and Recalls
Provides a synopsis of how data is read and written to a warm or cold tier.

Once offloaded to the storage tier, data is considered to be warm or cold on the storage tier, but the data can still be accessed (read, written, and recalled).

Read of Tiered Data

Depending on whether the standard volume data is outside the data-fabric cluster and in the cloud (cold tiering) or on the data-fabric cluster (warm tiering), data-fabric processes the request to read standard volume data and mirror volume data.

Data Reads on Tiering-Enabled Standard Volumes

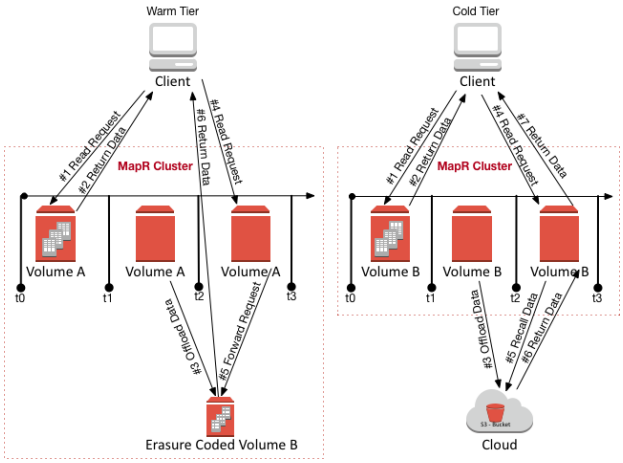
Data Fabric processes client requests to read standard volume data on the warm tier and the cold tier differently.

Warm Tier	When a client attempts to read, the read request is first sent to the front-end volume and if the data exists in the front-end volume, the data is returned from the front-end volume. If data is not in the front-end volume, the data is returned from the erasure coded volume.
Cold Tier	When a client attempts to read, the read request is first sent to the volume on the data-fabric cluster and if the data exists in the volume on the cluster, the data is returned from the volume. On the other hand, if the data was offloaded, the MAST Gateway recalls the data from the cold-tier to process the read request. See Recall of Tiered Data on page 522 for more information on recalled data.

The following illustration shows a client sending the data read request first (#1) to the tiering-enabled volume and the response (#2) being served from the volume on the data-fabric cluster. Then (#3), data is offloaded to the back-end erasure coded volume (for Volume A) and to the cloud (for Volume B). When the client next sends a read request to the volume on the data-fabric cluster (#4), for:

- Volume A, the MAST Gateway forwards the request to the back-end erasure-coded volume (#5) from where data is returned (#6) to the client.

- Volume B, the MAST Gateway recalls the data (#5 and #6) from the cloud to the volume on the data-fabriccluster, from where data is returned (#7) to the client.



Data Reads on Tiering-Enabled Mirror Volumes

Data Fabric processes client requests to read mirror volume data on the warm tier and the cold tier differently.

Warm Tier

When a client attempts to read, the read request is first sent to the front-end volume and if the data exists in the front-end mirror volume, the data is returned from the front-end volume. If data is not in the front-end volume, the data is returned from the erasure coded volume.

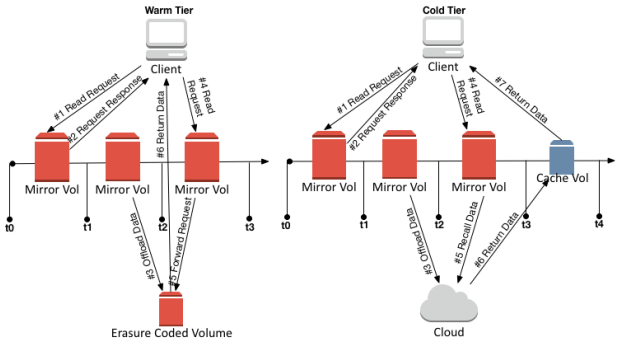
Cold Tier

When a client attempts to read, the read request is first sent to the volume on the data-fabric cluster and if the data exists in the volume on the cluster, the data is returned from the volume. On the other hand, if the data was offloaded, the MAST Gateway recalls or fetches a copy of the data (from the tier) into an associated cache-volume, from where data is returned to the client. See Recall of Tiered Data on page 522 for more information on recalled data.

The following illustration shows a client sending the read request first (#1) to the tiering-enabled mirror volume and the response (#2) being served from the volume on the data-fabric cluster. Then (#3), data is

offloaded to the back-end erasure coded volume (for warm tier) and to the cloud (for cold tier). When the client next sends a read request to the volume on the data-fabric cluster (#4), for:

- Warm tier, data is returned from the back end erasure-coded volume (#5).
- Cold tier, data is recalled in the associated cache-volume (#5 and #6), from where data is returned to the client (#7).



The cache-volume named `mapr.internal.cv.<volume-name>_<id>` is created when the tiering-enabled mirror volume is created. Although it may not hold any data initially, a copy of the tiered data is fetched into the cache-volume whenever there is a read of the cold-tiered mirror volume data or explicit recall of (cold or warm) tiered mirror volume data. You can use the `volume info` on page 2628 command on the tiering-enabled mirror volume to get the offload and recall statistics, which are from the cache-volume, for the mirror volume.

The cache-volume has the same replication factor as the mirror volume (at the time of volume creation); changes to the mirror volume replication factor do not trigger a change to the replication factor of the associated cache-volume.

If the tiering-enabled mirror volume is deleted, the cache-volume is also deleted. If the tiering-enabled mirror volume is promoted to a read-write volume, the associated cache-volume is deleted.

Write on Tiered Data

When writes happen, if the write is:

- An append, new data is offloaded when the data meets the criteria in the rule (associated with the volume) for offload.
- A change to existing data (overwrite), the data is recalled to the data-fabric filesystem to allow the write to succeed and then offloaded when the data meets the criteria in the rule (associated with the volume) for offload. See Recall of Tiered Data on page 522 for more information on recalled data.

NOTE: If cold data is accessed (read/written) frequently, I/O to that file may suffer large latencies. In such scenarios, recall the whole volume or the corresponding files.

Recall of Tiered Data

Offloaded data is automatically recalled when a client performs a read or overwrite on the data in the cold-tier, or when a client performs an overwrite on the data in the warm-tier. The MAST Gateway fetches a copy of the data to allow the operations to succeed. You can also manually trigger a recall of:

- All volume data using the `maprcli` command or REST API.

  See Recalling a Volume to file system on page 1258 for more information.

- File using the `hadoop` command, `maprcli` command, REST API, (loopbacknfs or FUSE-based) POSIX client, or the NFS client.

  See Recalling a File to file system Using the CLI and REST API on page 1340 and Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1342 for more information.

Based on the expiration time period set at the volume level for recalled data, recalled data is:

- Offloaded again based on the rules if there are changes to the data.
- Purged when the compactor runs if there are no changes to the data.

For a cold tiering volume, explicitly recall the volume before running any analytics jobs.

For mirror volumes, when you recall tiered data, data from the tier is recalled into an associated cache-volume, which is created at the time of the creation of the tiering-enabled mirror volume. For all explicit recall of warm-tiered data and explicit and automatic recalls of cold-tiered data, the MAST Gateway recalls data into the associated cache-volume. The data in the cache-volume is "hot" in the cluster, or available for reads, for the duration of the expiry-period. The recalled data is purged by the compactor when the expiration time that is set at the volume level is reached or has passed.

If the recall fails, CLDB retries the operation after some time. See Retrying Failed Operation on page 1261 for more information.

Moving Data from Non-Tiered Volumes to Tier Enabled Volumes
Provides a synopsis of how to move data from non-tiered volumes to tier-enabled volumes.

Non-tiered volumes cannot be offloaded.

Use the following procedure to transfer data from a non-tiered volume to a fresh tiered volume, and then offload the data from the tiered volume.

If you are short on space, you can first break up large volumes into multiple small volumes.

You can then transfer one sub-volume at a time.

For example, assume that there are sub-volumes `/hugevolume/dir1`, `/hugevolume/dir2`, ..., `/hugevolume/dirN`. To transfer:

1. Create a new tiering enabled volume say `dir1`.
2. Mount it at `/tmp/dir1`.
3. Snapshot `/hugevolume/dir1`.
4. Use `distcp` to copy the snapshot to `/tmp/dir1`.
5. After the initial transfer, perhaps snapshot again and use rsync to sync the changes to `/tmp/dir1` to minimize downtime.
6. Delete `/hugevolume/dir1`.
7. Unmount the `dir1` volume and re-mount at `/hugevolume/dir1`.

8. Now `/hugevolume/dir1` will tier according to the schedule and rule specified when creating it in step 1.

9. Repeat the process for dir2 to dirN.

Data Compaction and Recall Criteria
The topic describes the criteria for MAST gateway to decide whether compaction is to be performed for a container (data container or namespace container).

Containers are of two types:

- Namespace containers
- Data Containers

Containers can be of two sizes:

- **Large containers**: Containers can be termed as large containers when the number of inodes in the container is greater than the value of the configuration variable, `mastgateway.offload.opt.largenuminodes`.
- **Non-large containers**: Containers can be termed as non-large containers when the number of inodes in the container is less than the value of the configuration variable, `mastgateway.offload.opt.largenuminodes`.

Compaction Criteria for Large Container

Compaction is carried out for large containers (namespace container/data container), where the size of garbage present in the container is greater than the garbage threshold. The garbage threshold is the value set for the configuration variable, `mastgateway.ctc.opt.largenuminodes.threshmb` (default value is 2 GB).

Compaction is skipped for large containers, where the garbage in the container is less than the garbage threshold.

Recall Expiry Criteria for Large Containers

If data has been recalled from a tier into a Data Fabric cluster, and the size of recalled data is greater than configured value for `mastgateway.recallexp.opt.largenuminodes.minpurgemb`, the compactor purges the qualified recalled data from the container.

If data has been recalled, and the size of recalled data is less than the configured value for `mastgateway.recallexp.opt.largenuminodes.minpurgemb` recall expiry is skipped and recalled data is retained on the container of the tiered volume.

Skip Compaction for Large Containers with Garbage Size Greater than Garbage Threshold

You might want to skip the scheduled compaction for a very large container, and run the compaction manually, at a convenient time.

For this purpose, set the configuration variable, `mastgateway.ctc.opt.largenuminodes.skipqualifiedctrs.enabled` (default value is 0), to true. For details on this configuration variable, refer to config on page 2096.

When `mastgateway.ctc.opt.largenuminodes.skipqualifiedctrs.enabled` is set to 1, large containers qualifying the threshold skip the compaction. CLDB raises the alarm, VOLUME_ALARM_COMPACTION_SKIPPED_LARGE_CONTAINER, when the compaction is skipped for a large namespace container qualifying the threshold.

When compaction is skipped in such a case, compaction can be forced to run on such qualified containers by running compaction manually using the `maprcli volume compact` command. Refer to Compaction Skipped Large Container Volume Alarm on page 3024 for the alarm details.

Compaction Criteria for Non-large Containers

Non-large containers are compacted, by default.

Recall Expiry Criteria for Non-large Containers

If the size of the recalled data in a container (`mastgateway.recallexp.opt.largenuminodes.minpurgemb`, default value is 2 GB) is greater than configured recall expiry min threshold (`mastgateway.recallexp.opt.minpurgemb`, default value is 8 MB), recall expiry occurs on the recalled data. The compactor purges the qualified recalled data from the tiered volume.

Refer to config on page 2096 for information about the configuration variables, `mastgateway.recallexp.opt.largenuminodes.minpurgemb` and `mastgateway.recallexp.opt.minpurgemb`.

Data Compaction
Describes how data is purged from a cluster.

When you release the space allocated to a volume on the Data Fabric cluster by deleting a file or snapshot, or by truncating a file, the Data Fabric tier compactor can be set up to run automatically or manually to release the space on the tier associated with the volume by deleting the corresponding stripes or objects from the tier. In addition, when you recall data, the compactor automatically purges the recalled data on the Data Fabric cluster if there are no changes to the data. By default, the compactor runs on an automatic internal schedule to determine if any deletion has happened on the Data Fabric cluster since it last ran, and if necessary, remove the corresponding stripelets or objects from the tier.

Data Fabric uses two settings (at the volume level) to determine when and how frequently to run the compactor:

- Overhead threshold — You can specify a percentage of offloaded data that must have been deleted to trigger the compaction operation. By default, the compactor performs the compaction operation only if at least 30% of the offloaded data is deleted.
- Compactor schedule — You can set up a custom schedule to run the compactor. By default, Data Fabric uses the Internal Automatic Scheduler (ID is 4), which is based on internal parameters, to run the compactor.

The compactor runs only when there are no other tiering operations running for the volume. If there are other tiering operations, such as offload or recall, running for the volume, the compactor does not run until the tiering operation completes. If a tiering operation is triggered while the compactor is running, the tiering operation will fail. You cannot trigger a volume-level tiering job when another job is running for the volume. You can trigger a file-level offload or recall operation when a volume level job is running and vice-versa.

Purging Recalled Data

When you recall data to the Data Fabric cluster explicitly (by running the `recall` command) or implicitly (by doing a read or an overwrite), the recalled data is purged by the compactor if there are no changes to the data and if the expiration time for recalled data has been reached or has passed. You can also manually run the compactor to force an immediate purge of recalled data. See Running the Compactor to Purge Recalled Data on the Data Fabric Cluster on page 1264 for more information.

Purging Stale Data

When you release space on the Data Fabric cluster by deleting or modifying data, the compactor purges the data on the tier also. Depending on whether file data is completely deleted or partially deleted on the Data Fabric cluster, the Data Fabric compactor processes purging of data on the tier.

Warm Tier	For warm tiered volumes, the Data Fabric compactor identifies corresponding objects (or stripes) on the tier and deletes entire objects first. After deleting entire objects, if there are partial objects to delete, the Data Fabric compactor identifies the objects (with partially deleted data) that can be coalesced, fetches them, creates new objects with combined data, updates the metadata in the DB tables, deletes the old objects from the tier, and offloads the new objects to the tier. The compactor handles partial deletions only after deleting entire objects and only if the size of the remaining data to delete exceeds the compaction threshold.
Cold Tier	For cold tiered volumes in the S3 environment, while entire objects can be easily deleted, modifications and partial deletions are not supported. For example, assume that data associated with a file is distributed across objects. When a file is deleted on the Data Fabric cluster, corresponding data on the S3 tier can be easily removed if the object in the S3 tier only contains data associated with the deleted file. On the other hand, if the object also contains data from other files, the object cannot be deleted, and S3 does not support changes to the object or partial deletion of the object. For partial deletions, the Data Fabric compactor identifies the objects (with partially deleted data) that can be coalesced, fetches them, creates new objects with combined data, updates the metadata in the DB tables, deletes the old objects from the tier, and offloads the new objects to the S3 tier. The compactor handles partial deletions only after deleting entire objects and only if the size of the remaining data to delete exceeds the compaction threshold.

You can manually trigger the compactor to purge the stale data on the tier. See Running the Compactor to Purge Stale Data on the Tier on page 1265 for more information.

Restoring a Volume From a Snapshot

Provides a synopsis of restoring a volume from a snapshot. Describes the implications, and the prerequisites.

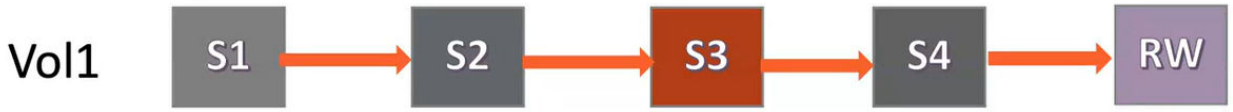
For an introduction to Snapshots, see Volumes, Snapshots, and Mirrors on page 495.

To create snapshots, see Creating Volume Snapshots on page 1270.

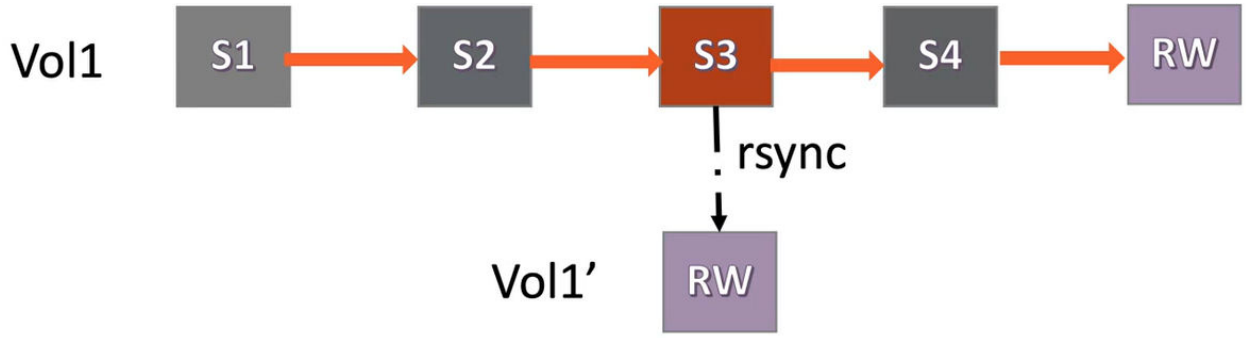
High Level Functionality

When files are accidentally deleted or data inside a volume is corrupted, you must manually restore older data from an earlier snapshot by creating a new volume and copying data from the snapshot.

For example, consider a volume with the following snapshots:



To restore from snapshot S3, you need to first create a new volume and then copy over data from snapshot S3, as shown:



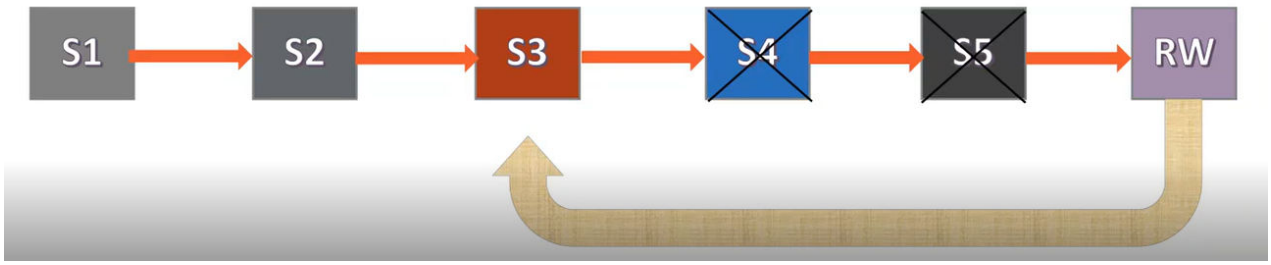
This process results in serious deficiencies such as:

- Being unable to meet the SLAs of restoring snapshots in under 10 minutes, because of the time taken to do the copying file by file.
- Data duplication and wasted space consumption, because snapshots after the restored snapshot, are retained (snapshot S4 in this example).

The snapshot restore functionality has the capability to restore an entire volume to a point-in-time snapshot. The snapshots taken prior to the one that has been restored to, are retained and snapshots taken after the one that has been restored to, are deleted. The data prior to the restored snapshot remains intact, and only the data newer to the restored snapshot is deleted.

For example, consider a volume with the following snapshots:

To restore from snapshot S3, first delete snapshots S4 and S5, as shown:



The snapshot S3 is then pointed over to the current RW volume.

This optimization speeds up the restore operation when compared to manually copying the data to a new volume.

last-updated: Jun 06, 2024

For another example, assume that volume `vol1` has a daily snapshot schedule and currently has 7 snapshots `ss1`, `ss2`, `ss3`, `ss4`, `ss5`, `ss6` and `ss7`. `ss1` is the oldest snapshot, while `ss7` is the most recent snapshot.

The snapshot restore functionality allows you to restore `vol1` to a snapshot, say `ss5`. After `vol1` is restored, snapshots `ss6`, and `ss7` are automatically deleted.

You can take additional snapshots on `vol1`, say snapshots `ss8`, `ss9` and `ss10`, and restore `vol1` to any earlier snapshot.

Salient Features of Snapshot Restore

- Is almost instantaneous
- Uses minimum or no network/disk IO
- Works across all volume types including tiering-enabled, RW and mirror volumes. Works with HPE Ezmeral DB tables without secondary indexes as well
- Uses ACID semantics (recovers on node reboots)
- Is parallel and distributed
- Permits access to older snapshots during operation
- Has zero down-time
- Gracefully handles timeouts, retries and failures
- Does not hinder normal user operations

Advantages of Snapshot Restore

Using the Snapshot Restore feature, you can:

- Quickly restore a volume if files get corrupted or accidentally deleted.
- Periodically add modifications to a snapshot's data and use it as a mirror volume to sync the current RW source when needed.

Considerations to Use Snapshot Restore

Restoring a volume from an earlier snapshot is a disruptive operation. Thousands of Hadoop applications may be running on the cluster at any given time, and are likely to be impacted. When restoring from an earlier snapshot, some recent data may be lost. The data-fabric cluster administrator must therefore consider the following implications, before restoring a snapshot.

- To ensure data consistency, by default, the volume restore operation is allowed only if the volume is unmounted, ensuring that no application is accessing any data in the volume. See Unmounting one or more Volumes on page 1218.

  You can override this behaviour by setting `cldb.snapshot.restore.on.volume.unmount.only` to `0`.

  To check the current value of this setting, run:

  ```
  /opt/mapr/bin/maprcli config load -json | grep cldb.snapshot.restore
  ```

Set this flag to `0` to perform the restore operation in a single step, without verifying whether the volume is unmounted or not. To set this flag to `0`, run:

```
/opt/mapr/bin/maprcli config save -values
'{"cldb.snapshot.restore.on.volume.unmount.only":"0"}' -json
```

You may encounter the following issues, if the volume is not unmounted:

- Stale (ESTALE) errors as files might get deleted, truncated or modified.
- Inconsistent or wrong results as subset of containers might not yet get restored.
- Client crashes due to the ongoing restore operation.

- In addition to files and directories, a volume **can** contain database tables, secondary indices for tables, and Kafka topics. If you are restoring a volume that contains one or more of these additional entities, you need to understand the following implications:
  - Tables and their associated secondary indices may be out of sync after a restore from snapshot operation. OJAI or Drill queries that retrieve data from tables (that reside on the restored volume) do not use secondary indices.

    Therefore, queries use full table scan, and may take longer to complete. To leverage secondary indices during query execution, the data-fabric cluster administrator must re-create the secondary indices that reside on the volume. Refer to Re-enabling a Volume for Secondary Indices and Replication after Restoring From a Snapshot on page 529 for details.
  - Tables (across volumes or cluster) may have been setup with multi master replication.

    When a volume is restored from an earlier snapshot, the replication relationship is broken between the tables.

    The data-fabric cluster administrator must re-establish the replication relationship. Refer to Re-enabling a Volume for Secondary Indices and Replication after Restoring From a Snapshot on page 529 for details.
  - Topics (across clusters) may have been setup with global replication.

    When a volume is restored from an earlier snapshot, the replication relationship is broken between the topics.

    The data-fabric cluster administrator must re-establish the replication relationship. Refer to Re-enabling a Volume for Secondary Indices and Replication after Restoring From a Snapshot on page 529 for details.
  - For change data capture, the replication to the destination data-fabric ES stream topic is stopped. However, the stream is preserved.

    The data-fabric cluster administrator must create a new data-fabric Table to ES topic relationship after the Snapshot Restore operation is complete.
- The volume level *Access Control Expression (ACE)*s are restored to the values which were set at the time of creation of snapshot to which the volume is being restored.

  The file level tagging done for Policy Based Security (PBS) is reverted to the point of time of the snapshot to which the volume is being restored.
- Only one snapshot restore operation can be in progress at a time for a given volume. Use the `snapshot restorestatus` command to check the status of the snapshot restore operation.

  If a second snapshot restore operation is initiated before the first operation is complete, the second snapshot restore operation is queued.

last-updated: Jun 06, 2024

- You need to have `FullControl` access on the volume to perform the snapshot restore operation. Refer to Volume ACLs for information on access controls.
- Snapshot restore functionality can be performed only if the following conditions are met:
  - Snapshots should be at a minimum of version 6.2 to be restored, which means that you need to create a snapshot after installing data-fabric version 6.2.
  - Volumes must be of type `Standard Volume (rw)` or `Standard Mirror (mirror)` (which can be created from data-fabric version 4.0.2 onwards). For a complete list of volume types, refer Types of Volumes.

    If volumes are not of the type specified, run the upgrade utility on older volumes, and then use the snapshot restore functionality. For details on the upgrade utility, refer maprcli volume upgradeformat.
  - Operations such as mirroring, offload, and tiering should not be in progress on the volume where the snapshot restore is in progress. These operations fail if performed when the snapshot operation is in progress.
  - The volume being considered for the snapshot operation should not be an internal volume. Snapshot restore operation is allowed only on standard, tiering, and mirror volumes.
- The Snapshot Restore operation takes precedence over all other operations. For example, if a tiering operation is in progress, when a Snapshot Restore operation is requested, the tiering operation is paused, and the Snapshot Restore operation is performed. The tiering operation is resumed after the Snapshot Restore operation is complete.
- When restoring a snapshot that does not contain child volumes over a volume that does contain child volumes, the child volumes are preserved, but the volume links are not preserved. You need to relink the child volumes once the Snapshot Restore operation is complete.
- At a container level:
  - Any ongoing resync operation is aborted.
  - The Snapshot Restore operation is optimized to skip if there are no new versions in RW when compared to the snapshot.

Re-enabling a Volume for Secondary Indices and Replication after Restoring From a Snapshot

Restoring a volume from an earlier snapshot, permanently stops all operations such as updating secondary indices, replication between source and destination tables, until you configure a new relationship. Administrators need to note the following implications of restoring a volume from a snapshot.

- Volume is restored to a point of snapshot.
- Ongoing operations of Secondary Indices and Table replication fail

To re-enable a volume for secondary indices and replication, administrators must delete existing relationships, and recreate them.

Effects of Snapshot Restore

On Object Tiering	• All tiering operations continue to work smoothly after Snapshot Restore is complete. • Offloaded data from newer snapshots are purged as part of compaction.

On Mirrors	• Data on the destination volume is purged in a subsequent resync operation if Snapshot Restore occurs on the source volume. • The destination volume always reconciles to the source volume on a subsequent resync operation after every Snapshot Restore operation. You can preserve the changes by taking a snapshot on the mirror.
On Table Replication and Secondary Indices	• Snapshot Restore on the source volume makes replicas and secondary indices go out of sync. • All operations from source to replica or secondary indices are permanently stopped. • Administrators must delete existing relationships and reconfigure them, • Table replications fail and the table replication errors alarm is raised as expected.

Enabling Snapshot Restore on an Upgraded Cluster

The Snapshot Restore operation is enabled by default on a new data-fabric version 6.2 cluster.

However, when upgrading a cluster from an older data-fabric version to data-fabric version 6.2, you need to enable the Snapshot Restore feature with the following command:

```
maprcli cluster feature enable -name
mfs.feature.snapshot.restore.support -force true
```

Related Alarms

The Snapshot Restore operation is retried indefinitely till it succeeds. However, the `VOLUME_ALARM_SNAPRESTORE_MAXRETRIES_EXCEEDED` alarm is raised if the snapshot restore operation failed and has been retried for more than five (5) times for a single container.

For more information, see VOLUME_ALARM_SNAPRESTORE_MAXRETRIES_EXCEEDED.

Related Log Files

Administrators can view the following events and logs for troubleshooting.

- Start and end of volume level snapshot restore (*cldb.log*)
- Removal of intermediate snapshots (*cldb.log*)
- Any failures or retries (both *cldb.log* and *mfs.log*)
- Start and end of container level snapshot restore (*mfs.log*)
- Container level operation already in progress (*mfs.log*)
- Snapshot and RW are on the same version and no Snapshot Restore operation is needed (*mfs.log*)
- Message if container level operation takes longer than the threshold time at MFS (*mfs.log*)

last-updated: Jun 06, 2024

Control System

Refer to Restoring Volume Snapshots Using the Control System on page 1276 to restore snapshots using the Control System.

CLI Commands

Displays information about the specified volume. For JSON formatted output, use the `-json` option when running the command.

Tuning Last Access Time

Provides an overview of the Last Access Time feature and its tuning.

What is Last Access Time?

Last Access Time (`atime`) is *file* metadata that is updated whenever a file is read. You can use `atime` for file management and governance decisions such as:

- Deleting files that have not been accessed for a while
- Tiering files (to warm or cold tier) that have not been accessed for a while
- Migrating files that have not been accessed frequently
- Purging files that have not been accessed for a time

Considerations When Enabling Last Access Time

- `atime` update can be enabled only on Standard/Erasure Coding/Object Tiering volumes. It cannot be enabled on mirrored volumes. If you convert the mirror volume to a Read/Write volume, `atime` is disabled by default. You can enable `atime` with the volume modify command.
- `atime` is applicable only for files. The `atime` of directories is NEVER updated.

last-updated: Jun 06, 2024

- While the `read` operation is audited, the `atime` operation is not audited as it is an internal operation.
- The volume offload operation does not update `atime` but a file read from a backend/frontend volume updates `atime`.
- The file recall operation also updates `atime`.
- The file read operation on the EC/Tiered backend volume updates `atime` on the frontend volume.
- At the time of mirroring, the `atime` update frequency (`atimeUpdateInterval`) is propagated from the source volume to the mirror volume. However, any subsequent changes made to this frequency on the source volume, are not automatically propagated to the mirror volume.
- The time when you enabled `atime` updates (`atimeTrackingStartTime`) is updated to the current time in the following cases:
  - Just started tracking `atime`, which means that the `atime` update frequency was previously zero
  - If the value of `atime` update frequency is decreased
  - If the value of `atime` update frequency is increased and `atime` has not been tracked for the duration of the new frequency value

Exceptions to Last Access Time Updates
`atime` is never updated when:

- Only the meta data of the file is being read
- The file is read from the client cache
- The file is read from a snapshot
- The `atimeUpdateInterval` has not been exceeded:

  For example, assume that for a volume the `atimeUpdateInterval` is set to 1 day. A file is created at 11AM and the file is read at 10:55AM the next day. If the read finishes at 10:58AM, `atime` will not be updated as the `atimeUpdateInterval` did not cross a day.

  For another example, assume that for a volume the `atimeUpdateInterval` is set to 1day. A file is created at 11AM and the file is read at 10:55AM the next day. If the read completes at 11:10AM, the `atime` will still not be updated though the read completed after 24 hours, because read was triggered at 10:55AM. `atime` will only be updated when the file is next read.

Upgrade Considerations

When a cluster is upgraded to HPE Ezmeral Data Fabric 6.2, `atime` is not enabled on the old volumes. You need to enable `atime` manually using the volume modify command.

When a cluster along with a few clients are upgraded to HPE Ezmeral Data Fabric 6.2, while the remaining clients are not upgraded, the older clients can not update `atime` on files. Only the upgraded clients can trigger an `atime` update. However, the older clients can see the updated `atime` value (updated by the upgraded clients).

Enabling the Last Access Time Feature

The Last Access Time feature is not automatically enabled irrespective of whether you perform a fresh installation or an upgrade. To enable and activate the Last Access Time feature, run:

```
maprcli cluster feature enable -name mfs.feature.update.atime
```

Enabling Last Access Time on Volumes

For performance reasons, the `atime` feature is disabled on volumes by default. You can enable `atime` updates at the volume level when creating or modifying volumes.

To set the frequency of `atime` updates, use the `atimeUpdateInterval` parameter when creating or modifying volumes. ***The value is in days***. The default value of `0` indicates that `atime` is never updated.

For example, a value of **2** indicates that the `atime` is updated *Once* every **2** days (48 hours) with the first read on the file. `atime` will not be updated on further reads on the file till the 48 hours have passed.

Viewing the Last Access Time Value

To view the `atime` value of a specific volume, use the volume info on page 2628 command.

Last Access Time Example

The following command creates a volume and sets the `atime` to 2 days:

```
maprcli volume create -name stdvol1 -path /stdvol1 -atimeUpdateInterval 2d
```

To view the Last Access Time frequency, run:

```
maprcli volume info -name stdvol1 -json | grep atime
            "atimeUpdateInterval":"2",
            "atimeTrackingStartTime":"2021-03-14 22:45:25 GMT-0700",
```

Here, the frequency is set to 2 days. The time when `atime` was enabled on the volume is also displayed.

Multitenancy on File System

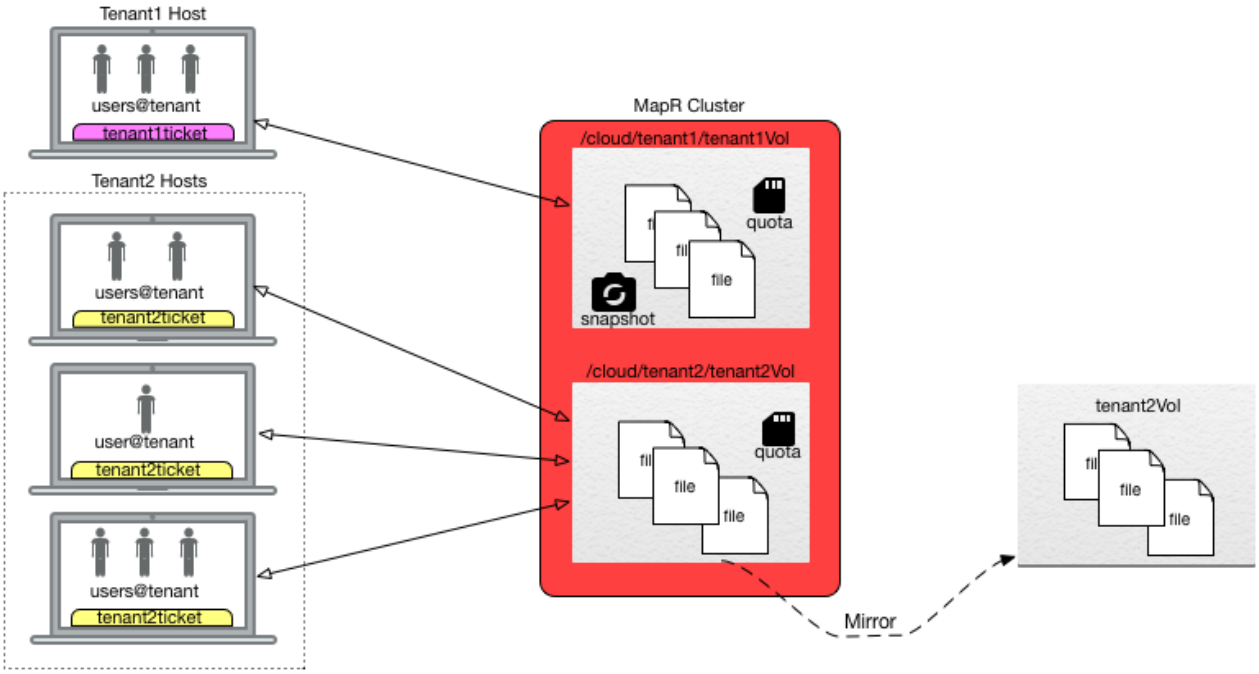
Describes what multitenancy is and how tenant data is kept private for each tenant.

Multitenancy architecture enables a single instance of a software to be provisioned for multiple customers or users, who are referred to as tenants. Each tenant, or group of users, has a specific share of the instance including access to its data, configuration, and access management. On the cloud, this enables a software-as-a-service (SaaS) provider to provision the software for multiple tenants.

The file system multitenancy architecture enables you to create and restrict a data-fabric volume (referred to as a share) to a subset of client nodes. By doing this, you can isolate users or hosts (referred to as tenants). Isolation enables you to set policies, quotas, and access privileges for specific tenants. You can provision the data-fabric file system on the cloud to various tenants, with each tenant owning its own copy of storage space, users, data security, administration, and so on.

In a multitenant environment, tenants operate in their own provisioned spaces, unaware of other tenants on the cluster. Tenants have exclusive access to data in their environment only.

For example, the following diagram depicts a cluster provisioned on the cloud for two tenants, Tenant1 and Tenant2. The cluster has two separate volumes, mounted at directories `/cloud/tenant1`, and `/cloud/tenant2`. Each tenant volume contains file data created and managed by tenant users on the tenant host. Each tenant maps to a different volume and therefore, data in each volume can have different policies, disk-usage quotas, snapshot and mirroring schedules. By using appropriate tenant tickets, access to data in these volumes is restricted only to users on the appropriate tenant hosts, and eliminates the possibility of a user from Tenant2 accessing data on the Tenant1 volume, and vice versa.



You can access tenant shares using loopbacknfs and FUSE-based POSIX clients only. After you mount the tenant volume for access using (FUSE-based and loopbacknfs) POSIX clients, you can perform operations using standard Linux commands.

Setting Up a Tenant
Lists the process for setting up a tenant.

About this task

To set up a tenant:

Procedure

1. On the server:
   a) Log in to the cluster as the administrator and create a user (for the tenant admin) on the cluster.
   The user (for the tenant) must exist on all the cluster nodes with the same UID and GID or all the cluster nodes must connect to the same LDAP server. See Managing Users and Groups on page 1026 for more information.

   NOTE: The superuser for a tenant, referred to as tenant admin, must have a UID of `0` on the tenant host(s) to access the tenant volume (only) and all data in the tenant volume. Although the tenant admin has the same UID as the HPE Ezmeral Data Fabric superuser, the tenant admin does not have the same level of access and administration privileges as the HPE Ezmeral Data Fabric superuser because the tenant admin's access is based on the tenant ticket and is restricted to the tenant volume.

last-updated: Jun 06, 2024

b) Generate a tenant ticket for the user.
   For more information, see Generating a Ticket for a Tenant on page 1836.

c) Copy the ticket to the tenant host and grant the tenant administrator read access to the ticket.

d) Create a volume (or share) on the cluster for the tenant.
   For more information, see Creating a Volume for a Tenant on page 1191.

2. On the tenant instance:
   a) Log in as tenant administrator (`root`).

   b) Mount the filesystem using loopbacknfs or the FUSE-based POSIX client.
      For more information, see Mounting a Tenant Volume on page 1219.

      NOTE: While starting the POSIX client, use the tenant ticket configured in step 1.

   c) As tenant admin, grant access to users by setting permissions to data using either file ACEs or mode bits.
      For more information, see Enabling and Restricting Access to Tenant Volume and Data on page 1243.

Provisioning File System for Multiple Tenants - Sample Workflow
Illustrates a sample workflow for provisioning the data-fabric file system to multiple clients.

About this task

For example, suppose there are two tenants Tenant1 and Tenant2. The following steps show the workflow for provisioning the two tenants:

Procedure

1. The cluster administrator creates two users, Tenant1 and Tenant2, on the data-fabric cluster and creates volumes (or shares) on the cluster for the two tenants.
   For example, to create volumes on the cluster:

```
$ /opt/mapr/bin/maprcli volume create -name tenant1Vol -path /
tenant1Enoke -tenantuser Tenant1
$ /opt/mapr/bin/maprcli volume create -name tenant2Vol -path /
tenant2Enoke -tenantuser Tenant2
```

2. The cluster administrator generates tickets for the users, copies the tickets to the tenant servers (tenant1Host and tenant2Host), and grants the tenant admins (tenant1Admin and tenant2Admin) read access to the ticket.
   For example, to:

   - Generate ticket for the users:

```
$ maprlogin generateticket -type tenant -cluster myCluster -user
tenant1 -out /tmp/tenant_Tenant1_ticket.txt
$ maprlogin generateticket -type tenant -cluster myCluster -user
tenant2 -out /tmp/tenant_Tenant2_ticket.txt
```

- Copy tickets to appropriate tenant hosts:

```
$ scp /tmp/tenant_Tenant1_ticket.txt
tenant1Admin@tenant1Host:~tenant1Admin/
$ scp /tmp/tenant_Tenant2_ticket.txt
tenant2Admin@tenant2Host:~tenant2Admin/
```

3. The tenant administrators log into their respective hosts and mount their shares by starting the client. For example, to start the:

FUSE-based POSIX client

a. Update the following parameters in the `fuse.conf` file:

`fuse.ticketfile.location`	For: • Tenant1, `tenant1Admi tenant_Tenant1_tic` • Tenant2, `tenant2Admi tenant_Tenant2_tic`
`fuse.mount.point`	For: • Tenant1, `/tenant1Eno` • Tenant2, `/tenant2Eno`
`fuse.export`	For: • Tenant1, `/tenant1Eno tenant1Vol` • Tenant2, `/tenant2Eno tenant2Vol`

b. Run the following command to start the service:

```
$ service mapr-posix-client-*
start
```

loopbacknfs POSIX client

a. Update the tenant ticket file location in `/etc/loopbacknfs/initscripts/mapr-loopbacknfs` file.

b. Run the following command to start the service:

```
$ service mapr-loopbacknfs start
```

4. The tenant administrators can grant access to users within their tenant namespace by modifying data access using *ACE*s.

Direct Access NFS

Describes the Data Fabric direct access file system.

The Data Fabric direct-access file system enables real-time read/write data flows using the Network File System (NFS) protocol. Standard applications and tools can directly access the file system storage layer using NFS. Legacy systems can access data, and traditional file I/O operations work as expected on a

last-updated: Jun 06, 2024

conventional UNIX file system. A remote client can easily mount a Data Fabric cluster over NFS to move data to and from the cluster. Application servers can write log files and other data directly to the Data Fabric cluster storage layer instead of caching the data on an external direct or network-attached storage.

You can mount a Data Fabric cluster directly through a network file system (NFS) from a Linux or a Mac client. When you mount a Data Fabric cluster, applications can read and write data directly into the cluster with standard tools, applications, and scripts. Data Fabric enables direct file modification and multiple concurrent reads and writes with POSIX semantics. For example, you can run a MapReduce application that outputs to a CSV file, and then import the CSV file directly into SQL through NFS.

Data Fabric exports each cluster as the directory `/mapr/<cluster name>`. If you create a mount point with the local path `/mapr`, Hadoop FS paths and NFS paths to the cluster will be the same. This makes it easy to work on the same files through NFS and Hadoop. In a multi-cluster setting, the clusters share a single namespace. You can see them all by mounting the top-level `/mapr` directory.

POSIX Clients

Describes the usage of Data Fabric POSIX clients.

The Data Fabric file system supports direct and secure access to data using loopback NFS or FUSE-based POSIX clients.

The loopbacknfs POSIX client allows app servers, web servers, and other client nodes and apps to read and write data directly and securely to a Data Fabric cluster, with transmitted data compressed in both directions. The Data Fabric single-user mapr-loopbacknfs licenses gives secure access to one or more clusters, which allows native client applications to run securely on cluster data.

The FUSE-based POSIX basic and platinum clients run as a user space process to connect to one or more Data Fabric clusters and allow app servers, web servers, and applications to read and write data directly and securely to the Data Fabric clusters like a Linux file system. Each client implies a specific Data Fabric file system throughput optimization of *n/G* per second.

Both loopbacknfs and FUSE-based POSIX clients can be installed on supported Linux and Ubuntu distributions and require direct network access to all Data Fabric cluster nodes. They connect to the Data Fabric cluster directly (no NFS gateway) to read and write data securely.

Copying Data from Apache Hadoop to a Data Fabric Cluster

Describes the procedure to copy data from an Apache Hadoop to a Data Fabric cluster.

You can use the hdfs protocol, webhdfs protocol, or NFS for the HPE Ezmeral Data Fabric to copy data from Apache Hadoop to a Data Fabric cluster.

The following table describes these methods:

Method	Description
hdfs:// protocol	Use the `hadoop distcp` command with the `hdfs://` protocol to copy data from an HDFS cluster into a Data Fabric cluster if the HDFS cluster and the Data Fabric cluster use the same RPC protocol version. For all other scenarios, use the `webhdfs://` protocol or NFS for the HPE Ezmeral Data Fabric gateway to copy data to a Data Fabric cluster.
webhdfs:// protocol	Use the `hadoop distcp` command with the `webhdfs://` protocol to copy data from an HDFS cluster into a Data Fabric cluster.
NFS	Mount a Data Fabric cluster to an HDFS cluster using NFS for the HPE Ezmeral Data Fabric mount. Then use the `hadoop distcp` command to copy data between the two clusters.

About the HPE Ezmeral Data Fabric Persistent Application Client Container (PACC)

This container gives you seamless access to HPE Ezmeral Data Fabric cluster services.

This topic introduces the Data Fabric Persistent Application Client Container (PACC), including its function, benefits, components, and applications.

The Data Fabric (PACC) is a Docker-based container image that includes a container-optimized Data Fabric client. The PACC provides seamless access to Data Fabric Converged Data Platform services, including the file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Streams. The PACC makes it fast and easy to run containerized applications that access data in the Data Fabric.

FUSE POSIX Client for File-Based Applications

To support persistent, file-based applications, the Data Fabric PACC includes a FUSE-Based POSIX Client, optimized for containers, that allows app servers, web servers, and other applications to read and write data directly to the Data Fabric file system. If your cluster has a Data Fabric POSIX Client for Containers license, the PACC can connect with Data Fabric 5.1 or later clusters.

Traditionally, all file data created by containers is lost when a container is terminated, which can happen during an application or hardware failure. By using the POSIX client within the PACC, applications can reliably persist file data directly to the Data Fabric file system, where it can be re-attached to the container in the event of application or hardware failures.

Support for Microservice Applications

To support stateful microservice applications, the PACC also contains a container-optimized version of the Data Fabric client, which includes libraries for accessing HPE Ezmeral Data Fabric Database and HPE Ezmeral Data Fabric Streams.

Secure Access

The Data Fabric PACC is designed to provide access to a secure cluster for all Data Fabric Converged Platform data services. Users can pass a Data Fabric ticket file into the container at runtime. All data access, whether to the file system, HPE Ezmeral Data Fabric Database, or HPE Ezmeral Data Fabric Streams, is authorized and audited according to the authenticated identity of the ticket file.

PACC Contents

The PACC includes the following components:

- HPE Ezmeral Data Fabric Database Client[1]

- HPE Ezmeral Data Fabric Streams Client
- POSIX Client for Containers
- Hadoop Client with YARN[2]
- HBase Client[2]
- Hive Client[2]
- Pig Client[2]
- Python
- Java
- Curl, Wget, Openssl, NFS-common, etc

[1]The HPE Ezmeral Data Fabric Database client includes support for HPE Ezmeral Data Fabric Database binary tables and HPE Ezmeral Data Fabric Database JSON tables.

[2]Included only if specified and only in Data Fabric PACC images created using `mapr-setup.sh`.

Using the PACC

To get started with the Data Fabric PACC, you can take advantage of pre-built Docker images or create your own images to include site-specific environmental parameters:

To . . .	See this topic
See a list of the data-fabric pre-built Docker images	Extending a PACC on page 439
Create your own images containing data-fabric software	Creating a PACC Image Using mapr-setup.sh on page 440

HPE Ezmeral Data Fabric Control System

Provides a brief description of the HPE Ezmeral Data Fabric Control System.

The HPE Ezmeral Data Fabric Control System provides a graphical control panel for cluster administration with all the functionality of the command-line or REST APIs. The Control System provides job monitoring metrics and helps you troubleshoot issues, such as which jobs required the most memory in a given week, or which events caused job and task failures.

The Control System provides various views, which you can use to configure and monitor your cluster:

Overview

The Control System **Overview** page provides a summary of information about the cluster including a cluster heat map that displays the health of each node organized by service, an alarms summary, cluster utilization that shows the CPU, memory, and disk space usage, the number of available, unavailable, and under replicated volumes, and MapReduce applications.

ATTENTION: This page is not available when running on a Kubernetes cluster.

Services

The Control System **Services** page provides a summary of the services running across the cluster.

Nodes

The Control System **Nodes** page provides a summary of information about the nodes on the cluster including a heat map that displays the health of each node,

	resource utilization that shows the CPU and memory usage, all active alarms, and a list of all the nodes on the cluster with links that provide shortcuts to more detailed information about the node. **ATTENTION:** This page is not available when running on a Kubernetes cluster.
Data	The Control System **Data** drop-down menu contains links to pages that provide summary of information about volumes, tables, and streams. **ATTENTION:** This page is not available when running on a Kubernetes cluster.
Admin	The Control System **Admin** drop-down menu contains links to pages for user and cluster management tasks such as setting up permissions, quotas, and email settings for users, enabling cluster-level and data auditing, configuring balancer settings, and adding licenses.

NOTE: During installation using the Installer, you can configure metrics and logging using settings on the Monitoring page of the Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the panes on the Control System.

URL Sharing Feature

The Control System supports URL Sharing. As one uses filters and sort column information, the URL records these filters. This URL can then be shared with other users who can then login and view the filtered information.

NOTE:

- Filters will be preserved if one logs in as the same user within the current session.
- Filters will not be preserved if one logs in as a different user within the current session.
- URL can be shared with any valid user and can be opened in any browser, using valid user credentials.

URL Sharing works on the Volumes page, Security Policies page, Nodes page, and the Snapshots tab both in the Volumes page and the Volume Details page.

Using HPE Ezmeral Data Fabric Monitoring (Spyglass Initiative)

HPE Ezmeral Data Fabric Monitoring (part of the Spyglass initiative) provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications.

Metric Monitoring

Administrators can monitor the current status of the cluster and anticipate future cluster requirements with dashboards. For example, you can use metrics dashboards to visualize the following:

last-updated: Jun 06, 2024

Storage Utilization	Use metrics dashboards to monitor storage trends. For example, you can compare the volume of file system usage at different times to the file system capacity and then allocate resources to the file system accordingly.
Node Utilization	Use metrics dashboards to check for node overload. For example, if the CPU usage is high on a few nodes, you may want to distribute the load across more nodes for better performance and efficiency.
HPE Ezmeral Data Fabric Database Operational Trends	Use metrics dashboards to display historical trends for HPE Ezmeral Data Fabric Database operations. For example, if a user reports HPE Ezmeral Data Fabric Database slowness, the historical trends associated with row scans, get, and put operations can be used to identify the node(s) on which the performance degradation occurs.

Log Monitoring

Administrators can use dashboards to visualize, search, and review logs when troubleshooting issues. For example, you can use log dashboards to troubleshoot the following issues:

Service Failures	When metrics indicate that one or more services are down, use log dashboards to check the logs for each failed service and drill-down to each associated node.
Application Failures	When an application or job fails, use log dashboard to identify possible bottlenecks. For example, you can search the logs for a given application ID across all the nodes in the cluster.
file system Performance	When users experience file system or NFS for the HPE Ezmeral Data Fabric slowness, use log dashboards to search the HPE Ezmeral Data Fabric file system logs for service errors or application issues.

HPE Ezmeral Data Fabric Object Store

The HPE Ezmeral Data Fabric Object Store is a native object storage solution that efficiently stores objects and metadata for optimized access.

You can deploy Object Store on-premises, on edge, or in the cloud and access data through multiple protocols, including the native S3 API, S3 Select, and mc, s3cmd, and aws CLI commands.

No limit on the number or size of buckets and objects used with Object Store exists. Data is secured through the following mechanisms.

Authentication	Users and applications authenticate to Object Store through S3 keys (accessKey/secretKey).
Authorization	Object Store authorizes access to buckets and objects through AWS S3-compliant resource and user policies.

last-updated: Jun 06, 2024

Wire-level encryption	Object Store uses HTTPS. Object Store leverages the patented HPE Ezmeral Data Fabric filesystem capabilities that protect data and make object storage reliable and scalable. This capability includes snapshots, mirroring, replication, global namespace, data tiering, and erasure coding. In addition to the filesystem features, Object Store provides:
Object Store UI	Administrators can manage accounts, buckets, objects, access policies, and users through a simple, intuitive interface.
Multi-part uploads	The ability to upload a large object as a set of contiguous parts. Each part is uploaded independently, in any order. Multi-part uploads are useful for objects greater than 100 MB.
WORM (Write Once Read Many)	When the Object Lock feature is enabled (using the CLI or UI), write operations that would normally overwrite existing objects result in the creation of new versions of that object in the same bucket.
Load balancing	Object Store supports: • DNS and VIP-based load balancing • IP-based load balancing Multiple S3 gateways can serve one bucket, and any S3 gateway can serve any bucket.
Accounts	Like AWS accounts, accounts in Object Store are the administrative units that own buckets, policies, and users.

Use Cases

Some potential Object Store use cases include:

- Archive data and build on-premises applications, or migrate to cloud-native applications.
- Store media for operational use; reduce costs of storing globally distributed media, such as music, video, and images.
- Run analytics on data with tools like Apache Spark, Apache Drill, Presto, and S3 Select to gain valuable insights into customers, operations, or markets.
- Maintain Spark Delta Lake time travel information. You can time travel to see different versions of the data when Object Store is configured as a data lake for Spark Delta Lake.
- Store ML model data and share the ML models in real-time with downstream applications.
- Publish S3 events to HPE Ezmeral Data Fabric Streams.

Object Store vs S3 Gateway

The following table compares the HPE Ezmeral Data Fabric Object Store to the S3 Gateway that was previously supported (EEP 6.0 – EEP 8.0):

HPE Ezmeral Data Fabric Object Store	S3 Gateway Ecosystem Component

last-updated: Jun 06, 2024

Bucket namespaces (list of objects in a bucket) and object metadata are stored in database tables.	Bucket namespaces and metadata are stored as files in a directory.
Object size determines how objects are stored for efficiency and optimized performance.	Objects are all stored as files regardless of size.
Provides simultaneous bucket access from multiple cluster nodes.	Storage restricts bucket access to one cluster node at a time.
Introduces the AWS account concept for bucket ownership, access control, and usage show back.	No concept of account.
Object Store UI is included in the HPE Ezmeral Data Fabric Management Control System UI.	Object storage UI is within the MinIO UI.

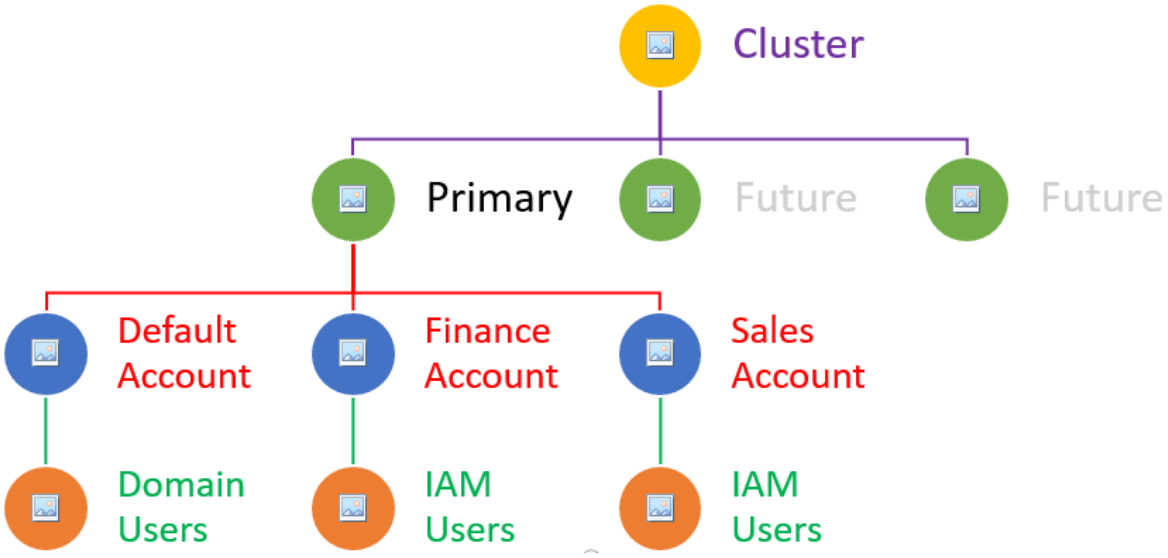
Known Issues and Limitations on page 629
Lists known issues and limitations in HPE Ezmeral Data Fabric Object Store.

Entities and Resources

Describes HPE Ezmeral Data Fabric Object Store entities, including domain, accounts, and resources (buckets, users, and access policies).

An Object Store cluster has a domain, accounts, buckets, users, and access policies associated with it. Installing Object Store in a cluster provides a *primary* domain and a *default* account.

The following image shows the hierarchy of entities in an Object Store cluster.



The following sections describe the entities in an Object Store cluster and provide links to additional information.

Primary Domain

- Management entity for accounts and users.

last-updated: Jun 06, 2024

- Tracks the number of users in the domain, the amount of disk space used by the domain, number of buckets in each of the accounts, total number of accounts in the domain, and the number of disabled accounts.
- Currently, Object Store only supports the primary domain. You cannot create additional domains.

Related information:

- s3domain info on page 2405
- Display Domain Information on page 603

Accounts

A unique administrative unit that owns buckets, policies, and users. Administrators control access to resources through access policies.

- Default Account:
  - Exists by default when Object Store is installed.
  - Account for domain users and groups only.
  - You cannot create IAM users and groups in the *default* account.
  - You can add AD/LDAP users/groups (domain users) to the account.
  - Applications can access buckets in the default account if they are granted permission.
- Account Creation:
  - Any user with FC permission can create accounts. The account administrator is configured at the time of account creation by indicating the LDAP username to be designated as the account `root`. Otherwise, defaults to the cluster administrator.
  - Account administrators can create resources in that account. Users in the non-default account are called as IAM users or service account. Applications can use these service accounts credentials to access objects in specific buckets.

    NOTE: If you do not specify an account administrator, then the `mapr` user becomes the administrator for that account.

last-updated: Jun 06, 2024

Buckets	Buckets are cloud storage resources that store objects. Objects are unstructured data, such as video and audio files, web pages, and photos. Objects include metadata and a globally unique identifier used to quickly locate an object regardless of where the object is stored in Object Store. To control access to buckets and objects, you apply an access policy on a bucket. The access policy defines who can access the bucket and the objects in it. Enable versioning on a bucket to provides the ability to restore buckets. If you enable the Object Lock feature for a bucket, versioning is automatically enabled. When the Object Lock feature is enabled, write operations that would normally overwrite an existing object result in the creation of a new version of that object in the same bucket. Enable Object Lock from the CLI or Object Store UI. Related information: • Create Buckets on page 615 • Modify Buckets on page 616 • List Buckets on page 617 • Display Bucket Information on page 617 • View Bucket Metrics on page 617 • Delete Buckets on page 618 • Object Lock on page 622 • Administering Account Resources on page 578
Domain Users/Groups	• Cluster security principals are authenticated through AD/LDAP. This authentication can be a corporate-wide AD/LDAP. No requirement exists for the co-location of AD/LDAP on Data Fabric servers. The only requirement is that the AD/LDAP service must be accessible from Data Fabric. • Add domain users to the domain AD/LDAP. • Only domain users can log in to the Object Store UI with their domain username and password. Other users and applications (IAM users/groups) must have S3 access keys (accessKey and secretKey) to access the cluster from REST calls.

IAM Users/Groups	• Identity and Access Management (IAM) users are entities that represent users and applications that interact with Object Store.
	• IAM groups are collections of IAM users. User groups let you specify permissions for multiple users, simplifying user management.
	  • An IAM group can contain many IAM users.
	  • An IAM user can belong to multiple IAM groups.

last-updated: Jun 06, 2024

    - You cannot nest IAM groups. An IAM group can only contain users. IAM groups cannot contain other user groups.
    - No default IAM group that automatically includes all users in the Object Store account exists. You can create one and assign each new user to it.
- Only account administrators can create IAM users/groups. Domain users and IAM users (local to an account) can create IAM users and groups if permitted to do so.
- IAM users need access keys (accessKey and a secretKey) to make programmatic calls to Object Store.

Provides information to help get you started with HPE Ezmeral Data Fabric Object Store.

Access Policies on page 546
Describes access policies and provides example policies. Also describes how Object Store evaluates access requests based on settings in access policies.

Access Policies

Describes access policies and provides example policies. Also describes how Object Store evaluates access requests based on settings in access policies.

About Access Policies

Access policies stipulate which Object Store resources users can access. You can create access policies and apply them to accounts, buckets, and users.

Policies applied to accounts and buckets are referred to as *resource-based policies*. Those applied policies applied to users are referred to as *user policies*. Object Store accepts access policies in JSON format. Typically, an account administrator applies policies; however, given the proper permissions, domain and IAM users can also apply policies.

last-updated: Jun 06, 2024

Bucket Policy

You can specify bucket policies when you create a bucket or you can update the bucket policy using the mc policy set command, for example:

```
/opt/mapr/bin/mc policy set-json
bucketpolicy.json alias/bucket
```

When you create or modify a bucket, you can apply a bucket policy. A bucket policy specifies domain users and the operations they can perform on buckets. Bucket policies override the default policy inherited from the account. You create a bucket policy in a JSON file and then associate the file with a bucket.

The following example bucket policy grants anonymous read permission on all objects in a bucket. The bucket policy has one statement, which allows the `s3:GetObject` action (read permission) on objects in a bucket named `sales`. By specifying the `principal` with a wild card (*), the policy grants anonymous access, and should be used carefully. For example, the following bucket policy would make objects publicly accessible.

```
{
    "Version":"2012-10-17",
    "Statement": [
        {

"Sid":"GrantAnonymousReadPermissions",
            "Effect":"Allow",
            "Principal": "*",
            "Action":["s3:GetObject"],
            "Resource":
["arn:aws:s3:::awssales/*"]
        }
    ]
}
```

The following policy allows all users in *group1* to get, put, and delete objects, and list the bucket contents. The `${bucket}` keyword is a placeholder that the system automatically replaces with the bucket name.

```
{

    "Version": "2012-10-17",
    "Id": "PolicyContent1",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal":
"arn:primary:default:group:group1",
            "Action":
["s3:GetObject", "s3:PutObject",
"s3:DeleteObject"],
            "Resource":
"arn:aws:s3:::${bucket}/*"
        },
        {
            "Effect": "Allow",
            "Principal":
"arn:primary:default:group:group1",
```

```
            "Action":
["s3:ListBucket"],
            "Resource":
"arn:aws:s3:::${bucket}"
        }
    ]
}
```

The following policy allows all users in *group1* to get, put, and delete objects, and list the bucket contents while also denying *user1* and *user2* in *qagroup1* permission to perform get, put, and delete operations.

```
{

    "Version": "2012-10-17",
    "Id": "PolicyContent1",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal":
"arn:primary:default:group:group1",
            "Action":
["s3:GetObject", "s3:PutObject",
"s3:DeleteObject"],
            "Resource":
"arn:aws:s3:::${bucket}/*"
        },
        {
            "Effect": "Deny",
            "Principal": {
                "AWS": [

"arn:primary:default:user:user1",

"arn:primary:default:user:user2"
                ]
            },
            "Action":
["s3:GetObject", "s3:PutObject",
"s3:DeleteObject"],
            "Resource":
"arn:aws:s3:::${bucket}/*"
        },
        {
            "Effect": "Allow",
            "Principal":
"arn:primary:default:group:group1",
            "Action":
["s3:ListBucket"],
            "Resource":
"arn:aws:s3:::${bucket}"
        }
    ]
}
```

The following policy allows *user1* to perform all the specified operations:

```
{
```

```
  "ID": "PolicyContent1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal":
"arn:primary:default:user:user1",
      "Action": [
        "s3:GetObjectRetention",
        "s3:GetObjectTagging",
        "s3:DeleteObjectTagging",

"s3:DeleteObjectVersionTagging",
        "s3:GetObject",
        "s3:GetObjectLegalHold",
        "s3:PutObject",
        "s3:PutObjectLegalHold",
        "s3:PutObjectRetention",
        "s3:PutObjectTagging",
        "s3:DeleteObject"
      ],
      "Resource": "arn:aws:s3:::$
{bucket}/*"
    },
    {
      "Effect": "Allow",
      "Principal":
"arn:primary:default:user:user1",
      "Action": [
        "s3:DeleteBucket",
        "s3:DeleteBucketPolicy",
        "s3:GetBucketPolicy",
        "s3:GetBucketTagging",
        "s3:ListBucket",
        "s3:PutBucketPolicy",
        "s3:PutBucketTagging"      ],
        "Resource": "arn:aws:s3:::$
{bucket}"
    }
  ]
}
```

User Policy

When you create or modify a user, you can apply a user policy. A user policy specifies which operations users can perform on buckets. You can create a user policy in a JSON file and attach the file to IAM users/groups or domain users. You can attach multiple policies to users and groups. You cannot grant anonymous permissions in a user policy.

The following example user policy allows the associated user to perform six different Object Store operations on a bucket with the objects in it.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowUserActions",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
```

```
                "s3:GetObject",
                "s3:ListBucket",
                "s3:DeleteObject",
                "s3:GetBucketLocation"
            ],
            "Resource": [

"arn:aws:s3:::awsesales/*",

"arn:aws:s3:::awssales"
            ]
        },
        {
            "Sid":
"AllowListingBuckets",
            "Effect": "Allow",
            "Action":
"s3:ListAllMyBuckets",
            "Resource": "*"
        }
    ]
}
```

IAM Policy

Identity and Access Management (IAM) securely controls access to Object Store resources. IAM controls who is authenticated (signed-in) and authorized (has permissions) to use resources through policies.

Create policies using the mc admin policy add command. To attach policies, use either the mc admin policy set on page 2750 command, or attach the policy from the UI.

The following IAM policy allows users to get, put, and delete objects from bucket *bk1*, as well as list the contents of *bk1*.

```
{

  "Version": "2012-10-17",
  "Id": "PolicyContent1",
  "Statement": [
      {
          "Effect": "Allow",
          "Action": ["s3:GetObject",
"s3:PutObject", "s3:DeleteObject"],
          "Resource":
"arn:aws:s3:::bk1"
      },
      {
          "Effect": "Allow",
          "Action": ["s3:ListBucket"],
          "Resource":
"arn:aws:s3:::bk1/*"
      }
  ]
}
```

The following IAM policy allows users to get, put, and delete objects from any bucket in the account where this policy exists.

```
{

  "Version": "2012-10-17",
  "Id": "PolicyContent1",
  "Statement": [
      {
          "Effect": "Allow",
          "Action": ["s3:GetObject",
"s3:PutObject", "s3:DeleteObject"],
          "Resource":
"arn:aws:s3:::*/*"
      },
      {
          "Effect": "Allow",
          "Action": ["s3:ListBucket"],
          "Resource": "arn:aws:s3:::*"
      }
  ]
}
```

The following IAM policy allows users to create, delete, and list any bucket in the account where this policy exists.

```
{

  "Version": "2012-10-17",
  "Id": "PolicyContent1",
  "Statement": [
      {
          "Effect": "Allow",
          "Action":
["s3:CreateBucket",
"s3:DeleteBucket",
"s3:ListAllMyBuckets"],
          "Resource": "arn:aws:s3:::*"
      }
  ]
}
```

How Object Store Evaluates Access Requests

When Object Store receives a request, it evaluates all the access policies to determine whether to authorize or deny the request. When HPE Ezmeral Object Store receives a request for a bucket or an object operation, it first verifies that the requester is permitted to perform the operation. Object Store evaluates all the relevant access policies, user policies, and resource-based policies during authorization.

Authorization includes:

1. Converting all the relevant access policies (at runtime) into a set of policies for evaluation.
2. Evaluating the resulting set of policies in the following order:

a. User context – In the user context, the parent account to which the user belongs is the context authority.

Object Store evaluates a subset of policies owned by the parent account. This subset includes the user policy that the parent attaches to the user. If the parent also owns the resource in the request (bucket/object), Object Store also evaluates the corresponding resource policies at the same time.

A user must have permission from the parent account to perform the operation.

b. Bucket context – In the bucket context, Object Store evaluates policies owned by the Object Store account that owns the bucket.

If the request is for a bucket operation, the requester must have permission from the bucket owner. If the request is for an object, Object Store evaluates all the policies owned by the bucket owner to check if the bucket owner has not explicitly denied access to the object. If there is an explicit deny set, Object Store does not authorize the request.

c. Object context – If the request is for an object, HPE Ezmeral Object Store evaluates the subset of policies owned by the object owner.

Related Information

Getting Started with HPE Ezmeral Data Fabric Object Store

Provides information to help get you started with HPE Ezmeral Data Fabric Object Store.

You must have HPE Ezmeral Data Fabric File and Object Store installed and enabled. See Installing HPE Ezmeral Data Fabric Object Store on page 274 and Enabling the HPE Ezmeral Data Fabric Object Store on page 217. You may also want to review Entities and Resources on page 543.

Generate S3 Keys to Authenticate Users and Applications

Cluster Administrator	The cluster administrator (typically the `mapr` user) must authenticate to the Object Store cluster and generate S3 keys (accessKey and secretKey) on the *default* Object Store account. Perform this operation before performing any CLI operations in Object Store. If the cluster is secure, use `maprlogin` to authenticate the cluster administrator, and then generate the keys: `maprcli s3keys generate -domainname primary -accountname default -username mapr -json` If the cluster is not secure, this command returns an error. The *primary* domain is the only domain that exists in Object Store. Currently, you cannot create additional domains.

last-updated: Jun 06, 2024

TIP: To work properly, the `maprcli s3keys generate` command requires a quorum of the CLDB s3server modules. Before you run `maprcli s3keys generate`, run the `maprcli dump cldbstate -json` command to check the status of the quorum. The dump output should indicate that the primary and secondary s3server modules are running.

IAM Users and Applications

IAM users need S3 keys (accessKey and secretKey) to authenticate to Object Store. The accessKey is the identity, such as user@account@org. The secretKey is used to generate a signature with S3 requests. The S3 Gateway verifies access to a bucket by checking to see if user@account@org has access to objects based on the S3 bucket and user policies.

Cluster and account administrators can generate access keys for IAM users through any of the following methods:

- Running the `maprcli s3keys generate` command from the command line.
- Logging in to the Object Store UI and generating the keys for the user/application.
- S3 request through a REST API call.

S3 requests have the following authentication fields in the HTTP request header that the S3 gateway uses to authenticate a user or application:

- accessKey
- Signature: SHA256-HMAC (some specific fields in the request encrypted with a secretKey)

Log in to the Object Store UI

Using the Object Store UI is recommended over the MinIO UI for an integrated experience. You can access the Object Store UI at `https://<node-ip-address>:8443/app/mcs/opal/`. Cluster and account administrators can monitor Object Store and perform several tasks from the Object Store UI. For example, they can create, modify, and delete:

- Accounts
- IAM users and groups
- Buckets
- Access policies

AD/LDAP users can authenticate to the Object Store UI using their AD/LDAP credentials. Other users need S3 keys (accessKey and secretKey) to log in.

Note the following Object Store requirements for AD/LDAP users:

- All cluster nodes must be part of AD/LDAP. This is required for AD/LDAP users to log in to the Object Store UI.

- The AD/LDAP user logging in to Object Store must have log in permission. You can set log in permission from the Control System. Go to `https://<node-ip-address>:8443/app/mcs/#/overview` and select **Admin** > **User Settings**. Click the **Permissions** tab. Add the AD/LDAP user and select the **Login** checkbox next to the username.

Availability of Access Keys

Access keys are available for download only once, at the time of creation. You must create a new key set if you do not download your keys at the time of creation or if you lose them. Assign up to two access keys per user. Having two access keys is useful if you want to rotate them. If you disable an access key, you cannot use it. Note also that unused keys still count toward your limit of two access keys. You cannot restore a deleted access key. Instead, replace deleted keys with a new access key.

Set a user alias to access Object Store

Create a user or service alias to simplify access to Object Store instead of repeatedly entering the Object Store URL and accessKey/secretKey. Use the `mc alias` command to create and manage aliases.

Accounts and resources (buckets, IAM users, and access policies)

Only enterprise license users can create accounts. By default, the cluster administrator (typically the `mapr` user) and account administrator can perform all operations. Administrators can create and manage accounts and resources from the Object Store UI or CLI. A cluster or account administrator must create accounts and IAM users to deploy S3-based applications.

After creating or editing an account, you can apply a default bucket policy (inherited by all buckets created in the account) and an ACL policy. Access policies define the operations users can perform. The ACL defines bucket and object-level permissions. Object Store accepts policies in JSON format only. For information about how to define bucket policies, see AWS S3 Bucket Policies.

If you create/edit an IAM user/group or a bucket, you can assign an access policy that defines which bucket operations users can perform. For information about how to define user policies, see Access Policies on page 546, Administering Account Resources on page 578, and AWS S3 User Policies.

The following table provides two examples of permissions in JSON format valid for a user policy.

Bucket Operation	Action	Resource Values	Sample Statement
add	`admin:CreateUser`	`"arn:aws:s3:::user"`	`"Statement": [ { "Effect" :"Allow", "Principal" :"AWS": ["jack"], "Action" : ["admin:CreateUser"], "Resource" : ["arn : aws : s3 ::: user"], }]` The user "jack" can create users in the account.

list	admin:ListUsers	"arn:aws:s3:::user"	"Statement": [{ "Effect" :"Allow", "Principal" :"AWS": ["jill"], "Action" : ["admin:ListUser"], "Resource" : ["arn : aws : s3 ::: user"], }] The user "jill" can list users in the account.

Access HPE Ezmeral Data Fabric File Store via S3 Interface

You can use mc commands to access files in HPE Ezmeral Data Fabric File Store. To access files, you must include the "filestore" keyword in the path to the files, as shown below.

```
/opt/mapr/bin/mc ls <alias>/filestore/<VolumeName>/
```

The following example shows the commands you could run to create a volume, populate the volume with data, and access the data using the `mc ls` command:

```
maprcli volume create -name vol1 -path /vol1/
hadoop fs -put /opt/mapr/conf /vol1/
/opt/mapr/bin/mc ls alias_m2/filestore/vol1/
```

Manage accounts and resources

Find instructions for several Object Store-related tasks performed from the CLI or Object Store UI in Operations on page 603.

The following sections provide links to help information to get you started with accounts and resources in Object Store.

Working with objects

- Upload objects
- Copy objects
- Administering Account Resources on page 578
- List buckets and objects
- Stream Standard Input to an object
- Display object content
- Find objects that meet specific criteria
- Query objects
- Object Lock on page 622
- Set and manage a legal hold for buckets and objects
- Set and manage a retention lock

Managing Accounts

- Create and manage accounts

last-updated: Jun 06, 2024

Managing users and groups	• Create and manage users for an account • Create IAM Users on page 611 • Create IAM Groups on page 608
Managing Buckets	• Create Buckets on page 615 • Modify Buckets on page 616
Managing Access Keys	• Create and manage access keys • Commands for managing keys
Managing policies	• Create Policies on page 613 • Create and manage user and group policies • Administering Account Resources on page 578

Supported S3 APIs

Lists the Amazon S3-compatible APIs that HPE Ezmeral Object Store supports.

The following table lists the S3-compatible APIs and their parameters that HPE Ezmeral Object Store supports.

API	Supported URI Request Parameters	Supported Request Body Parameters	Supported Response Elements
AbortMultipartUpload	• Bucket • Key • UploadID	None	None
CompleteMultipartUpload	• Bucket • Key • UploadID	• CompleteMultipartUpload • Part	• x-amz-version-id • CompleteMultipartUpload Result • Bucket • ETag • Key • Location

API	Supported URI Request Parameters	Supported Request Body Parameters	Supported Response Elements
CopyObject	• Bucket • Content-Type • Key • x-amz-copy-source • x-amz-copy-source-if-match • x-amz-copy-source-if-modified-since • x-amz-copy-source-if-none-match • x-amz-copy-source-if-unmodified-since • x-amz-metadata-directive • x-amz-tagging • x-amz-tagging-directive • x-amz-website-redirect-location	None	• x-amz-copy-source-version-id • x-amz-version-id • CopyObjectResult • ETag • LastModified
CreateBucket	• Bucket • x-amz-bucket-object-lock-enabled	None	Location
CreateMultipartUpload	• Bucket • Content-Type • Key • x-amz-object-lock-legal-hold • x-amz-object-lock-mode • x-amz-object-lock-retain-until-date • x-amz-tagging • x-amz-website-redirect-location	None	• InitiateMultipartUploadResult • Bucket • Key • UploadID
DeleteBucket	Bucket	None	None
DeleteBucketCors	Bucket	None	None
DeleteBucketEncryption	Bucket	None	None

last-updated: Jun 06, 2024

API	Supported URI Request Parameters	Supported Request Body Parameters	Supported Response Elements
DeleteBucketOwnershipControls	Bucket	None	None
DeleteBucketPolicy	Bucket	None	None
DeleteBucketTagging	Bucket	None	None
DeleteObject	• Bucket • Key • versionId	None	• x-amz-delete-marker • x-amz-version-id
DeleteObjects	Bucket	• Delete • Object • Quiet	• DeleteResult • Deleted • Error
DeleteObjectTagging	• Bucket • Key • versionId	None	x-amz-version-id
GetBucketPolicy	• Bucket	Policy (in JSON format)	If successful, the service returns an HTTP response with the policy in JSON format.
GetObject	• Bucket • If-Match • If-Modified-Since • If-None-Match • If-Unmodified-Since • Key • Range • response-content-type • versionId	None	• accept-ranges • Content-Length • Content-Range • Content-Type • ETag • Last-Modified • x-amz-delete-marker • x-amz-tagging-count • x-amz-version-id
GetObjectLegalHold	• Bucket • Key • versionId	None	• LegalHold • Status
GetObjectLockConfiguration	Bucket	None	• ObjectLockConfiguration • ObjectLock Enabled

last-updated: Jun 06, 2024

API	Supported URI Request Parameters	Supported Request Body Parameters	Supported Response Elements
GetObjectRetention	• Bucket • Key • versionId	None	• RetentionMode • RetainUntilDate
GetObjectTagging	• Bucket • Key • versionId	None	• x-amz-version-id • Tagging • TagSet
HeadBucket	Bucket	None	None
HeadObject	• Bucket • If-Match • If-Modified-Since • If-None-Match • If-Unmodified-Since • Key	None	• accept-ranges • Content-Length • Content-Type • ETag • Last-Modified • x-amz-delete-marker • x-amz-version-id

API	Supported URI Request Parameters	Supported Request Body Parameters	Supported Response Elements
UploadPart	• Bucket • Key • partNumber • UploadID	Body	None
UploadPartCopy	• Bucket • Key • partNumber • UploadID • x-amz-copy-source	None	• CopyPartResult • ETag • LastModified

Supported Interfaces

Lists the supported interfaces used to perform operations on HPE Ezmeral Data Fabric Object Store and provides links to additional information.

You can perform operations on HPE Ezmeral Data Fabric Object Store using the following interfaces, clients, and SDKs:

ATTENTION:

- Before you can use any of the command line interfaces with Object Store, you must enable Object Store, as described in Enabling the HPE Ezmeral Data Fabric Object Store on page 217.
- Currently, you cannot use awscli, s3cmd, or SDK to create buckets in an account. You must create buckets from the Object Store UI or the `/opt/mapr/bin/mc` command. After you create a bucket, you can perform all operations through any interface, including awscli, s3cmd, SDK, Object Store UI, and `/opt/mapr/bin/mc`. This behavior does not apply to the *default* account. If you have permissions and keys (accessKey/secretKey) to access the *default* account, you can create buckets in the default account through any interface.

Object Store UI

Access the Object Store UI at `https://<ip-address>:8443/app/mcs/opal/`. Refer to Operations on page 603 for supported operations and instructions.

s3cmd

S3cmd is a command line S3 client for Linux and Mac. For usage, see https://s3tools.org/usage.

s3cmd -help

```
$ s3cmd -help

Usage: s3cmd [options] COMMAND
[parameters]

S3cmd is a tool for managing objects
in Amazon S3 storage.
It allows for making and removing
"buckets" and uploading,
```

```
downloading and removing "objects"
from these buckets.
Options:

  -h, --help            show this
help message and exit
  --configure           Invoke
interactive (re)configuration tool.
Optionally
                        use as
'--configure s3://some-bucket' to
test access
                        to a specific
bucket instead of attempting to list
them all.

  -c FILE, --config=FILE
                        Config file
name. Defaults to $HOME/.s3cfg

  --dump-config         Dump current
configuration after parsing config
files and
                        command line
options and exit.

  --access_key=ACCESS_KEY
                        AWS Access Key

  --secret_key=SECRET_KEY
                        AWS Secret Key

  --access_token=ACCESS_TOKEN
                        AWS Access
Token

  -n, --dry-run         Only show
what should be uploaded or downloaded
but
                        don't
actually do it. May still perform S3
requests to
                        get bucket
listings and other information though
(only
                        for file
transfer commands)

  -s, --ssl             Use HTTPS
connection when communicating with
S3.
                        (default)

  --no-ssl              Don't use
HTTPS.

  -e, --encrypt         Encrypt files
before uploading to S3.

  --no-encrypt          Don't encrypt
files.
```

```
  -f, --force           Force
overwrite and other dangerous
operations.

  --continue            Continue
getting a partially downloaded file
(only for
                        [get]
command).

  --continue-put        Continue
uploading partially uploaded files or
                        multipart
upload parts.  Restarts parts/files
that
                        don't have
matching size and md5.  Skips files/
parts
                        that do.
Note: md5sum checks are not always
sufficient
                        to check
(part) file equality.  Enable this at
your own risk.

  --upload-id=UPLOAD_ID
                        UploadId for
Multipart Upload, in case you want
                        continue an
existing upload (equivalent
to --continue-
                        put) and
there are multiple partial uploads.
Use
                        s3cmd
multipart [URI] to see what UploadIds
are
                        associated
with the given URI.

  --skip-existing       Skip over
files that exist at the destination
(only
                        for [get] and
[sync] commands).

  -r, --recursive       Recursive
upload, download or removal.

  --check-md5           Check MD5
sums when comparing files for [sync].
                        (default)

  --no-check-md5        Do not check
MD5 sums when comparing files for
[sync].
                        Only size
will be compared. May significantly
speed up
                        transfer but
may also miss some changed files.
```

```
  -P, --acl-public      Store objects
with ACL allowing read for anyone.

  --acl-private         Store objects
with default ACL allowing access for
you
                        only.

  --acl-grant=PERMISSION:EMAIL or
USER_CANONICAL_ID

                        Grant stated
permission to a given amazon user.
                        Permission is
one of: read, write, read_acp,
                        write_acp,
full_control, all

  --acl-revoke=PERMISSION:USER_CANONIC
AL_ID

                        Revoke stated
permission for a given amazon user.
                        Permission is
one of: read, write, read_acp,
                        write_acp,
full_control, all

  -D NUM, --restore-days=NUM

                        Number of
days to keep restored file available
(only
                        for 'restore'
command). Default is 1 day.

  --restore-priority=RESTORE_PRIORITY

                        Priority for
restoring files from S3 Glacier (only
for
                        'restore'
command). Choices available: bulk,
standard,
                        expedited

  --delete-removed      Delete
destination objects with no
corresponding
                        source file
[sync]

  --no-delete-removed   Don't delete
destination objects [sync]

  --delete-after        Perform
deletes AFTER new uploads when
delete-removed
                        is enabled
[sync]

  --delay-updates       *OBSOLETE*
```

```
Put all updated files into place at
end
                         [sync]

  --max-delete=NUM       Do not delete
more than NUM files. [del] and [sync]

  --limit=NUM            Limit number
of objects returned in the response
body
                         (only for
[ls] and [la] commands)

  --add-destination=ADDITIONAL_DESTINA
TIONS

                         Additional
destination for parallel uploads, in
                         addition to
last arg.  May be repeated.

  --delete-after-fetch  Delete remote
objects after fetching to local file
                         (only for
[get] and [sync] commands).

  -p, --preserve         Preserve
filesystem attributes (mode,
ownership,
                         timestamps).
Default for [sync] command.

  --no-preserve          Don't store
FS attributes

  --exclude=GLOB         Filenames and
paths matching GLOB will be excluded
                         from sync

  --exclude-from=FILE
Read --exclude GLOBs from FILE

  --rexclude=REGEXP      Filenames and
paths matching REGEXP (regular
                         expression)
will be excluded from sync

  --rexclude-from=FILE
Read --rexclude REGEXPs from FILE

  --include=GLOB         Filenames and
paths matching GLOB will be included
                         even if
previously excluded by one of
                         --(r)exclud
e(-from) patterns

  --include-from=FILE
Read --include GLOBs from FILE

  --rinclude=REGEXP      Same
as --include but uses REGEXP (regular
```

```
expression)
                        instead of
GLOB

  --rinclude-from=FILE
Read --rinclude REGEXPs from FILE

  --files-from=FILE     Read list of
source-file names from FILE. Use - to
                        read from
stdin.

  --region=REGION, --bucket-location=R
EGION

                        Region to
create bucket in. As of now the
regions are:
                        us-east-1,
us-west-1, us-west-2, eu-west-1, eu-
                        central-1,
ap-northeast-1, ap-southeast-1, ap-
                        southeast-2,
sa-east-1

  --host=HOSTNAME       HOSTNAME:PORT
for S3 endpoint (default:

s3.amazonaws.com, alternatives such
as s3-eu-

west-1.amazonaws.com). You should
also set --host-
                        bucket.

  --host-bucket=HOST_BUCKET

                        DNS-style
bucket+hostname:port template for
accessing
                        a bucket
(default: %(bucket)s.s3.amazonaws.com)

  --reduced-redundancy, --rr

                        Store object
with 'Reduced redundancy'. Lower
per-GB
                        price. [put,
cp, mv]

  --no-reduced-redundancy, --no-rr

                        Store object
without 'Reduced redundancy'. Higher
per-
                        GB price.
[put, cp, mv]

  --storage-class=CLASS

                        Store object
```

```
with specified CLASS (STANDARD,
                        STANDARD_IA,
ONEZONE_IA, INTELLIGENT_TIERING,
GLACIER
                        or
DEEP_ARCHIVE). [put, cp, mv]

  --access-logging-target-prefix=LOG_T
ARGET_PREFIX

                        Target prefix
for access logs (S3 URI) (for
[cfmodify]
                        and
[accesslog] commands)

  --no-access-logging   Disable
access logging (for [cfmodify] and
[accesslog]
                        commands)

  --default-mime-type=DEFAULT_MIME_TYP
E

                        Default
MIME-type for stored objects.
Application
                        default is
binary/octet-stream.

  -M, --guess-mime-type

                        Guess
MIME-type of files by their extension
or mime
                        magic. Fall
back to default MIME-Type as
specified by
                        --default-mim
e-type option

  --no-guess-mime-type  Don't guess
MIME-type and use the default type
                        instead.

  --no-mime-magic       Don't use
mime magic when guessing MIME-type.

  -m MIME/TYPE, --mime-type=MIME/TYPE

                        Force
MIME-type. Override
both --default-mime-type and
                        --guess-mime-t
ype.

  --add-header=NAME:VALUE

                        Add a given
HTTP header to the upload request.
Can be
                        used multiple
```

```
times. For instance set 'Expires' or

'Cache-Control' headers (or both)
using this option.

  --remove-header=NAME  Remove a
given HTTP header.  Can be used
multiple
                        times.  For
instance, remove 'Expires' or 'Cache-
                        Control'
headers (or both) using this option.
[modify]

  --server-side-encryption

                        Specifies
that server-side encryption will be
used
                        when putting
objects. [put, sync, cp, modify]

  --server-side-encryption-kms-id=KMS_
KEY

                        Specifies the
key id used for server-side encryption
                        with AWS
KMS-Managed Keys (SSE-KMS) when
putting
                        objects.
[put, sync, cp, modify]

  --encoding=ENCODING   Override
autodetected terminal and filesystem
encoding
                        (character
set). Autodetected: UTF-8

  --add-encoding-exts=EXTENSIONs

                        Add encoding
to these comma delimited extensions
i.e.
                        (css,js,html)
when uploading to S3 )

  --verbatim            Use the S3
name as given on the command line. No
pre-
                        processing,
encoding, etc. Use with caution!

  --disable-multipart   Disable
multipart upload on files bigger than
                        --multipart-ch
unk-size-mb

  --multipart-chunk-size-mb=SIZE

                        Size of each
chunk of a multipart upload. Files
```

```
bigger
                        than SIZE are
automatically uploaded as
multithreaded-
                        multipart,
smaller files are uploaded using the
                        traditional
method. SIZE is in Mega-Bytes, default
                        chunk size is
15MB, minimum allowed chunk size is
5MB,
                        maximum is
5GB.

  --list-md5            Include MD5
sums in bucket listings (only for 'ls'
                        command).

  -H, --human-readable-sizes

                        Print sizes
in human readable form (eg 1kB
instead of
                        1234).

  --ws-index=WEBSITE_INDEX

                        Name of
index-document (only for [ws-create]
command)

  --ws-error=WEBSITE_ERROR

                        Name of
error-document (only for [ws-create]
command)

  --expiry-date=EXPIRY_DATE

                        Indicates
when the expiration rule takes
effect. (only
                        for [expire]
command)

  --expiry-days=EXPIRY_DAYS

                        Indicates the
number of days after object creation
the
                        expiration
rule takes effect. (only for [expire]
                        command)

  --expiry-prefix=EXPIRY_PREFIX

                        Identifying
one or more objects with the prefix to
                        which the
expiration rule applies. (only for
[expire]
                        command)
```

```
  --progress            Display
progress meter (default on TTY).

  --no-progress         Don't display
progress meter (default on non-TTY).

  --stats               Give some
file-transfer stats.

  --enable              Enable given
CloudFront distribution (only for

                        [cfmodify]
command)

  --disable             Disable given
CloudFront distribution (only for

                        [cfmodify]
command)

  --cf-invalidate       Invalidate
the uploaded filed in CloudFront.
Also see

                        [cfinval]
command.

  --cf-invalidate-default-index

                        When using
Custom Origin and S3 static website,
                        invalidate
the default index file.

  --cf-no-invalidate-default-index-roo
t

                        When using
Custom Origin and S3 static website,
don't
                        invalidate
the path to the default index file.

  --cf-add-cname=CNAME  Add given
CNAME to a CloudFront distribution
(only for
                        [cfcreate]
and [cfmodify] commands)

  --cf-remove-cname=CNAME

                        Remove given
CNAME from a CloudFront distribution
                        (only for
[cfmodify] command)

  --cf-comment=COMMENT  Set COMMENT
for a given CloudFront distribution
(only
                        for
```

```
[cfcreate] and [cfmodify] commands)

  --cf-default-root-object=DEFAULT_ROO
T_OBJECT

                        Set the
default root object to return when no
object
                        is specified
in the URL. Use a relative path, i.e.
                        default/
index.html instead of /default/
index.html or
                        s3://bucket/
default/index.html (only for
[cfcreate]
                        and
[cfmodify] commands)

  -v, --verbose         Enable
verbose output.

  -d, --debug           Enable debug
output.

  --version             Show s3cmd
version (2.2.0) and exit.

  -F, --follow-symlinks

                        Follow
symbolic links as if they are regular
files

  --cache-file=FILE     Cache FILE
containing local source MD5 values

  -q, --quiet           Silence
output on stdout

  --ca-certs=CA_CERTS_FILE

                        Path to SSL
CA certificate FILE (instead of system
                        default)

  --ssl-cert=SSL_CLIENT_CERT_FILE

                        Path to
client own SSL certificate CRT_FILE

  --ssl-key=SSL_CLIENT_KEY_FILE

                        Path to
client own SSL certificate private key
                        KEY_FILE

  --check-certificate   Check SSL
certificate validity

  --no-check-certificate
```

```
                        Do not check
SSL certificate validity

  --check-hostname      Check SSL
certificate hostname validity

  --no-check-hostname   Do not check
SSL certificate hostname validity

  --signature-v2        Use AWS
Signature version 2 instead of newer
signature
                        methods.
Helpful for S3-like systems that
don't have
                        AWS Signature
v4 yet.

  --limit-rate=LIMITRATE

                        Limit the
upload or download speed to amount
bytes per
                        second.
Amount may be expressed in bytes,
kilobytes
                        with the k
suffix, or megabytes with the m suffix

  --no-connection-pooling

                        Disable
connection re-use

  --requester-pays      Set the
REQUESTER PAYS flag for operations

  -l, --long-listing    Produce long
listing [ls]

  --stop-on-error       stop if error
in transfer

  --content-disposition=CONTENT_DISPOS
ITION

                        Provide a
Content-Disposition for signed URLs,
e.g.,
                        "inline;
filename=myvideo.mp4"

  --content-type=CONTENT_TYPE

                        Provide a
Content-Type for signed URLs, e.g.,
                        "video/mp4"
```

s3cmd commands

```
 Make bucket
      s3cmd mb s3://BUCKET
```

```
  Remove bucket
      s3cmd rb s3://BUCKET

  List objects or buckets
      s3cmd ls [s3://BUCKET[/PREFIX]]

  List all object in all buckets
      s3cmd la

  Put file into bucket
      s3cmd put FILE [FILE...] s3://
BUCKET[/PREFIX]

  Get file from bucket
      s3cmd get s3://BUCKET/OBJECT
LOCAL_FILE

  Delete file from bucket
      s3cmd del s3://BUCKET/OBJECT

  Delete file from bucket (alias for
del)
      s3cmd rm s3://BUCKET/OBJECT

  Restore file from Glacier storage
      s3cmd restore s3://BUCKET/OBJECT

  Synchronize a directory tree to S3
(checks files freshness using size
and md5 checksum, unless overridden
by options, see below)
      s3cmd sync LOCAL_DIR
s3://BUCKET[/PREFIX] or s3://BUCKET[/
PREFIX] LOCAL_DIR or s3://BUCKET[/
PREFIX] s3://BUCKET[/PREFIX]

  Disk usage by buckets
      s3cmd du [s3://BUCKET[/PREFIX]]

  Get various information about
Buckets or Files
      s3cmd info s3://BUCKET[/OBJECT]

  Copy object
      s3cmd cp s3://BUCKET1/OBJECT1
s3://BUCKET2[/OBJECT2]

  Modify object metadata
      s3cmd modify s3://BUCKET1/OBJECT

  Move object
      s3cmd mv s3://BUCKET1/OBJECT1
s3://BUCKET2[/OBJECT2]

  Modify Access control list for
Bucket or Files
      s3cmd setacl s3://BUCKET[/
OBJECT]

  Modify Bucket Policy
      s3cmd setpolicy FILE s3://BUCKET
```

```
  Delete Bucket Policy
      s3cmd delpolicy s3://BUCKET

  Modify Bucket Requester Pays policy
      s3cmd payer s3://BUCKET

  Show multipart uploads
      s3cmd multipart s3://BUCKET [Id]

  Abort a multipart upload
      s3cmd abortmp s3://BUCKET/
OBJECT Id

  List parts of a multipart upload
      s3cmd listmp s3://BUCKET/OBJECT
Id

  Enable/disable bucket access logging
      s3cmd accesslog s3://BUCKET

  Sign arbitrary string using the
secret key
      s3cmd sign STRING-TO-SIGN

  Sign an S3 URL to provide limited
public access with expiry
      s3cmd signurl s3://BUCKET/
OBJECT <expiry_epoch|+expiry_offset>

  Fix invalid file names in a bucket
      s3cmd fixbucket s3://BUCKET[/
PREFIX]

  Create Website from bucket
      s3cmd ws-create s3://BUCKET

  Delete Website
      s3cmd ws-delete s3://BUCKET

  Info about Website
      s3cmd ws-info s3://BUCKET

  Set or delete expiration rule for
the bucket
      s3cmd expire s3://BUCKET

  Upload a lifecycle policy for the
bucket
      s3cmd setlifecycle FILE s3://
BUCKET

  Get a lifecycle policy for the
bucket
      s3cmd getlifecycle s3://BUCKET

  Remove a lifecycle policy for the
bucket
      s3cmd dellifecycle s3://BUCKET

  List CloudFront distribution points
      s3cmd cflist
```

```
  Display CloudFront distribution
point parameters
      s3cmd cfinfo [cf://DIST_ID]

  Create CloudFront distribution point
      s3cmd cfcreate s3://BUCKET

  Delete CloudFront distribution point
      s3cmd cfdelete cf://DIST_ID

  Change CloudFront distribution
point parameters
      s3cmd cfmodify cf://DIST_ID

  Display CloudFront invalidation
request(s) status
      s3cmd cfinvalinfo cf://DIST_ID[/
INVAL_ID]
```

MinIO Client (mc) Commands and MinIO Console

You can perform several operations on HPE Ezmeral Data Fabric Object Store using MinIO Client (mc) or the MinIO Console. The `/opt/mapr/bin` directory contains `mc`. Set your path to include this directory. See MinIO client (mc) commands.

MinIO SDK

You can programmatically manipulate objects in HPE Ezmeral Data Fabric Object Store using MinIO SDKs. Download the SDKs here.

MinIO provides the following SDKs to programmatically manipulate objects in the HPE Ezmeral Data Fabric Object Store.

- Python
- Java

AWS CLI

AWS CLI is a unified tool for managing AWS services. This tool is frequently used to transfer data in and out of AWS S3. It works with any S3-compatible cloud storage service. To install AWS CLI, see these instructions. For usage, see these instructions.

Before you can access Object Store through the AWS CLI, you must set the location of the chain certificate authority using one of the following methods.

- Set the following environment variable:

  ```
  export AWS_CA_BUNDLE=/opt/mapr/conf/ca/chain-ca.pem
  ```

- In `~/.aws/config`, set `ca_bundle = /opt/mapr/conf/ca/chain-ca.pem`.

You can perform the following operations on HPE Ezmeral Data Fabric Object Store using AWS CLI:

- ls (list bucket/contents)
- mb (make bucket)
- cp (add object)

- rm (delete object)
- rb (remove bucket)

AWS SDK

You can programmatically manipulate objects in HPE Ezmeral Data Fabric Object Store using the AWS SDK. You can download the SDKs here.

AWS SDK allows the Java SDK to programmatically manipulate objects in HPE Ezmeral Data Fabric Object Store.

Administering Account Resources

Describes how to set policies for controlling access.

Entities in an Account (users, groups, and policies) are treated as resources. Buckets are the containers that hold objects.

While specifying a policy document, the **create** and **list** operations are performed on a bucket. Hence, they are called *bucket operations*:

- create a user in the bucket *sales*
- list all users in the bucket *sales*

Other operations that act on a specific user, group, or policy are seen as being performed on a specific object(s). Therefore, they are seen as *object operations*.

Examples:

- user* (all users in an account)
- user/john (user john in a specific account)
- group* (all groups in an account)
- group/sales (group ‘sales’ in a specific account)

While specifying objects under the resource heading in a policy document, objects are specified in two formats:

1. bucket* (one of the 3 bucket names followed by * to mean all objects in that bucket)
2. bucket/object (one of the 3 bucket names followed by a slash and the object name, to specify a single object)

Bucket operations can be performed only on a Bucket resource, and Object operations can be performed only on an Object resource.

By default, the account administrator is allowed to perform all operations. The following policy framework applies when the Account Admin wants to allow other users in the account to perform the Admin Operations.

Principals Format

Principals are users or groups that are allowed access to specific operations and are part of a policy under the `Principal` tag of a JSON document. The format of the principal is as follows:

```
arn:<domain_name>:<account_name>:user/<username>
```

User Admin Operations Authorization

Operation	Action	Resource/Values	Sample Statement
add (bucket operation)	admin:CreateUser	"arn:aws:s3:::user"	`"Statement": [{"Effect" : "Allow", "Principal" : "AWS" : [ "arn:primary:default:user:asok"], "Action" : [ "admin:CreateUser" ], "Resource" : [ "arn : aws : s3 : : : user" ]} ]` meaning: User *asok* can create users in an account
list (bucket operation)	admin:ListUsers	"arn:aws:s3:::user"	`"Statement": [{"Effect": "Allow", "Principal" : "AWS" : ["arn:primary:default:user:asok" ], "Action": [ "admin:ListUsers" ], "Resource" : [ "arn : aws : s3 : : : user" ]} ]` meaning: User *asok* can list users in an account

last-updated: Jun 06, 2024

Operation	Action	Resource/Values	Sample Statement
addgroups/removegroups (object operations)	admin:AddUserToGroups admin:RemoveUserFromGroups	• "arn:aws:s3:::user*" • "arn:aws:s3:::user/<username>"	<pre>"Statement": [{"Effect": "Allow", "Principal" : "AWS" : ["arn:primary:default:user:joe", "arn:primary:default:user:alok"], "Action": ["admin:AddUserToGroups"], "Resource" : ["arn : aws : s3 : : : user*"]}]</pre> Meaning: Users *asok* and *joe* can add groups to all users. <pre>"Statement": [{"Effect": "Allow", "Principal": "AWS" : ["arn:primary:default:user:asok"], "Action": ["admin:RemoveUserFromGroups"], "Resource" : ["arn : aws : s3 : : : user/joe"]}]</pre> Meaning: User *asok* can remove groups only for user *joe*.

last-updated: Jun 06, 2024

Operation	Action	Resource/Values	Sample Statement

disable/enable
(object operations)
	admin:DisableUser
	admin:EnableUser
		• "arn:aws:s3:::user*"
		• "arn:aws:s3:::user/<username>"
			`"Statement" : [{"Effect": "Allow", "Principal" : "AWS" : [ "arn:primary:default:user:asok","arn:primary:default:user:joe" ], "Action" : [ "admin:DisableUser" ], "Resource" : [ "arn : aws : s3 : : : user*" ]} ]`
			Meaning: Users *asok* and *joe* can disable all users.
			`"Statement": [{"Effect" : "Allow", "Principal" : "AWS" : [ "asok" ], "Action" : [ "admin:EnableUser" ], "Resource" : [ "arn : aws : s3 : : : user/joe" ]} ]`
			Meaning: User *asok* can enable only user *joe*.

last-updated: Jun 06, 2024

Operation	Action	Resource/Values	Sample Statement

remove info
(object operations)
	admin:RemoveUser
	admin:GetUserInfo
		• "arn:aws:s3:::user*"
		• "arn:aws:s3:::user/<username>"
			<pre>"Statement":
			[{"Effect" :
			"Allow",
			"Principal" :
			"AWS" :
			["arn:primary:def
			ault:user:asok","a
			rn:primary:default
			:user:joe"],
			"Action" :
			["admin:GetUserIn
			fo"],"Resource" :
			["arn : aws :
			s3 : : :
			user*"]}]</pre>
			Meaning: Users *asok* and *joe* can fetch (display) information about all users.
			<pre>"Statement":
			[{"Effect" :
			"Allow",
			"Principal" :
			"AWS" :
			["arn:primary:def
			ault:user:asok"],
			"Action" :
			["admin:RemoveUse
			r"],
			"Resource" :
			["arn : aws :
			s3 : : : user/
			joe"]}]</pre>
			Meaning: User *asok* can remove only user *joe*.

last-updated: Jun 06, 2024

Group Admin Operations Authorization

Operation	Action	Resource/Values	Sample Statement
add (bucket operation)	admin:CreateGroup	"arn : aws : s3 : : : group"	`"Statement": [ {"Effect" : "Allow", "Principal" : "AWS" : [ "arn:primary:default:user:asok"], "Action" : [ "admin:CreateGroup" ], "Resource" : [ "arn : aws : s3 : : : group" ]} ]` meaning: User *asok* can create groups in an account.
list (bucket operation)	admin:ListGroups	"arn : aws : s3 : : : group"	`"Statement": [ {"Effect": "Allow", "Principal" : "AWS" : [ "arn:primary:default:user:asok"], "Action" : [ "admin:ListGroups" ], "Resource" : [ "arn : aws : s3 : : : group" ]} ]` meaning: User *asok* can list groups in an account.

last-updated: Jun 06, 2024

Operation	Action	Resource/Values	Sample Statement

remove info (object operations)	admin:RemoveGroup
	admin:GetGroupInfo
		• "arn : aws : s3 : : : group*"
		• "arn : aws : s3 : : : group/<groupname> "
			`"Statement": [ {"Effect" : "Allow", "Principal" : "AWS" : [ "arn:primary:default:user:asok"], "Action" : [ "admin:RemoveGroup" ], "Resource" : [ "arn : aws : s3 : : : group/sales" ]} ]`
			meaning: User *asok* can remove group *sales* in an account.
			`"Statement": [ {"Effect" : "Allow", "Principal" : "AWS" : ["arn:primary:default:user:sharad" ], "Action" : [ "admin:RemoveGroup" ], "Resource" : [ "arn : aws : s3 : : : group*"]} ]`
			meaning: User *sharad* can remove any group in an account.

last-updated: Jun 06, 2024

Policy Admin Operations Authorization

Operation	Action	Resource/Values	Sample Statement
add, update, list, remove info (bucket operation)	admin:CreatePolicy admin:ListPolicies admin:RemovePolicy admin:GetPolicyInfo	"arn : aws : s3 : : :policy"	`"Statement": [ {"Effect":"Allow", "Principal": {"AWS" : [ "arn:primary:default:user:joe" ]}, "Action" : [ "admin:GetPolicyInfo", "admin:ListPolicies" ], "Resource" : [ "arn:aws:s3:::policy" ]} ]` meaning: user *joe* can read all policies and list all policies in the account. We are not trying to secure each policy separately. A user can operate on all policies or none.
set, unset (object operations)	• admin:AttachPolicy • admin:DetachPolicy	• "arn : aws : s3 : : : user*" • "arn : aws : s3 : : : user/<username>" • "arn : aws : s3 : : : group*" • "arn : aws : s3 : : : group/<groupname>"	`"Statement": [ {"Effect":"Allow", "Principal": {"AWS" : [ "arn:primary:default:user:joe" ]}, "Action" : [ "admin:AttachPolicy", "admin:DetachPolicy" ], "Resource" : [ "arn:aws:s3:::user*" ]} ]` meaning: user *joe* can attach and detach policies from all users. Here *user* is the resource that needs to be guarded, and hence the resource value will have *user* as the resource type.

last-updated: Jun 06, 2024

AccessKey Admin Operations Authorization

Operation	Action	Resource/Values	Sample Statement
• add • list • delete • enable • disable (object operation on a user)	• admin:AddAccessKey • admin:ListAccessKeys • admin:RemoveAccessKey • admin:EnableAccessKey • admin:DisableAccessKey	• "arn : aws : s3 : : : user*" • "arn : aws : s3 : : : user/<username>"	None

Understanding Object Versioning

Explains how versioning works for objects.

Buckets in the HPE Ezmeral Object Store can be versioning enabled, versioning suspended, or completely unversioned.

See mc version enable on page 2754, mc version suspend on page 2755, mc mb on page 2788 and mc ub on page 2789for enabling and suspending bucket versioning.

The following table explains the behavior of common operations such as PUT, DELETE and GET on these bucket types.

Operation	Versioning Enabled Bucket	Versioning Suspended Bucket	Unversioned Bucket
PUT object	Creates a new version of the object and retains all old versions (if any).	Adds new object with *null* version and overwrites any object having the same name and the version as *null*. Retains old versions (if any).	Add new object with *null* version and overwrites any existing object with the same name.
Simple DELETE object	Adds a delete marker and makes the deleted object as the current version.	Permanently deletes object with the *null* version and adds the delete marker.	Permanently deletes object with the *null* version.
DELETE object with version ID	Permanently deletes an object with the given version ID.	Permanently deletes an object with the given version ID.	Permanently deletes an object with the given version ID. The only valid version ID is *null*.
Simple GET object	Returns the current version of the object, or a *Not Found* error if the current version is a delete marker.	Returns the current version of the object, or a *Not Found* error if the current version is a delete marker.	Returns the object with the *null* version.
GET object with version ID	Returns the object with the specified version, or a *Not Found* error if the object is not found.	Returns the object with the specified version, or a *Not Found* error if the object is not found.	Returns the object with the specified version, or a *Not Found* error if the object is not found. The only valid version ID is *null*.

Using VIPs with Object Store

Explains how to use VIPs for HPE Ezmeral Object Store, similar to VIPs in NFS.

last-updated: Jun 06, 2024

You can configure Virtual IPs (VIPs) for HPE Ezmeral Object Store just as you do for the NFS v3/v4 service. VIPs help achieve High Availability (HA) with failover; if one Object Store node fails, the VIP is automatically reassigned to another Object Server node in the pool.

Pass in the *s3* service parameter to configure Object Store VIPs, exactly like you pass in the nfs4 parameter for NFSv4 VIPs. The `ifconfig -a` command uses the *~mc[0-255]* convention to represent Object Store VIPs.

To use VIPs, use the mc alias command to create aliases using VIP or hostname mapped to VIP. If the Object Store server crashes, the assigned Object Store VIPs seamlessly failover to other Object Store servers in the given MAC pool. There might be IO failures for the duration of the VIP failover, based on the mc client retry logic. However, IO eventually starts succeeding once failover is complete.

For Object Store servers over HTTP, directly specify the VIP during alias creation. For Object Store servers over HTTPS, you can only specify hostnames (FQDN). For servers over HTTPS, configure a DNS hostname that maps to a VIP before creating an alias.

Display Object Store VIP

Use the `ifconfig -a` command to display the VIP.

```
ifconfig -a
          enp5s0f0:~mc0 Link encap:Ethernet  HWaddr e8:39:35:1b:05:72
            inet addr:10.163.163.80  Bcast:0.0.0.0  Mask:255.255.248.0
            UP BROADCAST RUNNING MULTICAST  MTU:1500  Metric:1
            Memory:fbe60000-fbe7ffff
```

Add Object Store VIPs

Use the maprcli virtualip add command with the *s3* service to add VIPs.

```
maprcli virtualip add -virtualip 10.163.163.80 -virtualipend
10.163.163.82 -macs "e8:39:35:1b:05:72 e8:39:35:1a:65:e2
0c:c4:7a:8e:35:ee" -netmask 255.255.248.0 -service s3 -json
  {
        "timestamp":1642577221460,
        "timeofday":"2022-01-18 11:27:01.460 GMT-0800 PM",
        "status":"OK",
        "total":0,
        "data":[

        ]
  }
```

List Object Store VIPs

Use the maprcli virtual ip list command to list VIPs.

```
maprcli virtualip list -json
  {
        "timestamp":1642577245672,
        "timeofday":"2022-01-18 11:27:25.672 GMT-0800 PM",
        "status":"OK",
        "total":0,
        "data":[
                {
                        "vip":"10.163.163.80",
                        "hn":"m2-dl2k-19-n4.mip.storage.hpecorp.net",
                        "ip":"10.163.163.168",
                        "mac":"e8:39:35:1b:05:72",
                        "nm":"255.255.248.0",
```

last-updated: Jun 06, 2024

```
                        "AssignableTo":"e8:39:35:1b:05:72,
e8:39:35:1a:65:e2, 0c:c4:7a:8e:35:ee",
                        "service":"S3"
                },
                {
                        "vip":"10.163.163.81",
                        "hn":"m2-dl2k-19-n2.mip.storage.hpecorp.net",
                        "ip":"10.163.163.166",
                        "mac":"e8:39:35:1a:65:e2",
                        "nm":"255.255.248.0",
                        "AssignableTo":"e8:39:35:1b:05:72,
e8:39:35:1a:65:e2, 0c:c4:7a:8e:35:ee",
                        "service":"S3"
                },
                {
                        "vip":"10.163.163.82",
                        "hn":"m2-sm2028-05-n1.mip.storage.hpecorp.net",
                        "ip":"10.163.162.69",
                        "mac":"0c:c4:7a:8e:35:ee",
                        "nm":"255.255.248.0",
                        "AssignableTo":"e8:39:35:1b:05:72,
e8:39:35:1a:65:e2, 0c:c4:7a:8e:35:ee",
                        "service":"S3"
                }
        ]
  }
```

Create VIP Alias Over HTTP

Use the mc alias command to create the alias.

```
/opt/mapr/bin/mc alias set newmoss http://10.163.163.80:9000
AZ7FQCEREA9199VQB4WG6Z2ZDSGRBXYHQKFUGPOCCAQDLTAGIUYJ2PS9HFXZG4WWSIFPEC7O4AS5
ZGWT4UYGEZR88Z7Y V6FKJ22KEG1F6NB5HT6ZDQUEE
  Added `newmoss` successfully.
```

Test if you can create a bucket with this alias.

```
/opt/mapr/bin/mc mb newmoss/buck11
  Bucket created successfully `newmoss/buck11` in account default
```

Create VIP Alias Over HTTPS

Ensure that the alias name you want to use is a fully qualified domain name that resolves. For example:

```
cat /etc/hosts | grep s3server1
  10.163.163.80 s3server1.mip.storage.hpecorp.net //The alias name resolves
to an IP.
```

Use the mc alias command to create the alias.

```
/opt/mapr/bin/mc alias set newmoss1 https://
s3server1.mip.storage.hpecorp.net:9000
AZ7FQCEREA9199VQB4WG6Z2ZDSGRBXYHQKFUGPOCCAQDLTAGIUYJ2PS9HFXZG4WWSIFPEC7O4AS5
ZGWT4UYGEZR88Z7Y V6FKJ22KEG1F6NB5HT6ZDQUEE
  Added `newmoss1` successfully.
```

Test if you can create a bucket with this alias.

```
/opt/mapr/bin/mc mb newmoss1/buck122
  Bucket created successfully `newmoss1/buck122` in account default
```

Using Custom Signed Certificates with Object Store

Describes how to run the HPE Ezmeral Data Fabric Object Store using custom certificates rather than the default self-signed certificates provided during installation.

Default installations of the HPE Ezmeral Data Fabric use encrypted, self-signed certificates to enable SSL communication. For example, the following certificates are created and self-signed by the manageSSLKeys.sh on page 2897 tool:

Certificate File	Store Location*
`public.crt`	`/opt/mapr/conf/ssl_usertruststore.p12`
`private.key`	`/opt/mapr/conf/ssl_userkeystore.p12`

*With Data Fabric 7.0.0.5 and later, the `public.crt` and `private.key` are no longer available, but the self-signed certificates are created if your installation needs them.

If your environment does not permit self-signed certificates, or if you prefer to generate your own certificates rather than use the default certificates, you must use one of the following options.

Alternatives to Using the HPE-Provided Certificates

If you do not want to use the default self-signed certificates, you have two options:

- **Option 1:** Obtain a public certificate and private key from a well-known certificate authority, such as Verisign or Comodo. Then replace the default `public.crt` and `private.key` files with the new public certificate and private key. If you choose Option 1, you must perform only steps 6 and later in the following procedures
- **Option 2:** Generate your own self-signed certificates to replace the `public.crt` and `private.key` files provided in the default installation. If you choose Option 2, perform all steps in the following procedure.

IMPORTANT: This procedure is valid only for clusters running Data Fabric 7.0.0.5 or later.

Generating Your Own Self-Signed Certificates

Use this procedure to generate your own self-signed certificates if your installation has Data Fabric 7.0.0.5 or later:

1. Use the OpenSSL utility to create your own root CA certificate and CA private key:

   ```
   openssl req -x509 -sha256 -days 356 -nodes -newkey rsa:2048 -subj "/
   CN=*.<domain_name>/C=IN/L=HYD" -keyout rootCA.key -out rootCA.crt
   ```

   where <domain_name> is your domain (for example, `mydomain.mycorp.net`).

2. Create a private key to generate the certificate signing request (CSR):

   ```
   openssl genrsa -out private.key 2048
   ```

last-updated: Jun 06, 2024

3. Create the CSR configuration. Be sure to provide all required information. For example:

```
csr.conf
=========
[ req ]
default_bits = 2048
prompt = no
default_md = sha256
req_extensions = req_ext
distinguished_name = dn
[ dn ]
C = IN
ST = TEL
L = HYD
O = HPE
OU = QA
CN = *.<domain_name>
[ req_ext ]
subjectAltName = @alt_names

[ alt_names ]
DNS.1 = *.<domain_name>
```

4. Generate the CSR using a private key. For example:

```
openssl req -new -key private.key -out server.csr -config csr.conf
```

5. Using the root CA and CA private key, create an SSL certificate with the CSR:

   a. Create the `cert.conf` file. For example:

```
cert.conf
==========
basicConstraints=CA:FALSE
keyUsage = digitalSignature, nonRepudiation, keyEncipherment,
dataEncipherment
subjectAltName = @alt_names
[alt_names]
DNS.1 = *.<domain_name>
```

   b. Generate the SSL certificate with the self-signed CA:

```
openssl x509 -req -in server.csr -CA rootCA.crt -CAkey
rootCA.key -CAcreateserial -out public.crt -days 365 -sha256 -extfile
cert.conf
```

   You should now have the following files:

   - `private.key`
   - `server.csr`
   - `rootCA.crt`
   - `rootCA.key`
   - `public.crt`

6. Stop the Multithreaded Object Store Server (MOSS) service:

```
maprcli node services -nodes <node_name> -name s3server -action
stop -json
```

7. Use OpenSSL and the `keytool` command to add the custom certificates to the `ssl_userkeystore` and `ssl_usertruststore` so that the MOSS `public.crt` and `private.key` are available from these files:

   a. Use the `openssl` command to generate the `keypair.p12` file. For the `<password>`, specify a new password of your choosing:

```
openssl pkcs12 -export -nodes -passout pass:<password> -in
public.crt -inkey private.key -name moss -out keypair.p12
```

   b. Use the `keytool` command to import the key store:

For this password variable . . .	Use
`<keystore password>`	The password for the `ssl.server.keystore.password` key displayed in the `/opt/mapr/conf/store-passwords.txt` file.
`<password>`	The new password you specified in step 7a.

```
keytool -importkeystore -deststorepass
<keystore password> -destkeystore /opt/mapr/conf/
ssl_userkeystore.p12 -srckeystore keypair.p12 -srcstorepass
<password> -srcstoretype PKCS12
```

   c. When prompted to overwrite the entry, specify `yes`:

```
Existing entry alias moss exists, overwrite? [no]: yes
```

   d. Use the `keytool` command to delete the MOSS key store:

```
keytool -delete -noprompt -alias "moss" -keystore /opt/mapr/conf/
ssl_usertruststore.p12
```

   e. When prompted for the keystore password, use the password for the `ssl.server.truststore.password` key displayed in the `/opt/mapr/conf/store-passwords.txt` file:

```
Enter keystore password:
```

   f. Use the `keytool` command to import the `public.crt`:

```
keytool -importcert -alias moss -file public.crt -keystore /opt/mapr/
conf/ssl_usertruststore.p12
```

g. When prompted for the keystore password, use the password for the `ssl.server.truststore.password` key displayed in the `/opt/mapr/conf/store-passwords.txt` file:

```
Enter keystore password:
```

h. Use the `keytool` command to delete the MOSS key store. For the `<truststore password>`, use the password for the `ssl.server.truststore.password` key displayed in the `/opt/mapr/conf/store-passwords.txt` file:

```
keytool -delete -noprompt -alias "moss" -keystore /opt/mapr/conf/
ssl_usertruststore -storepass <truststore password>
```

i. Use the following command to add the `public.crt` to the key store. For the `<truststore password>`, use the password for the `ssl.server.truststore.password` key displayed in the `/opt/mapr/conf/store-passwords.txt` file:

```
keytool -importcert -alias moss -file public.crt -keystore /opt/mapr/
conf/ssl_usertruststore -storepass <truststore password>
```

j. When the following prompt appears, type `yes`:

```
Trust this certificate? [no]: yes
```

k. On all other nodes where the MOSS service is running, replace these files:

- `/opt/mapr/conf/ssl_usertruststore`
- `/opt/mapr/conf/ssl_usertruststore.p12`
- `/opt/mapr/conf/ssl_userkeystore.p12`

l. Restart the MOSS service:

```
maprcli node services -nodes <node_name> -name s3server -action start
```

8. Copy the public certificate to the `/.mc/certs/CAs/` directory:

```
cp /opt/mapr/conf/public.crt ~/.mc/certs/CAs/
```

9. Use `mc` commands to create an alias bucket to confirm that MOSS uses the newly generated self-signed certificates. For example:

a. Use the following command to create a bucket:

```
/opt/mapr/bin/mc mb alias/<bucket_name>
```

b. Use the following command to copy an object to the bucket you created in step 9a. If you are successful, the Object Store is loaded with the custom certificates:

```
/opt/mapr/bin/mc cp /root/file.txt alias/<bucket_name>
```

How to Create Self-Signed Certificates Using OpenSSL

Object Recovery Basics

Explains object recovery modes.

HPE Ezmeral Data Fabric Object Store features the ability to recover objects. Recovery operations include cleaning partially written objects, purging non-current versions of unversioned objects, and cleaning incomplete multi-part objects. Recovery also claims space by deleting dangling delete markers and objects marked for purge. In addition, recovery aggregates bucket statistics.

NOTE: Recovery can run only on the node where the master copy of OLT table's first tablet is hosted . Recovery must be triggered using the alias of the node to which the bucket is assigned. Triggering recovery using a wrong node alias leads to a failure.

There are two recovery modes: mini and full.

Mini recovery mode	In a mini recovery, the system scans for buckets to recover every hour. The system picks up buckets that were created or modified in the last hour and examines them for any recovery to perform. The recovery deletes dangling delete markers.
Full recovery mode	In a full recovery, the system scans ALL buckets every week and examines them for any recovery to perform. Similar to the mini recovery, the system deletes all incomplete multipart uploads and dangling delete markers.

See mc admin recovery start on page 2774 and mc admin recovery stop on page 2775 to start and stop recovery.

Working with Bucket Volumes

Describes how to identify the volume associated with a bucket for offloading, mirroring, and creating snapshots.

Underlying each Object Store bucket is a volume. Every bucket created in an Object Store account is automatically associated with a volume. You can snapshot or mirror a bucket volume for disaster recovery. You can also offload data to reclaim storage space.

Offloading relates to data tiering. If you create an account in Object Store, specify the erasure coding scheme (ecscheme) in the `storage_class`. All buckets created in the account inherit the ecscheme. Underlying volumes are automatically tiered such that data in a bucket volume can be offloaded to a back-end volume to reclaim storage space.

Before you can snapshot, mirror, or offload a bucket, you must identify the volume associated with the bucket.

Identifying the Volume Associated with a Bucket

Before you mirror, snapshot, or offload a bucket, identify the name of the volume associated with the bucket. You can run the `mrconfig s3 bucketinfo` or `/opt/mapr/bin/mc admin account info` command to get to the volume name.

Using the `mrconfig s3 bucketinfo` command

1. Run the mrconfig s3 bucketinfo on page 2962 command to get the volume ID (volid) of the volume hosting the bucket:

```
/opt/mapr/server/mrconfig s3
bucketinfo <bucketName>

//Example: /opt/mapr/server/
mrconfig s3 bucketinfo acct01bkt01
```

   Note the `volid` in the output:

```
bucketdirfid 20578.43.131282
oltFid 20578.44.131284
odtFid 20578.48.131292
f2oFid 20578.51.131298
volid 150046236
creationTime 1644592034617
accountName acct01
```

   Now that you have the `volid`, you can find the name of the volume.

2. Run the volume list on page 2648 command, indicating the columns for which you want data and filtering on the `volid`:

```
maprcli volume list -columns
volumename,volumeid,mountdir -filte
r volumeid==150046236
```

   The output provides data for the columns specified - `volume name`, `volumeid`, and `mount path` respectively:

```
mapr.s3bucketVol.0000021b
150046236  /var/objstore/domains/
primary/accounts/201/bucketVols/
mapr.s3bucketVol.0000021b
```

Using the `mc admin account info` command

1. Run the mc admin account info command to locate the volume ID (volid) of the volume associated with the bucket:

```
/opt/mapr/bin/mc admin account
info myalias myaccount
```

Note that the Id is the account Id, which you use to get the volume information for a bucket:

```
Name: myaccount
Id: 1
Admin: bob
DefBucketPolicy: …
Acl: { []}
Quota: 102400
AdvisoryQuota: 51200
LabelName: default
EcLabelName:
MetaLabelName:
Topology:
EcTopology:
DareEnabled: false
MinRep1: 1
DesiredRepl: 3
EcScheme: 2+1
Size: 1108
BucketCount: 1
UserCount: 0
```

last-updated: Jun 06, 2024

2. Use the account Id (`s3aId==1`) to find information for the volumes, including the name:

```
maprcli volume list -columns
volumename,id,mountdir,ae,used -fil
ter '[s3aId==1]'
```

Note the `volumename` in the output:

```
numFidMap
volumename
numFile numS3Bucket  volid
mountdir

   used   numDir  numTable
0
mapr.s3.internal.objecstore.account
1   0    0
232398301   /var/objstore/domains/
primary/
accounts/1
            0    2    7
0
mapr.s3.bucketVol.0000002
 0    1    5 9138624    /var/
objstore/domains/primary/
accounts/1/bucketVols/
mapr.s3bucketVol.00000002
1108    0    4
```

Viewing Volume Information

Once you have the name of the volume associated with a bucket, run the volume info on page 2628 command to view volume details, such as data tiering information.

Run the `volume info` command with the name of the volume:

```
maprcli volume info -name <volumeName> -json

//Example: maprcli volume info -name mapr.s3bucketVol.0000021b -json
```

Note that the following example output is truncated, but you can see the data tiering details:

```
{
    "timestamp":1529546449530,
    "timeofday":"2022-02-22 07:00:49.530 GMT-0700 PM",
    "status":"OK",
    "total":1,
    "data":[
        {…
            },
            "fixCreatorId":"false",
            "ReplTypeConversionInProgress":0,
            "creationTime":1529342213327,
            "metricsEnabled":0,
            "dareEnabled":0,
            "tierlocal":"0",
            "tierpurged":"0",
            "tierrecall":"0",
```

```
            "tierenable":"true",
            "tierid":"136140692",
            "tierruleid":"1",
            "tieroffloadscheduleid":"4",
            "tierencryption":"false",
            "tierrecallexpirytime":"1",
            "tiercompactionscheduleid":"4",
            "tiercompactionoverheadthresh":"30",
            "gateway":"Currently down",
            "ecscheme":"4+2",
            "ecstripedepthmb":"4",
            "ecstorevolume":"mapr.internal.ec.
mapr.s3bucketVol.0000021b.236703387",
            "ectopology":"/data",
                    "eclabel":"anywhere",
            "ectotalused":0,
            "filefilter":"nojpg"
        }
    ]
}
```

Manually Trigger Offloading for a Bucket Volume

When you create an account in Object Store, you configure the erasure coding (EC) topology which specifies where the back-end volume should reside. You also specify the topology (where the front-end volume resides) and the storage capacity for buckets. When you create a bucket, the system automatically creates the volumes (front-end and back-end) and configures data tiering.

The erasure coded (EC) volumes are automatically offloaded to the back-end volumes when they cross the storage threshold set for buckets. If you want to offload data from a bucket to reclaim storage space before the bucket crosses the storage threshold, you can perform a manual offload of the data.

When data is offloaded, you access the off-loaded data the same way you accessed the data prior to the offload.

To perform a manual offload, you need the name of the volume associated with a bucket.

To offload data from a bucket volume, run maprcli volume offload on the volume:

```
maprcli volume offload -name <volumeName> -json

//Example: maprcli volume offload -name mapr.s3bucketVol.0000021b -json
```

The command outputs the following information:

```
{
    "timestamp":1529546449530,
    "timeofday":"2022-02-22 07:00:49.530 GMT-0700 PM",
    "status":"OK",
    "total":0,
    "data":[
    ],
    "messages":[ "Successfully started offload."
    ]
}
```

To check the status of the tier job and offload, run maprcli volume tierjobstatus:

```
maprcli volume tierjobstatus -name <volumeName> -json

//Example: maprcli volume tierjobstatus -name
mapr.s3bucketVol.0000021b -json
```

Once the offload completes, you can still access the data as you did before it was offloaded. For example, to find the tiering information for the offloaded data, run:

```
maprcli volume info -name <volumeName> -json | grep -i tier

//Example: maprcli volume info -name mapr.s3bucketVol.0000021b -json |
grep -i tier
```

Mirroring a Bucket Volume

Typically, you mirror data for disaster recovery purposes. You can mirror bucket volumes and then use an S3 interface to access buckets and objects in the mirrored volume. Currently, you cannot promote a mirrored bucket volume to a read/write mirror; you can only read data from the mirrored volume.

Before you can mirror the volume associated with a bucket, you must first identify the name of the volume associated with a bucket. To mirror a bucket volume:

1. Run the maprcli volume create command, indicating the source volume, path to the mirrored volume, and volume type:

   ```
   /opt/mapr/bin/maprcli volume create -name <mirrorVolumeName> -source
   <sourceVolumeName> -path <path/to/mirrorVolume> -type mirror

   //Example: /opt/mapr/bin/maprcli volume create -name mirvolbk2 -source
   mapr.s3bucketVol.0000021b@mycluster.mapr.com -path /mirvolbk2 -type
   mirror
   ```

2. Run the maprcli volume mirror start command to start volume mirroring:

   ```
   maprcli volume mirror start -name <mirrorVolumeName>

   //Example: maprcli volume mirror start -name mirvolbk2
   ```

3. When mirroring completes, access data in the mirrored volume using an S3 interface, such as the mc ls command:

   ```
   /opt/mapr/bin/mc ls <alias>/filestore/<mirrorVolumeName>/

   //Example: /opt/mapr/bin/mc ls alias_m2/filestore/mirvolbk2/
   ```

ATTENTION: You must include the keyword `filestore` in the path to access the mirror.

Creating a Snapshot of a Bucket Volume

You can snapshot a bucket volume and then access objects in the snapshot. Snapshots provide a point-in-time copy of a volume. Only authorized users can access buckets and objects from a snapshot. The bucket policy (from the snapshotted bucket volume) and the IAM policy associated with the user must allow the user access to the bucket and/or objects. An IAM user can access buckets or an objects in snapshots if authorized; however, the system will deny IAM users access to files.

Before you create a snapshot of a bucket volume, get the name of the volume and its mount path, as described in Identifying the Volume Associated with a Bucket on page 593.

To create a snapshot from a bucket volume, run the maprcli volume snapshot create command:

```
maprcli volume snapshot create -volume <volumeName> -snapshotname
<snapshotName>
```

last-updated: Jun 06, 2024

```
//Example: maprcli volume snapshot create -volume
mapr.s3bucketVol1.00000002 -snapshotname snap1
```

You can access snapshots in the `.snapshot` directory. To access snapshots, you need the volume mount path. In the following example, the volume mount path is `/var/objstore/domains/primary/accounts/1/bucketVols/mapr.s3bucketVol.00000002`. You also need to include the keyword `/filestore/` with the alias to access the snapshot. The following example has the alias and keyword `kalyanalias/filestore/`.

To access the data in a snapshot, run:

```
/opt/mapr/bin/mc ls <alias>/filestore//volume/mount/path/.snapshot/
<snapshotName>

//Example: /opt/mapr/bin/mc ls kalyanalias/filestore//var/objstore/domains/
primary/accounts/1/bucketVols/mapr.s3bucketVol.00000002/.snapshot/snap1
Output returned:
[2022-02-22 10:41:27
PST]  3B /filestore/var/objstore/domains/primary/accounts/1/bucketVols/
mapr.s3bucketVol.00000002/.snapshot/snap1/BucketListTable
[2022-02-22 10:41:47 PST]  0B /filestore/var/objstore/domains/primary/
accounts/1/bucketVols/mapr.s3bucketVol.00000002/.snapshot/snap1/testac1
```

In the example, snap1 contains the `BucketListTable` and an account named testac1.

You can also perform operations on snapshots, such as copying data from an object in a snapshot to another directory. In the following example, `bucket f1` data is copied to the `/tmp/f11` directory:

```
/opt/mapr/bin/mc
cp kalyanalias/filestore//var/objstore/domains/primary/accounts/1/
bucketVols/mapr.s3bucketVol.00000002/.snapshot/snap1/testac1/f1  /tmp/f11
```

Related concepts

Data Offload and Purge on page 512
Describes the process of offloading data to warm and cold tiers, and purging data from storage pools.

Create Buckets on page 615
Describes how to create a bucket.

Create Account on page 605
Explains how to create object store account within a domain.

Data Tiering on page 507
Provides an overview of what tiering is, its various types, and how it works in the HPE Ezmeral Data Fabric.

More information

Erasure Coding Scheme for Data Protection and Recovery on page 1244
Describes the erasure coding (EC) schemes for data protection and recovery.

Traefik Load Balancing

Describes how to use the Traefik load balancer to distribute the Object Store load across multiple MOSS servers in a release 7.0.0 or later Data Fabric cluster.

Use the following steps to install and configure the Traefik binary:

1. Install Traefik on a non-cluster node. You can access the binary from the Traefik website.
2. Download the tar file, and extract it to a well-known location:

   ```
   tar -xvzf traefik_v2.7.1_linux_386.tar.gz
   ```

3. Specify the Traefik configuration for the type of request (http or https) that you plan to use. Traefik supports both static and dynamic configurations, and you must configure both. For more information about static and dynamic configurations, see Traefik Configuration Introduction.

http

a. Specify the Traefik configuration in the `/etc/traefik/traefik.yml` file. For example:

```
entryPoints:
  web:
    address: ":80"
api:
  dashboard: true
  insecure: true

log:
 filePath: "/etc/traefik/
traefik.log"
 level: debug

providers:
  file:
    filename: "/etc/traefik/
router.yml"
```

b. Specify the router configuration in the `/etc/traefik/router.yml` file. The `router.yml` file identifies the MOSS service and load balancer server details:

```
# cat /etc/traefik/router.yml
http:
   routers:
      moss-router:
        entryPoints:
           - "web"
        rule: PathPrefix("/")
        service: moss-service
   services:
      moss-service:
         loadBalancer:
            servers:
              - url: "http://
m2-hux6k-34-n2.mip.storage.hpecor
p.net:9000"
              - url : http://
m2-hux6k-34-n4.mip.storage.hpecor
p.net:9000
```

https

a. Specify the static and dynamic configuration files as shown in the following example.

For https requests, you must copy the `chain-ca.pem` file from the MOSS server to the Traefik client node and include the path for the config parameter in the static configuration file, as shown in the `serversTransport section`:

- Example of Static Configuration File

```
/etc/traefik/traefik.yml:
============================
entryPoints:
  web:
    address: ":80"
  websecure:
    address: ":443"
api:
  dashboard: true
  insecure: true

log:
 filePath: "/etc/traefik/
traefik.log"
 level: debug

providers:
  file:
     directory: "/root/traefik/
dynamic/"
     watch: true

serversTransport:
  rootCAs:
       - /root/traefik/
chain-ca.pem
```

- Example of Dynamic Configuration Files

  For https, two dynamic configuration files are required. Create a directory for these files, and place both files in the directory. For example:

```
# ls -rlth dynamic/
total 8.0K
-rw-r--r-- 1 root root 390 Jun
26 23:57 router.yml
-rw-r--r-- 1 root root 270 Jun
27 02:04 certificates.yaml
```

last-updated: Jun 06, 2024

b. Specify the router configuration in the `/etc/traefik/router.yml` file. For example:

```
dynamic/router.yml
http:
   routers:
      moss-router:
        entryPoints:
           - "websecure"
        rule: PathPrefix("/")
        service: moss-service
        tls: true
   services:
      moss-service:
         loadBalancer:
            servers:
              - url: "https://
m2-hux6k-34-n2.mip.storage.hpecor
p.net:9000"
               - url : "https://
m2-hux6k-34-n4.mip.storage.hpecor
p.net:9000"
```

c. Specify the certificates file:

```
dynamic/certificates.yaml
 ============================
tls:
  certificates:
    - certFile: /root/traefik/
public.crt
      keyFile: /root/traefik/
private.key
      stores:
        - default
  stores:
    default:
      defaultCertificate:
        certFile: /root/traefik/
public.crt
        keyFile: /root/traefik/
private.key
```

4. Start the Traefik binary:

```
./traefik
```

5. Check the `/etc/traefik/traefik.log` to make sure there are no errors in loading the static or dynamic configuration files.

6. Send an http or https request to the MOSS server using the load balancer server in the URL, and verify that the load is distributed across the specified nodes. For example:

http Client Example

```
import boto3

try:
    s3 =
```

```
boto3.client('s3',endpoint_url='http
:/
<loadbalancer_serverhostname>:80',
aws_access_key_id='<access_key>',
aws_secret_access_key='<secret_key>'
, region_name='us-east-1',
use_ssl=False, verify=False)
    resp = s3.put_object(
            Body = 'test putobject
with loadbalancer',
            Bucket = 'bucket1',
            Key ='test_demo.txt'
            )
    print(resp)
except ClientError as e:
    print(e.response)
```

https Client Example

```
import boto3

try:

boto3.setup_default_session(region_n
ame='us-east-1')
    s3 =
boto3.client('s3',endpoint_url='http
s://
<loadbalancer_servername>:443/',
aws_access_key_id='<access_key>',
aws_secret_access_key='<secret_key>'
, region_name='us-east-1',
use_ssl=True, verify="/root/traefik/
chain-ca.pem")
    resp = s3.put_object(
            Body = 'test putobject
with loadbalancer',
            Bucket = 'bucket2',
            Key ='secureobj4.txt'
            )
    print(resp)
```

Operations

Describes the operations that HPE Ezmeral Object Store supports.

All operations that HPE Ezmeral Object Store supports are strongly consistent and are reflected immediately once they are acknowledged.

Display Domain Information

Describes how to list domains and view detailed domain information.

List Domains Using the CLI

To list domains and domain groups from the CLI, use the maprcli s3domain list command.

Display Domain Information Using the CLI

To view domain information from the CLI, use the maprcli s3domain info command.

last-updated: Jun 06, 2024

List Domain Groups Using the Object Store Interface

To list domain groups from the Object Store interface:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administrator** > **Domain Groups** to view the domain groups.

List Domain Users Using the Object Store Interface

To list domain users from the Object Store interface:

1. Login to the Object Store interface as the administrator.
2. Click **Administrator** > **Domain Users** to view the domain users.
3. Click each user to view detailed information such as the IAM groups if any, the attached IAM policies if any, and the number of active/disabled access keys.

Create Access and Secret Keys

Describes how to create access and secret keys for each IAM user (up to two sets) to access the Object Store.

Using the CLI

Use the s3keys generate command to create access and secret keys for IAM users.

Using the Object Store Interface

To generate access and secret keys:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administrator** > **Access Keys** to view the **Access Keys** page which lists all the generated access keys.
3. Click **Generate Access Key**. The access and secret keys are displayed.

   NOTE: Download and save these keys. These keys will never again be displayed.

Enable and Disable Access Keys

Describes how to enable and disable access keys. IAM users cannot use the Object Store with a disabled access key.

A disabled access key still counts toward your limit of two access keys.

Using the Object Store Interface

To disable or enable an access key:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administrator** > **Access Keys** to view the Access Keys page. This page lists all the generated access keys.
3. Scroll through the list of access keys, or select a user to display the access keys for that user alone.
4. From the **Actions** menu for the relevant access key, select either **Disable Access Key** or **Enable Access Key**, as appropriate.
5. Confirm the action.

last-updated: Jun 06, 2024

List Access Keys
Describes how to list Access keys.

Using the CLI

Use the s3keys list command to list all access keys.

Using the Object Store Interface

To list access keys:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administrator** > **Access Keys** to view the Access Keys page. This page lists all the access keys.

Delete Access Keys
Describes how to delete access keys. Deleting an access key automatically deletes the associated secret key.

Using the CLI

Use the s3keys delete command to delete an access key.

Using the Object Store Interface

To delete an access key:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administrator** > **Access Keys** to view the **Access Keys** page which lists all the generated access keys.
3. Scroll through the list of access keys, or select a user to display the access keys for that user alone.
4. From the **Actions** menu for the relevant access key, select **Delete Access Key**.
5. Confirm the deletion.

Create Account
Explains how to create object store account within a domain.

Using the CLI

Use the mc admin account create command to create an account.

Using the Object Store Interface

You can create an object store account using the Object Store UI.

NOTE: You can enable erasure coding via the UI. When you turn on erasure coding you can select the erasure coding topology and, optionally, enable local parity. The erasure coding scheme is without local parity, by default. If you wish to disable erasure coding, you can disable it via the command line only.

While creating an account, you must provide the following information.

- unique name for the account. The name must be unique across the cluster.
- user who is to be designated as the administrator for the account to be created. Only one user can be designated as an administrator.

- disk quota for the account
- topology, that is, the location of the volume to which the account belongs.
- default bucket policy for the account
- access control list(ACL) policy for objects associated with the account.

  NOTE: You can either fill in the policy or select a JSON file containing the policy. For an example ACL policy, see Access Policies on page 546. You may also want to review Administering Account Resources on page 578.

- erasure coding(EC) details
  - if erasure coding is enabled, labels for erasure coded volume, EC topology, enabling or disabling of local parity, EC scheme, number of data and parity fragments(global parity fragments and local parity fragments, if local parity is enabled)
- minimum replication factor, that is, the minimum number of copies of the volume to be maintained by the cluster for normal operation
- desired replication factor, that is, the desired number of copies of the volume to be maintained by the cluster for normal operation
- storage label to confine volumes to specific pools to meet objectives such as low latency
- label for meta containers and namespace containers and corresponding bucket volumes

  NOTE: See Erasure Coding Scheme for Data Protection and Recovery on page 1244 for details on configuring erasure coding while creating the account.

To create an account:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click the menu bar in the top left corner and go to **Administration** > **Accounts**
3. Click **Create Account**.
4. Enter the name for the account.
5. Specify the LDAP user that must be designated as the administrator for the account.
6. Set the total disk quota size in either GB or MB for the account. All the buckets and objects associated with the account add up to this quota.
7. Set the default bucket policy for all buckets in the account. You can either fill in the policy or select a JSON file that contains the policy.
8. Set the default ACL for objects in the account.
9. Turn on the **Erasure Coding** toggle under Storage Policy Settings to enable erasure coding on the cluster.
10. Enter the topology.
11. If you have enabled erasure coding, select the EC topology (the location of the erasure-coded volume to which this account belongs).
12. Specify the Erasure Coding Scheme. All buckets use the specified scheme.

last-updated: Jun 06, 2024

13. If you have enabled erasure coding and wish to enable local parity, turn on the **Local Parity Scheme** toggle.
14. Enter the number of data fragments, the number parity fragments. If you have enabled local parity, enter the number of data fragments, the number of global parity fragments, and the number of local parity fragments.
15. Select the desired replication factor for buckets and objects within this account.
16. Enter a label for storage classification. All buckets and objects inherit this storage label and are placed on the appropriate disks based on this label.
17. Enter the label for Erasure Coded volumes and a meta label.
18. Click **Create Account**.

The object store account is created successfully. You can view the newly created account in the accounts list.

Click the menu bar in the top left corner and go to **Administration** > **Accounts** to view the **Accounts** page which lists all the available accounts.

After creating an account, you can create IAM users and buckets for the account. In the **Action** column, click **...** to see the operations you can perform on the account.

Modify Account
Explains how to modify an object store account within a domain.

Using the CLI

Use the mc admin account modify and mc admin account modify-storageclass on page 2738 commands to modify accounts.

Using the Object Store Interface

To modify an account:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administration** > **Accounts** to view the **Accounts** page which lists all the available accounts.
3. Scroll through the list of accounts, or enter a name in the search field to search for the account.
4. Click the account that you want to edit. The system displays the account details.
5. Click **Edit Account**.
6. Edit the account details as desired. For an explanation of the account fields, see Create Account on page 605.
7. Click **Edit Account**.

Alternatively, to edit the quota:

1. Change the account administrator, and then change the default bucket policy.
2. From the **Accounts** page, select **Change Quota**, **Change Account Admin** and **Change Bucket Policy** respectively, from the **Actions** menu for the appropriate account.
3. Set the new values, and then click **Save Changes**.

List Accounts
Explains how to list accounts.

Using the CLI

Use the mc admin account list command to list accounts.

Using the Object Store Interface

To list accounts:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administration** > **Accounts** to view the **Accounts** page which lists all the available accounts.

Viewing Account Information
Explains how to view account information.

Using the CLI

Use the mc admin account info command to view account information.

Using the Object Store Interface

To view account information:

1. Login to the Object Store interface. as the administrator or as the `root` user.
2. Click **Administration** > **Accounts** to view the Accounts page.
3. Scroll through the list of accounts, or enter a name in the search field to search for the account.
4. Click the account to view its details.

Delete Accounts
Explains how to delete accounts.

You can delete accounts only if they are empty. Be sure to remove all users, buckets and objects from the account, before deleting the account.

Using the CLI

Use the mc admin account delete command to delete accounts.

Using the Object Store Interface

To list accounts:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administration** > **Accounts** to view the **Accounts** page which lists all the available accounts.
3. Scroll through the list of accounts, or enter a name in the search field to search for the account.
4. Select **Delete Account** from the **Actions** menu for the account that you want to delete.
5. Confirm the deletion.

Create IAM Groups
Explains how to create IAM groups for programmatic access to the Object Store functions.

You cannot add IAM groups to the *default* account. Create another account to add IAM groups.

Using the CLI

Use the mc admin group create command to add an IAM group to an account.

Using the Object Store Interface

To add an IAM group:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Select an account other than the `default` from the **Account** drop down.
3. Click **Administration** > **IAM Groups** to view the IAM Groups page. This page lists all the available IAM Groups.
4. Click **Create IAM Group**.
5. Enter a name for the IAM group.
6. The account name is auto-populated.
7. Optionally, select the IAM users to be added to the group.
8. Optionally, specify the IAM policy to apply to the members of the group.

   NOTE: You can add a user to an IAM group and apply an IAM policy at a later time, after user creation as well.
9. Click **Create IAM Group**.

Edit IAM Groups

Explains how to edit users and policies for IAM groups.

Using the CLI

Use the mc admin user addgroups command to add an IAM group to an IAM user. To remove an IAM group from an IAM user, use the mc admin user removegroups command. To set an IAM policy to an IAM group, use the mc admin policy set command.

Using the Object Store Interface

To edit an IAM group:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Select an account other than the `default` from the **Account** drop down.
3. Click **Administration** > **IAM Groups** to view the **IAM Users** page which lists all the available IAM groups.
4. Scroll through the list of groups, or enter a name in the search field to search for the group.
5. Click the IAM group to edit.
6. Click **Edit IAM Group**.
7. Select the IAM users to be added to the group.
8. Specify the IAM policy to apply to the members of the group.
9. Click **Save Changes**.

last-updated: Jun 06, 2024

You can also set a new IAM policy and add IAM users to the group from the **IAM Groups** page through the Object Store interface. To do so, select **Manage IAM Policies** and **Manage IAM Users** (respectively) from the **Actions** menu for the appropriate group. Set the new values, and then click **Save Changes**.

List IAM Groups
Explains how to list IAM groups.

Using the CLI

Use the mc admin group list command to list IAM groups.

Using the Object Store Interface

To list IAM groups:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Select an account other than the `default` from the **Account** drop down.
3. Click **Administration** > **IAM Groups** to view the IAM Groups page. This page lists all the available IAM groups.

Display IAM Group Information
Explains how to display IAM group information.

Using the CLI

Use the mc admin group info command to display information on an IAM group.

Using the Object Store Interface

To display IAM group information:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Select an account other than the `default` from the **Account** drop down.
3. Click **Administration** > **IAM Groups** to view the IAM Groups page. This page lists all the available IAM Groups.
4. Scroll through the list of groups, or enter a name in the search field to search for the group.
5. Click the group to display its information.

Delete IAM Groups
Explains how to delete an IAM group.

Using the CLI

Use the mc admin group remove command to delete an IAM group.

Using the Object Store Interface

To delete an IAM group:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Select an account other than the `default` from the **Account** drop down.

3. Click **Administration** > **IAM Groups** to view the IAM Groups page. This page lists all the available IAM Groups.
4. Scroll through the list of groups, or enter a name in the search field to search for the group.
5. Select **Delete IAM Group** from the **Actions** menu of the appropriate group.
6. Confirm the deletion.

Create IAM Users
Explains how to create IAM users for programmatic access to the Object Store functions.

You cannot add IAM users to the *default* account. Create another account to add IAM users.

Using the CLI

Use the mc admin user add command to add an IAM user to an account.

Using the Object Store Interface

To add an IAM user:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administration** > **Accounts** to view the **Accounts** page which lists all the available accounts.
3. From the Actions menu for an account other than `default`, select **Create IAM User**.
4. Enter a name for the IAM user. The account name is already populated.
5. Optionally, specify the IAM group to which to add the user, and the IAM policy to apply.

   NOTE: You can add the user to an IAM group and apply an IAM policy at a later time, after user creation as well.
6. Click **Create IAM User**.

Edit IAM Users
Explains how to edit groups and policies for IAM users.

Using the CLI

Use the mc admin user addgroups command to add an IAM group to an IAM user. To remove an IAM group from an IAM user, use the mc admin user removegroups command. To set an IAM policy to an IAM user, use the mc admin policy set command.

Using the Object Store Interface

To edit an IAM user:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Select an account other than the `default` from the **Account** drop down.
3. Click **Administration** > **IAM Users** to view the IAM Users page. This page lists all the available IAM users.
4. Scroll through the list of users, or enter a name in the search field to search for the user.
5. Click the IAM user to edit.

last-updated: Jun 06, 2024

6. Click **Edit IAM User**.
7. Select the IAM users to be added to the user.
8. Specify the IAM policy to apply to the members of the group.
9. Click **Save Changes**.

Alternatively, to just set a new IAM policy and add IAM groups to the user, from the IAM Users page, select **Manage IAM Policies**, and **Add to Group(s)** respectively, from the **Actions** menu for the appropriate user. Set the new values and click **Save Changes**.

To create and manage access keys, select **Manage Access Key(s)** from the **Actions** menu for the appropriate user.

List IAM Users
Explains how to list IAM users.

Using the CLI

Use the mc admin user list command to list IAM users.

Using the Object Store Interface

To list IAM users:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Select an account other than the `default` from the **Account** drop down.
3. Click **Administration** > **IAM Users** to view the IAM **Users** page which lists all the available IAM users.

Display IAM User Information
Explains how to display IAM user information.

Using the CLI

Use the mc admin user info command to display information on an IAM user.

Using the Object Store Interface

To display IAM user information:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Select an account other than the `default` from the **Account** drop down.
3. Click **Administration** > **IAM User** to view the IAM Users page. This page lists all the available IAM users. '
4. Scroll through the list of users, or enter a name in the search field to search for the user.
5. Click the user to display its information.

Delete IAM Users
Explains how to delete an IAM user.

Using the CLI

Use the mc admin user remove command to delete an IAM user.

Using the Object Store Interface

To delete an IAM user:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Select an account other than the `default` from the **Account** drop down.
3. Click **Administration** > **IAM Users** to view the IAM Users page. This page lists all the available IAM users.
4. Scroll through the list of users, or enter a name in the search field to search for the user.
5. Select **Delete IAM User** from the **Actions** menu of the appropriate user.
6. Confirm the deletion.

Create Policies

Describes how to create a domain or an IAM policy.

Policies, attached to domain users are Domain policies; and when attached to IAM users, are IAM policies.

Using the CLI

Use the mc admin policy add command to create a policy.

Using the Object Store Interface

To create a policy:

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click **Administration** > **IAM Policies** to display the **Policy** page.
3. Click **Create IAM Policy**.
4. Enter a name for the policy.
5. Either enter the policy details, or select a JSON file containing the policy.
6. Click **Create IAM Policy**.

Edit Policies

Describes how to edit a domain or an IAM policy.

Policies when attached to domain users are Domain policies, and when attached to IAM users, are IAM policies.

Using the CLI

Use the mc admin policy add command to edit a policy. Use the mc admin policy set and mc admin policy unset commands to attach and detach policies to and from users and groups.

Using the Object Store Interface

To edit a policy:

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click **Administration** > **IAM Policies** to display the Policy page. The page displays the list of policies.
3. Scroll through the list of policies, or enter a name in the search field to search for the policy.

last-updated: Jun 06, 2024

4. Click the policy to edit.
5. Click **Edit IAM Policy**.
6. Either enter the policy details, or select a JSON file containing the edited policy.
7. Select the list of users and groups to which the policy applies.
8. Click **Save Changes**.

Alternatively, to add a policy to selected domain and IAM users and groups:

1. Select **Manage IAM Policy** from the **Actions** menu of the policy in the **Policy** listing page.
2. Click **Manage Policy** to save the changes.

List Policies
Describes how to list available policies.

Using the CLI

Use the mc admin policy list command to list available policies.

Using the Object Store Interface

To list policies:

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click **Administration** > **IAM Policies** to display the **Policy** page which displays the list of policies.

Display Policy Information
Explains how to display information for a policy.

Using the CLI

Use the mc admin policy info command to view the information for a policy.

Using the Object Store Interface

To display policy information:

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click **Administration** > **IAM Policies** to display the **Policy** page which displays the list of policies.
3. Scroll through the list of policies, or enter a name in the search field to search for the policy.
4. Click the policy to display its information.

Delete Policies
Explains how to delete a policy.

Using the CLI

Use the mc admin policy remove command to delete a policy.

Using the Object Store Interface

To delete a policy:

1. Login to the Object Store interface as the administrator or as the `root` user.
2. Click **Administration** > **IAM Policies** to display the **Policy** page which displays the list of policies.
3. Scroll through the list of policies, or enter a name in the search field to search for the policy.
4. Select **Delete IAM Policy** from the Actions menu of the appropriate policy.
5. Confirm the deletion.

Create Buckets
Describes how to create a bucket.

The bucket name is unique for each Object Store domain. For example, if a domain has a bucket named *FinancialData*, another domain can also have a bucket named *FinancialData*.

Usage Notes

Review the following notes before you create buckets.

Creating buckets	Currently, you cannot use awscli, s3cmd, or SDK to create buckets in an account. You can only create buckets in an account that is not *default* account from the Object Store UI or the `/opt/mapr/bin/mc` command. After you create a bucket, you can perform all operations through any interface, including awscli, s3cmd, SDK, Object Store UI, and `/opt/mapr/bin/mc`. This behavior does not apply to the *default* account. If you have permissions and keys (accessKey/secretKey) to access the *default* account, you can create buckets in the default account through any interface.
Naming buckets	When you name a bucket, do not include `mapr.` as a prefix for the bucket name. For example, `mapr.bucket1` is not supported.

Create a Bucket Using the CLI

Use the mc mb command to create a bucket.

Create a Bucket Using the Object Store Interface

To create a bucket, using the Object Store Interface:

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. From the Buckets page, click **Create Bucket**
4. In **Bucket name**, enter a DNS-compliant name for your bucket.

   The bucket name must:

   - Be unique across all of HPE Ezmeral Object Store.
   - Be between 3 and 63 characters long.
   - Not contain uppercase characters.
   - Start and end with a lowercase letter or number.

NOTE: After you create the bucket, you cannot change its name.

5. Select the account to which the bucket belongs. By default, a bucket belongs to the *default* account.
6. To enable locking of objects, turn on **Object Lock**.

   NOTE: Turning on Object Locking automatically enables Versioning. After enabling Object Locking, you cannot disable it for a bucket.

7. Specify the retention mode and retention period.
   - Governance mode - Users cannot overwrite or delete an object version or alter its lock settings unless they have special permissions. Users with the `s3:BypassGovernanceRetention` permission can alter the retention period and delete objects.
   - Compliance mode - The admin user cannot alter the retention period, nor delete the object until the retention period has lapsed.
8. To use versioned buckets, enable **Versioning**. Versioning is selected by default if you turned Object Locking on.
9. Enter a bucket policy or select the bucket policy JSON file.
10. Add any tags as key-value pairs for the bucket. These tags are used to categorize storage.
11. Specify the size of the objects to be considered as Tiny (Max Inline Object Size should be a maximum of 1 MB) and Small (Max Object Size in DB should be a maximum of 8 MB). Both tiny and small objects are stored in appropriate database tables. Specify the object chunk size to use when writing objects to disk.
12. Click **Create Bucket**.

Modify Buckets
Describes how to edit the properties of a bucket

You cannot modify the name of the bucket.

Modify a Bucket Using the CLI

Use the mc ub command to change bucket properties. Use mc admin policy update on page 2746 to update the bucket policy.

Modify a Bucket Using the Object Store Interface

To modify a bucket, using the Object Store Interface:

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. On the **Buckets** page, scroll through the list of buckets, or enter a name in the search field to search for the bucket.
4. Click the **Actions** menu for the bucket to be modified, and select **Edit Bucket**. Alternatively, click the name of the bucket to navigate to its page, and then click **Edit Bucket**.

5. Edit the properties of the bucket.

   NOTE: You cannot edit the Bucket Name, Account and Object Lock settings.

   For an explanation of the fields, see Create a Bucket.

Alternatively, to add tags to a bucket, select **Add Tags** from the **Actions** menu of the appropriate bucket.

List Buckets
Describes how to list buckets.

List Buckets and Objects Using the CLI

Use the mc ls command to list buckets and objects.

List Buckets and Objects Using the Object Store Interface

To list a bucket, using the Object Store Interface:

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. The list of buckets is displayed.

Display Bucket Information
Describes how to view bucket information.

Using the CLI

Use the mc stat command to view bucket properties.

Using the Object Store Interface

To list a bucket, using the Object Store Interface:

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. The list of buckets is displayed.
4. Click a bucket to display its information.

View Bucket Metrics
Describes how to view bucket statistics such as Total Bucket Size and Number of Objects.

Using the CLI

Use the mc stat command to view bucket statistics. Use the mc ls command to list objects with versions.

Using the Object Store Interface

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. From the **Buckets** page, click the bucket for which you want the statistics displayed. The statistics are displayed in three tabs:

last-updated: Jun 06, 2024

- **Bucket Details**: Displays the properties of the bucket set at the time of bucket creation or modification.
- **Bucket Metrics**: Graphs the changes over a specified frequency in the storage space used for the bucket, and the number of objects contained in the bucket. Supported frequencies are 24 hours, Last Week, Last Month and Custom. With Custom, enter a date range to view the graphs.
- **Objects**: Displays the objects within the bucket. By default, only the latest version of each object is displayed. To see all versions, turn on the **Show Versions** option.

Delete Buckets
Describes how to delete a bucket.

NOTE: You cannot delete buckets that are locked. Wait five minutes after deletion before creating another bucket with the same name to prevent adverse object operations on the newly and successfully created bucket.

Delete Bucket Using the CLI

Use the mc rb command to delete a bucket.

Delete Bucket to Reclaim Space

When you want to reclaim space, you can remove objects from one or more buckets. Deleting objects is, however, a time-consuming process. Instead, you could delete the volume associated with the bucket (bucket volume), if the volume contains only a single non-WORM on page 6297 bucket.

WARNING: If a volume holds multiple buckets, volume deletion could leads to loss of data of multiple buckets in that volume.

Run the following command to remove the volume containing a single non-WORM on page 6297 bucket.

```
maprcli volume remove -deletes3bucket true -name <volumeName>
```

NOTE: When an account is deleted, the root volume is automatically deleted. To delete the root volume for an account, you must delete the account.

Delete Bucket Using the Object Store Interface

To delete a bucket:

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. On the **Buckets** page, scroll through the list of buckets, or enter a name in the search field to search for the bucket.
4. Click the **Actions** menu for the bucket to be deleted and select **Delete Bucket**.
5. Confirm the deletion.

Upload Objects
Describes how to create folders and upload objects to the Object Store.

NOTE: The object to be uploaded must be upto 5 TiB in size for a successful upload.

Using the CLI

Use the mc cp command to upload objects.

Using the Object Store Interface

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. From the **Buckets** page, click the bucket to which you need to upload objects.
4. Navigate to the **Objects** tab.
5. To create a folder, click **Create New Folder**, enter a folder name and click **Create**.

   NOTE: The folder name must be unique across the Object Store.
6. To upload objects, click **Upload Object**.
7. Either drag and drop, or select the files to be uploaded.
8. Optionally, to save the file at the destination with another name, enter the destination file name.
9. Enter tags and metadata as key-value pairs. These tags and metadata identify objects across the Object Store.
10. Click **Upload Object**.

Update Objects

Describes how to update objects that are already present in the Object Store.

Using the CLI

Use the mc cp command to update objects.

Using the Object Store Interface

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. From the **Buckets** page, click the bucket to which you uploaded the object to update.
4. Navigate to the **Objects** tab.
5. From the list of objects, click the object to update.
6. Click **Update Object**.
7. Either drag and drop, or select the files to be uploaded.
8. Enter tags and metadata as key-value pairs. These tags and metadata identify objects across the Object Store.
9. Click **Save Changes**. The object is then uploaded as a new version.
10. (Optional) To update the tags of an object from the list of objects, select **Update Tags** from the **Actions** menu for the object, enter the tags as key-value pairs, and click **Add**.

Download Objects

Describes how to download objects from the Object Store.

last-updated: Jun 06, 2024

Using the CLI

Use the mc cp command to download objects.

Using the Object Store Interface

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. From the **Buckets** page, click the bucket in which the object exists.
4. Navigate to the **Objects** tab.
5. Scroll through the list of objects, or enter a name in the search field to search for the object.
6. Select **Download** from the **Actions** Menu for the object.

View Objects

Describes how to view objects that are in a bucket on the Object Store.

Using the CLI

Use the mc ls command to view objects.

Using the Object Store Interface

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. From the **Buckets** page, click the bucket in which the object exists.
4. Navigate to the **Objects** tab.
5. View the list of objects.
6. Scroll through the list of objects, or enter a name in the search field to search for the object.

Alternatively, select **View Objects** from the **Actions** menu of the desired bucket.

View Object Details

Describes how to view the details of an object in the Object Store.

Using the CLI

Use the mc ls command to view object details.

Using the Object Store Interface

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. From the **Buckets** page, click the bucket in which the object exists.
4. Navigate to the **Objects** tab.
5. View the list of objects.

6. Scroll through the list of objects, or enter a name in the search field to search for the object.
7. Click the object to view its details.

Alternatively, select **View Objects** from the **Actions** menu of the desired bucket, and then click an object to view its details.

Query with S3 Select

Describes how to query objects.

You can query CSV, JSON, and Apache Parquet files.

Usage Notes

Review the following notes related to the use of `S3 Select` before you run any queries.

Parquet files	Before you run any queries against Parquet files, set `export MINIO_API_SELECT_PARQUET=on` in the `/opt/mapr/conf/env.sh` file and restart the Object Store server. You can restart the Object Store server from the Services page in the Control System or from the CLI by running the following command: `/opt/mapr/bin/maprcli node services -nodes <space-delimited list of node names> -s3server restart`
JSON documents	When you query a JSON document, you must include the `--json-input` parameter and `type=document`, as shown in the following example: `/opt/mapr/bin/mc sql --json-input type=document --query "select * from S3Object" alias0/mybucket/example5.json`

Using the CLI

Use the mc sql command to query objects.

Using the Object Store Interface

1. Login to the Object Store Interface.
2. Click the bucket icon from the left pane.
3. From the **Buckets** page, click the bucket in which the object exists.
4. Navigate to the **Objects** tab.
5. View the list of objects.
6. Scroll through the list of objects, or enter a name in the search field to search for the object.
7. Select **Query with S3 Select** from the **Actions** menu of the object to query.
8. Select the characteristics of the object such as the format, the number of lines that the object spans, the CSV delimiter for the fields and the compression type if any for the object.
9. Select the output type either CSV or JSON and the CSV delimiter to use.

last-updated: Jun 06, 2024

10. Enter the query to run. The default query is `SELECT * FROM s3object s LIMIT 5`.
11. Click **Run SQL Query**.

Delete Objects
Describes how to delete objects from the Object Store.

Using the CLI

Use the mc rm command to delete objects.

Using the Object Store Interface

1. Login to the Object Store Interface as the administrator or as the `root` user.
2. Click the bucket icon from the left pane.
3. From the **Buckets** page, click the bucket in which the object exists.
4. Navigate to the **Objects** tab.
5. From the list of objects, select **Delete** from the **Actions** Menu for the object.
6. Confirm deletion.

Object Lock
Describes how to lock objects for a specific period or indefinitely.

Typically you lock objects to prevent them from being deleted. You can lock objects for a specific time or indefinitely. You can lock objects from the Object Store UI or CLI. See Create Buckets on page 615 and mc retention on page 2776.

Enable object locking at the bucket level only during bucket creation. Creating a bucket with automatic locking enables versioning. After it is enabled, you cannot disable object locking or suspend versioning.

There are two kinds of object locking: Retention and Legal Hold.

CAUTION: Merely enabling object locking does not protect objects. You must configure either Retention or Legal Hold to protect objects.

Retention

Retention allows protection of objects for a fixed period. Specify the retention duration in days or years at the bucket or object level. HPE Ezmeral Object Store automatically calculates the end of the retention period.

NOTE: Changes in the retention period apply only to objects placed after the change. The existing objects in the bucket still retain the older retention period.

NOTE: Objects with a retention period set cannot be deleted until the retention period has lapsed.

There are two types of retention modes:

Governance	In Governance mode, users cannot overwrite or delete an object version or alter its lock settings unless they have special permissions. Users with the `s3:BypassGovernanceRetention` permission can alter the retention period and delete objects.
Compliance	In Compliance mode, not even the administrative user can alter the retention period, nor delete the object until the retention period has lapsed.

Use the mc retention command to set and manage the retention lock.

Legal Hold

A legal hold prevents an object version from being deleted or overwritten. There is no retention period associated with a legal hold. The legal hold remains in effect until removed.

Any user with the `s3:PutObjectLegalHold` permission can place and remove a legal hold on an object at will. You cannot delete objects that have a legal hold set unless you explicitly clear the legal hold.

You cannot set a legal hold from the Object Store UI. Use the mc legalhold command to set and manage a legal hold.

Troubleshooting Object Store

Provides methods for troubleshooting issues in Object Store.

Before You Troubleshoot

Verify that Object Store is properly installed and enabled, as described in Installing HPE Ezmeral Data Fabric Object Store on page 274 and Enabling the HPE Ezmeral Data Fabric Object Store on page 217. Enabling the HPE Ezmeral Data Fabric Object Store on page 217 includes several important steps required to use Object Store successfully, including steps for setting up certificates. If certificates are not properly configured, applications cannot access Object Store.

You can also perform the following pre-troubleshooting verification checks:

Check access to the Object Store UI	The Object Store UI is the Object Store entry point. If Object Store is installed and running, you should be able to access the Object Store UI from the MCS (management control system). Go to `https://<node-ip-address>:8443/app/mcs/#/app/login` and log in. Click on the **Data** tab and look for **Object Store** in the dropdown. If you see Object Store in the dropdown, Object Store is installed and running. If you do not see Object Store in the dropdown, the CLDB S3server quorum is not properly set up or the quorum has not finished setting up.
Check the status of the CLDB and S3 server quorum	To check the status of the CLDB and S3 server quorum, run `maprcli dump cldbstate -json`. In the output, look for `s3Info`. S3Info contains the status of all S3 servers.

last-updated: Jun 06, 2024

	• When the status of all S3 servers is *running*, you should be able to access Object Store through the Object Store UI. If you followed all the instructions in Enabling the HPE Ezmeral Data Fabric Object Store on page 217, it may just take a bit more time for the status to change. • If the `s3State` is `AWAITING_FEATURE_ENABLE`, restart the CLDB service. See node services on page 2292.
Verify that users have permission to log in to Object Store.	Before a user that is listed in LDAP/AD can access Object Store, the cluster administrator (typically the `mapr` user) must first give the user permission to log in. In the MCS go to **Admin > User Settings** and click on the **Permissions** tab. Add the user and assign **Login** permission to the user. Click **Save Changes** when done.

Logging

Object Store generates log files for the following components:

- MOSS on page 6293
- CLDB S3 server module
- MSI (interface module between MOSS and the file system)

The following table lists and describes the log files produced by Object Store:

Log File	Description
moss.log	• Contains MOSS server logs. • Located in `/opt/mapr/logs/moss.log`. • To increase Object Store server logging, change logging in `/opt/mapr/conf/moss.conf` to DEBUG. The system outputs debug messages to `moss.log`.
moss.fileclient.log	• Contains MOSS file client related messages. • Located in `/opt/mapr/logs/moss.fileclient.log`. • To increase Object Store client logging, change the `fs.mapr.trace` property in `/opt/mapr/conf/moss-core-site.xml` to DEBUG.
moss.out	• Logs all service orchestration messages and messages for failures and crashes. • Located in `/opt/mapr/logs/moss.out`.
cldb.log	• Logs the CLDB S3 server module debug information. • Located in `/opt/mapr/logs/cldb.log`. • To generate the CLDB S3 server module debug log messages, run: `maprcli setloglevel cldb -classname -loglevel DEBUG -node cldbnode`

Log File	Description
mfs.log	• Contains MSI log information. • Located in `/opt/mapr/logs/mfs.log-5`. • To set the log level for MSI to DEBUG, run: `maprcli trace setlevel -module MSI -level DEBUG`

Debugging

You can debug MOSS with the `mc admin profile` command or DNU/GDB debugger.

Before a user can run the `mc` commands, the `/opt/mapr/conf/ca/chain-ca.pem` file must be copied to `~/.mc/certs/CAs/` on the node running `mc`. Also, a symbolic link must be created in the user directory. To create the symbolic link for a user, run:

```
su - <user>
mkdir -p ~/.mc/certs/CAs
ln -s /opt/mapr/conf/ca/chain-ca.pem ~/.mc/certs/CAs/chain-ca.pem
```

MOSS Profile

The `mc admin profile` command returns information about the MOSS thread activities. Run the `start` command, wait a few seconds and then run the `stop` command. The command outputs a zip file that you can unzip to access text files. View (vim or cat) the text files to see the activity of the MOSS threads.

Run the `mc admin profile` command, as shown:

```
/opt/mapr/bin/mc admin profile
start --type goroutines mapralias

/opt/mapr/bin/mc admin profile stop
mapralias
```

Debug with DNU/GDB Debugger

Running the debugger is helpful if MOSS crashes.

Run the debugger, as shown in the following example:

```
gdb /opt/mapr/server/moss <moss/core/
path>
```

Debugging Bucket Metrics

Bucket metrics provide you with account-level and bucket-level statistics, such as the total size of an account, the total object count, historical usage of buckets, and so on. The MOSS server includes an SRM (storage recovery metrics) component that automatically recovers metrics for buckets, updates statistics, and reclaims space when any issues occur; for example, if a put operation does not complete. SRM loads metrics into the BucketList table.

The BucketList table is the source of truth for statistics; it provides the last time a bucket recovery occurred. You can access the BucketList table through the `mc lb` and `mc stat` commands or in the Object Store UI. You can also get stats from `olt statsfid` when you run the `mrconfig s3 bucketstats` command.

The following table describes the interfaces through which you can access bucket metrics:

Interface	Description
Object Store UI	• Collectd collects statistics from the BucketList table and pushes them to OpenTSDB. The Object Store UI and Grafana query OpenTSDB to plot and chart data. • The graphs may not always reflect changes to a bucket or show accurate data.
`mc stat`	Returns bucket-level statistics.
`mc lb`	• Returns aggregated statistics from the BucketList table for all buckets. • Gives additional statistics, such as inProgressCount, inProgressSize, and deleteMarker count.
`mrconfig s3 bucketstats`	Returns statistics from OLT StatsFid for a given bucket.

Resolving Issues with Bucket Metrics

The following issues could result in inaccurate metrics. If the solutions provided do not resolve the issue, you can manually trigger recovery. Recovery is performed by the MOSS server on the node where the master copy of the OLT table's first tablet is hosted.

Verify that SRM Triggered on the Correct MOSS Node

Each bucket is assigned to a different MOSS server for recovery. If recovery is triggered on the wrong node, the system outputs the following error:

```
mc: <ERROR> Unable to start
bucket recovery. We encountered an
internal error, please try again.:
cause(bucket not assigned).
```

You can view recovery details in the table dump:

```
/opt/mapr/server/tools/mossdb dump
table -type bucket /var/objstore/
domains/primary/BucketListTable
```

Metrics do not display or do not update in the Object Store UI.

If you cannot see statistics for objects uploaded to Object Store or if the statistics that display are not accurate, there may be an issue with collectd or opentsdb. Collectd pulls data from nodes and opentsdb is needed to view charts in the Object Store UI. Collectd should be installed and running on all nodes. If collectd stops running on a node, statistics will not display for objects. Opentsdb should be installed and running on at least one node.

If the collectd or opentsdb service is not running, restart the service.

Metrics in Object Store UI are accurate, but do not reflect correctly elsewhere.

If any of MOSS or the file server nodes are down, statistics will not be pushed to the BucketList table.

Each bucket is associated with a MOSS server. The SRM component in the MOSS server updates the

last-updated: Jun 06, 2024

BucketList table. If the BucketList table is not updated, this could indicate that a MOSS server assigned to the bucket is down.

- Verify that all MOSS servers are running. If a MOSS server or file server are down, restart the server. Once restarted, the server should automatically push the data to the bucket and update the metrics.
- If restarting the MOSS server does not work, run `s3 bucketstats <bucketname>` and look at `olt statsFid`.
- You can also look at the logs and enable debugging to see if you can identify the issue in the debug log.
- If you need an immediate statistics update, run `mrconfig s3 refreshstats <bucketName>`. This command sends a request for all tables to push individual statistics to the file server. Eventually the aggregated statistics will be pushed to the BucketList table. If you do not run `mrconfig s3 refreshstats <bucketName>`, statistics will be automatically refreshed at the next recover.

Debugging Volumes

Every account is associated with a volume and every bucket is associated with a volume. An account is associated with a root volume, which stores metadata for the account, including users, groups, and policies. Bucket volumes store data and metadata.

Account and bucket volumes are not exposed externally to users and users do not interact directly with the volumes; however, you may need to see volume details if issues related to a volume arise or the system raises an alarm, for example:

- If a container is not accessible.
- You need to run fsck.
- An offload fails, which would trigger an offload failure in the UI.

In an offload failure scenario, you may not recognize the volume. Should this occur, you can look at the volume name in the volume list to identify which bucket the offload failure is related to and then respond accordingly. You can also look at the logs to see why the offload failed.

Find the Volume Name and Details	Working with Bucket Volumes on page 593 provides instructions for finding the name of a volume and viewing volume details.
Delete a Volume to Reclaim Space	If you want to reclaim space, you can remove objects; however, deleting objects is a time-consuming process. Instead, you may prefer to delete the volume if deleting all buckets in the volume is feasible. To delete the *root volume for an account,* you must delete the account. When the account is deleted, the root volume is automatically deleted.

To delete a *bucket volume*, run:

```
maprcli volume remove -deletes3bucket
true -name <volumeName>
```

CAUTION: This command only works on volumes where all buckets are non-worm buckets. Running this command against a volume with worm buckets fails.

Additional Tips

In addition to the troubleshooting information provided in this topic, you may also find the following tips helpful:

Check if a bucket exists

To see if a bucket exists, check in the MOSS file client log by running:

```
grep -nira "<bucketName> /opt/mapr/
logs/moss.fileclient.log | more
```

Check if a bucket is created

To see if a bucket is created, you can check the mfs log by running:

```
grep -nir "<bucketName>" /opt/mapr/
logs/mfs.log-3
```

The output will state S3BucketCreateFinish.

Get the container ID for a bucket

The request to create a bucket goes to the CLDB and the CLDB creates a volume for the bucket. You can look at the CLDB log to gather data for troubleshooting, such as the container ID, by running:

```
grep -nira "<volumeName>" /opt/mapr/
logs/cldb.log
```

TIP: Working with Bucket Volumes on page 593 provides instructions for finding the name of a volume associated with a bucket.

You can dump the container to get additional details, such as the file server node IP address, for example:

```
maprcli dump containerinfo -ids
<containerID> -json
```

Issues running S3 cmd

If the system returns an error similar to the following when you run S3cmd, such as `S3cmd ls s3://`:

```
ERROR: SSL certificate
verification failure:
[SSL: CERTIFICATE_VERIFY_FAILED]
certificate verify failed (_ssl.c:897)
```

Run the following command to resolve the error:

```
s3cmd -ca-certs=/opt/mapr/conf/ca/
chain-ca.pem ls s3://
```

When you run this command, the system returns an error about the access key and prompts you for the keys. To add an access key, run:

```
s3cmd -configure
```

And follow the instructions at the prompt.

Issues running AWS

If you try to run the following AWS command:

```
aws s3 ls s3:// --endpoint-url
https://<hostname>:9000
```

You may get an error similar to the following:

```
SSL validation failed
for https://<hostname>:9000/
[SSL: CERTIFICATE_VERIFY_FAILED]
certificate verify failed: unable
to get local issuer certificate
(_ssl.c:1125)
```

To resolve the error, point the aws configuration file to the `/opt/mapr/conf/ca/chain-ca.pem` directory or export it, as shown:

```
export AWS_CA_BUNDLE=/opt/mapr/
conf/ca/chain-ca.pem
```

If that does not work, run:

```
aws configure
```

Known Issues and Limitations

Lists known issues and limitations in HPE Ezmeral Data Fabric Object Store.

HPE Ezmeral Data Fabric Object Store has the following known issues and limitations.

You can only test account policies through the CLI

The account administrator can create and edit an account policy from the Object Store UI and CLI (`/opt/mapr/bin/mc`). The account policy can only be tested through the CLI.

Any user granted permission to perform operations in an account must perform the operations from the CLI

An account administrator can perform operations in an account from the Object Store UI or CLI (`/opt/mapr/bin/mc`), such as creating users, groups, policies, and buckets. However, if the account administrator grants another user permission to perform operations, that user can only perform operations from the CLI (`/opt/mapr/bin/mc`). The user cannot perform operations from the Object Store UI.

You cannot create buckets in non-default accounts using awscli, s3cmd, SDK

Currently, you cannot use awscli, s3cmd, or SDK to create buckets in an account. You must create buckets from the Object Store UI or the `/opt/mapr/bin/mc` command. After you create a bucket, you can

last-updated: Jun 06, 2024

	perform all operations through any interface, including awscli, s3cmd, SDK, Object Store UI, and `/opt/mapr/bin/mc`. This behavior does not apply to the *default* account. If you have permissions and keys (accessKey/secretKey) to access the *default* account, you can create buckets in the default account through any interface.
No object access via file interfaces	Currently, you cannot access objects through file interfaces (NFS, POSIX, CSI). Use `mc` commands to access files in HPE Ezmeral Data Fabric File Store. The `mc` commands provide an S3 interface to File Store.
You cannot use mapr. as a prefix when naming buckets	By design, you cannot name buckets with `mapr.` as the prefix, for example `mapr.bucket1`.
Jobs cannot reclaim space when delete markers exist on versioned objects	In Object Store, versioning and delete markers work the same as they do in S3 – If you remove a directory or object from a versioned bucket using the `mc rm` command, a delete marker is placed against that directory or object while all previous versions of the directory or object are retained. These retained versions occupy space that jobs cannot reclaim when they run against the versioned bucket. If you want jobs to reclaim space, you must use the `--versions` option to remove all versions of a directory or object when you run the `mc rm` command, for example: `/opt/mapr/bin/mc rm --recursive --force --versions <alias>/<versionedbucket>/<directory>`
S3 Select limitations	• The maximum length of a record in the input or result is 1 MB. • Amazon S3 Select can only emit nested data using the JSON output format. • S3 select returns a stream of encoded bytes. As a workaround, loop over the returned stream and decode the output records. Example: ['Payload'].decode('utf-8') • S3 Select only works on objects stored in CSV, JSON, or Apache Parquet format. • Compressed formats are available for CSV and JSON file formats only.

last-updated: Jun 06, 2024

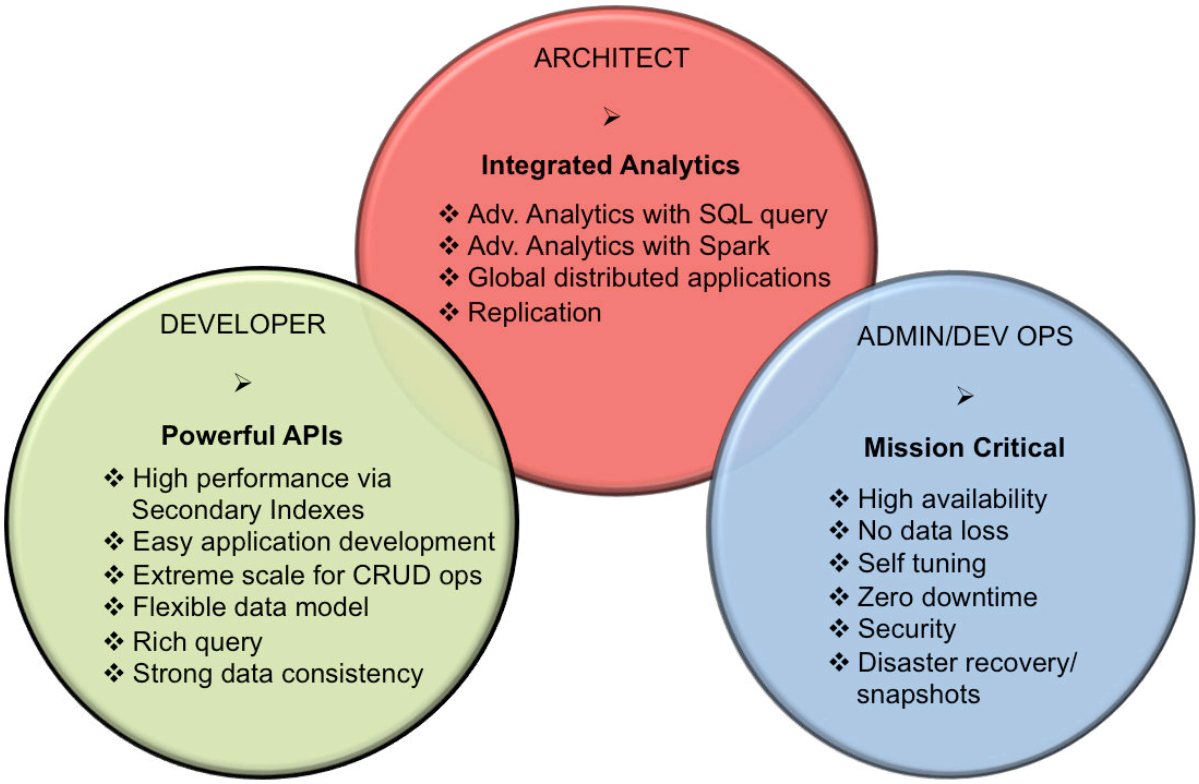
Access policy limitation in Object Store	• Currently, Object Store only supports the `IpAddress` condition. You can add the `Condition` block to a policy, only specifying `IpAddress` within it: `"Condition": { "IpAddress": { "aws:SourceIp": [ "192.48.100.222" ] }, }`
Cannot audit data access operations	Currently, Object Store does not support the auditing of data access operations, as described in Auditing Data Access Operations on page 849.

HPE Ezmeral Data Fabric Database

HPE Ezmeral Data Fabric Database is an enterprise-grade, high-performance, NoSQL database management system that you can use for real-time, operational analytics.

Why HPE Ezmeral Data Fabric Database?

HPE Ezmeral Data Fabric Database is built into the HPE Ezmeral Data Fabric platform. It requires no additional process to manage, leverages the same architecture as the rest of the platform, and requires minimal additional management.



last-updated: Jun 06, 2024

1. The HPE Ezmeral Data Fabric Database and Apps section provides information and examples on developing applications for HPE Ezmeral Data Fabric Database binary and JSON tables.
2. This section provides information on how to adminster tables, table regions, and column families. The tools for performing administration are the MCS (MapR Control System) user interface and the maprcli.
3. The HPE Ezmeral Data Fabric Database architecture covers topics associated with database design issues.

What databases does the HPE Ezmeral Data Fabric Database include?

The HPE Ezmeral Data Fabric Database includes two NoSQL databases:

- **Key-value and columnar database with HBase API**
  - Supports Apache HBase tables and databases.
  - Provides a native implementation of the HBase API for optimized performance on the Data Fabric platform.
- **JSON document database based on the OJAI API**
  - Supports JSON documents as a native data store.
  - Stores JSON documents in HPE Ezmeral Data Fabric Database JSON tables.
  - Starting in HPE Ezmeral Data Fabric 7.0.0, all fields of JSON tables support DDM (dynamic data masking). The JSON database supports eight predefined dynamic data masks.

How do I get started?

The following table provides links to useful resources for developers, architects, and administrators.

Architecture

HPE Ezmeral Data Fabric Database is an enterprise-grade, high performance, NoSQL (“Not Only SQL”) database management system. You can use it to add realtime, operational analytics capabilities to big data applications. As a multi-model NoSQL database, it supports both JSON document models and key-value data models.

Why use HPE Ezmeral Data Fabric Database?

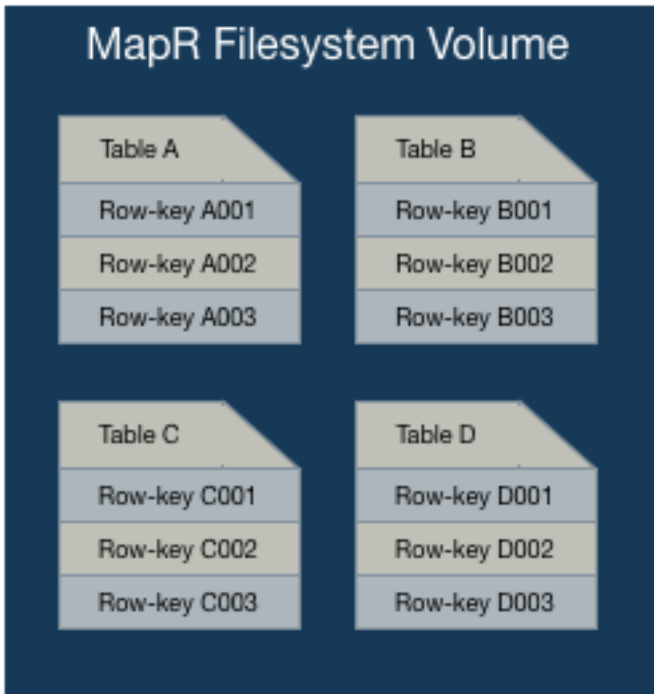
- **Integrated analytics with SQL**: HPE Ezmeral Data Fabric Database's integration with Drill for Data Fabric provides a low latency, distributed, SQL query engine for large-scale datasets, including structured and semi-structured, nested data.
- **Operational analytics**: HPE Ezmeral Data Fabric Database can run in the same cluster as Apache™ Hadoop® and Apache Spark, letting you immediately analyze or process live, interactive data. This also enables you to eliminate data silos to speed the data-to-action cycle, providing a more efficient data architecture.

last-updated: Jun 06, 2024

- **Global distribution of applications**: Application access to HPE Ezmeral Data Fabric Database tables is distributable on a global scale.
- **Flexible data model**: You can use HPE Ezmeral Data Fabric Database as both a document database and a column-oriented database. As a document database, HPE Ezmeral Data Fabric Database stores JSON documents in JSON tables. As a column-oriented database, it stores binary files in binary tables.

How is HPE Ezmeral Data Fabric Database Related to HPE Ezmeral Data Fabric File Store?

HPE Ezmeral Data Fabric Database implements tables within the framework of the Data Fabric filesystem. HPE Ezmeral Data Fabric Database creates tables (both binary and JSON tables) in logical units called *volumes*.



What are HPE Ezmeral Data Fabric Database's Architectural Advantages?

HPE Ezmeral Data Fabric Database's architecture has the following advantages:

- It reduces process overhead because it has no extra layers to pass through when performing operations on data.

  HPE Ezmeral Data Fabric Database, like several other NoSQL databases, is a log-based database. HPE Ezmeral Data Fabric Database runs inside of the Data Fabric filesystem process, which enables it to read from and write to disks directly. In contrast, other NoSQL databases must communicate with a separate process to performs disk reads and writes. The approach taken by HPE Ezmeral Data Fabric Database eliminates extra process hops, duplicate caching, and needless abstractions, with the consequence of optimizing I/O operations on your data.

- It minimizes compaction delays because it avoids I/O storms when it merges logged operations with structures on disk.

  As a log-based database, HPE Ezmeral Data Fabric Database must write logged operations to disk. HPE Ezmeral Data Fabric Database stores table *regions* (also called *tablets*) and smaller structures within them partially as b-trees. Together with write-ahead logs (WAL), these b-trees comprise log-structured-merge trees. Write-ahead logs for the smaller structures within regions are periodically restructured by rolling merge operations on the b-trees. As HPE Ezmeral Data Fabric Database performs these merges at small scales, applications running against HPE Ezmeral Data Fabric Database see no significant effects on latency while the merges are taking place.

   **NOTE:** Apache HBase also uses the term *regions*.

What Design Factors are Important when Using HPE Ezmeral Data Fabric Database?

- **Rowkey Optimization**: The design of a table's rowkeys affects the speed at which client applications can access data. It also impacts database performance if hotspotting occurs. The better the design, the faster the data access. See Table Rowkey Design on page 680 for more information.
- **Column Family Optimization**: Column families enable you to group related sets of data and restrict queries to a defined subset, leading to better performance. When you design a column family, think about what kinds of queries you are going to use most often, and group your columns accordingly. See Column Families in JSON Tables on page 662 and Column Families in Binary Tables on page 679 for more information.
- **Replication Implementation**: The design of table replication (in addition to the automatic replication that occurs with table regions within a volume) depends on your desired outcome and the complexity of your environment. See Table Replication on page 749 for more information.
- **Security Implementation**: You can implement security at various levels including for table replication, JSON documents, and general access. Determining what level and where is part of the architectural design. See Security on JSON Tables on page 665, and Security on page 830.

HPE Ezmeral Data Fabric Database and File Store

Describes how HPE Ezmeral Data Fabric Database tables are implemented directly in the Data Fabric file system, which allows HPE Ezmeral Data Fabric Database to leverage the same architecture as the rest of the platform and results in minimal additional management.

- HPE Ezmeral Data Fabric Database tables are created in logical units called *volumes*.
- HPE Ezmeral Data Fabric Database tables are sharded by implementing *table regions* (also called *tablets*)
- Table regions are stored in abstract entities called *data containers*.
- Data containers belong to file system volumes.

Tables and Volumes

As volumes are a management entity that logically organize a cluster’s data, they can be used to enforce disk usage limits, set replication levels, define snapshots and mirrors, and establish ownership and accountability.

Volumes do not have a fixed size and they do not occupy disk space until the file system writes data to a container within the volume. A large volume may contain anywhere from 50-100 million containers.

Tables are stored in containers and implemented in volumes, and provide the following capabilities:

- Multi-Tenancy

last-updated: Jun 06, 2024

- Snapshots
- Mirroring and Replication

Table Regions and Containers

Each region of a table, along with its corresponding write-ahead log (WAL) files, b-trees, and other associated structures, is stored in one container. Each container (which can be from 16 to 32 GB in size) can store more than one region (which by default is 4096MB in size). The recommended practice is to use the default size for a region and allow it to be split automatically. Massive regions can affect synchronization of containers and load balancing across a cluster. Smaller regions spread data better across more nodes.

NOTE: Since a container always belongs to exactly one volume, that container's replicas all belong to the same volume as well.

The following are the key advantages to storing table regions in containers:

- Cluster Scalability
- High Data Availability

For more information about containers, see Containers and the CLDB on page 491.

Cluster Scalability

Information about and location of tables (and files) is not tracked directly, but through file system containers by the CLDB. As this architecture keeps the CLDB size small, it becomes practical to store 10s of exabytes in a data-fabric cluster, regardless of the number of tables and files.

The location of containers in a cluster is tracked by that cluster's container location database (CLDB). CLDBs are updated only when a container is moved, a node fails, or as a result of periodic block change reports. The update rate, even for very large clusters, is therefore relatively low. The data-fabric filesystem does not have to query the CLDB often, so it can cache container locations for very long times.

Moreover, CLDBs are very small in comparison to Apache Hadoop namenodes. Namenodes track metadata and block information for all files, and the locations for all blocks in every file as well. As blocks are typically 200 MB in size on an average, the total number of objects that a namenode tracks is very large. CLDBs, however, track containers, which are much larger objects, so the size of the location information can be 100 to 1000 times smaller than the location information in a namenode. CLDBs do not track information about tables and files.

High Availability

Due to the way updates to table regions (also called tablets) are applied and replicated, data in table regions are instantly available. Tables and table regions are part of abstract entities called *containers* that provide the automatic replication of table regions (with a default of three) across the nodes of a cluster.

Containers are replicated to a configurable number of copies. These copies are distributed to different nodes in the same cluster as the original or primary container. The cluster CLDB determines the order in which the replicas are updated. Together, the replicas form a replication chain that is updated transactionally. When an update is applied to a region (also called tablets) in the primary container (which is at the head of a replication chain), the update is applied serially to the replicas of that container in the chain. The update is complete only when all replicas in the chain are updated.

As a result of this architecture, when a hardware failure brings down a node, the regions served by that node are available instantly from one of the other nodes that have the replicated data.

HPE Ezmeral Data Fabric software can detect the exact point at which replicas diverge, even at a 2-GB-per-second update rate. The software randomly picks any one of the three copies as the new master, rolls back the other surviving replicas to the divergence point, and then rolls forward to converge with the chosen master. HPE Ezmeral Data Fabric software can do this on the fly with very little impact on normal operations.

last-updated: Jun 06, 2024

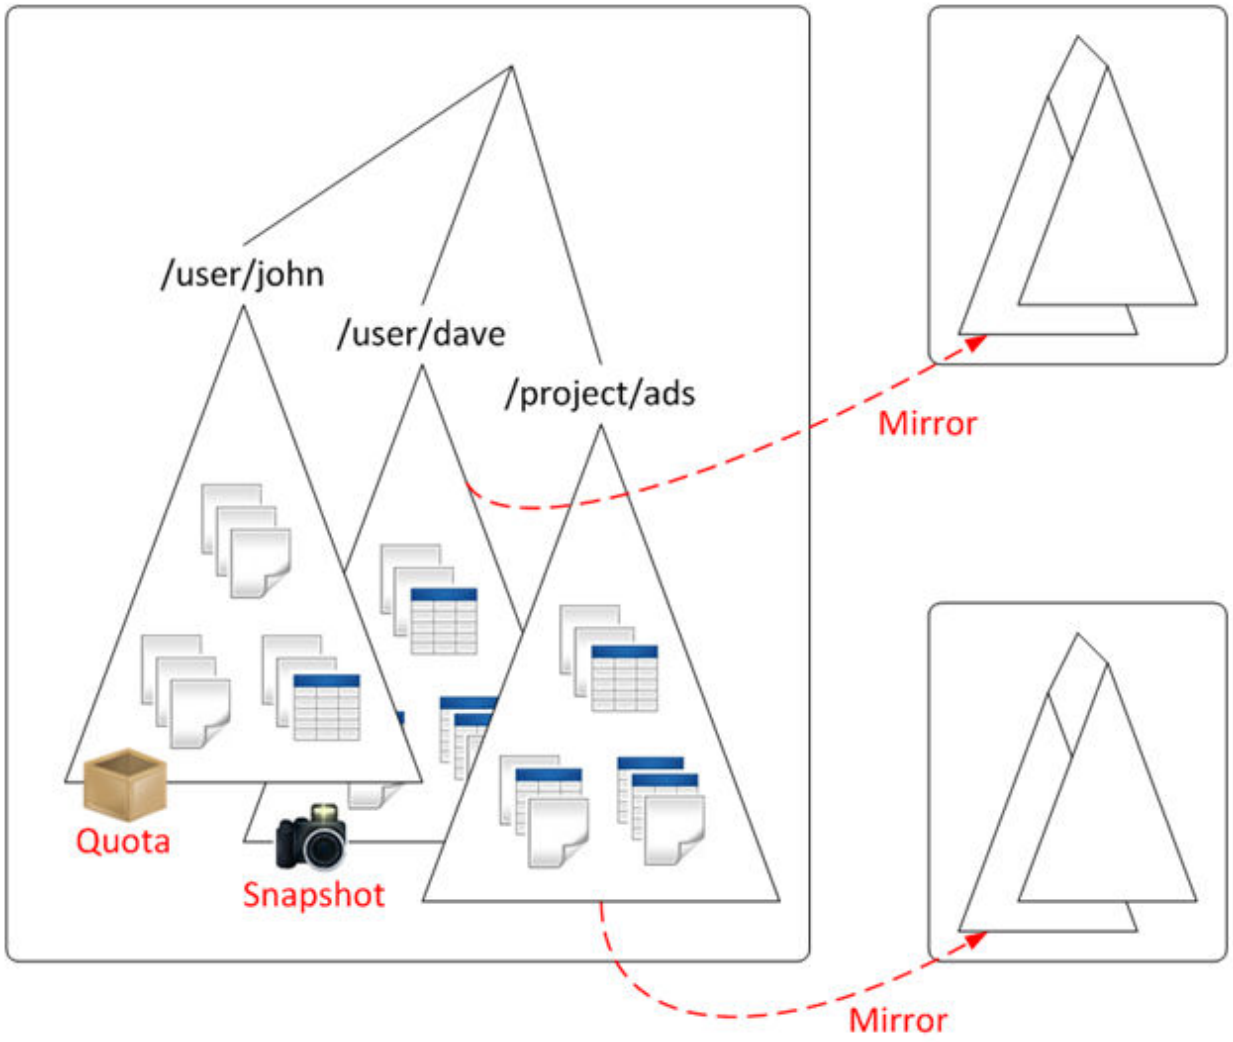
NOTE: Since containers are contained in volumes, the automatic replication factor is set at the volume level.

Multi-Tenancy
Since HPE Ezmeral Data Fabric Database tables are created in volumes, when you restrict the volume, you also restrict the table data. If a volume is restricted to a subset of a cluster's nodes, then it allows you to isolate sensitive data or applications, and even use heterogeneous hardware in the cluster for specific workloads.

For example, you can use data placement to keep personally identifiable information on nodes that have encrypted drives, or to keep HPE Ezmeral Data Fabric Database tables on nodes that have SSDs. You can also isolate work environments for different database users or applications and place HPE Ezmeral Data Fabric Database tables on specific hardware for better performance or load isolation.

Isolation of work environments for different database users or applications lets you set policies, quotas, and access privileges for specific users and volumes. You can run multiple jobs with different requirements without conflict.

As an example, the following diagram depicts a data-fabric cluster storing table and file data. The cluster has three separate volumes mounted at directories `/user/john`, `/user/dave`, and `/project/ads`. As shown, each directory contains both file data and table data, grouped together logically. Since each directory maps to a different volume, data in each directory can have a different policy. For example, `/user/john` has a disk-usage quota, while `/user/dave` is on a snapshot schedule. Furthermore, two directories, `/user/john` and `/project/ads` are mirrored to locations outside the cluster, providing read-only access to high-traffic data, including the tables in those volumes.



Example: Restricting table storage with quotas and physical topology

This example creates a table with disk usage quota of 100GB restricted to certain data nodes in the cluster. First, create a volume named `project-tables-vol`, specifying the quota and restricting storage to nodes in the `/data/rack1` topology, and mounting it in the local namespace. Next, use the HBase shell to create a new table named `datastore`, specifying a path inside the `project-tables-vol` volume.

```
$ pwd
/mapr/cluster1/user/project

$ls
bin   src

$ maprcli volume create -name project-tables-vol -path /user/project/tables
\
    -quota 100G -topology /data/rack1

$ ls
bin   src   tables

$ hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
hbase(main):001:0> create '/user/project/tables/datastore', 'colfamily1'
```

last-updated: Jun 06, 2024

```
0 row(s) in 0.5180 seconds
hbase(main):002:0> exit

$ ls -l tables
total 1
lrwxr-xr-x 1 mapr mapr 2 Oct 25 15:20 datastore ->
mapr::table::2252.32.16498
```

Snapshots

Since HPE Ezmeral Data Fabric Database tables are created in volumes, you can use a volume snapshot to capture the state of a volume's directories, HPE Ezmeral Data Fabric Database tables, and files at an exact point in time.

Use volume snapshots for rollbacks, hot backups, model training, and real-time data analysis management.

Rollback from errors	Application errors or inadvertent user errors can mistakenly delete data or modify data in an unexpected way. With volume snapshots, you can rollback your HPE Ezmeral Data Fabric Database tables to a known, well-defined state.
Hot backups	You can create backups of table data on the fly for auditing or governance compliance.
Model training	Machine-learning frameworks can use snapshots to enable a reproducible and auditable model training process. Snapshots allow the training process to work against a preserved image of the training data from a precise moment in time. In most cases, the use of snapshots requires no additional storage and snapshots are taken in less than one second.
Managing real-time data analysis	By using snapshots, query engines such as Apache Drill can produce precise synchronic summaries of data sources subject to constant updates, such as sensor data or social media streams. Using a snapshot of your HPE Ezmeral Data Fabric Database data for such analyses allows very precise comparisons to be done across multiple ever-changing data sources without the need to stop real-time data ingestion. See MapR Snapshots for more details.

Mirroring

Since HPE Ezmeral Data Fabric Database tables are created in volumes, volume mirroring lets you automatically replicate differential data across clusters and is done so, as designated, through the use of mirror schedules or through a manual mirroring operation one time without defining a schedule. Consider mirroring volumes to create disaster recovery solutions for databases or provide read-only access to data from multiple locations.

As HPE Ezmeral Data Fabric Database does not require RegionServers to be reconstructed, databases can be brought up on the mirrored site if the active site goes down.

Mirroring is a parallel operation, copying data directly from the nodes of one data-fabric cluster to the nodes in a remote data-fabric cluster. The contents of the volume are mirrored, even if the files in the volume are being written to or deleted.

Data Fabric captures only data that has changed at the file-block level since the last data transfer. After the data differential is identified, it is then compressed and transferred over the WAN to the recovery site, using very low network bandwidth. Finally, checksums are used to ensure data integrity across the two clusters. There is no performance penalty on the cluster because of mirroring.

See Mirror Volumes on page 501 for more details on mirror volumes.

last-updated: Jun 06, 2024

See Guidelines for Setting Mirror Schedules on page 1282 for more details on setting mirror schedules.

Replication
Automatically replicating differential data across clusters is possible when coupling this feature with volume mirroring processes. Consider using replication to allow for reliable data protection and uninterrupted access to data, in addition to combining its features with mirroring for data recovery features.

You can initiate data replication processes to specifically allow for high availability of data. The process involves copying volume data from one node to another within and across clusters. Specifically, streams and tables can be replicated through gateways on a record-by-record basis in real-time within the HPE Ezmeral Data Fabric Database.

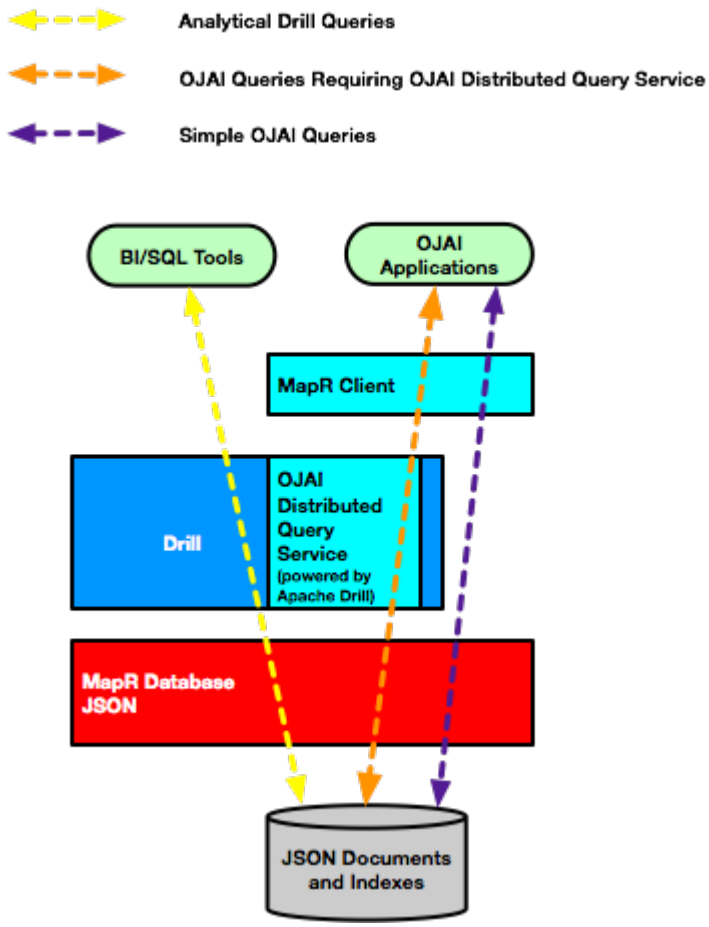
See Stream Replication on page 795 for more details on replicating streams.

See Table Replication on page 749 for more details on replicating tables.

See Understanding Replication on page 492 for more details on the replication process.

OJAI Distributed Query Service
OJAI queries either directly access HPE Ezmeral Data Fabric Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for HPE Ezmeral Data Fabric Database JSON, powered by Apache Drill. The data-fabric client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of Drill.

The following diagram summarizes the different code paths and the components involved for processing HPE Ezmeral Data Fabric Database JSON queries.



Data Fabric automatically chooses which code path to use.

The following table summarizes the functionality that each code path supports:

Simple OJAI Queries	OJAI Queries Requiring OJAI Distributed Query Service	Analytical Drill Queries
• Can use single secondary index • Configurable limit on sorts • Serial query execution	• Can use multiple secondary indexes • No imposed limit on sort size • Parallel query execution • Query optimization for operational queries	• Can use multiple secondary indexes • No imposed limit on sort size • Parallel query execution • Query optimization for analytical queries

Simple OJAI Queries

The right path in the preceding image represents simple queries issued through an OJAI application. These queries can leverage a single index and operate on smaller data sets that do not benefit from parallel query execution.

Queries in this code path do not use the OJAI Distributed Query Service. If the OJAI Distributed Query Service is not installed, all OJAI queries use this code path. When queries run through this code path, sorts on large data sets may fail if the result size exceeds the size of a configurable parameter. See Querying in OJAI Applications on page 3360 for more details.

OJAI Queries Requiring OJAI Distributed Query Service

The middle path represents more complex queries issued through an OJAI application. These queries use the enhanced functionality available in the OJAI Distributed Query Service. This includes sorting large data sets and distributed, parallel query execution. When the Distributed Query Service is installed, the data-fabric client decides whether a query benefits from the service and automatically redirects the query to the service.

The OJAI Distributed Query Service is a lightweight subset of the full Drill query engine that is well suited for the typical queries issued by OJAI. It excludes the more advanced functionality needed by analytical queries.

The OJAI Distributed Query Service also provides more sophisticated index selection, including leveraging multiple indexes in a single query. It uses a cost based optimizer to select the indexes that provide the best performance.

Analytical Drill Queries

The left path represents SQL queries issued by BI and SQL tools to Drill. This path leverages Drill's analytical capabilities. It can optimize and process complex queries on large data sets in parallel and provide interactive query response times.

The optimizer used by Drill is a superset of the optimizer used by the OJAI Distributed Query Service. It is also a cost based optimizer, but includes more comprehensive optimization techniques needed by complex analytical queries.

For more information about how secondary index selection and execution works in HPE Ezmeral Data Fabric Database JSON, see Selection and Execution of Secondary Indexes on page 721.

last-updated: Jun 06, 2024

NOTE: Prior to data-fabric version 6.0.1, the OJAI Distributed Query Service was named the OJAI Query Service.

Data Models

HPE Ezmeral Data Fabric Database can be used as both a document database and a column-oriented database. As a document database, JSON documents are stored in HPE Ezmeral Data Fabric Database JSON table. As a column-oriented database, binary files are in stored HPE Ezmeral Data Fabric Database binary tables.

HPE Ezmeral Data Fabric Database as a Document Database

JSON documents are stored in HPE Ezmeral Data Fabric Database JSON tables. When you create a table in a volume, the table type is specified as JSON. Only JSON-like documents can be stored in JSON tables. Typically, tables of the same type (in this case, JSON) are created in their own volume.

Each document is stored in a table row and indexed by the "_id" field.

JSON Table
{“_id … }
{“_id … }
{“_id … }

HPE Ezmeral Data Fabric Database as a Column-Oriented Database

Data is stored as a collection of key-value pairs where the key serves as a unique identifier. Typically, tables of the same type (in this case, binary) are created in their own volume.

Binary Table			
Row Key	**Column A**	**Column B**	**Column C**
Key 001	Value for A	Value for B	Value for C
Key 002	Value for A	Value for B	Value for C
Key 003	Value for A	Value for B	Value for C

HPE Ezmeral Data Fabric Database as a Document Database

HPE Ezmeral Data Fabric Database supports JSON documents as a native data store. A JSON document is a tree of fields. These JSON documents are stored in HPE Ezmeral Data Fabric Database tables.

HPE Ezmeral Data Fabric Database as a document database, implements JSON documents in HPE Ezmeral Data Fabric Database JSON tables.

- HPE Ezmeral Data Fabric Database JSON tables use the OJAI data model and support the OJAI API.
- Documents are in JSON format; HPE Ezmeral Data Fabric Database stores them in an efficient binary encoding, rather than plain ASCII text.

last-updated: Jun 06, 2024

- With JSON tables, each value has a unique key (`_id`). You identify fields in the document using field paths. For example, `address.street`:

```
{
    "_id": "ID001",
    "name" : "Bob",
    "address": {
        "house" : 123,
        "street": "Main",
        "phones": [
            { "mobile": "555-1234" },
            { "work": "+1-123-456-7890" }]},
    "hobbies": ["badminton", "chess", "beaches"]
}
```

NOTE: Each JSON document can have different fields.

With JSON document support, you can:

- Store data that is hierarchical and nested, and evolves over time.
- Read and write individual document fields, subsets of fields, or whole documents from and to disk. To update individual fields or subsets of fields, there is no need to read entire documents, modify them, and then write the modified documents to disk.
- Build applications with the HPE Ezmeral Data Fabric Database JSON API library, which is an implementation of the Open JSON Application Interface (OJAI). This is an API library for easily managing complex, evolving, hierarchical data. You can use more data types than the standard types that JSON supports, create complex queries, and access JSON table documents without connection or configuration objects. This allows large-scale applications to manage JSON documents.
- Filter query results within HPE Ezmeral Data Fabric Database before results are returned to client applications.
- Run client applications on Linux, OS X, and Windows systems.
- Perform complex data analysis on your JSON data with Apache Drill or other analytical tools in real time without having to copy data to another cluster.
- Scale your data to span thousands of nodes.
- Control read and write access to single fields and subsets of fields within a JSON table by using access-control expressions (ACEs).
- Control the disk layout of single fields and subdocuments within JSON tables.
- Use Secondary Indexes on page 682 to improve query performance.

JSON Documents
A JSON document is a tree of fields. Each field has a name, type, and value. In the case of an array type, the array field name and array index identify individual elements in the array. Field names are strings. The root of each document is a map. The advantages of JSON documents include the data types it supports and its schema flexibility. HPE Ezmeral Data Fabric Database provides tools that enable you to operate on JSON documents.

An online retailer of sports equipment might have this JSON document for storing data about a set of bicycle pedals:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    }
}
```

Data Types

HPE Ezmeral Data Fabric Database JSON documents support a richer set of data types beyond what JSON supports. JSON documents can have scalar data, nested documents, and arrays. HPE Ezmeral Data Fabric Database JSON stores the data in a format that maintains the types. To access JSON documents, you can use the OJAI API. The API exposes data types in a manner specific to the programming language of the API. JSON Document Data Types on page 646 describes each category of types in relation to the sample JSON document shown earlier.

Comparing and Sorting Data Types

Comparisons and sorts of data types differ depending on whether the types are comparable or not. See Using Comparable JSON Document Data Types in Comparisons and Sorts on page 649 and Using Non-comparable JSON Document Data Types in Comparisons and Sorts on page 650 to learn which types fall into each category and to understand their behavior.

Schema Flexibility

The structure of each document, called the document's *schema*, is easy to change. Simply add new fields. For example, if the online retailer wants to allow customers to review products, it is simple to add the reviews to any document for a product.

In this example, highlighted in bold, the `comments` are added as an array with two nested documents:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    },
```

```
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

Identifying Document Fields

To learn about how to access JSON document fields, see JSON Document Field Paths on page 651. The material includes examples that use the JSON document shown earlier.

Querying Document Fields

HPE Ezmeral Data Fabric Database allows you to specify query conditions in a JSON format using syntax supported by the OJAI API. See OJAI Query Condition Syntax on page 3387 for details.

JSON Document Size

The default maximum size of a JSON document is 32 MB. This size includes the field values in the document, as well as the names, types, and other field metadata. You can configure this size by running the command described at Configuring Maximum Row Sizes Using the CLI on page 1354.

Tools for Working with JSON Documents

These are the tools you can use to create, read, update, and delete JSON documents in HPE Ezmeral Data Fabric Database:

HPE Ezmeral Data Fabric Database Shell	This shell is a light-weight tool for administering, manipulating, and querying JSON tables and documents. Learn more about it at HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5469.
OJAI API	The OJAI API provides an interface for creating, reading, updating, and deleting JSON documents. HPE Ezmeral Data Fabric Database JSON supports the OJAI API in the following languages: • Java • Node.js • Python • C# • Go To learn about how to create, update, and delete JSON documents, see Managing JSON Documents on page 3322. To learn about how to query JSON documents, see Querying in OJAI Applications on page 3360. For information that is specific to each language, see the following:

Java	See Java OJAI Client API for the complete API.
Node.js	See Using the Node.js OJAI Client on page 3453 for an introduction to this client. See Node.js OJAI Client API for the complete API.
Python	See Using the Python OJAI Client on page 3458 for an introduction to this client. See Python OJAI Client API for the complete API.
C#	See Using the C# OJAI Client on page 3468 for an introduction to this client. See C# OJAI Client API for the complete API.
Go	See Using the Go OJAI Client on page 3473 for an introduction to this client. See Go OJAI Client API for the complete API.
HPE Ezmeral Data Fabric Database JSON REST API	The REST API enables you to use HTTP calls to perform basic operations on HPE Ezmeral Data Fabric Database JSON tables. Learn more about it at Using the HPE Ezmeral Data Fabric Database JSON REST API on page 3478.

JSON Document Data Types

HPE Ezmeral Data Fabric Database JSON documents support a richer set of data types beyond what JSON supports. JSON documents can have scalar data, nested documents, and arrays.

Scalar Data

Scalar data fields can contain strings or numbers. The scalar fields in the sample document are highlighted in bold as follows:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
```

last-updated: Jun 06, 2024

```
        "color" : "black"
    },
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

Scalar fields can contain the following data types:

Data Type	Description
Binary	An uninterpreted sequence of bytes
Boolean	A data type of two possible values that are typically denoted by `true` and `false`
Byte	A 8-bit signed integer that ranges in value from -128 to 127
Date	A 32-bit integer that represents the number of DAYS since epoch, that is. January 1, 1970 00:00:00 UTC. The value is absolute and is time-zone independent.
Double	A double-precision 64-bit floating-point number
Float	A single-precision 32-bit floating-point number
Int	A 32-bit signed integer that ranges in value from −2,147,483,648 to 2,147,483,647
Long	A 64-bit signed integer that ranges in value from -(2^{63}) to 2^{63} - 1
Short	A 16-bit signed integer that ranges in value from −32,768 to 32,767
String	A sequence of characters
Time	A 32-bit integer that represents time of the day in milliseconds. The value is absolute and is time-zone independent.
Timestamp	A 64-bit integer that represents the number of milliseconds since epoch, that is, January 1, 1970 00:00:00 UTC. Negative values represent dates before epoch.

Nested Documents

Nested document fields can contain documents that themselves contain scalar data, nested documents, arrays, or a combination of any of these types. The nested documents in the sample document are highlighted in bold as follows:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
```

```
    },
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

NOTE: Nested documents can also be referred to as *maps*.

A nested document can include subfields that are themselves nested documents. In the following example, `location` is a nested document that has two nested document subfields, `address` and `geoCoordinates`:

```
{
   "_id": "001",
   "location": {
      "address": {
         "number": 100,
         "street": "Main St.",
         "city": "San Francisco",
         "state": "CA",
         "zipCode": "90210"
      },
      "geoCoordinates": {
         "latitude": 37.7817529521,
         "longitude": -122.39612197
      }
   }
}
```

There is no limit on the number of nestings in a nested document. However, you should consider the extra complexity that additional nestings may add to your applications.

Arrays

Array fields contain lists of values that are accessible by means of index numbers. The values can be scalar, nested documents, arrays, or a combination of any of these types. For example, the following document has two arrays, both highlighted in bold:

- `features`: An array with two scalar strings
- `comments`: An array with two nested documents

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
```

```
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    },
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

NOTE: Arrays can also be referred to as *lists*.

Using Comparable JSON Document Data Types in Comparisons and Sorts

Defines comparable data types and their usage.

Data types that have a well defined order amongst the types are comparable data types. In a filter condition, if a document's field value and the comparison value are of comparable types, the document qualifies if the condition returns true. This applies regardless of whether you have created secondary indexes on the comparison fields.

Based on the preceding definition, numeric types are comparable. This includes the following types:

- INT
- SHORT
- LONG
- FLOAT
- DOUBLE

NOTE: FLOAT and DOUBLE are approximate representations of decimal values. They may not return `true` in equality comparisons against their equivalent decimal values.

Example

Consider the following example where you have four documents, each with a field, `AccountBalance`. The types of the field differ, as noted in the table, but they are all comparable numeric types:

Document Name	`AccountBalance` Field Value	`AccountBalance` Field Type
DOCUMENT1	1900.12	FLOAT
DOCUMENT2	10000	INT
DOCUMENT3	10	LONG
DOCUMENT4	27.88	DOUBLE

If you specify a sort on the field `AccountBalance`, HPE Ezmeral Data Fabric Database sorts the field in the following order:

Document Name	`AccountBalance` Field Value
DOCUMENT3	10

last-updated: Jun 06, 2024

Document Name	`AccountBalance` Field Value
DOCUMENT4	27.88
DOCUMENT1	1900.12
DOCUMENT2	10000

Secondary indexes sort and store data based on the values of the indexed fields. When reading through the index, HPE Ezmeral Data Fabric Database returns the documents in the order of index.

For example, suppose you have an index where `AccountBalance` is the indexed field. A query with the condition, `"AccountBalance > 20"`, returns the documents in the following order if HPE Ezmeral Data Fabric Database processes the query using the index:

- DOCUMENT4
- DOCUMENT1
- DOCUMENT2

Using Non-comparable JSON Document Data Types in Comparisons and Sorts

Defines non-comparable data types and their usage.

Non-comparable data types are data types that do not follow a well-defined order. In contrast to comparisons between comparable types, comparisons between fields and values of non-comparable types do not qualify even if you perceive a match in values. This is true whether you have indexed the field you are comparing or not.

Arrays and nested documents also fall into the non-comparable category. Since these entities do not have a defined ordering, only equality comparisons on these types are meaningful. For arrays, the order of the array elements must match; for nested documents, all fields in the nested document must match, but the order of the fields is not relevant.

You cannot order on Container Field Paths on page 653. For example, you cannot order on the field `a[].b`, even if the subfield `b` has scalar data.

Example

Consider the following example. If your field, `docField`, has string values and you compare it against a numeric value, none of the string values in the field match the numeric. Likewise, if your field has numeric values and you compare it against a string value, none of the numeric values in the field match the string. Both field and comparison values must be strings or integers to match:

Document Name	Value of Field `docField`	Type of Field `docField`	Filter Condition	Field Value Qualifies Filter Condition?
DOCUMENT1a	23	STRING	`docField = 23`	No
DOCUMENT1b	23	INT	`docField = 23`	Yes
DOCUMENT2a	45	INT	`docField = '45'`	No
DOCUMENT2b	45	STRING	`docField = '45'`	Yes
DOCUMENT3		No type due to missing value	`docField = 23`	No
DOCUMENT4	NULL	No type due to NULL value	`docField = '45'`	No

HPE Ezmeral Data Fabric Database does not define a fixed ordering across non-comparable types. It sorts the values within comparable types and within each non-comparable type, but not across both.

last-updated: Jun 06, 2024

In the previous example, when sorting on `docField`, you could obtain the following for a sort in ascending order:

Document Name	Value of Field `docField`	Type of Field `docField`
DOCUMENT1b	23	INT
DOCUMENT2a	45	INT
DOCUMENT1a	23	STRING
DOCUMENT2b	45	STRING
DOCUMENT4	NULL	No type due to NULL value
DOCUMENT3		No type due to missing value

Note the independent ordering of the integer and string values. Also note that for the rows with NULL and missing field values, the row with NULL appears before the row with a missing value.

JSON Document Field Paths
To access fields in a JSON document, you use a *field path*. The syntax for a field path can vary, depending on the data type you are accessing: nested documents, arrays, nested documents within arrays, and multidimensional arrays.

The examples in this topic reference the following sample JSON document:

```
{
    "_id" : "2DT3201",
    "product_ID" : "2DT3201",
    "name" : " Allegro SPD-SL 6800",
    "brand" : "Careen",
    "category" : "Pedals",
    "type" : "Components",
    "price" : 112.99,
    "features" : [
        "Low-profile design",
        "Floating SH11 cleats included"
    ],
    "specifications" : {
        "weight_per_pair" : "260g",
        "color" : "black"
    },
    "comments" : [
        {
            "username" : "hlmencken",
            "comment" : "Best money I ever spent!"
        },
        {
            "username" : "vwoolf",
            "comment" : "What hlmencken said!"
        }
    ]
}
```

In the simplest case, the field path is the name of the field and refers to the entire field.

Nested Documents

If a field is a nested document, specifying the nested document identifies the entire nested document.

To identify individual fields in a nested document, you use a *dot notation* to specify their paths. A field path is a sequence of field names that leads to the particular field that you are interested in. The names are separated by dots.

last-updated: Jun 06, 2024

The following shows a document with multiple levels of nested documents:

```
{
   "a" : {
       "b" : {
            "c" : {
                "d" : "value_for_d"
            }
        }
    }
}
```

The field path for field `d` using dot notation is `a.b.c.d`.

The following table shows examples of field paths using dot notation for the sample JSON document:

Field Path	Value Returned
`specifications`	`{ "specifications": {"color":"black","weight_per_pair":"260g"} }` The entire nested document field `specifications`
`specifications.weight_per_pair`	`{"specifications":{"weight_per_pair":"260g"}}` The `weight_per_pair` subfield in `specifications`
`specifications.color`	`{"specifications":{"color":"black"}}` The `color` subfield in `specifications`

Arrays

If the field is an array, specifying the array's field name identifies the entire array.

To access an element in an array, specify the position of the element in the array, starting at offset zero.

The following table shows examples of field paths that reference arrays for the sample JSON document:

Field Path	Value Returned
`features`	`{ "features":[ "Low-profile design", "Floating SH11 cleats included" ] }` The entire `features` array
`features[0]`	`{"features":["Low-profile design"]}` The first element of the `features` array

last-updated: Jun 06, 2024

Field Path	Value Returned
`features[1]`	`{ "features": [null,"Floating SH11 cleats included"] }` The second element of the `features` array **NOTE:** `null` is shown in the first element of the array to signify that the element returned is the second entry from the array.
`comments[0]`	`{ "comments": [{"comment":"Best money I ever spent!","username":"hlmencken"}] }` The first element of the `comments` array, which is a nested document

Container Field Paths

Starting in data-fabric 6.1, HPE Ezmeral Data Fabric Database introduces the notion of a *container field path*. Using a container field path, you can access a field that is either a single value or an arbitrary array element.

If you have a field that has a single value (rather than an array of values), when using a container field path, HPE Ezmeral Data Fabric Database treats the single value as an array with one element. This enables you to use a container field path to access a field that has both array elements and scalar values. The array elements and scalar values can be of any type.

To specify a container field path, place square brackets after the field name:

```
fieldName[]
```

A container field path is useful if you want to perform one of the following scenarios:

- Perform comparisons on a field path that is either a single value or an arbitrary array element
- Access subfields in a nested document, where the nested document is either an arbitrary array element or a single nested document
- Access arbitrary elements in an array

See OJAI Query Conditions Using Container Field Paths on page 3396 for more details about the first scenario. The next two sections describes the second and third scenarios.

Nested Documents Within Arrays

Array elements can be nested documents. You can reference individual subfields within these nested documents with container field paths, starting in data-fabric 6.1. If you have a field that has a single value (rather than an array of values), if you use a container field path, HPE Ezmeral Data Fabric Database treats the single value as an array with one element. This enables you to use a container field path to access a field that has both array elements and scalar values.

For example, suppose you have the following two JSON documents in a HPE Ezmeral Data Fabric Database table, and `addresses` has an array of nested documents in the first document and a nested document in the second document:

```
{
  "_id":"1",
  "addresses":[
    {"state":"CA","city":"SJ"},
    {"state":"CA","city":"SC"},
    {"state":"WA","street":"NE 39th"}
  ]
}
{
  "_id":"2",
  "addresses":{"state":"CA","city":"SJ"}
}
```

You can use `addresses[].state` to reference the `state` subfield across all nested documents in both documents.

The following table describes the field paths supported and what each field path returns:

Field Path	Value Returned *(Number in Description Corresponds to Document ID)*
`addresses`	`{ "addresses": [ {"city":"SJ","state":"CA"}, {"city":"SC","state":"CA"}, {"state":"WA","street":"NE 39th"}] } { "addresses":{"city":"SJ","state":"CA"} }` **1.** The array containing three nested documents **2.** The single nested document
`addresses.city`	`{} {"addresses":{"city":"SJ"}}` **1.** Empty because `addresses` is not a nested document **2.** The `city` subfield in the nested document
`addresses[0]`	`{ "addresses": [{"city":"SJ","state":"CA"}] } {}` **1.** The first element in the `addresses` array **2.** Empty because `addresses` is not an array

last-updated: Jun 06, 2024

Field Path	Value Returned *(Number in Description Corresponds to Document ID)*

`addresses[2].state`	`{`
	`  "addresses":`
	`  [null,null,{"state":"WA"}]`
	`}`
	`{}`
	
	1. The `state` subfield from the nested document in the third element of the `addresses` array
	
	NOTE: `null` is shown in the first two elements of the array to signify that the element returned is the third entry from the array
	
	2. Empty because `addresses` is not an array

`addresses[0].state, addresses[0].city`	`{"addresses":[{"city":"SJ","state":"CA"}]}`
	`{}`
	
	1. The `city` and `state` subfields from the nested document
	
	2. Empty because `addresses` is not an array

`addresses[].city`
 	
NOTE: Supported starting in MapR 6.1
	`{`
	`  "addresses":`
	`  [`
	`  {"city":"SJ"},`
	`  {"city":"SC"},`
	`  {}`
	`  ]`
	`}`
	`{`
	`  "addresses":`
	`  {"city":"SJ"}`
	`}`
	
	1. An array of nested documents with a `city` subfield; the third array element is empty because the third nested document does not have a `city` subfield
	
	2. A single nested document with a `city` subfield

last-updated: Jun 06, 2024

Field Path	Value Returned *(Number in Description Corresponds to Document ID)*
`addresses[].state, addresses[].city` **NOTE:** Supported starting in MapR 6.1	`{ "addresses": [ {"city":"SJ","state":"CA"}, {"city":"SC","state":"CA"}, {"state":"WA"} ] } { "addresses": {"city":"SJ","state":"CA"} }` **1.** An array of nested documents with `city` and `state` subfields; the third array element has only a `state` subfield because the third nested document does not have a `city` subfield **2.** A single nested document with `city` and `state` subfields

Container Field Paths Across Multiple Levels of Nested Documents

You can use container field paths at any level of a nested document.

For example, suppose you have the following document:

```
{
   "_id": "account001",
   "projects": [
      {
         "id": "proj001",
         "manager": { "name": "Guy Bones", "email": "gbones@pro.com" },
         "customer": {
            "name": "My Company",
            "contacts": [
               {
               "id": "user_jdoe",
               "emails": [
                  { "type": "work", "value": "jdoe@comp.com" },
                  { "type": "personal", "value": "jdoe@gmail.com" }
               ],
               "addresses": [
                  {
                     "type": "work",
                     "value": {"street":"21 King Av","city": "Redwood",
"zip": 94065, "state": "CA" }
                  }
               ],
               "phones": [
                  { "type": "cell", "value": "+16505556764" },
                  { "type": "office", "value": "+14075556764" }],
               "role": "CEO"
               },
               {
               "id": "user_simsom",
               "emails": [
                  { "type": "work", "value": "simson@comp.com" },
                  { "type": "personal", "value": "simson@gmail.com" }
               ],
```

```
                "addresses": [
                   {
                   "type": "work",
                   "value": {"street":"21 King Av.","city":"Redwood","zip":
94065,"state": "CA" }
                   }
                ],
                "phones": [
                   { "type": "cell", "value": "+16505556777" },
                   { "type": "office", "value": "+1407555444" }],
                "role": "PM"
                }
             ]
          }
       },
       {
          "id": "proj002",
          // ...
       }
   ]
}
```

The following table shows field paths that use the container field paths across multiple nested documents and the values returned:

Field Path	Value Returned
`projects[].customer.contacts[].emails[].value`	`{ "projects":[ { "customer":{ "contacts":[ { "emails":[ {"value":"jdoe@comp.com"}, {"value":"jdoe@gmail.com"} ] }, { "emails":[ {"value":"simson@comp.com"}, {"value":"simson@gmail.com"} ] } ] }, { // data for proj002 } ] }`

last-updated: Jun 06, 2024

Field Path	Value Returned
`projects[].customer.contacts[].role`	`{ "projects":[ { "customer": { "contacts":[ {"role":"CEO"}, {"role":"PM"} ] } }, { // data for proj002 } ] }`

Multidimensional Arrays

Arrays can have more than one dimension.

For example, suppose you want to store the high and low temperatures by week. The following document contains the high and low temperatures in Fahrenheit for the seven days beginning on April 29th, 2018. The document uses a two-dimensional array to store the high and low temperatures for each day. The first element of each nested array element is the high temperature for a day, and the second element is the low:

```
{
   "_id" : "001",
   "temps" : [[61,49],[74,51],[75,51],[74,52],[78,54],[75,53],[75,54]],
   "weekOf" : "4/29/2018"
}
```

To access individual high or low temperatures by day, you specify a two-dimensional array element with the desired array indexes. To access a pair of high and low temperatures, you specify a single array index.

Field Path	Value Returned
`temps[0]`	`{"temps":[[61,49]]}`
`temps[5][1]`	`{"temps":[null,null,null,null,null,[null,53]]}` **NOTE:** `null` is shown for all array elements preceding the desired element

There is no limit on the number of dimensions in an array.

Container Field Paths with Multidimensional Arrays

Starting in data-fabric 6.1, a container field path can refer to arbitrary array elements across multiple array dimensions. To reference arbitrary elements in the two-dimensional `temps` array shown earlier, you specify:

```
temps[][]
```

Extending the convention by which a container field path with one set of square brackets treats a scalar value as an array with one element, a container field path with two square brackets treats a one-dimensional array as a two-dimensional array with a single element, where the element is that one-dimensional array.

For example, in the following document, although `temps` has only a single array, you can use `temps[][]` to refer to either the high or low temperature in the array:

```
{
   "_id" : "002",
   "temps" : [81,60],
   "weekOf" : "5/12/2018"
}
```

The same convention applies across *N* dimensions. A container field path with *N* square brackets treats an *(N-1)*-dimensional array as the only element in an *N*-dimensional array.

You can also use the container field paths for a subset of dimensions, provided a dimension that specifies container field path does not precede a dimension that specifies an explicit element. The following table illustrates this:

Field Path	Value Returned

`temps[0][]`	`{"temps":[[61,49]]}`
	`{"temps":[81,60]}`
	The temperatures on the first day of the week

`temps[2][]`	`{"temps":[null,null,[75,51]]}`
	`{"temps":[]}`
	The temperatures on the third day of the week

`temps[]`	`{"temps":[[61,49],[74,51],[75,51],[74,52],[78,54],[75,53],[75,54]]}`
	`{"temps":[81,60]}`
	The temperature pairs across all days

`temps[][0]`	Disallowed because the container field path in the first dimension precedes element 0 in the second dimension

HPE Ezmeral Data Fabric Database JSON Tables

JSON documents are stored in HPE Ezmeral Data Fabric Database JSON tables. HPE Ezmeral Data Fabric Database supports schema flexibility in the documents and provides the tools to efficiently access them. It optimizes the storage of the JSON documents, providing high performance.

When a JSON document is added to a JSON table, it is put in a table row. The table row is part of one column family (although you can create more, as described in Column Families in JSON Tables on page 662). The value in the row is a single JSON document that is stored in a binary format. The binary format allows HPE Ezmeral Data Fabric Database to make a number of optimizations to the document's layout to make data access fast and efficient. HPE Ezmeral Data Fabric Database also maintains the data types associated with fields in a JSON document.

The JSON documents in a table need not have identical structures. It is possible to include in a table any number of JSON documents that have no common fields or share only a subset of fields.

For example, an online retailer might have the following three documents in a single JSON table. Only a subset of fields is common to all three documents. These are key differences:

- Each document has a different nested document in a field named `specifications`.
- Only two of the documents have arrays in the field `features`.
- The `retailers` field has different types in the first and third documents.

            "green"
        ]
    },

    "retailers" : [
        {
            "name" : "Bespoke Cycles",
            "city": "San Francisco",
            "state" : "CA"
        },
        {
            "name" : "Trek Bicycle",
            "city" : "New York",
            "state" : "NY"
        }
    ]
}
```

Container Syntax

Starting in HPE Ezmeral Data Fabric Database 6.1, even though the `retailers` field is an array of nested documents in document 1 and a nested document in document 3, you can reference subfields of the nested documents in both documents using the following container syntax:

```
retailers[].name
```

Specifying that field reference returns the following for the three documents:

```
{
    "retailers":{"name":"Eden Bicycles"}
}
{}
{
    "retailers":[
        {"name":"Bespoke Cycles"},
        {"name":"Trek Bicycle"}]
}
```

last-updated: Jun 06, 2024

NOTE: An empty document is returned for the second document because that document does not have a `retailers` field.

See Container Field Paths on page 653 for more information.

Table Paths

Tables are stored in the data-fabric filesystem. When providing the path to a table in data-fabric tools and APIs, use these conventions:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` in `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

Tools for Creating and Administering JSON Tables

These are the tools available for creating and administering JSON tables in HPE Ezmeral Data Fabric Database:

HPE Ezmeral Data Fabric Database Shell	This shell is a light-weight tool for manipulating JSON tables and documents. Learn more about it at HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5469.
HPE Ezmeral Data Fabric Database JSON Client API	This API allows you to manage HPE Ezmeral Data Fabric Database JSON tables. The API includes methods to create, alter, and drop tables and column families. Learn more about these APIs at Managing JSON Tables on page 3302.
Python OJAI Client	This API allows you to create and drop HPE Ezmeral Data Fabric Database JSON tables in Python. Learn more about it at Using the Python OJAI Client on page 3458.
HPE Ezmeral Data Fabric Database JSON REST API	The REST API allows you to create and drop HPE Ezmeral Data Fabric Database JSON tables using HTTP calls. Learn more about it at Using the HPE Ezmeral Data Fabric Database JSON REST API on page 3478.
HPE Ezmeral Data Fabric Database JSON utilities	HPE Ezmeral Data Fabric Database JSON supports several utilities for loading tables. Learn more about these utilities at Loading Documents into JSON Tables on page 1385.
maprcli commands	The `maprcli table` commands fully support JSON tables. See table.

NOTE: For a list of tools available to query and manage documents in HPE Ezmeral Data Fabric Database JSON tables, see Tools for Working with JSON Documents on page 645.

Column Families in JSON Tables

JSON tables store data in column families. A column family is a collection of fields that are stored together on disk. You can use column families to improve the performance of your queries.

Each table has a default column family, which is default storage for all fields in the documents of a table. You can create additional column families to store data for a collection of fields in a separate location on disk. Queries and other operations that only run on the data stored in a column family are more efficient

and better performing than queries on the same data when that data is stored with other data in a table. You can also cache values from a column family in memory.

Default Column Families

Suppose you have three JSON documents in a table and all three documents have the field `a`.

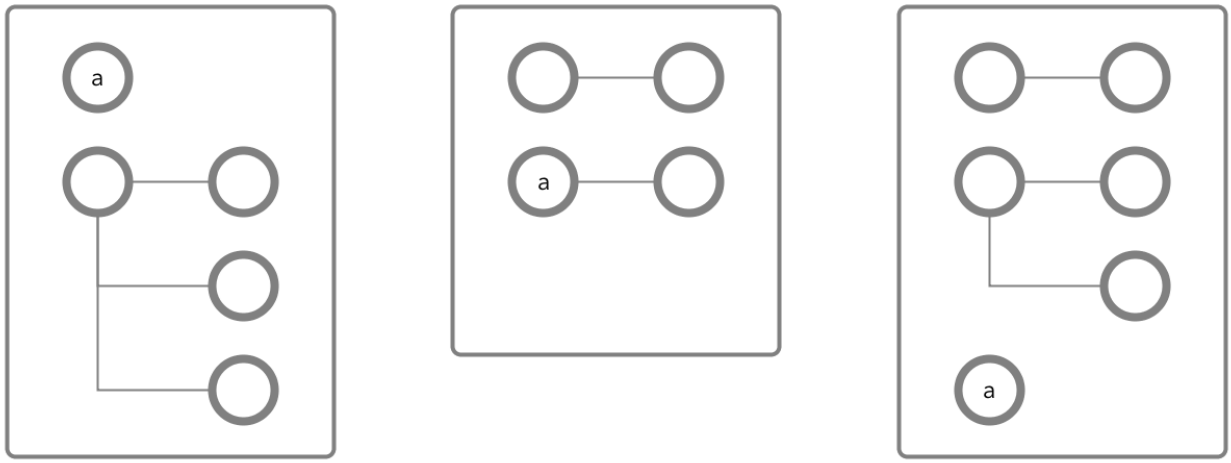

Figure 1: Schematic diagrams of three JSON documents, showing fields but not values, each document with a field named a

At this point, you have not created any non-default column families. So, all of the data in the table resides in the *default* column family. Each JSON table is created with a *default* column family.

Using Column Families to Optimize Data Access

To optimize data access for your applications, you plan to place some data that will be heavily queried in a new column family at path `a.b`, where `b` is a field that does not exist yet. Fields do not have to exist before you create column families on them.

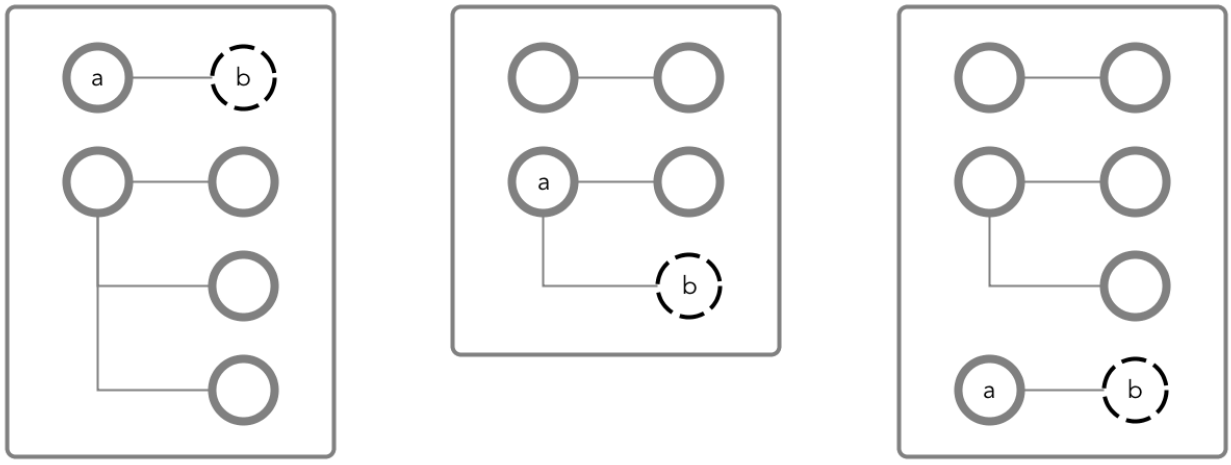

Figure 2: The same three JSON documents, showing where the new column family will be created

You create a column family at the path `a.b` with the name `CF1`.

When you create field `b`, it will belong to the column family `CF1`. All values of `b`, as well as the values of all fields that might be created after `b`, will be stored together on disk. Applications can read data directly from

this column family and avoid reading the rest of the document at the same time, making queries faster and more efficient.

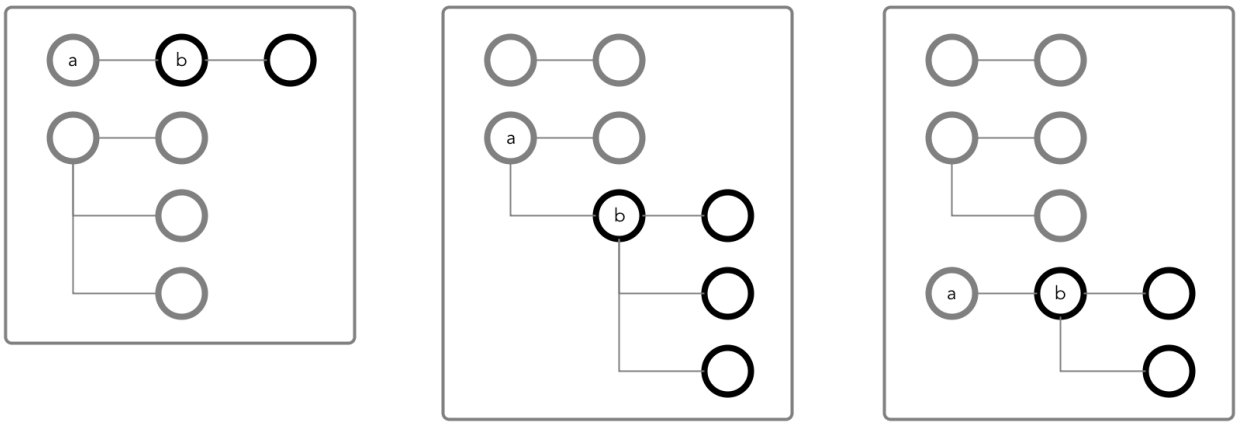

Figure 3: The three JSON documents with column family `CF1` in black

Creating Multiple Column Families

You can create up to 64 column families in a JSON table. The column families can be at any location in your documents. For example, these two documents both use the same non-default column families at the paths `a.b`, `a.b.c`, and `d`.

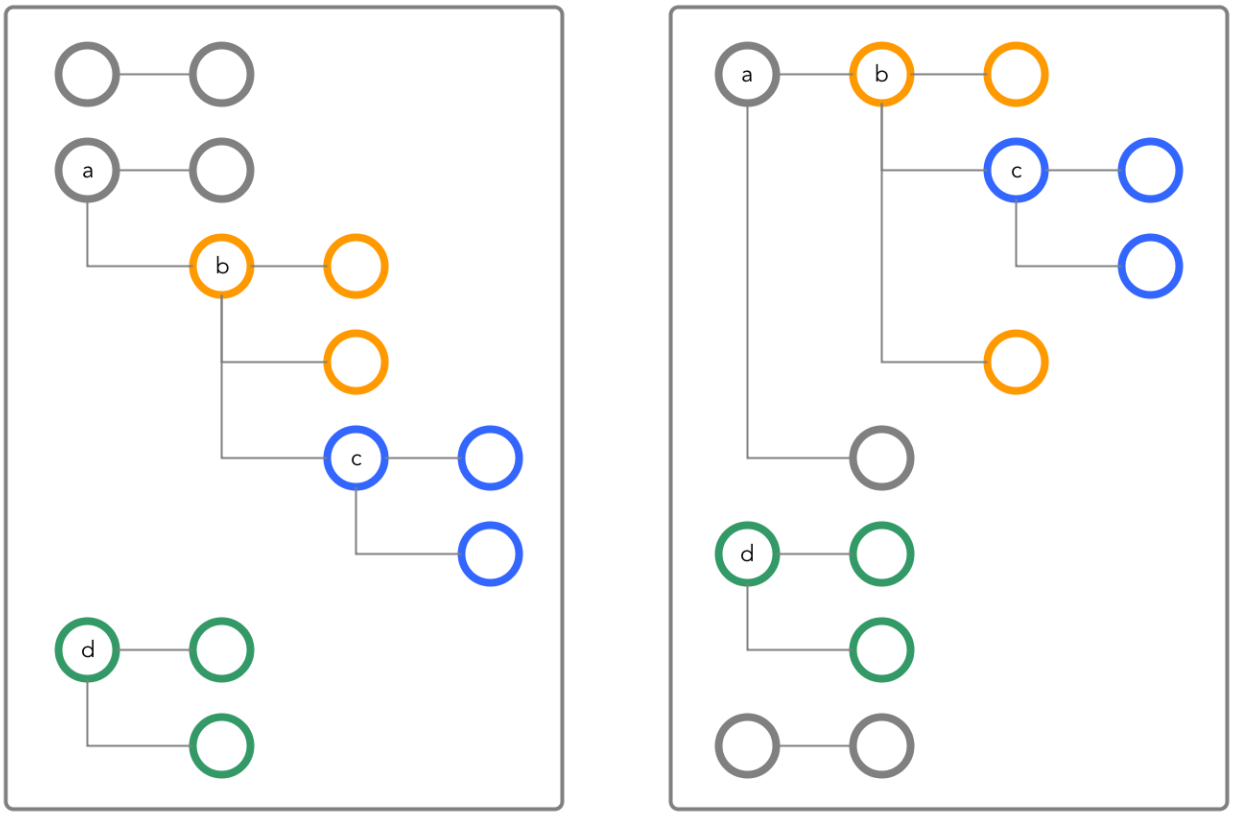

Figure 4: Two JSON documents that use the same non-default column families are highlighted in orange, blue, and green

Column Family Best Practices

If the path at which you want to create a column family already exists, it is recommended that the path and any fields under it contain no data. After the conversion of the path to a column family, it is possible that data existing in the path before the conversion could become inaccessible.

Applications and Column Families

Applications do not need to be aware of the existence of column families. They perform CRUD operations using the paths of fields in a document. For example, to update any of the fields under `a.c`, an application does not need to be aware that the field is in the column family at the path `a.c`. The application simply moves through the document along the path to the field.

Column Family Limitation

You cannot define column families across array type fields, for example:

```
maprcli table cf create -path /tbl-mcf -cfname abc -force true -jsonpath
a.b[0]
ERROR (22) -  Malformed path "a.b[0]", valid format is like "a.b.c".
```

For information about array fields, see JSON Document Field Paths.

Security on JSON Tables

By using access control expressions (ACEs), you can grant or deny access to fields and column families that are in JSON tables.

For an explanation of the syntax of ACEs, see ACE Syntax on page 1855.

There are three types of permission:

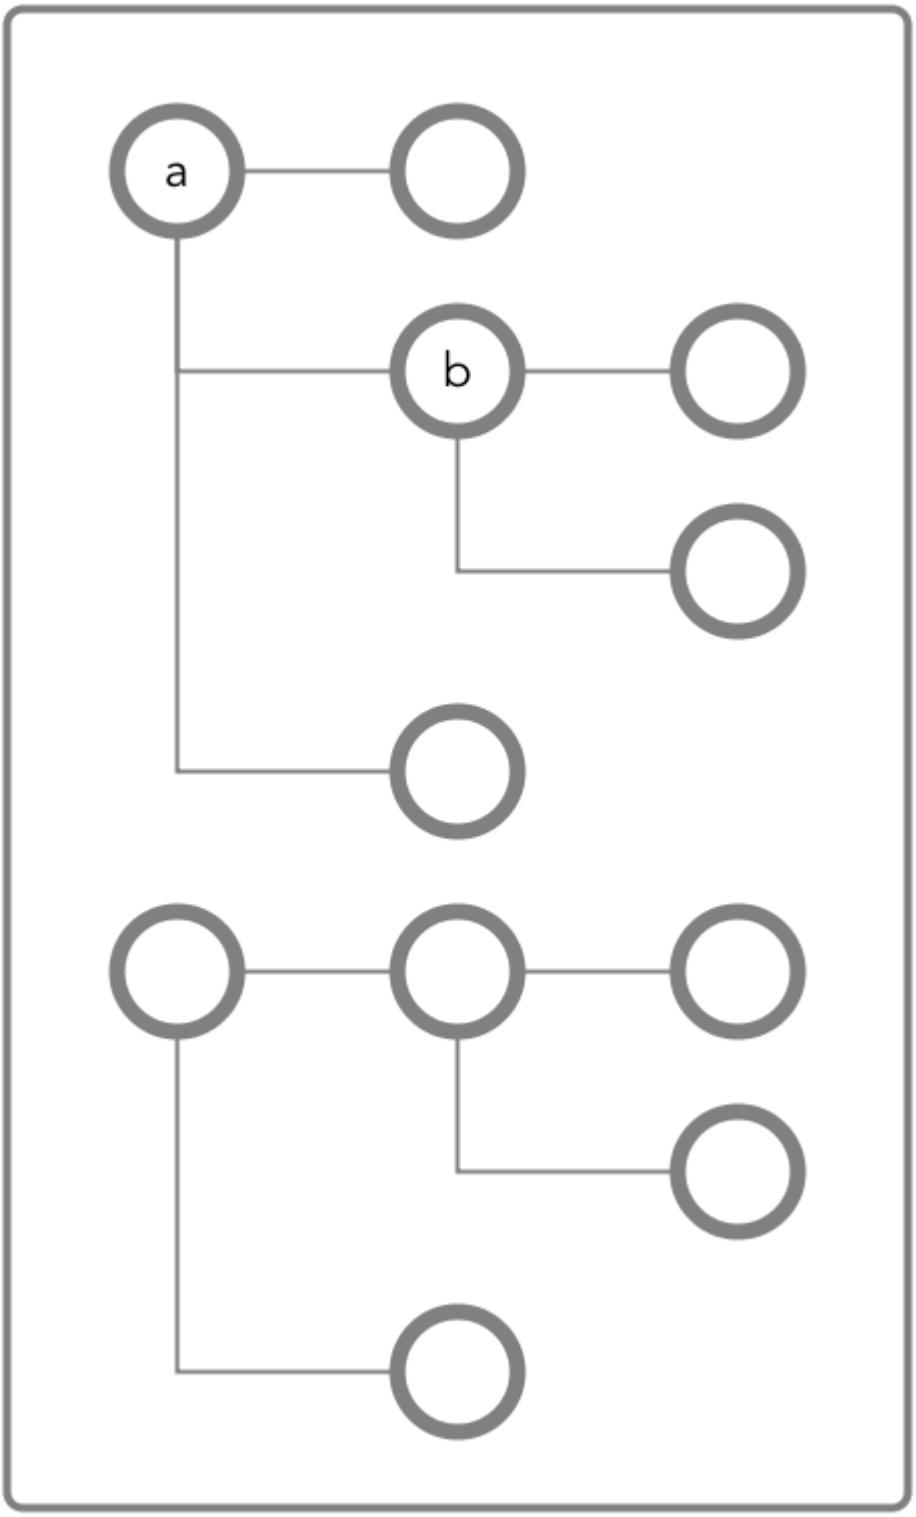
- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access the fields to which the grantee has write or read permission.

For example, suppose that a user has read and write access only on field b in this document.

last-updated: Jun 06, 2024

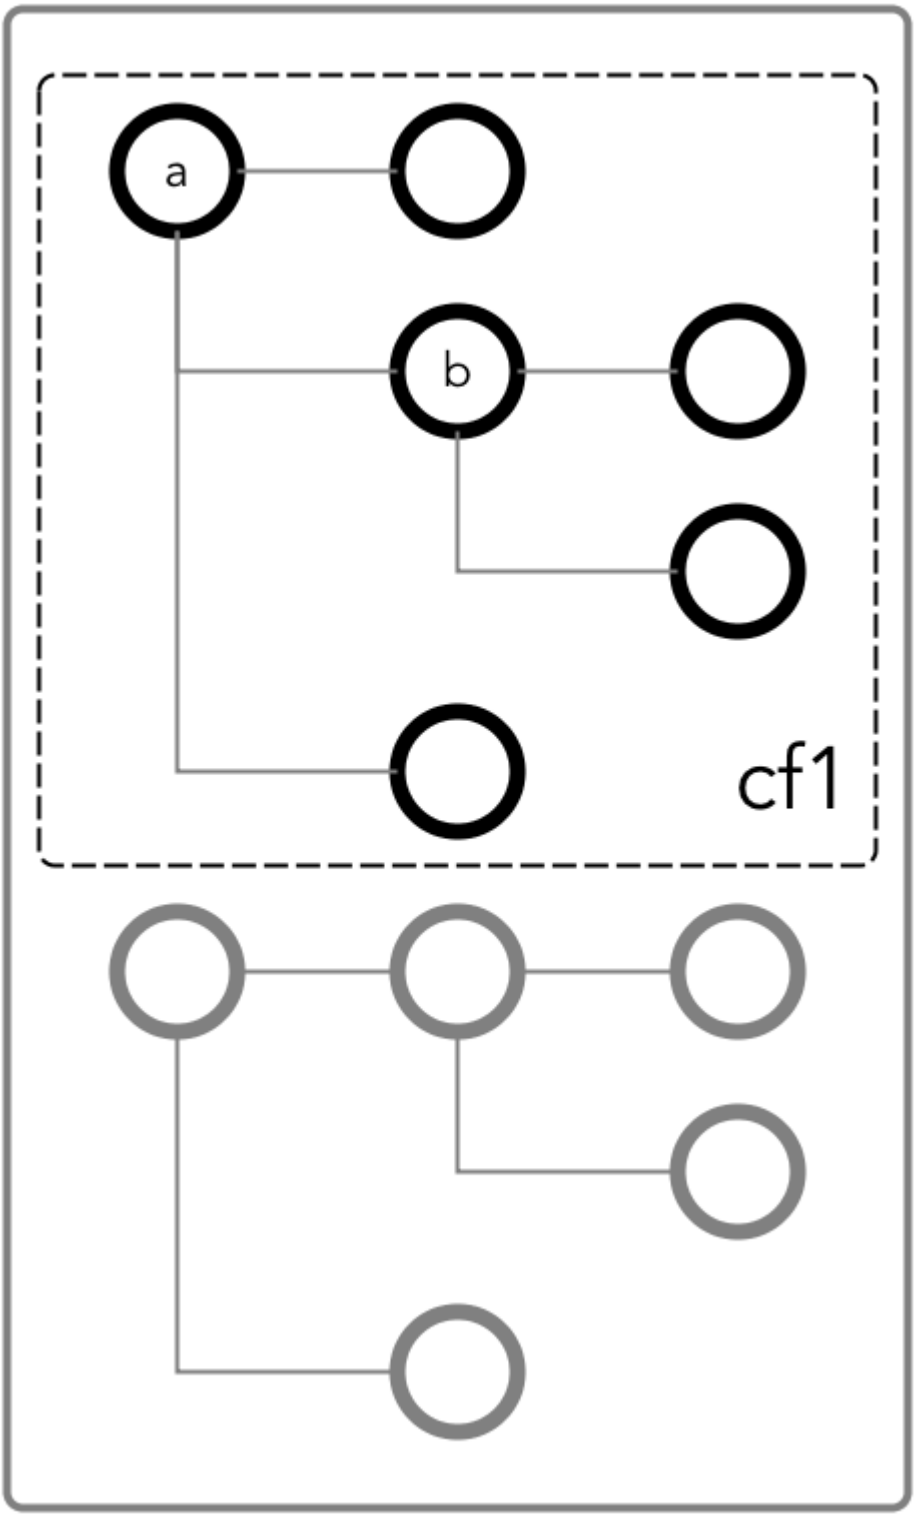


To access field b, the user would need to be able to traverse (pass through) field a. In this case, as the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If the user is denied the traverse permission on the default column family, the user cannot access field b. Granting traverse permission on field a in this case has no effect.

last-updated: Jun 06, 2024

In the next example, field a is a column family named `cf1`.



To be able to read and write at field b, the user could be granted the traverse permission on the column family.

last-updated: Jun 06, 2024

Read (`readperm`)

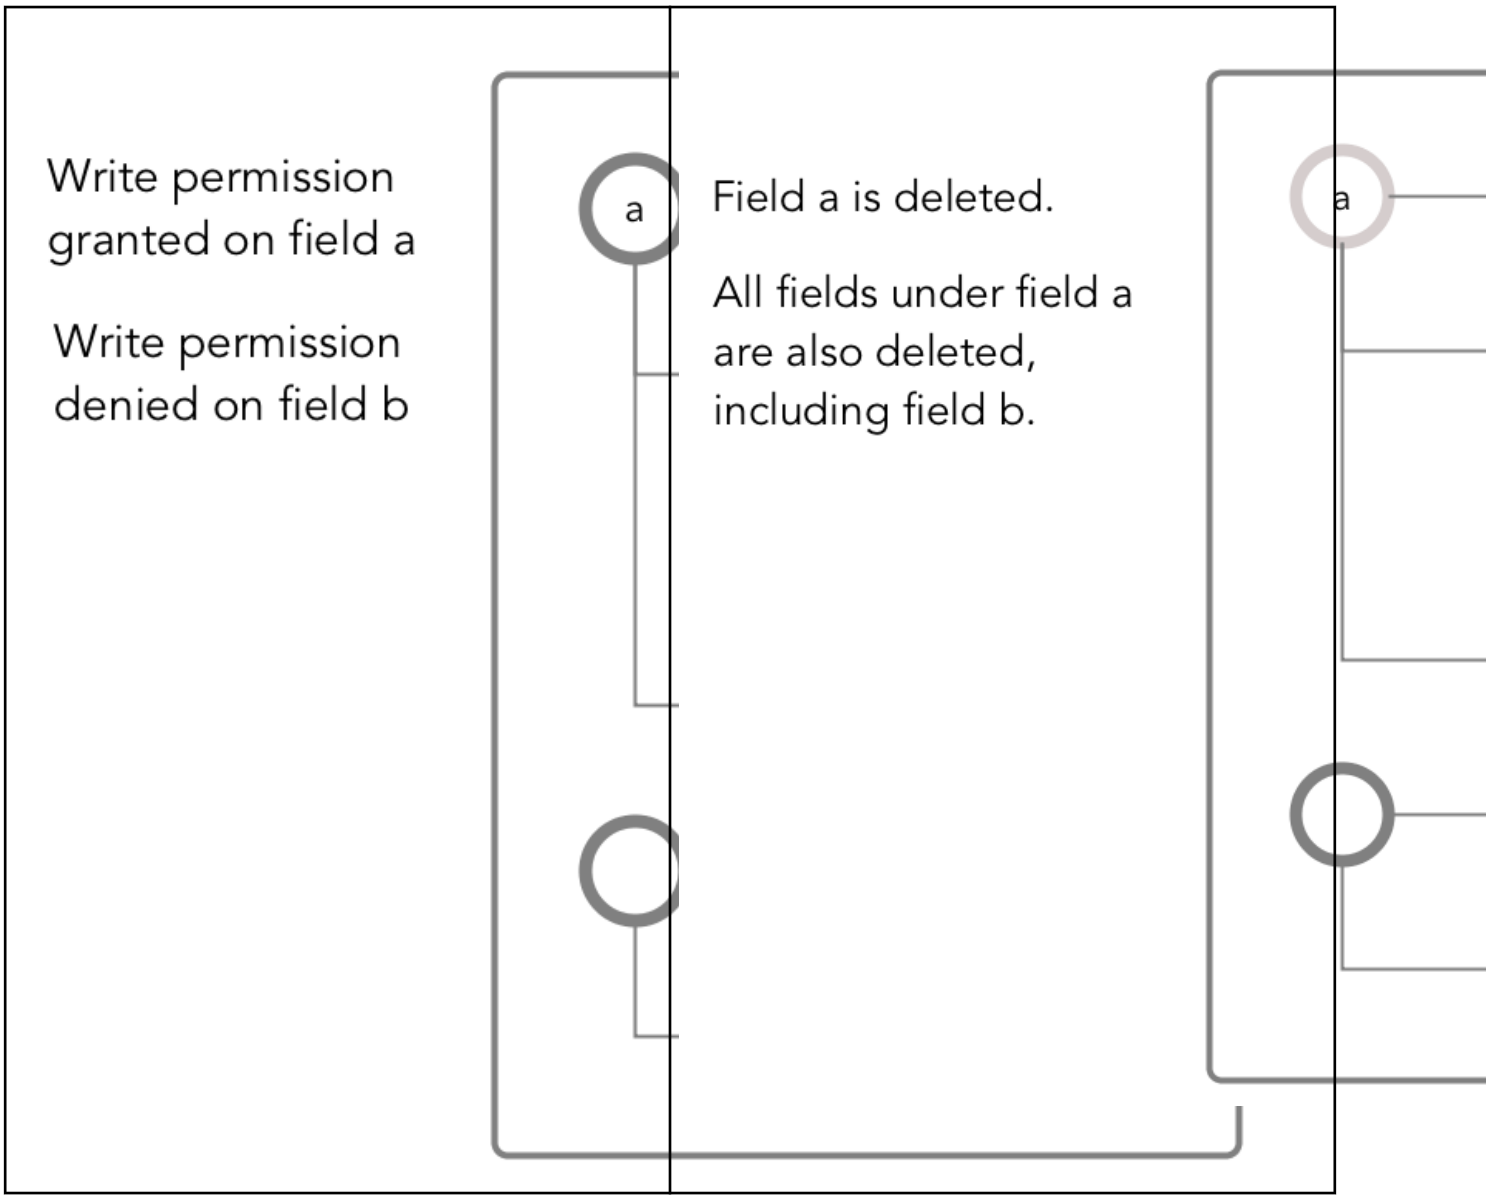
This permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field that was granted permission. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (`writeperm`)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite a field's value.

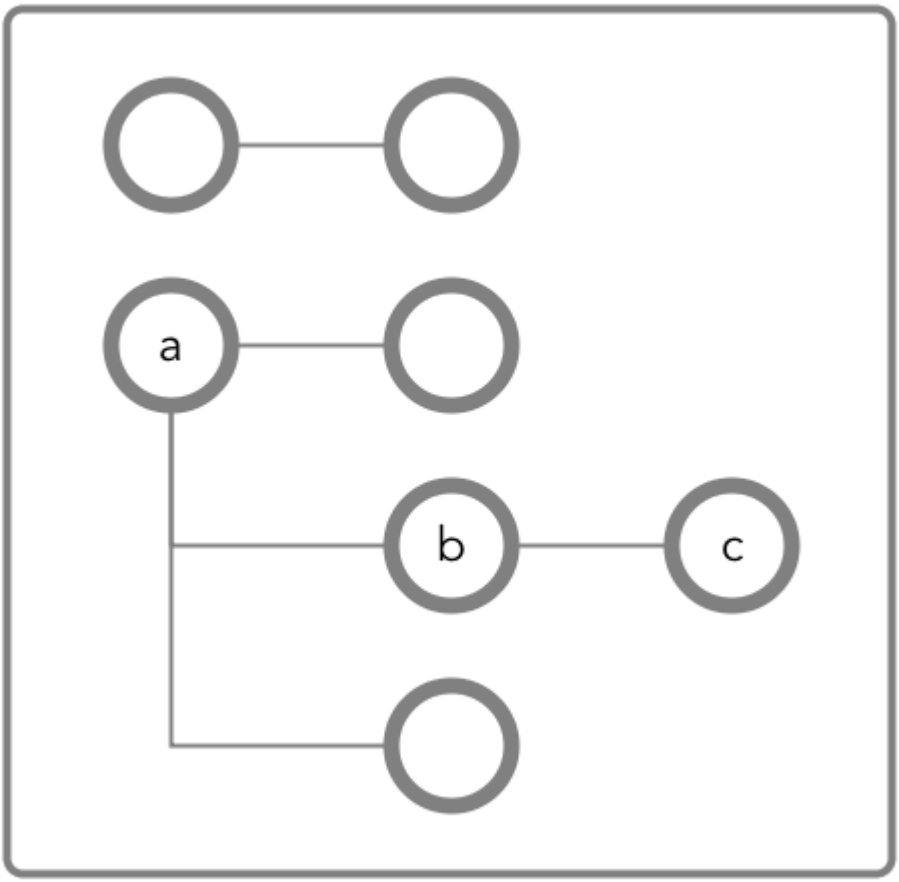
As illustrated in the following two diagrams, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.



Permissions on the Default Column Family
If a JSON document field is in the HPE Ezmeral Data Fabric Database JSON default column family, you must have `readperm` and `writeperm` permissions to perform read and write operations on the field. To mask data fields, you must have the `defaultunmaskedreadperm` or the `unmaskedreadperm` permission. You either receive the permissions from the default column family, inherit them from the field's parent field, or have the permissions from an explicit grant on the field.

last-updated: Jun 06, 2024

The following diagram shows a JSON document where all fields are in the default column family.



Granting Read and Write Permissions on Field c

To perform both read and write operations on field `c`, when it is in the default column family, you must have both `readperm` and `writeperm` access on field `c`:

- If you have `readperm` and `writeperm` permissions on the default column family, then you have access to field `c`.
- If you have `readperm` and `writeperm` permissions on field `b`, then you have access to field `c`. You do not need any further permissions. Field `c` inherits your `readperm` and `writeperm` permissions from field `b`.
- If you have `readperm` and `writeperm` permissions on the default column family *but* either field `a` or `b` denied you permissions:
  - You must have `traverseperm` permission granted to you on the field that denied you access (field `a` or `b`).
  - You must have `readperm` and `writeperm` permissions explicitly granted to you on field `c`.
- If you do *not* have `readperm` and `writeperm` permissions on the default column family:
  - You must have `traverseperm` permission granted to you on either the default column family or field `b`.

- You must have `readperm` and `writeperm` permissions explicitly granted to you on field `c`.

The following are examples of commands that grant these permissions:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname default
  -name a.b
  -traverseperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname default
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
  -writeperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf edit
  -path <path to JSON table >
  -cfname default
  -traverseperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname default
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
  -writeperm u:<user ID> | <existing ACE for this field>
```

Granting Read or Write Permission on Field c

To perform either read or write operations on field `c`, when it is in the default column family, you must have either `readperm` or `writeperm` access on field `c`:

- If you have the same permission (`readperm` or `writeperm`) on the default column family, then you have access to field `c`.
- If you have the same permission (`readperm` or `writeperm`) on field `b`, then you have access to field `c`. You do not need any further permissions. Field `c` inherits your `readperm` or `writeperm` permission from field `b`.
- If you have the same permission (`readperm` or `writeperm`) on the default column family *but* either field `a` or `b` denied you permission:
  - You must have `traverseperm` permission granted to you on the field that denied you access (field `a` or `b`).
  - You must have `readperm` or `writeperm` permission explicitly granted to you on field `c`.
- If you do *not* have the same permission (`readperm` or `writeperm`) on the default column family:
  - You must have the `traverseperm` permission granted to you on either the default column family or field `b`.
  - You must have `readperm` or `writeperm` permission explicitly granted to you on field `c`.

last-updated: Jun 06, 2024

The following example grants `traverseperm` permission:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table>
  -cfname default
  -name a.b
  -traverseperm u:<user ID> | <existing ACE for this field>
```

The following example grants `readperm` permission:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table>
  -cfname default
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
```

Permissions for Dynamic Data Masking

In addition to the existing `readperm`, `writeperm` and `traverseperm` database permissions, there are two new database permissions to support Dynamic Data Masking:

- The `defaultunmaskedreadperm` permission, when set at the table level, applies to all column families within that table unless otherwise overridden by the `unmaskedreadperm` setting at the CF or column level.
- The `unmaskedreadperm` permission, when applied at the CF or column level, specifies the users who can retrieve unmasked values for the specified database column. Users with regular `readperm` privileges but without `unmaskedreadperm` privileges will only be able to view the masked data. This permission is only applicable to columns that have the dynamic data mask attribute set. Specifying this permission on an unmasked column will have no effect.

In the following example, only user `mapr` can read column `Creditcard` from the default CF of table `/table1` unmasked. User `user1` can read the `Creditcard` column, but it will be masked:

```
maprcli table cf colperm set -path /table1 -cfname default \
  -name Creditcard -readperm "u:user1|u:mapr" -unmaskedreadperm "u:mapr" \
  -writeperm "u:mapr"

maprcli table cf column securitypolicy set -path /table1 -cfname default \
  -name Creditcard -securitypolicy pci

maprcli table cf column datamask set -path /table1 -cfname default \
  -name Creditcard -datamask mrddm_last4

maprcli table cf column list -path /table1 -cfname default -json

{

  "timestamp":1612303576139,

  "timeofday":"2021-02-02 02:06:16.139 GMT-0800 PM",

  "status":"OK",

  "total":1,

  "data":[

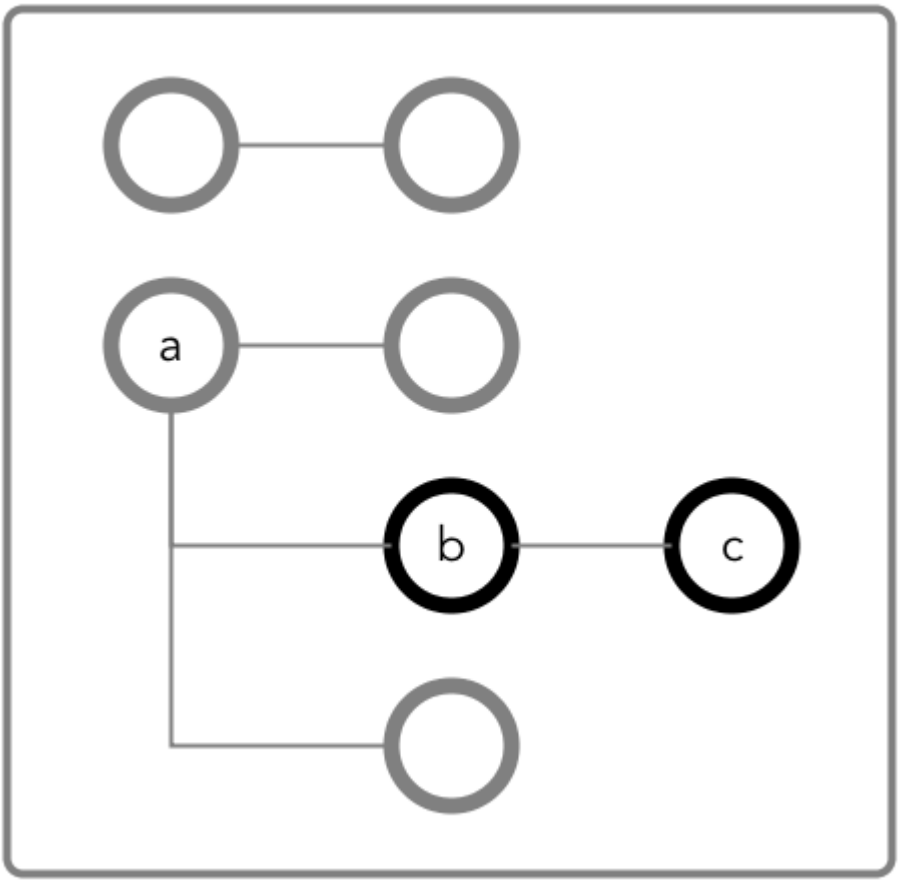
    {
```

```
      "name":"Creditcard",
      "aces": {
        "readperm":"u:user1|u:mapr",
        "unmaskedreadperm":"u:mapr",
        "writeperm":"u:mapr"
      },
      "securitypolicy":"pci",
      "datamask":"mrddm_last4"
    }
  ]
}
```

Permissions on Non-default Column Families
If a JSON document field is not in the HPE Ezmeral Data Fabric Database JSON default column family, you must have `readperm` and `writeperm` permissions to perform read and write operations on the field. To mask data fields, you must have the `defaultunmaskedreadperm` or the `unmaskedreadperm` permission. You either receive the permissions from the column family, inherit them from the field's parent field, or have the permissions from an explicit grant on the field.

NOTE: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For more information, see Managing Column Families on page 3319.

The following diagram shows a JSON document where fields b and c are in a column family `cf1` that is defined at field b with the path `a.b`.



Granting Read and Write Permissions on Field c

To perform both read and write operations on field c, when it is in column family `cf1`, you must have both `readperm` and `writeperm` access on field c:

- If you have `readperm` and `writeperm` permissions on `cf1`, then you have access to field c.
- If you have `readperm` and `writeperm` permissions on field b, then you have access to field c. You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.
- If you have `readperm` and `writeperm` permissions on `cf1` *but* either field a or b denied you permissions:
  - You must have `traverseperm` permission granted to you on the field that denied you access (field a or b).
  - You must have `readperm` and `writeperm` permissions explicitly granted to you on field c.
- If you do *not* have `readperm` and `writeperm` permissions on `cf1`:
  - You must have `traverseperm` permission granted to you on either `cf1` or field b.
  - You must have `readperm` and `writeperm` permissions explicitly granted to you on field c.

last-updated: Jun 06, 2024

The following are examples of commands that grant these permissions:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname cf1
  -name a.b
  -traverseperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname cf1
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
  -writeperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf edit
  -path <path to JSON table >
  -cfname cf1
  -traverseperm u:<user ID> | <existing ACE for this field>
```

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table >
  -cfname cf1
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
  -writeperm u:<user ID> | <existing ACE for this field>
```

Granting Read or Write Permission on Field c

To perform either read or write operations on field c, when it is in column family `cf1`, you must have either `readperm` or `writeperm` access on field c:

- If you have the same permission (`readperm` or `writeperm`) on `cf1`, then you have access to field c.
- If you have the same permission (`readperm` or `writeperm`) on field b, then you have access to field c. You do not need any further permissions. Field c inherits your `readperm` or `writeperm` permission from field b.
- If you have the same permission (`readperm` or `writeperm`) on `cf1` *but* either field a or b denied you permission:
  - You must have `traverseperm` permission granted to you on the field that denied you access (field a or b).
  - You must have `readperm` or `writeperm` permission explicitly granted to you on field c.
- If you do *not* have the same permission (`readperm` or `writeperm`) on `cf1`:
  - You must have the `traverseperm` permission granted to you on either `cf1` or field b.
  - You must have `readperm` or `writeperm` permission explicitly granted to you on field c.

The following example grants `traverseperm` permission:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table>
  -cfname cf1
```

```
  -name a.b
  -traverseperm u:<user ID> | <existing ACE for this field>
```

The following example grants `readperm` permission:

```
/opt/mapr/bin/maprcli table cf colperm set
  -path <path to JSON table>
  -cfname cf1
  -name a.b.c
  -readperm u:<user ID> | <existing ACE for this field>
```

Permissions for Dynamic Data Masking

In addition to the existing `readperm`, `writeperm` and `traverseperm` database permissions, there are two new database permissions to support Dynamic Data Masking:

- The `defaultunmaskedreadperm` permission, when set at the table level, applies to all column families within that table unless otherwise overridden by the `unmaskedreadperm` setting at the CF or column level.
- The `unmaskedreadperm` permission, when applied at the CF or column level, specifies the users who can retrieve unmasked values for the specified database column. Users with regular `readperm` privileges but without `unmaskedreadperm` privileges will only be able to view the masked data. This permission is only applicable to columns that have the dynamic data mask attribute set. Specifying this permission on an unmasked column will have no effect.

In the following example, only user `mapr` can read column `Creditcard` from the default CF of table `/table1` unmasked. User `user1` can read the `Creditcard` column, but it will be masked:

```
maprcli table cf colperm set -path /table1 -cfname default \
  -name Creditcard -readperm "u:user1|u:mapr" -unmaskedreadperm "u:mapr" \
  -writeperm "u:mapr"

maprcli table cf column securitypolicy set -path /table1 -cfname default \
  -name Creditcard -securitypolicy pci

maprcli table cf column datamask set -path /table1 -cfname default \
  -name Creditcard -datamask mrddm_last4

maprcli table cf column list -path /table1 -cfname default -json

{

  "timestamp":1612303576139,

  "timeofday":"2021-02-02 02:06:16.139 GMT-0800 PM",

  "status":"OK",

  "total":1,

  "data":[

    {

      "name":"Creditcard",

      "aces": {

        "readperm":"u:user1|u:mapr",
```

last-updated: Jun 06, 2024

```
        "unmaskedreadperm":"u:mapr",
        "writeperm":"u:mapr"
      },
      "securitypolicy":"pci",
      "datamask":"mrddm_last4"
    }
  ]
}
```

Permissions on Arrays
When granting permissions on a field, if the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

NOTE: This topic describes the behavior of permissions in HPE Ezmeral Data Fabric Database version 6.1 and later, regardless of the data-fabric version you used to grant the permissions.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
    "_id" : "id001",
    "person" : [
        {"name" : {"last" : "Smith", "first" : "John"}},
        {"name" : {"last" : "Subramanium", "first" : "Ananya"}}
    ]
}
{
    "_id" : "id002",
    "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
    "_id" : "id003",
    "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person` to avoid having to remove the conflicting `person` permission.

last-updated: Jun 06, 2024

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

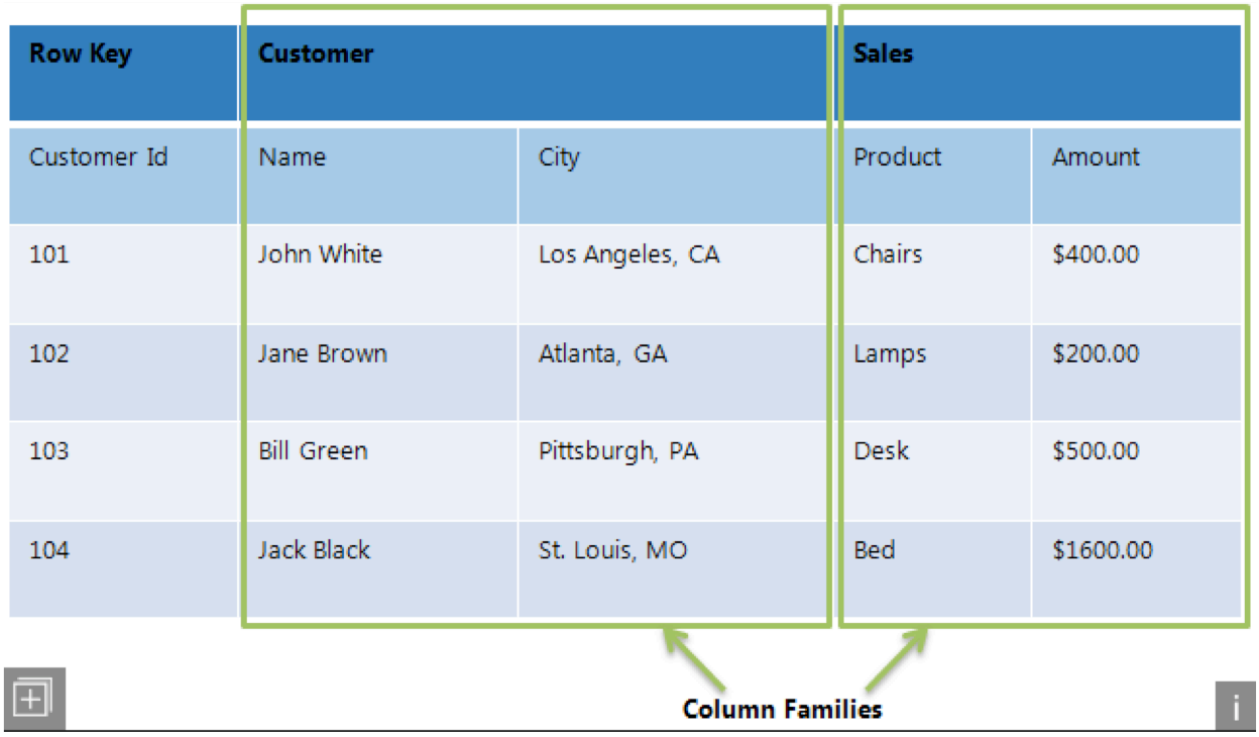
If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

HPE Ezmeral Data Fabric Database as a Column-Oriented Database

HPE Ezmeral Data Fabric Database supports column-oriented databases as a native data store. Column-oriented database tables in HPE Ezmeral Data Fabric Database are conceptually identical to tables in Apache HBase.

As a column-oriented database, HPE Ezmeral Data Fabric Database stores data in binary format. HPE Ezmeral Data Fabric Database supports the Apache HBase API and provides a native implementation of the HBase API. HBase applications can use HPE Ezmeral Data Fabric Database tables without modifying any code.

- HPE Ezmeral Data Fabric Database tables use the HBase data model.
- Allows for large-scale applications managing columnar data.
- Binary compatibility with applications using standard HBase application APIs.
- With the binary tables, rows are indexed by key, columns identify data elements in each row, and column families are made up of columns.



HPE Ezmeral Data Fabric Database Binary Tables
HPE Ezmeral Data Fabric Database stores data as a nested series of maps. Each map consists of a set of key-value pairs, where the value can be the key in another map.

HPE Ezmeral Data Fabric Database stores structured data as a nested series of maps. Each map consists of a set of key-value pairs, where the value can be the key in another map. Keys are kept in strict lexicographical order: 1, 10, and 113 come before 2, 20, and 213.

In descending order of granularity, the elements of a binary table are:

- **Key**: Keys identify the rows in a table. In HPE Ezmeral Data Fabric Database, the maximum supported size of a row key is 64 KB. However, the recommended practice is to keep it lower than a few hundred bytes.
- **Row:** Rows span one or more column families and columns. In HPE Ezmeral Data Fabric Database, the maximum supported size of a row is 2 GB. However, the recommended practice is to keep the size under 2 MB. In general, HPE Ezmeral Data Fabric Database performs better with many small rows, rather than with fewer very large rows.
- **Column family**: A column family is a key associated with a set of columns. Specify this association according to your individual use case, creating sets of columns. A column family can contain an arbitrary number of columns. HPE Ezmeral Data Fabric Database binary tables support up to 64 column families.
- **Column**: Columns are keys that are associated with a series of timestamps that define when the value in that column was updated.
- **Timestamp**: The timestamp in a column specifies specifies when the data was written to that column.
- **Value**: The data written to that column at the specific timestamp.

This structure results in values with versions that you can access flexibly and quickly. Since HPE Ezmeral Data Fabric Database binary tables are *sparse*, any of the column values for a given key can be null.

last-updated: Jun 06, 2024

Example Table

This example uses JSON notation for representational clarity. In this example, timestamps are arbitrarily assigned.

Queries return the most recent timestamp, by default. For example, a query for the value in "arbitrarySecondKey"/"secondColumnFamily:firstColumn" returns `valueThree`. Specifying a timestamp with a query for "arbitrarySecondKey"/"secondColumnFamily:firstColumn"/11 returns `valueSeven`.

```
{
 "arbitraryFirstKey" : {
     "firstColumnFamily" : {
          "firstColumn" : {
               10 : "valueFive",
               7 : "valueThree",
               4 : "valueOne",
               }
          "secondColumn" : {
               16 : "valueEight",
               1 : "valueSeven",
               }
          }
     "secondColumnFamily" : {
          "firstColumn" : {
               37 : "valueFive",
               23 : "valueThree",
               11 : "valueSeven",
               4 : "valueOne",
               }
          "secondColumn" : {
               15 : "valueEight",
               }
          }
     }
 "arbitrarySecondKey" : {
     "firstColumnFamily" : {
          "firstColumn" : {
               10 : "valueFive",
               4 : "valueOne",
               }
          "secondColumn" : {
               16 : "valueEight",
               7 : "valueThree",
               1 : "valueSeven",
               }
          }
     "secondColumnFamily" : {
          "firstColumn" : {
               23 : "valueThree",
               11 : "valueSeven",
               }
          }
     }
}
```

Column Families in Binary Tables

Scanning an entire table for matches can be very performance-intensive. *Column families* enable you to group related sets of data and restrict queries to a defined subset, leading to better performance. When you design a column family, think about what kinds of queries are going to be used the most often, and group your columns accordingly.

You can specify compression settings for individual column families, which lets you choose the settings that prioritize speed of access or efficient use of disk space, according to your needs.

last-updated: Jun 06, 2024

Be aware of the approximate number of rows in your column families. This property is called the column family's *cardinality*. When column families in the same table have very disparate cardinalities, the sparser table's data can be spread out across multiple nodes, due to the denser table requiring more splits. Scans on the sparser column family can take longer due to this effect. For example, consider a table that lists products across a small range of *model* numbers, but with a row for the unique serial numbers for each individual product manufactured within a given model. Such a table will have a very large difference in cardinality between a column family that relates to the model number compared to a column family that relates to the serial number. Scans on the model-number column family will have to range across the cluster, since the frequent splits required by the comparatively large numbers of serial-number rows will spread the model-number rows out across many regions on many nodes.

For a list of the properties that you can set when you create a column family, see the documentation for the `maprcli` command `table cf create` .

NOTE: When replicating a specific column family or column from a binary source table and a row is deleted, the destination table will show only a deletion for the specific column family or column. When replicating a specific column from a binary source table and its column family is deleted, the destination table will show only a deletion for the specific column.

Column Design

HPE Ezmeral Data Fabric Database tables split at the row level, not the column level. For this reason, extremely wide tables with very large numbers of columns can sometimes reach the recommended size for a table split at a comparatively small number of rows.

WARNING: In general, design your schema to prioritize more rows and fewer columns.

As the HPE Ezmeral Data Fabric Database tables are *sparse*, you can add columns to a table at any time. Null columns for a given row do not take up any storage space.

Table Rowkey Design

The design of a table's rowkeys affects the speed at which client applications can access data and the database performance if hotspotting occurs. The better the design, the faster the data access.

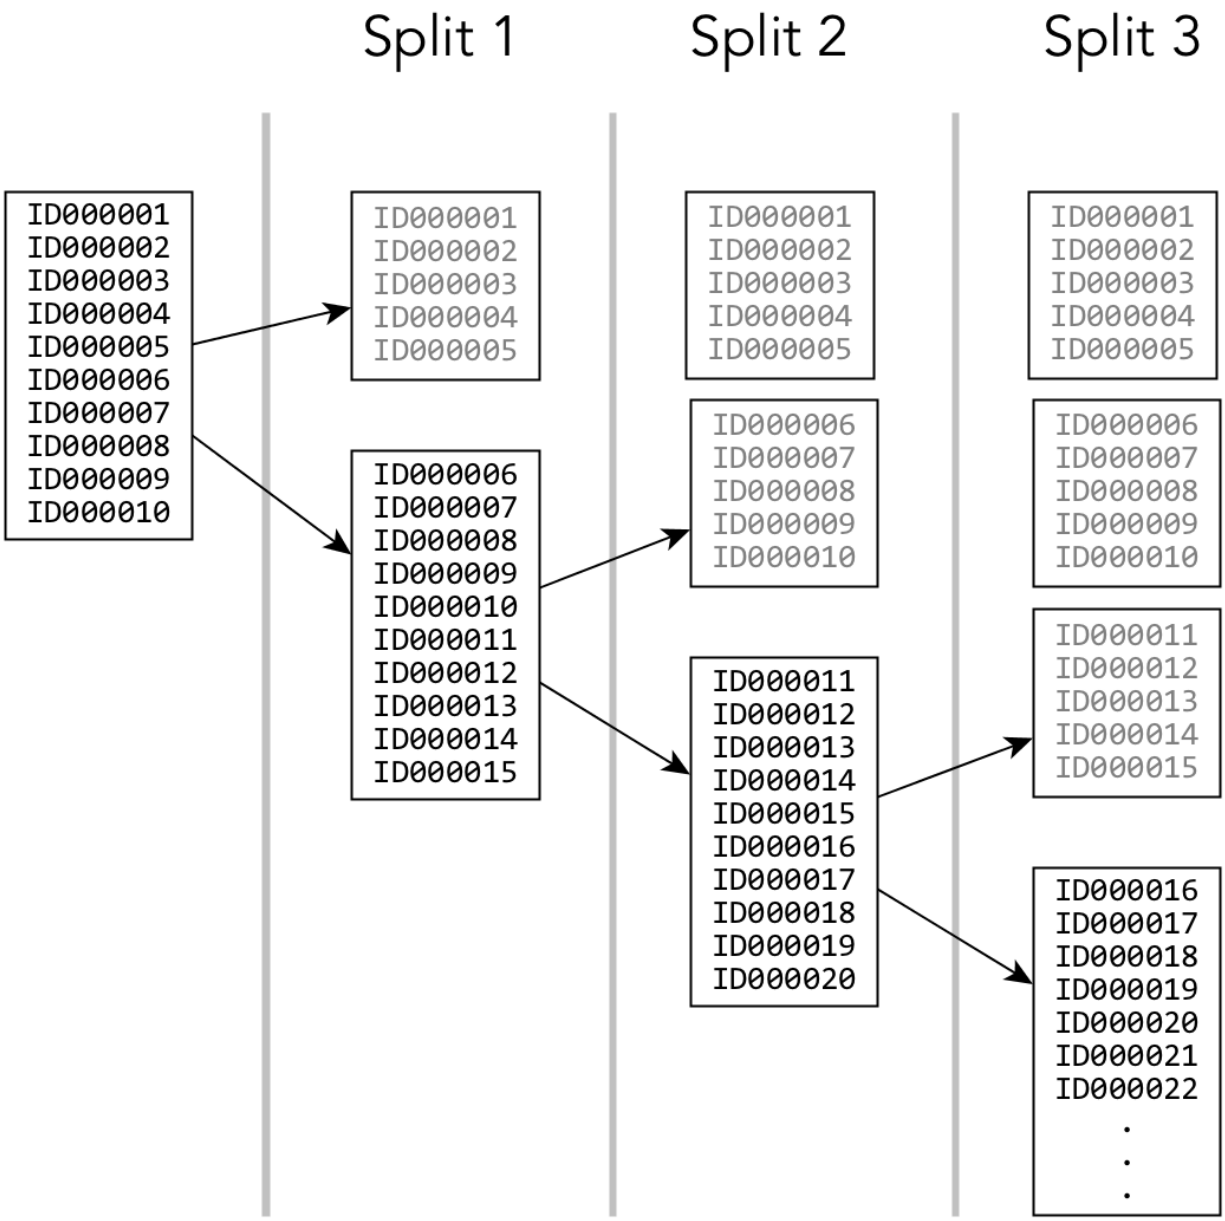
What is a Row Key?

For binary tables:	A row key identifies a row in a HPE Ezmeral Data Fabric Database binary table.
For JSON tables:	A row key identifies a row in a HPE Ezmeral Data Fabric Database JSON table. You specify row keys in the _id field in JSON documents. For example, if the value of the _id field in a JSON document is user000001, that value is also the rowkey for the row in which the JSON document is stored in a JSON table.

Avoiding Hotspotting

Because records in tables are stored in lexicographical order of their rowkeys, using a sequential generation method for rowkeys can lead to a hot-spot problem, as illustrated in this diagram.

last-updated: Jun 06, 2024



A table region reaches a predetermined size and then splits into two regions. Because the rowkeys for new records are being created sequentially, new rows are added to only one of the new regions. The other region is not written to and remains at half of its maximum size. The problem is repeated with each subsequent split.

With HPE Ezmeral Data Fabric Database tables, the cluster handles sequential keys and table splits to keep potential hotspots moving across nodes, decreasing the intensity and performance impact of hot spots. However, hotspotting can still hamper database performance.

There are two strategies that you can use to avoid hotspotting:

Hashing keys	To spread write and insert activity across the cluster, you can randomize sequentially generated keys by hashing the keys, inverting the byte order. Note that these strategies come with trade-offs. Hashing keys, for example, makes table scans for key subranges inefficient, since the subrange is spread across the cluster.

last-updated: Jun 06, 2024

Salting keys	Instead of hashing the key, you can salt the key by prepending a few bytes of the hash of the key to the actual key. For a key based on a timestamp, for instance, a timestamp value of `1364248490` has an MD5 hash that ends with `ffe5`. By making the key for that row `ffe51364248490`, you avoid hotspotting. Because you know that the first four digits are a hash salt, you can derive the original timestamp by dropping those digits.

Composite Keys

Each row in a table can have only a single key. You can create composite keys to approximate multiple keys in a table. A composite key contains several individual IDs joined together, for example userID and applicationID. You can then scan for the specific segments of the composite row key that represent the original, individual ID.

Because rows are stored in sorted order, you can affect the results of the sort by changing the ordering of the fields that make up the composite row key. For example, if your application IDs are generated sequentially but your user IDs are not, using a composite key of userID+applicationID will store all rows with the same user ID closely together. If you know the userID for which you want to retrieve rows, you can specify the first userID row and the first userID+1 row as the start and stop rows for your scan, then retrieve the rows you're interested in without scanning the entire table.

When designing a composite key, consider how the data will be queried during production use. Place the fields that will be queried the most often towards the front of the composite key, bearing in mind that sequential keys will generate hotspotting.

For binary tables:	You must create your own custom logic for working with composite keys in applications that use the HBase Java API. This API does not have built-in support for composite keys.
For JSON tables:	You must create your own custom logic for working with composite keys in applications that use the HPE Ezmeral Data Fabric Database OJAI Java API library. This API library does not have built-in support for composite keys.

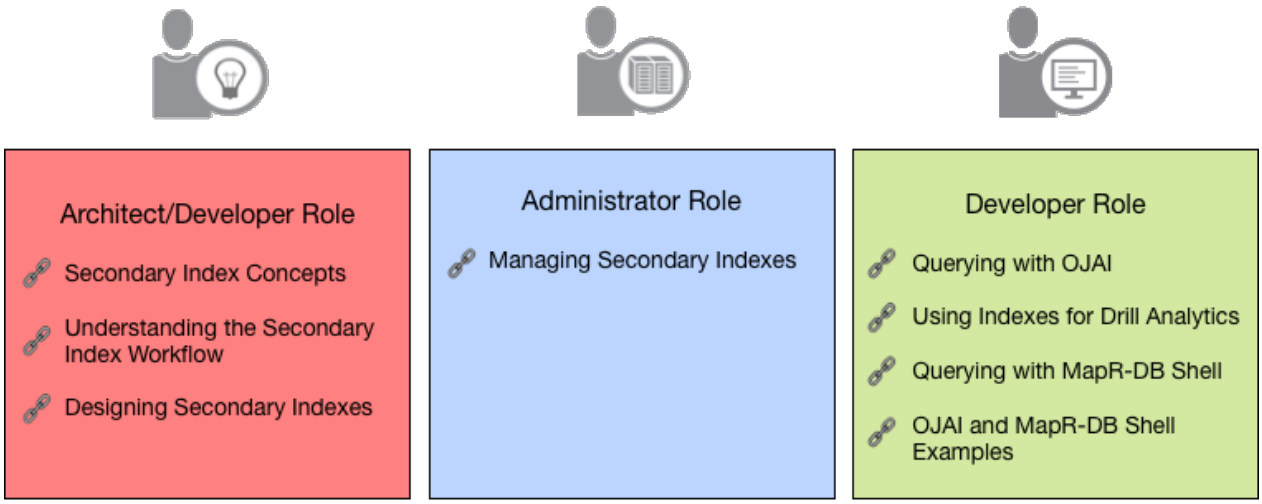
Secondary Indexes

Beginning with data-fabric 6.0, HPE Ezmeral Data Fabric Database JSON natively supports secondary indexes on fields in JSON tables. Indexes provide you with flexible, high performance access to data stored in HPE Ezmeral Data Fabric Database.

How Do I Get Started?

The following diagram provides links to topics that you need to understand and use Secondary Indexes. Topics include conceptual information about indexes, how to decide what indexes to create, how to set up and use indexes, the `maprcli` commands used to create and maintain indexes, and how to query your data to leverage indexes. The information is organized based on roles.

last-updated: Jun 06, 2024



1. Describes secondary index concepts, including use cases, types of indexes, types of queries that benefit from indexes, and how indexes are implemented
2. Describes the overall workflow for using secondary indexes. This includes the roles of different users and the workflow steps involved.
3. Describes how to design secondary indexes to provide the most benefit to HPE Ezmeral Data Fabric Database JSON queries
4. Describes how to manage secondary indexes including creating, deleting, and listing indexes, setting up your cluster for querying, and troubleshooting
5. Describes how to use the OJAI API library to query JSON tables, including special considerations related to secondary indexes
6. Describes how to leverage indexes when issuing SQL queries with Drill
7. Describes how to use the HPE Ezmeral Data Fabric Database Shell to query JSON tables
8. Contains samples of OJAI programs and HPE Ezmeral Data Fabric Database Shell commands that query JSON tables

What are Secondary Indexes?

A *secondary index* (also sometimes referred to in this documentation as an *index*) is a special table that stores a subset of document fields from a JSON table. The index orders its data on a set of fields, defined as the *indexed fields*. This is in contrast to the JSON table that orders its data on the table primary key (rowId or rowKey). If you have administrator privileges, you can create one or more indexes on each JSON table. After the indexes are created, applications can leverage them to accelerate query response times. Secondary indexes can also contain additional fields known as *included fields* (or sometimes *covered fields*) beyond those being indexed, so that many queries can be satisfied with a single read.

Secondary indexes provide efficient access to a wider range of queries on data in HPE Ezmeral Data Fabric Database. They allow queries to efficiently query data through fields other than the primary key. This capability results in HPE Ezmeral Data Fabric Database supporting a broader set of use cases. Applications that benefit include rich, interactive business applications and user-facing analytic applications. Secondary indexes also enable Business Intelligence tools and ad-hoc queries on operational datasets. See Uses for Secondary Indexes on page 686 for more information.

IMPORTANT: Secondary indexes can be created only on HPE Ezmeral Data Fabric Database JSON tables.

Why Use Secondary Indexes?

With the ever increasing amount of data stored in HPE Ezmeral Data Fabric Database JSON, indexing that data becomes critical. Without indexes, queries unnecessarily scan large amounts of data from the underlying JSON table. Queries could potentially scan every document in the table, even if they contain conditions that limit the documents to select. Query performance suffers and resource bottlenecks are inevitable when you use this data model.

Without indexes, applications and query layers resort to limited interactivity to avoid performance concerns. Using indexes solves this limitation in application scale, by reducing the number of documents client applications read, even when querying large data sets. This reduces I/O and CPU costs, resulting in improved performance.

The functionality and benefits of indexing available in HPE Ezmeral Data Fabric Database are similar to that of indexes in relational databases. The difference is that HPE Ezmeral Data Fabric Database indexes provide performance benefits at high scale, in combination with JSON flexibility on the query side and simplicity on the management side.

How Can I Use Secondary Indexes?

You can leverage HPE Ezmeral Data Fabric Database secondary indexes by using either the OJAI API, the HPE Ezmeral Data Fabric Database JSON REST API, or Drill.

OJAI is the business application development interface on HPE Ezmeral Data Fabric Database. Typically, business applications are characterized by ultra low latency and extremely high throughput. When you build an application using OJAI, filtering and sorting through the API can leverage secondary indexes to accelerate query response times.

The HPE Ezmeral Data Fabric Database JSON REST API enables you to use HTTP calls to perform basic operations on HPE Ezmeral Data Fabric Database JSON tables, including querying.

Drill is the analytics SQL interface on HPE Ezmeral Data Fabric Database. Drill is a distributed SQL query engine that provides interactive response time for operational analytics, Business Intelligence (BI) tools such as Tableau, and ad-hoc queries on HPE Ezmeral Data Fabric Database. With Drill, SQL queries can also leverage secondary indexes to accelerate query response times.

Regardless of whether queries originate from OJAI or Drill SQL, each interface seamlessly selects the optimal indexes to use. You do not need to write explicit code or provide directives on which indexes to use. If an appropriate index exists for a query, HPE Ezmeral Data Fabric Database leverages the index.

For more information about the OJAI API, see the following API links:

- Java OJAI Client API
- Node.js OJAI Client API
- Python OJAI Client API
- C# OJAI Client API
- Go OJAI Client API

For information about the HPE Ezmeral Data Fabric Database JSON REST API, see Using the HPE Ezmeral Data Fabric Database JSON REST API on page 3478.

For information about MapR Drill, see Apache Drill on MapR.

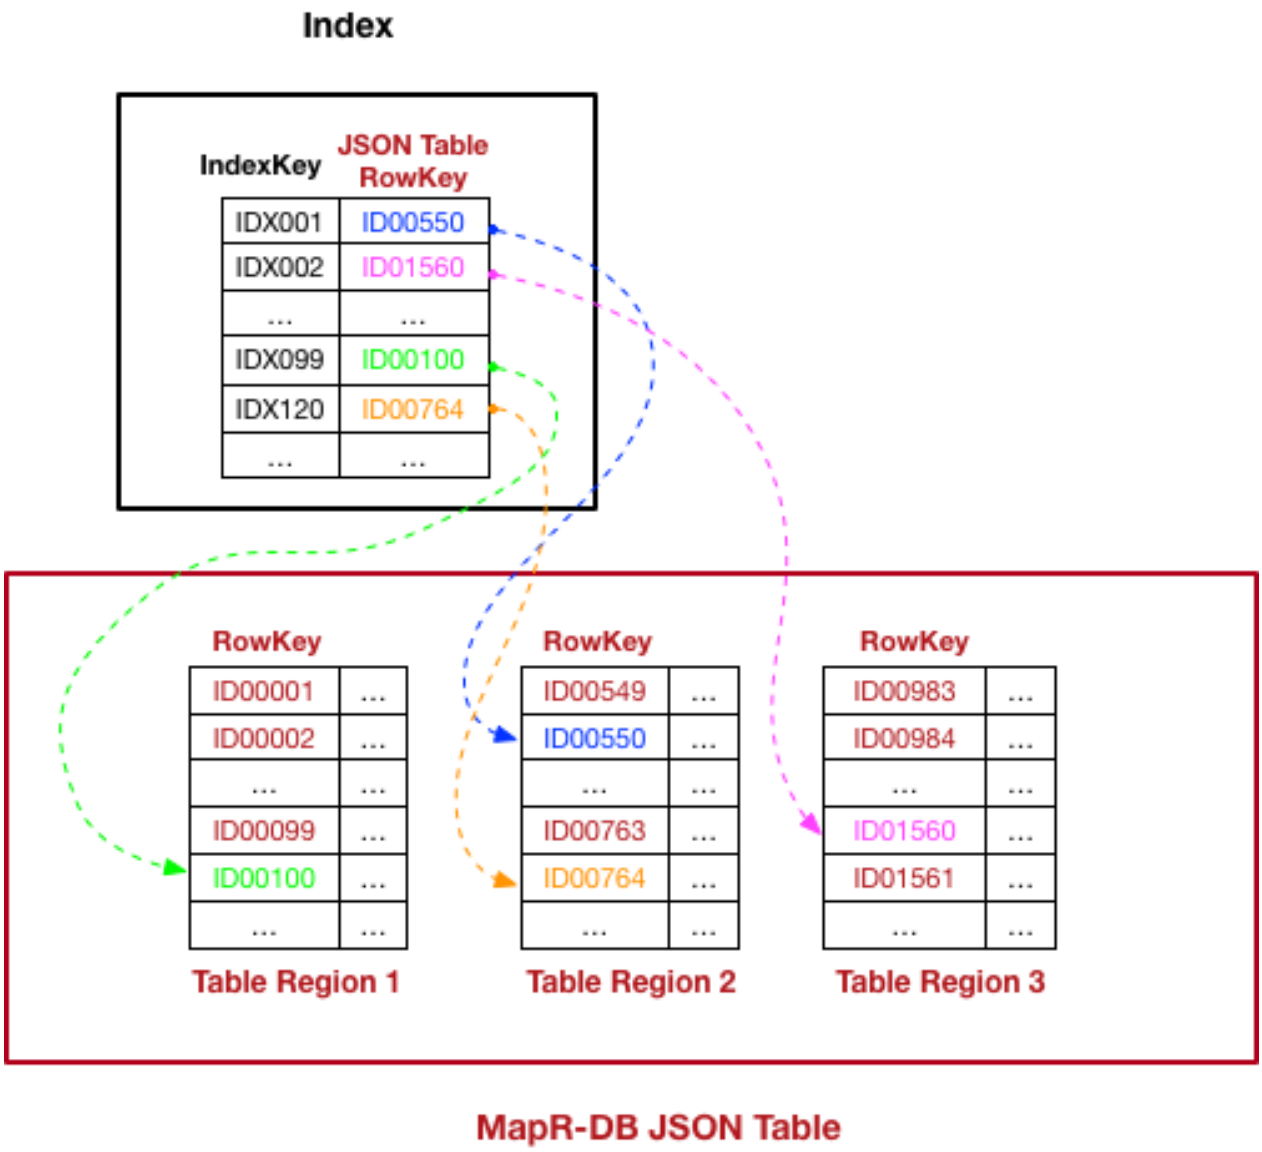
Secondary Index Concepts
Describes secondary index concepts, including use cases, types of indexes, types of queries that benefit from indexes, and how indexes are implemented.

Indexes created on regularly queried JSON table fields provide HPE Ezmeral Data Fabric Database quick access to data. Indexes primarily benefit queries with filters in the WHERE clause, queries with an ORDER BY clause for sorting, and queries where all fields projected in the query are included in the index. They provide the most benefit when an index contains all fields referenced in a query. For filters, indexes reduce the amount of data read. HPE Ezmeral Data Fabric Database implements indexes using JSON tables. Like JSON tables, an index stores data in sort order. Reading data through the index eliminates the need to sort the data if the index and query sort orders match.

Each JSON table in HPE Ezmeral Data Fabric Database has a unique field that serves as the rowkey. A secondary index contains indexed and included fields. The indexed fields, also referred to as *index keys*, define the sort order of the index. The index stores the values of the index keys along with the rowkey corresponding to each key value. The rowkey links the index to the JSON table. HPE Ezmeral Data Fabric Database can perform a range scan on the index and then use the corresponding rowkeys to quickly locate data in the JSON table. Additional fields can be included in the index so that queries that only need these included (or covered) fields can get all the data they need from the index and therefore will not require access to the base table.

The following diagram illustrates the mapping. Each index entry consists of the index key value followed by the rowkey of the corresponding JSON document. The color coding highlights the matching index and JSON table entries.

last-updated: Jun 06, 2024



IMPORTANT: Secondary indexes can only be created on HPE Ezmeral Data Fabric Database JSON tables.

Uses for Secondary Indexes

Describes typical use cases that can benefit from secondary indexes.

Operational Analytics	Operational analytics require highly scalable, highly responsive, interactive, user-facing applications. Application developers can use OJAI API to build richer and more interactive applications. This enables users to retrieve data on a variety of columns in HPE Ezmeral Data Fabric Database JSON tables in a flexible way. In addition to processing queries, OJAI also enables them to sort on columns and paginate or restrict the results. The applications can be operational applications or operational analytical applications. For both categories, the level of user interactivity and query complexity is high. Sample applications include Customer 360, expense reporting systems,

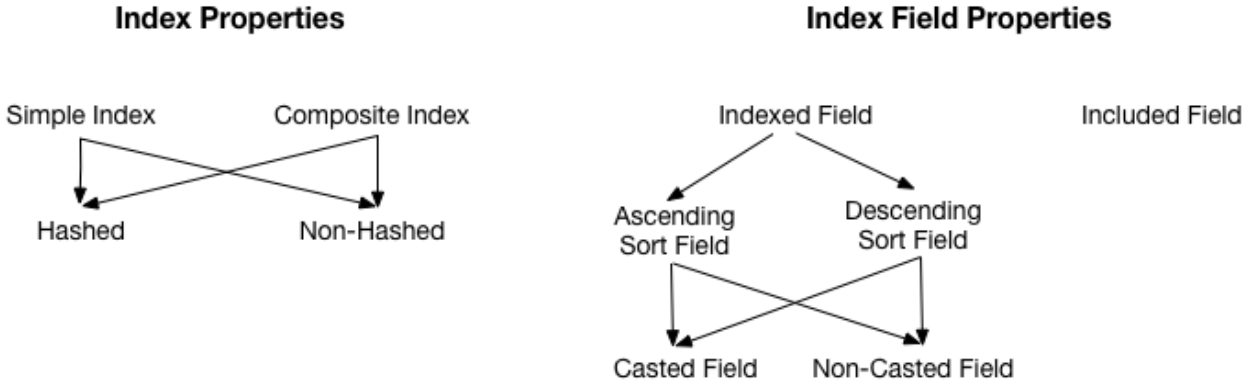
last-updated: Jun 06, 2024

	game management, product catalogs, and a variety of domain-specific analytics as service applications.
Operational BI and Dashboards	Typical analytical workloads query snapshots of read-only data. Querying against HPE Ezmeral Data Fabric Database using Drill SQL enables these applications to get insights into the latest, changing data. Moreover, operational analytical queries usually access only a subset of fields from a table, often aggregating the data on a variety of dimensions and time ranges. Secondary indexes are extremely useful in these use cases. They improve the performance of well known query patterns.
Self-service Data Exploration	Users want to use their favorite BI reporting tool to issue ad-hoc queries against HPE Ezmeral Data Fabric Database JSON tables. They can achieve a simple, high performing data exploration experience using HPE Ezmeral Data Fabric Database and Drill SQL, while leveraging the capabilities of both. Using the HPE Ezmeral Data Fabric Database document model provides end to end JSON flexibility at the data storage level. Using Drill SQL provides dynamic schema discovery.

Types of Secondary Indexes

HPE Ezmeral Data Fabric Database JSON supports several index types, including simple indexes, composite indexes, hashed indexes, and indexes with casting. This section describes the properties of these indexes and the situations where each provides value.

The following diagram illustrates the different properties of indexes and index fields. Lines connecting properties represent properties that can be used in combination with one another. Click on the text in the diagram for a description of each property.



1. Simple vs Composite Indexes
2. Simple vs Composite Indexes
3. Hashed vs Non-Hashed Indexes
4. Hashed vs Non-Hashed Indexes
5. Indexed vs Included Fields
6. Indexed vs Included Fields
7. Indexed Field Sort Order

8. Indexed Field Sort Order
9. Casting
10. Casting

Indexed vs Included Fields

An index consists of indexed and included fields. Indexed fields are also referred to as *index keys*. The following lists describe the characteristics of each type of field:

Indexed Fields	• Determine the sort order of the index and the order of the query result when used • Allow filter conditions and ORDER BY conditions defined on these fields to be optimized
Included Fields (sometimes referred to as *covered fields*)	• Do not affect the sort order of the index or the order of the query result • Can avoid the need to read the base table if all required fields are included in the index

In general, you should define indexed fields on fields you filter and order on, and included fields on fields you reference but do not filter and order.

The following example illustrates when you would define an indexed vs an included field in your index. Assume you have a HPE Ezmeral Data Fabric Database JSON table with the following sample data that contains customer information.

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
        {"Type": "Home", "Number": "555-555-1234"},
        {"Type": "Mobile", "Number": "555-555-5678"},
        {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

Your query does the following:

1. Filters on `Address.Zipcode`
2. Selects `FullName.FirstName` and `FullName.LastName`

last-updated: Jun 06, 2024

Since your query filters on `Address.Zipcode`, you should include that field as an indexed field. Also, because this query only needs the fields `FullName.FirstName` and `FullName.LastName`, you can set `FullName` as an included field. The result is that this query will only need to read from the index and will not need to look at the original table. Other queries that, for example, need to read the phone numbers or address would still need to go back to the base table.

```
maprcli table index add -path /customerInfo -index zipCodeIdx \
   -indexedfields Address.Zipcode \
   -includedfields FullName
```

There are additional differences in how indexed and included fields behave. The following table summarizes these differences:

Indexed Field	Included Field
There are some restrictions in the data types of indexed fields. See Data Types and Secondary Index Fields on page 699 for the complete list of types.	Data types of included fields can be any type. There is no data type restriction.
The collective size of all indexed fields is a maximum of 32KB.	Included fields do not affect the size limit of an index.
Adding indexed fields increases the cost of key comparisons when scanning the index, due to the increase in the index key size.	Adding included fields does not impact the index scan cost.

Included fields influence whether an index is a *covering index* for a query. See Covering Indexes on page 698 for more information about this concept.

Indexed Field Sort Order

You can define each field in your index key to sort in either ascending or descending order. The default is ascending. Typically, you define the sort order to match the ORDER BY clause in your query. This allows the HPE Ezmeral Data Fabric Database to avoid performing an explicit sort. For example, if you issue queries where you return `AccountBalance` in descending order, create the following index.

```
maprcli table index add -path /customerInfo -index BalanceIdx \
   -indexedfields AccountBalance:-1
```

Simple vs Composite Indexes

Simple indexes are indexes with a single indexed field (or key). Composite indexes have more than one key. In both cases, you can define zero or more included fields. See Simple Indexes on page 690 and Composite Indexes on page 691 for additional details.

Hashed vs Non-Hashed Indexes

By default, indexes are stored in sort order across the index key values. This can lead to hotspots if the sort order of the index keys match the order data that is inserted into the JSON table. For example, if the indexed field has monotonically increasing timestamp values, such as the date a document is created, the tail end of the index becomes a hotspot. Hashed indexes avoid hotspotting by evenly distributing index writes across a number of logical partitions.

The following example creates a hashed index named `idx` on table, `tab`, with a single key, `idxKeyCol`.

```
maprcli table index add -path /tab -index idx -indexedfields idxKeyCol \
    -hashed true
```

See Hashed Indexes on page 693 for further details.

last-updated: Jun 06, 2024

Casting

You can CAST individual indexed fields to a specific data type. This is applicable when Drill SQL queries contain CAST expressions. The following example creates an index that casts the `age` field to an INT type and the `height` field to a FLOAT type.

```
maprcli table index add -path /castTable -index castIdx \
   -indexedfields '$CAST(age@INT)','$CAST(height@FLOAT)'
```

See Using Casts in Secondary Indexes on page 695 for further details.

NOTE: This feature only applies for queries issued through the Drill SQL interface. The OJAI API does not have CAST support.

Simple Indexes
A *simple index* is a secondary index that has only one indexed field and zero or more included fields. Simple indexes enable you to optimize queries that filter and sort on a single field. If all fields referenced in a query are either indexed or included fields in a simple index, then you can process the query by reading only the index.

Sort Order

HPE Ezmeral Data Fabric Database sorts simple indexes on the single indexed field. HPE Ezmeral Data Fabric Database sorts the indexed field values in ascending order by default, although you can specify a descending order when you create the index. Sorting indexes benefits your ORDER BY queries because the index eliminates the need for a SORT operator in the query plan.

Simple Index Examples

The following CLI commands demonstrate how you can create various types of simple indexes. For these examples, assume that you have a HPE Ezmeral Data Fabric Database JSON table with the following sample data:

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
       {"Type": "Home", "Number": "555-555-1234"},
       {"Type": "Mobile", "Number": "555-555-5678"},
       {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

last-updated: Jun 06, 2024

CLI Command	Description

`maprcli table index add -path /people \`
`-index emailIdx \`
`-indexedfields Email`
	• Creates a simple index on the `Email` field, with no included fields
	• Enables you to filter on the `Email` field

`maprcli table index add -path /people \`
`-index dobIdx \`
`-indexedfields DateOfBirth \`
`-includedfields FullName`
	• Creates a simple index, with an included field
	• Enables you to filter on `DateOfBirth` and project on `FullName`

`maprcli table index add -path /people \`
`-index LastNameIdx \`
`-indexedfields FullName.LastName:-1`
	• Creates a simple index on the `FullName.LastName` subfield, as a descending sort key
	• Allows you to filter on `FullName.LastName` and sort on the subfield in descending order

`maprcli table index add -path /people \`
`-index fullNameIdx \`
`-indexedfields FullName`
	• Creates a simple index on the nested document field `FullName`
	• Allows you to perform equality lookups on both the `LastName` and `FirstName` subfields of `FullName`

`maprcli table index add -path /people \`
`-index hobbiesIdx \`
`-indexedfields Hobbies`
	• Creates a simple index on the `Hobbies` array field
	• Allows you to filter for a specific list of hobbies

`maprcli table index add -path /people \`
`-index hobbyIdx \`
`-indexedfields Hobbies[]`
	• Creates a simple index using the container field path `Hobbies[]`
	• Allows you to filter for a specific hobby

`maprcli table index add -path /people \`
`-index phoneNumberIdx \`
`-indexedfields Phones[].Number`
	• Creates a simple index on the container field path `Phones[].Number`
	• Allows you to filter for a phone number, regardless of whether it is a home, work, or cell phone

Composite Indexes
A *composite index* is an index that has more than one indexed field and zero or more included fields. Composite indexes enable you to optimize queries that filter and sort on multiple fields. If all fields referenced in a query are either indexed or included fields in a composite index, then you can process the query by reading only the index.

Sort Order

HPE Ezmeral Data Fabric Database sorts the composite index in the order in which you have defined the indexed fields. For example, if you have an index on `Field1` and `Field2`, HPE Ezmeral Data Fabric Database sorts on `Field1` as the primary sort key and `Field2` as the secondary.

Each component in a composite index can have its own ordering. For example, you can specify an ascending sort order for one field and a descending sort order for another.

Composite Indexes and Container Field Paths

The indexed fields in a composite index can be Container Field Paths on page 653. However, if you specify more than one container field path in your indexed fields, the prefixes of the container field paths must be the same. This allows HPE Ezmeral Data Fabric Database to store index values that originate from the same array element in a single index row.

Examples of Supported Composite Indexes

Indexed Fields Allowed for Composite Index	Why Allowed?
`a[].b, x.z`	The indexed fields have only one container field path.
`a[].b, a[].c`	The indexed fields have a common container prefix, `a[]`.
`a[].b, a[].c[]`	The indexed fields have a common container prefix, `a[]`.
`a[].b[].c, a[].b[].d`	The indexed fields have a common container prefix, `a[].b[]`.

Examples of Unsupported Composite Indexes

If a composite index includes the same subfield in multiple indexed fields, the implied types of the subfields must also be consistent. The third and fourth rows in the following table show examples of this restriction:

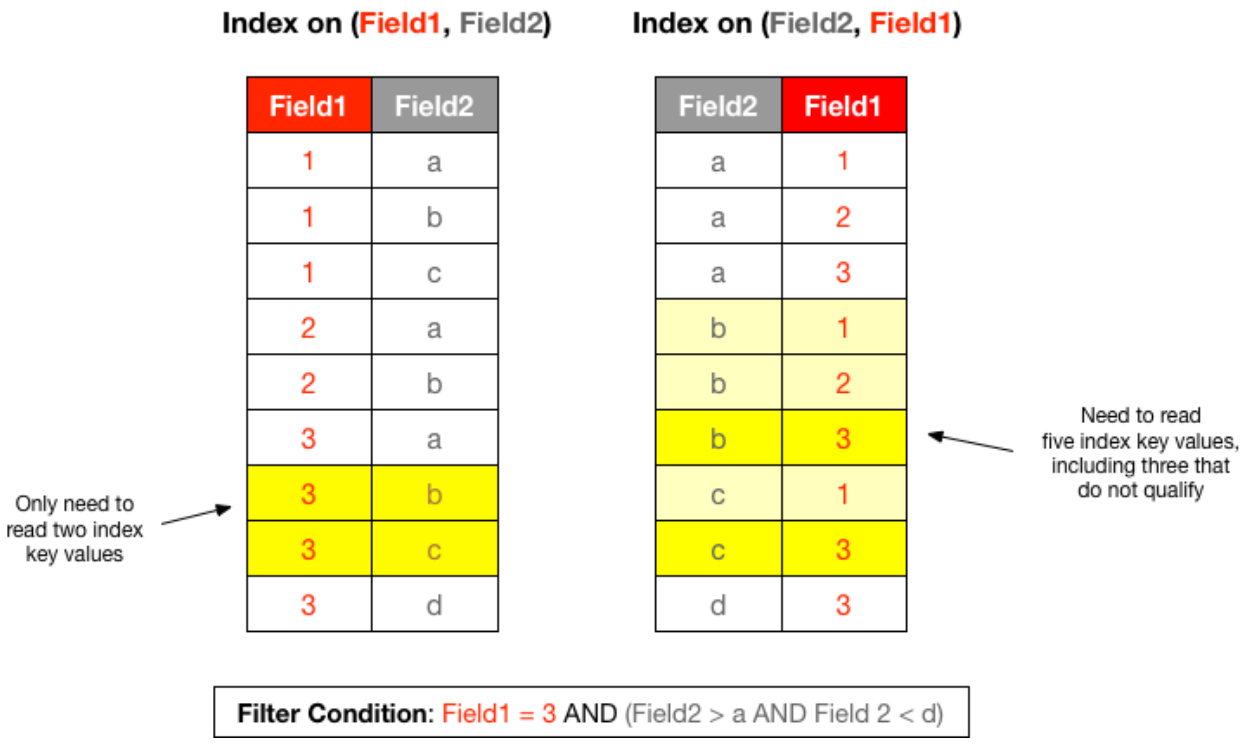
Indexed Fields Disallowed for Composite Index	Why Disallowed?
`a[].b, x[].y`	`a[]` and `x[]` are different container prefixes.
`a[].b[], a[].c[]`	Although both indexed fields have a common container prefix of `a[]`, `b[]` and `c[]` are different container field paths.
`a.b[].c, a.b.d`	In the first indexed field, subfield `b` is an array of nested documents. In the second, `b` is a single nested document. This results in a type conflict.
`a, a[]`	The first indexed field `a` is a scalar type while the second is an array. This also results in a type conflict.

Query Conditions Using Composite Indexes and Container Field Paths

When you have a composite index defined on container field paths, your query condition must use the elementAnd operator to use all keys of the index. With the `and` operator, the conditions do not have to match the same array element; as a result, the matching indexed field values might span different index rows, preventing use of the composite index. See OJAI Query Conditions Using elementAnd on page 3399 for more details.

Composite Index Example

Consider the following example, which illustrates the impact of key order in a composite index:



In the index on the left, the prefix key is `Field1`. HPE Ezmeral Data Fabric Database sorts the index first on `Field1`, and then on `Field2`. This aligns with the equality condition, `Field1 = 3`. HPE Ezmeral Data Fabric Database reads the least number of entries from the index on the left, due to this equality condition and the range condition on `Field2`.

In the index on the right, HPE Ezmeral Data Fabric Database sorts the index on `Field2`, followed by `Field1`. In this case, the matching key values are not contiguous in the index, as highlighted by the entries in a lighter shade of yellow. HPE Ezmeral Data Fabric Database uses the filter conditions on `Field2` to start the search in the index. It applies the filter condition on `Field1` while reading the index. This is less efficient because HPE Ezmeral Data Fabric Database must read those extra non-matching key values.

Related concepts

Restrictions on Secondary Indexes on page 703
This topic lists and describes the restrictions on secondary indexes. It is important for you to understand the type, size, field definition, option, and index use restrictions when defining and using secondary indexes.

Hashed Indexes

A *hashed index* is a secondary index that distributes keys across logical partitions to avoid creating hot spots when HPE Ezmeral Data Fabric Database updates the index with new keys from the JSON table.

Hot spots occur when data inserted into an indexed field has monotonically increasing values, or when a burst of write activity occurs. The former occurs with timestamp values. The latter occurs when you have a burst of updates on an indexed field over a small range of values. Hashed indexes enable HPE Ezmeral Data Fabric Database to evenly distribute new writes on an index and avoid hot spots.

NOTE: Hashed indexes do not resolve hot spots on the JSON table. For information about how to design rowkeys and avoid hot spots in the JSON table, see Table Rowkey Design.

Hashed indexes support the same conditional queries as non-hashed indexes, except that hashed indexes do not have a guaranteed sort order. Hashed indexes do not support ORDER BY queries due to the distribution of data across logical partitions. Consequently, sorting is performed by the query layer, which can increase the CPU costs and negatively impact performance.

By default, HPE Ezmeral Data Fabric Database creates ten partitions for a hashed index. You can modify this value when you create a hashed index using the maprcli table index add command or through the Control System. When a hashed index exists, HPE Ezmeral Data Fabric Database distributes table updates to the index across the logical partitions, which reside on different nodes. HPE Ezmeral Data Fabric Database orders the keys within each partition instead of ordering them across the entire index.

NOTE: Once you create an index with hashing enabled, you cannot disable hashing. You can remove the hashed index and then create a non-hashed (default) index on the field. See Removing Indexes and Adding Indexes.

Guidelines on Creating Hashed Indexes

- Create a hashed index on fields with monotonically increasing values, such as timestamp values.
- Create a hashed index on fields that HPE Ezmeral Data Fabric Database updates in bursts of write activity, for example when HPE Ezmeral Data Fabric Database updates a small range of possible values for the indexed field.
- Do not create hashed indexes for ORDER BY queries.
- Use the `maprcli table index list` command or the Control System to determine if an index is hashed. See maprcli table index list or Listing Indexes.
- After you create an index with hashing enabled, you cannot disable hashing.

Example Comparison of a Non-Hashed Index and Hashed Index

The following images depict a non-hashed (default) index and a hashed index. For the purpose of this example, assume that an index was created on the `DateCreated` field of a JSON table in HPE Ezmeral Data Fabric Database. Yellow highlighted areas indicate updates to the index.

Non-Hashed (Default) Index

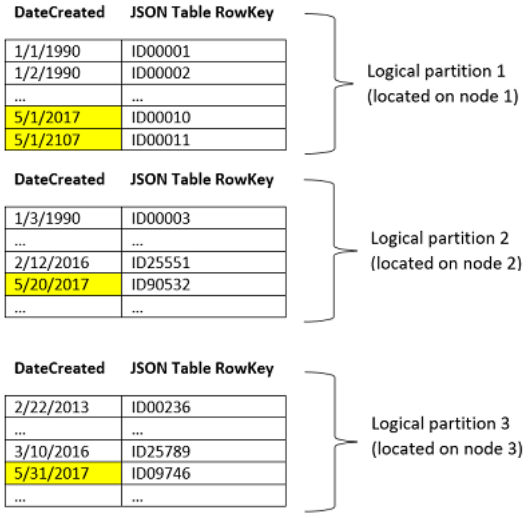
The non-hashed index propagates `DateCreated` field updates from the JSON table to the index. Notice that the dates are sorted within the index and no partitions exist. Depending on the size of the index, the index may exist on one or multiple nodes

DateCreated	JSON Table RowKey
1/1/1990	ID00001
1/2/1990	ID00002
...	...
...	...
5/1/2017	ID00010
5/1/2017	ID00011
...	...
5/20/2017	ID90532
...	...
5/31/2017	ID09746

.

Hashed Index

The hashed index propagates `DateCreated` field updates across the index partitions which reside on different nodes. Notice that dates are sorted within each partition and each partition resides on a different node.



Using Casts in Secondary Indexes
Defining an index that specifies index keys with CAST functions provides fast access for queries that contain CAST functions. The index converts the indexed field to the type specified by the CAST function and stores the result.

Create indexes using CAST functions if you want to CAST fields to specific data types in your queries. To define an index with the CAST function applied to a field, specify a CAST when defining the index key. The following example creates an index that casts the `age` field to an INT type and the `height` field to a FLOAT type.

```
maprcli table index add -path /castTable -index castIdx \
   -indexedfields '$CAST(age@INT)','$CAST(height@FLOAT)'
```

When issuing Drill queries through Business Intelligence (BI) tools, you can include CAST functions in your queries to create Drill views. Including CAST functions provides the metadata needed to optimally process the queries. For more information about using the CAST function with Drill, see Data Type Conversion.

Casting from NULL in Drill

You can cast from null to any data type supported by the indexes with the CAST function. However, null can be a valid JSON value for the string data type, for example:

```
{ "name": null }
```

Null can also represent the absence of an actual value, for example:

```
{ "_id":1,"name":"Annie" }
{ "_id":2 }  (name does not exist)
```

When you cast on columns with missing values, Drill does not return null for the missing values. Drill only returns null in cases where an actual value of null exists.

For example, if you have the following data stored in a JSON table named t1:

a1	b1
1	'abc'
2	null
3	'null'

And you issue the following query against the table:

```
SELECT a1, b1(cast b1 as varchar(20))) from t1;
```

Drill returns the following data:

a1	b1
1	abc
2	
3	null

Drill does not return null where null represents a missing value. Drill only returns null in the instance where null is stored as a string value.

Guidelines for Using Casts in Indexes

The following rules apply to CAST functions used in secondary indexes:

- You can include the CAST function only on indexed fields.
- You do not have to cast between comparable data types.
- Indexes support casting to the following data types:
  - Boolean
  - String
  - Int
  - Long
  - Float
  - Double
  - Date
  - Time
  - Timestamp

  NOTE: HPE Ezmeral Data Fabric Database does not support casting from any data type to `byte`, `short`, `decimal`, `binary`, or `interval`.

  NOTE: Queries that use the CAST function on fields with `timestamp` and `binary` data types are not supported.
- When casting to a `string` type, you can optionally specify a length. If you do not specify a length, it defaults to the maximum length of 255.
- When casting a `float` or `double` type to a `string` type, you cannot control the precision of the digits in the resulting string value. `Float` and `double` are approximate representations of decimal values.
- When casting from a `binary` type, HPE Ezmeral Data Fabric Database assumes that the binary value is a UTF-8 formatted string representation of the resulting data type.

last-updated: Jun 06, 2024

- If HPE Ezmeral Data Fabric Database cannot cast a value, HPE Ezmeral Data Fabric Database indexes the row with an encoding error that specifies a CAST issue.
- You cannot cast all data types to the supported data types. See the Casting Matrix below for supported and unsupported combinations.

Casting Matrix

The following matrix displays supported and unsupported casting, from the data type shown in the column to the data type shown in the row. **Y** indicates a supported casting; **N** indicates an unsupported casting. Hyphen (**-**) indicates that casting is unnecessary, because the data types are comparable.

	int	**long**	**float**	**double**	**string**	**boolean**	**date**	**time**	**timestamp**
byte	Y	Y	Y	Y	Y	Y	N	N	N
short	Y	Y	Y	Y	Y	Y	N	N	N
int	-	Y	Y	Y	Y	Y	Y[1]	Y[2]	Y
long	Y	-	Y	Y	Y	Y	Y	Y	Y
float	Y	Y	-	Y	Y	Y	N	N	N
double	Y	Y	Y	-	Y	Y	N	N	N
string	Y	Y	Y	Y	-	Y[3]	Y	Y	Y
boolean	Y	Y	N	N	Y	-	N	N	N
date	N	N	N	N	Y	N	-	Y	Y
time	N	N	N	N	Y	N	N	-	N
timestamp	N	N	N	N	Y[4]	N	Y	Y	-
binary	Y	Y	Y	Y	Y	N	N	N	N
array	N	N	N	N	N	N	N	N	N
nested document	N	N	N	N	N	N	N	N	N

[1] When casting int/long to a date type, the date value is constructed based on the int/long value being the number of milliseconds since epoch.

[2] When casting int/long to a time type, the time value is constructed based on the int/long value being the time of day in milliseconds.

[3] HPE Ezmeral Data Fabric Database casts the strings `true`, `yes`, `on`, `y`, `t`, and `1` to boolean `true`. HPE Ezmeral Data Fabric Database casts the strings `false`, `no`, `off`, `n`, `f`, and `0` to boolean `false`.

[4] The string represents the time in UTC timezone.

Example Using Cast Function in an Index

This example shows you how to create an index with the CAST function.

The following statement queries a table named `lineitem` and casts the `L_LINENUMBER` and `L_ORDERKEY` fields to the `int` data type:

```
SELECT L_LINESTATUS, L_QUANTITY FROM lineitem WHERE CAST(L_LINENUMBER as
int) = 1 AND CAST(L_ORDERKEY as int) = 550;
```

You can create an index on the `L_LINENUMBER` and `L_ORDERKEY` fields and indicate the use of the CAST function and data type for each field, as follows:

```
maprcli table index add -path /drill/testdata/qa/sf1/maprdb/json/
lineitem -index l_cast_comp_1 \
   -indexedfields '$CAST(L_LINENUMBER@INT)','$CAST(L_ORDERKEY@INT)' \
   -includedfields L_LINESTATUS,L_QUANTITY
```

The index stores the values of the `L_LINENUMBER` and `L_ORDERKEY` fields as the `int` data type. HPE Ezmeral Data Fabric Database can use the index for any subsequent queries that use the CAST function to retrieve these fields as the `int` type, instead of accessing data in the primary table and converting the values to `int`.

NOTE: If you created an index on the `L_LINENUMBER` and `L_ORDERKEY` fields without the CAST function, the query used in this example would not benefit from the index.

Covering Indexes
A *covering index* is an index that allows HPE Ezmeral Data Fabric Database to process a query using secondary indexes without reading the JSON table. Using a *covering index* makes a query more efficient by avoiding the I/O overhead of fetching data from the JSON table.

If all fields referenced in a query are either indexed or included fields in a secondary index, then the secondary index is a covering index for that query. HPE Ezmeral Data Fabric Database determines whether an index is covering for a query.

A query that uses a covering index can reference only indexed fields from the index or a combination of indexed and included fields. While adding included fields to an index enables it to become a covering index, note that each field you add to an index increases its storage requirement. As the storage size increases, the cost of reading the index also increases; likewise, for the cost of adding and updating documents. Consider the impact on storage and updates when adding included fields to an index.

In contrast to a covering index, a noncovering index is an index that does not store all fields referenced by a query. In this case, lookups occur on the JSON table to retrieve the referenced fields that are not available in the index itself.

Whether an index is covering or noncovering depends on the query that uses the index. In the example at Types of Secondary Indexes on page 687, `zipCodeIdx` is a covering index for the noted query. If the query also selects the `Gender` field, `zipCodeIdx` is no longer a covering index for the query, but it still optimizes the filter condition.

Covering Indexes and Container Field Paths

When a query uses an index in which the indexed fields are container field paths, HPE Ezmeral Data Fabric Database cannot rely on only the indexed fields to treat the index as covering. This is due to the way HPE Ezmeral Data Fabric Database stores data in an index for container field paths. As described in Using Container Field Paths as Indexed Fields on page 700, HPE Ezmeral Data Fabric Database stores one row in the index for each array element. Thus, reading only the rows corresponding to matching array elements might not retrieve the other elements of the array.

To allow an index to be covering in this scenario, the referenced field must be an included field in the index.

For example, using the example at Types of Secondary Indexes on page 687, suppose you want to run the following query:

- Filter where `Hobbies[]` contains "Baseball"
- Select the `FullName` and all `Hobbies`

For an index to be covering for this query, you must define the index with following fields:

- Indexed Fields: `Hobbies[]`

- Included Fields: `Hobbies`, `FullName`

NOTE: HPE Ezmeral Data Fabric Database does not permit you to specify the same field as both an indexed and included field, unless the indexed field is a container field path.

Data Types and Secondary Index Fields
Secondary indexes support a specific set of data types. This section describes how indexed and included fields in secondary indexes behave for various categories of data types.

Data Types of Indexed Fields

Prior to data-fabric 6.1, the indexed fields in a secondary index had to contain scalar data. For each scalar data value, HPE Ezmeral Data Fabric Database stored a row in the index. See the table in the **Scalar Data** section of JSON Document Data Types for a list of scalar types.

Beginning with data-fabric 6.1, indexed fields can also be nested documents or arrays, but not array elements. As with scalar data values, HPE Ezmeral Data Fabric Database stores a row in the index for each nested document and array. The index improves equality filters on the entire nested document or array.

data-fabric 6.1 also supports using container field paths as indexed fields.

The following table summarizes what HPE Ezmeral Data Fabric Database supports, depending on the characteristics of the indexed field:

Characteristics of Indexed Field	Pre-6.1 Behavior	6.1 Behavior
Field contains scalar data	Supported	Supported
Field contains nested document data	Not supported	Supported
Field contains array data	Not supported	Supported
Field path is a nested document subfield	Supported only if the subfield contains scalar data	Supported for any data type
Field is an individual array element	Not supported	Not supported
Field uses a container field path	Not applicable	Supported

To understand what HPE Ezmeral Data Fabric Database stores for an indexed field defined on different data types, consider an example in which you have the following documents:

```
{"_id":"0", "field":0}
{"_id":"1", "field":[0,1,2]}
{"_id":"2", "field":{"subField":1}}
{"_id":"3", "field":{"subField":[1,2,3]}}
{"_id":"4", "field":[{"subField":1},{"subField":2}]}
{"_id":"5", "field":[{"subField":[1,2,3]},{"subField":[4, 5]}]}
```

The following table shows what an index defined on `field` stores and an OJAI query condition that matches the value stored in the index:

Document ID	Value Stored in Index Defined on `field`	Matching OJAI Query Condition
0	`0`	`{"$lt":{"field":1}}`
1	`[0,1,2]`	`{"$eq":{"field":[0,1,2]}}`

last-updated: Jun 06, 2024

Document ID	Value Stored in Index Defined on `field`	Matching OJAI Query Condition
2	`{"subField":1}`	`{"$eq":{"field":{"subField":1}}}`
3	`{"subField":[1,2,3]}`	`{"$eq":{"field":{"subField":[1,2,3]}}}`
4	`[{"subField":1},{"subField":2}]`	`{"$eq":{"field":[{"subField":1},{"subField":2}]}}`
5	`[{"subField":[1,2,3]},{"subField":[4, 5]}]`	`{"$eq":{"field":[{"subField":[1,2,3]},{"subField":[4,5]}]}}`

The following table shows what an index defined on `field.subField` stores and an OJAI query condition that matches the value stored in the index:

Document ID	Value Stored in Index Defined on `field.subField`	Matching OJAI Query Condition
0	*Missing* [1]	N/A
1	*Missing* [1]	N/A
2	`1`	`{"$lt":{"field.subField":5}}`
3	`[1,2,3]`	`{"$eq":{"field.subField":[1,2,3]}}`
4	*Missing* [2]	N/A
5	*Missing* [2]	N/A

NOTE:

[1] The index entry for documents 0 and 1 are missing because `field` is not a nested document in these documents.

[2] The index entries for documents 3 and 4 are missing because `field` is an array in those documents.

These indexes enable HPE Ezmeral Data Fabric Database to quickly look up values stored in the index. As shown in the table, these values can be scalars, arrays, or nested documents. In the case of the latter two types, HPE Ezmeral Data Fabric Database can only use the index for equality conditions.

Data Types of Included Fields

There are no type restrictions on the included fields in an index.

Using Container Field Paths as Indexed Fields

Starting in data-fabric 6.1, indexed fields in an index can be Container Field Paths on page 653. When you use a container field path as your indexed field and the field contains an array, then the index contains one row per array element. Therefore, the size of your index is proportional to the number of elements in the array.

last-updated: Jun 06, 2024

IMPORTANT: Consider the storage implications of your index if you decide to use a container field path as an indexed field. Also consider the performance impact from index updates. Updating an indexed array field in a single JSON document may require updating multiple index rows.

When an indexed field is not a container field path, the index contains one row per field value.

For example, suppose you have the same set of documents shown earlier:

```
{"_id":"0", "field":0}
{"_id":"1", "field":[0,1,2]}
{"_id":"2", "field":{"subField":1}}
{"_id":"3", "field":{"subField":[1,2,3]}}
{"_id":"4", "field":[{"subField":1},{"subField":2}]}
{"_id":"5", "field":[{"subField":[1,2,3]},{"subField":[4, 5]}]}
```

The following table shows what each index stores if you define the index on the following container field paths:

- `field[]`
- `field[].subField`
- `field.subField[]`
- `field[].subField[]`

Each entry in the table represents a row in the index.

Document ID	Indexed Field Path			
	`field[]`	`field[].subField`	`field.subField[]`	`field[].subField[]`
0	`0`	*Missing* [1]	*Missing* [1]	*Missing* [1]
1	`0`	*Missing* [1]	*Missing* [1]	*Missing* [1]
	`1`			
	`2`			
2	`{"subField":1}`	`1`	`1`	`1`
3	`{"subField": [1,2,3]}`	`[1,2,3]`	`1`	`1`
			`2`	`2`
			`3`	`3`

last-updated: Jun 06, 2024

Document ID	Indexed Field Path			
	`field[]`	`field[].subField`	`field.subField[]`	`field[].subField[]`
4	`{"subField":1}`	`1`	*Missing* [2]	`1`
	`{"subField":2}`	`2`		`2`
5	`{"subField": [1,2,3]}`	`[1,2,3]`	*Missing* [2]	`1`
				`2`
	`{"subField":[4, 5]}`	`[4, 5]`		`3`
				`4`
				`5`

NOTE:

[1] The index entries for documents 0 and 1 are missing in all indexes except the index on `field[]` because `field` is not a nested document.

[2] The index entries for documents 3 and 4 are missing in the index on `field.subField[]` because `field` is an array in those documents.

To use these indexes, your query condition must use container field paths that correspond to the indexed fields. The following are sample OJAI query conditions that you might use with each index:

Indexed Field Path	Sample OJAI Query Condition	Matching Document(s)
`field[]`	`{"$eq":{"field[]":0}`	0, 1
	`{"$eq":{"field[]":{"subField": [1,2,3]}}}`	3, 5
`field[].subField`	`{"$eq":{"field[].subField":1}}`	2, 4
`field.subField[]`	`{"$gt":{"field.subField[]":2}}`	3
`field[].subField[]`	`{"$eq":{"field[].subField[]":2}}`	3, 4, 5

See OJAI Query Conditions Using Container Field Paths on page 3396 for further details about how these types of conditions behave.

last-updated: Jun 06, 2024

Defining an Index With and Without a Container Field Path

As shown in these examples, defining an index on a container field path is different from defining an index on an entire array field. For example, an index on `field[]` can filter on individual array elements, whereas the index on `field` can filter only the entire value. Similarly, defining an index on `field[].subField[]` provides the most generality. It allows you to filter on any elements in `subField`, regardless of the data types in *both* `field` and `subField`. However, you also incur the overhead of storing more data in your index and the performance impact of updating the index.

Using Container Field Paths in Covering and Composite Indexes

With a container field path, you may need to add included fields in your index to make the index covering. See Covering Indexes and Container Field Paths on page 698 for details.

There are also limitations in the composite indexes you can define. See Composite Indexes and Container Field Paths on page 692 for details.

Comparisons and Sorts on Indexed Fields

Comparisons and sorts across data types differ depending on whether the types are comparable or noncomparable. This is not specific to secondary indexes. However, it impacts comparisons when using secondary indexes and the order HPE Ezmeral Data Fabric Database stores data in an index. See Using Comparable JSON Document Data Types in Comparisons and Sorts on page 649 and Using Non-comparable JSON Document Data Types in Comparisons and Sorts on page 650 to learn which types fall into each category and to understand their behavior.

Restrictions on Secondary Indexes on page 703
This topic lists and describes the restrictions on secondary indexes. It is important for you to understand the type, size, field definition, option, and index use restrictions when defining and using secondary indexes.

Restrictions on Secondary Indexes

This topic lists and describes the restrictions on secondary indexes. It is important for you to understand the type, size, field definition, option, and index use restrictions when defining and using secondary indexes.

Name Restrictions	You cannot use the following characters in the index name and in the indexed fields:
	`< > ? % \`
	To use the following characters in the index name and in the indexed fields, enclose them either in single or double quotes:
	`; | ( ) /`
	For example:
	`maprcli table index add -path /volume1/MYTABLE -index "MYTABLE1_ANALYSIS_1♦=#;{}&()/" \ -indexedfields "●timestamp":desc,"●♥","LOTNo" -includedfields \ "♥","♦=#;{}&()/" (or)`
	`maprcli table index add -path /volume1/MYTABLE -index 'MYTABLE1_ANALYSIS_1♦=#;{}&()/' \`

last-updated: Jun 06, 2024

```
  -indexedfields "●timestamp":desc,"●
●,"LOTNo" -includedfields \
  '●,'♠=#;{}&()/'
```

To use either the ' or the " character in the index name and in the indexed fields, enclose:

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"'MYTABLE1_ANALYSIS_1♠=#;{}&()/" \
  -indexedfields "●timestamp":desc,"●●
●,"LOTNo" -includedfields \
  "●","♠=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'"MYTABLE1_ANALYSIS_1♠=#;{}&()/' \
  -indexedfields "'●timestamp":desc,"●
●,"LOTNo" -includedfields \
  '●','♠=#;{}&()/"
```

Type Restrictions

- If a composite index includes the same subfield in multiple indexed fields, the implied types of the subfields must be consistent.

  For example, you cannot create an index with the following indexed fields:

  ```
  a.b[].c, a.b.d
  ```

  Although subfield b appears in both indexed fields, in the first, it is an array and in the second, it is a nested document.

  See Composite Indexes and Container Field Paths on page 692 for more details.

Size Restrictions

- The maximum size of all indexed fields in an index is 32 KB.

  If the collective size exceeds 32 KB, then an insert of the corresponding document results in an encoding error (`INDEX_ROW_KEY_ENCODER_ERROR_ENCODING_IS_TOO_LONG`).

- The maximum number of indexes that you can create on a JSON table is 32.

Field Definition Restrictions

- You cannot specify individual array elements as indexed fields.
- You cannot specify a table's `_id` field as an indexed field.

- If a field contains an array of nested documents and you want to index on subfields in the nested documents, then you must define the indexed field using a container field path.
- You can include a specific field only once as either an indexed or included field, with the following two exceptions:
  - The indexed field is a container field path:

    ```
    maprcli table index add -path /
    people \
       -index phoneNumberIdx \
       -indexedfields
    Phones[].Number \
       -includedfields
    Phones[].Number
    ```

  - The field specifies a cast to another type.

    You can create an index in which the `score` field is an indexed field cast as a `double` type, and `score` is also an included field. The included field retains the original data type of the `score` field:

    ```
    maprcli table index add -path /
    castTable \
       -index castIdx1 \
       -indexedfields
    '$CAST(score@DOUBLE)' \
       -includedFields score
    ```

    You can create an index in which the `score` field is an indexed field, cast as a `double` type, and the `score` field is also another indexed field, cast as a `long` type:

    ```
    maprcli table index add -path /
    castTable \
       -index castIdx2 \
       -indexedfields
    '$CAST(score@DOUBLE)','$CAST(scor
    e@LONG)'
    ```

- You cannot use casts with included fields.

- You cannot specify a field as either an indexed or included field if the field is also specified as a column family JSON path name.

  For example, suppose you have the following JSON table:

```
{
     "_id" : "ID",
     "a" :
          {
               "b" :
                    {
                         "c" :
"value",
                         "d" :
"value"
                    },
               "e" : "value"
          }
}
```

  If you create a column family at field `c` in the JSON path `a.b.c`, you cannot define field `a.b.c` as either an indexed or included field. You can define the fields `a`, `a.b`, and `a.b.d` as either indexed or included fields.

last-updated: Jun 06, 2024

- You cannot specify an included field in which the data in the field spans more than one column family.

  In the following example, the included field `sl1.sl2` spans column families, `cf2` and `cf3`:

```
maprcli table cf list -path /cftab
compressionperm  readperm
traverseperm  jsonfamilypath
writeperm  minversions
maxversions  compression
ttl         inmemory  cfname
memoryperm
u:root           u:root
u:root
u:root     0
1            lz4
2147483647  false     default
u:root
u:root           u:root
u:root         sl1
u:root     0
1            lz4
2147483647  false     cf1
u:root
u:root           u:root
u:root         sl1.sl2.sl3
u:root     0
1            lz4
2147483647  false     cf2
u:root
u:root           u:root
u:root         sl1.sl2.sl3.sl4
u:root     0
1            lz4
2147483647  false     cf3
u:root

maprcli table index add -path /
cftab -index i1 -indexedfields
sl1.sl2.sl3.sl4.l4a,
sl1.l1a -includedfields
sl1.sl2,sl1.sl2.sl3.sl4.sl5.l5b -js
on
{
        "timestamp":1507419777919,
        "timeofday":"2017-10-07
04:42:57.919 GMT-0700 PM",
        "status":"ERROR",
        "errors":[
                {
                        "id":22,

"desc":"Data for included field
sl1.sl2 may not span more than one
column family."
                }
         ]
}
```

	• You cannot specify a composite index with more than one container field path as your indexed fields, unless the prefixes of the container field paths are the same. See Composite Indexes and Container Field Paths on page 692 for more details. • You cannot specify a composite index with an indexed field that is a subfield of another indexed field. For example, you cannot create an index with the following indexed fields: `a, a.b` The indexed field `a.b` is a subfield of the indexed field `a`.
Option Restrictions	• As indexes are automatically split, you cannot disable splits when you create your index.
Index Use Restrictions	• Indexes do not optimize non-existence filter conditions.

Queries that Benefit from Secondary Indexes

Secondary indexes benefit queries with filter conditions, ORDER BY clause, and projections.

They benefit these query elements in the following ways:

Filter Conditions	Eliminates full table scans, reducing the number of documents that HPE Ezmeral Data Fabric Database reads, if the filtering fields are keys in an index.
ORDER BY Clause	Eliminates the need to sort the data after scanning the index, if the index's sort order matches the query's sort order.
Projections	Eliminates the need to read the HPE Ezmeral Data Fabric Database JSON table, if all fields referenced in the query are fields in an index.

NOTE: The projections optimization is not supported for OJAI queries that execute through the OJAI Distributed Query Service, and SQL queries issued to Drill. See OJAI Distributed Query Service on page 640 for details about the types of OJAI queries that use the service.

The following topics describe the specific query types and provide examples.

Using Indexes to Optimize Equality Conditions

Using indexes can help you improve the performance of queries that have equality conditions. You can define indexes that optimize equality conditions on scalar data fields, nested document and array fields, and container field paths.

If the index has a single key, the condition limits the index search to only the keys matching the scalar value. If the index has more than one key and there are equality conditions on all keys, the conditions limit the search to the combined matching values. If there are conditions on a subset of fields and the most significant keys have equality conditions, HPE Ezmeral Data Fabric Database limits the search to those scalar values.

last-updated: Jun 06, 2024

Assume that you have a HPE Ezmeral Data Fabric Database JSON table with documents in the following format:

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
        {"Type": "Home", "Number": "555-555-1234"},
        {"Type": "Mobile", "Number": "555-555-5678"},
        {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

The examples in the following sections reference this sample JSON document.

Indexes on Scalar Data Fields in Equality Conditions

The following table provides examples where HPE Ezmeral Data Fabric Database can and cannot use the index with equality conditions on scalar data. The last entry in the table illustrates the case where you can use index to optimize an equality condition in combination with a range condition.

NOTE: This example assumes that a composite index exists on fields `Address.State` and `Address.City`.

Query Condition	How HPE Ezmeral Data Fabric Database Uses the Index
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$eq":{"Address.City":"Oakland"}} ] }`	Performs a lookup on the specified state and city values, and reads the index until the conditions no longer match.
`{"$eq":{"Address.State":"CA"}}`	Performs a prefix lookup to find matching state values. The value of the `Address.City` field is not relevant. Continues reading from the index until the state field no longer matches `"CA"`.

last-updated: Jun 06, 2024

Query Condition	How HPE Ezmeral Data Fabric Database Uses the Index
`{ "$and":[ {"$in":{"Address.State": ["CA","NY","MA"]}}, {"$eq":{"Address.City":"Springfield"}} ] }`	Performs the following three lookups in the index: • `Address.State = "CA" and Address.City = "Springfield"` • `Address.State = "NY" and Address.City = "Springfield"` • `Address.State = "MA" and Address.City = "Springfield"`
`{"$eq":{"Address.City":"Oakland"}}`	Even if the query references the field `Address.State`, HPE Ezmeral Data Fabric Database cannot use the index unless there is also an equality condition on the leading key of the index, `Address.State`.
`{"$in":{"Address.State":["CA","NY","MA"]}}`	Performs three prefix lookups, one for each of the values in the `IN` clause.
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$ge":{"Address.City":"Oak"}} ] }`	Reads from the index starting at the condition `Address.State = "CA"` and `Address.City = "Oak"`. Continues reading the index until the condition `Address.State = "CA"` no longer qualifies.

Indexes on Nested Document Fields in Equality Conditions

Starting in data-fabric 6.1, you can define an index on fields that contain nested documents. These indexes benefit only equality conditions. The query condition must specify all subfields from the nested document. They must match the subfields of nested documents stored in your HPE Ezmeral Data Fabric Database JSON table. The order of the subfields is not relevant.

For example, if you define an index on the `Addresses` field, and specify the following query condition:

```
{
  "$eq":{
    "Addresses":{
      "Street":"123 SE 22nd St.",
      "City":"Oakland",
      "State":"CA",
      "Zipcode":"94601-1001"
    }
  }
}
```

HPE Ezmeral Data Fabric Database can use the index to locate the sample document shown earlier.

On the other hand, if you specify the following condition instead:

```
{
  "$eq":{
    "Addresses":{
      "City": "Oakland",
      "State": "CA"
    }
```

last-updated: Jun 06, 2024

```
  }
}
```

When HPE Ezmeral Data Fabric Database reads using the index and applies this query condition, it does not match the sample document. The condition is missing the `Street` and `Zipcode` subfields. If you want to match on only the `City` and `State` subfields, you can define a composite index on those subfields as described in the previous section.

Indexes on Array Fields in Equality Conditions

Starting in data-fabric 6.1, you can define an index on fields that contain array data. These indexes benefit only equality conditions. The array elements and their order specified in your query condition must match the content and order stored in your HPE Ezmeral Data Fabric Database JSON table.

For example, if you define an index on the `Hobbies` field, and specify the following query condition:

```
{"$eq":{"Hobbies":["Baseball", "Cooking", "Reading"]}}
```

HPE Ezmeral Data Fabric Database can use the index to locate the sample document shown earlier.

On the other hand, if you specify the following condition instead:

```
{"$eq":{"Hobbies":["Cooking", "Baseball", "Reading"]}}
```

When HPE Ezmeral Data Fabric Database reads using the index and applies this query condition, it does not match the sample document. Although the individual array elements match, the order does not.

If `Hobbies` also has scalar data, HPE Ezmeral Data Fabric Database can use the index to locate documents with the following condition:

```
{"$eq":{"Hobbies":"Baseball"}}
```

If your HPE Ezmeral Data Fabric Database JSON table has a document where the `Hobbies` field has a single value "Baseball", HPE Ezmeral Data Fabric Database can use the index to locate the matching document.

Indexes on Container Field Paths in Equality Conditions

Starting in data-fabric 6.1, you can define an index using a container field path as the indexed field.

For example, suppose you want to search for individual hobbies within the `Hobbies` array field, rather than matching the entire array field. You can define an index on the following field:

```
Hobbies[]
```

The following examples show equality conditions that benefit from this index:

Query Condition	Description
`{"$eq":{"Hobbies[]":"Baseball"}}`	Finds documents that contain Baseball as a hobby
`{"$in":{"Hobbies[]":["Baseball","Cooking"]}}`	Finds documents that contain either Baseball or Cooking as a hobby

last-updated: Jun 06, 2024

Query Condition	Description
`{ "$and":[ {"$eq":{"Hobbies[]":"Baseball"}}, {"$eq":{"Hobbies[]":"Cooking"}} ] }`	Finds documents that contain both Baseball and Cooking as hobbies

When using the `Hobbies[]` container field path in the query condition, the condition matches both array elements and individual scalar values.

For another example, suppose you want to filter on phone types. You can define an index on the following field:

```
Phones[].Type
```

The following examples show equality conditions that benefit from this index:

Query Condition	Description
`{"$eq":{"Phones[].Type":"Mobile"}}`	Finds documents that have a mobile phone number
`{"$in":{"Phones[].Type":["Mobile","Work"]}}`	Finds documents that contain either a mobile or work phone number
`{ "$and":[ {"$eq":{"Phones[].Type":"Mobile"}}, {"$eq":{"Phones[].Type":"Work"}} ] }`	Finds documents that contain both mobile and work phone numbers

When using the `Phones[].Type` container field path in the query condition, the condition matches instances where `Phones` is an array of nested documents as well as a single nested document.

IMPORTANT: To use an index defined on a container field path, the container field paths in the query condition and indexed fields must match.

The following table shows examples of conditions that **do not** benefit from the index shown:

Indexed Field	Query Conditions that *do not* Benefit
`Hobbies`	`{"$eq":{"Hobbies[]":"Baseball"}}` This condition requires an index defined on `Hobbies[]`.
`Hobbies[]`	`{"$eq":{"Hobbies":["Baseball", "Cooking"]}}` This condition requires an index defined on `Hobbies`.

last-updated: Jun 06, 2024

Indexed Field	Query Conditions that *do not* Benefit
`Phones[].Type`	`{"$eq":{"Phones[0].Type":"Mobile"}}` This condition cannot be used with indexes because you cannot define an index on array elements.
`temps[][]`	`{"$ge":{"temps[][1]":60}}` This condition cannot be used with indexes because you cannot define an index on array elements..
	`{"$eq":{"temps[]":[78,54]}}` This condition requires an index defined on `temps[]`.
`temps[]`	`{"$ge":{"temps[][]":60}}` This condition requires an index defined on `temps[][]`.

OJAI Query Condition Syntax on page 3387
OJAI defines a syntax for specifying query conditions that allows you to express query conditions in a JSON format. This topic describes the supported operators and provides examples of these query conditions.

Using Indexes to Optimize Range Conditions

Indexes can improve the performance of queries that have range conditions. The range conditions can appear in combination with equality conditions when the most significant index keys have equality conditions. You can define indexes that optimize range conditions on scalar data fields and container field paths.

The following range condition operators benefit from indexes:

- Less than (or equal to)
- Greater than (or equal to)
- Pattern matching operator LIKE, provided the pattern in the condition does not start with a wildcard character

Assume you have a HPE Ezmeral Data Fabric Database JSON table with documents in the following format:

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
```

last-updated: Jun 06, 2024

```
    "Email": "john.smith@company.com",
    "Phones": [
         {"Type": "Home", "Number": "555-555-1234"},
         {"Type": "Mobile", "Number": "555-555-5678"},
         {"Type": "Work", "Number": "555-555-9012"}
    ],
    "Hobbies": ["Baseball", "Cooking", "Reading"],
    "DateOfBirth": "10/1/1985"
}
```

The examples in the following sections reference this sample JSON document.

Indexes on Scalar Data Fields in Range Conditions

The following table provides examples of when HPE Ezmeral Data Fabric Database can and cannot use the index with range conditions on scalar data. Assume that a composite index exists on the `Address.State` and `Address.City` fields. To use both indexed fields in the composite index, you must have an equality condition on `Address.State`.

Filter Condition	How HPE Ezmeral Data Fabric Database Uses the Index
`{"$le":{"Address.State":"CA"}}`	Reads from the beginning of the index up to and including the condition `Address.State <= "CA"`.
`{"$gt":{"Address.State":"CA"}}`	Reads from the index starting at the condition `Address.State > "CA"` through the end of the index.
`{"$like":{"Address.State":"C%"}}`	Performs a simple prefix match starting at the condition `Address.State >= "C"`. Continues reading the index until the filter no longer qualifies.
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$ge":{"Address.City":"Oak"}} ] }`	Reads from the index starting at the condition `Address.State = "CA" and Address.City >= "Oak"`. Continues reading from the index until the condition `Address.State = "CA"` no longer qualifies.
`{ "$and":[ {"$in":{"Address.State": ["CA","NY","MA"]}}, {"$gt":{"Address.City":"Spring"}} ] }`	Performs these three lookups and reads through the index: • `Address.State = "CA" and Address.City > "Spring"` • `Address.State = "NY" and Address.City > "Spring"` • `Address.State = "MA" and Address.City > "Spring"`
`{ "$and":[ {"$gt":{"Address.State":"C"}}, {"$gt":{"Address.City":"Oak"}} ] }`	Reads from the index starting at the condition `Address.State > "C"` through the end of the index. Although `Address.City` is part of the index key, HPE Ezmeral Data Fabric Database does not use `Address.City > "Oak"` when initiating the index search. Applies that filter while reading the index.

last-updated: Jun 06, 2024

Filter Condition	How HPE Ezmeral Data Fabric Database Uses the Index
`{"$le":{"Address.City":"Oak"}}`	Even if the query references the field `Address.State`, HPE Ezmeral Data Fabric Database cannot use the index unless there is also an equality condition on the prefix key of the index, `Address.State`.

Indexes on Container Field Paths in Range Conditions

Starting in data-fabric 6.1, you can define an index using a container field path as the indexed field.

For example, suppose you want to apply range conditions on individual hobbies within the `Hobbies` array field. You can define an index on the following field:

```
Hobbies[]
```

The following examples show range conditions that benefit from this index:

Query Condition	Description
`{"$like":{"Hobbies[]":"B%"}}`	Finds documents that contain hobbies that start with the letter "B"
`{"$gt":{"Hobbies[]":"Read"}}`	Finds documents that contain hobbies with a value greater than "Read"
`{ "$elementAnd":{ "Hobbies[]":[ {"$ge":{"$":"D"}}, {"$lt":{"$":"J"}} ] } }`	Finds documents that contain hobbies that start with letters between "D" and "I", inclusive

When using the `Hobbies[]` container field path in the query condition, the condition matches both array elements and individual scalar values.

For another example, suppose you want to apply range filters on phone numbers. You can define an index on the following field:

```
Phones[].Number
```

The following examples show range conditions that benefit from this index:

Query Condition	Description
`{"$like":{"Phones[].Number":"555%"}}`	Finds documents with phone numbers that have a 555 prefix

last-updated: Jun 06, 2024

Query Condition	Description

<pre>{
    "$elementAnd":{
        "Phones[]":[
            {"$gt":
{"Number":"408-555-1234"}},
            {"$lt":{"Number":"408-555-9999"}
        ]
    }
}</pre>
	Finds documents that contain phone numbers in the specified range

When using the `Phones[].Number` container field path in the query condition, the condition matches instances where `Phones` is an array of nested documents as well as a single document.

Related concepts

OJAI Query Condition Syntax on page 3387
OJAI defines a syntax for specifying query conditions that allows you to express query conditions in a JSON format. This topic describes the supported operators and provides examples of these query conditions.

Using Indexes to Optimize ORDER BY Queries

Using indexes can help you improve the performance of queries that have an ORDER BY clause. This includes ORDER BY clauses with either ascending or descending sorts, as well as more than one ordering field. The same index can optimize both filter conditions and the ORDER BY clause.

To use the index for an ORDER BY query, the index's key list order and sort order must match the orderings specified in the query. If the index's keys also match filter conditions in the query, using the index also reduces the amount of data read from the index.

Index Key List Order and Sort Order Examples

The following table provides examples of when HPE Ezmeral Data Fabric Database can and cannot use an index for ordering, based on the index key list ordering and sort ordering specified. Assume that you have a table that has a composite index on fields `Address.State` and `FullName.LastName`. You have defined both keys in ascending order. Further assume that the query has an ORDER BY on the fields `Address.State` and `FullName.LastName`, both in ascending order:

Ordering in Query	Use of Index for Ordering
`Address.State:ASC`	Yes
`Address.State:DESC`	No Sort direction does not match.
`Address.State:ASC,` `FullName.LastName ASC`	Yes
`FullName.LastName:ASC`	No `Address.State` must be included as a prefix in the ordering.
`FullName.LastName:ASC,` `Address.State:ASC`	No Sort directions match, but the order of fields does not match.

last-updated: Jun 06, 2024

Filtering and ORDER BY Query Examples

Assume that you have a composite index defined with the following two indexed fields:

- `Address.State:ASC`
- `FullName.LastName:ASC`

The following table shows examples for different filtering and ORDER BY scenarios using this composite index:

Query Condition	Ordering in Query	Index Use
`{"$eq":{"Address.State":"CA"}}`	`FullName.LastName:ASC`	Both filtering and ordering
`{"$gt":{"Address.State":"CA"}}`	`Address.State:ASC`	Both filtering and ordering
`{"$gt":{"Address.State":"CA"}}`	`Address.State:DESC`	Only filtering, because the sort direction does not match
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$ge": {"FullName.LastName":"Smith"}} ] }`	`FullName.LastName:ASC`	Both filtering and ordering
`{"$gt":{"Address.State":"CA"}}`	`Address.State:ASC, FullName.LastName:ASC`	Both filtering and ordering
`{"$gt":{"Address.State":"CA"}}`	`FullName.LastName:ASC`	Only filtering
`{"$in":{"Address.State":["CA","TX"]}}`	`FullName.LastName:ASC`	Only filtering
`{"$ge":{"FullName.LastName":"Smith"}}`	`Address.State:ASC, FullName.LastName:ASC`	Only ordering, because `FullName.LastName` is not a prefix in the filter lookup

Index Sort Order for Complex Types

Although you can define indexes on complex data types, there are limitations in the behavior.

Arrays and Nested Documents

Indexes defined on arrays and nested documents do not have a meaningful ordering because these types do not have a defined ordering.

Container Field Paths

You cannot order on a container field path.

For example, you can define an index on the field `a[].b`, but you cannot order on it.

last-updated: Jun 06, 2024

Partial Sorts with Non-Covering Indexes

HPE Ezmeral Data Fabric Database updates secondary indexes asynchronously, which can result in updates to the index lagging the parent JSON table. You can avoid this behavior in your OJAI application by setting a query option in your application. See Avoiding Partial Sorts with Secondary Indexes in OJAI on page 3369 for details about how to do this.

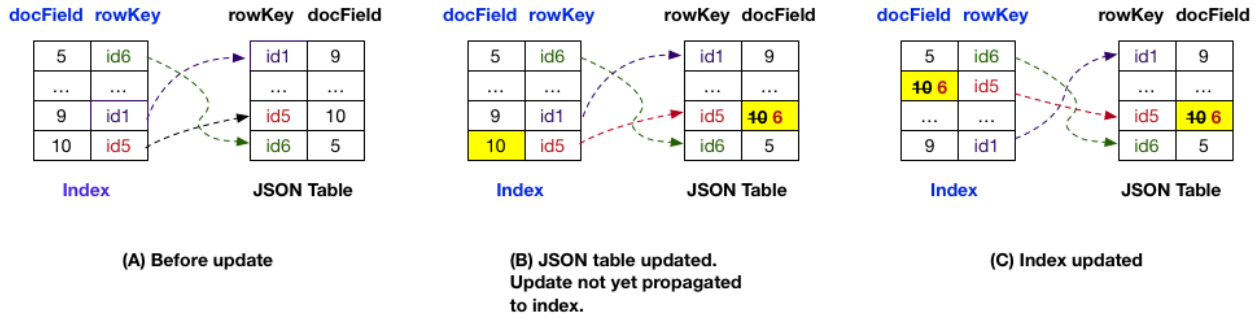
One consequence of this index update lag is the impact on queries that use non-covering indexes to provide the ordering of a query. Since the index is not fully synchronized with its parent JSON data, data read through the index might be out of date.

The following example illustrates this behavior.

- Suppose you have a query with the following criteria:
  - Selects `docField`
  - Filter condition where `docField >= 5`
  - Order by on `docField`
- You have an index where `docField` is an indexed field. The index optimizes both the filter condition and order by clause. The query also selects other fields, so the index is a non-covering index for the query.
- When reading through the index, HPE Ezmeral Data Fabric Database reads a document in which the `docField` value is 9. The data for that field in the JSON table is also 9. The data is consistent.
- The next entry in the index has `docField` set to 10. This value is in the proper sort order relative to the previous value of 9, but the data in the JSON table has changed from 10 to 6. The update is not yet reflected in the index.
- HPE Ezmeral Data Fabric Database returns the value 6 (not 10), which is out of order, relative to data previously read from the index.

The following table and diagram illustrates this example:

Update State	Query Result in docField Sort Order
Before update	5, …, 9, 10
JSON table updated, but not index	5, …, 9, 6
Index updated	5, 6, …, 9



NOTE: This behavior does not occur with covering indexes. HPE Ezmeral Data Fabric Database only reads from a single data source, the index, when using covering indexes.

See Asynchronous Secondary Index Updates on page 726 for a more detailed discussion of asynchronous index updates.

Using Indexes to Optimize Projections in Queries
OJAI queries that do not use the OJAI Distributed Query Service can use indexes even when there are no filter conditions referencing the fields of an index. This requires a full scan of the index. However, in cases where all fields referenced in the query are fields in an index, the need to read the HPE Ezmeral Data Fabric Database JSON table is eliminated. The referenced fields can be either indexed fields or included fields

The following table provides examples where HPE Ezmeral Data Fabric Database can and cannot use the index for projections. Assume you have an index with the following fields:

- Indexed fields - `IdxField1`, `IdxField2`
- Included fields - `Field3`, `Field4`, `Field5`

Further assume that the fields referenced in the index are a small subset of the total fields in the HPE Ezmeral Data Fabric Database JSON table. With these assumptions, avoiding reads on the JSON table is beneficial.

OJAI Query Elements	Use of Index for Projections
• SELECT `IdxField1`, `Field4`	Yes All fields referenced are fields in index.
• SELECT `Field3`, `Field4`	Yes All fields referenced are fields in index.
• SELECT `IdxField1`, `Field6`	No `Field6` not included in index.
• SELECT `IdxField1`, `Field3` • WHERE condition on `IdxField2`	No All fields referenced are fields in the index, but the index cannot be used with the WHERE condition.
• SELECT `IdxField1`, `Field3` • WHERE condition on `Field4`	No All fields referenced are fields in the index, but the index cannot be used with the WHERE condition.
• SELECT `IdxField1`, `Field4` • ORDER BY on `IdxField2`	No All fields referenced are fields in the index, but the index cannot optimize the ORDER BY. The query needs the OJAI Distributed Query Service to sort large data sets.

Projections on Container Field Paths

When your query projects a container field path and the container field path is an included field in an index, then HPE Ezmeral Data Fabric Database can use the index for the projection. It is not enough for the container field path to be an indexed field. See Covering Indexes and Container Field Paths on page 698 for details.

Using Multiple Indexes to Optimize Query Conditions
Indexes benefit queries that have multiple filter conditions. The OJAI Distributed Query Service can optimize these queries by creating query plans that scan multiple indexes and take the intersection of the matching documents.

Scanning multiple indexes is an alternative to using Composite Indexes on page 691. The following example illustrates how the OJAI Distributed Query Service does this.

Suppose you have a JSON table with an index on the `Address.State` field, another index on the `Address.City` field, and the query has the condition:

```
{
  "$and":[
    {"$lt":{"Address.State":"D"}},
    {"$gt":{"Address.City":"Oak"}}
  ]
}
```

The OJAI Distributed Query Service creates a query plan that uses the indexes as follows:

- Performs a scan on the first index using the `Address.State < "D"` condition.
- Performs a scan on the second index using the `Address.City > "Oak"` condition.
- Takes the intersection of the document IDs that match both conditions.

If you do not apply conditions on both `Address.State` and `Address.City` in most of your queries, defining separate indexes instead of a single composite field index may be more desirable. With a composite index on fields `Address.State` and `Address.City`, the query service does not choose the index unless there is a condition on field `Address.State`. If there is a condition on `Address.State`, the query service can choose the composite index. However, in order to restrict the search on both fields, there must be an equality condition on `Address.State`. See Using Indexes to Optimize Equality Conditions on page 708 for further details.

You can define separate single key indexes as well as a composite index, but this requires more storage and impacts performance throughput. See the sections on storage and throughput considerations in Designing Secondary Indexes on page 731 for further guidance.

The following table illustrates the differences between using a composite index versus multiple indexes. The second column shows the behavior when you have a composite index defined on `(Address.State, Address.City)`. The third column shows the behavior when you have separate simple indexes defined on each field.

Filter Condition	Composite Index	Two Simple Indexes
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$eq": {"Address.City":"Oakland"}} ] }`	Index searched using both conditions	Separate index searches using each filter condition. Results intersected.
`{ "$and":[ {"$eq":{"Address.State":"CA"}}, {"$ge":{"Address.City":"Oak"}} ] }`	Index searched using both conditions	Separate index searches using each filter condition. Results intersected.
`{"$eq":{"Address.State":"CA"}}`	Index searched using single filter condition	Same as composite index case. However, since the simple index has only a single indexed field, it is smaller and more efficient to read.

last-updated: Jun 06, 2024

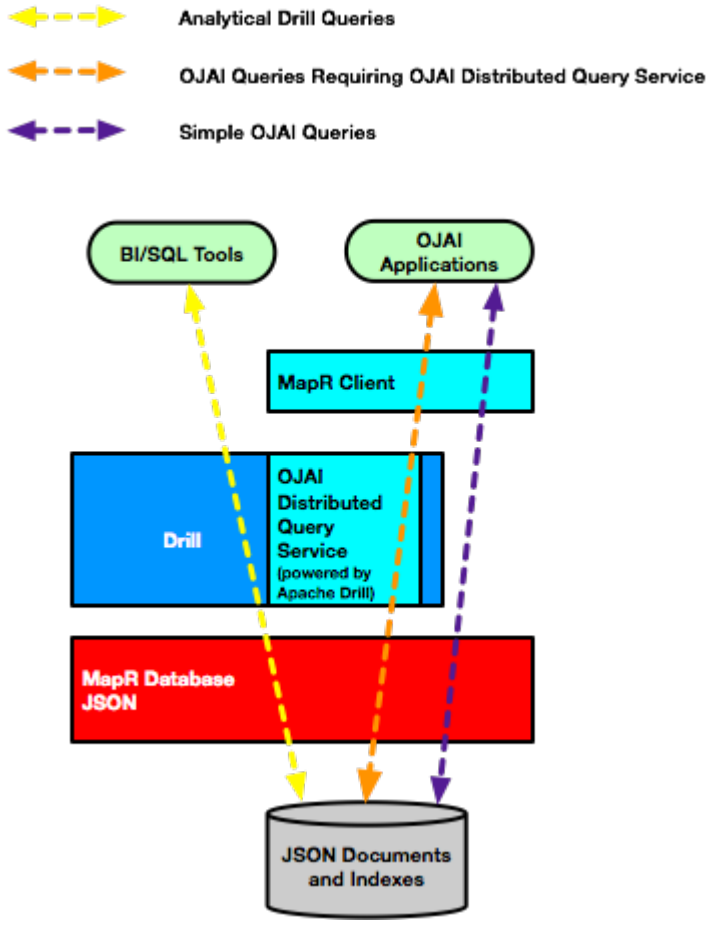
<pre>{
  "$and":[
  {"$ge":{"Address.State":"CA"}},
  {"$eq":
{"Address.City":"Oakland"}}
  ]
}</pre>
	Index search initiated using only the `Address.State` condition. `Address.City` filter applied while reading the index.	Separate index searches using each filter condition. Results intersected.

<pre>{"$eq":{"Address.City":"Oakland"}}</pre>	Cannot use index	Index searched using single filter condition

Selection and Execution of Secondary Indexes

This section provides an overview of secondary index selection and execution in HPE Ezmeral Data Fabric Database JSON. It describes the variations in functionality, depending on the components you are using.

The following diagram summarizes the code paths and the components involved when using secondary indexes in HPE Ezmeral Data Fabric Database JSON. See OJAI Distributed Query Service on page 640 for more information about the components and code paths.



Index Selection

All three code paths use a cost-based approach to select an optimal query plan. Cost based optimization chooses between alternatives where it may not be obvious which is the better index to use. Assume that you have the following two indexing options:

- Index 1 can be used to filter condition A in a query but cannot satisfy the sort criteria.

last-updated: Jun 06, 2024

- Index 2 can be used to filter condition B in a query and also satisfy the sort criteria.

If filter condition A is more selective than filter condition B, although using index 1 requires reading less data, it requires a sort of the data. In contrast, using index 2 requires reading more data but does not incur the cost of sorting the data. A cost based optimizer estimates the cost of both options and chooses the one with the lower cost. It also estimates the cost of a full table scan. It may choose the full table scan if the index-based plans do not use selective filters.

The Simple OJAI Query code path can use indexes even when a query does not have filter or ORDER BY conditions that match the fields of an index. See Using Indexes to Optimize Projections in Queries on page 719 for details.

The Drill query optimizer and the optimizer used by the OJAI Distributed Query Service can select multiple indexes to process a query. The OJAI Distributed Query Service scans the indexes and takes the intersection of the matching documents from each index. The data-fabric client invokes scans of only a single index.

The rest of this section generally discusses the optimizer flow. Except where noted, the discussion applies to the optimizer used in all three code paths.

HPE Ezmeral Data Fabric Database gives the optimizer a list of indexes associated with the JSON table referenced in the query. The optimizer enumerates through the possible index choices using the following steps:

1. Identifies the set of indexes whose keys match filter conditions and possibly also the ORDER BY specification.
2. Estimates the cost of using each index.
3. Considers combinations of indexes and estimates the cost of these combinations. (Applies to the Drill and OJAI Distributed Query Service optimizers only.)

Using the cost estimates, the optimizer selects the index (or indexes) with the lowest cost, or if appropriate, a full table scan. The cost is a function of the index properties, table size, and selectivity of the filter conditions applied. Each of these factors contribute to the estimated cost in the following ways:

Index Properties	HPE Ezmeral Data Fabric Database provides the Drill optimizer with index properties. Index properties include the fields that comprise the index, whether the field is an indexed or included field, and the sort direction of each indexed field.
Table Size	HPE Ezmeral Data Fabric Database maintains information about table regions, including table size. The optimizer uses table size when calculating the cost of the query plan. If JSON tables are small and fit into a single region, the overhead of using indexes on the table may not provide enough performance benefits to justify an index-based plan. In such a scenario, the optimizer could calculate a full table scan as cheaper to perform than an index scan, rendering any index on the table unnecessary. Even if you apply selective filters on small tables, the overhead of using indexes may not provide performance benefits.
Filter Selectivity	Filter Selectivity is the estimated number of rows based on the selectivity of each conditional expression

in the WHERE clause. Filter selectivity is calculated as:

```
(output row count)/(total table row count)
```

For example, if you have 100 documents and 25 documents qualify the filter condition, the selectivity is .25.

Filter selectivity ranges between 0 and 1. The closer to 0, the more selective the filter. The more selective a filter, the lower the cost. High filter selectivity results in better query performance. If filter conditions are not selective enough for the optimizer to choose the index, remove the index to free up storage.

For example, defining an index on a field like `gender`, which has only two possible values, does not result in selective filtering. Consider adding other fields to define a composite index to make filtering with that index more selective. In general, define indexes on high cardinality fields unless your queries also sort on those fields.

For covering queries, Drill selects an index plan if the number of rows selected is less than or equal to .75 of the total number of rows in the JSON table. If the number of rows selected is greater than .75 of the total number of rows in the JSON table, Drill performs a full table scan.

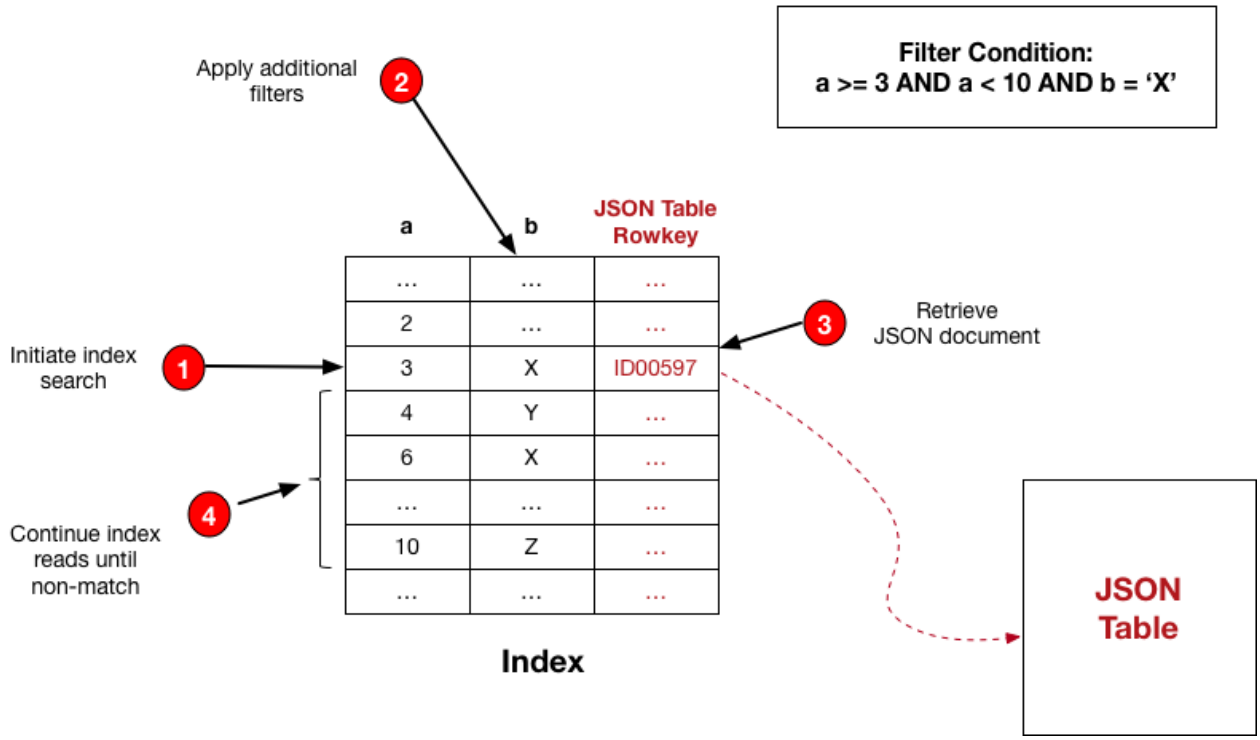
For non-covering queries, the threshold is .025.

NOTE: In the **Simple OJAI Queries** code path, if you are using the OJAI API, you can force the data-fabric client to use a particular index, regardless of cost considerations. See Forcing Secondary Index Usage in OJAI on page 3369 for details.

Index Execution

After either the data-fabric client or Drill select an optimal query plan, HPE Ezmeral Data Fabric Database has the index (or list of indexes, in the case of a plan generated by Drill) from which to read. It reads the index to retrieve the corresponding documents from the JSON table. The following diagram and table illustrate the flow for a read from a composite index created on fields a and b.

last-updated: Jun 06, 2024



Step #	Description	Details
1	Initiates index search	HPE Ezmeral Data Fabric Database searches the index, starting at the condition `a >= 3`.
2	Applies additional filters	HPE Ezmeral Data Fabric Database applies the filter condition on field b. It either moves to step 3 or 4, depending on whether the condition `b = 'X'` matches. For example, when b contains the value `'X'`, it proceeds to step 3. When b contains the value `'Y'`, it skips to step 4.
3	Retrieves JSON document	Using the rowkey in the entry, HPE Ezmeral Data Fabric Database reads the corresponding JSON document.
4	Continues index reads until non-match	HPE Ezmeral Data Fabric Database reads the subsequent index keys provided they match the filter condition `a < 10`. If the condition matches, it goes back to step 2. Otherwise, HPE Ezmeral Data Fabric Database stops the search. For example, the reads stop when HPE Ezmeral Data Fabric Database reads the value 10 from field a.

NOTE: When a covering index satisfies the query, HPE Ezmeral Data Fabric Database skips reading the JSON table. TThis read is not required because the index provides all selected fields. In the preceding example, the HPE Ezmeral Data Fabric Database skips step 3.

last-updated: Jun 06, 2024

Implementation of Secondary Indexes

This topic describes how HPE Ezmeral Data Fabric Database implements secondary indexes. It provides an overview of basic architectural concepts and the rationale behind design choices.

Global Indexes

HPE Ezmeral Data Fabric Database implements secondary indexes as *global indexes* rather than *local indexes*. With local indexes, each JSON table's regions (also called tablets) has a corresponding index tablet. The JSON table's and index's tablets are co-located. In contrast, with a global index, the index is a single, separate table with its own tablets and split points. Unlike JSON tables, indexes are always auto-split. There is no option to disable auto-splitting. When splitting index tablets, indexes are range partitioned by default. An alternative to range partitioning is to use hash partitioning to avoid creating hot spots.

Global indexes have the following advantages:

- They provide an ordering across all values in the indexed fields. A scan through the index can generate the sort required by ORDER BY clauses.
- They avoid having to read all partitions. When the data is range partitioned, HPE Ezmeral Data Fabric Database can direct index scans to the subset of partitions that qualify the desired key range.
- They require less data processing by minimizing the partitions that need to be read.

In summary, global indexes are well suited for scalable, read intensive use cases.

While global indexes are optimized for read intensive use cases, maintaining a global index incurs more overhead. Updates are more expensive if the JSON table and its indexes are on different nodes in the cluster.

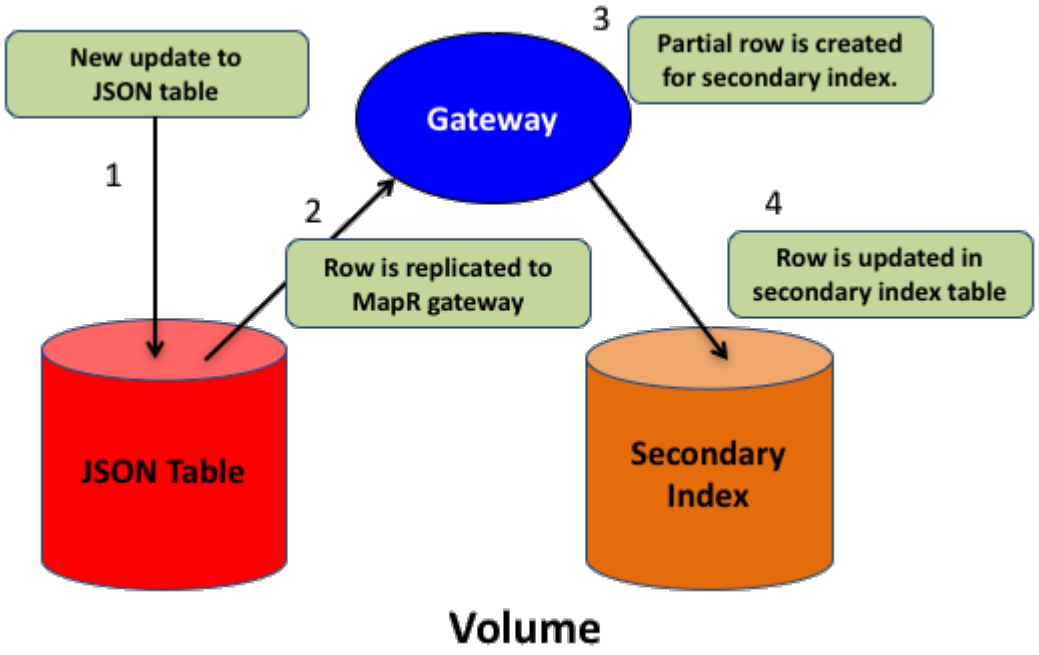
Index Placement

Each secondary index shares the same volume and topology as its JSON table. Users cannot specify the path of an index. This simplifies the behavior of snapshot and mirroring.

Data Flow

After a secondary index has been created on a JSON table, the following occurs when an update (put operation) is made to the table:

last-updated: Jun 06, 2024



1. A document in the JSON table is updated.
2. The row with the change is replicated to an internal data-fabric gateway.
3. The data-fabric gateway determines whether a secondary index is impacted and, if so, creates a partial row that contains the secondary index's indexed and included fields.
4. The secondary index row is updated.

When a secondary index is added, data that is already present in the JSON table is propagated to the index using a scan of the JSON table that retrieves indexed and included fields. This replaces step 2. Steps 3 and 4 are executed to populate the index.

Asynchronous Secondary Index Updates
Secondary indexes are updated asynchronously. The asynchronous approach favors performance and scalability over synchronous, transactional updates. However, this also means that indexed data can be stale compared to data in the JSON table, even though the data eventually becomes consistent with the JSON table data.

Impact of Asynchronous Indexes

By updating the index asynchronously, this avoids delaying updates to the JSON table.

From a user point of view, secondary indexes updates are complete when the HPE Ezmeral Data Fabric Database table data appears in the index. This occurs without application developers having to write any explicit code. Because indexes are asynchronously updated relative to the JSON table, there is a lag in updates appearing in the index. For a reasonably sized cluster, secondary index updates will typically occur within a few seconds of the update on the JSON table. When the JSON table and its secondary indexes are on separate nodes, the updates to the index are more expensive. The lag is potentially higher.

The following example illustrates how the lag in updates impacts queries that use indexes.

Suppose you have a JSON table that has a document with `_id=DOC1`. An update occurs on the indexed field, `a.b.c`, changing the value from v1 to v2. For queries that use a covering index, any of the following values might be returned for the `(_id, a.b.c)` pair:

- Only (DOC1,v1) - This occurs if the new value v2 has not yet been indexed.

last-updated: Jun 06, 2024

- Only (DOC1,v2) - This occurs if the new value v2 is indexed and the old value v1 is deleted.
- Both (DOC1,v1) and (DOC1,v2) - This occurs if the new value v2 is indexed and the old value v1 is not yet deleted.
- Neither (DOC1,v1) nor (DOC1,v2) - This occurs if the value v1 is not indexed. The newer value v2 is not yet indexed, because value v1 is always indexed first.

For queries that use non-covering indexes, HPE Ezmeral Data Fabric Database re-reads the indexed and included fields when reading additional fields from the JSON table. This ensures that the query results are consistent in spite of update lags.

In the case where a non-covering index provides the ordering for the ORDER BY specification of a query, index lag can result in a partial sort of the result. See Partial Sorts with Non-Covering Indexes on page 718 for further details.

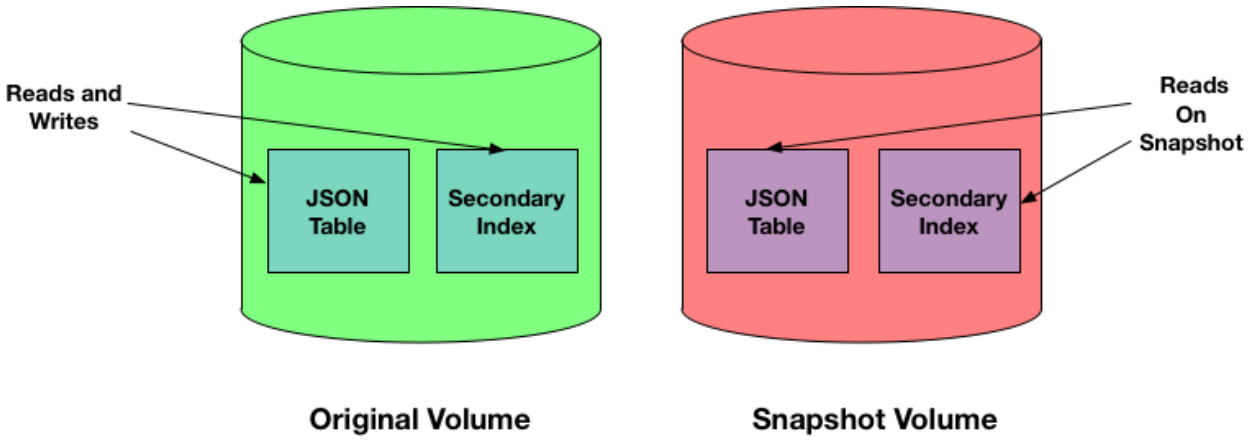
See Troubleshooting Secondary Indexes on page 1460 for information about how to determine if an index is lagging its JSON table.

Snapshots

Queries against snapshots containing tables with secondary indexes can return inconsistent results. This occurs if the data queried is actively changing at the time of snapshot creation. When creating a snapshot, if a secondary index on a JSON table does not have current data due to asynchronous updates of the index, the snapshot retains the lag in updates. The lag leads to the following behavior, which is similar to the behavior discussed in the previous section.

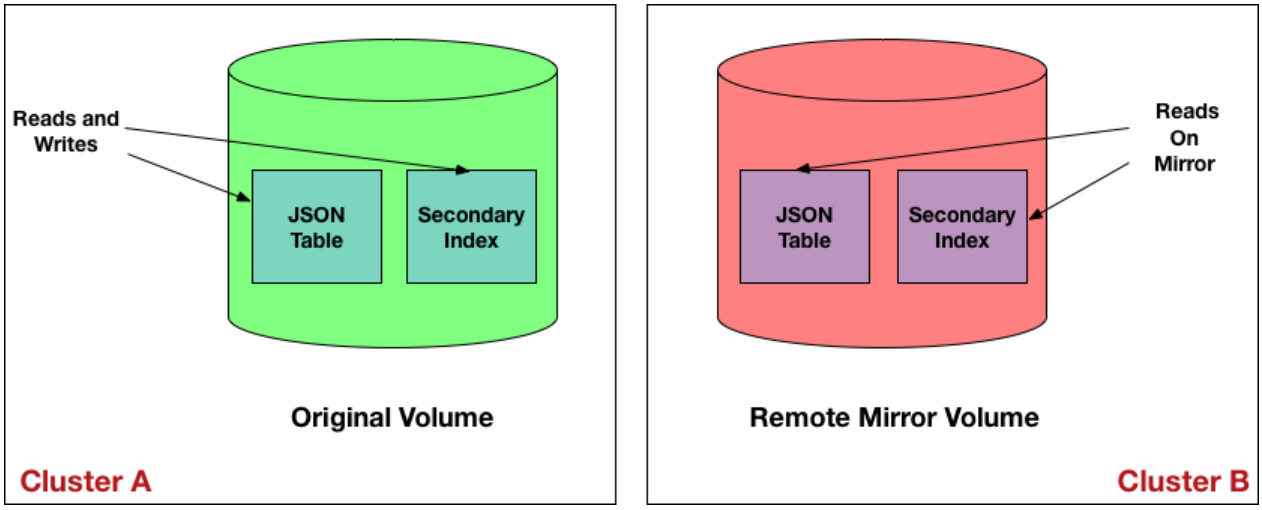
- For a query using a covering index, if the indexed data is out of sync, the query could return data that is current, old, or both.
- For a query using a non-covering index, if the indexed data is out of sync, the query returns the most recent data records.

IMPORTANT: Unlike data in the original volume, with snapshots, any lag between a JSON table and its secondary index will never get resolved. The snapshot data is read-only and never updated..



Mirroring

Queries against mirror volumes behave like queries against snapshots. Lags in the source volume carry over into the mirror volume. Upon refreshing a mirror volume, the lag can resolve itself.



Reading Your Own Write Operations

Certain classes of applications require users to immediately see the data they have written. In these cases, getting stale data can confuse users. Think about an expense report application example where the user enters his expenses and wants to immediately see the entries. The asynchronous nature of indexes could be an issue in such a case. To avoid the possibility of reading stale data due to asynchronous indexes, the Java OJAI API Library provides functionality that enables you to read the result of your own write operation. See Reading Your Own Writes in Java OJAI on page 3448 to learn about how to use this feature in your application.

Replication and Security
Describes how secondary indexes are impacted by replication and security.

Replication

Secondary indexes are not replicated when tables are replicated by table replication (using the replication gateway). Only the JSON table data is replicated.

If you intend to query destination tables and use indexes, you must explicitly add an index to the replica table. Replicating tables and adding indexes are independent of each other.

Security

Secondary indexes reflect the access permissions of the underlying JSON table. *ACE* permissions are required on all indexed and included fields of an index before a query can use an index.

To add a secondary index on a JSON table, you need the `indexperm` permission. The table owner automatically has permission, but any other user must be assigned `indexperm` permission.

See table create on page 2412 for information about *ACE*, and table edit on page 2468 for information about table permissions.

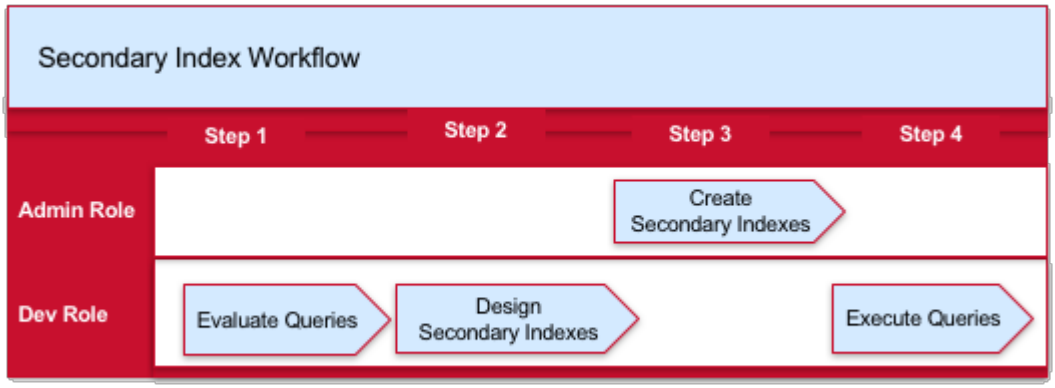
Understanding the Secondary Index Workflow

Describes the overall workflow for using secondary indexes. This includes the roles of different users and the workflow steps involved.

Before deploying secondary indexes, it is assumed that you have installed and configured HPE Ezmeral Data Fabric Database and Drill to use secondary indexes, and have created and populated your HPE Ezmeral Data Fabric Database JSON tables. Implementing secondary indexes on JSON tables in HPE Ezmeral Data Fabric Database requires that you understand indexing concepts, know which administrative tasks to perform, and design your indexes to provide the most benefits for your queries.

last-updated: Jun 06, 2024

The following diagram depicts the workflow and identifies the roles and order of tasks. Each step contains a link to a section in this page with further details.



1. How to Evaluate Queries that Benefit from Secondary Indexes
2. How to Design Secondary Indexes
3. How to Create Secondary Indexes
4. How to Query HPE Ezmeral Data Fabric Database JSON Tables

The following is a brief summary of each step:

1. Evaluate your queries to identify those that can benefit from indexes.
2. Design your indexes by determining which fields need to be indexed.
3. Create your indexes using either the Control System or `maprcli`.
4. Execute your queries.

How to Evaluate Queries that Benefit from Indexes

HPE Ezmeral Data Fabric Database JSON supports indexes with various properties. Each property benefits a certain class of queries. As part of deciding which of your queries will benefit from indexes, it is important to have a general understanding of these concepts. See Types of Secondary Indexes on page 687 and Queries that Benefit from Secondary Indexes on page 708 for more information.

How to Design Secondary Indexes

After you decide which queries can benefit from indexes, determine the set of indexes that provide the maximum benefits. See Designing Secondary Indexes on page 731 for more information.

How to Create Secondary Indexes

You can create secondary indexes using either the Control System or the maprcli table index command.

For example, to create a secondary index on the `name` field, use the following `maprcli` command:

```
maprcli table index add -path /Data/business -index newIndex -indexedfields
name
```

See Managing Secondary Indexes on page 1457 for other commands to manage secondary indexes.

last-updated: Jun 06, 2024

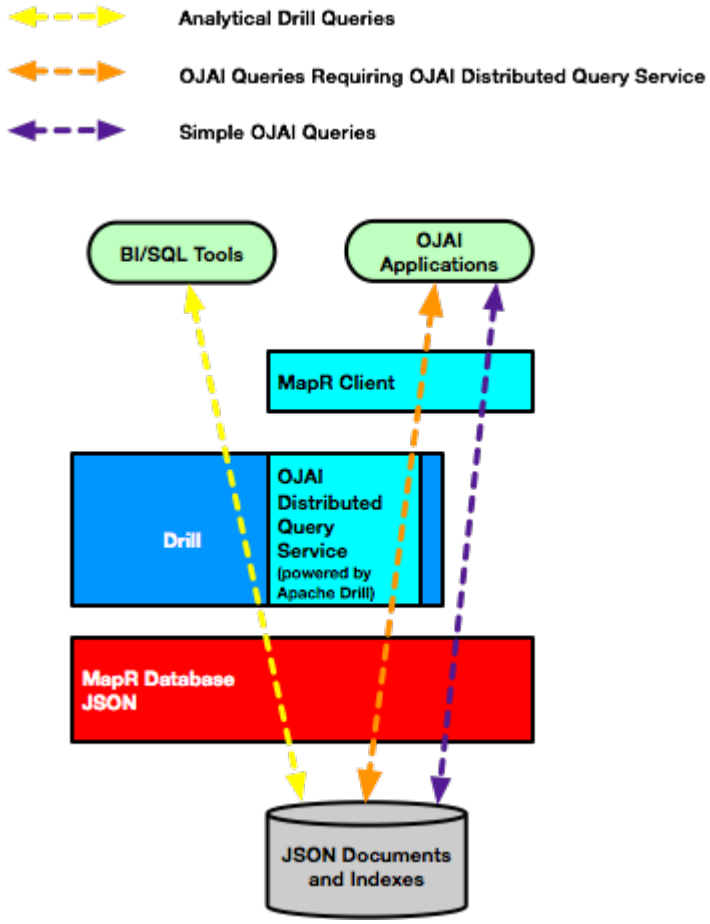
How to Query HPE Ezmeral Data Fabric Database JSON Tables

Depending on your use case, applications can access data in HPE Ezmeral Data Fabric Database through the following client interfaces:

OJAI Client API	Use for user-facing applications that need very high concurrency and ultra-low latency. The API is available in Java, Node.js, and Python.
HPE Ezmeral Data Fabric Database JSON REST API	Use for applications in which you want to access HPE Ezmeral Data Fabric Database JSON with HTTP calls.
Drill SQL	Use for performing operational analytics or Business Intelligence (BI) for medium-to-high complexity queries that require low-to-medium concurrency and interactive response times.

These APIs seamlessly select the optimal indexes to use. You do not need to write explicit code or provide directives on which indexes to use.

The following diagram summarizes the components involved in the different scenarios.



For OJAI applications, the HPE Ezmeral Data Fabric client chooses the more appropriate of two possible execution paths, without user interaction. One of the paths leverages the OJAI Distributed Query Service on page 640, which supports more advanced index selection and parallel query execution. It also supports sorting large data sets. For example, if the sort order specified in your OJAI query does not match the sort order of an index, the HPE Ezmeral Data Fabric client automatically invokes the OJAI Distributed Query Service to perform the sort.

last-updated: Jun 06, 2024

Designing Secondary Indexes

It is important that you create secondary indexes that provide the most benefit to your HPE Ezmeral Data Fabric Database JSON queries. This topic describes a general design approach that includes identifying query patterns, using common query patterns involving filters and ordering to determine which indexes to create, weighing the benefits of indexes against their update and storage costs, and taking into consideration index limitations.

The following diagram summarizes the general approach to designing your indexes:

1. Identify common query patterns
2. Determine potential indexes to create based on your query patterns
3. Evaluate the impact of index synchronization
4. Evaluate the storage requirements of indexes
5. Consider index restrictions
6. Evaluate tradeoffs and limitations

Before designing your secondary indexes in relationship to your queries, make sure you understand the index feature, how to set up and use indexing, the commands used to perform tasks, and how to query the data through your application. The following cover these topics:

- Secondary Index Concepts on page 685
- Understanding the Secondary Index Workflow on page 728

Identify Query Patterns

Query patterns, such as queries with filter conditions and ORDER BY clauses, indicate where indexes can improve performance. If a query does not contain selective filters, the overhead of using an index may cost more than a full table scan. You should also define your indexes so a single index benefits either multiple queries or individual queries that you run most often.

See Selection and Execution of Secondary Indexes on page 721 to understand how HPE Ezmeral Data Fabric Database chooses which secondary indexes to use and how they improve performance.

Determine Potential Indexes Based on Query Patterns

Based on your query patterns, the following table describes the types and characteristics of indexes you might want to create:

Identified Query Pattern	Potential Indexes to Create
Compares individual fields with selective filter conditions	Define single field indexes on the fields that you compare against. Verify that the fields contain supported data types.

last-updated: Jun 06, 2024

Filters against specific combinations of fields	Define composite field indexes instead of single field indexes. Specify the sequence of the index keys so fields that appear in equality conditions are the prefixes in the keys. See Using Multiple Indexes to Optimize Query Conditions on page 719 for additional guidance on defining composite vs single field indexes.
Accesses a subset of fields in a document, but does not filter or sort on these fields	Add those fields as included fields in indexes.
Filters on a subfield in a nested document	Define the index key on the subfield.
Filters on subfields in nested documents that are array elements	Define the index key using a container field path: for example, `arrayField[].subField`.
Filters and projects using a container field path	Define the container field path as both an indexed field and included field. See Covering Indexes and Container Field Paths on page 698 for more details.
Filters on individual elements of an array, which can appear in any position in the array	Define an index using a container field path: for example, `arrayField[]`.
Issues Drill SQL queries with filter conditions that contain CAST expressions	Specify the CAST function when defining the index key.
Sorts on fields	Define the sequence and order direction of the index keys to match the sequence and order direction of the fields your query sorts. If the sort order of the index keys matches the insertion order of documents, define hashed indexes.
Sorts on one set of fields and filters on another set using equality conditions	Define a composite index so that fields using equality conditions are the prefixes in the index keys, followed by the sort fields.

Evaluate Tradeoffs and Limitations

Synchronizing Indexes

When you design your indexes, remember that HPE Ezmeral Data Fabric Database must synchronize each index when you insert and update documents in the corresponding JSON table. This impacts the throughput performance of inserts and updates because HPE Ezmeral Data Fabric Database must perform additional writes. The impact increases with each additional index.

HPE Ezmeral Data Fabric Database performs the synchronization operation asynchronously, which minimizes throughput overhead. The consequence is that an index may be inconsistent relative to its JSON table. If your application cannot tolerate lag time between the update to the JSON table and the update to the index, you should take that into consideration when deciding whether to index specific fields.

See Asynchronous Secondary Index Updates on page 726 for more details about this feature.

Index Storage Requirements

Indexes increase your storage requirements. The storage size depends on the number of indexed and included fields in the index and the size of values stored in those fields. As the size of the index increases, the cost of reading the index also increases.

Consider the storage costs when creating indexes and deciding on the fields to add to the index.

Index Restrictions

When designing your indexes, make sure HPE Ezmeral Data Fabric Database indexes support the functionality you need. For example, it may not be possible to create an index on a particular field path.

See Restrictions on Secondary Indexes on page 703 for a complete list.

last-updated: Jun 06, 2024

Related concepts

Types of Secondary Indexes on page 687
HPE Ezmeral Data Fabric Database JSON supports several index types, including simple indexes, composite indexes, hashed indexes, and indexes with casting. This section describes the properties of these indexes and the situations where each provides value.

Queries that Benefit from Secondary Indexes on page 708
Secondary indexes benefit queries with filter conditions, ORDER BY clause, and projections.

Examples of Designing Secondary Indexes

These examples illustrate the concepts behind designing your secondary indexes. Although the examples focus on query patterns and do not account for sizing, storage, and updates, you should always weigh the benefits of indexes against these other requirements.

Assume that you have a HPE Ezmeral Data Fabric Database JSON table with the following customer data:

```
{
   "_id": "10000",
   "FullName": {
      "LastName": "Smith",
      "FirstName": "John"
   },
   "Address": {
      "Street": "123 SE 22nd St.",
      "City": "Oakland",
      "State": "CA",
      "Zipcode": "94601-1001"
   },
   "Gender": "M",
   "AccountBalance": 999.99,
   "Email": "john.smith@company.com",
   "Phones": [
      {"Type": "Home", "Number": "555-555-1234"},
      {"Type": "Mobile", "Number": "555-555-5678"},
      {"Type": "Work", "Number": "555-555-9012"}
   ],
   "Hobbies": ["Baseball", "Cooking", "Reading"],
   "DateOfBirth": "10/1/1985"
}
```

The following table contains fields in the document that are candidates for indexing based on the sample queries:

Query #	Query	Candidate Fields for Indexing
1	Find all customers who were born in the 1970s.	• `DateOfBirth`
2	Find all customers who have an account balance greater than $10K. Order the information in descending order of balance.	• `AccountBalance`
3	List customers who live in California, ordering the list by `LastName`, `FirstName`.	• `Address.State` • `FullName.LastName` • `FullName.FirstName`
4	Find the ids and emails of customers who live in a specific zip code.	• `Address.Zip`

last-updated: Jun 06, 2024

Query #	Query	Candidate Fields for Indexing
5	Find customers who live in a specific set of states and have an account balance less than a specific value.	• `Address.State` • `AccountBalance`
6	Find male customers having a last name starting with the letter "S."	• `Gender` • `FullName.LastName`
7	Find all customers who have "Reading" as a hobby.	• `Hobbies[]`
8	Find all customers who have a mobile phone number with a prefix of "650".	• `Phones[].Type` • `Phones[].Number`

The following table contains indexes you can create to optimize the queries listed in the previous table and the rationale for doing so:

Index	Rationale
Simple index on `DateOfBirth`	Optimizes the range condition on `DateOfBirth` in Query 1. You need not create a hashed index, because it is unlikely that the order of `DateOfBirth` correlates with the insert order of new data.
Simple index on `AccountBalance`, specified as a descending key	• Optimizes the range condition on `AccountBalance` in Query 2. • Descending order of key meets the ordering criteria in Query 2. • Also optimizes the range condition on `AccountBalance` in Query 5 in combination with the index on `Address.State`.
Composite index on: • `Address.State` • `FullName.LastName` • `FullName.FirstName`	• Optimizes both the equality condition on `Address.State` and ordering in Query 3. • Inclusion of the name fields in the index meets Query 3 ordering. • Also optimizes the IN condition in Query 5 when used in combination with the index on `AccountBalance`.

Simple index with:
• Indexed field on `Address.Zip`
• Included fields on:
  • `Id`
  • `Email`
	• Optimizes the equality condition on `Address.Zip` in Query 4.
	• Adding the included fields avoids reading the JSON table in Query 4.

Composite index on: • `Gender` • `FullName.LastName`	• Optimizes equality condition on `Gender` and pattern matching condition on `FullName.LastName` for Query 6. • Specifying `Gender` as the leading key in combination with `FullName.LastName` results in more selective index lookups for Query 6.

last-updated: Jun 06, 2024

Index	Rationale
Simple index on `Hobbies[]`	Optimizes the equality condition on array elements of `Hobbies` in Query 7: `{"$eq":{"Hobbies[]":"Reading"}}`
Composite index on: • `Phones[].Type` • `Phones[].Number`	Optimizes the following two conditions in Query 8: • Equality condition on the `Type` subfield in nested documents in the `Phones` array. • Pattern matching condition on the `Number` subfield in nested documents in the `Phones` array.

Example with Multiple Container Field Paths

The following example references documents that store the high and low temperatures for each day in a week. They use an array to store the data, where each element in the array corresponds to a day of the week. For each day of the week, there is a two-element array of nested documents. The nested documents indicate whether the temperature corresponds to the high or low for that day. Typically, the outermost array has seven elements, one for each day of the week. But in cases where data is unavailable, the document has only the available days.

```
{
   "_id": "001",
   "temps": [{"hiLo": [{"type": "hi", "temp": 61}, {"type": "lo", "temp":
49}], "dow": "Sun"},
            {"hiLo": [{"type": "hi", "temp": 74}, {"type": "lo", "temp":
51}], "dow": "Mon"},
            {"hiLo": [{"type": "hi", "temp": 75}, {"type": "lo", "temp":
51}], "dow": "Tue"},
            {"hiLo": [{"type": "hi", "temp": 74}, {"type": "lo", "temp":
52}], "dow": "Wed"},
            {"hiLo": [{"type": "hi", "temp": 78}, {"type": "lo", "temp":
54}], "dow": "Thu"},
            {"hiLo": [{"type": "hi", "temp": 75}, {"type": "lo", "temp":
53}], "dow": "Fri"},
            {"hiLo": [{"type": "hi", "temp": 75}, {"type": "lo", "temp":
54}], "dow": "Sat"}],
   "weekOf": "4/29/2018"
}
{
   "_id": "002",
   "temps": {"hiLo": [{"type": "hi","temp": 81}, {"type": "lo", "temp":
60}], "dow":"Sat"},
   "weekOf": "5/12/2018"
}
{
   "_id": "003",
   "temps": [{"hiLo": [{"type": "hi", "temp": 80}, {"type": "lo", "temp":
55}], "dow": "Sun"},
            {"hiLo": [{"type": "hi", "temp": 78}, {"type": "lo", "temp":
54}], "dow": "Mon"},
            {"hiLo": [{"type": "hi", "temp": 79}, {"type": "lo", "temp":
54}], "dow": "Tue"},
            {"hiLo": [{"type": "hi", "temp": 77}, {"type": "lo", "temp":
53}], "dow": "Wed"},
            {"hiLo": [{"type": "hi", "temp": 79}, {"type": "lo", "temp":
54}], "dow": "Thu"},
            {"hiLo": [{"type": "hi", "temp": 77}, {"type": "lo", "temp":
```

last-updated: Jun 06, 2024

```
54}], "dow": "Fri"},
             {"hiLo": [{"type": "hi", "temp": 78}, {"type": "lo", "temp":
54}], "dow": "Sat"}],
   "weekOf": "5/13/2018"
}
```

Suppose you frequently run the following queries:

Query	Description	Documents Returned

`find /apps/hiLoTemps`
`--f weekOf`
`--c '{"$eq":`
`{"temps[].hiLo[].temp":60}}'`
	Find weeks where any day has either a high or low temperature of 60.	002

`find /apps/hiLoTemps`
`--f`
`weekOf,temps[].hiLo[].type,temps[].hiLo[`
`].temp`
`--c`
`'{`
`"$elementAnd":{`
`"temps[].hiLo[]":[`
`{"$eq":`
`{"type":"hi"}},`
`{"$ge":{"temp":80}}`
`]`
`}`
`}'`
	Find weeks and the high/low temperatures for all days on those weeks where any day of the week has a high temperature of at least 80.	002, 003

To optimize these queries, you should define an index with the following fields:

- Indexed fields: `temps[].hiLo[].temp`, `temps[].hiLo[].type`
- Included fields: `weekOf`, `temps[].hiLo`

By defining the composite index with `temps[].hiLo[].temp` as the first indexed field, the index can optimize both queries.

By adding `weekOf` as an included field, the index is a covering index for the first query. By adding `temps[].hiLo`, the index becomes a covering index for the second query as well. Note that you must add this included field even though the sub-fields are also indexed fields. This is due to how indexes with container field paths store data. For more details, see Covering Indexes and Container Field Paths on page 698.

Change Data Capture

The Change Data Capture (CDC) system allows you to capture changes made to data records in HPE Ezmeral Data Fabric Database tables (JSON or binary) and propagate them to a HPE Ezmeral Data Fabric Streams topic.

These data changes are the result of inserts, updates, and deletions and are called change data records. Once the change data records are propagated to a topic, a HPE Ezmeral Data Fabric Streams/Kafka consumer application is used to read and process them.

NOTE: The order of the records in the topic-partition is the same as the order of the changes made to the table. The order is retained because change data records for the same key are propagated to the same topic-partition.

last-updated: Jun 06, 2024

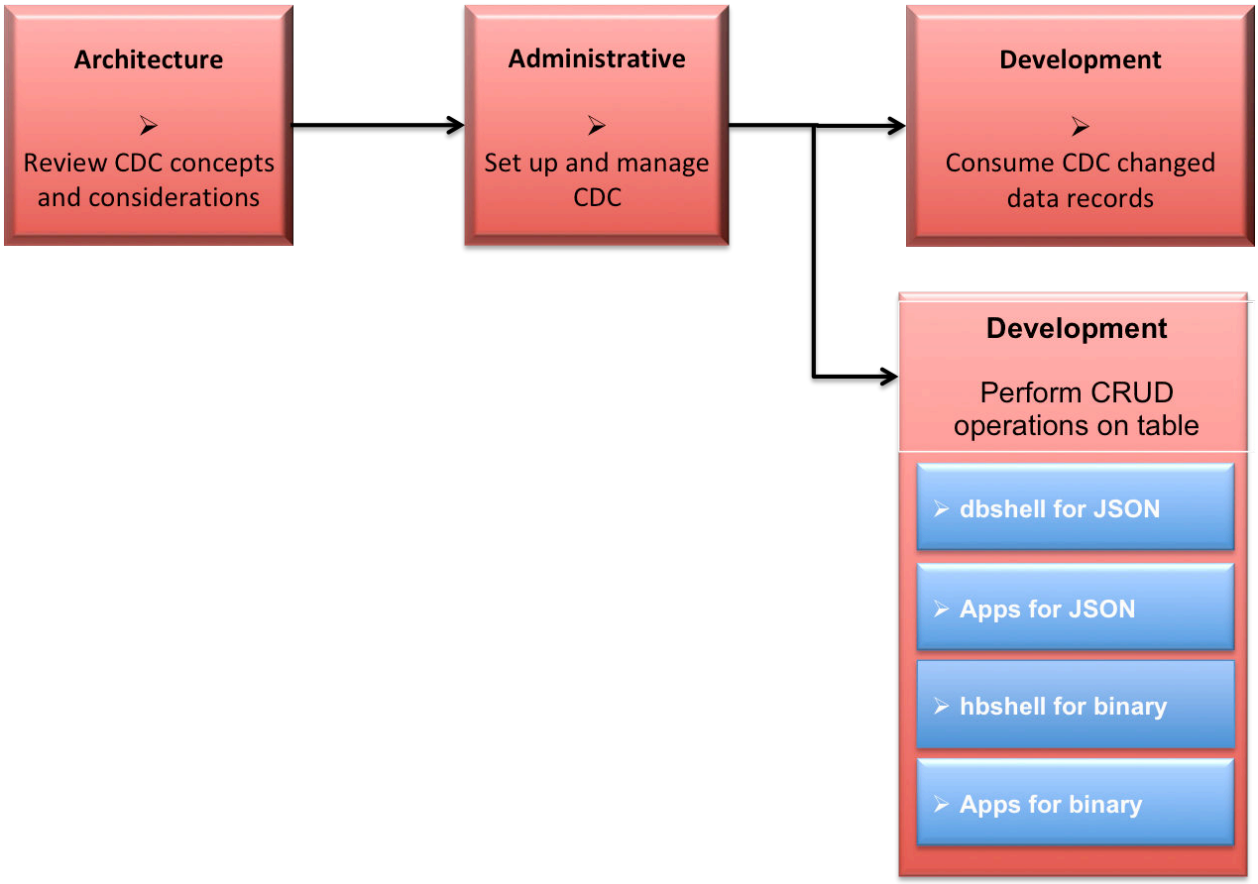
Why Use Change Data Capture?

CDC can be used in many ways, including the following:

- To track changes occurring in a HPE Ezmeral Data Fabric Database table and perform real-time processing on the data.
- To keep caches for search indexes (such as Elastic Search, Solr), materialized views, synchronization between data warehouses or data marts with data stored in HPE Ezmeral Data Fabric Database in real time.
- To manage separate HPE Ezmeral Data Fabric Database instances for transactional and reporting purposes and to keep them in sync in real time for real time analytics.
- To provide arbitrary external systems the ability to globally consume HPE Ezmeral Data Fabric Database table changes.

How Do I Get Started?

The following topics provide information you need to understand the CDC feature, to setup and use CDC, the maprcli commands used to perform tasks, and to consume the data via your application.



1. Learning about CDC
2. Administering Change Data Capture
3. Consuming CDC changed data records
4. Using dbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database JSON tables

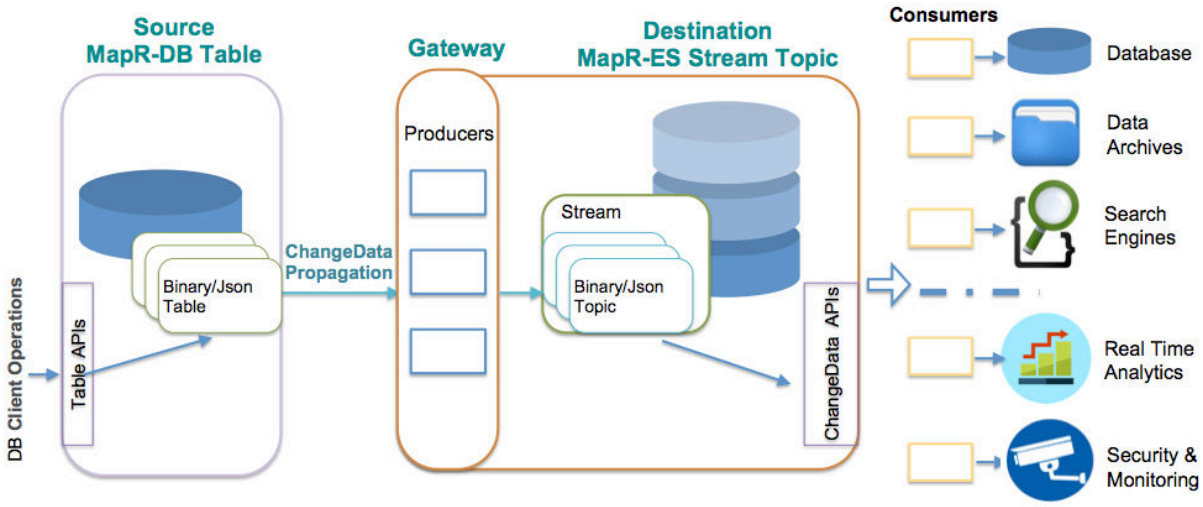
last-updated: Jun 06, 2024

5. Developing client applications for HPE Ezmeral Data Fabric Database JSON tables.
6. Using hbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database binary tables.
7. Developing client applications for HPE Ezmeral Data Fabric Database binary tables.

Architecture and CDC

This section provides an overview of how CDC works.

CDC uses a log-based data capture for the changed data records, propagates the data (from the source table) using replication remote procedural calls (RPCs) through an internal data-fabric gateway and produces the data to a HPE Ezmeral Data Fabric Streams destination stream topic(s). Once data is received by the topic, the changed data records can be consumed by external applications. The consumer application registers the CDC Deserializer as its record value deserializer and pulls the topic data by using a Kafka API. The data changes can be read from the ChangeDataRecord through the OJAI ChangeData APIs. Consumers could be databases, data archives, search engines, or applications that perform real-time analytics, security, or monitoring.



How are the Change Data Records Propagated?

The propagation is accomplished by setting up a change log that establishes a relationship between the source table and the destination stream. The change log can be setup by using the Control System, maprcli, or REST. Each change log can be paused, resumed, and removed. See Administering Change Data Capture on page 1475 and the `maprcli` table changelog on page 2459 command for more information.

As data is changed on the source table (through CRUD operations), each changed data record is propagated (replicated) to an internal data-fabric gateway. The order of when the data is produced to the stream topic is the same order of when the changed data records are replicated to the gateway. The data flow is one way, meaning, the flow is from a HPE Ezmeral Data Fabric Database source table to a HPE Ezmeral Data Fabric Streams destination stream topic(s).

NOTE: When an array value is updated, the changed data record is the full array record rather the specific data change.

What is the Impact of using Columns/Column Families?

When propagating a specific column family or column from a binary source table and a row is deleted, the destination stream topic shows only a deletion event for the specific column family or column. When propagating a specific column from a binary source table with its entire column family deleted, the destination stream topic shows only a deletion event for the specific column.

last-updated: Jun 06, 2024

In the scenario where you have a binary source table with fam0, fam1, and fam2 and you set up the change log *without* columns or column families:

- If you delete fam0, fam1, and fam2, the change data event will be "delete fam0", "delete fam1" and "delete fam2".
- If you delete the row, the change data event will be "delete row".

In the scenario where you have a binary source table with fam0, fam1, and fam2 and you set up the change log *with* a column setup as fam1:col1, fam2.

- If you delete fam0, fam1, and fam2, the change data event will be "delete fam1:col1", "delete fam2".
- If you delete the row, the change data event will be "delete fam1:col1", "delete fam2".

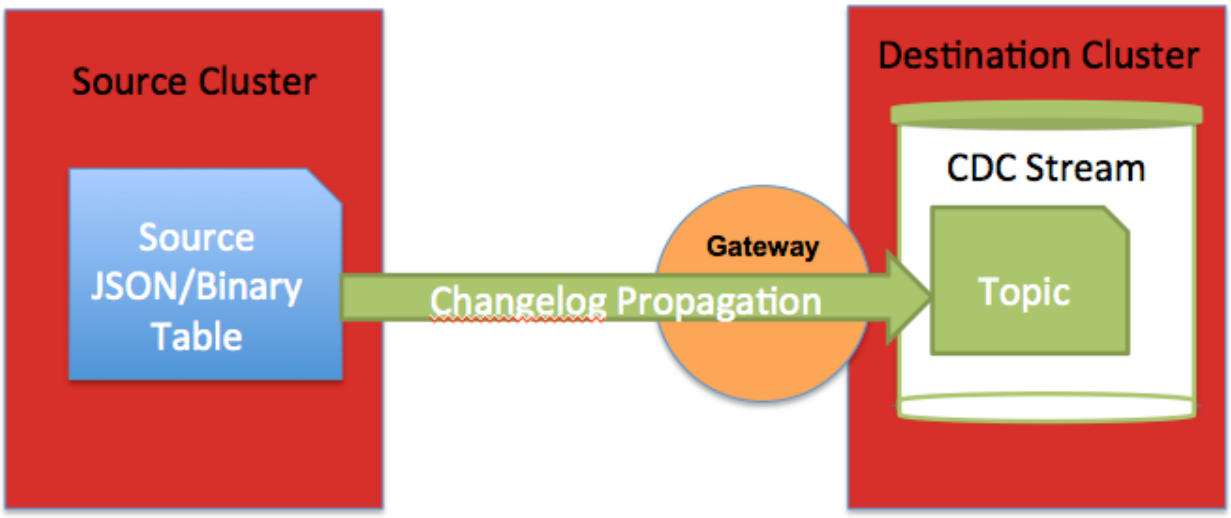
Where is the Destination Stream Setup?

The destination HPE Ezmeral Data Fabric Streams stream can either be on the same cluster as the HPE Ezmeral Data Fabric Database source table or on a remote data-fabric cluster. Where and how destination streams are setup depends on the purpose for using CDC.

If you are propagating changed data from a source table on a source cluster to a destination stream topic on a remote destination cluster, you must setup a gateway. Gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. See Administering Data Fabric Gateways on page 1526 and Configuring Gateways for Table and Stream Replication on page 1528.

The following diagram shows a simple CDC data model, with one source table to one destination topic on one stream. Since this scenario has the destination stream topic on a remote destination cluster, you must setup and configure a gateway.

NOTE: More complex CDC scenarios can be implemented and multiple gateways can be setup.



IMPORTANT: If you have a secure cluster, you must setup secure configuration. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1952.

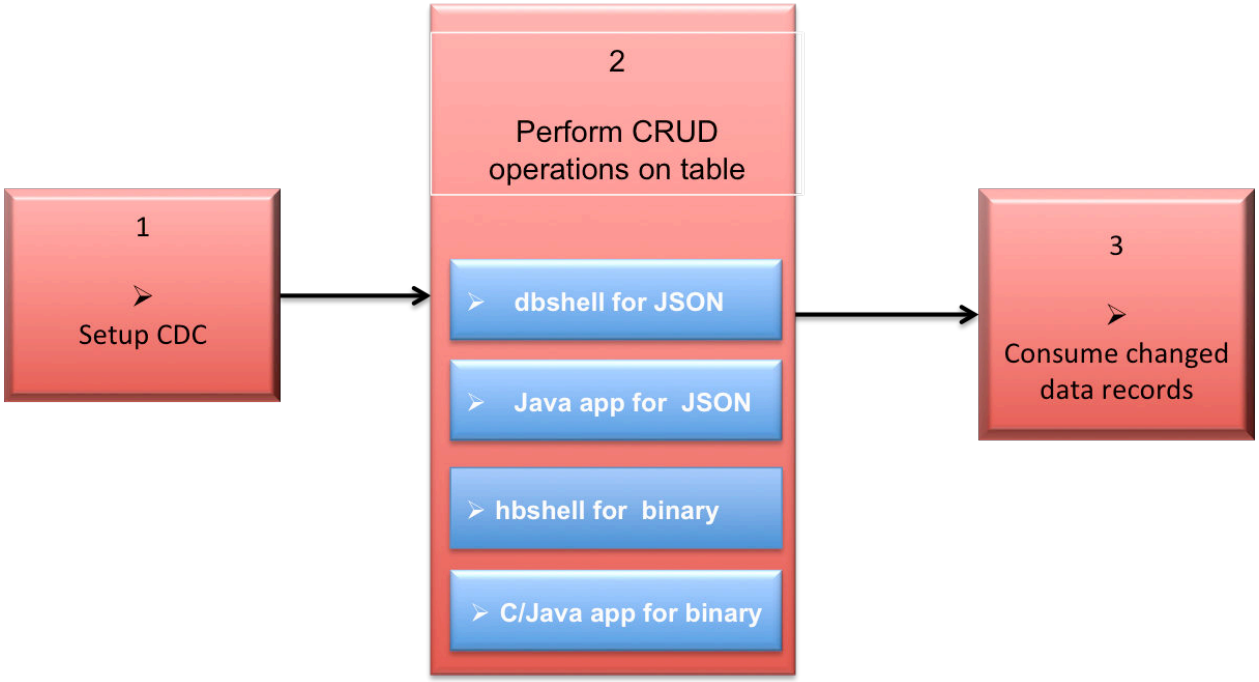
Getting Started with CDC

Describes an end-to-end flow of how to establish and use Change Data Capture (CDC). It assumes that a new table and dataset will be created, although an existing table with data can also be used.

End-to-End Workflow

The following diagram shows an end-to-end workflow of the Change Data Capture (CDC) feature.

NOTE: Steps 2 and 3 are interchangable. You may decide to start the consumer application for CDC changed data records *before* performing CRUD operations on the table.



1. Setup the CDC Environment
2. Using dbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database JSON tables
3. Developing client applications for HPE Ezmeral Data Fabric Database JSON tables.
4. Using HBase to perform CRUD operations on HPE Ezmeral Data Fabric Database binary tables.
5. Developing client applications for HPE Ezmeral Data Fabric Database binary tables.
6. Consuming CDC changed data records

1. Setup the CDC environment.
   a. If you are propagating changed data from a source table on a source cluster to a destination stream topic on a *remote* destination cluster, you must setup a gateway. Gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. See Administering Data Fabric Gateways on page 1526 and Configuring Gateways for Table and Stream Replication on page 1528.

   b. If you have a secure cluster, you must set up secure configuration. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1952.

   c. Establish a HPE Ezmeral Data Fabric Database table (JSON or binary) with data. You can create a new table and add data, or use an existing table with data. See maprcli table create for creating a new table or use the Control System. If you are using an existing table with data, skip to the next step.

d. Create a HPE Ezmeral Data Fabric Streams stream for the propagated changed data records using the `maprcli stream create -ischangelog` parameter. See maprcli stream create or use the Control System.

e. Create a HPE Ezmeral Data Fabric Streams stream topic for the changed data records. You can use the maprcli stream topic create command, the maprcli table changelog add command (this command creates a changelog relationsip between the source table and the destination stream topic), or the Control System when creating either a stream topic or a table changelog.

f. Create a changelog relationship between the source table and the destination stream topic with the maprcli table changelog add command or use the Control System. By creating a changelog relationship, you are creating an environment that propagates changed data records from a source table to a HPE Ezmeral Data Fabric Streams topic.

NOTE: Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is `true`.

NOTE: Propagation is enabled as soon as you add the table changelog relationship. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See table changelog resume on page 2466 for more information.

g. Verify that the changelog exists. See table changelog list on page 2462 for information about your changelogs.

2. Perform CRUD operations (inserts, updates, and deletes) on the source table. The following utility and application can be used:

- mapr dbshell for HPE Ezmeral Data Fabric Database JSON documents
- hbshell for HPE Ezmeral Data Fabric Database binary data
- Java applications for HPE Ezmeral Data Fabric Database JSON
- C or Java applications for HPE Ezmeral Data Fabric Database binary data

3. Write a consumer with the Apache Kafka and OJAI API libraries that subscribes to the topic and consumes the change data records. There are multiple interfaces that are used for writing a CDC consumer. See Consuming CDC Records on page 3515 for a list of interfaces. See Building Consumers for CDC on page 3518 for an example.

Use Cases

Scenario	Setup Task	Notes
You want a CDC stream topic to contain all of the table data as changed data records.	You would setup CDC in the following manner before performing operations on the source table and consuming the change data records. **1.** Create an **empty** source table. **2.** Create the changelog stream. **3.** Create the changelog stream topic. **4.** Add the table changelog relationship. In this case, it does not matter if the `-propagateexistingdata` is set to true or false because you are starting with an empty source table. **5.** Verify that the changelog exists and that `replicaState` is REPLICA_STATE_REPLICATING. See table changelog list on page 2462 for more information.	In this case, all table data is propagated to the stream topic as change data records and the operation type is identified on each individual data record.
You want a CDC stream topic to contain all of the existing table data and changed data records.	You would setup CDC in the following manner before performing operations on the source table and consuming the change data records. **1.** Create a source table and add **data**, or alternatively, use an existing table that contains data. **2.** Create the changelog stream. **3.** Create the changelog stream topic. **4.** Add the table changelog relationship. Be sure that the `-propagateexistingdata` parameter is set to **true**. If you are using the command line to add the changelog, then you do not need to specify this parameter because the default is `true`. **5.** Verify that the changelog exists and no error is reported in the changelog list. When all the existing data in the table is delivered to the changelog, the replicaState becomes REPLICA_STATE_REPLICATING. See table changelog list on page 2462 for more information.	In this case, the existing table data is propagated to the stream topic and that data's operation type is identified as a SET operation. Subsequently, operations on the source table are propagated as changed data records and the operation type is identified on each individual data record. You can consume data at any time, however, there may be a delay before all of the existing table data is completely propagated, expecially if you have a large dataset. Be sure to check the `copyTableCompletionPercentage` field.

last-updated: Jun 06, 2024

Scenario	Setup Task	Notes
You want a CDC stream topic to *not* contain any original table data and to capture only subsequent changed data records	You would setup CDC in the following manner before performing operations on the source table and consuming the change data records. **1.** Create a source table and **add** data, or alternatively, use an existing table that contains data. **2.** Create the changelog stream. **3.** Create the changelog stream topic. **4.** Add the table changelog relationship. Be sure that the `-propagateexistingdata` parameter is set to **false**. **5.** All new data operations applied to a source table after the replicaState becomes REPLICA_STATE_REPLICATING is *not* treated as original data and is delivered to the changelog. See table changelog list on page 2462 for more information.	In this case, the existing table data is not propagated to the stream topic and the operation type is identified on each individual data record.

Data Modeling and CDC

Change Data Capture (CDC) changed data records propagate in one direction - from a source table to a topic in a changelog stream. One stream with one topic can be created for the changed data records or multiple streams with multiple topics can be created.

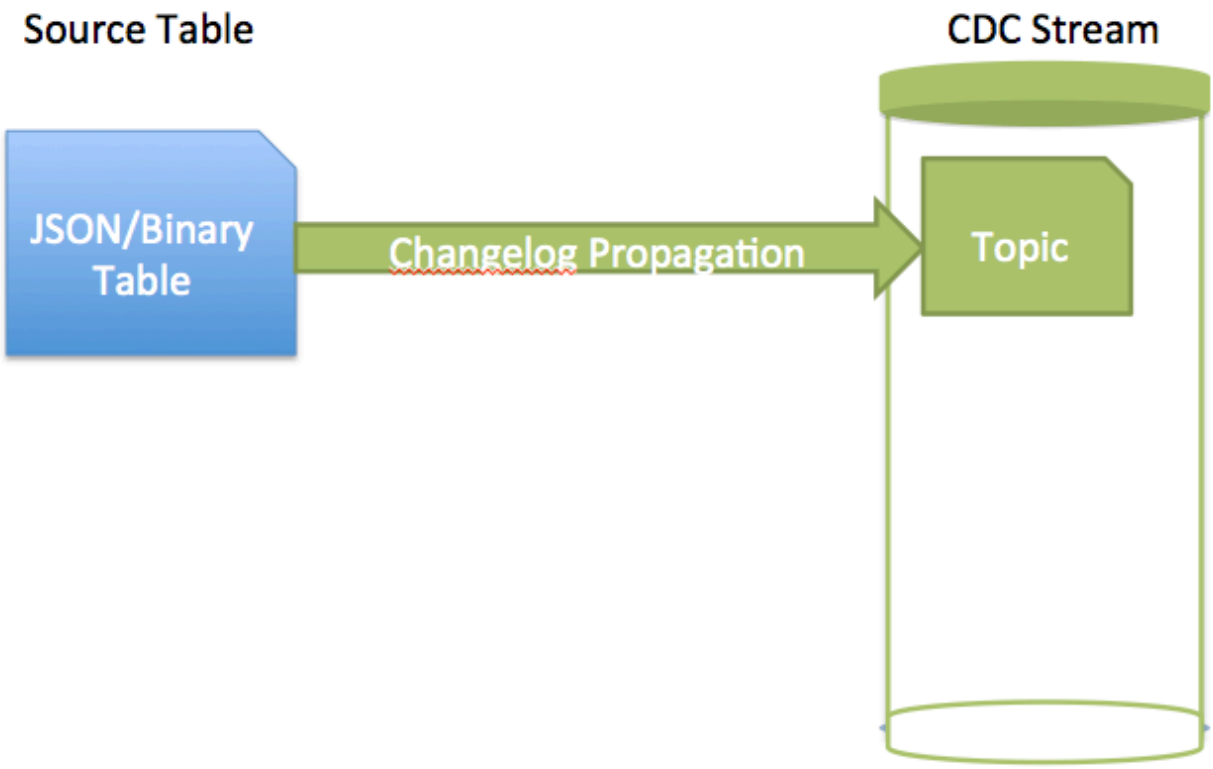
NOTE: Propagation from multiple source tables to one stream topic is not supported.

One source to one destination topic on one stream

You might use this scenario if there are a large number of changed data records being propagated, and you want the topic on a separate or isolated volume, so that resources are dedicated to these particular changed data records.

The following graphic shows a source table's change data records being propagated to one topic on one stream.

last-updated: Jun 06, 2024

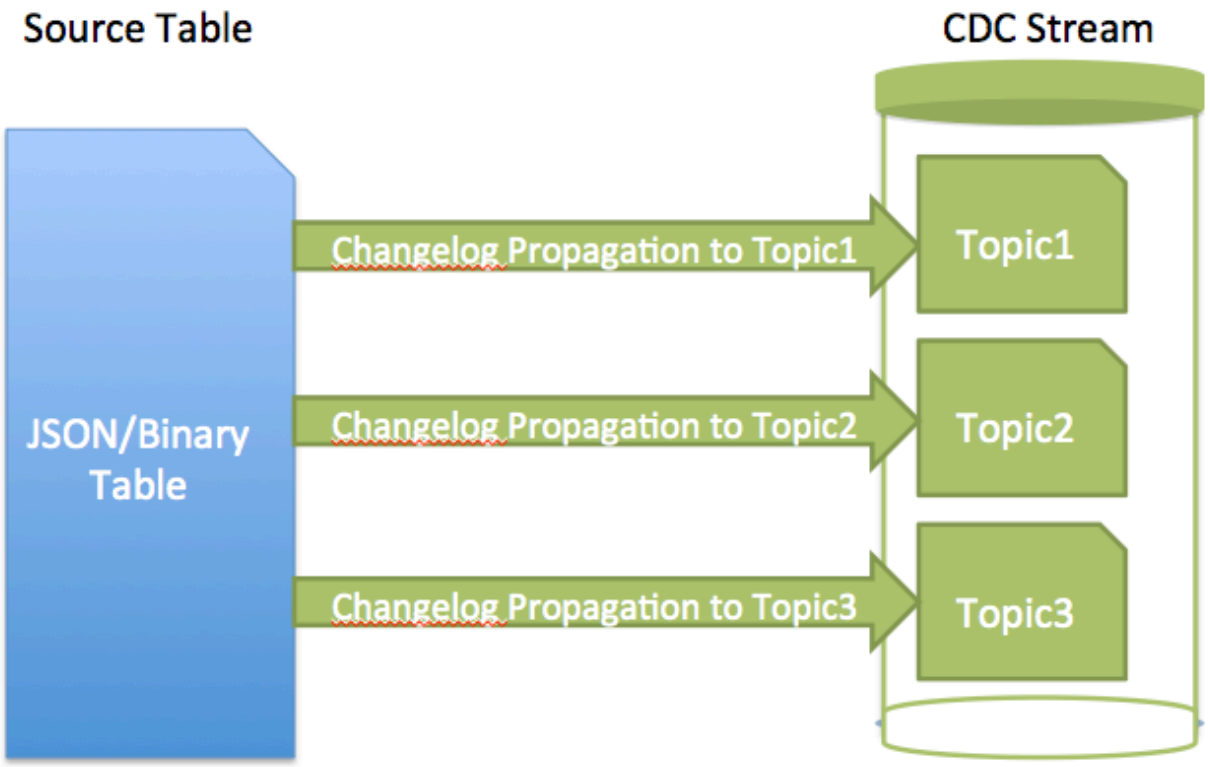


One source to multiple destination topics on one stream

You might use this scenario if you want to propagate specific changed data records from one source table to different topics.

When you set up a table changelog for data propagation, you can specify the column parameter to propagate a specific field or column family. Default: All fields are propagated. See table changelog add on page 2459 for information about adding a table changelog.

The following graphic shows a source table's change data records being propagated to multiple topics on a stream.

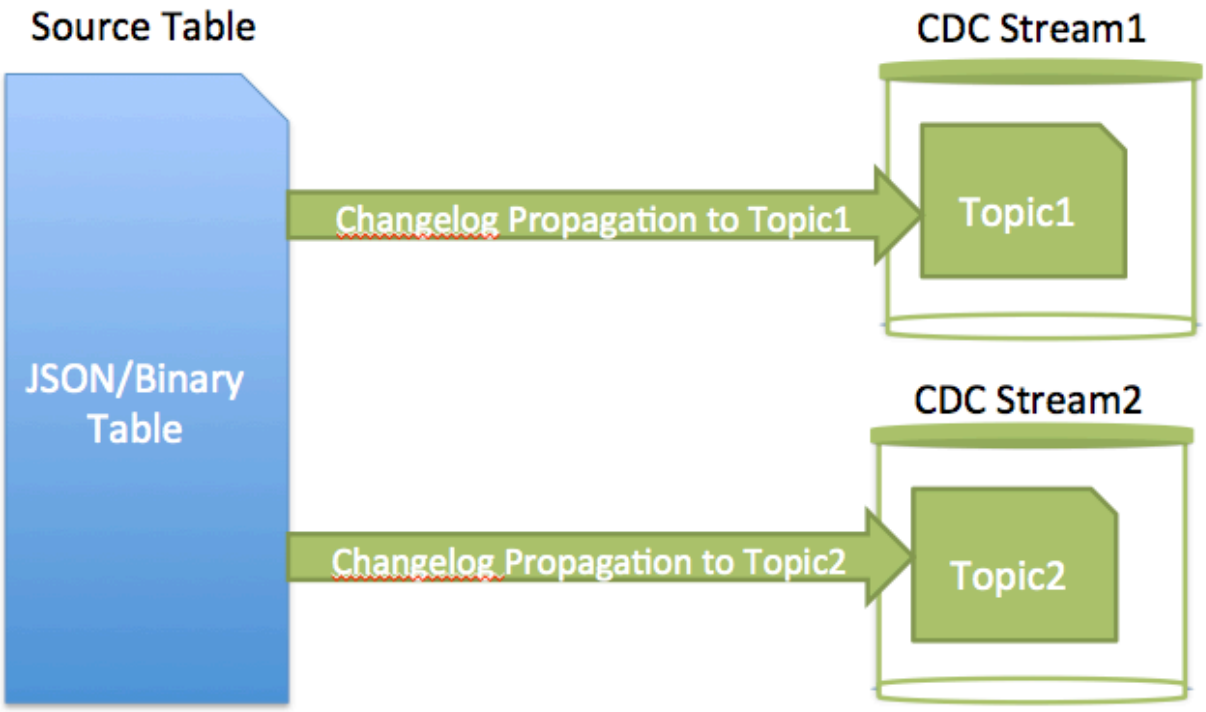


One source to multiple destination topics on multiple streams

You might use this scenario if the change data records are important and you want to have an extra copy for backup purposes.

The following graphic shows a source table's change data records being propagated to topics on multiple streams.

last-updated: Jun 06, 2024

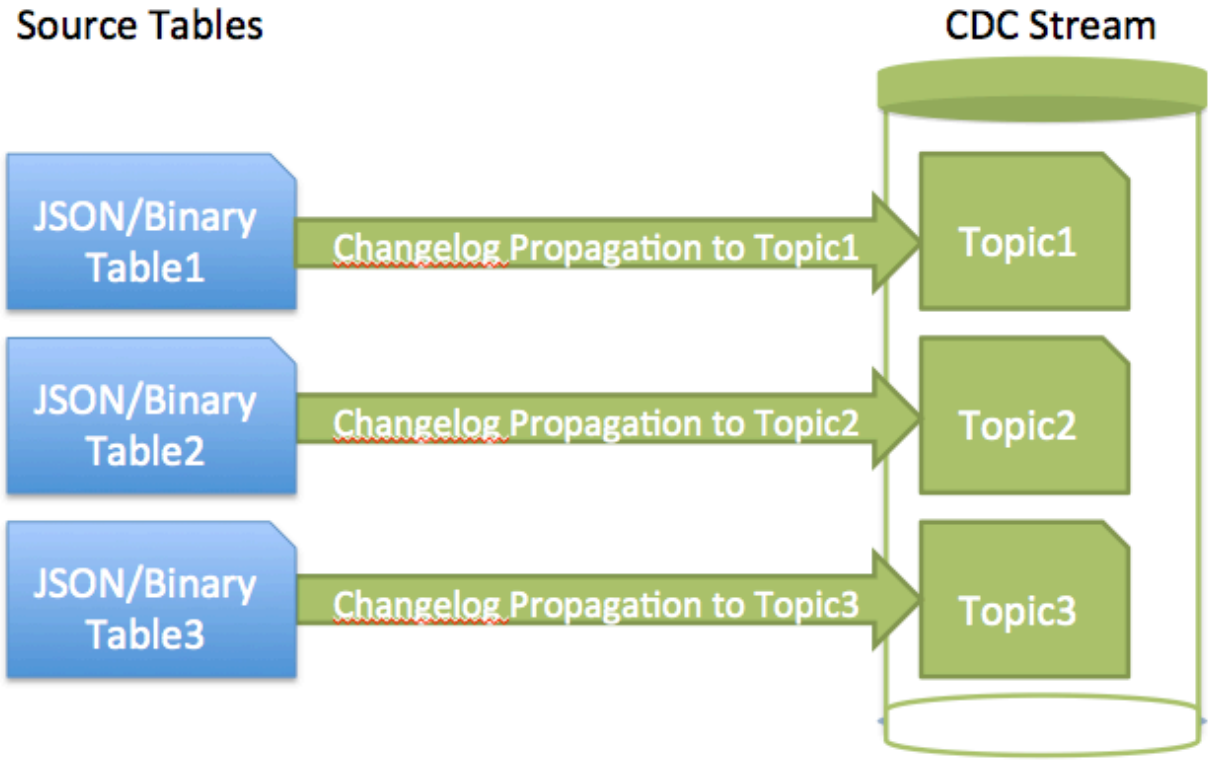


Multiple sources to multiple destination topics on one stream

You might use this scenario if you want to set up permissions to one stream so that a team has access to all the topics that they want to access. For example, if table1 and table2 has change data records that a team wants to monitor, then on the stream, you would grant permission to the monitoring team.

The following graphic shows three source tables' change data records being propagated to three topics on the same stream.

last-updated: Jun 06, 2024

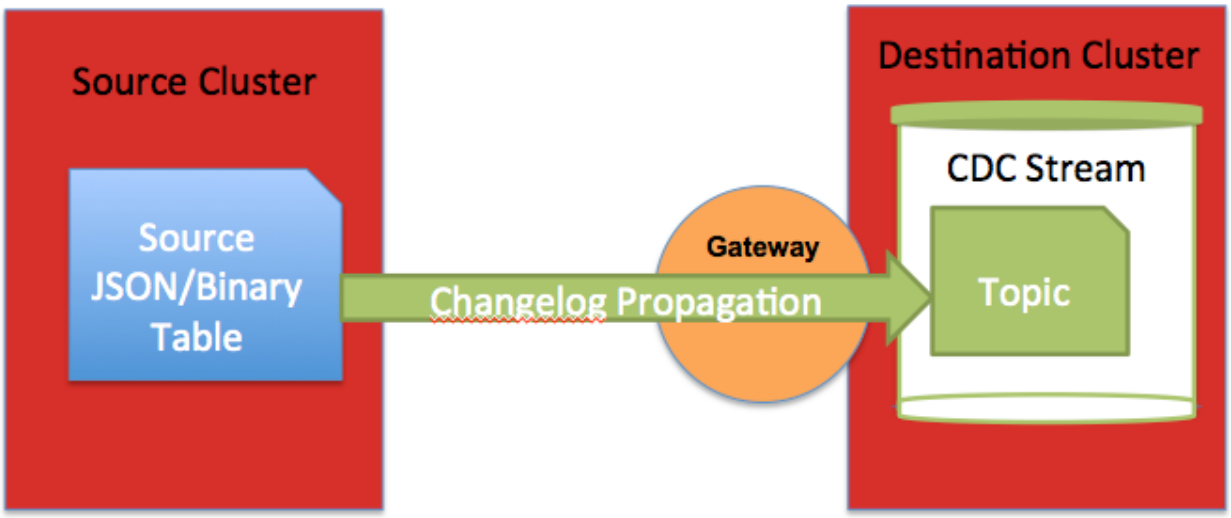


Source Cluster to Destination Cluster

If you are propagating changed data from a source table on a source cluster to a destination stream topic on a remote destination cluster, you must setup a gateway. Gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. See Administering Data Fabric Gateways on page 1526 and Configuring Gateways for Table and Stream Replication on page 1528.

The following diagram shows a simple CDC data model, with one source table to one destination topic on one stream. Since this scenario has the destination stream topic on a remote destination cluster, you must setup and configure a gateway.

NOTE: More complex CDC scenarios can be implemented, and multiple gateways can be setup.



IMPORTANT: If you have a secure cluster, you must setup secure configuration. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1952.

Security and CDC
Security for CDC is applied through Access Control Expressions (ACEs). In addition, if a secure cluster configuration is implemented, then additional setup may be needed depending on the configuration.

Access Control Expressions (ACEs)

Since Change Data Capture (CDC) changed data records are propagated from a HPE Ezmeral Data Fabric Database source table to a HPE Ezmeral Data Fabric Streams stream topic, use the access control expressions (ACEs) on the source table and destination stream for establishing permissions.

Once a HPE Ezmeral Data Fabric Streams stream is created for purposes of receiving change data records, it is dedicated for that sole purpose. For example, a producer application should not perform CRUD operations on the topics in the stream.

The following permissions are applicable depending on the scenario:

- If you are a normal user and you want to create a changelog from a source table and to a destination stream topic, the following permissions are required:
  - `replperm` on the source table in the source cluster
  - `topicperm` on the destination stream in the destination cluster
- If you are a normal user and want to create a changelog between your own HPE Ezmeral Data Fabric Database table and someone else's stream topic, you must be granted `topicperm` permissions on the destination stream.
- If you are a normal user and want to receive or read the data in a stream topic, you must be granted `consumeperm` permission on the destination topic.

For more information about ACEs, see Managing Access Control Expressions on page 1855

Secure Clusters

The destination HPE Ezmeral Data Fabric Streams stream could be in same cluster as the HPE Ezmeral Data Fabric Database source table or it could be on a remote data-fabric cluster. The configuration setup depends on the purpose for using CDC.

- If your destination stream is on the same cluster as the source table and the cluster is secure, then additional configurations are *not* required.
- If your destination stream is on a remote secure cluster, then a gateway and secure configuration must be setup. See Table Replication on page 749, Administering Data Fabric Gateways on page 1526, and Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1952

Restrictions for CDC
Lists the limitations for Change Data Capture.

The limitations for Change Data Capture are as follows:

- Non-CDC data cannot be propagated to changelog stream topics.
- Metadata or policy-driven operations are not propagated to changelog stream topics; only the changed data is propagated. For example, since column family and time-to-live (TTL) is metadata, they are not propagated to changelog stream topics. If metadata is changed in the source table, that information is unknown in relation to the destination stream topic data.
- Propagation of HPE Ezmeral Data Fabric Database JSON arrays is expensive because the full array is propagated to the changelog stream topic.

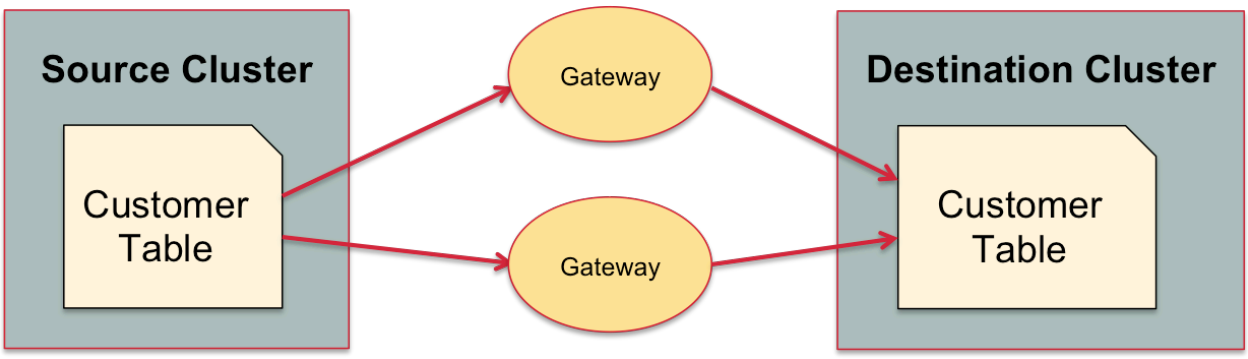
Table Replication

You can replicate data in one table to another table that is in the same cluster or in a separate cluster. This type of replication is in addition to the automatic replication that occurs with table regions within a volume.

You can replicate changes (puts and deletes), entire tables, specific column families, and specific columns.

Data Fabric binary tables can only be replicated to binary tables; Data Fabric JSON tables can only be replicated to JSON tables.

- Tables from which data is replicated are called source tables. Tables to which the data is replicated are called replicas.
- Clusters from which data is replicated are called source clusters. Clusters to which data is replicated are called destination clusters. A single cluster can be both a source cluster and a destination cluster, depending on the replication configuration in which the cluster participates.
- Replication takes place between source and destination clusters. However, source clusters do not send data to nodes in the destination cluster directly. The replication stream (the data being pushed to the replicas) is consumed by one or more data-fabric gateways in the destination cluster. The gateways receive the updates from the source cluster, batch them, and apply them to the replica tables. Multiple gateways serve the purpose of both load balancing and failover.



For more information about gateways, see Administering Data Fabric Gateways on page 1526.

The maximum number of replicas that a source table can replicate to is 64. The maximum number of source tables from which a replica can accept updates is 64.

Modes of replication

Describes the asynchronous and synchronous modes of table replication.

You can replicate table data in one of two replication modes. You specify the mode per source-replica pair.

Asynchronous replication

In this replication mode, HPE Ezmeral Data Fabric Database confirms to client applications that operations are complete after the operations are performed on source tables. Updates are replicated in the background. Therefore, the latency of updates from client applications is not affected by the time required for the network round trip between the source cluster and the destination cluster.

This type of replication is well-suited for clusters that are geographically separated in wide-area networks.

HPE Ezmeral Data Fabric Database can throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. Throttling distributes disk reads and CPU usage more evenly over time, so that incoming operations on a source table can be completed faster. Throttling is disabled by default.

Asynchronous replication is the default replication mode.

Synchronous replication

In this replication mode, HPE Ezmeral Data Fabric Database confirms to client applications that changes have been applied to a source table only when these two conditions are true:

- The change was sent to all of the container copies in the local cluster.
- The change was sent to a gateway in the destination cluster. This operation takes place only after the first. Puts are not sent to gateways until after they are sent to all container copies in the cluster where the source table is located.

If a gateway fails, the source detects this and resends operations to the gateway when it is restarted or a new gateway is brought online.

Due to the confirmations that HPE Ezmeral Data Fabric Database receives on source clusters, synchronous replication is especially well-suited for creating a backup of your data for disaster recovery.

When the latency of a replication stream is high, HPE Ezmeral Data Fabric Database switches to asynchronous replication temporarily so that client applications are not blocked indefinitely. After the latency is sufficiently reduced, HPE Ezmeral Data Fabric Database switches back to synchronous replication. The same switching occurs when a gateway fails, and HPE Ezmeral Data Fabric Database does not resume synchronous replication until a new gateway is established or the failed gateway is restarted.

Supported replication topologies

Lists the `primary-secondary` and `multi-master` replication technologies.

There are two types of basic topologies that you can use for your replication scenarios: `primary-secondary` replication, with which you can construct several different types of more complicated topologies, and `multi-master` replication.

Primary-Secondary Replication

In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located.

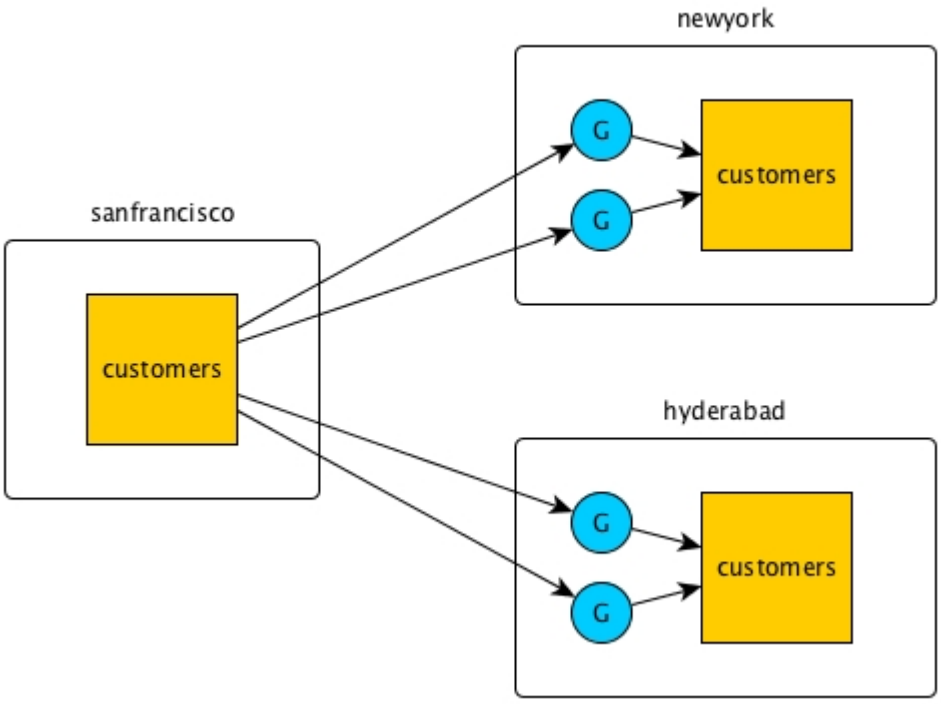
Several topologies are possible for primary-secondary replication:

Replication from one source table to one or more replica tables

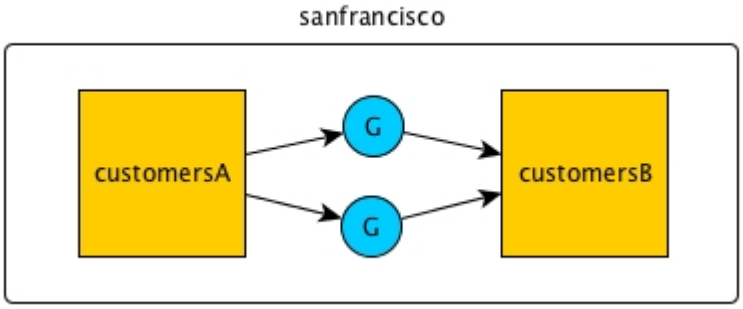
In this topology, updates on a source table are replicated to one or more replicas, but updates to the replicas are not replicated back to the source table.

For example, in this diagram, updates to the `customers` table in the cluster `sanfrancisco` are being replicated to the `newyork` and `hyderabad` clusters. The circles marked G each represent a HPE Ezmeral Data Fabric gateway.

However, changes to the table in the `newyork` and `hyderabad` clusters are not replicated back to the table in the `sanfrancisco` cluster.



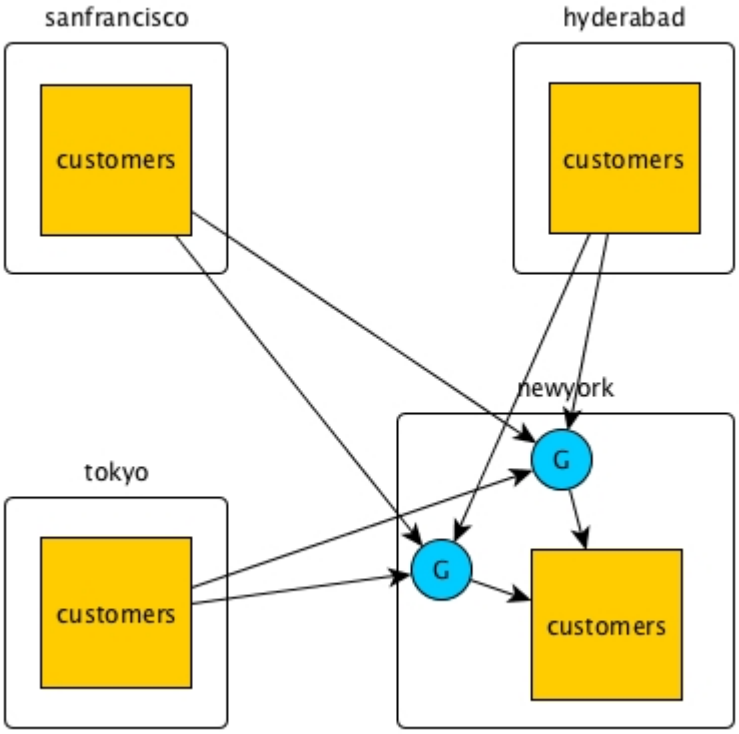
You can also replicate within a single cluster. In this example, the cluster `sanfrancisco` contains both the source table and the replica.



Many-to-one replication

Multiple source tables can replicate to a single replica. In this diagram, operations on `customers` tables in three different clusters are replicated via gateways to the `customers` table in the `newyork` cluster.

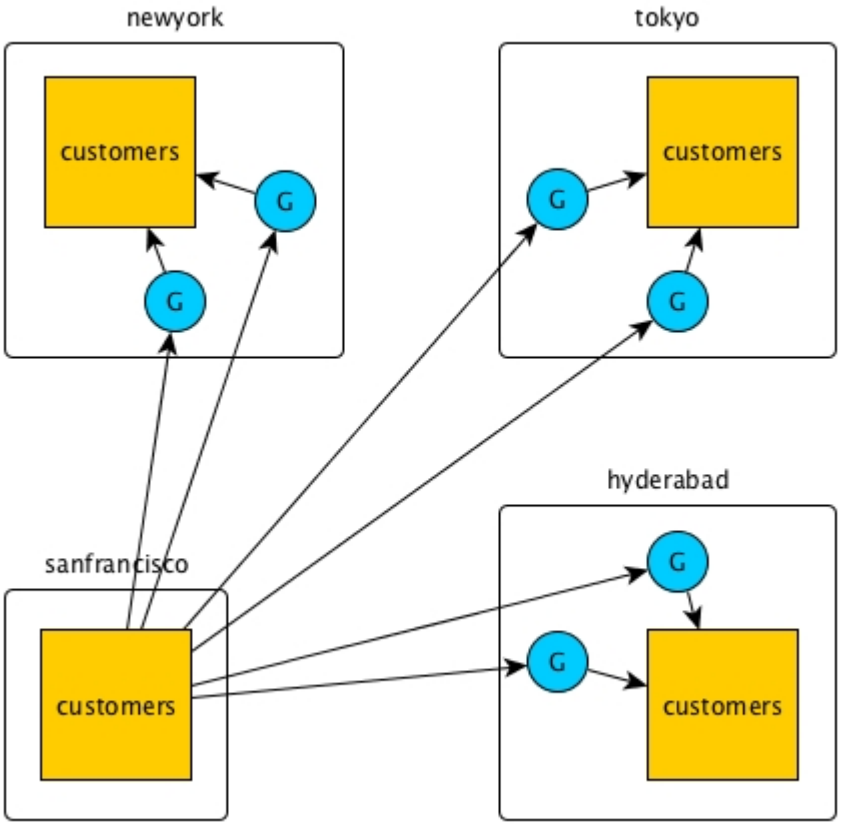
last-updated: Jun 06, 2024



One-to-many replication

A single source table can replicate to multiple replicas. In this diagram, operations on the `customers` table in the `sanfrancisco` cluster are replicated via gateways to replicas in three other clusters.

last-updated: Jun 06, 2024

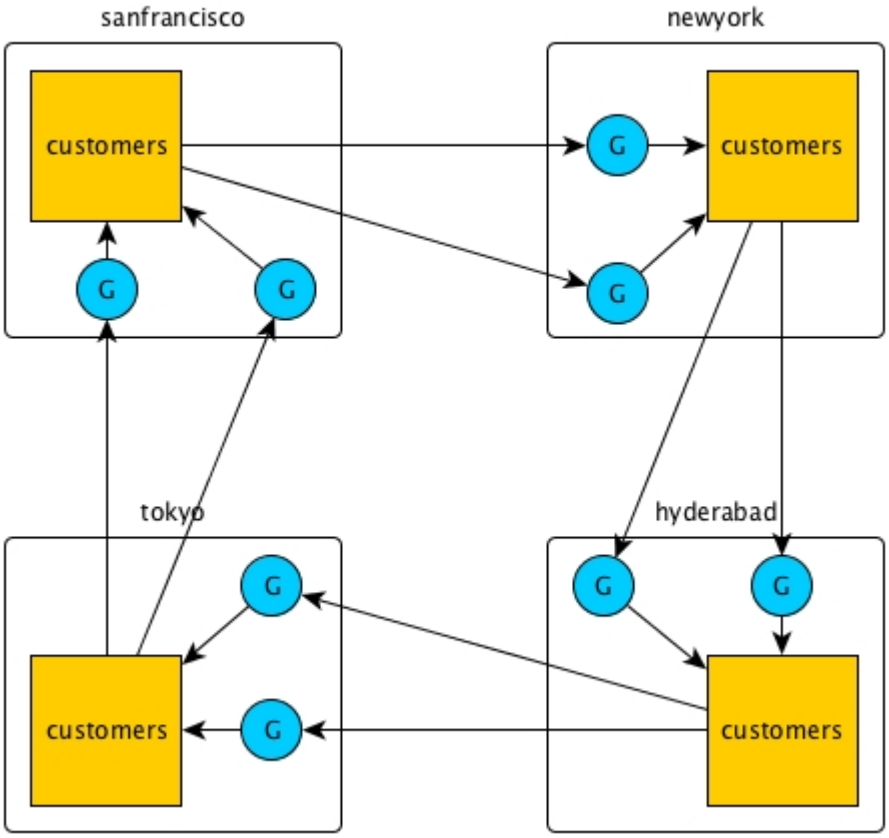


Replication loops

When three or more tables need to be kept in sync, you can set up primary-secondary replication between pairs of them to form a replication loop. Operations on a table are propagated to the other clusters in the loop, but there is no attempt to reapply the operations at the originating table. This is because the operations are tagged with a universally unique identifier (UUID) that identifies the table where the operations originated.

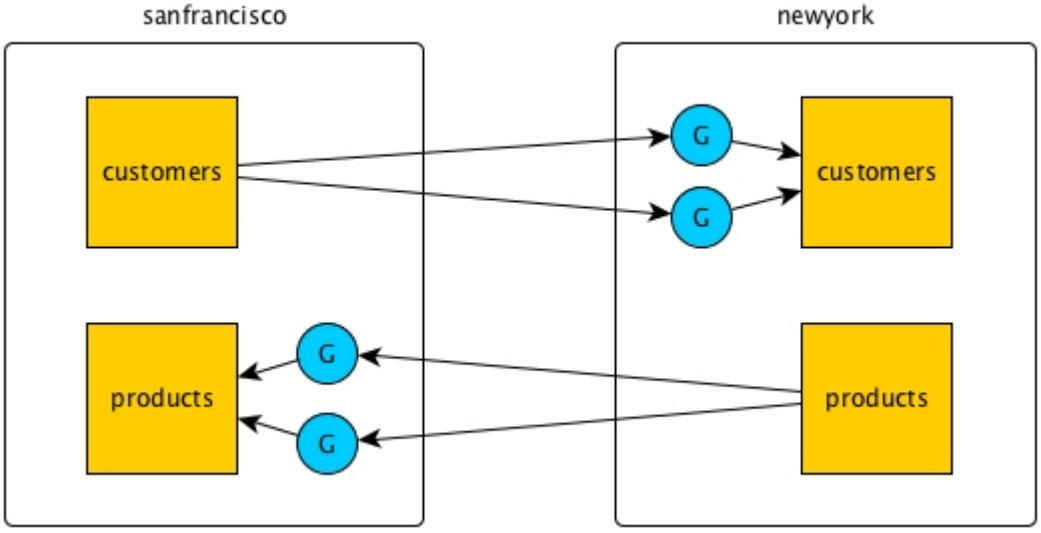
In this diagram, for example, operations on the `customers` table in the `hyderabad` cluster are replicated first to the `customers` table in the `tokyo` cluster. The operations are then replicated from the `tokyo` cluster to the `customers` table in the `sanfrancisco` cluster. Finally, the operations are replicated from the `sanfrancisco` cluster to the `customers` table in the `newyork` cluster. The `newyork` cluster does not replicate the operations to the `customers` table in the `hyderabad` cluster.

last-updated: Jun 06, 2024



Primary-Secondary replication in two directions

You can combine primary-secondary replication configurations to replicate data between clusters. Two clusters engaged in replication can each act as a source cluster and a destination cluster.

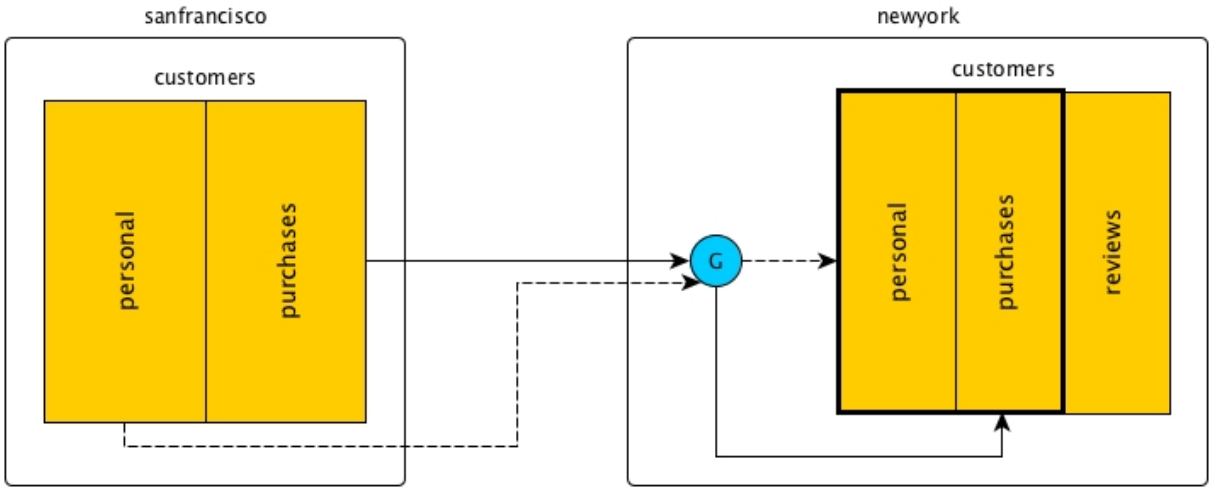


In this example, the data in the `customers` table in the cluster `sanfrancisco` is replicated to the `customers` table in the cluster `newyork`. At the same time, the data in the `products` table in the `newyork` cluster is replicated to the `products` table in the cluster `sanfrancisco`.

last-updated: Jun 06, 2024

In all primary-secondary configurations, changes made to replica tables are not replicated back to source tables. Therefore, if the replicated data is modified at the replica by client applications, the replica will become out of sync with the source table.

For example, you might replicate the two column families `personal` and `purchases` from the `customer` table in the `sanfrancisco` cluster to the `customers` table in the `newyork` cluster, as in this diagram. (For simplicity, the blue circle labeled G represents two or more gateways, rather than one as in the other diagrams in this topic.)



In primary-secondary replication, no updates to a replica are replicated back to the source. Any updates that applications might make to those two column families in the `customers` table in the `newyork` cluster will not be replicated to the `customers` table in the `sanfrancisco` cluster.

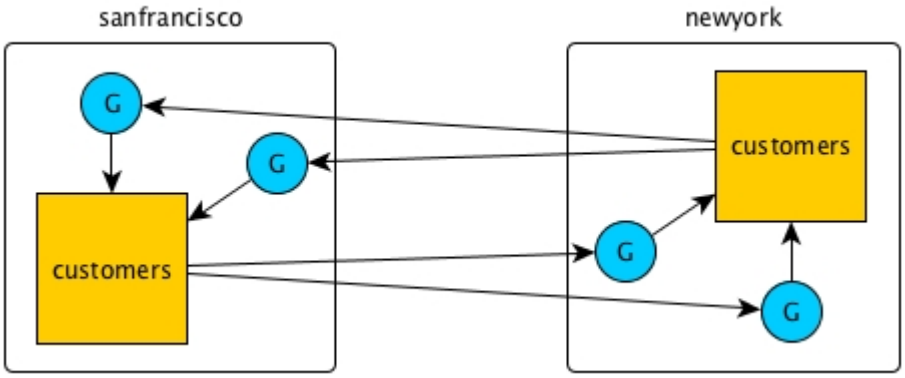
However, you do not have to protect a replica from all updates that are not due to replication. For example, the `customers` table in the `newyork` cluster might have an additional column family that is not populated with replicated data: `reviews`.

Multi-Master Replication
In this replication topology, there are two primary-secondary relationships, with each table playing both the primary and secondary roles. Client applications update both tables and each table replicates updates to the other.

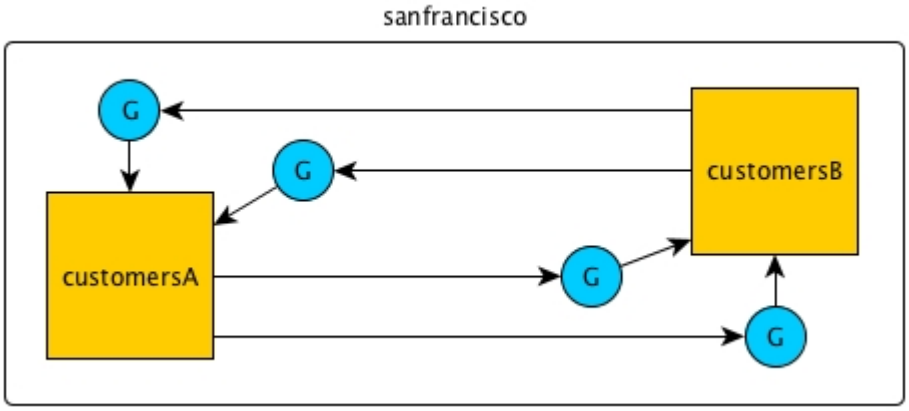
All updates from a source table arrive at a replica after having been authenticated at a gateway. Therefore, access control expressions on the replica that control permissions for updates to column families and columns are irrelevant; gateways have the implicit authority to update replicas.

In this diagram, the `customers` table on the cluster `sanfrancisco` replicates updates to the `customers` table in the cluster `newyork`. The latter table in turn replicates updates to the former table. HPE Ezmeral Data Fabric Database tags each table operation with the universally unique ID (UUID) that it has assigned the table at which the operation originated. Therefore, operations are replicated only once and are not replicated back to the originating table.

last-updated: Jun 06, 2024



In this diagram, both tables are in a single cluster. Operations on table `customersA` are replicated to table `customersB` and vice versa.

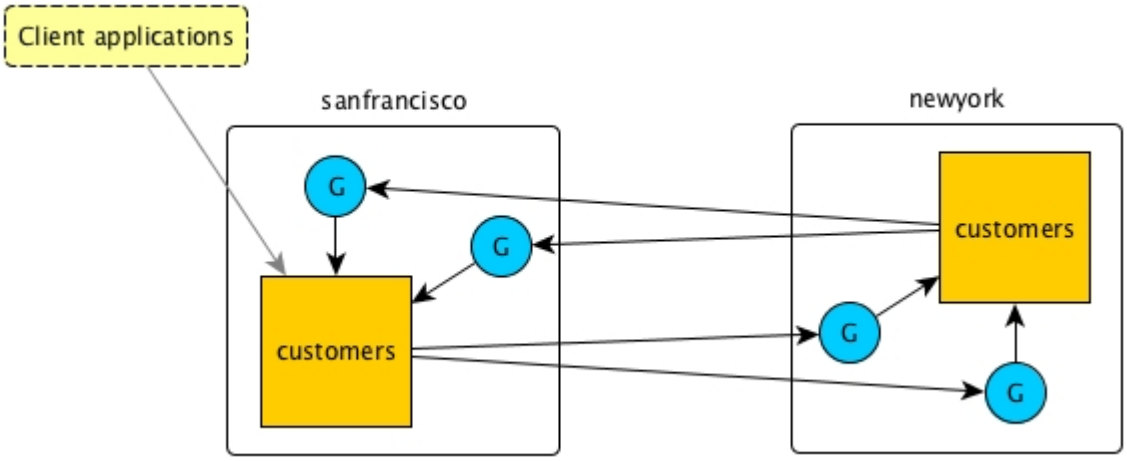


Offline Tables

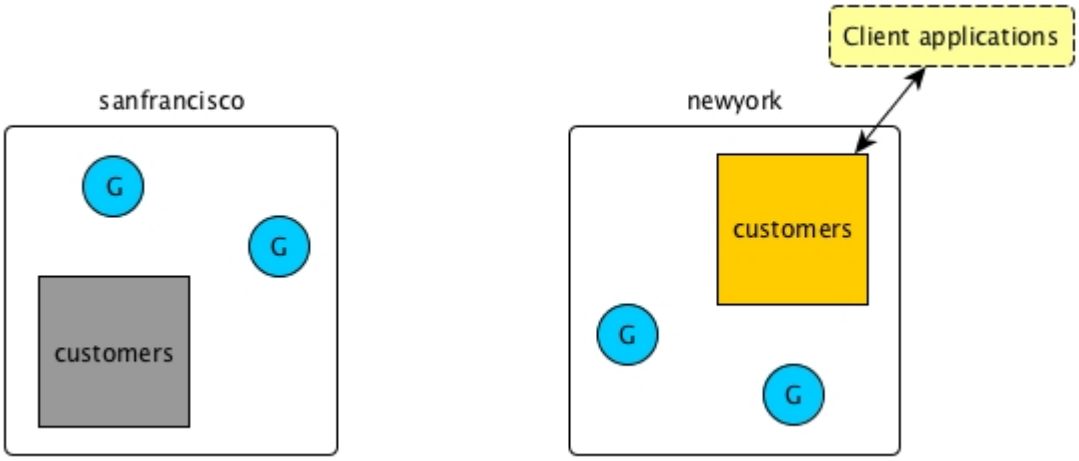
If one of the tables goes offline, you can direct client applications to the other table. When the offline table comes back online, replication between the two tables resumes automatically. When both tables are in synch again, you can redirect client applications back to the original table.

For example, assume that client applications are using the `customers` table that is in the cluster `sanfrancisco`.

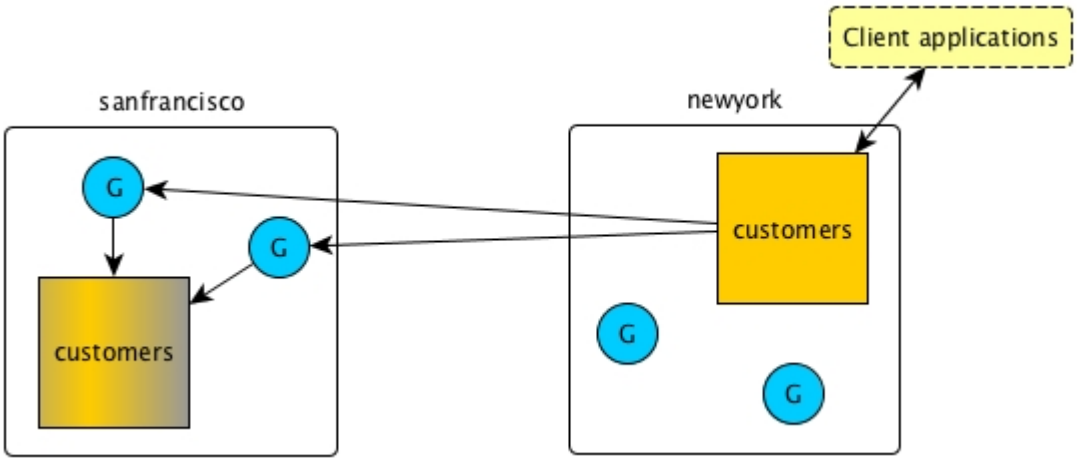
last-updated: Jun 06, 2024



The `customers` table in the `sanfrancisco` cluster becomes unavailable, so you redirect those client applications to the `customers` table in the `newyork` cluster.

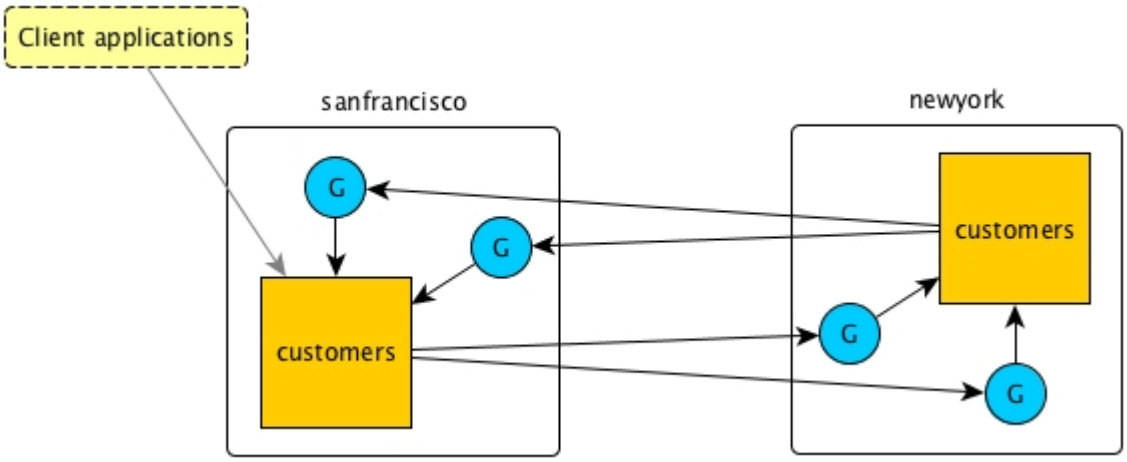


After the `customers` table in the `sanfrancisco` cluster comes back online, replication back to it starts immediately. As client applications are not yet using this table, there are no updates to replicate to the table in the `newyork` cluster.



last-updated: Jun 06, 2024

When the `customers` table in the `sanfrancisco` cluster is in sync with the other table, you can redirect your client applications back to it.



Conflict Resolution

The method that HPE Ezmeral Data Fabric Database uses to resolve conflicts depends on the type of table involved in a multi-master replication scenario.

Conflict resolution for binary tables	In the case of conflicting changes, HPE Ezmeral Data Fabric Database compares the cell timestamps of the two changes. In the rare event that the cell timestamps are identical, HPE Ezmeral Data Fabric Database compares the timestamps for when the changes arrived at their respective source tables. In the even rarer event that these latter timestamps are identical, HPE Ezmeral Data Fabric Database uses the C library function `memcmp` to compare the data that is being modified by the conflicting changes, favoring the greater value.
Conflict resolution for JSON tables	If two values conflict, HPE Ezmeral Data Fabric Database compares their types. The value of the type with the higher precedence is retained. Here is a list of the supported types in descending order of precedence: • Array • Document • Binary • Interval • Timestamp • Time • Date • Decimal • Double • Float

last-updated: Jun 06, 2024

- 64-bit integer
- 32-bit integer
- 16-bit integer
- 8-bit integer
- UTF-8
- Boolean
- NULL

If both the conflicting values are of the same type, HPE Ezmeral Data Fabric Database compares the values themselves. All values are comparable except for values that are arrays or NULL.

Type	How Values Are Compared
Binary	The greater value is retained.
Interval	The later interval is retained.
Timestamp	The later timestamp is retained.
Time	The later time is retained.
Date	The later date is retained.
Decimal	The greater value is retained.
Double	The greater value is retained.
Float	The greater value is retained.
64-bit integer	The greater value is retained.
32-bit integer	The greater value is retained.
16-bit integer	The greater value is retained.
8-bit integer	The greater value is retained.
UTF-8	The greater lexicographic value is retained.
Boolean	TRUE is retained.

Time-to-Live for Deletes

Normally, delete operations are purged after the affected table cells are updated. Whereas the result of an update is saved in a table until another change overwrites or deletes it, the result of a delete is not saved. In multi-master replication, this difference can lead to tables being unsynchronized.

last-updated: Jun 06, 2024

Example Scenario to Illustrate Time-to-Live for Deletes

1. On `/mapr/sanfrancisco/customers`, put row A at 10:00:00 AM.
2. On `/mapr/newyork/customers`, delete row A at 10:00:01 AM.

On `/mapr/sanfrancisco/customers`, the order of operations is:

- Put row A with a timestamp of 10:00:00 AM
- Delete row A with a timestamp of 10:00:01 AM (This operation is replicated from `/mapr/newyork/customers`.)

On `/mapr/newyork/customers`, the order of operations is:

- Delete row A with a timestamp of 10:00:01 AM
- Put row A with a timestamp of 10:00:00 AM (This operation is replicated from `/mapr/sanfrancisco/customers`.)

Now, though the put happened on `/mapr/sanfrancisco/customers` at 10:00:00 AM, the put reaches `/mapr/newyork/customers` several seconds after that. Assume that the actual time the put arrives at `/mapr/newyork/customers` is 10:00:03 AM.

To ensure that both tables stay synchronized, `/mapr/newyork/customers` should preserve the delete until after the put is replicated. Then, the delete can be applied after the put. Therefore, the time-to-live for the delete should be at least long enough for the put to arrive at `/mapr/newyork/customers`. In this case, the time-to-live should be at least 3 seconds.

In general, the time-to-live for deletes should be greater than the amount of time that it takes replicated operations to reach replicas. By default, the value is 24 hours. Configure the value with the `-deletettl` parameter in the `maprcli table edit` command.

For example, suppose (to extend the scenario above) that you pause replication during weekdays and resume it on weekends. The put takes place on Monday morning `/mapr/sanfrancisco/customers` at 10:00:00 AM and the delete takes place at `/mapr/newyork/customers` at 10:00:01 AM. Replication does not resume until 12:00:00 AM Saturday morning. Given the volume of operations to be replicated and the potential for network problems, it is possible that these operations will not be replicated until Sunday. In this scenario, a value of 7 days for `-deletettl` (7 multiplied by 24 hours) should provide sufficient margin.

Gateways for Replicating HPE Ezmeral Data Fabric Database Tables

In HPE Ezmeral Data Fabric Database table replication, HPE Ezmeral Data Fabric Database replicates updates to tables (binary and JSON) on source Data Fabric clusters to replicas of those tables on destination Data Fabric clusters. Gateways are services that receive these updates and apply them to the replicas. These gateways also propagate updates from JSON tables to their secondary indexes.

To set up gateways for replicating HPE Ezmeral Data Fabric Database tables:

- On the nodes of destination clusters, install the gateways.

  You must install gateways in the destination clusters.

  - If the destination cluster is remote from the source cluster, then the gateways must be in the remote cluster.
  - If the destination cluster is the source cluster, meaning that a source table and its replica are located in a single cluster, then the gateways must be in the local cluster.
  - If you have secondary indexes on your HPE Ezmeral Data Fabric Database JSON tables, then the gateways must be in the local cluster.

last-updated: Jun 06, 2024

- On the source clusters, configure the gateways by listing the destination cluster and the gateways that are running on them.

For information on configuring, and managing gateways, see:

- Configuring Gateways for Table and Stream Replication on page 1528
- Managing Gateways on page 1530

How Replication Works

During replication, HPE Ezmeral Data Fabric Database sends source table updates to the gateways on the destination clusters where the replicas of those source tables are located. Gateways batch the updates and then apply them to replicas.

All updates from a source table arrive at a replica after having been authenticated at a gateway. Therefore, *ACE* on the replica that control permissions for updates to column families and columns are irrelevant; gateways have the implicit authority to update replicas.

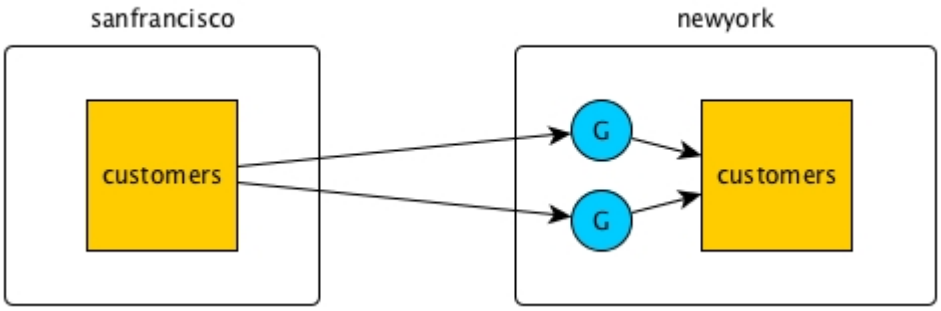
HPE Ezmeral Data Fabric Database distributes updates to a destination cluster's gateways in round-robin fashion. If a gateway is down or unreachable, HPE Ezmeral Data Fabric Database chooses another gateway or retries the operation on the same gateway.

NOTE: If a table is replicated to another table using the replication gateway, and you run a truncate operation on the source table, this operation is not replicated.

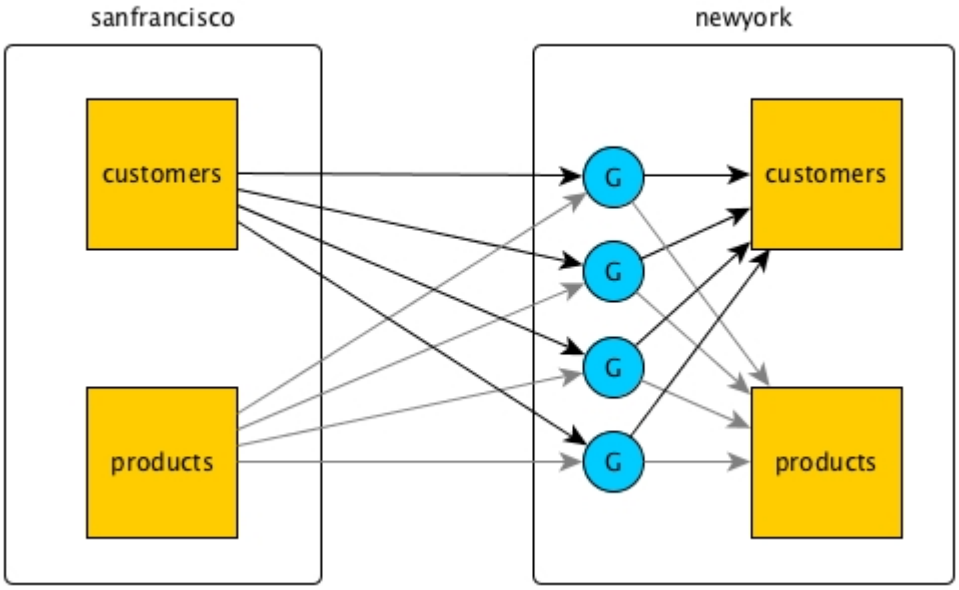
Gateways on nodes in remote destination Data Fabric clusters

In this type of topology, gateways receive updates that are made to source tables, authenticate with the destination cluster on behalf of the source cluster, and apply the updates to the corresponding replicas.

This schematic diagram of basic inter-cluster primary-secondary replication shows updates to the customers table in the cluster `sanfrancisco` being sent to gateways. The gateways then apply the updates to the replica that is in the cluster `newyork`.



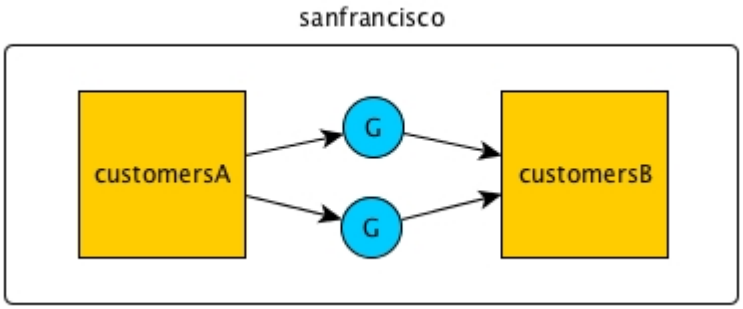
The gateways on a destination cluster are not assigned to particular replicas. They apply updates to all replicas on the destination cluster. For example, in this diagram, updates to two source tables in the cluster `sanfrancisco` are being replicated to two replicas in the cluster `newyork`. There are four gateways. Each gateway receives updates to both source tables, and each gateway applies those updates to both replicas.



Gateways on nodes within a Data Fabric cluster serving as source and destination

In this type of topology, gateways again receive updates that are made to source tables and apply the updates to the replicas. However, all of this activity takes place within a single Data Fabric cluster.

This schematic diagram of basic inter-cluster primary-secondary replication shows updates to the `customersA` table in the cluster `sanfrancisco` being sent to gateways. The gateways then apply the updates to the table `customersB`.



Related concepts

Administering Data Fabric Gateways on page 1526
A HPE Ezmeral Data Fabric gateway mediates one-way communication between a source HPE Ezmeral Data Fabric cluster and a destination cluster. You can replicate HPE Ezmeral Data Fabric Database tables (binary and JSON) and HPE Ezmeral Data Fabric Streams streams. HPE Ezmeral Data Fabric gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

Configuring Gateways for Table and Stream Replication on page 1528
Configuring gateways involves installing the `mapr-gateway` package on nodes on a Data Fabric destination cluster and then configuring the Data Fabric source cluster to communicate with the destination cluster. The Data Fabric source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

Replica Autosetup for HPE Ezmeral Data Fabric Database Tables

The option to automatically set up table replication, also known as replica autosetup, performs the steps to set up and start the replication of HPE Ezmeral Data Fabric Database binary table and HPE Ezmeral Data Fabric Database JSON tables. The replica autosetup option is available through the Control System and maprcli commands.

In general, replica autosetup performs the following steps to set up replication:

1. Creates a new table with metadata from the source table in the destination cluster. The primary table attributes are copied initially if an auto setup is used, because auto setup creates the destination table and any subsequent changes to the primary table's metadata are not propagated to the destination table. In the manual table replication setup, no metadata is propagated, even during the setup.
2. Declares the new table to be a replica of the source table and sets a paused replication state to ensure that replication does not begin immediately after the next step.
3. Declares the source table as an upstream source for the replica.
4. Loads a copy of the source data into the replica.
5. For multi-master replication, replica autosetup declares the source table to be a replica of the new table and then declares the new table to be an upstream source for the source table.
6. Clears the paused replication state to start the replication stream.

By default, replica autosetup uses the directcopy option. However, based on how you run replica autosetup, you also have the choice not to use directcopy.

Replica Autosetup with Directcopy (default)

The directcopy option uses gateways to perform all setup operations including the initial population of data into the replica table. Directcopy is the default option when you setup table replication using the Control System or with the `maprcli table replica autosetup` command.

When a client submits a request to automatically setup table replication to the cluster, the source cluster acknowledges the request and begins to track the replica autosetup request from start to finish.

If a failure occurs when replica autosetup operations are in progress, the source cluster resumes operations from the point of failure.

NOTE: To check the replication status of a table, run the `maprcli table replica list` command. To stop the automatic setup of table replication, run `maprcli table replica remove`, or delete the source or replica table.

Replica autosetup with directcopy provides the following benefits:

- **Replica autosetup operations do not block the client from submitting additional requests.** When setting up table replication, the process to copy source data to the replica can be time consuming. The client does not need to wait for the replica autosetup request to complete before submitting another request.
- **Source cluster retries replica autosetup operations in case of failure.** The source cluster keeps track of the replica autosetup progress. This allows the source cluster to resume autosetup operations in the event of an intermittent failure. If you choose to not use directcopy, user intervention is required if a failure occurs.
- **Throttling of copy table operations is done by default.** Throttling prevents the initial copy of data from the source to the replica table from consuming all cluster resources.

Replica Autosetup without Directcopy (not default)

Without the directcopy option, replica autosetup submits a majority of the replication setup requests through the client and then runs a copy table utility to populate the initial table data. To use replica autosetup without the directcopy option, run `maprcli table replica autosetup` command with the `-directcopy` parameter set to `false`.

Without the directcopy option, once a client submits a replica autosetup request to the cluster, it must wait until the source cluster sends a notification that the autosetup request is complete before it can submit another request to the cluster. In this case, replica autosetup uses the client connection to submit autosetup operation requests such as create replica, add replica, and add upstream source. To populate the initial table data, the client runs `mapr copytable` for JSON tables and the `CopyTable` utility for binary tables.

If a failure occurs when replica autosetup operations are in progress, the client hangs and any replica tables that were created during the failed autosetup operations must be manually deleted before trying to setup replication again.

Table Replication States

The replication state indicates when table replication is in progress and displays the status of operations related to replica autosetup.

The `maprcli table replica list` command displays the following replication states.

State	Description
REPLICA_STATE_WAIT_TILL_BULKLOAD	Replica autosetup with directcopy has not started because bulkload is in progress on the source table.
REPLICA_STATE_CREATE_SCHEDULE	Replica autosetup with directcopy had scheduled the creation of the replica table.

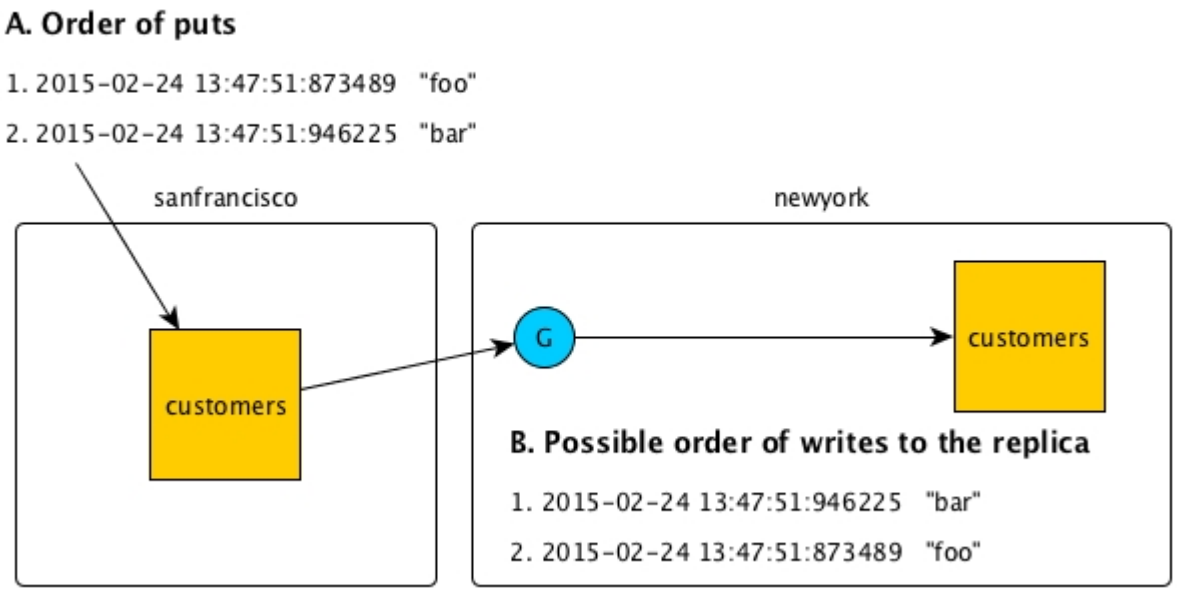
last-updated: Jun 06, 2024

State	Description
REPLICA_STATE_COPY_SCHEDULE	Replica autosetup with directcopy has not started the initial copying of source data to the replica because it is waiting for other in-progress copy operations to complete.
REPLICA_STATE_COPY_IN_RECOVER	Replica autosetup with directcopy is resuming the copy of source data to the replica after a connection failure.
REPLICA_STATE_COPY_IN_PROGRESS	Replica autosetup with directcopy is copying the source data to the replica.
REPLICA_STATE_DELETING_CURSORS	Replica autosetup with directcopy is deleting progress cursors since the initial copy of source data to the replica is complete.
REPLICA_STATE_REPLICATING	Replication is in progress.
REPLICA_STATE_UNEXPECTED	Replica is in an unexpected state. See the `error` field in the output from `maprcli table replica list` for more information.

Order of Writes at Replicas

It is possible for replicated operations to arrive at and be written to a replica in an order different from the order they were written to a source table.

In this diagram, the values “foo” and then “bar” are written to the source table. However, due to network issues, the values are written to the replica in the reverse order: “bar”, “foo”



Client applications on the destination cluster should not depend on updates being written to the replica in the same order in which they were written to the source table.

Security and Replication
Describes how to replicate data between secure clusters.

Security is configured at all locations in the replication stream.

last-updated: Jun 06, 2024

On clusters

You can replicate between clusters that are secure. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1952 for more information about replication between secure clusters.

At source tables

The `-replperm` parameter lets you specify an *ACE* to declare who has permission to replicate data from a table. This parameter is available in the `maprcli table create` and `maprcli table edit` commands.

Across a network

You can send data encrypted or unencrypted when replicating between secure clusters by using the `-networkencryption` parameter when adding a replica to a source table.

At gateways

Gateways ensure that replicas receive updates only from source tables that are designated as upstream sources.

Moreover, gateways handle authentication with secure destination clusters.

At replicas

Due to several upstream security checks, no parameters are needed for setting *ACE* to declare who has permission to update a replica through a replication stream. However, before replication begins, replicas can be loaded with a snapshot of the data in corresponding source tables. Permission to perform such a load is controlled by the *ACE* that you set in the `-bulkloadperm` parameter for a replica. You can set the *ACE* with either the `maprcli table create` or the `maprcli table edit` command.

All other *ACE* defined for a replica still apply for local updates and reads.

Licensing

Describes the licensing requirements for data-fabric.

Table replication requires a license for data-fabric Enterprise Database Edition (M7) on source and destination clusters.

Gateways for Indexing HPE Ezmeral Data Fabric Database Data in Elasticsearch

As of data-fabric 6.0, HPE Ezmeral Data Fabric Database Elastic Search integration capability is deprecated and no longer available in the HPE Ezmeral Data Fabric Database product.

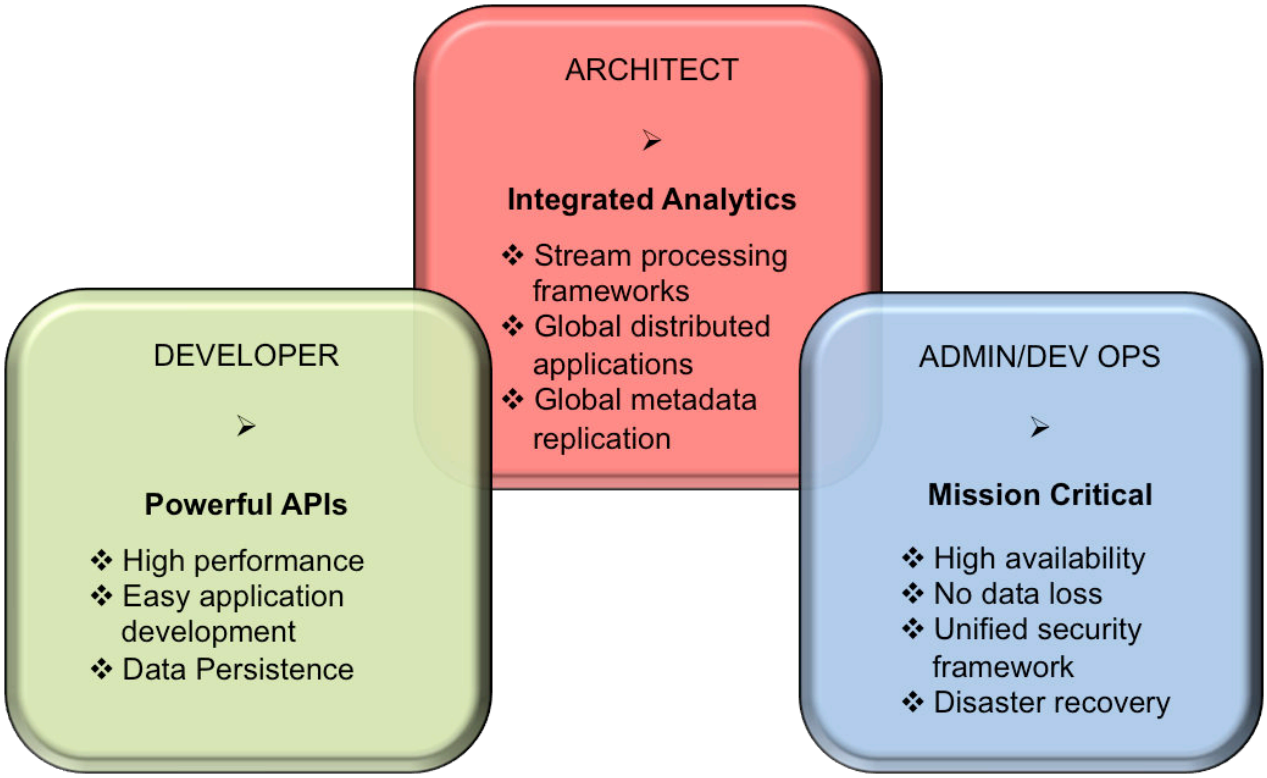
ATTENTION: HPE Ezmeral Data Fabric Database Change Data Capture (CDC) framework can be used to integrate with latest versions of Elasticsearch. See Change Data Capture on page 736 for more information.

HPE Ezmeral Data Fabric Streams

HPE Ezmeral Data Fabric Streams brings integrated publish and subscribe messaging to the HPE Ezmeral Data Fabric.

Why HPE Ezmeral Data Fabric Streams?

HPE Ezmeral Data Fabric Streams is built into the data-fabric platform. It requires no additional process to manage, leverages the same architecture as the rest of the platform, and requires minimal additional management.



1. The HPE Ezmeral Data Fabric Streams and Apps section information and examples for developing Producer and Consumer applications.
2. The HPE Ezmeral Data Fabric Streams concepts section covers information associated with streams, topics, and messages.
3. The Administering Streams section provides information about creating and managing streams, topics, and stream replication.

How Do I Get Started?

Based on your role, review the HPE Ezmeral Data Fabric Streams documentation. The following table identifies useful resources based on your role.

Architecture

Streams contain topics that have logical collections of messages.

In HPE Ezmeral Data Fabric Streams, topics are grouped into *streams*. Administrators can apply security, retention, and replication policies on streams. Combined with file system and HPE Ezmeral Data Fabric Database in the Data Fabric Data Platform, using these streams enables organizations to create a centralized, secure data lake that unifies files, database tables, and message topics.

Messages (topic data) are published to *topics* by Producer applications and are read by Consumer applications. All messages published to HPE Ezmeral Data Fabric Streams are persisted, allowing future consumers to “catch-up” on processing and analytics applications to process historical data. Additionally, messages are specifically written to *topic partitions*.

NOTE: Topic partitions are stored in containers within volumes. Containers are written to storage pools, which are made up of disks on the nodes in the cluster. See Containers and the CLDB on page 491 for more information about containers.

Why Use HPE Ezmeral Data Fabric Streams?

HPE Ezmeral Data Fabric Streams is ideal for a variety of use cases, including the following:

Application event pipelines	Many types of applications generate event or log data that must be centrally stored and analyzed to gain insights about user activity or application performance. HPE Ezmeral Data Fabric Streams simplifies these pipelines by transporting events to a central location, from which they can undergo event-by-event transformation and analysis.
Database change capture	Most modern databases enable users to generate an event each time an entry is added or modified. These events can be published to HPE Ezmeral Data Fabric Streams to keep systems like search indexes and caches synchronized, as well as to feed security or notification applications.
Internet of Things	The explosion in the number of smart devices and sensors has created many situations in which billions of data points are created by millions of geographically dispersed sensors. HPE Ezmeral Data Fabric Streams provides a reliable, global transport for these messages, enabling you to perform analytics both at the source and at a central location.

Replication

In addition to reliably delivering messages to applications within a single data center, HPE Ezmeral Data Fabric Streams can continuously replicate data between multiple clusters, delivering messages globally. Like other data-fabric services, HPE Ezmeral Data Fabric Streams has a distributed, scale-out design, allowing it to scale to billions of messages per second, millions of topics, and millions of producer and consumer applications.

last-updated: Jun 06, 2024

Server and Client Libraries

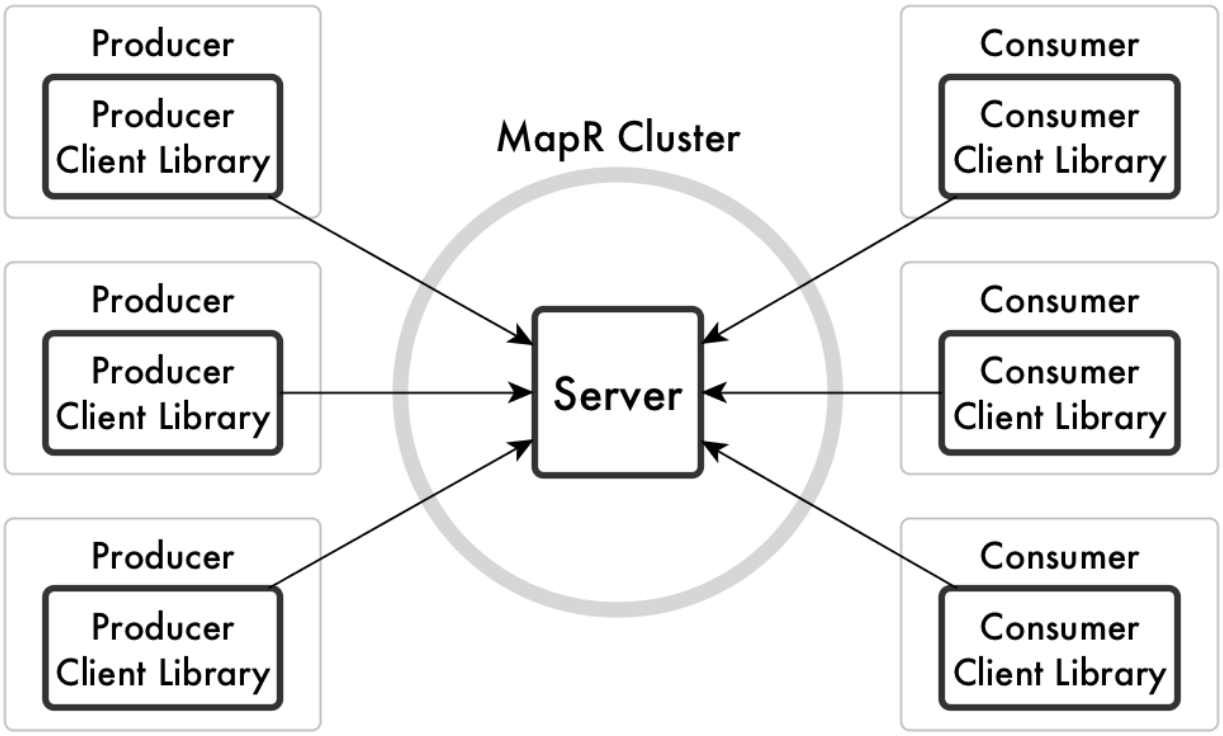

Figure 5: The relationship of the HPE Ezmeral Data Fabric Streams server to producers, consumers, and client libraries

Server	The server manages streams, topics, and partitions and handles requests from the producer client library and the consumer client library.
Producer client library	This client side library which is part of the producer process receives the messages that are sent by producers, buffers the messages, and sends them to the server, which then publishes the messages and sends the client acknowledgements.
Consumer client library	This client side library which is part of the consumer process receives requests from consumers to poll subscriptions for unread messages, reads messages from topic partitions, and sends messages to consumers.

Stream Design

Streams are created in volumes and contain topics, which in turn, contain messages. Security, replication, retention, and compression policies are applied at the stream-level.

When designing the architecture, take in account the following factors:

- Security Permissions (using access-control expressions)

  Security permissions are set at the stream-level and, subsequently, topics inherit the stream permissions. See Stream Security on page 803 for more information.

- Data Replication

  HPE Ezmeral Data Fabric Streams streams can be replicated to other streams in the same or different data-fabric clusters. For example, you can create a backup copy of a stream so that producers and consumers fail over to the backup if the original stream goes offline. See Stream Replication on page 795

- Data Retention

  The time-to-live of a message is the elapse time (in seconds) between the publication of a message in a topic in this stream and the expiration of that message. See Time-to-Live for Messages on page 776 for more information.

- Data Compression

  Topic messages can be sent to the server compressed. When compression is implemented, the messages are stored compressed, replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. See Managing Compression on page 1327 for more information.

Pollution Monitor Example

Suppose that you plan to create the stream `pollution_monitors` to collect various measurements about pollution levels in European cities. However, during a planning session, the representative from Amsterdam says that her country wants to analyze the data for its cities and would like your company to replicate the data to its own data-fabric cluster, where its own consumers can read the replicated messages.

In this scenario, you might do the following:

- Create a stream dedicated to the Netherland's pollution data or even for every country you are monitoring. For example, create streams named `pollution_monitors_netherlands`, `pollution_monitors_sweden`, `pollution_monitors_france`, and so on.
- Within each stream, create topics for each city in that county. For example, create a topic named `amsterdam` that contains data from Amsterdam's pollution sensors.
- Since, in this scenario, the Amsterdam representative also requested stream replication to their own data-fabric cluster, you would set up stream replication from your data-fabric cluster to Amsterdam's data-fabric cluster. See Managing Stream Replication on page 1501 for information about setting up and managing replication.

Alternatively, consider that the Netherlands did not request replication to their own data-fabric cluster. However, you want to restrict access to the pollution data where consumers could read only pollution data for their respective country.

In this scenario, you might do the following:

- Create streams for each country.
- Create topics for each city in that country.
- Set each stream's `consumeperm` permission for consumers associated with that country. See Stream Security on page 803 for more information about security permissions used with HPE Ezmeral Data Fabric Streams streams. For general information about access-control expressions, see ACE Syntax on page 1855.

Stream Topics

Topics are created in streams and contain logical collections of messages. These collections of messages are published to partitions in the topic.

Using HPE Ezmeral Data Fabric Streams with file system and HPE Ezmeral Data Fabric Database in the Data Fabric, enables organizations to create a centralized, secure data lake that unifies files, database tables, and message topics.

NOTE: Topics inherit security permissions, time-to-live data retention, and data compression policies at the stream-level.

You can design topic usage in a variety of ways. For example, you might have an application that monitors the logs for mission-critical software. Your monitoring application could send informational messages to a topic named `info`, warning messages to a topic named `warnings`, and error messages to a topic named `errors`. Different downstream applications might monitor each topic.

You can manage topics for different scenarios:

- Set security policies that apply all of the topics in that stream. Security policies are set at the stream-level. See Stream Security on page 803 for more information.
- Set a default number of partitions for each new topic that is created in the stream. The default number partitions is set at the stream-level, however, individual topics can override the default. See Topic Partitions on page 773 for more information.
- Set a time-to-live for messages in every topic in the stream. Every message in every topic in a stream expires after a duration of time, unless you set the time-to-live to 0, meaning messages never expire. Time-to-live is set at the stream-level. See Time-to-Live for Messages on page 776 for more information.

Restrictions

- After a topic is created in a stream, it is not possible to move that topic to a different stream.

  For example, suppose you create the topic `structural_integrity_sensors_us_western_region`, one of a number of topics that collect data from sensors that keep watch over various measurements for bridges, buildings, and other structures. However, you have mistakenly created the topic in the stream `ventilation_systems` instead of the stream `structural_integrity_sensors`.

  NOTE: There is no command that will move a topic from its current stream to a different stream.

  To rectify this mistake:

  - You must delete the topic and recreate it in the other stream.
  - Any producers that published messages to the topic and any consumers that read messages from the topic must be modified to point to the new location of the topic. This is because producers and consumers refer to topics with a combination of stream name and topic name.
- Only the following characters are allowed for stream topic names:
  - Alphanumeric characters
  - Period, underscore, and dash
- When producing or consuming stream topic messages, you must specify the stream's path and name along with the topic name in the following manner:

  ```
  /<stream name>:<topic name>
  ```

  NOTE: If a topic is specified but the stream's path and name is not, depending on the application's programming language, you might get an error or nothing. If nothing happens and you are using Java, the assumption is that you are publishing to Apache Kafka.

last-updated: Jun 06, 2024

Topic Partitions

Partitions, which exist within topics, are parallel, ordered, immutable sequences of messages that are continually appended to.

Topics can contain multiple partitions, which make topics scalable by spreading the load for a topic across multiple servers.

Downstream applications that read messages can read from multiple partitions within a topic for faster performance than would be possible if they read from a single partition per topic. Downstream applications can also scale by having separate instances read from separate partitions.

When creating or editing a stream, a default number of partitions can be specified for that stream's topics. Topics inherit the stream's partition default. However, topics can also override the stream's partition default by setting the number of partitions to be used.

Performance

The default number of partitions for data-fabric streams and topics can impact performance. Depending on the volume of messages being published to a topic, the default number of partitions might be increased for efficient consumption.

When there is a high volume of messages being published to a topic:

- Multiple consumers, in consumer groups, reading from multiple partitions are handled more efficiently.
- Individual consumers each reading from a single partition are handled less efficiently.

Reference

The following lists topics that have more detailed information.

- See the maprcli stream create on page 2368 for information about creating streams with the `-defaultpartitions` parameter.
- See the maprcli stream edit on page 2375 for information about editing streams with the `-defaultpartitions` parameter.
- See the maprcli stream topic create on page 2391 for information about creating topics with the `-partitions` parameter.
- See the maprcli stream topic edit on page 2394 for information about modifying topics with the `-partitions` parameter.
- See the maprcli stream topic info on page 2395 for information about topic data including the `-partitions` parameter.
- See the HPE Ezmeral Data Fabric Streams Java API Library on page 3548 for the methods used to create and edit streams and to create and edit topics.

Topic Creation

Topics are created in streams and contain logical collections of messages. They can be created either automatically through your producer application or manually through the Control System or the `maprcli` commands.

Automatic Creation

If the topic does not already exist, a topic is created automatically when a producer first publishes a message to it. This is the default behavior.

For example, you created the stream **anonymous_usage** that you intend to use to collect data about the usage of a software application that is soon to be released. However, you did not create any stream topics because the topics were not known at the time. After the software is released to the public, at some point, a

last-updated: Jun 06, 2024

producer application starts publishing messages to a topic that is created based on the range within which the producer's IP address falls. At another point in time, another producer application starts publishing messages to a topic based on a different range of IP addresses. Eventually, the stream contains a number of topics for different IP address ranges.

NOTE: Automatic creation of topics can be turned off by setting the `autocreate` parameter to **false** either when creating the stream or by editing the stream. See the `maprcli` stream create on page 2368 or stream edit on page 2375 command for more information. If you turn off automatic creation, you must manually create the stream topic, otherwise, the publishing of a message fails.

Manual Creation
To create topics manually, use either the Control System or the `maprcli` commands. See Administering Streams on page 1488 for information about managing HPE Ezmeral Data Fabric Streams streams, topics and replication. See the stream topic create on page 2391 command for specific information about creating stream topics with the `maprcli` command.

For example, you created a stream called **systemMetrics** that you intend to use to collect operational metrics from systems in your enterprise. You did create several topics based on system, location, company department, project, or some other criterion. In this case, you could create topics in advance because they were pre-planned.

NOTE: When you manually create a topic, you can have the option of customizing the number of topic partitions used, otherwise, the default number of partitions is inherited from the stream.

Topic Messages
Messages are key/value pairs, where keys are optional. The values contain the data payload, which can be text, images, video files, or any other types of data.

Messages are published into *topic partitions* by Producer applications and are read by Consumer applications. All messages published to HPE Ezmeral Data Fabric Streams are persisted, allowing future consumers to “catch-up” on processing and analytics applications to process historical data. See Producers on page 782 and Consumers on page 786 for more information.

Offsets

Messages are assigned offsets when published to partitions. Offsets are monotonically increasing and are local to partitions. The order of messages is preserved within individual partitions, but not across partitions.

NOTE: In data-fabric version 6.0 and later, the message offset in a partition starts from zero (0). If you are upgrading and did not enable the HPE Ezmeral Data Fabric Database/HPE Ezmeral Data Fabric Streams feature **mfs.feature.db.streams.v6.support**, the message offset in a partition starts from one (1).

Logical Schema of Messages
Each message has the same logical schema: _id, topic, partition, offset, timestamp, producer, key, and value.

As the logical schema of each message is the same, analytics applications can run queries on these fields. See HPE Ezmeral Data Fabric Streams Java API Library on page 3548 for information about querying messages and mapr streamanalyzer on page 5532 for a sample application used to query and count messages in topics.

```
{
          "_id":<STRING>,
          "topic":<STRING>,
          "partition":<SHORT>,
          "offset":<LONG>,
          "timestamp":<LONG>,
          "producer":<VARCHAR>,
```

```
            "key":<BINARY>,
            "value":<VARBINARY>
            }
```

Field	Description
`_id`	A STRING value that represents the ID of the topic in which the message is located.
`topic`	A STRING value that represents the name of the topic in which the message is located.
`partition`	A SHORT value that represents the index of the partition in the topic.
`offset`	A LONG value that represents the position of the message within a partition.
`timestamp`	A LONG value that represents the date and time of the message. As of data-fabric 6.0.1, HPE Ezmeral Data Fabric Streams supports an event-time timestamp. The timestamp type can be either `createtime` (default) or `logappendtime`. A `createtime` value (default) is the time defined by the user or application (when creating the message). If user or application does not define this value (or passes null), the client uses the current system timestamp. A `logappendtime` value is the time when the message (log) was appended to the server. **TIP:** Because each message is automatically produced into a topic-partition with an event-time timestamp as part of the message record, this allows the Consumer to seek based on the timestamp.
`producer`	A VARCHAR value that represents the value of the `client.id` configuration parameter for the producer that published the message. HPE Ezmeral Data Fabric Streams does not require a value for this configuration parameter, so the value for this field could be empty.
`key`	A BINARY value that represents the key of the message. HPE Ezmeral Data Fabric Streams does not require each message to have a key, so this value could be empty. The configuration parameter `key.serializer` for the producer that published the message specifies the means by which the key was serialized.
`value`	A VARBINARY value that represents the value of the message. The configuration parameter `value.serializer` for the producer that published the message specifies the means by which the value was serialized.

Time-to-Live for Messages

The time-to-live (TTL) for messages means that messages persist in the partitions of a stream topic for a specific time period. During that time, messages can be read or re-read by consumers. Once the TTL for a message expires, the message is marked for deletion.

Setting TTL for Message

Set the TTL for topic messages when you create or edit a stream. Since the TTL setting is specified at the stream-level, all messages in all topics associated with the stream will have the same TTL. The default TTL is 604,800 seconds (7 days).

Deleting Expired Messages

Whenever there are any consumer or producer operations on any stream tablet, the partitions in that tablet qualify for purge only if

- it has been more than 24 hours since the last purge on this tablet and,
- more than TTL/10 secs have expired since the last purge on this tablet and,
- reclaimed disk space percentage at the tablet partition level is greater than or equal to 10.

For example, if the reclaimed disk space at the tablet partition level is greater than or equal to 10% and:

- If the TTL is set to 24 hours, the expired messages are deleted once every 24 hours.
- If the TTL is set to 7 days (168 hours, which is the default), the expired messages are deleted once every 24 hours because 24 is greater than 168/10.
- If the TTL is set to 20 days (480 hours), the expired messages are deleted once every 48 hours because 48 is greater than 24.

ATTENTION: The messages from *active* streams that have an expired TTL are deleted using the aforementioned mechanism. Deleted messages with an expired TTL from *idle* streams are not purged until producer or consumer operations are performed on such streams.

You must monitor disk space utilization and manually delete messages from streams, as needed, to reclaim disk space.

To manually delete expired messages, run the `maprcli` command stream purge on page 2379.

Life of a Message

To show how the HPE Ezmeral Data Fabric Streams concepts fit together, here is an example of the flow of one message from a producer to a consumer.

The Setup

Suppose that you are using HPE Ezmeral Data Fabric Streams as part of a system to monitor traffic in San Francisco. Your producers are sensors in streets, freeways, bridges, overpasses, and other infrastructure,

last-updated: Jun 06, 2024

as well as sensors reporting the weather in many different locations. Your consumers are various analytical and reporting tools.

In a volume in a data-fabric cluster, you create the stream `/somepath/traffic_monitoring`. In that stream, you create the topics `traffic`, `infrastructure`, and `weather_conditions`.

Of all of the sensors (producers) that your system uses to monitor traffic, let us choose a sensor that is under the pavement of Market Street and follow a message that it generates. We will follow a message that is generated by this sensor and published in the `traffic` topic.

Suppose that, when you created this topic, you created several partitions within it to help spread the load among the different nodes in your data-fabric cluster and to help improve the performance of your consumers. For simplicity, we will assume that the `traffic` topic has only one partition.

A Message Enters the System

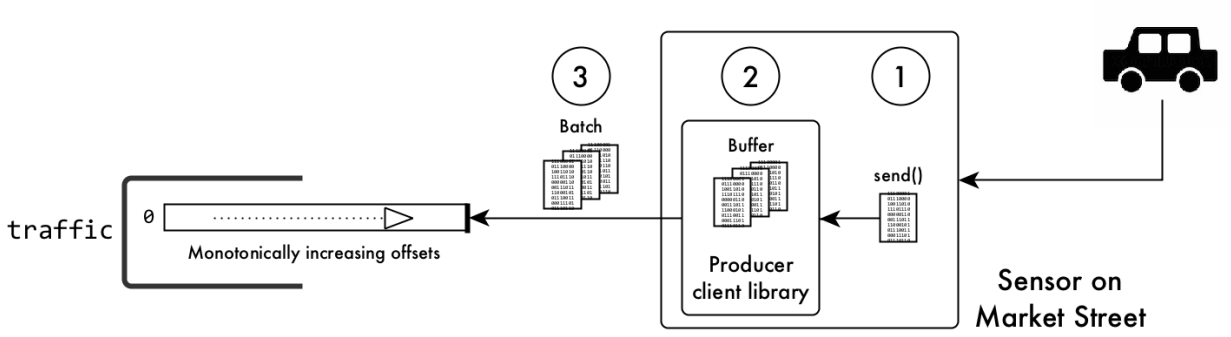

Figure 6: A car runs over a sensor, triggering the sending of a message

1. A car, one of hundreds on Market Street in morning rush-hour traffic, runs over the sensor. This action triggers the sensor to send a message to a HPE Ezmeral Data Fabric Streams producer client library.

   NOTE: This message might list geospatial coordinates, time, date, direction, weight, distance between front and rear wheels, and more. HPE Ezmeral Data Fabric Streams does not help you decide which data to collect.

2. The client buffers the message.

3. When the client has a large number of messages buffered (because other cars have subsequently triggered the sensor) or after an interval of time has expired, the client batches and sends the messages in the buffer. The message that we are following is published in the partition along with the rest of the messages in the batch. When the message is published, the HPE Ezmeral Data Fabric Streams server assigns it the offset 001030 (which is only an example offset; real offsets are more sophisticated). These messages being the most recent to be published, are written to the head of the partition.

   For a moment, suppose that this example used more than one partition. In that case, the sensor could influence how the HPE Ezmeral Data Fabric Streams server determines which messages go to which partition. In the example that we are following, the sensor could include a key with each message. The HPE Ezmeral Data Fabric Streams server would hash the key to determine the partition to place the messages received from the sensor. More information about how partitions are selected if there are more than one in a topic is explained later in this documentation.

4. Each partition and all of its messages are replicated. The server owning the primary partition for the `traffic` topic assigns the offset 001030 to the message that we are following, and replicates the message to replica containers (replication rules are controlled at the volume level) within the data-fabric cluster.

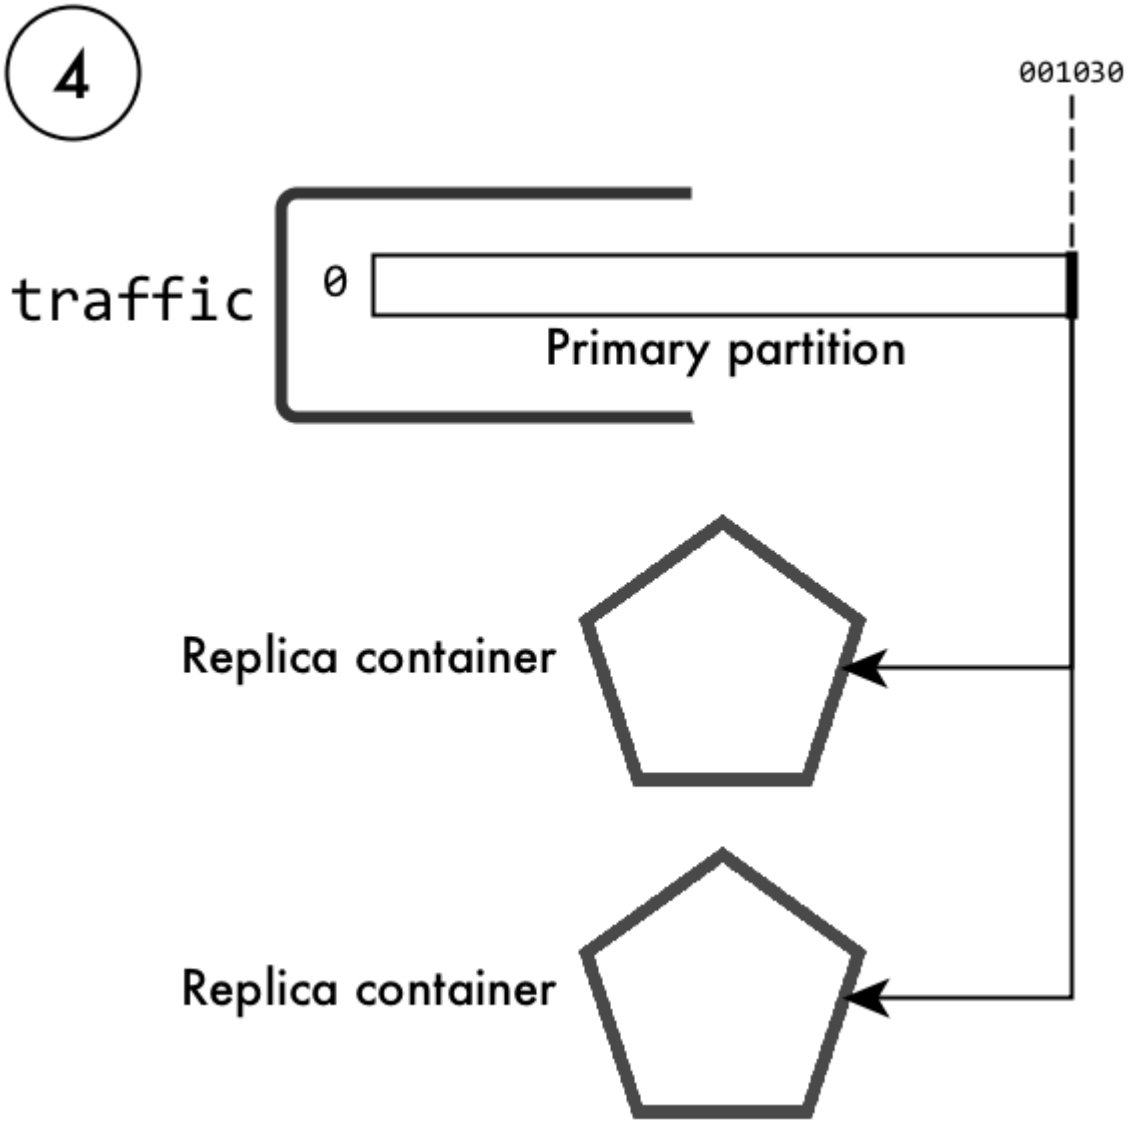

Figure 7: Replication of the partition in the topic `traffic`

5. The server acknowledges receiving the batch of messages and sends the offsets that it assigned to them.

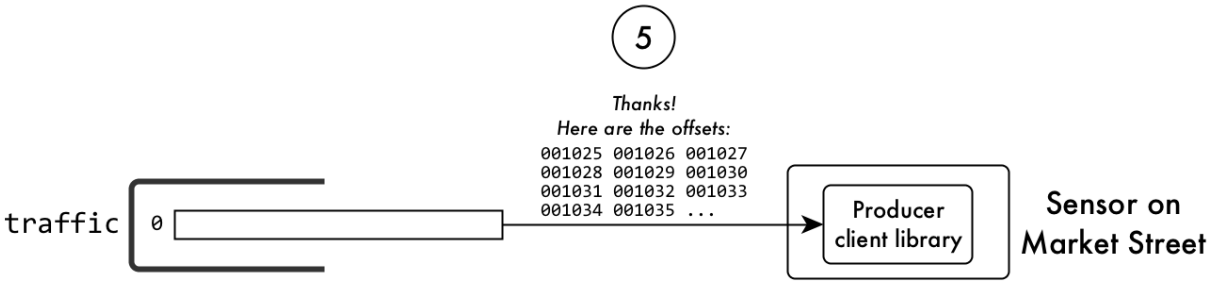

Figure 8: The server acknowledges receiving the messages

The Message is Read from the System

An analytics application (consumer) that correlates traffic volume with weather conditions is subscribed to the `traffic` topic. Many more consumers could subscribe to it, too.

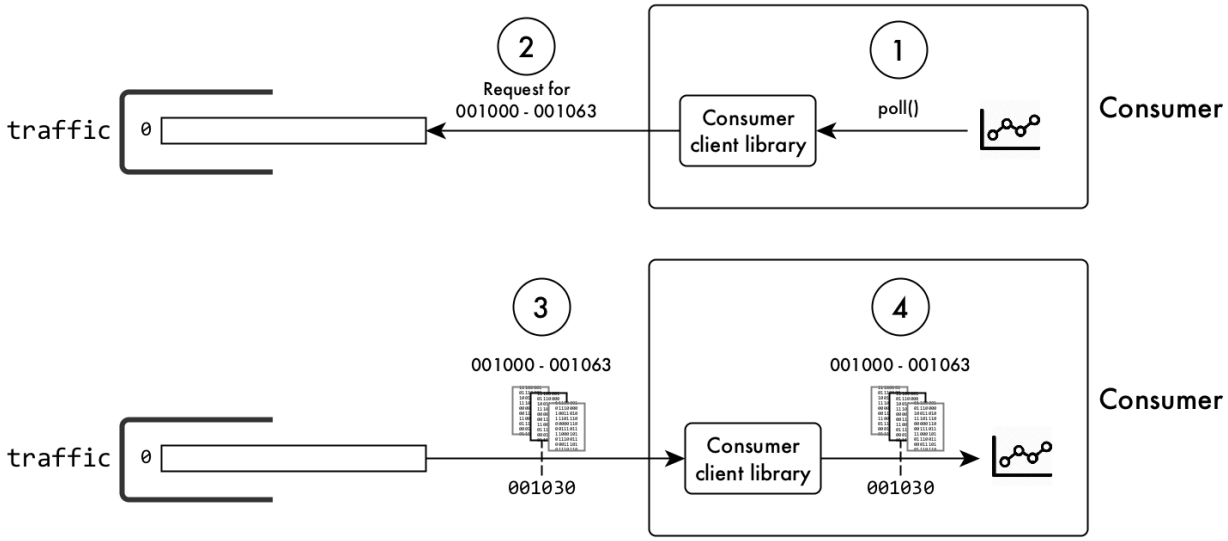

Figure 9: How messages are read

1. The application issues a request to the consumer client library to poll the topic for messages that the application has not yet read.
2. The client requests messages that are more recent than the consumer has yet read.
3. The primary partition returns multiple messages to the client. The originals of the messages remain on the partition and are available to other consumers.
4. The client passes the messages to the application, which extracts the data from them and processes it.
5. If more unread messages remain in the partition, the process repeats from step 2.

The Original Message is Deleted

Back in the cluster in San Francisco, messages are being continuously published to the partition in the `traffic` topic. Message 001030 is much further in the partition. More recent messages have filled the partition ahead of it.

When you created the stream, you set the time-to-live for messages to be six months. Message 001030 and messages around it have now been in the partition for that period, and are now expired. An automatic process eventually reclaims the disk space that message 001030 and the other expired messages are using.

last-updated: Jun 06, 2024

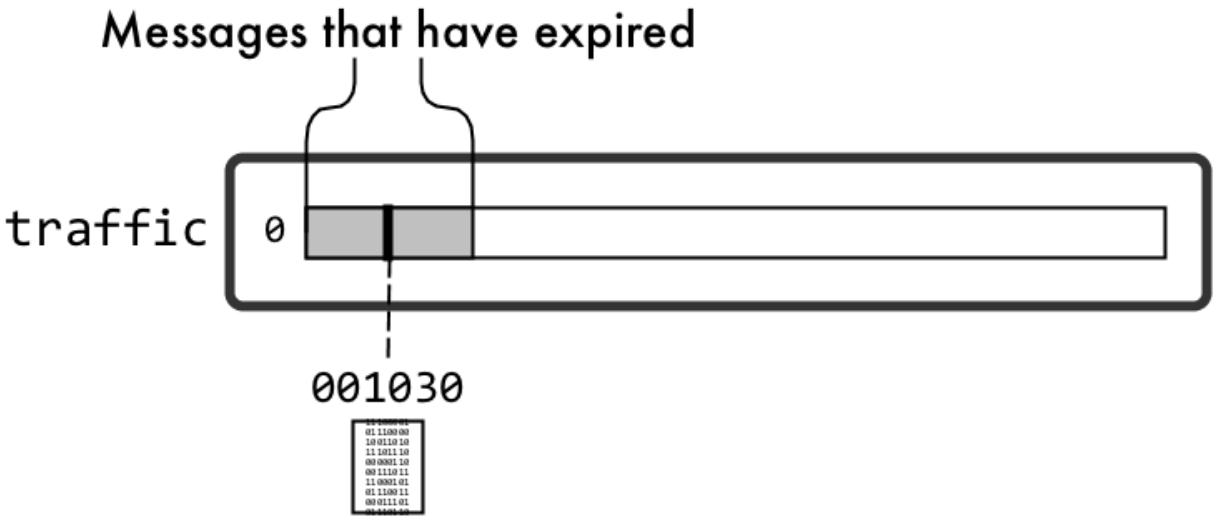

Figure 10: Messages to be deleted automatically

Log Compaction

Log compaction purges previous, older messages that were published to a topic-partition and retains the latest version of the record.

Log compaction reduces the size of a topic-partition by deleting older messages and retaining the last known value for each message key in a topic-partition. The `mincompactionlag` parameter provides a lower bound on how long each message remains prior to compaction and the `deleteretention` parameter provides a lower bound on how long a tombstone (a message with a null value) is retained. See the maprcli stream create on page 2368 and stream edit on page 2375 commands and Enabling Log Compaction on page 3556 for more information about these retention parameters.

NOTE: Log refers to the topic-partition pair. So when you are performing log compaction on the stream, you are compacting the stream and all the topic-partitions.

Log compaction is used for the following purposes:

- Application recovery time - Since log compaction retains the last known value, it is a full snapshot of the latest records. It is useful for restoring state after a crash or system failure.
- Storage space - This becomes noticeable when there is a high volume of messages.

Compaction Process

Log compaction is implemented by running a compaction process in the background that identifies duplicates, determines whether older messages exist, and purges older messages from the topic-partition.

The following diagram shows an initial message (published to a topic-partition) that is identified by the key-value pair, K1V1. When a subsequent message (K1V2) is published to the topic-partition, based on it's key-value pair, it is identified as a duplicate. The compactor then deletes the older message (K1V1) from the topic-partition.

Log compaction never re-orders messages, just deletes them. Any consumer reading from the start of the log sees at least the final state of all records in the order they were written. In addition, the offset for a message never changes.

Compaction and Gateways

The log compaction process uses a gateway that has an internal index and a compactor. The internal index tracks message key-value pairs. this allows duplicate messages in the topic-partition to be identified. Based on the identification of duplicate messages, the compactor runs the compaction process which purges the older message from the topic-partition. This process results in stream data being compacted.

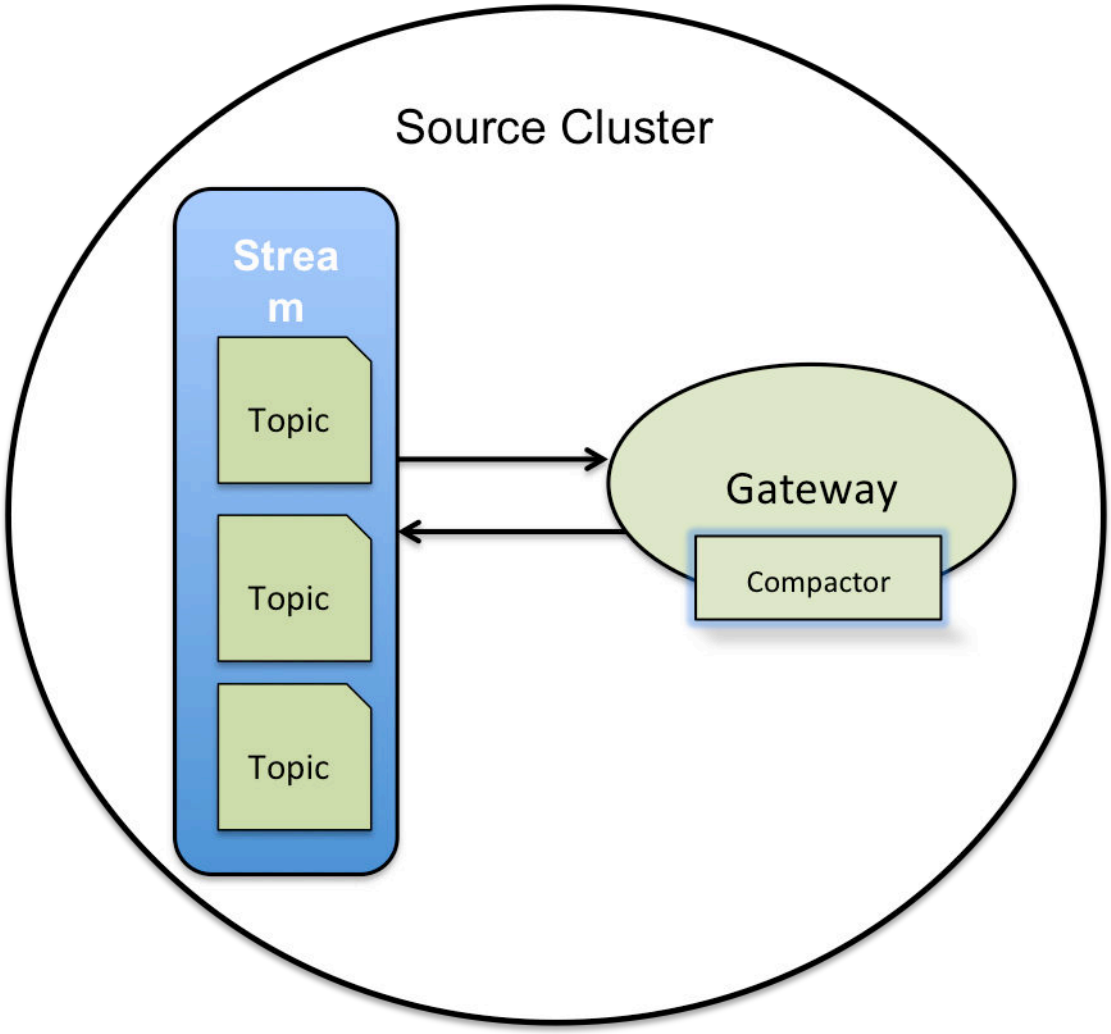

Figure 11: Log compaction with one gateway

The number of gateways impacts the compaction process, in that, increasing the number of gateways on the cluster improves the load distribution of the log compaction activity.

IMPORTANT: Log compaction requires a gateway to be installed on the same cluster as the data-fabric stream. See Preparing Clusters for Log Compaction on page 1514 for more information about implementing gateways for this purpose. For example, if you are manually installing or upgrading, you must install a data-fabric gateway locally.

Stream Replication

When a stream on a source cluster has both log compaction and replication enabled, the replica cluster does not automatically have log compaction enabled. You must explicitly enable log compaction on the replica cluster.

If a replica cluster has been upgraded and the stream data for a source cluster is compacted (that is, one or more messages have been deleted), then the source cluster replicates the compacted data to the replica cluster.

If a replica cluster has ***not*** been upgraded, the source cluster:

- Fails the replication.
- Automatically retries replication with an exponential backoff.
- Resumes replication when the replica cluster has been upgraded.

NOTE: The error message associated with the failed replication is displayed via the `maprcli stream replica status` command. This error requests that you upgrade the replica cluster.

Performance

Log compaction has a performance impact on other HPE Ezmeral Data Fabric Database and HPE Ezmeral Data Fabric Streams applications running on the system. If log compaction is enabled on a very active stream (with more than 100K messages per second), all HPE Ezmeral Data Fabric Database and HPE Ezmeral Data Fabric Streams applications running on the same cluster could see a drop in their performance (close to 2x).

NOTE: It is possible that the NODE_ALARM_TINY_BUCKET_FLUSH alarm may occur during high ingestion rates on source clusters with high topic-partition count. Under these circumstances, consider increasing the memory for file system.

For More Information

See the following topics for more information:

- maprcli stream create on page 2368 and stream edit on page 2375
- Preparing Clusters for Log Compaction on page 1514
- HPE Ezmeral Data Fabric Streams Java Applications on page 3546, HPE Ezmeral Data Fabric Streams Java API Library on page 3548, and Enabling Log Compaction on page 3556

Producers

Producers are data-generating applications, such as sensors in automobiles or activity loggers in servers. Producers create messages with the collected data and publish the messages to HPE Ezmeral Data Fabric Streams topics, specifically, to HPE Ezmeral Data Fabric Streams topic-partitions.

Permissions

Before a producer can publish to topics, the user ID running the producer needs these permissions:

- The `writeAce` permission on the volume where the streams are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1365.
- The `produceperm` permission on the streams where the topics are located. Users with the `adminperm` permission on those streams can grant the `produceperm` permission.

Producing Messages

Producers create messages about the collected data and send the collected data to a HPE Ezmeral Data Fabric Streams producer client library. In addition to the actual message, the producer specifies the topic that the message is intended for and an optional partition ID. The producer client buffers incoming messages and sends them (in batches) to the HPE Ezmeral Data Fabric Streams server.

NOTE: In case of server failure, the producer client automatically continues to retry sending messages.

ATTENTION: As of data-fabric 6.1, the HPE Ezmeral Data Fabric Streams API enforces a maximum of 4096 partitions for a topic. That is, when you create an application with the API, the maximum number of partitions is 4096. If you previously created an application with HPE Ezmeral Data Fabric Streams 6.0.1 API (or older) and you have upgraded, the original number of partitions can be used. For example, if you were using more than 4096 partitions in data-fabric 6.0.1 or earlier, you will be able to continue with the same number of partitions after upgrading.

Event-time Timestamp

As of data-fabric 6.0.1, HPE Ezmeral Data Fabric Streams supports an event-time timestamp. The timestamp type can be either `createtime` (default) or `logappendtime`. See the `maprcli` stream create on page 2368 and stream edit on page 2375 for more information about these parameters.

TIP: Since each message is automatically published into a topic-partition with an event-time timestamp as part of the message record, this allows the Consumer application to seek records based on the timestamp.

Idempotent (exactly once) Producers

An "exactly-once" message delivery semantic produces messages without duplication. Each message is delivered once and only once. Exactly-once is insured by uniquely identifying a group of messages that are atomically persisted. Exactly-once message delivery is set with the producer idempotence option. See Modes of Publishing on page 784 for more information.

The following failure scenarios are addressed with idempotence:

- The stream processor might take input from multiple source topics and the ordering across these source topics is not deterministic across multiple runs. So if you re-run your stream processor that takes input from multiple source topics, it might produce different results.
- The stream processor might produce output to multiple destination topics. If the producer cannot do an atomic write across multiple topics, then the producer output can be incorrect if writes to some (but not all) partitions fail.
- The stream processor might aggregate or join data across multiple inputs. If one of the instances of the stream processor fails, then you need to be able to rollback the state materialized by that instance of the stream processor. On restarting the instance, you also need to be able to resume processing and recreate its state.
- The stream processor might look up enriching information in an external database or by calling out to a service that is updated out of band. By depending on an external service, the stream processor can be fundamentally non-deterministic. For example, if the external service changes its internal state between two runs of the stream processor, it can lead to incorrect results downstream.

How Messages are Published
To publish a message, a producer sends a record to the producer client library, which batches the records before sending them to the server.

The producer client library sends the records to the server when any of the following conditions are met:

- The producer client library has batched enough messages to make an efficient remote procedure call (RPC) to the server.
- A message has been queued for the amount of time that is specified for the `streams.buffer.max.time.ms` configuration parameter.

  For the Java client, the default interval for flushes is 3000 milliseconds. For clients based on librdkafka (for example, C, Python, and C#), the default interval for flushes is 0 (zero) milliseconds.
- The producer client library has batched messages beyond the value of the `buffer.memory` configuration parameter.
- The application explicitly flushes messages.

  TIP: The default number of threads used for flushing messages is 64. In most cases, this number provides excellent performance. However, you can adjust this number by setting a value for the `fs.mapr.threads` parameter in the `core-site.xml` file on your client node.

Modes of Publishing
Describes different modes of publishing.

When publishing a message, a producer sends a record to the producer client library. The producer client library batches messages into multiple publish requests which are sent to the HPE Ezmeral Data Fabric Streams server.

At Least Once

The default message delivery semantics is "at-least-one". At-least-once means that the message delivery guarantees that a message is published at least once to the HPE Ezmeral Data Fabric Streams server. Messages are never lost but may be re-delivered.

Exactly Once

An "exactly once" message delivery semantics produces messages without duplication. Each message is delivered once and only once. Exactly once is insured by uniquely identifying a group of messages that are atomically persisted. Exactly once message delivery is set with the producer `idempotence` option.

NOTE: Exactly-once message deliver semantics is enabled by setting the producer configurable option, `enable.idempotence` to **true**. By supporting an idempotent producer, retries no longer introduce duplicates. See Enabling an Idempotent Producer on page 3556 for more information.

The following unique identifiers are associated with each message:

- Producer ID - A unique identifier is generated internally for each client and group of messages that are atomically persisted.

  As a minimum, the ID is a unique ID for a given stream-topic-partition. Producer IDs expire if a producer ID is inactive for a period of time. The default Producer ID expiration is 7 days. At that point, a new Producer ID is requested once the Producer ID is expired. To change the expiration date, see the `pidexpirysecs` parameter in `maprcli` stream create on page 2368 and stream edit on page 2375 for more information.

- Sequence Number - A number that is monotonically incremented on every produced group of messages for the given Producer ID, assigned when received, and generated internally.

NOTE: If the producer `idempotence` option, is not set to **true**, then "at least once" message delivery semantics applies.

If the client resends a message after the producer ID has expired, then `UnknownProducerIdException` is thrown.

For example:

- If message1 from clientA is sent to a stream-topic-partition0 and 7 days go by, the Producer ID expires.
- Then, if clientA sends another message that has the same data to the same stream-topic-partition (stream-topic-partition0), then `UnknownProducerIdException` is thrown because the Producer ID has expired..

NOTE: With the alternative "at least once" message delivery, in some failure scenarios, a message can be produced more than once for a single send call. Common reasons for message duplication include network error or server failure. For example, if a network error occurs and the message has been processed and persisted by the server, if the client re-tries sending a message to a server node, then the result could be duplicate messages in the system.

Server Acknowledgements

By default, publishing requests for messages are sent without waiting for acknowledgement (ack) from the HPE Ezmeral Data Fabric Streams server.

The acknowledgement behavior is determined by the producer configuration parameter `streams.parallel.flushers.per.partition`, which defaults to **true**.

With an "at-least-once" message delivery, in some failure scenarios, a message can be produced more than once for a single send call. A common reason for message duplication is when a network error occurs, a client may retry sending a message to a server node. If the network error occurs after the message is processed and persisted by the server, it can lead to duplicate messages in the system.

Publishing without Ack	When publishing without ack (default), it is possible for messages to be published to the partitions out of order due to the presence of multiple network interface controllers, network errors, or retries. For example, suppose a producer is sending messages that are specifically for Partition 1. The producer client library buffers the messages and sends a batch to Partition 1. Meanwhile, the producer keeps sending messages for Partition 1 and the client

	continues to buffer them. The next time the producer client library has enough messages for Partition 1, the client sends another batch, irresepctive of whether or notHPE Ezmeral Data Fabric Streams server has acknowledged the previous batch.
Publishing with Ack	If you always want messages to arrive to partitions in the order in which they were sent, set the configuration parameter `streams.parallel.flushers.per.partition` to **false**. This causes the producer client library to wait for ack (acknowledgements) from the HPE Ezmeral Data Fabric Streams server before sending subsequent publish requests.

How Partitions are Chosen for Messages

Since the number of partitions in a topic can change over time, producers regularly refresh the information that they have about the topics that they know. This refresh interval is controlled by the `metadata.max.age.ms` configuration parameter.

Partitions of a topic are identified by their index number. For example, if a topic has four partitions, their IDs are 0, 1, 2, and 3.

Partitions are chosen for a message in the following ways:

- If the producer specifies a partition ID or if the StreamsPartitioner interface specifies one, the HPE Ezmeral Data Fabric Streams server publishes the message to the partition specified.
- If the producer does not specify a partition ID but provides a key, the HPE Ezmeral Data Fabric Streams server hashes the key and sends the message to the partition that corresponds to the hash.
- If neither a partition ID nor a key is specified, the HPE Ezmeral Data Fabric Streams server randomly chooses an initial partition and sends messages in a sticky round robin fashion. .

  For example, suppose that for topic `traffic_sensors`, the server chooses Partition 1. The server then accumulates enough messages for an RPC of optimal size and sends the batch of messages to Partition 1. The server then does the same with Partition 2, and so on, eventually returning to Partition 1.

Consumers

Consumers are applications that you create such as analytics applications, reporting tools, or enterprise dashboards.

Consumers use the HPE Ezmeral Data Fabric Streams APIs to request messages from the topics in which they are interested. If the server fails, consumer clients automatically retry requests continuously. A consumer client library sends unread messages, from which consumers extract data.

Consumers can run as separate processes on a single machine and as processes on different machines.

Before a consumer can read messages from topics, the user ID running the consumer needs these permissions:

- The `readAce` permission on the volume where the streams are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1365.
- The `consumeperm` permission on the streams where the topics are located. Users with the `adminperm` permission on those streams can grant the `consumeperm` permission.

Subscriptions

Consumers subscribe to topics. When a consumer subscribes to a topic or partition, it means that the consumer wants to receive messages from that topic or partition. For example, an analytics application might subscribe to the topics `rfids_productA`, `rfids_productB`, and more to track movement of products from factories to distribution centers. A reporting tool might subscribe to the topics `meters_NW`, `meters_SW`, and more to get a report of electricity usage in different geographic regions that a power company services.

A subscription is the list of the topics to which a consumer is subscribed.

Consumer Subscriptions

Consumers subscribe to topics. When a consumer subscribes to a topic or partition, it means that the consumer wants to receive messages from that topic or partition. A subscription is the list of the topics, specific partitions, or both to which a consumer is subscribed.

For example, an analytics application might subscribe to the topics `rfids_productA`, `rfids_productB`, and more to track movement of products from factories to distribution centers. A reporting tool might subscribe to the topics `meters_NW`, `meters_SW`, and more to get a report of electricity usage in different geographic regions that a power company services.

Consumers can subscribe to:

Topics

When a consumer subscribes to a topic, it reads messages from all of the partitions that are in the topic. The exception is when a consumer is part of a consumer group. Consumer groups and this exception are explained in Consumer Groups.

Consumers can subscribe to topics in two ways:

By name

Consumers specify the names of the topics to which they subscribe.

By regular expression

Consumers specify a regular expression and subscribe to all topics with names that match the regular expression.

The ability to use regular expressions is helpful when the `-autocreate` parameter for a stream is set to `true` and producers are allowed to create topics automatically at runtime.

To unsubscribe from topics to which you are subscribed with regular expressions, you must use the same regular expressions.

For example, suppose that you use this regular expression to subscribe to `topic0` and `topic1`:

```
topic[0-1]
```

last-updated: Jun 06, 2024

Next, you add `topic2`, `topic3`, and `topic4` to the subscription, as follows:

```
topic[0-4]
```

Trying subsequently to unsubscribe from, say, `topic0` has no effect. The consumer remains subscribed to it because `topic0` was subscribed to as part of a regular expression.

Trying to unsubscribe from `topic[0-1]` also has no effect because the regular expression `topic[0-4]` was used after `topic[0-1]`, and the latter is a superset of the former.

To unsubscribe from `topic0`, you have to follow these steps:

1. Unsubscribe from `topic[0-4]`. This step unsubscribes you from `topic2`, `topic3`, and `topic4`. You must follow this step because a) this regular expression was used last, and b) because it is a superset of `topic[0-1]`. The order in which regular expressions are used in subscriptions matters. If you were to unsubscribe from `topic[0-1]` first, you would still be subscribed to `topic[0-4]`.
2. Unsubscribe from `topic[0-1]`. This step unsubscribes you from `topic0` and `topic1`.

Partitions

Consumers can subscribe to individual partitions within topics. This is helpful when you want a consumer to read the messages published to a specific partition. For example, a producer might

publish messages for high-priority data to a specific partition for processing by a dedicated consumer.

When a consumer subscribes to individual partitions within a topic, the consumer does not receive messages from any of the other partitions in the topic.

Subscriptions to individual partitions can cause problems in consumer groups, as explained in the section Consumer Groups.

Consuming Messages
Describes the process by which consumers consume messages.

Consumers request the HPE Ezmeral Data Fabric Streams consumer client library to check whether any new messages have been published in the topics or partitions to which they are subscribed, or the partitions that they are assigned. Consumers can do this at any time.

If a minimum number of bytes worth of messages is waiting across a consumer's subscription, HPE Ezmeral Data Fabric Streams sends those messages to the consumer, up to a maximum number of bytes. You can configure this minimum and maximum in the configuration parameters for each consumer.

The HPE Ezmeral Data Fabric Streams consumer client library sends the consumer messages that have been published by producers but not yet flushed to disk. If a consumer is able to consume data at the rate at which a producer publishes messages, the consumer client library continuously sends messages to consumers from its memory, increasing the speed of throughput from producer to consumer.

Time-based Consumption

As of data-fabric 6.0.1, HPE Ezmeral Data Fabric Streams supports the consumption of messages based on the message's timestamp. When a consumer wants to search for messages based on a timestamp, the consumer provides the topic-partition and the timestamp, and then, HPE Ezmeral Data Fabric Streams locates the message and returns the offset for that message. The returned message offset corresponds to the *earliest* message in a topic-partition whose timestamp is *equal to* or *greater than* (>=) the consumer-provided timestamp.

For example, with the following topic-partition, if your consumer-provided timestamp is 1522195**205**, then **offset 1** would be returned because it is the *earliest* message with a timestamp that is greater than or equal to the consumer-provided timestamp. In this case, greater than (>).

```
topic:partition0
        offset 0: 1522195200
        offset 1: 1522195210
        offset 2: 1522195205
        offset 3: 1522195215
```

> **TIP:** The consumer-provided timestamp and the returned message offset is in seconds since a Epoch Unix timestamp is used. In this example, the consumer-provided timestamp is March 26th, 2018 @ 12:00:05am and the message offsets are timestamped March 28th @ 12:00:00, 12:00:010, 12:00:05, and 12:00:15 in that order.

Resources

For information about HPE Ezmeral Data Fabric Streams streams or topics, see:

- maprcli stream info on page 2378 for information about stream data.
- maprcli stream topic info on page 2395 for information about topic data.

Consumer Groups
Group consumers together by setting the same value for the `group.id` configuration parameter when you start each consumer.

For example, if you create three consumers and give each of them the group ID `clickstream_consumers`, together these consumers form the consumer group `clickstream_consumers`. HPE Ezmeral Data Fabric Streams does not generate IDs for consumer groups. You can create IDs that make sense for your purposes. You specify the group ID by using the `group.id` configuration parameter when you create a consumer. IDs are strings that can be up to 2457 bytes long.

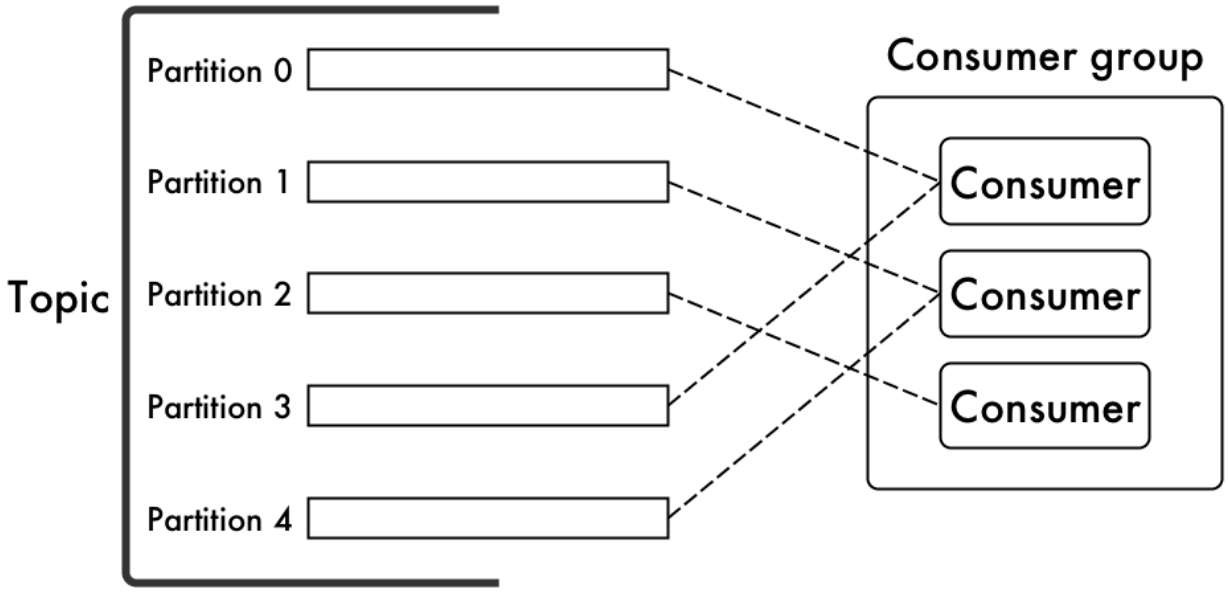
You can even create a consumer group that consists of only one consumer. In such a case, the unique ID that identifies the group would be shared with no other consumers.

The following are the benefits to creating consumer groups:

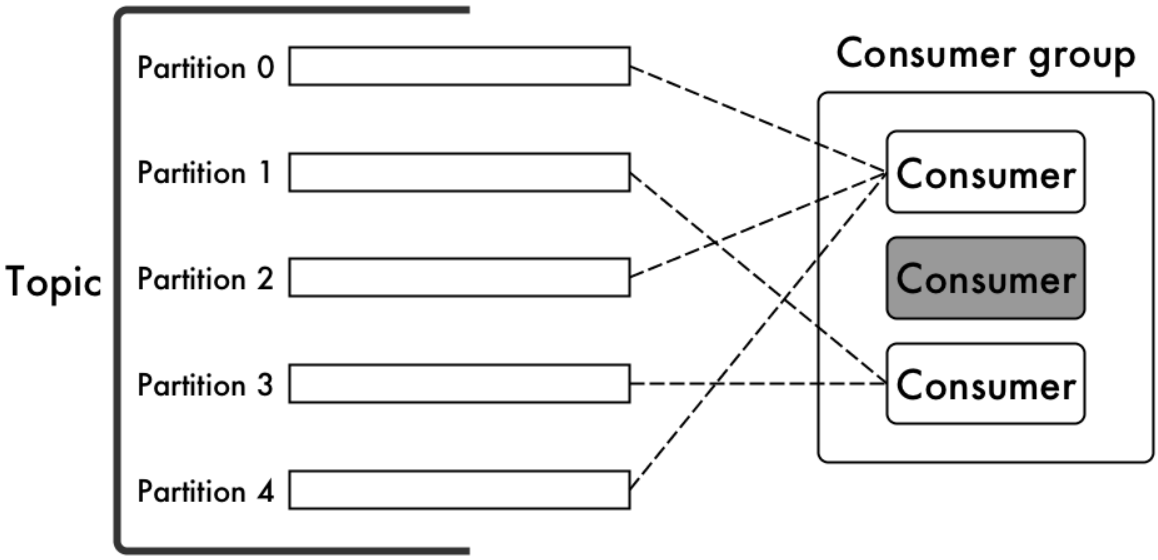
Parallelism when Consuming Messages
For parallelism when reading messages from topics, you can create consumer groups. These groups consist of consumers that are associated with an ID that you set for each of the participating consumers with the `group.id` configuration parameter. The partitions in each topic to which all of the consumers are subscribed, are assigned dynamically to the consumers in round-robin fashion.

These groups consist of consumers that are associated with an ID that you set for each of the participating consumers with the `group.id` configuration parameter. The partitions in each topic to which all of the consumers are subscribed, are assigned dynamically to the consumers in round-robin fashion.

For example, suppose that there are three consumers in a group and each consumer is subscribed to the same topic. There are five partitions in the topic. HPE Ezmeral Data Fabric Streams assigns each partition to a consumer, with two consumers both being assigned two partitions.



If one of the consumers goes offline, the partitions are reassigned dynamically among the remaining consumers in the group.



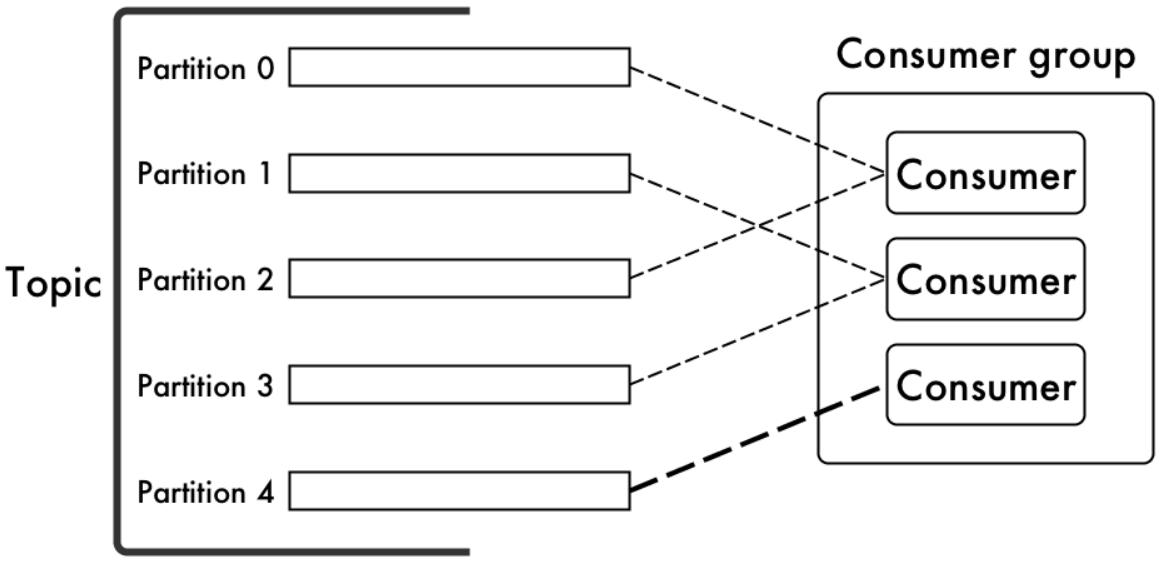
If the offline consumer comes back online or a different consumer is added to the group, again the partitions are redistributed among the consumers in the group.

This parallelism and dynamic reassignment is possible only when none of the consumers in a consumer group subscribe to individual partitions.

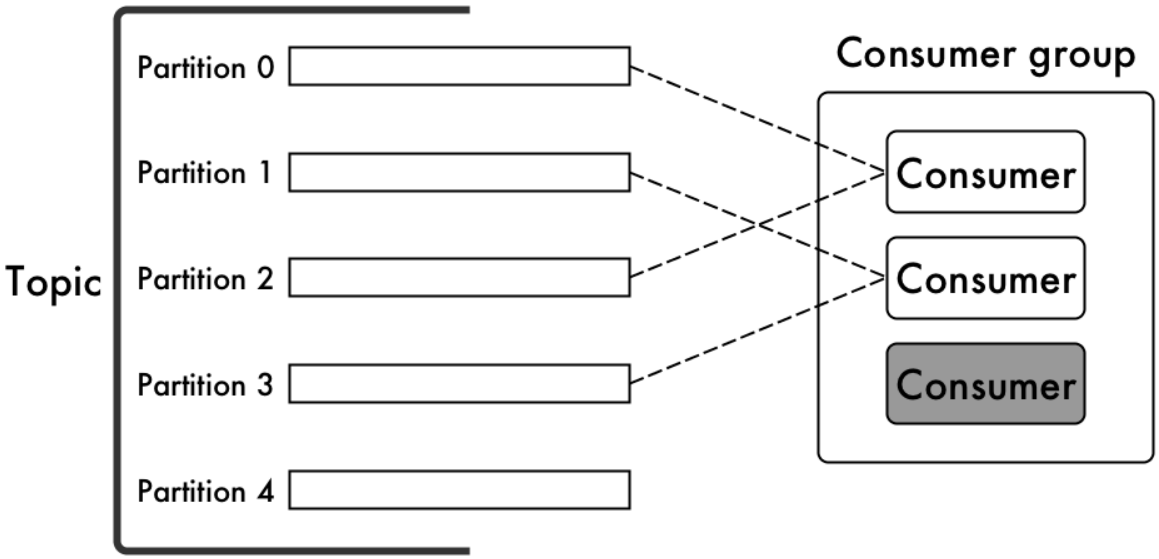
For example, suppose that from three consumers in a consumer group:

- Two subscribe to the same topic.
- One subscribes to a single partition within that topic.

If the topic has five partitions, HPE Ezmeral Data Fabric Streams assigns four of them via round robin to two of the consumers. Only the remaining partition is read from the third consumer.



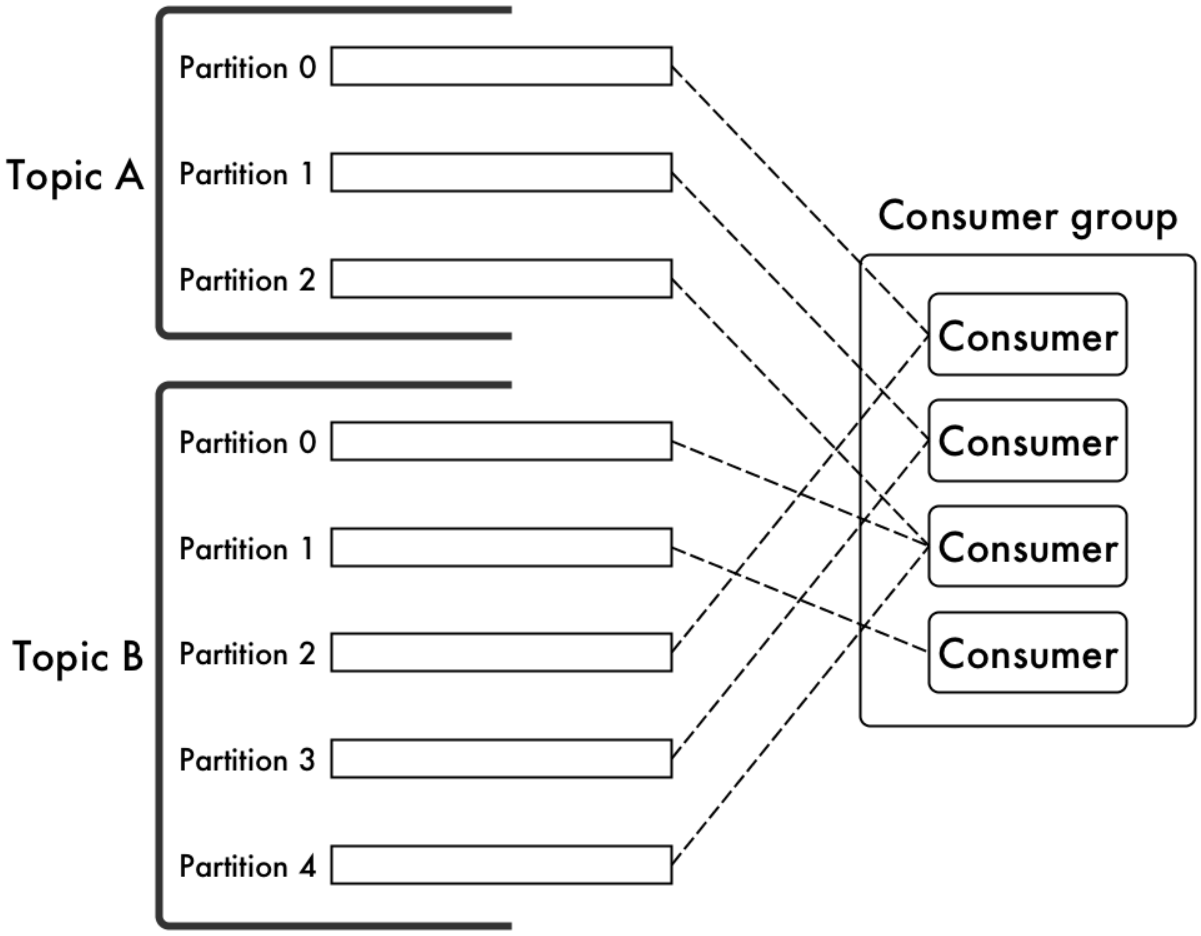
If that third consumer fails, HPE Ezmeral Data Fabric Streams does not reassign its partition to either of the other consumers.



Now that you understand how partitions are assigned when the number of partitions is equal to or greater than the number of consumers in a consumer group, you might be wondering what happens if the number of partitions in a topic is less than the number of consumers in a consumer group. The answer is simply that one or more consumers in the consumer group will not be assigned any partitions from the topic.

That does not necessarily mean those consumers will be idle. There could be other topics to which the consumer group is subscribed, and those consumers could be assigned partitions from those other topics.

For example, in this diagram there is a consumer group with four consumers. Topic A has only three partitions, and those are assigned to the first three consumers shown in the group. However, the fourth consumer is not idle. The consumer group also subscribes to Topic B, which has more partitions than there are consumers. Each of the consumers in the group is assigned at least one partition from Topic B.



Moreover, if a consumer that is assigned a partition from Topic A happens to fail, its partition will be reassigned to the fourth consumer.

Saving Cursor Position

The HPE Ezmeral Data Fabric Streams server uses cursors to keep track of the messages that consumers in consumer groups have read.

There is one cursor per partition per consumer group. There are two kinds of cursors: read cursors and committed cursors.

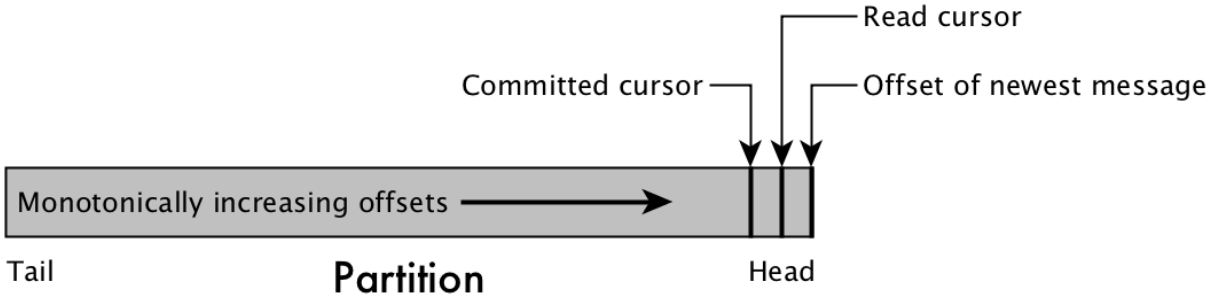


Figure 12: A topic partition and the cursors of a consumer group

A consumer's read cursor is the offset of the most recent message that HPE Ezmeral Data Fabric Streams has sent to a consumer from a partition.

Consumers that are part of a consumer group can save the current position of their read cursor. Consumers can do this either automatically or manually. The saved cursor is called a committed cursor because it indicates that the consumer has processed all messages in a partition up to and including the one with this offset.

There are two benefits to committing cursors:

Failover on consumer failure	One benefit is that if a consumer fails and HPE Ezmeral Data Fabric Streams reassigns the consumer's partitions to other consumers in a group, those consumers can start reading from the next offset after the committed cursor in each of those partitions.
Failover on cluster failure	When you backup a stream by replicating it to another cluster, committed cursors are also replicated. If the main cluster fails, consumers that are redirected to the standby copy of a stream can start reading from the next offset after committed cursors.
Read cursors	A consumer's read cursor is the offset of the most recent message that HPE Ezmeral Data Fabric Streams has sent to a consumer from a partition.
Committed cursors	Consumers that are part of a consumer group can save the current position of their read cursor. Consumers can do this either automatically or manually. The saved cursor is called a committed cursor because it indicates that the consumer has processed all messages in a partition up to and including the one with this offset.

How often a consumer should commit depends on how much read duplication you are willing to tolerate. The more often a consumer commits, the less read duplication with which the consumer must contend.

The length of time since the failed consumer last committed determines (together with the rate at which messages are published to its partitions) how many messages are read a second time. For example, suppose that the auto-commit interval is five seconds. A consumer saves its commit cursor and then fails after three seconds. During those three seconds, the consumer's read cursor has continued to move through the messages. When its partitions are reassigned to other consumers in the group, those consumers will read three seconds of messages that the failed consumer already read.

There are two ways of committing cursors:

Automatic commits	The HPE Ezmeral Data Fabric Streams server commits the cursors for a consumer that is in a consumer group based on the value of the `enable.auto.commit` configuration parameter. Set this parameter to `true` to enable auto-commit. The default value is `true`. The `auto.commit.interval.ms` configuration parameter determines the frequency of the commits in milliseconds. The default is value is 1000.
Manual commits	The Java API provides a method of committing cursors manually.

Consumer Failure and Recovery

When a consumer that is not associated with a consumer-group ID recovers from failure and comes back online, it can either start reading its partitions from the earliest offsets or from the latest offset. This choice is determined by the `auto.offset.reset` configuration parameter.

If the consumer reads from the earliest offset in a partition, which is the offset of the message that has been in the partition longest without being deleted because of the expiration of the time-to-live interval for the stream, it might re-read a large number of messages before reading messages that were published after it failed.

If the consumer reads from the latest offset in a partition, which is the offset of the most current message at the time the consumer requests new messages from HPE Ezmeral Data Fabric Streams, the consumer starts off up-to-date, but skips over the messages between its time of failure and the current time.

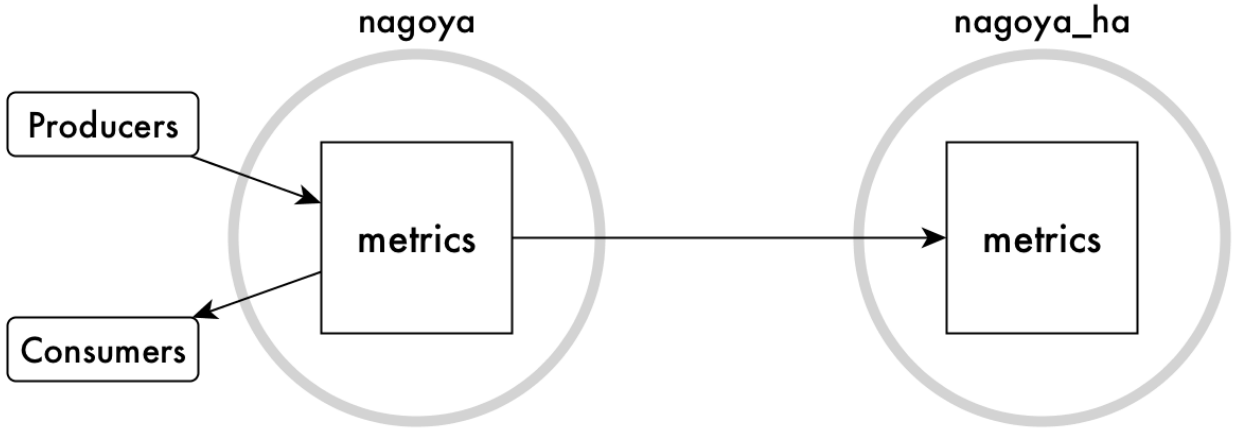
Stream Replication

You can replicate streams to other Data Fabric clusters worldwide, or to other streams within a Data Fabric cluster.

There are many scenarios in which replicating HPE Ezmeral Data Fabric Streams streams can be useful.

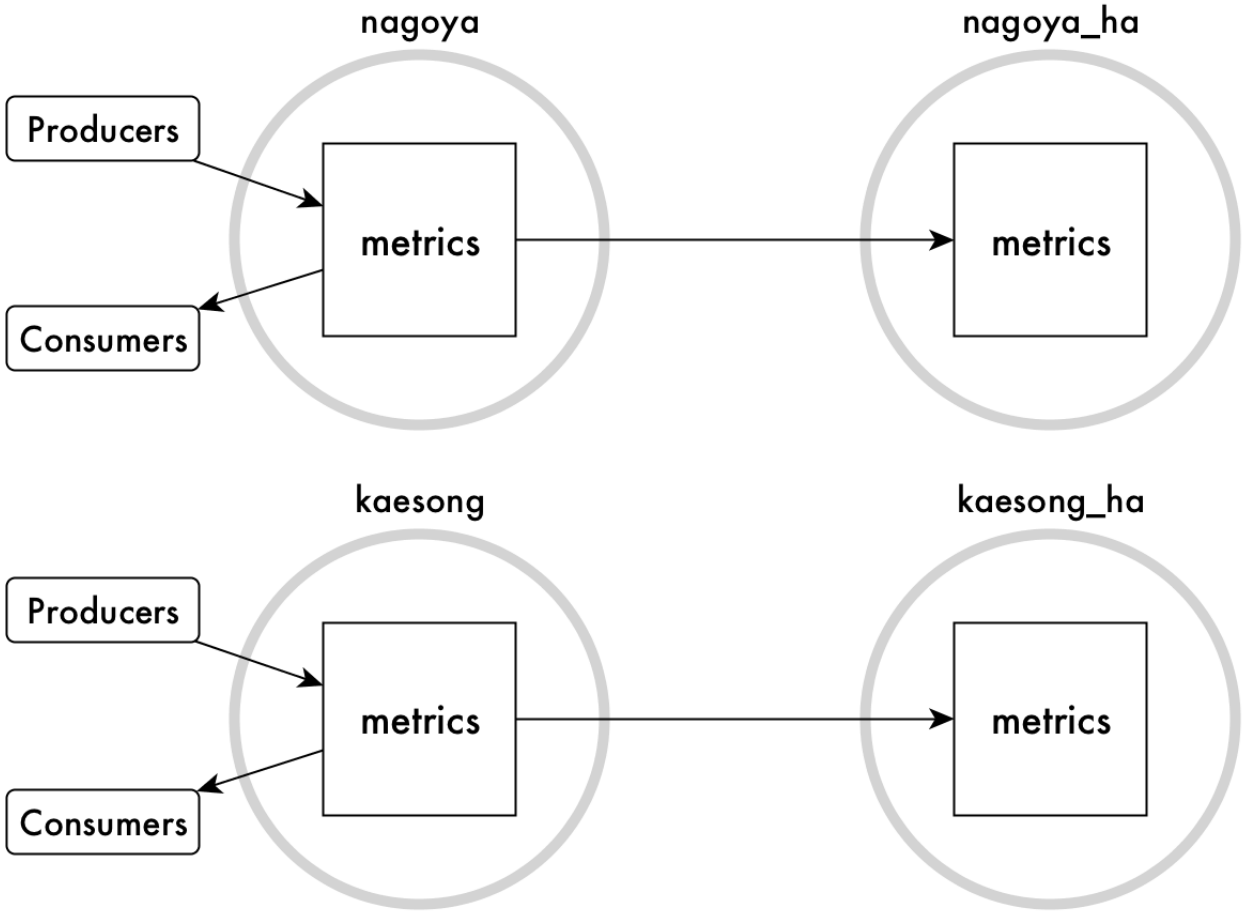
Basic Primary-Secondary Replication

For example, suppose that your company has a factory in Nagoya, and sensors in the equipment track different metrics. The sensors are producers publishing messages to a stream named `metrics`. The applications that use the collected metrics would read the messages from the stream, playing the role of consumers. With replication, the factory could create a stream in the `nagoya` cluster and maintain a backup of the stream in the `nagoya_ha` cluster.



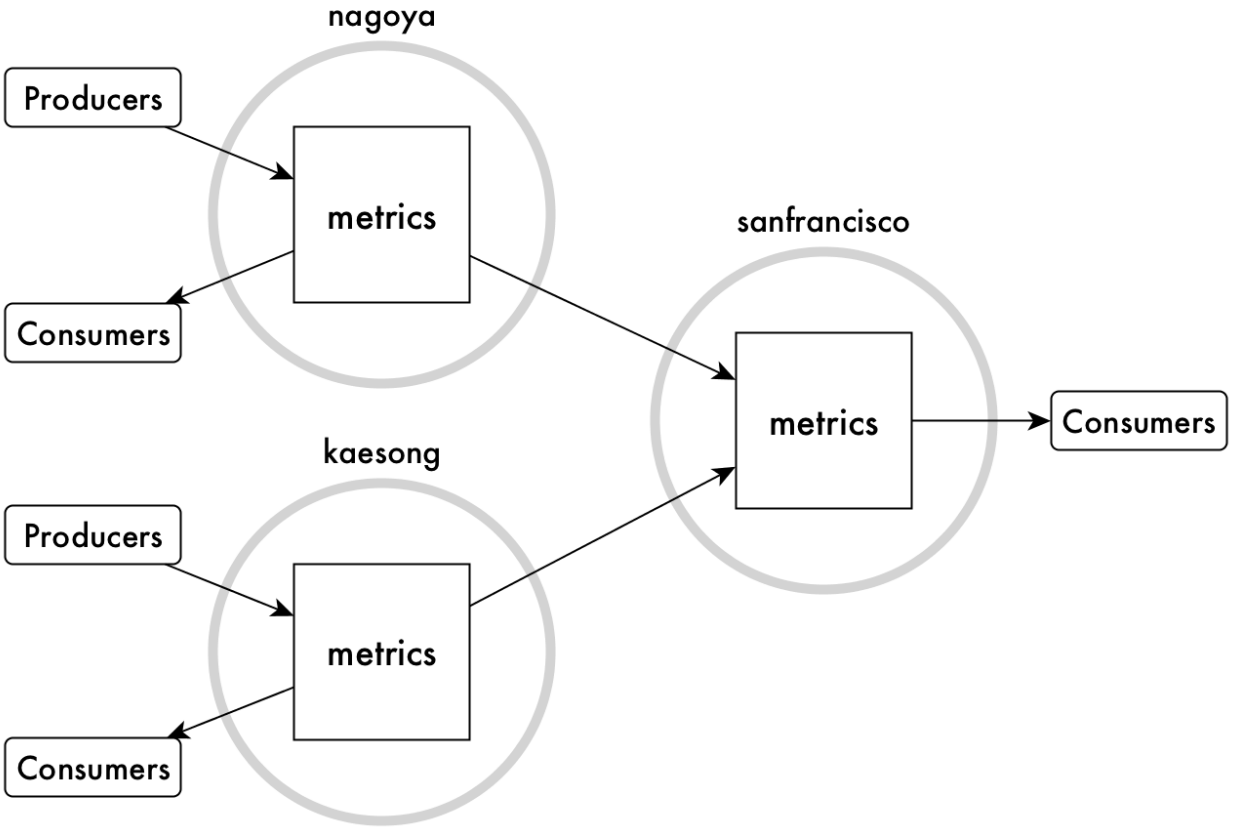
This type of replication is called *basic primary-secondary replication* because replication is in one direction only. The metrics stream in the `nagoya_ha` cluster is considered to be a *replica*. The original metrics stream is considered to be the *upstream source* for the replica. This type of replication is simple to set up with the command `maprcli stream replica autosetup`.

Suppose further that your company also has a factory in Kaesong that collects metrics from its equipment, analyzes the data, and replicates its own `metrics` streams to a backup.



Many-to-One Replication

Your company's headquarters are in San Francisco and you want data analysts there to analyze all data company-wide. You can replicate the two `metrics` streams that are in the your factories to the `metrics` stream in the `sanfrancisco` cluster. In this scenario, the replica is the `metrics` stream in the `sanfrancisco` cluster. This replica has two upstream sources: the `metrics` streams that are replicated from the two factories.



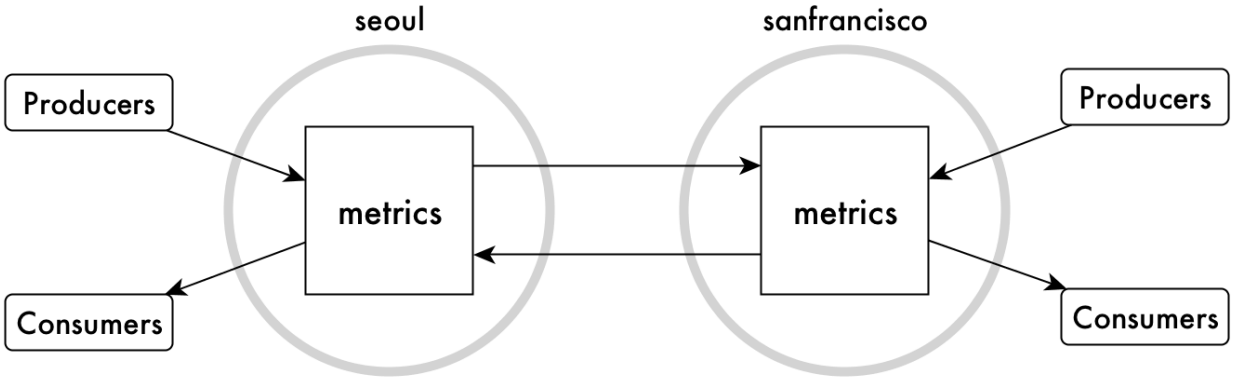
This type of replication, called *many-to-one replication*, requires that the topics in each stream have unique names, so that message offsets do not conflict. For example, suppose both factories have an assembly line named Line 2 and the topic in each factory's stream for collecting metrics from this line is named `line_2`. At some point, the Nagoya factory and the Kaesong factory both replicate messages that use the same offsets. Since offsets are replicated together with messages, messages can be overwritten in this case.

To avoid this type of problem, the sensors for Line 2 in the Nagoya factory might publish to a topic named `line_2_nagoya`, the sensors for Line 2 in the Kaesong factory might publish to a topic named `line_2_kaesong`, and so on. The consolidated stream in San Francisco would contain the topics `line_2_nagoya` and `line_2_kaesong`.

Multi-Master Replication

Another kind of of replication that can be useful is *multi-master replication*. You can use it when you need two streams, both to send updates to and receive updates from the other stream. Each stream is a replica and an upstream source. HPE Ezmeral Data Fabric Streams keeps both streams synchronized with each other. This type of replication is also simple to set up with the command `maprcli stream replica autosetup`.

last-updated: Jun 06, 2024



As with many-to-one replication, the names of the topics in each stream must be unique across both streams, so that offsets for messages do not conflict.

Updates are applied to replica streams by Data Fabric gateways. See Gateways and Stream Replication on page 801 for more information.

Modes of Stream Replication
You can replicate streams in one of two replication modes. You specify the mode per source-replica pair.

Asynchronous replication

In this replication mode, HPE Ezmeral Data Fabric Streams confirms to producers that messages are published after the messages are placed in partitions. Messages are replicated in the background. Therefore, the latency of message publishing is not affected by the time required for the network round trip between the source cluster and the destination cluster.

This type of replication is well-suited for clusters that are geographically separated in wide-area networks.

Asynchronous replication is the default replication mode.

Synchronous replication

In this replication mode, HPE Ezmeral Data Fabric Streams confirms to producers that messages have been placed in partitions only after the messages are sent to a gateway in the destination cluster.

Due to the confirmations that HPE Ezmeral Data Fabric Streams receives on source clusters, synchronous replication is especially well-suited for creating a backup of your data for disaster recovery.

When the latency of a replication stream is high, HPE Ezmeral Data Fabric Streams switches to asynchronous replication temporarily so that producers are not blocked indefinitely. After the latency is sufficiently reduced, HPE Ezmeral Data Fabric Streams switches back to synchronous replication.

The same switching from synchronous to asynchronous replication occurs if all gateways fail. HPE Ezmeral Data Fabric Streams does not resume synchronous replication until a new gateway is established or at least one of the failed gateways is restarted.

Replica Autosetup for Streams
The option to automatically set up stream replication, also known as replica autosetup, performs the steps to set up and start the replication of streams. The replica autosetup option is available through the Control System and the CLI.

In general, replica autosetup performs the following steps to set up replication:

1. Creates a stream in the destination cluster.
2. Declares the new stream to be a replica of the source stream and ensures that replication does not begin immediately after the next step.

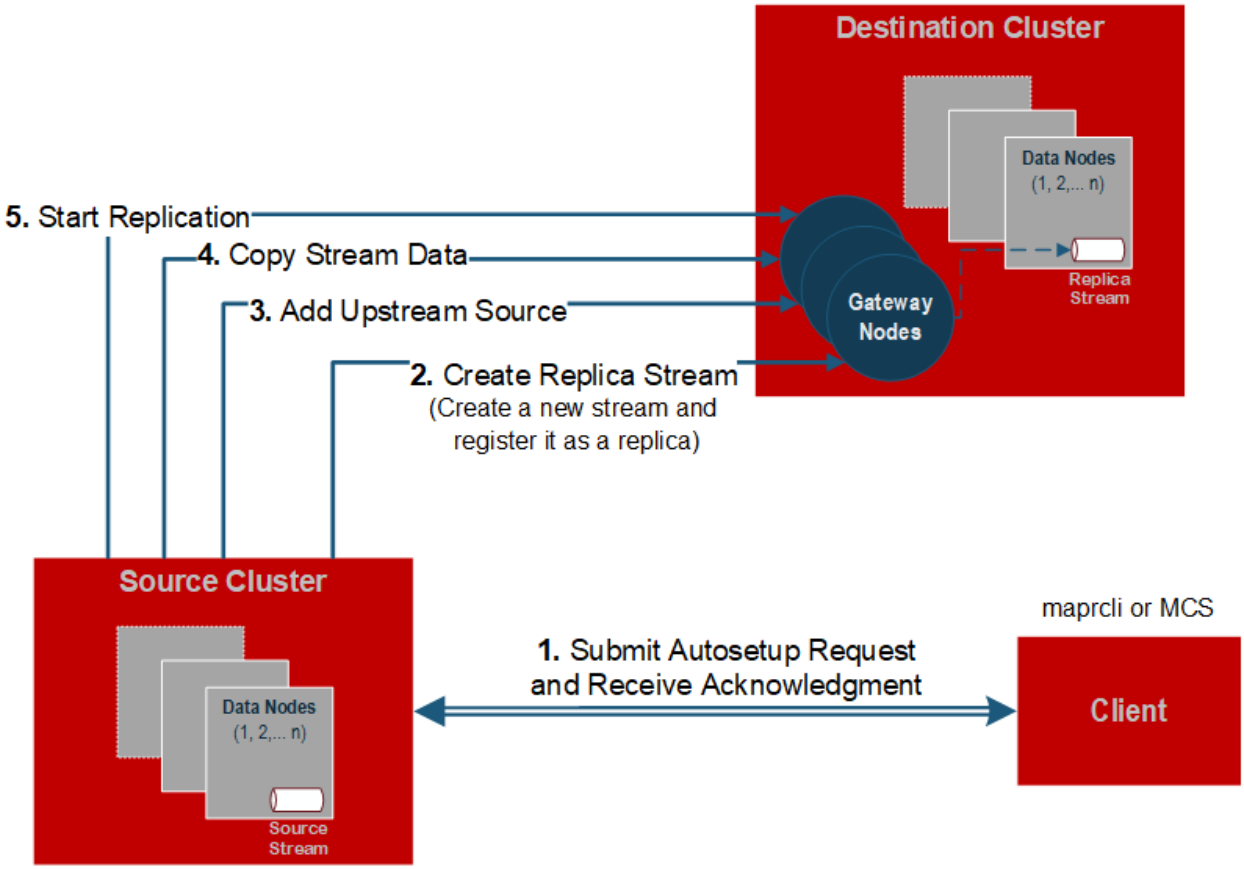
3. Declares the source stream as the original of the replica stream.
4. Loads a copy of the source stream into the replica.
5. For multi-master replication, replica autosetup declares the source stream to be a replica of the new stream and then declares the new stream to be an upstream source for the source stream.
6. Clears the paused replication state to start replication.

By default, replica autosetup uses the directcopy option. However, based on how you run replica autosetup, you also have the option not to use directcopy.

Replica Autosetup with Directcopy (default)

The directcopy option uses gateways to perform all setup operations including the initial population of data into the replica stream. Directcopy is the default option when you setup stream replication using the Control System or with the `maprcli stream replica autosetup` command.

When a client submits a request to automatically setup stream replication to the cluster, the source cluster acknowledges the request and begins to track the replica autosetup request from start to finish.



If a failure occurs when replica autosetup operations are in progress, the source cluster resumes operations from the point of failure.

NOTE: To check the replication status of a stream, run the `stream replica list` on page 2385 command. To stop the automatic setup of stream replication, run `stream replica remove` on page 2388, or delete the source or replica stream.

Replica autosetup with directcopy provides the following benefits:

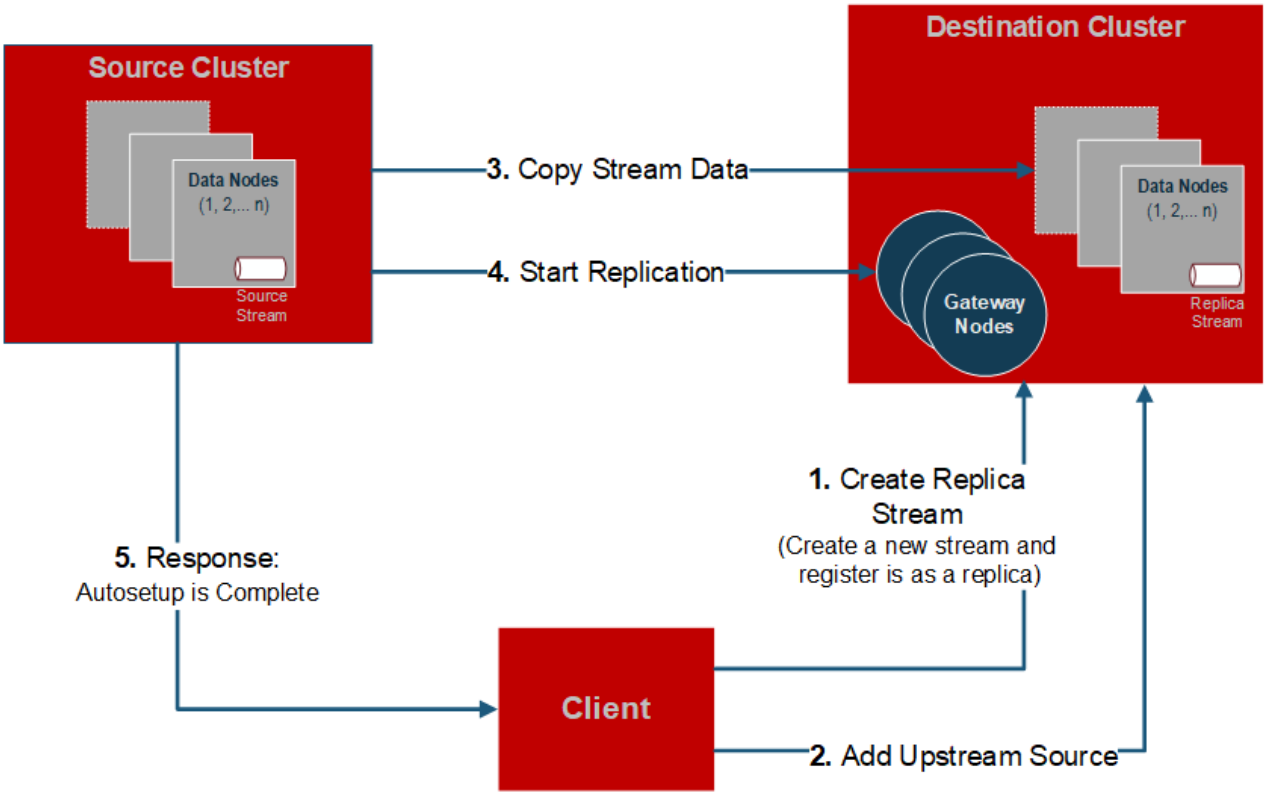
last-updated: Jun 06, 2024

- **Replica autosetup operations do not block the client from submitting additional requests.** When setting up stream replication, the process to copy source data to the replica can be time consuming. The client does not need to wait for the replica autosetup request to complete before submitting another request.
- **Source cluster retries replica autosetup operations in case of failure.** The source cluster keeps track of the replica autosetup progress. This allows the source cluster to resume autosetup operations in the event of an intermittent failure. If you choose to not use directcopy, user intervention is required if a failure occurs.
- **Throttling of copy table operations is done by default.** Throttling prevents the initial copy of data from the source to the replica stream from consuming all cluster resources.

Replica Autosetup without Directcopy (not default)

Without the directcopy option, replica autosetup submits a majority of the replication setup requests through the client and then runs the `mapr copystream` utility to populate the initial table data. To use replica autosetup without the directcopy option, run `maprcli stream replica autosetup` command with the `-directcopy` parameter set to `false`.

Without the directcopy option, once a client submits a replica autosetup request to the cluster, it must wait until the source cluster sends a notification that the autosetup request is complete, before it can submit another request to the cluster. In this case, replica autosetup uses the client connection to submit autosetup operation requests such as create replica, add replica, and add upstream source. Then, to populate the initial table data, it runs `mapr copystream`.



If a failure occurs when replica autosetup operations are in progress, the client hangs and any replica streams that were created during the failed autosetup operations must be manually deleted before you can try to setup replication again.

last-updated: Jun 06, 2024

States of Stream Replication

The replication state indicates when stream replication is in progress and it also displays the status of operations related to replica autosetup with directcopy. The `maprcli stream replica list` command displays the following replication states.

State	Description
REPLICA_STATE_WAIT_TILL_BULKLOAD	Replica autosetup with directcopy has not started because bulkload is in progress on the source table.
REPLICA_STATE_CREATE_SCHEDULE	Replica autosetup with directcopy had scheduled the creation of the replica table.
REPLICA_STATE_COPY_SCHEDULE	Replica autosetup with directcopy has not started the initial copying of source data to the replica because it is waiting for other in-progress copy operations to complete.
REPLICA_STATE_COPY_IN_RECOVER	Replica autosetup with directcopy is resuming the copy of source data to the replica after a connection failure.
REPLICA_STATE_COPY_IN_PROGRESS	Replica autosetup with directcopy is copying the source data to the replica.
REPLICA_STATE_DELETING_CURSORS	Replica autosetup with directcopy is deleting progress cursors since the initial copy of source data to the replica is complete.
REPLICA_STATE_REPLICATING	Replication is in progress.

Security for Stream Replication

Describes where security can be implemented for stream replication.

On clusters	You can replicate between streams that are in secure clusters.
At source streams	The `-adminperm` parameter in the commands `maprcli stream create` and `maprcli stream edit` lets you specify an *ACE* to declare who has administrative permissions on a stream, including permission to replicate the stream. The *ACE*s themselves are copied the first time during auto setup but are not replicated continuously. You need to manage the replicated and source *ACE*s separately after the initial setup.
Across a network	You can send data encrypted or unencrypted when replicating streams by using the `-networkencryption` parameter when you create or edit a replica.
At gateways	Gateways ensure that replicas receive data only from approved source streams.

Gateways and Stream Replication

When replicating streams, HPE Ezmeral Data Fabric Streams replicates messages that are published to a source stream. Gateways are services that receive messages from source streams and publish them in replica streams.

You configure gateways on nodes that are in destination clusters. On source clusters, you list the destination clusters and the gateways that are running on them.

For information on configuring and managing gateways, see:

- Configuring Gateways for Table and Stream Replication on page 1528
- Managing Gateways on page 1530

last-updated: Jun 06, 2024

During replication, HPE Ezmeral Data Fabric Streams sends messages from source streams to the gateways on the destination clusters, where the replicas of those source streams are located. Gateways batch the messages and then apply them to replicas. All messages from a source stream arrive at a replica after having been authenticated at a gateway. Therefore, access control expressions on the replica that control permission to publish messages are irrelevant; gateways have the implicit authority to publish messages to replicas.

HPE Ezmeral Data Fabric Streams distributes messages to a destination cluster's gateways in round-robin fashion. If a gateway is down or unreachable, HPE Ezmeral Data Fabric Streams chooses another gateway. If all of the gateways are down, HPE Ezmeral Data Fabric Streams retries the operation periodically until a gateway comes online.

You must configure gateways in destination clusters. If the destination cluster is remote from the cluster in which a source stream is located, then the gateways must be in the remote cluster. If the destination cluster is the source cluster, meaning that a source stream and its replica are located in a single cluster, then the gateways must be in the local cluster.

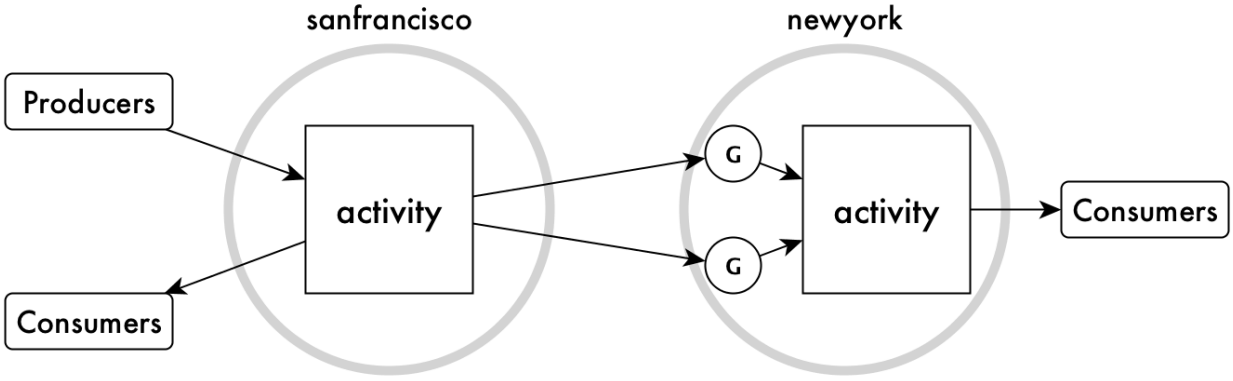
In a Primary-Secondary setup, you cannot have two primary instances with the same topic name replicating to the same secondary instance. It creates a conflict for that topic name. This is similar to Multi-Master replication where you must have separate topic names for Master1 (Cluster1) and Master2 (Cluster2).

For more information about replicating streams, see Stream Replication on page 795.

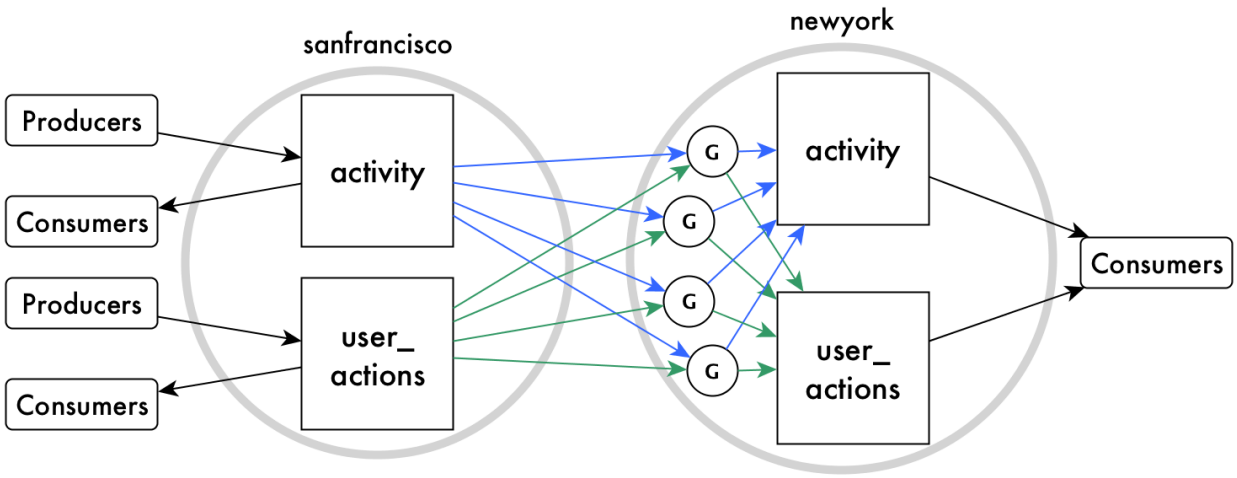
Gateways on nodes in remote destination Data Fabric clusters

In this type of topology, gateways receive messages that are published to source streams, authenticate with the destination cluster on behalf of the source cluster, and publish the messages to the corresponding streams.

This diagram of basic intercluster primary-secondary replication shows messages from the `activity` stream in the cluster `sanfrancisco` being sent to gateways. The gateways then publish the messages to the replica stream that is in the cluster `newyork`.



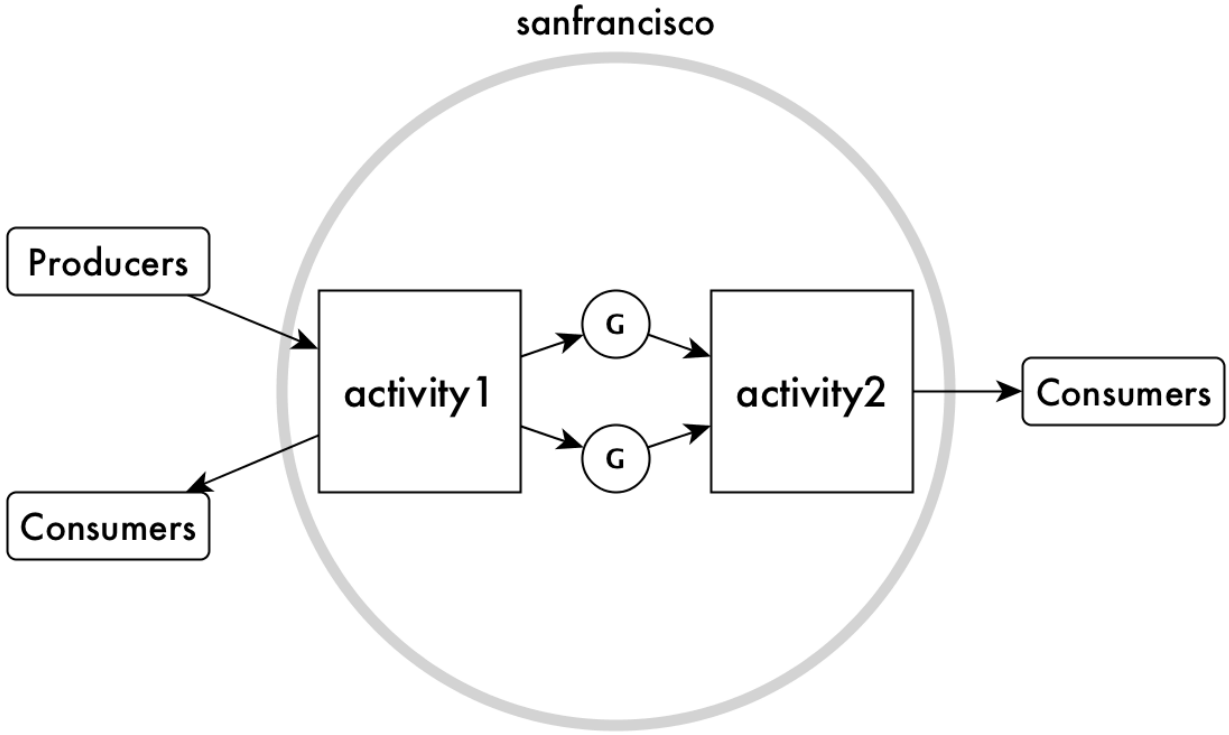
The gateways on a destination cluster are not assigned to particular replicas. They publish messages to all replicas on the destination cluster. For example, in the following diagram, messages from two source streams in the cluster `sanfrancisco` are replicated to two replicas in the cluster `newyork`. There are four gateways. Each gateway receives messages from both source streams, and each gateway applies those messages to the corresponding replicas.



Gateways on nodes within a Data Fabric cluster serving as source and destination

In this type of topology, gateways also receive messages that are published to source streams and publish the streams to the replicas. However, all of this activity takes place within a single Data Fabric cluster.

The following schematic diagram of basic intracluster primary-secondary replication shows messages from the `activity1` stream in the cluster `sanfrancisco` being sent to gateways. The gateways then publish the messages to the stream `activity2`.



Stream Security

The adminperm, copyperm, comsumeperm, produceperm, and topicperm security permissions protect topics in a stream from unauthorized access. In addition, data-fabric supports user impersonation.

last-updated: Jun 06, 2024

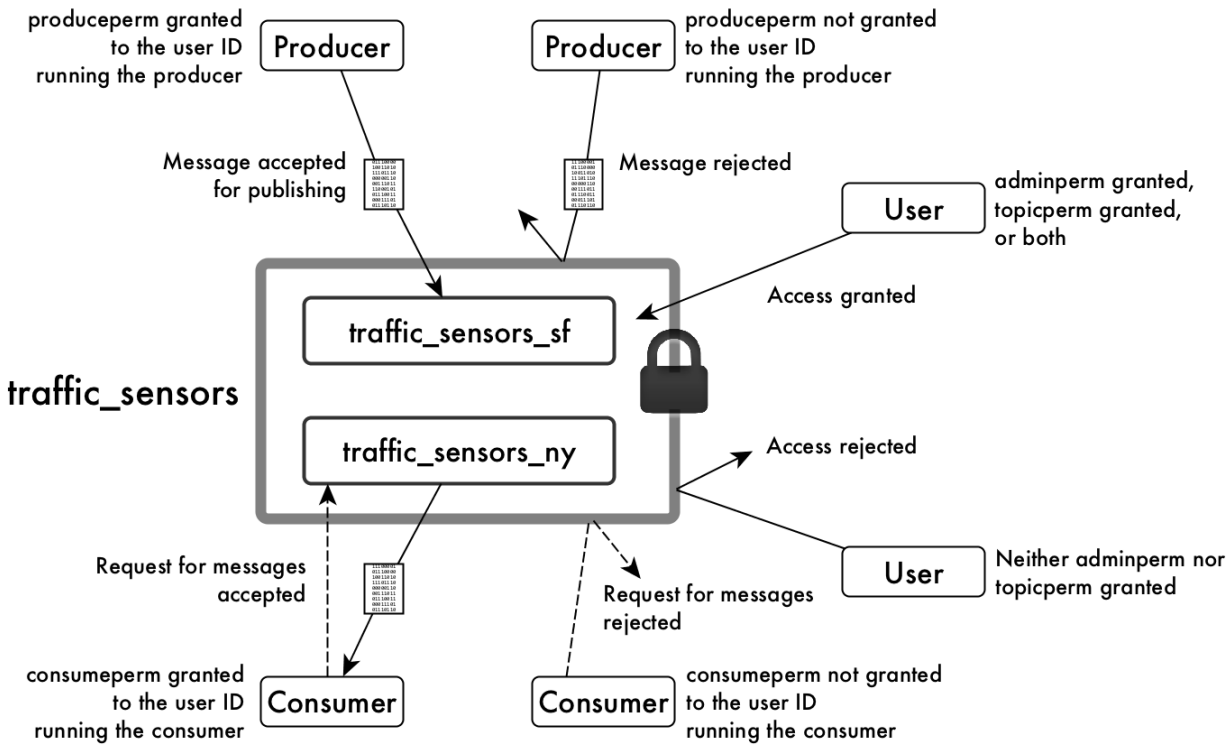
ACE Permissions

The following *ACE*s are used to protect topics in a stream from unauthorized access. *ACE*s are set when you create or edit a stream.

adminperm	Determines which users can modify *ACE*s for a stream, set up replication of a stream, and modify other attributes of a stream. By default, the stream owner and the Data Fabric user can modify this setting.
copyperm	Determines the users who can run the `mapr copystream` and `mapr diffstreams` utilities on the stream.
	Users with this permission can publish messages to topics in a stream, read messages in topics from a stream, and create or remove topics in a stream. This permission is a combination of the `consumeperm`, `produceperm`, and `topicperm` permissions.
consumeperm	Determines the users who can read messages in topics from a stream.
produceperm	Determines the users who can publish messages to topics in a stream.
topicperm	Determines the users who can create topics in a stream or remove them.

The following example shows the `adminperm`, `consumeperm`, `produceperm`, and `topicperm` permissions on a stream named `traffic_sensors`, which includes the topics `traffic_sensors_sf` and `traffic_sensors_ny`.

Figure 13: How permissions grant or deny access to a stream



For general information about *ACE*s, see ACE Syntax on page 1855.

last-updated: Jun 06, 2024

User Impersonation

HPE Ezmeral Data Fabric Streams supports user impersonation through the Java API. See HPE Ezmeral Data Fabric Streams Java API Library on page 3548 for more information. HPE Ezmeral Data Fabric Streams does not support user impersonation through the C API or Python API.

Kafka REST supports outbound user impersonation. See User Impersonation on page 4472 for more information.

HPE Ezmeral Unified Analytics

Describes the HPE Ezmeral Unified Analytics Software and provides a link to more information.

Hewlett Packard Enterprise recommends the HPE Ezmeral Data Fabric as the hybrid data lakehouse for HPE Ezmeral Unified Analytics Software.

HPE Ezmeral Unified Analytics Software is a usage-based Software-as-a-Service (SaaS) model that operationalizes hybrid and multi-cloud analytical workloads through a simple user interface.

Available for use in connected or air-gapped environments, HPE Ezmeral Unified Analytics Software separates compute and storage for flexible, cost-efficient scalability. With HPE Ezmeral Unified Analytics, you can securely access data stored in multiple data platforms, and run traditional and advanced analytics workloads using open-source tools.

For more information, see the Unified Analytics Software Documentation home page.

Kubernetes Interfaces for Data Fabric

This section describes the Kubernetes Interfaces for Data Fabric, which include the Container Storage Interface (CSI) driver for multiple container-orchestration systems, and the FlexVolume driver for Kubernetes.

The following table describes these features:

CSI Storage Plugin	The CSI Storage Plugin is a volume driver that uses the industry-standard container-storage interface to expose the HPE Ezmeral Data Fabric to workloads on container-orchestration systems.
Kubernetes Interfaces for Data Fabric FlexVolume Driver	The FlexVolume Driver is a set of Docker containers that provide persistent storage for Kubernetes objects through the file system.

Container Storage Interface (CSI) Storage Plugin Overview

This page describes how the Container Storage Interface (CSI) Storage Plugin can be used to expose the HPE Ezmeral Data Fabric to the containerized workload on Kubernetes.

To install or use the Container Storage Interface (CSI) Storage Plugin, see:

- Installing, Uninstalling, and Upgrading the Container Storage Interface (CSI) Storage Plugin on page 279
- Using the Container Storage Interface (CSI) Storage Plugin on page 3821

About the Container Storage Interface (CSI) Storage Plugin

The Container Storage Interface (CSI) Storage Plugin is an industry-standard interface that Container Orchestration systems can use to expose HPE Ezmeral Data Fabric to their containerized workloads. Traditionally, storage vendors had either to write and support multiple volume drivers for different Container Orchestration systems or choose not to support Container Orchestration systems. Using CSI, you can use the same volume driver with different Container Orchestration systems. Also, CSI enables the volume plug-ins to be containerized to make it agnostic to the host underneath, which might run other software

last-updated: Jun 06, 2024

such as HPE Ezmeral Data Fabric, allowing both Kubernetes and HPE Ezmeral Data Fabric to co-exist on the same node with CSI support.

The CSI driver:

- Allows other software to run on the same node.
- Does not require volume plug-ins to be built into the Kubernetes binaries.
- Does not require direct access to the machine to deploy the volume plug-in.

The CSI Driver for HPE Ezmeral Data Fabric consists of `.yaml` configuration files for installation into Kubernetes. Once installed, a Kubernetes Container Storage Interface (CSI) driver for the file system and a Kubernetes Dynamic Volume Provisioner are available for both static and dynamic provisioning of data-fabric storage.

The CSI driver uses sidecar containers, which are containers included with the driver for handling Kubernetes events and for communicating with CSI drivers for storage provisioning. Specifically:

- The `csi-provisioner` provisions and creates volumes for the HPE Ezmeral Data Fabric.
- The `csi-driver-registrar` registers the driver to the kubelet.
- The `csi-attacher` attaches volumes to the node and mounts the volumes.
- The `livenessprobe` probes the driver for health and readiness.
- The `csi-snapshotter` and `snapshot-controller` provision and create snapshots on the HPE Ezmeral Data Fabric.

When you install the CSI driver, it creates a DaemonSet Pod for the CSI node service and StatefulSet Pod for CSI controller service.

Additional Resources

For more information about application containers and Kubernetes, see the following HPE Ezmeral Data Fabric references:

Static and Dynamic Volume Provisioning Using Container Storage Interface (CSI) Storage Plugin
Explains static and dynamic volume provisioning using the CSI plugin.

Kubernetes makes a distinction between static and dynamic provisioning of storage.

Static Provisioning

In static provisioning, a data-fabric administrator first creates data-fabric volumes (mount points) and then ensures that they are mounted, and a Kubernetes administrator exposes those data-fabric mount points in Kubernetes through Kubernetes PersistentVolumes. In a typical static-provisioning scenario, a Pod author requests that a Kubernetes admin create a PersistentVolume that references an existing data-fabric mount point with a dataset that the Pod author is interested in. This PersistentVolume references the CSI driver. The CSI Driver mounts and unmounts data-fabric mount points for the requesting Pod. In addition, CSI supports the creation of a PersistentVolume directly by creating a PersistentVolumeClaim. The Pod author

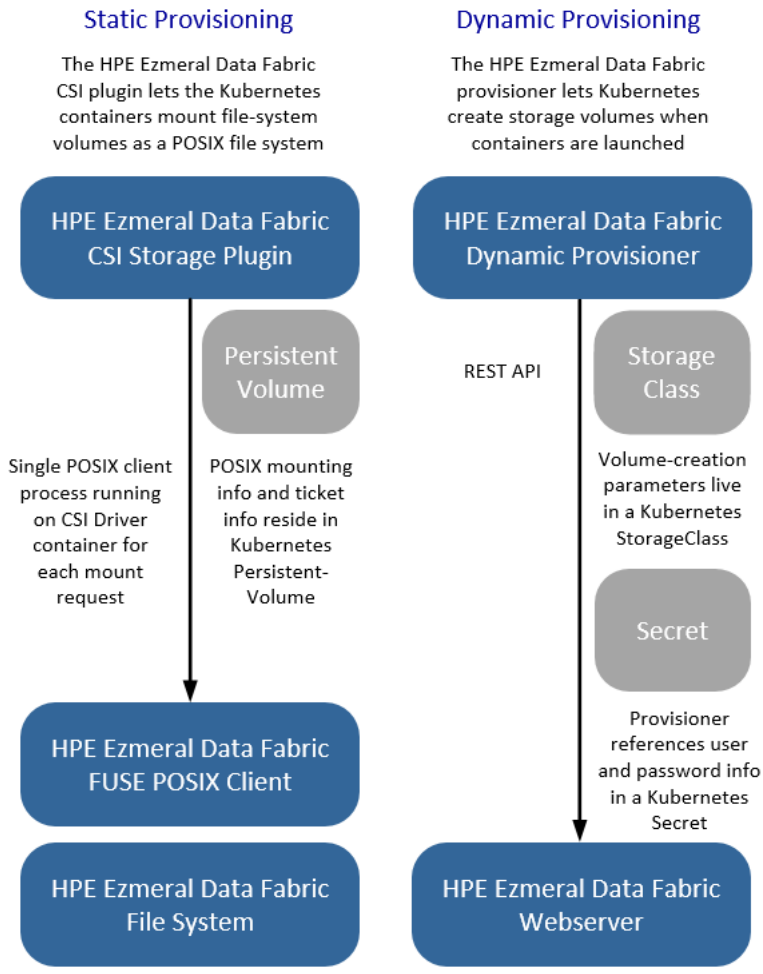
requests that a Kubernetes admin to create a PersistentVolume that points to the CSI driver and references an existing data-fabric mount point.

Dynamic Provisioning

In dynamic provisioning, a Kubernetes administrator creates a set of StorageClasses pointing to the CSI provisioner for Data Fabric. Each StorageClass has a predefined set of storage characteristics. Examples of these characteristics include the CLDB hosts, REST server hosts, provisioner secret name and namespace, data-fabric volume name prefix, data-fabric volume mount path, and volume advisory quota size. The Pod creator searches the predefined Storage Classes for the one that best matches the creator's requirements. When the Pod references this StorageClass through a PersistentVolumeClaim, the StorageClass calls the CSI Provisioner for Data Fabric to allocate storage for the requesting Pod dynamically and creates the volume.

To leverage the data-fabric file system with a Kubernetes cluster, you can create a PersistentVolume in Kubernetes.

The following diagram shows the two ways in which the PersistentVolume can be provisioned for the POSIX client. In the case of the Loopback NFS plugin, the Loopback NFS server performs the functions of the POSIX client shown in the diagram:



Static Provisioning Implementation

To accomplish static provisioning, the CSI Driver for Data Fabric for Kubernetes is deployed to all nodes in the Kubernetes cluster via a Kubernetes DaemonSet. The CSI Driver uses the Basic, which is the default, or the optional Platinum POSIX client to mount the data-fabric file system. The information that the

last-updated: Jun 06, 2024

POSIX client uses to connect to data-fabric is contained in a Kubernetes Volume or PersistentVolume. A data-fabric ticket inside a Secret, referenced by the Kubernetes Volume or PersistentVolume specification, is used by the POSIX client to pass secure data to the file system.

Dynamic Provisioning Implementation

To accomplish dynamic provisioning, the CSI provisioner is deployed as a StatefulSet in the Kubernetes cluster.

A Kubernetes Administrator must configure at least one storage class with data-fabric parameters (for example, mirroring, snapshots, quotas, and other parameters) for use during creation of the data-fabric volume. The storage class passes data-fabric administrative credentials to the provisioner through a Kubernetes Secret. Security for the provisioner is handled through role-based access control (RBAC) in Kubernetes.

Related tasks

Example: Statically Provisioning a Volume Using the Container Storage Interface (CSI) Storage Plugin on page 3828

Example: Mounting a PersistentVolume for Static Provisioning on page 3831

Example: Mounting a PersistentVolume for Dynamic Provisioning Using Container Storage Interface (CSI) Storage Plugin on page 3838

Raw Block Volumes

This page describes support for raw block volumes by the Container Storage Interface (CSI) Storage Plugin.

The HPE implementation of CSI supports raw block volumes. Inside a container, this feature enables a persistent volume to appear as a block device instead of as a mounted file system. This feature can be useful for applications that do not work with NFS or FUSE or perform better on a standard Linux file system, such as EXT4 or XFS.

The following (or later) releases of the storage plugin support raw block volumes:

- Container Storage Interface (CSI) Storage Plugin Release 1.2.x (FUSE POSIX) on page 6165
- Container Storage Interface (CSI) Storage Plugin Release 1.0 (Loopback NFS) on page 6167

For more information, see Raw Block Volume Support in the Kubernetes documentation.

Comparing the FUSE POSIX and Loopback NFS Plugins

This page compares the two types of Container Storage Interface (CSI) Storage Plugins and describes when to use them.

Features Common to Both Plugins

The FUSE POSIX and Loopback NFS plugins both support the following features:

- Create a volume
- Delete a volume
- Expand a volume
- Clone a volume
- Create a snapshot
- Delete a snapshot
- Restore a snapshot

last-updated: Jun 06, 2024

Current versions of both plugins include the release 6.2 binaries and can be used with releases 6.1 or 6.2. In addition, both plugins can exist on the same Kubernetes cluster at the same time. Both plugins can also be used without a license; however, the FUSE POSIX plugin provides a `license` parameter that allows you to control the number of resources used, as described in Example: Mounting a PersistentVolume for Static Provisioning on page 3831.

How the Loopback NFS Plugin is Different

The Loopback NFS plugin leverages the loopbacknfs POSIX Client. For more information about this client, see HPE Ezmeral Data Fabric loopbacknfs POSIX Client on page 1604.

The plugins differ in how they handle I/O. The Loopback NFS plugin uses asynchronous I/O, allowing more I/O operations. The Loopback NFS plugin also uses less memory and provides better performance for small-file writes and raw block storage.

How the FUSE POSIX Plugin is Different

The FUSE POSIX plugin leverages the FUSE-Based POSIX Client. For more information about this client, see HPE Ezmeral Data Fabric FUSE-Based POSIX Client on page 1613.

The FUSE POSIX plugin uses synchronous I/O. FUSE POSIX runs with at most five clients (platinum license) and incurs resource overhead because of the high number of client threads, but works better for use cases that require high throughput.

Kubernetes Interfaces for Data Fabric FlexVolume Driver Overview

Describes how the FlexVolume driver for Kubernetes Interfaces for Data Fabric integrates with Kubernetes to provide persistent data for containers.

IMPORTANT: The Data Fabric FlexVolume Driver for Kubernetes is officially deprecated and becomes an unsupported product on October 31, 2022. Users of the FlexVolume Driver are encouraged to migrate to one of the available CSI drivers. See CSI Version Compatibility on page 5763.

To review the FlexVolume Driver end-of-life announcement, see support advisory 4822. For a comparison of the CSI and FlexVolume technologies, see FlexVolume.

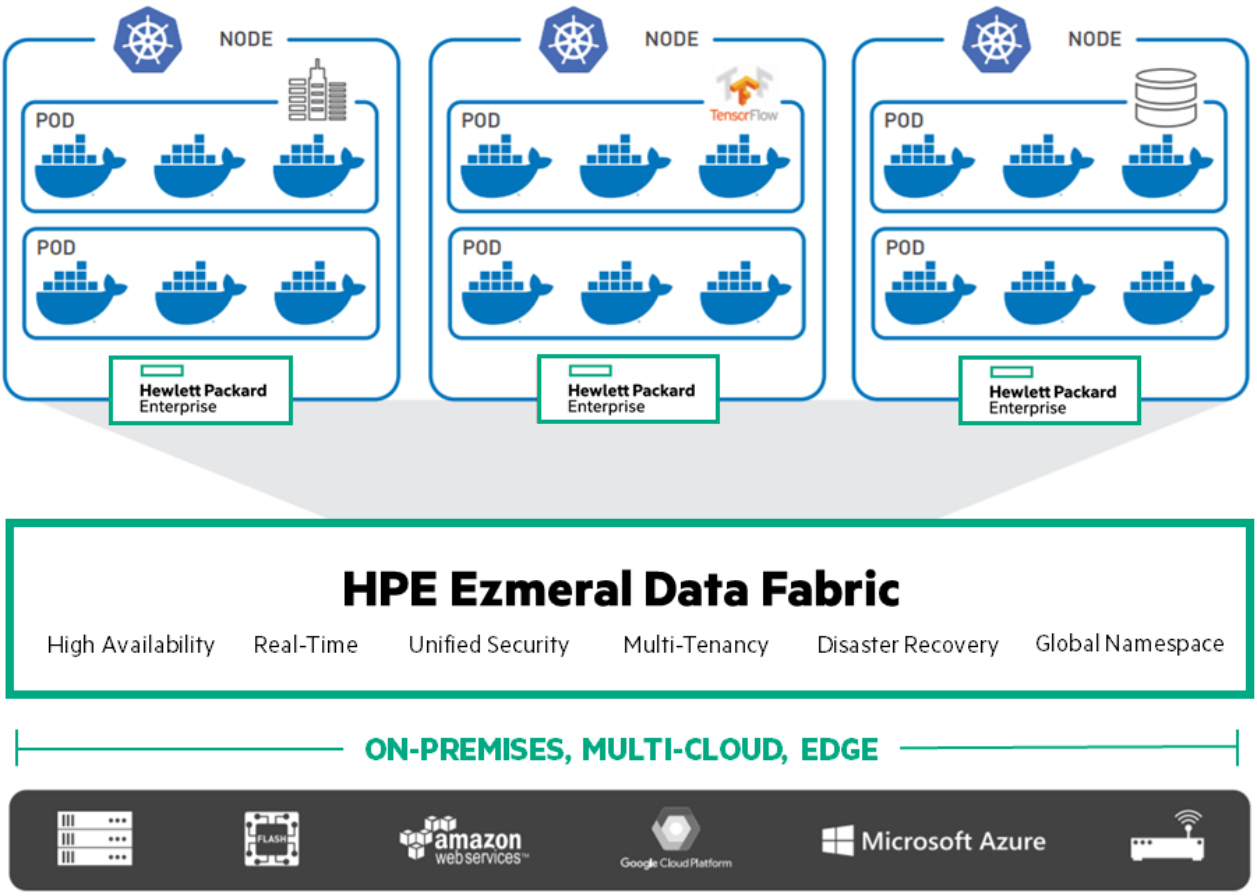
To install or use the Data Fabric for Kubernetes, see:

- Installing the MapR Data Fabric for Kubernetes FlexVolume Driver on page 292
- Using the MapR Data Fabric for Kubernetes FlexVolume Driver on page 3870

About the Data Fabric for Kubernetes

Most Pods in a Kubernetes environment should be portable, short-lived, and stateless. Traditionally, when a Pod is stopped or moved, the state of its containers could be lost. The Data Fabric for Kubernetes:

- Provides long-lived, persistent storage for Pods and their containers.
- Allows containers running in Kubernetes to use the data-fabric filesystem for all of their storage needs.
- Allows secure storage of all container states in HPE Ezmeral Data Fabric File Store.



The Data Fabric for Kubernetes consists of a set of Docker containers and their respective `.yaml` configuration files for installation into Kubernetes. Once installed, both a Kubernetes FlexVolume Driver for MaprFS and a Kubernetes Dynamic Volume Provisioner are available for both static and dynamic provisioning of data-fabric storage.

Containers

Containers are stand-alone, executable images of applications. They freeze all code needed to run an application, including an OS. Unlike VMs, containers run directly on an operating system without the need for a HyperVisor. Both Linux- and Windows-based applications can be packaged as containers. Containers represent an easy way to deploy applications in development and test environments. Using containers, developers can quickly create a development platform to test their code.

Containers are ephemeral by nature and light-weight. They enable setting up compute clusters quickly. They also allow a cluster to be dismantled quickly. To accomplish this task, containers are designed to be ephemeral. That is, they are designed to be somewhat stateless. However, truly stateless containers would eliminate many classes of applications. It is therefore important to provide containers with persistent data independent of the container lifecycle. A natural solution is to have persistent storage (data) presented to the containers, just as persistent storage is presented today for VMs and in bare-metal environments.

Container Management

Simple container solutions are somewhat limited when orchestrating multiple containers to solve complex business challenges. Managing containers for production is challenging. With many workloads transitioning to fully production-grade containers, cluster admins need something beyond a container engine like Docker. Several container-orchestration engines are now available to manage containers in production. Kubernetes is the most prominent example of these container-orchestration solutions.

last-updated: Jun 06, 2024

Kubernetes Volume Drivers

Kubernetes introduced the concept of FlexVolume drivers. FlexVolume drivers are intended to allow storage vendors to provide storage to containers managed by Kubernetes. The Data Fabric for Kubernetes leverages Kubernetes FlexVolume drivers. There are additional Kubernetes components and concepts you should also be aware of:

- Kubernetes Volumes: A Kubernetes volume is a Kubernetes-managed resource concept. Kubernetes Volumes are associated with Kubernetes Pods. Kubernetes Volumes are different from data-fabric volumes. The lifecycle of a Kubernetes volume is tied to the lifecycle of a Kubernetes Pod, and the Kubernetes Volume is destroyed when the Pod is deleted.
- Kubernetes Persistent Volumes: As the name indicates, a Kubernetes Persistent Volume (PV) lifecycle is separate from the Pod that uses it. Persistent Volumes are referenced by Persistent Volume Claims (PVC), which are in turn referenced by Pods. Multiple Pods can claim a single PVC, but only a single PVC can bind with a PV.
- Storage Classes: A Storage Class is a way for administrators to advertise the different classes of storage they offer. For example, the admin can provide parameters in the storage class that define the frequency of snapshots or the number of mirrors associated with the storage. Storage Classes are used to dynamically provision a new storage volume for use by containers.
- MapR Volumes: The Glossary defines a data-fabric volume as a tree of files and directories grouped for the purpose of applying a policy or set of policies to all of them at once. To avoid confusion, this document uses the terms *Kubernetes volume* and *MapR volume* to distinguish between the different types of volumes.

Kubernetes and MapR Volumes

In general, Kubernetes is not aware of data-fabric volumes. When static provisioning a data-fabric path, Kubernetes simply uses a data-fabric POSIX client to obtain a specific mount point within the data-fabric file system. When dynamically provisioning a new data-fabric volume for a container to use, the dynamic provisioner issues REST calls to the data-fabric REST server to create actual data-fabric volumes.

Static and Dynamic Provisioning Using FlexVolume Driver

Describes static and dynamic storage provisioning using the FlexVolume driver on a Kubernetes cluster.

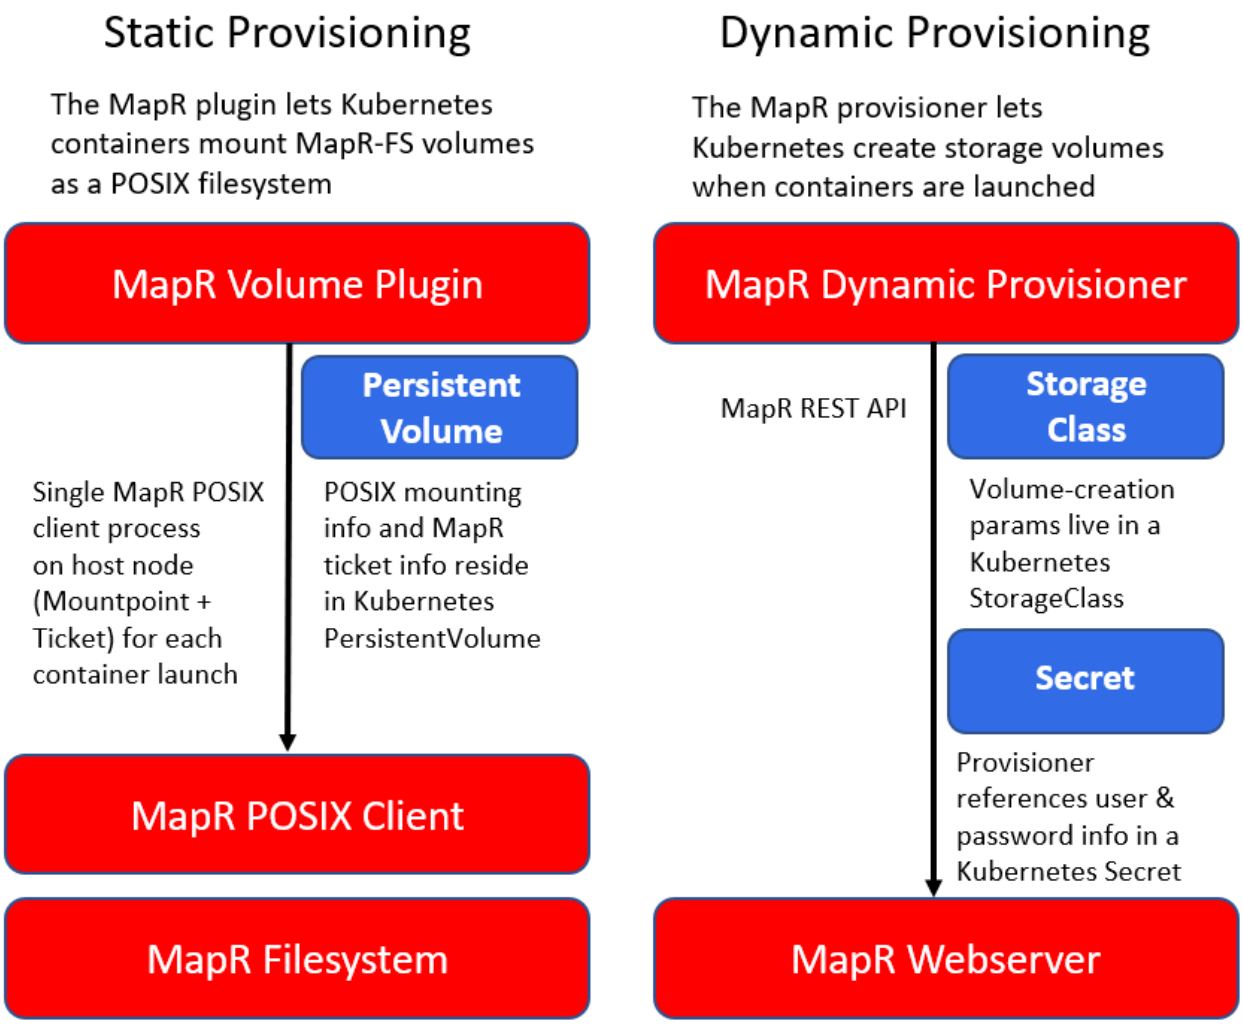
Kubernetes makes a distinction between static and dynamic provisioning of storage.

In static provisioning, a data-fabric administrator first creates data-fabric volumes (mount points) and then ensures that they are mounted. A Kubernetes administrator exposes these data-fabric mount points in Kubernetes through Kubernetes PersistentVolumes. In a typical static-provisioning scenario, a Pod author requests that a Kubernetes administrator create a PersistentVolume that references an existing data-fabric mount point with a dataset that the Pod author is interested in. This PersistentVolume references the FlexVolume plug-in. The FlexVolume plug-in mounts and unmounts data-fabric mount points for the requesting Pod.

In dynamic provisioning, a Kubernetes administrator creates a set of StorageClasses for Pods to invoke. Each StorageClass has a predefined set of storage characteristics. Examples of these characteristics include the data-fabric volume advisory quota size and snapshot rules. The Pod creator searches the predefined Storage Classes for the one that best matches the creator's requirements. When the Pod references this StorageClass through a PersistentVolumeClaim, the StorageClass calls the Dynamic Provisioner to allocate storage for the requesting Pod dynamically.

To leverage file system with a Kubernetes cluster, you can create a PersistentVolume in Kubernetes. This diagram shows the two ways in which the PersistentVolume can be provisioned:

last-updated: Jun 06, 2024



Static Provisioning Implementation

To accomplish static provisioning, the KDF FlexVolume plug-in is deployed to all nodes in the Kubernetes cluster via a Kubernetes DaemonSet. The volume plug-in uses the Basic or Platinum POSIX client to mount the data-fabric filesystem The information that the POSIX client uses to connect to data-fabric is contained in a Kubernetes Volume or PersistentVolume. A data-fabric ticket inside a Secret, referenced by the Kubernetes Volume or PersistentVolume specification, is used to pass secure data to the file system.

Dynamic Provisioning Implementation

To accomplish dynamic provisioning, the KDF provisioner is deployed as a Kubernetes Deployment to a single node in the Kubernetes cluster. The provisioner requests the creation of data-fabric volumes when a container is launched. You can scale your provisioner deployment to multiple nodes for high availability. If a provisioner Pod is deleted, a new provisioner is started on another worker node in the cluster.

A Kubernetes Administrator must configure at least one storage class with data-fabric parameters (for example, mirroring, snapshots, quotas, and other parameters) for use during creation of the data-fabric volume. The storage class passes data-fabric administrative credentials to the provisioner through a Kubernetes Secret. Security for the provisioner is handled through role-based access control (RBAC) in Kubernetes.

POSIX Integration and Licensing
Explains how the basic and platinum POSIX clients are supported on a Kubernetes cluster,

last-updated: Jun 06, 2024

The data-fabric POSIX client provides fast-data access between the container and the data-fabric filesystem. For FlexVolume plug-in, the POSIX client is installed onto all Kubernetes worker nodes when you install the volume plug-in through its `.yaml` configuration file. For CSI Driver, the POSIX client is installed onto the CSI Driver container only.

For static provisioning, the volume plug-in uses the POSIX client to mount the data-fabric filesystem. The provisioner does not use the POSIX client to provision volumes, but a provisioned volume is mounted through POSIX when the plug-in is called after PV creation.

Support for Basic and Platinum Licenses

By default, the product includes the Basic POSIX client package, but you can enable the Platinum license, if needed. See Enabling the Platinum Posix Client for FlexVolume Driver and CSI Driver. Only the POSIX client is supported. NFSv3 and NFSv4 are currently not supported.

While the Platinum POSIX client offers up to five times better performance than the Basic POSIX client, resource utilization is significantly higher for the Platinum client. For a comparison of the Basic and Platinum packages, see Preparing for Installation.

Mounting Multiple MapR Paths

It is inefficient in both host resources and licenses to mount multiple data-fabric paths in the same Pod. In FlexVolume Driver, multiple mount points will consume additional resources on the Kubernetes host node. A more resource-efficient strategy is to use subpaths. See Using subpaths in the Kubernetes documentation.

Cluster Management

Provides a synopsis of the various cluster components and their management.

Data Fabric provides high availability management and data processing services for automatic continuity throughout the cluster. You can use the Control System, command-line interface, or REST API to start, stop, and monitor services at the node or cluster level. MapReduce services such as the ResourceManager, management services such as the ZooKeeper, and data access services such as NFS provide continuous service during any system failure.

Data Fabric Monitoring (part of the Spyglass initiative) provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications.

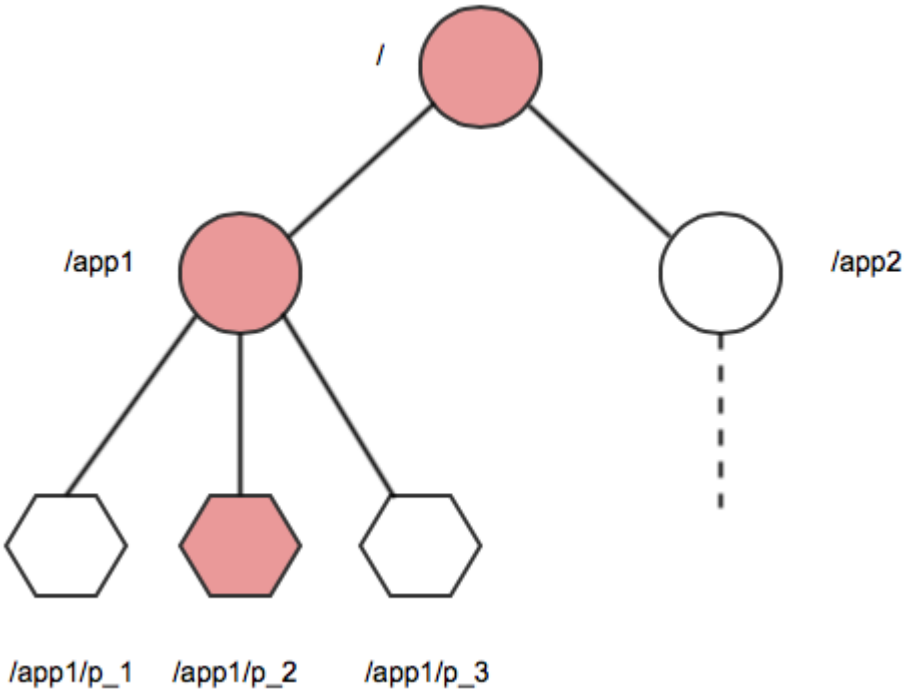
This section describes the following components and services, and also describes their roles in managing a data-fabric cluster:

ZooKeeper

Provides an overview of the ZooKeeper service.

ZooKeeper is a coordination service for distributed applications. It provides a shared hierarchical namespace that is organized like a standard filesystem. The namespace consists of data registers called znodes, for ZooKeeper data nodes, which are similar to files and directories. A name in the namespace is a sequence of path elements where each element is separated by a / character, such as the path `/app1/p_2` shown here:

last-updated: Jun 06, 2024



Namespace

The znode hierarchy is kept in-memory within each ZooKeeper server in order to minimize latency and to provide high throughput of workloads.

The ZooKeeper Ensemble

The ZooKeeper service is replicated across a set of hosts called an ensemble. One of the hosts is designated as the leader, while the other hosts are followers. ZooKeeper uses a leader election process to determine which ZooKeeper server acts as the leader, or master. If the ZooKeeper leader fails, a new leader is automatically chosen to take its place.

Establishing a ZooKeeper Quorum

As long as a majority (a quorum) of the ZooKeeper servers are available, the Zookeeper service is available. For example, if the ZooKeeper service is configured to run on five nodes, three of them form a quorum. If two nodes fail (or one is taken off-line for maintenance and another one fails), a quorum can still be maintained by the remaining three nodes. An ensemble of five ZooKeeper nodes can tolerate two failures. An ensemble of three ZooKeeper nodes can tolerate only one failure. As a quorum requires a majority, an ensemble of four ZooKeeper nodes can only tolerate one failure, and therefore offers no advantages over an ensemble of three ZooKeeper nodes. In most cases, you should run three or five ZooKeeper nodes on a cluster. Larger quorum sizes result in slower write operations.

Ensuring Node State Consistency

Each ZooKeeper server maintains a record of all znode write requests in a transaction log on the disk. The ZooKeeper leader issues timestamps to order the write requests, which when executed, updates elements in the shared data store. Each ZooKeeper server must sync transactions to disk and wait for a majority of ZooKeeper servers (a quorum) to acknowledge an update. Once an update is held by a quorum of nodes, a successful response can be returned to clients. By ordering the write requests with timestamps and waiting for a quorum to be established to validate updates, ZooKeeper avoids race conditions and ensures that the node state is consistent.

last-updated: Jun 06, 2024

Warden

Describes the Warden daemon that monitors and restarts services if they terminate.

Warden is a light Java application that runs on all the nodes in a cluster and coordinates cluster services. Warden's job on each node is to start, stop, or restart the appropriate services, and allocate the correct amount of memory to them. Warden makes extensive use of the znode abstraction discussed in the ZooKeeper section of this document to monitor the state of cluster services.

Each service running in a cluster has a corresponding znode in the ZooKeeper namespace, named in the pattern `/services/<servicename>/<hostname>`. Warden's Watcher interface monitors znodes for changes and acts when a znode is created or deleted, or when child znodes of a monitored znode are created or deleted.

Warden configuration is contained in the `warden.conf` file, which lists service triplets in the form `<servicename>:<number of nodes>:<dependencies>`. The `number of nodes` element of this triplet controls the number of concurrent instances of the service that can run on the cluster. Some services are restricted to one running instance per cluster, while others, such as the File Server, can run on every node. The Warden monitors changes to its configuration file in real time.

When a configuration triplet lists another service as a dependency, the Warden only starts that service after the dependency service is running.

NOTE: When Warden is started/restarted, the irqbalancer is enabled on nodes running file system because it balances IRQ SMP affinities, which provide better performance.

Memory Management with the Warden

System administrators can configure how the cluster's memory is allocated to running the operating system, file system, and Hadoop services. The configuration files `/opt/mapr/conf/warden.conf` and `/opt/mapr/conf/conf.d/warden.<servicename>.conf` include parameters that define how much of the memory on a node is allocated to the operating system, file system, and Hadoop services.

You can edit the following memory parameters to reserve memory:

- The `service.<servicename>.heapsize.percent` parameter controls the percentage of system memory allocated to the named service.
- The `service.<servicename>.heapsize.max` parameter defines the maximum heapsize used when invoking the service.
- The `service.<servicename>.heapsize.min` parameter defines the minimum heapsize used when invoking the service.

For example, the `service.command.os.heapsize.percent`, `service.command.os.heapsize.max`, and `service.command.os.heapsize.min` parameters in the `warden.conf` file control the amount of memory that Warden allocates to the host operating system before allocating memory to other services.

The actual heap size used when invoking a service is a combination of the three parameters according to the formula:

```
max(heapsize.min, min(heapsize.max, total-memory * heapsize.percent / 100))
```

For more information, see Memory Allocation for Nodes.

The Warden and Failover

The Warden on each node watches appropriate znodes to determine whether to start or stop services during failover. The following paragraphs provide failover examples for the CLDB and ResourceManager. Note that not all failover involves the Warden; NFS failover is accomplished using VIPs.

last-updated: Jun 06, 2024

CLDB Failover	The ZooKeeper contains a znode corresponding to the active primary CLDB. This znode is monitored by the secondary CLDBs. When the primary CLDB znode is deleted, the secondary CLDBs recognize that the primary CLDB is no longer running. The secondary CLDBs contact ZooKeeper in an attempt to become the new primary CLDB. The first CLDB to get a lock on the znode in ZooKeeper becomes the new primary instance.
ResourceManager Failover	Starting in version 4.0.2, if the node running the ResourceManager fails and the Warden on the ResourceManager node is unable to restart it, Warden starts a new instance of the ResourceManager on another node. The Warden on every ResourceManager node watches the ResourceManager's znode for changes. When the active ResourceManager's znode is deleted, the Wardens on other ResourceManager nodes attempt to launch the ResourceManager. The Warden on each ResourceManager node works with the ZooKeeper to ensure that only one ResourceManager is running in the cluster. In order for failover to occur in this manner, at least two nodes in the cluster should include the ResourceManager role and your cluster must be use the zero configuration failover implementation.

The Warden and Pluggable Services

Services can be plugged into the Warden's monitoring infrastructure by setting up an individual configuration file for each supported service in the `/opt/mapr/conf/conf.d` directory, named in the pattern `warden.<servicename>.conf`. The `<servicename>:<number of nodes>:<dependencies>` triplets for a pluggable service are stored in the individual `warden.<servicename>.conf` files, not in the main `warden.conf` file.

The following services/packages have configuration files pre-configured at installation:

- Hue
- HTTP-FS
- The Hive metastore
- HiveServer2
- Spark-Master
- mapr-apiserver
- mapr-collectd
- mapr-drill
- mapr-elasticsearch
- mapr-fluentd
- mapr-grafana
- mapr-hbase

last-updated: Jun 06, 2024

- mapr-hbasethrift
- mapr-historyserver
- mapr-hive
- mapr-hivemetastore
- mapr-hiveserver2
- mapr-hivewebchat
- mapr-httpfs
- mapr-hue
- mapr-impala
- mapr-impalacatalog
- mapr-impalaserver
- mapr-impalastore
- mapr-kafka
- mapr-kibana
- mapr-ksql
- mapr-livy
- mapr-nodemanager
- mapr-objectstore
- mapr-opentsdb
- mapr-resourcemanager
- mapr-schema
- mapr-sentry
- mapr-spark
- mapr-sqoop2
- mapr-storm
- mapr-tez
- mapr-timelineserver
- mapr-webserver

A package can contain multiple services. For example, `mapr-spark` contains all of Spark services including Spark Thrift Server and Spark Master.

After you install a package and run the configure.sh on page 2821 utility, the associated Warden files are present in `/opt/mapr/conf/conf.d`.

The Warden daemon monitors the znodes for a configured component's service and restarts the service as specified by the configuration triplet. The configuration file also specifies resource limits for the service, ports used by the service (if any), and a location for log files.

In the triplet `<servicename>:<number of nodes>:<dependencies>`, the `<number of nodes>` can be set to `all`. The value `all` specifies that the service is to be started on every node on which the service is installed.

For example, consider the entry `services=kvstore:all;cldb:all:kvstore;hoststats:all:kvstore`. This entry specifies the following:

1. Start `kvstore` on all the nodes on which it is installed.
2. Start `cldb` on all the nodes on which it is installed, but wait until `kvstore` is up on all nodes. In other words, `cldb` depends on `kvstore` to be up.
3. Start `hoststats` on all nodes on which it is installed but wait until `kvstore` is up on all nodes. In other words, `hoststats` depends on `kvstore` to be up.

As another example, consider the entry: `resourcemanager:1:cldb`. Here, only one instance of `resourcemanager` is started, after `cldb` is up.

If this instance of `resourcemanager` goes down, Warden notices that the number of running instances is below the specified count, and automatically handles the failover. If multiple instances of `resourcemanager` get started, Warden terminates all the extra instances.

Dependencies are usually handled internally. Some non-core components do have dependencies among themselves, such as for example:

```
services=nodemanager:all:resourcemanager
hbmaster:all:cldb
hbregionserver:all:hbmaster
```

Here:

1. `nodemanager` depends on `resourcemanager`
2. `hbmaster` depends on `cldb`
3. `hbregionserver` depends on `hbmaster`

CLDB

Describes the Container Location Database (CLDB).

CLDB

The Container Location Database (CLDB) service tracks the following information about every container in the data-fabric file system:

- The node where the container is located.
- The container's size.
- The volume to which the container belongs.
- The policies, quotas, and usage for that volume.

For more information on containers, see File System on page 490.

The CLDB also tracks fileservers in the cluster and node activity. Running the CLDB service on multiple nodes distributes lookup operations across those nodes for load balancing, and also provides high availability.

When a cluster runs the CLDB service on multiple nodes, one node acts as the primary CLDB and the others act as secondary instances. The primary node has read and write access to the filesystem, while secondary nodes only have read access. The kvstore (key-value store) container has the container ID 1, and holds cluster-related information. The ZooKeeper tracks container information for the kvstore container. The CLDB assigns a container ID to each new container it creates. The CLDB service tracks the location of containers in the cluster by the container ID.

When a client application opens a file, the application queries the CLDB for the container ID of the root volume's name container. The CLDB returns the container ID and the IP addresses of the nodes in the cluster where the replicas of that container are stored. The client application looks up the volume associated with the file in the root volume's name container, then queries the CLDB for the container ID and IP addresses of the nodes in the cluster with the name container for the target volume. The target volume's name container has the file ID and inode for the target file. The client application uses this information to open the file for a read or write operation.

Each fileserver heartbeats to the CLDB periodically, at a frequency ranging anywhere from 1-3 seconds depending on the cluster size, to report its status and container information. The CLDB may raise alarms based on the status communicated by the FileServer.

Explains how to enable the CLDB tunable for optimizing CLDB tables.

HPE Ezmeral Data Fabric Control System

Provides a brief description of the HPE Ezmeral Data Fabric Control System.

The HPE Ezmeral Data Fabric Control System provides a graphical control panel for cluster administration with all the functionality of the command-line or REST APIs. The Control System provides job monitoring metrics and helps you troubleshoot issues, such as which jobs required the most memory in a given week, or which events caused job and task failures.

The Control System provides various views, which you can use to configure and monitor your cluster:

Overview	The Control System **Overview** page provides a summary of information about the cluster including a cluster heat map that displays the health of each node organized by service, an alarms summary, cluster utilization that shows the CPU, memory, and disk space usage, the number of available, unavailable, and under replicated volumes, and MapReduce applications. **ATTENTION:** This page is not available when running on a Kubernetes cluster.
Services	The Control System **Services** page provides a summary of the services running across the cluster.
Nodes	The Control System **Nodes** page provides a summary of information about the nodes on the cluster including a heat map that displays the health of each node, resource utilization that shows the CPU and memory usage, all active alarms, and a list of all the nodes on the cluster with links that provide shortcuts to more detailed information about the node. **ATTENTION:** This page is not available when running on a Kubernetes cluster.

last-updated: Jun 06, 2024

Data	The Control System **Data** drop-down menu contains links to pages that provide summary of information about volumes, tables, and streams. **ATTENTION:** This page is not available when running on a Kubernetes cluster.
Admin	The Control System **Admin** drop-down menu contains links to pages for user and cluster management tasks such as setting up permissions, quotas, and email settings for users, enabling cluster-level and data auditing, configuring balancer settings, and adding licenses.

NOTE: During installation using the Installer, you can configure metrics and logging using settings on the Monitoring page of the Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the panes on the Control System.

URL Sharing Feature

The Control System supports URL Sharing. As one uses filters and sort column information, the URL records these filters. This URL can then be shared with other users who can then login and view the filtered information.

NOTE:

- Filters will be preserved if one logs in as the same user within the current session.
- Filters will not be preserved if one logs in as a different user within the current session.
- URL can be shared with any valid user and can be opened in any browser, using valid user credentials.

URL Sharing works on the Volumes page, Security Policies page, Nodes page, and the Snapshots tab both in the Volumes page and the Volume Details page.

Setting Up the Control System on page 454
Describes how to configure and access the Control System.

Data Fabric UI

Describes how to use the Data Fabric UI on a customer-managed cluster and lists some of the benefits and limitations of doing so.

The Data Fabric UI was created to be the principal user interface for the as-a-service deployment of the HPE Ezmeral Data Fabric. You can access and use the Data Fabric UI on a customer-managed cluster. However, you should understand certain benefits and limitations when using the interface in this way. The Control System is still the preferred interface for managing a customer-managed cluster.

To learn more about the differences between the as-a-service and customer-managed Data Fabric platforms, see What's New in Release 7.7 on page 30.

last-updated: Jun 06, 2024

Accessing the Data Fabric UI on a Customer-Managed Cluster

To launch the Data Fabric UI, navigate to the host that is running the WebServer in the cluster. Access to the cluster typically uses HTTPS on port 8443. For example:

```
https://<host-name>:8443/app/dfui
```

Benefits of Using the Data Fabric UI on a Customer-Managed Cluster

The Data Fabric UI:

- Provides GUI support for some newer Data Fabric features that are not supported by the Control System. For example, the Data Fabric UI provides a graphical user interface for administering OTel endpoints. You can also use `maprcli` commands to administer OTel. The Control System does not support OTel.
- Makes it easy to import external NFS or S3 servers.
- Lists resource endpoints.
- Provides additional capabilities for working with topics in a stream.

Limitations of Using the Data Fabric UI on a Customer-Managed Cluster

The Data Fabric UI:

- Can only be used with release 7.3.0 and later clusters.
- Displays limited information about ecosystem components.
- Is optimized to help you display and administer the resources of multiple fabrics (clusters) that belong to the same global namespace. If your customer-managed cluster is not a member of a global namespace, consider using the Control System. The Control System provides more visibility into the services.
- Has no support for streams or for JSON tables.
- Can return errors if you try to create a fabric or import a fabric while connected to a customer-managed cluster. Fabric creation and import operations require a functioning global namespace.
- Does not allow you to configure refresh intervals for metrics and the session rate.
- Does not expose system volumes and the APIServer logs.
- Is documented in another location. Instructions for using the Data Fabric UI are located in the as-a-service documentation. See the link later on this page.

Data Fabric UI Documentation

For more information about using the Data Fabric UI, see Administration in the as-a-service documentation:

Performance

Describes how to tune system performance, manage RDMA, and optimize CLDB tables.

Tuning System Performance

Indicates the kernel parameters that you need to tune for enhanced system performance.

last-updated: Jun 06, 2024

Tune the following kernel parameters to enhance system performance.

fs.aio-max-nr	*Preferred Value*: 262144 *Purpose*: Enhances throughput. Tunes the Asynchronous non-blocking I/O (AIO) feature that allows a process to initiate multiple I/O operations simultaneously without having to wait for any of them to complete. This helps boost performance for applications that are able to overlap processing and I/O. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: No *Applicable to Containerized Client*: No
fs.epoll.max_user_watches	*Preferred Value*: 32768 *Purpose*: Enhances throughput for high memory/CPU machines. Specifies a limit on the total number of file descriptors that a user can register across all epoll instances on the system. The limit is per real user ID. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
fs.file-max	*Preferred Value*: 32768 *Purpose*: Enhances throughput for high memory/CPU machines. Tunes the number of concurrently open file descriptors on the system. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.ipv4.route.flush	*Preferred Value*: 1 *Purpose*: Makes the TCP configurations effective instantly. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.core.rmem_max	*Preferred Value*: 4194304 *Purpose*: Enhances throughput by tuning the TCP stack. Sets the maximum OS receive buffer size for all types of connections. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.core.rmem_default	*Preferred Value*: 1048576 *Purpose*: Enhances throughput by tuning the TCP stack. Sets the default OS receive buffer size for all types of connections. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.core.wmem_max	*Preferred Value*: 4194304

last-updated: Jun 06, 2024

	Purpose: Enhances throughput by tuning the TCP stack. Sets the maximum OS send buffer size for all types of connections. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.core.wmem_default	*Preferred Value*: 1048576 *Purpose*: Enhances throughput by tuning the TCP stack. Sets the default OS send buffer size for all types of connections. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.core.netdev_max_backlog	*Preferred Value*: 30000 *Purpose*: Enhances throughput by tuning the TCP stack. Sets the maximum number of packets, queued on the INPUT side, when the interface receives packets faster than kernel can process them. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.ipv4.tcp_rmem	*Preferred Value*: 4096 1048576 4194304 *Purpose*: Enhances throughput by tuning the TCP stack. Increase the read-buffer space allocatable (minimum size, initial size, and maximum size in bytes). *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.ipv4.tcp_wmem	*Preferred Value*: 4096 1048576 4194304 *Purpose*: Enhances throughput by tuning the TCP stack. Increase the write-buffer space allocatable (minimum size, initial size, and maximum size in bytes). *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.ipv4.tcp_mem	*Preferred Value*: 8388608 8388608 8388608 *Purpose*: Enhances throughput by tuning the TCP stack. Increase the maximum total buffer-space allocatable ((minimum size, initial size, and maximum size in pages (4096 bytes each)). *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.ipv4.tcp_syn_retries	*Preferred Value*: 4 *Purpose*: Maintains High Availability by detecting failures rapidly. This is a TCP setting that ensures that the TCP stack takes about 30 seconds to detect failure of a remote node. Note that this is a setting that

	impacts all TCP connections. Hence, exercise caution in lowering this further. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
net.ipv4.tcp_retries2	*Preferred Value*: 5 *Purpose*: Maintains High Availability by detecting failures rapidly. Influences the timeout of a TCP connection that is alive, when RTO retransmissions remain unacknowledged. Given a value of N, a hypothetical TCP connection following exponential backoff with an initial RTO of TCP_RTO_MIN would retransmit N times before killing the connection at the (N+1)th RTO. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
vm.dirty_ratio	*Preferred Value*: 6 *Purpose*: Maintains High Availability by guaranteeing fast resync time. Denotes the absolute amount of system memory which when dirty, the process doing writes would block and write out dirty pages to the disks. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
vm.dirty_background_ratio	*Preferred Value*: 3 *Purpose*: Maintains High Availability by guaranteeing fast resync time. Denotes the percentage of system memory that can be filled with dirty pages — memory pages that still need to be written to disk — before being written to disk. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
vm.overcommit_memory	*Preferred Value*: 0 *Purpose*: Enhances throughput. Allows the system to heuristically manage memory rather than overcommiting and experiencing crashes when memory is exhausted. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes
vm.swappiness	*Preferred Value*: 1 *Purpose*: Enhances throughput. A value of 1 means start using swap only when 99% of RAM is utilized. This is not required if the containers do not have swap. *Applicable to MFS (Bare Metal or Containerized)*: Yes, if containerized MFS uses swap space. *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes, if container uses swap space.

last-updated: Jun 06, 2024

max_sectors_kb	*Preferred Value*: 1024 *Purpose*: Enhances throughput. Sets the maximum I/O per block disk. For example: `echo "1024" > /sys/block/$devName/queue/max_sectors_kb` *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: No *Applicable to Containerized Client*: No
scheduler	*Preferred Value*: noop *Purpose*: Enhances throughput. NOOP is the simplest I/O scheduler for the Linux kernel based upon the FIFO queue concept. The NOOP scheduler inserts all incoming I/O requests into a simple FIFO queue and implements request merging. The scheduler assumes that I/O performance optimization will be handled at some other layer of the I/O hierarchy. Set NOOP per disk controller. For example: `echo noop > /sys/block/hda/queue/scheduler` **NOTE:** For a high performance SSD on RHEL 8.x, it is recommended to set the scheduler to *none* or *kyber*, as explained. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: No *Applicable to Containerized Client*: No
core-pattern	*Preferred Value*: `/opt/cores/%e.core.%p.%h` *Purpose*: Enhances supportability. Indicates where and what should be the core file name in case a process crashes. *Applicable to MFS (Bare Metal or Containerized)*: Yes *Applicable to Bare Metal Client*: Yes *Applicable to Containerized Client*: Yes

Remote Direct Memory Access

This page introduces Remote Direct Memory Access (RDMA), describes the advantages of RDMA over TCP/IP, documents RDMA system requirements, and lists commands you can use to disable RDMA.

What is RDMA?

TCP/IP communication uses copy operations that involve user-kernel context switching, user-kernel memory copies, Linux kernel interrupt processing, and kernel packet processing. TCP/IP suffers from two major problems:

- TCP/IP consumes significant CPU cycles and memory resources
- TCP/IP has large end-to-end latency

Remote Direct Memory Access (RDMA) mitigates these major problems by copying data directly between virtual memory buffers on two different machines, resulting in lower latency, higher throughput, and smaller CPU footprint.

last-updated: Jun 06, 2024

RDMA transfers do not involve the CPU, and there are no context switches. Transfers occur in parallel with other system operations.

The following diagram compares TCP and RDMA operations:

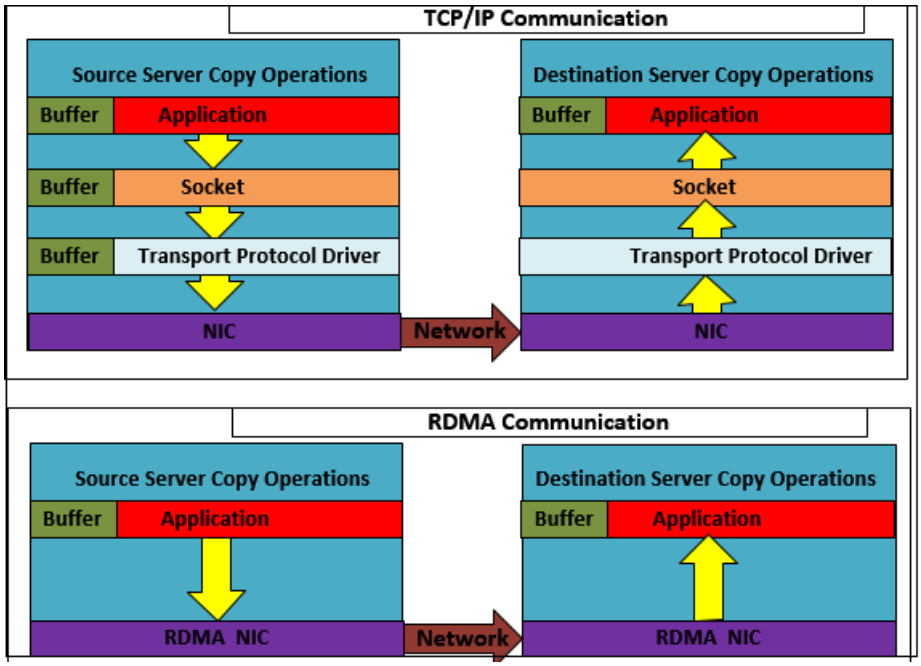

Figure 14: TCP/IP vs RDMA Communication

Supported RDMA Type

There are two kinds of RDMA protocols in existence - RDMA over Converged Ethernet (RoCE) and iWARP. HPE Ezmeral Data Fabric supports only RoCE.

When HPE Ezmeral Data Fabric Uses RDMA

HPE Ezmeral Data Fabric uses RDMA when it needs to transfer data between:

- Fileclient (Java Client, FUSE, NFS) and MFS
- NFS clients and NFS gateway
- MFS instances

RDMA System Requirements

To benefit from RDMA, your system needs to have a Network Interface Card (NIC) that supports RDMA. HPE Ezmeral Data Fabric is tested with Mellanox cards, but any NIC that supports RDMA should work. Ensure that you have Infiniband support installed. To install Infiniband support, run:

On CentOS:

```
yum -y groupinstall "Infiniband Support"
```

To determine whether your NIC supports RDMA, run:

```
ibv_devinfo | grep "PORT_ACTIVE"
```

If the command returns the active ports, then your NIC(s) support(s) RDMA.

last-updated: Jun 06, 2024

For example:

```
# ibv_devinfo | grep "PORT_ACTIVE"
                        state:                  PORT_ACTIVE (4)
                        state:                  PORT_ACTIVE (4)
```

Optionally, to determine the interfaces with RDMA support:

1. Run:

   ```
   ibv_devices
   ```

   The output returns the Infiniband devices. For example:

   ```
   device                 node GUID
       ------              ----------------
       mlx4_0              040973ffffd661f0
       mlx4_1              b88303ffff9e5440
   ```

2. Run:

   ```
   ls /sys/class/infiniband/<Infiniband_Device_Name>/device/net/
   ```

   to determine the RDMA NIC. For example:

   ```
   ls /sys/class/infiniband/mlx4_0/device/net/
     eno5d1  ib0
   ```

   Here, the NIC is **eno5d1**.

3. To confirm that this NIC exists, run:

   ```
   ip a | grep <NIC>
   ```

   For example:

   ```
   ip a | grep eno5d1
     6: eno5d1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state
   UP group default qlen 1000
       inet 10.163.160.63/21 brd 10.163.167.255 scope global noprefixroute
   eno5d1
       inet 10.163.160.47/24 scope global eno5d1:~m0
   ```

RDMA is automatically enabled only when the NICs/nodes are RDMA capable. HPE Ezmeral Data Fabric automatically uses TCP/IP when the system does not support RDMA.

Disabling RDMA

By default, RDMA is automatically enabled and functional on all nodes and clients that support RDMA. To disable RDMA, use any of the following options:

last-updated: Jun 06, 2024

To Disable RDMA	Perform the Following Task
On all nodes in the cluster	Set `/opt/mapr/bin/maprcli config save -values '{"support.rdma.transport":"0"}'`. With this option, clients can have RDMA enabled but will revert to TCP because RDMA is disabled cluster wide.
On a local node for MFS, clients, and NFS server	In the `/opt/mapr/conf/env_override.sh` file on that node, set `export MAPR_RDMA_SUPPORT=false`
Only for a local MFS node (and NOT for any client)	In the `/opt/mapr/conf/mfs.conf` file on that node, set `mfs.listen.on.rdma=0`
For communication between an NFS server and MFS only	In the `/opt/mapr/conf/nfsserver.conf` file on that NFS node, uncomment `NfsRdmaToMfs=0`
For the clients (FUSE, Hadoop) only	Set the property `fs.mapr.disable.rdma.transport` to `true` in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file.

NFS Port for RDMA Communication

By default, NFS servers use port **20049** to communicate with NFS clients using RDMA. To change this port, set the `NfsRdmaPort` parameter in `/opt/mapr/conf/nfsserver.conf` to the desired port. For example:

```
NfsRdmaPort=20050
```

NOTE: Setting this port to `0` causes NFS servers to use TCP to communicate with NFS clients.

NFS Mount With RDMA

To mount an NFS server with RDMA support on an NFS client, use the following command:

```
mount -o vers=3,proto=rdma,port=20049 <NFSserver IP>:<directory> <mount point>
```

RDMA Specific Commands

You can use the following `mrconfig` commands to display RDMA information:

- mrconfig rdma dumpServerInfo on page 2954 – Displays RDMA server information.
- mrconfig rdma listEndPoints on page 2954 – Displays RDMA connection information similar to `netstat` for RPC listings.

Data Fabric Support for NVIDIA GDS

Describes HPE Ezmeral Data Fabric support for the NVIDIA GPU Direct Storage (GDS) bypass protocol.

Data Fabric NFS with Remote Direct Memory Access (RDMA) in release 7.2.0 supports NVIDIA GPU Direct Storage (GDS). See the NVIDIA storage support matrix.

GDS uses RDMA to bypass system CPU and memory when transferring data from a storage system to GPU memory. Because NVIDIA has enabled GDS for standard Linux NFS clients using RDMA, you can use the Data Fabric NFS client with RDMA to send and receive data between the Data Fabric and GPU without involving the host processor.

last-updated: Jun 06, 2024

Optimizing CLDB Tables

Explains how to enable the CLDB tunable for optimizing CLDB tables.

Data Fabric contains a CLDB tunable called `cldb.feature.optimize.volume.kvstores`. Enabling this tunable automatically optimizes the B-Tree of CLDB tables with a large number of volumes and read-write containers, and results in enhanced CLDB performance.

Prerequisites for enabling this feature

Before enabling this feature, ensure that **all** CLDB nodes are at the current version. Also, enable all features that were present in the previous version of data-fabric, using the maprcli cluster feature enable command.

Enabling and Activating Optimization

To enable and activate CLDB optimization:

1. Run:

```
maprcli cluster feature enable -name
cldb.feature.optimize.volume.kvstores
```

2. Restart the CLDB primary instance and wait till the instance comes to the `MASTER_READ_WRITE` state.

   TIP: To check the CLDB state, run `maprcli dump cldbstate`. For example:

```
root@qa108-181 ~]# maprcli dump cldbstate
mode               ip             state
stateDuration  desc
SLAVE_READ_ONLY    10.10.108.181  CLDB_IS_SLAVE_READ_ONLY
40:10:11       cldb running as slave
SLAVE_READ_ONLY    10.10.108.182  CLDB_IS_SLAVE_READ_ONLY
40:11:42       cldb running as slave
MASTER_READ_WRITE  10.10.108.183  CLDB_IS_MASTER_READ_WRITE
40:11:38      kvstore tables loading

       complete,

       cldb running as master
```

3. Restart the secondary CLDB nodes.

last-updated: Jun 06, 2024

NOTE: To know whether the optimization is complete, check if both `cldb.string.table.conversion.done` and `cldb.spcontainersmap.table.conversion.done` are both set to 1.

For example:

```
 maprcli config load -json | grep -i cldb.string.table.conversion.done
          "cldb.string.table.conversion.done":"1",
```

```
 maprcli config load -json | grep -i
cldb.spcontainersmap.table.conversion.done
          "cldb.spcontainersmap.table.conversion.done":"1",
```

The CLDB does some part of the optimization on every CLDB start, hence it may take some time to optimize the SP Container Map Tables (`cldb.spcontainersmap.table.conversion.done`) depending on the cluster size.

Security

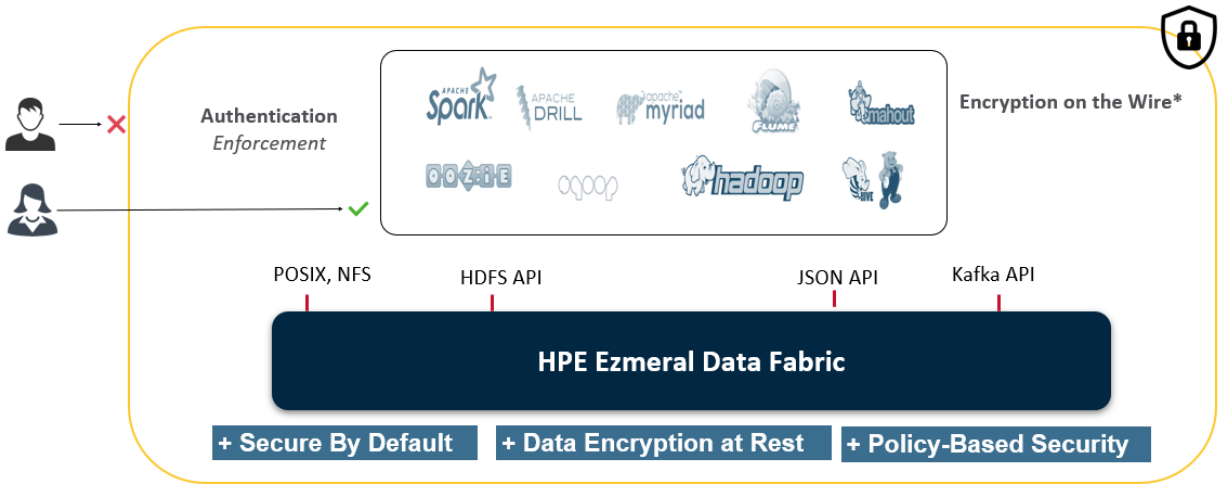
Provides an overview of the Data Fabric security features.

Securing enterprise data is critical. To make securing data in clusters easy, the HPE Ezmeral Data Fabric has a data protection scheme built directly into the platform that is enabled by default, simplifying the process of protecting critical data. You can take advantage of the default security settings, or you can implement data security manually. Either way, it is important to identify which data to secure.

Since data must be shared between nodes on the cluster, data transmissions between nodes, and from the cluster to the client are vulnerable to interception. Networked computers are also vulnerable to attacks where an intruder successfully pretends to be another authorized user and then acts improperly as that user. Additionally, networked machines share the security vulnerabilities of a single node. The HPE Ezmeral Data Fabric supports the ability to apply protection directly as data enters and exits the platform. You do not need to apply an external management server or particular security plugin.

Secure by Default	Data Fabric, which includes the HPE Ezmeral Data Fabric and EEP components, is secure out-of-the-box on all new installations, ensuring all network connections require authentication and all data in motion is protected with wire-level encryption. Data Fabric provides the ability to apply security protection directly for data as it comes into and out of the platform without requiring an external security manager server or a particular security plugin for each ecosystem component. The security semantics are applied automatically on data being retrieved or stored by any ecosystem component, application, or users.
Platform-Based Security	The HPE Ezmeral Data Fabric applies security semantics automatically as data is being stored and retrieved from the platform. It supports all four pillars of security (authentication, authorization, auditing, and encryption), using platform-level capabilities that do not require external security tools or plugins. Starting with Data Fabric 6.2, the platform introduces support for Policy-Based Security. Policy-based security enables you to more easily manage the four pillars of security.
Encryption	On the HPE Ezmeral Data Fabric, data is protected by encrypting all data being transmitted over the wire and encrypting all data that is stored in the platform.

last-updated: Jun 06, 2024



The following sections describe the Data Fabric security capabilities and security architecture.

Security Capabilities

A secure Data Fabric environment is predicated on authentication, authorization, auditing, and encryption capabilities. You can use policy-based security to classify and manage these capabilities.

Authentication	Restricting access to a specified set of users. Robust authentication prevents third parties from representing themselves as legitimate users. Data Fabric supports a wide range of authentication mechanisms depending on the network transport. These mechanisms include Data Fabric tickets, Kerberos, Pluggable Access Module (PAM), Basic Authentication, Data Fabric SASL, and SPNEGO. See Configuring Authentication on page 1828 for more information.
Authorization	Restricting an authenticated user's capabilities on the system. Data Fabric provides sophisticated authorization controls to ensure that users can perform only the activities for which they have permissions, such as data access, job submission, cluster administration, and more. These permissions can be granted by an administrator through the browser-based Control System management and monitoring interface, or by using the command-line utilities. See Managing Access Controls on page 1852 for more information.
Auditing	Logging audit records of operations. Data Fabric allows you to log audit records of cluster-administration operations and operations on directories, files, and tables. See Managing Auditing on page 1057 for more information.
Encryption	Restricting an external party's ability to read data. Encryption is used to avoid exposure to breaches, such as packet sniffing and theft of storage devices.

	In a secure Data Fabric cluster, data transmission between nodes, and between a Data Fabric cluster and ecosystem application is encrypted, preventing an attacker with access to that communication from gaining information about the contents of the transmission. Optionally, you can enable encryption for data at rest to prevent unauthorized users from accessing sensitive data, and protect against data theft through sector-level disk access. Data is protected by encrypting all data being transmitted over the wire and optionally encrypting all that is stored on the Data Fabric platform. The Data Fabric data encryption scheme is built directly into the platform and is enabled by default. See Managing Encryption on page 1797 for more information.
Policy-Based Security	Create security policies and apply them to data objects to simplify the management of security controls on data. Policy-Based Security is a feature that administrators can use to classify security controls into a manageable number of *security policies* instead of defining security controls on individual data objects. The security controls defined in a security policy identify which users are authorized to access and modify data objects, whether to audit data operations, and whether to protect data in motion with wire-level encryption. When you apply security policies on data objects, such as volumes, files, and tables, the HPE Ezmeral Data Fabric automatically enforces the security controls defined in the policies during data operations. In cases where data is not associated with a security policy, the system enforces the security controls directly defined on data objects. See Policy-Based Security on page 854 for more information.

Security Architecture

Data Fabric provides the following authentication and authorization functionality:

File System Permissions	For files and directories on the Data Fabric cluster, you can leverage standard Unix-style permissions to grant access to authorized users. Since file system is a POSIX-like file system, you can set user permissions as you would on any other Linux system. See Setting file system Permissions on page 1319 for more information.
Cluster, Volume, and Job Queue Access Control Lists (ACLs)	You can specify the actions that a given user can perform on each of these cluster elements. You can use access control lists (ACLs) to grant permissions for performing administrative tasks at both the cluster and the volume level. See Managing Access Control Lists on page 1852 for more information.
Access Control Expressions for File System and Natively Stored HPE Ezmeral Data Fabric Database Tables	ACEs control which files, directories, volumes, streams, and tables users or groups can access. ACEs are a powerful and flexible mechanism to grant permissions on structured and unstructured data. See Managing Access Control Expressions on page 1855 for more information.

last-updated: Jun 06, 2024

Impersonation for Centralized Control of Access to Resources	Impersonation, also known as identity assertion, is one user accessing data and submitting jobs on behalf of another user. See Managing Impersonation on page 1942 for more information.

What to do Next

The secure-by-default data platform provides security through a single option in the Installer on page 5579 or by running the `configure.sh on page 2821` script with the `-secure` option after a manual installation. You can enable security on your cluster using the procedure described in the following topics:

- Using the Enable Secure Cluster Option on page 5611 if you are installing with the Installer on page 5579.
- Enabling Security on page 1776 if you are Installing without the Installer on page 179.

After enabling security, optionally, you can perform the following tasks:

- Understand the security exceptions and take corrective action, where applicable.
- Configure authorization on the resources.
- Configure auditing on administration and resources.
- Configure security policies to manage security controls on data resources.
- Configure encryption for data at rest.
- If you have Hive installed, enable storage-based authorization for the Hive Metastore server.

Authentication in Data Fabric

Describes types of authentication available with the HPE Ezmeral Data Fabric and how to manage user authentication with the `maprlogin` utility.

Authentication ensures that who you really are and who you claim to be, match when identifying the end user to the system. data-fabric authentication supports standard Basic Authentication and SPNEGO authentication for web-based interfaces, and supports data-fabric tickets for many of the core system component non-web-based interfaces. A ticket is an object that contains specific information about a user, an expiration time, and a key. Tickets uniquely identify a user and are encrypted to protect their contents. You can use tickets to establish sessions between a user and the cluster.

Types of Authentication in Data Fabric

Data Fabric supports two methods of authenticating a user and generating a ticket: a username-password pair and Kerberos. Both of these methods are mediated by the maprlogin on page 2911 utility. When you authenticate with a username-password pair, the system verifies your credentials using Pluggable Authentication Modules (PAM). You can configure the cluster to use any registry that has a PAM module.

Data Fabric tickets contain the following information:

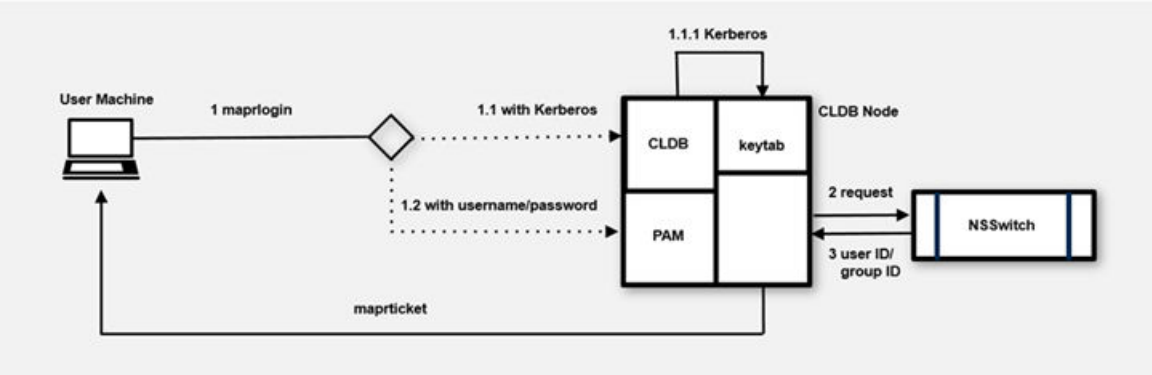
- UID (generated from the UNIX user ID)
- GIDs (group IDs for each group the user belongs to)
- Ticket creation time
- Ticket expiration time (by default, 14 days)
- Renewal expiration time (by default, 30 days from the date of ticket creation)

last-updated: Jun 06, 2024

A data-fabric ticket determines the user's identity. The system uses the ticket as the basis for authorization. A data-fabric cluster with security features enabled does not rely on the client-side operating system identity.

The maprlogin Utility for Generating Tickets

The `maprlogin` on page 2911 utility supports user authentication with either username and password, or Kerberos to generate a unique session token called a *ticket*. The following diagram outlines the process flow:



Data Fabric tickets are either implicitly or explicitly generated. On clusters that use Kerberos for authentication, a user that runs a data-fabric command without first using the `maprlogin` utility implicitly obtains a data-fabric ticket. During usage, the client runtime process first checks for a valid user ticket, and uses that ticket if it exists. If a ticket does not exist, the runtime process checks if Kerberos is enabled for the cluster and then checks for an existing valid Kerberos identity. When a valid Kerberos identity is found, the client implicitly generates a ticket for that Kerberos identity.

When you explicitly generate a ticket, you can authenticate either with your username and password, or with Kerberos:

1. The user on the client machine invokes the `maprlogin` utility, which connects to a CLDB node in the cluster using HTTPS. The host name for the CLDB node is specified in the `mapr-clusters.conf` file.
   - For username-password authentication, the node authenticates using PAM modules with the Java Authentication and Authorization Service (JAAS).

     The JAAS configuration is specified in the `mapr.login.conf` file. The system can use any registry that has a PAM module available.
   - For Kerberos authentication, the CLDB node verifies the Kerberos principal with the `keytab` file.
2. After authenticating, the CLDB node uses the standard UNIX APIs `getpwnam_r` and `getgrouplist`, which are controlled by the `/etc/nsswitch.conf` file, to determine the user IDs and group IDs.
3. The CLDB node generates a ticket and returns it to the client machine, completing the login communication between the client and the CLDB.
4. After login, the data-fabric server validates that the ticket is properly encrypted, to verify that the ticket was issued by the cluster's CLDB.
5. The server also verifies that the ticket has not expired or been included in denylist.
6. The server checks the ticket for a privileged identity such as the `mapr` user.

   Privileged identities have impersonation functionality enabled.

last-updated: Jun 06, 2024

7. The ticket's user and group information are used for authorization to the cluster, unless impersonation is in effect.

Authentication Enhancements for Ticket Handling
Describes limitations in the data-fabric SASL authentication mechanism for earlier releases and the enhancements to the mechanism for release 7.0.0.

With these enhancements, applications that are not cluster aware can still authenticate with other clusters. Client applications that need to authenticate with a non-default cluster using data-fabric SASL now automatically select the correct ticket if the user has a valid ticket for that cluster.

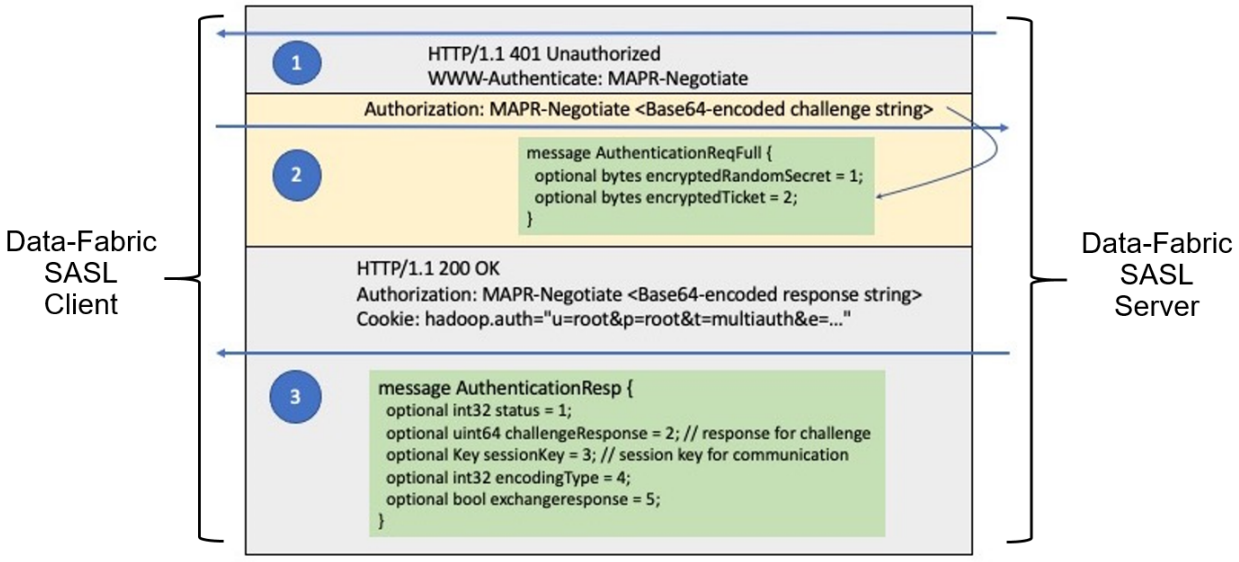
Authentication Mechanism for Releases 6.1.x and 6.2.0
Describes limitations of the authentication mechanism used in Releases 6.1.x and 6.2.0.

Overview of the Data Fabric SASL Authentication for Releases 6.1.x and 6.2.0

Hadoop and the ecosystem components supported by the HPE Ezmeral Data Fabric use tickets and Data Fabric SASL to authenticate to the Data Fabric core platform. ZooKeeper and most ecosystem components, such as Drill, Hive, Oozie, Spark, and other components use Data Fabric SASL to enable client and server communication.

Description of the Authentication Mechanism

The Data Fabric SASL protocol, illustrated here, follows the RFC-7235 standard for HTTP/1.1 authentication:



Step 1

When a client sends a server a request for a resource, either without a token or with an invalid (for example, expired) token, the server returns the HTTP/1.1 `401 Unauthorized` response to the client. The `WWW-Authenticate` property is set to `MAPR-Negotiate`, indicating that Data Fabric SASL is supported. If other authentication mechanisms are supported, multiple `WWW-Authenticate` properties are returned, one for each mechanism.

Step 2

The SASL client invokes the Data Fabric SASL authentication handler, which in turn constructs an `AuthenticationReqFull` request message containing the encrypted client ticket and a random secret encrypted with the user key. Since there is no mechanism in the SASL client to specify which ticket to use or which cluster the authentication request should be sent to, the Data Fabric SASL authentication handler finds the default cluster in `${MAPR_HOME}/conf/mapr-clusters.conf`. The authentication handler

last-updated: Jun 06, 2024

then finds the ticket for the default cluster in one of the designated ticket locations, which defaults to `/tmp/maprticket_<uid>`. It then serializes the `AuthenticationReqFull` request message, encodes it in Base64 format, and sends the request message to the CLDB of the default cluster over HTTPS in the `Authorization` property.

Step 3

Upon receipt of the `AuthenticationReqFull` request message, the CLDB decrypts the client ticket using the server key and validates the ticket to ensure it is not in deny list or expired. The CLDB then extracts the user key from the ticket to decrypt the random secret. It adds 1 to the challenge (random secret), returns the response to the Data Fabric SASL authentication handler over HTTPS in the `Authorization` property. Upon successful authentication, the Data Fabric SASL authentication handler returns the token to the client in the `Cookie` property, since this is a Hadoop client. Different clients can return tokens in different formats.

Limitations of the Data Fabric SASL Implementation Used in Releases 6.1.x and 6.2.0

Some drawbacks of the Data Fabric SASL implementation used in release 6.1.x and 6.2.0 are as follows:

- Keys used to decrypt tickets in the core platform are cluster specific. However, the upper layers have no concept of clusters and no way to specify which cluster the request is to be sent to. Therefore, this Data Fabric SASL implementation works only for the default cluster. Applications can be written using the client REST API to specify the destination cluster and overwrite the limitation of the default cluster, but other problems remain.
- Even if the Data Fabric SASL implementation is enhanced to be cluster-aware, single sign-on does not work in Data Fabric SASL because it is not aware of trust relationships. It requires the destination cluster ticket even when the source and destination clusters have a user-level trust relationship established. The application must not only know which cluster it is trying to contact, but also acquire tickets for every cluster that it needs to contact even if user-level trust relationships have been established between the source and destination clusters.
- If the CLDB node of a non-default cluster receives the request, the authentication fails because the user ticket cannot be decrypted. However, the CLDB node does not know why the decryption failed, and which cluster keys should be used.
- Tickets can be encrypted using various keys, such as the CLDB key or server key. However, there is no indication in the `AuthenticationReqFull` request message as to what key to use to decrypt the request. The CLDB always assumes that tickets are encrypted using the server key. This limits the ability of Data Fabric SASL to handle various kinds of tickets in future enhancements, such as OIDC tickets.

Drawbacks in the Data Fabric SASL protocol implementation created various issues in the ecosystem layers:

- Data Fabric ecosystem components often do not know which cluster a particular request is to be forwarded to, as this is determined by the lower layers. As such, the components typically use the ticket for the local cluster. That ticket is encrypted with a key that is available only to the local cluster itself, but not to remote clusters. Hence, Data Fabric SASL authentication fails.
- ODBC and JDBC secure connections work only for the local cluster.
- The implementation of various Data Fabric commands relies on unsupported features. For example, if the `maprcli service list` command is issued on a remote cluster, `maprcli` forwards the request to the ZooKeeper node on the remote cluster, giving the ticket to the local cluster for authentication credentials. The remote ZooKeeper node fails the request, since it is unable to decrypt the ticket. The ticket is encrypted with a key that is not available to the remote cluster. While this issue can be fixed easily by selecting the correct ticket for the remote cluster, this is not a long-term solution. It is equivalent to requiring a person to acquire a passport to every foreign country he wants to visit.

These issues pointed to the need for an architecture in which remote clusters can read local tickets with proper authorizations. This is akin to the real-world scenario where a person needs to acquire a passport only for the person's home country. Then the person is allowed to use the same passport to travel to foreign countries that have a pre-established relationship with the person's home country.

For solutions to these issues, see Authentication Enhancements for Release 7.0.0 on page 837.

Authentication Enhancements for Release 7.0.0
Release 7.0.0 extended data-fabric SASL to support cross-cluster communication.

In previous releases, the data-fabric SASL protocol only supported authentication within the same cluster, even if the client had a valid ticket for the remote cluster. In release 7.0.0, the protocol was enhanced to address this limitation, and now supports authentication across different clusters, provided the client has a valid ticket for the destination cluster. Consequently, ecosystem components such as Drill and Hive now work across multiple clusters, if properly configured.

Authorization in Data Fabric

Describes the basics of authorization including Access Control Lists and Access Control Expressions.

Authorization restricts what an authenticated user can do with data. Data Fabric enables you to create flexible authorization systems that grant a user capabilities to perform desired tasks, but prevents the user from performing tasks outside of that scope. Use a combination of Access Control Lists and Access Control Expressions to set up a flexible authorization system.

Access Control Lists

Data Fabric supports Access Control Lists (ACLs) in several areas, including for regulating user privileges to the job queue and cluster. Data Fabric also uses ACLs to control administrative access to volumes (administrative access is distinct from data access).

An Access Control List (ACL) is a list of users or groups. Each user or group in the list is paired with a defined set of permissions that limit the actions that the user or group can perform on the object secured by the ACL. In data-fabric, the objects secured by ACLs are the job queue, volumes, and the cluster itself.

A job queue ACL controls who can submit jobs to a queue, kill jobs, or modify their priority. A volume-level ACL controls which users and groups have administrative access to that volume, and what actions they may perform, such as mirroring the volume, altering the volume properties, dumping or backing up the volume, or deleting the volume.

Access Control Expressions

Data Fabric also provides a more powerful authorization known as Access Control Expressions. *ACE*s allow you to control access using powerful boolean logic expressions. You can use *ACE*s to control data access to data-fabric tables, files, directories, volumes, and streams. The file system also supports standard POSIX filesystem permission levels.

An *ACE* is a combination of user, group, and role definitions. A *role* is a custom defined name that is determined and implemented by your custom authorization code. It can be a property of a user or group that defines a set of behaviors that the user or group performs regularly. You can use ACEs to secure files, directories, volumes, tables, and streams that use native storage.

last-updated: Jun 06, 2024

See the Configuring Data Fabric Security on page 1773 section for information about the procedures for setting up and modifying ACLs and ACEs for the cluster, the volumes on the cluster, the job queue, the data-fabric filesystem, and the natively stored data-fabric tables and streams.

Encryption in Data Fabric

Describes encryption types available on the HPE Ezmeral Data Fabric.

Data Fabric encryption restricts an external party's ability to read or modify data.

Data Fabric supports encryption of data on wire and data at rest for preventing unauthorized access to sensitive data. These encryption methods are in addition to authentication and authorization protections. Encryption can be used to avoid exposure to breaches such as packet sniffing and theft of storage devices.

Data transmission between nodes on a secure data-fabric cluster is encrypted, preventing an attacker with access to that communication from gaining information about the contents of the transmission. Encryption of data-at-rest prevents unauthorized users from accessing sensitive data and protects against data theft through sector-level disk access.

On-Wire Encryption

Data transmission between nodes on a secure data-fabric cluster over any network connection supported by data-fabric is encrypted. When you run the `configure.sh on page 2821` utility with the `-secure` option, you are enabling the cluster for security, authentication, and wire-level encryption for the platform and all ecosystem components. In secure mode, data-fabric automatically encrypts all data traffic. Enabling encryption ensures that data to and from the locations you specify is encrypted as it travels over the network.

Data Fabric uses the following technologies to protect network traffic:

- The Secure Sockets Layer/Transport Layer Security (SSL/TLS) protocol secures several channels of HTTP traffic supporting TLS 1.0, 1.1(default), and 1.2.
- In compliance with the NIST standard, the 256-bit Advanced Encryption Standard in Galois/Counter Mode (AES256/GCM) secures several communication channels between cluster components.

The information in Security Protocols Used by Data Fabric on page 839 includes details on the specific technologies used by particular elements of a cluster.

Nodes with CPUs that support AES encryption at the hardware level provide superior performance on encryption tasks. You can determine if the CPU of a node supports the AES instruction set, by running the following command:

```
$ cat /proc/cpuinfo | grep flags | grep aes
```

Data-at-Rest Encryption

Data on disk (or data-at-rest) on a secure data-fabric cluster can be encrypted, enabling you to protect the data if a disk is compromised. Encryption of data-at-rest not only prevents unauthorized users from accessing sensitive data, but it also protects against data theft via sector-level disk access. When you run the `configure.sh on page 2821` utility with the `-dare` option, you are enabling data at rest encryption feature at the cluster level. If encryption of data at rest is enabled, new volumes are encrypted by default with the option to create a volume without encryption. For example, if you have a volume that contains data that is not at all sensitive, you might not want to encrypt it. For encrypted volumes, data-fabric automatically encrypts data at rest and manages the keys used to encrypt data seamlessly; you do not need special utilities to encrypt or decrypt the data. Data Fabric uses AES256/XTS to protect data on the disk.

SSL Certificates

Describes how certificates are used to perform authentication and encryption for websites that use the HTTPS protocol.

The TLS (Transport Layer Security, formally SSL Secure Sockets Layer) certificate performs authentication and encryption for websites that use the HTTPS protocol. A certificate contains information about an entity and contains a public key. The public key is related to a private key that is NOT part of the certificate, but it is used by one entity when it communicates with another entity.

HPE Ezmeral Data Fabric stores the private key and certificate in a key store file called `ssl_keystore`. A certificate is also digitally signed so that it cannot be altered. The signer is known as the signing certificate.

In order for an HTTPS connection to be established, the following criteria must be met:

- The *server* must have a key file that contains a certificate and a private key
- The *client* must provide a trust file that contains a signer who signed the certificate used by the server
- The server certificate must be valid and not expired
- The client must determine that the SubjectDN in the certificate is acceptable

The process of enabling security generates the common `ssl_keystore` and `ssl_truststore` files on the first CLDB server that are used by all clients and servers.

- The `ssl_keystore` contains a single self-signed certificate with a wildcard SubjectDN. For example, if the hostname of the CLDB is `a.b.com` the SubjectDN would be `CN=*.b.com`.
- The `ssl_truststore` contains the signer for the certificate in the `ssl_keystore`.

The REST API calls in a Data Fabric cluster communicate over the HTTPS protocol on port 8443. These calls are secured with SSL certificates that identify a node to the cluster.

Security Protocols Used by Data Fabric
Lists the various security protocols that data-fabric uses for encryption and authentication.

Protocol	Encryption	Authentication
Data Fabric RPC	AES/GCM	maprticket
Hadoop RPC and MAPRSASL	AES/GCM	maprticket
Hadoop RPC and Kerberos	Kerberos	Kerberos ticket
Generic HTTP Handler	HTTPS using SSL/TLS	maprticket, username and password, or Kerberos SPNEGO

For detailed information about component-level support for authentication, impersonation, and wire-level encryption, see Security Support Matrix on page 5775.

HTTPS Excluded Ciphers
Lists the weak ciphers that are excluded from the data-fabric HTTPS implementation.

By default, the following weak TLS/SSL ciphers are excluded from the data-fabric HTTPS implementation:

- `SSL_DHE_RSA_EXPORT_WITH_DES40_CBC_SHA`
- `SSL_RSA_EXPORT_WITH_DES40_CBC_SHA`
- `SSL_RSA_EXPORT_WITH_RC4_40_MD5`
- `SSL_DHE_RSA_EXPORT_WITH_DES40_CBC_SHA`
- `SSL_RSA_EXPORT_WITH_DES40_CBC_SHA`
- `SSL_RSA_EXPORT_WITH_RC4_40_MD5`

last-updated: Jun 06, 2024

- TLS_DHE_RSA_WITH_AES_128_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_256_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_256_CBC_SHA
- TLS_DHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_128_CBC_SHA256
- TLS_DHE_DSS_WITH_AES_128_CBC_SHA

Cipher Exclusion for Core Components

To exclude weak ciphers from the CLDB and Control System, typically you must add the ciphers to the `java.security` file in the installed java home path. However, the best practice for your JDK might be different. For information about enabling and disabling ciphers, consult your JDK documentation. In the following example, the `ECDHE-RSA-AES256-GCM-SHA384` cipher has been added to `java.security`:

```
updated: java.security
jdk.tls.disabledAlgorithms=SSLv3, TLSv1, TLSv1.1, RC4,
TLS_AES_256_GCM_SHA384, TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384, DES,
MD5withRSA,
DH keySize < 1024, EC keySize < 224, 3DES_EDE_CBC, anon, NULL,
include jdk.disabled.namedCurves
```

Because the cipher is excluded, using the `openssl` client to connect to the CLDB using this cipher results in a handshake failure:

```
openssl s_client -connect 10.163.164.136:7443 -tls1_2 -cipher
ECDHE-RSA-AES256-GCM-SHA384
CONNECTED(00000005)
139705826673088:error:14094410:SSL routines:ssl3_read_bytes:sslv3 alert
handshake failure:../ssl/record/rec_layer_s3.c:1528:SSL alert number 40
no peer certificate available
No client certificate CA names sent
SSL handshake has read 7 bytes and written 165 bytes
Verification: OK
New, (NONE), Cipher is (NONE)
Secure Renegotiation IS NOT supported

```

TLS 1.2 Supported Ciphers

Lists the ciphers that are supported (and not supported) by HPE Ezmeral Data Fabric for use with TLS 1.2.

Ciphers Supported for TLS 1.2

The following ciphers are supported:

- `TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256`
- `DHE-RSA-AES256-GCM-SHA384`
- `TLS_ECDHE_RSA_WITH_CHACHA20_POLY1305_SHA256`
- `TLS_DHE_RSA_WITH_CHACHA20_POLY1305_SHA256`
- `TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`
- `TLS_DHE_RSA_WITH_AES_128_GCM_SHA256`

Ciphers Not Supported for TLS 1.2

The following ciphers are not supported:

- `TLS_ECDHE_ECDSA_WITH_CHACHA20_POLY1305_SHA256`
- `TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384`
- `TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256`

Prevent Storage of Specified Types of Files

Provides an overview of how to prevent certain types of files from being stored on certain volumes.

HPE Ezmeral Data Fabric offers the capability to prevent certain types of files from being stored on specified volumes. For example, you might want to prevent executable files *(.exe)* from being stored on a volume meant to contain just financial spreadsheets.

The filefilter command provides filters to prevent storage of specified file types on the volumes to which these filters are assigned.

Impersonation in Data Fabric

Describes impersonation in Data Fabric, which allows centralized control of access to resources in the file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Streams.

Also known as identity assertion, impersonation is one user (authorized to impersonate another) or the `mapr` super user accessing data and submitting jobs on behalf of another user. Implementing impersonation provides authoritative, end-to-end security for your Data Fabric installation, independent of remote authentication and security mechanisms that control user access to application features.

To implement impersonation in Data Fabric, there are both Data Fabric core and ecosystem component requirements that must be met as well as requirements at the application development level. These requirements are described in Access Control and Impersonation in Data Fabric.

When all other requirements are met, enabling impersonation for the mapr superuser or for any other user is a simple task.

Auditing in Data Fabric

Data Fabric allows you to log audit records of cluster-administration operations, and operations on directories, files, streams and tables.

last-updated: Jun 06, 2024

The auditing capabilities in data-fabric are critical for regulatory compliance as well as for understanding user behavior. Regulations often require the ability to prove which user accessed which data. Logging user behavior helps to identify suspicious activities on sensitive data.

What Information is Collected?

If you enable auditing, data-fabric records information about data access, operations on data objects, and execution of `maprcli` commands, including the following:

- All administrator activities that use `maprcli` commands, REST API calls, and actions performed on a cluster through the Control System
- Authentication to the Control System
- Operations on directories and files
- Operations on HPE Ezmeral Data Fabric Database objects
- Operations on HPE Ezmeral Data Fabric Streams

How is Auditing Typically Used?

By analyzing audit records, security analysts can answer questions such as these:

- Who accessed customer records outside of business hours?
- What actions did users take in the days before leaving the company?
- What operations were performed without following change control?
- Are users accessing sensitive files from protected or secured IP addresses?
- Why do my reports sourced from the same underlying data look different?

Data scientists can analyze audit records to answers these questions:

- Which data is used most frequently, is therefore of high value, and should be shared more broadly?
- Which data is least commonly used, is therefore of low value, and could be purged?
- Which data should be used more, is therefore underused, and needs better advertising?
- Which administrative actions are most commonly performed and are therefore candidates for automation?

How does Auditing Work?

For a comprehensive explanation on how auditing works, see How Does Auditing Work? on page 1060.

What are the Levels of Auditing?

Levels of Auditing on page 844 explains the two levels of auditing.

What are the Prerequisites to Enable Auditing?

Ensure that you perform the prerequisites mentioned in Managing Auditing on page 1057 before enabling auditing.

How to Enable or Disable Auditing of Data Access Operations?

To enable or disable auditing of data access operations, see Enabling and Disabling Auditing of Data Access Operations on page 1059.

What is Audited for Data Access Operations?

Auditing Data Access Operations on page 849 describes the data access operations that are audited.

How to Enable or Disable Auditing of Cluster Administration Operations?

To enable or disable auditing of cluster administration operations, see Enabling and Disabling Auditing of Cluster Administration on page 1058.

What is Audited for Cluster Administration Operations?

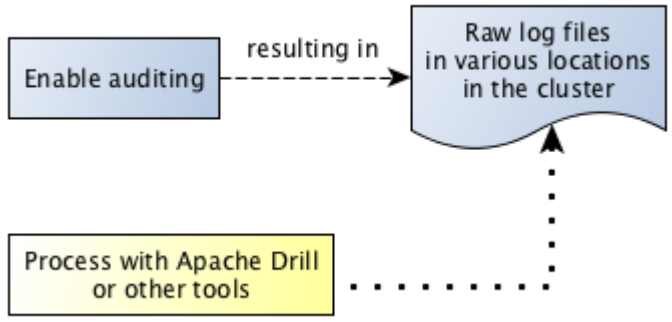
Auditing Cluster Operations on page 847 describes the operations that are audited on a cluster.

How to Selectively Audit Data Fabric Objects?

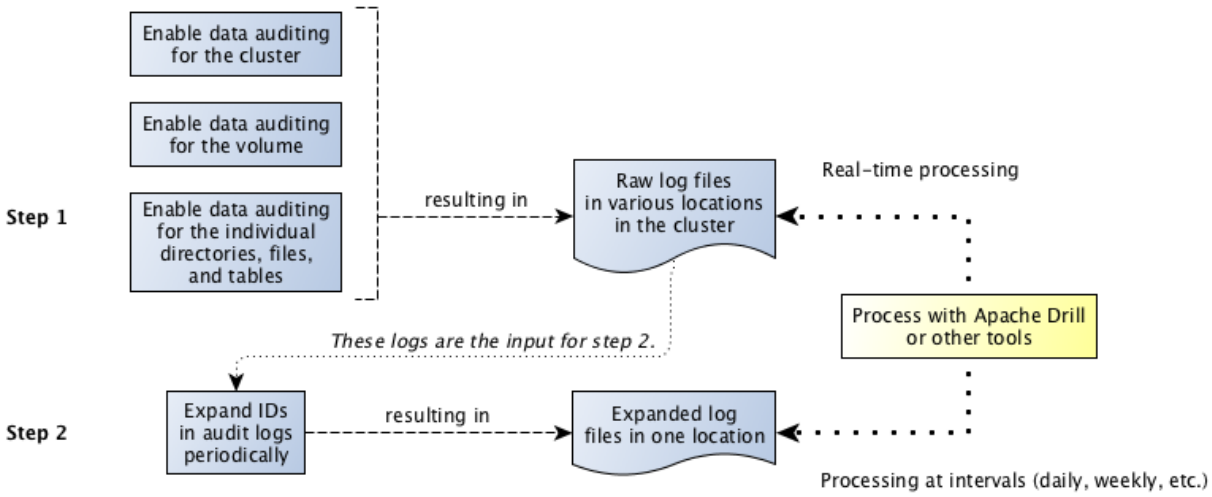
To selectively audit Data Fabric Objects, see Selective Auditing of File-System, Table, and Stream Operations Using the CLI on page 1061.

How to use Audit Logs?

After you enable auditing, audit records immediately start to be recorded in audit logs. You can use Apache Drill or other tools to process these logs. The following diagram shows the workflow for processing audit logs of cluster-administration operations:



The next diagram shows the workflow for processing audit logs of filesystem and table operations.



The step "Expand IDs in log files periodically" refers to the use of the `expandaudit` utility. Raw audit logs contain file identifiers, volume identifiers, and user identifiers. The `expandaudit` utility looks up the names that are associated with those identifiers and puts them in new copies of the audit logs. In addition, the data-fabric audit streaming feature uses an API to convert file and volume IDs. The information on audit log files can be used to interpret auditing messages.

How to Stream Audit Logs?

To stream audit logs, see Streaming Audit Logs on page 852.

How to Enable or Disable Audit Streaming

To enable or disable audit streaming, see Enabling and Disabling Audit Streaming Using the CLI on page 1065.

Levels of Auditing

Describes the two levels of auditing and the requirements to enable each level.

There are two levels of auditing:

- Auditing for cluster level operations
- Auditing of filesystem, table, and stream operations

In contrast to auditing cluster-level operations, auditing of filesystem, table, and stream operations needs to be enabled at multiple levels. For auditing file, table, and stream operations, you must first enable auditing at the cluster level and then enable auditing at the volume level. If you want:

- Granular or selective auditing of content in the volume, you must also enable auditing on each individual directory, file, table, and/or stream in the volume, recursively from the root directory, using the `hadoop` command. If auditing is enabled at the root directory, all new files inherit the property.
- To audit all content (files, tables, and/or streams) in the volume, you can set the `forceaudit` parameter at the volume level, irrespective of what is set (or whether or not auditing is enabled) at the individual file, table, and/or stream level.

The following table summarizes the requirements:

For this type of auditing...	You must enable...	Using...
Cluster-level operations	Auditing at the cluster level	`audit cluster` on page 2035 command
Granular or selective auditing of content (files, tables, and streams) in the volume	1. Auditing at the cluster level 2. Auditing at the volume level 3. Auditing on each individual file, table, and/or stream in the volume, recursively from the root directory	1. `audit cluster` on page 2035 command 2. `audit data` on page 2036, `volume create` on page 2588, or `volume modify` on page 2676 command 3. `hadoop mfs` on page 5557 command
Auditing all content (files, tables, and streams) in the volume (whether or not auditing is selectively enabled or disabled on the individual file, table, or stream)	1. Auditing at the cluster level 2. Auditing at the volume level	1. `audit cluster` on page 2035 command 2. `audit data` on page 2036, `volume create` on page 2588, or `volume modify` on page 2676 command

In the following diagram, the illustration on the left shows data auditing enabled at three levels: the cluster level, through the `maprcli audit data` command; the volume level, through any of the three volume commands shown in the diagram; and the level of the individual directory, file, table, or stream, recursively from the root directory, using the `hadoop` command. This allows you to include and/or exclude specific directories, files, tables, and streams for auditing. If auditing is not enabled at any one of these levels, operations on an object are not logged.

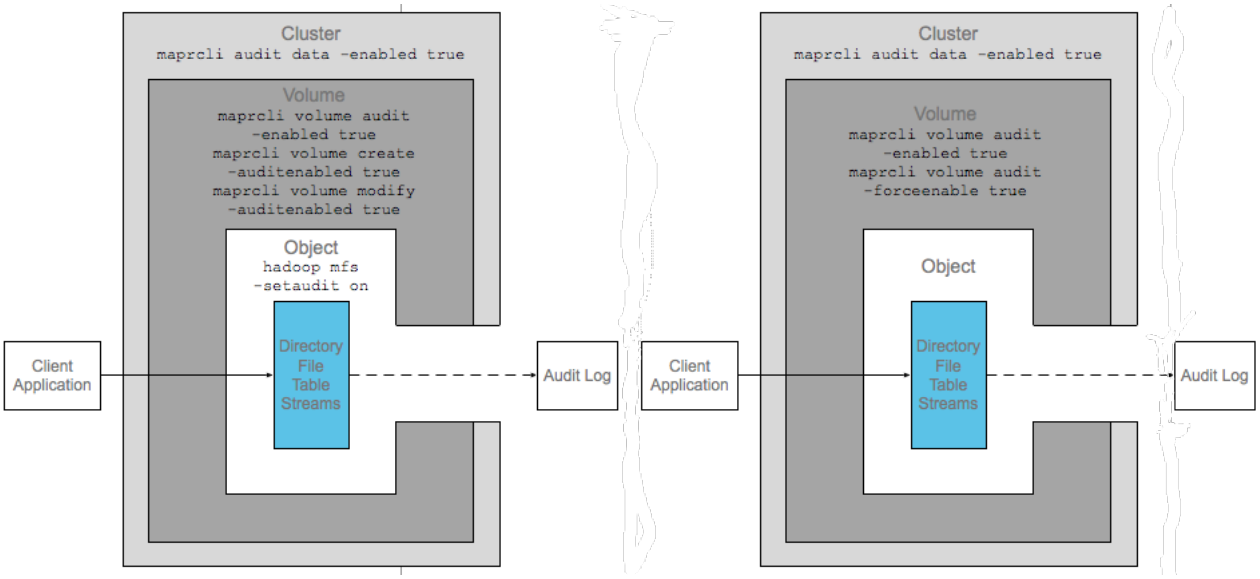
Alternatively, after enabling auditing at the cluster level, you can enforce auditing for all directories, files, tables, and streams at the volume level itself, irrespective of audit setting at the individual file, table, and/or stream level, using:

- `auditenabled` and `forceauditenable` parameters with the `volume create` on page 2588 or `volume modify` on page 2676 command.
- `enabled` and `forceenable` parameters with the `volume audit` on page 2579 command.

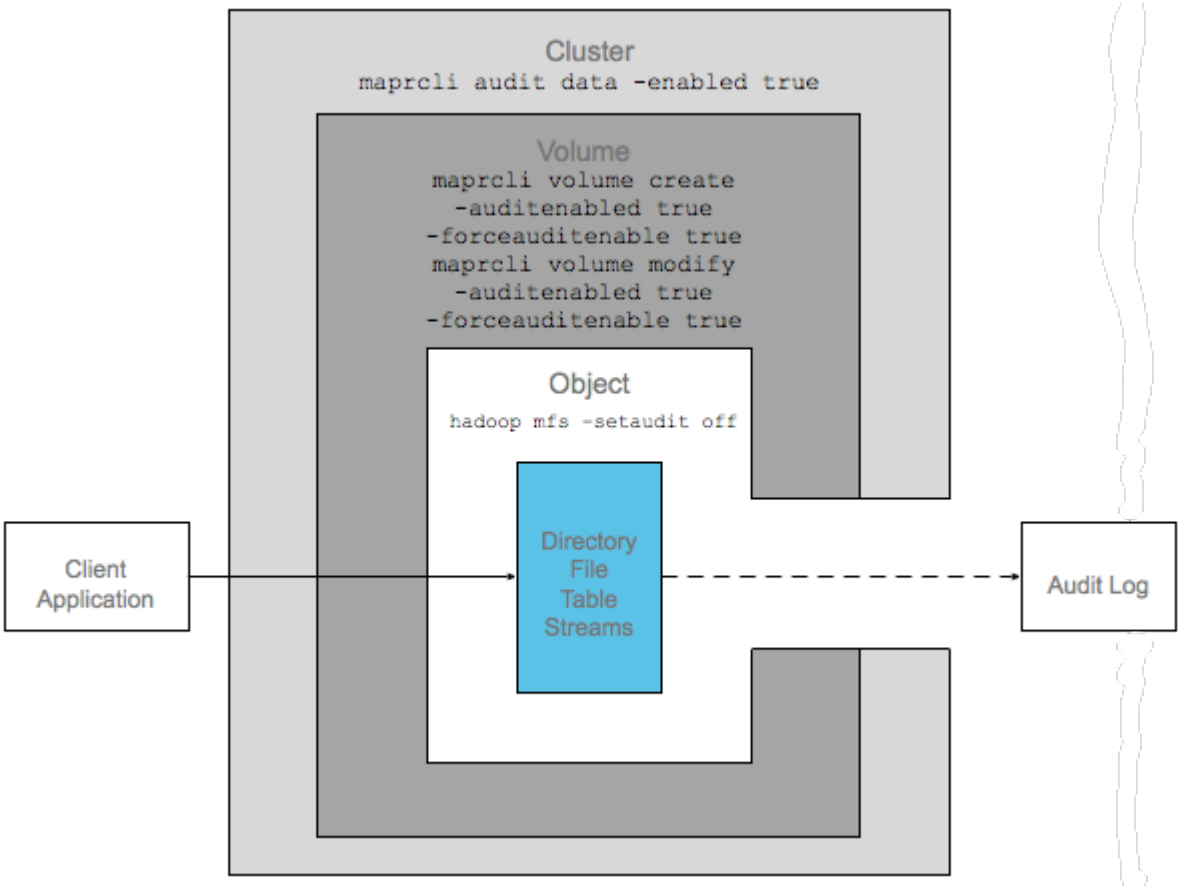
The illustration on the right shows auditing enabled at two levels: the cluster level, through the `audit data` on page 2036 command and the volume level through `volume audit` on page 2579 command (`enabled` and `forceenable` parameters).

NOTE: You can enable auditing at the volume level using the `volume create` on page 2588 and `volume modify` on page 2676 commands also.

As all levels are enabled, operations that, for example, a client application makes on a directory, file, table, or stream are recorded in an audit log.

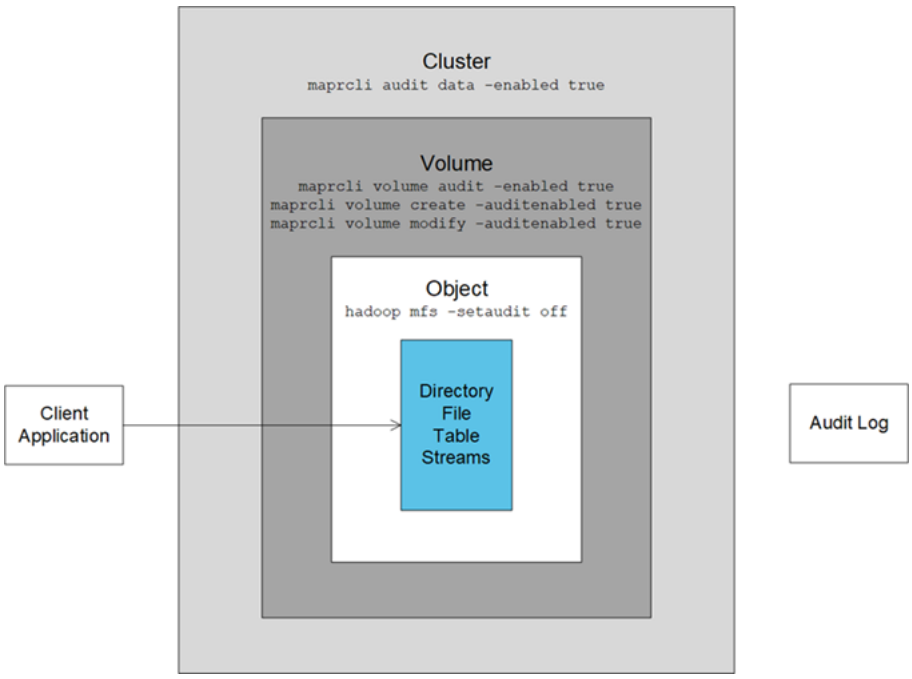


To state another example, in the following diagram, auditing is enabled at the cluster level using the `audit data` on page 2036 command and at the volume level through the `auditenabled` and `forceauditenable` parameters set using any one of the volume commands. Also note that although auditing is explicitly disabled at the directory, file, table, and/or stream level, operations on all directories, files, tables, and streams in the volume are audited because `forceauditenable` is set to `true` at the volume level.

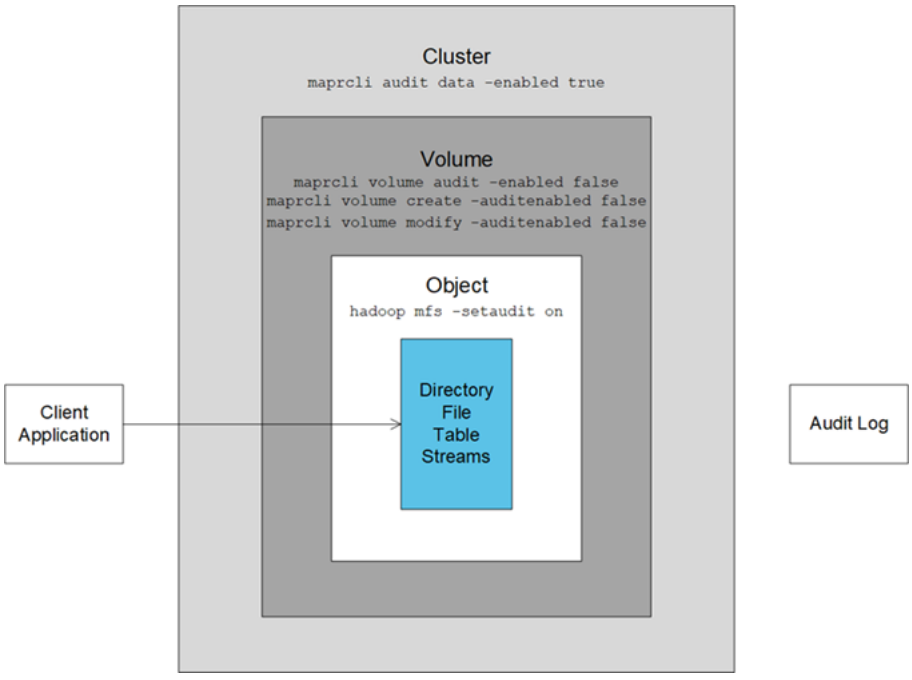


For granular or selective auditing, the following diagram shows auditing enabled at the cluster level and the volume level (with just the `auditenabled` parameter), but not on the directory, file, table, or stream on

which an operation is performed. Although the two higher levels are enabled for auditing, the operation is not logged in an audit log because the objects on which auditing has to be performed is not enabled for auditing.



For granular or selective auditing, as a final example, in the next diagram auditing is enabled on the individual directory, file, table, or stream, and at the cluster level. However, auditing is not enabled at the volume level. Therefore, the operation that the client application performs on the object is not recorded in an audit log.



Auditing Cluster Operations
Explains the operations that are audited for a cluster.

The following types of operations are audited when you run the `maprcli audit cluster` command on a cluster:

- All `maprcli` commands, REST calls, and actions in the Control System that have effects at the cluster level, including those that enable auditing, are audited.
- All authentications to the Control System and authentications to data-fabric clusters via `maprlogin` are audited.
- All volume level tiering operations are audited.

Audit records for these operations are recorded in the following audit logs:

Audit logs for operations related to cluster management and authentications to clusters via maprlogin

Every CLDB operation is logged in the local filesystem of the CLDB node that responded to the operation. The log file is `/opt/mapr/logs/cldbaudit.log.json`.

Audit logs for maprcli commands, REST API calls, and actions in the Control System

Executions of `maprcli` commands, REST API calls, and actions in the Control System are logged in the local filesystem on the nodes where they are executed. Log files are located at `/opt/mapr/mapr-cli-audit-log/audit.log.json`. To see what information is recorded in typical log entries, see Example Log Entries for Audited maprcli Command Executions, REST API Calls, and Actions in the Control System.

The following `maprcli` commands, as well as their equivalent REST API calls and actions in the Control System, are also logged in audit logs on the servers where they are processed.

Command Family	Commands
acl	`acl edit, acl set, acl show`
audit	`audit cluster, audit data, audit info`
blacklist	`blacklist listusers, blacklist user`
cluster	`cluster mapreduce get, cluster mapreduce set`
config	`config load, config save`
entity	`entity info, entity list, entity modify`
license	`license add, license addcrl, license apps, license list, license listcrl, license remove, license showid`
nagios	`nagios generate`
rlimit	`rlimit get, rlimit set`
schedule	`schedule create, schedule list, schedule modify, schedule remove`
virtualip	`virtualip add, virtualip edit, virtualip list, virtualip move, virtualip remove`

last-updated: Jun 06, 2024

volume	`volume compact, volume container move, volume container switchmaster, volume create, volume fixmountpath, volume info, volume list, volume mirror push, volume mirror start, volume mirror stop, volume modify, volume mount, volume move, volume offload, volume recall, volume remove, volume rename, volume showmounts, volume snapshot list, volume snapshot preserve, volume snapshot remove, volume tierstats, volume tierjobabort, volume tierjobstatus, volume unmount`  **NOTE:** These commands are not audited: `volume dump create, volume dump restore, volume link create, volume link remove, volume snapshot create`

Audit logs for authentications to the Control System

Every attempt at authentication to the Control System, whether successful or unsuccessful, is logged to the local filesystem in `/opt/mapr/logs/authaudit.log.json` on the webserver node where an attempt was made.

Audit logs for volume level tiering operations

All volume level tiering operations, whether successful or unsuccessful, are logged in the `/opt/mapr/logs/cldbaudit.log.json` file.

Auditing Data Access Operations

Describes file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Streams operations that are audited by default, and operations that can be selectively enabled or disabled for auditing.

This type of auditing is for operations that are managed by the file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Streams. These operations take place within volumes and have effects at the level of the Data Fabric file system.

Auditing of Operations on Directories and Files

The following table shows whether (`Y`) or not (`N`) the following operations on files and directories are audited. In the table, the operations with `Y` in the **Selective Auditing Support** column can be included and/or excluded from auditing. Operations with `N` in the **Selective Auditing Support** column are audited by default and cannot be excluded from auditing. Use the name specified in the **Operation Name to use for Selective Auditing** column when you run the maprcli command to enable or disable auditing for that operation.

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Directories	Files	Selective Auditing Support
Change group owner	CHGRP	chgrp	Y	Y	Y
Change owner	CHOWN	chown	Y	Y	Y
Change permissions	CHPERM	chperm	Y	Y	Y
Create	CREATE	create	N/A	Y	Y
Create device (not used)	CREATEDEV	createdev	N/A	Y	Y
Create symbolic link	CREATESYM	createsym	Y	Y	Y

last-updated: Jun 06, 2024

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Directories	Files	Selective Auditing Support
Delete file	DELETE	delete	N/A	Y	Y
Disable auditing	DISABLEAUDIT	N/A	Y	Y	N
Enable auditing	ENABLEAUDIT	N/A	Y	Y	N
Offload file to tiered storage	FILE_OFFLOAD	fileoffload or filetieroffloadevent	N/A	Y	Y
Recall file from tiered storage	FILE_RECALL	filerecall or filetierrecallevent	N/A	Y	Y
Scan offset ranges owned by given FID. Used in tiered operations to get owned offsets during offload and recall operations.	FILE_SCAN	filescan	N/A	Y	Y
Abort ongoing offload or recall of file	FILE_TIER_JOBABORT	filetierjobabort	N/A	Y	Y
Retrieve status for an existing file level tier job (offload/recall)	FILE_TIER_JOBSTATUS	filetierjobstatus	N/A	Y	Y
Audit event generated on file server while purging data during offload operation	FILE_TIER_OFFLOAD_EVENT	filetieroffloadevent	N/A	N	Y
Audit event generated on file server while recalling data during recall operation	FILE_TIER_RECALL_EVENT	filetierrecallevent	N/A	N	Y
Get attributes	GETATTR	geattr	N	N	Y
Get extended attributes	GETXATTR	getxattr	Y	Y	Y
Get the mode bits for files/directories accessed over NFS	GETPERM	getperm	Y	Y	Y
Create hardlink	HARDLINK	hardlink	Y	Y	Y
List extended attributes	LISTXATTR	listxattr	Y	Y	Y
Lookup	LOOKUP	lookup	Y	Y	Y
Create directory	MKDIR	mkdir	Y	N/A	Y
Read a file	READ	read	N/A	Y	Y
Read a directory	READDIR	readdir	Y	N/A	Y
Remove extended attributes	REMOVEXATTR	removexattr	Y	Y	Y
Rename	RENAME	rename	Y	Y	Y
Delete a directory	RMDIR	rmdir	Y	N/A	Y
Set attributes	SETATTR	setattr[1]	Y	Y	Y
Set extended attributes	SETXATTR	setxattr	Y	Y	Y
Truncate a file	TRUNCATE	truncate	N/A	Y	Y

last-updated: Jun 06, 2024

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Directories	Files	Selective Auditing Support
Write to a file	WRITE	write	N/A	Y	Y

[1]Enabling `setattr` automatically enables the following operations:

- `chown`
- `chgrp`
- `chperm`

If you disable `setattr`, these operations are automatically disabled. If you do nothing with `setattr` (neither enable nor disable), you can enable or disable `chown, chgrp,` and `chperm` in any combination.

Auditing of Operations on HPE Ezmeral Data Fabric Database Binary Tables and JSON Tables

The following operations on both types of HPE Ezmeral Data Fabric Database tables are audited by default. Operations with `Y` in the **Selective Auditing Support** column can be included or excluded from auditing. Operations with `N` in the **Selective Auditing Support** column are audited by default and cannot be excluded from auditing. Use the name specified in the **Operation Name to use for Selective Auditing** column when you run the maprcli command to enable or disable auditing for that operation.

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Selective Auditing Support
Create a column family	DB_CFCREATE	tablecfcreate	Y
Modify a column family	DB_CFMODIFY	tablecfmodify	Y
Delete a column family	DB_CFREMOVE	tablecfdelete	Y
Scan a column	DB_CFSCAN	tablecfscan	Y
Get data	DB_GET	tableget	Y
Perform incremental bulk load	DB_IMPORTBUCKET	N/A	N
Perform full bulk load	DB_IMPORTSEGMENT	N/A	N
Put data	DB_PUT	tableput	Y
Compact a table region	DB_REGIONCOMPACT	N/A	N
Look up a region on the current node	DB_REGIONLOOKUP	N/A	N
Merge two consecutive regions	DB_REGIONMERGE	N/A	N
Split a region into two	DB_REGIONSPLIT	N/A	N
Configure a replica for a table	DB_REPLICAADD	N/A	N
Edit the replica for a table	DB_REPLICAEDIT	N/A	N
List the replicas for a table	DB_REPLICALIST	N/A	N
Remove a replica for a table	DB_REPLICAREMOVE	N/A	N
Scan a table	DB_SCAN	tablescan	Y
Create a table	DB_TABLECREATE	tablecreate	Y
View information about a table	DB_TABLEINFO	tableinfo	Y

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Selective Auditing Support
Modify a table	DB_TABLEMODIFY	tablemodify	Y
Add an upstream source to a replica	DB_UPSTREAMADD	N/A	N
List all upstream sources for a replica	DB_UPSTREAMLIST	N/A	N
Remove an upstream source for a replica	DB_UPSTREAMREMOVE	N/A	N

Auditing of Operations on HPE Ezmeral Data Fabric Streams

The following operations on HPE Ezmeral Data Fabric Streams are audited by default. Operations with `Y` in the **Selective Auditing Support** column can be included or excluded from auditing. Operations with `N` in the **Selective Auditing Support** column are audited by default and cannot be excluded from auditing. Use the name specified in the **Operation Name to use for Selective Auditing** column when you run the maprcli command to enable or disable auditing for that operation.

Operation	Name in Audit Logs	Operation Name to use for Selective Auditing	Selective Auditing Support
Modify attributes or permissions of a stream	DB_CFMODIFY	tablecfmodify	Y
Produce messages to topics of a stream	DB_PUT	tableput	Y
Add a replica	DB_REPLICAADD	N/A	N
Edit a replica	DB_REPLICAEDIT	N/A	N
List the replicas for a stream	DB_REPLICALIST	N/A	N
Remove a replica	DB_REPLICAREMOVE	N/A	N
Consume messages from topics of a stream	DB_SCAN	tablescan	Y
Add an upstream source to a replica	DB_UPSTREAMADD	N/A	N
List all upstream sources for a replica	DB_UPSTREAMLIST	N/A	N
Remove an upstream source from a replica	DB_UPSTREAMREMOVE	N/A	N

Streaming Audit Logs

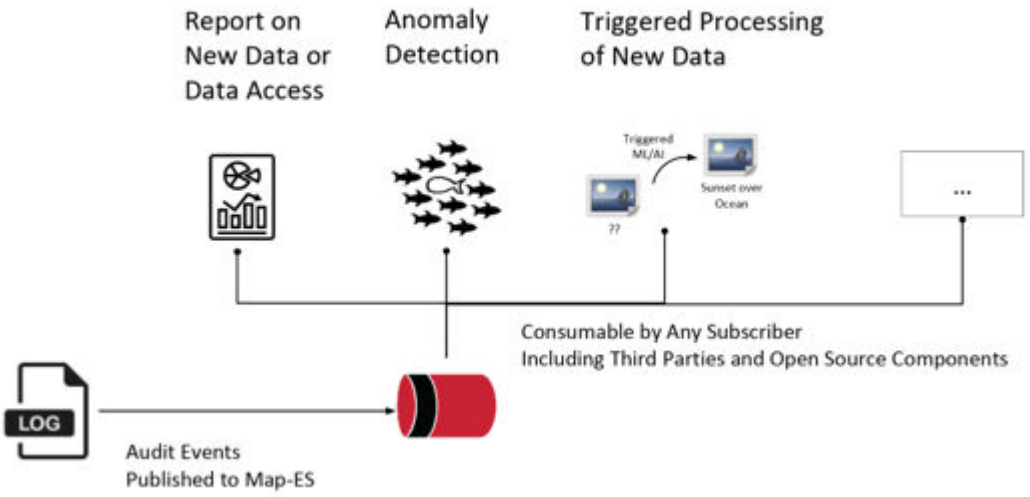
Describes the audit streaming feature and how to consume the audit stream messages.

Audit-streaming (available from v6.0.1) eliminates the need to process the logs nightly using the `expandaudit on page 2868` utility and provides a way to process the audit data in real-time. The audit data is sent as a audit stream as the audit data is generated, opening the possibility for real-time processing of the audit data. You can use it to monitor data access such as:

- Who accessed certain files, tables, and/or streams at certain times
- What type of action is/was performed on the files, tables, and/or streams
- How many failed attempts were made on the files, tables, and/or streams in a certain period

last-updated: Jun 06, 2024

- When did a particular property or configuration change and who changed it



Audit Stream Creation, Location, and Topic

Audit streaming is not enabled by default; you can enable audit streaming using the CLI. If the feature is enabled, file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Streams operation-related audit logs and CLDB and auth audit logs are available as HPE Ezmeral Data Fabric Streams topics. The audit-streaming consumer can view all audited operations on a node in the cluster in near real-time by subscribing to one or more topics associated with a node.

The audit stream is created when the hoststats process starts. If the hoststats process is restarted, the audit stream starts publishing to topics from where it left off processing audit logs; some audit log entries might be republished.

The audit log stream topic is available at the following location:

```
/var/mapr/auditstream/
```

Topics named `<clusterName>_<logType>_<nodeName>` are published to the stream (`/var/mapr/auditstream/auditlogstream:<clustername>_<logType>_<nodename>`). Here:

- `<clustername>` is the name of the cluster.
- `<logType>` is the type of the log. Valid types are `cldb`, `auth`, `fs`, and `db` (for both HPE Ezmeral Data Fabric Database and HPE Ezmeral Data Fabric Streams logs).
- `<nodeName>` is the hostname of the node on which the operation was logged.

The message is in JSON format and is identical to the audit log content, as in the following example:

```
{"timestamp":
{"$date":"2017-04-27T10:53:37.239Z"},"operation":"CREATE","uid":0,"ipAddress
":"10.20.30.140","nfsServer":"10.20.30.140","parentFid":"2066.32.131358","ch
ildFid":"2066.33.262630","childName":"abc.txt","volumeId":106738640,"status"
:0}
```

Duration of Audit Stream Topics

Messages in the topics are stored by default for 7 days.

last-updated: Jun 06, 2024

Consuming Audit Stream Messages

Only the `mapr` user can consume the stream. Refer to Sample Cached Consumer Application for Audit Stream on page 3533 and Sample Uncached Consumer Application for Audit Stream on page 3539 for information on consuming the messages using the sample consumers.

Policy-Based Security

Starting in core version 6.2.0 (EEP 7.0.0), HPE Ezmeral Data Fabric supports Policy-Based Security, a feature that administrators can use to classify security controls into a manageable number of security policies.

A security policy is a classification that encapsulates security controls on data. Security controls define which users are authorized to access and modify data objects, whether to audit data operations, and whether to protect data in motion with wire-level encryption. You can create and manage security policies through the Control System, maprcli, REST API, Hadoop and Linux commands, and Java APIs.

You can apply security, such as access control expressions (ACEs), directly on data objects; however, this can be cumbersome and inconsistent especially if you have to modify security settings across thousands of data objects. Instead, you can define the security controls in a security policy and then apply the security policy to the data objects. If you need to modify the security controls on the data objects, just update the security policy. The update propagates across all the data objects to which the policy is applied and the system automatically enforces the controls set in the policy.

For example, consider sensitive employee information as a data classification. You could create a security policy that defines which users are authorized to access the sensitive employee information and then apply the security policy to all the data objects that contain the sensitive information. When you need to add or remove user access to the data, you can easily update the security policy and the change is reflected across all the data objects with sensitive employee information.

The following image shows the Policy-Based Security architecture and process within HPE Ezmeral Data Fabric:

The following steps summarize the Policy-Based Security process, list the requirements for creating and using security policies, and include links to related documentation. The information presented is intended to familiarize you with Policy-Based Security before you start creating and using security policies. Once you are familiar with Policy-Based Security, see Policy-Based Security Quick Reference on page 1934.

1. Create security policies

An administrator defines data classifications for a business and then creates a security policy for each classification. A data classification represents a group of data with corresponding security controls to control access to data. Security policies can include the following security controls:

Security Control	Description
ACEs (access control expressions)	Authorizes users and groups to access and modify various data objects; lists users and groups with read, write, and execute access to the data objects.
Auditing Data Access Operations on page 849	Advanced auditing controls that define which operations on the data to audit.
Encryption in Data Fabric on page 838	On-wire and data-at-rest encryption.

An administrator with cluster-level `cp` (create security policy) permission can create security policies through the Control System, `maprcli` command-line interface, or REST API. Administrators with the proper permissions can view and modify security policies. The administrator that creates a security policy can delegate the management of the security policy to a policy owner.

last-updated: Jun 06, 2024

Table

Some setup is required before an administrator can create security policies and apply them to data objects. The following points briefly discuss the requirements and provide links to related topics for additional information:

- **Enable Policy-Based Security**

  Policy-Based Security is enabled by default in new HPE Ezmeral Data Fabric installations (version 6.2.0 and later). If you upgrade from an earlier version of HPE Ezmeral Data Fabric, you must manually enable Policy-Based Security. Before you enable Policy-Based Security, verify that all features in your current version are enabled. If you upgrade from a version that does not support extended attributes, enable extended attributes before you enable Policy-Based Security, as shown:

  ```
  /opt/mapr/bin/maprcli cluster feature enable -name mfs.feature.fileace.support
  ```

  To enable Policy-Based Security, run:

  ```
  /opt/mapr/bin/maprcli cluster feature enable -name mfs.feature.pbs
  ```

  For changes to take effect, run the following command to restart the CLDB service:

  ```
  maprcli node services -cldb start -nodes <node name>
  ```

  ATTENTION: If you enable extended attribute support on a release that supports generic extended attributes but does not support Policy-Based Security, the extended attribute for security policy (`security.mapr.policy`) is treated as a generic key-value extended attribute and is not interpreted as a security policy attribute by the HPE Ezmeral Data Fabric filesystem.

  See Upgrade Workflows (Releases 6.x or 7.x to 7.7.0) on page 301 and Installer on page 5579.

- **Designate a global policy master**

  You must set one cluster as the global policy master before you can create security policies. The cluster set as the global policy master is the only cluster on which you can create or update security policies. After you create or update policies, you must propagate the policies to other clusters via volume mirroring or export/import commands, as described in Security Policy Domain and Policy Management on page 857.

- **Set permissions for creating and managing security policies**

  Administrative permissions are required to create and manage security policies. Administrators can set permissions through cluster-level and policy-level ACLs. Policy-level permissions can be set when creating and modifying a security policy through the maprcli, REST API, or the Control System.

  - To create security policies, an administrator must have cluster-level `cp` (create security policy) permission. By default, the `cp` permission is not assigned to any administrator. Administrators can assign this permission to themselves or other users with administrative privileges.
  - The cluster owner/`mapr` administrator has overriding permissions and can view, create, and edit any security policy, regardless of the permissions specified in the administrative ACLs, even if the permissions specified in the administrative ACLs are removed.
  - After creating a security policy, the administrator can delegate the management of the policy to a user they define as the policy owner.
  - Any user with a valid `mapr` ticket can view security policy IDs and names regardless of administrative permissions.

  See Granting Security Policy Permissions on page 1889.

- **Set the security policy state**

  The security policy state indicates whether a security policy can be applied to data objects and whether security policy ACEs are enforced. When a security policy is first created, users cannot apply it to data objects until a user with the appropriate privileges changes the security policy to allow tagging. By default, a security policy has `allowtagging=false` and `accesscontrol=Disarmed` when created.

  In their default state, policies applied to resources are not enforced until a user with the appropriate privileges changes the access control from `Disarmed` to `Armed`.

  See Changing the State of a Security Policy on page 1910.

  For additional information, see:

  - Creating a Security Policy on page 1893
  - Viewing the List of Security Policies on page 1898

last-updated: Jun 06, 2024

2. Tag data objects with security policies

Users with the appropriate permissions can apply security policies to data objects in the HPE Ezmeral Data Fabric. Users can apply security policies to the following data objects:

HPE Ezmeral Data Fabric File System	HPE Ezmeral Data Fabric Database
• Volumes • Directories • Files	• JSON tables • JSON column families • JSON fields

NOTE: If you upgraded your HPE Ezmeral Data Fabric cluster to 6.2.x from a pre-6.2.0 version, you can add security policies to existing tables using the `maprcli table set|add` command after you enable Policy-Based Security.

Table

Permission requirements vary depending on the HPE Ezmeral Data Fabric core component. The following table lists the users that can apply security policies to data objects in the HPE Ezmeral Data Fabric filesystem and database:

HPE Ezmeral Data Fabric File System	HPE Ezmeral Data Fabric Database
• Owner of the data object • HPE Ezmeral Data Fabric administrator (typically `mapr`) • Superuser (`root`) The superuser cannot tag filesystem objects when the `cldb.reject.root` flag is set. See Tagging Volumes, Directories, and Files with Security Policies.	• HPE Ezmeral Data Fabric administrator (typically `mapr`) • User with ACE administrative access (`adminaccessperm` permission) See Tagging JSON Tables, Column Families, and Fields with Security Policies on page 1919

You may also want to read about Security Policy Inheritance and Replication on page 870.

When you tag an object with a security policy, the policy remains effective when the object is mirrored to another cluster because the clusters are part of a global namespace. This global namespace is created by designating one cluster as the global policy master and the other clusters as members. You can only create policies on the global policy master. Member clusters can import the policies from the global policy master or export them to other member clusters.

3. Enforce security policies

Security policies ensure consistent security enforcement and prevent applications from bypassing security controls. Applications can securely read and write to a HPE Ezmeral Data Fabric cluster because HPE Ezmeral Data Fabric enforces security policies across all filesystem clients, including the HPE Ezmeral Data Fabric FUSE-based and NFS POSIX clients. When performing data operations, HPE Ezmeral Data Fabric automatically enforces the security controls defined in security policies. If security policies are not applied to data objects, the system enforces security controls directly defined on the data objects, such as ACEs or POSIX mode bits.

last-updated: Jun 06, 2024

Table

There are three levels of enforcement for security policies:

- **Security policy level** - Enforced through settings that control the security policy state.

  The security policy state indicates whether a security policy can be applied to data objects and whether the system enforces security policy ACEs. When a security policy is first created, you cannot apply it to data objects until you change the security policy state. By default, a security policy has `allowtagging=false` and `accesscontrol=Disarmed` when first created. See Changing the State of a Security Policy on page 1910, policy create on page 2316, and policy modify on page 2346.

- **Volume level** - Enforced through volume-level enforcement modes.

  The enforcement mode is set at the volume-level and applies to all data objects within a volume, such as files and tables. The enforcement mode defines the security controls to enforce on data objects in a volume during data access. By default, security policies applied to data objects and resource controls (POSIX mode bits or ACEs) are evaluated to determine access. See Volume-Level Security Policy Enforcement Mode on page 861, Security Policy Enforcement Process on page 865, and Enforcing Security Policies at the Volume-Level on page 1929.

- **Cluster level** - Enforced through the `cldb.pbs.access.control.enabled` option.

  When the `cldb.pbs.access.control.enabled` option is disabled, the system does not evaluate or enforce access controls (ACEs set in security policies) for any data operations in the cluster. When disabled, the `cldb.pbs.access.control.enabled` option overrides volume-level enforcements. The system only evaluates and enforces the POSIX mode bits or ACEs directly applied to data objects to determine access. The system continues to enforce wire-level encryption and auditing controls configured in the security policies. See Disabling Policy Access Controls at the Cluster-Level on page 1887.

Use Case with Example Configuration

See Example Using Security Policies.

Security Policy Domain and Policy Management
Describes how to create the security-policy domain, propagate security policies to all the clusters within the domain, and some considerations for moving data.

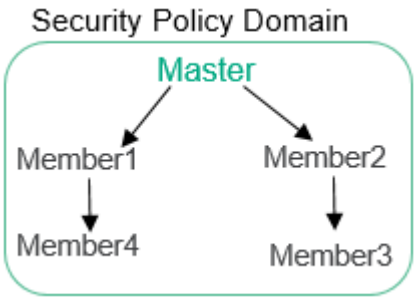
A security-policy domain is a group of clusters that directly or indirectly share data and use the same security policies to control access to the data. A security-policy domain consists of one master security-policy cluster and zero or more member security-policy clusters to create a global security-policy namespace. Before you can create security policies, you must set one cluster as the security-policy master.

Each security-policy cluster operates independently and therefore does not require network connectivity to the other clusters to enforce policies. A security-policy server in each of the security-policy clusters enforces the policies and manages the security-policy metadata in an internal volume named `mapr.pbs.base`.

You can only create and modify security policies on the cluster designated as the global policy master. When you create or update security policies, the policy server updates the `mapr.pbs.base` volume with the security policy metadata. The policy server does not propagate the security policies to member clusters. To propagate the policies to a member cluster, you must schedule volume mirroring or export the metadata to a file and then import the file into a member cluster. Once a member cluster has the security-policy metadata, the metadata can be propagated from that cluster to other member clusters using the same methods.

In the following diagram, Member1 and Member2 get the security policy metadata from Master and Member4 and Member3 get the policy metadata from Member1 and Member2. If Member2 goes down, Member3 can mirror from Master, Member1, or Member4.

last-updated: Jun 06, 2024



1 – Create a Security Policy Domain

By default, all clusters are member security-policy clusters. You cannot create security policies until you set one cluster as the global policy master. You can set a cluster as the global policy master from the Control System (GUI) or CLI through the `cldb.pbs.global.master` option. See Configuring the Global Policy Master on page 860 for instructions.

A best practice is to create only one security-policy domain. Plan your security-policy domain such that the security policies you create can be applied to resources across all clusters in the domain. The UID must be consistent across all clusters in the domain, similar to access control expressions (ACEs).

IMPORTANT: For future reference, note which cluster you set as the global policy master. There is no failover or recovery if the cluster specified as the security-policy cluster goes down. If a master cluster needs to go offline or fails, set one of the member security-policy clusters as the new master. When the original master cluster comes back up, set it as a member cluster. To identify which cluster is master, run:

```
maprcli dashboard info -json | grep -i global "globalPolicyMaster":true
```

You can also identify the role of a cluster in the Control System.

2 - Create and Update Security Policies on the Global Policy Master

You can create and update security policies on the global policy master only. You cannot create or modify security policies on member security-policy clusters. See Creating Security Policies for instructions.

The following table lists the operations you can and cannot perform on the global policy master and member security-policy clusters:

Security-policy cluster type	Allowed operations	Prohibited operations
Master (cluster set as the global policy master)	• Create • Modify • Export • View • Tagging	• Import
Member	• Import • Export • View • Tagging	• Create • Modify

3 – Propagate Security Policies to Member Clusters

After you create or update security policies on the global policy master, you can schedule volume mirroring or use the export and import commands to propagate the policies to a member cluster. Once a member cluster has the security-policy metadata, it can propagate the policy metadata to the other member clusters through the same methods.

IMPORTANT: Policies must be present on a destination cluster for tagging and operations, such as mirroring and dump-restore, to succeed. When you restore a volume from a snapshot or promote a snapshot to a read-write volume, the security policies and settings applied to the volume at the time of the snapshot are also restored.

Schedule Volume Mirroring	Schedule automatic volume mirroring to propagate the security-policy metadata in the `mapr.pbs.base` volume on the global policy master to a member cluster. Once a member cluster has the policy metadata, propagation can occur between the member cluster and other member clusters. Refer to Mirror Volumes for instructions.
Export Policy Metadata from the Global Policy Master	Manually export the security policy metadata in the `mapr.pbs.base` volume on the master cluster to a file and then import the file into a member cluster. Once the member cluster has the policy metadata, you can export from that member cluster and then import into another member cluster. Run policy export on page 2325 on the global policy master cluster, and then run policy import on page 2335 on the target member cluster.

Data Movement Considerations

The policy server in each security-policy cluster manages security policies and composite IDs. A composite ID is a unique, internal integer that maps to a security policy or set of security policies. The policy server stores the mapping in an internal volume named `mapr.pbs.composite`.

When you assign a security policy to a filesystem resource, the composite ID for that security policy is stored with the resource. Storing the composite ID with the resource instead of the security policy itself optimizes storage. For example, if a policy named HIPAA maps to composite ID 200, this composite ID is stored with any file you tag with HIPAA.

Security policies are shared across the security policy domain, but composite IDs are not. The same security policy on ClusterA will have a different composite ID on ClusterB and ClusterC, as shown in the following table:

Cluster Name	Security Policy	Cluster ID
ClusterA	HIPAA	200
ClusterB	HIPAA	500
ClusterC	HIPAA	800

By default, up to one million composite IDs can be created instantly after which there is a throttle process in place. The default limit of one million composite IDs is sufficient for about one thousand security policies. Using security policies as intended should not trigger the throttle process. However, using security policies for general tagging purposes can quickly exhaust composite IDs and trigger throttling.

Important Notes About Composite IDs

last-updated: Jun 06, 2024

- You cannot see or interact with composite IDs. However, if you copy a file from one cluster to another, only the data is copied. The policy server on the destination cluster does not recognize the composite ID associated with the file and therefore cannot enforce the access controls configured in the policy. To avoid this issue, use mirroring to synchronize data. During mirroring, security policies are propagated to the destination cluster. The policy server on the destination cluster assigns new composite IDs to the security policies before data synchronization starts. The composite ID/security policy mappings are present when data synchronizes.
- Do not schedule mirroring for the composite ID internal volume `mapr.pbs.composite`.
- Composite IDs are only used with filesystem resources. The database stores policies as an array of policy IDs in the key-value store. The database policy IDs are unique across the global policy domain, which simplifies table replication. For example, policy IDs in JSON tables can be copied from one cluster to another. The server deals with the policy ID, not the policy name. Policy IDs are evaluated and translated to the policy name on the client side.

More information

Security Policy Inheritance and Replication on page 870
Security policies are inherited during data-object creation and copied over during mirroring and replication.

Setting Global Configuration Options for Policy-Based Security on page 1886
The CLDB stores global configuration settings for Policy-Based Security. Before creating security policies, an administrator must designate a master security policy cluster through the `cldb.pbs.global.master` option.

Configuring the Global Policy Master

This topic describes how to configure a cluster as the global policy master from the CLI, REST API, and Control System.

Setting the Global Policy Master from the Control System

Complete the following steps in the Control System to set a cluster as the global policy master:

1. Click the **Security Settings** icon.
2. Click the **PBS Mode** setting.
3. Select the **PBS Mode** as **Master** from the drop-down.
4. Click **Submit** to save the setting.

Setting the Global Policy Master from the CLI or REST API

Complete the following steps from the CLI or REST API to set a cluster as the global policy master:

CLI

Run the following command to set a cluster as the global policy master:

```
maprcli config save -values
'{"cldb.pbs.global.master":"1"}'
```

REST

Send a request of type POST. For example, to designate a cluster as the global policy master, send a request similar to the following:

```
curl -k -X POST 'https://
<hostname>:8443/rest/config/save?
values={"cldb.pbs.global.master":"1"}'
 --user mapr:mapr
```

last-updated: Jun 06, 2024

Changing the Global Policy Master Cluster

If the cluster designated as the global policy master goes offline or fails, there is no automatic fail-over or recovery for security policies. In such a scenario, promote one of the member security-policy clusters as the new master. When the original master cluster comes back up, set it as a member cluster.

You can identify the role of a cluster from the Control System or by running the following command:

```
maprcli dashboard info -json | grep globalPolicyMaster
```

To elect a new global policy master, perform the following steps:

1. Verify that the cluster you plan to promote to global policy master is set as a member. If the cluster is a member, the value of `cldb.pbs.global.master` on the cluster is `0`. If the cluster is master, the value is `1`.
2. Verify that no policies are being created or modified on the current master cluster.
3. Export all policies from the current global policy master and then import them to the cluster you will promote to global policy master.
4. Demote the original global policy master cluster to a member, by setting `cldb.pbs.global.master` to `0`.
5. Promote the member cluster to global policy master by setting `cldb.pbs.global.master` to `1`.

More information

Setting Global Configuration Options for Policy-Based Security on page 1886
The CLDB stores global configuration settings for Policy-Based Security. Before creating security policies, an administrator must designate a master security policy cluster through the `cldb.pbs.global.master` option.

Volume-Level Security Policy Enforcement Mode

Before Core 6.2.0, Data Fabric supported enforcement based on mode and ACEs set directly on data objects. With Core 6.2.0 and above, security policies provide an additional or alternative way to control access to data. The volume-level enforcement mode specifies which of these methods a volume uses to govern access to data.

NOTE: If you upgraded to Data Fabric 6.2.x from a pre-6.2.0 version, data objects in volumes behave as they did in the pre-6.2.0 version of Data Fabric if security policies have not been applied to them.

Volume-Level Enforcement Modes

Regardless of the enforcement mode set, the system always enforces the ACEs directly set on a volume. HPE Ezmeral Data Fabric Database tables inherit the enforcement mode setting from the parent volume.

The enforcement mode governs access checks on volumes as follows:

Mode: PolicyAceAndDataAce (Default)	*Enforce Security Policies*: `Yes` *Enforce Data ACEs and POSIX Mode Bits*: `Yes` The system enforces the ACEs set in security policies AND the ACEs and POSIX mode bits set directly on objects. If the volume is tagged with security policies, the ACEs set in the security policies apply to all data objects within that volume, including files and tables.

If ACEs set in a security policy conflict with ACEs and POSIX mode bits directly applied to data objects, the system enforces the most restrictive setting.

Mode: PolicyAceOnly

Enforce Security Policies: `Yes`

Enforce Data ACEs and POSIX Mode Bits: `No`

If a data object is associated with one or more security policies, the system only enforces the ACEs set in the security policies; the system ignores the ACEs and POSIX mode bits set directly on the data object. However, if the access check on a data object does not encounter at least one security policy (no security policy tagged at the volume-level or data-object level), the system will enforce the ACEs and POSIX mode bits set directly on the data object.

- If the volume is tagged with security policies, the ACEs set in the security policies apply to all data objects within that volume, including files and tables.
- If multiple security policies are applied to a data object, the system enforces the security policy with the most restrictive setting.
- The system denies access to a data object if the data object is not associated with a security policy and ACEs or POSIX mode bits do not allow access.

Mode: DataAceOnly

Enforce Security Policies: `No`

Enforce Data ACEs and POSIX Mode Bits: `Yes`

The system enforces the ACEs and POSIX mode bits applied directly to data objects only. The system ignores all ACEs set in security policies. This mode is useful when switching off the Policy-Based Security feature on a per-volume basis in an emergency.

Mode: PolicyAceAuditAndDataAce (Permissive mode)

Enforce Security Policies: `Performs checks, but does not fail; audits instead`

Enforce Data ACEs and POSIX Mode Bits: `Yes`

Evaluates the policies, but does not enforce them. The system only audits operations if auditing is enabled when a policy fails access. The audit log will contain the issues that would arise if the policy had been enforced, for example:

```
{"timestamp":
{"$date":"2020-10-28T06:35:56.762Z"},

"operation":"RENAME","username":"fuser
2","uid":2000,
"ipAddress":"10.10.10.100","srcFid":"2
178.16.2","dstFid":"2178.16.2",
"srcName
":"mfs._COPYING_","dstName":"mfs","vol
umeId":98960073,
"AccessDeniedPolicyId":1,"AccessDenied
PolicyName":PCI,"PolicyPmStatus":13,"s
```

```
tatus":0}
```

The permissive mode is helpful for testing to ensure security policies work before use. You can access the logs in the location configured to store the volume's audit logs. Note that the file server logs data access to the node on which the data is being accessed.

IMPORTANT: To enforce permissive mode across the entire cluster (regardless of the volume-level enforcement mode set), run:

```
/opt/mapr/bin/maprcli config
save -values
{"cldb.pbs.audit.only.policy.chec
k":"1"}
```

Permissive mode at the cluster level overrides volume-level mode. The behaviour is as though the volume has set the SecurityPolicy mode to `AuditOnly`. When applied at the cluster level, the volume level mode behaves as follows:

- **DataAceOnly** > **PolicyAceAuditAndDataAce**
- **PolicyAceAndDataAce** > **PolicyAceAuditAndDataAce**
- **PolicyAceOnly** > **PolicyAceAuditOnly**
- **PolicyAceAuditAndDataAce** > **PolicyAceAuditAndDataAce**

ATTENTION: This mode does not apply to snapshots. Suppose the mode is PolicyAceAuditAndDataAce when the snapshot is taken. In that case, the snapshot performs the access check as if the mode is DataAceOnly and will not evaluate the security policy for audit purposes.

Important Information Related to the Enforcement Mode

The following sections describe some additional requirements, options, and behaviors related to the enforcement mode:

Modifying the enforcement mode

You must have volume-level ACL permission to change the enforcement mode. You can change the enforcement mode when you create or modify a volume through the Control System, CLI, or REST API. See Enforcing Security Policies at the Volume-Level on page 1929 for instructions.

Volume-level enforcement mode override

The only setting that supersedes the volume-level enforcement mode is the `cldb.pbs.access.control.enabled` cluster-level setting. If you disable `cldb.pbs.access.control.enabled`, the ACEs set in all security policies are disabled across the cluster. Typically, you would only disable security policies at the cluster-level if the security policies

	caused a serious issue. See Disabling Policy Access Controls at the Cluster-Level on page 1887.
Auditing and wire-level encryption	The enforcement mode does not govern auditing and wire-level encryption; auditing and wire-level encryption is always enforced regardless of the enforcement mode set. • Wire-level encryption for tables is controlled by the filesystem through `hadoop mfs -setnetworkencryption on|off <table_path>`. • Auditing must be enabled at the volume level for auditing to occur. To enable audit for all data objects in the volume, use the `-forceauditenable` parameter. If auditing is disabled, permissive mode will not audit operations. • You can selectively turn all volume-level audit operations on or off through an optional `audit` flag. You cannot set this flag on individual objects within a volume. When you set this flag on a volume, it applies to all objects within that volume. See volume create on page 2588 and volume modify on page 2676. • Data Fabric Database JSON tables also have an `audit` flag that controls the auditing of database operations. See table create on page 2412 and table edit on page 2468. • Although you can tag resources at the volume, table, column family, and column (field) level in the database, the database only performs auditing and wire-level encryption at the volume and table level. The database does not perform auditing and wire-level encryption at the column family and column (field) level.
Snapshot of a volume	The *Snapshot of a volume* is set to the enforcement mode that was set on the volume when the snapshot was taken. For example, if the enforcement mode on a volume was `PolicyAceOnly` when the snapshot was taken and later changed to `PolicyAceAndDataAceOnly`, access to the snapshot is based on `PolicyAceOnly`. When you restore a volume from a snapshot or promote a snapshot to a read-write volume, the security policies and settings applied to the volume at the time of the snapshot are also restored.

Related concepts

Changing the State of a Security Policy on page 1910
The security policy state indicates whether users can apply a security policy to data objects and whether the system enforces the ACEs set in the security policy. An administrator can change the state of a security policy through the `allowtagging` and `accesscontrol` parameters when creating or modifying a security policy from the `maprcli` or equivalent REST API comands.

Enforcing Security Policies at the Volume-Level on page 1929
Describes how to set enforcement modes for security policies at the volume-level.

Disabling Policy Access Controls at the Cluster-Level on page 1887

last-updated: Jun 06, 2024

Disable policy ACEs that are set in security policies at the cluster-level through the `cldb.pbs.access.control.enabled` option in the CLI and REST API and through the Ignore Policy Access Control option in the Control System.

More information

Security Policy Enforcement Process on page 865
Data Fabric Database and Data Fabric File System enforce security policies hierarchically, starting at the volume level.

Security Policy Enforcement Process

Data Fabric Database and Data Fabric File System enforce security policies hierarchically, starting at the volume level.

Order of Enforcement

If the volume-level enforcement mode is set to `PolicyAceAndDataAce` (default setting), the system evaluates and enforces the ACEs directly applied to data objects AND the ACEs defined in the security policies applied to data objects. When a user submits a data-operation request, the system evaluates and enforces the ACEs hierarchically, starting with the volume in which the data resides.

For example, to perform a write operation on a file, the system first evaluates permissions on the volume in which the file resides. If at least one security policy is applied to the volume, the system evaluates the ACEs set in the security policy AND the ACEs or POSIX mode bits directly applied to the volume. Both sets of ACEs must allow permit the user to access the volume. If one set of ACEs does not permit access to the volume, the system denies the user permission to perform the operation. If both sets of ACEs permit access to the volume, the system checks access permissions on the file. The system evaluates security policies applied to the file AND any ACEs or POSIX mode bits applied directly to the file. Both sets of ACEs must permit the user write access on the file. If they both allow access (`writefileeace`), the user can perform the data operation on the file. If not, the system denies access.

Note the following behaviors related to the enforcement mode setting:

- When set to `PolicyAceOnly`, the system only enforces the ACEs set in security policies. A user can only perform data operations on a data object if the security policies associated with the data object allow the user access. However, if a data object is not associated with at least one security policy, the system enforces any ACEs or POSIX mode bits set directly on the data object. In this case, a user can only access the data object if the ACEs or POSIX mode bits set directly on the data object allow the user access.
- In `PolicyAceOnly` and `PolicyAceAndDataAce` modes, if a security policy is applied to a data object, and ACEs are not defined in the policy (`""`), the system continues to the next level data object to evaluate permissions.

Data Fabric File System Enforcement Process

The Data Fabric filesystem enforces security policies on data objects, in the following order:

- Volumes
- Files/Directories

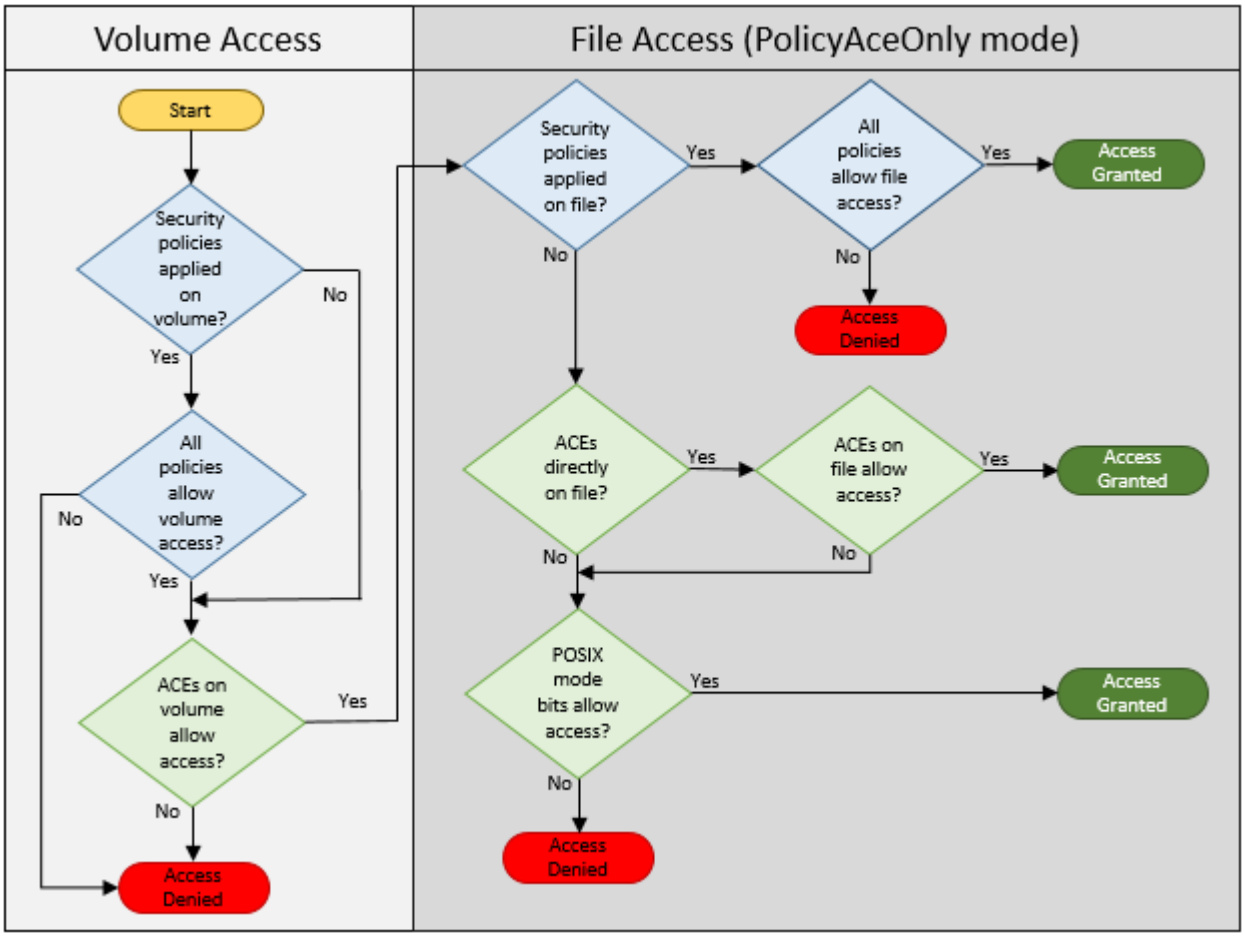
  NOTE: The system only enforces directory ACEs when determining access to the directory during directory operations. For read and write operations, directory ACEs are enforced during the path-walk operation when opening a file. If the user has a handle (FID) to the file, the user can access the file directly with the FID. In that case, the system ignores directory ACEs.

The following diagram shows the order in which the Data Fabric filesystem evaluates and enforces data operations on data objects when the enforcement mode is set to `PolicyAceOnly`:

last-updated: Jun 06, 2024

NOTE: If no policy is applied at the volume or file/directory level, the system will enforce DataAces (mode and ACEs applied directly on data object) to protect the data.

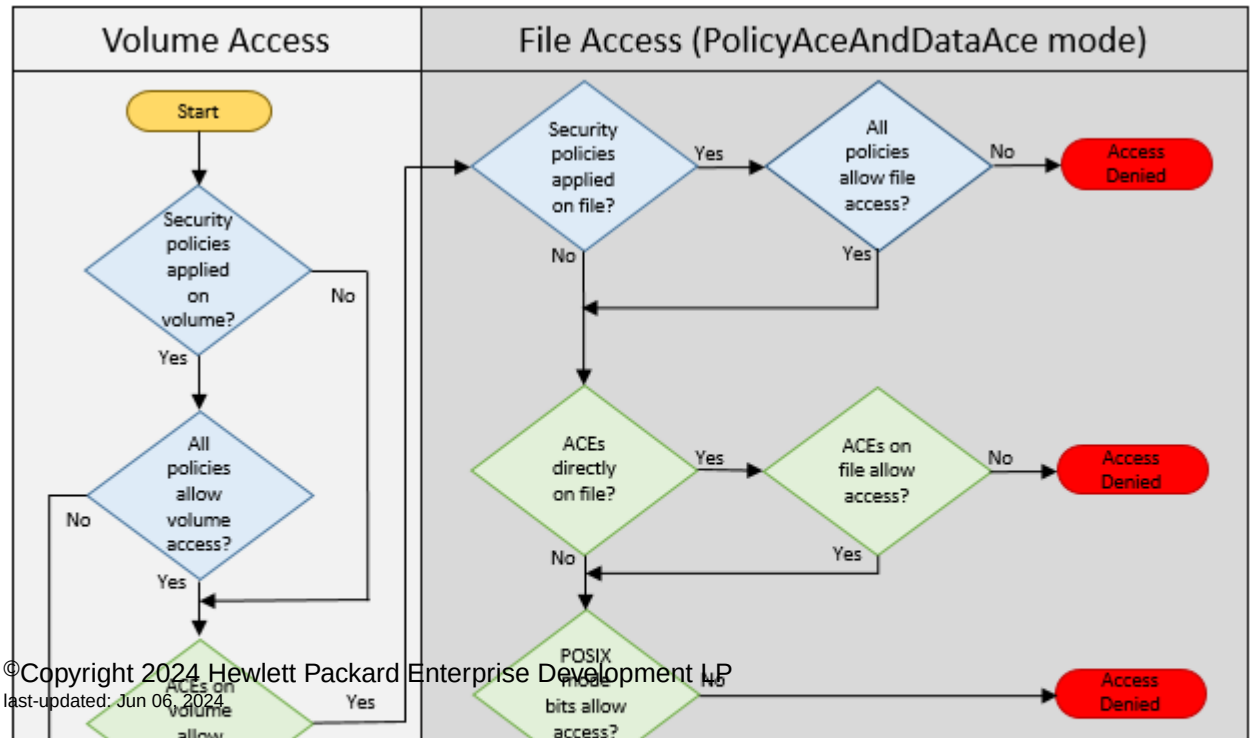
last-updated: Jun 06, 2024



Indicates system evaluation and enforcement of ACEs defined in the security policies applied to data objects

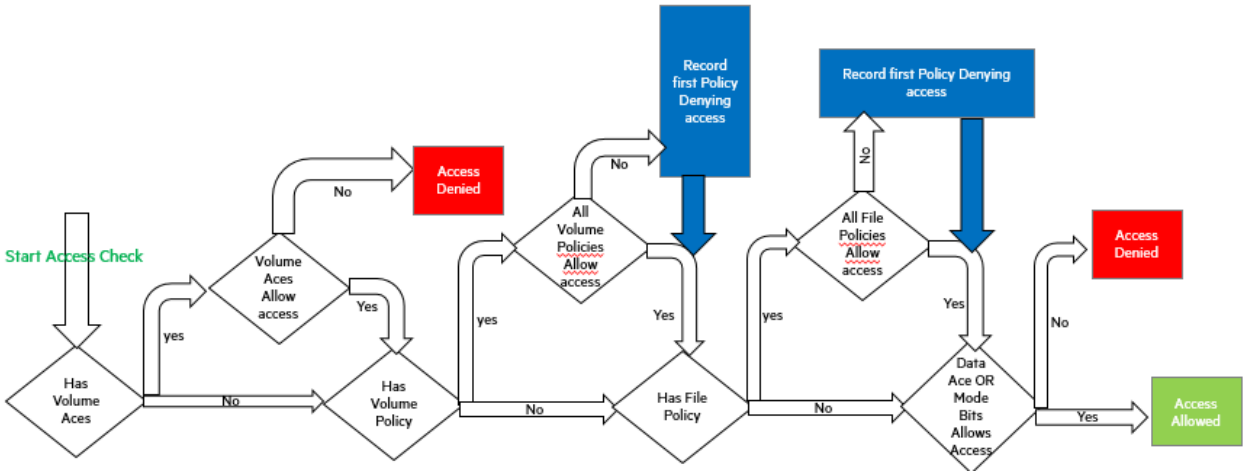
Indicates system evaluation and enforcement of ACEs defined directly on data objects

The following diagram shows the order in which the Data Fabric file system evaluates and enforces data operations on data objects when the enforcement mode is set to `PolicyAceAndDataAce` (default mode):



The following diagram shows the order in which the Data Fabric file system evaluates and audits data operations on data objects when the enforcement mode is set to `PolicyAceAuditAndDataAce` (permissive mode):

NOTE: The system does not enforce denied access checks, but does log the information about the denied check in the audit logs.



Data Fabric Database Enforcement Process

The security policies and ACEs applied to a volume also apply to JSON tables within that volume. The user that issues a data operation against a table in a volume must have permission to access the data in the volume through ACEs or security policies set on that volume.

For data operations, Data Fabric Database enforces ACEs (directly set on data objects) in the following order:

- Volume
- JSON column families
- JSON fields

NOTE: Data Fabric Database does not enforce table ACEs during data operations; however, when you create a table you can define default ACEs. Default ACEs are the permissions automatically applied to new column families when they are created for a table. Similarly, *new column families created for a table inherit the security policies applied to the table*.

Data Fabric Database supports ACEs for the following types of data operations:

- Read
- Write
- Traverse (JSON Only)
- Append (Binary Only – Currently, Policy-Based Security does not support binary tables.)

Data Fabric Database enforces security policies in the following order:

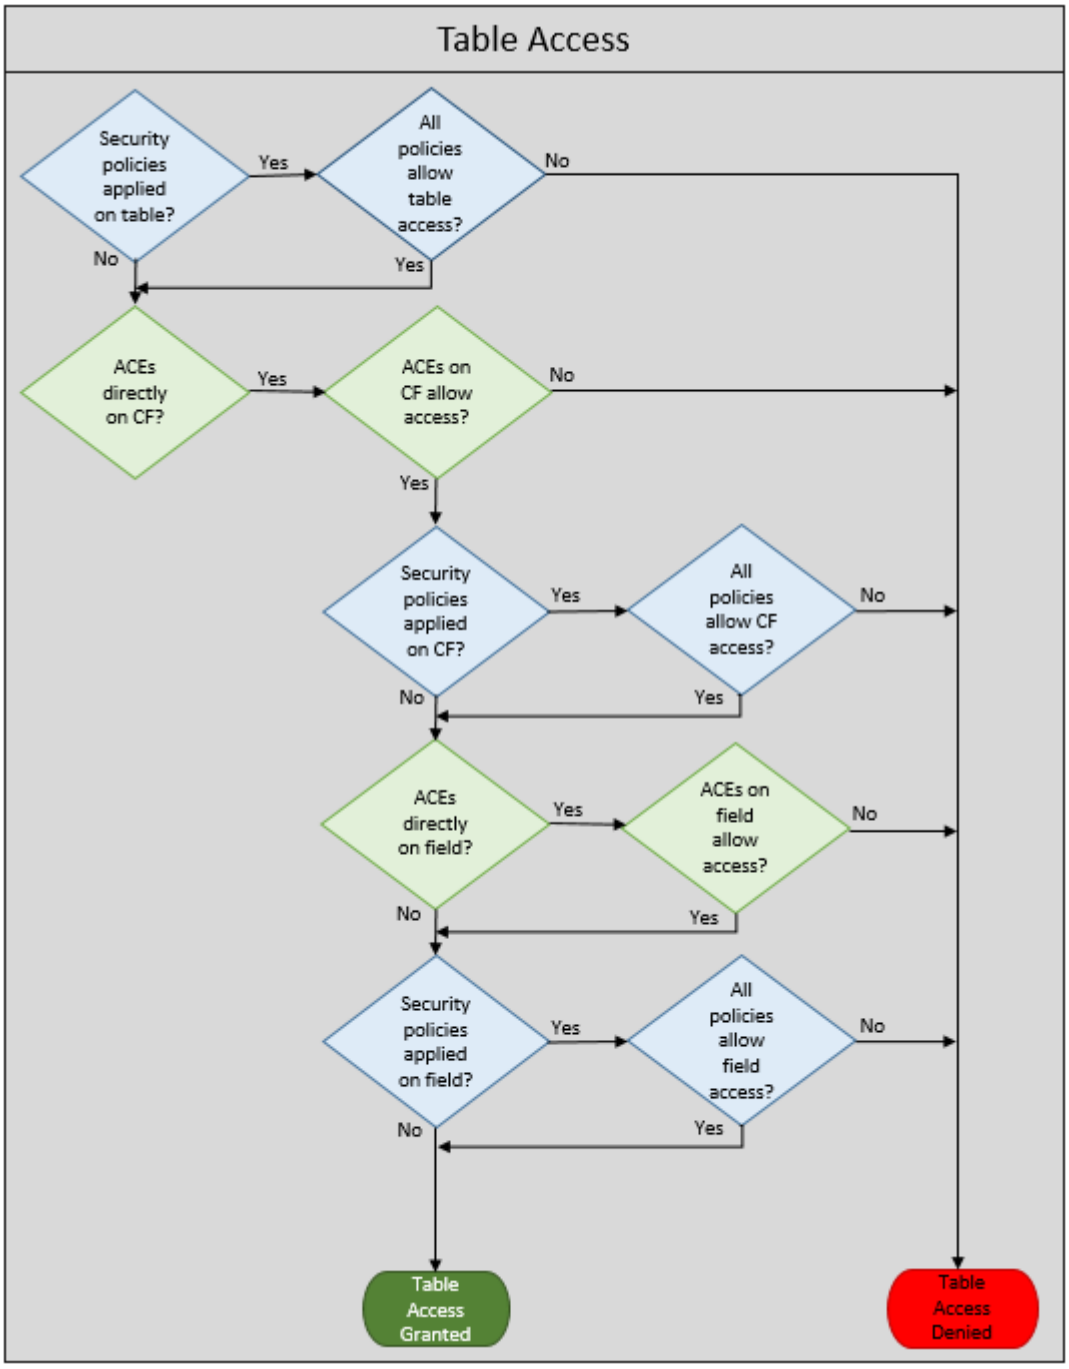
- JSON table
- JSON column family
- JSON field

last-updated: Jun 06, 2024

NOTE: Policies enforced on a primary table are also enforced on the secondary indices for the table.

The following diagram shows the order in which Data Fabric Database evaluates and enforces data operations on data objects when the enforcement mode is set to `PolicyAceAndDataAce` (default mode):

NOTE: Data Fabric Database evaluates and enforces the security policies and ACEs set on the volume before evaluating data access controls on the table. Refer to the preceding Data Fabric filesystem diagrams.



last-updated: Jun 06, 2024

Indicates system evaluation and enforcement of ACEs defined in the security policies applied to data objects

Indicates system evaluation and enforcement of ACEs defined directly on data objects

Related concepts

Volume-Level Security Policy Enforcement Mode on page 861
Before Core 6.2.0, Data Fabric supported enforcement based on mode and ACEs set directly on data objects. With Core 6.2.0 and above, security policies provide an additional or alternative way to control access to data. The volume-level enforcement mode specifies which of these methods a volume uses to govern access to data.

Related tasks

Enforcing Security Policies at the Volume-Level on page 1929
Describes how to set enforcement modes for security policies at the volume-level.

Security Policy Inheritance and Replication

Security policies are inherited during data-object creation and copied over during mirroring and replication.

Security policies cannot be mirrored or replicated unless you have configured a global policy master. For information about the security policy domain and configuring a global policy master, see Security Policy Domain and Policy Management on page 857.

How Volumes, Directories, and Tables Inherit Security Policy Settings

Volume Inheritance	By default, child and mirror (remote and local) volumes inherit the following volume properties: • `securitypolicy` • `enforcementmode` A mirror volume can inherit the properties from the source volume of the mirror. A standard volume can inherit properties from another standard volume, referred to as the parent volume in this context. In addition, data objects inside a volume can inherit the security settings from the volume in which they reside. The `allowgrant` flag controls whether new volumes inherit the properties set in the parent volume. The parent volume is the last volume in the `path` parameter when you create and mount a volume using the `path` parameter for the mount point. Volumes created under the parent volume inherit the properties of the parent volume. If you modify the settings in the parent volume after you create child volumes, the modified properties in the parent volume do not propagate to the child volumes.
Directory Inheritance	The `setinherit` flag controls whether or not subdirectories and files inherit the security policies applied to the parent directory. When `setinherit` is enabled (true), new files and directories under the parent directory inherit the security policies applied to the parent directory. If you modify the security policies applied to the parent directory, existing files and subdirectories within the parent directory do not change When `setinherit` is disabled (false), files and subdirectories created under the parent directory do

not inherit the security policies applied to the parent directory. By default, the files and directories get the default *access control expression (ACE)*, an empty string (""

). Note that POSIX mode bits are set on the files and directories.

Table Inheritance

JSON tables inherit the `enforcementmode` set on the parent volume. The enforcement mode controls which data access controls the system enforces on the volume and data objects within the volume. You cannot set the enforcement mode directly on a table. See Enforcing Security Policies at the Volume-Level on page 1929.

When a security policy is applied to a table, column families created within the table inherit the security policy, as described:

- Any new column family created (without a security policy) inherits and enforces the table security policy during runtime. The security policy of the column family, which is undefined, remains unchanged.
- Any new column family created (with a column family security policy) enforces the security policy of the table in conjunction with the security policy applied to the column family.
- Modifying the security policy applied to the table does not affect the security policies applied to column families, whether they are defined or not.
- All column families (without security policies) inherit and enforce the latest security policies of the table.

Within a JSON table, each comma-separated segment of characters is called a JSON *field*. For example, a given JSON field path may be represented as “a.b.c.” One or more security policy tags can be assigned to a JSON field. If a JSON field has no security policy, the field inherits the security policy of its predecessor at the field level. For example, if security policies are applied to fields "a" and "c," but not to "b," field "b" inherits its permission level from field "a." This behavior mimics the inheritance behavior of ACEs.

How Security Policy Settings Propagate During Volume and Table Replication

Volume Replication

The following table describes how security policy settings propagate during volume replication:

Data Object	Behavior
Standard and local mirror volumes	The system copies the security policy settings over during replication.

Data Object	Behavior
Remote mirror volumes	The system copies the security policy settings and policies with which the resource is tagged, over to the destination cluster during replication, if the following condition is met: The remote mirror volume cluster must be associated with the same master security policy cluster as the source volume cluster. For information about master security policy clusters, see Setting Global Configuration Options for Policy-Based Security on page 1886.
Tiered volumes	The system does not propagate the security policy settings because security is enforced by the primary (or front-end) volume
Files and directories	When individual files and directories are copied, the security policies associated with the files and directories are also copied over.

JSON Table Replication

When tables are replicated, all security policies attached are transferred at time of replication.

The following table describes how security policy settings propagate during some common replication scenarios:

Replication Scenario	Description
Replicate tables from a data-fabric 6.2.x cluster to a pre-data-fabric 6.2.0 cluster	Replication fails because the pre-data-fabric 6.2.0 destination cluster does not support Policy-Based Security.

last-updated: Jun 06, 2024

Replication Scenario	Description
Replicate tables from a data-fabric 6.2.x cluster to another data-fabric 6.2.x (or later) cluster	The security policies applied to tables, column families, and columns are preserved. Note these considerations for replication in this scenario: • When creating the replica as part of the ReplicaSetup phase in Autosetup, the destination table is created with the same security policy settings, and column family and column security policies as the source. • The security policies defined for the source cluster must be available on the destination cluster by way of the security policy global namespace. See Setting Global Configuration Options for Policy-Based Security on page 1886. • If a security policy defined for the source is not found on the destination, creation of the table, column family, or column will fail, thereby failing the ReplicaSetup. Autosetup will keep retrying the ReplicaSetup until the tags are replicated. • Column-family creation from the Gateway during replication is not distinguishable from column-family creation from the client.
Change Data Capture (CDC)	When you replicate to a CDC stream, the system ignores and drops the security policies.
Secondary-index table schema	While security policies are not replicated as part of a secondary-index table schema, the same security policies are enforced as the primary table. This behavior is similar to the behavior of *ACE*s on column families and columns.

Example Using Security Policies

This example demonstrates how to secure data, set permissions, and create, view, and modify a security policy.

Assume that you want to protect sensitive employee data in the cluster, and you only want to permit security policy and data access to the following users and groups:

last-updated: Jun 06, 2024

Type	Name	Role
User	`PolicyAdmin`	• Creates security policies
User	`ITAdmin`	• Modifies nonsensitive properties of security policies
User	`HrVP`	• Decides who can access employee data • Is a member of the `HR` group
Group	`HR`	• Views the properties of the employee data policy • Reads and writes employee data
Group	`Finance`	• Reads employee data

The following commands grant cluster-level permissions and create a security policy named `employeeData` with the policy-level permissions and *ACE*s needed to fulfill the roles shown in the preceding table:

1. User `mapr` grants cluster-level permissions and confirms that the permissions are properly set:

```
/opt/mapr/bin/maprcli acl edit -type cluster \
  -user PolicyAdmin:login,cp ITAdmin:login,fc \
  -group HR:login Finance:login
/opt/mapr/bin/maprcli acl show -type cluster
```

Verify that the ACLs are set correctly:

```
/opt/mapr/bin/maprcli acl show -type cluster

Allowed actions             Principal
[login, cp]                 User PolicyAdmin
[login, ss, cv, fc]         User ITAdmin
[login]                     Group HR
[login]                     Group Finance
```

2. User `PolicyAdmin` creates the security policy, and sets policy-level permissions and *ACE*s for only `HrVP`:

```
/opt/mapr/bin/maprcli security policy create -name employeeData \
  -description "Confidential Employee Data" \
  -user HrVP:r,a \
  -readace u:HrVP -writeace u:HrVP
```

The following output shows that only `HrVP` has permissions and *ACE*s:

```
/opt/mapr/bin/maprcli security policy info -name employeeData \
  -columns acl,securityPolicyAces -json

{
    "timestamp":1541086042314,
    "timeofday":"2018-11-01 08:27:22.314 GMT-0700 AM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "acl":{
                "Principal":"User HrVP",
                "Allowed actions":"[r, a]"
            },
            "securityPolicyAces":{
                "readfileace":"u:HrVP",
                "readdirace":"u:HrVP",
                "lookupdirace":"u:HrVP",
                "readdbace":"u:HrVP",
                "traversedbace":"u:HrVP",
                "consumeace":"u:HrVP",
                "writefileace":"u:HrVP",
                "addchildace":"u:HrVP",
                "deletechildace":"u:HrVP",
                "writedbace":"u:HrVP",
                "produceace":"u:HrVP",
                "topicace":"u:HrVP"
            }
        }
    ]
}
```

3. User `HrVP` modifies the policy, adding policy-level permissions and ACEs for the `HR` and `Finance` groups:

```
/opt/mapr/bin/maprcli security policy modify -name employeeData \
  -user HrVP:a -group HR:r \
  -readace 'g:HR|g:Finance' -writeace g:HR
```

The following sample output shows that the groups `HR` and `Finance` now have permissions and ACEs:

```
/opt/mapr/bin/maprcli security policy info -name employeeData \
  -columns acl,securityPolicyAces -json

{
    "timestamp":1541086614445,
    "timeofday":"2018-11-01 08:36:54.445 GMT-0700 AM",
    "status":"OK",
    "total":1,
    "data":[
```

```
        {
            "acl":[
                {
                    "Principal":"User HrVP",
                    "Allowed actions":"[r, a]"
                },
                {
                    "Principal":"Group HR",
                    "Allowed actions":"[r]"
                }
            ],
            "securityPolicyAces":{
                "readdirace":"g:HR | g:Finance",
                "topicace":"g:HR",
                "traversedbace":"g:HR | g:Finance",
                "lookupdirace":"g:HR | g:Finance",
                "consumeace":"g:HR | g:Finance",
                "addchildace":"g:HR",
                "readdbace":"g:HR | g:Finance",
                "readfileace":"g:HR | g:Finance",
                "writedbace":"g:HR",
                "deletechildace":"g:HR",
                "produceace":"g:HR",
                "writefileace":"g:HR"
            }
        }
    ]
}
```

The policy-level permissions and ACEs defined in step 3 could have been included in step 2; however, they were separated to illustrate the following:

- The need to reapply policy-level permissions from step 2 because the new settings overwrite the previous settings
- Use of the | symbol when specifying ACEs

4. A user in the HR group checks the state of the security policy:

```
/opt/mapr/bin/maprcli security policy info -name employeeData \
-columns allowtagging,accesscontrol -json
```

The security policy is still in a state that restricts it from being used (`allowtagging=false`) or enforced (`accesscontrol=Disarmed`):

```
{
    "timestamp":1541087645422,
    "timeofday":"2018-11-01 08:44:05.422 GMT-0700 AM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "allowtagging":false,
                     "accesscontrol":"Disarmed"        }
    ]
}
```

5. User `ITAdmin` changes the state of the policy from `allowtagging=false` and `accesscontrol=Disarmed` to `allowtagging=true` and `accesscontrol=Armed` and then confirms the changes:

```
/opt/mapr/bin/maprcli security policy modify -name
employeeData -allowtagging true -accesscontrol Armed

/opt/mapr/bin/maprcli security policy info -name employeeData -columns
allowtagging,accesscontrol -json

{
    "timestamp":1541087645422,
    "timeofday":"2018-11-01 08:44:05.422 GMT-0700 AM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "allowtagging":true,
                    "accesscontrol":"Armed"        }
    ]
}
```

After the state is changed, users can apply the policy to data objects and the system will enforce the security controls set in the policy. In the following example, the policy is applied during volume creation:

```
/opt/mapr/bin/maprcli volume create \
  -securitypolicy employeeData ... other options ... \
  -name employeeDataVolume
```

With this policy applied, users in the `HR` group can read and write data in `employeeDataVolume`. Users in the `Finance` group can only read data.

Related concepts

Configuring Policy-Based Security on page 1886
Starting in HPE Ezmeral Data Fabric 6.2.0 (EEP 7.0.0), HPE Ezmeral Data Fabric supports Policy-Based Security. Policy-Based Security is a mechanism that enables administrators to create security policies for simplified data management. Administrative users can create and manage security policies through the control system, maprcli, REST API, Hadoop and Linux commands, and Java APIs.

Granting Security Policy Permissions on page 1889
Permissions define which administrative users can create, view, and modify security policies. Administrators set the permissions on security policies through cluster-level and security policy-level ACLs.

Changing the State of a Security Policy on page 1910
The security policy state indicates whether users can apply a security policy to data objects and whether the system enforces the ACEs set in the security policy. An administrator can change the state of a security policy through the `allowtagging` and `accesscontrol` parameters when creating or modifying a security policy from the `maprcli` or equivalent REST API comands.

FIPS Compliance for HPE Ezmeral Data Fabric

Describes how the HPE Ezmeral Data Fabric complies with Federal Information Processing Standard (FIPS) 140-2 Level 1.

Release 7.0.0 and later releases of the HPE Ezmeral Data Fabric provide FIPS compliance with some restrictions.

Considerations for FIPS Support

Note the following important considerations for FIPS support in Release 7.0.0:

- Release 7.0.0 supports FIPS for new installations only.
- Release 7.0.0 supports FIPS only on Red Hat Enterprise Linux (RHEL). For the supported RHEL versions, see the Operating System Support Matrix on page 5719.
- Upgrades are not supported. You cannot upgrade from a non-FIPS cluster to a FIPS-compliant cluster in release 7.0.0.
- Some, but not all, EEP components support FIPS. For more information, see What's New in EEP 8.1.0 on page 6153.
- For manual installations, FIPS mode implies secure mode as well. Thus, on a FIPS-enabled node, `-secure` is the default, whereas in a regular, non-FIPS-enabled node, `-unsecure` is the default.
- The HPE Ezmeral Data Fabric Object Store is not FIPS compliant.
- Only the operating systems listed on this page are FIPS compliant for the HPE Ezmeral Data Fabric. Other operating systems either are undergoing testing or will never be FIPS compliant. CentOS 8.x and the newer CentOS Stream, for example, are not FIPS compliant with the HPE Ezmeral Data Fabric. CentOS 8 users who need to run data-fabric software in a FIPS-validated configuration should migrate to RHEL 8.x.

About FIPS and 140-2 Level 1

The Federal Information Processing Standard (FIPS) is a US government standard used to approve cryptographic modules. FIPS-validated products give users the assurance that data within the product is protected using cryptographic algorithms meeting the stringent guidelines and testing procedures established by the FIPS standard. FIPS was established by the National Institute of Standards and Technology (NIST), and defines critical security parameters that vendors must use for encryption. Products sold to the US government must meet FIPS validation criteria. In addition, there is a growing need by organizations processing sensitive data, such as banks, financial institutions, legal and medical institutions, to have the products that they use be FIPS 140-2/3 validated.

FIPS 140-2 requires that any hardware and software cryptographic module implement algorithms from an approved list. FIPS-validated algorithms cover both symmetric and asymmetric encryption algorithms as well as the use of hash standards and message authentication. FIPS 140-2 specifies multiple levels of security, with level 1 being the least secure and level 4 being the most secure. In particular, FIPS 140-2 Level 1 compliance is applicable to software-only distributions such as the HPE Ezmeral Data Fabric. FIPS 140-2 Level 2 and above require control of physical security mechanisms, which do not apply to the data-fabric platform. For more information about the different levels here.

last-updated: Jun 06, 2024

Data-Fabric Approach to FIPS Level 1 Compliance

The HPE Ezmeral Data Fabric solution is installed on user-supplied operating systems, with the JDK supplied by the user. HPE Ezmeral Data Fabric does not bundle the operating system or associated libraries, such as OpenSSL, with the products. Neither does it bundle the JDK.

Therefore, the data-fabric approach to FIPS 140-2 Level 1 compliance is to leverage the operating systems that include FIPS 140-2 Level 1 certified cryptographic libraries provided by the user, as well as support for the Bouncy Castle Java FIPS API bundled with HPE Ezmeral Data Fabric, which runs on a compatible user-supplied JDK. The HPE Ezmeral Data Fabric therefore:

- Uses the OpenSSL cryptographic module distributed in operating systems supported by the data-fabric core platform that have obtained FIPS 140-2 Level 1 approval. These include:
  - RedHat 8.x (CMVP #3784)
  - Ubuntu 18.04 and 20.04 (CMVP #3980 and 3966)
  - SLES 15 SP 2 (CMVP #3991)
- For all supported operating systems listed above, uses the Java FIPS API from Bouncy Castle (CMVP #3514) which has FIPS 140-2 Level 1 approval.
- Includes enhancements to the data-fabric core platform so that all components use only FIPS 140-2 Level 1-validated cryptography when FIPS mode is enabled, and ensures that no sensitive data is stored in plain text.

FIPS 140-2 Certifications

The following certifications are relevant to the HPE Ezmeral Data Fabric core platform as indicated in the Operating System Support Matrix on page 5719. All certifications in the following table are for FIPS 140-2 since this is the current standard for which approvals can be obtained. Since HPE validates at FIPS 140-2 Level 1, the following certifications can be used on any general- purpose computer running the specified operating system:

Components	Operating System / Module	Certification
Java Components	Linux CentOS/SLES/Ubuntu Bouncy Castle BC-FJA (FIPS Java API) v1.0.2.1	• FIPS 140-2 Level 1 • Java Cryptographic API for Java SE 11 • Tested on Dell PowerEdge R830 Photon OS 2.0, valid for any general-purpose computer running HP-UX and Linux CentOS/SLES/Ubuntu or equivalent • CMVP #3514, obtained 8/23/2019, valid until 8/22/2024 • See Security Policy

Components	Operating System / Module	Certification
C/C++ Components	Ubuntu 18.04 OpenSSL Cryptographic Module 2.1	• FIPS 140-2 Level 1 • OpenSSL 1.1.1 • Tested on Supermicro SYS-5018R-WR and IBM z14 • CMVP #3980, obtained 7/12/2021, valid until 7/11/2026 • See Security Policy .
	Ubuntu 20.04 OpenSSL Cryptographic Module	• FIPS 140-2 Level 1 • OpenSSL 1.1.1 • CMVP #3966, obtained 7/6/2021, valid until 7/5/2026
	RedHat Enterprise Linux 8 OpenSSL Cryptographic Module rhel8.20200305	• FIPS 140-2 Level 1 • OpenSSL 1.1.1 • CMVP #3781, obtained 12/21/2020, valid until 12/20/2025
	SUSE Linux Enterprise Server (SLES) 15 SP 2	• FIPS 140-2 Level 1 • OpenSSL 1.1.1 (OpenSSL Cryptographic Module 4.1) • CMVP #3991, obtained 7/21/2021, valid till 7/21/2026

Interoperability in Mixed-Mode Clusters

Both FIPS-compliant and regular installations work seamlessly on a single cluster and across cluster. Interoperability is supported for mixed-mode clusters running a combination of FIPS-compliant and non FIPS-compliant solutions. Thus, there will be no disruption in operations during a rolling upgrade.

Sensitive Data Is Protected

All sensitive data such as key and trust store passwords, as well as CLDB and DARE master keys, will be protected using FIPS 140-2 Level 1 compliant cryptography. No sensitive data such as passwords and keys are stored in plain text.

FIPS 140-2 Level 1 Compliance for C/C++ Components

Describes how the HPE Ezmeral Data Fabric C/C++ components comply with Federal Information Processing Standard (FIPS) 140-2 Level 1.

The C/C++ components of the HPE Ezmeral Data Fabric need to use FIPS-approved cryptographic libraries for FIPS 140-2 Level 1 compliance. The data-fabric cryptographic library of choice is OpenSSL 1.1.1. Only FIPS-approved cryptographic algorithms are used in the core platform. Weaker, non-FIPS approved cryptographic algorithms such as MD5 are no longer supported.

OpenSSL 1.1.1 Distributions

On FIPS-enabled nodes, the HPE Ezmeral Data Fabric uses the FIPS-certified OpenSSL 1.1.1 distribution from the following operating system vendors:

last-updated: Jun 06, 2024

OS	Module	Description
Ubuntu 18.04	OpenSSL Cryptographic Module 2.1	• FIPS 140-2 Level 1 • OpenSSL 1.1.1 • CMVP #3980, valid until 7/11/2026
Ubuntu 20.04	OpenSSL Cryptographic Module	• FIPS 140-2 Level 1 • OpenSSL 1.1.1 • CMVP #3966, valid until 7/6/2021, valid until 7/5/2026
RHEL 8	OpenSSL Cryptographic Module rhel8.20200305	• FIPS 140-2 Level 1 • OpenSSL 1.1.1 • CMVP #3781, valid until 12/20/2025
SLES 15 SP2	OpenSSL Cryptographic Module 4.1	• FIPS 140-2 Level 1 • OpenSSL 1.1.1 • CMVP #3991, valid until 7/21/2026

How OpenSSL Cryptographic Modules Are used

OpenSSL is a robust, commercial-grade, and full-featured toolkit for the Transport Layer Security (TLS) and Secure Sockets Layer (SSL) protocols. It is also a general-purpose cryptography library. The HPE Ezmeral Data Fabric uses OpenSSL 1.1.1 cryptographic modules exclusively for all cryptographic operations, including but not restricted to the following:

- Data at-rest encryption/decryption (DARE) using AES-256 XTS
- Encryption of data transmitted over-the-wire using AES-256 GCM
- Signatures using HMAC SHA-256 for Amazon S3 access in the MAST gateway
- Random number generation as part of the challenge-response authentication
- Certificate validation and display

Cryptographic Libraries Used Before Release 7.0.0

Prior to release 7.0.0, the HPE Ezmeral Data Fabric used the CryptoPP cryptographic library for most C++ cryptographic operations. CryptoPP was certified at FIPS 140-2 Level 1 in 2007. The status for CMVP certificate #819 for CryptoPP is *Historical*, which means that it has expired. There are no plans to revalidate to get FIPS approved again. Release 7.0.0 replaces all CryptoPP cryptographic functionality used in earlier releases with equivalent FIPS 140-2 Level 1-validated OpenSSL cryptographic functionality that is fully compatible with older releases.

The Intel ISA-L cryptographic library used in earlier releases for cryptographic operations such as AES-XTS encryption are also replaced with the equivalent FIPS 140-2 Level 1 validated OpenSSL cryptographic functions.

last-updated: Jun 06, 2024

Cryptographic Algorithms Used

The following table provides a list of cryptographic algorithms used in the HPE Ezmeral Data Fabric core platform. When applicable, such as in AES algorithms, the platform uses Initialization Vectors (IVs) that are 16 bytes long:

Algorithm	How It's Used
AES-256 GCM	Used to Encrypt/Decrypt messages and RPC over the wire with authentication of the message. These functions have a message authentication tag (MAC) of length of 16 bytes.
AES-256 CTR	To generate the storage pool and block encryption keys for DARE.
AES-256 XTS	Used for DARE Encryption/Decryption of data at rest on the disk. The Length of both keys needed is 32 bytes, with a 16-byte tweak.
DRBG Random Number Generator	Used to generate bytes/numbers randomly for Initialization Vectors, Key, challenge-response authentication, and other cases.
SHA-256 Hashing Function (FIPS-approved as per FIPS 180-4)	Hash is used to derive and generate the keys (serverkey, clusterkey, and other keys) from the master CLDB key.

Bouncy Castle Cryptographic Library for Java

Describes the data-fabric implementation of the Bouncy Castle cryptographic library for Java.

The Java components of the HPE Ezmeral Data Fabric need to use FIPS-approved cryptographic libraries for FIPS 140-2 Level 1 compliance. The data-fabric cryptographic library of choice is Bouncy Castle. Bouncy Castle is an open-source Java cryptographic API package with a license similar to the MIT license. The Bouncy Castle Java APIs are FIPS-validated for Java 11, and the CMVP #3514 FIPS approval includes the Linux operating systems mentioned in the Operating System Support Matrix on page 5719 (Ubuntu and CentOS but not Red Hat).

Bouncy Castle Description

The following table describes the Bouncy Castle cryptographic library:

OS	Module	Description
Linux CentOS/ SLES/Ubuntu	Bouncy Castle BC-FJA (FIPS Java API v1.0.2.1)	• FIPS 140-2 Level 1 • Java Cryptographic API for Java SE 11 • Tested on Dell PowerEdge R830 Photon OS 2.0, valid for any general purpose computer running HP-US and Linux CentOS/SLES/Ubuntu • CMVP #3514, obtaiend 8/23/2019, valid until 8/22/2024 • See Security Policy

The majority of the cryptographic functions in the HPE Ezmeral Data Fabric core platform are done in the C/C++ layers using OpenSSL. Java components make calls to it through the Java Native Interface (JNI) using the `Security` class.

Security Files and Subdirectories

This section describes new security files and subdirectories added for release 7.0.0 to support FIPS compliance.

To support FIPS compliance and other security enhancements, release 7.0.0 added some new security files and subdirectories that must be copied during installation.

last-updated: Jun 06, 2024

Files to Copy When All Nodes Are FIPS Compliant or All Nodes Are Non-FIPS Compliant

A manual installation of the HPE Ezmeral Data Fabric involves running `configure.sh` with the `-genkeys` option on the primary CLDB node and then copying various files to the `$[MAPR_HOME]/conf` directory on all other nodes. After copying the files from the first CLDB node, you must run the `configure.sh` command with the same parameters as the first CLDB node but without the `-genkeys` option.

The following table shows the files and subdirectories that must be copied:

Table

Destination Node Type	These Files and Subdirectories Must Be Copied
CLDB and/or ZooKeeper Nodes	• `conf/ssl_keystore.bcfks`[1] • `conf/ssl_keystore.p12`[1] • `conf/ssl_keystore.pem`[1] • `conf/maprkeycreds.*` • `conf/maprtrustcreds.*` • `conf/maprhsm.conf` • `conf/maprserverticket` • `hadoop/hadoop-2.7.6/etc/hadoop/ssl*.xml` • `conf/tokens` (use `scp -r` to copy everything in this folder)
All other cluster nodes, including MFS-only nodes	• `conf/ssl_keystore.bcfks`[1] • `conf/ssl_keystore.p12`[1] • `conf/ssl_keystore.pem`[1] • `conf/maprkeycreds.*` • `conf/maprtrustcreds.*` • `conf/maprhsm.conf` • `conf/maprserverticket` • `hadoop/hadoop-2.7.6/etc/hadoop/ssl*.xml`
Client nodes	• `conf/ssl_truststore*` • `conf/maprtrustcreds.*`

[1]Do NOT copy the `ssl_` symlink files contained in the `conf/` directory. The symlinks are:

- `ssl_keystore` (symlink)
- `ssl_truststore` (symlink)
- `ssl_userkeystore` (symlink)
- `ssl_usertruststore` (symlink)

Dynamic Data Masking

Describes the Dynamic Data Masking feature that allows you to mask sensitive information when retrieving data.

Dynamic Data Masking (DDM) is the ability to apply a variety of data masks in real time, depending on who is accessing the data. DDM aims to mask data in transit, but leaves the original data in the database unaltered. You can configure DDM on designated database fields to hide sensitive data in the result set of queries. Starting in release 7.0.0 of HPE Ezmeral Data Fabric, all fields of JSON tables support DDM.

HPE Ezmeral Data Fabric has column family, column, and field-level ACEs, as well as Policy-Based Security, which allows you to create security policies that control access to information. ACEs and security policies provide an all-or-nothing approach - either the data for the column or field is returned or not returned.

As a typical example, consider the credit card industry. The application that prints receipts for credit card purchases does not need the full credit card numbers but only needs the last four digits of the credit card number to identify the credit card being used. However, in the same organization, the full credit card number should be available for payment processing. With ACEs and policies, you either get the credit card number or not. You cannot use ACEs or policies to return only the last four digits of the credit card number. Dynamic Data Masking offers the solution.

The advantage of DDM is that it is easy to use and backward compatible with existing applications. DDM applies the masking rules to query results, with no modifications required to existing queries. The disadvantage of DDM is that it is not a fully secure solution for the sensitive fields; it does not prevent users from connecting to the database and running exhaustive queries that expose pieces of sensitive data. Therefore, view DDM as a complementary solution to other database security features, such as auditing, encryption, and row/column-level security.

The maximum number of supported dynamic data masks is 128. There are eight predefined dynamic data masks supported on the JSON database.

NOTE: Release 7.0.0 of HPE Ezmeral Data Fabric does not support custom dynamic data masks.

Predefined Mask Types
Describes the predefined Dynamic Data Masks.

The following table describes the predefined masks that Dynamic Data Masking supports.

Mask	Description	Supported Data Types
`mrddm_redact`	This data mask will mask all alphabetic characters with “x” and all numeric characters with “0” for Strings. For other data types, the mask replaces all values with whatever is equivalent to 0 for that data type. For dates, this will set the date to January 1, 1970. If the data type is a Timestamp, the mask will zero out the time to show 00:00:00. This will protect all data, except the general format and patterns of the data. **Examples** "mapr123" → "xxxx000" 12345 → 0 July 29, 2021 → Jan 01, 1970	Binary, Boolean, Byte, Int, Long, Short, String, Float, Double, Time, Timestamp, Date, Array
`mrddm_last4`	Displays only the last four characters and replaces everything else with *. This can be used in a wide number of applications, including credit card numbers, passport information, and social security numbers. If the string is four characters or less, all data for that column is masked. **Examples** "mapr123" → "***r123" "310027890" → "*****7890"	String, Array
`mrddm_first4`	Displays only the first four characters. This is very similar to the `last4` data mask, but just shows the first characters instead. **Examples** "mapr123" → "mapr***" "4400000000000008" → "4400**********"	String, Array
`mrddm_first6last4`	Displays only the first six characters and last four characters. This is very similar to the `last4` data mask format. **Example** "4400000000000008" → "440000******0008"	String, Array

Mask	Description	Supported Data Types
`mrddm_email`	Displays the first two characters and the last two characters of the user name, and the first character of the domain and the whole top-level domain. For example *example@hpe.com* will be masked to ex***le@h**.com. An email address with four or fewer characters in the name is fully masked. This mask format will work only for email formats, that is has a prefix with an “@” after, followed by a domain that is represented by a string with a dot, then another string. If the row has an incorrect format, xx*xx@xxx.badFormat will be displayed for that row in that column. **Examples** "bobb@snd.org" → "****@s**.org" "helloword@hpe.com" → "he******ld@h**.com" "helloworld123" → "x*x@x.badFormat"	String (in format of email) , Array
`mrddm_hash`	Displays the hash of the data. This is useful for verifying if two cells match but will not show the pattern or the length of the data. **Example** "helloworld123" → "A1FE8F79A121256842E7AAEF2AB1E339A553A74FE05834CA081259CF66AC5FB5"	String, Array
`mrddm_date`	Displays a generic date for all date fields but shows the correct year. This mask makes all months and days of the month into the value one. **Example** "March 21, 2021" → "Jan 1, 2021" If the data type is a Timestamp, the mask zeroes out the time to show 00:00:00.	Timestamp, Date

You can apply any data mask to arrays that contain elements of allowed datatypes for that specific DDM. The behavior of this will just mask each value inside the array individually with whatever mask was tagged to the column the array is in. Any values that have the incorrect type, or is a document inside the array, will not get masked. For example:

```
Unmasked Values:
  {"_id":"1","CC_Number":
["4602991456888310","4485525035496110","4539575160102150"],
  "Email":["bob@hpe.com","alice@hpe.com","bill@hpe.com"],"Name":
["Bob","Alice","Bill"],
  "SSN":["210549785","512491532","710254675"]}

Masked Values:
  {"_id":"1","CC_Number":
["460299******8310","448552******6110","453957******2150"],
  "Email":["***@h**.com","al*ce@h**.com","****@h**.com"],"Name":
["xxx","xxxxx","xxxx"],
  "SSN":["*****9785","*****1532","*****4675"]}
```

Dynamic Data Mask Enforcement Rules
Explains how data masks are enforced.

Dynamic data masks are enforced on all JSON table columns that have a data mask set. Data returned to the user has the masks applied unless the user has `unmaskedreadperm` permission for the table, either at a resource level or security-policy level. For users with `unmaskedreadperm` permission, data is returned in clear text and not masked.

If the `unmaskedreadperm` permission is set at multiple locations – for example, both at the resource level and in a security policy – the ACE evaluation is the AND of all the `unmaskedreadperm` permissions. Since the `unmaskedreadperm` permission is a special case of the more general read permission, read permission for that column must be allowed for the user before evaluating for the `unmaskedreadperm` permission.

Additional Enforcement Considerations

The following considerations also apply to special cases:

1. Certain dynamic data masks are applicable to only a subset of available JSON data types. For example, the pre-defined `mrddm_last4` dynamic data mask applies only to `String` and `Array` data types. The concept of a “column” or “field” in a JSON table is fluid, and it is possible that a certain column may sometimes contain a `String` data type and sometimes contain other data types, e.g. Boolean. All attempts to enforce DDM rules on invalid data types will be logged and the data will not be masked. It is the application’s responsibility to ensure that the DB columns contain the correct data types when dynamic data masks are applied.

2. All dynamic data mask configurations are enforced on users with `readperm` access permission for that DB column family but not `unmaskedreadperm` permission. For users with both `readperm` and `unmaskedreadperm`permission for that DB column family, data is returned in cleartext as-is. Both the `readperm` and `unmaskedreadperm` permissions are required to return data in masked format.

3. If a column is tagged with a custom data mask that no longer exists when the data is accessed, the data will be returned in cleartext as-is and the event audited. It is your responsibility to ensure that all dynamic data masks that are set on JSON table columns are not deleted.

External KMIP Keystore Overview

Describes the External KMIP Keystore functionality.

An external keystore is a third party server that securely manages authentication keys used by a client. The functions of an external keystore include:

- Secure cryptographic key generation
- Secure cryptographic key storage at least for the top level and most sensitive keys, often called master keys

- Key management

Keystores meet the requirements of international standards such as Common Criteria and various levels of FIPS 140-2 to provide users with independent assurance that the design and implementation of the product and cryptographic algorithms are secure. With external keystore support, enterprise customers in sectors such as finance, legal and government sectors, can obtain the highest levels of protection.

NOTE: General purpose Hardware Security Modules (HSMs) can also function as external keystores, so although their feature set may be different, the ***terms HSM and keystore may be used interchangeably in this topic.***

Use the external keystore to store data-fabric cryptographic keys, and passwords.

ATTENTION: You can use HSM keystores from only one vendor per cluster.

Advantage of the KMIP Keystore

KMIP is a key management standard defined by the Organization for the Advancement of Structured Information Standards (OASIS), a global nonprofit consortium that works on the development, convergence and adoption of open standards for security and other areas.

The primary advantage of KMIP for key management is interoperability. With KMIP, the key management client and the server communicate using the same protocol, allowing data-fabric customers to choose any HSM vendor that supports KMIP.

KMIP Use Case Examples

Use KMIP to secure customer deployments that require highly secure, automated workflows to protect data at rest. The use cases for HSMs for data-fabric are as follows:

- Store the CLDB master key. Use the CLDB master key to encrypt server keys. Use the server key to generate tickets, protect user keys, and data in transit.
- Store the DARE master key. Use the DARE master key to derive keys to encrypt storage pools to protect data-at-rest.
- Securely generate master keys. HSMs incorporate True Random Number Generators (TRNG), which are used as seeds for secure generation of cryptographic keys.
- Onboard secure key management, including storage, backup and restore, guaranteeing that critical master keys can never be accidentally deleted or lost.
- FIPS 140-2 validation to provide users with the confidence that the HSM is certified to professional international standards.

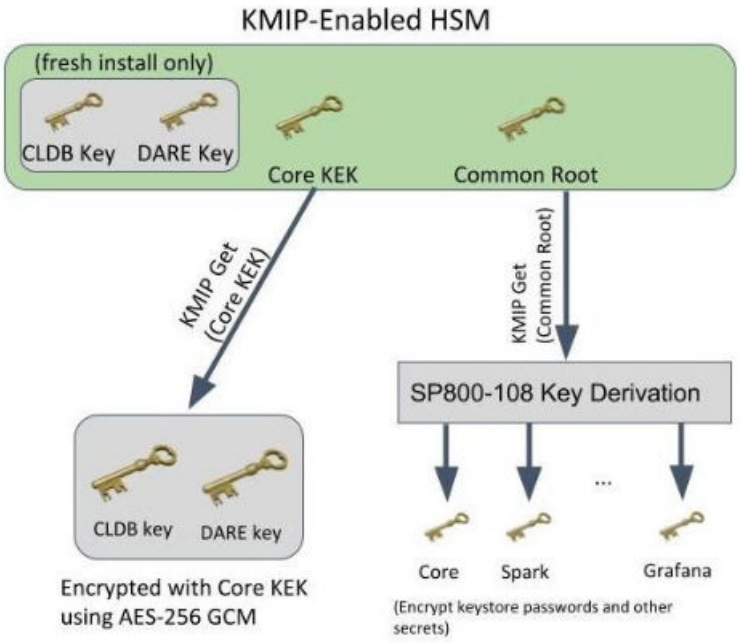
HSM Functionality Description
Describes how KMIP Keystores work.

ATTENTION: For an overview of what KMIP and HSM are, see External KMIP Keystore Overview on page 888

HSM integration with data-fabric works as follows:

last-updated: Jun 06, 2024



- If the external HSM functionality is enabled and there is an active connection to the external key store, the CLDB and DARE master keys are encrypted with the data-fabric Core Key Encryption Key (KEK) that is stored in the external key store.
- For fresh installations, the CLDB and DARE master keys are generated in the external key store, and remain in the external key store for backup purposes. The CLDB and DARE keys are stored in the `${MAPR_HOME/conf/tokens/mrhsm.conf` configuration file, encrypted with the data-fabric Core KEK.
- For existing installations that already have the CLDB and DARE keys generated, the existing keys remain, but are stored in an encrypted format, encrypted with the Core KEK.
- Installations upgrading from an existing data-fabric release will also have its CLDB and DARE keys stored in the external HSM for disaster recovery purposes.
- Re-keying of the Core or Common KEK is supported. Re-keying the Core KEK requires re-encrypting the CLDB and DARE master keys using the new Core KEK.

IMPORTANT: The SP800-108 key derivation is not supported for the data-fabric 6.2 release.

The data-fabric core platform contains the external HSM integration functionality. You can access the HSM using the industry standard PKCS#11 API and KMIP, which provide enhanced security for enterprise grade applications to protect data-at-rest. This access is transparent both to the data-fabric core functionality and to ecosystem components such as Spark, Drill and Hive after you set up the KMIP integration to the data-fabric core platform using the mrhsm Commands on page 905, as illustrated in the following diagram:

KMIP Supported Operations
Lists the KMIP operations that HSM should support, to use the external KMIP keystore.

last-updated: Jun 06, 2024

IMPORTANT: HPE has validated its KMIP solution on Utimaco ESKM, SafeNet KeySecure, and Vormetric DSM. KMIP is still in its early stages, so just because a HSM advertises support for the list of operations, it does not necessarily mean that it works with the HPE KMIP solution, but only that it has a good chance of working. Use at your own risk if you use HSMs that HPE did not validate. You do not have to explicitly perform any operation that is mentioned in this list.

Activate	Description: Activates managed objects. Purpose: Activates the KEK by setting the state to Active either at the current (default) or later date. Only keys in the Active state can be used. For the data-fabric platform, the CLDB and DARE master keys are encrypted using the KMIP key.
Create	Description: Creates managed objects. Purpose: Creates the CLDB and DARE AES-256 master keys. Keys are initially created in PreActive state and need to be activated before they can be used.
Destroy	Description: Destroys managed objects. Purpose: Destroys a KMIP key that is no longer used.
Discover Versions	Description: Discovers supported protocol versions. Purpose: Ensures that the KMIP server can support at least one of the KMIP protocol versions that are supported by the data-fabric client. Since this operation does not change the KMIP server state, the data-fabric KMIP client also uses it to ping the server to ensure that it is alive.
Get	Description: Retrieves managed objects. Purpose: Retrieves the key from the HSM when the UUID (unique identifier) or name is specified.
Locate	Description: Locates managed objects based on specified attributes. Purpose: Searches for keys by name instead of UUID.
Rekey	Description: Rekeys the Core or Common KEK. Purpose: Used to rekey the Core or Common KEK either on a periodic basis or when the keys are compromised.
Register	Description: Imports CLDB and/or DARE key. Purpose: Imports an existing CLDB and/or DARE key into the HSM for backup purposes for upgrade deployments.
Revoke	Description: Revokes specified keys. Purpose: KMIP keys in the Active state cannot be deleted; they need to be revoked and placed in the Deactivated state before they can be destroyed. Used prior to deleting unused keys.

KMIP Supported Attributes

Lists the KMIP attributes supported by the data-fabric KMIP client library.

The KMIP attributes supported by the data-fabric KMIP client library are as follows:

Activation Date	Description: Date and time when the managed cryptographic object may begin to be used.
Cryptographic Algorithm	Description: Cryptographic algorithm of an object, for example, AES.

Cryptographic Length	Description: Length in bits of the cleartext cryptographic material. For example, this value will be 256 for an AES-256 symmetric key.
Cryptographic Usage Mask	Description: A bit mask defining the cryptographic usage of a key, for example, encrypt and decrypt.
Digest	Description: Digest value of the key or secret data.
Fresh	Description: Indicates whether or not the object has been served to the client.
Initial Date	Description: Date when the managed object was first created or registered at the server.
Key Format Type	Description: Key format, for example, Raw, PKCS#1, Opaque, etc.
Last Change Date	Description: Date and time of the last change to the contents or attributes of the managed object.
Lease Time	Description: Time interval for a managed cryptographic object beyond which the client shall not use the object without obtaining another lease.
Name	Description: Name assigned by the KMIP client to identify and locate the object.
Object Group	Description: Specifies the group to which the object belongs.
Object Type	Description: Type of the managed object, for example, symmetric key.
Operation Policy Name	Description: Specifies the entities and their corresponding key management operations on the object.
State	Description: Indicates the object state, for example, Pre-Active, Active.
Unique Identifier	Description: Generated by the key manager to uniquely identify a managed object.
x-ClusterName	Description: Data Fabric-specific custom attribute to specify the cluster name to which this managed object relates.

KMIP Rekey Process

Describes the rekey process for CLDB and DARE keys.

External keystores ensure that the keys are always securely backed up and replicated, and guaranteed never to be lost. You can never accidentally delete KMIP keys - only the administrator can set the state to DESTROYED, but the keys still remain in cryptographic storage. Therefore, the rekey procedure is used mainly for key rotation and in the unlikely event of a compromise.

Key Types

The data-fabric platform comprises two main keys:

- Core Key: Encryption key used to encrypt the data-fabric CLDB and DARE keys

- Common Key: The key used to derive keys for various core, ecosystem and SpyGlass components that are in turn used to encrypt the Java Cryptography Extension Keystore (JCEKS) and other sensitive files

Rekeying the Core or Common KEK

To rekey, see mrhsm rekey on page 920.

Setting Up the External KMIP Keystore
Describes how to set up the KMIP keystore and how to enable integration with data-fabric.

Prerequisite to Setting Up the KMIP Keystore

Data Fabric will have a minimum of 3 hosts to 10 hosts that need to communicate with your External KMIP Keystore vendor. Contact your External Key Management vendor for license considerations.

The steps to first set up the external KMIP key store and then enable KMIP integration with Data Fabric are the same irrespective of whether the cluster is an existing one with DARE enabled, or whether it is a new cluster.

Set up the Keystore

Setting up the external KMIP key store involves the following steps:

1. Set up the external KMIP-enabled key management appliance for the HSM of your choice as described in the Utimaco ESKM Integration Guide on page 930, or the Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, or the Vormetric Data Security Manager (DSM) Integration Guide on page 959, or the HashiCorp Vault Integration Guide on page 973.

   At the end of this step, you should have the following on one of your data-fabric cluster hosts that is running the CLDB:

   - Private client key
   - Signed client certificate in PEM format
   - Signed CA certificate in PEM format

2. On your host running CLDB, initialize the PKCS#11/KMIP configuration using the mrhsm init on page 917 command. Alternatively, you can do this in multiple steps, using the mrhsm set on page 925 and mrhsm info on page 911 commands, until you have achieved a successful connection to the external KMIP-enabled key manager.

   A sample mrhsm init on page 917 session is as follows:

```
# mrhsm init -label "Utimaco ESKM"
Enter SO PIN (4-255 characters): ********
Please reenter SO PIN: ********
```

   After running the mrhsm init on page 917 command, the Token info section is initialized, with a serial number assigned. You will need this serial number for various mrhsm configuration tasks. For example:

```
# mrhsm info -slots
Available slots:
Slot 1298274617
    Slot info:
        Description:          MapRHSM slot ID
0x4d621939
        Manufacturer ID:      HPE MapR-HSM
        Token present:        yes
    Token info:
        Manufacturer ID:      HPE MapR-HSM
        Model:                MapRHSM
        Serial number:        07137a824d621939
        Initialized:          yes
        User PIN initialized: yes
        Label:                Utimaco ESKM
```

   Alternatively, a sample session with mrhsm set on page 925 and mrhsm info on page 911 commands is as follows:

```
The following example shows how the mrhsm set command is used. Since the
port number
and KMIP version is not specified, they default to 5696 and 1.1
respectively:

# mrhsm set -ip 12.1.78.164,12.1.78.165 -cacert /root/eskm/
LocalCA.crt -clientcert \
 /root/eskm/client.pem -clientkey /root/eskm/client.key
Enter SO PIN: ****
```

   After the preceding mrhsm set on page 925 command, the configuration settings are updated in `${MAPR_HOME}/conf/tokens/mrhsm.conf` and can be displayed using the mrhsm info on page 911 command:

```
# mrhsm info -config
Displaying information for KMIP token with serial b819261a33fbe5a1
IPs
  IP 1                : 12.1.78.164 Active
  IP 2                : 12.1.78.165 Active
Port                  : 5696
KMIP Version          : 1.1
KMIP Client Key       : Configured

KMIP Client Certificate:
    Subject: /C=US/ST=California/L=Santa Clara/O=HPE/OU=MapR/
CN=kmipclient/emailAddress=johndoe@hpe.com
    Issuer: /C=US/ST=OR/L=Campbell/O=Utimaco/OU=Atalla/CN=LocalCA/
emailAddress=support@utimaco.com
```

```
    Version: 3
    Signature Algorithm: rsaEncryption

    Signature Algorithm: id-ecPublicKey
    Validity:
        Not before: Aug  6 23:49:09 2019 GMT
```

3. When you have successfully verified your KMIP setup and ensured that all the HSMs are **Active** , enable the KMIP functionality using the mrhsm enable on page 907 command. A sample session for an *existing DARE enabled cluster* is as follows:

```
# ls /opt/mapr/conf | grep cldb.key
cldb.key
# ls /opt/mapr/conf | grep dare.master.key
dare.master.key
# mrhsm enable
Existing DARE master key found at /opt/mapr/conf/dare.master.key,
and -dare is not specified
Use the -dare option to import the DARE master key into the HSM.
# mrhsm enable -dare
Enter SO PIN: ****
Obtained cluster name my.cluster.com from mapr-clusters.conf
Enabling MapR HSM on cluster my.cluster.com
Successfully generated Core KEK, UUID

Successfully set encrypted DARE key in KMIP configuration
################################################################################
#####
The CLDB and DARE master keys are now protected by the HSM.
The CLDB key cldb.key and DARE master key dare.master.key in /opt/mapr/
conf
are no longer used. Back up these keys in a safe location, and then
remove
them from /opt/mapr/conf. All keys in the HSM, including the CLDB and
DARE
master keys, should be safely backed up. Without the DARE master key, the
cluster cannot be started and data cannot be accessed.

Copy the entire contents of the KMIP token directory /opt/mapr/conf/
tokens to
all CLDB and Zookeeper nodes. All files in /opt/mapr/conf/tokens must be
owned
by the mapr user and mapr group.
################################################################################
#####
```

As an alternative to Steps 2 and 3, run the configure.sh on page 2821 script with the HSM parameters as many times as needed until the setup is successful.

last-updated: Jun 06, 2024

4. Use the mrhsm info on page 911 command to verify that KMIP is enabled. For example:

```
# mrhsm info -kmip
Displaying information for KMIP token with serial 8ce465dd102da8f6
KMIP Configuration Version 1

```

5. Copy the contents of the `/opt/mapr/conf/tokens` directory to all the CLDB and ZooKeeper hosts in the cluster.

Enable KMIP Integration with Data Fabric

You can integrate KMIP with data-fabric in one of the following ways.

- Perform a manual data-fabric installation and run the configure.sh on page 2821 script with the new HSM parameters for a fresh installation, or run the configure.sh on page 2821 script with the normal parameters followed by the mrhsm Commands on page 905.
- Run the mrhsm Commands on page 905 for an upgrade, or to import the CLDB and DARE keys into the KMIP key management appliance after a regular fresh install.
- Use the graphical installer to perform a regular (non-KMIP) installation, and then use mrhsm Commands on page 905 to import the CLDB and (if applicable) DARE keys into the KMIP key management appliance. Finally, manually copy the KMIP configuration to other CLDB and ZooKeeper nodes in the cluster.

  NOTE: There is no direct support in the data-fabric graphical installer to enable KMIP integration.

mrhsm Commands

This section discusses the `mrhsm` commands.

mrhsm dump

Dumps the contents of the PKCS#11 KMIP token.

Use the `mrhsm dump` command to dump the contents of the PKCS#11 KMIP token. This is helpful when debugging the PKCS#11 configuration.

Syntax

```
# mrhsm dump -path
```

last-updated: Jun 06, 2024

Parameters

path	The directory in which the dump should be written. The format of the path is `/opt/mapr/conf/tokens/<token-dir/token.object`

Example

```
# mrhsm dump -path /opt/mapr/conf/tokens/
69255cf4-0ac3-8d22-b12c-fd503a740cda/token.object
File to dump is /opt/mapr/conf/tokens/69255cf4-0ac3-8d22-b12c-fd503a740cda/
token.object
Dump of object file "XDG_SESSION_ID=1049"

mrhsm remove on page 923
Removes specified components of the KMIP configuration.

mrhsm set on page 925
Sets KMIP parameters.

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

mrhsm enable

Enables external KMIP keystore support.

Use the `mrhsm enable` command to enable external KMIP keystore support, which is disabled by default. See External KMIP Keystore Overview on page 888 for more information. This command is usually run as part of the configure.sh on page 2821 script to configure the system for a fresh install or upgrade. However, you can run this command manually as the superuser (`root`) to change settings such as client certificates.

NOTE: Run this command only after you run the mrhsm init on page 917 and mrhsm set on page 925 commands to initialize and set the KMIP parameters.

last-updated: Jun 06, 2024

Release 7.0.0 enhanced the `mrhsm enable` command to generate either the CLDB and DARE master key in the file-based store or the KMIP-based store. The invocation sequence remains the same as in release 6.2.0, but the behavior is different:

- Enabling a file-based store has the following effect:
  - The Core KEK and Common Root master keys are created in `${MAPR_HOME}/conf/tokens`.
  - If the CLDB and/or DARE master keys exist in `${MAPR_HOME}/conf/cldb.key` and `${MAPR_HOME}/conf/dare.master.key`, they are imported into the `mrhsm` configuration file. Otherwise, new CLDB and DARE master keys are generated. In both cases, the keys are encrypted using the Core KEK in the file store. Note that importing from the KMIP store into the file store is not supported.
- Once the file store is enabled, there is no way to disable it, and attempting to do so with the `-active false` flag yields an error while the `storetype` is `file`.
- The Data Fabric software can enable both the KMIP and File store at the same time. To load the keys, the software first checks the KMIP-based store, then the file-based store. Finally, the software checks the `cldb.key/dare.master.key`.
- Enabling a KMIP-based store is similar to release 6.2.0, except in the case when the CLDB and DARE master keys already exist. In this case, the keys are either imported from the file-based store in `${MAPR_HOME}/conf/tokens` or the `${MAPR_HOME}/conf/cldb.key` and `${MAP_HOME}/conf/dare.master.key`. If the file-based store is enabled and the `cldb.key` and `dare.master.key` are available, the software checks for consistency between the two. If they are different, the software returns an error on the enable.
- While there is consistency between any CLDB or DARE keys that are stored, the Core KEK and the Common KEK are different in the KMIP and file stores, yielding different encrypted text.

Syntax

```
# /opt/mapr/server/mrhsm enable
enable
  -sopin <PIN>            The PIN for the Security Officer (SO).
  [ -dare ]               Generate the DARE key. Set for DARE-enabled
clusters
  [ -active true|false ]  Activate/Deactivate the KMIP configuration.
Default: true
```

Parameters

active	Activates or deactivates the KMIP configuration. If set to `true`, this command activates (enables) the KMIP feature by creating or retrieving the Core and Common KEKs in the HSM, as well as importing or creating the CLDB and DARE keys. When this is successful, the Data Fabric core platform components, including the CLDB and MFS, retrieve the CLDB and DARE keys that are protected by the HSM Core KEK instead of from configuration files. The KMIP configuration cannot be modified using the mrhsm set on page 925 command if it is active. To modify any part of the KMIP configuration after activating it, you need to first deactivate the KMIP feature by using `mrhsm enable -active false`. After the configuration is deactivated, modify the KMIP

	configuration as needed, and use the mrhsm enable on page 907 command to activate it again.
dare	Generate the DARE key. This option takes no parameters. Specify this option to generate the DARE key for fresh installations for a DARE-enabled cluster.
sopin	The PIN for the Security Officer. If not specified in the command line, a prompt will be displayed to enter the SO PIN.

After it is enabled, you cannot disable the external KMIP feature without reconfiguring Data Fabric security using the configure.sh on page 2821 script.

Example

A sample session is as follows:

```
# mrhsm enable -sopin 12345678
Dare key not found in /opt/mapr/conf/dare.master.key
Found slot ID 1365794501
Obtained cluster name abc.cluster.com from mapr-clusters.conf
Enabling MapR HSM on cluster abc.cluster.com
Successfully generated CLDB key, UUID b2cc0c4f-9a7b-4580-8577-a81ac44cc022
Successfully generated Core KEK, UUID bba15392-1ef0-4ea6-8156-1da2e86a2771
Successfully generated Common KEK, UUID
efac20ec-e9d2-40f3-9bd7-bbdc63b10fd5
```

mrhsm get

Retrieves the contents of the CA and client certificates, and puts them in a file.

Use the `mrhsm get` command to retrieve the contents of the CA and client certificates, and put them in a file.

You can run this command only as the superuser (`root`). You can only retrieve the CA certificate chain, and client certificates from the encrypted KMIP configuration file `mrhsm.conf`. You cannot retrieve the client private key. Keep a copy of the client private key in a secure place. See External KMIP Keystore Overview on page 888 for more information.

Syntax

```
# mrhsm get
   [ -cacert <ca-cert> ]  Path to store KMIP server CA certificate in PEM
format
   [ -clientcert <cert> ] Path to store client certificate in PEM format
   -sopin <so-pin>        PIN for SO (Security Officer)
```

Parameters

cacert	The full or relative path name of the file used to store the CA certificate chain retrieved from the storage pool in PEM format.
clientcert	The full or relative path name of the file used to store the client certificate in PEM format.
sopin	The PIN for the Security Officer. If not specified in the command line, a prompt will be displayed to enter the SO PIN.

mrhsm info

Displays HSM configuration information.

Use the `mrhsm info` command to display HSM configuration information and status. See External KMIP Keystore Overview on page 888 for more information on HSM keystores.

- Use the `-config` option to display the KMIP configuration.
- Use the `-file` option to display the status of file-based backends.

last-updated: Jun 06, 2024

- Use the `-kmip` option to display the KMIP status.
- Use the `-slots` option to display information on the PKCS#11 slots.

Syntax

```
mrhsm info
```

Examples

- **Viewing the PKCS#11 Slot Configuration**

  You can view the PKCS#11 slot configuration after initialization. Immediately after a fresh installation, the *Token info* section will be shown as uninitialized:

```
# mrhsm info -slots
Available slots:
Slot 0
    Slot info:
        Description:          MapRHSM slot ID
0x0
        Manufacturer ID:      HPE MapR-HSM
        Token present:        yes
    Token info:
        Manufacturer ID:      HPE MapR-HSM
        Model:                MapRHSM
        Serial number:
       Initialized:          no
        User PIN initialized: no
        Label:
```

  After running the `mrhsm init` command, the `Token info` section will be shown as initialized, with a serial number assigned. You will need this serial number for various mrhsm configuration tasks:

```
# mrhsm info -slots
Available slots:
Slot 1298274617
    Slot info:
        Description:          MapRHSM slot ID
0x4d621939
        Manufacturer ID:      HPE MapR-HSM
        Token present:        yes
    Token info:
        Manufacturer ID:      HPE MapR-HSM
        Model:                MapRHSM
       Serial number:        07137a824d621939
        Initialized:          yes
        User PIN initialized: yes
        Label:                Utimaco ESKM
```

- **Viewing the KMIP Configuration**

  You can view the KMIP configuration after initialization. The KMIP configuration constitutes the various configuration settings that you obtain from the KMIP-enabled HSM after setting up the HSM as per the instructions in the Data Fabric HSM integration guides ((Utimaco ESKM Integration Guide on page 930, Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, or Vormetric Data Security Manager (DSM) Integration Guide on page 959).

  Beginning with release 7.0.0, the mrhsm info command shows a `Backend` parameter with a value of `kmip` (the default) or `file`. These values indicate a KMIP- or file-based backend key store.

The following settings are required to connect to the HSM:

1. The comma-separated list of IP addresses.
2. The KMIP port number, which is `5696` by default.
3. The client private key.
4. The client certificate in PEM format.
5. The CA certificate in PEM format. In the case of a certificate chain containing root and intermediate CA certificates, all certificates will be stored sequentially.

```
# mrhsm info -config
Displaying information for KMIP token with serial b819261a33fbe5a1
Backend                : kmip
IP                     : Not configured
Port                   : 5696
KMIP Version           : 1.1
KMIP Client Key        : Not configured
KMIP Client Certificate: Not configured
KMIP CA Certificate    : Not configured
```

For a file-based backend, the `Backend` value is `file`, and no other entries are displayed for the `mrhsm info -config` option:

```
# mrhsm info -config
Displaying information for file token with serial b54a261a364fe5a1
Backend                : file
```

All KMIP configuration settings are stored in an encrypted format in `/opt/mapr/conf/tokens/mrhsm.conf` in each of the CLDB nodes in the cluster.

- **Viewing the KMIP Configuration for an Enabled HSM**

  Use the `-kmip` argument to view the KMIP configuration for an enabled HSM:

```
# mrhsm info -kmip
Displaying information for KMIP token with serial b819261a33fbe5a1
CLDB Key        : Set
DARE Key        : Not set
Core KEK UUID   : bba15392-1ef0-4ea6-8156-1da2e86a2771
Common KEK UUID : efac20ec-e9d2-40f3-9bd7-bbdc63b10fd5
Enabled         : Yes
```

- **Viewing Information for File-Based Backends**

  Release 7.0.0 introduced a `-file` option for displaying the status of file-based backends:

```
# mrhsm info -file
Displaying information for file token with serial 9693057db789a262
Backend                : file

```

- **Using `mrhsm info` with No Parameters**

  Using `mrhsm info` with no parameters automatically detects the store backend and displays the combined output for the `-config` and `-kmip` options for the KMIP backend and the `-config` and `-file` options for the file backend.

  Here is a sample display for a KMIP token that has been enabled:

```
# mrhsm info
Displaying information for KMIP token with serial 8ce465dd102da8f6
Backend               : kmip
IPs
    IP  1             : 12.1.78.164 Active

Removes specified components of the KMIP configuration.

mrhsm set on page 925
Sets KMIP parameters.

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

mrhsm init

Creates the KMIP token and initializes the KMIP configuration for first use.

Use the `mrhsm init` command to create the KMIP token for the first time and initialize the KMIP configuration. On successful initialization, the command creates the KMIP token that is used for authentication and communication with the external KMIP key store. In addition, the command generates a random user PIN used to encrypt the KMIP configuration in `/opt/mapr/conf/tokens/mrhsm.conf`.

Syntax

```
mrhsm init
  [ -cacert <ca-cert> ]     Path to KMIP server CA certificate in PEM format
  [ -clientcert <cert> ]    Path to client certificate in PEM format
  [ -clientkey <key> ]      Path to client private key in PEM format
  [ -ip <ip1,ip2,...> ]     Comma-separated list of KMIP server IP addresses
  [ -kmipversion <version>] KMIP version: 1.0, 1.1, 1.2, 1.3, or 1.4.
Default: 1.1
  -label <text>             Defines the label of the object or the token.
  [ -storetype file|kmip ]  Store type. Default: kmip
  [ -port <kmip-port> ]     KMIP port number. Default is 5696
  -sopin <so-pin>           PIN for SO (Security Officer)
```

Parameters

The list of parameters are as follows. Only the PKCS#11 label and SO PIN are required; you can configure the remainder later using the mrhsm set on page 925 command.

IMPORTANT: Other than the KMIP port number and version which have default values, you must configure all parameters before you use the mrhsm enable on page 907 command to establish a connection to the KMIP server and initialize it.

cacert	The full or relative path name of the CA certificate chain in PEM format used to sign the KMIP server certificate. The Data Fabric KMIP client enforces peer validation and requires the CA certificate chain to verify the KMIP server. At the minimum, the root CA certificate is required. If an intermediate CA is used to sign the KMIP server certificate, then this file must contain all the certificates in the chain starting from the root CA certificate in PEM format. Refer to the KMIP Integration Guide for the respective KMIP server (Utimaco ESKM Integration Guide on page 930, Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, or Vormetric Data Security Manager (DSM) Integration Guide on page 959) for instructions on how to obtain the CA certificate chain.
clientcert	The full or relative path name of the CA certificate chain in PEM format used to sign the KMIP server certificate. The Data Fabric KMIP client enforces peer validation and requires the CA certificate chain to verify the KMIP server. At the minimum, the root CA certificate is required. If an intermediate CA is used to sign the KMIP server certificate, then this file must contain all the certificates in the chain starting from the root CA certificate in PEM format. Refer to the KMIP Integration Guide for the respective KMIP server (Utimaco ESKM Integration Guide on page 930, Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, or Vormetric Data Security Manager (DSM) Integration Guide on page 959) for instructions on how to obtain the client certificate.
clientkey	The full or relative path name of the client private key used to generate the client CSR. Refer to the KMIP Integration Guide for the respective KMIP server (Utimaco ESKM Integration Guide on page 930, Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, or Vormetric Data Security Manager (DSM) Integration Guide on page 959) for instructions on how to obtain the client private key.
ip	A comma-separated list of host names or IP addresses of KMIP servers. Most KMIP deployments have at least two KMIP servers in the HSM cluster for reliability and high availability. The Data Fabric KMIP client cycles through each KMIP server in the list in a round-robin manner until an accessible server is reached.
kmipversion	The KMIP version to use when communicating with the external KMIP -enabled key management appliance. Supported values are 1.0, 1.1, 1.2, 1.3 and 1.4 Refer to the vendor-specific documentation for information about the KMIP versions they support. At present, set this value to `1.1` for SafeNet KeySecure.

last-updated: Jun 06, 2024

	Utimaco ESKM and Vormetric DSM should work with all Data Fabric supported KMIP versions. Default value is `1.1`.
storetype	A descriptor for the type of object store. Beginning with release 7.0.0, possible values are `file` and `kmip`. The default store type is set to `kmip`. The `file` option designates a file-based object store. Note these considerations: • The `-ip, -port, -cacert, -clientcert, -clientkey`, and `-kmipversion` options do not apply to file-based stores. Specifying any of these options with the `-storetype file` option results in an error. • The `mrhsm init` should be invoked only once per node, regardless of whether the `file` or `kmip` store type is used. Subsequent configuration changes should be performed using `mrhsm set`. • Specifying `-storetype file` in `mrhsm init` sets the `objectstore.backend` parameter in the `mrhsm` configuration file `${MAPR_HOME}/conf/maprhsm.conf` to a value of `file`.
label	An ASCII string which defines the label of the object or the token. The maximum length is 32 characters.
port	The listening port number of the KMIP server. All KMIP servers in the HSM cluster must listen to the same port. Port numbers must be from 1-65535 inclusive and cannot start with a 0. Default is `5696`.
sopin	The PIN for the Security Officer. If not specified in the command line, a prompt will be displayed to enter the SO PIN.

Example

The following code demonstrates an example of a sample session.

```
# mrhsm init -label "Utimaco ESKM"
Slot 0 has a free/uninitialized token.
Enter SO PIN (4-255 characters): ********
Please reenter SO PIN: ********
Generated random user PIN Ve%h*tz^G7Qev@8
```

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

mrhsm rekey

Rekeys the common or core Key Encryption Keys (KEK).

Use the `mrhsm rekey` command on a CLDB node to rekey the common or core KEK, and use the core KEK to re-encrypt the CLDB and DARE keys. See External KMIP Keystore Overview on page 888 for more information on HSM keystores. See KMIP Rekey Process on page 898 for a discussion on the KMIP Rekey process.

Rekeying the Core KEK also involves decrypting the CLDB and DARE keys using the existing Core KEK before generating a new Core KEK, and then re-encrypting the CLDB and DARE keys using the new Core KEK. This command only updates the KMIP configuration on the CLDB node onwhich this command was invoked.

On successful re-keying, copy the contents of the token directory `${MAPR_HOME}/conf/tokens` to all CLDB and ZooKeeper nodes in the cluster. Ensure that all files in the `${MAPR_HOME}/conf/tokens` directory are owned by the `mapr` user and group.

Syntax

```
# mrhsm rekey
  -keytype core|common  Specifies the key type, which is either core or
common
  -sopin <so-pin>       PIN for SO (Security Officer)
```

Parameters

keytype	The type of key , either common or core, to rekey.
sopin	The PIN for the Security Officer. If not specified in the command line, a prompt will be displayed to enter the SO PIN.

Example

A sample session is as follows. Use `mrhsm info -kmip` to display the SHA-256 checksums of the various keys before the re-key. After the re-key, use `mrhsm info -kmip` to display the SHA-256 checksums again. The UUID and SHA-256 checksums for the CLDB and DARE keys should remain the same since the CLDB and DARE keys are not changed, but instead re-encrypted with the re-keyed Core KEK.

The UUID and SHA-256 checksum for the Core KEK is now different, since it is rekeyed.

mrhsm remove
Removes specified components of the KMIP configuration.

Use the `mrhsm remove` command to remove various components of the KMIP configuration or to set them to their default values.

NOTE: You must set all components of the KMIP configuration to enable communication with the external KMIP-enabled key store. Therefore, if you remove any component, use the mrhsm set on page 925 command to reconfigure the settings, and then re-enable the HSM.

Syntax

```
# mrhsm remove
  [ -cacert ]            Remove configured CA certificate
  [ -clientcert ]        Remove configured client certificate
  [ -clientkey ]         Remove configured client private key
  [ -ip ]                Remove IP addresses
  [ -kmipversion ]       Remove KMIP version. Reverts to 1.1
  [ -port ]              Remove KMIP port number. Reverts to 5696.
  -sopin <so-pin>        PIN for SO (Security Officer)
```

Parameters

cacert	The full or relative path name of the CA certificate chain in PEM format used to sign the KMIP server certificate. The Data Fabric KMIP client enforces peer validation and requires the CA certificate chain to verify the KMIP server.
clientcert	The full or relative path name of the client certificate in PEM format.
clientkey	The full or relative path name of the client private key used to generate the client CSR.
ip	A comma-separated list of host names or IP addresses of KMIP servers. Most KMIP deployments have at least two KMIP servers in the HSM cluster for reliability and high availability.
kmipversion	The KMIP version to use when communicating with the external KMIP -enabled key management appliance. Supported values are 1.0, 1.1, 1.2, 1.3 and 1.4
port	The listening port number of the KMIP server. All KMIP servers in the HSM cluster must listen to the same

last-updated: Jun 06, 2024

	port. Port numbers must be from 1-65535 inclusive and cannot start with a 0. Default is 5696.
sopin	The PIN for the Security Officer.

last-updated: Jun 06, 2024

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

mrhsm set
Sets KMIP parameters.

Use the `mrhsm set` command to configure KMIP settings. This command is usually run as part of the configure.sh on page 2821 script to configure the system for a fresh install or upgrade. However, you can run this command manually as the superuser (`root`) to change settings such as client certificates.

Syntax

```
# mrhsm set
  [ -cacert <ca-cert> ]     Path to KMIP server CA certificate in PEM format
  [ -clientcert <cert> ]    Path to client certificate in PEM format
  [ -clientkey <key> ]      Path to client private key in PEM format
  [ -ip <ip1,ip2,...> ]     Comma-separated list of KMIP server IP addresses
  [ -kmipversion <version>] KMIP version: 1.0, 1.1, 1.2, 1.3, or 1.4.
Default: 1.1
  [ -storetype file|kmip ]  Store type. Default: kmip
  [ -port <kmip-port> ]     KMIP port number. Default is 5696
  -sopin <so-pin>           PIN for SO (Security Officer)
```

Run this command ONLY after you have configured the external KMIP server. See the appropriate Data Fabric KMIP Integration Guide (Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, Utimaco ESKM Integration Guide on page 930, or Vormetric Data Security Manager (DSM) Integration Guide on page 959, or HashiCorp Vault Integration Guide on page 973) for instructions on how to configure the external KMIP server and obtain the CA certificate chain, client certificate, and client private key.

Set all the parameters before running the mrhsm enable on page 907 command to establish a connection to the KMIP server and initialize it.

Parameters

cacert	The full or relative path name of the CA certificate chain in PEM format used to sign the KMIP server certificate. The Data Fabric KMIP client enforces peer validation and requires the CA certificate chain to verify the KMIP server. At the minimum, the root CA certificate is required. If an intermediate CA is used to sign the KMIP server certificate, then this file must contain all the certificates in the chain starting from the root CA certificate in PEM format. Refer to the KMIP Integration Guide for the respective KMIP server (Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, Utimaco ESKM Integration Guide on page 930, or Vormetric Data Security Manager (DSM) Integration Guide on page 959, or HashiCorp Vault Integration Guide on page 973) for instructions on how to obtain the CA certificate chain.
clientcert	The full or relative path name of the client certificate in PEM format. Pre-configure this certificate in the KMIP server so that the server recognizes and trusts the Data Fabric KMIP client. Refer to the KMIP Integration Guide for the respective KMIP server (Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, Utimaco

	ESKM Integration Guide on page 930, or Vormetric Data Security Manager (DSM) Integration Guide on page 959, or HashiCorp Vault Integration Guide on page 973) for instructions on how to obtain the client certificate.
clientkey	The full or relative path name of the client private key used to generate the client CSR. Refer to the KMIP Integration Guide for the respective KMIP server (Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, Utimaco ESKM Integration Guide on page 930, or Vormetric Data Security Manager (DSM) Integration Guide on page 959, or HashiCorp Vault Integration Guide on page 973) for instructions on how to obtain the private client key.
ip	A comma-separated list of host names or IP addresses of KMIP servers. Most KMIP deployments have at least two KMIP servers in the HSM cluster for reliability and high availability. The Data Fabric KMIP client cycles through each KMIP server in the list in a round-robin manner until an accessible server is reached.
kmipversion	The KMIP version to use when communicating with the external KMIP -enabled key management appliance. Supported values are 1.0, 1.1, 1.2, 1.3 and 1.4 Refer to the vendor-specific documentation for information about the KMIP versions they support. At present, set this value to `1.1` for SafeNet KeySecure. Utimaco ESKM and Vormetric DSM should work with all Data Fabric supported KMIP versions. Default value is `1.1`.
storetype	A descriptor for the type of object store. Beginning with release 7.0.0, possible values are `file` and `kmip`. The default store type is set to `kmip`. The `file` option designates a file-based object store. Note these considerations: • The `-ip, -port, -cacert, -clientcert, -clientkey`, and `-kmipversion` options do not apply to file-based stores. Specifying any of these options with the `-storetype file` option, or when the existing store type is file-based, results in an error. • Setting the `storetype` controls the `storetype` that is used for the next `mrhsm enable` or `mrhsm info` commands. • Specifying `mrhsm set -storetype` does not require the `sopin` unless other parameters are specified. • As in release 6.2.0, the `mrhsm set` command changes only the configuration settings in `${MAPR_HOME}/conf/tokens/mrhsm.conf` or the `objectstore.backend` in the `${MAPR_HOME}/conf/maprhsm.conf`. It does not create any keys.

port	The listening port number of the KMIP server. All KMIP servers in the HSM cluster must listen to the same port. Port numbers must be from 1-65535 inclusive and cannot start with a 0. Default is 5696.
sopin	The PIN for the Security Officer. If not specified in the command line, a prompt will be displayed to enter the SO PIN.

mrhsm sopin
Changes the security officer PIN (SO PIN).

Use the `mrhsm sopin` to change the SO PIN, which is used by the cluster administrator to perform PKCS#11 file or KMIP store modifications.

Syntax

```
# mrhsm sopin
    [ -oldsopin <PIN> ]
    [ -newsopin <PIN> ]
```

The `mrhsm sopin` can be called with or without the `-oldsopin <PIN>` or `-newsopin <PIN>` parameters. If either parameter is not used while issuing the `mrhsm sopin` command, the system prompts you to specify the old or new SO PIN accordingly.

The PIN you specify can be 4-255 characters. All characters are allowed, including combinations of alphabetic, numeric, and special characters.

See About the SO PIN on page 928 for more information.

Parameters

oldsopin	The `-oldsopin <PIN>` parameter requires you to specify the current SO PIN.
newsopin	The `-newsopin <PIN>` parameter assigns a new SO PIN.

Example

```
# mrhsm sopin
Current SO PIN: ****
Enter new SO PIN (4-255 characters): ****
Please reenter new SO PIN: ****
New SO PIN is set successfully
```

Related concepts

About the SO PIN on page 928
The Security Officer PIN (SO PIN) is a string of at least four characters that the cluster administrator must supply to perform certain operations that modify the PKCS#11 file or KMIP store.

Related reference

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

About the SO PIN

The Security Officer PIN (SO PIN) is a string of at least four characters that the cluster administrator must supply to perform certain operations that modify the PKCS#11 file or KMIP store.

How the SO PIN Is Used

In a KMIP environment, the cluster admin must enter the SO PIN to change certain system settings, which can include:

- Rekeying the common or core KEK keys.
- Setting a new client certificate to replace an expired certificate.
- Configuring KMIP IP addresses.

In the file-store environment:

- The SO PIN prevents unauthorized configuration changes to the PKCS#11 store.
- The cluster admin does not need to use the SO PIN directly, but it is a best practice to change it to something other than the default value.
- You must provide the SO PIN only during an `mrhsm rekey` operation. `mrhsm rekey` creates a new Core KEK, which is used to encrypt the CLDB key and DARE key.
- The SO PIN becomes more useful if the cluster is later reconfigured to use an external KMIP keystore.

Specifying the SO PIN

The SO PIN is configured during the initial invocation of `configure.sh` after you specify the `-hsmsopin <so-pin>` parameter. See configure.sh on page 2821. The PIN you specify can be 4-255 characters. All characters are allowed, including combinations of alphabetic, numeric, and special characters.

Default SO PIN

For a new installation of a release 7.0.0 or later Data Fabric cluster, the default SO PIN is 1234 unless you specify the SO PIN after you use `configure.sh`.

Changing the SO PIN

To change the SO PIN, use the `mrhsm sopin` command. The command requires you to specify the old (current) and new SO PIN values. For example:

```
# mrhsm sopin
Current SO PIN: ****
Enter new SO PIN (4-255 characters): ****
Please reenter new SO PIN: ****
New SO PIN is set successfully
```

If You Lose the SO PIN

Losing or forgetting the SO PIN does not affect normal cluster operations but prevents certain KMIP configuration changes. See FAQ #2 in Frequently Asked Questions on page 983.

Upgrading and the SO PIN

By default, the Data Fabric software initializes `mrhsm` using the same default hsm label and SO PIN as done during a new release 7.0.0 installation (if `mrhsm` has not already been initialized). You can change default values by specifying `-hsmlabel <label>` and `-hsmsopin <so-pin>` options in `configure.sh`. See Upgrade Notes (Release 7.7) on page 37.

Integration Guides
This section contains the data-fabric integrations guides with external vendors for KMIP.

The vendors currently supported are:

Utimaco ESKM Integration Guide
Describes how to integrate the data-fabric platform with the Utimaco ESKM server.

This integration guide outlines the steps required to integrate the data-fabric platform with the Utimaco Enterprise Software Key Manager (ESKM) server:

- For a fresh installation, perform the following steps before installing the data-fabric platform.
- For an upgrade, perform these steps before running the configure.sh on page 2821 script.

The difference between the fresh installation and upgrade is that for a fresh installation, the CLDB and DARE master keys are generated by the ESKM and saved in the ESKM for disaster recovery purposes, whereas for an upgrade, the existing CLDB and DARE master keys are used.

The data-fabric integration will work with any ESKM release from 4.0 onwards, although this integration guide is based on the ESKM 5.2 release. Changes in the ESKM user interface and functionality in different ESKM releases may affect the steps outlined in this integration guide. Refer to the **Utimaco ESKM documentation** (get it from the vendor) for the authoritative guide for the ESKM appliance.

The steps to integrate data-fabric platform are as follows:

1. Install and set up the ESKM
2. Download the CA Certificate
3. Create and download the client certificate
4. Create the KMIP group and user

Step 1: Install and Setup ESKM
Describes how to install and setup Utimaco ESKM server.

To start, install and set up the ESKM server using the steps in the **ESKM Read Me First** and **ESKM 5.2 Installation and Replacement Guide** (get them from the vendor). If you are using an existing ESKM appliance, you can skip this installation and setup step. At the end of this step, you should have obtained the following:

1. IP address of the ESKM server.
2. KMIP port number of the ESKM server. The default KMIP port number is 5696.
3. The Local CA certificate.

Step 3: Download the Client Certificate
Describes how to create and download the local client certificate from the ESKM server.

This section describes the steps to obtain a client certificate that is signed by the local CA of the ESKM. You can also import custom client certificates from a trusted CA. For more information, refer to Chapter 4 in the *Certificate Procedures* and *Certificate Authority Procedures* section of the **ESKM 5.2 User Guide** (get it from the vendor).

The steps required to create and download the client certificate are as follows:

1. Generate the certificate signing request (CSR).
2. Sign the CSR.
3. Download the signed client certificate.
4. Install the signed client certificate.

Generate the Certificate Signing Request (CSR)

Describes how to generate a CSR using OpenSSL.

To generate the CSR:

Use OpenSSL. In this example, the client private key is saved in a file named `client.key`, and the CSR is saved in a file named `client.csr`:

```
$ openssl req -newkey rsa:2048 -nodes -keyout client.key -out client.csr
Generating a 2048 bit RSA private key
.....................................................................
..............................+++
.....................................+++
writing new private key to 'client.key'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [XX]:US
State or Province Name (full name) []:California
Locality Name (eg, city) [Default City]:Santa Clara
Organization Name (eg, company) [Default Company Ltd]:HPE
Organizational Unit Name (eg, section) []:MapR
Common Name (eg, your name or your server's hostname) []:maprkmipclient1
```

```
Email Address []:security@hpe.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []:
An optional company name []:
```

In this example, the client private key is saved in a file name `client.key`, and the CSR is saved in a file named `client.csr`.

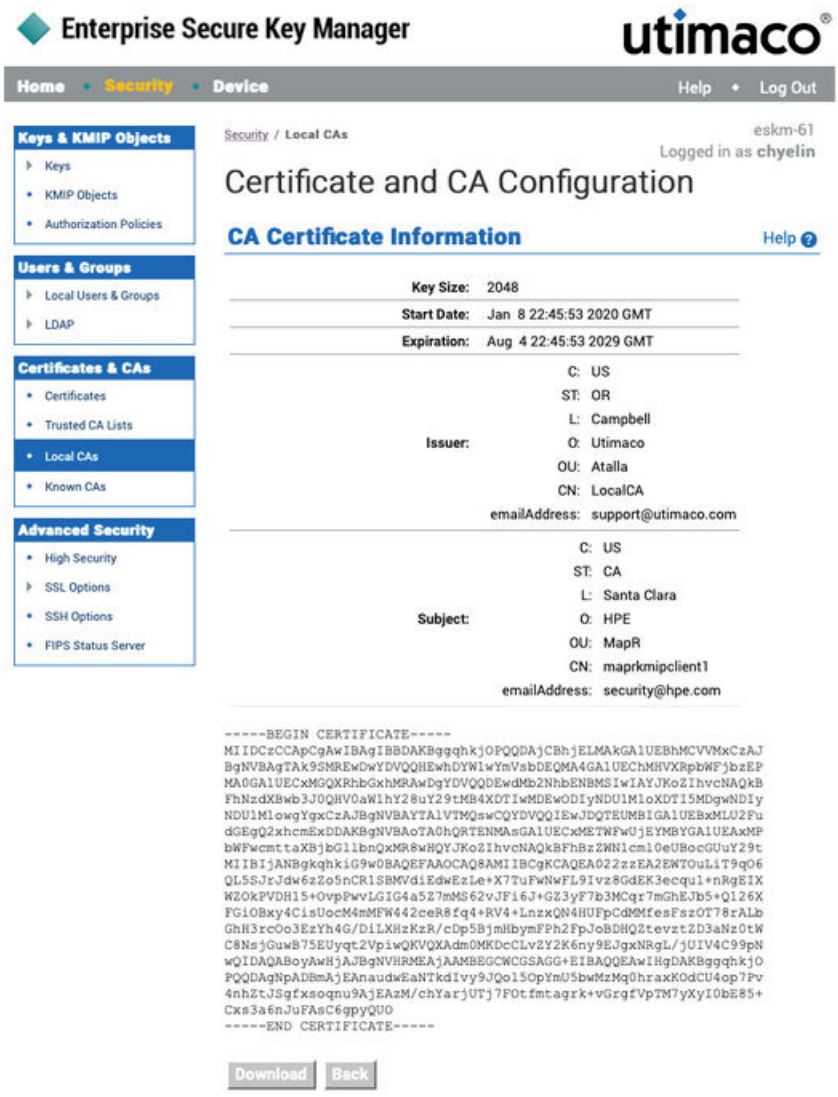
Sign the Certificate Signing Request (CSR)
Describes how to sign a CSR.

To sign the CSR:

1. From the `Certificate Name` section, click the CSR that you just generated. In the example, it is `maprkmipclient1`.
2. The CSR properties are displayed. Select the contents of the CSR starting from -----BEGIN CERTIFICATE REQUEST---- to -----END CERTIFICATE REQUEST----- and copy the contents to the clipboard.
3. Navigate to **Security** > **Local CAs** and click the `Sign Request` option corresponding to the local CA in the `Local Certificate Authority List` listing. Then:
   a. Select `Client` for `Certificate Purpose`.
   b. Change the `Certificate Duration` if needed.
   c. Paste the contents of the CSR that you previously copied to the clipboard, to the `Certificate Request` section.
   d. Click `Sign Request` to sign the CSR.



4. Copy the contents of the signed client certificate starting with -----BEGIN CERTIFICATE----- and ending with -----END CERTIFICATE----- to your clipboard.

   TIP:

   If you have overwritten the clipboard contents, you can obtain the signed client certificate using the following steps:

   1. Navigate to **Security** > **Local CAs**.
   2. Click **Show Signed Certs**.
   3. In the `Signed Certificates` section, select the certificate matching the CN and other details that you configured in Step 1 from the list. In this example, the certificate is `maprkmipclient1`.
   4. Click **Properties**. The Signed Certificate Information page appears.
   5. Copy the contents of the signed client certificate starting with -----BEGIN CERTIFICATE----- and ending with -----END CERTIFICATE----- to your clipboard.

Download the Signed Client Certificate

Describes how to download a signed client certificate to the data-fabric system.

After you have installed your signed client certificate on the ESKM server, you need to download it to the data-fabric hosts running the KMIP client, that is. the data-fabric CLDB hosts. To do this:

1. Click **Security** > **Certificates**, and navigate to the `Certificate List` section.
2. Select the certificate where the Certificate Name matches the Common Name (CN) that you specified when creating your CSR. Then click **Properties**. The Certificate Information page is displayed.
3. Click **Download** to download the client certificate to your data-fabric CLDB host. In the example, since the CN for the certificate is `maprkmipclient1`, the signed client certificate is saved to a file named `maprkmipclient1.crt` in PEM format.

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Install the Signed Client Certificate
Describes how to install a signed client certificate on the ESKM server.

To install the signed client certificate on the ESKM server:

1. Navigate to **Security** > **Certificates**.
2. Select the CSR for the client certificate that you created. The `Certificate Request Information` page appears. Click **Install Certificate**.
3. The `Certificate Installation` page appears. Paste the contents of the certificate that you copied to the clipboard into the `Certificate Response` box. Click **Save**.

   The `Certificate and CA Configuration / Certificate List` page is now displayed. You should see the signed client certificate in the list, with its status changed to `Active`.

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Step 4: Create the Data Fabric KMIP Group and User for the Cluster
Describes how to create the KMIP group and user to store cluster keys on the ESKM server.

You now need to create a KMIP user/object group pair to store your keys. As KMIP keys for data-fabric are cluster-specific, you should create a different KMIP user/object group pair for each cluster so that each cluster can only access its own KMIP keys.

Create the Cluster-Specific Data Fabric KMIP Group

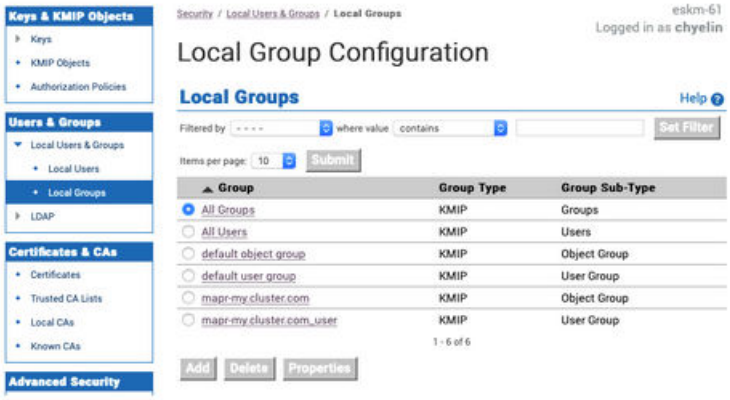
To create a cluster-specific KMIP group:

1. Navigate to **Security** > **Local Users & Groups** > **Local Groups** and click **Add**.
2. Enter the name of the group in the format **mapr-<*cluster*>** where <*cluster*> is the cluster name.
3. In the drop-down box for the Group Type, select `KMIP`.
4. Click **Next**.

   The system displays a confirmation page to create two KMIP groups:

   - A KMIP user group called **mapr-<*cluster*>_user**
   - A KMIP object group called **mapr-<*cluster*>**
5. Click **Save**.

   The system creates two KMIP groups. In this example, the data-fabric cluster is named `my.cluster.com`. Therefore, the system creates the KMIP group pair: `mapr-my.cluster.com` object group, and `mapr-my.cluster.com_user` user group, as shown.

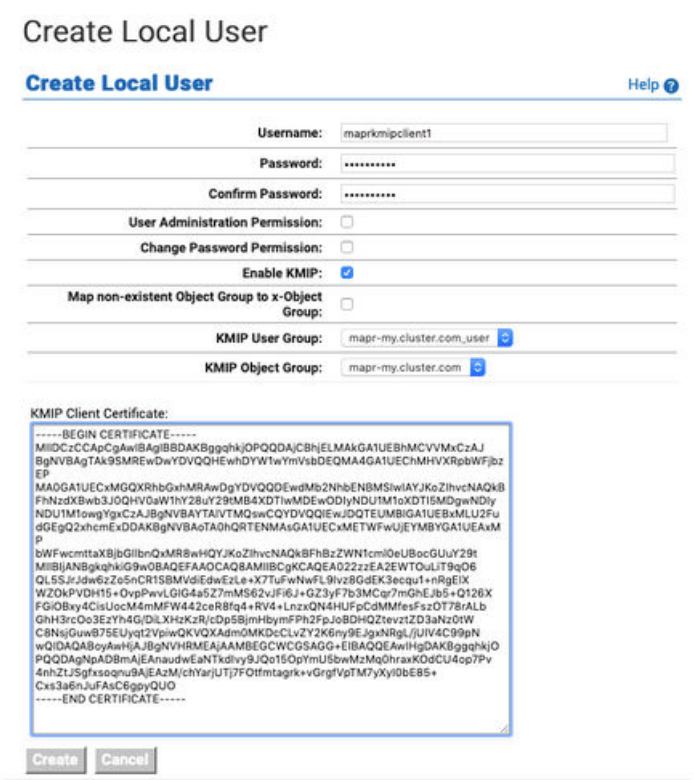


Create the Data Fabric KMIP User for the Cluster

To create the KMIP user:

1. Navigate to **Security** > **Local Users & Groups** > **Local Users** and click **Add**. The `Create Local User` page appears.
2. Enter the information for the local user:
   a. The user name must match the CN of the client certificate. In the example, the CN for the client certificate is `maprkmipclient1`, and therefore this is also the user name.
   b. The `User Administration Permission` and `Change Password Permission` fields do not apply to KMIP groups, so leave these unchecked.
   c. Check the `Enable KMIP` option.
   d. Leave the `Map non-existent Object Group to x-Object Group` option unchecked.
   e. Set the KMIP User Group to the user group that you created earlier. In this example, the user group is `mapr-my.cluster.com_user`.
   f. Set the KMIP Object Group to the object group that you created earlier. In this example, the object group is `mapr-my.cluster.com`.
   g. In the `KMIP Client Certificate` field, paste the contents of the signed client certificate that you copied to your clipboard.
3. Click **Create**. The system creates the KMIP user (`maprkmipclient1` in this example), and returns to the Local Users listing.

last-updated: Jun 06, 2024



At the end of this phase, you should have the following files that are needed to set up your data-fabric KMIP client, in addition to the list of IP addresses and port number of the key management appliances:

- The CA used to sign the client certificate. This is the local CA that is downloaded from the ESKM.
- The signed client certificate that was signed by the KeySecure local CA and downloaded from the ESKM.
- The client private key which was generated using OpenSSL.

Continue the setup on the data-fabric CLDB node using the configure.sh on page 2821 script with the HSM parameters, or the mrhsm Commands on page 905.

Gemalto SafeNet KeySecure Key Manager Integration Guide

Describes how to integrate the data-fabric platform with the Gemalto SafeNet KeySecure Key Manager.

The data-fabric integration should work with any KMIP-enabled SafeNet KeySecure Key Manager, although this integration guide is based on the KeySecure 8.11.1 release. Changes in the SafeNet KeySecure user interface and functionality in different KeySecure releases may affect the steps outlined in this integration guide. Refer to the **SafeNet KeySecure documentation** (get it from the vendor) for the authoritative guide for the KeySecure appliance.

This guide assumes that the SafeNet KeySecure Local CA is used to sign the client certificate. This may not always be the case in production deployments, since trusted CA's may be imported. Refer to the **SafeNet KeySecure Appliance Installation and Configuration Guide** (get it from the vendor) for details on how to configure and/or import CAs and client certificates.

The integration steps are as follows:

1. Install and set up the SafeNet KeySecure appliance
2. Download the CA certificate
3. Create and download the client certificate
4. Create the local group and user

Step 1: Install and set up the SafeNet KeySecure Appliance
Describes how to install and configure the Gemalto SafeNet KeySecure Appliance.

To start, install and set up the SafeNet KeySecure Appliance by following the steps in the **SafeNet KeySecure Appliance Installation and Configuration Guide** (get it from the vendor). You must enable the KMIP server following the instructions in *Chapter 5, Adding A KMIP Server* as mentioned in that guide. If you are using an existing KeySecure appliance, you can skip the installation and setup step. At the end of this installation, you should have obtained the following:

1. IP address of the SafeNet KeySecure appliances in the cluster.
2. KMIP port number of the KeySecure appliance. The default KMIP port number is 5696. All KeySecure appliances in the cluster must have the same port number.
3. The Local CA certificate

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Step 2: Download the Local CA Certificate
Describes how to download the local CA certificate from the SafeNet KeySecure appliance.

Download the local CA certificate from the SafeNet KeySecure appliance to the data-fabric platform. If you are performing a manual installation, place the certificate in a temporary location on the CLDB node on which you are running the configure.sh on page 2821 script or the mrhsm Commands on page 905.

To download the certificate from the Admin interface:

1. Navigate to the **Security** > **Local CAs** page.
2. Click the local CA in the `CA Name` column from the `Local Certificate Authority List` section.

3. Click **Download** at the bottom of the Local Certificate Authority List section to download the local CA. In this example, the CA should be saved in a file named `HPE SafeNet CA.crt` on the local system.

Step 3: Create and Download the Client Certificate
Describes the steps to obtain a client certificate that is signed by the local CA of the SafeNet KeySecure appliance.

Alternatively, you can import custom client certificates from a trusted CA. Refer to the SafeNet KeySecure documentation for more details.

The steps required to create and download the client certificate are as follows:

1. Generate the certificate signing request (CSR).
2. Sign the CSR.
3. Download the signed client certificate.

Generate the Certificate Signing Request (CSR)

Describes how to generate the CSR

Before you can obtain a signed client certificate, you need to first generate a Certificate Signing Request. One way to do this is using OpenSSL. For example:

```
openssl req -newkey rsa:2048 -nodes -keyout client.key -out client.csr

Generating a 2048 bit RSA private key
```

```
.....................................................................
.....................................................+++
.....................................+++
writing new private key to 'client.key'
-----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [XX]:US
State or Province Name (full name) []:California
Locality Name (eg, city) [Default City]:Santa Clara
Organization Name (eg, company) [Default Company Ltd]:HPE
Organizational Unit Name (eg, section) []:MapR
Common Name (eg, your name or your server's hostname) []:safenetclient1
Email Address []:

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []:
An optional company name []:
```

In this example, the client private key is saved in a file name `client.key`, and the CSR is saved in a file named `client.csr`.

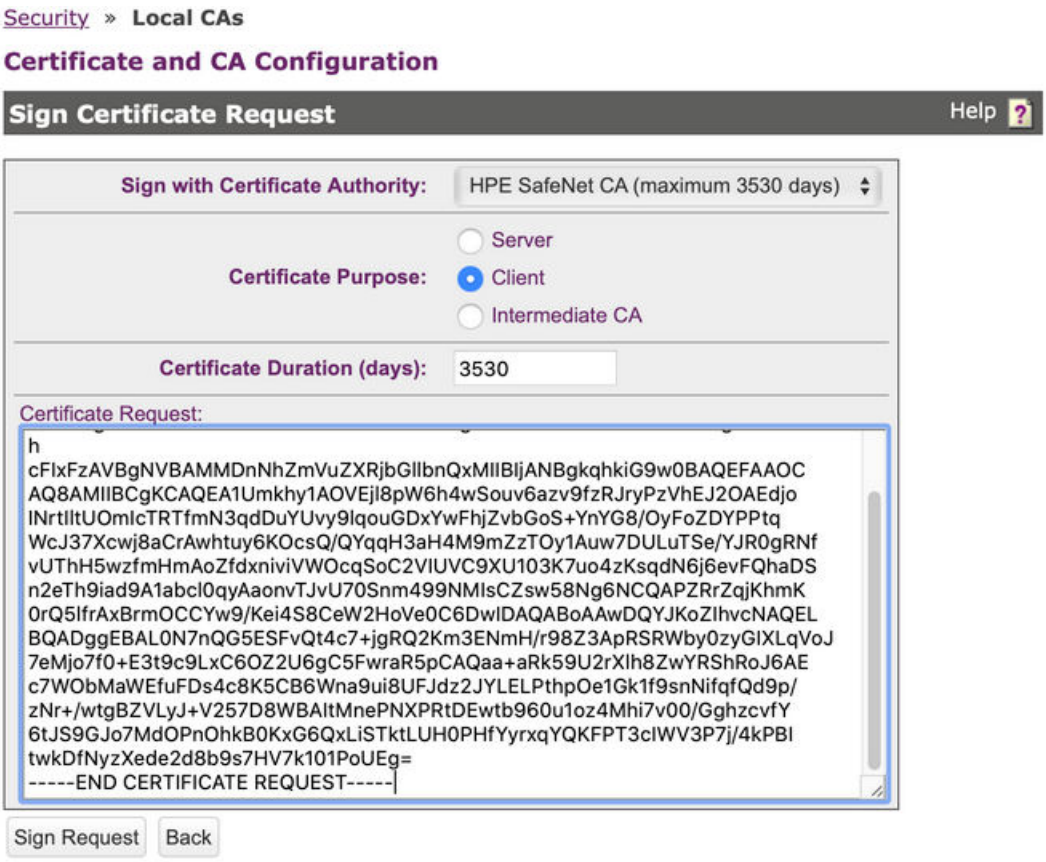
-----END CERTIFICATE REQUEST-----
```

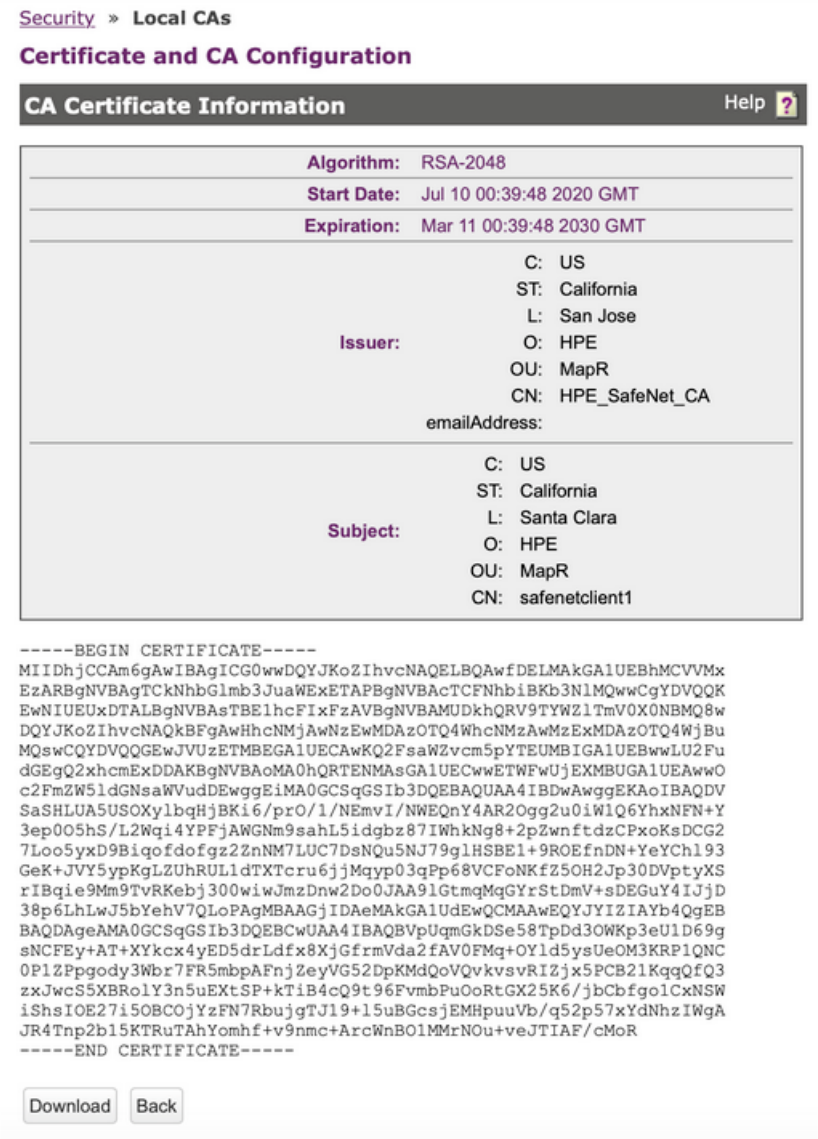
2. Navigate to **Security** > **Local CAs** and click **Sign Request** at the local CA in the `Local Certificate Authority List` listing:
   a. Select `Client` from the Certificate Purpose options.
   b. Change the `Certificate Duration` if needed.

c. Paste the contents of the CSR that you previously copied, from the clipboard to the Certificate Request section.

d. Click **Sign Request** to sign the CSR.



3. The system then displays the signed client certificate as shown in the following example.



For configuring the client certificate section of the local user, copy the contents of the signed client certificate starting with -----BEGIN CERTIFICATE----- and ending with -----END CERTIFICATE----- to your clipboard.

TIP:

If you have overwritten the clipboard contents, you can obtain the signed client certificate using the following steps:

1. Navigate to **Security** > **Local CAs**.
2. Click **Show Signed Certs**.
3. In the `Signed Certificates` section, select the certificate matching the CN and other details that you configured in Step 1 from the list. In this example, the certificate is `safenetclient1`.
4. Click **Properties**. The Signed Certificate Information page appears.
5. Copy the contents of the signed client certificate starting with -----BEGIN CERTIFICATE----- and ending with -----END CERTIFICATE----- to your clipboard.

Download the Signed Client Certificate

last-updated: Jun 06, 2024

Describes how to download the signed CSR.

After you have signed your client certificate, you need to download it to the data-fabric hosts running the KMIP client, that is the data-fabric CLDB host on which you are running the `/opt/mapr/server/configure.sh` script with HSM options, or the `/opt/mapr/server/mrhsm` utility.

1. Navigate to **Security** > **Local CAs** to bring up the CA Certificate Information page.
2. Click **Download** to download the client certificate to your data-fabric CLDB host. The signed client certificate is saved in PEM format.

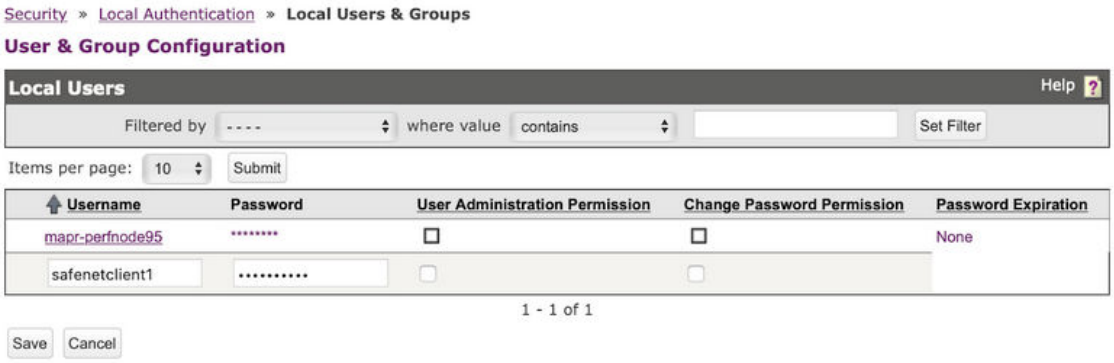
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Step 4: Create the KMIP User for the Cluster
Describes how to create a KMIP user on the data-fabric cluster to store SafeNet Key Secure credentials.

You need to create the KMIP user for the data-fabric cluster. To do this:

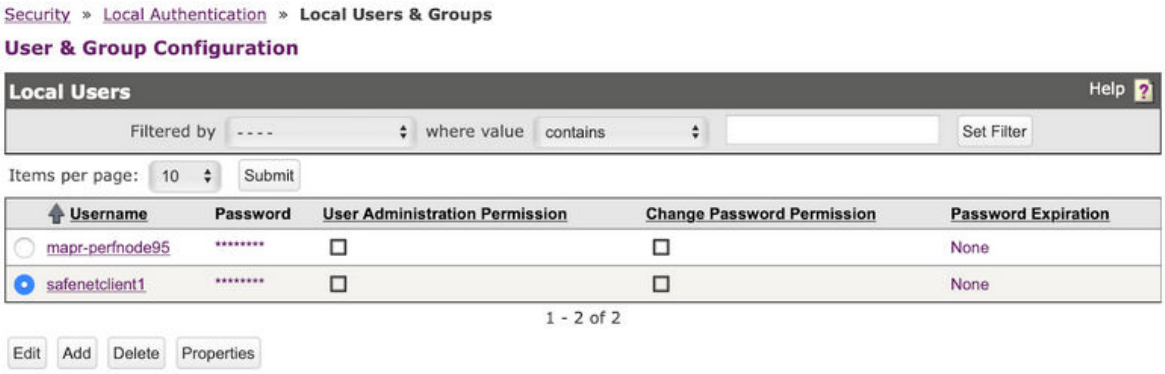
1. Navigate to **Local Authentication** > **Local Users & Groups** and then click **Add** in the `Local Users` section.

   NOTE: The user name must match the common name in your client certificate for the KMIP certificate authentication to succeed. In this example, since the CN for the client certificate is `safenetclient1`, the username must also be `safenetclient1`:



2. Enter the password for the user. This is required when creating a user, but is not used for KMIP, as authentication is performed using certificate authentication. You do not need to check the User Administration Permission and Change Password Permission boxes, as these are not used for KMIP.

3. Click **Save** to create the user. The newly created user is added to the Local Users listing, as shown in the following example:



At the end of this phase, you should have the following files that are needed to set up your data-fabric KMIP client, in addition to the list of IP addresses and port number of the key management appliances:

last-updated: Jun 06, 2024

- The CA used to sign the client certificate. This is the local CA that is downloaded from the Gemalto SafeNet KeySecure Key Manager.
- The signed client certificate that was signed by the KeySecure local CA and downloaded from the KeySecure appliance.
- The client private key which was generated using OpenSSL.

Continue the setup on the data-fabric CLDB node using the configure.sh on page 2821 script with the HSM parameters, or the mrhsm Commands on page 905.

Vormetric Data Security Manager (DSM) Integration Guide
Describes how to integrate the data-fabric platform with the Vormetric Data Security Manager.

This chapter discusses how to set up the Vormetric Data Security Manager (DSM) and prepare it for integration with the data-fabric KMIP client.

Data Fabric integration works with any DSM release that supports KMIP 1.0-1.4, although this integration guide is based on the Data Security Manager Release 6. Changes in the DSM user interface and functionality in different DSM releases may affect the steps outlined in this integration guide. For more information, refer to the Vormetric DSM documentation for the authoritative guide for the DSM appliance:

- **Data Security Manager Release 6 Installation and Configuration Guide**
- **Data Security Manager DSM Release 6 Administration Guide** (get these two guides from the vendor)

This chapter provides an overview of DSM setup and installation as it relates to the data-fabric core platform and KMIP. DSM requires a KMIP license in order to run the KMIP server and connect KMIP clients to the DSM. Details of how to set up and manage KMIP in DSM can be found in *Chapter 25: Key Management Interoperability Protocol* of the **Data Security Manager DSM Release 6 Administration Guide** (get it from the vendor).

It is assumed that the Vormetric DSM Local CA is used to sign the client certificate. This may not always be the case in production deployments, since trusted CA's may be imported. Refer to the **Vormetric DSM Administration Guide** (get it from the vendor) for details on how to configure and/or import CAs and client certificates.

The steps for integration are as follows:

1. Install and set up the DSM, including high availability
2. Install the KMIP license
3. Install the KMIP trusted CA certificate
4. Create and download the client certificate
5. Create the KMIP group and user
6. Create a KMIP-enabled DSM domain

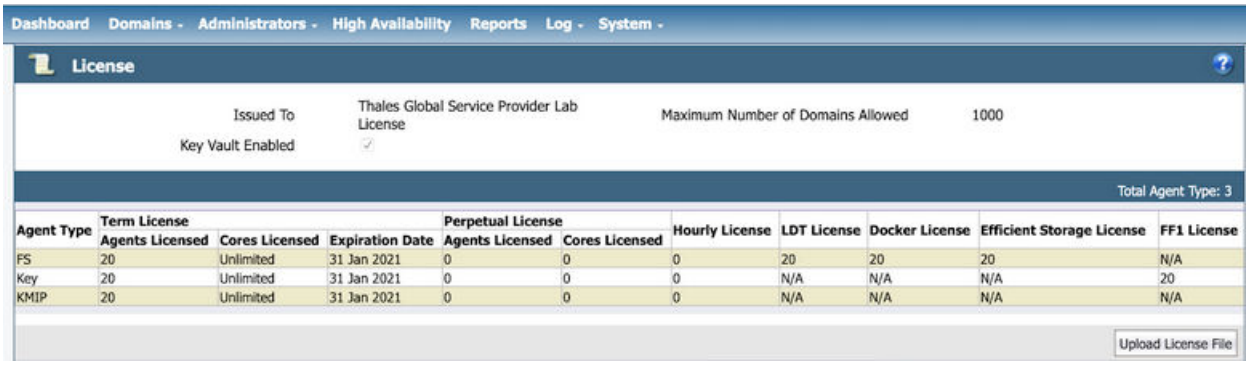
Step 2: Install the KMIP License
Upload KMIP License for Vormetric DSM.

The Vormetric DSM requires a KMIP license to run. If this is not already done during the previous step, upload your KMIP license now. Ensure that `Agent Type` column of your license display includes `KMIP`, as shown in the following example:



For more details on the KMIP license, refer to the *Enable the DSM for KMIP* section in the *Key Management Interoperability Protocol* chapter of the **Vormetric DSM Administration Guide** (get it from the vendor).

Step 3: Install the KMIP Trusted CA Certificate
Illustrates how to upload an external CA certificate to the DSM.

The Vormetric DSM requires that the CAs used to sign the client certificate be obtained from an external source and uploaded to the DSM. After you have obtained the external CA certificate:

1. Log on to the DSM as an administrator of type `System Administrator` or `All`.
2. Navigate to **System** > **KMIP Trusted CA Certificates**.
3. In the `KMIP CA` section, click **Choose File** to select the external CA certificate.
4. Click **Import/Update Certificate** to import the certificate.

On successful completion, the external CA is uploaded to the DSM and displayed in the KMIP CA listing as shown in the following example.:

For details, refer to the *Establish Trust Between DSM and KMIP Client* section in the *Key Management Interoperability Protocol* chapter of the **Vormetric DSM Administration Guide** (get it from the vendor).

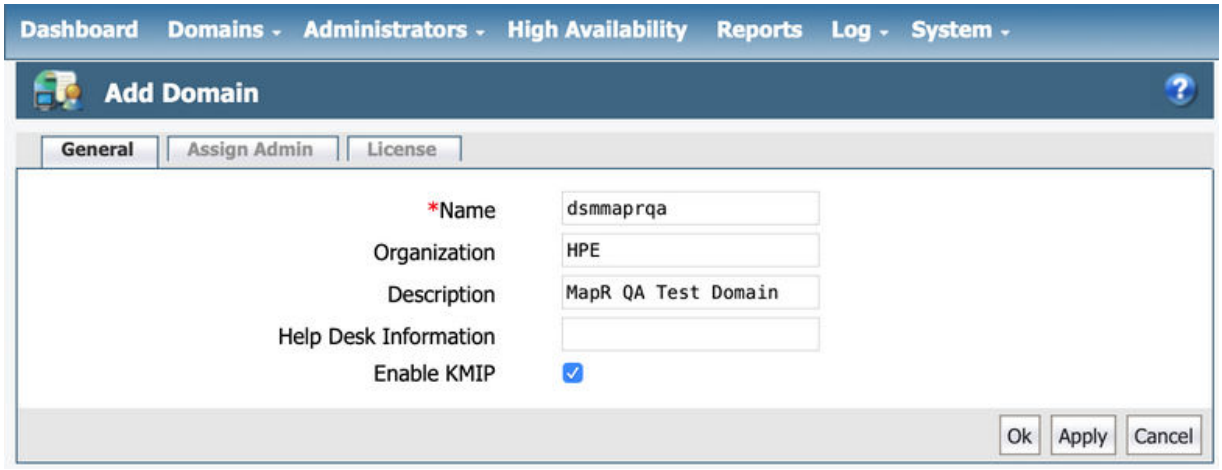
Step 4: Create a KMIP-Enabled Domain
Describes how to create a KMIP-enabled domain to add KMIP clients.

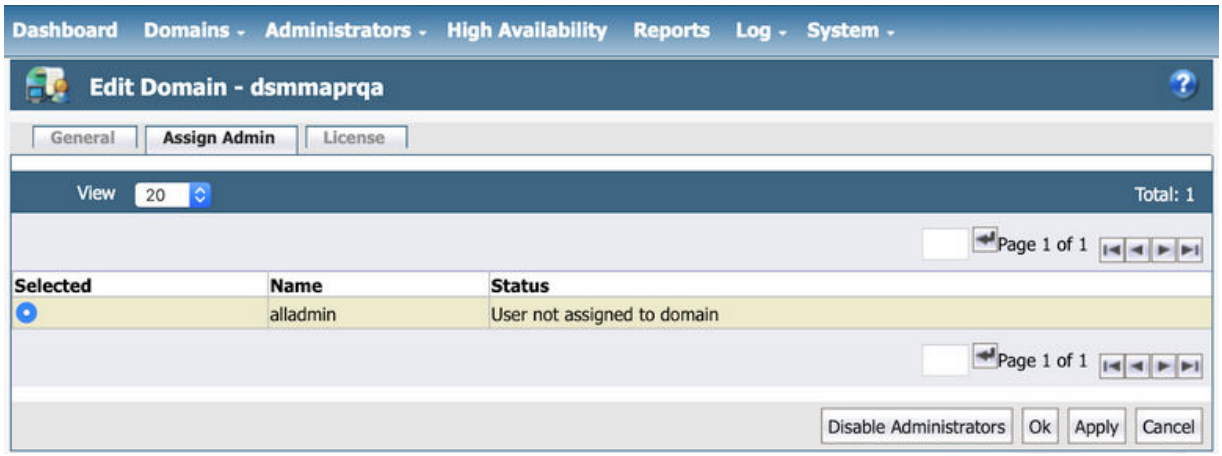
To create a KMIP-enabled domain where you can add your KMIP clients:

1. Navigate to **Domains** > **Manage Domains**.
2. Click **Add**.
3. Enter the domain name.

4. Select the **Enable KMIP** option.
5. Click **Apply** to create the domain, as shown in the following example:



6. Click the **Assign Admin** tab to assign an administrator to this domain. Select the administrator from the list. In this example, this is administrator `alladmin` with administrative privileges of type All. Then, click **OK**:



The domain is then added to the list of domains, as shown in the following example:

last-updated: Jun 06, 2024

mrhsm set on page 925
Sets KMIP parameters.

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Step 5: Add the KMIP Client to the Domain
Describes how to add the KMIP client to the KMIP-enabled domain.

To add the KMIP client to the KMIP-enabled domain:

1. Obtain a signed client certificate.
2. Add the KMIP host to the domain.
3. Import the signed client certificate associated with this KMIP host.

   IMPORTANT: The `Common Name (CN)` field of the signed client certificate must match the host name.

The certificate can either be self-signed certificate or a signed by an external CA that is trusted by the DSM. In this example, the KMIP trusted CA certificate is already installed in Step 3, and will be used to sign the CSR.

To obtain a signed client certificate:

1. Use OpenSSL to create a Certificate Signing Request (CSR) that will be used to sign the client certificate. Note that the name we entered into the Common Name field is `dsmqatest`, which must match the KMIP host name in a later step:

```
[root@qa-node125 vormetric_dsm_qa]# openssl req -newkey
rsa:2048 -nodes -keyout dsmqatest.key -out dsmqatest.csr
Generating a 2048 bit RSA private key
.............................................+++
.....................................................................
+++
writing new private key to 'dsmqatest.key'
----
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a
DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [XX]:US
State or Province Name (full name) []:San Jose
Locality Name (eg, city) [Default City]:California
Organization Name (eg, company) [Default Company Ltd]:Hewlett-Packard
Enterprise
Organizational Unit Name (eg, section) []:MapR
Common Name (eg, your name or your server's hostname) []:dsmqatest
Email Address []:

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []:
An optional company name []:
```

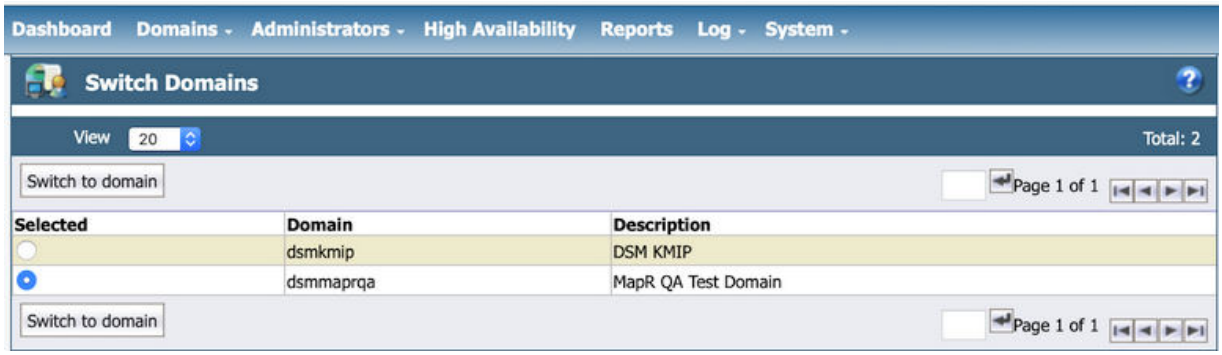
2. Get the certificate signed by the trusted CA.

To add the KMIP host to the domain:

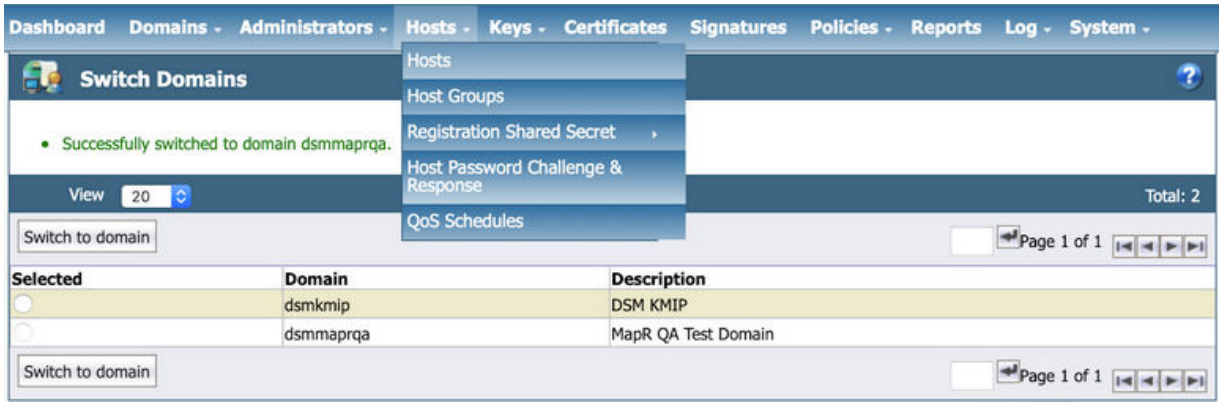
1. Log on to the DSM Web UI as an administrator with privileges of type `All`. In our example, the administrator is `alladmin`.

2. Navigate to **Domains** > **Switch Domains** and select the domain you have just created. In this example, the domain is `dsmmaprqa`.

3. Click **Switch to domain**:



4. From the `Hosts` menu, click **Hosts**:



5. Click **Add**. Enter the following information in the `Add Host dialog`:

   a. The Host Name must match EXACTLY with the common name (CN) that you have configured in your KMIP client certificate. In this example, the CN is `dsmqatest`, so the hostname must also be `dsmqatest`.

   b. Leave the **Password Creation Method** at its default value of `Generate`.

   c. DO NOT select the **Automatically Assign to a Server** option.

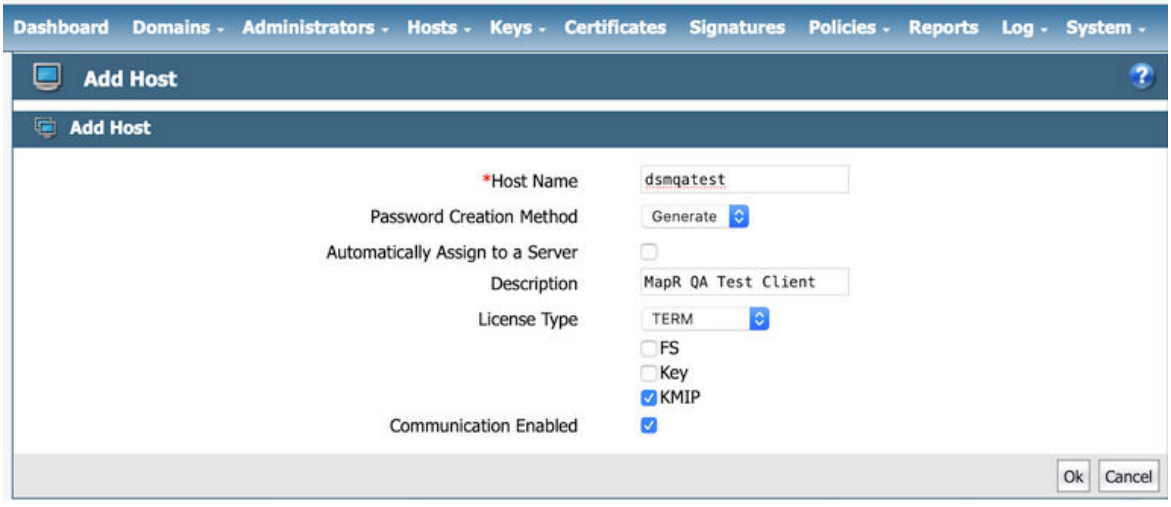
   d. Enter a description for the KMIP client.

   e. Select the license type. This must match the KMIP license that you have configured for this DSM. After you enter the correct license type, a few license choices appear. Select **TERM** as the license type.

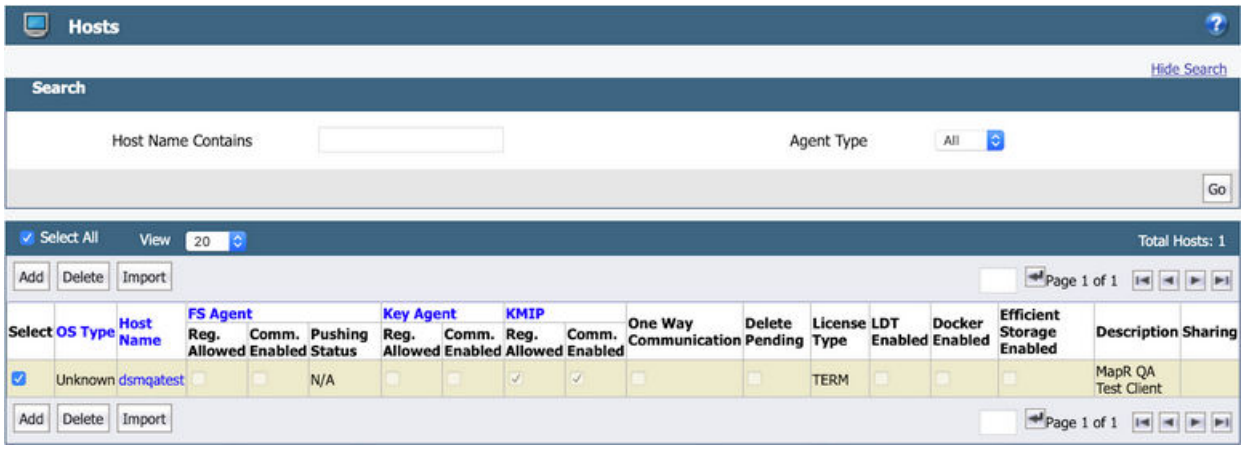
   f. Select the **KMIP** option.

   g. Select the **Communication Enabled** option to enable your KMIP client to communicate with the DSM KMIP server.

   h. Click **Ok** to add the KMIP client.

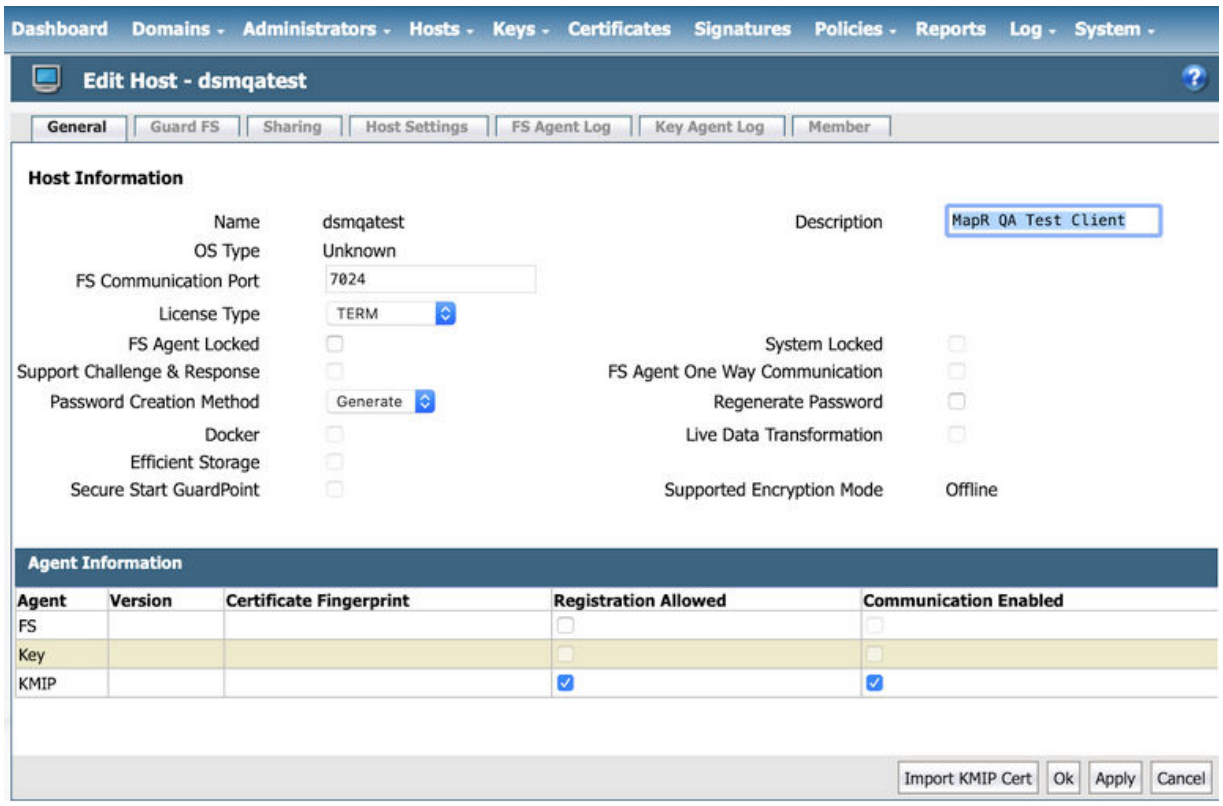


The KMIP client is then added to the list of hosts, as shown in the following example:



To import the KMIP certificate for the host:

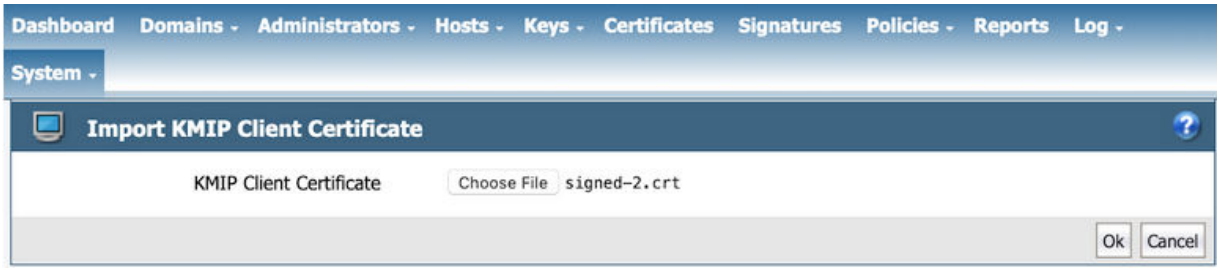
1. Click the Host Name field, which is `dsmqatest` in the example.
2. Scroll down to the end of the `Edit Hosts` page and click **Import KMIP Cert**:



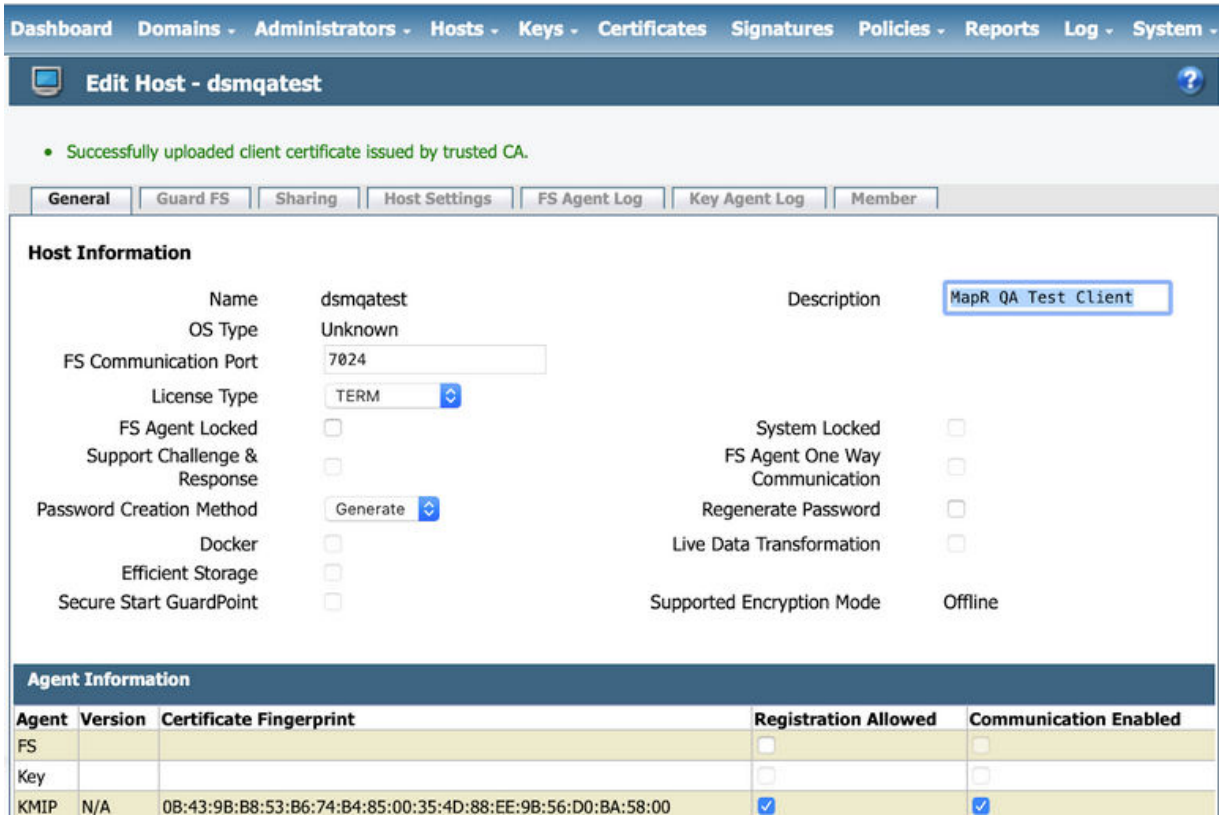
3. Click **Choose File** to select the client certificate that you have created.

   IMPORTANT: If you are uploading a client certificate signed by an external CA, then that external CA must first be configured into the DSM.

last-updated: Jun 06, 2024



4. Click **OK** to import the client certificate. The certificate is then imported, as shown in the following example:

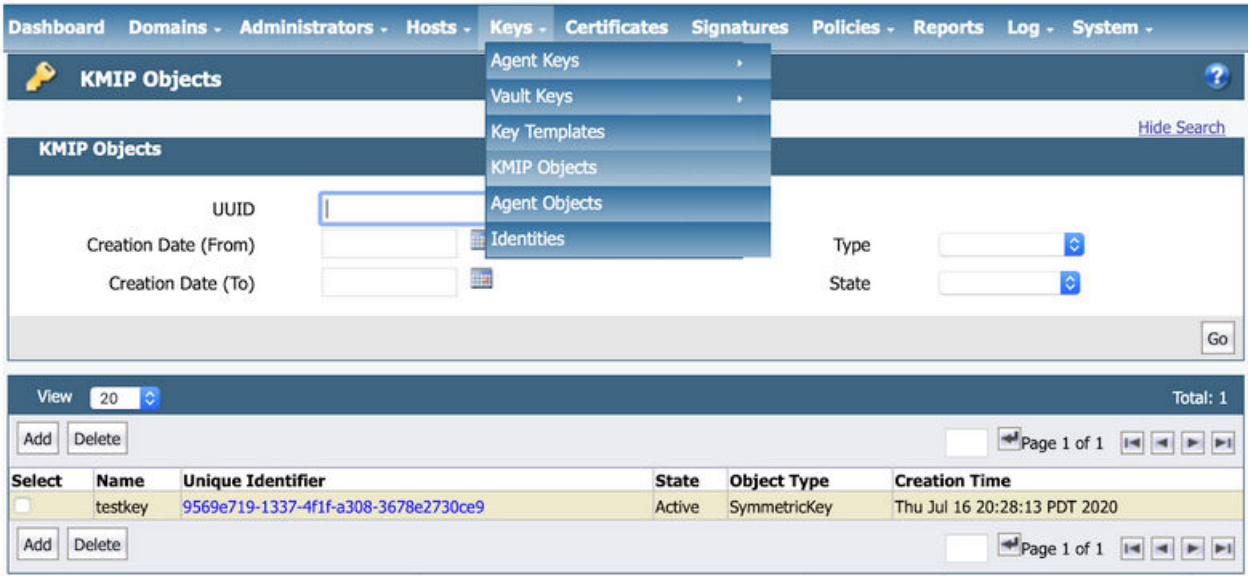


The integration is now complete. You should have the following pieces of information, either downloaded from the DSM or obtained externally:

- DSM CA certificate used to sign the KMIP server certificate
- KMIP client certificate
- KMIP client private key
- IP addresses of DSM servers
- KMIP port number (default 5696)

To test the KMIP connection, view the KMIP objects under **Keys** > **KMIP Objects** as shown in the following example:

last-updated: Jun 06, 2024



At the end of this phase, you should have the following files that are needed to set up your data-fabric KMIP client, in addition to the list of IP addresses and port number of the key management appliances:

- The CA used to sign the client certificate. This is the local CA that is downloaded from the Vormetric DSM.
- The signed client certificate that was signed by the KeySecure local CA and downloaded from the Vormetric DSM.
- The client private key which was generated using OpenSSL.

Continue the setup on the data-fabric CLDB node using the configure.sh on page 2821 script with the HSM parameters, or the mrhsm Commands on page 905.

Sets KMIP parameters.

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

HashiCorp Vault Integration Guide

Describes how to integrate the data-fabric platform with HashiCorp Vault.

This chapter discusses how to set up HashiCorp Vault and prepare it for integration with the data-fabric KMIP client.

Data Fabric integration works with HashiCorp release versions from 1.5.0+ent onwards, although this integration guide is based on the Vault 1.5.3+ent release. Changes in the Vault user interface and functionality in different Vault releases may affect the steps outlined in this integration guide. For more information, refer to the HashiCorp Vault documentation for the authoritative guide for the Vault appliance.

This chapter assumes that the HashiCorp Vault Local CA is used to sign the client certificate. This may not always be the case in production deployments, since trusted CAs may be imported. Refer to the HashiCorp Vault documentation for details on how to configure and/or import CAs and client certificates. Steps 2-4 are outlined in HashiCorp's Guide for deploying Vault's KMIP secrets engine.

The steps for integration are as follows:

1. Install and set up Vault
2. Enable and Configure the KMIP secrets engine
3. Create Scopes and Rules
4. Generate the CA and Client certificate

Step 1: Install and Set Up the Vault
Explains how to setup HashiCorp Vault.

To start, install and set up the Vault. HashiCorp's Vault Deployment Guide might be a helpful resource to use. If you are using an existing Vault appliance, make sure that the version is at least 1.5.0+ent . If so, you can skip the installation.

This guide walks you through enabling and configuring the KMIP secrets engine in the next step.

Step 2: Configure KMIP Secrets Engine
Explains how to setup the KMIP secrets engine.

This guide uses CLI commands but these steps can be accomplished through the Web UI as outlined in HashiCorp's Vault Deployment Guide.

1. Create and set policies to allow the Secrets engine to work. The following permissions are needed to successfully perform all the steps in this guide:

```
# Work with kmip secrets engine
path "kmip/*" {
  capabilities = [ "create", "read", "update", "delete", "list" ]
}

# Enable secrets engine
path "sys/mounts/*" {
  capabilities = [ "create", "read", "update", "delete", "list" ]
}

# List enabled secrets engine
path "sys/mounts" {
  capabilities = [ "read", "list" ]
}
```

2. Write these permissions to a new file called `kmip-policy.hcl`:

```
$ tee kmip-policy.hcl <<EOF
# Work with kmip secrets engine
path "kmip/*" {
  capabilities = [ "create", "read", "update", "delete", "list" ]
}

# Enable secrets engine
path "sys/mounts/*" {
  capabilities = [ "create", "read", "update", "delete", "list" ]
}

# List enabled secrets engine
path "sys/mounts" {
  capabilities = [ "read", "list" ]
}
EOF
```

3. Load this policy into the active configuration:

```
$ vault policy write kmip kmip-policy.hcl
Success! Uploaded policy: kmip
```

4. Now that the correct policies are enabled, start to set up the KMIP secrets engine. First enable the engine using the command:

```
vault secrets enable kmip
```

5. Set up the configuration. Find out the machine's IP address as well as the port that you want to use for KMIP. This guide assumes the port used for the KMIP server is 5696. To configure Vault's KMIP, run:

```
$ vault write kmip/config listen_addrs=<Host's IP Address>:5696
```

   The KMIP configuration should be similar to the following:

```
$ vault read kmip/config
Key                           Value
---                           -----
default_tls_client_key_bits   256
default_tls_client_key_type   ec
default_tls_client_ttl        336h
listen_addrs                  [0.0.0.0:5696]
server_hostnames              [localhost]
server_ips                    [127.0.0.1 ::1]
tls_ca_key_bits               256
tls_ca_key_type               ec
tls_min_version               tls12
```

   The KMIP secrets engine is now properly configured.

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Step 3: Create Scopes and Rules
Explains how to setup Scopes and Rules.

Scopes partition KMIP managed object storage into multiple named buckets, while Roles in the KMIP secrets engine determine the set of KMIP operations that KMIP clients are allowed to perform.

1. Create a Scope. In this example, it is named `mapr`.

```
$ vault write -f kmip/scope/mapr
```

2. Create a new Role under the example Scope `mapr`. Name the Role `maprkmipclient1`.

```
$ vault write kmip/scope/mapr/role/maprkmipclient1 operation_all=true
```

The Role should be displayed as follows:

```
$ vault read kmip/scope/mapr/role/maprkmipclient1
Key                   Value
---                   -----
operation_all         true
tls_client_key_bits   0
tls_client_key_ttl    0s
tls_client_key_type   n/a
```

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Step 4: Generate the CA and the Client Certificate
Explains how to generate the CA and the Client certificate to install on the data-fabric platform.

Download the local CA certificate from the Vault, as well as create and download the client certificates and install them on the data-fabric platform.

1. Retrieve the CA certificates:

```
$ vault read kmip/ca
Key       Value
---       -----
ca_pem    -----BEGIN CERTIFICATE-----

/zxa8PYxFi62BpmjIKPsyw4U7l0rJ0JBMn3unS8=
-----END CERTIFICATE-----
```

   The **bold** block is part of the response that is your CA certificate. Copy this into a file called `ca.pem` using your favorite text editor.

2. Generate a certificate in PEM format and save it to a JSON file named `credential.json`:

```
$ vault write -format=json \
    kmip/scope/mapr/role/maprkmipclient1/credential/generate \
    format=pem > credential.json
```

3. Extract the private key from the `credential.json` file using the `jq` tool and save it in a file named `key.pem`:

```
$ jq -r .data.private_key < credential.json > key.pem
```

4. Find the certification serial numbers associated with the `maprkmipclient1` role:

```
$ vault list kmip/scope/mapr/role/maprkmipclient1/credential
Keys

----

693751915900546682090704263335075174345458639865
```

   In this example, the key is `693751915900546682090704263335075174345458639865` but your serial number may be different. Copy this down for the next step.

last-updated: Jun 06, 2024

5. Lookup the client and CA certificates using this serial number (make sure to use your own serial number):

```
$ vault read kmip/scope/mapr/role/maprkmipclient1/credential/lookup \
       serial_number=693751915900546682090704263335075174345458639865

```
-----END CERTIFICATE-----
serial_number    693751915900546682090704263335075174345458639865
```

In the preceding response, the **bold** block is the CA certificate, which should look similar to the CA certificate saved earlier, while the *italics* block is the client certificates. Save the client certificates to a file called `cert.pem` using your text editor.

6. Combine the `cert.pem` and the `key.pem` files to create a file called `client.pem`, which is the file that the mrhsm commands use.

This concludes the Vault-specific setup and configuration steps. At the end of this phase, you should have the following files that are needed to set up your data-fabric KMIP client, in addition to the list of IP addresses and the port number of the key management appliances:

1. The CA used to sign the client certificate. This is contained in `ca.pem`.
2. The signed client certificate contained in `client.pem`.
3. The client private key which is contained in `key.pem`.

Continue the setup on the data-fabric CLDB node using the configure.sh on page 2821 script with the HSM parameters, or the mrhsm Commands on page 905.

Frequently Asked Questions
Answers the frequently asked questions on disaster recovery for KMIP.

1. **My client certificate has expired. How do I update it?**

   You would first need to obtain a new valid, signed client certificate. Follow the instructions from the HSM vendor to update it on the HSM, if needed. For example, Utimaco ESKM requires that you enter the new certificate contents into the KMIP-enabled local user.

   On the Data Fabric side, first disable the KMIP feature using the mrhsm set on page 925 command with the `-active` parameter set to `false`, then use the mrhsm set on page 925 command to replace the client certificate. Then, re-enable the KMIP feature using the mrhsm enable command. You will need your SO PIN to do this task. See About the SO PIN on page 928.

2. **I forgot my SO PIN. Can I still perform KMIP operations? Can I still make changes to the KMIP configuration?**

   Keep your SO PIN in a safe place. The SO PIN is not stored in the Data Fabric platform or the HSM. Although you can continue normal operations such as starting the MFS and CLDB without the SO PIN, you would not be able to make any changes to your configuration without it.

   If you lose your SO PIN but you want to change some KMIP configuration settings, you would have to delete your KMIP token and the `mrhsm.conf` configuration file, that is, everything in the `/opt/mapr/conf/tokens` directory, and then configure the KMIP settings from scratch, using either the mrhsm Commands on page 905 or the configure.sh on page 2821 script. Your CLDB, DARE, Core KEK and Common Master keys are saved in the external HSM, so you would not lose any keys.

3. **I accidentally deleted my `/opt/mapr/conf/tokens` directory and I cannot start the CLDB and MFS. How do I recover from this?**

   The CLDB and DARE keys are stored in the encrypted `/opt/mapr/conf/tokens/mrhsm.conf` file. If you enable HSM functionality, the CLDB and MFS will not be able to start if they cannot find this file. You would need to perform your HSM configuration again from scratch, using either the mrhsm Commands on page 905 or the configure.sh on page 2821 script. Your CLDB, DARE, Core KEK and Common Root keys are saved in the external HSM, so you would not lose any keys.

4. **I deleted my `/opt/mapr/conf/tokens` directory, and I did not save a copy of my private client key. How do I recover from this?**

   Once configured, the client private key is stored in encrypted format in the `mrhsm.conf` file and cannot be extracted. You are responsible for keeping a copy of your private client key for disaster recovery purposes. If you deleted your `/opt/mapr/conf/tokens` directory, then, as stated in the previous answer, you would need to perform your HSM configuration again from scratch, and to do this, you would need your client private key.

   If you did not save a copy of the client private key, then you would have to follow the instructions in the integration guides (Utimaco ESKM Integration Guide on page 930, Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, or Vormetric Data Security Manager (DSM) Integration Guide on page 959) to generate the client private key and CSR, and then obtain a new signed client certificate, which may have to be configured into the HSM depending on the vendor.

5. **Can I mix and match HSMs from different vendors?**

   Not within the same Data Fabric cluster. Data Fabric supports multiple HSM vendors, but you can only select one vendor per Data Fabric cluster. HSM vendors normally implement their own clustering solutions, so key propagation to other HSMs in the cluster only works for HSMs from the same vendor. Most HSM vendors recommend a cluster of at least 2 appliances for high reliability and availability purposes. For example, if you choose the Utimaco ESKM, then you would normally configure at least 2 Utimaco ESKM appliances.

6. **Can I use different HSM vendors on different clusters, even if there is volume mirroring and table replication between the clusters?**

   Yes. The HSMs only protect the critical keys within a single Data Fabric cluster, so it is possible to use different HSM vendors for different clusters if there is a good reason to do so. However, this may not be cost-effective as maintaining multiple HSMs from different vendors may result in higher operating costs. HSMs are designed to accommodate multiple keys from different clients.

   The Data Fabric KMIP solution is engineered to generate cluster-specific key names, so there will be no namespace conflict between keys from different clusters.

7. **If I initially go for one HSM vendor and store my keys there, can I later migrate to a different HSM vendor?**

   This is a general migration issue that does not pertain to Data Fabric. Normally, HSMs will be used to store master keys from different applications, of which Data Fabric is one. Migrating to a different HSM vendor will require migrating all the keys from the old HSM vendor to the new one, and involves exporting the KMIP keys (using the KMIP Get operation) from the old HSM vendor, and then importing the keys (using the KMIP Register or Import operation) to the new HSM.

   Customers will need to write an application to do this themselves, or engage a professional service provider to do this. After the keys are migrated, follow the steps in the integration guides (Utimaco ESKM Integration Guide on page 930, Gemalto SafeNet KeySecure Key Manager Integration Guide on page 945, or Vormetric Data Security Manager (DSM) Integration Guide on page 959) to configure the new HSM, and use either the mrhsm Commands on page 905 or the configure.sh on page 2821 script to set up the Data Fabric CLDB node to work with the new HSM. Then, copy the contents of the `/opt/mapr/conf/tokens` directory to the other CLDB nodes in the cluster. Ensure that all the files in the `/opt/mapr/conf/tokens` directory are owned by the `mapr` user and the `mapr` group.

8. **I do not want to use the HSM to store my master keys anymore. However, I already encrypted my disks using DARE, and I do not want to regenerate my Data Fabric tickets. Can I revert to the old file-based solution?**

   Assuming you did an upgrade from the file-based solution to use the HSM, and you have saved a copy of your `/opt/mapr/conf/cldb.key` and `/opt/mapr/conf/dare.master.key`, the steps to revert are as follows:

last-updated: Jun 06, 2024

- Backup the contents of the `/opt/mapr/conf/tokens` directory, in case you want to go back to the HSM solution.
- Remove the `/opt/mapr/conf/tokens` directory.
- Restore the `/opt/mapr/conf/cldb.key` and the `/opt/mapr/conf/dare.master.key` that you have backed up before you moved to the HSM solution.

9. **I do not want to use the HSM to store my master keys anymore, but I do not have backups of `/opt/mapr/conf/cldb.key` and `/opt/mapr/conf/dare.master.key`. Can I still revert to the old file-based solution?**

   This is not a supported scenario, but you can still do this. Contact HPE Support.

10. **I have successfully upgraded from the old file-based solution to use the HSM. Do I still need to backup my `/opt/mapr/conf/cldb.key` and `/opt/mapr/conf/dare.master.key`?**

    If you have successfully upgraded to use the HSM, then the HSM should contain backups of the CLDB and DARE master keys for disaster recovery purposes. Provided you do not intend to revert to the older (insecure) file-based solution in the future, you can safely delete the `/opt/mapr/conf/cldb.key` and the `/opt/mapr/conf/dare.master.key`.

    However, if, for some reason, you feel you may revert from the more secure HSM solution to the less secure file-based solution, you should keep backups of these keys.

11. **I am trying to upgrade to use the HSM, but I need time to configure it. Can the Data Fabric platform continue to function while I am testing my configuration?**

    The HSM functionality will not take effect until you enable it using either the mrhsm Commands on page 905 or the configure.sh on page 2821 script. HSM will be enabled only if all settings are correct and all configured HSMs are accessible using the Discover Versions KMIP operation. If the CLDB or MFS detects that HSM functionality has not been enabled and the `/opt/mapr/conf/cldb.key` and the `/opt/mapr/conf/dare.master.key` exist, it will use those files.

Security for Ecosystem Components

Whether you install Data Fabric software by using the Installer or by using manual steps, the platform and its ecosystem components are installed with security ON by default.

Installer: Security with a Single Click

A single option in the Installer controls security for the platform and ecosystem components. The **Enable MapR Secure Cluster** option is checked by default for new installations.

Before starting a new installation, if you want to disable security for the platform and ecosystem components, you can deselect the **Enable MapR Secure Cluster** option. Later, after the cluster is installed, if you want to add or remove security, you can select or deselect the option during an **Incremental Install** operation. For more information, see Enable Data Fabric Secure Cluster.

NOTE: Note that some exceptions to secure by default can require manual intervention. Also, before enabling security using the Incremental Install function, be sure to review the known issue (IN-1084) related to custom certificates. See Installer Known Issues.

Manual Installation: Security with configure.sh

When you install a Data Fabric cluster by using the manual steps, you configure security on all nodes by using the `configure.sh` script with the `-secure -genkeys` options, as described in Enabling Security on page 199.

Manual installation also creates a cluster that is *secure by default*. For individual ecosystem components, additional security measures are supported, depending on the component. See the notes in the following table.

Security and Ecosystem Components

The Data Fabric platform and the majority of ecosystem components are installed to be secure by default (with some exceptions). The following table lists the EEP 6.0.0 ecosystem components that are secure by default when installed using the Installer or manual installation steps.

Component	Supports Secure by Default	Notes
AsynchHBase	N/A	Security is not applicable. This component acts as a library.
Data Access Gateway 2.0	Yes	For more information, see Understanding the HPE Ezmeral Data Fabric Data Access Gateway on page 1024.
Drill	Yes	For more information about Drill security, see Securing Drill on page 4016.
HBase	Yes	For more information, see HBase Configuration Properties on page 4132.
HBase REST / Thrift Gateway	Yes	For more information, see HBase REST Gateway and HBase Thrift Gateway Secured By Default to Use SSL on page 4149.
Hive	Yes	For more information, see Hive Security on page 4173.
Httpfs	Yes	For more information, see Configuring HttpFS on page 4369.
Hue	Yes	For more information, see Configure Hue with Security on page 4389.
Kafka-Connect	Yes	For more information, see Worker Configuration on page 4510.
Kafka-REST	Yes	For more information, see User Impersonation on page 4472 and SSL Security Configuration on page 4471.
KSQL	Yes	For more information, see KSQL Security on page 4439.
Kafka Streams	No	For more information, see Kafka Streams Security on page 4462.
Livy	Yes	For more information, see Configure Livy on page 4434.
MapR Installer	Yes	For more information, see Using the Enable MapR Secure Cluster Option and Using the Enable MapR DARE Option.
Pig	N/A	Security is not applicable. This component acts as a library.
Schema Registry	Yes	For more information, see Security Parameters on page 4547.
Sentry	No	This component can be configured to run on a secure Data Fabric

last-updated: Jun 06, 2024

Component	Supports Secure by Default	Notes
		cluster. Security must be configured manually.
Spark	Yes	For more information, see Spark configure.sh on page 4622.
Sqoop 1	N/A	Security is not applicable. This component acts as a library.
Timeline Server	Yes	For more information, see Configuring the Timeline Server to Use the Hive-on-Tez User Interface on page 4260.
Data Fabric Monitoring Components		
collectd	Yes	Communicates over Data Fabric streams. See Spyglass on Streams on page 1698.
ElasticSearch	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 1019.
FluentD	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 1019.
Grafana	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 1019.
Kibana	Yes	For additional steps that you can take to enhance security, see Security Exceptions on page 1019.
OpenTSDB	Yes	Communicates over Data Fabric streams. See Spyglass on Streams on page 1698.

Security Settings for Ecosystem Components

Lists the security settings for all HPE Ezmeral Data Fabric ecosystem components.

The security settings for the various ecosystem components are as follows:

Security Settings for Hadoop/Yarn

File or command: `core-default.xml`

Description: Authentication used for the HTTP web-consoles

Default Secure Setting:
`hadoop.http.authentication.type:org.apache.hadoop.security.authentication.server.MultiMechsAuthenticationHandler`

Alternate Value or Change Command: simple | kerberos | #AUTHENTICATION_HANDLER_CLASSNAME#

Notes: None

File or command: `core-default.xml`

Description: Custom principal of the service

Default Secure Setting:
`hadoop.security.custom.auth.principal.class:com.mapr.security.MapRPrincipal`

last-updated: Jun 06, 2024

	Alternate Value or Change Command: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: LDAP Configuration *Default Secure Setting*: `hadoop.security.group.mapping.ldap.search.filter.user:(&(objectClass=user)(sAMAccountName={0}))` *Alternate Value or Change Command*: None *Notes*: An additional filter to use when searching for LDAP users. The default filter is usually appropriate for Active Directory installations. If connecting to an LDAP server with a non-AD schema, replace the default filter with `(&(objectClass=inetOrgPerson)(uid={0})`. {0} is a special string used to denote where the username fits into the filter. If the LDAP server supports posixGroups, Hadoop can enable the feature by setting the value of this property to *posixAccount* and the value of the `hadoop.security.group.mapping.ldap.search.filter.group` property to *posixGroup*.
File or command: `core-default.xml & core-site.xml`	*Description*: Client authentication types *Default Secure Setting*: `hadoop.security.authentication: CUSTOM` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Java class that handles HTTP auth secret *Default Secure Setting*: `hadoop.http.authentication.signature.secret:com.mapr.security.maprauth.MaprSignatureSecretFactory` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Group authentication cache duration *Default Secure Setting*: `hadoop.security.groups.cache.secs:300` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Name of the SignerSecretProvider class to use *Default Secure Setting*: `hadoop.http.authentication.signer.secret.provider:org.apache.hadoop.security.authentication.util.MapRSignerSecretProvider` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Service that manages the HPE Ezmeral Data Fabric ticket *Default Secure Setting*: `yarn.external.token.manager:com.mapr.hadoop.yarn.security.MapRTicketManager`

	Alternate Value or Change Command: None *Notes*: None.
File or command: `core-default.xml` & `core-site.xml`	*Description*: OS security random device file path *Default Secure Setting*: `hadoop.security.random.device.file.path:/dev/urandom` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Key to set if the registry is secure *Default Secure Setting*: hadoop.registry.secure:false *Alternate Value or Change Command*: true *Notes*: Turning it on, changes the permissions policy from `open access` to restrictions on kerberos with the option of a user adding one or more auth key pairs down their own tree.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Authentication class name *Default Secure Setting*: `hadoop.log.level.authenticator.class:com.mapr.security.maprauth.MaprAuthenticator` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*:Indicates if administrator ACLs are required to access instrumentation servlets (JMX, METRICS, CONF, STACKS) *Default Secure Setting*: hadoop.security.instrumentation.requires.admin:false *Alternate Value or Change Command*: true *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*:The keystores factory to use for retrieving certificates *Default Secure Setting*: hadoop.ssl.keystores.factory.class:org.apache.hadoop.security.ssl.FileBasedKeyStoresFactory *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Comma-separated list of crypto codec implementations for AES/CTR/NoPadding *Default Secure Setting*: hadoop.security.crypto.codec.classes.aes.ctr.nopadding:org.apache.hadoop.crypto.OpensslAesCtrCryptoCodec,org.apache.hadoop.crypto.JceAesCtrCryptoCodec *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: The attribute of the group object that identifies the users that are members of the group.

	Default Secure Setting: hadoop.security.group.mapping.ldap.search.attr.member:member *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: Logs a warning message, if looking up a single user to group takes longer than the specified number of milliseconds *Default Secure Setting*: hadoop.security.groups.cache.warn.after.ms:5000 *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: The attribute applied to the LDAP Search Control properties to set a maximum time limit when searching and waiting for a result *Default Secure Setting*: `hadoop.security.group.mapping.ldap.directory.search.timeout:10000` *Alternate Value or Change Command*: The unit is in milliseconds. Set to `0` if an infinite wait period is desired. Default is `10` seconds. *Notes*: None
File or command: `core-site.xml`	*Description*: HPE Ezmeral Data Fabric service account ("mapr") impersonation *Default Secure Setting*: • `hadoop.proxyuser.mapr.hosts:*` • `hadoop.proxyuser.mapr.groups:*` *Alternate Value or Change Command*: None *Notes*: Set by default in version 6.1 secure install.
File or command: `yarn-site.xml`	*Description*: Defines the authentication used for the timeline server HTTP endpoint. *Default Secure Setting*: `yarn.timeline-service.http-authentication.type:com.mapr.security.maprauth.MaprDelegationTokenAuthenticationHandler` *Alternate Value or Change Command*: Supported values are: `simple / kerberos / #AUTHENTICATION_HANDLER_CLASSNAME # Defaults to simple.` *Notes*: None.
File or command: `yarn-default.xml`	*Description*: The allowed pattern for UNIX user names enforced by the Linux-container-executor when used in Nonsecure mode (use case for this is using cgroups). *Default Secure Setting*: `yarn.nodemanager.linux-container-executor.nonsecure-mode.user-pattern:^[_.A-Za-z0-9][-@_.A-Za-z0-9]{0,255}?[$]?$`

last-updated: Jun 06, 2024

	Alternate Value or Change Command: None *Notes*: The default value is taken from `/usr/sbin/adduser`.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Indicates whether or not to use SSL when connecting to the LDAP server. *Default Secure Setting*: `hadoop.security.group.mapping.ldap.ssl:false` *Alternate Value or Change Command*: true *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: An additional filter to use when searching for LDAP groups *Default Secure Setting*: `hadoop.security.group.mapping.ldap.search.filter.group:(objectClass=group)` *Alternate Value or Change Command*: None *Notes*: Change this filter when resolving groups against a non-Active Directory installation. See the description of `hadoop.security.group.mapping.ldap.search.filter.user` to enable `posixGroups` support.
File or command: `core-default.xml` & `core-site.xml`	*Description*: This setting is the configuration controlling the validity of the entries in the cache containing the `userId` to `userName` and `groupId` to `groupName` mappings that are used by `NativeIO getFstat()`. *Default Secure Setting*: `hadoop.security.uid.cache.secs:14400` *Alternate Value or Change Command*: None *Notes*:None
File or command: `yarn-default.xml`	*Description*: Determines which of the two modes LCE should use on a nonsecure cluster. *Default Secure Setting*: `yarn.nodemanager.linux-container-executor.nonsecure-mode.limit-users:true` *Alternate Value or Change Command*: false *Notes*:Set this value to `true`, to launch all containers as the user specified in `yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user`. Set this value to `false` to run containers as the user who submitted the application.
File or command: `yarn-default.xml`	*Description*: Disable insecure protocols *Default Secure Setting*: `hadoop.ssl.exclude.insecure.protocols:SSLv3,TLSv1,TLSV1.1` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Class for user to group mapping (get groups for a given user) for ACL.

	Default Secure Setting: `hadoop.security.group.mapping:org.apache.hadoop.security.JniBasedUnixGroupsMappingWithFallback` *Alternate Value or Change Command*: None *Notes*: The default implementation `org.apache.hadoop.security.JniBasedUnixGroupsMappingWithFallback` determines if the Java Native Interface (JNI) is available. If JNI is available, the implementation uses the API within Hadoop to resolve a list of groups for a user. If JNI is not available, then the shell implementation `ShellBasedUnixGroupsMapping`, is used. This implementation shells out to the Linux/Unix environment with the `bash -c groups` command to resolve a list of groups for a user.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Class for the 'custom type of authentication' method *Default Secure Setting*: `hadoop.security.custom.rpc.auth.method.class:org.apache.hadoop.security.rpcauth.MaprAuthMethod` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xm`	*Description*: The attribute of the group object that identifies the group name *Default Secure Setting*: `hadoop.security.group.mapping.ldap.search.attr.group.name:cn` *Alternate Value or Change Command*: None *Notes*: The default setting is usually appropriate for all LDAP systems.
File or command: `core-default.xml` & `core-site.xm`	*Description*: The Java secure random algorithm. *Default Secure Setting*: `hadoop.security.java.secure.random.algorithm:SHA1PRNG` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xm`	*Description*: Indicates whether service-level authorization is enabled *Default Secure Setting*: `hadoop.security.authorization:true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `core-default.xml` & `core-site.xm`	*Description*: Expiration time for entries in the the negative user-to-group mapping caching, in seconds *Default Secure Setting*: `hadoop.security.groups.negative-cache.secs:30` *Alternate Value or Change Command*: None *Notes*: This setting is useful when invalid users retry frequently. Set a low value for this expiration, since a

	transient error in group lookup could temporarily lock out a legitimate user. Set this parameter to zero or a negative value, to disable negative user-to-group caching.
File or command: `yarn-default.xml`	*Description*: Linux-container-executor setting *Default Secure Setting*: `yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user:nobody` *Alternate Value or Change Command*: None *Notes*: The UNIX user that containers run as when Linux-container-executor is used in Nonsecure mode (a use case for this is using cgroups) if the `yarn.nodemanager.linux-container-executor.nonsecure-mode.limit-users` is set to `true`.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Cipher suite for crypto codec. *Default Secure Setting*: `hadoop.security.crypto.cipher.suite:AES/CTR/NoPadding` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Denotes the buffer size used by `CryptoInputStream` and `CryptoOutputStream`. *Default Secure Setting*: `hadoop.security.crypto.buffer.size:8192` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Path to the JAAS configuration file *Default Secure Setting*: `hadoop.security.java.security.login.config.jar.path:/mapr.login.conf` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Indicates if anonymous requests are allowed when using `simple` authentication. *Default Secure Setting*: `hadoop.http.authentication.simple.anonymous.allowed:true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `yarn-default.xml`	*Description*: Indicates if anonymous requests are allowed by the timeline server when using `simple` authentication. *Default Secure Setting*: `yarn.timeline-service.http-authentication.simple.anonymous.allowed:true` *Alternate Value or Change Command*: false *Notes*: None

last-updated: Jun 06, 2024

File or command: `core-default.xml & core-site.xml`	*Description*: Indicates how long (in seconds) an authentication token is valid before it has to be renewed. *Default Secure Setting*: `hadoop.http.authentication.token.validity:36000` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: IPC client fallback. *Default Secure Setting*: `ipc.client.fallback-to-simple-auth-allowed:false` *Alternate Value or Change Command*: true *Notes*: When a client is configured to attempt a secure connection, but attempts to connect to an insecure server, that server may instruct the client to switch to SASL SIMPLE (unsecure) authentication. This setting controls whether or not the client accepts this instruction from the server. When false (the default), the client does not allow the fallback to SIMPLE authentication, but aborts the connection.
File or command: `yarn-default.xml`	*Description*: Initial duration of the data-fabric ticket *Default Secure Setting*: `yarn.mapr.ticket.expiration:604800000` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml & core-site.xml`	*Description*: Protocols supported by SSL. *Default Secure Setting*: `hadoop.ssl.enabled.protocols:TLSv1.2` *Alternate Value or Change Command*: true *Notes*: When a client is configured to attempt a secure connection, but attempts to connect to an insecure server, that server may instruct the client to switch to SASL SIMPLE (unsecure) authentication. This setting controls whether or not the client accepts this instruction from the server. When false (the default), the client does not allow the fallback to SIMPLE authentication, but aborts the connection.
File or command: `core-default.xml & core-site.xml`	*Description*: List of excluded ciphers *Default Secure Setting*: `hadoop.ssl.exclude.cipher.suites:SSL_DHE_RSA_EXPORT_WITH_DES40_CBC_SHA,SSL_RSA_EXPORT_WITH_DES40_CBC_SHA, SSL_RSA_EXPORT_WITH_RC4_40_MD5,TLS_DHE_RSA_WITH_AES_128_CBC_SHA,TLS_DHE_RSA_WITH_AES_256_CBC_SHA, TLS_DHE_RSA_WITH_AES_256_CBC_SHA256,TLS_DHE_DSS_WITH_AES_256_CBC_SHA256,TLS_DHE_DSS_WITH_AES_256_CBC_SHA, TLS_DHE_RSA_WITH_AES_128_CBC_SHA256,TLS_DHE_DSS_WITH_AES_128_CBC_SHA256, TLS_DHE_DSS_WITH_AES_128_CBC_SHA` *Alternate Value or Change Command*: None *Notes*: None

last-updated: Jun 06, 2024

File or command: `core-default.xml` & `core-site.xml`	*Description*: Indicates whether client certificates are required *Default Secure Setting*: `hadoop.ssl.require.client.cert:false` *Alternate Value or Change Command*: true *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: The hostname verifier to provide for `HttpsURLConnections` *Default Secure Setting*: `hadoop.ssl.hostname.verifier:DEFAULT` *Alternate Value or Change Command*: Valid values are: `DEFAULT`, `STRICT`, `STRICT_I6`, `DEFAULT_AND_LOCALHOST`, and `ALLOW_ALL` *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Resource file from which SSL client keystore information is extracted *Default Secure Setting*: `hadoop.ssl.client.conf:ssl-client.xml` *Alternate Value or Change Command*: None *Notes*: This file is looked up in the classpath, and is usually present in the Hadoop `conf/` directory.
File or command: `mapred-default.xml`	*Description*: Buffer size for reading spills from file when using SSL. *Default Secure Setting*: `mapreduce.shuffle.ssl.file.buffer.size:65536` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: The keystores factory to use for retrieving certificates. *Default Secure Setting*: `hadoop.ssl.keystores.factory.class:org.apache.hadoop.security.ssl.FileBasedKeyStoresFactory` *Alternate Value or Change Command*: None *Notes*: None
File or command: `core-default.xml` & `core-site.xml`	*Description*: Comma-separated list of crypto codec implementations for AES/CTR/NoPadding. *Default Secure Setting*: `hadoop.security.crypto.codec.classes.aes.ctr.nopadding:` `org.apache.hadoop.crypto.OpensslAesCtrCryptoCodec,org.apache.hadoop.crypto.JceAesCtrCryptoCodec` *Alternate Value or Change Command*: None *Notes*: The first implementation is used, if available. Other implementations are fallbacks.
File or command: `core-default.xml` & `core-site.xml`	*Description*: Resource file from which SSL server keystore information is extracted.

	Default Secure Setting: `hadoop.ssl.server.conf:ssl-server.xml` *Alternate Value or Change Command*: None *Notes*: This file is looked up in the classpath, and is usually present in the Hadoop `conf/` directory.
File or command: `core-default.xml & core-site.xml`	*Description*: Configures the HTTP endpoint for Yarn daemons. *Default Secure Setting*: `yarn.http.policy:HTTP_ONLY` *Alternate Value or Change Command*: The following values are supported: • HTTP_ONLY: Service is provided only on HTTP • HTTPS_ONLY: Service is provided only on HTTPS *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Indicates whether or not to use SSL when connecting to the LDAP server. *Default Secure Setting*: `hadoop.security.group.mapping.ldap.ssl:false` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `core-default.xml & core-site.xml`	*Description*: Enables or disables SSL connections to S3. *Default Secure Setting*: `fs.s3a.connection.ssl.enabled:true` *Alternate Value or Change Command*: false *Notes*: None.
File or command: `mapred-default.xml`	*Description*: Indicates whether to use SSL for for the Shuffle HTTP endpoints. *Default Secure Setting*: `mapreduce.shuffle.ssl.enabled:false` *Alternate Value or Change Command*: true *Notes*: None.

Security Settings for Hive

File or command: `hive-site.xml`	*Description*: Hive client authenticator manager class name *Default Secure Setting*: `hive.security.authenticator.manager:org.apache.hadoop.hive.ql.security.HadoopDefaultAuthenticator` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `hive-site.xml`	*Description*: Enables or disables Hive client authorization *Default Secure Setting*: `hive.security.authorization.enabled:true`

	Alternate Value or Change Command: false *Notes*: None.
File or command: `hive-site.xml`	*Description*: The Hive client authorization manager class name *Default Secure Setting*: `hive.security.authorization.manager:org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.FallbackHiveAuthorizerFactory` *Alternate Value or Change Command*: None *Notes*: None.
File or command: `hive-site.xml`	*Description*: List of comma separated Java regexes *Default Secure Setting*: `hive.security.authorization.sqlstd.confwhitelist:hive\.exec\.pre\.hooks` *Alternate Value or Change Command*: None *Notes*: You can modify configurations parameters that match these regexes when you enable SQL standard authorization.
File or command: `hive-site.xml`	*Description*: Authorization DDL task factory implementation *Default Secure Setting*: `hive.security.authorization.task.factory:org.apache.hadoop.hive.ql.parse.authorization.HiveAuthorizationTaskFactoryImpl` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Comma-separated list of non-SQL Hive commands that users are authorized to execute *Default Secure Setting*: `hive.security.command.whitelist:set,reset,dfs,add,list,delete,reload,compile` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Authenticator manager class name to be used in the metastore for authentication. *Default Secure Setting*: `hive.security.metastore.authenticator.manager:org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticator` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: When set to true, the metastore authorizer authorizes read actions on the database and table *Default Secure Setting*: `hive.security.metastore.authorization.auth.reads:true` *Alternate Value or Change Command*: false *Notes*: None

File or command: `hive-site.xml`	*Description*: Names of authorization manager classes (comma-separated) to be used in the metastore for authorization. *Default Secure Setting*: `hive.security.metastore.authorization.manager:org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthorizationProvider` *Alternate Value or Change Command*: None *Notes*: The user defined authorization class should implement interface `org.apache.hadoop.hive.ql.security.authorization.HiveMetastoreAuthorizationProvider`. All authorization manager classes have to successfully authorize the metastore API call for the command execution to be allowed.
File or command: `hive-site.xml`	*Description*: If true, the HiveServer2 WebUI is secured with PAM *Default Secure Setting*: `hive.server2.webui.use.pam=true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `hive-site.xml`	*Description*: Class for PAM authentication *Default Secure Setting*: `hive.server2.webui.pam.authenticator:org.apache.hive.http.security.PamAuthenticator` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Determines whether the metastore performs authorization checks against the underlying storage for operations such as drop-partition *Default Secure Setting*: `hive.metastore.authorization.storage.check.externaltable.drop:true` *Alternate Value or Change Command*: false *Notes*: Disallow the drop-partition if the user in question does not have permissions to delete the corresponding directory on the storage
File or command: `hive-site.xml`	*Description*: Determines whether the metastore performs authorization checks against the underlying storage for operations such as drop-partition *Default Secure Setting*: `hive.metastore.authorization.storage.checks:false` *Alternate Value or Change Command*: true *Notes*: Disallow the drop-partition if the user in question does not have permissions to delete the corresponding directory on the storage
File or command: `hive-site.xml`	*Description*: Client authentication types.

Default Secure Setting:
`hive.server2.authentication:PAM`

Alternate Value or Change Command:

- NONE: no authentication check – plain SASL transport
- LDAP: LDAP/AD based authentication
- KERBEROS: Kerberos/GSSAPI authentication
- CUSTOM: Custom authentication provider (use with property `hive.server2.custom.authentication.class`)
- PAM: Pluggable authentication module (added in Hive 0.13.0 with HIVE-6466)
- NOSASL: Raw transport (added in Hive 0.13.0)

Notes: None

File or command: `hive-site.xml`

Description: Use this property in LDAP search queries for finding LDAP group names to which a user belongs

Default Secure Setting:
`hive.server2.authentication.ldap.groupClassKey:groupOfNames`

Alternate Value or Change Command: None

Notes: Use this property to construct a LDAP group search query, and to indicate the `objectClass` of a group. Every LDAP group has a certain `objectClass`. For example: `group`, `groupOfNames`, and `groupOfUniqueNames`.

File or command: `hive-site.xml`

Description: LDAP attribute name on the group object that contains the list of distinguished names for the user, group, and contact objects that are members of the group.

Default Secure Setting:
`hive.server2.authentication.ldap.groupMembershipKey:member`

Alternate Value or Change Command: None

Notes: For example: `member`, `uniqueMember`, or `memberUid`. Use this property in LDAP search queries when finding LDAP group names to which a particular user belongs. The value of the LDAP attribute as indicated by this property, should be a full DN for the user or the short username or userid.

For example, a group entry for `fooGroup` containing `member : uid=fooUser,ou=Users,dc=domain,dc=com` helps determine that `fooUser` belongs to LDAP group `fooGroup`.

See Group Membership for a detailed example. You can use this property to find the users, if a custom-configured LDAP query returns a group instead of a user (as of Hive 2.1.1). For details, see Support for Groups in Custom LDAP Query.

last-updated: Jun 06, 2024

File or command: `hive-site.xml`

Description: This property indicates the prefix to use when building the `bindDN` for LDAP connection (when using only `baseDN`).

Default Secure Setting: `hive.server2.authentication.ldap.guidKey:uid`

Alternate Value or Change Command: None

Notes: `bindDN` is `<guidKey>=<user/group>,<baseDN>`. If the configuration uses `userDNPattern` and/or `groupDNPattern`, the `guidKey` is not required. The `guidKey` is required when only the `baseDN` is being used.

File or command: `hive-site.xml`

Description: When `true`, HiveServer2 in HTTP transport mode uses a cookie-based authentication mechanism.

Default Secure Setting: `hive.server2.thrift.http.cookie.auth.enabled:true`

Alternate Value or Change Command: None

Notes: None

File or command: `hive-site.xml`

Description: Sasl QOP value; set it to one of the following values to enable higher levels of protection for HiveServer2 communication with clients.

Default Secure Setting: `hive.server2.thrift.sasl.qop:auth-conf`

Alternate Value or Change Command: One of:

- auth – authentication only (default)
- auth-int – authentication plus
- integrity protection auth-conf – authentication plus integrity and confidentiality protection

Notes: Note that setting `hadoop.rpc.protection` to a higher level than HiveServer2 does not make sense in most situations. HiveServer2 ignores `hadoop.rpc.protection` in favor of `hive.server2.thrift.sasl.qop`. This setting is applicable only if HiveServer2 is configured to use Kerberos authentication.

File or command: `hive-site.xml`

Description: Applies test settings for HS2 (for example for standard base authorization verification in `FallbackHiveAuthorizer` or in `SQLAuthorizationUtils`).

Default Secure Setting: `hive.test.authz.sstd.hs2.mode:false`

Alternate Value or Change Command: None

Notes: None

File or command: `hive-site.xml`

Description: Setting this property to `true` enables HiveServer2 to execute Hive operations as the user making the calls.

Default Secure Setting: `hive.server2.enable.doAs=true`

Alternate Value or Change Command: false

	Notes: None
File or command: `hive-site.xml`	*Description*: Indicates whether metastore should use SSL *Default Secure Setting*: `hive.metastore.use.SSL:false` *Alternate Value or Change Command*: false *Notes*: None
File or command: `hive-site.xml`	*Description*: SSL certificate keystore location. *Default Secure Setting*: `hive.server2.keystore.path:/opt/mapr/conf/ssl_keystore` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Set this to `true` to use SSL encryption in HiveServer2. *Default Secure Setting*: `hive.server2.use.SSL:true` *Alternate Value or Change Command*: false *Notes*: None
File or command: `hive-site.xml`	*Description*: SSL certificate keystore location for HiveServer2 WebUI. *Default Secure Setting*: `hive.server2.webui.keystore.path:/opt/mapr/conf/ssl_keystore` *Alternate Value or Change Command*: None *Notes*: None
File or command: `hive-site.xml`	*Description*: Set this to `true` to use SSL encryption for HiveServer2 WebUI. *Default Secure Setting*: `hive.server2.webui.use.ssl:true` *Alternate Value or Change Command*: true *Notes*: None
File or command: `hive-site.xml`	*Description*: SSL protocols that need to be disabled *Default Secure Setting*: `hive.ssl.protocol.blacklist:SSLv2,SSLv3` *Alternate Value or Change Command*: None *Notes*: None

Security Settings for HTTPFS

File or command: `httpfs-site.xml`	*Description*: PAM authentication for `HttpFS` *Default Secure Setting*: • `httpfs.hadoop.authentication.type:multiauth` • `httpfs.authentication.type:multiauth` *Alternate Value or Change Command*: None

Notes: None

File or command: `httpfs-site.xml`

Description: User impersonation for `HttpFS`

Default Secure Setting:

- `httpfs.proxyuser.mapr.hosts:*`
- `httpfs.proxyuser.mapr.groups:*`

Alternate Value or Change Command: None

Notes: None

Security Settings for Hue

File or command: `hue.ini`

Description: Configure HTTPS for Hue UI

Default Secure Setting:

```
[desktop]
  ssl_certificate=${ssl_certificate}
  ssl_private_key=${ssl_private_key}
  ssl_password_script=${HUE_HOME}/bin/
ssl_password_script.sh
```

Alternate Value or Change Command: true

Notes: Value is picked from the following files:

```
cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/.isSecure
true

cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/env.d/20secure

HUE_SECURE_FILE="${HUE_HOME}/desktop/
conf/.isSecure"
if [ -e "$HUE_SECURE_FILE" ] && [ $
(cat "$HUE_SECURE_FILE") = "true" ] ;
thee
  export mechanism=$
{mechanism:-"MAPR-SECURITY"}
  export security_enabled=$
{security_enabled:-"true"}
  export ssl_cacerts=${ssl_cacerts:-"$
{MAPR_HOME}/conf/ssl_truststore.pem"}
  export ssl_validate=$
{ssl_validate:-"true"}
  export ssl_certificate=$
{ssl_certificate:-"${MAPR_HOME}/conf/
ssl_keystore.pem"}
  export ssl_private_key=$
{ssl_private_key:-"${MAPR_HOME}/conf/
ssl_keystore.pem"}
fi
```

The password for the SSL private key is parsed from the `/opt/mapr/conf/ssl-server.xml` file with the `${HUE_HOME}/bin/ssl_password_script.sh` script.

last-updated: Jun 06, 2024

File or command: `hue.ini`

Description: Path to PEM truststore, and option to enable/disable certificate verification for SSL-encrypted connections to other services (RM, HS, NM, Spark HS, Oozie, Livy, HBase, Hive, Impala)

Default Secure Setting:

```
[desktop]
  ssl_cacerts=${ssl_cacerts}
  ssl_validate=${ssl_validate}
```

Alternate Value or Change Command: true

Notes: Values are picked in the same way, as values for the previous parameter. Also, the installer overrides this property with value `false` by creating the following file:

```
cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/env.d/30installer

# Do not edit this file. It
was generated automatically by MapR
Installer.
# Disable certificate verification,
as Installer allows to use node
IPs instead of proper hostnames:
export ssl_cacerts=""
export ssl_validate="false"
```

File or command: `hue.ini`

Description: Configure Hue to use MapR-SASL for YARN (RM, NM, HS, Spark HS)

Default Secure Setting:

```
[hadoop]
  [[yarn_clusters]]
    [[[default]]]
      # ...
      # Change this if your YARN
cluster is secured
      # security_enabled=$
{security_enabled}
      # Security mechanism
of authentication none/GSSAPI/
MAPR-SECURITY
      # mechanism=${mechanism}
      # In secure mode(HTTPS), if SSL
certificates from Resource Manager's
      # Rest Server have to be
verified against certificate authority
      # ssl_cert_ca_verify=false
```

Alternate Value or Change Command: true

Notes: Value is picked from the following files:

```
cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/.isSecure
true

cat /opt/mapr/hue/hue-4.6.0/desktop/
conf/env.d/20secure
```

last-updated: Jun 06, 2024

```
HUE_SECURE_FILE="${HUE_HOME}/desktop/
conf/.isSecure"
if [ -e "$HUE_SECURE_FILE" ] && [ $
(cat "$HUE_SECURE_FILE") = "true" ] ;
thee
  export mechanism=$
{mechanism:-"MAPR-SECURITY"}
