	Notes: None

File or command: `hue.ini`	*Description*: User impersonation between Hue and YARN services (RM, NM, HS) + Spark HS *Default Secure Setting*: Enabled by default *Alternate Value or Change Command*: false *Notes*: Hue always send requests to RM, NM, HS and SparkHS with the `doAs=<impersonation_target>` parameter
File or command: `hue.ini`	*Description*: User impersonation between Hue and HttpFS *Default Secure Setting*: Enabled by default *Alternate Value or Change Command*: false *Notes*: Hue always send requests to HttpFS with the `doAs=<impersonation_target>` parameter
File or command: `hue.ini`	*Description*: User impersonation between Hue and Oozie *Default Secure Setting*: Enabled by default *Alternate Value or Change Command*: false *Notes*: Hue always send requests to Oozie with the `doAs=<impersonation_target>` parameter
File or command: `hue.ini`	*Description*: User impersonation between Hue and Livy *Default Secure Setting*: Enabled by default *Alternate Value or Change Command*: false *Notes*: Hue always send requests to Livy with the the `proxyUser=<impersonation_target>` option
File or command: `hue.ini`	*Description*: User impersonation between Hue and Hive *Default Secure Setting*: `true` (enabled) *Alternate Value or Change Command*: false *Notes*: Hue automatically detects impersonation settings of Hive from `hive-site.xml`
File or command: `hue.ini`	*Description*: User impersonation between Hue and HBase Thrift (MapR-DB) *Default Secure Setting*: `false` (disabled) *Alternate Value or Change Command*: false *Notes*: Hue automatically detects impersonation settings of Hive from `hbase-site.xml`
File or command: `hue.ini`	*Description*: User impersonation between Hue and Drill

Default Secure Setting:

```
[librdbms]
  [[databases]]
    # ...
    [[[drill]]]
      # ...
      # Available options:
      # "impersonation" to enable or
disable outbound impersonation.
      # "principal" of Drill service.
Used when Kerberos authentication is
enabled.
      options='{"impersonation":true}
```

Alternate Value or Change Command: true

Notes: None

File or command: `hue.ini`

Description: Authenticating Hue users with LDAP credentials

Default Secure Setting: TDB

Alternate Value or Change Command: None

Notes: None

File or command: `hue.ini`

Description: Determines which authentication method to use: `search and bind`, or `direct bind`

Default Secure Setting: `search_bind_authentication`

Alternate Value or Change Command: None

Notes: When set to `true`, Hue performs an LDAP search using `bind_dn` and `bind_password` as provided in `hue.ini`. The search can be further limited by the search filter `user_filter`. When set to `false`, Hue performs a direct bind to LDAP using the credentials provided from one of these sources:

- The UPN, formed by concatenating <shortname> (the user name provided on the Hue login page) and nt_domain (if nt_domain is specified)
- The ldap_username_pattern (if nt_domain is not specified)

File or command: `hue.ini`

Description: The NT domain to connect. This parameter is only used with Active Directory.

Default Secure Setting: `nt_domain`

Alternate Value or Change Command: None

Notes: Used with the `direct bind` method of authentication. If `nt_domain` is specified, then `ldap_username_pattern` is ignored.

File or command: `hue.ini`

Description: Used to connect to directory services other than Active Directory.

Default Secure Setting: `ldap_username_pattern`

Alternate Value or Change Command: None

Notes: Used with the `direct bind` method of authentication. Usually takes the form `cn=<username>,dc=example,dc=com`

File or command: `hue.ini`

Description: The backend to use for authenticating users.

Default Secure Setting: `backend`

Alternate Value or Change Command: None

Notes: Set it to `desktop.auth.backend.LdapBackend` for Hue authentication.

File or command: `hue.ini`

Description: Configure Hue with HiveServer2 High Availability

Setting:

```
[beeswax]
  #Whether to use service discovery
for llap.
  hive_discovery_llap = true
  #Is llap (hive server interactive)
running in HA.
  hive_discovery_llap_ha = true
  #Whether to use service discovery
for HiveServer2.
  hive_discovery_hs2 = true
[libzookeeper]
  #ZooKeeper ensemble;
comma-separated list of host/port.
  ensemble=<host:port>:5181
```

Notes: None

Security Settings for Drill

File or command: `drill-override.conf`

Description: Determines if encryption on the server is enabled for negotiating privacy with the Drill client.

Default Secure Setting: `drill.exec.security.user.encryption.sasl.enabled=false`

Alternate Value or Change Command: true

Notes: None.

File or command: `drill-override.conf`

Description: Determines if the server is enabled for negotiating privacy with another Drillbit.

Default Secure Setting: `drill.exec.security.bit.encryption.ssl.enabled=true`

Alternate Value or Change Command: false

Notes: None.

File or command: `drill-override.conf`

Description: TLS/SSL versions allowed

Default Secure Setting: `drill.exec.impersonation.ssl.protocol: TLSv1.2`

Alternate Value or Change Command: Other versions are possible

	Notes: None.
File or command: `drill-override.conf`	*Description*: Format of the keystore file *Default Secure Setting*: `javax.net.ssl.keyStoreType: JKS` *Alternate Value or Change Command*: jks, jceks, pkcs12 *Notes*: None.
File or command: `drill-override.conf`	*Description*: Location of the Java keystore file *Default Secure Setting*: `drill.exec.ssl.keyStorePath` *Alternate Value or Change Command*: ssl.server.keystore.location: /opt/mapr/conf/ssl_keystore *Notes*: Using it from HPE Ezmeral Data Fabric Hadoop properties, leveraging it from `drill-distrib.conf` property `drill.exec.ssl.useHadoopConfig: true`
File or command: `drill-override.conf`	*Description*: Password to access the private key from the keystore file. *Default Secure Setting*: `drill.exec.ssl.keyStorePassword` *Alternate Value or Change Command*: ssl.server.keystore.password *Notes*: Using it from HPE Ezmeral Data Fabric Hadoop properties, leveraging it from `drill-distrib.conf` property `drill.exec.ssl.useHadoopConfig: true`
File or command: `drill-override.conf`	*Description*: Format of the truststore file *Default Secure Setting*: `drill.exec.ssl.trustStoreType: JKS` *Alternate Value or Change Command*: jks, jceks, pkcs12 *Notes*: None
File or command: `drill-override.conf`	*Description*: Location of the Java keystore file containing the collection of CA certificates trusted by the Drill client. *Default Secure Setting*: `drill.exec.ssl.trustStorePath` *Alternate Value or Change Command*: ssl.server.truststore.location: /opt/mapr/conf/ssl_truststore *Notes*: None
File or command: `drill-override.conf`	*Description*: Password to access the private key from the keystore file specified as the truststore *Default Secure Setting*: `drill.exec.ssl.trustStorePassword` *Alternate Value or Change Command*: ssl.server.truststore.password *Notes*: None

File or command: `drill-distrib.conf`	*Description*: Changes the underlying implementation to the chosen value *Default Secure Setting*: `drill.exec.ssl.provider: JDK` *Alternate Value or Change Command*: OpenSSL/JDK *Notes*: None
File or command: `drill-distrib.conf`	*Description*: Use HPE Ezmeral Data Fabric SSL trust and key store *Default Secure Setting*: `drill.exec.ssl.useHadoopConfig` *Alternate Value or Change Command*: true *Notes*: None
File or command: `drill-distrib.conf`	*Description*: Drill Web UI HTTPS protocol for encryption *Default Secure Setting*: `drill.exec: { http.ssl_enabled: true, ssl.useHadoopConfig: true }` *Alternate Value or Change Command*: Default from Drill 1.13 *Notes*: None
File or command: `drill-distrib.conf`	*Description*: Zookeeper znode ACL for Drill cluster info and query info *Default Secure Setting*: `zk.apply_secure_acl: true` *Alternate Value or Change Command*: false *Notes*: Set by default on HPE Ezmeral Data Fabric Secure cluster with installer in `drill-distrib.conf`. `drill.exec.zk.apply_secure_acl: true`
File or command: `drill-distrib.conf`	*Description*: Drill user impersonation, needed for MapR-DB to work properly with CF access *Default Secure Setting*: `drill.exec.impersonation.enabled: true` *Alternate Value or Change Command*: false *Notes*: Set by default on HPE Ezmeral Data Fabric Secure cluster with installer in `drill-distrib.conf`. `drill.exec.impersonation.enabled: true`, also see impersonation inbound policies for information on setting which users can impersonate others.
File or command: `drill-override.conf`	*Description*: Drill user impersonation, maximum number of hops - when one user creates a view on data and shares with other, how many hops are allowed *Default Secure Setting*: `drill.exec.impersonation.max_chained_user_hops: 3` *Alternate Value or Change Command*: Other numeric values

last-updated: Jun 06, 2024

	Notes: Set by default on HPE Ezmeral Data Fabric Secure cluster with installer in `drill-distrib.conf`.
File or command: `drill-override.conf`	*Description*: Authentication mechanisms *Default Secure Setting*: `drill.exec.security.auth.mechanisms: ["MAPRSASL", "PLAIN"]` *Alternate Value or Change Command*: KERBEROS *Notes*: Set by default on HPE Ezmeral Data Fabric Secure cluster with installer in `drill-distrib.conf`.
File or command: `drill-override.conf`	*Description*: End user encryption mechanism *Default Secure Setting*: `drill.exec.security.user.encryption.sasl.enabled: true` *Alternate Value or Change Command*: Can set `drill.exec.security.user.encryption.ssl.enabled: true` *Notes*: Set by default on HPE Ezmeral Data Fabric Secure cluster with installer in `drill-distrib.conf`. To use SSL, set `drill.exec.security.user.encryption.ssl.enabled: true`. To use PLAIN (user/pass) authentication, SASL encryption cannot be set to `true`. You have to set SSL encryption to use PLAIN authentication. You can also use HPE Ezmeral Data Fabric tickets (SASL) with SSL encryption, but only with SSL encryption for both.

Security Settings for Spark

File or command: `spark-defaults.conf`	*Description*: SSL option for file download client (used to download jars and files from HTTPS-enabled servers). *Default Secure Setting*: `spark.ssl.fs.enabled true` *Alternate Value or Change Command*: https://spark.apache.org/docs/2.3.1/security.html *Notes*: None
File or command: `spark-defaults.conf`	*Description*: The password to the private key in the key store. *Default Secure Setting*: `spark.ssl.keyPassword <ssl-keystore-password>` *Alternate Value or Change Command*: None *Notes*: None
File or command: `spark-defaults.conf`	*Description*: Path to the key store file. The path can be absolute or relative to the directory in which the process is started. *Default Secure Setting*: `· spark.ssl.keyStore /opt/mapr/conf/ssl_keystore`

last-updated: Jun 06, 2024

Alternate Value or Change Command: None

Notes: None

File or command: `spark-defaults.conf`

Description: Password to the key store.

Default Secure Setting:
`· spark.ssl.keyStorePassword <ssl-keystore-password>`

Alternate Value or Change Command: None

Notes: None

File or command: `spark-defaults.conf`

Description: Path to the trust store file. The path can be absolute or relative to the directory in which the process is started.

Default Secure Setting:
`· spark.ssl.trustStore /opt/mapr/conf/ssl_truststore`

Alternate Value or Change Command: None

Notes: None

File or command: `spark-defaults.conf`

Description: Password for the trust store.

Default Secure Setting:
`· spark.ssl.trustStorePassword <ssl-truststore-password>`

Alternate Value or Change Command: None

Notes: None

File or command: `spark-defaults.conf`

Description: The TLS protocol to use. The protocol must be supported by the JVM.

Default Secure Setting: `· spark.ssl.protocol TLSv1.2`

Alternate Value or Change Command: None

Notes: None

File or command: `spark-defaults.conf`

Description: Configure encryption for the Spark HTTP file and broadcast servers

Default Secure Setting:
`spark.ssl.enabledAlgorithms TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA`

Alternate Value or Change Command: None

Notes: None

Security Settings for Livy

File or command: `livy.conf`

Description: MapR-SASL authentication

Default Secure Setting: `livy.server.auth.type = multiauth`

Alternate Value or Change Command: true

Notes: None

File or command: `livy.conf`

Description: User impersonation with Livy

Default Secure Setting:

`livy.impersonation.enabled = true`

last-updated: Jun 06, 2024

	`livy.superusers = <MAPR_USER>` *Alternate Value or Change Command*: true *Notes*: None

File or command: `livy.conf`	*Description*: HTTPS
	Default Secure Setting:
	`livy.keystore`
	`livy.keystore.password`
	`livy.key-password`
	Alternate Value or Change Command: true
	Notes: Values automatically filled on runtime using `com.mapr.web.security.WebSecurityManager`

Security Settings for Tez

File or command: `/opt/mapr/tez/tez-0.8/tomcat/apache-tomcat-9.0.1/conf/server.xml`	*Description*: SSL Config for Tez *Default Secure Setting*: `<Connector port="9444" protocol="org.apache.coyote.http11.Http11NioProtocol" maxThreads="150" SSLEnabled="true" scheme="https" secure="true" keyAlias="edl-dev-r01-tezui" keystoreFile="/opt/mapr/tez/tez-0.8/tomcat/apache-tomcat-9.0.1/conf/bdx1xxx0125.xxxxx.com.jks" keystorePass="xxxxxxxxxx" keystoreType="JKS" clientAuth="false" sslProtocol="TLS" /> <!-- Define an AJP 1.3 Connector on port 8009 --> <Connector port="8009" protocol="AJP/1.3" redirectPort="9444" />` *Alternate Value or Change Command*: None *Notes*: Tez UI redirectPort value changed to 9444 (default value 8443 conflicts with the Control System)
File or command: `/opt/mapr/elasticsearch/elasticsearch-5.4.1/usr/share/elasticsearch/plugins/search-guard-5/sgconfig/sg_internal_users.yml`	*Description*: Kibana and ElasticSearch login account and password file *Default Secure Setting*: `admin:hash:<$2a$12$6ASxMQEBKYPyGUc10RyleOhz3c8RrvPGb7oqLC9xGGwPxJFwOLJtq>` *Alternate Value or Change Command*: https://docs.datafabric.hpe.com/home/AdministratorGuide/Changing_Password_for_ES_Kibana.html *Notes*: None
File or command: `/opt/mapr/conf/ssl_truststore*` and `/opt/mapr/conf/ssl_keystore*`	*Description*: SSL Keys *Default Secure Setting*: `Created at install, should rarely change, used by all web and REST HTTPS interfaces.` *Alternate Value or Change Command*: Add site specific certificates with keytool utiliity *Notes*: None

last-updated: Jun 06, 2024

Security Settings for Grafana

File or command: /opt/mapr/grafana/grafana-version/etc/grafana/grafana.ini	*Description*: Certificate File *Default Secure Setting*: `/opt/mapr/grafana/grafana-4.6.1/etc/grafana/cert.pem` *Alternate Value or Change Command*: None *Notes*: None
File or command: /opt/mapr/grafana/grafana-version/etc/grafana/grafana.ini	*Description*: Certificate Key *Default Secure Setting*: `/opt/mapr/grafana/grafana-4.6.1/etc/grafana/key.pem` *Alternate Value or Change Command*: None *Notes*: None

Security Exceptions

"Secure by default" means network-safe authentication and encryption. This page describes areas in which secure-by-default capabilities are not yet implemented for the data-fabric platform or ecosystem components. Included where applicable, are links to more information to help you work around those issues.

Hive

MapR-SASL is not supported for Hive in HTTP mode.

Hue

Certificate verification is disabled on Hue.

NFSv3

NFSv3 is not secure by default, and there are no provisions for authentication or network encryption.

NFSv4

NFSv4 is not secure by default, but it can be secured using Kerberos to enable both encryption and authentication. See Configuring NFSv4 Server for Kerberos on page 1584.

OpenTSDB

There is no authentication or network encryption by default for read access over REST, and authentication and encryption cannot be enabled. However, note that no updates are allowed over REST; therefore, intruders cannot alter cluster metric data.

ZooKeeper

ZooKeeper supports server-to-server authentication by default, but ZooKeeper does not support encryption and cannot be configured to do so.

YARN

For data-fabric 6.2.0 (EEP 7.0.0) and later, YARN is delivered as an ecosystem component. For more information, see YARN on page 4720.

last-updated: Jun 06, 2024

Client Connections

The following sections describe how a client connects to local and remote data-fabric clusters.

How Data Fabric Clients Connect to the Cluster

Explains how clients connect to a HPE Ezmeral Data Fabric cluster.

The Data Fabric client connects to the cluster via CLDB nodes. When a connection attempt fails, the Data Fabric client returns an error. When an existing connection is no longer available, the Data Fabric client attempts to reconnect to a CLDB node.

For information about installing the Data Fabric client, see HPE Ezmeral Data Fabric Client on page 404.

How the Data Fabric Client Establishes Connections to the Cluster

Client applications connect to a cluster via CLDB nodes. To identify the CLDB nodes, check the connection request or the `mapr-clusters.conf` file on the node that submits the connection request. When a client application attempts to connect to the cluster for the first time, the following scenarios can occur:

- At least one of the CLDB nodes is online, in which case the connection is successful.
- None of the CLDB nodes is online, in which case the connection attempt fails.
- The CLDB nodes are listed incorrectly (for example, the IP addresses are incorrect), in which case the connection attempt fails.

When a connection attempt fails, the Data Fabric client returns one of the following errors based on the application type:

Application Type	Error
C Application using HBase API	`ErrorCode = 1`.
C Applications using HDFS API	`NULL handle`
Java Application using HBase, OJAI, or file system API	`java.io.IOException: Could not create FileClient`
Java Application using Kafka API for HPE Ezmeral Data Fabric Streams	`org.apache.kafka.common.errors.NetworkException.`

How the Data Fabric Client Re-establishes Failed Connections to the Cluster

If the CLDB goes down after a client application establishes its first connection to HPE Ezmeral Data Fabric, the client behavior depends on the setting for the `fs.mapr.hardmount` property in the `core-site.xml` file. The `core-site.xml` file is located in the client installation directory.

- If `fs.mapr.hardmount` is set to `true`, the Data Fabric client is nonresponsive as it continuously attempts to reconnect to the CLDB. The Data Fabric client responds when the CLDB comes back online. This is the default behavior.
- If `fs.mapr.hardmount` is set to `false`, the Data Fabric client attempts to connect to each CLDB node that is listed in the `mapr-clusters.conf` file on the node that submitted the connection request. If all of the CLDB nodes are down, the Data Fabric client returns the error EAGAIN/-EAGAIN to the client application. This error indicates that a connection could not be established because the CLDB nodes were not available or because the request timed out for specific reasons. For example, heavy traffic might have caused the network to be slow, or other nodes were unavailable.

last-updated: Jun 06, 2024

Configuring Timeout for Inactive Connections

Configure `fs.mapr.binding.inactive.threshold` in `core-site.xml`. This parameter accepts a value in seconds, and refreshes existing bindings before performing the next I/O, if the time from the previous I/O crosses the given threshold. For example:

```
<property>
<name>fs.mapr.binding.inactive.threshold</name>
<value>600</value>
</property>
```

In this example, when the client tries to send data to the CLDB after a certain idle time, the system checks if the specified time (here 600 seconds, which is 10 minutes) is crossed after the previous request was sent. If so, the system tears down the existing TCP connection and creates a new TCP connection for the file client and CLDB to use for communication.

How Clients Connect to the Replica

Provides an overview of what Replicas are, and how data-fabric clients connect to them.

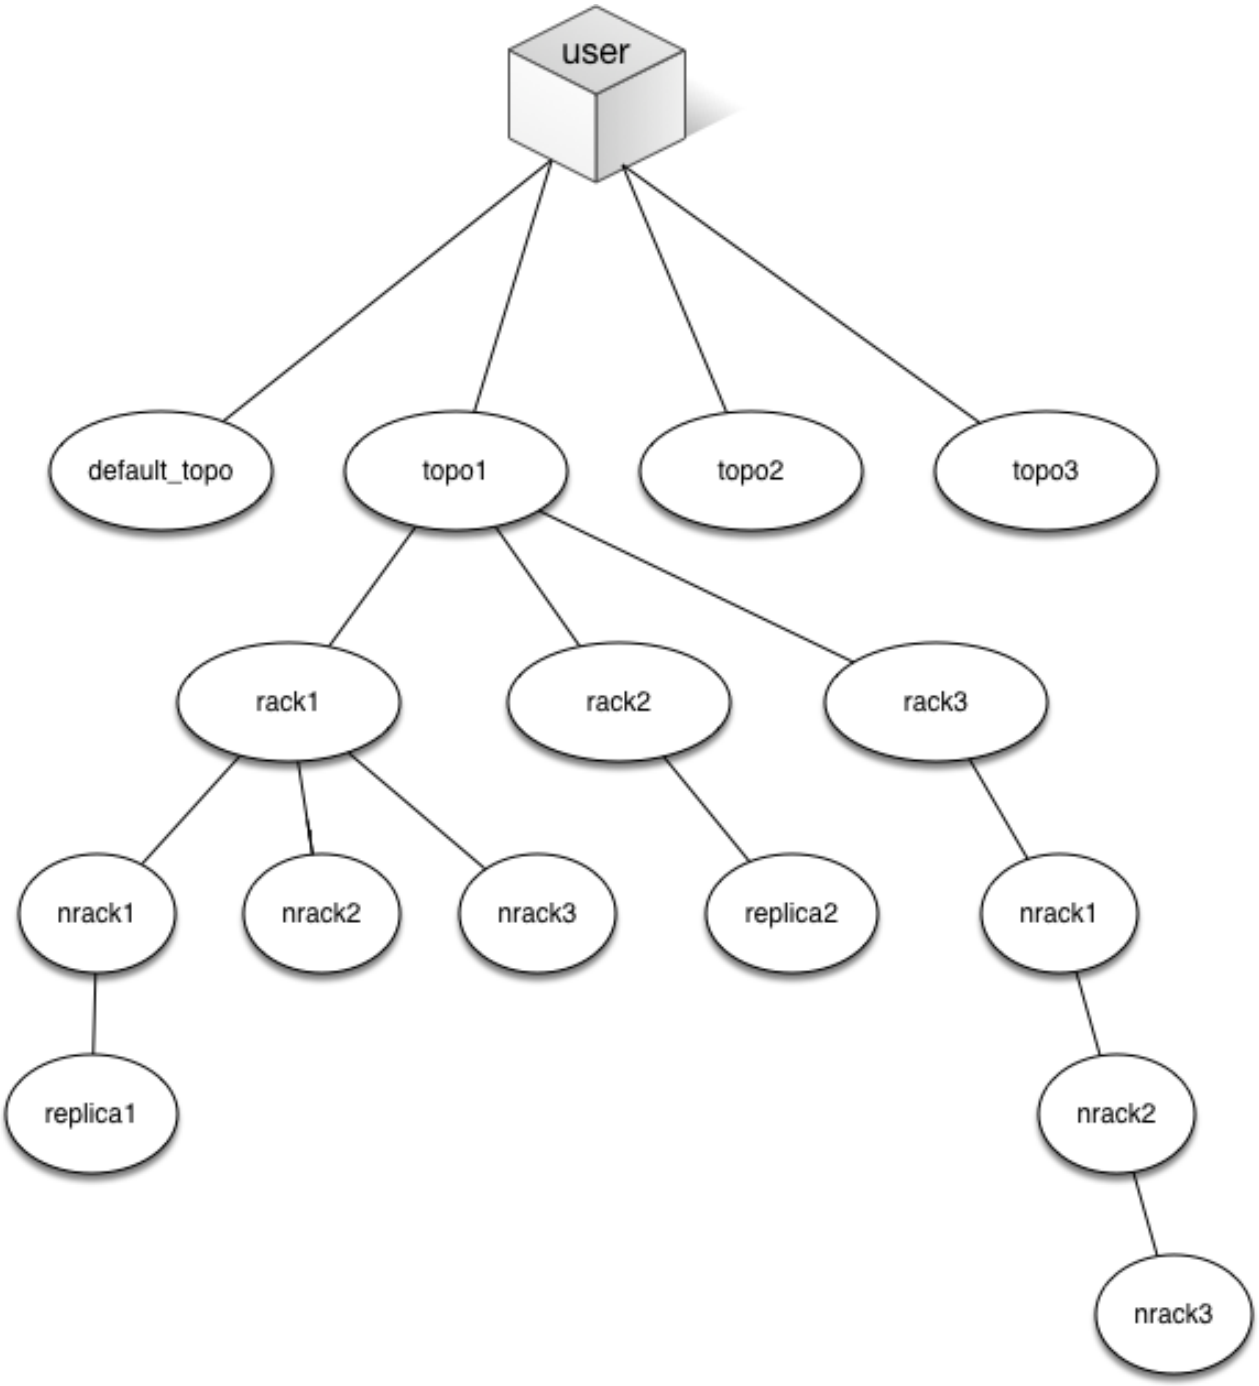
When a client connects to the data-fabric cluster for I/Os, the client is directed to the replica with the shortest distance. To calculate the distance, every client is given a specific path based on whether the client is connecting from within the cluster or from outside the cluster.

For clients connecting from outside the cluster, because the topology is unknown, and data-fabric defines the path based on the topology configured in the CLDB configuration property (`cldb.default.node.topology`), the default rack (which is hard-coded as default-rack), and the client IP address. For example, suppose the client IP address is 10.10.10.1 and the value for the CLDB configuration property is `default_topo`. The client topology (or path) is: `/default_topo/default_rack/10.10.10.1`.

For clients on the cluster, the client node has a known topology and the path is built based on that topology, rack, and the client IP address. For example, suppose the client IP address is 10.10.10.1 and the client node topology is `/topo1/rack1`, the client path is: `/topo1/rack1/10.10.10.1`.

Assume the following node topology:

last-updated: Jun 06, 2024



For the client connecting from outside or within the cluster, the replica that the client connects to is calculated based on the client's node topology (or path) and the distance between the nodes on the cluster. When trying to find the nearest replica, the system does a distance calculation based upon how far away the replica is from the data-fabric client looking for the replica and chooses the replica with the shortest topology or least number of hops from the client node. In the above example, the client connecting from:

- Outside the cluster with the path `/default_topo/default_rack/10.10.10.1` will connect to replica2
- Within the cluster with the path:
  - `/topo1/rack1/10.10.10.1` will connect to replica1

- `/topo1/rack2/10.10.10.2` will connect to replica2
- `/topo1/rack3/10.10.10.3` will connect to replica2

Locking Support in Data Fabric

Provides a synopsis of how Data Fabric supports locking for clients.

The Data Fabricfile system does not support server-side locking. This means that locks are held by components outside of the filesystem layer and are therefore not shared or enforced globally. As a result, when locking is available, you will need to carefully understand exactly where this enforcement occurs and ensure that all programs using the same locks access them through the same enforcement point. Also, locks, when supported in Data Fabric, are always whole file locks and advisory, not mandatory. The following table describes the locking support in Data Fabric for the clients.

Client Type	Locking Support	Default Value	Notes
Hadoop	No	N/A	Hadoop does not support locking APIs.
FUSE-based POSIX	Yes	Lock	Data Fabric supports advisory locking using kernel locking. This lock is locally enforced on that single Linux host and not shared with other hosts. The lock is only meaningful if all users accessing the file are using FUSE and are on the same host.
Loopback NFS POSIX	No	N/A	No support in Data Fabric for locking. However, you can use Network Lock Manager to lock with the `nolock` option on the `mount` command. This lock is locally enforced on that single Linux host and not shared with other hosts. The lock is only meaningful if all lock users are using loopbacknfs and are on the same host.
NFS v3	No	N/A	No support for locking in Data Fabric. However, you can use Network Lock Manager to lock with the `nolock` option on the `mount` command. This lock is locally enforced on that single Linux host and not shared with other hosts. The lock is only meaningful if all lock users are using NFS v3 and are on the same host.

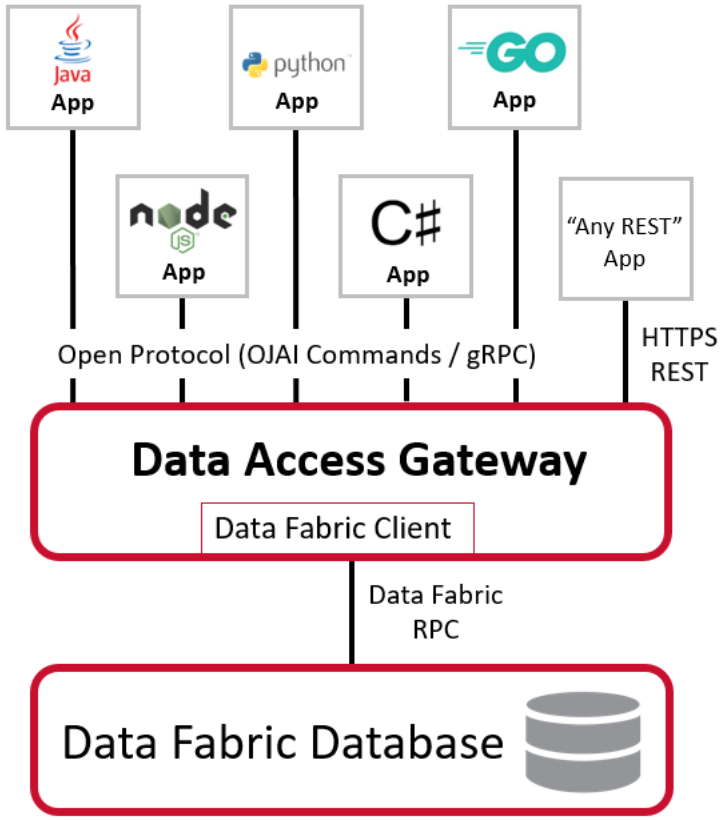
Client Type	Locking Support	Default Value	Notes
NFS v4	Yes	NoLock	Data Fabric supports advisory locking for NFS v4 server. The lock is enforced locally on the NFS v4 server, which means the lock is only meaningful if all lock users are using the same NFS v4 server. See Advisory Locking in NFS v4 on page 1593 for more information.

Understanding the HPE Ezmeral Data Fabric Data Access Gateway

The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster.

For the EEP 5.0 release, the service is used by the HPE Ezmeral Data Fabric Database JSON REST API. Starting with the EEP 6.0 release, the service can be used by the Node.js, Python, C#, and Go OJAI clients. Beginning with the EEP 6.3.0 release, the service can be used by the Java OJAI thin client.

The OJAI clients that connect to the Data Access Gateway use gRPC, an open-source RPC framework, to expose the HPE Ezmeral Data Fabric Database OJAI API to the client. RPC message headers for individual messages are encoded using Protocol Buffers. The message payload is encoded using OJAI JSON encoding. Depending on whether your HPE Ezmeral Data Fabric cluster has security enabled, TLS is either enabled or disabled, by default, for the gRPC service. When TLS is enabled, the SSL provider is OpenSSL.



The service runs on nodes in your HPE Ezmeral Data Fabric cluster. You can install the service manually or by using the Installer on page 5579. Both installation methods support upgrades of existing HPE

Ezmeral Data Fabric clusters. When installing the service, you can decide the number of nodes on which to install the service. The number of nodes you need depends on your scalability requirements.

Regardless of your scalability requirements, you should install the service on at least two nodes to provide high availability. To load balance requests and to achieve high availability and failover, you must use an external load balancer. For recommendations and best practices when using an external load balancer with gRPC, see gRPC Load Balancing.

The service runs as user `mapr`. However, the service issues all data access calls on behalf of the user requesting the data. For example, if user `john` is running the client application, the service reads data using the authorization of `john`, not `mapr`.

All traffic between the Data Access Gateway and other HPE Ezmeral Data Fabric services is encrypted. This is done regardless of whether the underlying HPE Ezmeral Data Fabric file system volume has encryption enabled.

Warden on page 815 manages the HPE Ezmeral Data Fabric Data Access Gateway. It handles stopping and starting of the service during node failovers and also controls the amount of memory assigned to the service.

Related concepts

Using the HPE Ezmeral Data Fabric Database JSON REST API on page 3478
Starting in the EEP 5.0 release, you can use a REST API to access HPE Ezmeral Data Fabric Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on HPE Ezmeral Data Fabric Database JSON tables.

Using the Node.js OJAI Client on page 3453
Starting with EEP 6.0, you can use the Node.js OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON from middleware components, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Using the Python OJAI Client on page 3458
Starting with EEP 6.0, you can use the Python OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Using the C# OJAI Client on page 3468
Starting with EEP 6.1.0, you can use the C# OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Using the Go OJAI Client on page 3473
Starting with EEP 6.0.0, you can use the Go OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Using the Java OJAI Thin Client on page 3450
Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write HPE Ezmeral Data Fabric Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Administering the Data Access Gateway on page 1961
The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Related tasks

Installing Data Access Gateway on page 262
This topic includes instructions for using package managers to download and install the Data Access Gateway from the EEP repository.

7.7.0 Administration

This section describes how to manage the nodes and services that make up a cluster.

This section is for system administrators tasked with managing data-fabric clusters. Topics include how to manage data by using volumes, how to monitor the cluster for performance, how to manage users and groups, how to add and remove nodes from the cluster, and more. The focus of this section is managing the nodes and services that make up a cluster using the Control System and the CLI or REST API.

Administering Users and Clusters

Lists topics that help manage a data-fabric cluster.

This section describes processes involved in managing a data-fabric cluster. Topics include setting up users and groups, adding licenses to the cluster, enabling/disabling auditing of cluster administration, configuring disk and role balancers, and allocating quotas for users and groups and setting cluster reserve limit.

Managing Users and Groups

Provides a brief introduction to user management on an HPE Ezmeral Data Fabric cluster.

The following two users are important when installing and setting up Data Fabric software:

- `root` is used to install Data Fabric software on each node.
- The “Data Fabric user” is the user that Data Fabric services run as (typically named **mapr** or **hadoop**) on each node. The Data Fabric user has full privileges to administer the cluster. Administrative privilege with varying levels of control can be assigned to other users as well.

Before installing Data Fabric, decide on the name, user ID (UID) and group ID (GID) for the Data Fabric user. The Data Fabric user must exist on each node, and the user name, UID and primary GID must match on all nodes.

- When adding a *user* to a cluster node, specify the `--uid` option with the `useradd` command to guarantee that the user has the same UID on all machines.
- When adding a *group* to a cluster node, specify the `--gid` option with the `groupadd` command to guarantee that the group has the same GID on all machines.

Data Fabric uses the native operating system configuration of each node to authenticate users and groups for access to the cluster. If you are deploying a large cluster, you should consider configuring all nodes to use LDAP or another user management system. You can use the Control System to grant specific permissions to particular users and groups. For more information, see Setting User Permissions. Each user can be restricted to a specific amount of disk usage. For more information, see Setting Quotas for Users and Groups.

By default, Data Fabric grants the user `root` full administrative permissions. If the nodes do not have an explicit `root` login, grant full permissions to another user after deployment. See Adding Cluster Permissions on page 1054.

last-updated: Jun 06, 2024

On the node where you plan to run the `mapr-apiserver` (the Control System), install Pluggable Authentication Modules (PAM). See PAM Configuration for more information.

You can perform the following procedures to manage users and groups in a Data Fabric cluster using the Control System (click **Admin** > **User Settings**) and the CLI:

Setting Up Email Addresses
Describes how to set up email addresses using the Control System and the CLI.
Setting Up Email Addresses Using the Control System

About this task

To set up email addresses for cluster users, in the Control System under **Admin** > **User Settings** > **Email Address**:

Procedure

1. Choose one of the following to configure the cluster to use an SMTP server to send email:
   - **Use Company Domain** to specify a domain to append after each user name to complete each user's email address
   - **Use LDAP** to obtain each user's email address from an LDAP server.
2. Specify, for:

Use Company Domain

Domain to append after each user name to complete each user's email address in the **user** @ field.

Use LDAP

LDAP Server	The LDAP server address.
LDAP Port	The LDAP server port number. You can select the **Use Secured Port** checkbox to use port 636.
Bind Domain	The bind domain for the users.
Bind Domain Password	The bind password for the users.
Base Domain	The base domain.
UID Attribute	The user ID.
Mail Attribute	The mail attribute.

3. Click **Save Changes**.

Setting Up Email Addresses Using the CLI or the REST API

About this task

The basic command to set up email address for a user is:

```
maprcli entity modify -name <entityname> -type 0 -email <email>
```

For complete reference information, see `entity modify` on page 2185.

last-updated: Jun 06, 2024

Setting Up SMTP

Describes how to set up SMTP information using the Control System and the CLI.

About this task

You can specify SMTP server information for the cluster using the Control System and the CLI.

Setting Up SMTP Using the Control System

About this task

Use the following procedure to configure the cluster to use an SMTP server to send email:

Procedure

1. Log in to the Control System and click **Admin** > **User Settings** > **SMTP**.
2. Set up the email account the HPE Ezmeral Data Fabric cluster must use to send alerts and other notifications.

Provider	Select **Gmail**, **Office 365**, or **SMTP** from the drop-down menu. If you select **Gmail** or **Office 365**, the SMTP server and port information will be pre-filled for you.
SMTP Server	The SMTP server to use for sending mail.
This server requires an encrypted connection (SSL)	Specifies an SSL connection to SMTP.
SMTP Port	The SMTP port to use for sending mail.
Sender's Full Name	The name that HPE Ezmeral Data Fabric should use when sending email. Example: `MapR Cluster`
Sender's Email Address	The email address that HPE Ezmeral Data Fabric should use when sending email.
Sender's Username	(Optional) The user name that HPE Ezmeral Data Fabric should use when logging on to the SMTP server.
Sender's SMTP Password	(Optional) The password that HPE Ezmeral Data Fabric should use when logging on to the SMTP server.

3. Click **Save Changes**.

   An email request is sent to the specified email address. You can check the `/opt/mapr/logs/cldb.log` file if there is a problem sending the email. If there is a problem, also check the fields to make sure that the SMTP information is correct. Click **Revert** if you wish to cancel the changes.

Setting Up SMTP Using the CLI

About this task

Use the `maprcli config save` command to set the SMTP server. For example:

```
maprcli config save -values '{"mapr.smtp.provider":"gmail",
               "mapr.smtp.server":"smtp.gmail.com",
               "mapr.smtp.sslrequired":"true",
               "mapr.smtp.port":"465",
               "mapr.smtp.sender.fullname":"Ab  Cd",
               "mapr.smtp.sender.email":"xxx@gmail.com",
               "mapr.smtp.sender.username":"xxx@gmail.com",
               "mapr.smtp.sender.password":"abc"}'
```

For complete reference, see `config save` on page 2106.

last-updated: Jun 06, 2024

Configuring SSO

Describes how the HPE Ezmeral Data Fabric supports single sign-on (SSO) and how to configure it.

HPE Ezmeral Data Fabric releases 7.3.0 and later support SSO when configured with the Keycloak identity and access management (IAM) solution. No other IAM solution is currently supported.

Configuring SSO is optional. If you do not configure SSO, you must use Data Fabric user names and passwords for access to the cluster. While SSO is supported for Data Fabric core, it is not supported for the Installer or ecosystem components.

Keycloak Is Preinstalled and Preconfigured

Keycloak is the identity and access management (IAM) solution that provides single-sign-on (SSO) support for the Data Fabric. Starting with release 7.5.0, Keycloak is preinstalled and preconfigured when you install the `mapr-keycloak` package and specify the `-keycloak` option in configure.sh on page 2821 as part of cluster creation.

During cluster installation, Keycloak can be installed on all the nodes in the cluster. However, the Keycloak server is started on only one node. When installed, Keycloak is preconfigured with users, groups, and roles that enable integration of Keycloak with the Data Fabric. The following table describes the preconfigured items:

Keycloak Preconfigured Items	How Many?	Names	Notes
Users	1	`admin`	Any additional users that are added must be created with `uid` and `gid` attributes, as described in Adding New Users to Keycloak on page 1034.
Groups	1	`fabric-manager`	Any additional groups that are added must be created with the `gidNumber` attribute, as described in Adding a Group to Keycloak on page 1040.

Roles	3	`fabric-manager`
		`infrastructure-admin`
		`developer`
			These are the only supported roles. The `developer` role is sometimes referred to as the "fabric user" role.

Clients	1	`edf-client`	This is the dedicated client for the Data Fabric. In Keycloak, a client is an application or service that can request authentication for a user.

Keycloak installation also gives you access to the Keycloak admin portal.

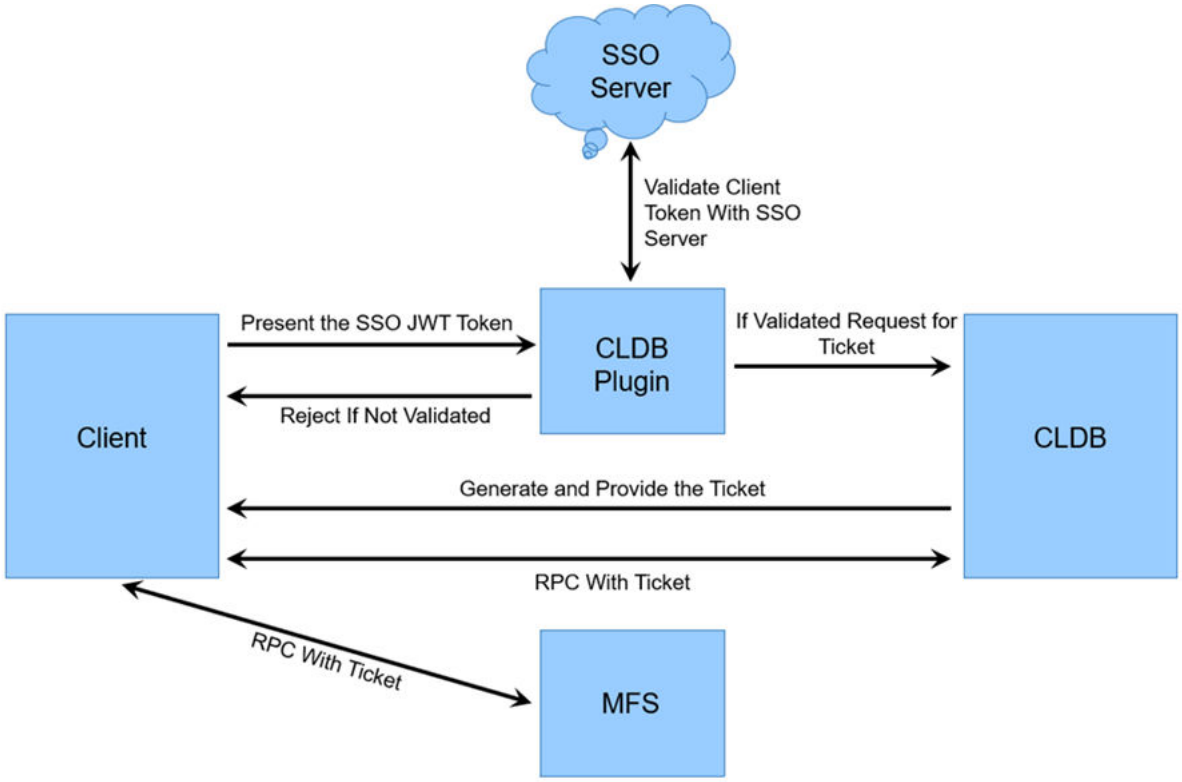
SSO and Temporary Tickets

Enhancements in release 7.3.0 and later allow clients that aren't aware of user passwords to access the cluster if they have a valid token from an SSO provider.

In Data Fabric installations that are not configured for SSO, users authenticate by providing a username and password and must obtain a user ticket to issue commands. The ticket enables RPC communication between various Data Fabric services. RPC communication cannot occur without a ticket.

Beginning with release 7.3.0, in installations where SSO is configured, a user provides a password to an SSO provider. The SSO provider authenticates the user and provides a JSON web token (JWT). The client presents the JWT to the CLDB using HTTPS. A CLDB plugin (new in release 7.3.0) functions as an HTTPS server and validates the JWT from the SSO provider. If the token is valid, the CLDB provides a short-lived ticket to the client.

last-updated: Jun 06, 2024



Object Store and Temporary Tickets

Releases 7.3.0 and later also provide enhancements to enable MinIO Client (mc) communication with the HPE Ezmeral Data Fabric Object Store by using temporary tickets. In non-SSO installations, users and applications authenticate to the Object Store through S3 keys (AccessKey and SecretKey). Release 7.3.0 extended the MC framework to use `maprcli` with JWT to obtain a temporary AccessKey and SecretKey in the background. Optimizations in the CLDB allow the CLDB to cache the AccessKey and SecretKey for 15 minutes.

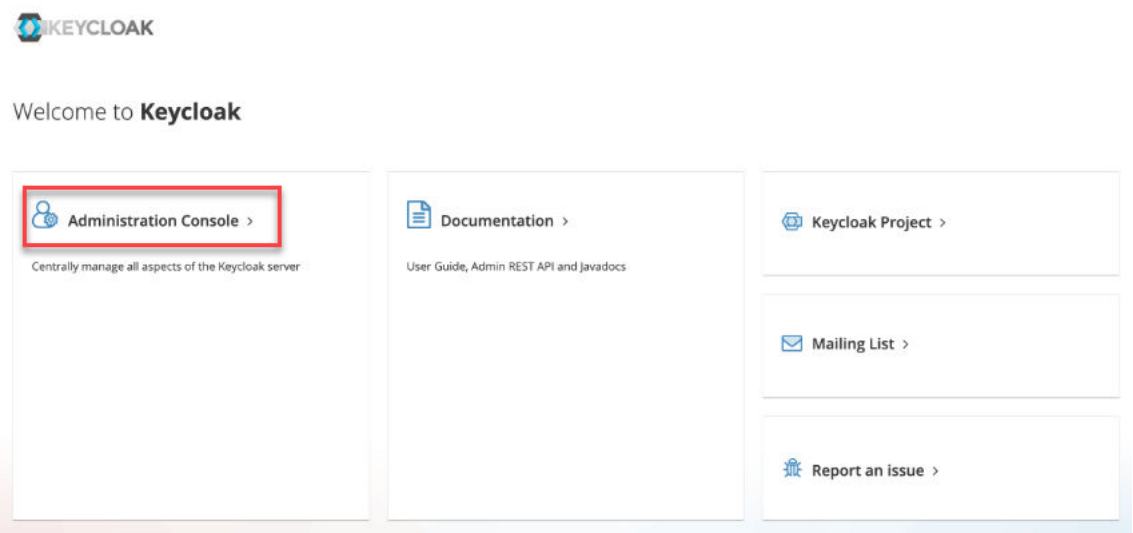
Accessing the Keycloak Administration Console
Describes how to start the Keycloak administration console so you can manage Keycloak and your SSO users.

If a new cluster has been created, you can access the Keycloak administration console by using these steps:

1. In a browser, append port 6443 to the URL for the host that is running the WebServer. For example:

   ```
   https://<FQDN_of_WebServer_node>:6443
   ```

2. Click **Administration Console**:

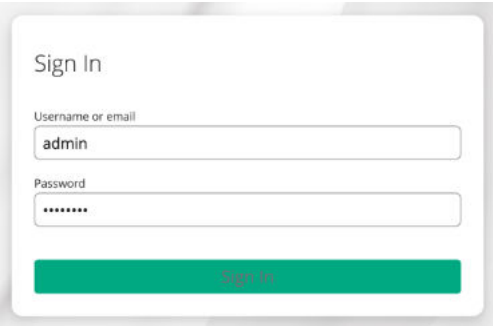


The **Sign In** page is displayed:

3. Sign in using the default credentials:

   Username: `admin`

   Password: `p@ssw0rd`



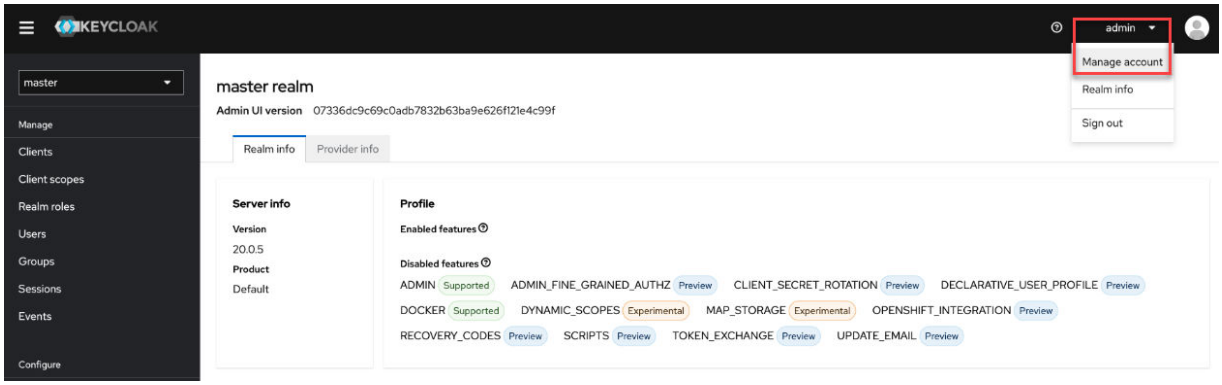
IMPORTANT: HPE recommends that you change the password for the `admin` user soon after sign in. See Changing the Keycloak admin Password on page 1031.

Changing the Keycloak admin Password
Describes how to change the default Keycloak *admin* password to prevent unauthorized access to Keycloak and your Data Fabric user information.

The default `admin` password provided in the bundled version of Keycloak is a well-known password that must be changed immediately after installation. Use these steps to change the password:

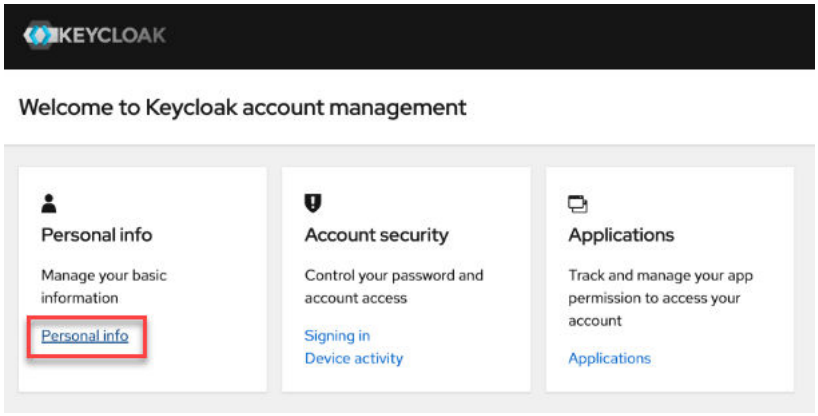
1. Sign in to the Keycloak administration console as described in Accessing the Keycloak Administration Console on page 1030. The master realm information is displayed:

2. In the top right corner of the page, click the down arrow for the **admin** user, and select **Manage account**:



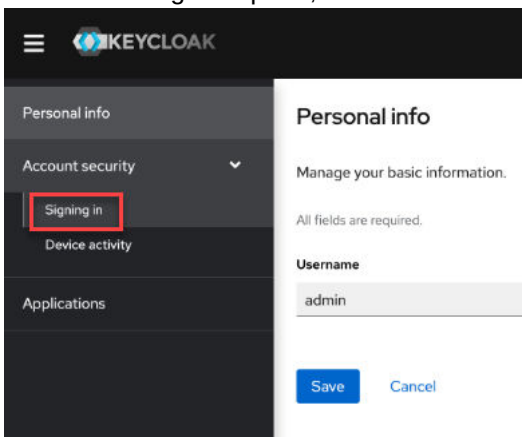
The account management information is displayed.

3. Click the **Personal Info**:



The **Personal Info** page is displayed.

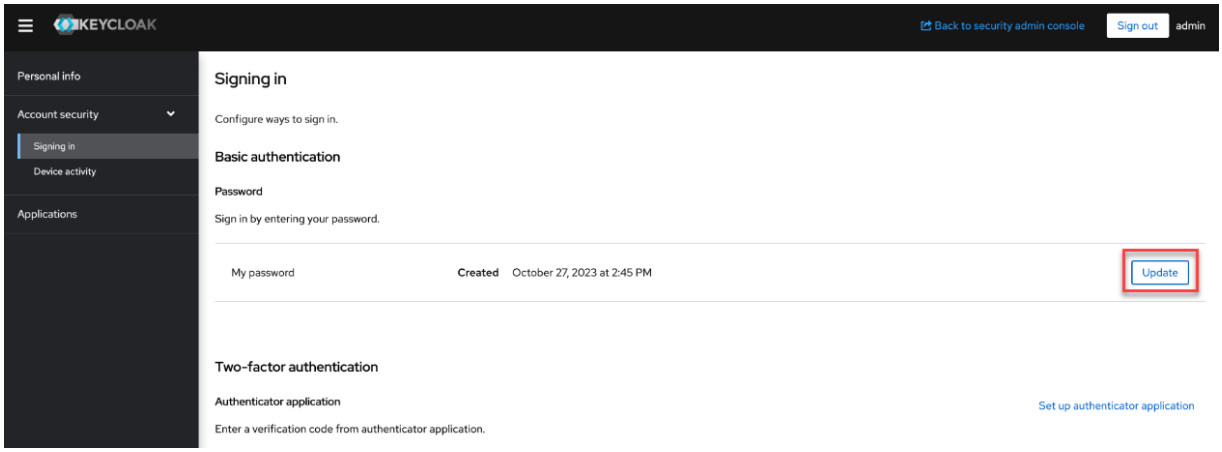
4. In the left navigation pane, under **Account security**, click **Signing in**:



The **Signing in** page is displayed.

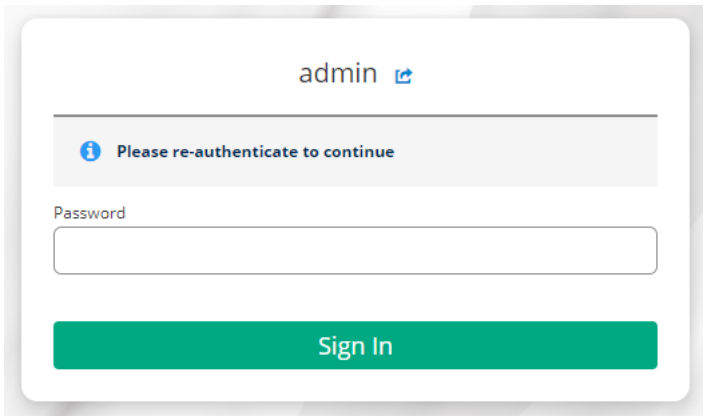
5. On the **Signing In** page, click **Update**:

last-updated: Jun 06, 2024



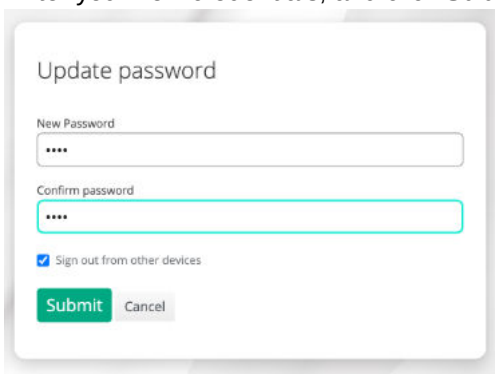
Keycloak asks you to re-authenticate.

6. Type the default `admin` password again:

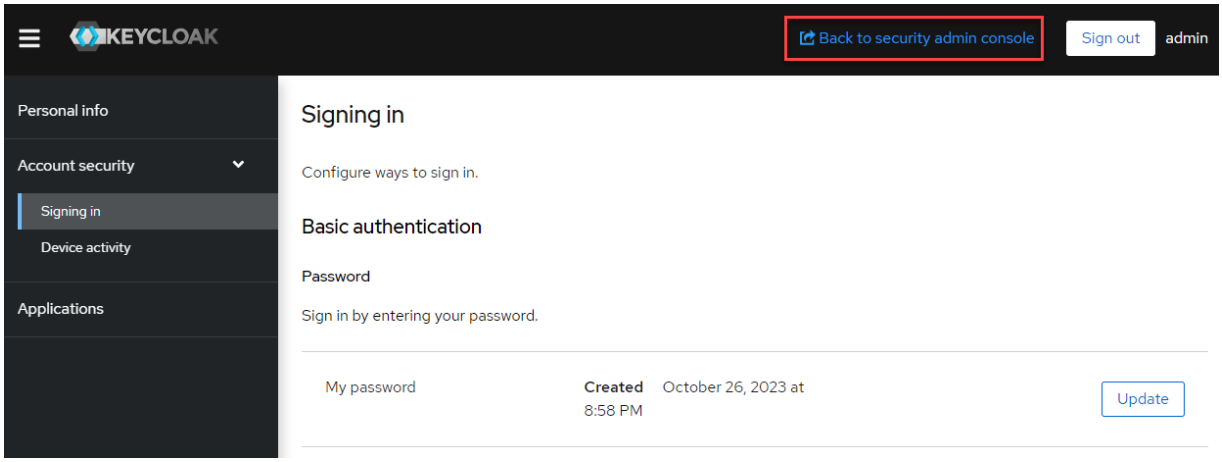


The **Update password** page is displayed.

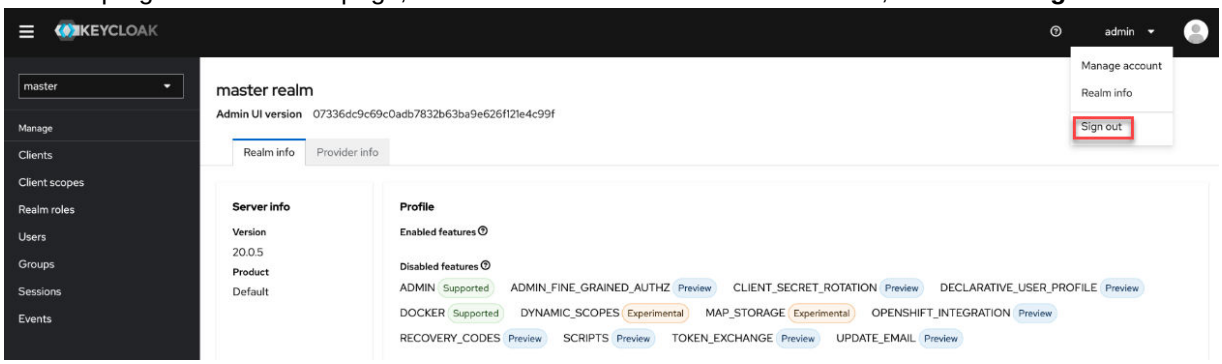
7. Enter your new credentials, and click **Submit**:



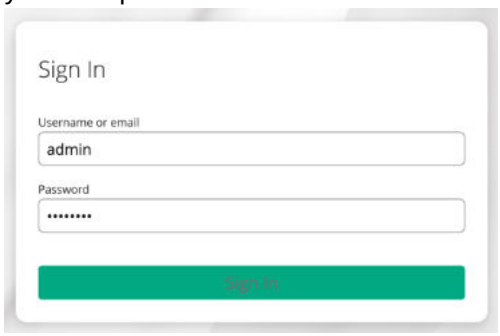
8. Click **Back to security admin console** to return to the administration console:



9. In the top right corner of the page, click the down arrow for the **admin** user, and select **Sign out**:



10. Repeat step 1, signing in to the Keycloak administration console as described in Accessing the Keycloak Administration Console on page 1030. On the **Sign In** page, sign in as the `admin` user with your *new* password:

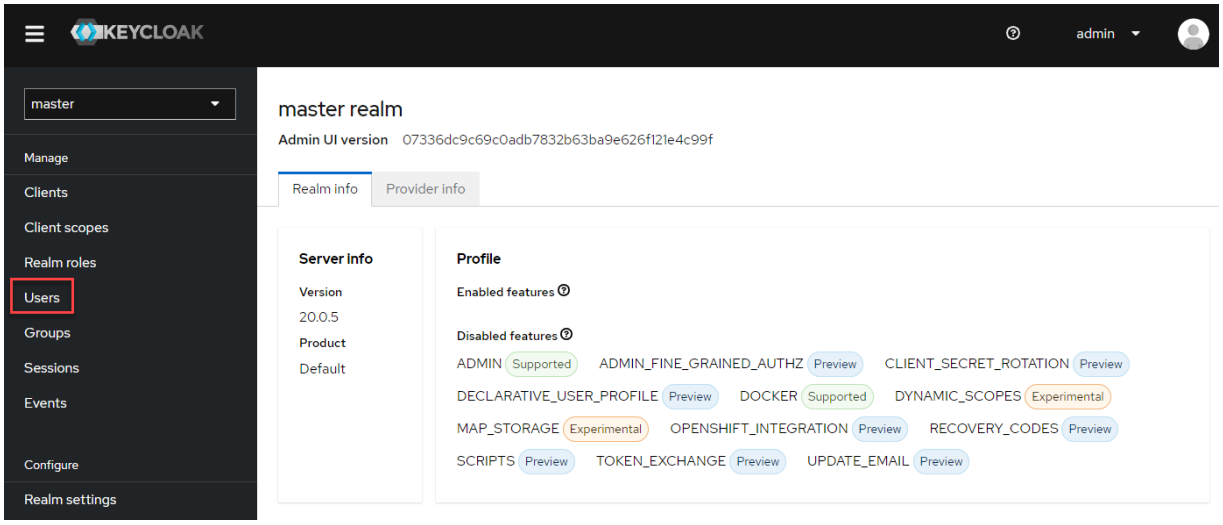


Adding New Users to Keycloak
Describes how to add new users in Keycloak so you can use them to sign in to the HPE Ezmeral Data Fabric.

By default, the Keycloak software provided with release 7.5.0 and later is preconfigured with only one user (the `admin` user). To add new users:

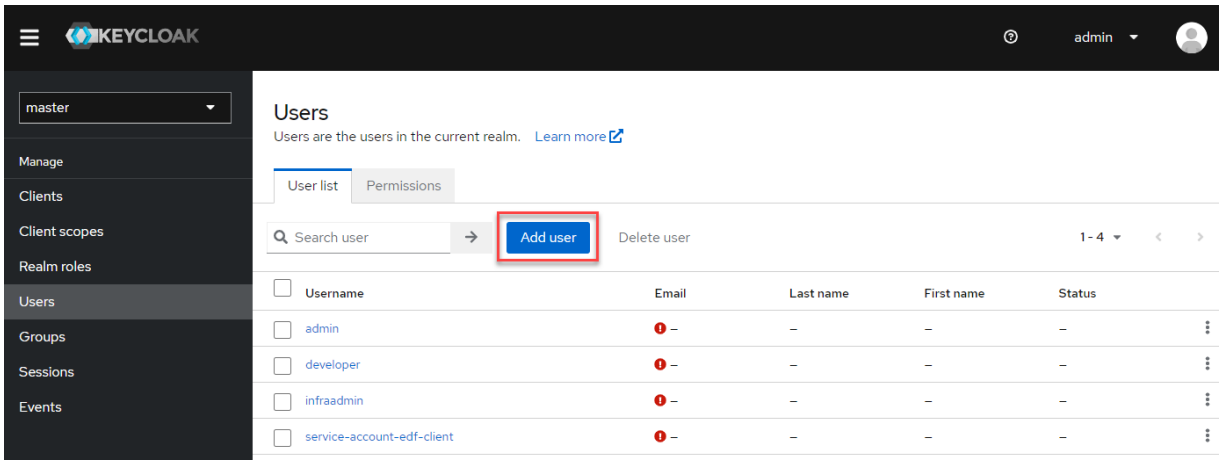
1. Sign in to the Keycloak administration console as described in Accessing the Keycloak Administration Console on page 1030. The master realm information is displayed.

2. In the left navigation pane, click **Users**:



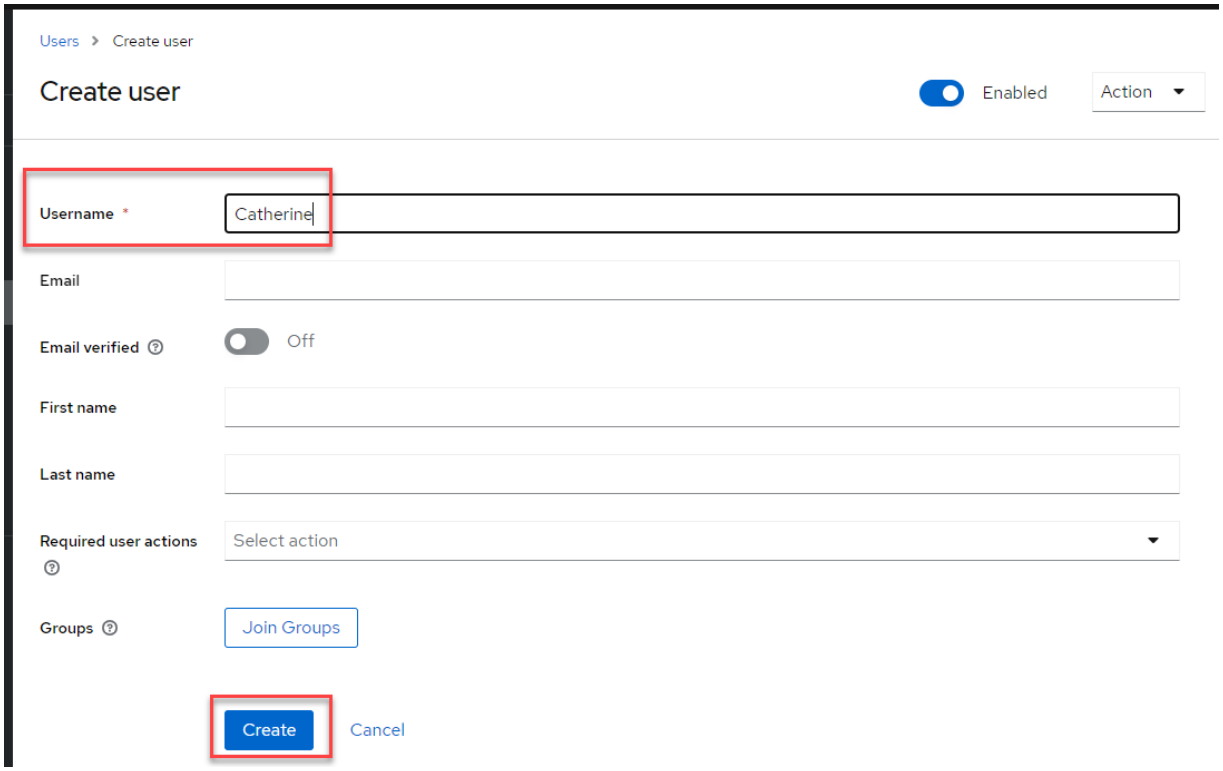
The **Users** page is displayed, showing the preconfigured `admin` user.

3. Click **Add user**:



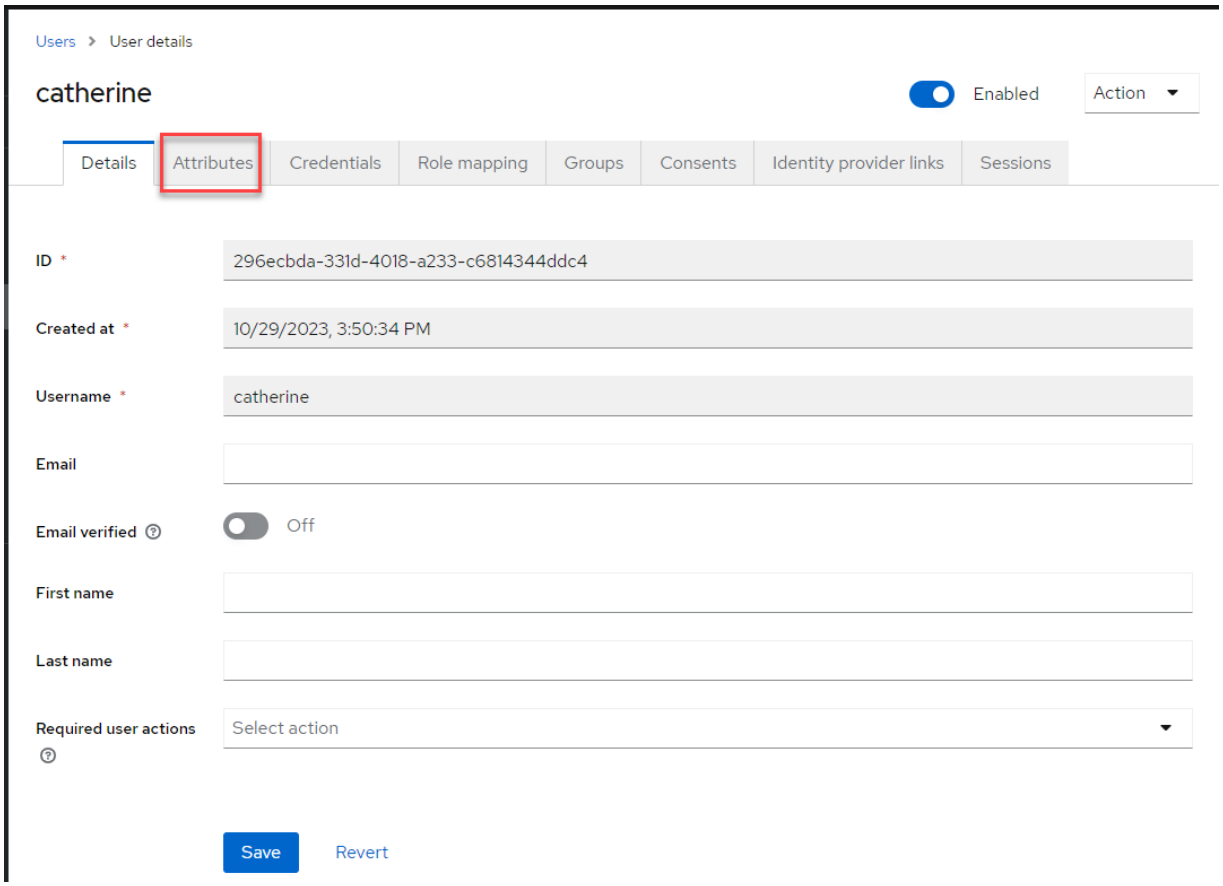
The **Create user** page is displayed.

4. In the **Username*** field, type the name of a new user, and click **Create**:



The **User details** page for the new user is displayed.

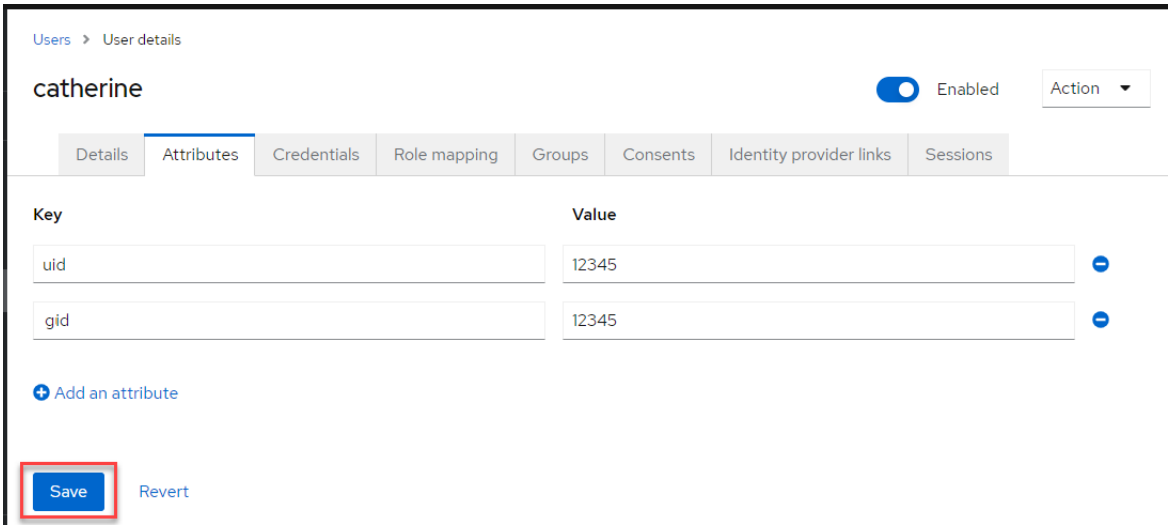
5. Click the **Attributes** tab:



The **Attributes** page is displayed.

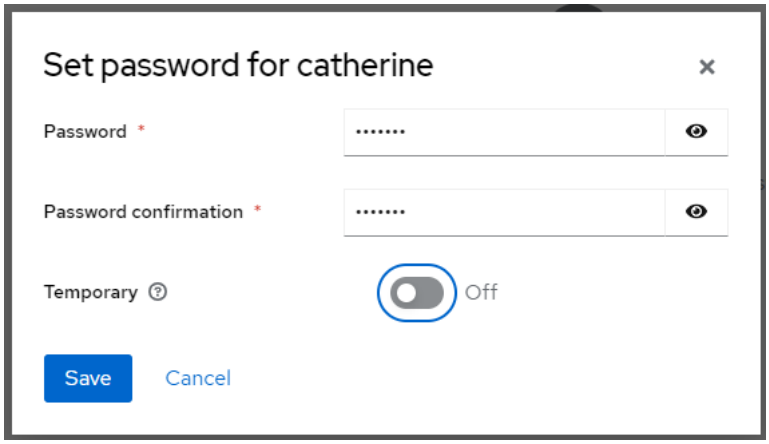
last-updated: Jun 06, 2024

6. Enter `uid` and `gid` values for the new user:
   a. In the **Key** field, type `uid`, then specify a `uid` value, such as `12345`, in the **Value** field.
   b. Click **Add an attribute**.
   c. In the second **Key** field, type `gid`, then specify a `gid` value, such as `12345`, in the **Value** field:

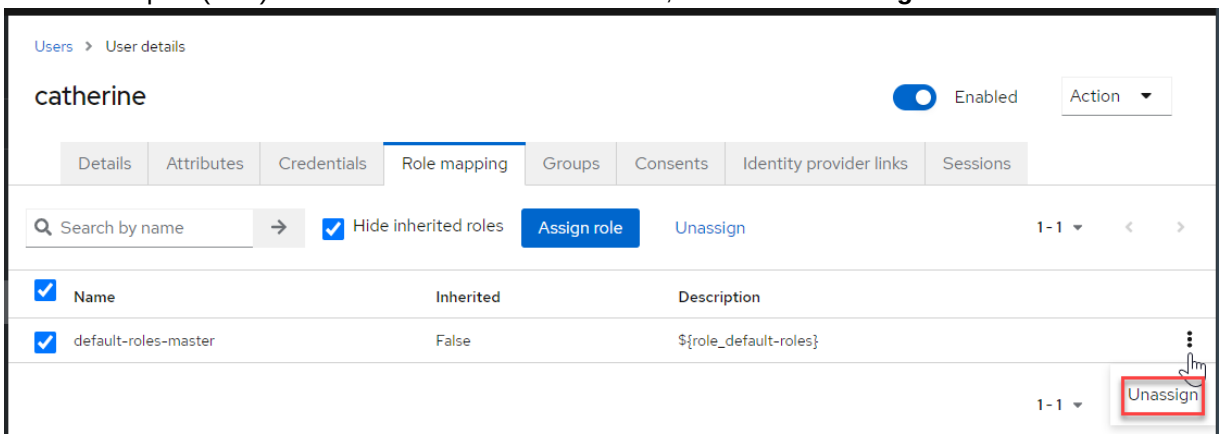


7. Click **Save**.
8. Click the **Credentials** tab. The **Credentials** page shows **No credentials**.
9. Click **Set password**:

   The **Set password for <new_user>** dialog box is displayed.
10. Enter a password for the new user, and confirm the password.
11. Move the **Temporary** slider to the **Off** position:



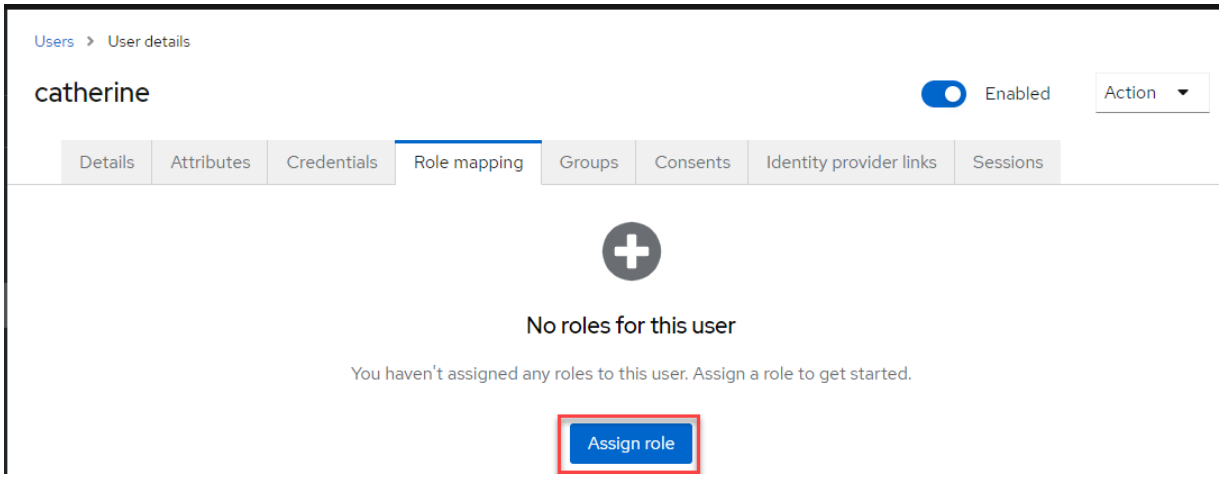
12. Click **Save**. The **Set password?** confirmation dialog box is displayed.
13. On the **Set password?** confirmation screen, click **Save password**. The **Credentials** tab of the **User details** page is displayed.
14. Click the **Role mapping** tab. The **Role mapping details** are displayed.
15. Click the **default-roles-master** role.
16. Click the ellipsis (⋮) for the **default-roles-master** role, and select **Unassign**:



The **Remove mapping?** dialog box is displayed.

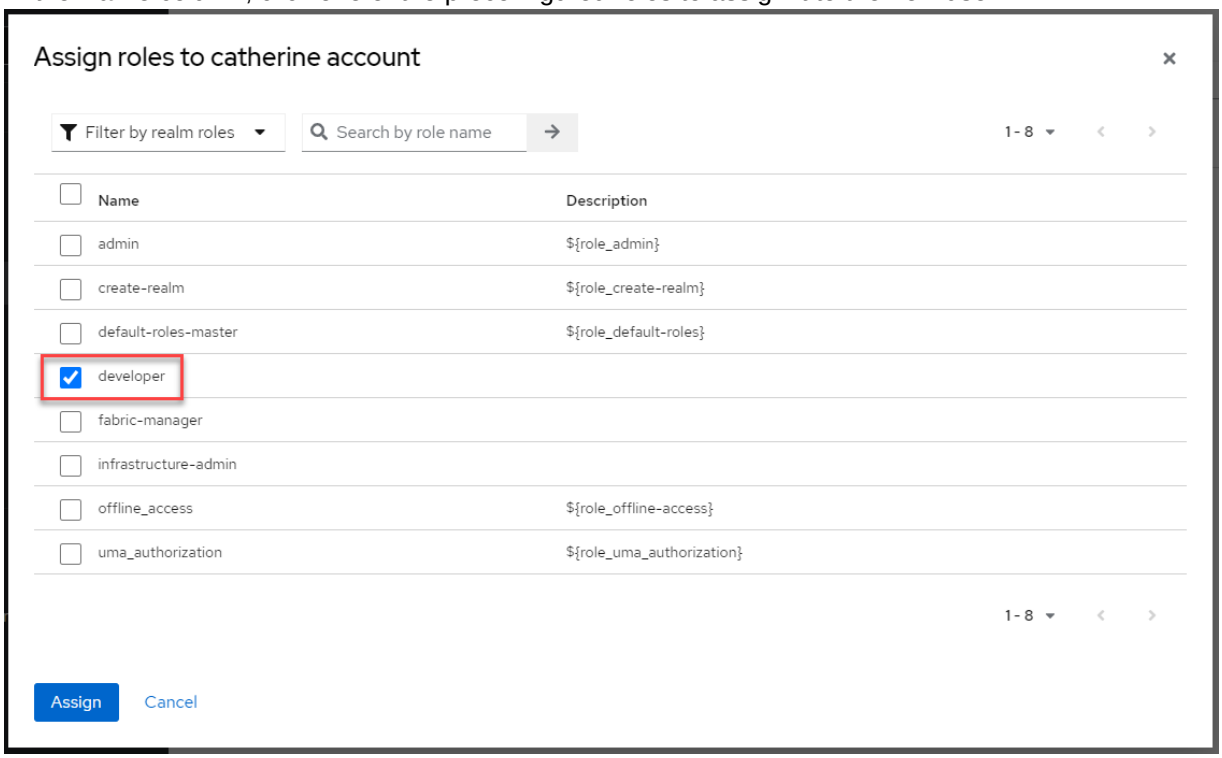
17. Click **Remove**. The **Role mapping details** page shows **No roles for this user**.
18. Click **Assign role**:

last-updated: Jun 06, 2024



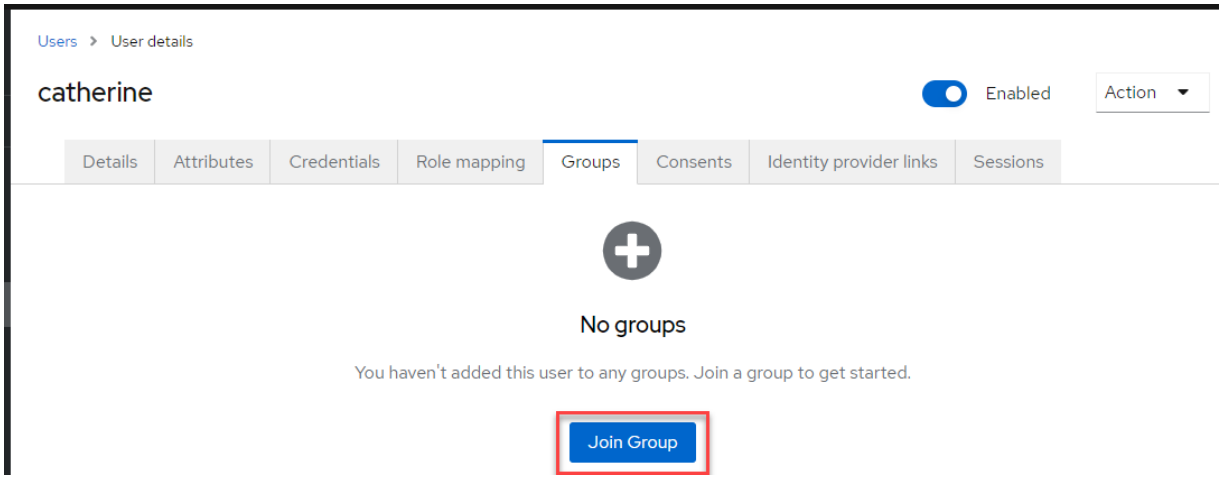
The **Assign roles to <new_user> account** is displayed.

19. In the **Name** column, click one of the preconfigured roles to assign it to the new user:

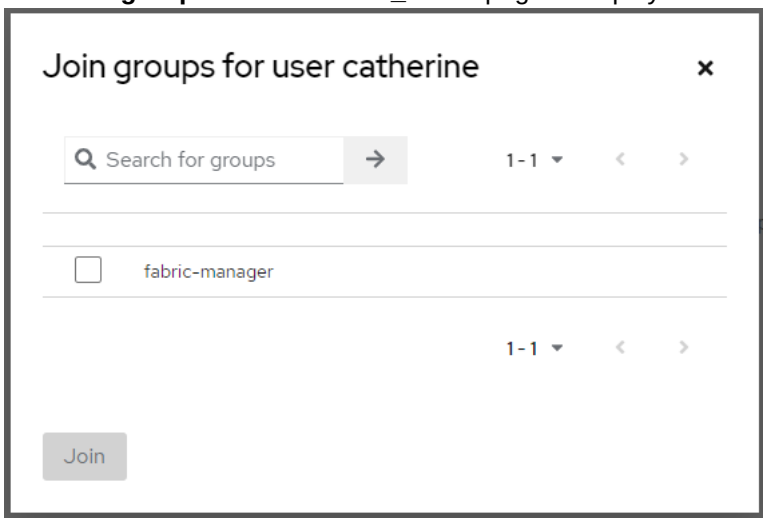


20. Click **Assign**. Next, you must assign the user to a group. Every user must belong to at least one group.
21. To add the user to a group, click the **Groups** tab. To add a new group, see Adding a Group to Keycloak on page 1040.
22. Click **Join Group**:

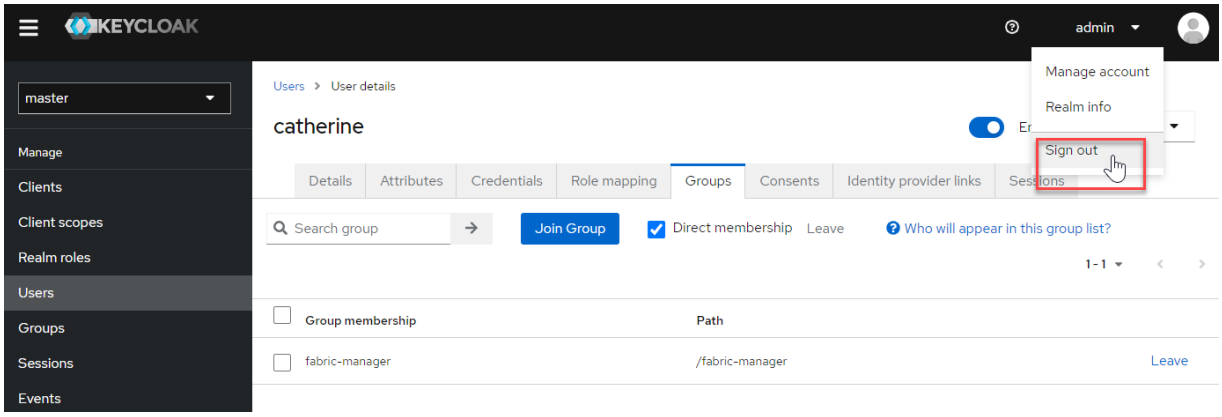
last-updated: Jun 06, 2024



The **Join groups for user <new_user>** page is displayed:



23. To add the user to a group, click the check box for a group.
24. Click **Join**. The **Groups** page is displayed.
25. In the top right corner of the page, click the down arrow for the `admin` user, and select **Sign out**:



You can now sign in to the HPE Ezmeral Data Fabric using the new user.

Adding a Group to Keycloak
Describes how to add a Keycloak user group.

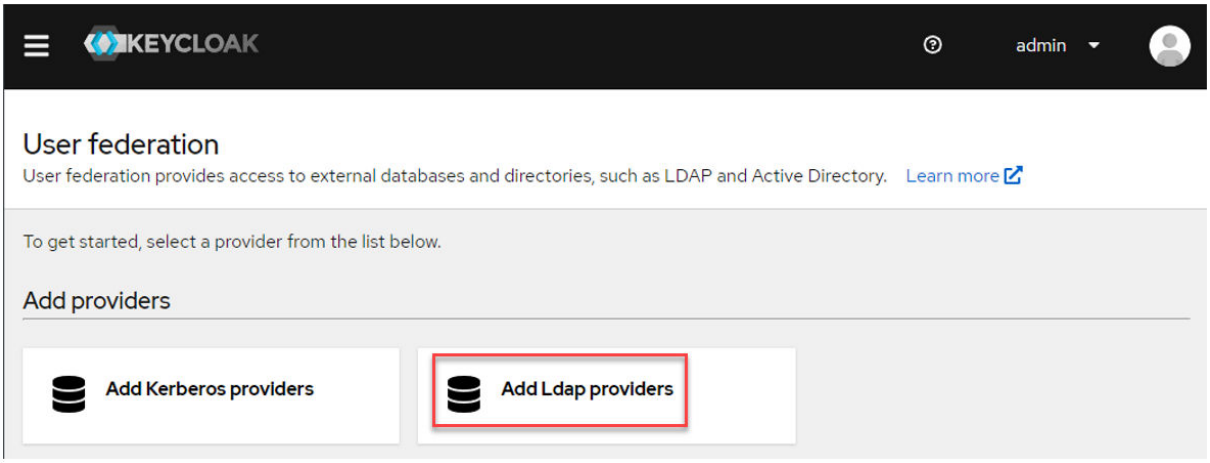
By default, the Keycloak software provided with release 7.5.0 and later is preconfigured with only one user group (the `fabric-manager group`). To add a new group:

1. Sign in to the Keycloak administration console as described in Accessing the Keycloak Administration Console on page 1030. The master realm information is displayed:
2. In the left navigation pane, click **Groups**.
3. Click **Create a group**.
4. Specify a name for the group, and click **Create**. The **Groups** page is displayed showing the new group. Click the link for the new group.
5. Click the **Attributes** tab.
6. In the **Key** field, type `gidNumber`, then specify a `gidNumber` value, such as `12345`, in the **Value** field.
7. Click **Save**.
8. In the left navigation pane, click **Users**.
9. From the list of users, click a user that you want to add to the new group.
10. Click **Join Group**.
11. Click the name of the group to which you want to add the user, and click **Join**.

Integrating Your LDAP Directory with Keycloak
Keycloak can interface with an external LDAP directory so that LDAP users can access the HPE Ezmeral Data Fabric.

To add an external LDAP provider in Keycloak:

1. Sign in to the Keycloak administration console as described in Accessing the Keycloak Administration Console on page 1030.
2. In the left-navigation pane, click **User federation**. The **User federation** screen is displayed:



3. Click **Add Ldap providers**. The Keycloak **User federation** page is displayed.
4. Fill in the information for your LDAP provider. For field-specific information, click the online help icon (?) for the field. For Keycloak documentation, see this page.

last-updated: Jun 06, 2024

Using LDAP Mappers

Describes how to use mappers to auto-populate Keycloak with the mandatory attributes it needs for users and groups to access the Data Fabric UI.

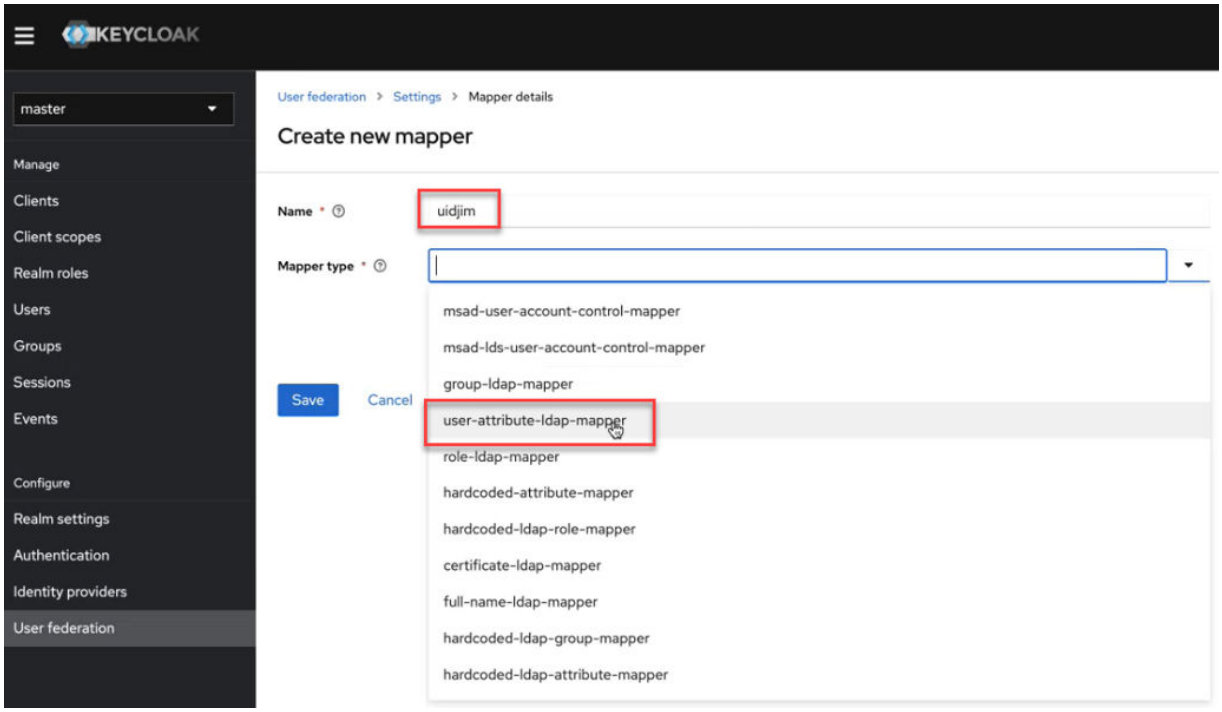
If you integrated your LDAP Directory with Keycloak as described in Integrating Your LDAP Directory with Keycloak on page 1041, you must configure mappers to associate Keycloak user, role, and group attributes with your LDAP users. Three mappers need to be created:

- UID mapper
- GID mapper
- User group mapper

Creating the UID Mapper

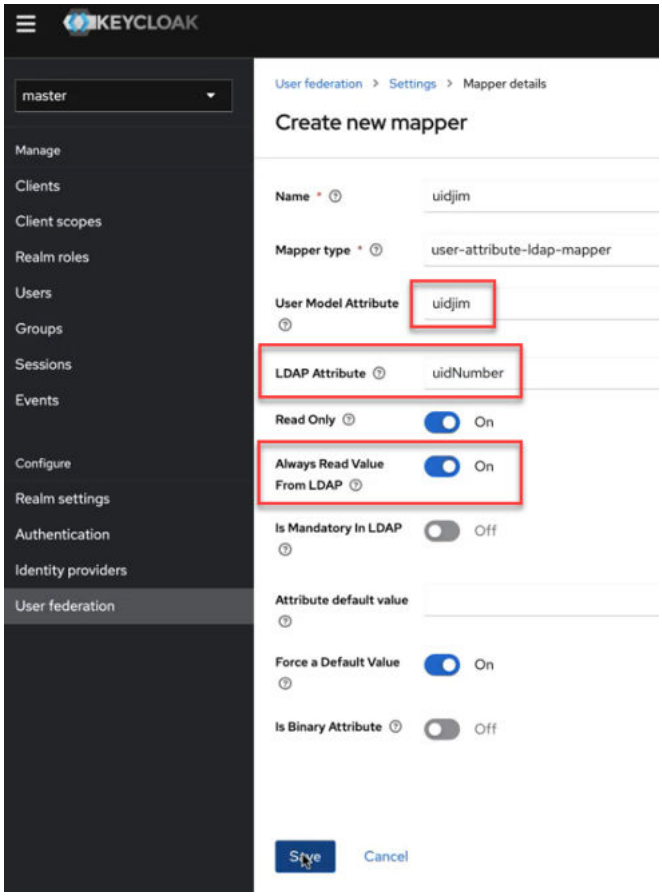
To create the UID mapper:

1. Sign in to the Keycloak administration console as described in Accessing the Keycloak Administration Console on page 1030. The master realm information is displayed:
2. In the left-navigation pane, click **User federation**. The **User federation** screen appears.
3. Click the box for the LDAP provider that you configured in Integrating Your LDAP Directory with Keycloak on page 1041. The **LDAP** screen appears.
4. Click the **Mappers** tab to display the current list of mappers.
5. To add a mapper, click **Add mapper**. The **Create new mapper** screen appears.
6. Specify a name for the UID mapper. The following example uses the name `uidjim`:



7. In the **Mapper type** field, click the down arrow, and select `user-attribute-ldap-mapper`. The **Mapper details** screen appears.
8. Fill out the UID mapper as follows:

last-updated: Jun 06, 2024



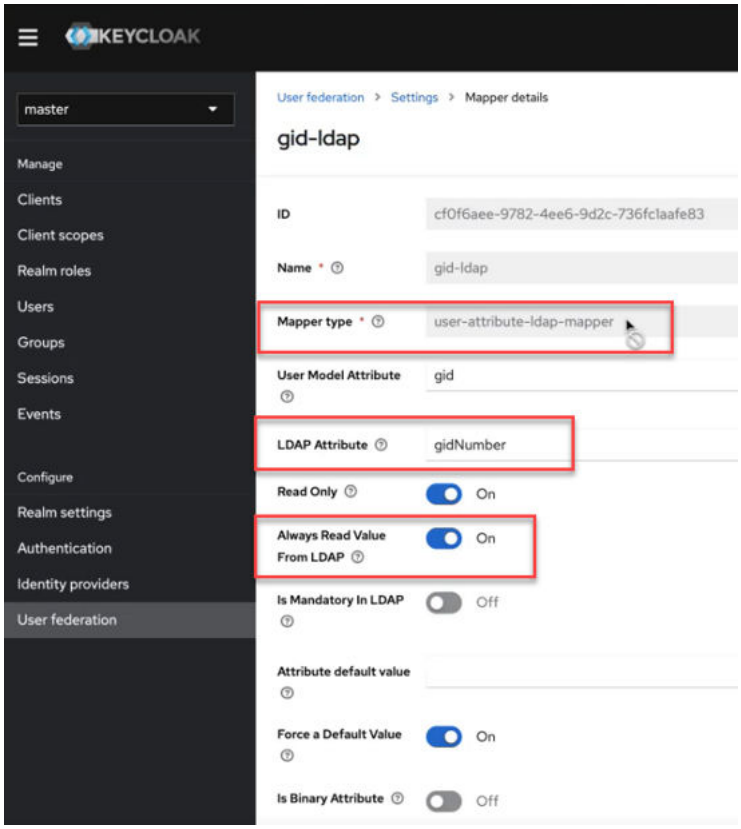
9. Click **Save**.

Creating the GID Mapper

To create the GID mapper:

1. Sign in to the Keycloak administration console as described in Accessing the Keycloak Administration Console on page 1030. The master realm information is displayed:
2. In the left-navigation pane, click **User federation**. The **User federation** screen appears.
3. Click the box for the LDAP provider that you configured in Integrating Your LDAP Directory with Keycloak on page 1041. The **LDAP** screen appears.
4. Click the **Mappers** tab to display the current list of mappers.
5. To add a mapper, click **Add mapper**. The **Create new mapper** screen appears.
6. Specify a name for the GID mapper.
7. In the **Mapper type** field, click the down arrow, and select `user-attribute-ldap-mapper`. The **Mapper details** screen appears.
8. Fill out the UID mapper as follows:

last-updated: Jun 06, 2024

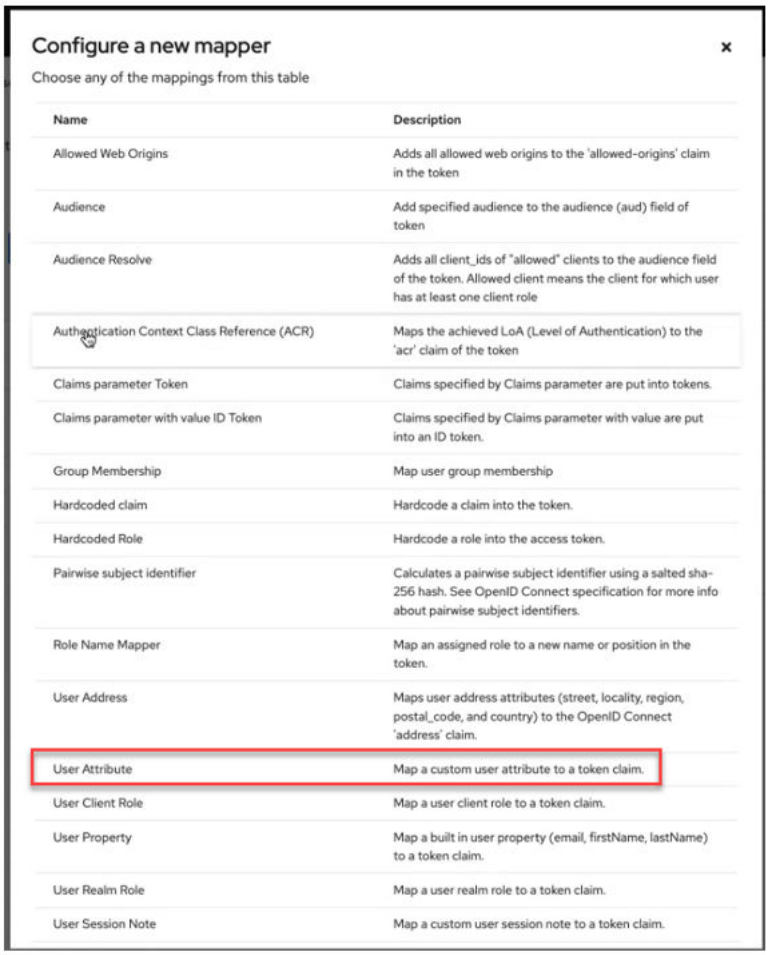


9. Click **Save**.

Creating the User Group Mapper

To create the User Group mapper:

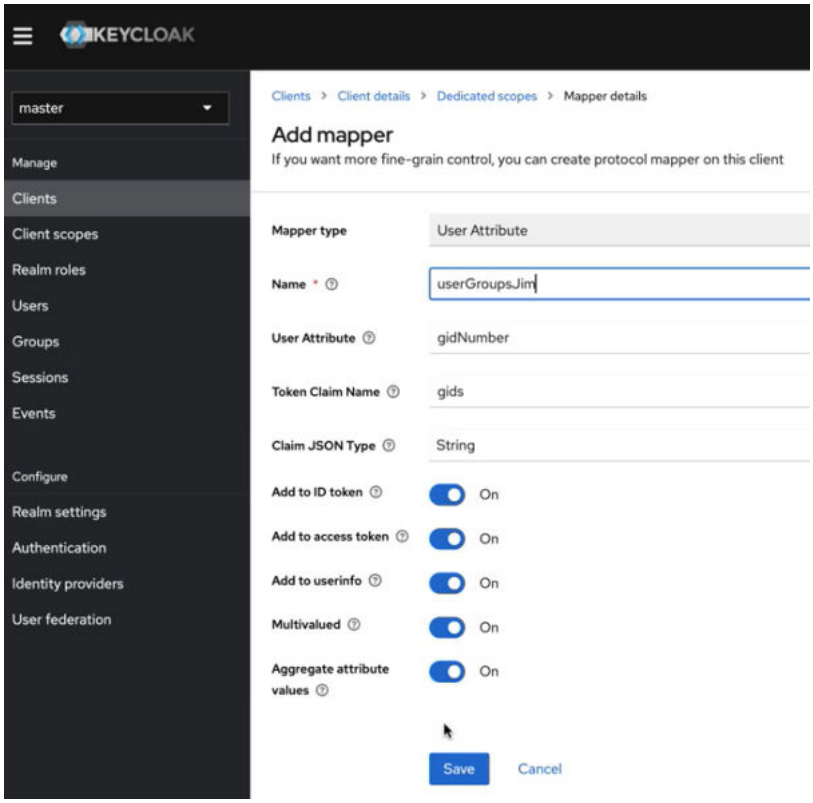
1. Sign in to the Keycloak administration console as described in Accessing the Keycloak Administration Console on page 1030. The master realm information is displayed:
2. In the left-navigation pane, click **Clients**. The **Clients list** tab appears.
3. Click the **edf-client** entry.
4. In the right pane, click the **Client scopes** tab.
5. Click the **edf-client-dedicated** entry.
6. Click **Add mapper > By configuration**. The **Configure a new mapper** screen appears:



7. Click the **User Attribute** row. Selecting this row allows you to map a custom attribute to a token claim. The **Add mapper** screen appears.

8. Fill out the form like this, using a name that is appropriate for your installation:

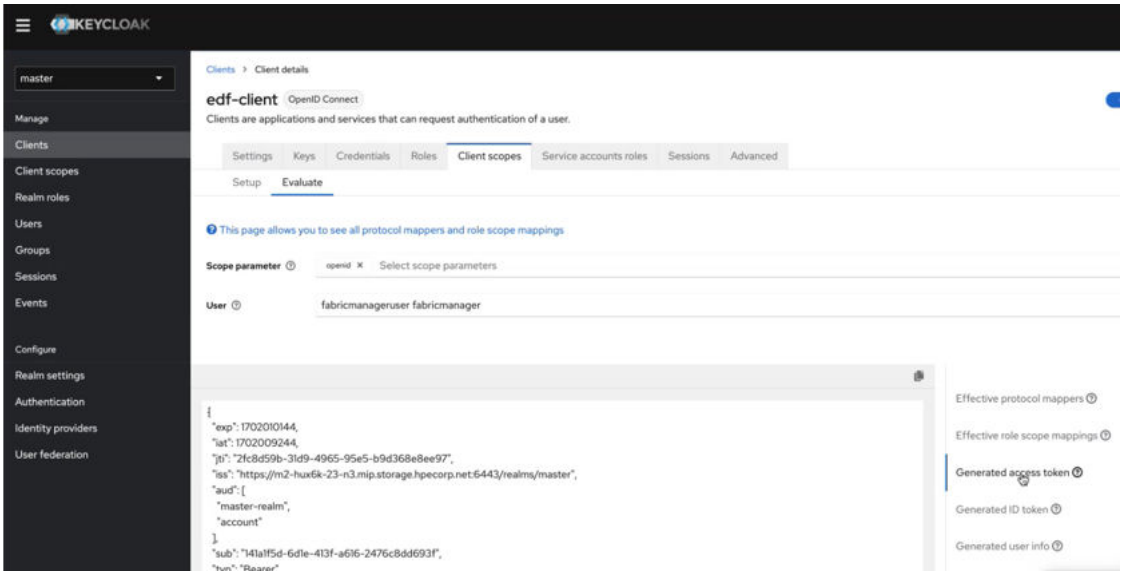
last-updated: Jun 06, 2024



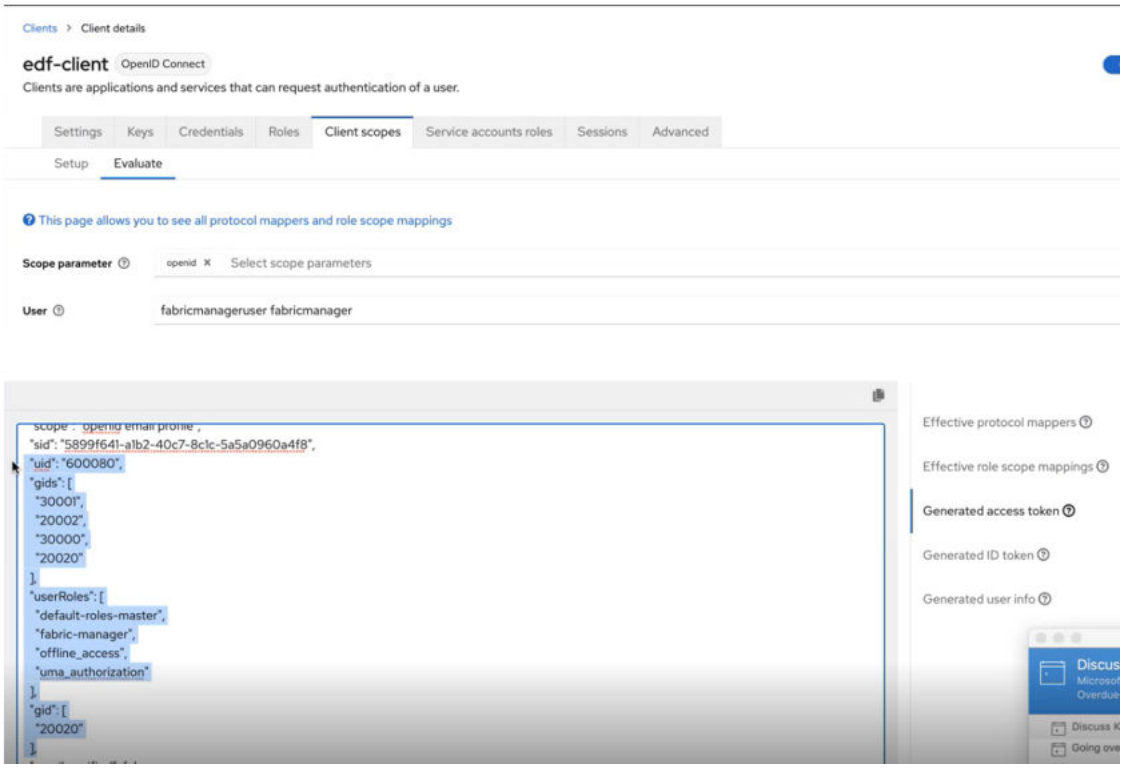
Confirming that Required Attributes Are Part of the JWT Token for a User

To confirm the required attributes:

1. Sign in to the Keycloak administration console as described in Accessing the Keycloak Administration Console on page 1030. The master realm information is displayed:
2. In the left-navigation pane, click **Clients**. The **Clients list** tab appears.
3. Click the **edf-client** entry.
4. In the right pane, click the **Client scopes** tab.
5. Click **Evaluate**.
6. In the **User** field, type the name of a user. For example, type the name of the fabric manager user:



7. Scroll down to check that the following four items are populated in the JWT token. If any of them are missing, there might be issues with user permissions:



Configuring Data Fabric Communications with Your SSO Server
Describes how to configure the HPE Ezmeral Data Fabric to work with an SSO server.

To enable your SSO provider to communicate with the HPE Ezmeral Data Fabric, release 7.4.0 or later must be installed, and you must configure SSO information by running the `maprcli cluster setssoconf` command.

Note these considerations:

- Only the cluster admin or a user with the fabric manager role can run the `maprcli cluster setssoconf` command.

last-updated: Jun 06, 2024

- For a customer-managed data fabric, you must run the command only on the primary CLDB node. SSO information is propagated automatically to other CLDB nodes in the cluster.
- For a consumption-based data fabric, you must run the command only on the primary CLDB node of the primary data fabric. SSO information is propagated automatically to other CLDB nodes and other fabrics in the global namespace.

To configure SSO:

1. Identify the primary CLDB node by using one of the following methods:
   - On any node in the cluster, run the following `maprcli` command:

     ```
     maprcli clustergroup getcgtable -showprimary true -json
     ```

   - Log in to the Control System and go to the service information page for CLDB. The primary CLDB is the CLDB with a CLDB Mode equivalent to `MASTER_READ_WRITE`. For more information, see Viewing CLDB Information.
2. Log on to the primary CLDB node as the cluster admin (typically the `mapr` user).
3. Run the cluster setssoconf on page 2073 command and specify the following options:
   - `-issuerendpoint`
   - `-providername`
   - `-clientid`
   - `-clientsecret`
   - `-certfile`
   - `-json` (optional)

   For example:

   ```
   maprcli cluster setssoconf -issuerendpoint https://<IP_address>:8443/
   realms/TestReallm/
   -providername keycloak -clientid testclient -clientsecret <secret>
   -certfile /opt/mapr/keycloak/conf/<hostname>.crt -json
   {
      "timestamp":1693834990616,
      "timeofday":"2023-09-04 06:43:10.616 GMT-0700 AM",
      "status":"OK",
      "total":1,
      "data":[
           {
                  "status":"SUCCESS: SSO configuration set on CLDB."
           }
      ]
   }
   ```

   For information about each option, see cluster setssoconf on page 2073.

cluster getssoconf on page 2064
Fetches the cluster-level SSO parameters.

cluster setssoconf on page 2073

Specifies how to configure the HPE Ezmeral Data Fabric to work with an SSO server.

Checking and Changing the Temporary Ticket Duration
Describes how to gather information about the temporary ticket and change the duration of the ticket.

In SSO-enabled installations, the default duration for the temporary ticket is 20 minutes. To check to see if a ticket has been generated, use the `ls` command to view the contents of the `/tmp` directory. For example:

```
ls -ltr /temp/maprticket_*
-rw-rw-r-1 mapruser2 mapruser2 315 Feb 16 21:43 /tmp/maprticket_50088
```

To view the current ticket expiration, use the `maprlogin print` command:

```
$ maprlogin print
Opening keyfile /tmp/maprticket_200080
cluster-150-A: user = mapruser82, created = 'Mon May 15 20:23:42 PDT 2023',
expires = 'Mon May 15 20:43:42 PDT 2023', RenewalTill = 'Mon May 15
20:43:42 PDT 2023',
uid = 200080, gids = 20002, CanImpersonate = false, CanGenerateTicket =
false, isExternal = true, capabilities = [login, cv, a, fc]
```

To change the ticket duration:

1. Change to the `root` user (or use `sudo` for the following commands).
2. Modify the value of the `cldb.sso.temp.ticket.expiry.time` parameter in the `/opt/mapr/conf/cldb.conf` file. For more information, see cldb.conf on page 2971.
3. One node at a time on each CLDB node:
   a. Stop Warden:
      ```
      sudo service mapr-warden stop
      ```
   b. Restart Warden.
      ```
      service mapr-warden start
      ```

Using CLI Commands Without a User Ticket When SSO Is Configured
Describes how to use temporary tickets with certain command line interfaces in SSO-enabled clusters.

In this case, "command line interface" refers to any of the following:

- `maprcli`
- `hadoop`
- `mc`
- `fuse (service start)`
- `loopback nfs (service start)`

When SSO is not configured, issuing a CLI command requires a user or client to have a valid ticket in order for the command line to connect to the CLDB service.

last-updated: Jun 06, 2024

When SSO is configured, it is possible for the CLI to create temporary tickets automatically. To use this feature, you must set an environment variable before issuing the CLI command. For example:

```
export MAPR_JWT_TOKEN_LOCATION="/tmp/jwt"
```

Obtain the JWT from your SSO provider, and place it in a secure location that can be specified in the environment variable.

Exporting the environment variable creates a temporary ticket, enabling the CLI to talk to the CLDB server. This method permits the use of any command without a password for the duration of the ticket.

Using MinIO Client (mc) Without a User Ticket When SSO Is Configured
Describes how to use temporary tickets with MinIO Client (mc) commands in SSO-enabled clusters.

When SSO is not configured, issuing `mc` commands requires you to specify an AccessKey and SecretKey. You generate the keys by using the `maprcli s3keys generate` command, as described in Getting Started with HPE Ezmeral Data Fabric Object Store on page 552.

With SSO configured, it is still necessary to provide AccessKey and SecretKey. However, you can set an environment variable to satisfy this requirement. For example:

```
export MAPR_JWT_TOKEN_LOCATION="/tmp/jwt"
/opt/mapr/bin/mc alias setdemo https://<hostname> -f:9000
Added 'demo' successfully.
```

Obtain the JWT from your SSO provider, and place it in a secure location that can be specified in the environment variable.

After setting the JWT location, you can issue `mc` commands without specifying the AccessKey or SecretKey. When the environment variable is set, Data Fabric reads the JWT location from the environment variable and uses `maprcli` to contact the CLDB to obtain the AccessKey and SecretKey seamlessly.

To view the AccessKey and SecretKey for an alias, use the `mc alias ls` command. For example:

```
/opt/mapr/bin/mc alias ls demo
demo
  URL       : https://127.0.0.1:9000
  AccessKey : 6TTSP773RPYKQ8511SWVQT924MTA4M57U2BYKVB5Q83GNOABR
  SecretKey : 8KFL9W77LFMG36MJXGD057QZPL9FMN73BFJ5CDSEW09LNMHSW
  API       : s3v4
  Path      : auto
```

SSO User Login from a Cluster Node or Edge Node
Describes how to log in from a cluster node or edge node using an SSO user.

SSO users who want to log in to a cluster node or edge node must obtain the JWT from the SSO provider, and place it in a secure location that can be specified in an environment variable.

Export the JWT token file path as follows. For example:

```
export MAPR_JWT_TOKEN_LOCATION="/tmp/testuser1.jwt"
```

Exporting the environment variable creates a temporary ticket, enabling `maprcli` to talk to the CLDB server. This method permits the use of any `maprcli` command without a password for the duration of the ticket.

Temporary Ticket Expiration
Describes what happens when a temporary ticket expires.

last-updated: Jun 06, 2024

Ticket Expiration and JWT Expiration

As described in Checking and Changing the Temporary Ticket Duration on page 1049, the default duration for the temporary ticket is 20 minutes. You can increase the duration. However, it is important to understand that the JWT has an expiry time too. The SSO provider controls the JWT expiration. Data Fabric software recognizes both expiry settings and expires the temporary ticket when the lesser expiry setting is reached.

For example, if the temporary ticket expiration is set to 2880 minutes (2 days), and the JWT expiration is set to one day, the temporary ticket will expire in one day.

When a Ticket Expires

If a temporary ticket expires while you are using `maprcli`, `hadoop`, or the Minio Client (`mc`), and you have exported the location of the JWT, `maprcli` or `mc` will create a new ticket automatically. If you have not exported the location of the JWT, as described in Using CLI Commands Without a User Ticket When SSO Is Configured on page 1049 and Using MinIO Client (mc) Without a User Ticket When SSO Is Configured on page 1050, the command prompt will indicate that the ticket is not valid.

Roles and Permissions When SSO Is Configured

Describes the roles supported by the HPE Ezmeral Data Fabric in SSO-enabled clusters.

SSO-configured clusters support the following roles:

Role	Permissions	ACL Permission Code
Developer (fabric user)	Readonly and create volume permission	login, cv, cp
Infrastructure Admin	Permission to log in and start or stop services	login, ss
Fabric Manager	Full control of the cluster	login, cv, cp, fc

When SSO is not configured, Data Fabric clusters implement permissions through cluster-level access control lists (ACLs). See Creating Cluster-Level ACLs on page 1852.

When SSO is configured, Data Fabric relies on the roles defined in the JSON web token (JWT). For example:

```
  "userRoles": [
    "default-roles-user46",
    "offline_access",
    "admin",
    "developer",
    "uma_authorization",
    "cluster-admin"
  ],
```

The LDAP administrator configures these roles when a user is added to LDAP. The roles are then passed into the JWT. You can view the role permissions by issuing the `maprlogin print` command:

```
maprlogin print
testcluster: user = mapr, created = 'Fri Mar 10 02:10:34 PST 2023', expires
= 'Fri Mar 10 02:30:34 PST 2023', RenewalTill = 'Fri Mar 10 02:30:34 PST
2023',
uid = 5000, gids = 5000, 5001, CanImpersonate = true, CanGenerateTicket
= false, isExternal = true, isRemoteTempTicket = false, capabilities =
[login, cv, a, fc]
```

Data Fabric honors permissions embedded in the JWT first and then honors permissions in cluster-level ACLs.

last-updated: Jun 06, 2024

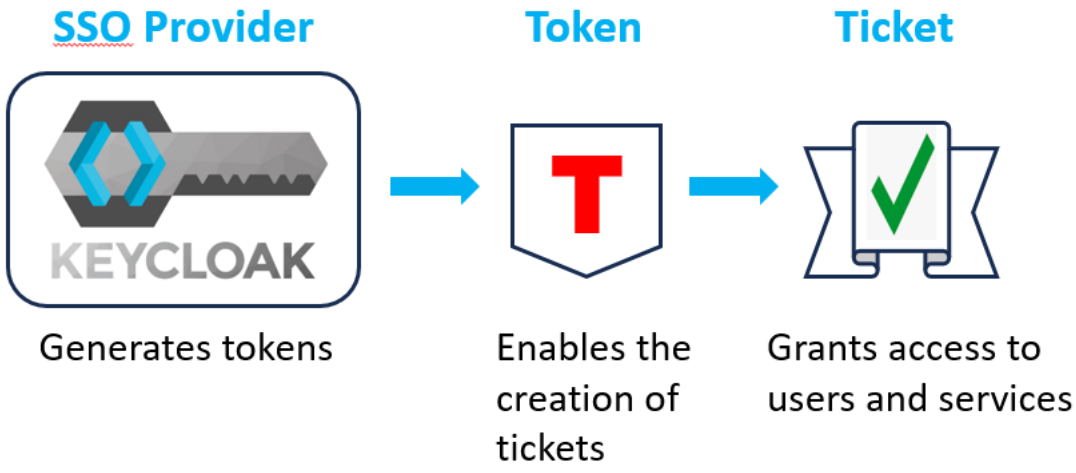
About Access and Refresh Tokens

Describes how to use the downloadable tokens provided for client access in the Data Fabric UI.

How Clients Use Tokens

In Data Fabric deployments where SSO is configured, you must provide an SSO user name and password for access to a fabric. Clients that aren't aware of SSO user names and passwords can gain access to RPC communications by using JSON web tokens (JWTs). A JSON Web Token (JWT) is a method for securely transmitting information between services in a computing system.

In a Data Fabric deployment, the Keycloak SSO provider can generate tokens when a user supplies an SSO user name and password. The tokens enable the creation of short-lived Data Fabric tickets that facilitate communication with the file system.



Issuing commands from any of the following command line interfaces (CLIs) or clients requires the user or client to have a valid ticket.

- `maprcli`
- `hadoop`
- `mc`
- `fuse` (service start)
- `loopback nfs` (service start)

The ticket allows the command line to connect to the CLDB service. To facilitate the process, you must obtain a token from the SSO provider and place it in a secure location that can be specified in an environment variable. Exporting the environment variable creates a temporary ticket, enabling the CLI to talk to the CLDB server. This method permits the use of any command without a password for the duration of the ticket.

For more information about Data Fabric tickets, see Managing Tickets.

Downloading the Tokens

In the Data Fabric UI, you use the **Client library** command to download the tokens. The tokens are contained in the `jwt_tokens.tar.gz` file, which are extracted to the client. The `jwt_tokens.tar.gz` file contains the following token files:

last-updated: Jun 06, 2024

Token Type	File	Function
Access	`jwt_access`	Encapsulates the user's authentication information within the fabric.
Refresh	`jwt_refresh`	Enables the creation of a new access token when the current access token expires.

For more information about downloading the tokens, see Installing Client Libraries.

Exporting the Tokens

To enable a client to use the tokens, you must export the path to each token. This must be done each time you establish a host session. To export the paths:

Client	To export the tokens . . .

Hadoop	Use these commands:
	`export MAPR_JWT_TOKEN_LOCATION="/root/jwt_access"`
	`export MAPR_REFRESH_TOKEN_LOCATION="/root/jwt_refresh"`

Fuse POSIX	Add the export paths shown for the Hadoop client in the first row of this table to the top of the following file: `/opt/mapr/initscripts/mapr-posix-client-basic`
Loopback NFS	Add the export paths shown for the Hadoop client in the first row of this table to the top of the following file: `/usr/local/mapr-loopbacknfs/initscripts/mapr-loopbacknfs`

Alternatively, you can add the tokens to the `core-site.xml` file. Adding them to `core-site.xml` file causes the fabric to use the designated tokens *every time you log on*. To add the tokens, specify the following property in the `core-site.xml`:

```
<property>
    <name>fs.mapr.sso.tokenpath</name>
    <value>/root/jwt_access</value>
</property>
```

Token and Ticket Expiration and Renewal

Tokens and tickets expire after a short time. By default, Keycloak-generated tokens expire after two (2) hours. Short-lived tickets expire after 20 minutes.

If an access token expires or becomes invalid, the client application can use a refresh token to obtain a new access token without requiring the user to re-authenticate. The client application sends Keycloak a token-refresh request along with the current refresh token. Keycloak validates the refresh token and issues a new access token. This automatic-refresh mechanism repeats itself to allow client jobs to run for days or weeks as long as the tokens remain valid.

Changing Token and Ticket Durations

You can change the valid duration of tokens and tickets. Note that a ticket is valid for no more than 20 minutes or the expiry time of its associated access token, *whichever is lower*. Thus, if a ticket expiry time is set for 20 minutes and the associated access token is valid only for 10 minutes, the ticket will be valid for only 10 minutes.

last-updated: Jun 06, 2024

CAUTION: Setting long lifetimes for tokens or tickets can introduce a considerable security risk. Hewlett Packard Enterprise recommends finding a balance between security and usability and, whenever possible, erring on the side of security in your use of tokens and tickets.

To check or change the expiry setting for short-lived tickets, see Checking and Changing the Temporary Ticket Duration.

To change the expiration setting for a token, you must be the fabric manager and have access to the Keycloak UI.

Access Token Expiry

You can configure the access token expiry time at the realm level or at the client level.

1. Log in to the Keycloak admin console. See Accessing the Keycloak Administration Console on page 1030.
2. Select the realm for which you want to configure the access token expiry time.
3. Go to the **Realm Settings > Tokens** tab.
4. In the **Access Token Lifespan** field, specify the desired expiration time for the access tokens in hours, minutes, or days.
5. Save your changes.

Refresh Token Expiry

You typically configure the refresh token expiry time at the realm level:

1. Log in to the Keycloak admin console. See Accessing the Keycloak Administration Console on page 1030.
2. Select the realm for which you want to configure the access token expiry time.
3. Go to the **Realm Settings > Sessions** tab.
4. In the **SSO Session Max** field, specify the desired maximum lifespan for refresh tokens in minutes, hours, or days.
5. Save your changes.

Managing Permissions
Provides an overview of managing user permissions at the cluster, volume and file system levels.

You can manage user permissions at the cluster, volume, and filesystem levels. Cluster and volume permissions use access control lists (ACLs) to specify which actions a user can perform on a cluster or volume. File system permissions and *ACE*s control user access to volumes, directories, and files, similar to Linux file permissions. Users get the permissions that are directly assigned to them as well as the permissions assigned to the groups they are in. You must have `fc` permissions to manage permissions.

Adding Cluster Permissions
Describes how to set cluster permissions for users and groups through the Control System and the CLI.

About this task

The following table lists the actions that a user can perform on a cluster with the corresponding UI columns and codes used in the cluster *Access Control List (ACL)*:

last-updated: Jun 06, 2024

UI	ACL	Allowed Action
Login	login	Log in to the Control System, use the API and command-line interface, read access on cluster and volumes
Start/Stop Service	ss	Start and stop services
Create Volumes	cv	Create volumes
Create Security Policy	cp	Required to create security policies. Users with Administrator (a) access can assign this permission to other administrators.
Administrator	a	Administrative access (can edit and view *ACL*s, but cannot perform cluster operations)
Full Control	fc	Full control over the cluster. This enables all cluster-related administrative options with the exception of changing the cluster *ACL*s.

Setting Permissions Using the Control System

About this task
Complete the following steps to add cluster permissions in the Control System:

Procedure

1. Log in to the Control System and click **Admin** > **User Settings** > **Permissions**.
2. Under **USER PERMISSIONS**, select the type and specify the name of the user or group in the **Name** field.
3. Select the checkbox associated with the permissions you want to grant to the user or group.
4. Click **Add Another** to add permissions for another user or group.
   Each row lets you assign permissions to a single user or group.

   NOTE: A user gets the permissions directly granted to the user as well as permissions granted to any group to which the user belongs.
5. Click **Save Changes** to save the changes.

Setting Permissions Using the CLI or the REST API

About this task

To set permissions using the CLI, run the following command:

```
/opt/mapr/bin/maprcli acl set
    [ -cluster <cluster name> ]
    [ -group <group> ]
    [ -name <name> ]
    -type cluster|volume|securitypolicy
    [ -user <user> ]
```

last-updated: Jun 06, 2024

See `acl set` on page `2001` for complete reference information.

Granting a User Full Control from the Command-Line

About this task

The user who has full control over the cluster can manage all aspects of the cluster operation except assign permissions for other users.

Complete the following steps to give full administrative control to a user:

Procedure

1. Log on to any cluster node as `root` (or use `sudo`).
2. Execute the following command, replacing `<user>` with the username of the account that gets administrative control: `sudo /opt/mapr/bin/maprcli acl edit -type cluster -user <user>:fc`

   For general information about users and groups in the cluster, see Managing Users and Groups.

Removing Cluster Permissions
Describes how to remove cluster permissions using the Control System or the CLI.
Removing Cluster Permissions Using the Control System

About this task
Complete the following steps to remove cluster permissions in the Control System:

Procedure

1. Log in to the Control System and click **Admin** > **User Settings** > **Permissions**.
2. Remove the desired permissions:
   - To remove all permissions for a user or group, click ⛔ associated with the row.
   - To change the permissions for a user or group, deselect the checkbox associated with the permissions you wish to revoke from the user or group.
3. Click **Save Changes** to save the changes.

Removing Cluster Permissions Using the CLI or REST API

About this task

The `acl set` command specifies the entire *ACL* for a cluster or volume. Any previous permissions are overwritten by the new values, and any permissions omitted are removed. To remove cluster permissions, run the `acl set` command and omit the permissions to remove. See `acl set` on page `2001` for complete reference information.

Blocking Users Using the CLI
Explains how to block users using the CLI.

About this task

You can block users using the CLI. When a user is blocked, all existing tickets for the user are canceled and any request sent by the user that has a ticket older than the blocked timestamp is rejected. For more information, see How Tickets Work on page 1831.

last-updated: Jun 06, 2024

Blocking Users Using the CLI or REST API

About this task

The basic command to blacklist a user is:

```
maprcli denylistuser -user <user name>
```

For complete reference information, see blockaccess user on page 2039.

Managing the Cluster

Lists the settings for managing the data-fabric cluster.

You can add licenses, set up auditing of cluster administration, configure disk space balancer tool settings and Role Balancer settings, configure how MapReduce programs run, allocate quotas for users and groups and set the cluster reserve limit, and generate the DNS Gateway record for table replication using both the Control System (click **Admin** > **Cluster Settings**) and the CLI.

Managing Auditing

Provides instructions for using data-fabric auditing features.

You can enable auditing of cluster administration and data-access operations using the Control System and the CLI. Enabling auditing of the filesystem, table, and streams operations requires running a command on a cluster, a command on individual volumes in the cluster, and a command on individual directories, files, and HPE Ezmeral Data Fabric Database tables and streams within those volumes.

These steps are summarized in the following table:

	Steps to enable auditing			
	Enable auditing of cluster administration	Enable data auditing on the cluster	Enable auditing of individual volumes	Enable auditing of individual directories, files, and HPE Ezmeral Data Fabric Database tables
Auditing of cluster administration		Not applicable	Not applicable	Not applicable

last-updated: Jun 06, 2024

Auditing of directories, files, and HPE Ezmeral Data Fabric Database tables	Not applicable			

Prerequisites for enabling auditing

- If you upgraded your data-fabric cluster from version 4.1 or earlier, you must enable the auditing feature.
  - Run `maprcli config save -values {"mfs.feature.audit.support":"1"}`
  - To verify that the feature is enabled, run `maprcli config load -json | grep "mfs.feature.audit.support"`
- Only the `root` user or `mapr` user can enable or disable auditing.

Enabling and Disabling Auditing of Cluster Administration
Describes how to enable and disable cluster administration auditing using the Control System and the CLI.

About this task

You can enable or disable auditing of cluster-management operations on a HPE Ezmeral Data Fabric cluster using the Control System and the CLI. See Auditing Cluster Operations on page 847 for the complete list of cluster management commands that are audited.

Enabling and Disabling Auditing of Cluster Administration Using the Control System

About this task

Procedure

1. Log in to the Control System and go to the **Auditing** tab in the **Admin** > **Cluster Settings** page.
2. Move the **Enabled** slider to **Yes** to enable and **No** to disable cluster auditing.
3. Click **Save Changes** for the changes to take effect.

Enabling and Disabling Auditing of Cluster Administration Using the CLI or REST API

About this task

To enable or disable auditing of cluster-management operations on a data-fabric cluster, run the `maprcli audit cluster` command.

```
maprcli audit cluster -enabled <true | false>
```

For complete reference information, see `audit cluster` on page 2035.

Enabling and Disabling Auditing of Data Access Operations
Describes how to enable or disable auditing of data-access operations using the Control System and the CLI.

About this task

See Auditing Data Access Operations on page 849 for the complete list of data-access operations that can be audited.

Enabling and Disabling Auditing of Data Access Operations Using the Control System

About this task

To enable or disable auditing of data-access operations on a cluster:

Procedure

1. Log in to the Control System and go to the **Auditing** tab in the **Admin** > **Cluster Settings** page.
2. Set the following:

Enabled	Move the slider to **Yes** to enable or to**No** to disable data auditing.
Maximum Size	Set the size in GB, which when reached causes an alarm to be sent to the dashboard on the Control System. The alarm is to notify the cluster administrator that the audit log size is large enough to need administrator intervention. The audit log continues to grow until the administrator takes action or until the retention period ends.
Retain Logs for	Set the period of time in days to keep the data in the audit log. After this period elapses, the content of the file is deleted and new entries are added to the file until the retention period elapses.

3. Click **Save Changes** for the changes to take effect.

NOTE: This action does not cause auditing to start for operations within the volumes. It only sets a flag that indicates that you allow auditing of individual volumes to be enabled when volume is created or modified.

Enabling and Disabling Auditing of Data Access Operations Using the CLI or REST API

Procedure

1. To enable or disable auditing of the filesystem, table, and streams operations on a cluster, run the `maprcli audit data` command.

   This command does not cause auditing to start for operations within those volumes. It only sets a flag that indicates you allow auditing of individual volumes to be enabled with the `maprcli volume audit` command. The audit logs for file operations, table operations, and stream operations are affected by the value that you set for the `-retention` parameter.

2. To enable or disable auditing for a particular volume, run the `maprcli volume audit` command. To verify that auditing is enabled for a volume, run the `maprcli volume info` command.
   You can grep with the search term `'audited\|coalesce'`.

   ```
   maprcli volume info -name <volume_name> -json | grep -i 'audited\|
   coalesce'
   ```

   The output of the command should be as follows, with a 1 for the `audited` key and the value for the `coalesceinterval` key: `"audited":1, "coalesceInterval":2`

last-updated: Jun 06, 2024

3. To enable or disable auditing for a particular directory, file, HPE Ezmeral Data Fabric Database table, or streams that existed in a volume at the time that you ran the `maprcli volume audit` command, run the `hadoop mfs` command with the `-setaudit` parameter.

   ```
   hadoop mfs -setaudit <on|off> <directory|file|table>
   ```

   NOTE: Wildcards are not supported for the names of filesystem objects in this command.

   Enabling auditing on a directory does not enable auditing on the files that already exist in the directory, though new files and directories created in the directory will have auditing enabled. For example, if you run this command on the root directory of a volume, all new files, directories, and tables that are subsequently created in the volume are audited. The creation of those objects is also audited.

Results

After enabling auditing, if you create a:

- Snapshot of a volume, the snapshot inherits the audit settings of the original volume.
- Local mirror or remote mirror of a volume, you must run the `maprcli volume audit` command to enable auditing on the mirror volume. Auditing for particular directories, files, and HPE Ezmeral Data Fabric Database tables in a mirror volume is automatically enabled if auditing is enabled for them in the source volume.

How Does Auditing Work?
Explains how auditing works on data-fabric objects.

When you enable the auditing of a particular directory, file, table, or stream, you set the *audit bit* to "on" for that object. You can tell whether auditing is enabled for a directory, file, or table by checking the status of the object's audit bit.

For example, the volume as shown in the following tree diagram, consists of the root directory, the two directories `dir1` and `dir2`, and two files in directory `dir1`. Every directory, file, table, and stream in a volume has an “audit bit” associated with it. You can tell whether, say, `dir1` has its audit bit on and is therefore enabled for auditing by running the `hadoop mfs -ls` command. The output of the command might look like as follows:

```
drwxrwxrwx Z U U 3 root root 100 2015-05-20 21:09 192473738 /dir1
```

The second `U` indicates that auditing is not enabled on the directory.

However, an `A` in place of that `U` indicates that auditing is enabled on the directory:

```
drwxrwxrwx Z U A 3 root root 100 2015-05-20 23:41 192473738 /dir1
```

In the first diagram, as well as in the next two diagrams, `U` indicates that the audit bit is turned off for a filesystem object and `A` indicates that the audit bit is on for that object. After you run `maprcli volume audit` on the volume, none of the audit bits are on:

```
/              U
-/dir1          U
 -file1         U
 -file2         U
-/dir2          U
```

Suppose you enable auditing on the root directory by running this command:

```
hadoop mfs -setaudit on /
```

last-updated: Jun 06, 2024

Then, you create the file `file3` in `dir2` and you create the directory `dir3` and the file `file4` in it. The tree diagram now looks as follows :

```
/           A
-/dir1          U
 -file1         U
 -file2         U
-/dir2          U
 -file3         U
-/dir3          A
 -file4         A
```

The audit bit is still `U` on `dir1`, and the files are in `dir1`, and `dir2`. The new file `file3` in `dir2` inherits the audit bit from `dir2`.

`dir3` inherits the audit bit from the root folder, so the audit bit for `dir3` is `A`. Moreover, `file4` inherits the audit bit from `dir3`, so its audit bit is `A`, as well.

Next, you run the following command to enable auditing in `dir1`:

```
hadoop mfs -setaudit on /dir1
```

Then, you create the file `file5`. The new file inherits the audit bit from its parent folder, so it is enabled for auditing immediately after it is created. However, `file1` and `file2` still have the audit bit turned off.

```
/         A
-/dir1          A
 -file1         U
 -file2         U
 -file5         A
-/dir2          U
 -file3         U
-/dir3          A
 -file4         A
```

As file1 and file2 existed before you turned on the audit bit for their parent folder, you need to enable auditing for them as follows:

```
hadoop mfs -setaudit on /dir1/file1
```

```
hadoop mfs -setaudit on /dir1/file2
```

Selective Auditing of File-System, Table, and Stream Operations Using the CLI
Explains how to audit Data Fabric objects selectively.

Administrators can specify file-system, table, or stream operations to include or exclude from auditing. The operations that can be included or excluded from auditing are listed here.

Including or excluding specific operations from auditing requires running the `maprcli` command. You can specify the list of operations to include or exclude from auditing during volume creation using the `maprcli volume create` command, and afterwards using the `maprcli volume modify` or `maprcli volume audit` command.

To:

- Include operations for auditing, use the plus sign (+) before the operation.

- Exclude operations from auditing, use the minus sign (`-`) before the operation.

  NOTE: If the first operation in the list is to be excluded from auditing, it must be preceded by two minus (`--`) signs. Subsequent operations to exclude from auditing must be preceded by only a single minus (`-`) sign, whether or not the first operation was included (using a plus (+) sign) or excluded (using two minus (`--`) signs).

NOTE: If neither (plus (+) or minus (`-`)) sign is specified before an operation, the given operation is included for auditing.

Including and/or Excluding Operations

Including or excluding specific operations from auditing requires running the `maprcli` command.

Include or Exclude Operations During Volume Creation

During volume creation, the specified list of operations must either be included for auditing or excluded from auditing. You cannot specify a mixed list of included and excluded operations.

By default, all other operations other than the specified operations are:

- Included for auditing if the specified list is a list of excluded operations.
- Excluded from auditing if the specified list is a list of included operations.

Examples

The following example shows how to enable auditing and exclude specific operations (such as `lookup`, `read`, and `write`) from auditing:

```
maprcli volume create -name test-volume -path /test/
test-volume -auditenabled true -dataauditops --lookup,-read,-write
```

In the above example, operations other than the ones specified are included for auditing.

The following example shows how to include all operations except `lookup` for auditing:

```
maprcli volume create -name test-volume -path /test/
test-volume -dataauditops --lookup
```

The following example shows how to include only `chown` operation for auditing and exclude all other operations from auditing:

```
maprcli volume create -name test-volume -path /test/
test-volume -dataauditops +chown
```

Include and Exclude Operations After Volume Creation

After volume creation, you can include and exclude certain operations from auditing using the `volume modify` or `volume audit` command. When you modify a volume (by running the `volume modify` command) or when you enable volume auditing (by running the `volume audit` command), you can specify a mixed list of included and excluded operations. There are no changes to operations that are not specified with the command.

For the list of operations that can be included and/or excluded from auditing, see Auditing of Filesystem Operations and Table Operations.

Examples

last-updated: Jun 06, 2024

The following example shows how to include `create` operation for auditing and exclude `lookup` operation from auditing:

```
maprcli volume modify -name test-volume -dataauditops +create,-lookup
```

The following example shows how to include all operations except `lookup` for auditing:

```
maprcli volume audit -name test-volume -dataauditops +all,-lookup
```

Grouping of Operations

You can group all file system and table operations using the keyword `all`. If the operations to:

- Include for auditing are specified using the keyword `all`, you cannot specify other individual operations to include as well.

  For example, the following is *not* allowed:

  ```
  maprcli volume modify -name v1 -dataauditops +all,+mkdir
  ```

- Exclude from auditing are specified using the keyword `all`, you cannot specify other individual operations to exclude as well.

  For example, the following is *not* allowed:

  ```
  maprcli volume modify -name v1 -dataauditops --all,-mkdir
  ```

If operations are specified using the keyword `all`, ensure that the individual operations specified with the same command are used to:

- Include, if `all` is used to exclude from auditing.
- Exclude, if `all` is used to include for auditing.

For example, the following is a valid combination of operations to audit:

```
maprcli volume modify -name v1 -dataauditops +all,-mkdir,-lookup
```

Verifying Selective Auditing of Operations

After you set up the list of operations to include and/or exclude from auditing, you can retrieve and verify the list of included and/or excluded operations using the `maprcli volume info` command. When you run the `volume info` command, the output will show the list of operations:

- Excluded (`disableddataauditoperations`) from auditing.
- Included (`enableddataauditoperations`) for auditing.

Example

The following example shows how to retrieve and verify the list of operations that are:

- Excluded from auditing
- Included for auditing

```
maprcli volume info -name test-volume -path /test/test-volume -json
```

last-updated: Jun 06, 2024

Output

```

```

Specifying Operations to Audit Using a Security Policy

About this task

You can specify the directory, file, and table operations to audit in a security policy. If you specify the operations to audit in a security policy and tag data objects (such as volumes and tables) with the policy, the enforcement mode setting in the policy is used to determine how the setting affects auditing of operations on the data objects. For more information, see Volume-Level Security Policy Enforcement Mode on page 861.

You can specify the directory, file, and table operations to audit in a security policy using the Control System, CLI, and the REST API.

Specifying Audit Operations in a Security Policy Using the Control System

Procedure

1. Log in to the Control System and go to one of the following pages:
   - Create Security Policy to set the list of operations to audit when creating a policy.
   - Edit Security Policy to set new or modify existing list of operations to audit.
2. Move the slider associated with **Enable Audit Operations** from **No** to **Yes** to enable auditing if it is already not enabled.

last-updated: Jun 06, 2024

3. Choose the **Default** radio button to accept the default list of operations to audit or choose the **Custom** radio button to select/deselect the operations to audit.

   For more information on the list of operations that can be audited, see Auditing Data Access Operations on page 849.

4. Specify or modify other properties as needed and click **Save** for the changes to take effect.

   For more information, see:

   - Creating a Security Policy on page 1893
   - Modifying a Security Policy on page 1902

Specifying Audit Operations in a Security Policy Using the CLI and REST API

Enabling and Disabling Audit Streaming Using the CLI

Explains how to enable or disable audit streaming using the CLI.

About this task

Audit streaming is not enabled by default. You can enable or disable audit streaming using the CLI.

Procedure

Run the following command to:

- Enable audit streaming:

```
maprcli config save -values '{"mfs.enable.audit.as.stream":"1"}'
```

  NOTE: If you are re-enabling audit streaming after disabling it, the audit stream starts publishing to topics from where it left off processing audit logs.

- Disable audit streaming:

```
maprcli config save -values '{"mfs.enable.audit.as.stream":"0"}'
```

Configuring Balancer Settings

Provides an overview of the HPE Ezmeral Data Fabric disk space and replication role balancers.

You can use the disk space balancer and the replication role balancer to redistribute data and containers in the HPE Ezmeral Data Fabric storage layer to ensure maximum performance and efficient use of space. The disk space balancer works to ensure that the percentage of space utilized on all storage pools in the cluster is similar and prevent nodes from being overloaded. The replication role balancer changes the replication roles of containers so that the replication process uses network bandwidth evenly.

You can pipe the `maprcli config load` command through `grep` to view the balancer configuration values.

Example:

```
maprcli config load -json | grep balancer
         "cldb.balancer.disk.deltaToRepopulateStoragePoolsBins":"5",
         "cldb.balancer.disk.deltatorepopulatestoragepoolsbins":"5",
         "cldb.balancer.disk.max.switches.in.nodes.percentage":"10",
         "cldb.balancer.disk.overused.threshold":"90",
         "cldb.balancer.disk.sleep.interval.sec":"120",
         "cldb.balancer.disk.threshold.percentage":"70",
         "cldb.balancer.logging":"0",
         "cldb.balancer.role.max.switches.in.nodes.percentage":"10",
         "cldb.balancer.role.paused":"1",
```

last-updated: Jun 06, 2024

```
          "cldb.balancer.role.skip.container.active.sec":"600",
          "cldb.balancer.role.sleep.interval.sec":"900",
          "cldb.balancer.startup.interval.sec":"1800",
          "cldb.disk.balancer.enable":"0",
          "cldb.role.balancer.replicascount.tolerance":"1",
          "cldb.role.balancer.replicassize.tolerance":"5",
          "cldb.role.balancer.strategy":"BySize",
         "prevent.volume.skew.by.diskbalancer":"0",
```

You can use the `config save` command to set the appropriate balancer configuration values.

Example:

```
maprcli config save -values
{"cldb.balancer.disk.max.switches.in.nodes.percentage":"20"}
```

NOTE: By default, the balancers are turned off.

- To turn on the disk space balancer, use `config save` to set `cldb.disk.balancer.enable` to `1`.
- To turn on the replication role balancer, use `config save` to set `cldb.balancer.role.paused` to `0`.

Disk Space Balancer
Describes the role of the disk space balancer.

The *disk space balancer* is a tool that balances disk space usage on a cluster by moving containers between nodes (subject to the constraints of the topology of the volume to which a container belongs). This movement of containers ensures that the percentage of space used on all the disks in the cluster is similar. The disk space balancer balances at the level of storage pools (SPs), keeping them at the same utilization level as the cluster average.

NOTE:

- Utilization Level of a SP = (Used space of the SP / Storage capacity of the SP)
- Cluster Average = (Used space across all SPs / Capacity of all SPs)

The disk space balancer distributes containers from highly utilized storage pools on one node in a cluster to less utilized storage pools on other nodes in the same cluster. It accomplishes this by first classifying storage pools into different bins (based on their utilization level). It checks every storage pool on a regular basis (every 2 minutes by default) and then classifies storage pools into bins based on their percentage utilization.

After classifying the storage pools into bins, the disk space balancer then moves containers (in two phases) out of the storage pools with more containers to storage pools with fewer containers. That is, it moves containers out of storage pools in higher bins to storage pools in lower bins in two phases:

- Phase 1 — storage pools in ‘Overused’ and ‘Above Average’ bins are balanced.
- Phase 2 — storage pools in ‘Average’ and ‘Below Average’ bins are balanced.

  NOTE: Movement of containers in phase 2 happens only when there are not many containers scheduled to be moved in phase 1, because movement of container at any point in time is throttled.

In both phases, the disk balancer attempts to move containers from storage pools in the highest utilized bin (the source SP) to suitable storage pools in the lowest utilized bin (the destination SP). If a suitable SP

last-updated: Jun 06, 2024

could not be found as the destination, the balancer attempts to move a container to the next least utilized bin. An SP is not deemed suitable as the destination if:

- Moving a container to that SP would cause the SP to move to the next bin.
- Data movement into the file server to which the SP belongs is blocked.
- SP is not in the same topology as specified by the volume.
- Certain number of containers are currently being moved into the SP.

  NOTE: The number of simultaneous moves to a SP is capped at 2.
- SP is in the same bin as the source SP.
- Many containers of a container group associated with the same tiering-enabled volume reside on the SP.

  This feature ensures that containers of a container group associated with a tiering-enabled volume are distributed evenly across SPs and do not gather in a few SPs. The balancer accomplishes this by determining whether the destination SP has containers from the container group for the volume associated with the container that is identified for being moved to the destination SP.

An SP or its containers are not considered for balancing if:

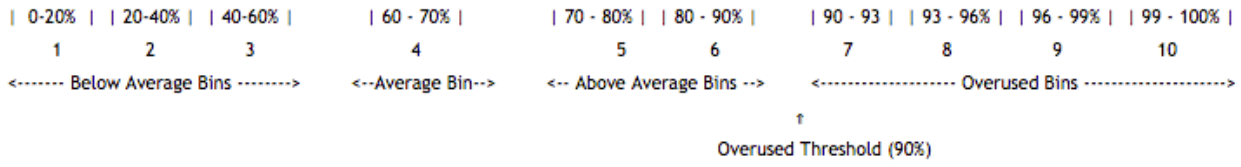
- Data movement from the file server to which the SP belongs is blocked.
- Container was active (that is, written to) in the previous 5 minutes.
- Containers were deleted in the previous minute.

  This is to allow space reclamation. If necessary, the bin will be balanced during the next iteration of the disk balancer.
- Percentage of data that is being transferred out of an SP is greater than or equal to 2% of the SP's storage capacity.
- Certain number of containers are currently being moved out of the SP.

  NOTE: The number of simultaneous moves out of an SP is capped at 2.

Sample Disk Balancer Settings for Organization of Bins

The following example illustrates disk balancer settings and the corresponding organization of bins to represent storage pool utilization:



In the preceding example, the:

1. Average cluster space utilization is 65%.
2. Average bin size is 10%. Hence, the average bin spans 5% on each side of the average space utilization.
3. Overused threshold is 90%.

last-updated: Jun 06, 2024

4. Below average bin size is 20%.

   Below average bin utilization is partitioned into required number of bins (3). During division, the bin that is immediately to the left of the average bin might not span the default value. In other words, if the average bin spans from 50% to 60%, the below average bins will be cast as 0-20%, 20-40%, 40-50%.

5. Above average bin size is 10%.

   Since the overused threshold is 90%, the above average bins span the utilization from the right boundary of the average bin up to the overused threshold. As with below average bins, as many possible bins are cast with the size of the above average bin, leaving the remaining utilization to be covered by the last (right-most) above average bin.

Enabling and Configuring Disk Balancer
Describes how to enable or disable the disk space balancer and other settings using the Control Panel and the CLI.

About this task
Enabling and Configuring Disk Balancer Using the Control System

About this task

To enable and configure disk space balancer using the Control System:

Procedure

1. Log in to the Control System and click **Admin** > **Clusters Settings** > **Balancer**.
2. In the Disk Balancer section, move the **Enabled** slider to **Yes**.
   To enable disk space balancer from the command-line, see Configuring Disk Balancer Execution on page 1069.
3. Select one of the presets or specify a custom percentage for **Threshold** and **Concurrent Disk Rebalancer** settings. You can :
   - **Disk Balancer Preset**:

     Moderate (Default)
     - **Threshold** — 70%
     - **Concurrent Disk Rebalancer** — 10%

     Rapid
     - **Threshold** — 50%
     - **Concurrent Disk Rebalancer** — 5%

     Relaxed
     - **Threshold** — 90%
     - **Concurrent Disk Rebalancer** — 25%

   - **Custom**, use the slider to set the threshold and concurrent disk rebalancer percentages.

   Here:

Threshold	Specifies the minimum utilization threshold for a storage pool to become eligible for rebalancing. Default value is 70%.
Concurrent Disk Rebalancer	Specifies the maximum percentage of data that can be rebalanced. The cluster will wait until the number of rebalancing operations affects less than this percentage of total data eligible for rebalancing. The default value is 10%.

last-updated: Jun 06, 2024

4. Click **Save Changes** for the changes to take effect.

Enabling and Configuring Disk Balancer Using the CLI

About this task

The disk space balancer checks every storage pool on a regular basis and moves containers from a storage pool when that pool's utilization meets the following conditions:

- The storage pool is over 70% full.
- The storage pool's utilization exceeds the average utilization on the cluster by a specified threshold:
  - When the average cluster storage utilization is below 80%, the threshold is 10%.
  - When the average cluster storage utilization is below 90% but over 80%, the threshold is 3%.
  - When the average cluster storage utilization is below 94% but over 90%, the threshold is 2%.

You can use the `config save` command to modify disk space balancer parameter values.

Example: `# maprcli config save -values {"cldb.balancer.disk.max.switches.in.nodes.percentage":"20"}`

The following list specifies the disk space balancer configuration parameters with their default values and descriptions:

cldb.disk.balancer.enable	*Default Value*: 1 *Description*: Specifies whether the disk space balancer runs: • 0 - Disabled (does not perform any container moves) • 1 - Enabled (normal operation) By default, the disk balancer is disabled.
cldb.balancer.disk.threshold.percentage	*Default Value*: 70 *Description*: Threshold for moving containers out of a given storage pool, expressed as utilization percentage. See also: Balancing Overused and Above Average Bins on page 1071.
cldb.balancer.disk.max.switches.in.nodes.percentage	*Default Value*: 10 *Description*: This can be used to throttle the disk balancer. If it is set to 10, the balancer will throttle the number of concurrent container moves (minimum 1) to 10% of the total nodes in the cluster rounded up. See Configuring Throttling on page 1071.

Configuring Disk Balancer Execution
Explains how to tune the disk balancer execution parameters.

Even when the disk balancer is enabled, the disk balancer waits during cluster startup to give enough time for the cluster to settle down. The default wait time (specified in seconds) is 30 minutes and can be changed using the parameter `cldb.balancer.startup.interval.sec`. After every run, the disk balancer pauses for 2 minutes by default. The pause time (specified in seconds) can be increased through the parameter `cldb.balancer.disk.sleep.interval.sec`.

Run the `maprcli config save` command and set the following parameters to configure disk balancer:

last-updated: Jun 06, 2024

Parameter	Default Value	Description
`cldb.balancer.startup.interval.sec`	1800 seconds	Wait time, in seconds, for cluster startup.
`cldb.balancer.disk.sleep.interval.sec`	120 seconds	Interval, in seconds, between disk balancer runs.

For example, to:

- Increase the wait time to an hour, change the default value of 1800 seconds to 3600 seconds:

```
maprcli config save -values {"cldb.balancer.startup.interval.sec":"3600"}
```

- Increase the pause time between disk balancer runs from 2 minutes to 5 minutes, change the default value of 120 seconds to 300 seconds:

```
maprcli config save -values
{"cldb.balancer.disk.sleep.interval.sec":"300"}
```

Preventing Volume Skew

By default, the disk balancer does not consider volume skew while moving containers out of a Storage Pool (SP). In the process, all containers of a volume may end up on only a few SPs. Such a volume skew is undesirable, specifically, for DB volumes. In such a skew, few servers handle all requests, resulting in reduced performance.

To prevent volume skew, set the `prevent.volume.skew.by.diskbalancer` parameter to `true` as follows:

```
maprcli config save -values {"prevent.volume.skew.by.diskbalancer":"true"}
```

This parameter checks whether moving a container out of a SP causes a volume skew elsewhere.

NOTE: Enabling this parameter may result in containers failing the volume underweight check and failing to be moved from a full SP. Consider this limitation and enable as per your need.

Configuring Bin Size
Explains how to configure the sizes of the various bins used by the disk balancer.

The number of bins used by the disk balancer is not constant and is determined by the sizes of different bins. You can configure the size of each of the bins (Below Average, Average, Above Average, and Overused) individually at run time. The larger the size of the bins, the greater the chance that two SPs that are in the vicinity of each other with respect to utilization fall in the same bin.

The default size of overused bins is only 3%, because SPs in this bin must be balanced at a finer granularity. The default size of above average, average, and below average bins is 20%. You can aggressively balance the storage pools across bins by reducing the size of each bin, forcing the SPs to fall into different bins. To reduce the size of each bin, specify the value for the following parameters using the `maprcli config save` command:

Parameter	Description
`dbal.above.avg.bin.size`	Specifies the bin size (%) of SPs whose usage is above the cluster average. The default is 20%.
`dbal.avg.bin.size`	Specifies the bin size (%) of SPs whose usage is in the average range. The default is 20%.
`dbal.below.avg.bin.size`	Specifies the bin size (%) of SPs whose usage is below the cluster average. The default is 20%.

last-updated: Jun 06, 2024

Parameter	Description
`dbal.overused.bin.size`	Specifies the bin size (%) of SPs whose usage is in the overused range. The default is 3%.

For example, to reduce the size of the Below Average bin to 10%, run the following command:

```
maprcli config save -values {"dbal.below.avg.bin.size":"10"}
```

Balancing Overused and Above Average Bins
Describes how to balance highly utilized Overused and Above Average bins.

Storage pools in the Overused and Above Average bins are highly utilized. The default threshold of “overused” is 90%, which means that the first overused bin’s lower bound is 90%. You should in normal circumstances, never reset this threshold, but you can, if necessary, by setting the value for the parameter `cldb.balancer.disk.overused.threshold` using the `maprcli config save` command. For example:

```
maprcli config save -values {"cldb.balancer.disk.overused.threshold":"95"}
```

In scenarios where the cluster average is low, storage pools in Above Average bins too might not be highly utilized. In this case, to prevent unnecessary balancing activity, disk balancer uses an additional criterion to prevent wasted moves: only those storage pools whose utilization equals to or is greater than a certain threshold are considered for balancing. This threshold is controlled by the configurable parameter `cldb.balancer.disk.threshold.percentage`, whose default value is 70%.

NOTE: If the threshold of the Overused bin is set below the default value of 90%, the balancing threshold specified in the `cldb.balancer.disk.threshold.percentage` parameter is also applicable to Overused bins also.

Balancing Average and Below Average Bins
Provides an overview of how the disk balancer balances the Average and Below Average storage pool bins.

The primary task of the disk balancer is to balance highly utilized storage pools in Overused and Above Average bins. However, the disk balancer can also balance storage pools that are less utilized, for example, to distribute workload evenly across the nodes, or if a new node is added to the topology to add more storage. By default, the disk balancer performs this kind of balancing less frequently than the balancing of disk space utilization.

By default, the disk balancer balances storage pools in Average and Below Average bins every 6 hours. You can configure the interval by the setting the value (in minutes) for the parameter `dbal.below.avg.bins.balancing.frequency` using the `marpcli config save` command. For example:

```
maprcli config save -values
{"dbal.below.avg.bins.balancing.frequency":"360"}
```

NOTE: The disk balancer considers storage pools in these two bins only under the following conditions:

1. When there is not already too much SP balancing activity in the highly utilized bins.
2. If container movement out of SPs in the highly utilized bins is not possible.

Configuring Throttling
Explains how to throttle the number of container moves.

last-updated: Jun 06, 2024

Although balancing storage pool disk space use is important, it requires network, computation, and disk bandwidth that must be shared with other functions. Hence, the number of container moves at any point of time is throttled.

The throttling factor controls the number of active container moves. If there are 100 nodes, and the throttling factor is 10, there can be 10 active moves. If however, the value is 12 (%), there can be 12 active moves.

NOTE: If you set the throttling factor to 0, the number of active moves is 1.

Therefore, effectively, the number of active moves is:

```
Max(1, throttling_factor x number_of_cluster_nodes)
```

By default, the maximum number of container moves is 10% of the number of nodes in the cluster. However, you can configure the throttling factor (percentage) by setting the parameter `cldb.balancer.disk.max.switches.in.nodes.percentage` using the `maprcli` command.

For example, to set the throttling factor to 12% of the number of nodes in the cluster, run the following command:

```
maprcli config save -values
{"cldb.balancer.disk.max.switches.in.nodes.percentage":"12"}
```

Retrieving Status of Storage Pools
Describes the CLI command to retrieve the status of Storage Pools.

You can use the `maprcli dump balancerinfo` command to view detailed information about the Storage Pools on a cluster.

Example:

```
# maprcli dump balancerinfo
usedMB  fsid                spid                              percentage
outTransitMB  inTransitMB  capacityMB
209     5567847133641152120  01f8625ba1d15db7004e52b9570a8ff3  1
0             0             15200
209     1009596296559861611  816709672a690c96004e52b95f09b58d  1
0             0             15200
```

If there are any active container moves when you run the command, `maprcli dump balancerinfo` returns information about the source and destination storage pools:

```
# maprcli dump balancerinfo -json
        ....
        {
        "containerid":7840,
        "sizeMB":15634,
        "From fsid":8081858704500413174,
        "From IP:Port":"10.50.60.64:5660-",
        "From SP":"9e649bf0ac6fb9f7004fa19d200abcde",
        "To fsid":3770844641152008527,
        "To IP:Port":"10.50.60.73:5660-",
        "To SP":"fefcc342475f0286004fad963f0fghij"
        }
```

Retrieving Balancer Status
Describes how to view the active container movement information from the Control Panel and the CLI.

last-updated: Jun 06, 2024

You can view the active container moves information from the CLDB page on the Control Panel or use the `maprcli dump balancermetrics` command to see a cumulative count of container moves and MB of data moved between storage pools since the current CLDB became the primary CLDB.

Example:

```
# maprcli dump balancermetrics -json
{
  "timestamp":1337770325979,
  "status":"OK",
  "total":1,
  "data":[
    {
      "numContainersMoved":10090,
      "numMBMoved":3147147,
      "timeOfLastMove": "Wed May 23 03:51:44 PDT 2012"
    }
  ]
}
```

Viewing the List of Active Container Moves
Explains how to view the list of containers being moved, from the CLDB page.

About this task

Procedure

- Log in to the Control System and go to the service information page for CLDB.
  The **Active Container Moves** section displays the following fields:

Container ID	The ID of the container being moved.
SizeMB	The size (in MB) of the container being moved.
From Location	The location from where the container is being moved.
From SP	The Storage Pool (SP) out of which the container is being moved.
To Location	The location to which the container is being moved.
To SP	The SP to which the container is being moved.

Volume Balancer
Describes the role of the volume balancer.

Volume balancer is used to distribute containers of a volume on all the storage pools that belong to the volume's topology. Although the disk balancer balances containers across storage pools, sometimes containers of a volume may accumulate on a few storage pools. For example:

- When the storage pools hosting a volume's containers are not highly utilized, the disk balancer might not spread the volume's containers across storage pools.
- When new storage pools are added to a topology and the storage pools on which the current containers reside are not highly utilized, although the disk balancer moves containers to new storage pools, it is not guaranteed that a specific volume's containers are evenly spread out.

In such cases, you can trigger the balancing of a volume using a `maprcli` command. Every time a volume gets out of balance, you can trigger the volume balancer (using the `maprcli` command) to balance the containers associated with the volume. The container moves triggered by disk and volume balancers do not cause other volumes to be imbalanced.

last-updated: Jun 06, 2024

NOTE: If both disk balancer and volume balancer are triggered at the same time, volume balancer activity takes precedence.

Managing Volume Balancer
Explains the CLI commands that you can use to balance the containers of a volume.

Enabling and Disabling the Volume Balancer

About this task
The volume balancer is disabled by default. To enable or disable the volume balancer:

Procedure
- Set the value for the `cldb.volume.balancing.enable` parameter using the `config save` on `page 2106` command. To:
  - Enable volume balancer, run the following command:
    ```
    maprcli config save -values {cldb.volume.balancing.enable:1}
    ```
  - Disable volume balancer, run the following command:
    ```
    maprcli config save -values {cldb.volume.balancing.enable:0}
    ```

  After enabling the volume balancer feature, you must run the `volume balancecontainers` on `page 2582` command to balance the containers associated with a volume.

Balancing the Containers of a Volume

Procedure
- Run the `maprcli volume balancecontainers` command to balance a volume.
  The basic command to balance a volume is:
  ```
  /opt/mapr/bin/maprcli volume balancecontainers -name <vol_name>
  ```
  For more information, see `volume balancecontainers` on page 2582.

Stopping the Volume Balancer

Procedure
- Run the `maprcli volume balancecontainers` command to stop or cancel a balancing activity.
  The command to cancel a volume balancer is:
  ```
  /opt/mapr/bin/maprcli volume balancecontainers -name <vol_name> -cancel
  true
  ```
  For more information, see `volume balancecontainers` on page 2582.

Related reference
config save on page 2106
Saves configuration information, specified as key/value pairs. Permissions required: `fc` or `a`.

volume balancecontainers on page 2582
Balances the containers, or stops the balancing of containers associated with the volume.

Retrieving Balancer Status
Retrieve the status of a balancer activity using the CLI.

Procedure

Run the `maprcli volume balancinginfo` command to retrieve the status of a currently running or scheduled balancer activity.

The basic command to retrieve the status of volume balancer is:

```
/opt/mapr/bin/maprcli volume balancinginfo -name <vol_name>
```

For more information, see `volume balancinginfo` on page 2583. For example:

```
# /opt/mapr/bin/maprcli volume balancinginfo -name Volume1 -json
{
  "timestamp":1502529117881,
  "timeofday":"2017-08-12 09:11:57.881 GMT+0000",
  "status":"OK",
  "total":5,
  "data":[
    {
      "volumeName":"Volume1"
    },
    {
      "isBalancingInProgress":false
    },
    {
      "numContainers":15
    },
    {
      "volumeSize":384
    },
    {
      "spInfo":[
        {
          "spId":"f891ae9e6663fa2000598ec48808155c",
          "capacity":152969,
          "usedSize":96,
          "desiredSize":95,
          "isUnderweight":false,
          "isOverweight":false
        },
        {
          "spId":"bed92c0ecfaefc8b00598ec48b01cdfe",
          "capacity":152969,
          "usedSize":96,
          "desiredSize":95,
          "isUnderweight":false,
          "isOverweight":false
        },
        {
          "spId":"b61aa1b814fd8bbc00598ec48d0af1d2",
          "capacity":157065,
          "usedSize":96,
          "desiredSize":97,
          "isUnderweight":false,
          "isOverweight":false
        },
        {
          "spId":"7af11d5b9d223baa00598ec4850efb57",
          "capacity":152969,
```

last-updated: Jun 06, 2024

```
          "usedSize":96,
          "desiredSize":95,
          "isUnderweight":false,
          "isOverweight":false
        }
      ]
    }
  ]
}
```

Replication Role Balancer

Describes the features of the replication role balancer.

The replication role balancer manages containers to optimize the following:

- Network bandwidth during the replication process
- Disk I/O and CPU when serving read requests

The replication role balancer switches the replication roles of name and data containers to balance them across each storage pool in a volume. You can modify the `cldb.role.balancer.strategy` parameter from the `maprcli` to change how the role balancer manages the containers, either by size or count. You can also run the `dump rolebalancerinfo` command to see the status of active role switches or how container roles are balanced across each storage pool for a particular volume.

Replicated Containers

The name container is the first container created in every volume. Name containers can have either a *primary* or a *replica* role. Data containers can have a *primary*, *intermediate*, or *tail* role. By default, each name and data container is replicated across the cluster three times, with the primary being the first container written. The primary is sequentially replicated two more times, into a container with either an intermediate or a tail container role. If too many primary or intermediate containers exist on a storage pool or if the primary and intermediate containers are too large, the role balancer switches some of these containers to tail containers.

By default, the role balancer compares the size of the primary and tail containers to determine if containers within a storage pool are balanced. For the best performance, the size of the primary containers in a volume should be evenly distributed across storage pools. The role balancer maintains this balance by ensuring that each type of container (primary, intermediate, and tail) accounts for `1/ReplicationFactor` of the total container size in a volume.

If the role balancer is configured to manage containers by count, it compares the number of primary and tail containers and balances the roles such that each type of container accounts for `1/ReplicationFactor` of the total number of containers in a volume. For example, if the replication factor is set to 3, the role balancer maintains a balance of ~~p~~rimary, ~~i~~ntermediate, and ~~t~~ail containers in each volume.

HPE Ezmeral Data Fabric Database Considerations

To optimize HPE Ezmeral Data Fabric Database performance, you should configure the role balancer to manage containers by size. As described at HPE Ezmeral Data Fabric Database and File Store on page 635, HPE Ezmeral Data Fabric Database shards tables into *tablets* and stores the tablets in data containers. Only primary data containers serve reads. Therefore, configuring the role balancer by size spreads read requests evenly across the storage pools for a volume. To ensure the most optimal balancing

for your HPE Ezmeral Data Fabric Database tables, you should consider storing them on dedicated volumes.

Assign Cache

The assign cache is a list of reserved containers on a particular file server node that are allocated by the CLDB (container location database). The replication role balancer does not balance the containers in the assign cache and does not include them when balancing the roles. See the maprcli dump rolebalancerinfo command for assign cache values and details.

Enabling and Configuring Replication Role Balancer
Describes how to use the Control System or the CLI to enable and configure the Replication Role Balancer.

Enabling and Configuring the Replication Role Balancer Using the Control System

About this task

Procedure

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Balancer**.
2. From the Role Balancer section, set the **Enabled** slider to **Yes** .
3. Select one of the presets or specify a custom value for the **Concurrent Role Rebalancer** and **Delay for Active Data in Seconds** settings. You can choose:
   - Presets:

     Default
     - **Concurrent Role Rebalancer** — 20%
     - **Delay for Active Data in Seconds** — 600 sec

     Rapid
     - **Concurrent Role Rebalancer** — 5%
     - **Delay for Active Data in Seconds** — 300 sec

     Moderate
     - **Concurrent Role Rebalancer** — 10%
     - **Delay for Active Data in Seconds** — 600 sec

     Relaxed
     - **Concurrent Role Rebalancer** — 25%
     - **Delay for Active Data in Seconds** — 1800 sec

   - **Custom**, use the slider to set the concurrent role rebalancer percentage and delay for active data in seconds.

   Here:

Concurrent Role Rebalancer	Specifies the maximum percentage of data affected by concurrent role rebalancer operations. The cluster will wait until the number of rebalancing operations affects less than this percentage of total data eligible for rebalancing.
Delay for Active Data in Seconds	At the time of calculation, the role rebalancer will skip any data that is active within this time interval. This prevents unnecessary tampering with data used in recent or ongoing computations.

4. Click **Save Changes** for the changes to take effect.

last-updated: Jun 06, 2024

Enabling and Configuring Replication Role Balancer Using the CLI

About this task

You can use the `config save` command to modify the replication role balancer parameter values.

Example: `# maprcli config save -values {"cldb.role.balancer.strategy":"BySize"}`

The following table lists the replication role balancer configuration parameters with their default values and descriptions:

Parameter	Value	Description
cldb.balancer.role.paused	1	Specifies whether the role balancer runs: • 0 - Not paused (normal operation) • 1 - Paused (does not perform any container replication role switches)
cldb.role.balancer.strategy	"BySize"	Specifies how the replication role balancer balances containers, either by size or count. Use `"BySize"` or `"ByCount"` to indicate how role balancer balances containers.
cldb.balancer.role.max.switches.in.nodes.percentage	10	This can be used to throttle the role balancer. If it is set to 10, the balancer will throttle the number of concurrent role switches to 10% of the total nodes in the cluster (minimum 2).

Retrieving Role Balancer Status Using the CLI
Lists the CLI command to view the number of active replication role switches.

About this task

You can use the `maprcli dump rolebalancerinfo` command to view the number of active replication role switches. During a replication role switch, the replication role balancer selects a primary or intermediate data container and switches its replication role to that of a tail data container.

Example

Example:

```
# maprcli dump rolebalancerinfo -json
{
    "timestamp":1335835436698,
    "status":"OK",
    "total":1,
    "data":[
            {
               "containerid": 36659,
               "Tail IP:Port":"10.50.60.123:5660-",
               "Updates blocked Since":"Wed May 23 05:48:15 PDT 2012"
            }
```

last-updated: Jun 06, 2024

    ]
}
```

Managing Licenses
Provides a synopsis of adding licenses using the Control System and the CLI.

You can add and remove licenses on your cluster using the Control System or the CLI:

- In the Control System, go to **Admin** > **Cluster Settings** > **Licenses**.
- On the command line, use the `maprcli license` commands.

WARNING: Remove old licenses from the cluster when you add a new license. If multiple licenses exist, the cluster activates only the license with the lowest node count.

Adding a License
Add a license through the Control System or the CLI.
Adding a License Using the Control System

About this task
Complete the following steps to add a license using the Control System:

Procedure

1. On a machine that is connected to the cluster and to the Internet, perform the following steps to open the Control System:
   a) In a browser, view the Control System by navigating to the node that is running the Control System: `https://<webserver>:8443`.

      Your computer will not have a HTTPS certificate yet, so the browser will warn you that the connection is not trustworthy. You can ignore the warning this time.

   b) Log in to the Control System as the administrative user you designated earlier.

      Until a license is applied, the Control System dashboard might show some nodes in the amber "degraded" state. Do not worry if not all nodes are green and "healthy" at this stage.
2. In the Control System, go to **Admin** > **Cluster Settings** > **Licenses**.
3. Add a license using the following options:

Import License	Allows you to import a license from the server. You must enter your credentials in the **Import License** window to retrieve your license information.
Upload License	Allows you to upload your license file through a browser.
Copy/Paste License	Allows you to copy and paste a license key in the **Copy and Paste License** window.
Get a Free Trial License	Navigates to the HPE Ezmeral Data Fabric licensing form online to get a trial license.

4. Click **Submit**.

   If the cluster is already registered, the license is applied automatically. Otherwise, go to hpe.com and follow the instructions there to register the cluster.

Adding a License Using the CLI or the REST API

About this task
To add a license from the CLI:

last-updated: Jun 06, 2024

Procedure

1. Obtain a valid license file from HPE Ezmeral Data Fabric.
2. Copy the license file to a cluster node.
3. Run the following command to add the license:

   ```
   maprcli license add [ -cluster <name> ] -license <filename> -is_file true
   ```

   See `license add` on page 2235 for complete reference information.

List the licenses on the cluster using either the Control System or the CLI.
Viewing the Licenses Using the Control System

About this task

To view licenses:

Procedure

1. Log in to the Control System.
2. Click **Admin** > **Cluster Settings** > **Licenses**.
   Under **LICENSES**, the pane displays the following information for each license:

Column Name	Column Description
Active	Indicates whether (✓) the license is active.
Grace	Denotes the remaining grace period (in days) before which you must renew the expired license.
Name	The name of the license.
Module/Type	The type of license.
Issued	The date the license was issued.
Expires	The license expiration date.
Nodes	The number of nodes to which the license applies.
Delete	The option to remove the license.

You can:

- Add a license
- Remove a license

Viewing the Licenses Using the CLI or REST API

About this task

The basic command to get a list of licenses on the cluster is:

```
maprcli license list -cluster <cluster>
```

Removing a License
Describes how to remove a license using the Control System and the CLI.
Removing a License Using the Control System

About this task
To remove a license:

Procedure

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Licenses**.
2. Click the **Delete** link associated with the license to display the **Remove License** confirmation dialog.
3. Click **Submit** to remove the license.

Removing a License Using the CLI or REST API

About this task

To remove a license on a cluster:

Procedure

1. From the command line, issue the `maprcli license list on page 2239` command. Example:
   ```
   maprcli license list
   ```
2. Look for the `id` parameter in the output from the license list command.
   This is the license ID. Example:
   ```
   grace id                          description       deletable license
   maxnodes
   true  5CTFWAeQQUIOc5Wm/onoOJqcCls MapR Base Edition false
        version: "1.0"
        customerid: "BaseLicenseUser"
        issuer: "MapR Technologies, Inc."
        licType: Base
        description: "MapR Base Edition"
        ...
   ```
3. Use the `maprcli license remove on page 2242` command to remove the license.
   Example:
   ```
   maprcli license remove -license_id 5CTFWAeQQUIOc5Wm/onoOJqcCls
   ```

Setting Quota Defaults for Users and Groups

Explains how to set disk space quotas for users and groups.

About this task

Quotas limit the disk space used by a volume or an *entity* (user or group) on an Enterprise Edition-licensed cluster, by specifying the amount of disk space the volume or entity is allowed to use. A volume quota limits the space used by a volume. A user/group quota limits the space used by all volumes owned by a user or group. These quotas work on tenant volumes as well.

You can set hard quota and advisory quota defaults for users and groups. When a user or group is created, the default quota and advisory quota apply unless overridden by specific quotas. You can set an entity quota that differs from the default using the entity modify on page 2185 command or through the Control System.

The size of a disk space quota is expressed in terms of the actual data stored from the user's point of view. Only post-compression data blocks are counted, and snapshot and replica space do not count against quotas. For example, a 10G file that is compressed to 8G and has a replication factor of 3 consumes 24G (3*8G), but charges only 8G to the user or volume's quota.

You can set an entity quota through the Control System and using the CLI.

Setting Quotas Using the Control System

About this task

Complete the following steps to set the entity quota in the Control System:

Procedure

1. Go to **Admin** > **Cluster Settings** > **Quotas**.
2. Set the advisory and hard quotas for the:

- User under **USER QUOTA**.
- Group under **GROUP QUOTA**.

Hard quota prevents writes above the specified threshold. Advisory quota does not enforce disk usage limit, but raises an alarm when the specified threshold is exceeded:

- AE_ALARM_AEADVISORY_QUOTA_EXCEEDED - an entity exceeded its advisory quota
- VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED - a volume exceeded its advisory quota

In most cases, it is useful to set the advisory quota a little lower than the hard quota, to give advance warning that disk usage is approaching the allowed limit.

3. Set the cluster reserve limit, which is the amount of disk space that you wish to allocate for all volumes on the cluster.

   When you set a reserve limit, you provision a certain amount of space to the volumes as a percentage of the cluster capacity. This allows you to free up space that could potentially be unused, or allocate more space for replication.

   As data is written to the volume, available space is automatically allocated. The volume reserve increases up to the reserve limit you set here.

4. After setting the quota, click **Save** to save the settings.

Setting Entity Quotas Using the CLI or the REST API

About this task

To set an entity (user or group) quota, run the following command:

```
maprcli entity modify -name <entityname> -advisoryquota <advisory
quota> -quota <quota>
```

To manage quotas, you must have a or `fc` permissions.

Quotas are expressed as an integer value plus a single letter to represent the unit:

- B - bytes
- K - kilobytes
- M - megabytes
- G - gigabytes
- T - terabytes
- P - petabytes

Example: 500G specifies a 500-gigabyte quota. Do not use two-letter abbreviations for units, such as MB or GB.

For complete reference information, see the `entity modify` on `page 2185` command.

Setting the Cluster Reserve Limit Using the CLI or REST API

About this task

To set the resource usage limit for the cluster's disk resource, run the following command:

```
maprcli rlimit set -resource disk -cluster <cluster name> -value <limit>
```

For complete reference information, see the `rlimit set` on page 2306 command.

Related reference

entity modify on page 2185
Modifies a user or group quota or email address. Permissions required: `fc` or `a`.

rlimit set on page 2306
Sets the resource usage limit for the cluster's disk resource.

Specifying the Location of Gateways

Describes how to set the location of the HPE Ezmeral Data Fabric gateways using either the Control System or the CLI.

About this task

On every source HPE Ezmeral Data Fabric cluster, you can specify the location of the gateways by adding a DNS record to your DNS server's zone file for your domain. In your DNS server's zone file for your domain, add a record for the cluster where gateways are located, listing the nodes to use as gateways. You can use the Control System to create a record that you can copy into a DNS configuration file, run a `maprcli` command to generate the record, or create a record manually. For more information on gateways, see Managing Gateways on page 1530.

Specifying the Location of Gateways Using the Control System

About this task

To create a record using the Control System, follow these steps:

Procedure

1. Log in to the Control System on the cluster where the gateways are located.
2. Click **Admin** > **Cluster Settings** > **Gateway**.
3. Click **Copy to Clipboard** to copy the generated DNS entry.
4. Paste the record into your zone file.

Specifying the Location of Gateways Using the CLI

About this task

To generate a record by using the `maprcli` command, follow these steps:

last-updated: Jun 06, 2024

Procedure

1. On the cluster where the gateways are located, run the following command.

   ```
   maprcli cluster gateway local -format dns
   ```

   If you want to run the command from a different cluster and point to the cluster that hosts the gateways, use the `-cluster` parameter to provide the name of the latter cluster.

2. Copy and paste the output of this command into your zone file.

Creating a Record Manually

About this task

If you want to create a record manually, use this format:

```
gateway.<clustername> IN TXT "<space-delimited list of hostnames>"
```

You can also specify IP addresses, though using hostnames is recommended so that it is easier to locate gateways if their IP addresses change. Combinations of hostnames and IP addresses are also supported. The default port is `7660`. If a gateway is using a different port, append a colon to the address and then specify the port number. Here is an example entry:

```
gateway.newyork.bigcompany.com gw1ny.bigcompany.com gw2ny.bigcompany.com
```

Multi-homing is also supported. Simply separate the entries for a single node with semicolons, as in this example that uses IP addresses:

```
gateway.newyork.bigcompany.com 10.10.34.20 10.10.34.22
10.10.34.24;173.194.79.121
```

Related concepts

Administering Data Fabric Gateways on page 1526
A HPE Ezmeral Data Fabric gateway mediates one-way communication between a source HPE Ezmeral Data Fabric cluster and a destination cluster. You can replicate HPE Ezmeral Data Fabric Database tables (binary and JSON) and HPE Ezmeral Data Fabric Streams streams. HPE Ezmeral Data Fabric gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

Configuring Gateways for Table and Stream Replication on page 1528
Configuring gateways involves installing the `mapr-gateway` package on nodes on a Data Fabric destination cluster and then configuring the Data Fabric source cluster to communicate with the destination cluster. The Data Fabric source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

gateway.conf on page 2980

Gateways for Replicating HPE Ezmeral Data Fabric Database Tables on page 760
In HPE Ezmeral Data Fabric Database table replication, HPE Ezmeral Data Fabric Database replicates updates to tables (binary and JSON) on source Data Fabric clusters to replicas of those tables on destination Data Fabric clusters. Gateways are services that receive these updates and apply them to the replicas. These gateways also propagate updates from JSON tables to their secondary indexes.

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

Managing Alarms

You can view all the alarms and configure settings, including severity and notifications, on the Control System and using the CLI.

Viewing the List of Alarms
Specifies how to view the list of alarms raised, using either the Control System or the CLI.

About this task

You can view all the alarms on the Control System and using the CLI.

Viewing the List of Alarms in the Control System

Procedure

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Alarms**.
   The **ALL ALARMS** pane displays all the alarms on the cluster.
2. Select:
   - **Cluster Alarms** — indicate problems that affect the cluster as a whole
   - **Node Alarms** — indicate problems on individual nodes
   - **Table Alarms** — indicate table replication-related problems
   - **User/Group Alarms** — indicate problems with user or group quotas
   - **Volume Alarms** — indicate problems in individual volumes

   For the selected view, the pane displays the following for each alarm:

Column Name	Column Description
Alarm Name	The name of the alarm.
Severity	The user-defined severity for the alarm.
Description	A one-line description of the alarm.
Info	Information on the alarm including alarm name, description, and recommended action to address the alarm.

You can click the alarm name to configure alarm settings.

Retrieving the List of Alarms Using the CLI or REST API

About this task

The basic command to list all alarms by type (Cluster, Node, User, or Volume) is:

```
maprcli alarm list -type (cluster|node|volume|AE)
```

For complete reference information, see `alarm list` on page 2023.

Configuring Alarm Settings
Set the severity and notifications for each alarm using either the Control System or the CLI.

About this task
Configuring Alarm Settings Using the Control System

About this task
To configure alarm setting from the Control System:

Procedure

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Alarms**.
2. Select:
   - **Cluster Alarms** to configure settings for the alarms that affect the cluster as a whole
   - **Node Alarms** to configure settings for the alarms that indicate problems on individual nodes
   - **Table Alarms** to configure settings for the alarms that indicate table replication-related problems
   - **User Alarms** to configure settings for the alarms that indicate problems with user or group quotas
   - **Volume Alarms** to configure settings for the alarms that indicate problems in individual volumes
3. Click the name of the alarm to display the **Alarm Settings** window.
4. Specify a description of the alarm under **GENERAL** settings.
5. Configure alarm notifications (under **NOTIFICATIONS**) to allow HPE Ezmeral Data Fabric to send an email notification when the alarm is raised.
   a) Select (to enable) or deselect (to disable) the **Email Notifications** checkbox.
   b) If notifications are enabled, enter the user name or group name to which to send email when the alarm is raised, and click **Add**.
   See Setting Up SMTP on page 1028 for additional information.
6. Click **Save Changes** to save your settings.

Configuring Alarm Settings Using the CLI or REST API

About this task

To set up alarm notifications, run the `alarm config save` command from the command line.

WARNING: You must have `fc` (full control) or a (admin) permissions to run this command.

The format of the command is:

```
maprcli alarm config save -cluster <cluster_name> -values
"<alarm>,<enableEmail>,<email>"
```

Assign values as follows:

Value	Description	Example
`alarm`	Name of the alarm	`DISK_FAILURE_ALARM`
`enableEmail`	Specifies whether individual alarm notifications are sent to any email address (including the default email address) for the alarm type. • 0 - do not send notifications to any email address for the alarm type • 1 - send notifications to all email addresses for the alarm type	`1`
`email`	One or more email addresses other than the default email address. If specified, alarm notifications are sent to these addresses as well, if *enableEmail* is set to *1*. Multiple email addresses must be separated by spaces only. You cannot use commas or other delimiters. For example, `user1@mycorp.com user2@mycorp.com` is valid.	`user1@mycorp.com`

Configuring the Alarm Threshold Using the CLI
You can configure the alarm threshold for certain alarms. For the alarms that support threshold configuration, this topic describes the command to run to set the threshold.

VOLUME_ALARM_INODES_EXCEEDED

Threshold is configurable at both the cluster and the volume level.

If configured at both the cluster and volume levels, the volume level threshold overrides cluster-level threshold.

To configure at the cluster-level, run the following commands:

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.max.inodes.volume.alarm.thresh
":"<value>"}'
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.default.max.namespace.size.mb.
alarm.thresh":"<value>"}'
```

For example,

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.max.inodes.volume.alarm.thresh
":"50000000"}'
# /opt/mapr/bin/maprcli config
save -values
```

last-updated: Jun 06, 2024

```
'{"cldb.default.max.namespace.size.mb.
alarm.thresh":"512000"}'
```

To configure at the volume-level, run the following commands:

```
# /opt/mapr/bin/maprcli
volume modify -name
<volname> -maxinodesalarmthreshold
<threshold>
# /opt/mapr/bin/maprcli
volume modify -name
<volname> -maxnssizembalarmthreshold
<threshold>
```

For example,

```
# /opt/mapr/bin/maprcli
volume modify -name
testvol -maxinodesalarmthreshold 0
# /opt/mapr/bin/maprcli
volume modify -name
testvol -maxnssizembalarmthreshold 0
```

VOLUME_ALARM_TOPOLOGY_ALMOST_FULL

Threshold is configurable at cluster level.

To configure, run the following command:

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.topology.almost.full.percentag
e":"<value>"}'
```

For example,

```
# /opt/mapr/bin/maprcli config
save -values
'{"cldb.topology.almost.full.percentag
e":"90"}'
```

VOLUME_ALARM_QUOTA_EXCEEDED

Threshold is configurable in volume properties.

To configure, run the following command:

```
# /opt/mapr/bin/maprcli volume
modify -name <volname> -quota <value>
```

For example,

```
# /opt/mapr/bin/maprcli volume
modify -name testvol -quota 204800
```

VOLUME_ALARM_TABLE_INDEX_LAG_HIGH

Threshold is configurable in volume properties.

To configure, run the following command:

```
# /opt/mapr/bin/maprcli
volume create -name
<volname> -dbindexlagsecalarmthresh
<value in seconds>
```

last-updated: Jun 06, 2024

	For example, `# /opt/mapr/bin/maprcli volume create -name testvol -dbindexlagsecalarmthresh 60`

VOLUME_ALARM_TABLE_REPL_LAG_HIGH	Threshold is configurable in volume properties.
	To configure, run the following command:
	`# /opt/mapr/bin/maprcli volume create -name <volname> -dbrepllagsecalarmthresh <value in seconds>`
	For example,
	`# /opt/mapr/bin/maprcli volume create -name testvol -dbrepllagsecalarmthresh 50`

VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED	Threshold is configurable in volume properties.
	To configure, run the following command:
	`# /opt/mapr/bin/maprcli volume modify -name <volname> -advisoryquota <value>`
	For example,
	`# /opt/mapr/bin/maprcli volume modify -name testvol -advisoryquota 450`

VOLUME_ALARM_LABEL_ALMOST_FULL	Threshold is configurable at cluster level.
	`# /opt/mapr/bin/maprcli config save -values '{"cldb.label.almost.full.percentage": "<value>"}'`
	For example,
	`# /opt/mapr/bin/maprcli config save -values '{"cldb.label.almost.full.percentage": "90"}'`
	The default value is 90% which means that this alarm is raised when the free storage space on Storage Pools/Nodes with the desired label for container creation/replication is down to 10% of the total storage space with the desired label.

AE_ALARM_AEQUOTA_EXCEEDED	Threshold is configurable in ae properties. `# /opt/mapr/bin/maprcli entity modify -name <entityname> -type <type> -quota <value>`

	For example, `# /opt/mapr/bin/maprcli entity modify -name newuser -type 0 -quota 0` **NOTE:** The value, 0, for the type parameter in the above example represents the user entity type.

AE_ALARM_AEADVISORY_QUOTA_EXCEEDED	Threshold is configurable in ae properties.
	`# /opt/mapr/bin/maprcli entity modify -name <entityname> -type <type> -advisoryquota <value>`
	For example,
	`# /opt/mapr/bin/maprcli entity modify -name newuser -type 0 -advisoryquota 0`
	NOTE: The value, 0, for the type parameter in the above example represents the user entity type.

NODE_ALARM_TOO_MANY_CONTAINERS	Threshold is configurable at cluster level.
	This alarm is also raised when total number of containers (including snap containers) exceed 10 times the value of `pernode.numcntrs.alarm.thr`.
	`# /opt/mapr/bin/maprcli config save -values '{"pernode.numcntrs.alarm.thr":"<value>"}'`
	For example,
	`# /opt/mapr/bin/maprcli config save -values '{"pernode.numcntrs.alarm.thr":"50000"}'`

NODE_ALARM_NO_HEARTBEAT	Threshold is configurable at cluster level.
	`# /opt/mapr/bin/maprcli config save -values '{"cldb.fs.mark.inactive.sec":"<value>"}'`
	For example,
	`# /opt/mapr/bin/maprcli config save -values '{"cldb.fs.mark.inactive.sec":"10"}'`

NODE_ALARM_HIGH_MFS_MEMORY	Threshold is configurable at cluster level.

last-updated: Jun 06, 2024

	This alarm is raised when file system memory consumption exceeds the threshold.
	`# /opt/mapr/bin/maprcli config save -values '{"mfs.high.memory.alarm.threshold":"<value>"}'`
	For example,
	`# /opt/mapr/bin/maprcli config save -values '{"mfs.high.memory.alarm.threshold":"110"}'`

CLUSTER_ALARM_CLUSTER_ALMOST_FULL	Threshold is configurable at cluster level.
	`# /opt/mapr/bin/maprcli config save -values '{"cldb.cluster.almost.full.percentage":"<value>"}'`
	For example,
	`# /opt/mapr/bin/maprcli config save -values '{"cldb.cluster.almost.full.percentage":"90"}'`

CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION	Threshold is configurable at cluster level.
	`# /opt/mapr/bin/maprcli config save -values '{"mapr.license.exipry.notificationdays":"<value>"}'`
	For example,
	`# /opt/mapr/bin/maprcli config save -values '{"mapr.license.exipry.notificationdays":"30"}'`

CLUSTER_ALARM_TOO_MANY_SNAPSHOT_CONTAINERS	Threshold is configurable at the cluster level by setting the value for the `cldb.snap.cntr.count.alarm.threshold` property in the `cldb.conf` file. See `cldb.conf` on page 2971 for more information. **NOTE:** The default value is `100000000`.

Viewing Alarm Information

Describes how to view alarm information using the Control System.

About this task

You can view notes for an alarm in the Control System.

last-updated: Jun 06, 2024

Viewing Alarm Information in the Alarms Page

Procedure

1. Log in to the Control System and click **Admin** > **Cluster Settings** > **Alarms**.
2. Select:
   - **Cluster Alarms** to view notes for the alarms that affect the cluster as a whole
   - **Node Alarms** to view notes for the alarms that indicate problems on individual nodes
   - **Table Alarms** to view notes for the alarms that indicate table replication-related problems
   - **User Alarms** to view notes for the alarms that indicate problems with user or group quotas
   - **Volume Alarms** to view notes for the alarms that indicate problems in individual volumes
3. Click  associated with the alarm in the **Info** column.
   The **Alarm Information** window displays a description of the alarm and the recommended action to address the alarm.

Viewing Alarm Information in the Active Alarms Pane

Procedure

- Click  associated with the alarm in the **Active Alarms** pane to view information on the alarm.
  The **Alarm Information** window displays a description of the alarm, type of alarm, information on the alarm, and recommended action to address the alarm.

Dismissing an Alarm
Describes how to dismiss an alarm, either manually or automatically, using either the Control System or the CLI.

About this task

You can dismiss an alarm using the Control System or the CLI. When you dismiss an alarm, it will be cleared. You can raise the alarm again:

- Manually using the CLI
- Automatically when the conditions for raising the alarm again are met

Dismissing Alarm(s) Using the Control System

About this task

The **Dismiss** action is available in all the **Active Alarms** pane and in the **Alarms Summary** page. To dismiss alarm(s):

Procedure

1. Click **Dismiss**.
   The **Dismiss Alarms** dialog displays.
2. Verify the alarm(s) to dismiss and click **Dismiss** to dismiss the alarm(s).

last-updated: Jun 06, 2024

Dismissing Alarm(s) Using the CLI

About this task

The basic command to dismiss an alarm is:

```
maprcli alarm clear -alarm <alarm>
```

For complete reference, see alarm clear on page 2009.

Muting and Unmuting Alarms
Describes how to mute and unmute alarms using either the Control System or the CLI.

About this task

You can mute (silence) one or more (non-critical) alarms for a specific period of time using either the Control System or the CLI. The alarm will be silenced for the duration of the mute period and CLDB will raise the alarm again after the mute period **only** if the conditions for raising the alarm instance again are met.

Muting Alarm(s) Using the Control System

About this task

The **Mute** action is available in all the **Active Alarms** pane and in the **Alarms Summary** page. To mute alarm(s):

Procedure

1. Click **Mute** to display the **Mute Alarms** dialog.
2. Verify the alarm(s) to mute.
3. Select the period of time (1 hour, 6 hours, or 24 hours) to mute the alarm for from the **Mute Alarms for** drop-down list.
4. Click **Mute Alarms** to mute the alarm(s).
   The alarm will be raised again if the associated issue is not resolved within the specified period of time.

Muting Alarm(s) Using the CLI

About this task

The basic command to mute an alarm is:

```
maprcli alarm mute -alarm <alarm name>[:<entity>]:<mute_period>
```

For complete reference, see alarm mute on page 2028.

Unmuting Alarm(s) Using the CLI

About this task

The basic command to mute an alarm is:

```
maprcli alarm unmute
```

For complete reference, see alarm unmute on page 2034.

last-updated: Jun 06, 2024

Working with Multiple Instances of the File System

The Multi-file system feature allows multiple instances of the file server to run on a single node in a single process.

Multiple instances of the data-fabric file server can run on a single node in a single process with the installation of the HPE Ezmeral Data Fabric File Store, or the HPE Ezmeral Data Fabric Database software. On servers with SSDs with at least 2 storage pools (SP), two instances (per node) are configured by default. On servers without SSDs, a single instance is configured by default. Each instance runs as a separate library that is dynamically loaded into a single process. In this mode, each instance has a separate host ID; however, all the instances share the same hostname.

The maximum number of supported instances is 32. Instances should be configured based on the available CPU, memory, disks, and SPs. Each instance needs a minimum of 2GB, and instances should not exceed:

- Number of CPUs / 2
- Number of SPs (enforced)

File Server Instances

On File Store and HPE Ezmeral Data Fabric Database installations, nodes with SSDs can run multiple file server instances. To determine whether a node has SSDs, data-fabric uses the value of `mfs.disk.is.ssd` in the `mfs.conf on page 2986` file, which must be set to `1`. Add this parameter to `mfs.conf on page 2986`, on a node that has SSDs.

For clusters with File Store or HPE Ezmeral Data Fabric Database license, if you set the `mfs.disk.is.ssd` in the mfs.conf on page 2986 file to 1, CLDB configures nodes with SSDs to have 2 file server instances by default. On homogeneous clusters, you can modify the number of instances by changing the value of the `multimfs.numsps.perinstance` parameter.

Ports for Multiple Instances of the file system

Each instance listens on its own set of ports. Ensure that the appropriate ports are open for this feature. For example, instance 0 will use four ports from 5660, 5692 (5660+32), 5724 (5660+64), and 5756 (5660+96), instance 1 will use four ports from 5661, 5693, 5725, 5757, and so on for every additional instance. The topology of all instances is the same.

The total number of instances depends on the number of MFS threads, as indicated by the parameter `mfs.numrpcthreads` in mfs.conf on page 2986.

To verify that these ports are open, run the following command from a remote machine:

```
mrconfig -i -h <ip> -p <port number> info threads
```

An error indicates that the port is not open. If a port (for example, port 5661) is blocked, this command prints something similar to the following:

```
------------------
|From Instance 5661::|
------------------
<...> rpc failed <...>
```

Host IDs for Multiple Instances of the file system

For multiple instances of the file system, do NOT add IDs manually, but let the system handle the host ID numbering.

Log Files

Each instance has its own set of log files in `$MAPR_HOME/logs`. When multiple instances are configured, the log files have the same name with a different instance ID; for example, `mfs.log.<N>-3` where `N` is the instance number.

NOTE: For the primary instance, the log file name does not include the instance number.

The RPC and security trace information are in a separate file per instance, `mfs-<N>.err`, where `N` is the instance number. For the primary instance, the file name does not include the instance number.

For example, suppose there are 2 instances running on ports 5660 and 5661. There are 2 sets of log files, one for each instance:

- `mfs.log-3` for the primary instance
- `mfs.log.1-3` for the second instance

The RPC and security trace information are present in the following files :

- `mfs.err` for the primary instance
- `mfs-1.err` for the second instance

Configuring the Number of Storage Pools per Instance

Describes how to set the number of storage pools for each file system instance, from the CLI.

About this task

As you add file system instances, data-fabric assigns SPs to them. If file system instances are removed, the SPs assigned to those instances are re-allocated among the remaining live file system instances. By default, the value is 1, which implies that there is only 1 SP for all instances. You can re-configure the number of SPs per instance globally or at the node-level.

NOTE: If the number of file system instances is not as configured, the Instance Mismatch Alarm will be raised. If the alarm is raised on a:

- CLDB node, restart warden by running the following command:

```
service mapr-warden restart
```

- Non-CLDB node, restart file server by running the following command:

```
maprcli node services -nodes <node-ip> -fileserver restart
```

Global Configuration

About this task

If you configure globally, the configuration will be applied to all the nodes in the cluster. Make the following changes only on homogeneous clusters (that is, when all nodes in the cluster have the same type of disks and the stripe width of the disks is the same):

last-updated: Jun 06, 2024

Procedure

1. Run the following commands:

   ```
   maprcli config save -values {multimfs.numsps.perinstance:3}
   maprcli config save -values {multimfs.numinstances.pernode:2}
   ```

   The default value of the `multimfs.numsps.perinstance` parameter is 0. Suppose a node reports 9 SPs:

   - For a value of 3, the node would need to start 3 instances.
   - For a value of 5, the node would need to start 2 instances.

   For clusters with fast SSDs, this can be set to 1.

   NOTE: On AWS nodes with HDD, set the `multimfs.numsps.perinstance` parameter value to 50 to use a single instance.

2. Restart Warden in every node for the configuration change to take effect.

Node-level Configuration

About this task

At the node level, you can configure different number of instances for each node in the cluster. To change the number of SPs per instance:

Procedure

1. Run the following command:

   ```
   maprcli node modify -nodes <nodename> -numSpsPerInstance <n>
   ```

   The number of instances changes automatically when new SPs are created.

2. Restart Warden on the nodes where the configuration has changed.

Monitoring Multiple Instances of the File System
Describes how to monitor the health and performance of your cluster.
Determining the Number of Running Instances

Procedure

- Run the following command to determine the number of instances actually running:

  ```
  /opt/mapr/server/mrconfig info instances
  ```

  Your output will look similar to the following. This output shows that two File Server instances are running on ports `5660` and `5661`.

  ```
  /opt/mapr/server/mrconfig info instances
      2
      5660 5661
  ```

  Alternatively, on large clusters, run the following command to:

- Determine the number of configured instances:

```
maprcli node list -columns numInstances
    hostname           numInstances  ip
    atsqa4-161.qa.lab  1             10.10.88.161
    atsqa4-162.qa.lab  1             10.10.88.162
    atsqa4-163.qa.lab  1             10.10.88.163
    atsqa4-164.qa.lab  1             10.10.88.164
```

- Determine the number of running instances reported by file system to CLDB:

```
maprcli node list -columns numReportedInstances
    numReportedInstances  hostname           ip
    2                     atsqa4-161.qa.lab  10.10.88.161
    1                     atsqa4-162.qa.lab  10.10.88.162
    1                     atsqa4-163.qa.lab  10.10.88.163
    2                     atsqa4-164.qa.lab  10.10.88.164
```

Determining the Number of file system Threads

About this task

You can run the mrconfig info threads on page 2944 command to view file system threads from all the instances. The output is tagged to identify the instance.

Converting a Cluster from Root to Non-Root User from the Command-Line
Provides a synopsis of changing the running user from `root` to a non-root user on a cluster.

You can change a data-fabric cluster that runs as `root` to a non-root user. In addition to converting the data-fabric user to a non-root user, you can also disable superuser privileges to the cluster for the `root` user for additional security.

WARNING: You must perform these steps on all nodes on a stable cluster. Do not perform this procedure concurrently while upgrading packages.

Converting a Data Fabric Cluster from Root to Non-Root User from the Command-Line
Lists the process to change the running user from `root` to a non-root user on a cluster.

Procedure

1. Create a user with the same UID/GID across the cluster. Assign that user to the `MAPR_USER` environment variable.
2. On each node:
   a) Stop the warden and the ZooKeeper (if present).

```
service mapr-warden stop
service mapr-zookeeper stop
```

   b) Run the `config-mapr-user.sh` script to configure the cluster to start as the non-root user.

```
/opt/mapr/server/config-mapr-user.sh -u <MapR user> [-g <MapR group>]
```

c) Start the ZooKeeper (if present) and the warden.

```
service mapr-zookeeper start
service mapr-warden start
```

3. After the previous step is complete on all nodes in the cluster, run the `upgrade2mapruser.sh` script on all nodes.

```
/opt/mapr/server/upgrade2mapruser.sh
```

This command may take several minutes to return. The script waits ten minutes for the process to complete across the entire cluster. If the cluster-wide operation takes longer than ten minutes, the script fails. Re-run the script on all nodes where the script failed.

WARNING: The `MAPR_UID_MISMATCH` alarm may be raised during this process. The alarm will be cleared when this process is complete on all nodes.

Disabling Superuser Access for the Root User from the Command-Line

Describes how to disable superuser access for the `root` user.

About this task

NOTE: Enabling the `cldb.squash.root` **OR** `cldb.reject.root` configuration values can cause instability with ecosystem open source components if they are running as `root`. [On data-fabric clusters, services are running as the admin cluster user, which is `mapr` (by default).] Root squash applies only to files, not tables or streams. Ensure that `root` is not running any services before performing this procedure.

IMPORTANT: You can enable either of the following parameters, but NOT both.

Procedure

1. To disable root user (UID 0) access to the data-fabric filesystem on a cluster that is running as a non-root user, use either of the following commands:
   - The *squash root* configuration value treats all requests from UID 0 as coming from UID -2 (nobody):

     ```
     /opt/mapr/bin/maprcli config save -values {"cldb.squash.root":"1"}
     ```

   - The *reject root* configuration value automatically fails all filesystem requests from UID 0.

     ```
     /opt/mapr/bin/maprcli config save -values {"cldb.reject.root":"1"}
     ```

2. You can verify that these commands worked, as shown in the following example.

```
/opt/mapr/bin/maprcli config load -keys cldb.squash.root,cldb.reject.root
cldb.reject.root cldb.squash.root
0 1
```

Starting Up a Cluster

Lists the steps to start a cluster that was previously shut down.

Procedure

1. If the cluster nodes are not running, start them.

2. Change to the `root` user (or use `sudo` for the following commands).
3. Start ZooKeeper on the nodes where it is installed:

```
service mapr-zookeeper start
```

4. On all nodes, start Warden:

```
service mapr-warden start
```

5. Over a period of time (depending on the cluster size and other factors), the cluster comes up automatically. After the CLDB restarts, there is a 15-minute delay before replication resumes. This delay allows all nodes to register and begin heartbeat processing. You can configure this delay by using the `config save on page 2106` command to set the `cldb.replication.manager.start.mins` parameter.

Shutting Down a Cluster
Lists the considerations to note and the procedure to shutdown a cluster.

Prerequisites
Verify that MapReduce processes are not active, and that no data is being loaded to the cluster or being persisted within the cluster.

About this task

When you shut down a cluster, follow this sequence to preserve your data and replication:

1. Verify that recent data has finished processing.
2. Shut down any NFS servers.
3. Shut down any ecosystem components that are running.
4. Shut down ResourceManager and NodeManager services if you are using YARN
5. Shut down Warden on all nodes that are not running CLDB.
6. Shut down Warden on the CLDB nodes.
7. Shut down ZooKeeper on the ZooKeeper nodes.

Complete the following steps to shut down the cluster:

Procedure

1. Change to the `root` user (or use `sudo` for the following commands).
2. Before shutting down the cluster, you will need a list of NFS nodes, CLDB nodes, and all remaining nodes. Once the CLDB is shut down, you cannot retrieve a list of nodes; it is important to obtain this information at the beginning of the process. Use the node list on page 2264 command as follows:

last-updated: Jun 06, 2024

- Determine which nodes are running the NFS gateway. Example:

```
/opt/mapr/bin/maprcli node list -filter "[rp==/
*]and[svc==nfs]" -columns id,h,hn,svc,rp
id
service
hostname             health  ip
6475182753920016590
fileserver,nodemanager,nfs,hoststats
node-252.cluster.us 0       10.10.50.252
8077173244974255917
nodemanager,cldb,fileserver,nfs,hoststats
node-253.cluster.us 0       10.10.50.253
5323478955232132984
webserver,cldb,fileserver,nfs,hoststats,resourcemanager
node-254.cluster.us 0  10.10.50.254
```

- Determine which nodes are running the CLDB. Example:

```
/opt/mapr/bin/maprcli node list -filter "[rp==/
*]and[svc==cldb]" -columns id,h,hn,svc, rp
```

- List all non-CLDB nodes. Example:

```
/opt/mapr/bin/maprcli node list -filter "[rp==/*]and[svc!
=cldb]" -columns id,h,hn,svc, rp
```

3. Shut down all NFS instances. Example:

```
/opt/mapr/bin/maprcli node services -nfs stop -filter [svc=="nfs"]
```

4. If your cluster is running any ecosystem components, shut down those components on all nodes.
5. Shut down all ResourceManager and NodeManager services on all nodes. To shut down ResourceManager and NodeManager services specify the maprcli node services command with the `name` parameter and either the `filter` or the `node` parameter . Example:

```
maprcli node services -name resourcemanager -filter <filter> -action stop
maprcli node services -name nodemanager -nodes <node> -action stop
```

6. SSH into each node that is not running CLDB and stop Warden with the command:

```
service mapr-warden stop
```

7. SSH into each CLDB node and stop Warden with the command:

```
service mapr-warden stop
```

8. SSH into each Zookeeper node and stop Zookeeper with the command:

```
service mapr-zookeeper stop
```

9. (Optional) Shut down the nodes using the Linux `halt` command.

last-updated: Jun 06, 2024

Allocating Cluster Resource from the Command-Line
Provides a general overview on allocating cluster resources for a Data Fabric Hadoop cluster.

In a Data Fabric Hadoop cluster, the Warden sets the default resource allocation for the operating system, file system, Data Fabric Hadoop services, and YARN applications. Warden allocates resources to Data Fabric Hadoop services and applications based on the roles installed on a node. For example, Warden allocates resources for YARN applications on nodes with NodeManager role installed.

In general, you should not need to override the values set in the default configuration files and by Warden. However, you can provide updated values by adding or updating parameters in the Hadoop site configuration files or Warden files. To override parameter values for a single job, the option can be overridden in the command line when submitting a YARN application to the cluster.

To determine the current value of a hadoop parameter, run `hadoop conf | grep <ParameterName>`. In the following example, the `hadoop conf` command was used to get the value of `mapreduce.map.memory.md`:

```
hadoop conf | grep mapreduce.map.memory.mb
<property><name>mapreduce.map.memory.mb</name><value>1024</
value><source>mapred-site.xml</source></property>
```

Alternatively, run `hadoop conf` without the `grep` command to get a full list of the current parameter values. To determine the current value of a Warden parameter, open the Warden files located in the following directories: `/opt/mapr/conf/conf.d` and `/opt/mapr/conf`.

NOTE: In some cases, the current value of the parameter can only be seen in the Control System or in ResourceManager.

Refer to Allocating Memory for Nodes on page 1127 to allocate memory and resources in a Data Fabric cluster.

Administering Nodes

Provides a synopsis of managing nodes in a cluster.

This section provides information about managing nodes in a data-fabric cluster. Topics include how to add nodes to the cluster and/or remove nodes from the cluster, manage the services installed on the nodes, and manage disks. You can manage nodes, disks, and services in the data-fabric cluster using the Control System and the CLI.

Managing Nodes

Describes the Nodes page on the Control System.

The **Nodes** page contains panes that display:

- Node Health — the health of the nodes organized by topology (by default) or service.
- Current Resource Utilization — the nodes that utilize the most (in percentage) CPU and memory.
- Active Node Alarms — the list of active node alarms on the cluster.
- List of nodes — the list of nodes on the cluster.

NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.

You can perform the following procedures to manage and monitor nodes using the Control System and the CLI:

Viewing the list of Nodes
Explains how to view the list of Nodes using either the Control System or the CLI.
Viewing the list of Nodes on the Control System

About this task

Procedure

- Log in to the Control System and click **Nodes**.

  NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.

  The page contains the following panes:

Node Health	Displays each node's health.
Active Alarms	Displays active alerts for nodes in the cluster.
Current Resource Utilization	Plots the current CPU and memory utilization for each node as a graph. This helps visualize the nodes that utilize the most CPU and memory.
Nodes	Displays all the nodes in the cluster.

  For each node in the cluster, the **Nodes** pane displays the following:

Column Name	Column Description
Health	The health of the node. Value can be: • — Healthy • — Degraded • — Critical • — Maintenance
Hostname	The hostname of the node.
Physical IPs	The physical IP address or addresses associated with the node.
Last FS Heartbeat	The time since the node's last heartbeat to the CLDB.
Memory Utilized	The amount of memory used by the node.
Memory Total	The total amount of memory on the node.
CPU Utilized	The CPU usage metric for the node.
Disk Utilized	The amount of disk space utilized on the node.
Total Disk Space	The total amount of disk space on the node.
Physical Topology	The rack path to the node.
Running Services	The number of services running on the node.

  Selecting the checkbox beside a node makes the following buttons available:

  - Change Topology
  - Remove Nodes
  - Manage Services

last-updated: Jun 06, 2024

Retrieving the list of Nodes Using the CLI or REST API

About this task

The basic command to view all the nodes on a cluster is:

```
maprcli node list -cluster <cluster>
```

For complete reference information, see node list on page 2264.

Customizing the List of Columns/Fields
Explains how to customize the columns that are displayed in the Control System, and the fields that are returned in the CLI.
Customizing the Columns in the Control System

Procedure

1. Log in to the Control System and go to:
   - **Data** > **Volumes** page to customize columns displayed in the **Volumes** pane.

     NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   - **Nodes** page to customize columns displayed in the **Nodes** pane.

     NOTE: The **Nodes** page is not available on the Kubernetes version of the Control Panel.

2. Click the **Customize Columns** icon ( ).
   In the **Customize Columns** dialog, the:
   - **Available** list displays the columns that are available for display.
   - **Selected** list displays the columns currently displayed in the pane.
3. Select the columns from the:
   a) Available list of columns and click ▶ to move selection to **Selected** columns (for display).
   b) Selected list of columns and click ◀ to remove selected columns from displaying.
4. (Optional) Click ^ and/or down ˅ arrows to sort the order of columns.
5. Click **Save Changes** for the customization to take effect.

   TIP: To reset the display to its default columns, click **Reset to default columns**.

Customizing the Fields Using the CLI or REST API

About this task

Use the `-column` parameter with the `maprcli` command to view specific fields in the list. For example:

- To view the health of the nodes and services installed on the nodes being retrieved, run the following command:

  ```
  maprcli node list -columns service,health
  ```

  For complete reference information, see the node list on page 2264 command.

- To view the volume name for the list of volumes being retrieved, run the following command:

  ```
  maprcli volume list -columns volumename
  ```

  For complete reference information, see volume list on page 2648 command.

Reverting to Default List of Columns
Describes how to revert to the default list of columns on the Control System

Procedure

1. Log in to the Control System and click:
   - **Data** > **Volumes** to revert to the default list of columns in the **Volumes** pane.

     NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   - **Nodes** to revert to the default list of columns in the **Nodes** pane.

     NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Click the **Customize Columns** icon ( ) .
3. Click **Reset to default columns**,
4. Click **Save Changes**.
   The pane displays the default list of columns.

Filtering the List of Nodes
Describes how to setup search expressions and filter nodes based on specific criteria.

About this task

The filter lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of nodes. Expressions are implicitly connected by the AND operator.

Filtering the Node List in the Control System

Procedure

1. Log in to the Control System and click **Nodes** to filter the list of nodes in the **Nodes** pane.

   NOTE: The **Nodes** menu is not available on the Kubernetes version of the Control System.
2. Click and select one of the following from the **Add Filter** drop down menu.
   - Health — to filter the list by node health
   - Hostname — to filter the list by hostname of node
   - Physical IP — to filter the list by IP address of node
   - Last FS Heartbeat — to filter the list by number of heartbeats sent to FS
   - CPU Utilized — to filter the list by number of cores utilized
   - Physical Topology — to filter the list by rack path

last-updated: Jun 06, 2024

- Running Services — to filter the list by installed services

3. Specify the value in the drop-down field for the selected filter (to filter the list of nodes by) and click **Filter**.

   As you make selections and specify the filtering criteria, the pane displays only the nodes that match the specified filtering criteria.

4. Click:
   - **Add Filter** to add another filtering criteria.
   - ✕ to remove a filtering criteria.
   -  to clear all filter settings.

Filtering the List Using the CLI

About this task

Use the `node list` on page 2264 command with the `-filter` option, to specify large numbers of nodes by matching specified values in specified fields rather than by typing the name of each node explicitly. For example, you can retrieve all nodes on a specific subnet as follows:

```
maprcli node list -filter [ip==20.30.40.*]
```

For more information, see Filters on page 1996.

Monitoring Nodes
Explains how to monitor nodes using either the Control System or the CLI.

About this task

You can check the health of the nodes on the cluster in the Control System, organized by service or by topology, or by using the CLI.

NOTE: To visualize the graphs and charts, you must install the metrics collection infrastructure during installation. If the metrics collection infrastructure is not installed, perform an Incremental Install to install the metrics collection infrastructure.

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

Monitoring Node Health Using the Control System

About this task
To monitor the health of nodes:

Procedure

1. Log in to the Control System and click:
   - **Overview** to view the health of the nodes in the **Node Health** pane.
   - **Nodes** to view the health of the nodes in the **Node Health** pane.
2. Select one of the following from the drop-down menu in the **Node Health** pane.
   - **By Service** to organize the display of nodes by services.

last-updated: Jun 06, 2024

This is the default view in the **Overview** page. This view contains the list of services and the nodes on which the service is running ( ) and is down ( ).

NOTE: The color of the node (which reflects the status of the service) is even when a service is stopped (not running) on the node.

- **By Topology** to view the display of nodes by topology.

  This is the default view in the **Nodes** page. This view contains the list of topologies and the health of the nodes (as shown in the following table) in the topology.

Node Color	Description
	Indicates the node is healthy.
	Indicates the node is degraded and/or may need attention. A node is considered to be in degraded state if: • There is no heartbeat from the HPE Ezmeral Data Fabric filesystem/NFS node for over 60 seconds. • One or more services are down on the node. • One or more alarms are raised on the node.
	Indicates the node is in maintenance mode.
	Indicates critical issue(s) on the node. A node is considered to be in critical state if: • There is no heartbeat from the node for more than 5 minutes. • All HPE Ezmeral Data Fabric files system disks on the node are dead or are offline. • All containers on the node are being re-replicated because either the node was removed, unregistered, or there was no heartbeat from the node for more than 1 hour. • File server is dead/inactive because there is no heartbeat for a long time. • NFS server on node is dead. • HPE Ezmeral Data Fabric install directory is full. • Node reported high HPE Ezmeral Data Fabric filesystem memory usage.

Monitoring Node Resource Utilization from the Control System

Procedure

- Log in to the Control System and click **Nodes** to view the nodes that consumed the most CPU and memory (in percentage) in the **Current Resource Utilization** pane. The shade of the bubble indicates node resource utilization with the darker shade indicating the nodes that are nearing disk capacity.

Monitoring Active Node Alarms from the Control System

About this task

See Viewing Active Node Alarms on page 1692 for more information.

Monitoring Node Health Using the CLI or REST API

About this task

You can check general health of the nodes with the following command:

```
maprcli node heatmap -cluster <cluster>
```

This command displays a heatmap for the nodes on the specified cluster; a subset of the output can also be visualized on the Control System. For complete reference information, see `node heatmap` on page 2262.

Gathering Node Metrics

Explains how to gather node metrics using the CLI.

About this task

You can gather metrics such as IO statistics, network throughput, CPU performance, memory consumption, swap space usage, disk usage, disk latency, and MFS throughput for each node, using the mrdiagnostics on page 2966 utility.

Viewing Node Details

Describes how to view node details using either the Control System or the CLI.

Viewing Node Details Using the Control System

Procedure

1. Log in to the Control System and click **Nodes**.

   NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.

2. Click the hostname of the node.
   The information page for the node displays.
   - Summary tab (default view)
   - Metrics tab

   You can:
   - Change the topology of the node
   - Remove the node

Viewing Node Details Using the CLI or REST API

About this task

The basic command to retrieve information on a node is:

```
maprcli node metrics -nodes <hostname> -columns <column names>
```

For complete reference information, see `node metrics` on page 2285.

Viewing Node Summary

View a summary of the alarms, services, and disks on a node using either the Control System or the CLI.

Viewing Node Summary Using the Control System

Procedure

- Log in to the Control System and go to the node information page.

  The page with information on the node displays and the **Summary** tab displays by default. The **Summary** tab contains panes for node-specific:

  - **Alarms** — displays active and recent alarms on the node. See Viewing Active Node Alarms on page 1692 for more information.
  - **Services** — displays services running on the node. See Viewing the Services Running on a Node Using the Control System on page 1137 for more information.
  - **Disks** — displays information on the disks on the node. See Viewing the List of Disks on page 1145 for more information.

Viewing Node Summary Using the CLI

About this task

The basic command to retrieve a summary of the disks on a node is:

```
maprcli node metrics -nodes <hostname> -columns DISKS
```

For complete reference information, see `node metrics` on page 2285.

Viewing Node Metrics
Explains how to view node metrics using the Control System.

About this task

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to visualize the metrics that are desribed in the following section.

Monitoring Node Metrics Using the Control System

Procedure

- Log in to the Control System and go to the **Metrics** tab in the node information page.

  By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

  You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

  - › to shift time window forwards.

last-updated: Jun 06, 2024

- to shift time window backwards.

Click associated with the chart to view information about the graph. Click to display the **Customize Active Charts** window. You can select charts to display and remove from the **Available** and **Selected** lists in the **Customize Active Charts** window. You can view up to 6 charts at a time in the page.

Use the following table when selecting the charts to view in the page. In the following table, the Charts column lists the charts that are available and the Metric column describes that type of metric that can be visualized in the chart:

Metric	Charts
CPU Usage	• Node Active CPU Usage • Node CPU Usage** • Node CPU Usage IDLE • Node CPU Usage NICE • Node CPU Usage SYSTEM • Node CPU Usage USER • Node CPU Usage WAIT • MFS CPU Usage • Allocated vs Available CPU Cores • MapR Process CPU Usage • MAST Gateway CPU Usage • DB Gateway CPU Usage • Data Access Gateway CPU Usage
Memory Usage	• Node Free Memory • Node Utilized Memory*** • Node Memory Free vs Used* • MFS Process Memory Usage • Data Fabric Process Memory Usage
SWAP Space	• Node Swap Free • Node Swap Used • Node Swap Space Available vs Used* • Node Swap IO

last-updated: Jun 06, 2024

Metric	Charts
Node IOs	• Node Network IO* • Node Network Interface Input • Node Network Interface Output • Node Network Interface Error Input • Node Network Interface Error Output
System Disk Throughput	• Disk Read Ops • Disk Write Ops • Disk Reads and Writes*
System Disk Latency	• Disk Avg Read Latency • Disk Avg Write Latency • Disk Read and Write Times
MFS Throughput	• MFS Read Throughput • MFS Write Throughput • MFS Read and Write Throughput • MFS System Disk Activity in Bytes*

* This metric is diplayed in the default chart view for a node.

** This metric is diplayed in the default chart view for a node and in the default list view for a table.

*** This metric is diplayed in the default list view for a table.

For information on viewing metrics for:

- All table activities on a node, see Viewing Per Node Metrics for Table Activities on page 1671.
- All stream activities on a node, see Monitoring Streams Operations Using the Control System on page 1688.

Setting Up Node Topology
Define node topologies for every node in the cluster.

Define your cluster's topology by specifying a topology for each node in the cluster. You can use topology to group nodes by rack or switch, depending on how the physical cluster is arranged and how you want data-fabric to place replicated data.

Topology paths can be as simple or complex as needed to correspond to your cluster layout. In a simple cluster, each topology path might consist of the rack only (for example, `/rack-1`). In a deployment consisting of multiple large datacenters, each topology path can be much longer (for example, `/europe/uk/london/datacenter2/room4/row22/rack5/`). Data Fabric uses topology paths to spread out replicated copies of data, placing each copy on a separate path. By setting each path to correspond to a physical rack, you can ensure that replicated data is distributed across racks to improve fault tolerance.

Changing the Topology of one or more Nodes
Describes how to move nodes from one topology to the other using either the Control System or the CLI.

last-updated: Jun 06, 2024

Changing the Topology of Multiple Nodes Using the Control System

About this task

To change the rack or switch path for one or more nodes, under **Nodes**:

NOTE: The **Nodes** menu is not available on the Kubernetes version of the Control System.

Procedure

1. Select the nodes from the list of nodes in the **Nodes** pane and click **Change Topology**.
   The **Change Node Topology** dialog displays.
2. Choose one of the following:
   - **Select Existing Topology** to select a topology from the list of existing topologies.
   - **Create New Topology** to specify a new topology for the selected nodes.
3. Click **Change Topology** for the changes to take effect.

Changing the Topology of a Node Using the Control System

About this task

To change the rack or switch path for a node:

Procedure

1. Go to the node information page and click **Change Topology**.
   The **Change Node Topology** dialog displays.
2. Choose one of the following:
   - **Select Existing Topology** to select a topology from the list of existing topologies.
   - **Create New Topology** to specify a new topology for the node.
3. Click **Change Topology** for the changes to take effect.

Changing the Topology Using the CLI or REST API

About this task

The basic command to move nodes to a different topology is:

```
/opt/mapr/bin/maprcli node move -serverids <server IDs> -topology <topology>
```

For complete reference information, see `node move` on page 2290.

The move will fail if the server ID is negative. To fix this issue, perform one of the following:

- If you are moving only a single server ID that is negative, or a bunch of server IDs that are all negative, prefix 0 as an additional server ID. For example:

  ```
  /opt/mapr/bin/maprcli node move -serverids
  0,-6151492882499457449,-2668056288676628812 -topology /data/mytopo -json
  ```

- If you are moving a bunch of server IDs with a mix of positive and negative server IDs, place a positive ID as the first ID. For example:

```
/opt/mapr/bin/maprcli node move -serverids
1507661865183706279,-6151492882499457449,-2668056288676628812 -topology /
data/mytopo -json
```

Setting Node Topology with a Script
Provides an overview of how to script setting up node topology.

For large clusters, you can specify complex topologies in a text file or by using a script. Each line in the text file or script output specifies a single node and the full topology path for that node in the following format:

```
<ip or hostname> <topology>
```

The text file or script must be specified and available on the local filesystem on all CLDB nodes:

- To set topology with a text file, set `net.topology.table.file.name` in `/opt/mapr/conf/cldb.conf` to the text file name
- To set topology with a script, set `net.topology.script.file.name` in `/opt/mapr/conf/cldb.conf` to the script file name

If you specify a script and a text file, the data-fabric system uses the topology specified by the script.

Adding Nodes to a Cluster
Describes how to add nodes to a cluster.

About this task
You can add nodes to a cluster using the web-based Installer (version 1.6 or later), the Installer Stanzas, or manually. To add nodes to your cluster using the Installer or Installer Stanzas, see Extending a Cluster by Adding Nodes on page 5624. Complete the following steps to add nodes manually to a cluster:

Procedure

1. Prepare all nodes.

   If you do not use the Domain Name System (DNS), ping the new node from an existing node and vice versa. Use the host name instead of an IP address. If you do not get a response, and if you rule out a network problem, a possible fix is to edit the `/etc/hosts` files of all nodes in the cluster. All nodes need to be listed in all `/etc/hosts` files.

2. Plan which packages to install based on services you want to run on the new nodes.

   See Select Services on page 79 and Data Fabric Repositories and Packages on page 101 for more information.

3. Install HPE Ezmeral Data Fabric Software.
   - On all new nodes, add the HPE Ezmeral Data Fabric Repository.
   - On each new node, install the planned packages.

   See Step 3: Prepare Packages and Repositories on page 182 and Step 4: Install Cluster Service Packages on page 192 for more information.

4. Configure all new nodes by running `configure.sh`.

   If you added a ZooKeeper role to a node, run the following command on all nodes with the new ZooKeeper list: `configure.sh -no-autostart`. See `configure.sh` on page 2821 for more information.

5. On all new nodes, format disks for use by HPE Ezmeral Data Fabric if you plan to re-use a node from another cluster.

   Format the disks from a re-used node to remove data from the old cluster.

   NOTE: All the disks (for use by HPE Ezmeral Data Fabric) on a node must be of the same type. That is, all the disks on a node must either be rotational or SSDs; node with disks of both types is not supported.

   See Formatting Disks on a Node From the Command-line on page 1151 for more information.

6. If you manually modified configuration files on the existing nodes and those changes apply to the new nodes, copy only those changes to the respective files on the new nodes.

7. Perform the following steps if you added the node(s) to any secure cluster that is configured for cross-cluster operations.

   a) Copy the `/opt/mapr/conf/mapr-clusters.conf` file and `/opt/mapr/conf/ssl_truststore` file from another node to the new node(s).

   b) Copy the `/opt/mapr/conf/maprserverticket` file from:

      - A CLDB node if the new node is a CLDB node.
      - A non-CLDB node if the new node is not a CLDB node.

      The `/opt/mapr/conf/maprserverticket` file contains additional entry for cross-cluster tickets. See Configuring Secure Clusters for Cross-Cluster NFS Access on page 1957 for more information.

8. Start ZooKeeper on all new nodes that have ZooKeeper installed:

   ```
   service mapr-zookeeper start
   ```

9. Start Warden on all new nodes:

   ```
   service mapr-warden start
   ```

10. Restart services that you reconfigured.

    Running `configure.sh` alone does not reconfigure services, such as ZooKeeper. Reconfigured services also require a restart. For example, restart ZooKeeper on each node, one at a time after running `configure.sh`. Restart the lead ZooKeeper last. Restarting ZooKeeper adds the new nodes into the existing ZooKeeper quorum. Services that need to connect to CLDB do not always discover a newly added CLDB node without restarting warden.

11. Set up node topology for the new nodes.

12. On any new nodes running NFS, set up NFS for HA.

Isolating CLDB Nodes

Lists the pros of creating CLDB-only nodes.

In a large cluster (100 nodes or more) create CLDB-only nodes to ensure high performance. This configuration also provides additional control over the placement of the CLDB data, for load balancing, fault tolerance, or high availability (HA). Setting up CLDB-only nodes involves restricting the CLDB volume to its own topology and making sure that all other volumes are on a separate topology. As both the

CLDB-only path and the non-CLDB path are children of the root topology path, new non-CLDB volumes are not guaranteed to keep off the CLDB-only nodes. To avoid this problem, set a default volume topology. See Setting Default Volume Topology Using the CLI on page 1234.

Setting Up a CLDB-Only Node
Describes how to setup a node for CLDB alone.

Procedure

1. SET UP the node as usual:
   a) PREPARE the node, making sure it meets the requirements.
   b) ADD the data-fabric repository.
2. INSTALL the following packages to the node.
   - `mapr-cldb`
   - `mapr-webserver`
   - `mapr-core`
   - `mapr-fileserver`

Setting Up Volume Topology to Restrict the CLDB Volume to Specific Nodes
Explains how to permit access to CLDB volumes only from specific nodes.

Procedure

1. Move all CLDB nodes to a CLDB-only topology (e. g. `/cldbonly`) using the data-fabric Control System or the following command:

   ```
   maprcli node move -serverids <CLDB nodes> -topology /cldbonly
   ```

2. Restrict the CLDB volume to the CLDB-only topology using the data-fabric Control System or the following command:

   ```
   maprcli volume move -name mapr.cldb.internal -topology /cldbonly
   ```

Moving Volumes to a Separate Topology from the CLDB-Only Nodes
Explains how to move non-CLDB volumes to a separate topology.

Procedure

1. Move all non-CLDB nodes to a non-CLDB topology (e. g. `/defaultRack`) using the data-fabric Control System or the following command: `maprcli node move -serverids <all non-CLDB nodes> -topology /defaultRack`
2. Restrict all existing volumes to the topology `/defaultRack` using the data-fabric Control System or the following command: `maprcli volume move -name <volume> -topology /defaultRack`
   All volumes except `mapr.cluster.root` are re-replicated to the changed topology automatically.

   WARNING: To prevent subsequently created volumes from encroaching on the CLDB-only nodes, set a default topology that excludes the CLDB-only topology.

Isolating ZooKeeper Nodes
Provides an overview on how to install a ZooKeeper-only node.

last-updated: Jun 06, 2024

For large clusters (100 nodes or more), isolate the ZooKeeper on nodes that do not perform any other function. Isolating the ZooKeeper node enables the node to perform its functions without competing for resources with other processes. Installing a ZooKeeper-only node is similar to any typical node installation, but with a specific subset of packages.

WARNING: Do not install the FileServer package on an isolated ZooKeeper node in order to prevent data-fabric from using this node for data storage.

Setting Up a ZooKeeper-Only Node
Explains how to install a ZooKeeper-only node.

Procedure

1. SET UP the node as usual:
   a) PREPARE the node, making sure it meets the requirements.
   b) ADD the HPE Ezmeral Data Fabric Repository.
2. INSTALL the following packages to the node.
   - `mapr-zookeeper`
   - `mapr-zk-internal`
   - `mapr-core`

Configuration Example
This example assumes you are adding a new node to a cluster that is running the CLDB and ZooKeeper on three other nodes: `node_a`, `node_b`, and `node_c`. To configure a `new node_d`, which is not a CLDB or ZooKeeper node, run the following command:

```
$ /opt/mapr/server/configure.sh -N my.cluster.com -C
node_a,node_b,node_c -Z node_a,node_b,node_c
```

To configure a ZooKeeper node, use the `-no-autostart` option and the `-Z` option followed by the list of ZooKeeper nodes.

Removing Nodes from a Cluster
Provides an overview of how to remove nodes from a cluster.

You can remove a node using the `node remove` command, or using the Control System. Removing a node detaches the node from the cluster, but does not remove the HPE Ezmeral Data Fabric software from the cluster.

The following sections provide information about removing nodes from a cluster:

Removing One or More Nodes
Describes how to decommission a node from service.

Prerequisites
Perform the following prerequisite steps before removing a node using the Control System or CLI or REST API:

1. Drain the node of data by moving the node to the `/decommissioned` physical topology. All the data on a node in the `/decommissioned` topology is migrated to other volumes and nodes in the appropriate topologies.

last-updated: Jun 06, 2024

2. Run the following command to check if a given volume is present on the node:

```
maprcli dump volumenodes -volumename <volume> -json | grep IP:Port
```

As an example, consider the volume `rocky` that is present on a node with IP `10.163.167.212`. To check whether this volume exists on this node, run the command:

```
 maprcli dump volumenodes -volumename rocky -json
{
        "timestamp":1606879372378,
        "timeofday":"2020-12-01 07:22:52.378 GMT-0800 PM",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "Servers":{

"IP:Port":"10.163.167.212:5660-192.168.122.1:5660--3-VALID"
                        }
                }
        ]
}
```

The output shows that the volume `rocky` exists on node `10.163.167.212` that is accessible on port `5660`.

To return just the IP and the Port alone, pipe the output through the `grep` command as follows:

```
 maprcli dump volumenodes -volumename test -json | grep IP:Port
 "IP:Port":"10.163.167.212:5660-192.168.122.1:5660--3-VALID"
```

Run this command for each non-local volume in your cluster to verify that the node being removed is not storing any volume data.

3. Install CLDB or ZooKeeper on another node (only) if the node you are removing is a CLDB or ZooKeeper node and run `configure.sh` with `-C` and `-Z` options.

   This is to ensure that ZooKeeper quorum is maintained and that an optimal number of CLDB is available for high availability.

About this task

You can remove one or more nodes using the Control System and the CLI.

Removing Multiple Nodes Using the Control System

About this task

To remove one or more nodes:

Procedure

1. Log in to the Control System and click **Nodes**.

   NOTE: The **Nodes** menu is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Remove Node(s)**.
   The **Remove Node(s)** dialog displays.

3. Verify the list of nodes to remove and click **Remove Nodes**.

Removing a Node Using the Control System

About this task

To remove a node:

Procedure

1. Go to the Viewing Node Details on page 1109 page and click **Remove Node**.
   The **Remove Node(s)** confirmation dialog displays.
2. Click **Remove Node**.

Removing one or more Nodes Using the CLI or REST API

About this task

Use the node remove on page 2291 command to remove one or more server nodes from the cluster. To run this command, you must have full control (`fc`) or administrator (a) permission. The syntax is:

```
maprcli node remove -nodes <node names> ]
```

If the following error is generated, you must wait for the state duration of the CLDB master node to reach 15 minutes or more. Otherwise, the node remove fails:

```
node remove failed for node <node_name>, Error: Resource temporarily
unavailable; CLDB just became master, node removed not allowed until
sometime
```

To check the state duration value, use this command:

```
maprcli dump cldbstate -json
```

After you issue the node remove on page 2291 command, wait several minutes to ensure that the nodes have been completely removed.

> **TIP:** To ensure that a node that is removed does not rejoin the cluster on reboot, either remove all data-fabric packages from the node, or remove the cluster configuration that is present in the `/opt/mapr/conf/mapr-clusters.conf` file on the node.

Related concepts

Migrating a Volume off a Node Using the CLI on page 1231

Decommissioning a Node and Uninstalling Data Fabric Software from the Command Line

About this task

Use the following procedure to remove a node and uninstall Data Fabric software. This procedure detaches the node from the cluster and removes the Data Fabric packages, log files, and configuration files, but does not format the disks.

> **NOTE:** Before decommissioning a node, make sure any data on the node is replicated and any needed services are running elsewhere. If the node you are decommissioning runs a critical service, such as CLDB or ZooKeeper, verify that enough instances of that service are running on other nodes in the cluster. See Planning the Cluster for recommendations about service assignment to nodes.

Complete the following steps to permanently decommission a node:

Procedure

1. Drain the node of data by moving the node to the `/decommissioned` physical topology. All data on a node in the `/decommissioned` topology is migrated to volumes and nodes in the `data` topology.
2. Run the following command to check if a given volume is present on the node:

   ```
   maprcli dump volumenodes -volumename <volume> -json | grep <ip:port>
   ```

   NOTE: Run this command for each non-local volume in your cluster to verify that the node being decommissioned is not storing any volume data.
3. Change to the `root` user (or use `sudo` for the following commands).
4. Stop Warden on the node by running the following command:

   ```
   service mapr-warden stop
   ```

5. If ZooKeeper is installed on the node, stop it: `service mapr-zookeeper stop`
6. Determine which Data Fabric packages are installed on the node:
   - `dpkg --list | grep mapr` (Ubuntu)
   - `rpm -qa | grep mapr` (Red Hat or CentOS)
7. Remove the packages by issuing the appropriate command for the operating system, followed by the list of services. Examples:
   - `apt-get purge mapr-core mapr-cldb mapr-fileserver` (Ubuntu)
   - `yum erase mapr-core mapr-cldb mapr-fileserver` (Red Hat or CentOS)
8. Remove the `/opt/mapr` directory to remove any instances of `hostid`, `hostname`, `zkdata`, and `zookeeper` left behind by the package manager.
9. Remove the `/mapr` directory to delete any NFS/POSIX client mount points.
10. Remove any data-fabric cores in the `/opt/cores` directory.
11. If the node you have decommissioned is a CLDB node or a ZooKeeper node, then run `configure.sh` on all other nodes in the cluster. See Configuring the Node.
12. Remove the node by running the following command:

    ```
    maprcli node remove -nodes <node-name>
    ```

Reconfiguring a Node from the Command-Line
Provides an overview of the procedure to reconfigure a node using the CLI.

This procedure is designed to make changes to existing HPE Ezmeral Data Fabric software on a machine that has already been set up as a HPE Ezmeral Data Fabric cluster node. If you need to install software for the first time on a machine to create a new node, see Adding Nodes to a Cluster.

Complete the following steps to reconfigure a node:

1. Stopping the Node
Describes how to stop a node.

last-updated: Jun 06, 2024

Procedure

1. Change to the `root` user (or use `sudo` for the following commands).
2. Stop Warden: `service mapr-warden stop`
3. Stop ZooKeeper, if installed on the node: `service mapr-zookeeper stop`

2. Formatting the Disks (Optional)
Provides an overview of how to format the disks.

If you are re-using a node that was used previously in another cluster, be sure to format the disks by using the `disksetup` script to remove any traces of data from the old cluster. Refer to the previous section, Formatting Disks on a Node, for instructions.

3. Installing or Removing Software or Hardware
Lists the considerations to install or remove software or hardware.

When the node is stopped, you can add, upgrade or remove software or hardware. At some point after adding or removing services, you should restart Warden, to re-optimize memory allocation among all the services on the node. It is not crucial to perform this step immediately; you can restart Warden any time when the cluster is not busy.

To add or remove individual HPE Ezmeral Data Fabric packages, use the standard package management commands for your Linux distribution:

- `apt-get` (Ubuntu)
- `yum` (Red Hat or CentOS)

For information about the packages to install, see Planning the Cluster.

The following sections provide information about adding or removing services from a node after it has been deployed in a cluster:

Adding a Service to an Existing Node
Explains how to add a service to a node.

About this task
The process of adding a service to a node is similar to the initial installation process for nodes. For further detail see Installing MapR Software.

Procedure

1. Install the package(s) corresponding to the new role(s) using `apt-get` or `yum`.
2. Run `configure.sh` with a list of the CLDB nodes and ZooKeeper nodes in the cluster.
3. If you added the CLDB or ZooKeeper role, you must run `configure.sh` on all other nodes in the cluster.
4. If you added the fileserver role, run `disksetup` to format and prepare disks for use as storage.
5. Restart Warden.

```
service mapr-warden restart
```

Results
When Warden restarts, it picks up the new configuration and starts the new services, making them active in the cluster.

last-updated: Jun 06, 2024

Removing a Service from an Existing Node
Explains how to remove a service from a node.

Procedure

1. Stop the service you want to remove by using the Control System or the `maprcli` command-line tool. The following example stops the Fileserver service:

   ```
   maprcli node services -fileserver stop -nodes mapr-node1
   ```

2. Purge the service packages with the `apt-get`, `yum`, or `zypper` commands, as suitable for your operating system.
3. Run the `configure.sh` script with the `-R` option.
4. When you remove the CLDB or ZooKeeper role from a node, run `configure.sh -R` on all nodes in the cluster.

4. Configuring the Node
Provides an overview of the `configure.sh` script to use to configure a node.

The script `configure.sh` configures a node to be part of a HPE Ezmeral Data Fabric cluster, or modifies services running on an existing node in the cluster. The script creates (or updates) configuration files related to the cluster and the services running on the node.

Before you run `configure.sh`, make sure you have a list of the hostnames of the CLDB and ZooKeeper nodes. You can optionally specify the ports for the CLDB and ZooKeeper nodes as well. The default ports are:

Service	Default Port #
CLDB	7222
ZooKeeper	5181

The script `configure.sh` takes an optional cluster name and log file, and comma-separated lists of CLDB and ZooKeeper host names or IP addresses (and optionally ports), using the following syntax:

```
/opt/mapr/server/configure.sh -C <host>[:<port>][,<host>[:<port>]...] -Z
<host>[:<port>][,<host>[:<port>]...] [-L <logfile>][-N <cluster name>]
```

NOTE:

Each time you specify the `-Z <host>[:<port>]` option, you must use the *same order* for the ZooKeeper node list. If you change the order for any node, the ZooKeeper leader election process will fail.

Example:

```
/opt/mapr/server/configure.sh -C
r1n1.sj.us:7222,r3n1.sj.us:7222,r5n1.sj.us:7222 -Z
r1n1.sj.us:5181,r2n1.sj.us:5181,r3n1.sj.us:5181,r4n1.sj.us:5181,r5n1.sj.us:5
181 -N MyCluster
```

5. Starting the Node
Explains how to start a node.

Procedure

1. If ZooKeeper is installed on the node, start it: `service mapr-zookeeper start`
2. Start Warden: `service mapr-warden start`

Renaming a Node from the Command-Line
Provides distribution-specific instructions for renaming a node.

Procedure

ATTENTION: Ensure that the host name you set is resolvable. Add the host name to the `/etc/hosts` file. For example: `10.10.19.22 host.qa.net`. Data Fabric installation and commands fail if the host name is not resolvable.

To rename a node:

1. Stop Warden on the node. Example:

```
service mapr-warden stop
```

2. If the node is a ZooKeeper node, stop ZooKeeper on the node. Example:

```
service mapr-zookeeper stop
```

3. Rename the host:
   - Red Hat 6.x and CentOS 6.x: To preserve the new host name after reboot, edit the `HOSTNAME` parameter in the `/etc/sysconfig/network` file and restart the `xinetd` service or reboot the node. To change the host name temporarily without a reboot, run:

     ```
     hostname desired-host-name
     ```

   - Red Hat 7.x and CentOS 7.x: Run the command:

     ```
     hostnamectl set-hostname desired-host-name --static
     ```

     Alternatively, enter the host name in the `/etc/hostname` file, and run:

     ```
     hostname -F /etc/hostname
     ```

     Both these methods preserve the host name across reboots.

   - On Ubuntu, first install *dbus* if it is not installed.

     ```
     apt-get install dbus
     ```

     Next, run the command:

     ```
     hostnamectl set-hostname desired-host-name --static
     ```

     Alternatively, edit the host name in the `/etc/hostname` file, and run:

     ```
     hostname -F /etc/hostname
     ```

     Both these methods preserve the host name across reboots.

last-updated: Jun 06, 2024

4. If the node is a ZooKeeper node or a CLDB node, run `configure.sh` on page 2821 with a list of CLDB and ZooKeeper nodes.
5. If the node is a ZooKeeper node, start ZooKeeper on the node. Run:

   ```
   service mapr-zookeeper start
   ```

6. Start Warden on the node. Run:

   ```
   service mapr-warden start
   ```

What to do next
After you rename a:

- CLDB or ZooKeeper node, run `configure.sh` on page 2821 on all the nodes with the new host name, to update the `mapr-clusters.conf` file with the new host name. Ensure that there are no duplicate entries in the file. Also, verify that the new host is accessible from all the nodes.
- Node, some local volumes (such as for audit, and metrics) may exist with both the old and new host names. If you want, you can remove the local volumes with the old host name, use the existing local volume path, or remount to the new path.

Changing the IP Address of a Node
Describes how to change the IP address of any node in the cluster using the CLI.
Changing the IP Address of a Data Node

About this task

Complete the following steps to change the IP address of a data node:

Procedure

1. Shut down Warden and ZooKeeper on the node to be changed.

   ```
   service mapr-zookeeper stop
   service mapr-warden stop
   ```

2. Change the IP address of the node.
3. Edit the `/etc/hosts` file on all nodes to reflect the IP address change, or ensure that the IP addresses are resolvable through a DNS search.
4. On the node where you changed the IP address, restart the network interface. The interface shuts down, so you lose the connection.
5. Log into the node using the new IP address.
6. Check the IP address.
   For example, run `ifconfig`.
7. If the `MAPR_SUBNETS` environment variable is set, edit the value for the `MAPR_SUBNETS` environment variable in the `/opt/mapr/conf/env.sh` file and make sure that the new IP address is part of it.
   See Setting Environment Variables for NIC Segregation on page 1162 for more information.
8. Restart Warden on the node(s) where the IP address has changed.

9. Check that all nodes appear in the output of the node list command.

```
/opt/mapr/bin/maprcli node list -columns ip
```

   You might have to wait a few minutes until all nodes are registered before you get the output from this command.

Changing the IP Address of CLDB Node

About this task

Complete the following steps to change an IP address of a CLDB node:

Procedure

1. Shut down Warden and ZooKeeper on the node to be changed.

```
service mapr-zookeeper stop
service mapr-warden stop
```

2. Change the IP address of the node.
3. Edit the `/etc/hosts` file on all nodes to reflect the IP address change, or ensure that the IP addresses are resolvable through a DNS search.
4. On the node where you changed the IP address, restart the network interface. The interface shuts down, so you lose the connection.
5. Log into the node using the new IP address.
6. Check the IP address. For example, run `ifconfig`.
7. Run `configure.sh`.

   Use the `-C` option to provide a list of CLDB nodes.

   NOTE:

   If the initial setting was based on the IP address, run `configure.sh` on all nodes in the cluster.

   If the initial setting was based on the hostname, there is no need to run `configure.sh` on any nodes when you change the IP address.

8. Perform a rolling restart of Warden on all the nodes.
9. Check that all nodes appear in the output of the node list command. You might have to wait a few minutes until all nodes are registered before you get output from this command.

```
/opt/mapr/bin/maprcli node list -columns ip
```

Changing the IP Address of ZooKeeper Node

About this task

Complete the following steps to change an IP address of a ZooKeeper node:

Procedure

1. Shut down Warden and ZooKeeper on the node to be changed.

   ```
   service mapr-zookeeper stop
   service mapr-warden stop
   ```

2. Change the IP address of the node.
3. Edit the `/etc/hosts` file on all nodes to reflect the IP address change, or ensure that the IP addresses are resolvable through a DNS search.
4. On the node where you changed the IP address, restart the network interface. The interface shuts down, so you lose the connection.
5. Log into the node using the new IP address.
6. Check the IP address.

   For example, run `ifconfig`.
7. Run `configure.sh`.

   Use the `-Z` option to provide the list of ZooKeeper nodes.

   NOTE:

   If the initial setting was based on the IP address, run `configure.sh` on all the ZooKeeper, CLDB, and Data nodes in the cluster.

   If the initial setting was based on the hostname, there is no need to run `configure.sh` on any nodes when you change the IP address.

8. If you run the Drillbit service on any nodes in the cluster:
   a) Change the ZooKeeper address in the `conf/drill-override.conf` file on the Drill nodes.

   b) Start ZooKeeper on the ZooKeeper node, and then perform a rolling restart of ZooKeeper on all other ZooKeeper nodes.

      A rolling restart of ZooKeeper means restart ZooKeeper on each node, one at a time, pausing until the last restart finishes before beginning the next. Restart the ZooKeeper leader last.
9. Verify that the new node joined the ZooKeeper quorum.

   ```
   service mapr-zookeeper status
   ```

10. Perform a rolling restart of Warden on all the nodes.
11. Check that all nodes appear in the output of the node list on page 2264 command. You might have to wait a few minutes until all nodes are registered before you get output from this command.

    ```
    /opt/mapr/bin/maprcli node list -columns ip
    ```

Viewing Active Node Alarms

Describes how to view active node alarms using the Control System and the CLI.

last-updated: Jun 06, 2024

Viewing Active Node Alarms in the Control System

Procedure

- **NOTE:** The **Nodes** page is not available in the Kubernetes version of the Control System.

  Log in to the Control System and:

  - Click **Nodes** to view all the node alarms on the cluster in the **Active Alarms** pane.
  - Go to the node information page to view alarms in the **Alarms** pane for the selected node.
  - Click (in the top navigation bar) to display the **Alarm Summary** page and select **Node Alarms** from the drop-down menu in the **All** alarms pane.
  - Click **Overview** and select **Node Alarms** from the drop-down menu in the **Active Alarms** pane to view all the node alarms on the cluster.

  You can:

  - View alarm notes
  - Mute an alarm
  - Dismiss an alarm

Retrieving Active Node Alarms Using the CLI or REST API

About this task

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type node
```

For complete reference information, see `alarm list` on page 2023.

Allocating Memory for Nodes

Describes how the Warden allocates memory for nodes.

When you run `configure.sh` on a node, Warden allocates memory for the operating system, `mfs service`, data-fabricHadoop services, and applications using the settings in the `warden.conf` and the `warden.<servicename>.conf` file.

Warden allocates memory to the following components in the following order:

1. Operating system
2. `mfs service`
3. Data Fabric Hadoop services
4. Applications, such as YARN applications
5. If the node only runs file system, NFS for the HPE Ezmeral Data Fabric, and gateway, then 85% of all memory is allocated to file system.

NOTE: In general, modify the settings in the warden files only under certain circumstances. If you modify the values in `warden.conf` or `warden.<servicename>.conf` file, you must restart Warden. Otherwise, updated parameters will not be used to allocate resources.

last-updated: Jun 06, 2024

Allocating Memory for the OS, file system, and Hadoop Services
Lists the parameters that control how Warden allocates memory for the OS, file system and the HPE Ezmeral Data Fabric Hadoop services.

Warden allocates memory to the operating system, file system, and HPE Ezmeral Data Fabric Hadoop services based on the following parameters:

Parameter	Default OS	file system	Hadoop Service(s)	Description
`service.command.<os|mfs|servicename>.heapsize.percent`	10	varies	varies	Defines the heap size percentage.
`service.command.<os|mfs|servicename>.heapsize.maxpercent`	Not Applicable	85	Not Applicable	Defines the heap size maximum percentage
`service.command.<os|mfs|servicename>.heapsize.max`	4000	Not Applicable	5000	Defines the maximum heap size in MB.
`service.command.<os|mfs|servicename>.heapsize.min`	256	512	256	Defines the minimum heap size in MB.

Memory settings for the operating system and the file system are configured in the `warden.conf` file. The `warden.conf` file is located in `/opt/mapr/conf`. Other services, such as NodeManager and ResourceManager, have their own `warden.<servicename>.conf` file within `/opt/mapr/conf/conf.d`. For more information about the Warden files, see `warden.conf` and `warden.<servicename>.conf`.

Note: Warden allocates resources only for the HPE Ezmeral Data Fabric Hadoop services associated with roles that are installed on the node.

Allocating Memory for the File System Service
Describes how Warden allocates memory for the file system service.

By default, Warden adds up the total memory consumed by all services and the OS, and then allocates 85% of the remainder to the file system. If you do not intend to use HPE Ezmeral Data Fabric Database, you can set the `-noDB` option in `configure.sh` to specify that 20% of the memory available should be allocated to the file system service. Allocating more memory to the file system improves performance due to greater data caching. Data caching is especially vital when your main constraint is disk I/O. For the parameters that you can configure to give Warden more memory, see Allocating Memory for the OS, file system, and Hadoop Services on page 1128.

Performing Maintenance on a Node from the Command-Line
Describes how to maintain the performance of a node using the CLI.

You can place a node into a maintenance mode for a specified timeout duration. For the duration of the timeout, the cluster CLDBs do not consider this node's data as lost and do not trigger a resync of the data on the node.

The following sections describe how to perform maintenance on a node.

Putting a Node into Maintenance Mode
Describes how to put a node into maintenance mode.

last-updated: Jun 06, 2024

About this task

If you put a node into maintenance mode, the node is marked unserviceable, but is still attached to the cluster.

Before putting a node into maintenance mode, ensure that:

- All copies of the CLDB volume exist if the node is a CLDB node. You *cannot* put a CLDB master into maintenance mode until the CLDB service is stopped. You can shut down the CLDB service only if the CLDB is a secondary CLDB or you have enabled high availability for CLDB.

  You *cannot* put a node into maintenance mode if the node is running as the CLDB master and also supporting file-system services.

- All running processing tasks (NodeManager and Spark, for example) that depend on the file system have been stopped.

WARNING: Do not put a node under maintenance if there are any volume under-replicated alarms because doing so might take some data completely offline.

To put a node into maintenance mode, perform the following actions:

Procedure

1. From a terminal, issue the `node maintenance` on page 2284 command:

   ```
   /opt/mapr/bin/maprcli node maintenance -nodes <IP|
   hostname> -timeoutminutes <minutes>
   ```

   If you run this command, specify a timeout (in minutes) long enough for you to perform necessary maintenance on the node.

   NOTE: For the duration of the timeout, the cluster CLDB considers this node as unavailable. Under this scenario, the CLDB does not trigger data replication for this node until it exits maintenance mode. Furthermore, clients accessing containers on the node receive the appropriate error and retry other container copies. Note also that if a node is put under maintenance for more than five minutes, the file system shuts down on that node to prevent any other operations from occurring. This value of five minutes is hard-coded and cannot be changed. Even if you reboot the node, the maintenance mode persists until the timeout is reached.

2. Stop Warden on the node:

   ```
   service mapr-warden stop
   ```

   To bring the node back online, see Taking a Node Out of Maintenance Mode on page 1129.

Taking a Node Out of Maintenance Mode
Describes how to bring a node back online from maintenance mode.

About this task

To take a node out of maintenance mode before the timeout expires, follow this process:

Procedure

1. From a terminal, issue the following command:

   ```
   maprcli node maintenance -nodes <IP address> -timeoutminutes 0
   ```

last-updated: Jun 06, 2024

2. Restart Warden:

```
service mapr-warden restart
```

Managing Roles

Describes how to manage roles on a node.

You must install *role*s on nodes in a cluster before their corresponding *services* can be launched. For information on how to install roles on nodes, see Adding Roles to a Node. Refer to the following topics for managing the roles using the CLI.

Adding Roles to a Node

Summarizes the process to add a role.

You can add a *role* on a node after you deploy the node in a cluster. The process of adding a *role* to a node involves installing a package on the node and updating the cluster to recognize the new *role*. The process of adding a *role* depends on the *role* type.

Once you have added a *role* to a node, you must restart Warden. Observe the following best practices when restarting Warden on ZooKeeper and CLDB nodes:

- Perform a rolling restart of Warden to ensure that all services are up. A rolling restart of Warden means restart Warden on each node, one at a time, pausing until the previous restart finishes, before beginning the next.
- To avoid a failover from occurring, identify nodes running critical services, such as ResourceManager, and restart Warden last on those nodes.
- Restart Warden on nodes that run critical cluster services, such as ResourceManager, during periods of low activity.

Adding a Role

Describes how to add various roles to a Data Fabric node.

About this task

Do not use these steps to add the CLDB or ZooKeeper role.

NOTE: When Collectd is installed on a node with YARN ResourceManager or NodeManager, running `configure.sh -R`, to add or remove roles on the node, triggers these services to restart. During a restart, the NodeManager and ResourceManager are temporarily unavailable for new application submission. A patch is available to resolve this behavior. See Applying Patches.

The following steps describe how to add a role to a node:

Procedure

1. Install the package corresponding to the new role using `apt-get, yum,` or `zypper,` depending on your platform. For more information, see Data Fabric Repositories and Packages on page 101.
2. Run `configure.sh -R` on the node where you added the role.

   If Warden is running, the new service starts automatically.
3. If you added the File server role, run `disksetup` to format and prepare disks for use as storage.
4. Issue the following command to restart Warden on the node where you installed the role:

```
% service mapr-warden restart
```

last-updated: Jun 06, 2024

Adding a CLDB Role Using the CLI

Describes how to add a CLDB role to an HPE Ezmeral Data Fabric node using the CLI.

About this task

Complete the following steps to add the CLDB role to a node in the cluster:
Adding a CLDB Role to a Node on a Secure Cluster

Procedure

1. Install the CLDB package, `mapr-cldb`, on the node by using `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
2. Copy the following files from the `/opt/mapr/conf` directory on any existing CLDB node on the cluster to the `/opt/mapr/conf` directory on this node.
   - `maprhsm.conf`
   - `maprkeycreds.conf`
   - `maprkeycreds.jceks`
   - `maprserverticket`
   - `maprtrustcreds.conf`
   - `maprtrustcreds.jceks`
   - `ssl_keystore`
   - `ssl_keystore.p12`
   - `ssl_keystore.pem`
   - `ssl_keystore-signed.pem`
   - `ssl_truststore`
   - `ssl_truststore.p12`
   - `ssl_truststore.pem`
   - `ssl_userkeystore`
   - `ssl_userkeystore.p12`
   - `ssl_userkeystore.pem`
   - `ssl_userkeystore-signed.pem`
   - `ssl_usertruststore`
   - `ssl_usertruststore.p12`
   - `ssl_usertruststore.pem`
   - `tokens` (use a command such as `scp -r` to copy everything in this folder)
3. Run `configure.sh` on page 2821 with the following options on the node where you added the new CLDB role.

last-updated: Jun 06, 2024

- `-secure`: Use this option to enable the node for security.
- `-C`: Use this option to include this node in the list of CLDB nodes. If Warden is running, the CLDB service starts automatically.
- `-dare`: Use this option only if the cluster is enabled for data-at-rest encryption. Do not specify `-dare` if the cluster is not enabled for data-at-rest encryption.
- Use one of the following to configure the list of ZooKeeper nodes:
  - `-R`: Use this option if the node is an existing cluster node. This option uses the previously configured list of ZooKeeper nodes. When `-R` is specified, the ZooKeeper credentials are read from `warden.conf` file.
  - `-Z`: Use this option if the node is a new node on the cluster. This option specifies the list of ZooKeeper nodes.

4. Run `configure.sh` on page 2821 with the following options on all other nodes in the cluster.
   - `-C`: Use this option to include the new CLDB node in the list of CLDB nodes.
   - `-R`: Use this option to use the previously configured list of ZooKeeper nodes.
5. Verify that the node has a CLDB role by running the following command:

   ```
   maprcli node listcldbs
   ```

   The output should show all the CLDB nodes, including the node where the role was added.

Adding a ZooKeeper Role
Describes how to add a ZooKeeper role to a Data Fabric node by using the CLI.

About this task
If you are increasing the number of ZooKeeper roles in the cluster, for example from one to three, shut down the cluster before you add the role to the nodes to prevent any problems. Then restart the cluster upon completion. Complete the following steps to add the ZooKeeper role to a node:

Procedure

1. Install the ZooKeeper package corresponding to the new role. For more information about packages, see Data Fabric Repositories and Packages on page 101.
2. To identify the ZooKeeper nodes in the cluster, run `maprcli node listzookeepers`.
3. Copy the tokens and all other directories needed from the existing nodes. You can find the list of files you need to copy in Enabling Security on page 1776.

   IMPORTANT: Copying files as `root` user results in the files being unreadable. Make sure the copied files are readable as the cluster admin user.
4. On all nodes in the cluster where you added the new ZooKeeper role, run configure.sh on page 2821 with the following options:
   - `-Z`: This option specifies the list of ZooKeeper nodes.
   - `-R`: This option uses all previously set configurations.

For example:

```
/opt/mapr/server/configure.sh -Z <all-nodes-including-new-one> -R
```

5. Restart the servies on all nodes:
   a. Run the following command on all nodes to start or restart ZooKeeper:

      ```
      systemctl restart mapr-zookeeper
      ```

   b. Perform a rolling restart of ZooKeeper on all nodes. A rolling restart of ZooKeeper means restart ZooKeeper on each node, one at a time, pausing until the last restart finishes before beginning the next. Restart the ZooKeeper leader last.

   c. Run the following command to verify that the new node joined the ZooKeeper quorum:

      ```
      /opt/mapr/initscripts/zookeeper qstatus
      ```

   d. Perform a rolling restart of Warden on all nodes. Warden picks up the new ZooKeeper node. Issue the following command on all nodes to restart Warden:

      ```
      systemctl restart mapr-warden
      ```

6. Run `maprcli node listzookeepers`. The output should show all ZooKeeper nodes, including the node where the role was added.

Removing Roles from a Node
Describes how to remove a role from a node.

You can remove *role*s from nodes in the data-fabric cluster. The process of removing a *role* from a node depends on the *role* type.

Once you remove a *role* from a node, you must restart Warden. Observe the following best practices when restarting Warden on nodes that were ZooKeeper or CLDB nodes:

- Perform a rolling restart of Warden to ensure that all services are up. A rolling restart of Warden means restart Warden on each node, one at a time, pausing until the previous restart finishes, before beginning the next.
- To avoid a failover from occurring, identify nodes running critical services, such as ResourceManager, and restart Warden last on those nodes.
- Restart Warden on nodes that run critical cluster services, such as ResourceManager, during periods of low activity.

Removing a Role
Describes how to remove a role from a node, using the CLI.

About this task
Do not use these steps to remove the CLDB, ZooKeeper, or Fileserver role from a node.

NOTE: When collectd is installed on a node with YARN ResourceManager or NodeManager, running configure.sh –R, to add or remove roles on the node, triggers these services to restart. During a restart, the NodeManager and ResourceManager are temporarily unavailable for new application submission. A patch is available to resolve this behavior. See Applying Patches.

The following steps describe how to remove a role from a node:

Procedure

1. If you are removing the NFS role, unmount any existing client mounts.
   Removing the NFS role from a node affects any Virtual IP (VIP) pools that include this node.
2. If the cluster has only one CLDB, run `configure.sh` with the `-C` option on all the nodes.
3. Stop the service for the role you want to remove, either through the Control System or by issuing a `maprcli` command:

   ```
   % maprcli node services -name <service_name> -action stop -nodes
   <node-name>
   ```

   The following example stops the webserver role on node "my-node":

   ```
   % maprcli node services -name webserver -action stop -nodes my-node
   ```

4. Purge the role packages with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
5. Run `configure.sh -R` on the node where you removed the role.
   Warden picks up the new configuration automatically.
6. Issue the following command to restart Warden on the node where you removed the role:

   ```
   % service mapr-warden restart
   ```

Removing a CLDB Role

Describes how to remove the CLDB role from a node.

About this task

Procedure

1. If you have only one CLDB node in the cluster, add the CLDB role to another node.
   When failover occurs after removal of the CLDB node, the new CLDB node becomes the primary CLDB.
2. Issue the following command to stop the CLDB service on the node:

   ```
   /opt/mapr/bin/maprcli node services -name cldb -action stop -nodes
   mapr-<node>
   ```

3. Purge the CLDB package, `mapr-cldb`, with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.
4. Run `configure.sh` on page 2821 with the `-C`, `-N` and `-Z` options on the node where you removed the role.
   Use the `-C` option to provide the list of CLDB nodes, excluding the node where you removed the role, `-N` to pass the name of the cluster, and `-Z` to specfy the list of ZooKeeper nodes.
5. Run `configure.sh` on page 2821 with the `-C`, `-N` and `-Z` options on all other nodes in the cluster.
   Use the `-C` option to provide the list of CLDB nodes, excluding the node where you removed the role, `-N` to pass the name of the cluster, and `-Z` to specify the list of ZooKeeper nodes.

Removing a ZooKeeper Role

Describes how to remove the ZooKeeper role from a node.

About this task

The following steps describe how to remove the ZooKeeper role from a node:

Procedure

1. Issue the following command to stop ZooKeeper on the node:

   ```
   % service mapr-zookeeper stop
   ```

2. Purge the ZooKeeper package `mapr-zookeeper`.
3. Run `configure.sh`.

   Use the `-Z` option and provide the list of ZooKeeper nodes that excludes the node where you removed the role.
4. Perform a rolling restart of ZooKeeper on all other ZooKeeper nodes.

   A rolling restart of ZooKeeper means restart ZooKeeper on each node, one at a time, pausing until the last restart finishes before beginning the next. Restart the ZooKeeper leader last.
5. Issue the following command to verify that ZooKeeper is healthy and that the expected nodes adopted the ZooKeeper node:

   ```
   % service mapr-zookeeper qstatus
   ```

6. Perform a rolling restart of Warden on all other nodes.

   Warden picks up the revised quorum.

Removing a Fileserver Role

Describes how to remove the Fileserver role from a node.

About this task

Removing the fileserver role from a node is more complex than removing other roles. The CLDB tracks data precisely on all fileserver nodes, and therefore you should direct the cluster CLDB to stop tracking the node before removing the fileserver role. For a planned decommissioning of a node, use node topologies to migrate data off the node before removing the fileserver role. For example, you could move the node out of a live `/data` topology into a `/decommissioned` topology that has no volumes assigned to it, in order to force data off the node. Otherwise, some data will be under-replicated as soon as the node is removed. Refer to Node Topology.

NOTE: The following procedure involves halting all data-fabric services on the node temporarily. If this might disrupt critical services on your cluster, such as CLDB, migrate those services to a different node first, and then proceed.

The following steps describe how to remove the fileserver role from a node:

Procedure

1. Stop the warden, which will halt all data-fabric services on the node. Wait 5 minutes, after which the CLDB will mark the node as critical.

last-updated: Jun 06, 2024

2. Remove the node from the cluster, to direct the CLDB to stop tracking this node.
   You can do this in the Control System GUI or with the `maprcli node remove` command.
3. Remove the fileserver role by deleting the file `/opt/mapr/roles/fileserver` on the node.
4. Run `configure.sh` on the node to reconfigure the node without the fileserver role.
5. Issue the following command to restart Warden on the node:

   ```
   % service mapr-warden restart
   ```

6. Remove any volumes that were stored locally on the node.
   You can do this in the Control System or with the `maprcli volume remove` command.

Assigning Roles to Nodes for Best Performance
Guidelines to optimise the cluster's service layout for best performance.

The architecture of data-fabric software allows virtually any service to run on any node, or nodes, to provide a high-availability, high-performance cluster. The following guidelines help plan your cluster's service layout.

Do not Overload ZooKeeper

High latency on a ZooKeeper node can lead to an increased incidence of ZooKeeper quorum failures. A ZooKeeper quorum failure occurs when the cluster finds too few copies of the ZooKeeper service running. If the ZooKeeper node is also running other services, competition for computing resources can lead to increased latency for that node. If your cluster experiences issues relating to ZooKeeper quorum failures, consider reducing or eliminating the number of other services running on the ZooKeeper node.

Separate High-Demand Services

The following guideline states the services to separate on large clusters:

- **ResourceManager on ZooKeeper nodes**: Avoid running the ResourceManager service on nodes that are running the ZooKeeper service. On large clusters, the ResourceManager service can consume significant resources.

Managing Services

Synopsis on managing services.

Once a role is installed on a node and the warden has been restarted, HPE Ezmeral Data Fabric recognizes the role for that node. You can then start the service. Refer to the following topics for information on managing services on a node using the Control System and the CLI.

Viewing the List of Services
Explains how to view the list of services using either the Control System or the CLI.
Viewing the Services Installed on the Cluster Using the Control System

Procedure

- Log in to the Control System and click **Services**.
  The **Services** pane displays all the services installed on the cluster. On the non-Kubernetes version of the Control System, the pane displays the following:

Column Name	Column Description
Service	The name of the installed service.

last-updated: Jun 06, 2024

Column Name	Column Description
Running Nodes	The number of nodes on which the associated service is running. The service can be stopped ( ) or restarted ( ). Click the number in this column to view the nodes on which the service is running.
Standby Nodes	The number of nodes on which the associated service is in standby (available, but not running) state. The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service is in standby state.
Failed Nodes	The number of nodes on which the service has failed. The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service has failed.
Stopped Nodes	The number of nodes on which the associated service is stopped (and not running). The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service has been stopped.
Log Viewer	(Displays only if Kibana is installed on a node) The link ( ) to the Kibana UI.

You can filter the list of services displayed by:

- **EEP**, which includes services such as Hive, Drill, etc.
- **Core**, which includes services such as CLDB, Hoststats, File server, etc.
- **Monitoring**, which includes services such as Grafana, Kibana, etc.

Viewing the Services Running on a Node Using the Control System

Procedure

1. Log in to the Control System and click **Nodes**.

   NOTE: The **Nodes** menu is not available in the Kubernetes version of the Control System.

2. You can:
   - Hover the cursor over the number listed in the **Running Services** column in the **Nodes** pane to view the list of services installed on that node.
   - Go to the **Summary** tab in the node information page to view detailed information on the services installed on a node.

   In the **Summary** tab, for each service running on the node, the **Services** pane displays the following:

Column Name	Column Description
Service	The name of the service.
State	The current state of the service. Value can be: • Running • Stopped
Memory Allocated	The amount of system memory allocated to the service.

last-updated: Jun 06, 2024

Column Name	Column Description
System Memory Utilized	The percentage of memory utilized by the service.
CPU Usage	The CPU used by the service.
Log Path	The path to the service log file.
Log Viewer	The link to the Kibana UI (only if Kibana is installed).

You can select the checkbox beside one or more services to take the following actions:

- Start Services
- Stop Services
- Restart Services

NOTE: If Kibana is installed, you can click to view the logs. See Kibana User Guide for more information.

Retrieving the Services Running on a Node Using the CLI or REST API

About this task

The command to list all the services on a node is:

```
maprcli service list -node <node name>
```

For complete reference information, see service list on page 2356.

Enabling and Disabling a Service Using the CLI and REST API

Describes how to enable or disable a service using either the REST API or the CLI.

About this task

You can disable a service to prevent it from starting or restarting when Warden starts or restarts, and enable a service to allow it to start or restart when Warden starts or restarts.

Disabling a Service Using the CLI or REST API

About this task

CLI

Run the following command:

```
maprcli node
services -nodes <hostName> -name
<serviceName> -action disable
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<host>:8443/rest/node/services?
nodes=<hostName>&name=<serviceName>
 &action=disable' --user mapr:mapr
```

NOTE: When you disable a service, the service is stopped and the service is not automatically starrted/restarted when Warden is started/restarted.

See node services on page 2292 for more information.

last-updated: Jun 06, 2024

Enabling a Service Using the CLI or REST API

About this task

CLI	Run the following command: `maprcli node services -nodes <hostName> -name <serviceName> -action enable`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<hostName>&name=<serviceName>&action=enable' --user mapr:mapr`

NOTE: When you enable a service, the service is started/restarted when Warden is started/restarted.

See `node services` on page 2292 for more information.

Related tasks

Restarting the Services on page 1141
Describes how to restart a service using either the Control System, the CLI or the REST API.

Starting the Services

Explains how to start services using either the Control System, the CLI or the REST API.

About this task

You can start one or more services using the Control System or the CLI if the service is not disabled. If the service is disabled, you must enable the service first, in order to start the service. See Enabling and Disabling a Service Using the CLI and REST API on page 1138 for more information.

Starting the Services Running on the Nodes Using the Control System

About this task

To start the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Start** radio button for the services you wish to start on the selected nodes and click **Save**.

Starting the Services Running on a Node Using the Control System

About this task

To start one or more services running on a node:

last-updated: Jun 06, 2024

Procedure

1. Go to the **Summary** tab in the node information page.
2. Select the services to start in the **Services** pane.
3. Click **Start Services**.
   The **Start Services** confirmation dialog displays.
4. Verify the list of services to start and click **Start Service**.

Starting the Services on the Cluster Using the Control System

Procedure

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. On the non-Kubernetes version of the Control System, click  for the service to start.
   The **Start Service** confirmation dialog displays.
3. Verify the list of nodes on which to start the service and click **Start Service**.

Starting a Service Using the CLI or REST API

About this task

The basic command to start a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action start
```

For complete reference information, see node services on page 2292.

Stopping the Services
Describes how to stop services using either the Control System, the CLI or the REST API.
Stopping the Services Running on the Nodes Using the Control System

About this task

To stop the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Stop** radio button for the services you wish to stop on the selected nodes and click **Save**.

Stopping the Services on a Node Using the Control System

About this task

To stop one or more services running on a node:

last-updated: Jun 06, 2024

Procedure

1. Go to the **Summary** tab in the node information page.
2. Select the services to stop in the **Services** pane.
3. Click **Stop Services**.
   The **Stop Services** confirmation dialog displays.
4. Verify the list of services to stop and click **Stop Service**.

Stopping a Service on the Cluster Using the Control System

Procedure

1. Log in to the Control System and click **Services**.
2. On the non-Kubernetes version, click  associated with the service to stop.
   The **Stop Service** confirmation dialog displays.
3. Verify the list of nodes on which to stop the service and click **Stop Service**.

Stopping the Services Using the CLI or REST API

About this task

The basic command to stop a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action stop
```

For complete reference information, see `node services` on page 2292.

Restarting the Services
Describes how to restart a service using either the Control System, the CLI or the REST API.

About this task

When a HPE Ezmeral Data Fabric system is rebooted, the following services are automatically restarted:

- mapr-warden
- mapr-zookeeper
- mapr-loopbacknfs
- mapr-posix-client-*

These services are also automatically restarted if they are shut down externally (as opposed to being shut down explicitly via `service` or `sysctl` commands).

NOTE: This feature is implemented with `systemd` and is only supported on the following operating systems:

- RHEL 7.0, 7.1
- CentOS 7.0, 7.1
- SLES 12

This feature is not supported on any of the Ubuntu versions that HPE Ezmeral Data Fabric currently supports.

You can restart one or more services using the Control System and the CLI if the services are not disabled. However, if a service is disabled, the service cannot be restarted. To restart a service, make sure the service is enabled. See Enabling and Disabling a Service Using the CLI and REST API on page 1535 for more information.

Restarting the Services Running on the Nodes Using the Control System

About this task

To restart the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Restart** radio button for the services you wish to restart on the selected nodes and click **Save**.

Restarting one or more Services on a Node Using the Control System

Procedure

1. Go to the **Summary** tab in the node information page.
2. Select the services to restart in the **Services** pane.
3. Click **Restart Service(s)**.
   The **Restart Service(s)** confirmation dialog displays.
4. Verify the list of services to restart and click **Restart Service**.

Restarting the Services on the Cluster Using the Control System

Procedure

1. Log in to the Control System and navigate to **Services**.
2. On the non-Kubernetes version, click associated with the service to restart.
   The **Restart Service** confirmation dialog displays.
3. Verify the list of nodes on which to restart the service and click **Restart Service**.

last-updated: Jun 06, 2024

Restarting a Service Using the CLI or REST API

About this task

The basic command to restart a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action restart
```

For complete reference information, see node services on page 2292.

Related tasks

Enabling and Disabling a Service Using the CLI and REST API on page 1535
Describes how to enable or disable a service using either the REST API or the CLI.

Changing the User for Data Fabric Services from the Command-Line

Explains how use the CLI to change the user that data-fabric services run as.

About this task

All services should run with the same uid/gid on all nodes in the cluster.

Running Data Fabric Services as the Root User

Procedure

1. Stop Warden.

   ```
   service mapr-warden stop
   ```

2. If ZooKeeper is installed on the node, stop it.

   ```
   service mapr-zookeeper stop
   ```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`
4. If Zookeeper is installed, start it.

   ```
   service mapr-zookeeper start
   ```

5. Start Warden.

   ```
   service mapr-warden start
   ```

Running Data Fabric Services as a Non-Root User

Procedure

1. Stop Warden.

   ```
   service mapr-warden stop
   ```

2. If ZooKeeper is installed on the node, stop it.

   ```
   service mapr-zookeeper stop
   ```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.
4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same as the value on the CLDB node.
5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`.
6. If Zookeeper is installed, start it.

   ```
   service mapr-zookeeper start
   ```

7. Start Warden.

   ```
   service mapr-warden start
   ```

8. After clearing NODE_ALARM_MAPRUSER_MISMATCH alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Running Data Fabric Services as the Root User

Procedure

1. Stop Warden:

   ```
   service mapr-warden stop
   ```

2. If ZooKeeper is installed on the node, stop it:

   ```
   service mapr-zookeeper stop
   ```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`
4. If ZooKeeper is installed, start it:

   ```
   service mapr-zookeeper start
   ```

5. Start Warden:

   ```
   service mapr-warden start
   ```

Running Data Fabric Services as a Non-Root User

Procedure

1. Stop Warden:

   ```
   service mapr-warden stop
   ```

2. If ZooKeeper is installed on the node, stop it:

   ```
   service mapr-zookeeper stop
   ```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.

4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same same as the value on the CLDB node.
5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`
6. If Zookeeper is installed, start it:

   ```
   service mapr-zookeeper start
   ```

7. Start Warden:

   ```
   service mapr-warden start
   ```

8. After clearing NODE_ALARM_MAPRUSER_MISMATCH alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Managing Disks

Provides a brief overview of adding and removing disks from the HPE Ezmeral Data Fabric file system.

You can add and remove disks in the file system from the control system or using the `diskadd` and `diskremove` commands. file system groups disks into *storage pools*, usually made up of two or three disks. When adding disks to the file system, it is a good idea to add at least two or three at a time so that HPE Ezmeral Data Fabric can create properly-sized storage pools. Each node in a HPE Ezmeral Data Fabric cluster can support up to 36 storage pools.

To see which disks are used by file system, check the `disktab` file that HPE Ezmeral Data Fabric maintains on each node.

WARNING: For instructions on performing disk maintenance on a node, see Performing Maintenance on a Node. If a disk failure alarm is raised (`NODE_ALARM_DISK_FAILURE`), see Handling Disk Failures for instructions.

Refer to the following procedures to manage disks using the Control System and the CLI.

Viewing the List of Disks
Explains how to view the disks on a node using either the Control System or the CLI.
Viewing the List of Disks Using the Control System

About this task

To view both the system and filesystem disks:

Procedure

1. Log in to the Control System and go to the node information page.
2. Go to the **Summary** tab.
   On this page, the **Disks** and **System Disks** panes display the following for each disk:

Column Name	Column Description
Status	The status of the disk. Value can be one of the following: • — indicates disk is active or good. • — indicates disk is on standby. • — indicates disk is offline.
Device	The disk partition(s).
Mnt	Indicates whether (✓) or not the disk is mounted.
file system	(Displayed in the **Disks** pane only) The disks available for file system. A ✓ indicates that the disk was added to file system.
File System	(Displayed in the **System Disks** pane only) The disks for system use.
Allocated	The amount of space allocated, in gigabytes.
Used	The percentage of disk space used.
Model#	The disk model number.
Firmware Version	The disk firmware version.
Storage Label	The label assigned to the disk.
Storage Pool	The ID of the storage pool associated with the disk.

Select the checkbox beside a disk in the **Disks** pane to:

- Add Disk(s) to file system
- Remove Disk(s) from file system

NOTE: Disks in the **System Disks** pane cannot be selected.

Retrieving the List of Disks Using the CLI or REST API

About this task

The basic command to list the disks on a node is:

```
maprcli disk list -host <host>
```

For complete reference information, see `disk list on page 2130`.

Setting Up Disks for HPE Ezmeral Data Fabric

This section describes how to set up disks during the normal installation process. Go to the `disksetup on page 2864` command page for information about other uses of this command.

HPE Ezmeral Data Fabric formats and uses disks for the Lockless Storage Services layer (file system), and records these disks in the `disktab on page 2978` file. In a production environment, or when testing performance, HPE Ezmeral Data Fabric should be configured to use physical hard drives and partitions. In some cases, it is necessary to reinstall the operating system on a node so that the physical hard drives are available for direct use by HPE Ezmeral Data Fabric. Reinstalling the operating system provides an unrestricted opportunity to configure the hard drives. If the installation procedure assigns hard drives to be managed by the Linux Logical Volume Manager(LVM) by default, you should explicitly remove the drives you plan to use with HPE Ezmeral Data Fabric from the LVM configuration. It is common to let LVM

last-updated: Jun 06, 2024

manage one physical drive containing the operating system partition(s) and to leave the rest unmanaged by LVM for use with HPE Ezmeral Data Fabric.

NOTE: It is not necessary to set up RAID (Redundant Array of Independent Disks) on disks used by file system. HPE Ezmeral Data Fabric uses the disksetup script to set up storage pools. In most cases, you should let HPE Ezmeral Data Fabric calculate storage pools using the default stripe width of two or three disks. If you anticipate a high volume of random-access I/O, you can use the `-W` option with disksetup to specify larger storage pools of up to 8 disks each.

NOTICE: For more information on setting up disks, see Drive Configuration.

The following procedures are intended for use on physical clusters or Amazon EC2 instances. On EC2 instances, EBS volumes can be used as HPE Ezmeral Data Fabric storage, although performance will be slow.

NOTE: If you are using HPE Ezmeral Data Fabric on Amazon EMR, you do not have to use this procedure; the disks are set up for you automatically.

Determine if a disk or partition is ready for use by HPE Ezmeral Data Fabric
Explains the procedure to determine whether a disk or partition is ready for use by HPE Ezmeral Data Fabric.

About this task

Any disk or partition that passes the following testing procedure can be added to the list of disks and partitions passed to the `disksetup` command.

1. Run the command `sudo lsof <partition>` to determine whether any processes are already using the disk or partition.

   There should be no output when running `sudo fuser <partition>`, indicating there is no process accessing the specific disk or partition.

2. The disk or partition should not be mounted, as checked via the output of the `mount` command. If the disk or partition is mounted, unmount it using the `umount` command.

3. The disk or partition should not have an entry in the `/etc/fstab file`; comment out or delete any such entries.

4. The disk or partition should be accessible to standard Linux tools such as `mkfs`. You should be able to successfully format the partition using a command like `sudo mkfs.ext3 <partition>` as this is similar to the operations that HPE Ezmeral Data Fabric performs during installation. If `mkfs` fails to access and format the partition, then it is highly likely that HPE Ezmeral Data Fabric will encounter the same problem.

Specify disks or partitions for use by HPE Ezmeral Data Fabric
Describes the use of the `disksetup` script to format disks.

About this task

The disksetup script is used to format disks for use by the HPE Ezmeral Data Fabric cluster. Create a text file `/tmp/disks.txt` listing the disks and partitions for use by HPE Ezmeral Data Fabric on the node. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

last-updated: Jun 06, 2024

Later, when you run the disksetup script to format the disks, specify the `disks.txt` file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

NOTE: The disksetup script removes all data from the specified disks. Make sure you specify the disks correctly, and that any data you wish to keep has been backed up elsewhere.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

NOTE: Run the disksetup script only after running the configure.sh script.

Evaluate HPE Ezmeral Data Fabric using a flat storage file instead of formatting disks
For evaluation, you can use a flat storage file instead of formatting disks.

About this task

When setting up a small cluster for evaluation purposes, if a particular node does not have physical disks or partitions available to dedicate to the cluster, you can use a flat file on an existing disk partition as the node's storage. Create at least a 16GB file, and include a path to the file in the disk list file for the `disksetup` script.

The following example creates a 20 GB flat file (`bs=1G` specifies 1 gigabyte blocks, multiplied by `count=20`) at `/root/storagefile`:

```
dd if=/dev/zero of=/root/storagefile bs=1G count=20
```

Add the created flat file to the disk list file `/tmp/disks.txt` to be used by `disksetup`:

```
/root/storagefile
```

Adding Disks to file system
Describes how to add disks using either the Control System or the CLI.

About this task

You can add disks to file system using the Control System and the CLI. Before adding the disks to file system, add the physical disks to the node or nodes according to the correct hardware procedure.

- If you are removing and replacing failed disks, you must install the replacements, then re-add the replacement disks to file system, along with the other disks that were in the same storage pool(s) as the failed disks. See Handling Disk Failures for more details.
- If you are removing disks but not replacing them, you can just re-add the other disks that were in the same storage pool(s) as the failed disks.

NOTE: Disks must be added on CLDB nodes one node at a time when Warden and HPE Ezmeral Data Fabric services are running.

ATTENTION: Disable write caching on all HPE Ezmeral Data Fabric disks if the disks are not battery backed.

Adding Disks Using the Control System

About this task

Complete the following steps to add disks of type file system using the Control System:

Procedure

1. Log in to the Control System and go to the **Summary** tab in the node information page.

   NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the disks not yet added to file system in the **Disks** pane and click **Add Disks to File System**. The **Add Disks to File System** confirmation dialog displays.

   NOTE: You cannot select disks of type *System* to add.

3. Review the list and click **Add Disk**.
   The disks are automatically formatted and properly-sized storage pools are automatically allocated.

Adding Disks Using the CLI or REST API

About this task

The basic command to add disks to a node is:

```
maprcli disk add -disks <disk names> -host <host>
```

NOTE: This step reformats the disks. Any data on these disks will be lost.

For complete reference information, see `disk add` on page 2125.

Removing Disks from the File System
Explains how to remove disks using either the Control System or the CLI.

About this task

When you remove a disk from the file system, other disks in the storage pool are also removed automatically from the file system and are no longer in use (they are available but off-line). Their disk storage goes to 0%, and they are eligible to be added again to the file system to build a new storage pool. You can either replace the disk and re-add it along with the other disks that were in the storage pool, or just re-add the other disks if you do not plan to replace the disk you removed. See Adding Disks to file system on page 1148 for more information.

WARNING: Removing a disk in the storage pool that contains Container ID 1 shuts down CLDB, triggering a CLDB failover. Container ID 1 contains CLDB data for the primary CLDB. From the command-line, run the `maprcli disk remove` command without the `-force 1` option first and examine the warning messages to make sure you are not removing the disk with Container ID 1. To safely remove such a disk, perform a CLDB Failover on page 1968 to make one of the other CLDB nodes the primary CLDB, then remove the disk as normal with addition of the `-force 1` option.

Before removing or replacing disks, make sure the Replication Alarm (VOLUME_ALARM_DATA_UNDER_REPLICATED), Data Alarm (VOLUME_ALARM_DATA_UNAVAILABLE), Warm-Tier Data Node Down (VOLUME_ALARM_DEGRADED_EC_STRIPES), and EC Degraded Alarm (VOLUME_ALARM_CRITICALLY_DEGRADED_EC_STRIPES) are not raised. These alarms can indicate potential or actual data loss. If either alarm is raised, you might be able to repair the problem using the `/opt/mapr/server/fsck` utility before removing or replacing disks.

NOTE: Using the `/opt/mapr/server/fsck` utility with the `-r` flag to repair a file system risks data loss. Call HPE Ezmeral Data Fabric support before using `/opt/mapr/server/fsck -r`.

last-updated: Jun 06, 2024

Removing Disks from file system Using the Control System

About this task

Complete the following steps to remove disks using the Control System:

Procedure

1. Log in to the Control System and go to the **Summary** tab in the node information page.
2. Select the disks to remove in the **Disks** pane and click **Remove Disk(s) from File System**.
   The **Remove Disk(s) from File System** confirmation dialog displays.

   WARNING: One or more disks you selected may have unreplicated data on it and this action will forcefully remove the disks.
3. Review the list and click **Remove Disk**.
   Wait several minutes while the removal process completes. After you remove the disks, any other disks in the same storage pools are taken offline and marked as *available* (not in use by HPE Ezmeral Data Fabric).
4. Remove the physical disks from the node or nodes according to the correct hardware procedure.
5. From a command line terminal, remove the failed disk log file from the `/opt/mapr/logs` directory.
   These log files are typically named like this:

   ```
   diskname.failed.info
   ```

Removing Disks from file system Using the CLI or REST API

Procedure

1. On the node, determine which disk to remove/replace by examining **Disk** entries in the `/opt/mapr/logs/faileddisk.log` file.
2. Run the following command, substituting the hostname or IP address for `<host>` and a list of disks for `<disks>`

   ```
   maprcli disk remove -disks <disk names> -host <host>
   ```

   NOTE: This command does not remove a disk containing unreplicated data unless forced.

   For complete reference information, see `disk remove` on page 2136.
3. Examine the screen output in response to the command you ran in step 2.
   For example:

   ```
   maprcli disk remove -host `hostname -f` -disks /dev/sdd
   message   host   disk
   removed.  host1  /dev/sdd
   removed.  host1  /dev/sde
   removed.  host1  /dev/sdf
   ```

   Make a note of the *additional* disks removed when the disk is removed. For example, the disks `/dev/sde` and `/dev/sdf` are part of the same storage pool and therefore removed along with the disk (`/dev/sdd`).

last-updated: Jun 06, 2024

4. Confirm that the removed disks do not appear in the `disktab` file.
5. Remove the disk log file from the `/opt/mapr/logs` directory.
   For failed disks, these log files are typically named in the pattern *`diskname`*`.failed.info`.

What to do next

When you replace a failed disk, add it back to the file system along with the other disks from the same storage pool that were previously removed. Adding only the replacement disk to the file system, results in a non-optimal storage pool layout, which can lead to degraded performance.

Once you add the disks to the file system, the cluster automatically allocates properly-sized storage pools. For example, if you add ten disks, HPE Ezmeral Data Fabric allocates two storage pools of three disks each and two storage pools of two disks each.

Determining the Amount of Free Disk From the Command-Line
Lists the command to display the amount of free disk space.

To determine the amount of used and available disk space on the file system, run `df -h`. When running this command, if:

- The given path points to the mount point, the output will display used and available disk space for the entire cluster. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/
Filesystem            Size  Used  Avail  Use%  Mounted on
posix-client-basic    4.4T  9.7G  4.4T   1%    /mapr
```

- The given path points to a volume with no (hard) quota, the output will display used and available disk space for the entire cluster. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/vol3
Filesystem          Size  Used  Avail  Use%  Mounted on
posix-client-basic  4.4T  9.7G  4.4T   1%    /mapr
```

- The given path points to a volume with (hard) quota set, the output will display the used and available disk space for the specific volume based on the allocated quota. For example:

```
[root@atsqa6c69 ~]df -h /mapr/clus.posix/vol2/
Filesystem          Size  Used  Avail  Use%  Mounted on
posix-client-basic  5.0G  2.5G  2.6G   49%   /mapr
```

Tolerating Slow Disks
Explains how to tune disk response timeouts.

The parameter `mfs.io.disk.timeout` in `mfs.conf` determines how long HPE Ezmeral Data Fabric waits for a disk to respond before assuming it has failed. If healthy disks are too slow, and are erroneously marked as failed, you can increase the value of this parameter.

Formatting Disks on a Node From the Command-line
Provides an overview of the disksetup script to format disks from the command line.

The disksetup script is used to format disks for use by the HPE Ezmeral Data Fabric cluster. Create a text file `/tmp/disks.txt` listing the disks and partitions for use by HPE Ezmeral Data Fabric on the

node. Each line lists either a single disk or all applicable partitions on a single disk. When listing multiple partitions on a line, separate by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

Later, when you run disksetup to format the disks, specify the `disks.txt` file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

NOTE: The disksetup script removes all data from the specified disks. Make sure you specify the disks correctly, and that any data you wish to keep has been backed up elsewhere.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

WARNING: Run disksetup only after running configure.sh.

Handling Disk Failures
Explains how to handle disk failures.

When a disk fails, data-fabric raises the node-level alarm `NODE_ALARM_DISK_FAILURE` on the node with the failed disk (or disks). At the same time, other disks in the same storage pool as the failed disk are taken offline. You can look at the Control System **Overview** page to view the health of the nodes and a list of alarms.

When you see a disk failure alarm, examine the log file at `/opt/mapr/logs/faileddisk.log` and check the **Failure Reason** field.

Examining the Cause of Failure
Names the log file that contains the cause of disk failures.

In the `faileddisk.log` file, you will see information on the cause of failure. In the following sample log output, the failure reason is *I/O error*. Notice that the log file also provides instructions for removing disks and adding them back to the file system.

```
############################ Disk Failure Report
############################
Disk                :    /dev/sdd
Vendor              :    [vendor]
Model Number        :    [model]
Serial Number       :    [serial]
Firmware Revision   :    [firmware]
Size                :    [total]
Failure Reason      :    I/O error
Time of Failure     :    Fri Jan 31 12:48:00 GMT 2014
Resolution          :   Please refer to MapR's online documentation at
https://docs.datafabric.hpe.com on how to handle
        disk failures.
In summary, run the following steps:
a. If this appears to be a software failure, go to step
b. Otherwise, physically remove the disk /dev/sdd. Optionally, replace it
with a new disk.
b. Run the command "maprcli disk remove -host 127.0.0.1 -disks /dev/sdd" to
remove
        /dev/sdd from MapR-FS.
c. In addition to /dev/sdd, the above command removes all the disks that
belong to the same
        storage pool, from MapR-FS.      Note down the names of all removed
disks.
```

```
d. Add all the above removed disks (exclude /dev/sdd) and the new disk to
MapR-FS by
   running the command:
   "maprcli disk add -host 127.0.0.1 -disks <comma separated list of
      disks>"
   For example, If /dev/sdx is the new replaced disk, and /dev/
sdy, /dev/sdz were removed in
        step c), the command would be:
   "maprcli disk add -host 127.0.0.1 -disks /dev/sdx,/dev/sdy,/dev/
sdz"      If there is no new disk, the command would just
be:                  "maprcli disk add -host 127.0.0.1 -disks
    /dev/sdy,/dev/sdz"
```

Recovering from Disk Failure
Lists the disk errors and their resolution.

Most software failures can be remedied by running the fsck utility, which scans the storage pool to which the disk belongs and reports errors. For hardware failures, remove the failed disk and replace it according to the procedure in Removing and Replacing Disks.

The following are the types of failures and the recommended courses of action:

I/OTimeOut Error	*Failure Reason*: The default value for `mfs.disk.io.timeout` parameter is 60 seconds. The time to declare an IO as stuck is 3 times the value of this parameter (3 x `mfs.disk.io.timeout`). The disk will be taken offline even if a single IO has not completed. *Action*: **1.** Check if the disks are good and still reliable. **2.** If disks are good, increase the value of the `mfs.io.disk.timeout` parameter in the `/opt/mapr/conf/mfs.conf` file. Otherwise, replace the disks.
No Such Device	*Failure Reason*: The `$INSTALL_DIR/conf/disktab` file contains `"/MissingDisk"` or references a disk path not found in `/proc/partitions` file. *Action*: Run `mrdisk <device path>` to determine whether a disk is formatted for file system. Also, check the device paths in `$INSTALL_DIR/conf/disktab` file. The `disktab` file contains the disk path and disk GUID that is used to load the disks in the file system. If the disk paths have been renamed, fix them or run `disksetup -X` command to regenerate the disktab from `/proc/partitions`. Alternatively, restart the file system to resolve disk name changes. If the problem still persists, contact HPE Ezmeral Data Fabric support.
ENODEV: MissingDisk# Error: disktab file contains a /MissingDisk# entry	*Failure Reason*: A disk corresponding to a GUID is missing and the corresponding disk path in the `disktab` file belongs to another disk. When an attempt is made to automatically fix the `disktab` file, this entry is replaced with `/MissingDisk# path`. *Action*: If a disk corresponding to a GUID is permanently lost, remove the line corresponding to it in the `disktab` file. Alternatively, run `maprcli disk remove _MissingDisk#` command, where #

	corresponds to the disk number, and restart the file system.
EIO Error	*Failure Reason*: I/O error. This could be due to a bad block or disk. The system will offline the SP after one final attempt to complete the IO. *Action*: Check `/var/log/messages` for errors from the disk drivers.

CRC Error	*Failure Reason*: This could be due to a bad block or bit flip on the disk. The SP will be taken offline immediately.
	Action: Run `fsck -n <sp> -d` to perform a CRC (Cyclic Redundancy Check) on the data blocks in the storage pool, then bring it back online.
	To load all the SPs to the list of SPs, run:
	`mrconfig disk load or mrconfig sp load`
	To bring back all SPs online, run:
	`mrconfig sp refresh`
	To bring specific SPs back online, run:
	`mrconfig sp online <sp path>`

SlowDisk Error	*Failure Reason*: The default value for the `mfs.disk.io.timeout` parameter is 60 seconds. The time to declare an IO as slow is equal to the value of this parameter (1 x `mfs.disk.io.timeout`). Thirty or more slow IO completions in a short span of time (5 seconds) on the same disk is recorded as a slow event. The SP will be taken offline if 3 such events are recorded within an hour. **NOTE:** After an hour, HPE Ezmeral Data Fabric filesystem will reset tracking (to 0). *Action*: **1.** Check if the disks are good and still reliable. **2.** If disks are good, increase the value of the `mfs.io.disk.timeout` parameter in the `/opt/mapr/conf/mfs.conf` file. Otherwise, replace the disks.
GUID of disk mismatches with the one in `$INSTALL_DIR/conf/disktab`	*Failure Reason*: Possible that disk names have changed. *Action*: After a node restart, the operating system can reassign the drive labels (for example, `/sda`), resulting in drive labels no longer matching the entries in the `disktab` file. The `disktab` file contains the disk path and disk GUID that is used to load the disks in the file system. Run `$INSTALL_DIR/server/disksetup -X` to update the `disktab` file by looking up the disks in `/proc/partitions` and make the disk paths match the GUIDs.

last-updated: Jun 06, 2024

Unknown Error	*Failure Reason*: Any reason *Action*: Contact HPE Ezmeral Data Fabric support.

Addressing Data Alarms
Lists all the data alarms and their mitigation.

When a disk fails, data on that disk becomes unavailable. As a result, you will probably see one of these two data alarms along with a **Disk Failure** alarm:

- **Data Unavailable** (`VOLUME_ALARM_DATA_UNAVAILABLE`) - if there was only one copy of data and it was on the failed disk; or if data was replicated more than once, but all disks with that data failed
- **Data Under Replicated** (`VOLUME_ALARM_DATA_UNDER_REPLICATED`) - if data on the failed disk is replicated elsewhere, but the minimum replication factor is not met as a result of the failed disk

If you see a **Data Unavailable** volume alarm in the cluster, follow these steps to run the /opt/mapr/server/fsck utility on all the offline storage pools. On each node in the cluster that has raised a disk failure alarm:

1. Run the following command to identify which storage pools are offline:
   ```
   [user@host] /opt/mapr/server/mrconfig sp list | grep Offline
   ```
2. For each storage pool reported by the previous command, run the following command, where `<sp>` specifies the name of an offline storage pool:
   ```
   [user@host] /opt/mapr/server/fsck -n <sp> -r
   ```
   When you run fsck with the `-r` option, it identifies corrupt blocks and removes them. If there are no corrupt blocks, fsck clears the error condition so you can bring the storage pool back online.

   NOTE: Using the /opt/mapr/server/fsck utility with the `-r` flag to repair a filesystem risks data loss. Call support before using `/opt/mapr/server/fsck -r`.
3. Verify that all **Data Unavailable** volume alarms are cleared. If **Data Unavailable** volume alarms persist, contact support or post on answers.mapr.com.

If there are any **Data Under Replicated** volume alarms in the cluster, can repair the problem by automatically replicating data and putting it on another disk. After you allow a reasonable amount of time for re-replication, verify that the under-replication alarms are cleared.

Using the /opt/mapr/server/fsck utility with the `-r` option produces different results depending on the scenario. The fsck utility does not interpret the scenario nor does it have a safe mode.

- If a disk is offline because of an imbalanced b-tree, using `fsck -r` may result in data loss from bad containers and data loss if additional replicas are unavailable.
- If a disk is offline because of an I/O error, using `fsck -r` produces indeterminate results. A disk that is throwing I/O errors is questionable in terms of data content and reliability. For example, an operation that completed on the disk but was never returned may have partial data remaining on the disk. Using `fsck -r` retains any partial data.
- If a disk is offline because of a slow I/O, using `fsck -r` does not produce data loss.

The most conservative usage of `fsck -r` is to run `fsck` without the `-r` option (verification mode) and check the output. If the output is ok, then run `fsck` with the `-r` option.

NOTE: Disk Failure node alarms that persist require disk replacement. If **Data Under Replicated** volume alarms persist, contact support or post on answers.mapr.com.

Removing and Replacing Disks

If a disk fails due to a hardware problem, you will need to remove the disk. You can replace it, and then add that disk back to file system along with the other disks that were automatically removed at the same time.

Refer to the following for information on how to remove and replace disks using the MapR command-line interface and the MapR Control System:

- Removing Disks from the File System on page 1149
- Adding Disks to file system on page 1148

Designating NICs for HPE Ezmeral Data Fabric

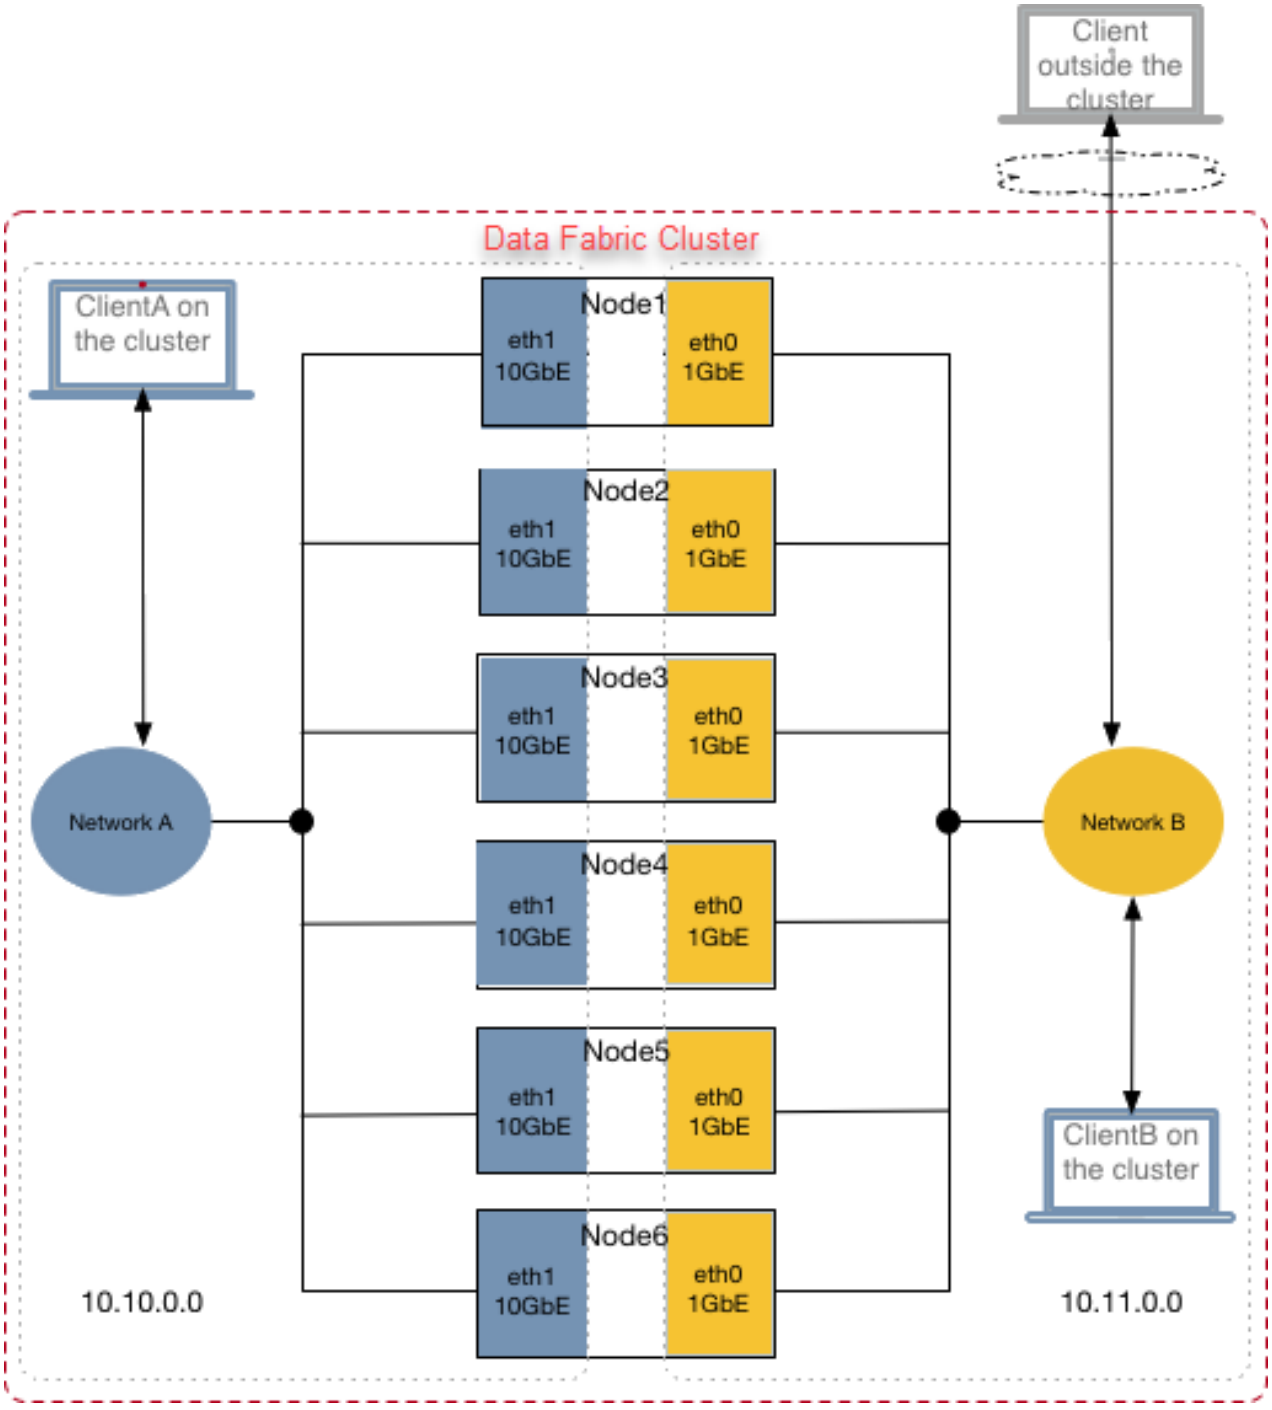
Explains how to assign IP address blocks for HPE Ezmeral Data Fabric.

By default, file-system instances and the CLDB nodes advertise all the available IP addresses, and HPE Ezmeral Data Fabric automatically uses all available network interface cards (NICs) on each node for all communication. For nodes that have multiple NICs, HPE Ezmeral Data Fabric supports segregation of the NICs. Segregation enables certain IPs to be used for clients or communication within the cluster, and certain IPs can be used for clients or communication from outside the cluster. Also, NICs can be segregated for specific (high-performance and/or low-performance) clients within the cluster.

For example, if you use multiple NICs of mixed speeds (such as 1GbE and 10GbE) on each node, you might want to separate them to two different networks depending on the Ethernet card speeds. You can assign IP addresses in the same network to the NICs of 1GbE and assign IP addresses in another network to the NICs of 10GbE. In this way, you can use the faster NICs for communication within the cluster or for certain high-performance clients (for example, FUSE-based POSIX clients) and the slower NICs for external communication or for low-performance clients or jobs.

To illustrate this arrangement, the following diagram shows six nodes on an HPE Ezmeral Data Fabric cluster, each with a 1GbE NIC (eth0) and a 10GbE NIC (eth1). All the 1GbE NICs are networked together and connected to Network B. Likewise, all the 10GbE NICs are networked together (as part of a subnet written as 10.10.10.0/24 in CIDR notation) and connected to Network A, where peak performance is required. ClientA, which is within the cluster, communicates with cluster nodes over Network A. Clients outside the cluster communicate with cluster nodes over Network B.

The illustration also shows ClientB, which is a low-performance client inside the cluster, communicating with cluster nodes over Network B:



HPE Ezmeral Data Fabric provides two environment variables, `MAPR_SUBNETS` and `MAPR_EXTERNAL`, that you can use to segregate NICs for internal and external clients or to segregate NICs for high-performance and low-performance clients.

MAPR_SUBNETS Environment Variable

The `MAPR_SUBNETS` environment variable can be used to restrict HPE Ezmeral Data Fabric to a subset of NICs. If `MAPR_SUBNETS` is not set, all IPs are available for all communication. The following table describes the behavior when `MAPR_SUBNETS` is set on:

last-updated: Jun 06, 2024

Node Type	Behavior
File System	The file system registers these IP addresses with CLDB as internal IP addresses on which file-system nodes can be reached.
CLDB	The CLDB advertises the IP address to clients on the cluster.

You can set the `MAPR_SUBNETS` environment variable in the `/opt/mapr/conf/env_override.sh` file on all the nodes. On the cluster nodes, the value for this environment variable is a comma-separated list of subnet masks. For example:

```
export MAPR_SUBNETS=10.10.15.0/24,10.10.16.0/24
```

You can specify up to four NICs in the `MAPR_SUBNETS` environment variable. If your system has more than four NICs, HPE Ezmeral Data Fabric advertises the first four it finds. Or, if the `MAPR_SUBNETS` environment variable is set, HPE Ezmeral Data Fabric restricts the networks or IPs that are advertised based on the subnets specified therein.

The `MAPR_SUBNETS` environment variable can be set on the client if there is a NAT between the server and client. On the client, the value for this environment variable is the IP address of the client. For example:

```
export MAPR_SUBNETS=10.11.12.13/32
```

When specifying the IP address in the `MAPR_SUBNETS` environment variable on the client, use `/32` to specify a single IP address.

For more information about the MAPR_SUBNETS environment variable, see Environment Variables on page 3076.

MAPR_EXTERNAL Environment Variable

If all the IP addresses on the servers are public and can be accessed from an external system, the `MAPR_EXTERNAL` environment variable need not be set. However, if your cluster nodes have private IP addresses, to allow clients outside the cluster to reach the cluster nodes (such as when data-fabric is installed on the cloud or Docker container), specify the public IP addresses in the `MAPR_EXTERNAL` environment variable.

On the cluster nodes, set this variable in the `/opt/mapr/conf/env_override.sh` file. The following table describes the behavior when `MAPR_EXTERNAL` is set on:

Node Type	Behavior
File System	The file system registers these IP addresses with CLDB as the IP addresses on which external clients can reach file system nodes. Communication between file system nodes on the cluster still occurs over the internal IP addresses.
CLDB	The CLDB advertises these IPs addresses to clients outside the cluster or data center.
MAST Gateway Nodes	The gateway registers these IP addresses with the CLDB as the IP addresses on which external clients can reach the MAST Gateway.

NOTE: Do not set the `MAPR_EXTERNAL` environment variable on client(s).

The value for this environment variable is a comma-separated list of IP addresses. You cannot specify the hostname as value. For example:

```
export MAPR_EXTERNAL="10.0.0.101,3.87.212.119"
export MAPR_SUBNETS="172.31.00/16"
```

last-updated: Jun 06, 2024

For example, you can specify the IP addresses of the 1GbE NICs (shown in the previous illustration) as the value for this environment variable, to allow external or low-performance clients to communicate with the cluster nodes.

```
export MAPR_EXTERNAL=10.11.0.0
```

For more information about the MAPR_EXTERNAL environment variable, see Environment Variables on page 3076.

IP Addresses for ZooKeeper Nodes

You can specify the IP addresses of ZooKeeper nodes by running the configure.sh on page 2821 utility with both the `-Z` and `-EZ` options during cluster configuration. The following table summarizes how to use these options:

When using this option	You specify
`-Z`	Internal IP addresses
`-EZ`	External IP addresses

When you specify the IP addresses using the `-Z` and `-EZ` options, these IP addresses are registered with the CLDB and included in the `cldb.conf` file. In the `cldb.conf` file, the internal IP addresses set using the `-Z` option are the values for the `cldb.zookeeper.servers` parameter. The external IP addresses set using the `-EZ` option are the values for the `cldb.external.zookeeper.servers` parameter.

NOTE: You do not need to run the `configure.sh` command with the `-EZ` option during client configuration.

For more information, see `configure.sh` on page 2821.

If all the ZooKeepers have different IP addresses, port forwarding is not required and, optionally, you can specify the same port with all the IP addresses. However, in some cases, such as when a single external IP address is used by multiple ZooKeepers (as in a Docker container), you can specify ports for ZooKeepers when you run the `configure.sh` utility with the `-Z` and `-EZ` options. For more information, see Specifying Ports on page 1164.

Internal and External Clients

Clients communicating with the the CLDB using internal IP address (of CLDB) are considered internal clients (or clients within the cluster). Clients communicating with the CLDB using external IP address (of CLDB) are considered external clients (or clients outside the cluster).

To configure a client as an internal or high-performance client, include the CLDB internal IP address in the `mapr-clusters.conf` file on the client host. Similarly, to configure a client as an external or low-performance client, include the CLDB external IP address in the `mapr-clusters.conf` file on the client host.

The `mapr-clusters.conf` file on the client host should not contain both internal and external IP addresses of the server on a cluster. The `mapr-clusters.conf` file can contain internal and external IP addresses only when the entries in the file on the client host are for multiple clusters.

For example, suppose you have a client, which is an internal client on one cluster and external client on another cluster. The `mapr-clusters.conf` file on the client host can contain the CLDB internal IP address for the cluster on which the client is considered an internal client and the CLDB external IP address for the cluster on which the client is considered an external client.

last-updated: Jun 06, 2024

NOTE: Update the environment variables for NIC segregation as specified in Setting Environment Variables for NIC Segregation on page 1162 and run `configure.sh` with the appropriate options to update the IP addresses in the `mapr-clusters.conf` file.

For more information, see `configure.sh` on page 2821.

The `mapr-clusters.conf` file on the cluster nodes should not contain any external IP address.

Limitations

Note the following limitations for using the environment variables:

- If both `MAPR_SUBNETS` and `MAPR_EXTERNAL` environment variables are set, the segregation of NICs for internal and external communication is possible. Internal communication happens over the IP addresses listed in the `MAPR_SUBNETS` environment variable, and external communication happens over the IP addresses listed in the `MAPR_EXTERNAL` environment variable. Do not directly change environment variable values in the `mapr-clusters.conf` file. Run the `configure.sh` script instead.
- If only the `MAPR_SUBNETS` environment variable is set, the file system registers the IP addresses in the `MAPR_SUBNETS` environment variable with the CLDB as internal IPs.

  NOTE: To segregate internal or high-performance clients, and external or low-performance clients, set both the environment variables in the `/opt/mapr/conf/env_override.sh` file.
- You can specify up to four IP addresses in the `MAPR_SUBNETS` environment variable, and four IP addresses in the `MAPR_EXTERNAL` environment variable.
- You must configure ZooKeeper with an IP address that is reachable by both internal and external clients.
- Do not run any of the following clients in a Docker image on a host server with multiple NICs:
  - File-system, database, or Marlin clients
  - NFS server variants
  - Applications using the `mapr-client` library

Summary

The following table describes the environment variables to set for the various services that use non-default ports and that support public IP address(es) for communication with external clients and remote clusters:

Service	Environment variable to set...	
	Public IP Address for External Clients/ Remote Clusters	**Non-default Port**
CLDB	`MAPR_EXTERNAL`	`CLDB_EXTERNAL_RPC_PORT`
File System	`MAPR_EXTERNAL`	`MAPR_EXTERNAL`
MAST Gateway	`MAPR_EXTERNAL`	`MASTGATEWAY_EXTERNAL_RPC_PORT`

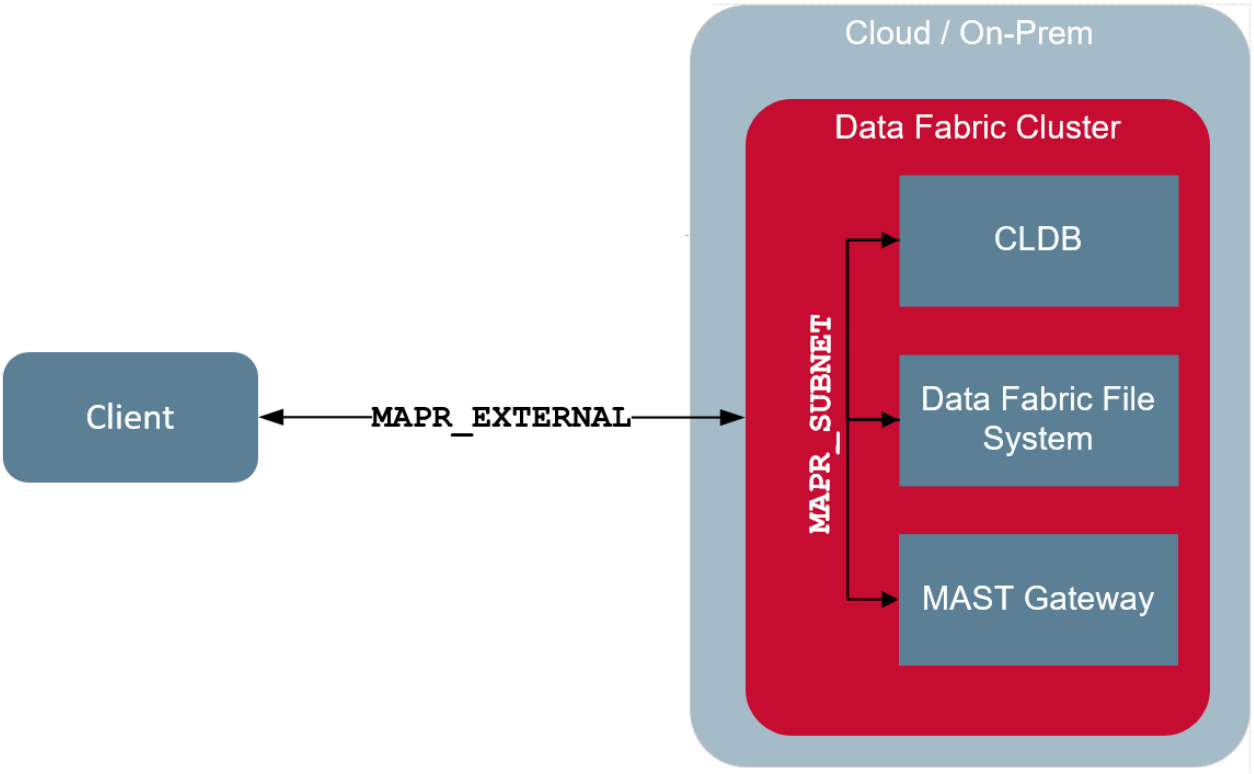
The following illustration shows the client communicating with the CLDB, HPE Ezmeral Data Fabric file system, and MAST Gateway using the IP address(es) defined in the `MAPR_EXTERNAL` environment variable. This is because all the IP addresses on the servers are not public and accessible outside the cluster. All communication between CLDB, file system, and MAST Gateway on the same cluster happen

last-updated: Jun 06, 2024

over the IP address specified in the MAPR_SUBNETS environment variable. This is because communication between the services and clients on the cluster is restricted to a subset of the available NICs.

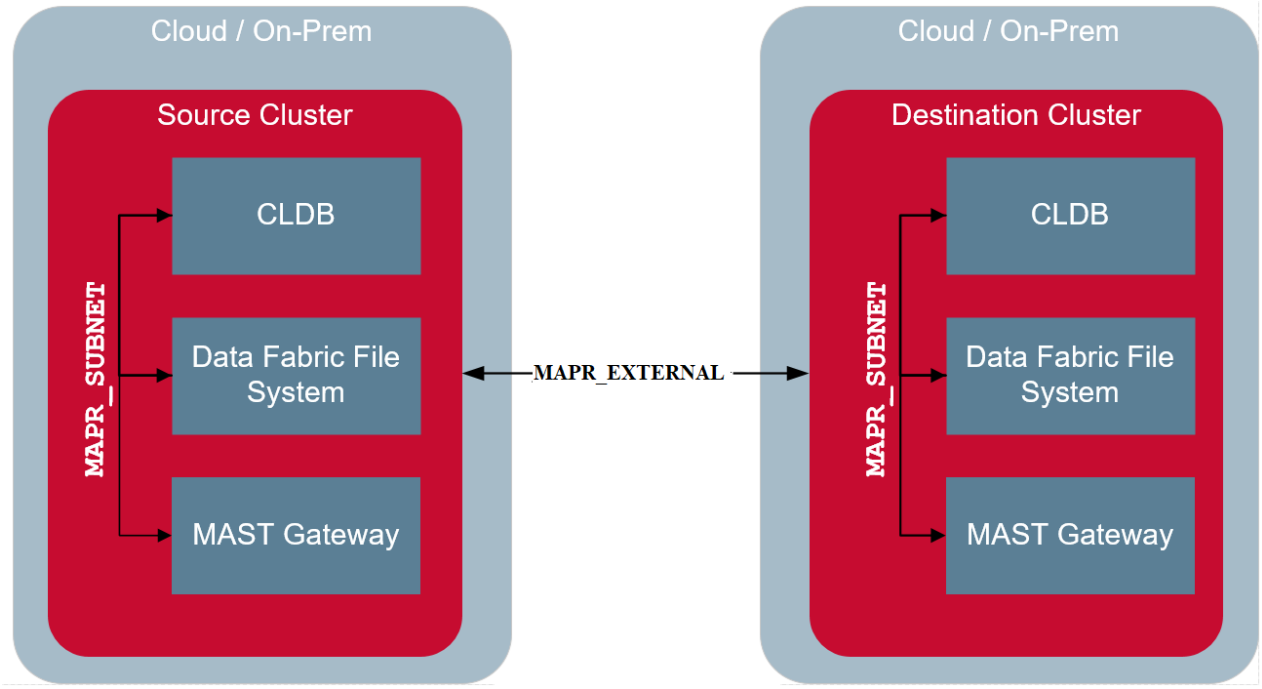
When the client connects to the HPE Ezmeral Data Fabric file system from outside the cluster, the client uses either the default port (5660) or the port specified for the data-fabric file system in the MAPR_EXTERNAL environment variable.

When communicating with the CLDB, if the CLDB_EXTERNAL_RPC_PORT environment variable is set, the client communicates with the CLDB over the port specified in this environment variable. Similarly for MAST Gateway, if the MASTGATEWAY_EXTERNAL_RPC_PORT environment variable is set, the client communicates with MAST Gateway over the port specified in this environment variable. For both CLDB and MAST Gateway, if the ports are not set in the CLDB_EXTERNAL_RPC_PORT and MASTGATEWAY_EXTERNAL_RPC_PORT environment variables respectively, the client communicates over the default port.



The following illustration shows that during mirroring and other cross-cluster activities, the services on the destination cluster communicate with the services on the source cluster using the IP address defined in the MAPR_EXTERNAL environment variable. As with the external client, the services and clients in the remote destination cluster communicate with the services in the source cluster over the default ports or the port specified in the environment variable for the service.

last-updated: Jun 06, 2024



Setting Environment Variables for NIC Segregation
Describes how to set environment variables to segregate NICs.

About this task

Use the MAPR_SUBNETS and MAPR_EXTERNAL environment variables to segregate NICs for internal and external clients, or to segregate NICs for high-performance and low-performance clients.

Setting the MAPR_SUBNETS Environment Variable

About this task

To specify the internal IP addresses of CLDB and file system nodes:

Procedure

1. Stop warden on all the nodes on the cluster.
2. Set the IP address range to use in the MAPR_SUBNETS environment variable in the `/opt/mapr/conf/env_override.sh` file. For more information about this file, see About env_override.sh on page 3077.

   For example:

   ```
   export MAPR_SUBNETS=10.10.0.0/24
   ```

   To specify multiple subnets for HPE Ezmeral Data Fabric, use comma to separate the IP addresses.

   Before specifying the IP address, make sure the client and cluster nodes can communicate using that IP address. That is, ensure that the client can send packets and that they can be routed to all the interfaces of the cluster nodes, and the cluster nodes all have a route that reaches back to the client IP address.

   NOTE: For standalone programs (not using the `mapr` classpath), which do not pick up the settings in the `/opt/mapr/conf/env.sh` file, set MAPR_SUBNETS explicitly before the start of program.

last-updated: Jun 06, 2024

3. Perform a rolling restart of warden on all the nodes for the changes to take effect.
4. Add CLDB's internal IP address (or IP address specified in the `MAPR_SUBNETS` environment variable on the CLDB host) to the `mapr-clusters.conf` file on the (internal or high-performance) client host(s).

   The `mapr-clusters.conf` file specifies IP addresses, on which the CLDB nodes (for one or more clusters) can be reached. For more information, see mapr-clusters.conf on page 2983.

Results

When you restrict HPE Ezmeral Data Fabric to certain subnets, HPE Ezmeral Data Fabric clients have full access to the HPE Ezmeral Data Fabric cluster on the designated subnets.

Setting the MAPR_EXTERNAL Environment Variable

About this task

To specify the external IP addresses of CLDB, file system, and/or MAST Gateway nodes:

Procedure

1. Stop warden on all the nodes on the cluster.
2. Set the IP addresses to use for external communication or for low-performance clients in the `MAPR_EXTERNAL` environment variable in the `/opt/mapr/conf/env_override.sh` file. For more information about this file, see About env_override.sh on page 3077.

   For example:

   ```
   export MAPR_EXTERNAL=10.11.0.0;
   ```

   To specify multiple subnets for HPE Ezmeral Data Fabric, use a comma to separate the IP addresses.
3. Perform a rolling restart of warden on all the nodes for the changes to take effect.
4. Add the following in the mapr-clusters.conf file on the (external or low-performance) client host(s):
   - CLDB's external IP addresses, which is the IP addresses specified in the `MAPR_EXTERNAL` environment variable on the CLDB hosts.
   - CLDB's external port, which is the value of the `CLDB_EXTERNAL_RPC_PORT` environment variable if this is set on the CLDB hosts. See Specifying Ports for CLDB for more information.

   The mapr-clusters.conf file contains the IP addresses, on which the CLDB nodes (for one or more clusters) can be reached. For more information, see mapr-clusters.conf on page 2983.

Examples

Suppose the value for the `MAPR_EXTERNAL` environment variable on file system node is the following:

```
10.10.103.80,10.10.30.205
```

External clients can connect to file system on IPs 10.10.103.80, 10.10.30.205 and the ports on which the file system is reachable are the default ports. If file system is running 2 instances, then:

- Instance 1 is reachable on 10.10.103.80:<5660>, 10.10.30.205:<5660>
- Instance 2 is reachable on 10.10.103.80:<5661>, 10.10.30.205:<5661>

If file system is running 3 instances:

- Instance 1 is reachable on 10.10.103.80:<5660>, 10.10.30.205:<5660>
- Instance 2 is reachable on 10.10.103.80:<5661>, 10.10.30.205:<5661>
- Instance 3 is reachable on 10.10.103.80:<5662>, 10.10.30.205:<5662>

Suppose the value for the `MAPR_EXTERNAL` environment variable on a MAST Gateway node is the following:

```
10.20.30.100
```

External clients can connect to MAST Gateway on IP 10.20.30.100 and the port on which MAST Gateway is reachable is the default port (8660). If file system is also running on this node, then both file system and MAST Gateway are reachable on the IP 10.20.30.100 and the ports on which they are reachable are the default ports.

Specifying External IP Address of ZooKeeper Nodes

About this task
To specify the external IP addresses of ZooKeeper nodes, during cluster configuration:

Procedure

- Run the configure.sh utility as follows:

```
/opt/mapr/server/configure.sh -C <hostname|IP>[,<hostname|IP>,..] -Z
<IP>[,<IP>..] \
-EZ <IP>[:<port>][,<IP>[:<port>]..] [-F <disk_list_file>] [-N
<cluster_name>]
```

  In the preceding command:

  - When each ZooKeeper node has a different external IP address, use the `-EZ` option to specify the IP address of each ZooKeeper node, and optionally the port as well (separated by a colon); the IP address can be different while the port number must be the same for every node.
  - When there are multiple ZooKeeper nodes listening on the same external IP (such as in a Docker container), use the `-EZ` option to specify IP address and port (separated by a colon); the port can be different while the IP address is the same for every node.

  For more information, see Specifying Ports on page 1164.

Specifying Ports

About this task

On installations where the file system instances, CLDB, and/or MAST Gateway must be reached on non-standard ports, you can specify the ports to advertise in the `MAPR_EXTERNAL`, `CLDB_EXTERNAL_RPC_PORT`, and `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variables respectively. This setting does not change the ports used by the servers, but changes the ports advertised to clients (to support port forwarding).

If the cluster nodes are no longer reachable on the standard ports, you can specify ports for file system using the `MAPR_EXTERNAL` environment variable. `MAPR_EXTERNAL` allows the specification of the advertised ports for the file system instances only; this environment variable cannot be used to specify ports for CLDB or the MAST Gateway. Instead, use `CLDB_EXTERNAL_RPC_PORT` environment variable to specify port for CLDB and `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable to specify port for MAST Gateway. If ZooKeeper is not available on the default port or if there are multiple

ZooKeepers listening on the same external IP address, you can specify ports for each ZooKeeper using the configure.sh utility.

See the following sections for more information on setting the ports.

Specifying Ports for file system

About this task

If the port forwarding table is set up, ports must be configured for every file system node on every file system instance. For more information on the number of ports used by file system instance(s), see Ports Used by HPE Ezmeral Data Fabric Software on page 3079. To specify the ports for file system:

Procedure

1. Open the `$MAPR_HOME/conf/env_override.sh` file. If the `env_override.sh` file is not present, you might have to create it. See About env_override.sh on page 3077.
2. Set the value for the `MAPR_EXTERNAL` environment variable.

   The value for the `MAPR_EXTERNAL` environment variable is a comma-separated list of IP addresses and colon-separated list of ports (to use for port forwarding).

   For example:

   ```
   export MAPR_EXTERNAL=10.11.0.0;9000,9001,9002,9003
   ```

   The following example shows 3 file system instances with 4 ports:

   ```
   export
   MAPR_EXTERNAL=10.11.0.0;9000,9001,9002,9003:10000,10001,10002,10003:11000
   ,11001,11002,11003
   ```

   To specify:

   - Multiple IP addresses, use comma to separate the IP addresses.
   - Ports for multiple instances, use:
     - comma (`,`) to separate the ports for an instance
     - colon (`:`) to separate the set of ports for each instance

   If ports are not specified, file system is assumed to be reachable on the default ports.
3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.

Specifying Ports for CLDB

About this task

The default port for CLDB is 7222. If you want to use another port:

Procedure

1. Open the `$MAPR_HOME/conf/env_override.sh` file on the CLDB host(s). If the env_override.sh file is not present, you might have to create it. See About env_override.sh on page 3077.

2. Set the value for the `CLDB_EXTERNAL_RPC_PORT` environment variable in the file.

   The value for this environment variable is the port to use for CLDB.

   For example:

   ```
   export CLDB_EXTERNAL_RPC_PORT=5000
   ```

   This is especially useful if HPE Ezmeral Data Fabric is installed in a Docker container or other guest hosts. If this is not set, CLDB must be reachable on the default port 7222.

3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.

4. Ensure that the mapr-clusters.conf file on the client host(s) contains the correct port number for CLDB.

What to do next

NOTE: After setting this environment variable, make sure that `cldb.feature.external.ip` is enabled if you upgraded from a prior version of MapR to v6.0. For more information on enabling this feature, see Step 4: Enable New Features on page 340.

Specifying Port for MAST Gateway

About this task

The default port for MAST Gateway is *8660*. If you want to use another port:

Procedure

1. Open the `$MAPR_HOME/conf/env_override.sh` file on the MAST Gateway host(s). If the env_override.sh file is not present, you might have to create it. See About env_override.sh on page 3077.

2. Set the value for the `MASTGATEWAY_EXTERNAL_RPC_PORT` environment variable in the file.

   The value for this environment variable is the port to use for MAST Gateway.

   For example:

   ```
   export MASTGATEWAY_EXTERNAL_RPC_PORT=15000
   ```

   If this is not set, MAST Gateway must be reachable on the default port *8660*.

3. Save and close the `$MAPR_HOME/conf/env_override.sh` file.

Specifying Ports for ZooKeeper

About this task

If ZooKeeper is not available on the default port or if all the ZooKeepers are listening on the same external IP address (such as in a Docker container), you can specify the port on which to reach each ZooKeeper. To specify the port on which to reach each ZooKeeper, during cluster configuration:

Procedure

- Run the configure.sh utility with the `-EZ` option.

The value for the `-EZ` option is a comma-separated list of external IP addresses of the ZooKeeper nodes and the port (for each IP address), separated by a colon, on which ZooKeeper can be reached. For example:

```
/opt/mapr/server/configure.sh -C <IP|Hostname>[,<IP|Hostname>,...] -Z <IP|
Hostname>[,<IP|Hostname>,...] \
-EZ <IP|Hostname>:<Port>[,<IP|Hostname>:<Port>,...]
```

For example, you can specify:

- Different ports when the same external IP address is used for all ZooKeeper nodes as shown below:

```
/opt/mapr/server/configure.sh -C 172.17.0.2,172,17.0.3,172.17.0.4 -Z
172.17.0.2,172,17.0.3,172.17.0.4 \
-EZ 10.10.104.34:5181,10.10.104.34:5182,10.10.104.34:5183 -N
my.cluster.com
```

- Same ports when different IP addresses are specified for ZooKeeper nodes:

```
/opt/mapr/server/configure.sh -C 172.17.0.2,172,17.0.3,172.17.0.4 -Z
172.17.0.2,172,17.0.3,172.17.0.4 \
-EZ 10.10.104.34:5181,10.20.105.34:5181,10.30.106.34:5181 -N
my.cluster.com
```

Configuring MR AppMaster Port Mapping

Procedure

1. Set the `yarn.app.mapreduce.am.job.client.port-range` parameter in the yarn-site.xml file to specific range of free ports in all the NodeManager nodes.

   Specify the range of ports that the MapReduce AppMaster can use when binding. Do not specify a value for this parameter if you want all possible ports. For example:

   ```
   50000-50050,50100-50200
   ```

   NOTE: Each Docker instance where NodeManager is running should have different range and the range should be different across all NodeManager nodes.

   For example:

   ```
   The yarn-site.xml file in docker container 1:
   <property>
           <name>yarn.app.mapreduce.am.job.client.port-range</name>
           <value>50000-50050</value>
   </property>
   The yarn-site.xml file in docker container 2:
   <property>
           <name>yarn.app.mapreduce.am.job.client.port-range</name>
           <value>50100-50150</value>
   </property>
   The yarn-site.xml file in docker container 3:
   <property>
           <name>yarn.app.mapreduce.am.job.client.port-range</name>
           <value>50151-50200,50250-50300</value>
   </property>
   ```

last-updated: Jun 06, 2024

2. Set the port forwarding rules in host machine for these specific ranges.

   For example, if NM1 contains ranges from 50000 to 50050, then set the IP table rules such that when requests come on these ports, it is forwarded to NM1.

3. Specify the AWS or Docker host name for the IP address in the `/etc/hosts` file on the client system so that external clients can resolve Docker or AWS hostname properly when running the jobs.

   For example, your entry in the `/etc/hosts` file should look similar to the following:

   ```
   54.208.145.112 ip-10-10-0-103.ec2.internal
   ```

Working with a Logical Volume Manager

Explains the role and usage of a Logical Volume Manager.

The Logical Volume Manager creates symbolic links to each logical volume's block device, from a directory path in the form:

```
/dev/<volume group>/<volume name>
```

HPE Ezmeral Data Fabric needs the actual block location, which you can find by using the `ls -l` command to list the symbolic links.

1. Make sure you have free, unmounted logical volumes for use by HPE Ezmeral Data Fabric:
   - Unmount any mounted logical volumes that can be erased and used for HPE Ezmeral Data Fabric.
   - Allocate any free space in an existing logical volume group to new logical volumes.
2. Make a note of the volume group and volume name of each logical volume.
3. Use `ls -l` with the volume group and volume name to determine the path of each logical volume's block device. Each logical volume is a symbolic link to a logical block device from a directory path that uses the volume group and volume name:

   ```
   /dev/<volume group>/<volume name>
   ```

   The following example shows output that represents a volume group named `mapr` containing logical volumes named `mapr1, mapr2, mapr3,` and `mapr4`:

   ```
   ls -l /dev/mapr/mapr*
    lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr1 -> /dev/mapper/
   mapr-mapr1
    lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr2 -> /dev/mapper/
   mapr-mapr2
    lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr3 -> /dev/mapper/
   mapr-mapr3
    lrwxrwxrwx 1 root root 22 Apr 12 21:48 /dev/mapr/mapr4 -> /dev/mapper/
   mapr-mapr4
   ```

4. Create a text file `/tmp/disks.txt` containing the paths to the block devices for the logical volumes (one path on each line). Example:

   ```
   cat /tmp/disks.txt
    /dev/mapper/mapr-mapr1
    /dev/mapper/mapr-mapr2
    /dev/mapper/mapr-mapr3
    /dev/mapper/mapr-mapr4
   ```

last-updated: Jun 06, 2024

5. Pass `disks.txt` to disksetup.

Tuning for SSDs
Lists the parameters to tune for optimal SSD performance.

About this task

On servers with SSDs:

Procedure

1. Enable TRIM operation in the `mfs.conf` file, if recommended by the SSD vendor.

   By default, TRIM is disabled. To enable, set the value for `mfs.ssd.trim.enabled` to 1 in the `mfs.conf` file. For example:

   ```
   mfs.ssd.trim.enabled=1
   ```

2. Disable IO throttling in the `mfs.conf` file.

   To disable, set the value for `mfs.disk.iothrottle.count` to 50000. The default value for `mfs.disk.iothrottle.count` is 100. For example:

   ```
   mfs.disk.iothrottle.count=50000
   ```

3. Create storage pool with multiple SSDs (so that the throughput is less than 2GB/sec).

   NOTE: Create one storage pool per SSD only if the device is high-end.

   To create, run `disksetup`:

   ```
   /opt/mapr/server/disksetup -W <n> disks.txt
   ```

   For example, to create a storage pool with 2 SSDs, run the following command:

   ```
   /opt/mapr/server/disksetup -W 2 disks.txt
   ```

   For more information, see `disksetup` on page 2864.

Administering Volumes

This section provide information about how to organize and manage data using volumes, a unique feature of HPE Ezmeral Data Fabric clusters.

HPE Ezmeral Data Fabric provides volumes as a way to organize data and manage cluster performance. A volume is a logical unit that allows you to apply policies to a set of files, directories, and sub-volumes. You can use volumes to enforce disk usage limits, set replication levels, establish ownership and accountability, and measure the cost generated by different projects or departments. Create a volume for each user, department, or project.

You can mount volumes under other volumes to build a structure that reflects the needs of your organization. Sub-volumes are created by mounting a volume in a sub-directory of an already mounted volume. This establishes a parent-child relationship between the volumes whereas the parent volume is mounted in top-level directory and the child volume is mounted in the sub-directory. The volume structure defines how data is distributed across the nodes in your cluster. Create multiple small volumes with shallow paths at the top of your cluster's volume hierarchy to spread the load of access requests across the nodes.

last-updated: Jun 06, 2024

A well-structured volume hierarchy is an essential aspect of your cluster's performance. As your cluster grows, keeping your volume hierarchy efficient maximizes data availability. Cluster performance is negatively affected when a volume structure is not in place.

The Control System **Volumes** page under **Data** contains the following tabs:

- Summary
- Snapshots
- User Disk Usage
- Schedules
- Storage Policies
- Remote Targets

Managing Data with Volumes

Provides an overview of how to manage volume data.

The **Summary** tab in the **Volumes** page displays the following panes:

- Top Volume Utilization — Volumes that use the most amount of disk space.
- Active Alarms — List of active volume alarms on the cluster.
- Local and Remote Tier Storage utilization.
- Volumes — List of volumes.

The page includes the **Create Volume** button to create standard or (local and/or remote) mirror volumes. You can perform the following procedures to manage volumes on the HPE Ezmeral Data Fabric cluster using the Control System and the CLI.

Viewing the List of Volumes
Explains how to view the list of volumes either through the Control Panel or the CLI.
Viewing All the Volumes Using the Control System

Procedure

- Log in to the Control Panel and click **Data** > **Volumes** > **Summary.**.

  NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

  The **Volumes** pane in the **Summary** tab (under **Data** > **Volumes**) displays the volumes in the cluster.

  NOTE: By default, system volumes are not displayed. If you wish to view system volumes also, select the **Include System Volumes** checkbox.

  If you are in another view, select **All Volumes** from the drop-down menu in the **Volumes** pane. Up to 10 volumes, sorted by name, are displayed in each page. For each volume, the pane displays the following information, by default:

Column Name	Column Description
Volumes	The name of the volume (used for default sorting).
Data Tiering	Whether volume is enabled or disabled for data tiering.

last-updated: Jun 06, 2024

Column Name	Column Description
Alarms	The number of alarms associated with the volume. Hover the cursor over the number for information on the alarm including alarm name, severity, and time when the alarm was raised.
Mnt	Specifies whether (✓) volume is mounted.
Type	The type of volume. Both standard and mirror volumes are displayed.
Mount Path	The path where the volume is mounted.
Creator	The user or group that owns the volume.
Quota	The amount of disk space allocated and utilized by the volume and associated snapshots and the cluster reserve limit (in red). If quota is not set, displays option to **Set Quota**.
Total Size	The total physical size of the volume and associated snapshots. When you move the cursor over the value, the popover shows the total logical size (**Data Size**), the logical size of the volume (**Volume Size**), and the logical size of the snapshots (**Snapshot Size**).
RF	The replication factor that specifies the number of copies for the volume.
Physical Topology	The rack path to the volume.

You can sort the list by volume name, mount, mount path, or creator.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- Edit the selected volume(s)
- Remove the selected volume(s)
- Create snapshot(s) of the selected volume
- Change the selected mirror volume(s) to standard volume(s)
- Start the mirroring operation(s) for the selected mirror volume(s)
- Stop the mirroring operation(s) for the selected mirror volume(s)
- Mount the selected volume(s)
- Unmount the selected volume(s)
- Offload selected volume(s)
- Recall selected volume(s)
- Abort currently running tiering job for selected volume(s)

last-updated: Jun 06, 2024

Viewing the List of Standard Volumes Using the Control System

About this task

The **Volumes** pane in the **Summary** tab under **Data** > **Volumes** (under **Volumes** in the Kubernetes version of the Control System) displays all the volumes in the cluster by default. To view a list of only the standard volumes:

Procedure

- Select **Standard Volumes** from the drop-down menu in the **Volumes** pane.

  The list of standard volumes in the cluster displays. By default, the list is sorted by volume name. For each volume, the page displays the following information by default:

Column Name	Description
Volumes	The name of the volume (used for default sorting).
Alarms	The number of alarms associated with the volume. You can view the **Active Alarms** pane for more information on the alarms associated with a volume.
Mnt	Specifies whether the volume is mounted.
Type	The type of volume. Only standard volumes are displayed.
Mount Path	The path where the volume is mounted.
Data Tiering	Whether volume is enabled or disabled for data tiering.
Creator	The user or group that owns the volume.
Quota	The amount of disk space allocated and utilized by the volume and associated snapshots and the reserve limit (in red). If quota is not set, displays option to **Set Quota**.
Total Size	The size of the volume and associated snapshots.
RF	The replication factor that specifies the number of copies for the volume.
Physical Topology	The rack path to the volume.

  Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

  - Edit the selected volume(s)
  - Remove the selected volume(s)
  - Create snapshot(s) of the selected volume
  - Mount the selected volume(s)
  - Unmount the selected volume(s)

Viewing the List of Mirror Volumes Using the Control System

About this task

The **Volumes** pane in the **Summary** tab under **Data** > **Volumes** (under **Volumes** in the Kubernetes version of the Control System) displays the list of (both) standard and mirror volumes in the cluster by default. To view a list of only the mirror volumes:

last-updated: Jun 06, 2024

Procedure

- Select **Mirror Volumes** from the drop-down menu in the **Volumes** pane.

  The list of mirror volumes in the cluster displays. By default, the list is sorted by volume name and the following columns are displayed:

Column Name	Description
Volumes	The name of the volume (used for default sorting).
Alarms	The number of alarms associated with the volume. You can view the **Active Alarms** pane (above) for more information on the alarms associated with a volume.
Mnt	Specifies whether the volume is mounted.
Source Volume	The source volume name for the mirror volume.
Source Cluster	The source cluster name for the mirror volume.
Originating Cluster	The originating cluster for the data being mirrored.
Originating Volume	The originating volume for the data being mirrored.
Mirror Status	The status of the last mirroring operation.
Percentage Complete	The percentage of the in-progress mirroring operation that has been completed.
Data Tiering	Whether or not the volume is enabled or disabled for data tiering.

  Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

  - Edit the selected volume(s)
  - Remove the selected volume(s)
  - Create snapshot(s) of the selected volume
  - Change the mirror volume to a standard volume
  - Start the mirroring operation(s) for the selected mirror volume(s)
  - Stop the mirroring operation(s) for the selected mirror volume(s)
  - Mount the selected volume(s)
  - Unmount the selected volume(s)

Viewing the List of Tiered Volumes Using the Control System

About this task

The **Volumes** pane in the **Summary** tab of the **Data** > **Volumes** page (under **Volumes** in the Kubernetes version of the Control System) displays the list of (both) standard and mirror volumes in the cluster by default. To view a list of tiered standard and mirror volumes:

Procedure

- Select **Tiered Volumes** from the drop-down menu in the **Volumes** pane.

  The list of tiered standard and mirror volumes in the cluster displays. By default, the list is sorted by volume name. For each volume, the pane displays the following information, by default:

last-updated: Jun 06, 2024

Column Name	Description
Volumes	The name of the volume (used for default sorting).
Offload Tier	The name of the tier where the volume data is stored.
Job	The tiering operation that is currently running or was last performed on the volume. Value can be one of the following: • Offload — if volume data was offloaded or is currently being offloaded • Abort — if volume data offload or recall operation was aborted or is being aborted • Recall — if volume data was recalled or is being recalled from the tier
State	The status of the job.
Progress	The job completion percentage.
Start Date/Time	The date and time when the job was started.
End Date/Time	The date and time when the job completed.
Offload Speed	The amount of data (in MB) offloaded or being offloaded per second.
Recall Speed	The amount of data (in MB) recalled or being recalled per second.

Selecting the checkbox beside a volume makes the **Actions** drop-down menu available. From the **Actions** drop-down menu, you can:

- Edit selected volume(s)
- Remove selected volume(s)
- Create snapshot(s) of selected volume(s)
- Change the mirror volume to a standard volume
- Start the mirroring operation(s) for the selected mirror volume(s)
- Stop the mirroring operation(s) for the selected mirror volume(s)
- Mount selected volume(s), if they are not already mounted
- Unmount selected volume(s), if they are currently mounted
- Offload selected volume(s)
- Recall selected volume(s)
- Abort currently running tiering job for selected volume(s)

last-updated: Jun 06, 2024

Retrieving the List of Volumes Using the CLI and REST API

About this task

The basic command to retrieve the list of volumes is:

```
maprcli volume list
```

For complete reference information, see volume list on page 2648.

Customizing the List of Columns/Fields
Explains how to customize the columns that are displayed in the Control System, and the fields that are returned in the CLI.
Customizing the Columns in the Control System

Procedure

1. Log in to the Control System and go to:
   - **Data** > **Volumes** page to customize columns displayed in the **Volumes** pane.

     NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   - **Nodes** page to customize columns displayed in the **Nodes** pane.

     NOTE: The **Nodes** page is not available on the Kubernetes version of the Control Panel.

2. Click the **Customize Columns** icon ( ).
   In the **Customize Columns** dialog, the:
   - **Available** list displays the columns that are available for display.
   - **Selected** list displays the columns currently displayed in the pane.
3. Select the columns from the:
   a) Available list of columns and click ▶ to move selection to **Selected** columns (for display).
   b) Selected list of columns and click ◀ to remove selected columns from displaying.
4. (Optional) Click ^ and/or down ˅ arrows to sort the order of columns.
5. Click **Save Changes** for the customization to take effect.

   TIP: To reset the display to its default columns, click **Reset to default columns**.

Customizing the Fields Using the CLI or REST API

About this task

Use the `-column` parameter with the `maprcli` command to view specific fields in the list. For example:

- To view the health of the nodes and services installed on the nodes being retrieved, run the following command:

  ```
  maprcli node list -columns service,health
  ```

  For complete reference information, see the node list on page 2264 command.

last-updated: Jun 06, 2024

- To view the volume name for the list of volumes being retrieved, run the following command:

  ```
  maprcli volume list -columns volumename
  ```

  For complete reference information, see volume list on page 2648 command.

Reverting to Default List of Columns
Describes how to revert to the default list of columns on the Control System

Procedure

1. Log in to the Control System and click:
   - **Data** > **Volumes** to revert to the default list of columns in the **Volumes** pane.

     NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   - **Nodes** to revert to the default list of columns in the **Nodes** pane.

     NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.
2. Click the **Customize Columns** icon ( ) .
3. Click **Reset to default columns**,
4. Click **Save Changes**.
   The pane displays the default list of columns.

Filtering the List of Volumes
Explains how to filter the list of volumes using either the Control System or the CLI.

About this task

The filter lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of volumes. Expressions are implicitly connected by the AND operator.

Filtering on the Control System

Procedure

1. Log in to the Control System and click **Data** > **Volumes** to filter volumes in the **Volumes** pane.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.
2. Select one of the following options from the **Add Filter** drop-down menu:
   - Volume — to filter the list by volume name
   - Usage — to filter the list by amount of disk used
   - Mount Path — to filter the list by mount path
   - Creator — to filter the list by entity or volume owner
   - Total Size — to filter the list by size of volume

last-updated: Jun 06, 2024

- Replication Factor — to filter the list by replication factor
- Physical Topology — to filter by the rack path
- Tier Type - to filter by a type of tier
- Quota — to filter by hard quota
- Data on Wire Encryption — to filter by volumes enabled (**On**) or disabled (**Off**) for on-wire encryption
- Data at Rest Encryption — to filter by volumes enabled (**On**) or disabled (**Off**) for data-at-rest encryption (DARE)
- Last Access Time - to filter by the Last Access Time
- Coalesce Interval - to filter on the coalesce interval

3. Specify the value in the drop-down field for the selected filter (by which to filter the list of volumes) and click **Filter**.

   As you make selections and specify the filtering criteria, the pane displays only the volumes that match the specified filtering criteria.

4. Click:
   - **Add Filter** to add another filtering criteria.
   - ✕ to remove a filtering criteria.
   -  to clear all filter settings.

Filtering Using the CLI

About this task

The `volume list` on page 2648 command can be used with the `-filter` option, which let you specify large numbers of volumes by matching specified values in specified fields rather than by typing each name explicitly. For example, you can display all volumes whose owner is *root* and whose name begins with *test* as follows:

```
maprcli volume list -filter [n=="test*"]and[on=="root"]
```

For more information, see Filters on page 1996.

Creating a Volume
Describes how to create a volume using the Control System, CLI and the REST API.

About this task

You can create a new (Standard or Mirror) volume using the Control System, the CLI, and the REST API.

Creating a Volume Using the Control System

About this task

To create a new (Standard or Mirror) volume using the Control System:

Procedure

1. Go to the **Data** > **Volumes** page and click **Create Volume** to display the **Create New Volume** page.

   NOTE: When running on a Kubernetes cluster, the **Create Volume** option is on the **Volumes** page.

2. Choose the **Volume Type** in the **Properties** section. Choose:
   - **Standard Volume** to create a read-write volume.
   - **Mirror Volume** to create a volume that is a read-only copy of an existing volume.

     TIP: See also: Mirror Types on page 502.

3. Specify the following required settings in the **Properties** section:

last-updated: Jun 06, 2024

Standard Volume

Volume Name	Enter a name for the volume. The name should contain only the following characters: `A-Z a-z 0-9 _ - .` **NOTE:** • The volume name should not begin with `mapr.` because `mapr.` is used for system volumes. If you use `mapr.` at the start of the volume name, the volume may not display in the default view of the list of volumes in the Control System; you must select the **Include System Volumes** checkbox in the **Volumes** pane to view volumes with names beginning with `mapr`. • For tiering-enabled volumes, volume name should not exceed ninety-eight characters.
Accountable Entity	Specifies a user or group whose use of a volume can be subject to quotas. You can set or modify quotas that limit the space used by all the volumes owned by an accountable entity.

last-updated: Jun 06, 2024

Mirror Volume

Volume Name	Enter a name for the volume. The name should contain only the following characters: `A-Z a-z 0-9 _ - .` **NOTE:** • The volume name should not begin with `mapr.` because `mapr.` is used for system volumes. If you use `mapr.` at the start of the volume name, the volume may not display in the default view of the list of volumes in the Control System; you must select the **Include System Volumes** checkbox in the **Volumes** pane to view volumes with names beginning with `mapr`. • For tiering-enabled volumes, volume name should not exceed ninety-eight characters.

last-updated: Jun 06, 2024

Source Cluster Name	Enter the name of the cluster on which the source volume exists. The name should contain only the following characters: `A-Z a-z 0-9 _ - .` Mirroring only works between two secure clusters or between two non-secure clusters. Mirroring does not work when one cluster is secure and the other is non-secure. **NOTE:** When setting up mirror volumes for mirroring between clusters, for the mirroring operation to run successfully, servers in one cluster cannot use the same IP addresses as servers in the other cluster. For example, if node A in cluster A has a private IP address of 10.10.20.29, no server in cluster B can have the same private IP address. Also, all the servers in destination cluster must be able to reach all the servers in the source cluster and vice versa. For example, suppose 10.10.20.29 is the only IP address used by node A in cluster A; then all servers in cluster B should be able to reach the IP address 10.10.20.29.

last-updated: Jun 06, 2024

Source Volume Name	Enter the name of the source volume, from which the mirror volume pulls data (after selecting the source volume cluster). The name should contain only the following characters: `A-Z a-z 0-9 _ - .` If the source volume is on: • Same cluster, you create a local mirror volume, which is useful for load balancing or for providing a read-only copy of a data set. See Local Mirroring on page 503 for more information. • Another cluster, you create a remote mirror volume, which is useful for offsite backup, for data transfer to remote facilities, and for load and latency balancing. See Creating Remote Mirrors on page 1190 for more information. **NOTE:** If you plan to enable tiering for the mirror volume, ensure that the selected source volume is also tiering-enabled. You cannot create tiering-enabled mirror volumes to mirror data in standard volumes that are not tiering-enabled. For information on setting up mirror cascades, see Mirror Cascades on page 504.

last-updated: Jun 06, 2024

Accountable Entity	Specifies a user or group whose use of a volume can be subject to quotas. You can set or modify quotas that limit the space used by all the volumes owned by an accountable entity.

Steps 4 to 10 are optional and allow you to define optional volume properties and optional settings for auditing, replication, data tiering, volume access, and volume administration. If you do not define these settings, default values, where available, are used. You can skip to:

- (Optional) Step 9 to associate a snapshot schedule and/or an offload schedule with the volume.
- Step 11 to create the volume with basic settings.

4. (Optional) Specify the following general settings under **Properties**:

Mount	Specifies whether to automatically mount (**Yes**) or not mount (**No**) the volume after creation. By default, volumes are mounted immediately after creation. If this is set to **Yes**, you must also specify the mount path.
Mount Path	The path to mount the volume. This is required if the value for **Mount** is **Yes**. **NOTE:** The path must be relative to `/` and cannot be in the form of a global namespace path (for example, `/mapr/<cluster-name>/`).
Collect Metrics	Specifies whether (**Yes**) or not (**No**) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1674 and Enabling Volume Metric Collection on page 1676.
Volume Access	Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume.
Last Access Interval	Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 531 for more information.

5. (Optional) Specify the following settings for data replication under **Replication and Storage** section:

Replication

Topology	Specifies the rack path to the volume. The default topology is `/data`.

Optimize Replication for	Specifies the basis for the replication factor: • High throughput, or cascading replication, where volumes are replicated sequentially on intermediate and tail containers. • Low latency, or star replication, where volumes are replicated on multiple containers in parallel. The default value is high throughput. See Selecting a Replication Type for High Availability on page 1225.
Guarantee Min Replication	Specifies whether (**Yes**) or not (**No**) to enforce minimum number of copies. If this is enabled (**Yes**), writes succeed only when the minimum number of copies exist. If this is enabled (**Yes**) and minimum number of copies are not available, the client is asked to retry. For more information, see Understanding Replication on page 492.
Replication	Specifies the minimum (**Minimum Replication**) and desired (**Target Replication**) number of copies of the volume data. The default minimum is 2, and the default target is 3.
Name Container Replication	Specifies the minimum (**Minimum Replication**) and desired (**Target Replication**) number of copies of the name container associated with the volume. The default minimum is 2, and the default target is 3.

Storage

Data Tiering — Specifies whether to enable (**Yes**) or disable (**No**) data tiering for volume data.

By default, data tiering is enabled and volume data is stored in the hot tier (HPE Ezmeral Data Fabric

cluster). If you choose to enable data tiering for the volume, you can associate a tier type with the volume either now, or later by editing the volume. If you decide to associate a type of tier with the volume, proceed to the next step; otherwise, proceed to step 7.

6. (Optional) Associate a type of tier with the volume by selecting a tiering type from the **Tiering Type** drop-down list and specifying the following settings for the tier:

Erasure Coding (Warm)

For offloading data to an erasure coded volume, specify values for the following properties. If values are not specified, default values are applied.

Topology	The topology of the erasure coded volume from the drop-down list.
Storage Policy	The rule for offloading data in this volume. You can click: • **Browse** to select an existing rule. • **Create** to create a new rule for offloading data. See steps 3 - 5 in the Creating a Storage Tier Policy on page 1303 topic for more information. If you do not select a storage policy, the default policy named `default.ectier.rule`, which is all files (p), is associated with the volume.

Scheme	The erasure coding scheme, which is the number of data chunks and number of parity chunks. Set the required Parity Scheme. The system indicates in real-time whether or not the parity scheme is valid. Some valid parity schemes include: • 3+2 — for 3 data chunks and 2 parity chunks. You must have 5 or more nodes on the cluster for this option. If selected, this scheme has 60% storage overhead and can tolerate failure of up to 2 nodes. • 4+2 — for 4 data chunks and 2 parity chunks. You must have 6 or more nodes on the cluster for this option. If selected, this scheme has 50% storage overhead and can tolerate failure of up to 2 nodes. • 5+2 — for 5 data chunks and 2 parity chunks. You must have 7 or more nodes on the cluster for this option. If selected, this scheme has 40% storage overhead and can tolerate failure of up to 2 nodes. • 6+3 — for 6 data chunks and 3 parity chunks. You must have 9 or more nodes on the cluster for this option. If selected, this scheme has 50% storage overhead and can tolerate failure of up to 3 nodes. To use local parity, set the Local Parity slider to Yes. The system then displays a third slider to set the number of local parity blocks. As you set the parity scheme, irrespective

last-updated: Jun 06, 2024

Remote Archiving (Cold)

For offloading data to a low cost storage alternative on the cloud, specify values for the following properties.

Storage Policy	The rule for offloading data in this volume. You can click: • **Browse** to select an existing rule. • **Create** to create a new rule for offloading data. See Creating a Storage Tier Policy on page 1303 for more information.
Remote Target	The location to which the data is offloaded. You can click: • **Browse** to select an existing tier. • **Create** to create a new tier. See Creating a Storage Tier on page 1287 for more information.
Retention Duration after Recall	The number of days to retain data recalled from the tier to the HPE Ezmeral Data Fabric cluster. Once the number of days is reached, recalled data on the HPE Ezmeral Data Fabric cluster is purged (if there are no changes), or offloaded (if there are changes).
Tier Encryption	Specifies whether (**Yes**) or not (**No**) to enable encryption of data on the tier. This cannot be modified once it is set. The default value is **No** (disabled).

7. (Optional) To use Label-Based Storage, enter the label and the namespace label . See Using Storage Labels on page 1314 for more information.

8. (Optional) Configure security for volume data by setting values for the properties in the **Security** section.
   a) Enter the name of the security policy in the **SECURITY POLICIES** field to search for the security policy to associate with the volume.

   b) Enable (**Yes**) or disable (**No**) the following audit and encryption settings by selecting the desired option:

last-updated: Jun 06, 2024

Auditing	Auditing of operations. You can either audit particular files or directories (**By File or Directory**) or audit all files and directories on the volume (**All Volume Content**. In either case, you can do the following: • Choose either **Default** or **Custom** to specify the list of directory, file, table, and streams operations to audit. **NOTE:** Enabling `setattr` automatically enables `chown`, `chgrp`, and `chperm`. If you exclude `setattr`, these operations are automatically disabled. If you do nothing with `setattr` (neither enable nor disable), you can enable or disable `chown, chgrp,` and `chperm` in any combination. • Specify a **Coalesce Interval**, which is the interval of time during which READ, WRITE, or GETATTR operations on one file from one IP address or UID are logged only once for a particular operation, if auditing is enabled.. The default value is 60 minutes.
Data on Wire Encryption	Encryption of data in the volume during transmission. By default, this is enabled (**Yes**) for all new volumes in secure cluster. This is not supported on insecure clusters.
Data at Rest Encryption	Encryption of data at rest. This should be enabled only if the feature is enabled at the cluster-level. By default, this is disabled (**No**). This is not supported on insecure clusters.
Coalesce Interval	The interval of time (in minutes) to use when logging multiple READ, WRITE, or GETATTR operations on one file from one client IP address, if auditing is enabled. The default value is 60 minutes.

9. (Optional) Specify the users, groups, and/or roles that have and/or do not have permissions to read and/or write in the **Data Access Control** section:
   a) Click **Add Data Access Control** to display the **Add Access Permissions** window.
   b) Move the slider associated with **Public** to **Yes** to grant access to all or to **No** to specify a list of users, groups, and or roles and do one of the following:
      • Enter the users, groups, and/or roles in the respective text boxes.
      • Select the **Custom ACE** checkbox to enter the custom *ACE*.
   c) Click **Add** to select permissions for the specified users, groups, and/or roles.
   d) Select the **Read** and/or **Write** checkbox in the **Permissions** column to grant that type of access to all (Public) or the specified users, groups, and/or roles.

   Click:
   • to modify the users, groups, and/or roles.
   • **Add Another** to grant permissions for other users, groups, and/or roles and repeat steps b and c.
   • to create a copy of the permissions, which you can then modify.
   • to remove a data access control setting.

last-updated: Jun 06, 2024

10. (Optional) Specify the users and groups that have volume administration permissions:
    a) Select the type of entity, user or group, and enter entity name in the **Entities** field.
    b) Select the checkbox associated with any of the following permissions to grant the user or group that type of administration control:

Dump & Backup	Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files.
Restore & Mirror	Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume.
Edit	Edit volume properties, create and delete snapshots.
Delete	Delete the volume.
Admin (Access Control)	View and edit access control settings (but cannot perform volume operations).
Full Control	Perform all volume-related administrative operations except changing access control settings.

    To define administrative access control settings for another user or group, click **Add Another** and repeat steps a and b.

    NOTE: To perform this action from the command line, refer to acl set on page 2001.

    By default, the root user and the volume creator have full control permissions on the volume.
11. Set read (**R**), write (**W**), and/or execute (**X**) permissions on the root directory for users, groups, and others by selecting the permission.
12. Click **Create Volume** to create the volume.

Creating a Volume Using the CLI and REST API

About this task

CLI

The basic command to create a (Standard) volume is:

```
/opt/mapr/bin/maprcli volume
create -name <volName> -path
<mountPath>
```

The name should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

If you are creating a:

- Mirror volume, you must specify `-type mirror` and `-source <sourceVolName>@<cluster>` in the command.
- Tiering-enabled volume, you must specify `-tieringenable true` in the command.

last-updated: Jun 06, 2024

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<mountPath>' --use
r mapr:mapr
```

The name should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

If you are creating a:

- Mirror volume, you must specify `type=mirror` and `source=<sourceVolName>@<cluster>` in the request.
- Tiering-enabled volume, you must specify `tieringenable=true` in the request. The `tieringenable` property of a mirror volume should be the same as the source volume.

For the complete list of parameters, see `volume create` on page 2588.

Creating Remote Mirrors

Describes the use of remote mirror volumes. The remote mirror volume is present on a different cluster from the source volume.

Creating remote mirrors is similar to creating local mirrors, except that the mirror volume resides in a different cluster from the source volume. To properly identify the source volume, you must specify the source cluster name when the mirror volume is created. In addition, you must edit the `mapr-clusters.conf` file so that each cluster can resolve the nodes in the other cluster.

To create a mirror on a remote cluster, you must have the same UID for the `MAPR_USER` (the cluster owner) for both the primary cluster (where the source volume resides) and the remote clusters (where the mirror volumes reside; also known as the destination clusters). You also need to have the following volume permissions:

- `dump` permission on the source volumes
- `restore` permission on the mirror volumes at the destination clusters

When a mirror volume is created on a remote cluster (according to the entries in the `mapr-clusters.conf` file), the CLDB checks that the local volume exists in the local cluster. If both clusters are not set up and running, the remote mirror volume cannot be created.

To summarize:

- Each cluster must be already set up and running.
- Each cluster must have a unique name.
- Every node in each cluster must be able to resolve all nodes in remote clusters, either through DNS or entries in `/etc/hosts`.
- The UID for the `MAPR_USER` (cluster owner) must be the same for the source and destination clusters, irrespective of which user account triggers the mirror operation.
- Volume permission must be set to `dump` on the source volumes.
- Volume permission must be set to `restore` on the mirror volumes.

last-updated: Jun 06, 2024

See also: Remote Mirroring on page 503.

Creating a Volume for a Tenant
Provides an overview of how to create a volume for a tenant using the CLI.

About this task

To create a volume for a tenant (when you have Multitenancy on File System on page 533), do the following:

Procedure

1. Log in to the cluster as administrator and ensure that the ticket for the tenant has already been generated and copied on to the tenant host.

   If necessary, follow steps in Generating a Ticket for a Tenant on page 1836 to set up the ticket for the tenant.

2. Create a volume for the tenant by running the following command:

   ```
   $ maprcli volume create -name <volumeName> -path
   <path_to_volume> -tenantuser <tenant_user>
   ```

   NOTE: For more information, see the `maprcli volume create` command.

Viewing Volume Information
Describes how to view volume information using either the Control System or the CLI.

About this task

You can retrieve and view volume information using either the Control System or the CLI.

Procedure

1. Log in to the Control System and go to the **Summary** tab in the **Data** > **Volumes** page.

   NOTE: The **Summary** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click the volume name in the **Volumes** pane.

   The volume information page displays. On this page, you can perform the following actions based on the type of the volume.

Standard Volume	Click the **Select Action** drop-down menu to: • Edit the volume • Remove the volume • Snapshot a volume • Change the mount path and mount or unmount the volume • Convert the volume to a mirror volume • Rename the volume • Manage Label

	• Manage Name Space Label
Mirror Volume	Click the **Select Action** drop-down menu to: • Edit the Volume • Remove the volume • Snapshot a volume • Start/stop mirroring • Promote the volume to a standard (read/write) volume • Change volume mount information • Rename the volume • Manage Label
Tiering Volume	Click the **Select Action** drop-down menu to: • Edit the Volume • Remove the volume • Snapshot a volume • Change volume mount information • Rename the volume • Manage Label • Offload a volume to a tier • Recall a volume from a tier • Abort a volume tiering job

The page displays tabs for viewing:

- Summary of the volume including:
  - All recent and active volume alarms
  - Metrics (such as disk usage) for the volume
  - Volume details such as the general, auditing, and tiering settings for the volume, ACLs and ACEs on the volume, and volume quotas and schedules
  - Labels associated with the volume
- Snapshots associated with the volume

Viewing Volume Details
Explains how to retrieve and view volume information using the Control System, the CLI, or the REST API.
Viewing Volume Details in the Control System

Procedure

- Log in to the Control System and go to the **Summary** tab in the volume information page for the volume.

last-updated: Jun 06, 2024

The page displays the following:

Quota Usage

Amount of disk space allocated to and utilized by the volume and associated snapshots. For more information, see Monitoring Volume Disk Usage Using the Control System on page 1674. You can set or edit hard and advisory quotas by clicking **Edit Quota**. See Setting or Modifying Quota for a Volume on page 1229 for more information.

Active Alarms

Currently active alarms associated with the volume. For more information, see Viewing Active Volume Alarms on page 1693. You can mute or dismiss alarms by clicking the associated link.

Schedules

The schedules associated with the volume. Standard volumes can have associated snapshot schedule; mirror volumes can have associated snapshot and mirroring schedules; tiered volumes can have associated snapshot and tiering schedules. You can:

- Create a new schedule by clicking **Create Schedule**.
- Set new or modify existing schedules by clicking  .

Properties

Created By	Indicates the user who created the volume.
Volume Type	Indicates the type of volume. Value can be one of the following: • Standard Volume • Mirror Volume
Volume Name	Indicates the name of the volume.
Accountable Entity	Indicates the name of the accountable entity.
Volume Access	Indicates the type of access allowed on the volume. Value can be one of the following: • Read/Write • Read-only
Mounted	Indicates whether or not volume is mounted.
Mount Path	Indicates the mount path of the volume.
Collect Metrics	Indicates if metrics collection is enabled for the volume.
Last accessed	Indicates the date when the volume was last accessed.

last-updated: Jun 06, 2024

Last Access Interval	Indicates the frequency (in days) at which the last access time of a file is updated,

Replication and Storage

REPLICATION **Table**

Topology	Denotes the location of the volume on the cluster rack.
Replication	Indicates the minimum (**Min Target**) and desired (**Max Target**) number of copies for the volume data.
Name Container Replication	Indicates the minimum (**Min Target**) and desired (**Max Target**) number of copies of the name container associated with the volume.

Table (Continued)

Optimize Replication	Indicates the basis for replication. Value can be one of the following: • High throughput, or cascading replication • Low latency, or star replication
Guarantee Min Replication	Indicates whether or not to enforce minimum number of copies.
Actual Replication	Indicates the actual number of replicas as a percentage.

STORAGE

The following information is common to all types of storage:

Table

Type	Indicates the storage type.
Label - Volume	Indicates the label assigned to the volume.
Label - Name Container	Indicates the label assigned to the volume's name container.

last-updated: Jun 06, 2024

Table (Continued)

Usage	Displays disk usage details for the volume.

NOTE: The following is visible only if warm tiering is enabled for the volume.

Table

Topology	Indicates the topology of the erasure-coded volume.
Remote Target	Indicates the name of the tier.
Storage Policy Name	Indicates the name of the storage policy.
Policy Detail	Indicates the rules in the policy for offloading data.
Retention Duration after Recall	Indicates the period of time to keep recalled data in the hot tier.
Erasure Coding Scheme	Indicates the number of data and parity chunks.
Tier Purged	Indicates the amount of offloaded data.

last-updated: Jun 06, 2024

NOTE: The following is visible only if cold tiering is enabled for the volume.

Table

Remote Target	Indicates the name of the remote storage.
Storage Policy Name	Indicates the name of the storage policy.
Policy Detail	Indicates the rules in the policy for offloading data.
Retention Duration after Recall	Indicates the number of days to keep recalled data in the data-fabric cluster (hot tier).
Tier Purged	Indicates the amount of offloaded data.

Security	**Enforcement Mode**	The enforcement mode for the security settings. See Volume-Level Security Policy Enforcement Mode on page 861 for more information. You can set new or modify existing enforcement mode by clicking .
	SECURITY POLICIES	The security policies associated with the volume. See Policy-Based Security on page 854 for more information.
	DATA ACCESS CONTROL	Indicates the entities — public or user, group, and/or role — that

last-updated: Jun 06, 2024

	have (read and/or write) access to volume data. See Managing Access Control Expressions on page 1855 for more information.
AUDIT AND ENCRYPTIONS	
Enable Auditing	Indicates whether auditing is enabled at the volume level.
Audit Operations	Indicates whether default or custom list of operations are being audited.
Data on Wire Encryption	Indicates whether (**Yes**) or not (**No**) on-wire encryption is enabled for the volume.
Data at Rest Encryption	Indicates whether (**Yes**) or not (**No**) data-at-rest encryption (DARE) is enabled for the volume.
Coalesce Interval	Indicates the interval of time (in minutes) used for logging multiple READ, WRITE, or GETATTR operations on one file from one client IP address, if auditing is enabled.

Volume Admin Control	Indicates the users and/or groups who have one or more of the following types of permissions on the volume: • **Dump & Backup** — Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files. • **Restore & Mirror** — Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume. • **Edit** — Edit volume properties, create and delete snapshots. • **Delete** — Delete the volume. • **Admin** — View and edit access control settings (but cannot perform other volume administrative operations). • **Full Control** — Perform all volume-related administrative operations except changing access control settings.

Viewing Volume Information Using the CLI and the REST API

About this task

CLI	The basic command to retrieve volume information is: `maprcli volume info (-name <volume_name> | -path <volume_path>)`
REST	Send a request of type GET. For example: `curl -k -X GET 'https://<hostname>:8443/rest/volume/info?name=<volName>' --user mapr:mapr`

You must specify either `name` or `path`, but not both. For more information, see `volume info` on page 2628.

Viewing the list of Snapshots

Describes how to view the list of snapshots that are present on a cluster, using the Control System or the CLI.

About this task

You can view the snapshots on the cluster using the Control System or the CLI.

Viewing All the Snapshots Using the Control System

Procedure

- The **Snapshots** tab under the **Data** > **Volumes** page displays all the snapshots on the cluster.

  NOTE: When running on a Kubernetes cluster, the **Snapshots** tab is under the **Volumes** page that is under the **Volumes** menu.

last-updated: Jun 06, 2024

For each snapshot, you can view the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	Disk space (in MB) used/owned by the snapshot

You can select one or more snapshots to:

- Preserve
- Remove

Viewing the Snapshots Associated with a Volume Using the Control System

Procedure

- Log in to the Control System and go to the **Snapshots** tab in the volume information page.
  The list of snapshots associated with the volume displays in this tab. For each snapshot, the pane displays the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	Disk space (in MB) used/owned by the snapshot

You can create a snapshot of the volume or select one or more snapshots to:

- Preserve
- Remove

Viewing Snapshots Using the CLI or REST API

About this task

The basic command to retrieve a list of snapshots is:

```
maprcli volume snapshot list
```

For complete reference information, see `volume snapshot list` on page 2705.

Removing Volumes
Explains how to remove a volume using either the Control System or the CLI.

last-updated: Jun 06, 2024

About this task

NOTE: When you remove a volume enabled for:

- Cold tiering, the directory/folder for the volume in the metadata volume associated with the tier is also removed asynchronously.
- Warm tiering, the directory/folder for the volume in the metadata volume associated with the tier and the erasure-coded volume are also removed asynchronously.

Removing Volumes Using the Control System

About this task

To remove one or more volumes, in the **Summary** tab under **Data** > **Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the volumes to remove from the list of volumes in the **Volumes** pane.

   NOTE: Alternatively, you can click the name of the volume to traverse to the volume details page.

2. Click **Remove Volume(s)** from the **Actions** drop-down menu.
   The **Remove Volume(s)** confirmation dialog displays.
3. Choose one of the following:
   - **Remove only if there are no dependent artifacts** — Specifies whether to check for dependencies before removing the volume. If the volume has dependencies, such as associated snapshots, the volume will not be deleted, but an alarm will be raised.

     NOTE: Volume will not be deleted if mirroring is in progress as the mirror volume is synchronized from a hidden internal snapshot of the source volume.

   - **Force remove even if there are dependent artifacts** — Indicates that volume must be removed forcefully, even if the volume has dependencies.
4. Click **Remove Volume**.
   The selected volumes are removed.

Removing Volumes Using the CLI or REST API

About this task

The basic command to remove a volume is:

```
maprcli volume remove -name <volume name>
```

For complete reference information, see volume remove on page 2701.

last-updated: Jun 06, 2024

NOTE: When a volume is removed, the data present in that volume is not purged from the filesystem immediately. The following parameters control when the deleted volumes are purged.

- `cldb.purge.delay.hours` — Time to wait (in hours) to trigger purge of any volume after CLDB becomes primary. The default value is 1 hour.
- `cldb.volumes.purge.frequency` — The frequency (in minutes) for purging the data of deleted volumes. The default value is 60 minutes.

  Use the `maprcli` command to set these parameters. For example:

```
maprcli config save -values {"cldb.purge.delay.hours":"2"}
maprcli config save -values {"cldb.volumes.purge.frequency":"120"}
```

Modifying Multiple Volumes
Explains how to modify volumes using either the Control System or the CLI.
Modifying Volumes Using the Control System

About this task

To edit multiple volumes, in the **Summary** tab under **Data** > **Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the volumes to edit in the **Volumes** pane and click **Edit Volume(s)** from the **Actions** drop-down menu.

   The **Edit Volumes** page displays. You can edit certain volume properties, authorization settings, usage settings, and schedule settings for the selected volumes.

2. Modify one or more of the following settings.

   NOTE: If the selected volumes share the same settings, the fields are pre-populated with the current value. If the selected volumes contain different settings, only the fields that have been set in all the selected volumes display.

Properties

SETTINGS AND AUDITING	**Accountable Entity**	The *entity* accountable for this volume's usage.
	Collect Metrics	Specifies whether (**Yes**) or not (**No**) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1674 and Enabling Volume Metric Collection on page 1676.
	Volume Access	Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume.
	Last Access Interval	Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 531 for more information.
	Enable Auditing	Select one of the following: • Disable auditing • Enable auditing for volume so that auditing can selectively be enabled for directories, files, tables, and streams in the volume • Enable auditing of operations

REPLICATION (HOT)	**Replication**	Toggle Minimum Replication and set the desired and minimum number of copies of the volumes.
	Name Container Replication	Set the desired and minimum number of copies of the name container associated with the volumes.

last-updated: Jun 06, 2024

SETTINGS AND AUDITING	**Accountable Entity**	The *entity* accountable for this volume's usage.
	Collect Metrics	Specifies whether (**Yes**) or not (**No**) to enable metrics collection for this volume. For more information, see Collecting Volume Metrics on page 1674 and Enabling Volume Metric Collection on page 1676.
	Volume Access	Specifies whether the volume is read-only or a read/write volume. By default, a standard volume is created with read/write access. A mirror volume can only be a read-only volume.
	Enable Auditing	Select one of the following: • Disable auditing • Enable auditing for volume so that auditing can selectively be enabled for directories, files, tables, and streams in the volume • Enable auditing of operations on all files, tables, streams in the volume whether or not auditing is enabled for files, tables, and streams in the volume.

REPLICATION (HOT)	**Replication**	Toggle Minimum Replication and set the desired and minimum number of copies of the volumes.
	Name Container Replication	Set the desired and minimum number of copies of the name container associated with the volumes.

Authorization

ADMINISTRATIVE CONTROLS	Users and groups that have permissions to perform administrative operations on this volume.

Usage

Volume Advisory Quota	Allocated disk space, which when exceeded raises an alarm but does not prevent writes.
Volume Hard Quota	Allocated disk space, which when exceeded prevents further writes.

Schedule

Snapshot Schedule	Schedule for creating snapshots of this volume.
Mirror Schedule	Schedule for running mirroring operation for the volumes. **NOTE:** This is available only if all the selected volumes are mirror volumes.

NOTE: To undo a change to a specific setting, click the associated ↶. This action will revert the value to the current setting.

3. Click **Save Changes** for the changes to take effect.

Modifying Volumes Using the CLI or REST API

About this task

The basic command to modify a volume is:

```
maprcli volume modify -name <volume name>
```

last-updated: Jun 06, 2024

For complete reference information including supported options, see volume modify on page 2676.

Modifying a Volume
Describes how to edit volume properties using the Control System, CLI and the REST API.
Modifying a Volume Using the Control System

Procedure

1. Log in to the Control System and go to the volume information page.
2. Click **Edit Volume** to display the **Edit Volume** page.

Modifying General Properties

3. Make changes, as needed, to the following general properties:

Standard Volume

Accountable Entity	The entity accountable for the volume's usage.
Collect Metrics	Whether (**Yes**) or not (**No**) to enable metrics collection for the volume.
Volume Access	Indicates whether volume is a read-only or read/write volume.
Last Access Interval	Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 531 for more information.

Mirror Volume

Source Cluster Name	The name of the cluster on which the source volume exists.
Source Volume Name	The name of the source volume to mirror.
Accountable Entity	The entity accountable for this volume's usage.
Collect Metrics	Whether (**Yes**) or not (**No**) to enable metrics collection for the volume.
Volume Access	Indicates whether volume is a read-only (default) or read/write volume. To promote the mirror volume to a standard volume, you can switch to read/write volume; see Changing Mirror Volumes to Standard Volumes on page 1221 for more information.

Last Access Interval	Denotes the frequency at which the access time of a file is updated. See Tuning Last Access Time on page 531 for more information.

Modifying Replication and Storage Settings

4. Make changes, as needed, to the following replication settings:

Topology	The location of this volume in the cluster rack topology.
Guarantee Min Replication	(Available from v6.0.1) Specifies whether (true) or not (false) to enforce minimum number of copies for the (read-write) volume. If this is enabled (Yes), writes succeed only when the minimum number of copies exist. **NOTE:** If this parameter was not already set on a volume or if you modify the setting for this property from **No** to **Yes**, restart all the nodes where the containers associated with the volume exist for the changes to take effect.
Replication	Desired and minimum number of copies of the volumes.
Name Container Replication	Desired and minimum number of copies of the name container associated with the volumes.

5. Set new (if **Data Tiering** was enabled (**On**) during volume creation) or modify existing **DATA TIERING** settings.

Erasure Coding (Warm)

For offloading data to a warm tier, set new or modify existing values for the following properties.

Topology	The topology of the erasure coded volume from the drop-down list only if it is already not set.
Storage Policy	The rule (or criteria) for automatically offloading data in this volume. You can click: • **Browse** to select an existing rule. • **Create** to create a new rule for offloading data. See Creating a Storage Tier Policy on page 1303 for more information.

Scheme	The erasure coding scheme, which is the number of data chunks and number of parity chunks, only if it is already not set; you cannot modify existing scheme. See Erasure Coding Scheme for Data Protection and Recovery on page 1244 for more information.

Remote Archiving (Cold)

For offloading data to a low cost storage alternative on the cloud, set new or modify existing values for the following properties.

Storage Policy	The rule (or criteria) for offloading data in this volume. You can click: • **Browse** to select an existing rule. • **Create** to create a new rule for offloading data. See Creating a Storage Tier Policy on page 1303 for more information.
Remote Target	The location to offload data to only if it is already not set; you cannot modify if it is already set. You can click: • **Browse** to select an existing tier. • **Create** to create a new tier. See Creating a Storage Tier on page 1287 for more information.
Retention Duration after Recall	The number of days to retain data recalled from the tier to the HPE Ezmeral Data Fabric cluster. Once the number of days is reached, recalled data on the HPE Ezmeral Data Fabric cluster is purged (if there are no changes) or offloaded (if there are changes).

last-updated: Jun 06, 2024

Tier Encryption	The setting to enable (**Yes**) or disable (**No**) encryption of data on the tier only if it is already not set.

Modifying Security Settings

6. Enter the name of the security policy in the **SECURITY POLICIES** field to search for the security policy to associate with the volume and click **Add** to tag the volume with the security policy.

7. Make changes to the auditing settings by moving the slider to **Yes** (to enable) or **No** (to disable).

   If enabled (**Yes**), you can make the following changes also:

   a) Choose the **Default** radio button to enable auditing of a default list of operations or choose the **Custom** radio button to select a custom list of directory, file, table, and streams operations to audit. Note that enabling `setattr` automatically enables `chown`, `chgrp`, and `chperm`. If you exclude `setattr`, these operations are automatically disabled. If you do nothing with `setattr` (neither enable nor disable), you can enable or disable `chown, chgrp,` and `chperm` in any combination.

   b) Specify a **Coalesce Interval**, which is the interval of time (in minutes) to use when logging multiple READ, WRITE, or GETATTR operations on one file from the same client IP address. The default value is 60 minutes.

8. Make changes to the following encryption settings by moving the slider to **Yes** (to enable) or **No** (to disable):

Data on Wire Encryption	Encryption of data in the volume during transmission. By default, this is enabled (**Yes**) for all new volumes in secure cluster.
Data at Rest Encryption	Encryption of data at rest. This should be enabled only if the feature is enabled at the cluster-level. By default, this is disabled (**No**).

9. Make changes, as needed, to the users, groups, and/or roles that have and/or do not have permissions to read and/or write by clicking one of the following in the **Data Access Control** section:

   - — to modify the users, groups, and/or roles.
   - — to create a copy of the permissions, which you can then modify.
   - — to remove a data access control setting.
   - Select or deselect **Read** and/or **Write** checkbox in the **Permissions** column — to grant or deny that type of access.
   - **Add Data Access Control** or **Add Another** — to display the **Add Access Permissions** window. To specify the users, groups, and/or roles that have and/or do not have permissions to read and/or write, do the following:

   a) Move the slider associated with **Public** to **Yes** to grant access to all or to **No** to specify a list of users, groups, and or roles and do one of the following:

      - Enter the users, groups, and/or roles in the respective text boxes.
      - Select the **Custom ACE** checkbox to enter the custom *ACE*.

   b) Click **Add** to select permissions for the specified users, groups, and/or roles.

last-updated: Jun 06, 2024

c) Select the **Read** and/or **Write** checkbox in the **Permissions** column to grant that type of access to all (Public) or the specified users, groups, and/or roles.

Modifying Volume Administration Control Settings

10. Make changes to the users and/or groups that can perform the following administrative operations on this volume:

Dump & Backup	Transport large amount of data or copies of the volume on physical media to a remote cluster using backup files.
Restore & Mirror	Restore a volume from a dump file and create mirror volumes, which is a read-only copy of the source volume.
Edit	Edit volume properties, create and delete snapshots.
Delete	Delete the volume.
Admin	View and edit access control settings (but cannot perform volume operations).
Full Control	Perform all volume-related administrative operations except changing access control settings.

To:

- Modify access for existing users and/or groups, select or deselect permissions.
- Grant access to other users and/or groups, click **Add Another**, enter the user/group name, and select permissions to grant to the user/group.

11. Click **Save Changes** for the changes to take effect.

Modifying a Volume Using the CLI or REST API

About this task

CLI

The basic command to modify a volume is:

```
/opt/mapr/bin/maprcli volume
modify -name <volume name>
```

REST

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<hostname>:8443/
rest/volume/modify?name=<volume
name>' --user mapr:mapr
```

For the complete list of editable parameters, see `volume modify` on page 2676.

Renaming a Volume

Describes how to rename a volume using the Control System, CLI or the REST API.

About this task

If you rename a volume, unmount and re-mount of the volume happens during the process, and the mount path of that volume may not be available for a short period of time.

last-updated: Jun 06, 2024

Renaming a Volume Using the Control System

Procedure

1. Log in to the Control System and go the volume information page.
2. Click **Rename Volume** from the **Select Action** drop-down menu to display the **Rename Volume** window.
3. Enter the new name for the volume in the **New Volume Name** field and click **Save Changes** for the changes to take effect.

   NOTE: For tiering-enabled volumes, volume name cannot exceed ninety-eight characters.

Renaming a Volume Using the CLI and REST API

About this task

CLI

The basic command to rename a volume is:

```
maprcli volume rename -name
<oldName> -newname <newName>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://<host>:8443/
rest/volume/rename?
name=<oldName>&newname=<newName>' --us
er mapr:mapr
```

See `volume rename` on page 2701 for more information.

Manage a Label

Describes how to apply a storage label to a volume using the Control System.

Managing a Label Using the Control System

For an overview on Storage Labels, refer to Using Storage Labels on page 1314.

To apply a label to a volume:

1. Log in to the Control System and go the volume information page.
2. Click **Manage Label** from the **Select Action** drop-down menu to display the **Manage Label** window.
3. Either select an existing label, or enter the name of a label to create, and click **Apply Label** to apply the label to the volume.

Specifying Volume Inheritance Using the CLI
Lists volume properties that can be inherited from other volumes.

Volumes can be mounted using the web console, the `maprcli` commands (volume create or volume mount), or the REST commands. If the mount point is specified while creating a volume, new volumes can inherit properties from the parent volume. Mirror volumes can also inherit properties from the source volume of the mirror.

Volume inheritance is a convenience that can only be used during volume creation.

The maprcli volume modify command can be used to change the volume inheritance settings of a volume. That is, you can toggle the flag (associated with `allowgrant`) that indicates whether a volume, as a parent volume, wants its properties to be inherited by default or not. When creating and mounting a volume, the location of the mount point can be specified using the `path` parameter. The volume that is last in the `path` parameter is referred to as the parent volume. (The parent volume is the volume on which the volume link is created.)

Inheritance applies during volume creation only. If the settings in the parent volume is modified after the child volumes are created, these modified properties do not propagate to the child volumes.

Inheritance

The following table shows the list of inheritable parameters that are (Yes) and are not (No) inherited by a:

- Mirror volume from the source volume on the same cluster
- Mirror volume from the source volume on a different cluster

NOTE: All (non-mirror) volumes inherit all the inheritable properties from the parent volume. For more information on the properties, refer to `volume create` parameters.

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
`advisoryquota`	Yes	Yes
`ae`	Yes	No
`aetype`	Yes	No
`allowgrant`	Yes	Yes
`allowinherit`	Yes	Yes
`auditenabled`	Yes	Yes
`coalesce`	Yes	Yes
`dare`	Yes	Yes[1], No[2]
`dataauditops`	Yes	Yes
`dbindexlagsecalarmthresh`	Yes	Yes

Inheritable Properties (which are inherited by non-mirror volumes by default)	Inherited by Mirror Volume on the same cluster as the source volume?	Inherited by Mirror Volume on a different cluster from the source volume?
dbrepllagsecalarmthresh	Yes	Yes
enforcementMode	Yes	Yes
ecscheme	Yes	No
ectopology	Yes	No
group	Yes	Yes
inherit	Yes	Yes
localvolumehost	No	No
localvolumeport	No	No
maxinodesalarmthreshold	Yes	Yes
minreplication	Yes	Yes

last-updated: Jun 06, 2024

- [1] If destination cluster is also enabled for data-at-rest encryption, `dare` setting is inherited by the mirror volume on the destination cluster.
- [2] If destination cluster is not enabled for data-at-rest encryption, `dare` setting is not inherited by the mirror volume on the destination cluster.
- [3] If `schedule` keyword is specified with the `skipinherit` parameter, schedule(s) are not inherited while inheriting volume properties from the source volume.
- [4] If `tiername` keyword is specified with the `skipinherit` parameter:
  - The tiering properties are not inherited by the mirror volume while inheriting volume properties from the tiering-enabled source volume.
  - For volumes enabled for warm-tier, the backend erasure-coded volume is not created.

Setting Data ACEs
Describes how to set ACEs using both the GUI and the CLI.

About this task

To set data *ACE* using the **Add Access Permission** window in the MapR Control System:

Procedure

1. Specify the entities to set permissions for by doing one of the following:
   - Move the slider associated with **Public** to **Yes** to grant access to all users or to **No** to set permissions for individual users, groups, and/or roles.
   - Specify the users, groups, and/or roles to set permissions for in the associated fields.
   - Select the **Custom ACE** checkbox and enter the access control expression in the field.
2. Click **Add** to set permissions for all or for the specified users, groups, and/or roles.
3. Select the permissions to grant the specified users, groups, and/or roles from the **Permissions** column associated with the entities.
4. Click **Save Changes** to save the *ACE* settings.

Setting Whole Volume ACEs Using the CLI

About this task
See Setting Whole Volume ACEs on page 1365.
Setting Table ACEs Using the CLI

About this task
See Enabling Table and Stream Authorizations with ACEs on page 1363.
Setting Stream ACEs Using the CLI

About this task
See Enabling Table and Stream Authorizations with ACEs on page 1363.

Changing or Setting Mount Information for a Volume
Describes how to set the mount path for a volume using either the Control System, the CLI, or the REST API.

About this task

You can set or change volume mount settings using the Control System, the CLI (`volume create` or `volume mount`), or the REST commands. To mount or unmount volumes under a directory, the user must have read/write permissions on the directory.

Changing or Setting Mount Information for a Volume Using the Control System

Procedure

1. Log in to the Control System and go to the volume information page.
2. Select **Change Mount Information** from the **Select Action** drop-down menu.
   The **Change Mount Information** dialog displays.
3. Make the necessary changes.
   a) Specify whether (**Yes**) or not (**No**) to mount the volume.
   b) Enter the path in the **Mount Path** field.
   The path must be relative to `/` and cannot be in the form of a global namespace path (for example, `/mapr/<cluster-name>/`).

   RESTRICTION:

   The path should contain only the following characters:

   ```
   A-Z a-z 0-9 _ - .
   ```
4. Click **Save Changes** for the changes to take effect.

What to do next

NOTE: After changing the mount point, run `maprcli volume fixmountpath` command to notify CLDB of the change in the volume mount path.

Changing or Setting Mount Information Using the CLI or REST API

About this task

The basic command to mount the volume is:

```
maprcli volume mount -name <volume name> -path <mount path>
```

RESTRICTION: The volume name and the path should contain only the following characters:

```
A-Z a-z 0-9 _ - .
```

For complete reference information including all available options, see `volume mount` on page 2695.

Mounting one or more Volumes

Explains how to set or change mount settings for volumes using the Control System or the CLI.

About this task

To mount volumes under a directory, you must have read/write permissions on the directory.

Changing or Setting Mount Information Using the Control System

About this task

To mount one or more volumes, in the **Summary** tab under **Data** > **Volumes**:

Procedure

1. Select the volumes to mount from the list of volumes in the **Volumes** pane.
2. Select **Mount Volume(s)** from the **Actions** drop-down menu.
   The **Mount Volume(s)** confirmation dialog displays.

   NOTE: Only unmounted volumes with mount paths can be mounted. Volumes with no mount paths and volumes that are currently mounted, if selected, cannot be mounted.
3. Verify list of selected volumes.
   If necessary, click ✕ to remove a volume from the list of volumes to mount.
4. Click **Mount Volumes** to mount the selected volumes.

Changing or Setting Mount Information Using the CLI or REST API

About this task

The basic command to mount the volume is:

```
maprcli volume mount -name <volume name> -path <mount path>
```

For complete reference information including all available options, see `volume mount` on page 2695.

Unmounting one or more Volumes
Describes how to unmount a volume using either the Control System or the CLI.

About this task

You can unmount multiple volumes using the Control System or the CLI. To unmount volumes under a directory, you must have read/write permissions on the directory.

Unmounting one or more Volumes Using the Control System

About this task

To unmount one or more volumes, in the **Summary** tab under **Data** > **Volumes**:

NOTE: When running on a Kubernetes cluster, the **Summary** tab is in the **Volumes** page under the **Volumes** menu.

Procedure

1. Select the volumes to unmount from the list of volumes in the **Volumes** pane.
2. Select **Unmount Volume** from the **Actions** drop-down menu.
   The **Unmount Volume** confirmation dialog displays.

   NOTE: Only mounted volumes can be unmounted. Volumes that are currently not mounted, if selected, cannot be unmounted.

last-updated: Jun 06, 2024

3. Verify list of selected volumes.
4. Click **Unmount Volumes** to unmount the selected volumes.

Unmounting one or more Volumes Using the CLI or REST API

About this task

The basic command to unmount the volume is:

```
maprcli volume unmount -name <volume name>
```

For complete reference information including all available options, see `volume unmount` on page 2724.

Mounting a Tenant Volume
Describes the steps to mount and access a tenant volume.

About this task

After the tenant volume is created on the cluster (for a multi-tenant environment), access the tenant volume on the tenant host with the following steps:

Procedure

1. Log in to the tenant host as the tenant admin (`root`) and verify that a valid tenant ticket is available on the tenant host.

   For example, run the following command:

   ```
   ~tenantAdmin@tenantHost: maprlogin print -ticketfile /user/tenantAdmin/
   tenant_sample_ticket.txt
   Opening keyfile /user/tenantAdmin/tenant_sample_ticket.txt
   cHost: user = sampleTenant, created = 'Mon Jul 11 07:14:53 UTC 2016',
   expires = 'Mon Jul 11 07:14:53 UTC 12016', RenewalTill = 'Mon Jul 11
   07:14:53 UTC 12016',
   uid = 500, gids = 500, 42, CanImpersonate = true, tenant = true
   ```

2. Perform one of the following:
   - Set up the FUSE-based POSIX client configuration parameters (see Configuring HPE Ezmeral Data Fabric FUSE-based POSIX Client for Tenant Environment on page 1628) and mount the volume (see Mounting the File System on page 1632).
   - Set up an alias for NFS exports to export the tenant volume path (see Setting Up Aliases for NFS Exports on page 1558) and mount the volume for loopbacknfs service (see Starting the mapr-loopbacknfs Service to Access a Cluster).
3. Create accessible directories within the provisioned space for the tenant users.

Unmounting a Tenant Volume
Explains how unmount a tenant volume using the CLI.

About this task

Procedure

To unmount a tenant volume and:

last-updated: Jun 06, 2024

- Kill the FUSE process, run the following command:

  ```
  service mapr-posix-client-* stop
  ```

  When you run the command, replace * with basic or platinum, which corresponds with the POSIX client package that is installed on the system.

  NOTE: For more information, see Unmounting the FUSE Mount.

- Stop the loopbacknfs service, run the following command:

  ```
  service mapr-loopbacknfs stop
  ```

  NOTE: For more information, see Managing the mapr-loopbacknfs Service on page 1610

Changing Volume Type

You can convert a standard volume to a mirror volume and promote a mirror volume to a standard volume.

A standard volume with one or more associated mirror volumes can be converted to a mirror volume that mirrors one of the its associated mirror volumes. The mirror volume that the converted standard volume is set to mirror must then be promoted to a standard volume. The converted standard volume then becomes a read-only copy of the promoted mirror volume.

NOTE: Standard volumes that do not have one or more associated mirror volumes cannot be converted to mirror volumes.

A mirror volume is a read-only physical copy of a standard volume. In general, mirror volumes are created for the purpose of preventing or minimizing data loss. Mirror volumes are also used to improve performance or to make copies of data for use in other clusters without impacting production. Mirror volumes can be changed to read-write volumes by converting the mirror volumes to standard volumes.

The following topics include procedures for converting a standard volume to a mirror volume and vice versa.

Changing a Standard Volume to a Mirror Volume
Describes how to convert a standard volume to a mirror volume.

About this task

You can convert a standard volume to a mirror volume and set it up to mirror one of its associated mirror volumes using the Control System, the CLI, or the REST API.

Changing a Standard Volume to a Mirror Volume Using the Control System

Procedure

1. Log in to the Control System and go to the Viewing Volume Details on page 1192 page for the standard volume.
2. Select **Make Mirror Volumes** from the **Select Action** drop-down menu.

   The **Mirror Volume** confirmation dialog displays.
3. Select the:
   - Name of the source cluster where the associated mirror volume that the converted volume will mirror, exists.

- Name of the source volume that the converted volume will mirror, from the list of associated mirror volumes.

The standard volume, when converted, can only be a mirror of one of its associated mirror volumes.

4. Click **Save Changes** for the changes to take effect.

NOTE: It might take some time (approximately 10 minutes or so) to convert a standard volume to a mirror volume. You need to wait until the operation is complete before performing other actions.

What to do next

After converting the standard volume to a mirror volume:

1. Convert the source (mirror) volume to a standard (read/write) volume to prevent a deadlock and to allow writes to continue on the volume.
2. Associate a mirroring schedule with this volume to ensure that data on this volume is in sync with the source volume.

Changing a Standard Volume to a Mirror Volume Using the CLI or the REST API

About this task

CLI

To convert a standard volume to a mirror volume from the CLI, run the `maprcli volume modify` command with the `-type` option value set to `mirror`.

```
maprcli volume modify -name <volume
name> -type mirror
```

REST

To convert a standard volume to a mirror volume, send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&type=mirror' --user
mapr:mapr
```

For more information, see `volume modify` on page 2676.

NOTE: It might take some time (approximately 10 minutes or so) to convert a standard volume to a mirror volume. You need to wait until the operation is complete before performing other actions.

After converting the standard volume to a mirror volume:

1. Convert the source (mirror) volume to a standard (read/write) volume to prevent a deadlock and to allow writes to continue on the volume.
2. Associate a mirroring schedule with this volume to ensure that data on this volume is in sync with the source volume.

Changing Mirror Volumes to Standard Volumes
Describes how to convert a mirror volume to a standard volume.

About this task

To change read-only mirror volumes to read-write (standard) volumes, you must promote the mirror volumes to standard volumes. After the mirror volume is promoted, the snapshot schedule specified for

the mirror is used for the promoted read-write volume and the mirror schedule is disabled. You can promote a mirror volume to a standard volume using the Control System or the CLI.

NOTE: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

Mirror promotion time is typically negligible, but is dependent on the number of containers in the volume being promoted. For a volume with thousands of containers and a few terabytes of data, it may take a few seconds. For enormous volumes with tens of thousands of containers and hundreds of terabytes of data, promotion could take a few minutes.

After the promotion is complete, a status message is logged in the `cldb.log` file with the time taken. For example:

```
2021-06-27 22:47:00,563 INFO  VolumeMirrorInfo [VolumeMirrorThread0]:
    Volume conversion successfully completed for volume
v100k.m@c.228toMirror false.
    Time taken : 142395ms
```

Changing Multiple Mirror Volumes to Standard Volumes Using the Control System

About this task

To change one or more mirror volumes to standard volumes, in the **Summary** tab under **Data** > **Volumes**:

NOTE: The **Summary** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the mirror volumes to promote from the list of volumes in **Volumes** pane.
2. Select **Change to Standard Volume(s)** from the **Actions** drop-down menu.
   The **Change to Standard Volume(s)** confirmation dialog displays.
3. Review the list of mirror volumes to promote and click **Change Volume(s)** to change the mirror volumes to standard volumes.

What to do next

NOTE: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see Handling Mount Points in Promoted Mirror Volumes on page 1223.

Changing a Mirror Volume to a Standard Volume Using the Control System

Procedure

1. Log in to the Control System and go to the volume information page for the mirror volume.
2. Select **Change to Standard Volume(s)** from the **Select Action** drop-down menu.
   The **Change to Standard Volume(s)** confirmation dialog displays.
3. Click **Change Volume(s)** to change the mirror volume to a standard volume.

What to do next

NOTE: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see Handling Mount Points in Promoted Mirror Volumes on page 1223.

Changing a Mirror Volume to a Standard Volume Using the CLI or REST API

About this task

For changing a mirror volume to a standard (read/write) volume using the CLI, run the `maprcli volume modify` command with the `-type` option value set to `rw` on the cluster where the mirror volume resides and specify the name of the mirror volume that is being promoted. In the following example, the mirror volume is named volA:

```
Cluster2> maprcli volume modify -name volA -type rw
```

For more information, see `volume modify` on page 2676.

What to do next

NOTE: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly. For more information, see Handling Mount Points in Promoted Mirror Volumes on page 1223.

Handling Mount Points in Promoted Mirror Volumes

Explains how to use mount points in promoted mirror volumes.

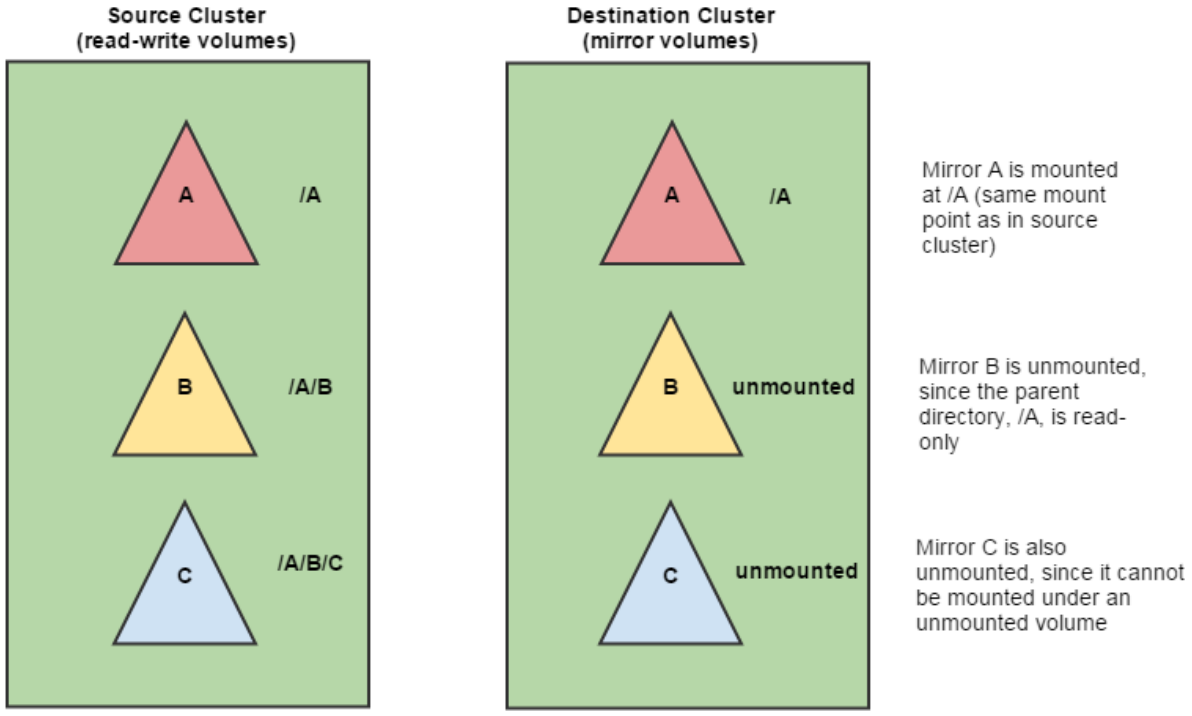
After you promote read-only mirror volumes to read-write standard volumes, you must re-establish the mount points that were set up in the source cluster. To understand the steps in this process, consider the following scenario:

A source cluster has volumes A, B, and C, which are mounted at /A, /A/B, and /A/B/C respectively. Each source volume is mirrored to a volume in another cluster (the destination cluster). The names of the corresponding mirror volumes are also A, B, and C.

NOTE: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

Mirror volume A is mounted at /A, but since the mirror is read-only, no mount point can be created beneath it for mirror B or mirror C.

last-updated: Jun 06, 2024



WARNING: Mirror volumes that are promoted to standard (read-write) volumes are not available for write operations until they are mounted explicitly.

Now suppose that all three mirror volumes are promoted to read-write volumes. Before any data can be written to these volumes, the volume links must be removed and the volumes must be remounted. The commands for each step are as follows:

1. Promote A, B, and C to read-write volumes.

   ```
   Cluster2> maprcli volume modify -name A -type rw
   Cluster2> maprcli volume modify -name B -type rw
   Cluster2> maprcli volume modify -name C -type rw
   ```

   To promote using the Control System, see Changing Mirror Volumes to Standard Volumes on page 1221.

2. Remove the volume links located at /A/B and /A/B/C. Since mirror A was already mounted, its volume links do not need to be removed.

   ```
   maprcli volume link remove -path /A/B
   maprcli volume link remove -path /A/B/C
   ```

3. Mount the promoted read-write volumes B and C at the same mount points used in the primary (source) cluster, in order to maintain an exact replica in the destination cluster.

   ```
   Cluster2> maprcli volume mount -name B -path /A/B
   Cluster2> maprcli volume mount -name C -path /A/B/C
   ```

   To mount using the Control System, see Mounting one or more Volumes on page 1217.

Now the promoted volumes are accessible for write operations.

Selecting a Replication Type for High Availability

Describes replication types for high-availability clusters, and the tradeoffs of using them.

HPE Ezmeral Data Fabric volumes, stored as pieces called containers, are replicated, typically three times, on separate nodes to protect data and provide uninterrupted access to data in the event of a node failure. Since all form of data is replicated, in the event of a node failure, after a brief delay while the failure is being detected, clients are simply directed to a replica, which serves as an alternative location for a data object, to continue normally. The latency as a result of the failure being detected can be reduced by adjusting the number of TCP retries. Furthermore, selecting a container replication type that is appropriate for your cluster layout allows for faster replication of container state, which in turn allows for retrieval of the most current data in the event of a node failure.

HPE Ezmeral Data Fabric supports two types of container replication -- high-throughput or cascading replication, where volumes are replicated sequentially on intermediate and tail containers and low-latency or star replication, where volumes are replicated on multiple containers in parallel.

NOTE: For more information, see How file system and Associated Services Work.

The tradeoffs between the replication types is one of latency and throughput. While the low-latency replication delivers relatively lower throughput than the high-throughput replication, the high-throughput replication suffers from relatively higher latencies than the low-latency replication. Another advantage of low-latency replication is that since the primary container is connected to all other replica containers, there is no need to failover a replica container in the event of a failure thus reducing the duration of recovery. However, with high-throughput replication, in the event of a failure of an intermediate container, clients may experience increased latency while CLDB, after detecting the failure, attempts to update the replication chain by making the next or tail container (whichever comes immediately after the failed container) as the next container in the chain.

Converting Volume Replication Type (Low Latency to High Throughput) Using the CLI

Lists the process to convert a volume's replication type using the CLI.

About this task

A high throughput replication type allows for volumes to be replicated sequentially on intermediate and tail containers from a primary container.

To convert from a low-latency to a high throughput-replication type:

Procedure

1. Change the permissions on the volume from read-write to read only.
   For example:

   ```
   maprcli volume modify -name mvol1,mvol2 -readonly true
   ```

   Wait for the running operations to complete before proceeding to the next step.

2. Convert the volume from `low_latency` replication type to `high_throughput` replication type using the `maprcli` command.
   For example:

   ```
   maprcli volume modify -name mvol1,mvol2 -replicationtype high_throughput
   ```

   Wait till replication type conversion is complete and the first container of the volume acquires a primary container. If necessary, run the following command to see if replication type has been converted:

   ```
   maprcli volume list -columns ReplTypeConversionInProgress,volumename
   ```

   If the conversion is complete, the `ReplTypeConversionInProgress` flag will be set to false (`0`). For example, the `0` in the `ReplTypeConversionInProgress` column in the following sample output indicates successful conversion of corresponding volume in the volumename column:

   ```
   maprcli volume list -columns ReplTypeConversionInProgress,volumename
   ReplTypeConversionInProgress
   volumename

   ```
   maprcli volume modify -name vol1,vol2 -readonly false
   ```

Converting Volume Replication Type (High Throughput to Low Latency) Using the CLI
Lists the process to convert the replication type of a volume using the CLI.

About this task

A low latency replication type allows for volumes to be replicated on multiple containers (in parallel) from the primary container.

NOTE: Contact HPE Ezmeral Data Fabric support before converting volumes to the `low_latency` replication type.

To convert from a high-throughput to a low-latency replication type:

Procedure

1. Change the permissions on the volume from read-write to read only.
   For example:

   ```
   maprcli volume modify -name mvol1,mvol2 -readonly true
   ```

   Wait for the running operations to complete before proceeding to the next step.

2. Convert the volume from `high_throughput` replication type to `low_latency` replication type using the `maprcli` command.
   For example:

   ```
   maprcli volume modify -name mvol1,mvol2 -replicationtype low_latency
   ```

   Wait till replication type conversion is complete and all the containers of the volume acquire a primary container. If necessary, run the following command to see if replication type has been converted:

   ```
   maprcli volume list -columns ReplTypeConversionInProgress,volumename
   ```

   If the conversion is complete, the `ReplTypeConversionInProgress` flag will be set to false (`0`). For example, the `0` in the `ReplTypeConversionInProgress` column in the following sample output indicates successful conversion of corresponding volume in the volumename column:

   ```
   maprcli volume list -columns ReplTypeConversionInProgress,volumename
                          volumename
   ReplTypeConversionInProgress
                          mapr.apps                     0
                          mapr.cldb.internal            0
                          mapr.cluster.root             0
                          mapr.configuration            0
                          mapr.doc22.lab.local.audit    0
                          mapr.doc22.lab.local.logs     0
                          mapr.doc22.lab.local.mapred   0
                          mapr.doc22.lab.local.metrics  0
                          mapr.doc23.lab.local.audit    0
                          mapr.doc23.lab.local.logs     0
                          mapr.doc23.lab.local.mapred   0
                          mapr.doc23.lab.local.metrics  0
                          mapr.hbase                    0
                          mapr.metrics                  0
                          mapr.opt                      0
                          mapr.resourcemanager.volume   0
                          mapr.tmp                      0
                          mapr.var                      0
                          users                         0
   ```

3. Reset the permissions on the volume to read-write.
   For example, to reset, run the following command:

   ```
   maprcli volume modify -name vol1,vol2 -readonly false
   ```

Setting or Modifying Quota for a Volume
Describes how to set or modify a quota for a volume.

About this task

You can set hard and advisory quotas for a volume using the Control System, CLI, and REST API. Hard quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. When the threshold for the hard quota is reached, an alarm is raised and further writes are not allowed. Advisory quota does not prevent further writes when the threshold is reached, but an alarm is raised.

Setting Quota for a Volume Using the Control System

About this task
You can set quota for a volume in the Volumes page and set or modify quotas for a volume in the volume information page.
Setting Quota for a Volume in the Volumes Page

Procedure

1. Log in to the Control System and click **Data** > **Volumes** to display the **Volumes** page.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Ensure that the **Quota** column is displayed in the **Volumes** pane.
   If necessary, customize the columns to see the **Quota** column.

3. Click the **Set Quota** link associated with the volume for which you want to set quotas to display the **Set Quota** window.

4. Specify the following in the **Set Quota** window:
   a) Hard quota, which raises an alarm when the threshold is reached and prevents further writes.

      NOTE: When you set a hard quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes will fail after you write 1GB of data whether or not the volume data is local (on the cluster) or offloaded (to the tier).

   b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

   NOTE: Both, advisory and hard, quotas can be expressed in megabytes (MB), gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).

5. Click **Save Changes** for the changes to take effect.

Setting or Modifying Quotas for a Volume in the Volume Information Page

Procedure

1. Log in to the Control System and go the **Summary** tab in the volume information page.

2. Click the **Edit Quota** in the **Quota Usage** pane to display the **Set Quota** window.

3. Specify the following in the **Set Quota** window:
   a) Hard quota, which raises an alarm when the threshold is reached and prevents further writes.

      NOTE: When you set a hard quota for a tiering-enabled volume, the quota is the total space allocated for the volume irrespective of the location (cluster or tier) where the volume data is stored. For example, if you allocate 1GB of hard quota for a tiering-enabled volume, writes will fail after you write 1GB of data whether or not the volume data is local (on the cluster) or offloaded (to the tier).

   b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

last-updated: Jun 06, 2024

NOTE: Both, advisory and hard, quotas can be expressed in megabytes (MB), gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).

4. Click **Save Changes** for the changes to take effect.

Setting Quota for a Volume Using the CLI or the REST API

About this task
You can set quotas for a volume when creating a new or modifying an existing volume.

CLI

The basic command to set quota for a volume is:

```
maprcli volume
create -name <volName> -path
<mountPath> -advisoryquota
<advisoryQuota> -quota <hardQuota>
```

```
maprcli volume
modify -name <volName> -advisoryquota
<advisoryQuota> -quota <hardQuota>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&adviso
ryquota=<advisoryQuota>&quota=<hardQuo
ta>' --user mapr:mapr
```

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&advisoryquota=<advisory
Quota>&quota=<hardQuota>' --user
mapr:mapr
```

For the complete list of required and optional parameters, see `volume create` on page 2588 and `volume modify` on page 2676.

Migrating a Volume off a Node Using the CLI

When you need to migrate a data volume off a particular node, move that node from the `/data` path to the `/decommissioned` path to avoid data under-replication.

- Establish a `/data` topology path to serve as the default topology path for the volumes in that cluster.
- Establish a `/decommissioned` topology path that is not assigned to any volumes.

TIP: It is recommended that CLDB and ZooKeeper nodes are not in the same topology as the data nodes to ensure fast failover of the failed data node in the event of a data node failure.

Since no data volumes are assigned to the `/decommissioned` topology path , standard data replication will migrate the data off that node to other nodes that are still in the `/data` topology path.

You can run the following command to check if a given volume is present on a specified node:

```
maprcli dump volumenodes -volumename <volume> -json | grep <ip:port>
```

last-updated: Jun 06, 2024

Run this command for each non-local volume in your cluster. Once all the data has migrated off the node, you can decommission the node or place it in maintenance mode.

If you need to segregate CLDB data, create a `/cldb` topology node and move the CLDB nodes under `/cldb`. Point the topology for the CLDB volume (`mapr.cldb.internal`) to `/cldb`. See Isolating CLDB Nodes for details.

NOTE: To move an existing volume to another topology, you must have the Converged Enterprise Edition. Without the Converged Enterprise Edition, when you run the `maprcli volume move` command to move a volume to another topology, the following error message is returned:

```
ERROR (10010) - Volume Move: No license for requested operation
```

Setting Up Volume Topology
Specifies how to use volume topology to place volumes on specific racks, nodes, or groups of nodes.

After you define the node topology for the nodes in your cluster, you can use volume topology to place volumes on specific racks, nodes, or groups of nodes.

This section describes the process of setting up:

- Default volume topology
- Local volume topology
- Custom topology for local volume replicas

Setting Up Volume Topology
Explains how to setup Volume Topology using either the Control System or the CLI.

About this task

HPE Ezmeral Data Fabric supports data placement control, in which you can place a volume on specific racks, nodes, or groups of nodes by setting its topology to an existing node topology. You can set volume topology using the Control System or with the volume move on page 2696 command.

To move an existing volume to another topology, you must have the Converged Enterprise Edition installed on your system. Without the Converged Enterprise Edition, when you try to move a volume to another topology, the following error message is returned:

```
ERROR (10010) - Volume Move: No license for requested operation
```

Setting Up Volume Topology Using the Control System

About this task
You can set up volume topology at the time of volume creation or change the volume topology after volume creation. To:

- Set up volume topology at the time of volume creation, see Creating a Volume on page 1177.
- Modify volume topology, see Modifying a Volume on page 1207.

Setting Up Volume Topology Using the CLI or REST API

About this task

To move a volume to a different topology, run the following command:

```
maprcli volume move -name <volume name> -topology <path>
```

For complete reference information, see volume move on page 2696.

Setting the Topology for Local Volume Replicas
Explains how to set the topology for local volume replicas using the CLI.

About this task

The primary copies for containers of local volumes are placed on the local node (specified with parameter `-localhost` in the `volume create` command). The nodes for the replica copies for containers of local volumes are chosen as follows:

Procedure

1. If a topology is explicitly specified for replicas during `volume create` or `volume edit`, that topology will be used.

   ```
   maprcli volume create -name egLocalVol -path /test/local/volumes/
   examples/sample1 \
   -localvolumehost 10.20.30.40 -topology /rack1/test
   ```

   In the above example, the primaries for the volume are placed on node 10.20.30.40, and replicas will be placed on nodes in the topology /rack1/test.

   The `-topology` parameter is optional, and if it is not specified, CLDB will fall back to 2 or 3 below.

2. If the configuration parameter that specifies a relative path for replicas of local volumes is set, that will be used.

   ```
   maprcli config save -values
   {"cldb.local.volume.topology.trim.index":"-1"}
   ```

   This will trim the topology of the node specified by the localhost parameter and restrict the replicas to the resultant topology.

   By default, this configuration parameter is not set. To set this configuration parameter, see Creating Replicas of Local Volumes in Custom Topology Using the CLI on page 1233. If the configuration parameter is not set, CLDB will fall back to 3 below.

3. The default volume topology will be used.

   The default volume topology is the value specified by the configuration parameter `cldb.default.volume.topology`. The default value for this parameter is `/data`. See Setting Default Volume Topology Using the CLI on page 1234.

Creating Replicas of Local Volumes in Custom Topology Using the CLI

To set the configuration parameter for placing replicas of volumes in a topology relative to the local node, run the `maprcli config save` command. The value can be a:

- Positive number to indicate the number of paths to keep from the initial root (of the topology path). For example:

  ```
  maprcli config save -values {"cldb.local.volume.topology.trim.index":"1"}
  ```

- Negative number to indicate the number of paths to skip from the end of the topology path. For example:

  ```
  maprcli config save -values {"cldb.local.volume.topology.trim.index":"-2"}
  ```

last-updated: Jun 06, 2024

For example, suppose the local volume is created on a node that is under the topology `/data-center1/lab2/rack3/shelf4/10.10.20.30`. To create a local volume where the replicas are restricted to `/data-center1/lab2/rack3` topology, run the following command:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"3"}
maprcli volume create -name egLocalVol -path /data-center1/lab2/rack3/
shelf4/10.10.20.30 -localvolumehost 10.10.20.30
```

Alternatively, you can run the following command to specify the path for the volume from the end of the topology path:

```
maprcli config save -values {"cldb.local.volume.topology.trim.index":"-2"}
maprcli volume create -name egLocalVol -path /data-center1/lab2/rack3/
shelf4/10.10.20.30 -localvolumehost 10.20.30.40
```

The replicas for containers of the volume, egLocalVol, will be created on nodes under `/data-center1/lab2/rack3`.

Setting Default Volume Topology Using the CLI
Use the `config save` command to set the default topology for volumes.

By default, new volumes are created with a topology of `/data`. To change the default topology, use the `config save` on page 2106 command to change the `cldb.default.volume.topology` configuration parameter. Example:

```
maprcli config save -values "{\"cldb.default.volume.topology\":\"/data/
rack02\"}"
```

After this command is run, new volumes have the volume topology `/data/rack02` by default, which could be useful to restrict new volume data to a subset of the cluster.

Changing the Volume Topology
Describes how to move a volume from one topology to another using the Control System or the CLI.
Changing the Topology of a Volume Using the Control System

About this task

Procedure

1. Go to the Viewing Volume Details on page 1192 page, and select a volume.
   The **Change Topology** dialog displays, showing the current topology value.
2. Enter the new value for the topology.
3. Click **Save Changes** for the changes to take effect.

Changing the Topology of a Volume Using the CLI or REST API

About this task

The basic command to move a volume to a different topology is:

```
/opt/mapr/bin/maprcli volume move -name <volume name> -topology <topology>
```

For complete reference information, see `volume move` on page 2696.

Viewing Active Volume Alarms
Describes how to view volume alarms using the Control System and the CLI.

About this task

You can view volume alarms in the Control System and using the CLI.

Viewing Active Volume Alarms in the Control System

Procedure

- Log in to the Control System and:
  - Click **Data** > **Volumes** to view all active volume alarms in the **Active Alarms** pane.

    NOTE: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.
  - Go to the **Summary** tab in the volume information page to view the recent and active alarms for the selected volume in the **Alarms** pane.
  - Click  (in the top navigation bar) and select **Volume Alarms** from the drop-down menu in the **All** alarms pane to view all the active volume alarms.
  - Click **Overview** and select **Volume Alarms** from the drop-down menu in the **Active Alarms** pane to view all active volume alarms.

  You can:
  - View information related to the alarm.
  - Dismiss an alarm.
  - Mute an alarm.

  See Volume Alarms on page 3024 for more information on the volume alarms.

Retrieving Active Volume Alarms Using the CLI or REST API

About this task

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see `alarm list` on page 2023.

Working with Mirror Volumes

The mirroring process transmits the differences between the source volume and the mirror. The initial mirroring operation copies the entire source volume, but subsequent mirroring operations are generally very fast. The following sections describe how to manage the mirroring operation.

Changing the Limit for Concurrent Mirror Operations Using the CLI

The system allows a maximum of 50 concurrent mirroring operations by default. Mirroring operations include both mirroring and promoting from read-only mirrors to read-write standard volumes. The system parameter that controls this limit is `mapr.mirror.concurrent.ops`. This system parameter is set on the destination cluster.

For large-scale mirror operations involving many volumes, a script automates the process. For example, if a script queues 100 volumes for mirroring operations, and the `mapr.mirror.concurrent.ops` limit is set to 50, the mirroring operations start on the first 50 volumes in the queue. As soon as one volume completes, another volume is processed from the queue until all 100 are completed. Since volumes

are processed from the queue in first-in first-out (FIFO) order, the script should specify the most critical volumes first.

If you want to process more volumes at a time, you can raise the limit of the `mapr.mirror.concurrent.ops` parameter. To tune this parameter for maximum efficiency, consider the number of containers per volume. A higher number of containers per volume requires a lower limit than a lower number of containers per volume. To raise the limit to 500 for example, run the following command on the destination cluster:

```
maprcli config save -values {"mapr.mirror.concurrent.ops":"500"}
```

Pushing Changes to Mirrors Using the CLI

To *push* a mirror means to start pushing data from the source volume to all of its local mirrors. You can push source volume changes out to all mirrors using the `volume mirror push` command, which returns after the data has been pushed.

Moving Large Amounts of Data to a Remote Cluster Using the CLI

You can use the `volume dump create` command to create volume copies for transport on physical media. The `volume dump create` command creates backup files containing the volumes, which can be reconstituted into mirrors at the remote cluster with the volume dump restore command. Associate these mirrors with their source volumes with the `volume modify` command to re-establish synchronization.

Another way to transfer large amounts of data to a remote cluster is to create a small cluster locally and mirror to that local cluster. Then move that cluster to a remote location and enlarge it by adding more nodes.

Disabling Mirror Throttling Using the CLI

By default, mirror throttling is enabled, which means that the server that sends mirror data, restricts itself to about 30% of the available bandwidth, as measured in HPE Ezmeral Data Fabric's internal environment, with the default settings of the following parameters. Mirror throttling is based on the number of outstanding requests on the network, and outstanding I/O requests on disk, and can be tuned using the parameters, `mfs.disk.iothrottle.count`, `mfs.disk.resynciothrottle.factor`, and `mfs.network.resynciothrottle.factor`, in the `mfs.conf` file. When other processes need more network bandwidth, the server throttles back to slow down the rate of data transfer.

By disabling throttling, the mirror operation completes faster.

To disable mirror throttling from the command line, run the `volume modify` command on the *source* volume and set the `-mirrorthrottle` option to `false`, as shown in this example:

```
/opt/mapr/bin/maprcli volume modify -name volA -mirrorthrottle false
```

This command disables throttling for all mirror volumes whose source is volA. Note that the `-mirrorthrottle` option only applies to volumes that have mirrors.

Recovering Volumes from Mirrors Using the CLI
Lists the process to recover mirror volumes, using the CLI.

1. Use the `volume dump create` command to create a full volume dump for each mirror volume you want to restore. Example: `maprcli volume create -e statefile1 -dumpfile fulldump1 -name volume@cluster`
2. Transport the volume dump to the rebuilt cluster.
3. For each volume on the mirror cluster, set up a corresponding volume on the rebuilt cluster.
   a. Restore the volume using the `volume dump restore` command. Example: `maprcli volume dump restore -name volume@cluster -dumpfile fulldump1`

b. Copy the files to a standard (non-mirror) volume.

Starting the Mirror
Explains how to start a mirror operation using either the Control System or the CLI.

About this task

When a mirror starts, all the data in the source volume is copied into the mirror volume. Starting a mirroring operation requires the mirror volume to exist and be associated with a source. After you start a mirror, synchronize it with the source volume regularly to keep the mirror current.

NOTE: The `getIPTypeForCluster` method in `CLDBRpcCommonUtils` is unable to determine whether the IP type is internal or external, if `mapr-clusters.conf` contains both internal and external IPs. The fix is to only put in the internal IP in `mapr-clusters.conf` and keep the external IP in the `env.sh` file, before starting the mirror.

Starting the Mirror for Multiple Mirror Volumes Using the Control System

About this task

To start mirroring, in the **Summary** tab under **Data** > **Volumes**:

NOTE: The **Summary** tab is under the **Volumes** tab in the Kubernetes version of the Control System.

Procedure

1. Select the mirror volume(s) to synchronize.
   You *cannot* start mirror for:
   - Standard volumes
   - Mirror volumes currently mirroring
2. Select **Start Mirroring** from the **Actions** drop-down menu.
   The **Start Mirroring Volume(s)** confirmation dialog displays.
3. Verify the list of volumes to synchronize and click **Start Mirroring**.
   When a mirror is started, the mirror volume is synchronized from a hidden internal snapshot so that the mirroring process is not affected by any concurrent changes to the source volume. The changes to the mirror volume occur atomically at the end of the mirroring process; deltas transmitted from the source volume do not appear until mirroring is complete.

Starting the Mirror for a Mirror Volume Using the Control System

About this task

To start mirroring:

Procedure

1. Go to the volume information page for the mirror volume to synchronize.
2. Select **Start Mirroring** from the **Select Action** drop-down menu.
   The **Start Mirroring Volume** confirmation dialog displays.

last-updated: Jun 06, 2024

3. Click **Start Mirroring**.

   When a mirror is started, the mirror volume is synchronized from a hidden internal snapshot so that the mirroring process is not affected by any concurrent changes to the source volume. The changes to the mirror volume occur atomically at the end of the mirroring process; deltas transmitted from the source volume do not appear until mirroring is complete.

Starting the Mirror Using the CLI or REST API

About this task

The basic command to start a mirror is:

```
maprcli volume mirror start -name <volume name>
```

For complete reference information, see `volume mirror start` on page 2661.

Stopping the Mirror
Explains how to stop a mirror operation using either the Control System or the CLI.

About this task

Stopping a mirror halts any replication or synchronization process currently in progress. Stopping a mirror does not delete or remove the mirror volume.

Stopping the Mirror for Multiple Mirror Volumes Using the Control System

About this task

To stop mirroring, in the **Summary** tab under **Data** > **Volumes**:

NOTE: The **Summary** tab is under the **Volumes** tab in the Kubernetes version of the Control System.

Procedure

1. Select the mirror volume(s) to stop.

   You *cannot* stop the mirror operation for:

   - Standard volumes
   - Mirror volumes that are currently not mirroring

2. Select **Stop Mirroring** from the **Actions** drop-down menu.

   The **Stop Mirroring Volume(s)** confirmation dialog displays.

3. Verify the list of volumes to stop and click **Stop Mirroring**.

   When a mirroring operation is stopped, replication or synchronization processes currently in progress will halt.

Stopping the Mirror for a Mirror Volume Using the Control System

About this task

To stop mirroring:

Procedure

1. Go to the volume information page for the mirror volume to stop.

last-updated: Jun 06, 2024

2. Select **Stop Mirroring** from the **Select Action** drop-down menu.
   The **Stop Mirroring Volume** confirmation dialog displays.
3. Click **Stop Mirroring**.
   When a mirroring operation is stopped, replication or synchronization processes currently in progress will halt.

Stopping the Mirror Using the CLI or REST API

About this task

The basic command to stop a mirror is:

```
maprcli volume mirror stop -name <volume name>
```

For complete reference information, see `volume mirror stop` on page 2675.

Viewing Mirror Status
List mirror volumes and their status using the Control System and the CLI.

You can see a list of all mirror volumes and their current status in the **Mirror Volumes** view (in the Control System, select **Mirror Volumes** from the drop-down menu in the **Volumes** page under **Data** > **Volumes**) or using the `volume list` on page 2648 command. Use the volume mirror status on page 2662 command to view the details of the mirroring operation that is in progress. The volume mirror status on page 2662 command helps in troubleshooting the mirroring operation. For more information on trouble shooting mirroring, see the support article titled Monitor and Understand Volume Mirroring in HPE Ezmeral Data Fabric.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

To use the volume list command to explicitly list mirror volumes, you must define a filter. For example:

```
maprcli volume list -filter [n==<mirror name>] -columns \
         n,p,mirror-percent-complete,mrt -cluster <target cluster>
```

Mirrors and Performance

Completion time for a mirroring operation is affected by the available network bandwidth, and the amount of data to transmit. For best performance, set the mirroring schedule according to the anticipated rate of data changes, and the available bandwidth for mirroring.

Using Promotable Mirrors for Disaster Recovery

The concept of promoting a mirror refers to the ability to make a read-only mirror volume into a read-write volume. The main use case for this feature is to support disaster-recovery scenarios in which a read-only mirror needs to be promoted to a read-write volume so that it can become the primary volume for data storage.

A MapR administrator can perform the following tasks from a remote datacenter before, during, and after a disaster:

- Set up mirroring to a remote cluster
- Fail over to a mirror volume
- Restore the mirror relationship

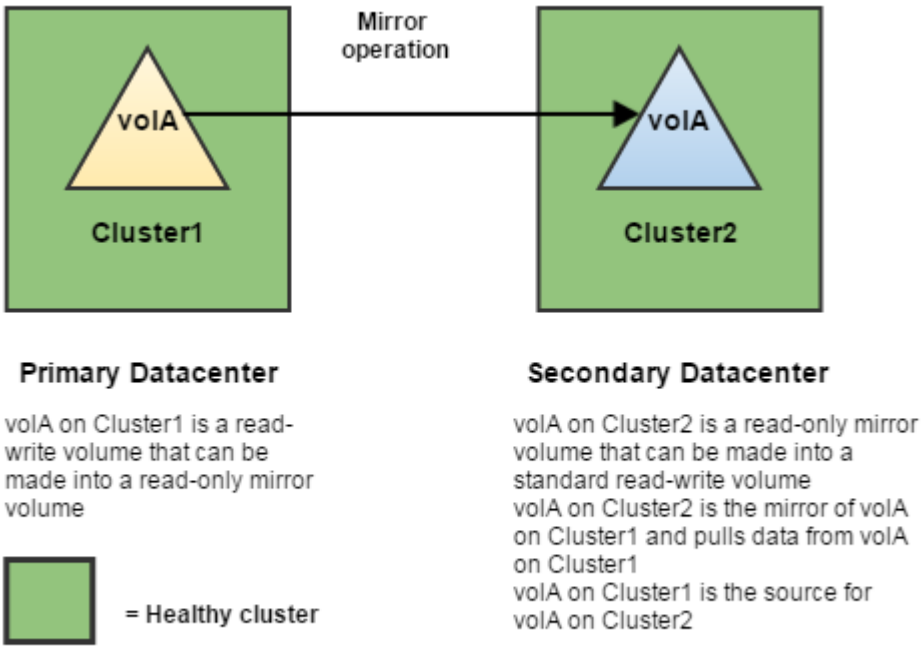
For a brief overview of the terminology used to describe volume types, along with some basic commands, see the Types of Volumes on page 498.

last-updated: Jun 06, 2024

The following sections provide information about how to use promotable mirrors for disaster recovery:

Setting up Mirroring to a Remote Cluster

Once data volumes are created in a primary datacenter, the MapR administrator creates mirror volumes in a remote secondary datacenter. The following diagram illustrates the mirror relationship between these two volumes:



NOTE: When you use promotable mirrors, the volumes on the destination cluster must be set up in the same way as on the primary site. This means that volume names are the same and mount points are the same. If a hierarchical mounting structure (such as /A/B) is used on the primary site, the same structure must be recreated once mirror volumes are promoted at the secondary site.

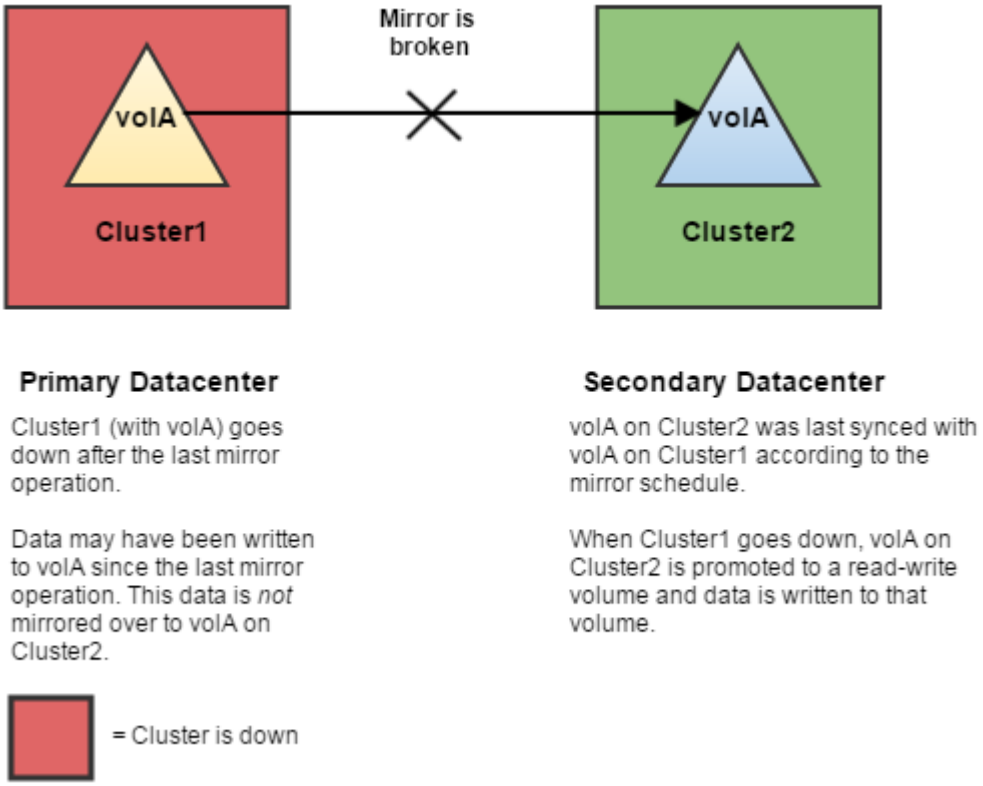
The following sections provides information about how to set up mirroring to a remote cluster:

1. Creating Remote Mirrors on page 1190
2. Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1952
3. Creating a Mirror Volume
4. Creating a Mirroring Schedule

Failing Over to a Mirror Volume

When a disaster occurs at a primary datacenter, data can no longer be written to the volumes in that location, and the mirror operation cannot be performed. In order to maintain business continuity, the administrator at the secondary datacenter promotes the read-only mirror volume to a read-write volume, which breaks the mirror relationship. At this point, the promoted mirror volume contains all the data that was on the source volume at the time of the most recent successful mirror operation.

last-updated: Jun 06, 2024



The following sections provide information about how to fail over to a mirror volume:

- Changing Mirror Volumes to Standard Volumes on page 1221
- Handling Mount Points in Promoted Mirror Volumes on page 1223
- Changing the Limit for Concurrent Mirror Operations Using the CLI on page 1235

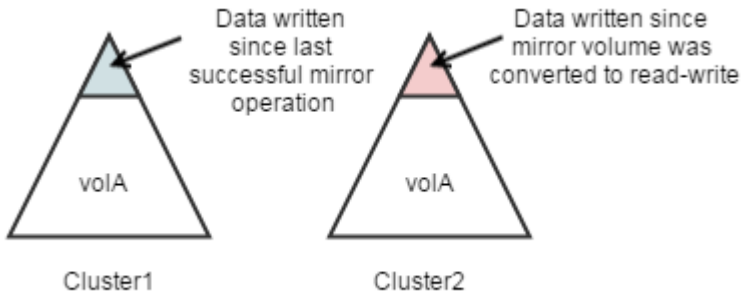
Restoring the Mirror Relationship
Explains how to restore the mirror relationship between the original read-write volume in the primary datacenter and the promoted read-write volume in the secondary datacenter.

About this task

If the primary datacenter comes back online, the administrator can re-establish the mirror relationship between the original read-write volume in the primary datacenter and the promoted read-write volume in the secondary datacenter.

Note that the two read-write volumes will have different data, since data was written to the promoted mirror while the original source volume was down. The original source volume might also have different data that was written after the last mirror operation, but before the cluster went down. The administrator must decide which data to keep and use as the source.

last-updated: Jun 06, 2024



WARNING: Some data loss is inevitable in a disaster recovery scenario. To minimize potential data loss, use mirrors to provide a synchronized copy of each volume with critical data, and in the event of discrepancies, decide which data to preserve based on your company's policies.

The following sections provide information about how to restore the mirror relationship:

Preserving volA/Cluster1's Data

Suppose that volA in the primary datacenter contains crucial data that must be preserved, and you want to mirror its data to volA in the secondary datacenter (the same mirror relationship that was established originally). To recreate the original mirror relationship, convert the promoted volume, volA/Cluster2, from a read-write volume to a mirror of volA/Cluster1 by running the following command:

```
Cluster2> maprcli volume modify -name
volA -type mirror -source
volA@Cluster1
```

To use the Control System to convert volA/Cluster2 from a read-write volume to a mirror of volA/Cluster1, follow steps for Changing a Standard Volume to a Mirror Volume on page 1220.

Preserving volA/Cluster2's Data on volA/Cluster1

Now suppose you want to preserve the data on volA/Cluster2 (in the remote datacenter) but you still want volA/Cluster1 to be the primary volume with volA/Cluster2 as its mirror. From the command line or the Control System, you can save volA/Cluster2's data on volA/Cluster1 and reestablish the original mirror relationship from volA/Cluster1 to volA/Cluster2.

You can use either of the following methods to preserve the data:

From the Control System

About this task

Complete the following steps from the Control System to save volA/Cluster2's data on volA/Cluster1 and reestablish the original mirror relationship from volA/Cluster1 to volA/Cluster2.

Procedure

1. Stop writing new data to volA/Cluster2 by making this volume read-only:
   For detailed steps, see Modifying a Volume on page 1207.
2. Make volA/Cluster1 a mirror of volA/Cluster2.
   For detailed steps, see Changing a Standard Volume to a Mirror Volume on page 1220.

last-updated: Jun 06, 2024

3. Start mirroring.
   For detailed steps, see Starting the Mirror on page 1237.
4. Promote volA/Cluster1 to a read-write volume.
   For detailed steps, see Changing Mirror Volumes to Standard Volumes on page 1221.
5. Make volA/Cluster2 a mirror of volA/Cluster1.
   For detailed steps, see Changing a Standard Volume to a Mirror Volume on page 1220.

From the Command Line

Procedure

1. Stop writing new data to volA/Cluster2. To be sure no data is written to this volume, make it read-only by running this command:

```
Cluster2> maprcli volume modify -name volA -readonly true
```

2. Pull the data from volA/Cluster2 to volA/Cluster1 by making volA/Cluster1 a mirror of volA/Cluster2.

```
Cluster1> maprcli volume modify -name volA -type mirror -source
volA@Cluster2
```

3. Start the mirror operation.

```
Cluster1> maprcli volume mirror start -name volA
```

4. Once mirroring is done, promote volA/Cluster1 to a read-write volume. Note that the mirror relationship breaks at this point.

```
Cluster1> maprcli volume modify -name volA -type rw
```

5. Make volA/Cluster2 a mirror of volA/Cluster1.

```
Cluster2> maprcli volume modify -name volA -type mirror -source
volA@Cluster1
```

Enabling and Restricting Access to Tenant Volume and Data
Describes how to restrict access to tenant volumes in a multi-tenant environment.

About this task

In a multi-tenant environment, the tenant volume (share) can be accessed by all users on the tenant instance by default. To restrict access to specific users and/or groups:

last-updated: Jun 06, 2024

Procedure

1. Log in to the cluster as the cluster administrator and set *ACE*s on the volume using the volume commands.

   For example:

   ```
   /opt/mapr/bin/maprcli volume modify -name <volumename> -readAce
   "u:<user>|g:<group>" -writeAce "u:<user>|g:<group>"
   ```

   Here, value for <user> must be the UID of the user and value of <group> must be GID of the group on the tenant host.

   TIP: For more information, see `maprcli volume modify` command.

2. Log in as the tenant admin and set permissions for data access.

   You can set permissions using:

   - Linux commands such as `chmod`, `chown`, and so on.
   - *ACE*s, which can be set on files and directories in the volume. For more information, see Enabling Volume, Directory, and File Authorizations with ACEs on page 1859.

Working with Tiered Volumes

This section describes how to create tiered volumes and manage automatic and manual tiering jobs on the tiered volume.

Erasure Coding Scheme for Data Protection and Recovery
Describes the erasure coding (EC) schemes for data protection and recovery.

Erasure coding (EC) is a data protection method in which data is broken into fragments, expanded and encoded with redundant data pieces, and stored across a set of different nodes or storage media.

EC ensures that if data becomes corrupted, it can be reconstructed using other data and parity fragments.

The time required to reconstruct data depends on the number of data fragments in the chosen EC scheme, and the number of failures that have occurred. For example, reconstruction of EC scheme *10+2* takes longer than the reconstruction of EC scheme *3+2*, as a larger number of data and parity fragments must be read.

There are two kinds of EC schemes that you can use:

- EC Schemes Without Local Parity: Even for a single failure, for a `m+n` scheme, the system must read a minimum of `m` other fragments to reconstruct data.
- EC Schemes With Local Parity: In such schemes, data fragments are logically divided into groups with one local parity fragment per group, hence for a single failure the system reads just the remaining fragments in the affected group, along with the local parity fragment of the affected group, to rebuild data. Rebuilding data for a single failure is much faster on a scheme with a local parity, as a fewer number of fragments must be read.

NOTE: The value of parity fragment must be a non-zero positive number less than or equal to the number of data fragments.

Considerations When Selecting an EC scheme

As an administrator, consider the following points when selecting an EC scheme:

- How many nodes can you afford to have?
- How many failures might occur? Do you anticipate a single failure, or multiple failures?

last-updated: Jun 06, 2024

- Consider the following when determining how long you are willing to wait for a node to be rebuilt:
  - Rebuilds overhead - For 4+2, you need to read data from 4 nodes to rebuild, for 6+3, you need to read from 6 nodes to rebuild.
  - Reads overhead - For 4+2, you need to read data from 4 nodes, for 6+3, you need to read from 6 nodes. For degraded states, parity calculation overhead is an add-on.
  - Data classification - High ecschemes 10+2 , 12+4, are ideal for archived data, since data mostly remains untouched.

EC Schemes Without Local Parity

In an erasure coded volume, an erasure coding scheme without Local Parity has the stripe layout *m+n*. The stripe is an array of *m* data fragments and *n* parity fragments.

Each fragment is called a stripelet. Each stripelet is present on a container and one stripe is across different containers on different nodes. The default stripelet size is 4MB. For an EC scheme *4+2* for example, the stripe size is 24MB.

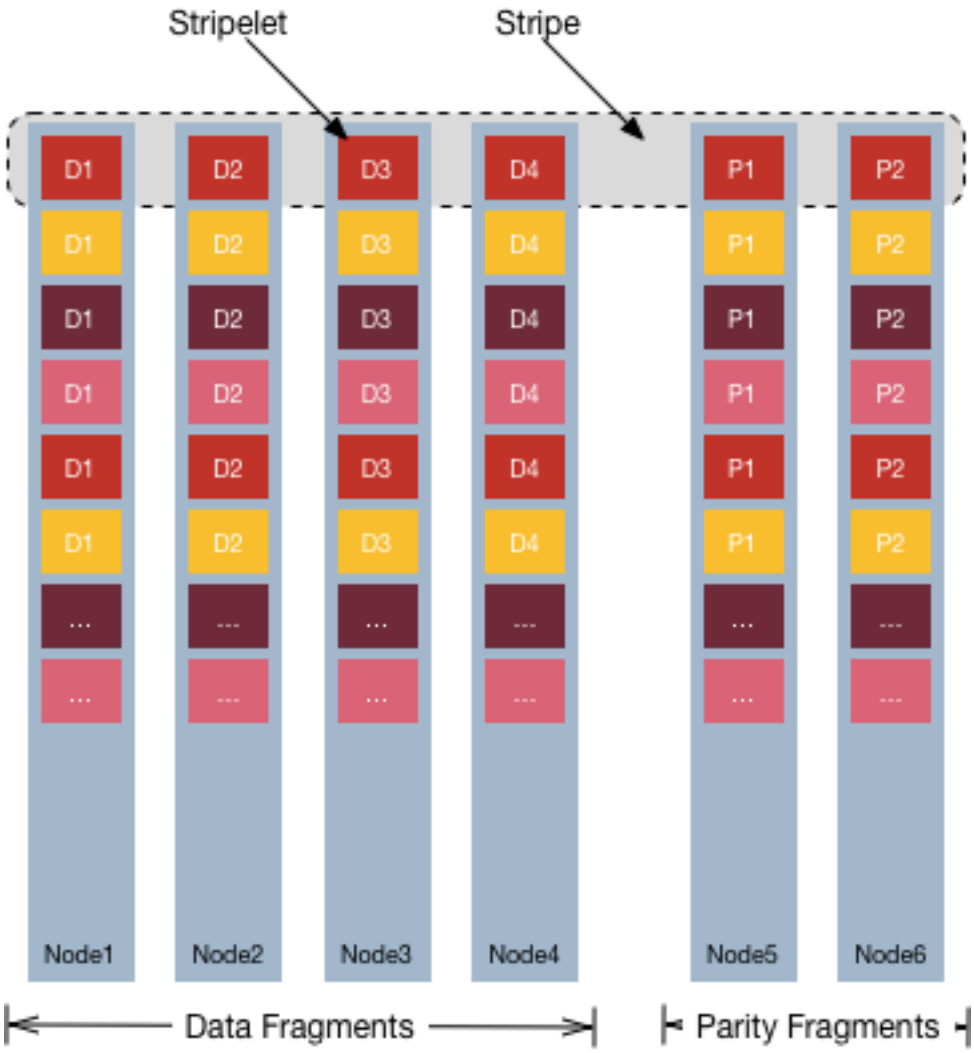
A Container Group (CG) is collection of such stripes. Based on the maximum size of a container (32 GB), the maximum number of stripes in a CG is 8K.

Each stripe is created by the same number of data fragments from all containers in the group of EC containers. Each container is placed on a different physical node.

- *m* is the number of data fragments.
- *n* is the number of redundant fragments (referred to as parity fragments).
- The parity is calculated using data from all data fragments.
- *m/(m+n)* is the encoding rate.
- *m+n* is the number of encoded fragments.
- You need to read a minimum of *m* blocks to recover data.
- You can recover data from a maximum of *n* failures.

For example, assume m=4, n=2, and stripe depth=4 MB.

last-updated: Jun 06, 2024



- The number of data fragments is four (4), and while the number of parity fragments is two (2).
- The number of encoded fragments is six (6).
- The stripe size is 16 MB (4x4 MB) of user data, and 8 MB (2x4 MB) of parity fragments.
- The system can handle two (2) failures, and any fragment can be recovered from four (4) other fragments.

Requirements for using an erasure coding scheme without local parity

- The number of data fragments must be between 2 and 10 (both inclusive) for erasure coding scheme without local parity.
- The number of nodes must be greater than or equal to the sum of data and parity fragments.
- The number of parity fragments must be greater than or equal to 1 and less than or equal to the number of data fragments.

Select from the following schemes for erasure-coded volumes:

last-updated: Jun 06, 2024

EC Scheme	Number of Data Nodes	Number of Parity Nodes	Total Number of Nodes Needed	Number of Failures Recoverable	Number of Nodes to Read to Recover Data
2+2	2	2	4	2	2
3+2	3	2	5	2	3
4+2	4	2	6	2	4
5+2	5	2	7	2	5
6+3	6	3	9	3	6
10+<x> where x is a value from 1 to 10	10	x	10+x	x	10

Although you can create a volume without the required number of nodes for a specific scheme, volume offload fails if the required number of nodes are not present.

When choosing the scheme, note that more nodes leads to longer recovery time, resulting in degraded performance, network expense, and lengthy time to rebuild.

If you anticipate only a single failure, use an EC scheme with local parity, as the number of nodes needed to be read for recovery is fewer, when compared to an EC scheme without local parity.

For example, consider a *12* + *4* EC scheme represented as `D0 + D1 + D2 +....+D10 + D11 + P0 +…+P3`

Suppose node D4 goes down, now to rebuild, a total of 12 stripelets must be read. This leads to huge performance degradation in network bandwidth, CPU cycles, and Disk IO .

To reduce the reconstruction cost, use EC Local Parity, where the number of stripelets to be read reduces to 6 for a single failure in the *12+2+2* scheme.

IMPORTANT: The recommended number of nodes required for erasure coding is M+2N (rather than M+N) to ensure HPE Ezmeral Data Fabric self-healing and proper operation after N failures. N failures with only M+N nodes allows you to continue reading the data, but with significantly reduced performance because each read requires rebuilding data fragments. Also, manual intervention is required to protect the data from further failures. Currently, data will not be erasure coded if only M nodes are available. With M+2N nodes, N failures will self-heal with no operator intervention.

EC Schemes With Local Parity

Choosing an EC scheme with local parity, reduces EC storage overhead without incurring high rebuild costs and longer rebuild times while lowering the probability of data loss. Currently, the only supported local parity scheme is 6+2+2:

EC Scheme	Number of Data Nodes	Number of Local Parity Nodes	Number of Global Parity Nodes	Total Number of Nodes Needed	Number of Failures Recoverable	Number of Nodes to Read to Recover Data
6+2+2	6	2	2	10	• 3 all the time • 4 most of the time	• 3 for a single failure • 6 for multiple failures

The following technical discussion provides more information about local parity schemes.

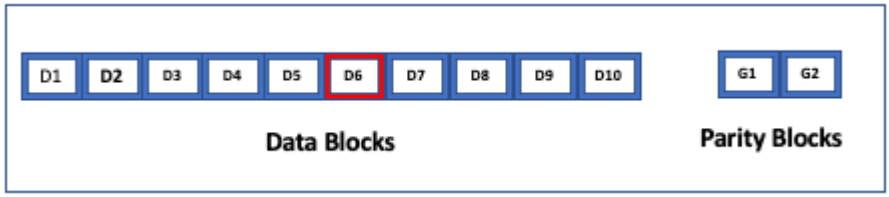
last-updated: Jun 06, 2024

IMPORTANT: The following discussion describes the *10+2+2* scheme for example purposes, but only the *6+2+2* local parity scheme is currently supported. For more information about specific parity schemes, contact HPE Support.

About Parity Schemes

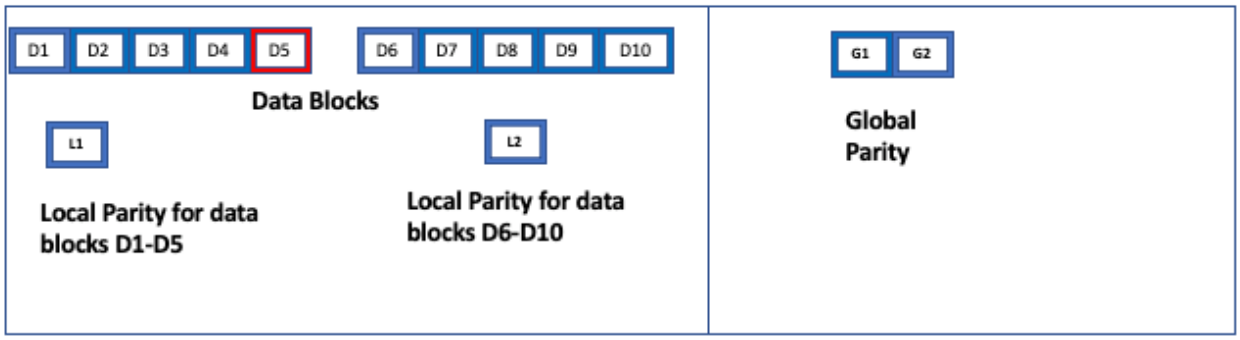
Local parity is calculated from a subset of data blocks.

Consider a *10+2* scheme *without* local parity.



In this example, if block D6 fails, the system needs to read a minimum of 10 other blocks, to recover data.

Now consider a 10+2+2 scheme with local parity. In this case, data fragments are divided into two (2) data groups, each containing five (5) data fragments, with a local parity for each group. The global parity blocks are common to both data groups. To recover from a single failure, the system must read only the four (4) remaining fragments in the affected data groups, and the corresponding local parity fragment:



In this example, since there is only a single failure in a data group (block D5), the system must only read fragments D1+D2+D3+D4+L1 (which is the local parity fragment of this data group). Recovery is much faster and more efficient, due to the local parity block.

Points to note for using an erasure coding scheme with local parity

- The number of data fragments must be between 2 and 16 (both inclusive) for erasure coding scheme with local parity.
- In an EC scheme represented as *k+g+l*, *k* is the number of data blocks, *g* is the number of global parity blocks, and *l* is the number of local parity blocks.
- You need *k+g+l* nodes for each local parity scheme.
- *k* must be divisible by l to get *k/l* data fragments in each data group. For example, in the 10+2+2 EC scheme, there are 10/2=5 data fragments in each data group.
- *l* must be greater than 1.
- *k* must be greater than *(g+l)*.
- With local parity, the system can recover from 1 to *g+1* failures at any time. In the *10+2+2* scheme, the system can recover from 1 to 3 failures at any time.

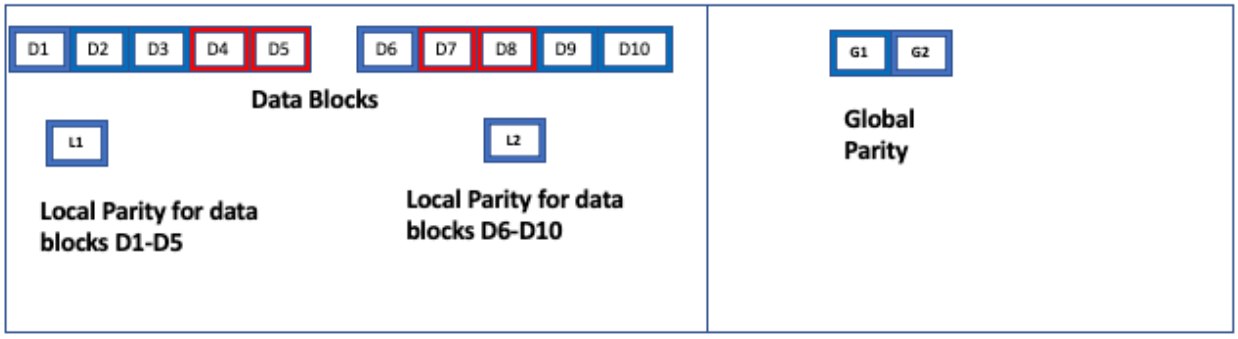
last-updated: Jun 06, 2024

- The system can recover from *g+2* to *g+l* failures in certain cases. With the *10+2+2* scheme, the system can recover from 4 failures, in certain cases.
- If none of the data fragments have failed in a data group, the system cannot use the corresponding local parity fragment, to recover from a failures in other data groups. For example:

  To recover D5, the system reads only D1+D2+D3+D4+L1. It does not read D1+D2+D3+D4+L2, since there are no failures in the data group D6 to D10, for which L2 is the local parity fragment.

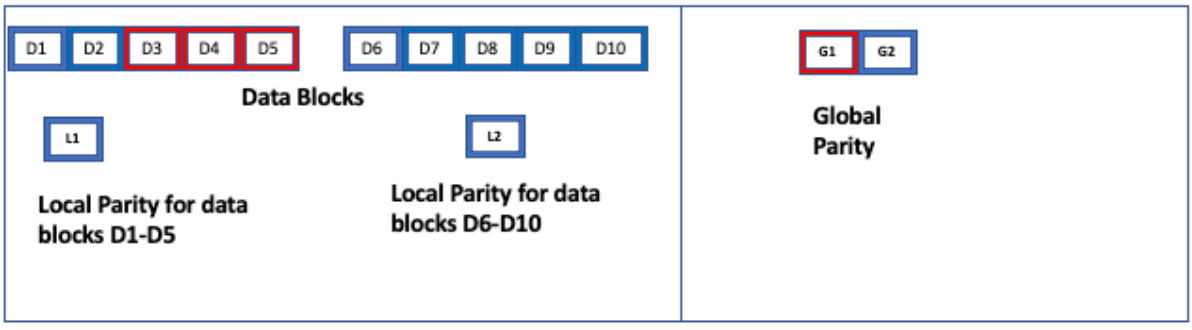
- For a single failure, the system needs to read *k/l* fragments to recover. For multiple failures, the system needs to read *k* fragments to recover.

With local parity, the system recovers from most of *g+l* failures. For the 10+2+2 scheme, the system can recover from most of 4 failures. For example:



Here, there are 4 failures. The required number of blocks to read (10 in this case) are available, for recovery. The system reads *D1+D2+D3+D6+D9+D10+L1+L2+G1+G2*.

However, consider the following example:



last-updated: Jun 06, 2024

Although there are 4 failures, the system does not have the required number of fragments (10) to read and recover. The only fragments that can be read are D1+D2+L1+D6+D7+D8+D9+D10+G1. Fragment L2 cannot be read because there are no failures in its corresponding data group D6 to D10. Therefore in this case, data cannot be reconstructed.

Specifying a Schedule for Offloading Data
Explains how to create a schedule for automatic offloading of data, using the Control System, the CLI and the REST API.

About this task

You can create a schedule using the Control System, the CLI, and REST API. After creating a schedule, you can associate it with the tiering-enabled volume when you create or modify the volume. If a schedule for offloading data is associated with the volume, data is offloaded automatically as scheduled based on the rules associated with the volume for offloading data. You can also manually trigger the `maprcli` command to offload data.

The following schedules are available out-of-the-box for offloading data:

Schedule Name	Schedule ID
Critical data	1
Important data	2
Normal data	3
Automatic Tiering Scheduler	4*

* The Automatic Tiering Scheduler ID might be different on different clusters. To retrieve the correct ID, run the `schedule list` on page 2310 command.

For volumes enabled for warm tiering, the Automatic Tiering Scheduler is used by default for offloading data if you do not explicitly assign a schedule. The frequency of the Automatic Tiering Scheduler run is based on two the following:

time	The frequency. The `cldb.auto.offload.frequency.minutes` property stores the default value of 24 * 60 minutes. This can be configured using the `config save` on page 2106 command. The value for this property must be in minutes.
size	The amount of data (that has not yet been offloaded) in the volume. The `cldb.auto.offload.threshold.gb` property stores the global value for the size threshold. The default value for this property is 1024GB, which cannot be modified. However, you can override the global value at the volume-level using the `autooffloadthresholdgb` parameter with the `Creating a Volume` on page 1177 and `volume modify` on page 2676 commands.

The Automatic Tiering Scheduler run is based on the time setting. However, it runs sooner if the size of the volume in the hot tier reaches or exceeds the size threshold.

For volumes enabled for cold tiering, you must assign a schedule to automatically offload data; if you do not assign a schedule, data is not offloaded automatically and you must manually run the offload command to offload data. You can associate the Automatic Tiering Scheduler with the cold-tier enabled volume or create a custom schedule and associate it with the volume to automatically offload data.

To:

- Create a schedule before creating the volume, see Creating a Schedule on page 1281.
- Create a schedule when you are creating the volume, see step 9 in Creating a Volume on page 1177.

Specifying a Schedule Using the Control System

About this task
You can associate a schedule with a tiering-enabled volume when you are:

- Creating a volume by clicking **Create Volume** button in the **Data** > **Volumes** page.
- Editing the tiering-enabled volume by clicking **Edit Volume** button in the volume information page.

Specifying a Schedule Using the CLI and REST API

About this task
You can associate a schedule with a tiering-enabled volume by specifying the `offloadschedule` parameter with the `volume create` on page 2588 or `volume modify` on page 2676 command.

CLI

Run a command similar to the following to associate a schedule when:

- Creating a volume:

```
maprcli volume
create -name <volName> -path
<mountPath> -tieringenable
true -tiername
<tierName> -offloadschedule
<scheduleID> -json
```

  For the list of all other required and optional parameters, see `volume create` on page 2588.

- Editing the volume:

```
maprcli volume modify -name
<volName> -offloadschedule
<scheduleID> -json
```

  For the list of all other required and optional parameters, see `volume modify` on page 2676.

REST

Send a request of type POST. For example, to associate a schedule when:

- Creating a volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&offloadschedule=<scheduleID>' --us
er mapr:mapr
```

  For the list of all other required and optional parameters, see `volume create` on page 2588.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&offloadschedule=<sch
eduleID>' --user mapr:mapr
```

  For the list of all other required and optional parameters, see `volume modify` on page 2676.

To disable automatic schedule-based offload of data, set the value for the `offloadschedule` parameter to `0`.

Creating a Tiering-Enabled Volume

About this task

You can create a tiering-enabled volume using the Control System, the CLI, and the REST API.

Creating a Tiering-Enabled Volume Using the Control System

Procedure

1. Go to **Data** > **Volumes** and click **Create Volume**.
   The **Create New Volume** page displays.
2. Select the **Volume Type**, specify values for required/optional settings and auditing, and move the slider to **Yes** for **Data Tier** in the **Properties** tab.
   For information on all other properties and settings, see Creating a Volume on page 1177.

   NOTE: The source volume for a tiering-enabled mirror volume must also be tiering-enabled. You cannot set up a tiering-enabled mirror volume to mirror a volume that is not tiering-enabled.
3. Click **Create Volume** to create the tiering-enabled volume.

What to do next

You can proceed to associate a tier, tiering rule, and/or schedule with the volume.

Creating a Tiering-Enabled Volume Using the CLI and REST API

About this task

CLI	Run the following command to create a tiering-enabled volume: `$maprcli volume create -name <volName> -path <volmountpath> -tieringenable true`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://abc.sj.us:8443/rest/volume/create?name=<volName>&path=<volmountpath>&tieringenable=true' --user mapr:mapr`

For more information, see `volume create` on page 2588.

Associating a Tier Tiering Rule with a Volume

About this task

You can associate a tier tiering rule with a new volume or with an already tiering-enabled volume using the Control System, CLI, and the REST API.

Associating a Tier Tiering Rule with a Volume Using the Control System

Procedure

- Perform the steps in the following topics to associate a tier, tiering rule, and/or schedule with:
  - A new volume
  - A tiering-enabled volume

Associating a Tier Tiering Rule with a Volume Using the CLI

Procedure

- Run the following command to associate a tier tiering rule with:
  - A new volume:

    ```
    $maprcli volume create -name <vol_name> -path <vol_mount_path> -tieringenable true -tiername <tier_name> -tieringrule <rule_name>
    ```

    For more information, see `volume create` on page 2588.

  - An already tiering-enabled volume:

    ```
    $maprcli volume modify -name <vol_name> -tiername <tier_name> -tieringrule <rule_name>
    ```

    For more information, see `volume modify` on page 2676.

NOTE: You cannot change the tier type or the tier for a volume after it is set.

last-updated: Jun 06, 2024

Associating a Tier Tiering Rule with a Volume Using the REST API

Procedure

- Send a request of type POST to associate a tier tiering rule with:
  - A new volume. For example:

    ```
    curl -k -X POST 'https://<host>:8443/rest/volume/create?
    name=<vol_name>&path=<vol_mount_path>&tieringenable=true&tiername=<tier_
    name>&tieringrule=<rule_name>' --user mapr:mapr
    ```

    For more information, see `volume create` on page 2588.

  - An already tiering-enabled volume. For example:

    ```
    curl -k -X POST 'https://<host>:8443/rest/volume/modify?
    name=<vol_name>&tiername=<tier_name>&tieringrule=<rule_name>' --user
    mapr:mapr
    ```

    For more information, see `volume modify` on page 2676.

NOTE: Volume's data tiering properties like tiername, ectopology, ecscheme, etc. cannot be modified after they are set.

Determining if a Volume is Enabled for Tiering

About this task

You can determine if a volume is enabled for tiering and if rules, schedules, and/or settings for recalled data are associated with the volume using the Control System and the CLI.

Determining if a Volume is Enabled for Tiering Using the Control System

Procedure

- Log in to the Control System and click **Data** > **Volumes**.
  In the list of volumes displayed in the **Volumes** pane, the **Data Tiering** column contains the value **Enabled** for a volume if the volume is enabled for tiering. If you do not see the column, you can see the column by selecting the columns to display in the Control System.

Determining if a Volume is Enabled for Tiering Using the CLI

Procedure

- Run one of the following commands to determine if a volume is enabled for tiering:
  - ```
    maprcli volume list -json
    ```
  - ```
    maprcli volume info -name <volName> -json
    ```

  The output, if the volume is tiering-enabled (and has associated settings), should look similar to the following:

  ```
  {
          "timestamp":1533959507772,
  ```

last-updated: Jun 06, 2024

```
        "timeofday":"2018-08-10 08:51:47.772 GMT-0700 PM",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "acl":{
                                "Principal":"User root",
                                "Allowed actions":"[dump, restore, m, a,
d, fc]"
                        },
                        ...
                        ...
                        "tierenable":"true",
                        "tierid":"169211273",
                        "tierruleid":"2",
                        "tieroffloadscheduleid":"6",
                        "tierencryption":"false",
                        "tierrecallexpirytime":"1",
                        "tiercompactionscheduleid":"4",
                        "tiercompactionoverheadthresh":"30",
                        "gateway":"10.10.108.120:8660",
                        "cvtotalused":0
                }
        ]
}
```

Offloading a Volume to a Tier

Explains how to offload a volume to a tier using either the Control System, the CLI, or the REST API.

About this task

At the volume level, data can be offloaded automatically by creating and associating a schedule with the tiering enabled volume or manually by triggering the offload operation. See Data Offload and Purge on page 512 for more information. The following sections describe how to set up an automatic offload of data and how to trigger a one-time manual offload data at the volume level using either the Control System, the CLI, or the REST API.

NOTE: For a tiered volume, there can be only one running job at any given time. For example, suppose another job is running on the tiered volume, if you trigger an offload operation, the offload operation will fail.

To offload volume data, you must have one of the following permissions:

- Cluster level fc permissions
- Volume level fc permissions
- Volume modify permissions

NOTE: You can also offload individual files in a tiering-enabled volume to the associated tier. See Offloading a File to a Tier Using the CLI and REST API on page 1340 for more information.

IMPORTANT: EC volumes are automatically offloaded once they crossed the size of `autooffloadthresholdgb` even if they are not using the Automatic scheduler. The default size is 1024 GB (1 TB). You can modify this size as specified in Offloading a Volume to a Tier on page 1255.

last-updated: Jun 06, 2024

Setting up Automatic Offload of Data Using the Control System

Procedure

1. Create a tier.
   See Creating a Cold Tier Using the Control System on page 1287 or Creating a Warm Tier Using the Control System on page 1287 for more information.
2. Create a storage policy to associate with the volume.
   See Creating a Storage Tier Policy Using the Control System on page 1303 for more information.
3. Create an offload schedule.
   See Specifying a Schedule for Offloading Data on page 1250 for more information.
4. Create a tiering enabled volume and associate the tier, the storage policy, and schedule with the volume.
   See Creating a Tiering-Enabled Volume Using the Control System on page 1252 for more information.

Triggering an Offload of all Data in a Volume to a Tier Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Volumes**.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.
2. Select the tiered volumes to offload from the list of volumes in the **Volumes** pane.
   Selecting a volume makes the **Actions** drop-down menu available.
3. Click **Offload Data** from the **Actions** drop-down menu to display the **Offload Volume Data** confirmation window.
4. Review the list of volumes to offload and click **Offload**.

Results
If the offload fails, CLDB retries the operation after some time. See Retrying Failed Operation on page 1261 for more information.
Setting up Automatic Offload of Data Using the CLI and REST API

About this task
To automatically offload data:

Procedure

1. Create a tier, a rule that contains the criteria for offloading data to the tier, and a schedule to automatically offload data to the tier.
   For example:

CLI	`/opt/mapr/bin/maprcli tier create -name <tier_name> -type ectier` `/opt/mapr/bin/maprcli tier create -name <tier_name> -type cold -url <tier_url> -credential`

```
<credentials>.txt -json
/opt/mapr/bin/maprcli tier rule
create -name <rule_name> -expr
<expressions>
/opt/mapr/bin/maprcli schedule
create -schedule <JSON>
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=<tier_name>&type=ectier' --user
 mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=<tier_name>&type=cold&url=<tier
_url>&credential=<credential_str>'
 --user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/
create?
name=<rule_name>&expr=<expressions>'
 --user mapr:mapr
curl -k -X POST 'https://
abc.sj.us:8443/rest/schedule/create?
schedule=<JSON>' --user mapr:mapr
```

For more information, see Managing Tiers on page 1284 and Managing Storage Policies on page 1301.

2. Create a tiering-enabled volume and associate the tier, rule, and schedule (that you created in step 1) with the volume.

   For example, to create a volume and enable it for:

   - Warm tier:

     CLI

     ```
     /opt/mapr/bin/maprcli volume
     create -name <vol_name> -path
     <vol_mount_path> -tieringenable
     true -tiername
     <tier_name> -ecscheme
     <coding_scheme> -ectopology
     <ec_vol_topo> -tieringrule
     <rule_name> -offloadschedule
     <schedule_ID>
     ```

     REST

     ```
     curl -k -X POST 'https://
     abc.sj.us:8443/rest/volume/create?
     name=<vol_name>&path=<vol_mount_pat
     h>&tieringenable=true&tiername=<tie
     r_name>&ecscheme=<coding_scheme>&ec
     topology=<ec_vol_topo>&tieringrule=
     <rule_name>&offloadschedule=<schedu
     le_ID>' --user mapr:mapr
     ```

   - Cold tier:

last-updated: Jun 06, 2024

CLI

```
/opt/mapr/bin/maprcli volume
create -name <vol_name> -path
<vol_mount_path> -tieringenable
true -tiername
<tier_name> -tieringrule
<rule_name> -offloadschedule
<schedule_ID> -recallexpirytime
2 -json
```

REST

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<vol_name>&path=<vol_mount_pat
h>&tieringenable=true&tiername=<tie
r_name>&tieringrule=<rule_name>&off
loadschedule=<schedule_ID>&recallex
pirytime=2' --user mapr:mapr
```

You can also specify the maximum amount of data (in GB) to offload automatically for warm-tier volumes using the `autooffloadthresholdgb` parameter. For more information, see Working with Tiered Volumes on page 1244.

Triggering an Offload of all Data in a Volume to a Tier Using the CLI and REST API

About this task

CLI

Run the following command to manually trigger an offload of all data in the volume:

```
maprcli volume offload -name
<volume-name>
```

If you run the command with the `ignorerule` option value set to `true`, rules for the volume where the data resides is ignored and data is offloaded immediately. If the `ignorerule` option value is not specified or is set to `false` (default), data is offloaded based on the rules associated with the volume where the data resides.

REST

Submit a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/offload?
name=sampleVol' --user mapr:mapr
{"timestamp":1519947659597,"timeofday"
:"2018-03-01 03:40:59.597 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully started
offload."]}
```

For more information, see `volume offload` on page 2698.

Results

If the offload fails, CLDB retries the operation after some time. See Retrying Failed Operation on page 1261 for more information.

Recalling a Volume to file system

Explains how to recall offloaded data to the file system.

About this task

When you:

- Read data offloaded to a remote target (or cold tier), data is automatically recalled to the file system to allow the read to succeed.
- Modify data offloaded to an erasure coded volume (or warm tier) or a remote target (or cold tier), data is automatically recalled to the file system to allow the write to succeed.

The recalled data is automatically:

- Purged based on the expiration time period set at the volume level for recalled data if there are no changes (for example, read operation).
- Offloaded based on the rule and the expiration time period set at the volume level for recalled data if there are changes (for example, overwrite operation).

See Data Reads, Writes, and Recalls on page 519 for more information. If the recall fails, CLDB retries the operation after some time. See Retrying Failed Operation on page 1261 for more information.

You can manually recall all data in a volume using the Control System, CLI, or the REST API.

NOTE: For a tiered volume, there can be only one running job at any given time. If you trigger a recall operation when another job is running on the tiered volume, the recall operation will fail.

You can also recall individual files from the tier. See Recalling a File to file system Using the CLI and REST API on page 1340 for more information.

Recalling Offloaded Volume Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Volumes**.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to recall from the list of volumes in the **Volumes** pane.

   Selecting a volume makes the **Actions** drop-down menu available.

3. Click **Recall Data** from the **Actions** drop-down menu to display the **Recall Tiered Data** confirmation window.

4. Review the list of volumes to recall and click **Recall Volumes**.

   For more information, see Recall of Tiered Data on page 522.

Recalling Offloaded Volume Using the CLI and REST API

About this task

CLI	Run the following command to recall volume data: `/opt/mapr/bin/maprcli volume recall -name <volName>`
REST API	Send a request of type POST to URL. For example: `curl -k -X POST 'https://abc.sj.us:8443/rest/`

last-updated: Jun 06, 2024

```
volume/recall?name=volName' --user
mapr:mapr
```

For more information, see `volume recall` on page 2700.

Viewing the List of Running Jobs

About this task

You can view the tiering jobs currently running for a volume using the CLI and REST API. For a tiered volume, at any given time, there can be only one running job.

Procedure

- Run the following command or send a request of type GET to retrieve the list of currently running tiering operations for a volume:

  CLI

  ```
  maprcli volume tierjobstatus -name
  <volName>
  ```

  REST

  ```
  curl -k -X
  GET 'https://<host>:8443/rest/volume/
  tierjobstatus?name=<volName>' --user
  mapr:mapr
  ```

  For more information, see `volume tierjobstatus` on page 2712.

Terminating a Running Volume-Level Tiering Job
Describes how to terminate a volume-level tiering job using either the Control System or the CLI.

About this task

You can terminate an ongoing offload or recall of a volume using the Control System or the CLI. Terminating a running:

- Offload operation does not prevent future offloads; if a schedule is associated with the volume, data that is still on the cluster is automatically offloaded based on the rules as per schedule. You can also manually offload data again at any time by running the `volume offload` on page 2698 command.
- Recall operation does not prevent future recalls; you can run the recall command again to recall the remaining data on the tier. Based on the expiry time set on the volume (associated with the recalled data), recalled data is offloaded if there are changes or purged if there are no changes. See Recalling a Volume to file system on page 1258 for more information.

You can check the status of an abort operation using the `volume tierjobstatus` on page 2712 command.

NOTE: If you terminate a job that CLDB was retrying after a prior failed attempt (FailureRetriable job), CLDB will stop trying to run the job again. For more information on FailureRetriable job, see Retrying Failed Operation on page 1261.

For information on terminating a file-level job, see Terminating a Running File-Level Tiering Job on page 1341 and Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1342.

Terminating a Volume Offload or Recall Operation Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Volumes**.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the tiered volumes to offload from the list of volumes in the **Volumes** pane.
   Selecting a volume makes the **Actions** drop-down menu available.
3. Click **Terminate Tiering Job** from the **Actions** drop-down menu to display the **Terminate Tiering Job** confirmation window.
4. Review the list of volumes and click **Terminate Job**.

Aborting Volume Offload or Recall Operation Using the CLI and REST API

About this task

CLI

Run the following command to abort a running offload or recall operation:

```
maprcli volume tierjobterminate -name
<volName>
```

For more information, see volume tierjobterminate on page 2711.

REST API

Send a request of type POST. For example:

```
curl -k -X POST 'https://<host>:8443/
rest/volume/tierjobterminate?
name=<volName>' --user mapr:mapr
```

Retrying Failed Operation

About this task

Volume-level

If an offload, recall, or abort operation for a volume fails, the volume tierjobstatus on page 2712 command shows one of the following statuses:

FailureFatal	Indicates failure is fatal and CLDB cannot retry the operation again.
FailureRetriable	Indicates failure to offload; however, CLDB will try again if the job is not manually restarted again or aborted.

CLDB tries the operation again (up to 5 times by default) after a specific wait time (of 30 minutes by default) for the following errors:

- EAGAIN
- ETIMEDOUT

- ENETUNREACH
- ENETDOWN
- ECONNRESET

The `RetryCount` field value in the `volume tierjobstatus` on page 2712 command output shows the number of times CLDB has retried so far. For example:

```
# maprcli volume tierjobstatus -name
testvol -json
{
 "timestamp":1503308792266,
 "timeofday":"2017-08-21 09:46:32.266
GMT+0000",
 "status":"OK",
 "total":1,
 "data":[
  {
   "offload":{
    "state":"FailureRetriable,
RetryCount: 5",
    "startTime":"2017-08-21
09:07:17.506 GMT+0000",
    "endTime":"2017-08-21
09:08:49.799 GMT+0000",
    "gateway":"10.10.102.68:8660"
   }
  }
 ]
}
```

File-level

If the offload or recall operation for an individual file fails, the `file tierstatus` on page 2213 or `hadoop mfs` on page 5557 command returns one of the following:

Code	Message	Description
0	HAS_LOCAL_DATA	Indicates that the file is not yet fully offloaded.
1	NO_LOCAL_DATA	Indicates that the file was completely offloaded.
2	OP_FAIL	Indicates that the operation to retrieve the status failed.
3	INVALID_FILE	Indicates that the file does not exist.
4	FILE_NOT_TIERED	Indicates that the file is not in a tiered volume.

Code	Message	Description
5	FILE_EMPTY	Indicates that the file specified for offload is an empty file.
6	NO_GATEWAY	Indicates that no MAST Gateways are available for offload operation.
7	OP_TIMEOUT	Indicates that there was no response from the MAST Gateway (maybe as a result of an error) during the offload or recall operation.
8	FTOS_SUCCESS	Indicates that the file was successfully offloaded or recalled.
9	FTOS_ABORTED	Indicates that the file offload or recall operation was aborted.
10	FTOS_ABORT_IN_PROGRESS	Indicates that the file offload or recall job is being aborted.
11	FTOS_TRANSFER_IN_PROGRESS	Indicates that the file offload is in progress.
12	FTOS_REQ_QUEUED	Indicates that the file offload is scheduled, but has not yet started.
13	FTOS_JOB_NOT_AVAILABLE	Indicates that the job ID specified with the tierjobstatus command is not available.

When a file-level offload or recall operation fails, CLDB **does not** retry the operation. For failed file-level:

- Offload operation, you can run the command to retry the operation. For more information, see Offloading a File to a Tier Using the CLI and REST API on page 1340. Alternatively, if the volume that the file is associated with has a data offload schedule, the file data is automatically offloaded based on the rules associated with the volume.

last-updated: Jun 06, 2024

- Recall or abort operation, you can run the command again to retry the operation if the error returned is not EIO.

You can configure the number of times CLDB retries and the interval between retries using the CLI.

Configuring the Number of Retries

Procedure

- Set the value for the `cldb.gateway.retry.count` parameter, whose default value is 5, to configure the number of times that CLDB tries again. For example, to configure CLDB to retry to offload, recall, or abort at least 10 times, run the following command:

```
# maprcli config save -values {"cldb.gateway.retry.count":"10"}
```

Configuring the Interval Between Retries

Procedure

- Set the value for the `cldb.gateway.retry.waittime.seconds` parameter, whose default value is 1800 seconds (30 minutes), to configure the amount of time CLDB waits between retries. For example, to configure CLDB to wait for up to 4 hours (14400 seconds), run the following command:

```
# maprcli config save -values
{"cldb.gateway.retry.waittime.seconds":"14400"}
```

Running the Compactor Using the CLI and REST API

About this task

You can trigger the compactor using the CLI and REST API to purge recalled data on the Data Fabric cluster or to purge stale data on the tier. See Data Compaction on page 524 for more information about data compaction.

Running the Compactor to Purge Recalled Data on the Data Fabric Cluster

About this task

CLI	Run the following command to trigger the compactor and purge data whether or not the expiry time for recalled data has been reached: `maprcli volume compact -name <volName> -forcerecallexpiry true`
REST	Send a request of type POST. For example: `curl -X POST --user <username> 'https://<host>:8443/rest/volume/compact?name=<volName>&forcerecallexpiry=true'`

For more information, see `volume compact` on page 2584.

Running the Compactor to Purge Stale Data on the Tier

About this task

CLI	Run the following command to trigger the compactor: `maprcli volume compact -name <volName>`
REST	Send a request of type POST. `curl -X POST --user <username> 'https://<host>:8443/rest/volume/compact?name=<volName>'`

When you trigger the compactor, the compactor purges stale data from the tier and also recalled data on the Data Fabric cluster if the expiry time for recalled data has been reached. For more information, see `volume compact` on page 2584.

Retrieving the Status of a Volume-level Tiering Operation

About this task

You can check the status of an active volume offload, completed offload, aborted offload, and recall operations using the Control System, the CLI, and the REST API. For information on file level tiering job, see Retrieving Status of File-level Tiering Operation and File Data on page 1343.

Retrieving Status of Volume-level Operation Using the Control System

Procedure

- Log in to the Control System and click **Data** > **Volumes**.
  The **Volumes** pane in the page displays the following for tiered volumes:
  - **Job** — The currently running or last completed tiering job for the volume.
  - **State** — The status of the tiering job.
  - **Progress** — The completion percentage of the tiering job.

Retrieving Status of Volume-level Operation Using the CLI and REST API

About this task

CLI	Run the following command to check the status of an active or completed offload, abort, and/or recall operation: `maprcli volume tierjobstatus -name <volume_name> -json`

NOTE: You must have full control (fc) permissions either at the cluster or at the volume level to run this command. To determine the status of a compaction operation, specify the `verbose` option with the `tierjobstatus` command. For example:

```
maprcli volume
tierjobstatus -name
<volume_name> -verbose true -json
```

REST

Send a request of type GET.

```
curl -k -X GET 'https://
<host>:8443/rest/volume/tierjobstatus?
name=<volume_name>' --user mapr:mapr
```

See Statuses on page 2713 for more information.

Retrieving Tiering Statistics Using guts

Explains how to use the `guts` utility to retrieve tiering statistics.

You can run the `/opt/mapr/bin/guts` utility to get granular information on ongoing offloads and recalls including:

- The number of objects that are offloaded to and recalled from the tier
- The number of reads and writes on HPE Ezmeral Data Fabric Database
- The number of reads and writes on file system

Syntax

```
/opt/mapr/bin/guts <argument>:<options>
```

Arguments

Argument	Description
`mastgateway`	Refers to operations on the MAST Gateway node. See Usage on page 1267 for information on the syntax for running the guts command with this argument.
`fstier`	Refers to operations on file system node. See Usage on page 1267 for information on the syntax for running the guts command with this argument.

Options

Option	Description
`all`	Statistics for all operations.
`db`	Statistics for MAST Gateway operations currently running on HPE Ezmeral Data Fabric Database.
`mfsops`	Statistics for MAST Gateway operations on file system.
`none`	Specifies the column(s) to exclude from the output.

last-updated: Jun 06, 2024

Option	Description
`tier`	Statistics for MAST Gateway operations on the storage tier.

Usage

MAST Gateway Node

```
/opt/mapr/bin/guts mastgateway:all
/opt/mapr/bin/guts mastgateway:db
/opt/mapr/bin/guts mastgateway:tier
/opt/mapr/bin/guts mastgateway:mfsops
/opt/mapr/bin/guts mastgateway:none
```

file system Node

```
/opt/mapr/bin/guts fstier:all
/opt/mapr/bin/guts fstier:none
```

NOTE: These commands might show statistics for several other fields. To skip, use `none` with the components whose fields you do not wish to retrieve. For example, to retrieve statistics for only the mastgateway tier, run the following command:

```
/opt/mapr/bin/guts allocator:none btree:none cache:none cleaner:none
client:none cpu:none db:none dbrepl:none disk:none fs:none fstier:none
gateway:none io:none kv:none log:none mastgateway:tier net:none
nfs:none rpc:none ssd:none streams:none time:none vcd:none
```

Output

`mastgateway:tier`

`objP`	Number of objects (whose maximum size is 8MB for cold-tier or whose size is computed based on the erasure coding scheme for warm-tier) that were offloaded to the storage tier.
`objG`	Number of objects (whose size is up to 1 MB for cold-tier and whose size is computed based on the erasure coding scheme for warm-tier) that were recalled from the storage tier.
`objD`	Number of deletions on the tier.
`objPM`	Amount of data (in MB) offloaded per second to the storage tier.
`objGM`	Amount of data (in MB) recalled per second from the storage tier.

last-updated: Jun 06, 2024

`mastgateway:db`

`tdbP`	Number of *puts* on HPE Ezmeral Data Fabric Database tables.
`tdbG`	Number of *gets* on HPE Ezmeral Data Fabric Database tables.
`tdbD`	Number of *deletes* on HPE Ezmeral Data Fabric Database tables.

`mastgateway:mfsops`

`moR`	Number of *read* requests from client to the MAST Gateway service to read from cache volumes.
`mp`	Number of file system *purge* requests sent by the MAST Gateway service.
`mrw`	Number of file system *reads* from the MAST Gateway service to perform modify/write operation.
`moRM`	Amount of file system *reads* (in MB) sent by the MAST Gateway service to read offloaded data.
`mrwM`	Amount of *recall writes* (in MB) sent by the MAST Gateway service.

`fstier:all`

`tp`	Number of blocks (of 64KB) *purged* during an offload operation.
`trw`	Number of blocks (of 64KB) *written* during recall of offloaded data.
`trr`	Number of blocks (of 64KB) *read* during read of offloaded data.
`twr`	Number of blocks (of 64KB) *recalled* for partial overwrites.

guts on page 2886
`guts` is a tool to measure/analyse performance. In the default mode, it prints one line every second, and counts the number of operations or bytes-processed in one second intervals. `guts` is an internal utility, and is subject to change without notice.

cldbguts on page 2852
Monitors the activity of the Container Location Database (CLDB). This utility prints information about the CLDB service that is running on the node from which you run the utility.

Moving back end Volume from the Command Line

This section contains information on migrating the following volumes to a different topology:

- Metadata volume, which stores the DB tables for the metadata associated with the tier.
- Erasure-coded volume, which stores the erasure-coded data.

Moving Metadata Volume to Another Topology

By default, the volume, which stores the DB tables for the metadata associated with the tier, is created in `/var/mapr/tier/mapr.internal.tier.<volName>` and is in the `/data` topology. However, you can move the metadata volume to another topology using the `volume move` on page 2696 command. For example:

CLI

```
/opt/mapr/bin/maprcli
volume move -name
<metadataVolName> -topology <newTopo>
```

REST

```
curl -k -X POST 'https://<host>:8443/
volume/move?
name=<metadataVolName>&topology=<newTo
po>' --user mapr:mapr
```

Moving Erasure-Coded Volume to Another Topology

The erasure-coded volume is by default created in the same topology as the front-end volume. You can specify a different topology for the erasure-coded volume when creating a front-end volume. You can also move the erasure coded volume to a different topology using the `volume move` on page 2696 command. For example:

CLI

```
/opt/mapr/bin/maprcli volume
move -name <volName> -ectopology
<newTopo>
```

REST

```
curl -k -X POST 'https://<host>:8443/
volume/move?
name=<volName>&ectopology=<newTopo>'
 --user mapr:mapr
```

Here, the `name` parameter takes the name of the front-end volume and the `ectopology` parameter takes the topology to which to move the erasure-coded volume associated with the front-end volume. For more information, see `volume move` on page 2696.

Using Volume Links for Read and Write Operations

When you mirror a volume, read requests to the source volume can be served by any of its mirrors on the same cluster via a volume link of type `mirror`. A volume link is similar to a normal volume mount point, except that you can specify whether it points to the source volume or its mirrors.

- To write to (and read from) the source volume, mount the source volume normally.

  As long as the source volume is mounted below a non-mirrored volume, you can read and write to the volume normally via its direct mount path. You can also use a volume link of type `writeable` to write directly to the source volume regardless of its mount point.

last-updated: Jun 06, 2024

- To read from the mirrors, use the `volume link create` command to make a volume link (of type `mirror`) to the source volume.

  Any read requests from the volume link are distributed among the volume's mirrors. Since the volume link provides access to the mirror volumes, you do not need to mount the mirror volumes.

Managing Snapshots

This section provide information about managing snapshots.

A snapshot is a read-only image of a volume at a specific point in time. On clusters with an Enterprise Edition or higher license, you can create a snapshot manually or automate the process with a schedule. Snapshots are useful any time you need to be able to roll back to a known good data set at a specific point in time. For example, before performing a risky operation on a volume, you can create a snapshot to enable rollback capability for the entire volume.

A snapshot takes no time to create, and initially uses no disk space, because it stores only the incremental changes needed to roll the volume back to the state at the time the snapshot was created. The storage used by a volume's snapshots does not count against the volume's quota. When you view the list of volumes on your cluster in the Control System, the value of the Snap Size column is the disk space used by all of the snapshots for that volume.

NOTE: Snapshot volumes inherit the auditing configurations of their original read-write volumes. For details about auditing, see Auditing.

You can perform the following tasks using the Control System and the CLI.

Creating Volume Snapshots

Describes how to create snapshots of volumes using the Control System and the CLI.

About this task

You can create a snapshot manually using the Control System and the CLI, or use a schedule to automate snapshot creation.

NOTE: The maximum number of snapshots that you can create for each volume is 4092. Exceeding this limit raises the snapshot failure alarm with an appropriate entry in the CLDB logs.

Creating Snapshots of Multiple Volumes Using the Control System

About this task

To create snapshots of multiple (standard and/or mirror) volumes manually:

Procedure

1. Log in to the Control System and go to the **Summary** tab in the **Data** > **Volumes** page.

   NOTE: When running on a Kubernetes cluster, the **Summary** tab is on the **Volumes** page.

2. Select the volume(s) for which you need to create the snapshots.
3. Click **Snapshot Volume** from the **Actions** drop-down menu.
   The **Snapshot Volume(s)** confirmation dialog displays.
4. Verify the list of volumes and enter a unique name for the snapshot in the **New Snapshot Name** field.
5. Click **Snapshot Volumes**.

last-updated: Jun 06, 2024

Creating a Snapshot of a Volume Using the Control System

About this task

You can create a snapshot manually or use a schedule to automate snapshot creation. To create a snapshot of a volume manually:

Procedure

1. Log in to the Control System and go to the **Snapshots** tab in the volume information page.
2. Click **Create Snapshot** to display the **Create Snapshot** window.
3. Enter a unique name for the snapshot in the **New Snapshot Name** field.
4. Click **Create Snapshot** to create a snapshot of the volume.
   By default, manually created snapshots do not have an expiration date.

Creating Volume Snapshots Using the CLI or REST API

About this task

The basic command to create a snapshot is:

```
maprcli volume snapshot create -snapshotname <snapshot> -volume <volume>
```

For complete reference information, see `volume snapshot create` on page 2703.

Viewing the list of Snapshots

Describes how to view the list of snapshots that are present on a cluster, using the Control System or the CLI.

About this task

You can view the snapshots on the cluster using the Control System or the CLI.

Viewing All the Snapshots Using the Control System

Procedure

- The **Snapshots** tab under the **Data** > **Volumes** page displays all the snapshots on the cluster.

  NOTE: When running on a Kubernetes cluster, the **Snapshots** tab is under the **Volumes** page that is under the **Volumes** menu.

  For each snapshot, you can view the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	Disk space (in MB) used/owned by the snapshot

  You can select one or more snapshots to:

  - Preserve

last-updated: Jun 06, 2024

- Remove

Viewing the Snapshots Associated with a Volume Using the Control System

Procedure

- Log in to the Control System and go to the **Snapshots** tab in the volume information page.
  The list of snapshots associated with the volume displays in this tab. For each snapshot, the pane displays the following:

Column Name	Column Description
Snapshot Name	The name of the snapshot.
Volume	The volume with which the snapshot is associated.
Created On	The date when the snapshot was created.
Expires On	The date when the snapshot expires.
Reclaim Size	Disk space (in MB) used/owned by the snapshot

You can create a snapshot of the volume or select one or more snapshots to:

- Preserve
- Remove

Viewing Snapshots Using the CLI or REST API

About this task

The basic command to retrieve a list of snapshots is:

```
maprcli volume snapshot list
```

For complete reference information, see `volume snapshot list` on page 2705.

Filtering the List of Snapshots
Describes how to filter the list of snapshots using the Control System or the CLI.

About this task

The filter in the **Snapshots** tab on the **Data** > **Volumes** page lets you build search expressions to provide sophisticated filtering capabilities for locating specific data on views that display a large number of volumes. Expressions are implicitly connected by the AND operator.

NOTE: When running on a Kubernetes cluster, the filter is present in the **Snapshots** tab on the **Volumes** page under the **Volumes** menu.

Filtering the List of Snapshots Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Volumes** > **Snapshots** to filter list of snapshots in the **Snapshots** page.

   NOTE: When running on a Kubernetes cluster, click **Volumes** > **Snapshots** to filter list of snapshots in the **Snapshots** page.

2. Click and select one of the following from the **Add Filter** drop down menu:

last-updated: Jun 06, 2024

- Snapshot Name — to filter the list by snapshot name
- Volume — to filter the list by volume name
- Created on — to filter the list by snapshot creation date range
- Expires on — to filter the list by snapshot expiration date range

3. Specify the value in the drop-down field for the selected filter (on which to filter the list of snapshots) and click **Filter**.

   As you make selections and specify the filtering criteria, the pane displays only the snapshots that match the specified filtering criteria.

4. Click:
   - **Add Filter** to add another filtering criteria.
   - ✕ to remove a filtering criteria.
   - to clear all filter settings.

Filtering the List of Snapshots Using the CLI and REST API

About this task

CLI	The `volume snapshot list` on page 2705 command can be used with the `-filter` option, which let you specify large numbers of snapshots by matching specified values in specified fields rather than by typing each name explicitly. For example, you can display all snapshots associated with the volume *test* as follows: `maprcli volume snapshot list -filter [vn=="test"] -json`
REST	Send a request of type GET. For example, to display all snapshots associated with the volume *test*, send a request similar to the following: `curl -k -X GET 'https://<hostname>:8443/rest/volume/snapshot/list?filter=%5Bvn%3D%3D%22test%22%5D' --user <username>:<pwd>`

For more information, see `volume snapshot list` on page 2705.

Viewing the Contents of a Snapshot from the Command Line
Describes how to view the contents of the `.snapshot` directory from the CLI.

At the top level of each volume is a directory named `.snapshot` containing all the snapshots for the volume. You can view the directory with `hadoop fs` commands or by mounting the cluster with NFS. To prevent recursion problems, `ls` and `hadoop fs -ls` do not show the `.snapshot` directory when you list the contents of the top-level volume directory. You must navigate explicitly to the `.snapshot` directory to view and list the snapshots for the volume.

last-updated: Jun 06, 2024

Example:

```
hadoop fs -ls /myvol/.snapshot
   Found 1 items
   drwxrwxrwx   - root root          1 2011-06-01 09:57 /myvol/.snapshot/
2011-06-01.09-57-49
```

In the preceding example, `/myvol` is the mount point of the volume for which the snapshot named `2011-06-01.09-57-49` was created and stored in the `.snapshot` directory.

Preserving one or more Snapshots
Describes how to preserve a snapshot using the `volume snapshot preserve` command, or using the Control System.
Preserving Snapshots Using the Control System

About this task

You can preserve a snapshot to prevent it from expiring. To preserve one or more snapshots, in the **Snapshots** tab (under **Data** > **Volumes**):

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the snapshot(s) you want to preserve.
2. Click **Preserve Snapshot** to preserve the snapshot(s).
   The **Preserve Snapshot(s)** confirmation dialog displays.
3. Verify the list of snapshots to preserve and click **Preserve Snapshots**.
   The **Expires On** column for the selected snapshots will show **No Expiration**. You *cannot* set an expiration date for a preserved snapshot; instead, if necessary, remove the preserved snapshot.

Preserving Snapshots Associated with a Volume Using the Control System

About this task

You can preserve a snapshot to prevent it from expiring. To preserve one or more snapshots (and prevent them from expiring) associated with a volume:

Procedure

1. Log in to the Control System and go to the **Snapshots** tab in the volume information page.
   The list of snapshots associated with the volume displays.
2. Select the snapshots to preserve and click **Preserve Snapshot**.
   The **Preserve Snapshot(s)** confirmation dialog displays.
3. Verify the list of snapshots to preserve and click **Preserve Snapshots**.
   The **Expires On** column for the selected snapshots will show **No Expiration**. You *cannot* set an expiration date for a preserved snapshot; instead, if necessary, remove the preserved snapshot.

Preserving Snapshots Using the CLI or the REST API

About this task

The basic command to preserve the snapshots is:

```
maprcli volume snapshot preserve
```

For complete reference information, see `volume snapshot preserve` on page 2707.

Removing one or more Snapshots

Explains how to remove a snapshot using the `volume snapshot remove` command or using the Control System.

About this task

Each snapshot has a date and time at which it expires. You can remove a snapshot manually before its expiration, or you can preserve a snapshot to prevent it from expiring.

Removing Snapshots Using the Control System

About this task

To remove one or more snapshots, in the **Snapshots** tab under **Data** > **Volumes**:

NOTE: The **Volumes** page is under the **Volumes** in the Kubernetes version of the Control System.

Procedure

1. Select the snapshots to remove.
2. Click **Remove Snapshot**.
   The **Remove Snapshots** confirmation dialog displays.
3. Verify the list of snapshots to remove and click **Remove Snapshots**.
   When you remove a snapshot, the snapshot is removed from the system and cannot be restored.

Removing Snapshots Associated with a Volume Using the Control System

About this task

To remove one or more snapshots associated with a volume:

Procedure

1. Log in to the Control System and go to the **Snapshots** tab in the volume information page.
   The list of snapshots associated with the volume displays.
2. Select the snapshots to remove and click **Remove Snapshot**.
   The **Remove Snapshots** confirmation dialog displays.
3. Verify the list of snapshots to remove and click **Remove Snapshots**.
   When you remove a snapshot, the snapshot is removed from the system and cannot be restored.

last-updated: Jun 06, 2024

Removing Snapshots Using the CLI or REST API

About this task

The basic command to remove a snapshot is:

```
maprcli volume snapshot remove
```

For complete reference information, see `volume snapshot remove` on page 2709.

Restoring Volume Snapshots Using the Control System

Describes how to restore snapshots of volumes using the Control System.

About this task

You can restore snapshots using the Control System.

For an overview on the Snapshot Restore functionality, refer to Restoring a Volume From a Snapshot on page 525.

To restore a snapshot, using the CLI, use the volume snapshot restore on page 2726 command.

To check the progress of a snapshot restore operation, use the volume snapshot restorestatus on page 2728 command.

Restoring Snapshots Using the Control System

About this task

To restore either a single or multiple snapshots of a single or multiple (standard and/or mirror) volumes:

Procedure

1. Log in to the Control System and go to the **Snapshots** tab on the **Data** > **Volumes** page.

   NOTE: When running on a Kubernetes cluster, the **Snapshots** tab is on the **Volumes** page under the **Volumes** menu .

2. Select a snapshot or multiple snapshots to restore.
3. Click **Restore Snapshot** from the menu.
4. Verify the list of snapshots, read through the information displayed, and click **Restore Snapshot**.

   TIP: The Control System displays notifications that show the status of the Snapshot Restore operation.

Related concepts

Restoring a Volume From a Snapshot on page 525
Provides a synopsis of restoring a volume from a snapshot. Describes the implications, and the prerequisites.

Related reference

Copying From a Snapshot Using the CLI

Describes how to create a volume by copying data from a snapshot

last-updated: Jun 06, 2024

NOTE: A snapshot must be restored into a volume to access the database tables or streams contained in the snapshot. Copying of data from tables or streams contained in a snapshot with Linux commands is not supported.

Copying data from a snapshot involves a simple copy operation from the `.snapshot` directory to the destination, as in the following example. User input is marked in **bold**:

NOTE: This example assumes that the file system is mounted on /mapr using FUSE as explained in Mounting the Filesystem.

```
[user@host]$ maprcli volume snapshot create -snapshotname
uservolsnap -volume users
[user@host]$ maprcli volume snapshot list
snapshotid  sharedSize  volumename  ownername  cumulativeReclaimSizeMB
numSizeUpdates  snapshotname  enforcementMode      ownedsize
sizeUpdateRequestedAt         ownertype  numSizeUpdatesDesired  volumeid
creationtime                  volumepath  volumeSnapshotAces
256000049   0           users       mapr       0
0               uservolsnap   PolicyAceAndDataAce  0          Mon Jun 14
05:44:11 UTC 2021  1          1                      77144951  Mon Jun 14
05:44:11 UTC 2021  /user       ...

[user@host]$ ls -l /mapr/my.cluster.com/user/
total 1
drwxr-xr-x 2 mapr mapr 2 Jun 13 14:34 mapr

[user@host]$ ls -l /mapr/my.cluster.com/user/.snapshot
total 1
drwxr-xr-x 2 mapr mapr 2 Jun 13 14:37 uservolsnap

[user@host]$ cp /mapr/my.cluster.com/user/.snapshot/uservolsnap/mapr/* /
mapr/my.cluster.com/user/
```

Managing User Disk Usage

The **User Disk Usage** tab in the **Data** > **Volumes** page displays information about disk usage by cluster users. You can perform the following tasks to manage disk quotas using the MapR Control System and the CLI.

Viewing User Disk Usage Information
Explains how to view user disk usage information using either the Control System or the CLI.
Viewing User Disk Usage Information Using the Control System

About this task

To view information about disk usage by cluster users:

Procedure

- Log in to the Control System and go to the **User Disk Usage** tab under **Data** > **Volumes**.

  NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

  The disk usage information for all the users displays. For each user, the **Accountable Entities** pane displays the following:

last-updated: Jun 06, 2024

Column Name	Column Description
Type	The type of *accountable entity (AE)*. Value can be User or Group.
Accountable Entity	The user or group responsible for the volume.
Disk Usage	The total disk space used by the user.
Volume Count	The number of volumes.
Hard Quota	The user's hard quota.
Advisory Quota	The user's advisory quota.
Email	The email address of the user.

Selecting the checkbox beside an accountable entity makes the **Edit Properties** button available. You can modify the quotas for the selected entities by clicking Edit Properties. Alternatively, you can click on an entity or associated to modify the email address and quotas for the entity.

Viewing User Disk Usage Information Using the CLI or REST API

About this task

The basic command to view user disk usage information is:

```
maprcli entity info -name <entity name> -type <type>
```

For complete reference information, see `entity info` on page 2182.

Set or Modify Quotas for Users and/or Groups
Explains how to set or modify quotas for one or more entities using either the Control System or the CLI.
Set or Modify Quotas for Multiple Users and/or Groups Using the Control System

About this task

To edit the quota, which limits the space used by all the volumes owned by a user or group, for one or more users, in the **User Disk Usage** tab under **Data** > **Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the users/groups from the list of users/groups in the **Accountable Entities** pane.
2. Click **Edit Properties**.
   The **Edit Properties** dialog displays.
3. Verify the list of users/groups and modify or set the following for the users/groups:
   a) Hard quota, which raises an alarm when the limit is reached and prevents further writes.
   b) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.

   NOTE: Both, advisory and hard, quotas can be expressed in megabytes (MB), which is the default, gigabytes (GB), or terabytes (TB).
4. Click **Save Changes** for the changes to take effect.

last-updated: Jun 06, 2024

Set or Modify Quotas for an Entity Using the Control System

About this task

To edit the quota, which limits the space used by all the volumes owned by a user or group, for a user, in the **User Disk Usage** tab under **Data** > **Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Click the user/group from the list of users/groups or the associated with the user/group in the **Accountable Entities** pane to display the **Edit Properties** window.
2. Modify or set the following for the user or group:
   a) Enter the email address of the user/group.
   b) Hard quota, which raises an alarm when the limit is reached and prevents further writes.
   c) Advisory quota, which raises an alarm when the threshold is reached, but does not prevent further writes.
      The advisory quota must be less than the hard quota.

   NOTE: Both, advisory and hard, quotas can be expressed in megabytes (MB), which is the default, gigabytes (GB), terabytes (TB), petabytes (PB), exabytes (EB), and zettabytes (ZB).
3. Click **Save Changes** for the changes to take effect.

Set or Modify Quotas for Users and/or Groups Using the CLI or the REST API

About this task

The basic command to set or modify quotas for multiple entities is:

```
maprcli entity modify
        -entities <entities>
        -advisoryquota <advisory quota>
        -quota <quota>
```

The basic command to set or modify quotas for an entity is:

```
maprcli entity modify
        -name <entityname>
        -type <type>
        -advisoryquota <advisory quota>
        -quota <quota>
```

For complete reference information, see `entity modify` on page 2185.

accountable entity (AE) on page 6284

Managing Schedules

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors and the offload of

volume data to a storage tier; after you create a schedule, it appears as a choice in the scheduling menu when you are creating or editing a volume.

When you specify a *snapshot* schedule on a mirror volume, it specifies how often to take a snapshot of the mirror volume. This snapshot schedule is distinct from the snapshot schedule for the standard volume. A snapshot schedule for a promotable mirror volume has two purposes:

- It specifies how often to take a snapshot of the mirror volume for the purpose of preserving the state of the mirror before a subsequent mirror operation. This way, if corrupt data is copied from the source volume's snapshot into the mirror volume, the mirror contents can be rolled back to the snapshot.
- If the promotable mirror volume is promoted to a read-write volume, the snapshot schedule specified for the mirror is used for the promoted read-write volume. Once a mirror volume is promoted to a read-write volume, the mirror schedule is disabled.

A *mirror* schedule specifies how frequently the mirror volume is synchronized with the source volume. In case of a disaster (or any type of data loss on a read-write source volume), the data can be recovered from the mirror volume, but any data written to the source volume since the last successful mirror operation will not be on the mirror volume. Therefore, you should set the mirror schedule such that it meets your RPO (Recovery Point Objective).

A *tier offload* schedule specifies how frequently data in the volume on the MapR cluster is offloaded to the tiered storage. The MAST Gateway uses this setting to automatically offload data to the storage tier.

Schedules require the Enterprise Edition license.

Viewing the List of Schedules
Explains how to view all the schedules using the Control System or the CLI.
Viewing the List of Schedules Using the Control System

About this task

To view all the schedules:

Procedure

Log in to the Control System and go to the **Schedules** tab under **Data** > **Volumes**.

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

The page displays all the schedules. For each schedule, the page displays the following:

Column Name	Column Description
Schedule Name	The name of the schedule.
ID	The schedule ID.
In Use	Checkmark (✓) indicates the schedule is currently being used.
Detail	The schedule details such as the recurring points in time when the associated actions occur and how long the data is preserved.

Selecting the checkbox associated with a schedule makes the **Remove Schedule** button available. You can:

- Create a new schedule by clicking **Create Schedule**
- Remove a schedule by selecting the checkbox beside the schedule (to remove) and then by clicking **Remove Schedule**

last-updated: Jun 06, 2024

- Edit a schedule by clicking the schedule name

Retrieving the List of Schedules Using the CLI or REST API

About this task

The basic command to retrieve a list of schedules is:

```
maprcli schedule list
```

For complete reference information, see `schedule list` on page 2310.

Creating a Schedule
Explains how to create a schedule using the Control System or the CLI.
Creating a Schedule Using the Control System

About this task

A schedule is a group of rules that specify recurring points in time at which certain actions are determined to occur. You can use schedules to automate the creation of snapshots and mirrors. To create a new schedule:

Procedure

1. Log in to the Control System and go to the **Schedules** tab in the **Data** > **Volumes** page.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click **Create Schedule**.
   The **Create Schedule** dialog displays.

3. Enter a name for the schedule in the **Schedule Name** text field.

4. Specify the schedule rules with the following components:

Frequency	Specify frequency (Once, Yearly, Monthly, Weekly, Daily, Hourly, Every X minutes).
Time	Specify the point of time within the specified frequency to perform the scheduled action. For example, if you selected Monthly from the first drop-down menu, select the day of the month from the second drop-down menu. Continue with each drop-down menu, proceeding to the right, to specify the time at which the scheduled action is to occur. **NOTE:** This is available only if the selected frequency is Once, Yearly, Monthly, Weekly, or Daily.
Retain for	Specify how long the data should be preserved. For example, if the schedule is attached to a volume for creating snapshots, the **Retain for** specifies how far after creation the snapshot expiration date is set.

   If necessary, click **Add Another** to add another rule to the schedule or to remove a rule.

5. Click **Create Schedule** to create the schedule.
   After the schedule is created, it appears as a choice in the scheduling menu when you are creating a new volume or editing a volume.

last-updated: Jun 06, 2024

Creating a Schedule Using the CLI or REST API

About this task

The basic command to create a schedule is:

```
maprcli schedule create -schedule <JSON>
```

For complete reference information, see schedule create on page 2309.

Guidelines for Setting Mirror Schedules

Although MapR allows mirroring frequencies up to once per minute, setting a schedule at this frequency is not practical nor advisable. When you choose the mirror schedule, consider the amount of data on the volume and the load on the cluster. Remember that the mirroring frequency must allow enough time to complete one mirror operation before the next scheduled mirror operation starts. In addition, if you have a cascaded mirror setup (where A mirrors to B which mirrors to C), you cannot set a mirror schedule for C that starts before B finishes mirroring from A.

WARNING: In general, you should not set a mirror schedule for more often than every 30 minutes.

If you set a mirror schedule to start mirroring before the previous mirror operation finishes, you will see an error message similar to this:

```
WARN Alarms [pool-2-thread-1]: Alarm raised: VOLUME_ALARM_MIRROR_FAILURE;
Cluster: Cluster1; Volume: ; Message: Cannot start new scheduled mirror
because existing mirror is in progress
```

Modifying a Schedule

Explains how to modify a schedule using either the Control System or the CLI.

Modifying a Schedule Using the Control System

About this task

When you modify a schedule, the new set of rules replaces any existing rules for the schedule. To edit a schedule, in the **Schedules** tab under **Data** > **Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Click the schedule name of the schedule to edit.
   The **Edit Schedule** dialog displays.
2. Modify the schedule as desired:
   a) Change the schedule name in the **Schedule Name** field.
   b) Add, modify, or remove rules in the **SCHEDULE RULE** section.
   Here:

Frequency	Specifies the frequency (Once, Yearly, Monthly, Weekly, Daily, Hourly, Every X minutes).
Time	Specifies the point of time within the specified frequency to perform the scheduled action. This is available only if the selected frequency is Once, Yearly, Monthly, Weekly, or Daily.
Retain for	Specifies how long the data should be preserved.

   To add another rule, click **Add Another** and to remove a rule, click .

last-updated: Jun 06, 2024

3. Click **Save Changes** for the changes to take effect.

Modifying a Schedule Using the CLI or REST API

About this task

The basic command to modify a schedule is:

```
maprcli schedule modify -id <schedule ID> -rules <JSON>
```

For complete reference information, see `schedule modify` on page 2314.

Selecting an Existing Schedule to Associate with a Volume

Explains how to associate an existing schedule with a volume using the Control System, the CLI, or the REST API.

Selecting an Existing Schedule Using the Control System

Procedure

1. Log in to the Control System and go to **Summary** tab in the volume details page.
2. Click the  (associated with the type of schedule in the **Schedules** pane) to display the **Edit Schedules** window.
3. Review the name and detail of each schedule and select a schedule from the list.
4. Click **Save Changes** to associate the schedule with the volume.

Selecting an Existing Schedule Using the CLI and REST API

About this task

CLI

You can associate a schedule with a volume using the `schedule` parameter when creating or editing a volume. For example:

```
maprcli volume create -name
<volName> -path <mountPath> -schedule
<scheduleID>
```

```
maprcli volume modify -name
<volName> -schedule <scheduleID>
```

REST

You can associate a schedule with a volume using the `schedule` parameter when creating or editing a volume. Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<volPath>&schedule
=<scheduleID>' --user mapr:mapr
```

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
name=<volName>&schedule=<scheduleID>'
 --user mapr:mapr
```

last-updated: Jun 06, 2024

For the complete list of all required and optional parameters, see `volume create` on page 2588 and volume modify on page 2676.

Removing one or more Schedules
Describes how to remove schedules not associated with any volumes using either the Control System or the CLI.

About this task

You can remove a schedule only if it is not associated with any volumes.

Removing one or more Schedules Using the Control System

About this task

To remove one or more schedules, in the **Schedules** tab under **Data** > **Volumes**:

NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

Procedure

1. Select the schedule(s) to remove from the list of schedules.
2. Click **Remove Schedule** to display the **Remove Schedule** confirmation dialog.
3. Verify the list of schedules to remove click **Remove Schedule** to remove the schedules.
   When you remove a schedule, the schedule is removed from the system and cannot be restored.

Removing one or more Schedules Using the CLI or the REST API

About this task

The basic command to remove a schedule by ID is:

```
maprcli schedule remove -id <schedule ID>
```

For complete reference information, see `schedule remove` on page 2315.

Managing Tiers

About this task

You can create, modify, and remove tiers using the Control System and the CLI.

Enabling Tiering
Describes how to enable data tiering using both the Control System and the CLI.

For a primer on Data Tiering, see Data Tiering on page 507.

On all new installations, the data tiering functionality is enabled and available for all new volumes. If you are upgrading, you must enable data tiering; see Step 4: Enable New Features on page 340 for more information. If the data tiering functionality is enabled, you can then selectively enable tiering for a volume at the time of volume creation using the Control system and the CLI.

Data tiering is only available for new volumes; you cannot enable data tiering for existing volumes. Enable tiering for new volumes where read/write latency is not the dominant concern. You can decide later whether you want to do local (or warm) or remote (or cold) tiering. Data tiering cannot be disabled after it is enabled for a volume.

Enabling Tiering Using the Control System

1. Move the **Data Tier** slider to **Yes** (to enable tiering) in the **Create New Volume** page in the Control System.

   Proceed to the next step only if you wish to select a tier type for the volume. You can create a tiering-enabled volume without selecting a tier type and select a tier type later by editing the volume.

   NOTE: You cannot disable tiering for a volume after it is enabled.

2. (Optional) Select **Erasure Coding** (for warm tiering) or **Remote Archiving** (for cold tiering) from the **Tiering Type** drop-down menu.

   You:

   - Can enable a volume for either warm or cold tiering, but not for both.
   - Cannot modify the tier type after the volume is created.

3. Specify all other required and optional properties for creating the volume and click **Create Volume**.

   For information on required and optional properties, see Creating a Volume on page 1177.

Enabling Tiering Using the CLI

- Run the following command to enable tiering:

```
maprcli volume create -name <vol-name> -path <mount-path> -tieringenable
true
```

  For more information, see `volume create` on page 2588.

Introduction to Parallel Offload

The MAST Gateway uses parallel threads to rapidly offload tiering-enabled volumes to either cold or warm tiers.

Prior to HPE Ezmeral Data Fabric version 6.2, for any given volume, by default, only one MAST Gateway is used to offload the data. All tiering tasks such as offloads, recall, and compaction are scheduled only on that one assigned gateway. This causes multiple tasks to contend for limited threads on that assigned node, resulting in slowdowns. EC encoding performance is limited because of a single gateway. S3 offload throughput is limited as well. MAST Gateway utilization is skewed as some nodes may be idle, while others may be over utilized. When the assigned gateway goes offline, the volume is assigned a new gateway and the tasks are restarted.

To mitigate these issues with a single gateway, when a new cluster is setup with version 6.2 software, multiple MAST Gateways are used in parallel to offload the data of a single volume.

Parallel Offload uses one primary MAST Gateway and multiple secondary MAST Gateways per volume. The primary gateway coordinates tasks across secondary gateways and reports their final status to CLDB.

Only volume level offload tasks are sharded. File level tasks and all non-offload volume tasks are run on the primary gateway itself.

Advantages of Parallel Offload

Multiple MAST Gateways provide the following advantages:

- Increased per-volume throughput
- Leverage idle/unused cluster nodes
- Increased per-gateway efficiency

last-updated: Jun 06, 2024

- Efficient usage of network bandwidth
- Leverage local reads to improve offload efficiency
- Only a subset of tasks need to be rescheduled if a gateway goes offline
- Resilient to failures
- Efficient volume and tasks level load balancing

Resiliency with Parallel Offload

Parallel Offload is resilient to the following scenarios:

Restart of the Primary Gateway	• Secondary gateways continue to run assigned tasks while the primary gateway is down or restarting. • CLDB reassigns the volume to another primary gateway. • CLDB restarts the tasks on the new primary gateway. • The primary gateway polls/reschedules the ongoing secondary gateway tasks.
Restart of the Secondary Gateway	• The primary gateway detects the failure of secondary gateway tasks when it polls the secondary gateway. • The primary gateway reschedules tasks that were terminated when the secondary gateway restarted.
Restart/Switchover of CLDB	• Reassign volume to the same primary gateway. • Reschedule pending volume task on the same primary gateway.

Load Balancing with Parallel Offload

Load Balancing involves:

Volume Level	• CLDB assigns each volume to a gateway with the least number of volumes. • Gateway Balancer reassigns volumes across gateways.
Task Level	CLDB balances tasks across MFS nodes.

Enabling Parallel Offload on an Upgraded Cluster

When the cluster is upgraded to version 6.2 from a previous release, only one MAST Gateway is used to offload the data of a single volume. To use multiple MAST Gateways, to offload a volume's data in parallel, you have to enable parallel offloads feature:

```
maprcli cluster feature enable -name mfs.feature.container.sharding.support
```

last-updated: Jun 06, 2024

To check whether parallel offloads are enabled, run:

```
maprcli config load -json | grep -i shard
```

A value of 0 indicates that parallel offloads are enabled. For example:

```
"mastgateway.disable.sharding":"0"
```

Creating a Storage Tier

Describes how to create a sotrage tier using the Control System and the CLI.

About this task

For a primer on Data Tiering, see Data Tiering.

You can create a tier using the Control System and the CLI.

When you create a tier, file system creates a volume, whose mount point is `/var/mapr/tier/mapr.internal.tier.<tiername>`, for the tier. For warm tier volumes automatically created using the `ecenable` parameter or the Control System, by default, a corresponding tier volume named `mapr.internal.tier.autoec.<volName>.<creationTime>` is created in the `/var/mapr/autoectier` path. The tier volume is visible and stores all the metadata tables and information on all the jobs running on the tier. Do not modify, move, or remove this volume.

NOTE: If the number of cluster nodes is more than five, by default, HPE Ezmeral Data Fabric (through the `enforceminreplicationforio` parameter) requires minimum number of copies of the tier volume for writes to succeed. If the number of cluster nodes is less than five, HPE Ezmeral Data Fabric does not enforce minimum number of copies for writes to succeed.

Creating a Warm Tier Using the Control System

About this task

When you create a volume enabled for erasure coding, the control system automatically creates a warm tier and associates the volume with that tier. See Creating a Volume on page 1177 for more information. You cannot create a warm tier separately using the Control System.

Creating a Cold Tier Using the Control System

About this task

To create a cold tier:

Procedure

1. Log in to the Control System, click **Data** > **Volumes**, and then do one of the following:
   - Go to the **Remote Targets** tab if you wish to create a remote target that is not (yet) associated with a volume.
   - Click **Create Volume** if you wish to create a remote target for a volume when you are creating the volume.

     NOTE: You must enable data tiering and select **Remote Archiving (Cold)** from the **Tiering Type** drop-down list to create the remote target.
   - Click **Edit Volume** in the volume information page if you want to create a remote target for the volume when you are editing the volume settings.

     NOTE: You can create a remote target only if a remote target is already not associated with the volume.

last-updated: Jun 06, 2024

2. Click one of the following to display the **Create Remote Target** window.
   - **Create Target** if you are in the **Remote Targets** tab.
   - **Create** link associated with the **Remote Target** field if you are in the **Create New Volume** page.
   - **Create** link associated with the **Remote Target** field if you are in the **Edit Volume** page.
3. Specify a name for the tier in the **Remote Target Name** field.
4. Select a topology for the metadata volume associated with the tier from the list of topologies in the **Lookup Topology** drop-down menu.
   The volume stores all the metadata tables and information on all the jobs running on the tier. If many volumes share the same tier (and thus the same lookup topology), the lookups might have an adverse affect by inadvertently adding background load to nodes in that topology. This property allows you to setup the lookups on other nodes.
5. Specify the following properties.

Vendor	The vendor from the **Vendor** drop-down list. **NOTE:** For cold tiering, HPE Ezmeral Data Fabric supports the following vendors: • AWS (Amazon AWS) • GCS (Google Cloud Platform) • HDS (Hitachi HCP) • IBM (IBM Cleversafe) • Azure Blob (Microsoft Azure) • Others (such as Minio) See Specifying the Vendor/Object Store for a Cold Tier on page 1293 for more information on the supported vendors.
URL	The URL to use to connect to the tier in the following format: `<protocol>://<IP|hostname>.<domain>` If the protocol is `https`, the MAST Gateway uses HTTPS to upload data to the cold-tier. If the cold-tier storage does not support HTTPS, all tier related operations will fail. If the cold tier does not support HTTPS, set the protocol to `http`. See Specifying the Vendor/Object Store for a Cold Tier on page 1293 for more information on the tier endpoint URLs and supported authentication protocols.
Bucket Name	The name of the bucket on the tier. This cannot be modified once associated with a tier. If the bucket does not already exist on the tier, HPE Ezmeral Data Fabric will attempt to create the bucket. **NOTE:** For Azure, the bucket/container is created in the region that is specified in the parent storage account.

last-updated: Jun 06, 2024

Region	The S3 region to create the bucket on. This cannot be modified once configured (explicitly or using the default) and associated with a tier. See region on page 1291 for more information.

6. Enter the credentials for accessing the tier in the **Access Key** and **Secret Key** fields.

   TIP: For Azure Blobs, the storage account name is the access key.

7. Click **Create Target** to create the cold tier that you can associate with a volume.

Creating a Tier Using the CLI and the REST API

About this task

CLI

Run the following command to create a tier:

- Cold tier:

```
$maprcli tier
create -name <tier_name> -type
cold -url <tier_url> -credential
<credentials_file_path>
```

  For using the `-credential` option, you must have the credential file already set up as described in Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API on page 1290. On the other hand, if you do not have the file already set up, use the `-credential_str` option as follows:

```
$maprcli tier create -name
<tier_name> -type cold -url
<tier_url> -credential_str
'<credential_string>'
```

- Warm tier with default values:

```
$maprcli tier create -name
<tier_name> -type ectier
```

  NOTE: You can associate the same tier with multiple volumes with different erasure coding scheme.

REST

Send a request of type POST. For example:

last-updated: Jun 06, 2024

- Cold Tier:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=egColdTier&type=cold&url=s3.am
azonaws.com&credential=credentials.
txt' --user mapr:mapr
{"timestamp":1525724933919,"timeofd
ay":"2018-05-07 01:28:53.919
GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully
created tier: 'egColdTier'"]}
```

- Warm tier:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/create?
name=egWarmTier&type=ectier' --user
 mapr:mapr
{"timestamp":1525725105206,"timeofd
ay":"2018-05-07 01:31:45.206
GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully
created tier: 'egWarmTier'"]}
```

NOTE: You can associate the same tier with multiple volumes with different erasure coding scheme.

For more information, see `tier create` on page 2527.

Setting up a Credentials File for Connecting to a Cold Tier Using the CLI or REST API
Describes how to create a credential file, with examples for AWS and Microsoft Azure.

Set up a credentials file on the host you plan to use for creating the cold tier if you are planning on using the `credential` option (and not pass the credentials on the command-line using the `credential_str` option).

For example, your `credentials.txt` file for AWS should look similar to the following sample file:

```
{
      "bucketName" : "defaultbucket3",
      "region": "us-east-1",
      "credentials" : {
         "accessKey" : "AB956CDE8F2GO7H9I4J2",
         "secretKey" : "5K1LmN92e65oPQRsTUvOfSbURxyEtYl2MmAocGi"
      }
}
```

The sample for Microsoft Azure is as follows:

```
maprcli tier create -name tier_azure_1 -type cold -url https://
myobjectpools1.blob.core.windows.net -credential ~/creds_azure.txt
$ cat creds_azure.txt
      {
      "bucketName" : "bucket4",
      "credentials" : {
      "accessKey" : "myobjectpools1",
      "secretKey" :
```

```
"N6GKkDPttqNc6rfTzhb2JNKwvdr9EraN89Mg8WaodrvPBeINBTZwhQu+Q3vX4ENeW+RQN42f+P8
nXN0YasZWNA=="
                    }
      }
```

The credentials file (`.txt` file) contains the following properties in JSON format:

bucketName	The name of the bucket on the tier. If the bucket does not already exist on the tier, the command to create the tier attempts to create the bucket using the credentials in the credentials file. You can modify the name of the bucket only by using the `-force` option with the `tier modify` on page 2535 command
region	The S3 region to create the bucket on. Use the information in the following table to specify region information.

Vendor	Default Value	Notes
AWS	us-east-1	Specify region information as defined here. On AWS, each region can have a different URL. The URL must be provided with the `maprcli tier create` command. **NOTE:** Because bucket names are unique across regions, make sure you specify the correct region for a given bucket in the credentials file. For example, suppose a bucket called myBucket3 in us-east-1; you cannot offload data to myBucket3 by specifying us-west-1 as the region in the credentials file.
GCS	us-east-1	Specify region information as described here.
HDP	N/A	Not required. If specified, MapR ignores the value.

last-updated: Jun 06, 2024

Vendor	Default Value	Notes
IBM	us-east-region	Not required. If specified, MapR ignores the value.
Azure-Blobs	N/A	Not required. The region of the storage account is determined from the URL and data is offloaded into that region.
Minio	us-east-1	If you specify region, export the `MINIO_REGION` environment variable on the minio server as described in the Configuration Guide.
Scality	us-east-region	Not required. If specified, MapR ignores the value.

You can modify the region only by using the `-force` option with the `tier modify` on page 2535 command.

accessKey and secretKey

The credentials for accessing the tier.

TIP: For Azure Blobs, the storage account name is the access key.

NOTE: Once the tier is created, MapR does not require this file because CLDB stores the bucket, region, and credentials information.

Specifying the Vendor/Object Store for a Cold Tier

Specify the vendor or object store where you plan to offload the (cold) data. The following table lists the supported vendors, URL of the tier endpoint, and authentication protocol supported by MapR:

last-updated: Jun 06, 2024

Supported Vendor/Object Store	Tier URL/Endpoint	Supported Authentication Protocol
AWS (Amazon AWS)	The URL varies based on the region. For: • us-east-1: https://s3.amazonaws.com • us-east-2: https://s3.us-east-2.amazonaws.com • us-west-1: https://s3-us-west-1.amazonaws.com • us-west-2: https://s3-us-west-2.amazonaws.com • ap-south-1: https://s3.ap-south-1.amazonaws.com • ap-southeast-1: https://s3-ap-southeast-1.amazonaws.com • ap-southeast-2: https://s3-ap-southeast-2.amazonaws.com • ap-northeast-1: https://s3-ap-northeast-1.amazonaws.com • ap-northeast-2: https://s3.ap-northeast-2.amazonaws.com • ap-northeast-3: https://s3.ap-northeast-3.amazonaws.com • ca-central-1: https://s3.ca-central-1.amazonaws.com • cn-north-1: https://s3.cn-north-1.amazonaws.com • cn-northwest-1: https://s3.cn-northwest-1.amazonaws.com • eu-central-1: https://s3.eu-central-1.amazonaws.com • eu-west-1: https://s3-eu-west-1.amazonaws.com • eu-west-2: https://s3.eu-west-2.amazonaws.com • eu-west-3: https://s3.eu-west-3.amazonaws.com	• HTTP • HTTPS

last-updated: Jun 06, 2024

Supported Vendor/Object Store	Tier URL/Endpoint	Supported Authentication Protocol
GCS (Google Cloud Platform)	`https://storage.googleapis.com`	• HTTP • HTTPS
HDS (Hitachi HCP)	`http://<hcptenant>.<hcphostname>` `https://<hcptenant>.<hcphostname>`	• HTTP • HTTPS
IBM (IBM Cleversafe)	`http://lb1.ait.cleversafelabs.com`	HTTP
Azure Blob (Microsoft Azure)	`https://<azureaccount>.blob.core.windows.net`	• HTTP • HTTPS
Minio	`http://10.10.88.198:9000`	HTTP
Scality	`https://<scality-instance-hostname>:8000`	HTTP

Viewing the List of Tiers

Describes how to view the list of tiers using the Control System, the CLI, and the REST API.

About this task

For a primer on Data Tiering, see Data Tiering.

In the Control System, you can only see the list of cold tiers (referred to as remote targets). Use the CLI or REST API to retrieve the list of both cold and warm tiers.

Viewing the List of Remote Targets Using the Control System

Procedure

- Log in to the Control System and click **Data** > **Volumes** > **Remote Targets**.
  The page displays the following for each remote target:

Column Name	Column Description
Remote Target Name	The name of the remote target.
External Storage Vendor	The name of the third-party storage vendor.
Bucket	The name of the bucket.
Region	The region where the bucket resides.
URL	The URL of the remote target.

You can:

- Create a remote target
- Remove a remote target

last-updated: Jun 06, 2024

Viewing the List of Tiers Using the CLI and REST API

About this task

CLI

Run the following command to retrieve the list of (warm and cold) tiers:

```
/opt/mapr/bin/maprcli tier list
```

REST

Send a request of type GET. For example:

```
# curl -k -X GET 'https://
10.10.82.24:8443/rest/tier/
list' --user mapr:mapr
{"timestamp":1525725765483,"timeofday"
:"2018-05-07 01:42:45.483 GMT-0700
PM","status":"OK","total":0,"data":
[{"tierid":"79082078","tiername":"egWa
rmTier","tiertype":"ectier","volume":"
mapr.internal.tier.egWarmTier","topolo
gy":"/data"},
{"tierid":"120198852","tiername":"egCo
ldTier","tiertype":"cold","url":"s3.am
azonaws.com","bucketname":"ksekhar-tes
t","region":"us-east-1","volume":"mapr
.internal.tier.egColdTier","topology":
"/data","objectstoretype":"S3_AWS"},
{"tierid":"158778422","tiername":"auto
ec.vol_tiered.1525463214","tiertype":"
ectier","volume":"mapr.internal.tier.a
utoec.vol_tiered.1525463214","topology
":"/data"}]}
```

For more information, see `tier list` on page 2533.

Editing a Tier

Describes how to modify a cold tier using the Control System, the CLI and the REST API.

About this task

For a primer on Data Tiering, see Data Tiering.

You cannot modify a warm tier. You can modify a cold tier (referred to as Remote Target in the Control System) using the Control System, the CLI, and REST API.

Modifying a Remote Target Using the Control System

Procedure

1. Log in to the Control System and go to the **Remote Target** tab under **Data** > **Volumes**.
2. Click the name of the remote target (cold tier) to display the **Edit Remote Target** window.
3. Make necessary changes to the **CREDENTIALS**.
4. Click **Save Changes** to save the changes.

Modifying a Cold Tier Using the CLI and REST API

About this task

CLI	Run the following command to modify a cold tier: `$maprcli tier modify -name <tier_name> -credential <credentials_file_path>`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://abc.sj.us:8443/rest/tier/modify?name=<tier_name>&credential_str=<JSON>' --user mapr:mapr`

For more information, see `tier modify` on page 2535.

Specifying a Tier

Describes how to associate a tier with a tiering-enabled volume using the Control System and the CLI.

About this task

NOTE:

For a primer on Data Tiering, see Data Tiering.

Using the Control System, you can only associate an exiting tier (referred to as **Remote Target** in the Control System) with a volume enabled for Remote Archiving (or cold-tier). You cannot associate an existing tier with a volume enabled for Erasure Coding (or warm-tier) because the Control System allows a new tier to be automatically created when you enable a volume for erasure coding. If you want to associate an existing tier with a volume enabled for erasure coding, use the CLI or REST API to create the volume.

Specifying a Remote Target Using the Control System

About this task

You can associate a remote target with a cold-tier enabled volume when you are:

- Creating the volume by clicking **Create Volume** button in the **Data** > **Volumes** page.
- Editing the volume by clicking **Edit Volume** button in the volume information page.

To associate a remote target with the volume, in the **Create Volume** or **Edit Volume** page:

Procedure

1. Click the **Browse** link associated with the **Remote Target** field to display the **Browse Remote Target** window.
2. Review the name, vendor, bucket, region, and URL for each remote target and choose a remote target from the list.
3. Click **Select** to associate the remote target with the volume.
4. Complete the steps for creating or editing the volume.

last-updated: Jun 06, 2024

Specifying a Tier Using the CLI and REST API

About this task

You can associate an existing tier with a volume when you are creating the tiering-enabled volume. You can associate an existing tier with a tiering-enabled volume when you are editing the volume only if the volume does not already have a tier associated with it. To associate an existing tier, you must specify the `tiername` parameter with the command.

CLI

Run a command similar to the following to associate a tier when:

- Creating a volume:

```
maprcli volume
create -name <volName> -path
<mountPath> -tieringenable
true -tiername <tierName> -json
```

  For the list of all other required and optional parameters, see `volume create` on page 2588.

- Editing the volume:

```
maprcli volume
modify -name <volName> -tiername
<tierName> -json
```

  For the list of all other required and optional parameters, see `volume modify` on page 2676.

REST

Send a request of type POST. For example, to associate a tier when:

- Creating a volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&tieringrule=<ruleName>' --user
mapr:mapr
```

  For the list of all other required and optional parameters, see `volume create` on page 2588.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&tieringrule=<ruleNam
e>' --user mapr:mapr
```

  For the list of all other required and optional parameters, see `volume modify` on page 2676.

Moving a Tier

Describes how to move a tier to a different database topology using both the Control System and the CLI. The operation is applicable to cold tiers only.

About this task

You can move a tier from the existing database topology to a different database topology in the same cluster by using the Control System and the CLI. A tier can be moved when the database topology for the tier gets bloated, and is required to be moved to a quieter part of the cluster.

Procedure

1. Log in to the Control System and navigate to **Data** > **Volumes**
2. Click the **Remote Targets** tab.

   NOTE: Cold tiers are referred to as remote targets.
3. Click **Change Topology**
4. Select a new topology from the list of existing topologies seen under **The new value** drop-down.
5. Click **Save Changes**.

Moving a Tier Using the CLI and the REST API

About this task

Explains moving a tier to a different database topology by using the CLI and REST API.

CLI	Run the following command to move a tier from one database topology to another: `$ maprcli tier move [-cluster <cluster_name> ] -name <tier_name> -dbtopology <path>`
REST	Send a request of type POST by using the following syntax: `# curl -k -X POST 'https://<host>:<port>/rest/tier/move?name=<tier_name>&dbtopology=<rack_path_of_destination_db_volume_topology>'`

For more information, see `tier move` on page 2538.

Removing a Tier

Describes how to remove a tier that is not associated with a tier, using the Control System, the CLI and the REST API.

About this task

For a primer on Data Tiering, see Data Tiering.

You can remove a tier that is not associated with a volume, using the Control System, the CLI, and REST API. In the Control System, a cold tier is referred to as remote target and you can only remove remote targets (or cold tiers) using the Control System. Use the CLI or REST API to remove cold and warm tiers.

last-updated: Jun 06, 2024

Removing a Remote Target Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Volumes** > **Remote Targets** to display the list of remote targets.
2. Select the checkbox associated with the tier to delete.
   Selecting the checkbox associated with a tier makes the **Remove Target** button available.
3. Click **Remote Target** to display the **Remove Remote Target** confirmation dialog.
4. Verify the list of remote targets to remove and click **Remove**.

Removing a Tier Using the CLI and REST API

About this task

CLI

Run the following command to remove a tier:

```
/opt/mapr/bin/maprcli tier
remove -name <tier-name>
```

You cannot remove a tier associated with a volume. If you run the command to remove a tier that is associated with a volume, the command returns an error (shown in bold) similar to the following:

```
{
   "timestamp":1516771078126,
   "timeofday":"2018-01-23
09:17:58.126 GMT-0800",
   "status":"ERROR",
   "errors":[{
       "id":10003,
        "desc":"Cannot remove tier,
as some volumes are still using it."
   }]
}
```

REST API

Send a request of type POST to remove a tier. For example:

```
curl -k -X
POST 'https://abc.sj.us:8443/rest/
tier/remove?name=ksTestTier' --user
mapr:mapr
```

You cannot remove a tier associated with a volume. If you send a request to remove a tier that is associated with a volume, an error (shown in bold) similar to the following is returned:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/remove?
name=ksTestTier' --user mapr:mapr
{"timestamp":1524675381333,"timeofday"
:"2018-04-25 09:56:21.333 GMT-0700
AM","status":"ERROR","errors":
[{"id":10003,"desc":"Can not remove
```

last-updated: Jun 06, 2024

```
tier, as some volumes are still using
it."}]}
```

For more information, see tier remove on page 2539.

Managing Storage Policies

About this task

Data offload is driven by rules, which are configured per volume. Data offload rule can be based on size of file (`s`), owner (`u`, `g`, or `p`) of the file, and/or file modification timestamp (`m`). You can apply one rule per volume.

When a rule is associated with a volume, the rule is first applied on the files in the tiering-enabled volume. When applied on the files in the tiering-enabled volume, the offload is triggered for all files in the snapshot chain as well when the criteria in the rule is met. If the file does not exist in the tiering-enabled volume, rule is applied on the latest state of the file in the snapshot chain. If the file exists in the tiering-enabled volume but has no latest state or if the file was deleted in the tiering-enabled volume, offload does not happen.

Rules can be defined using a combination of the following:

`u`	Username or user ID, as configured in the OS registry (such as `/etc/passwd` file, LDAP, etc.), of a specific user. **Usage:** `u:<username or user ID>`
`g`	Group name or group ID, as configured in the OS registry (such as `/etc/group` file, LDAP, etc.), of a specific group. **Usage:** `g:<groupname or group ID>`

last-updated: Jun 06, 2024

a	(`atime`) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending s to value and the number of days can be specified by appending d to the value. **Usage:** • `"a:<value>s"` — specifies `atime` in seconds • `"a:<value>d"` — specifies `atime` in days **NOTE:** If the system time on CLDB and file server nodes are different, the `atime` rule for offloading data may not work as intended. This tier rule is matched and files are offloaded, when **all** of the following conditions are met: **1.** `atime` tracking is enabled at volume level **2.** Time since `atime` that is configured on the volume is more than the time specified in the rule **3.** Duration since the file was last accessed is more than the time specified in the rule Assume that the `atime` feature is enabled on the volume and that the time in the rule is set to **a:300s**. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since `atime` tracking is enabled, is more than 300s. The volume level parameter `atimeTrackingStartTime` denotes the start time of `atime`. For more information, see Tuning Last Access Time on page 531.
m	(`mtime`) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending s to value and the number of days can be specified by appending d to the value. **Usage:** • `"m:<value>s"` — specifies mtime in seconds • `"m:<value>d"` — specifies mtime in days All files that are not modified since the specified amount of time, are offloaded. **NOTE:** If the system time on CLDB and file server nodes are different, the mtime rule for offloading data may not work as intended.

s	The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: `b` for bytes, `k` for kilobytes, `m` for megabytes, or `g` for gigabytes. **Usage** • `"s:<value>b"` — specifies file size in bytes • `"s:<value>k"` — specifies file size in KB • `"s:<value>m"` — specifies file size in MB • `"s:<value>g"` — specifies file size in GB All files whose size exceeds the specified size are offloaded.

Or, use the following:

p	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
`""`	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

&	AND operation to combine multiple expressions as the criteria for the rule.
|	OR operation to indicate either of the expressions as the criteria for the rule.
( )	Delimiters for subexpressions.

For volumes configured for erasure coding, a default storage policy, `default.ectier.rule` (ID `1` and expression p), is applied if one is not specified.

You can create, associate, and remove rules using the MapR Control System, the CLI, and REST API.

Creating a Storage Tier Policy
Explains how to create a tiering policy for storage using either the Control System, the CLI, or the REST API.
Creating a Storage Tier Policy Using the Control System

About this task
To create a storage tier policy (or rule) using the Control System:

Procedure

1. Log in to the Control System, click **Data** > **Volumes**, and then do one of the following:

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   - Go to the **Storage Policies** tab if you wish to create a storage policy that is not (yet) associated with a volume.

last-updated: Jun 06, 2024

- Click **Create Volume** if you wish to create a storage policy for a volume when you are creating the volume.

  NOTE: You must enable data tiering to create the storage policy.

- Click **Edit Volume** in the volume information page if you wish to create a storage policy for a volume when you are editing the volume settings.

2. Click one of the following to display the **Create Storage Policy** dialog.
   - **Create Policy** if you are in the **Storage Policies** tab.
   - **Create** link associated with the **Storage Policy** field if you are in the **Create New Volume** page.
   - **Create** link associated with the **Storage Policy** field if you are in the **Edit Volume** page.
3. Enter a name for the storage policy in the **Storage Policy Name** text field.
4. Choose **Build rule** or **Rule expression** radio button to define the criteria for offloading data.

   Use the **Build rule** option to build simple rules. Click `Add Condition` to add one of the following entities:
   - Group
   - User
   - File size
   - Time since the file was modified
   - Time since the file was accessed

   Use a condition group, to add AND and OR conditions.

   Click `Add condition group` to add AND and OR conditions. You can toggle the AND and OR conditions as needed.

   Use the **Rule expression** option to create advanced rules that comprise a combination of the following expressions:

u	Username or user ID, as configured in the OS registry (such as `/etc/passwd` file, LDAP, etc.), of a specific user. **Usage:** `u:<username or user ID>`
g	Group name or group ID, as configured in the OS registry (such as `/etc/group` file, LDAP, etc.), of a specific group. **Usage:** `g:<groupname or group ID>`

a	(`atime`) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending `s` to value and the number of days can be specified by appending `d` to the value. **Usage:** • `"a:<value>s"` — specifies `atime` in seconds • `"a:<value>d"` — specifies `atime` in days **NOTE:** If the system time on CLDB and file server nodes are different, the `atime` rule for offloading data may not work as intended. This tier rule is matched and files are offloaded, when **all** of the following conditions are met: **a.** `atime` tracking is enabled at volume level **b.** Time since `atime` that is configured on the volume is more than the time specified in the rule **c.** Duration since the file was last accessed is more than the time specified in the rule Assume that the `atime` feature is enabled on the volume and that the time in the rule is set to **a:300s**. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since `atime` tracking is enabled, is more than 300s. The volume level parameter `atimeTrackingStartTime` denotes the start time of `atime`. For more information, see Tuning Last Access Time on page 531.
m	(`mtime`) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending `s` to value and the number of days can be specified by appending `d` to the value. **Usage:** • `"m:<value>s"` — specifies mtime in seconds • `"m:<value>d"` — specifies mtime in days All files that are not modified since the specified amount of time, are offloaded. **NOTE:** If the system time on CLDB and file server nodes are different, the mtime rule for offloading data may not work as intended.

s	The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: `b` for bytes, `k` for kilobytes, `m` for megabytes, or `g` for gigabytes. **Usage** • `"s:<value>b"` — specifies file size in bytes • `"s:<value>k"` — specifies file size in KB • `"s:<value>m"` — specifies file size in MB • `"s:<value>g"` — specifies file size in GB All files whose size exceeds the specified size are offloaded.

Or, use the following:

p	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
`""`	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

&	AND operation to combine multiple expressions as the criteria for the rule.
|	OR operation to indicate either of the expressions as the criteria for the rule.
( )	Delimiters for subexpressions.

If a rule is not defined, the default rule, which is all files (p), is associated with the storage policy.

5. Click **Create Policy** to create the storage policy.

Creating a Rule Using the CLI and REST API

About this task

CLI

Run the following command to create a rule:

```
$ maprcli tier rule create -name
<rule_name> -expr <expressions>
```

REST

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/create?
name=rule1&expr=m:365d' --user
mapr:mapr
{"timestamp":1519681475025,"timeofday"
:"2018-02-26 01:44:35.025 GMT-0800
PM","status":"OK","total":0,"data":
[],"messages":["Successfully created
rule: 'rule1'"]}
```

last-updated: Jun 06, 2024

For more information, see tier rule create on page 2540.

Viewing the List of Storage Tier Policies
Explains how to view tiering policies for storage using either the Control System, the CLI, or the REST API.
Viewing the List of Storage Tier Policies Using the Control System

Procedure

- Log in to the Control System and click **Data** > **Volumes** > **Storage Policies**.

  NOTE: The **Storage Policies** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

  The list of storage policies displays. For each storage policy, the page displays the following:

Column Name	Column Description
Policy Name	The name of the policy.
Detail	The policy details.

  You can:

  - Create a Policy
  - Edit a Policy
  - Remove a Policy

Viewing the List of Storage Tier Policies Using the CLI and REST API

About this task

CLI

Run the following command to retrieve the list of tiers:

```
# maprcli tier rule list
```

REST

Send a request of type GET. For example:

```
# curl -k -X GET 'https://
abc.sj.us:8443/rest/tier/rule/
list' --user mapr:mapr
{"timestamp":1525728727729,"timeofday"
:"2018-05-07 02:32:07.729 GMT-0700
PM","status":"OK","total":6,"data":
[{"ruleid":"1","rulename":"default.ect
ier.rule","expression":"m:1d"},
{"ruleid":"2","rulename":"rule2","expr
ession":"s:5g"},
{"ruleid":"3","rulename":"rule1","expr
ession":"m:365d"},
{"ruleid":"4","rulename":"rule3","expr
ession":"u:m7user1"},
{"ruleid":"5","rulename":"rule4","expr
ession":"p"},
{"ruleid":"6","rulename":"testRule","e
xpression":"u:m7user1 | (u:mapr &
(s:5g | m:365d))"}]}
```

For more information, see tier rule list on page 2547.

last-updated: Jun 06, 2024

Modifying a Storage Tier Policy

Explains how to modify a storage tier policy using either the Control System, CLI, or the REST API.

About this task

If you modify a rule that is currently in use, the changes in the rule are only applied on future offloads; data offloaded using existing rule is not impacted by the change in the rule.

Modifying a Rule Using the Control System

Procedure

1. Log in to the Control System and go to **Storage Policies** tab in the **Data** > **Volumes** page.

   NOTE: The **Storage Policies** tab is under the **Volumes** menu in the Kubernetes version of the Control System.

   The list of storage policies displays.

2. Click the storage policy name to display the **Edit Storage Policy** window.

3. Make changes to the rule:

   You can modify the basic rule to:

   - Add (⊕) or remove (⊖) users and/or groups.
   - Change the name of the users and/or groups.
   - Change the number of days since the file was last modified for users and/or groups.

   If you switch from a basic rule to an advanced rule, all expressions from the basic rule are carried over to the advanced rule. You can modify an advanced rule using a combination of the following expressions:

u	Username or user ID, as configured in the OS registry (such as `/etc/passwd` file, LDAP, etc.), of a specific user. **Usage:** `u:<username or user ID>`
g	Group name or group ID, as configured in the OS registry (such as `/etc/group` file, LDAP, etc.), of a specific group. **Usage:** `g:<groupname or group ID>`

last-updated: Jun 06, 2024

a	(`atime`) Time (in seconds or days) since the files were last accessed. The number of seconds can be specified by appending `s` to value and the number of days can be specified by appending `d` to the value. **Usage:** • `"a:<value>s"` — specifies `atime` in seconds • `"a:<value>d"` — specifies `atime` in days **NOTE:** If the system time on CLDB and file server nodes are different, the `atime` rule for offloading data may not work as intended. This tier rule is matched and files are offloaded, when **all** of the following conditions are met: **a.** `atime` tracking is enabled at volume level **b.** Time since `atime` that is configured on the volume is more than the time specified in the rule **c.** Duration since the file was last accessed is more than the time specified in the rule Assume that the `atime` feature is enabled on the volume and that the time in the rule is set to **a:300s**. Based on this rule, all files that are not accessed since 300s, are offloaded. However, this rule is valid only if time since `atime` tracking is enabled, is more than 300s. The volume level parameter `atimeTrackingStartTime` denotes the start time of `atime`. For more information, see Tuning Last Access Time on page 531.
m	(`mtime`) Time (in seconds or days) since the files were last modified. The number of seconds can be specified by appending `s` to value and the number of days can be specified by appending `d` to the value. **Usage:** • `"m:<value>s"` — specifies mtime in seconds • `"m:<value>d"` — specifies mtime in days All files that are not modified since the specified amount of time, are offloaded. **NOTE:** If the system time on CLDB and file server nodes are different, the mtime rule for offloading data may not work as intended.

s	The size of the file in bytes, kilobytes, megabytes, or gigabytes. The size of the file can be specified by appending one of the following to the value: `b` for bytes, `k` for kilobytes, `m` for megabytes, or `g` for gigabytes. **Usage** • `"s:<value>b"` — specifies file size in bytes • `"s:<value>k"` — specifies file size in KB • `"s:<value>m"` — specifies file size in MB • `"s:<value>g"` — specifies file size in GB All files whose size exceeds the specified size are offloaded.

Or, use the following:

p	(Default) Specifies all files. Specifies that this operation is applicable to all the files without restriction. This cannot be combined with any other operator.
`""`	Indicates none of the files. Specifies that this operation cannot be performed on any of the files.

Use the following to string multiple criteria for offload:

&	AND operation to combine multiple expressions as the criteria for the rule.
|	OR operation to indicate either of the expressions as the criteria for the rule.
( )	Delimiters for subexpressions.

You cannot switch from an advanced rule that includes the following to a basic rule because the following are not supported in a basic rule:

- p — All the files
- s — The size of the file
- & — The AND operation used for specifying multiple users (u), groups (g), or criteria
- | — The OR operation used with s or m
- "" — None of the files.
- ( ) — Subexpressions

NOTE: The basic rule must contain mtime (`m`). It can also include one or more users or groups separated by the OR operation (`|`).

4. Click **Save Changes** to save the storage policy changes.

last-updated: Jun 06, 2024

Modifying a Rule Using the CLI and the REST API

About this task

CLI

Run the following command to modify a storage policy:

```
$ maprcli tier rule modify -name
<rule_name> -json
```

REST API

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/modify?
name=sampleRule&expr=m:3d' --user
mapr:mapr
{"timestamp":1523587392465,"timeofday"
:"2018-04-12 07:43:12.465 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully updated
rule: 'sampleRule'"]}
```

For more information, see `tier rule modify` on page 2548.

Specifying a Storage Tier Policy

Explains how to associate a storage tier policy with a tiering-enabled volume using either the Control System or the CLI.

Specifying a Storage Tier Policy Using the Control System

About this task

You can associate a storage policy with a tiering-enabled volume when you are:

- Creating a volume by clicking **Create Volume** in the **Data** > **Volumes** page.

  NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

- Editing the tiering-enabled volume by clicking **Edit Volume** button in the volume information page.

To associate a storage policy with the volume, in the **Create Volume** or **Edit Volume** page:

Procedure

1. Click the **Browse** link associated with the **Storage Policy** field to display the **Browse Storage Policies** window.
2. Review the name and detail of each storage policy and choose a storage policy from the list.
3. Click **Select** to associate the storage policy with the volume.
4. Complete the steps for creating or editing the volume.

Specifying a Storage Tier Policy Using the CLI and REST API

About this task

You can associate a rule with a tiering-enabled volume by specifying the `tieringrule` parameter with the `volume create` on page 2588 or `volume modify` on page 2676 command.

last-updated: Jun 06, 2024

CLI

Run a command similar to the following to associate a rule when:

- Creating a volume:

```
maprcli volume
create -name <volName> -path
<mountPath> -tieringenable
true -tiername
<tierName> -tieringrule
<ruleName> -json
```

  For the list of all other required and optional parameters, see volume create on page 2588.

- Editing the volume:

```
maprcli volume modify -name
<volName> -tieringrule
<ruleName> -json
```

  For the list of all other required and optional parameters, see volume modify on page 2676.

REST

Send a request of type POST. For example, to associate a rule when:

- Creating a volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&tie
ringenable=true&tiername=<tierName>
&tieringrule=<ruleName>' --user
mapr:mapr
```

  For the list of all other required and optional parameters, see volume create on page 2588.

- Editing the volume:

```
curl -k -X POST 'https://
<host>:8443/rest/volume/modify?
name=<volName>&tieringrule=<ruleNam
e>' --user mapr:mapr
```

  For the list of all other required and optional parameters, see volume modify on page 2676.

Removing a Storage Policy

Explains how to remove tiering policies for storage using either the Control System, the CLI, or the REST API.

About this task

WARNING: You cannot remove a storage policy that is associated with a volume.

last-updated: Jun 06, 2024

Removing a Rule Using the Control System

Procedure

1. Log in to the Control System and go to **Storage Policies** tab under **Data** > **Volumes**.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

   The list of storage policies displays.

2. Select the checkbox associated with the storage policy to remove and click **Remove Policy**.
   The **Remove Policy** confirmation window displays.

3. Review the list of policies to remove and click **Remove**.

Removing a Rule Using the CLI and the REST API

About this task

CLI

Run the following command to remove a storage policy that is not associated with a volume:

```
# maprcli tier rule remove -name
<rule_name>
```

If you try to remove a rule associated with a volume, the command returns an error (shown in bold) similar to the following:

```
# maprcli tier rule remove -name
rule1 -json
{
   "timestamp":1516771655669,
   "timeofday":"2018-01-23
09:27:35.669 GMT-0800",
   "status":"ERROR",
   "errors":[{
      "id":10003,
      "desc":"Cannot remove rule, as
some volumes are still using it."
   }]
}
```

REST

Send a request of type POST. For example:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/remove?
name=sampleRule' --user mapr:mapr
{"timestamp":1523571783113,"timeofday"
:"2018-04-12 03:23:03.113 GMT-0700
PM","status":"OK","total":0,"data":
[],"messages":["Successfully deleted
rule: 'sampleRule'"]}
```

If you try to remove a storage policy associated with a volume, the response contains an error (shown in bold) similar to the following:

```
# curl -k -X POST 'https://
abc.sj.us:8443/rest/tier/rule/remove?
name=sampleRule' --user mapr:mapr
{"timestamp":1523571741636,"timeofday"
:"2018-04-12 03:22:21.636 GMT-0700
PM","status":"ERROR","errors":
[{"id":10003,"desc":"Can not remove
rule, as some volumes are still using
it."}]}
```

For more information, see tier rule remove on page 2550.

Using Storage Labels

Describes the Storage Labels feature.

Synopsis of the Storage Labels Feature

Different applications have different requirements such as low latency, high throughput, and low variance in response times. Storage devices with various characteristics, for example SSD over SATA or SSD over NVME, are available as off-the-shelf storage. Therefore, it is now possible to cater exactly to the storage requirements of each application.

The Storage Label feature allows you to store particular kinds of data on particular classes of devices. For example, you could place data that needs to be fetched with lower latency on Solid State Drives (SSD), while placing data that can afford to be fetched with higher latency on Hard Disk Drives (HDD). Both classes of devices can be on the same node.

Use Cases for Storage Labels

Example use cases include:

- Latency-sensitive data can be placed on SSD, while data that is very rarely read can be placed on HDD.
- Active (warm) data can be placed on SSD while rarely used (cold) and archived data can be placed on HDD.
- Local volumes for Map Reduce tasks can be placed on SSD.
- Data can be securely segregated. For example, all finance data can be placed on volumes marked *finance*, engineering data on volumes marked *engineering*, and HR on volumes marked *HR*.

Components of the Storage Labels Feature

Storage Labels help you confine volumes to specific storage pools, to meet your desired objectives (such as low latency).

The Storage Labels feature has three main components: Labels, Storage Pools and Volumes.

What is a Label?

The Label acts as the bridge between a Storage Pool and a Volume.

The Label is a tag that associates a Volume with a Storage Pool. For example, a volume marked *SSD* will always be placed on a Storage Pool marked with the name *SSD*.

Labels have the following characteristics:

- Are a string of printable ASCII characters that should begin with a letter or a number in most cases, except when they represent device classes. For a device class, the label may contain properties that are enforced when the label is assigned to a Storage Pool or a Volume. For example, label SSD could have the following properties:

```
{
num_disks_per_instance; #used in partioning disks among multiple
instances of a file server
                          on the same node.
max_active_io_per_disk; # Number of concurrent IO operations to be used
on the disk.
}
```

- Are case-insensitive.
- Have a internal numeric value attached to each of them.
- Have to be registered with the CLDB before use.

What is a Storage Pool?

In the HPE Data Fabric platform, a storage pool (SP) constitutes a logical storage device. A SP can be composed of SSDs, while another SP can be composed of HDDs. A heterogeneous SP that is made up of different classes of devices is not permitted.

However, multiple classes of SPs can reside on the same node.

You can assign a single label to each SP to identify it. A SP that has not been labeled, automatically assumes the **default** label (with an internal numeric value of 0).

What is a Volume?

In the HPE Data Fabric platform, a volume is the logical unit for a class of data. Therefore, storing various types of data on various classes of devices is essentially placing particular volumes on the appropriate classes of devices.

Each volume can have only one label. Volumes that do not have a label, assume the **default** label with a numeric value of 0.

The CLDB servers are responsible for keeping track of these labels and moving volumes across storage pools based on these labels.

A volume is placed only on the SP matching its label. A volume labelled SSD is placed only on a SP with the label SSD. Similarly, a volume with the **default** label, will only be placed on a SP with the **default** label.

To override this matching placement, use the special label **anywhere** for a volume. A volume with the **anywhere** label is placed on any SP irrespective of its label. Use this label frugally as you might inadvertently end up storing a volume on your expensive disks where it is not needed to be stored.

The Disk Balancer takes care of moving volumes to appropriate SPs as needed. For example, assume that a volume with a label marked **anywhere** is stored on a SP with a label **SSD**. Now a request comes in to place volumes that are explicitly labelled as **SSD** but there are no more SPs labelled as **SSD**. The Disk Balancer will then move the volume marked **anywhere** off the SP labelled as **SSD** on to any other SP, and accommodate the volumes explicitly labelled as **SSD**.

You might assign a label to a namespace container of a volume. If a label is not assigned, the namespace container inherits the label of its data container. The namespace label is NOT changed when moving a volume from one label to another. The namespace inherits the data container label at the time of volume creation if you do not specify a label to a namespace container explicitly.

last-updated: Jun 06, 2024

However, if you assign a label to a namespace container but not to a data container, the data container is assigned the **default** label.

Once the data container and the namespace container are labelled, their labels are independent of each other.

At the time of Volume creation, the system chooses the SPs with matching labels. If the volume or its namespace container is associated with a label, creation fails if there are insufficient nodes with SPs having the same label.

If only one matching SP is present for a 2/3-way replicated volume, only a single replica is created for that volume.

When creating containers, the system checks for nodes/storage pools with matching labels in the topology requested. Container creation fails if there are no nodes/storage pools with matching labels in the topology requested, even if there are such nodes/storage pools in other topologies.

When the label of a volume is changed, replicas cannot be migrated within the file server, from one SP with the old label to another SP with the desired label. If there are no other SPs, all old copies will not be fully migrated to the new desired label.

ATTENTION: CLDB volumes are an exception. CLDB volumes can be created on any storage pool. Labels do not apply to CLDB volumes.

Enable the Storage Labels Feature on an Upgraded Cluster

The Storage Labels feature is already enabled on a new HPE Data Fabric version 6.2 cluster.

On a cluster upgraded to version 6.2, enable the Storage Labels feature with the command:

```
maprcli cluster feature enable -name cldb.lbs.support
```

This feature takes effect immediately without the need to fail over CLDB. This feature cannot be disabled once it is enabled.

Usage Sequence

You must perform label creation and assignment in the following sequence:

1. Register a label - Ensures that random labels are not assigned to SPs and Volumes. A label once registered cannot be deleted or prevented from being used.
2. Assign a label to a Storage Pool - Select any disk in the SP to assign a label. You can create a storage pool, and simultaneously set its label as well.
3. Assign a label to a volume. You can assign a label at volume creation using the volume create on page 2588 command.

Override Topology and Storage Pool Adherences

You can override topology and SP adherences for critically under-replicated containers. The Storage Labels feature contains the following two settings.

- `honor.topology.for.critical.replication` - default value is *1* (true). When set to *0* (false), critically under-replicated containers are replicated outside their topology, if space is not available within their topology.

  ```
  /opt/mapr/bin/maprcli config save -values
  '{"honor.topology.for.critical.replication":"0"}'
  ```

- `honor.label.for.critical.replication` - default value is *1* (true). When set to *0* (false), critically under-replicated containers are replicated on other SPs, even if their labels do not match the labels of the SPs.

```
/opt/mapr/bin/maprcli config save -values
'{"honor.label.for.critical.replication":"0"}'
```

Storage Label Commands

Use the label add on page 2245 command to register a label.

Use the disk add on page 2125 or the disk setlabel on page 2127 command to label an SP.

Use the volume create on page 2588 or the volume move on page 2696 command to label a volume.

Use the label list on page 2249 command to list all registered labels.

Use the node list on page 2264 command to list all labels associated with a node.

Use the dashboard info on page 2108 command to view the list of registered labels and the number of associated volumes and storage pools.

Use the mrconfig sp list command to view all storage pool information, including the labels associated with the storage pools.

Use the disk list command to view the labels associated with disks.

Lists nodes in the cluster.

dashboard info on page 2108
Displays a summary of information about the cluster.

mrconfig sp list on page 2956
Displays information about configured storage pools.

mrconfig disk list on page 2931

last-updated: Jun 06, 2024

dump volumeinfo on page 2172
Returns information about volumes and the associated containers. For JSON formatted output, use the -json option from the command line.

configure.sh on page 2821
Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Ezmeral Data Fabric client nodes, and configuring services for a node.

Administering Files and Directories

The following sections provide configuration information that you can use to set chunk size and compression in file system, as well as information on hard links, extended attributes, and core files:

Using Global File System Checking

Describes how to use the `gfsck` command to check and repair file system errors.

About this task

You can use the `gfsck on page 2875` (global file system check) command to perform a consistency check and repair operation on a volume or volume snapshot, including the following entities:

- All cross-container links (for example, from file to *filelet*, or from table to tablets)
- The tabletmap key range
- The attributes of *filelet* (uid/gid/mode)

This command identifies the unreachable files, directories, and tables in the volume, and moves them to */lost+found* to be repaired. It also identifies and fixes any unreachable DB inodes or dangling pointers to lost inodes.

Procedure

1. Take the affected storage pools offline by running the mrconfig sp offline on page 2959 command.
   For example:

   ```
   /opt/mapr/server/mrconfig sp offline /dev/sdc
   ```

2. Execute the `fsck on page 2873` command on the storage pools or disks.
3. Bring the storage pools back online by running the `mrconfig sp online on page 2960` command.
   For example:

   ```
   mrconfig sp online /dev/sdc
   ```

4. Run the `gfsck` command on the affected volumes, or snapshots, with the appropriate options.
   If there are alarms, such as `DataUnavailableAlarm` or `DataUnderReplicatedAlarm`, do not run the `gfsck` command with the `-r` (`--repair`) option. Running the `gfsck` command with the `-r` (`--repair`) option, might result in data loss. If necessary, first run `gfsck` without the `-r` (`--repair`) option, and attempt to repair only after analyzing the command output.

Related reference

gfsck on page 2875

Describes how you can use the `gfsck` command, under the supervision of HPE Ezmeral Data Fabric Support or Engineering, to perform consistency checks and appropriate repairs on a volume, or a volume snapshot.

Setting file system Permissions

The MapR file system permissions are similar to the POSIX permissions model. Each file and directory is associated with a user (the *owner*) and a group. You can set read, write, and execute permissions separately for:

- the owner of the file or directory.
- members of the group associated with the file or directory.
- all other users.

The permissions for a file or directory are called its *mode*. The mode of a file or directory can be expressed in two ways:

- Text - a string that indicates the presence of the read (`r`), write (`w`), and execute (`x`) permission or their absence (`-`) for the owner, group, and other users respectively. Example: `rwxr-xr-x`
- Octal - three octal digits (for the owner, group, and other users), that use individual bits to represent the three permissions. Example: `755`

Both `rwxr-xr-x` and `755` represent the same mode; the owner has all permissions, and the group and other users have read and execute permissions only.

When you access the MapR file system layer over NFS, the file-level permissions are controlled through the Linux interface by using the `chmod` (change mode) command or the `chown` (change owner) command, as well as the `hadoop fs -chmod` and `hadoop fs -chown` equivalents. For example:

```
chown jsmith /mapr/my.cluster.com/jsmith/fileA
hadoop -fs chown jsmith /mapr/my.cluster.com/jsmith/fileA
chmod 744 /mapr/my.cluster.com/jsmith/fileA
hadoop -fs chmod 744 /mapr/my.cluster.com/jsmith/fileA
```

These commands grant a user whose username is `jsmith` the read, write, and execute privileges on `fileA`.

Once you set file permissions, authorization checks are performed when a file is opened, *and* on every file access.

NOTE: To further protect your data, the MapR file system data cache is never included in a file server core dump.

Text Modes

String modes are constructed from the characters in the following table:

Text	Description
u	The file's owner.
g	The group associated with the file or directory.
o	Other users (users that are not the owner, and not in the group).
a	All (owner, group and others).

last-updated: Jun 06, 2024

Text	Description
=	Assigns the permissions Example: "a=rw" sets read and write permissions and disables execution for all.
-	Removes a specific permission. Example: "a-x" revokes execution permission from all users without changing read and write permissions.
+	Adds a specific permission. Example: "a+x" grants execution permission to all users without changing read and write permissions.
r	Read permission
w	Write permission
x	Execute permission

Octal Modes

To construct each octal digit, add the value of each permission that you want to grant:

- Read: 4
- Write: 2
- Execute: 1

For example, 7 which provides read, write, and execute permissions because 4+2+1=7.

Syntax

You can change the modes of directories and files in the MapR storage using either the `hadoop fs` command with the `-chmod` option, or using the `chmod` command via NFS. The syntax for both commands is similar:

- ```
  hadoop fs -chmod [-R] <MODE>[,<MODE>]... | <OCTALMODE> <URI> [<URI> ...]
  ```
- ```
  chmod [-R] <MODE>[,<MODE>]... | <OCTALMODE> <URI> [<URI> ...]
  ```

Parameters and Options

The following table provides the command parameters and options with their descriptions:

Parameter/Option	Description
-R	If specified, this option applies the new mode recursively throughout the directory structure.
MODE	A string that specifies a mode.
OCTALMODE	A three-digit octal number that specifies the new mode for the file or directory.
URI	A relative or absolute path to the file or directory for which to change the mode.

last-updated: Jun 06, 2024

Examples

The following examples are all equivalent:

- `chmod 755 script.sh`
- `chmod u=rwx,g=rx,o=rx script.sh`
- `chmod u=rwx,go=rx script.sh`

Managing File and Directory ACEs

Describes the implications of setting access control expressions (ACEs) on files and directories.

A file *ACE* allows you to define access (allowlist and denylist) to files and directories for a combination of users, groups, and roles. If ACEs are not set, POSIX mode bits for the file or directory are used to grant or deny access to the file or directory.

When you set ACEs, Data Fabric software sets or resets the corresponding POSIX mode bits to match the permissions granted through ACEs. For more information, see Setting/Modifying File and Directory ACEs.

- If both ACEs and POSIX mode bits are set, access is granted if access is allowed through ACEs or POSIX mode bits.
- If ACEs are not set, POSIX mode bits are used to grant access.
- If neither ACEs nor POSIX mode bits is set, access is denied.

The owner of the file or directory (and `mapr` and `root` users) can set, modify, and remove ACEs for that file or directory using `hadoop mfs` commands.

File ACEs

You can set and modify permissions to read, write, and execute files by using the `hadoop mfs` command or the FileACE Java APIs on page 1864 and FileACE C APIs on page 1864. Specifically, the following access types are supported:

Access Type		
Command Line	**Java API (Enum)**	**Description**
`-readfile`	`READFILE`	Read a file.
`-writefile`	`WRITEFILE`	Write to a file.
`-executefile`	`EXECUTEFILE`	Execute a file.

For more information, see `hadoop mfs`, FileACE Java APIs on page 1864, and FileACE C APIs on page 1864.

Directory ACEs

You can set the same ACEs on directories that you set on files. In addition, directory ACEs support permissions to list, add child, delete child, and lookup directories using the `hadoop mfs` command. Specifically, the following access types are supported:

last-updated: Jun 06, 2024

Access Type		Description
Command Line	**Java API (Enum)**	
`-readfile`	`READFILE`	Read a file.
`-writefile`	`WRITEFILE`	Write to a file.
`-executefile`	`EXECUTEFILE`	Execute a file.
`-readdir`	`READDIR`	List the contents of a directory. This access is required to write and/or execute files in the directory.
`-lookupdir`	`LOOKUPDIR`	Lookup a file in a directory. This access is required to find, read, write, and/or execute files in the directory.
`-addchild`	`ADDCHILD`	Add a file or subdirectory.
`-deletechild`	`DELETECHILD`	Delete a file or subdirectory.

Although you can set both file and directory ACEs on directories, only the directory ACEs are used for determining access to the directory. The file ACE on the directory is used as the default ACE setting for new files under that directory.

By default, when you set ACEs on a parent directory:

- Permissions for existing files and subdirectories under that parent remain unchanged.
- New files under that parent inherit the file ACEs and corresponding POSIX mode bits of the parent directory, if available. Otherwise, new files get the default ACE, the empty string (""), which indicates that no one has permissions to read, write, or execute the file. POSIX mode bits are set on the file in the traditional way.
- New subdirectories under the parent inherit both the directory and file ACEs and corresponding POSIX mode bits from the parent directory.

NOTE: When accessing files and directories, the ACEs on files have no effect on accessing the parent directory.

Workaround for Execute Operation when ACES are set on an executable file

When ACEs are set on any file, mode bits are cleared. For a binary to execute, the kernel checks whether the execute bit is set or not, and restricts execution if it is not set. To run an executable file with ACEs set on it, use one of the following workarounds:

1. Set owner mode exec bit on binaries/shell scripts.
2. Set group mode exec bit on binaries/shell scripts.
3. Change owning group for the files to the group used in MapRAces, and set the executable group mode bit.

Setting File and Directory ACEs

Describes how to set ACEs for files and directories.

For files and directories, run the `hadoop mfs` command to set *ACE*s. After *ACE*s are set, by default, the corresponding POSIX mode bits are also set. POSIX mode bits for owner and owning group are deduced by evaluating the corresponding *ACE*s. POSIX mode bits for others is set only if `"p"` is given as the value for an *ACE*.

The following table lists POSIX mode bits and corresponding access types.

	ACE	POSIX Mode Bits
File	`readfile`	r
	`writefile`	w
	`executefile`	x
Directory	`readdir`	r
	`addchild`	w
	`deletechild`	w
	`lookupdir`	x

The POSIX mode bit that grants write (`w`) access to a directory is set only if the user, role, or group is granted permission for both access types (`addchild` and `deletechild`).

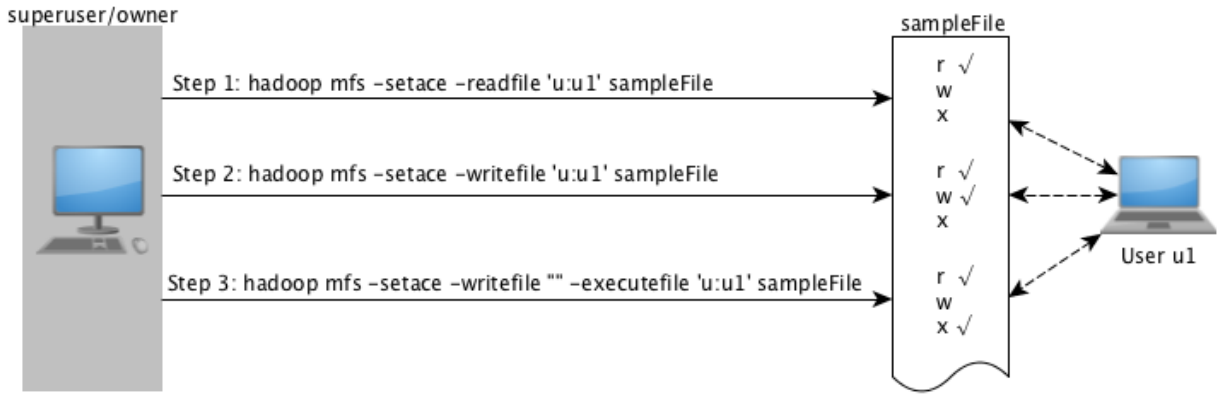
The `hadoop` command, by default, sets the POSIX mode bits that correspond to the given *ACE*s, and:

- Overwrites existing *ACE* values with new values, if specified, for access types that were previously set.
- Sets *ACE* values for access types that have not yet been set, if specified.
- Does not modify access types that are not specified with the command, regardless of how they were previously set.

WARNING: Changing the POSIX mode bits using `chmod` does not change the corresponding *ACE* setting and may result in different, conflicting permissions to files and directories.

File ACE Example
Illustrates setting access control expressions for files.

Suppose the following sequence of file *ACE* settings and corresponding POSIX mode bits are set for user u1.



As shown in the preceding illustration, in:

Step 1:

User u1 is granted permissions to read a file, `sampleFile`.

After the command runs, user u1 has permissions to (only) read the file. The POSIX mode bit for reading the file is set to u1 for owner/users.

There is no change in *ACE*s or POSIX mode bits for all other (write and execute) access types.

last-updated: Jun 06, 2024

Step 2:

User u1 is granted permissions to write to the same file.

After the command runs, user u1 has permissions to write to the file. The POSIX mode bit for writing to the file is set to u1 for owner/users.

There is no change in *ACE*s or POSIX mode bits for all other (read and execute) access types.

Step 3:

User u1's permissions are modified to remove write permission (using the empty string) and to grant access to execute file.

After the command runs, user u1 has permissions to execute the file, but user u1 can no longer write to the file. The POSIX mode bit for:

- Writing to the file is set to 0 for owner/users, groups, and others.
- Executing the file is set to u1 for owner/users.

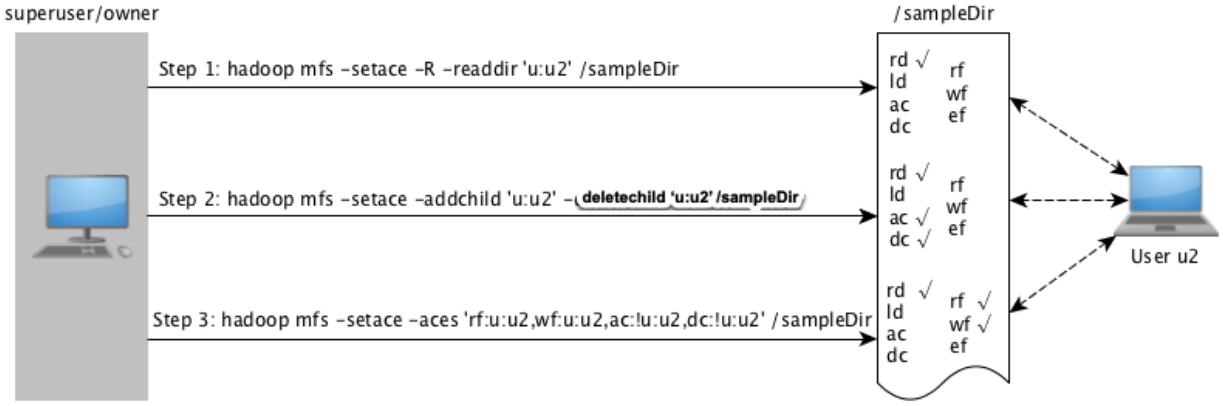
NOTE: When the empty string ("") is used to deny a specific type of file access, that type of file access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`).

There is no change in *ACE*s or POSIX mode bits for all other (read) access types.

Directory ACEs Example

Explains how to set access control expressions for directories.

For example, suppose the following diagram depicts the (command-line) sequence of directory *ACE* settings for user u2:



As shown in the preceding illustration, in:

Step 1:

User u2 is granted access to read directory and sampleDir, while all other directory/file *ACE*s are not specified.

After the command runs, user u2 has permissions to list the contents of the directory. The POSIX mode bits for listing the contents of the directory (`r`) is set to u2 for owner/users.

last-updated: Jun 06, 2024

	There is no change in *ACE*s or POSIX mode bits for all other (file- and directory-level) access types.
Step 2:	User u2 is granted permission only to add and delete child directories, while all other directory/file *ACE*s are not specified. After the command runs, user u2 has permissions to create and delete child directories. The POSIX mode bit for writing (`w`) to the directory for owner/user is set to u2 because user u2 is granted access for both (`addchild` and `deletechild`) access types. If user u2 creates child directories, by default, they inherit the *ACE* settings of the parent directory. There is no change in *ACE*s or POSIX mode bits for all other (file- and directory-level) access types.
Step 3:	User u2's permissions are modified to grant access to read and write to files in the directory. User u2's permissions for adding and deleting child directories are removed (using the negation operator). All other directory/file *ACE*s are not specified. After the command runs, user u2 can read and write to files in the directory, but user u2 can no longer add and delete child directories. The POSIX mode bits for directory write access (`w`) is set to 0 for owner/user. Although at the directory level, user u2 has permissions to read and write to files in the directory for existing files, the file level *ACE*s or the POSIX mode bits for the file are used to determine access. By default, user u2 gets read and write permissions to all new files created under the directory. If user u2 creates new files under the directory, the files inherit the file *ACE*s from the parent directory by default, and the POSIX mode bits for read (`r`) and write (`w`) access are set to u2 for owner/user. There is no change in *ACE*s or POSIX mode bits for all other (`lookupdir` and `executefile`) access types.

Deleting File and Directory ACEs

Describes how to delete file and directory ACEs using the CLI.

You can remove all *ACE* associated with a file or directory using the `hadoop mfs -delace` command. After you delete all the *ACE*s, the system sets the *ACE* for the file or directory to the default value, which is the empty string (`""`). The POSIX mode bits are not reset; if necessary, run the `chmod` command to reset POSIX mode bits.

You cannot remove specific access types that have been set. Use the empty string to deny specific types of access. After the empty string (`""`) is used to deny a specific type of access, that type of access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`). If you use the empty string (`""`) or the negation operation (`!`) to deny a specific type of access, the corresponding POSIX mode bit are also reset to match the *ACE* setting.

Managing Chunk Size

Describes the considerations for managing the chunk size for map tasks.

Files in the HPE Ezmeral Data Fabric filesystem are split into *chunks* (similar to Hadoop *blocks*) that are normally 256 MB by default. Any multiple of 65,536 bytes is a valid chunk size, but tuning the size correctly is important:

last-updated: Jun 06, 2024

- Smaller chunk sizes result in larger numbers of map tasks, which can result in lower performance due to task scheduling overhead.
- Larger chunk sizes require more memory to sort the map task output, which can crash the JVM or add significant garbage collection overhead. HPE Ezmeral Data Fabric can deliver a single stream at upwards of 300 MB per second, making it possible to use larger chunks than in the stock Hadoop implementation. Generally, it is wise to set the chunk size between 64 MB and 256 MB.

Chunk size is set at the directory level. Files inherit the chunk size settings of the directory that contains them, as do subdirectories on which chunk size has not been explicitly set. Any files written by a Hadoop application, whether using the file APIs or over NFS for the HPE Ezmeral Data Fabric, use chunk size specified by the settings for the directory where the file is written. If you change a directory's chunk size settings after writing a file, the file will keep the old chunk size settings. Further writes to the file will use the file's current chunk size.

NOTE: If chunk size is zero (`0`), when an application makes a request for block size, HPE Ezmeral Data Fabric will return 1073741824 (1GB); however, `hadoop mfs on page 5557` commands will continue to display `0` for chunk size.

Configuring Chunk Size

Chunk size also affects parallel processing and random disk I/O during MapReduce applications. A higher chunk size means less parallel processing because there are fewer map inputs, and therefore fewer mappers. A lower chunk size improves parallelism, but results in higher random disk I/O during shuffle because there are more map outputs. Set the `io.sort.mb` parameter to a value between 120% and 150% of the chunk size.

Here are the general guidelines for chunk size:

- For most purposes, set the chunk size to the default 256 MB and set the value of the `io.sort.mb` parameter to the default 380 MB.
- On very small clusters or nodes with not much RAM, set the chunk size to 128 MB and set the value of the `io.sort.mb` parameter to 190 MB.
- If application-level compression is in use, the `io.sort.mb` parameter should be at least 380 MB.

NOTE: If you have Drill running in the cluster, change the `store.parquet.block-size` parameter in Drill so that the Parquet block size is the same as the chunk size in the HPE Ezmeral Data Fabric filesystem. See Configuring the Parquet Block Size for more information.

Setting Chunk Size

You can set the chunk size for a given directory in two ways:

- Change the `ChunkSize` attribute in the .dfs_attributes file at the top level of the directory
- Use the command `hadoop mfs -setchunksize <size> <directory>`

For example, if the volume `test` is NFS-mounted at `/mapr/my.cluster.com/projects/test` you can set the chunk size to 268,435,456 bytes by editing the file `/mapr/my.cluster.com/projects/test/.dfs_attributes` and setting `ChunkSize=268435456`. To accomplish the same thing from the `hadoop` shell, use the following command:

```
hadoop mfs -setchunksize 268435456 /mapr/my.cluster.com/projects/test
```

Managing Compression

Lists the advantages of using compression.

Data Fabric provides compression for files stored in the cluster. Compression is applied automatically to uncompressed files unless you turn compression off. The advantages of compression are:

- Compressed data uses less bandwidth on the network than uncompressed data.
- Compressed data uses less disk space.

Choosing a Compression Setting

Lists the compression algorithms supported by data-fabric.

Data Fabric supports three different compression algorithms:

- lz4 (default)
- lzf
- zlib

Compression algorithms can be evaluated for compression ratio (higher compression means less disk space used), compression speed and decompression speed. The following table gives a comparison for the three supported algorithms. The data is based on a single-thread, Core 2 Duo at 3 GHz.

Compression Type	Compression Ratio	Compression Speed	Decompression Speed
lz4	2.084	330 MB/s	915 MB/s
lzf	2.076	197 MB/s	465 MB/s
zlib	3.095	14 MB/s	210 MB/s

Note that compression speed depends on various factors including:

- block size (the smaller the block size, the faster the compression speed)
- single-thread vs. multi-thread system
- single-core vs. multi-core system
- the type of codec used

Related Link

- LZO vs Snappy vs LZF vs ZLIB

Setting Compression on Files

Compression is set at the directory level. Any files written by a Hadoop application, whether via the file APIs or over NFS, are compressed according to the settings for the directory where the file is written. Sub-directories on which compression has not been explicitly set inherit the compression settings of the directory that contains them.

If you change a directory's compression settings after writing a file, the file will keep the old compression settings—that is, if you write a file in an uncompressed directory and then turn compression on, the file does not automatically end up compressed, and vice versa. Further writes to the file will use the file's existing compression setting.

WARNING: Only the owner of a directory can change its compression settings or other attributes. Write permission is not sufficient.

last-updated: Jun 06, 2024

File Extensions of Compressed Files
Lists extensions of compressed files.

By default, HPE Ezmeral Data Fabric does not compress files whose filename extensions indicate they are already compressed. The default list of filename extensions is as follows:

- bz2
- gz
- lzo
- snappy
- tgz
- tbz2
- zip
- z
- Z
- mp3
- jpg
- jpeg
- mpg
- mpeg
- avi
- gif
- png
- jar

The list of filename extensions not to compress is stored as comma-separated values in the `mapr.fs.nocompression` configuration parameter and can be modified with the `config save` command. For example, you can add `parquet` to the default list:

```
maprcli config save -values
'{"mapr.fs.nocompression":"bz2,gz,lzo,snappy,tgz,tbz2,zip,z,Z,mp3, \
jpg,jpeg,mpg,mpeg,avi,gif,png,parquet"}'
```

The list can be viewed with the `config load` command. Example:

```
maprcli config load -keys mapr.fs.nocompression
```

NOTE: The filename extensions given in the default list of filename extensions are case-sensitive. For example, Data Fabric compresses a file with the extension .JPG, even if .jpg files are not to be compressed, by default. If you do not want the files in the file system with the .JPG extension to be compressed, add JPG to the list of filename extensions for the `mapr.fs.nocompression` configuration parameter.

last-updated: Jun 06, 2024

Turning Compression On or Off on Directories Using the CLI

Explains how to turn off or turn on compression and optionally specify an algorithm, using the command line.

You can turn compression on or off for a given directory in two ways:

- Set the value of the `Compression` attribute in the .dfs_attributes file at the top level of the directory.
  - Set `Compression=lzf|lz4|zlib` to turn compression *on* for a directory.
  - Set `Compression=false` to turn compression *off* for a directory.
- Use the command hadoop mfs -setcompression on|off/lzf/lz4/zlib <dir|table>.

If you choose `-setcompression on` without specifying an algorithm, lz4 is used by default. This algorithm has improved compression speeds for HPE Ezmeral Data Fabric's block size of 64 KB.

The symbols for the various compression settings are explained here:

Symbol	Compression Setting
Z	lz4
z	zlib
L	lzf
U	Uncompressed, or previously compressed by another algorithm

Example

Suppose the volume `test` is NFS-mounted at `/mapr/my.cluster.com/projects/test`. You can turn off compression by editing the file `/mapr/my.cluster.com/projects/test/.dfs_attributes` and setting `Compression=false`. To accomplish the same thing from the `hadoop` shell, use the following command:

```
hadoop mfs -setcompression off /projects/test
```

You can view the compression settings for directories using the hadoop mfs -ls command. For example,

```

```

Suppose three directories `abc`, `klm`, and `xyz`. You can turn on compression and set different compression algorithm for the directories by running the following commands:

```
hadoop mfs -setcompression on /ksTestVol1/abc
hadoop mfs -setcompression lzf /ksTestVol1/klm
hadoop mfs -setcompression zlib /ksTestVol1/xyz
```

You can then view the compression settings for the directories using the hadoop mfs -ls command. For example:

```
hadoop mfs -ls /ksTestVol1/
  Found 3 items

Setting Compression During Shuffle

By default, MapReduce uses compression during the Shuffle phase. You can use the `-Dmapreduce.maprfs.use.compression` switch to turn compression *off* during the Shuffle phase of a MapReduce job. For example:

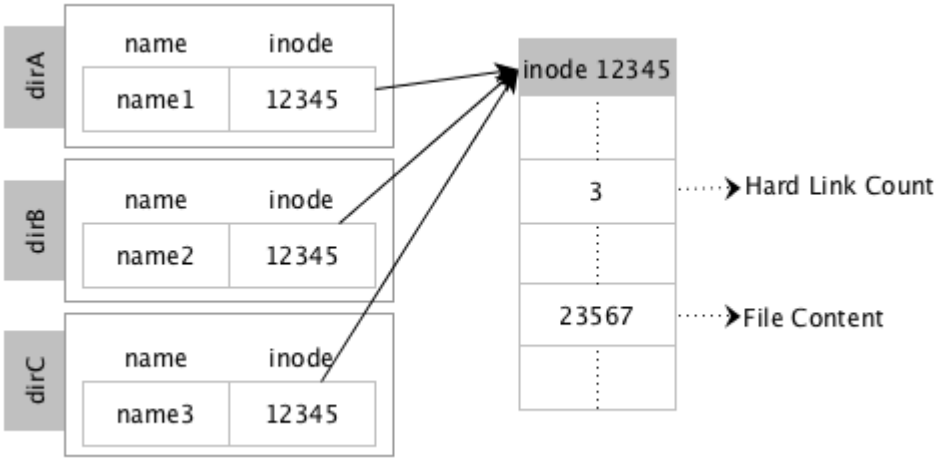
```
hadoop jar xxx.jar -Dmapreduce.maprfs.use.compression=false
```

Managing Hard Links

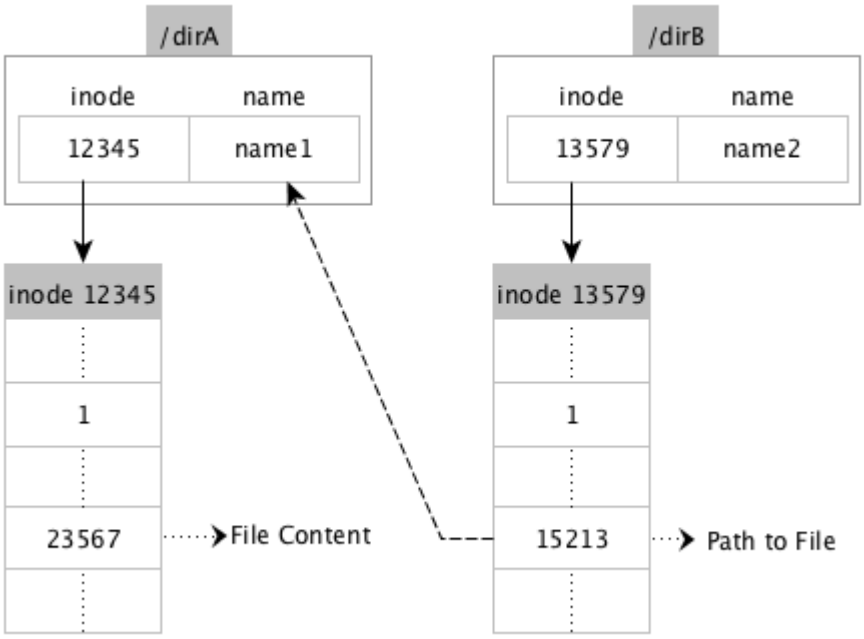
Explains what hard links are, and their limitations.

A hard link is a directory entry that associates a name with a file (or physical data) on the filesystem. Hard links allow multiple names to be associated with the same data (and associated inode) from within or outside of a directory. Every time a hard link is created, a directory entry is created and the inode (associated with the directory entry) remains the same across all hard links associated with that data. That is, all names associated with the data point to the same inode.

The following diagram illustrates the hard link semantics. Here, directory entries in dirA, dirB, and dirC for file names name1, name2, and name3 respectively all point to the inode 12345, which contains metadata including the text in the file and a count of the number of hard links to the file (or physical data).



In contrast, when a symbolic link is created, a new inode is created and the text part of the inode (associated with the symlink file) contains the path to the actual file. The following diagram illustrates the symbolic link semantics. Here, the directory entry in dirA for file name, name1, is associated with inode 12345, which contains the text in the file. The directory entry in dirB for symbolic link file, name2, is associated with inode 13579, which contains the path to file in dirA (*/dirA/name1*). Deleting the file, name1, in dirA will result in the symlink file in dirB, name2, pointing to stale content, which in turn will return errors when accessed.



Hard links can be created on regular files, symlink files, device files, and tables.

Limitations

- Hard links cannot be created on directories.
- Hard links cannot be created across volumes or clusters. Instead, use symbolic link to link to a file on a different volume.

last-updated: Jun 06, 2024

- Hard links within a volume are carried over to mirror volumes and volume snapshots. During cross-mirroring, there will be an error if support for hardlinks is not enabled on both the clusters.
- The `hadoop distcp` command cannot be used for creating and preserving copies of hard links.
- The maximum number of hard links is constrained by the integer width (32 bits), which means the maximum number possible for a file is 2^{32}.

Usage

Any user with access to the directory can create a hard link to any file under that directory. To create hard links, the user must have write permissions on the directory and execute permissions (to do the lookup for the path) on the target file. To read or modify the file, the user must have read or write permissions respectively on the file.

Errors

For information on the type of failures and errors, refer to the man page. In addition, please note that the EXDEV error is returned if command is run to create cross-volume or cross-cluster hard links.

Enabling Hard Links

By default, this feature is enabled on all new installation. If you upgrade, you must enable this feature. To enable this feature, run the following command:

```
maprcli cluster feature enable -name mfs.feature.hardlinks.support
```

Setting a Hard Link

Explains how to create a hardlink to a file.

To set a hard link using:

- POSIX loopbacknfs client or NFS client, run the following command:

  ```
  ln <sourcefile> <newfile>
  ```

  where <sourcefile> is the name of the file to link to and <newfile> is the name of the hard link, which must *not* already be present.

- Hadoop, run the following command:

  ```
  hadoop mfs -lnh <sourcefile> <newfile>
  ```

  where <sourcefile> is the name of the file (including full path) to link to and <newfile> is the name of the hard link (including the full path). When running this command, specify the full path to both files.

Retrieving the Number of Hard Links

Explains how to retrieve the number of hard links to a file.

To retrieve the number of hard links associated with a file, run the following command:

```
ls -l
```

The command, `ls -l`, will print the number of hardlinks in the second column. For example, your output will look similar to the following:

```
ls -l sample-link
  rw-r--r- 2 root root 0 Apr 21 11:09 sample-link
```

last-updated: Jun 06, 2024

To retrieve the list of the hard links associated with a file, run the following command:

```
find <dirpath> -samefile <sourcefile>
```

where `<dirpath>` is the path to the source file and `<sourcefile>` is the source file for the hard link. For example, your output will look similar to the following:

```
find . -samefile file8
  ./file8-link2
  ./file8-link100
  ./file8-link101
  ./file8
  ./file8-link
```

For POSIX (loopback NFS for the HPE Ezmeral Data Fabric) clients, the number of hardlinks to a file can be retrieved using the `stat64` system call. For example, your output will look similar to the following:

```
stat samplefile
  File: 'samplefile'
  Size: 0               Blocks: 0          IO Block: 131072 regular empty
file
  Device: 14h/20d Inode: 853785146   Links: 4
  Access: (0644/-rw-r--r--)  Uid: (    0/    root)   Gid: (    0/    root)
  Access: 2016-05-12 13:06:21.000000000 -0700
  Modify: 2016-05-12 13:06:30.002560000 -0700
  Change: 2016-05-12 13:06:30.002560000 -0700
```

If you are not using NFS for the HPE Ezmeral Data Fabric or the POSIX clients, to retrieve the number of hard links, you can run the `hadoop` command to retrieve the fid and then run the `maprcli` command to retrieve the number of hard links as follows. The `nlink` variable will print the number of links.

```
hadoop mfs -ls /p1
  Found 1 items
  -rw-r--r--  Z U U   3 root root       3054 2016-05-05 13:49  268435456 /p1
  p 2049.40.262550  node-31.lab:5660

maprcli fid stat -fid 2049.40.262550
  xattrInum  uid  atime       nblocks  deleteFlags     mtime
parent     nlink  type       version  size  mode  networkencryption
subtype   gid  compression
  0          0    1462481255  1        DeleteTypeNone  1462481376
2049.16.2  2      FTRegular  2097165  3054  644   false
FSTInval  0    lz4
```

Removing Hard Links

To remove a hard link using:

- Linux, run the following command:

  ```
  rm -f <hard link>
  ```

- Hadoop, run the following command:

  ```
  hadoop fs -rm <path to hard link>
  ```

Example

For example, suppose there are **4** hard links to file cite75_99.txt.

```
$ ls -l
total 1289433
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite75_99.txt
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link1
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link2
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link3
-rwxr-xr-x 5 root root 264075431 Jul 28 13:46 cite-link4

$ maprcli fid stat -fid 2142.34.131274
parent     deleteFlags     atime       gid  nlink  type       mtime
version  mode  uid  xattrInum  size       subtype   networkencryption
nblocks  compression
2142.16.2  DeleteTypeNone  1469738740  0    5      FTRegular  1469738771
1048600  755   0    0          264075431  FSTInval  false
8        lz4
```

To remove a hard link using:

- Linux, run the following command:

  ```
  rm -f cite-link1
  ```

  To verify that the command ran successfully, run the following command:

  ```
  $ ls -l
  total 1031546
  -rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite75_99.txt
  -rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link2
  -rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link3
  -rwxr-xr-x 4 root root 264075431 Jul 28 13:46 cite-link4
  ```

- Hadoop, run the following command:

  ```
  $ hadoop fs -rm /test-hl/cite-link2
  16/07/28 13:52:00 INFO Configuration.deprecation: io.bytes.per.checksum
  is deprecated. Instead, use dfs.bytes-per-checksum
  16/07/28 13:52:00 INFO fs.TrashPolicyDefault: Namenode trash
  configuration: Deletion interval = 0 minutes, Emptier interval = 0
  minutes.
  Deleted /test-hl/cite-link2
  ```

  To verify that the command ran successfully, run the following command:

  ```
  $ maprcli fid stat -fid 2142.34.131274
  parent  deleteFlags     atime       gid  nlink  type       mtime
  version  mode  uid  xattrInum  size       subtype   networkencryption
  nblocks  compression
  0.0.0   DeleteTypeNone  1469738740  0    3      FTRegular  1469738771
  1048603  755   0    0          264075431  FSTInval  false
  8        lz4
  ```

Managing Extended Attributes

Describes what extended attributes are, and the POSIX permissions that you need to manage them.

Extended attributes (referred to as `xattrs`) allow user applications to associate additional metadata with a regular file or directory. Unlike system-level inode metadata, such as file permissions or modification time, extended attributes are not interpreted by the system but are instead used by applications to store additional information about an inode. Multiple extended attributes can be associated with a single inode. The maximum size allowed for an extended attribute is 64 KB.

An extended attribute is a name-value pair, with a string name and binary value. The extended attribute names are prefixed with a namespace. For example, an `xattr` named `myXattr` in the user namespace would be specified as `user.myXattr`.

Limitations

- For the five valid namespaces supported by HDFS, HPE Ezmeral Data Fabric supports the following:

Namespace	HPE Ezmeral Data Fabric Functionality
user	Commonly used by client applications. Access to these extended attributes in the user namespace is controlled by corresponding file/directory permissions. For more information, see Permissions for Extended Attributes.
trusted	Available to superusers only. Access is denied for all other users. The extended attribute is not available through userspace methods.

NOTE: HPE Ezmeral Data Fabric does not support the raw namespace.

- Extended attributes cannot be associated with symbolic links. If extended attributes are used on symbolic links, they are instead applied to the symbolic link target file.
- The preserve options of commands like `cp -px` and `distcp -px` will work on extended attributes only in the following cases:
  - With Hadoop commands such as `hadoop fs`.
  - On FUSE mounted file paths.

NOTE: Extended attributes are not supported on NFS for the HPE Ezmeral Data Fabric file paths.

Permissions for Extended Attributes

The following table lists the permissions (POSIX mode bits or *ACE*s) you will need to set, retrieve, or modify extended attributes.

To...	For directories, you need...	For files, you need...
Set extended attributes	Mode bits: write (OR) *ACE*: addchild	Mode bits: write (OR) *ACE*: writefile
Remove extended attributes	Mode bits: write (OR) *ACE*: deletechild	Mode bits: write (OR) *ACE*: writefile
Retrieve extended attributes	Mode bits: read (OR) *ACE*: readdir	Mode bits: read (OR) *ACE*: readfile

last-updated: Jun 06, 2024

Enabling Extended Attributes

Extended attributes are enabled by default on all new installation. If you are upgrading, this feature must be explicitly enabled. To enable, run the following command:

```
maprcli cluster feature enable -name mfs.feature.fileace.support
```

Setting, Retrieving, and Removing Extended Attributes

You can set and retrieve extended attributes on files, directories, and FUSE mounted file path using Hadoop commands, Linux commands, and Java APIs.

Hadoop Commands for Extended Attributes

Lists the Hadoop commands to set, retrieve, and remove extended attributes on files, directories and FUSE mounted paths.

You can set, retrieve, and remove extended attributes on files, directories, and FUSE mounted file path using the `hadoop fs` command. When setting an extended attribute:

- The name must be prefixed with a namespace.
- The extended attribute value must be encoded as one of the following:

text	The given string must be enclosed in double quotes to be treated as text.
hex	The given string must begin with 0x or 0X to be treated as hexadecimal number.
base64	The given string must begin with 0s or 0S to be treated as base64 encoding.

NOTE: You must have the right permissions to set, retrieve, and/or remove extended attributes.

Set Extended Attributes

To set an extended attribute name and value for a file or directory, run the following command:

```
hadoop fs -setfattr -n name [-v value] <path>
```

For example:

```
hadoop fs -setfattr -n system.name -v system-hadoopfs /volforsnap/
smallfile.txt
hadoop fs -setfattr -n user.name -v user-hadoopfs /volforsnap/smallfile.txt
hadoop fs -setfattr -n security.name -v security-hadoopfs /volforsnap/
smallfile.txt
hadoop fs -setfattr -n trusted.name -v trusted-hadoopfs /volforsnap/
smallfile.txt
```

Retrieve Extended Attributes

To retrieve the extended attributes associated with a file or directory, run the following command:

```
hadoop fs -getfattr [-R] -n name | -d [-e en] <path>
```

For example:

```
hadoop fs -getfattr  -d /volforsnap/smallfile.txt
SLF4J: Class path contains multiple SLF4J bindings.
SLF4J: Found binding
in [jar:file:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/lib/
slf4j-log4j12-1.7.10.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: Found binding in [jar:file:/opt/mapr/lib/
```

last-updated: Jun 06, 2024

```
slf4j-log4j12-1.7.12.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: See http://www.slf4j.org/codes.html#multiple_bindings for an
explanation.
SLF4J: Actual binding is of type [org.slf4j.impl.Log4jLoggerFactory]
# file: /volforsnap/smallfile.txt
system.name="system-hadoopfs"
trusted.name="trusted-hadoopfs"
security.name="security-hadoopfs"
user.name="user-hadoopfs"
```

Remove Extended Attributes

To remove an extended attribute by name, run the following command:

```
hadoop fs -setfattr -x name <path>
```

For example:

```
hadoop fs -setfattr -x user.key1 /xattrs/m7user1/dir1
```

Linux Commands for Extended Attributes

You can set, retrieve, restore, and remove extended attributes on files, directories, and FUSE mounted file paths using Linux commands. For more information, refer to the respective Linux man page.

To use extended attributes on files on a MapR cluster with a FUSE client mounted path, see Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client on page 1615 to enable extended attributes through FUSE client.

Set Extended Attributes

To set an extended attribute name and value on a file/directory and/or a FUSE mounted file path, run the following command:

```
setfattr [-h] -n name [-v value] pathname...
```

For example:

```
setfattr -n system.name -v system /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n security.name -v test /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n trusted.name -v trusted /mapr_fuse/testcluster/volforsnap/
smallfile.txt
setfattr -n user.name -v user /mapr_fuse/testcluster/volforsnap/
smallfile.txt
```

For more information, refer to the Linux man page.

Retrieve Extended Attributes

To retrieve extended attributes, run one of the following commands:

```
getfattr [-hRLP] -n name [-e en] pathname...
getfattr [-hRLP] -d [-e en] [-m pattern] pathname...
```

For example:

```
getfattr  -d -m - /mapr_fuse/testcluster/volforsnap/smallfile.txt
getfattr: Removing leading '/' from absolute path names
```

last-updated: Jun 06, 2024

```
  file: mapr_fuse/testcluster/volforsnap/smallfile.txt
  security.name="test"
  system.name="system"
  trusted.name="trusted"
  user.name="user"
```

For more information, refer to the Linux man page.

Remove Extended Attributes

To remove an extended attribute by name, run the following command:

```
setfattr [-h] -x name pathname...
```

For example:

```
setfattr -x user.test test2
```

For more information, refer to the Linux man page.

Restore Extended Attributes

To restore extended attributes from a file, which must be in the format generated by the `getfattr` command with the `--dump` option, run the following command:

```
setfattr [-h] --restore=file...
```

For example:

```
setfattr --restore=testout
getfattr -d test2
 file: test2
 user.test="test"
```

For more information, refer to the Linux man page.

Java APIs for Extended Attributes

Java APIs to manage extended attributes

You can set, retrieve, and remove extended attributes on files, directories, and FUSE mounted file path using Extended Attribute Java APIs.

Set Extended Attributes

To set extended attributes, use the following APIs:

`public void setXAttr(Path path, String name, byte[] value) throws IOException`	Set an extended attribute on a file or directory. The name must be prefixed with the namespace followed by `"."`. For example, `"user.attr"`. By default, if a given extended attribute exists, then it will be replaced with the specified attribute.
`public void setXAttr(Path path, String name, byte[] value, Enum<SetXAttrSetFlag> flag) throws IOException`	Set an extended attribute on a file or directory. The name must be prefixed with the namespace followed by `"."`. For example, `"user.attr"`. The `XAttrSetFlag` value can be: • `CREATE` to create a new extended attribute. An error is returned if an extended attribute with the given name already exists.

last-updated: Jun 06, 2024

- REPLACE to replace an existing extended attribute. An error is returned if the specified extended attribute does not already exist.

Retrieve Extended Attributes

To retrieve extended attributes, use the following APIs:

`public byte[] getXAttr(Path path, String name) throws IOException`	Get an extended attribute name and value for a file or directory. The name must be prefixed with the namespace followed by `"."`. For example, `"user.attr"`.
`public Map<String,byte[]> getXAttrs(Path path) throws IOException`	Get all the extended attribute name/value pairs for a file or directory. Only those extended attributes that the logged-in user has permissions to view, are returned.
`public Map<String,byte[]> getXAttrs(Path path, List<String> names) throws IOException`	Get the extended attributes specified by the given list of names. Only those extended attributes that the logged-in user has permissions to view, are returned.
`public List<String> listXAttrs(Path path) throws IOException`	Get all the extended attribute names for a file or directory. Only those extended attribute names that the logged-in user has permissions to view, are returned.

Remove Extended Attributes

To remove an extended attribute associated with a file or directory, use the following API:

`public void removeXAttr(Path path, String name) throws IOException`	Remove an extended attribute of a file or directory. The name must be prefixed with the namespace followed by `"."`. For example, `"user.attr"`.

Managing Core Files

Describes how to set the location for core files.

The Linux `core_pattern` file (in `/proc/sys/kernel/core_pattern`) can be used to specify the location for storing core files. If any process launched by HPE Ezmeral Data Fabric crashes, the core files are created in the directory specified by the `core_pattern` file. A valid location in the `core_pattern` file is a full path to the directory you want to use. For example:

```
/tmp/dir1/cores/%e.core.%p.%h
```

> **TIP:** For details about the standard Linux `%` specifiers that you can use to name core files, see the core man page.

If the `core_pattern` file is empty, if the file does not contain a full path, or if it uses the `"|"` redirection feature, by default, HPE Ezmeral Data Fabric sets the location for core files (in the event of a core dump on a node) to `/opt/cores` directory when:

- The `configure.sh` utility is run.
- The Warden init script is run.
- The file system init script is run by Warden.

The default directory (`/opt/cores`) is also used if the `core_pattern` file contains the default HPE Ezmeral Data Fabric value for core files.

For HPE Ezmeral Data Fabric software, the directory being used to store core files should not be used for other purposes and should be empty. The cores directory cannot be the home directory, as it can cause

last-updated: Jun 06, 2024

problems during SSH access. The hoststats service monitors the directory specified in the `core_pattern` file and raises the node-level alarm if the directory contains any entry other than "`.`" and "`..`". When Warden is started, sticky bit is set on the cores directory.

Managing Tiered Files from the Command-line

After creating a tiered volume and associating a tier with the volume, you can manually trigger offload and recall of individual files in the volume using the CLI. This section describes how to offload file to and recall file from the tier, retrieve status of a file-level tiering operation, and how to perform certain tiering operations when hadoop and maprcli are not available on the host you wish to use for triggering the tiering operation.

Offloading a File to a Tier Using the CLI and REST API

Describes how to offload files to a tier using the CLI and the REST API.

About this task

Files, in tiering-enabled volumes, can be offloaded individually using the CLI and REST API. See Data Offload and Purge on page 512 for more information. For information on offloading files using (loopbacknfs or FUSE-based) POSIX or NFS clients when `maprcli` or `hadoop` commands are not available, see Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1342.

NOTE: Offloading a single file to a warm-tier might result in wasted space. See Data Offload and Purge on page 512 for more information

The user offloading the file data must have write permission (mode bit or *ACE*) on the file to offload data.

You can also offload all data in a tiering-enabled volume to the associated tier. see Offloading a Volume to a Tier on page 1255 for more information.

CLI	Run one of the following commands to offload file data to a tier: • `hadoop mfs -offload <file-path>` For more information, see `hadoop mfs` on page 5557. • `/opt/mapr/bin/maprcli file offload -name <file>` For more information, see `file offload` on page 2196.
REST API	Send a request of type POST. For example: `curl -k -X POST 'https://abc.sj.us:8443/rest/file/offload?name=fileName' --user mapr:mapr`

If the manual offload succeeds, the command returns nothing. If the offload fails, the command returns an error code. For more information on the codes, see Retrying Failed Operation on page 1261.

Recalling a File to file system Using the CLI and REST API

About this task

You can recall individual files from a storage tier. When you recall a file, the MAST Gateway fetches a copy of the data to the cluster. Based on the expiration time setting on the volume, recalled data is automatically:

- Offloaded again based on the storage policy (rules) if there are changes to the recalled data.
- Purged when the compactor runs if there are no changes to the recalled data.

See Data Reads, Writes, and Recalls on page 519 for more information.

NOTE: You can recall all data from the tier to the volume. See Recalling a Volume to file system on page 1258 for more information.

Recalling a File Manually Using the CLI

Procedure

- Run one of the following commands to recall a file:
  - `hadoop mfs -recall <pathToFile>`

    For more information, see `hadoop mfs` on page 5557.
  - `maprcli file recall -name <pathToFile>`

    For more information, see `file recall` on page 2197.

NOTE: For information on recalling files using (loopbacknfs or FUSE-based) POSIX or NFS clients when maprcli or hadoop commands are not available, see Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1342.

Recalling a File Using the REST API

Procedure

- Send a request of type POST to the URL. For example, send a request similar to the following:

```
curl -k -X POST 'https://abc.sj.us/rest/file/recall?name=fileName' --user
mapr:mapr
```

Terminating a Running File-Level Tiering Job

Explains how to terminate file tiering jobs using the Control System and the CLI.

About this task

You can terminate an ongoing offload or recall of a file using the CLI. Terminating a running:

- Offload operation does not prevent future offloads; if a schedule is associated with the volume, data that is still on the cluster is automatically offloaded based on the rules as per schedule. You can also manually offload data again at any time by running the `file offload` on page 2196 or `hadoop mfs` on page 5557 command.
- Recall operation does not prevent future recalls; you can run the recall command again to recall the remaining data on the tier. Based on the expiry time set on the volume (associated with the recalled data), recalled data is offloaded if there are changes or purged if there are no changes. See Recalling a Volume to file system on page 1258 for more information.

last-updated: Jun 06, 2024

For information on terminating a running offload or recall operation using (loopbacknfs or FUSE-based) POSIX or NFS clients when maprcli or hadoop commands are not available, see Running Tiering Commands when maprcli and hadoop Commands are not Available on page 1342. For information on terminating a running volume-level job, see Terminating a Running Volume-Level Tiering Job on page 1260.

Terminating a Running File-Level Offload or Recall Operation Using the CLI and REST API

About this task

CLI	Run the following command to terminate a currently running file-level offload or recall operation: `maprcli file tierjobterminate -name <filePath>` For more information, see `file tierjobterminate` on page 2198.
REST API	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/file/tierjobterminate?name=<filePath>' --user mapr:mapr`

Running Tiering Commands when maprcli and hadoop Commands are not Available

You can offload and/or recall a file with NFS, loopbacknfs, and FUSE-based POSIX clients even if `maprcli` or `hadoop` commands are not available. To perform file-level data tiering operations like offload and/or recall using NFS, loopbacknfs, and FUSE-based POSIX clients when `maprcli` or `hadoop` commands are not available, after mounting, provide the tiering command such as `offload`, `recall`, `tierjobstatus`, and/or `tierjobabort` as described below. When you run the command, the command creates a hidden `.tier_attributes` file (similar to `.dfs_attributes` file) that is purged immediately after the operation is submitted to the server.

NOTE: When you run the command, the tiering command is triggered immediately and storage policy (or rule), if any, at the volume-level is ignored.

Usage

```
/bin/echo "<command> <file-name>" > .tier_attributes
```

NOTE: Do not use `echo` in the terminal; instead, use `/bin/echo`.

Options

Option	Description
command	The tiering related command to run. The following commands are supported: • `offload` • `recall` • `tierjobstatus` • `tierjobabort`

last-updated: Jun 06, 2024

Option	Description
file-name	The name of the file.

Return Values

On success, the command returns nothing. Otherwise, the command returns one of the following `/bin/echo` return codes, which are displayed as write errors:

Code	Message	Description
EEXIST	File exists	Indicates tier job is queued or is already in progress.
ENOTEMPTY	Directory not empty	Indicates that tier job queue is full.
ENOENT	No such file or directory	Indicates that the specified file or job ID does not exist.
EIO	I/O error	Indicates that the job could not be submitted. Run the `tierjobstatus` command to determine the reason for this error.
EINVAL	Invalid argument	Indicates that the given command is invalid or not available. See Options on page 1342 for the list of supported commands.

Examples

Offload file named test

```
# /bin/echo "offload test"
> .tier_attributes
/bin/echo: write error: File exists
```

Recall a file named test

```
# /bin/echo "recall test"
> .tier_attributes
/bin/echo: write error: File exists
```

Check the status of a running job for a file

```
# /bin/echo "tierjobstatus test"
> .tier_attributes
```

Abort a running job

```
# /bin/echo "tierjobabort test"
> .tier_attributes
/bin/echo: write error: No such file
or directory
```

Retrieving Status of File-level Tiering Operation and File Data

About this task

You can retrieve the status of a file-level tiering operation using the CLI and REST API. For information on volume-level tiering operation, see Retrieving the Status of a Volume-level Tiering Operation on page 1265.

last-updated: Jun 06, 2024

Retrieving the Status of a Running Tiering Operation

Procedure

- Run the maprcli command or send a request of type GET to check the status of an active or completed offload, abort, and/or recall operation.
  See file tierjobstatus on page 2200 for more information. For example:

CLI

```
maprcli file tierjobstatus -name
<file_name> -json
```

REST

```
curl -k -X
GET 'https://<host>:8443/rest/file/
tierstatus?name<file_name>' --user
mapr:mapr
```

See Output on page 2200 for more information.

Retrieving Status of File Data

Procedure

- Run the maprcli command or send a request of type GET to determine the status of file data.
  See file tierstatus on page 2213 for more information. For example:

CLI

```
maprcli file tierstatus -name
<file_name>
```

REST

```
curl -k -X
GET 'https://<host>:8443/rest/file/
tierstatus?name=<file_name>' --user
mapr:mapr
```

See Output on page 2214 for more information.

Administering Tables

Administration of the HPE Ezmeral Data Fabric Database is done primarily via the command line (maprcli) or with the Managed Control System (MCS). Regardless of whether the HPE Ezmeral Data Fabric Database table is used for binary files or JSON documents, the same types of commands are used with slightly different parameter options. HPE Ezmeral Data Fabric Database administration is associated with tables, columns and column families, and table regions.

Why use HPE Ezmeral Data Fabric Database?

From an administrator's point-of-view, HPE Ezmeral Data Fabric Database provides the following capabilities:

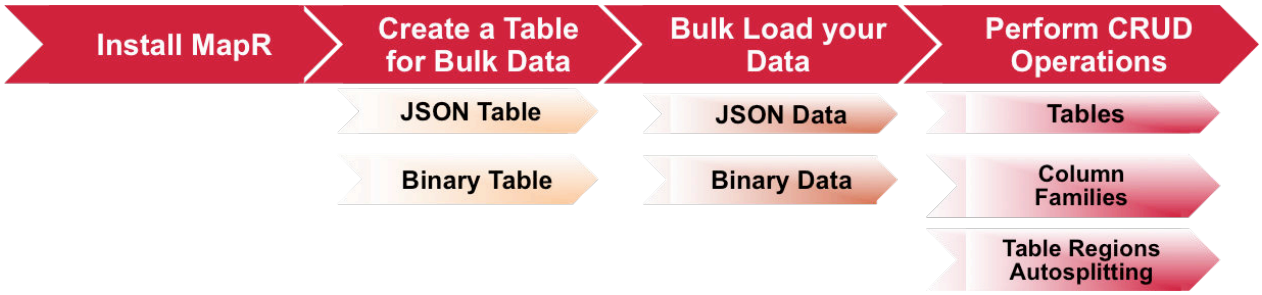
- **Minimal administration**: Single namespace for files, tables and streams, flexible schema that allows built-in data management and protection, automatic splits and merges as data grows and shrinks, and easy bulk data loading.
- **Self-healing from HW and SW failures**: Replicated state and data for instant recovery and automated re-replication of data.

last-updated: Jun 06, 2024

- **Global low-latency replication**: Multi-master (that is, active to active) replication which is important for disaster recovery. Includes reduced risk of data loss, application failover, and faster data access.
- **High performance and low latency**: Integrated system with fewer software layers, single hop to data, and no compactions with low I/O amplification.
- **Fine-grained security**: Access permissions can be granted to tables (as well as files and streams) at a granular level using MapR Access Control Expressions (ACEs), which are designed for flexibility and ease-of-use.

How Do I Get Started?

The following graphic shows the basics steps (with hotspot links) for getting started.



1. Install MapR
2. Creating a table for bulkloading data involves specifying the table type (JSON or binary) and setting the bulkload flag.
3. Bulkloading can be done either as a full or incremental bulkload. Different utilities are used for the bulk load depending on what you are trying to accomplish.
4. Both full and incremental bulkloads can be performed for HPE Ezmeral Data Fabric Database JSON tables. This topic describes the three command-line utilties available for loading documents into JSON tables.
5. Administration of tables describes how to create, read, update, and delete tables as well as other tasks such as managing permissions and auditing.
6. This section cover the administration of column families including how to create column families, alter them, delete them, set permissions on them, and set and display parameter values.
7. This topic describes administrative tasks associated with table regions including how to set autosplitting.

Useful Administrator Resources

Links to Resources	Descriptions
maprcli and REST API Syntax on page 1992	Command line reference for MapR operations. For HPE Ezmeral Data Fabric Database, the commands particularly applicable are assocociate with the `maprcli table` on page 2412 command. These commands include not only table CRUD operations but also table column family, table region, and table replication operations.

last-updated: Jun 06, 2024

Links to Resources	Descriptions
Utilities for HPE Ezmeral Data Fabric Database JSON Tables on page 5496	Utilities for HPE Ezmeral Data Fabric Database JSON tables. These utilities are used form managing JSON tables icluding importing and exporting data to and from JSON tables. Particularly useful are: • HPE Ezmeral Data Fabric Database JSON ImportJSON on page 5506 utility with imports JSON documents into a HPE Ezmeral Data Fabric Database JSON table. • HPE Ezmeral Data Fabric Database Shell (JSON Tables) on page 5469utility which performs CRUD operations on JSON documents and tables.
Utilities for HPE Ezmeral Data Fabric Database Binary Tables on page 5513	Utilities for HPE Ezmeral Data Fabric Database binary tables. These utitlies are used for managing binary tables. Particulary useful is HPE Ezmeral Data Fabric Database Binary CopyTable on page 5514 which is used to copy data from one HPE Ezmeral Data Fabric Database binary table to another. **NOTE:** To import HFile or Result files in a HPE Ezmeral Data Fabric Database binary table, the hbase command can be used. See Loading Data into Binary Tables on page 1388.
Configuring Security on page 1773	Information on security tasks for configuring MapR security, managing secure clusters, and administering auditing.
Hadoop and Big Data Security	MapR information on Security and Big Data Governance that identified key unique advantages including authentication, authorization, auditing, and encryption.
Provisioning Secure Access Controls in HPE Ezmeral Data Fabric Database	MapR blog discussing MapR's boolean Access Control Expressions (ACEs) which provide granular-level permissions including topics and examples of best practices.

Managing Tables

HPE Ezmeral Data Fabric Database supports two types of table: binary tables and JSON tables. This section covers how to create, edit, and delete tables, as well as how to set parameter values, display parameter values, grant permissions and access, replicate tables, and more using the Control System and the CLI.

After you log in to the Control System and click **Data** > **Table**, the **Tables** page displays the following in the various panes:

- Active Alarms — The active table (replication) alarms
- **Recently Viewed Tables** — The tables that were most recently accessed from the Control System
- List of volumes that you have access to and a search field to retrieve a table by table path

Click **Create Table** button to create a new binary or JSON table.

Creating a New Table
Explains how to create both binary tables and JSON tables using either the Control System, the CLI, or the REST API.

About this task

Different methods can be used to create HPE Ezmeral Data Fabric Database tables, such as maprcli, hbase shell, mapr dbshell commands, and the Control System. The following procedures describe how to create tables using these methods.

Creating a Table Using the Control System

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

   NOTE: This option is not available on the Kubernetes version of the Control System.

2. Click **Data** > **Tables** from the top of the page. The **Tables** page appears.
3. Click **Create Table**. The **Create New Table** page appears.
4. From the **Properties** pane of the **Create New Table** page, choose the table type:
   - JSON

     NOTE: You must select **JSON** for the table type to enable dynamic data masking.

   - Binary
5. Specify values for fields displayed under **Properties** pane of the **Create New Table** page, as appropriate:
   a) Enter the path to or location for the table in the **Table Path** field.

   Tables are stored in the Data Fabric file system. When providing the path to a table, use these conventions:

   - For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/test`
   - For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` in `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customer`

   b) Select the interval of time to apply for logging table metrics in the **Metric Interval** field.

   You can choose to log metrics every 10 seconds, 1 minute (default), or 10 minutes. For more information on visualizing the metrics, see *Visualizing Table Metrics in the Control System*.

   c) Enable (**Yes**) or disable (**No**) auto-splitting of table.

   If enabled, the table is split automatically into regions as the table grows. If disabled, the table can be split manually into regions. By default, this option is enabled.

   d) Choose whether to complete a full bulk load or incremental bulk load of the table.

   For more information, see Loading Documents into JSON Tables on page 1385. The default value is incremental bulkload.
6. (Optional) Configure the following **Security** settings:
   a) Click **Security** on the **Create New Table** page to open and display security options (if not already displayed). Fields and options for the **Security Policy**, **Audit**, and **Default Data Access Control for Column Families** appear.

b) Enter the name or the first few characters of an existing security policy in the **Search for security policy** field until the needed policy appears below the search box. The selected security policy is associated with the current table being created.

NOTE: The **Search for security policy** field under the **Security** pane appears only if security policies have been previously created. If the **Search for security policy** field does not appear under the **Security** pane, then, using the appropriate privileges, go to the **Security** screen, and set up necessary security policies.

c) Click the checkbox next to the name of the listed security policy you intend to use for this table.

d) Click **Add**. The name of the security policy that you selected appears above the search box. The security policy selected (along with its current data masking setting) is then associated with this table.

7. For the **Enable Auditing** field, either enable (**Yes**) or disable (**No**) auditing to audit table operations.

If auditing is enabled at the cluster and volume levels, it causes auditing to start for the table operations.

8. Define **Default Data Access Control for Column Family** settings:

a) Select either **Basic** or **Advanced**:

NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

- If you select **Basic** from the **Security** pane of the **Create New Table** page, then select a user type, enter a name in the **Name** field, and check associated permissions for the settings, as needed.

NOTE: You *cannot* specify **User**, **Group**, or **Role** individually if access is granted to all users (**Public**).

Selected permissions become the default table permissions after creating column families under this table and are displayed under the **DEFAULT DATA ACCESS CONTROL FOR COLUMN FAMILIES** pane of the **Create New Table** page.

JSON Table Security Permission Options

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.

last-updated: Jun 06, 2024

Permission	Permission Description
Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on `a.b`, but not on `a`. For sjohnson to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family.
Set Compression	Can set or change the compression setting for the column family.
Unmasked Data	Leaving the **Unmask Data** checkbox unchecked hides table column family data from the selected user. Checking the box allows the selected user to see all table data, based on and in coordination with other security and data access settings.

Binary Table Security Permission Options

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.

last-updated: Jun 06, 2024

Permission	Permission Description
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

- If you select **Advanced** from the **Security** pane of the **Create New Table** page, then specify public (`p`) or user (`u`), group (`g`), and/or role (`r`) and indicate, if required, user access options with the following boolean expressions and subexpressions:
  - `!` — Negation operator.
  - `&` — AND operation.
  - `|` — OR operation.

  Use `( )`, parentheses, for subexpressions.

  NOTE: You *cannot* specify **User**, **Group**, or **Role** individually if access is granted to all users (**Public**).

  NOTE: By default, all table permissions are given to the user creating the table.

  Alternatively, click associated with the type of access to use the selected **Access Control Expression** window to define access for **Public** or **User**, **Group**, and/or **Role**.

b) Opt to:

- Create a copy of permission settings for a listed public, user, group, or role type by clicking , which you can then modify.
- Delete permission settings for a listed public, user, group, or role type by clicking .

9. Optionally, repeat the above step to add another user type, as needed. Otherwise, proceed to the next step.

last-updated: Jun 06, 2024

10. Do one of the following to specify settings under the **Table Administration Control** pane of the **Create New Table** page:
    - Click **Basic** under the **Table Administration Control** pane, select **Public** (to grant access to all users) or **User**, **Group**, or **Role**. Then, enter a name for the current permission set in the **Name** field, and apply table permissions as described in the table below.

Table Administration Control Permission Options for JSON Tables

Permission	Permission Description
Administration	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.
Split Merge	Can take the following actions: • Split the table into regions or merge regions of the table together. • Change the size of the region.
Index	Can create index for this table.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

Table Administration Control Permission Options for Binary Tables

Permission	Permission Description
Administration	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.
Split Merge	Can take the following actions: • Split the table into regions or merge regions of the table together. • Change the size of the region.

last-updated: Jun 06, 2024

Permission	Permission Description
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

- Click **Advanced**, and then apply user permissions.

  Specify public (p) or user (u), group (g), and/or role (`r`) who have or do not have the type of access using the following boolean expressions and subexpressions:

  - `!` — Negation operator.
  - `&` — AND operation.
  - `|` — OR operation.

  Use `( )`, parentheses, for subexpressions.

  NOTE: You *cannot* specify user, group, or role individually if access is granted to all users (public).

  Alternatively, click  associated with the type of access to use the selected **Access Control Expression** window to define access for public or users, groups, and/or roles.

  NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (`&`) and negation (`!`) operations that are supported by advanced settings are not supported in the basic settings.

11. Optionally, click **Add Another** from the **Table Administration Control** pane of the **Create New Table** page, and repeat the above step to assign security permissions for another user type. Otherwise, proceed to the next step.
12. Review and update your selections, as needed.
13. Click **Create Table** at the bottom of the **Create New Table** page to create the table.
14. Opt to do the following:
    - Add column families to the table.
    - View the table information for the newly created table.

last-updated: Jun 06, 2024

Creating a Table Using the CLI or the REST API

About this task

CLI

The basic command to create a binary table is:

```
maprcli table create -path <path>
```

To create a JSON table, include the `-tabletype` parameter and set it to `json`:

```
maprcli table create -path
<path> -tabletype json
```

The `-tabletype` parameter is set to `binary` by default.

REST

Send a request of type POST. For example, to create a:

- Binary table:

```
curl -k -X
POST 'https://<hostname>:8443/rest/
table/create?path=<path>' --user
mapr:mapr
```

- JSON table:

```
curl-k -X POST 'https://
<hostname>:8443/rest/table/create?
path=<path>&tabletype=json' --user
mapr:mapr
```

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  NOTE: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♦=#;{}&()/"  (or)
  maprcli table create -path '/♦=#;{}&()/'
  ```

last-updated: Jun 06, 2024

To use either the **'** or the **"** character in the table name, enclose:

- the **'** character within double quotes (")
- the **"** character within single quote (')

For example:

```
maprcli table create -path "/'♦=#;{}&()/"  (or)
maprcli table create -path '/"♦=#;{}&()/'
```

If you create a table, you can set a number of properties. Refer to the `table create` command..

Creating Tables Using shell Command

About this task

JSON Tables	The HPE Ezmeral Data Fabric Database shell command is used on JSON tables only. To run this command, execute the following: `mapr dbshell` After starting the shell, run the `create` command.
Binary Tables	The HBase shell command is used on binary tables only. To run this command, execute the following: `hbase shell` After starting the HBase shell, run the `create` command. Type `help` to see a list of commands and their syntax.

Related tasks

Editing Tables on page 1355
Explains how to edit binary and JSON tables using either the Control System, the CLI, or the REST API.

Removing a Table on page 1361
Use either the Control System or the `maprcli table delete` command to drop a HPE Ezmeral Data Fabric Database table.

Creating Column Families on page 1391
Explains how to create column families using either the Control System, the CLI, or the HBase shell.

Configuring Maximum Row Sizes Using the CLI

The default maximum row size at installation is 32MB. You can configure this maximum by changing the value of the `mfs.db.max.rowsize.kb` parameter with the `maprcli config save` command.

Tables support rows up to 2 GB in size. Rows in excess of 100MB might show decreased performance.

Here is an example of changing the maximum row size:

```
maprcli config save -values {"mfs.db.max.rowsize.kb":<value in KB>}
```

The value of this parameter affects both JSON tables and binary tables.

To view the current setting of this parameter, use the `maprcli config load` command, as in this example:

```
maprcli config load -json | grep mfs.db.max.rowsize.kb
```

last-updated: Jun 06, 2024

Editing Tables
Explains how to edit binary and JSON tables using either the Control System, the CLI, or the REST API.

About this task

You can use the Control System, the CLI, or the REST API to edit the attributes of a HPE Ezmeral Data Fabric Database binary or JSON table. You can also use the HBase shell to edit a binary table. To edit a table, you must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminaccessperm` on the table

Editing Tables Using the Control System

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

   NOTE: This option is not available on the Kubernetes version of the Control System.

2. Click **Data** > **Tables** from the top of the page. The **Tables** page appears.
   See Viewing Table Information on page 1368.

3. Select the table needing to be edited (under the **Recently Viewed Tables** pane or in the bottom pane) or enter the path to the needed table in the available field, and then click **Edit Table** to display the **Edit Table** page.

4. Make changes to the following **Properties**, where necessary:

Property	Property Description
Metrics Interval	Select **10 sec**, **1 min** or **10 min** to update the interval of time for logging metrics.
Auto Split	Enable (**Yes**) or disable (**No**) auto-splitting of table. If enabled, the table is split automatically into regions as the table grows. If disabled, the table can be split manually into regions. By default, this is enabled.
Bulkload	Enable (**Yes**) or disable (**No**) full bulk load of the table.

5. Define **Default Data Access Control for Column Family** settings:
   a) Select either **Basic** or **Advanced**:

   NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (`&`) and negation (`!`) operations that are supported by advanced settings are not supported in the basic settings.

   - If you select **Basic** from the **Security** pane of the **Create New Table** page, then select a user type, enter a name in the **Name** field, and check associated permissions for the settings, as needed.

     NOTE: You *cannot* specify **User**, **Group**, or **Role** individually if access is granted to all users (**Public**).

     Selected permissions become the default table permissions after creating column families under this table and are displayed under the **DEFAULT DATA ACCESS CONTROL FOR COLUMN FAMILIES** pane of the **Create New Table** page.

JSON Table Security Permission Options

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on `a.b`, but not on `a`. For sjohnson to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family.
Set Compression	Can set or change the compression setting for the column family.

last-updated: Jun 06, 2024

Permission	Permission Description
Unmasked Data	Leaving the **Unmask Data** checkbox unchecked hides table column family data from the selected user. Checking the box allows the selected user to see all table data, based on and in coordination with other security and data access settings.

Binary Table Security Permission Options

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

- If you select **Advanced** from the **Security** pane of the **Create New Table** page, then specify public (`p`) or user (`u`), group (`g`), and/or role (`r`) and indicate, if required, user access options with the following boolean expressions and subexpressions:
  - `!` — Negation operator.
  - `&` — AND operation.
  - `|` — OR operation.

last-updated: Jun 06, 2024

Use ( ), parentheses, for subexpressions.

NOTE: You *cannot* specify **User**, **Group**, or **Role** individually if access is granted to all users (**Public**).

NOTE: By default, all table permissions are given to the user creating the table.

Alternatively, click associated with the type of access to use the selected **Access Control Expression** window to define access for **Public** or **User**, **Group**, and/or **Role**.

b) Opt to:

- Create a copy of permission settings for a listed public, user, group, or role type by clicking , which you can then modify.
- Delete permission settings for a listed public, user, group, or role type by clicking .

6. Make changes as needed to **Table Administration Control** settings:
   a) Modify the list of users, groups, and/or roles that have and/or do not have the following types of administration permissions on the table, as applicable:

JSON Table

Field	Field Description
Admin	Can view and edit the permissions for the table.
Index	Can create an index for the table.
Force Pack	Can pack table regions.
Split Merge	Can take the following actions: • Split the table into regions or merge regions of the table together. • Change the size of the region.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

last-updated: Jun 06, 2024

Binary Table

Field	Field Description
Admin	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.
Split Merge	Can take the following actions: • Split the table into regions or merge regions of the table together. • Change the size of the region.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

b) Opt to:

- Grant access to a new user, group, or role by clicking **Add Another**, selecting the **Type** entity, entering the **Name** entity, and selecting the permissions to grant the entity.
- Create a copy of permission settings for a listed public, user, group, or role type by clicking . You can then modify the copied settings, if necessary.
- Delete permission settings for a listed public, user, group, or role type by clicking .

7. Click **Save Changes** for the changes to take effect.

Editing Tables Using the CLI or the REST API

About this task

CLI

The following is the command to edit a table:

```
maprcli table edit -path <path>
```

REST

Send a request of type POST. For example:

```
curl -k -X
POST 'https://<hostname>:8443/rest/
```

last-updated: Jun 06, 2024

```
table/edit?path=<path>' --user
<username>:<pwd>
```

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  NOTE: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♦=#;{}&()/"  (or)
  maprcli table create -path '/♦=#;{}&()/'
  ```

  To use either the **'** or the **"** character in the table name, enclose:

  - the **'** character within double quotes (")
  - the **"** character within single quote (')

  For example:

  ```
  maprcli table create -path "/'♦=#;{}&()/"  (or)
  maprcli table create -path '/"♦=#;{}&()/'
  ```

When you edit a table, you can change a number of properties including:

- Enable or disable auditing, autosplitting, and bulkloading
- Set permissions on table
- Set permissions for default column families

For full reference for this command, see the `table edit` command.

Editing Binary Tables Using HBase Shell

About this task

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Related tasks

Creating a New Table on page 1346
Explains how to create both binary tables and JSON tables using either the Control System, the CLI, or the REST API.

Removing a Table on page 1361

last-updated: Jun 06, 2024

Use either the Control System or the `maprcli table delete` command to drop a HPE Ezmeral Data Fabric Database table.

Removing a Table
Use either the Control System or the `maprcli table delete` command to drop a HPE Ezmeral Data Fabric Database table.
Removing a Table Using the Control System

About this task
To remove a table:

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click **Remove Table**.
   The **Remove Table** confirmation window displays.
3. Click **Remove Table** to remove the table.
   After the table is removed, data in the table cannot be recovered.

Removing a Table Using the CLI or REST API

About this task

Run the command `maprcli table delete -path <path>`.

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  NOTE: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♦=#;{}&()/"  (or)
  maprcli table create -path '/♦=#;{}&()/'
  ```

  To use either the **'** or the **"** character in the table name, enclose:

  - the **'** character within double quotes (")
  - the **"** character within single quote (')

For example:

```
maprcli table create -path "/'♦=#;{}&()/"  (or)
maprcli table create -path '/"♦=#;{}&()/'
```

For more information, see the `table delete` command.

Defining ACEs Using the Access Control Expression Builder
Describes how to build ACEs using the Expression Builder.

About this task

To define access control expressions using the **Access Control Expression** builder in the MapR Control System:

Procedure

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.
   Here:

All	AND (&) operation	Indicates that all of the conditions must be met for public or user, group, and role to access the volume.
Any	OR (|) operation	Indicates that any one of the conditions must be met for public or user, group, and role to access the volume.

2. Click:

+	To add an expression.
( )	To add a subexpression.
x	To remove an expression or subexpression.

3. Select **Public or User**, **Group**, or **Role** from the drop-down menu and:
   a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
   b) Enter the name of the user, group, or role.
4. Click **Save Changes** to create an ACE.

Setting Whole Volume ACEs Using the CLI

About this task
See Setting Whole Volume ACEs on page 1365.
Setting Table ACEs Using the CLI

About this task
See Enabling Table and Stream Authorizations with ACEs on page 1363.

Setting Stream ACEs Using the CLI

About this task

See Enabling Table and Stream Authorizations with ACEs on page 1363.

Enabling Table and Stream Authorizations with ACEs

About this task

Permissions for MapR tables, column families, and columns are defined by ACEs. Set permissions for tables after you create or edit tables. Set default permissions for column families when you create or edit tables, and you can override these defaults when you create column families.

For the syntax to use when creating Access Control Expressions, see ACE Syntax on page 1855.

If a user, group, or role requests to read data from, write data to, or append data to a column, HPE Ezmeral Data Fabric Database checks whether that user, group, or role has read or write permission for the column family AND read or write permission for the column. By default, columns allow read and write access to all users; in such cases, only the read or write permission for the column family matters.

However, suppose that a table contains columns `col1` and `col2` in column family `cf1`, and these columns grant read and write permission only to the table creator. A different user tries to write data to these columns. HPE Ezmeral Data Fabric Database checks whether this user has write permission on `cf1` AND `col1` AND `col2`. If the user does not have all three permissions, HPE Ezmeral Data Fabric Database returns an error that says access for the write is denied.

If this user were to try to read from the same two columns, HPE Ezmeral Data Fabric Database would simply not return the data. If the user tried to read from those two columns and additional columns on which he had read permissions, the results would contain the data for those additional columns but exclude the data for `col1` and `col2`.

NOTE: Table Permissions for Older Releases: Because MapR tables are stored at the file-system level, you can also set permissions for HPE Ezmeral Data Fabric Database tables directly in the file system, if your version of MapR does not support ACEs. Support for ACEs was introduced in version 3.1.

To set permissions directly in the filesystem, see Performing File System Operations on HPE Ezmeral Data Fabric Database Tables on page 1390.

Setting Table ACEs Using the CLI

About this task

You can set ACEs with the following commands:

- `table create` on page 2412 — Creates a new MapR table.
- `table edit` on page 2468 — Edits a MapR table.
- `table cf create` on page 2438 — Creates a column family for a MapR table.
- `table cf edit` on page 2444 — Edits a column-family definition.
- `table cf colperm set` on page 2420 — Set Access Control Expressions (ACEs) for a specified column.

Setting Stream ACEs Using the CLI

About this task

You can set ACEs with the following commands:

- `stream create` on page 2368 — Creates a new MapR stream.
- `stream edit` on page 2375 — Edits a MapR stream.

Defining ACEs by using maprcli commands

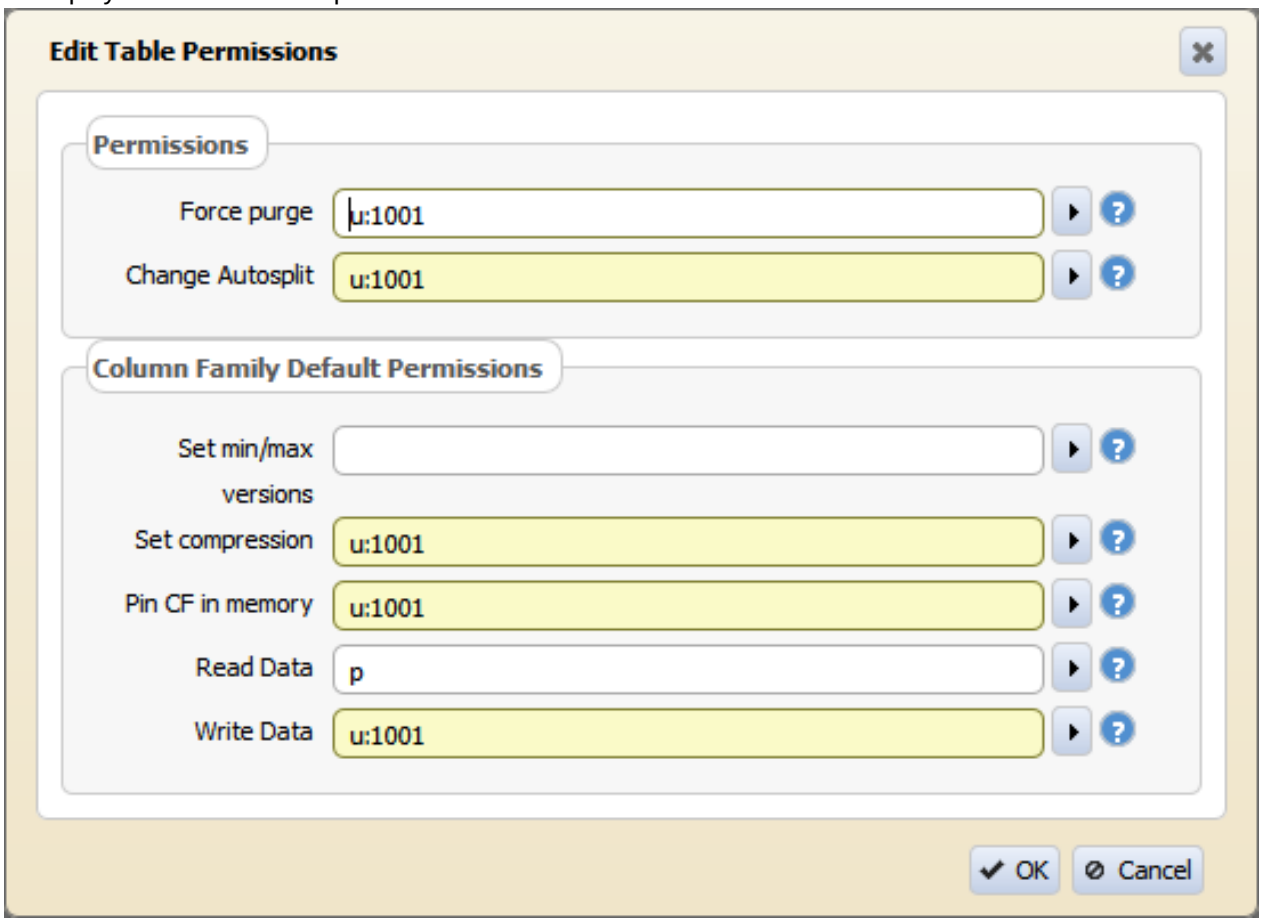
You can set ACEs with the following commands:

- `table create` – Creates a new MapR table.
- `table edit` – Edits a MapR table.
- `table cf create` – Creates a column family for a MapR table.
- `table cf edit` – Edits a column-family definition.
- `table cf colperm set` – Set Access Control Expressions (ACEs) for a specified column.

Defining ACEs with the MCS by using the Expression Builder

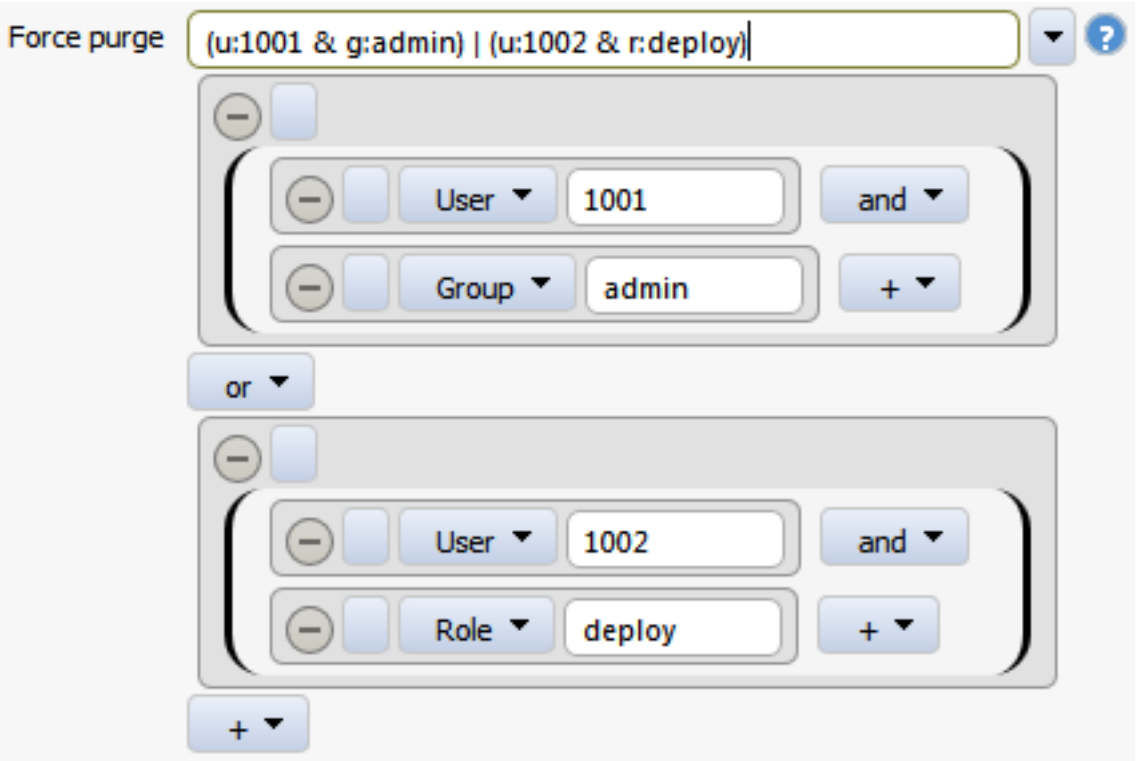
Procedure

1. To define an ACE for an existing table, click **Edit Table Permissions** from the table's pane in the MCS to display the **Permissions** pane.



2. Click the arrow at the right side of any field to display the Expression Builder for that field.

3. Use the **+** button to add a condition to the expression. Note that you cannot mix AND and OR without using subexpressions.



You can also type expressions directly into the field. The MCS validates expressions when focus leaves the field. The field is colored yellow for a warning and red for an error. Hover the cursor on the field to display the error or warning message.

Setting Whole Volume ACEs

Describes how to set ACE expressions when creating or modifying volumes.

You can set *ACE*s at the time of volume creation using the `volume create` on page 2588 command and modify them at a later time using the `volume modify` on page 2676 command. When you run the command to set or modify *ACE*s, the command does the following:

- Overwrites existing values with new values, if specified, for access types that were previously set.
- Sets values for access types that have not yet been set, if specified.
- Does not modify access types that were not specified with the command, whether they were previously set or are unset.

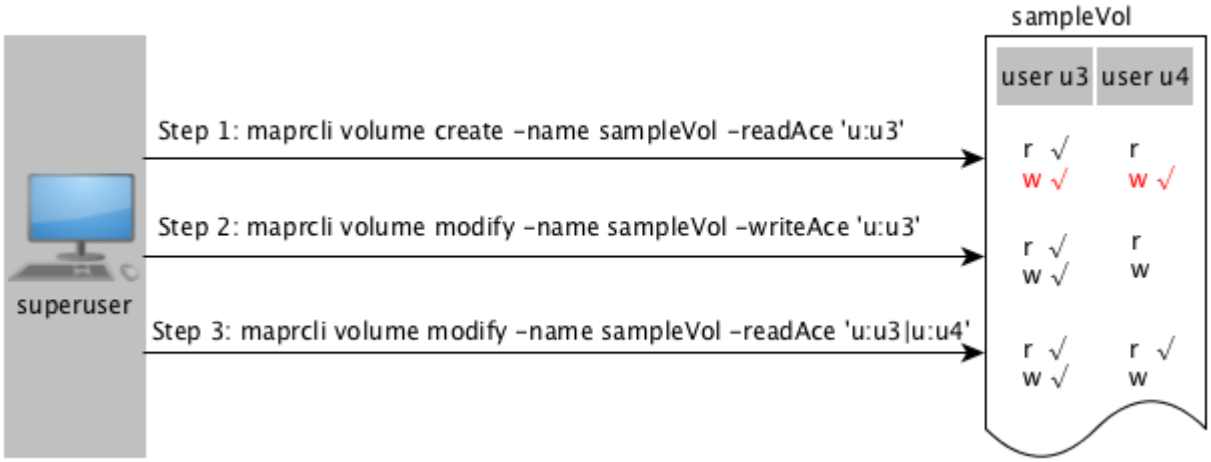
When you set whole volume *ACE*s, permissions on files and tables under that volume remain unchanged. Also, new files and tables in the volume do not inherit the whole volume *ACE*s of that volume. Instead, whole volume *ACE*s, if set, are used to determine volume level access to tables and files within the volume. To gain access to volume data, the user must have access at both the volume and file/table levels.

last-updated: Jun 06, 2024

Whole Volume *ACE* Example

For example, suppose the following sequence of whole volume *ACE* settings for users u3 and u4 is as follows.

NOTE: In the following illustration, default *ACE* values are shown in red.



As shown in the illustration above, in:

Step 1:

User u3 is granted permissions to read.

User u3: User u3 has permissions to read files and tables at the volume level and by default, user u3 has write permission (shown in red) at the volume level. However, for:

- Files in the volume, file *ACE* or POSIX mode bits are used to determine read and write access for user u3.
- Tables in the volume, table *ACE*s are used to determine read and write access for user u3.

User u4: User u4 cannot read files and tables within the volume because the *ACE* for the volume does not explicitly grant access to user u4. Although user u4 has write permission by default, user u4 cannot write to files/tables in the volume because user u4 does not have read permission.

Step 2:

User u3 is granted permissions to write.

User u3: User u3's read access remains unchanged and although user u3 has permissions to write to files and tables, for:

- Files in the volume, file *ACE* or POSIX mode bits are used to determine write access for user u3.
- Tables in the volume, table *ACE*s are used to determine write access for user u3.

User u4: User u4 cannot write to files/tables in the volume.

Step 3

User u4 is granted read access.

last-updated: Jun 06, 2024

User u3: User u3's read and write access remains unchanged.

User u4: User u4 has permissions to read files and tables at the volume-level; however, for:

- Files in the volume, file *ACE* or POSIX mode bits are used to determine read access for user u4.
- Tables in the volume, table *ACE*s are used to determine read access for user u4.

Viewing the List of Tables

Describes how to view the list of tables using either the Control System or the CLI.

Viewing the Tables in a Volume Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Tables** to view all the volumes to which you have access.

   NOTE: This option is not applicable on the Kubernetes version of the Control System.

   For each volume, the pane displays the following:

Column Name	Column Description
Name	The name of the volume.
Type	The type. Value can be: • — Volume • — Directory • — Table
Owner	The name of the owner.
Last Modified	The last modification date and timestamp.

2. Click on the name of the volume (to browse to the path to the table) or enter the name of the volume in the text field.

   The tables in the selected volume display. If necessary, click the name of the directory to browse further or to return to **All** volumes view.

Viewing a Table by Table Path Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Tables**.

   NOTE: This option is not applicable on the Kubernetes version of the Control System.

2. Enter the path to the table and click **GO**.

   The tables information page for the specified table displays.

last-updated: Jun 06, 2024

Listing the Tables in a Directory From the Command-line

Method for Binary Tables Only (HBase Shell)

About this task

After starting the HBase shell, run the `list` command. Include the directory path in the command if you want to list tables that are not in your home directory. Type `help` to see a list of commands and their syntax.

Method for JSON Tables Only (`mapr dbshell`)

About this task

After starting the shell, run the `list` command. Include the directory path in the command if you want to list tables that are not in your home directory.

Retrieving a Table by Table Path Using the CLI or the REST API

About this task

To retrieve table details for a table by specifying the table path from the CLI, run the following command:

```
maprcli table info -path <table-path>
```

For information on this command, see the `table info` command.

Viewing Table Information

Explains how to view table information using either the Control System, the CLI or the REST API.

About this task

You can view table information including table properties, column families, regions, replicas, upstream source, indexes, and metrics. Use either the `maprcli` command, REST API, or the Control System to display all of the information that HPE Ezmeral Data Fabric Database stores about a particular table.

Viewing Table Information Using the Control System

Procedure

1. Search and retrieve the table either by volume or by table path.
   For information on retrieving, see:
   - Viewing the Tables in a Volume Using the Control System on page 1367
   - Viewing a Table by Table Path Using the Control System on page 1367
2. Click the name of the table to see the table details.
   The page displays the following tabs:
   - Summary
   - Column Families
   - Regions
   - Replication
   - Change Data Capture
   - Indexes

- **Metrics**

On this page, you can:

- Edit the table
- Remove table

Viewing Table Information Using the CLI or REST API

About this task

CLI

The basic command to retrieve table information is the following:

```
maprcli table info -path
<tablePath> -json
```

REST

Send a request of type GET to retrieve table details. For example:

```
curl -k -X
GET 'https://<hostname>:8443/rest/
table/info?path=<tablePath>' --user
<username>:<pwd>
```

For more information, see the `table info` command.

Viewing Table Settings

Describes how to view table settings using the Control System, the CLI or the Rest API.

Viewing Table Settings Using the Control System

Procedure

- Log in to the Control System and go to the **Summary** tab in the table information page to view the following settings.

  NOTE: Some properties are only applicable to binary tables.

Throughput - By Op Type

This pane displays a graph for the operations on the table in the last hour. For more information, see *Monitoring Tables*.

Region Data Distribution by Node

This pane shows the distribution of the table or secondary index regions across the nodes in the cluster. For more information, see *Monitoring Tables*.

Properties

This pane shows the current value for the following table properties:

Table Path	The path to the table on the file system.
Table Type	The type of table. Value can be one of the following: • JSON • Binary
Total Rows	The total number of rows in the table.

last-updated: Jun 06, 2024

Region Size	The average size of the regions into which HPE Ezmeral Data Fabric Database tries to split the table as the table grows. The default is 4096 MB.
Total Logical Size	The estimated size (in bytes) of uncompressed data stored in table (excluding replication).
Total Physical Size	The estimated size (in bytes) of actual data stored in table (excluding replication). This includes internal metadata and reflects compressed data size when compression is enabled.
Auditing	The setting to enable or disable auditing of operations on the table.
Auto Split	The setting to automatically split the table into regions as the table grows.
Bulkload Type	The setting to allow a full bulk load of the table.
Metrics Interval	The table metrics collection interval, in seconds.

Security

This pane shows the following security settings on the table:

last-updated: Jun 06, 2024

Security Policy	The security policies associated with this table including: • Name of the security policy • Status of the security policy. Lists the path of the table location, name of table column families, and name of associated fields, if any. Click a listed security policy or **+** (plus sign) to add an additional security policy, or drill down through the listing under **Name** column, where the **Add Field** is displayed and add another data field to the table. Remove a security policy by clicking the security policy name to be deleted and then click **-** (minus sign) from the subsequent screen. **NOTE:** No warning confirmation screen is displayed whenever you opt to delete a security policy from the Security pane of the table information page. • Access control expression in the security policy
Audit	Whether or not auditing is enabled for table operations.

Table Admin Control

This pane shows the entities (users, groups, and/or roles) that have and/or do not have one or more of the following types of permissions to administer the table:

Admin (Access Control)	Can view and edit the permissions for the table.
Force Pack	Can pack table regions.

last-updated: Jun 06, 2024

Split Merge	Can take the following actions: • Split the table into regions or merge regions of the table together. • Change the size of the region.
Index	Can create index for this table. This permission is for JSON tables only.
Bulkload	Can load this table with bulk loads if the table was created with bulk load support.
Replication Access	Can set up replication either to or from a table.
Create/Rename Column Family	Can create column families for this table or rename existing column families.
Delete Column Family	Can delete column families associated with the table.

Viewing Table Settings Using the CLI and REST API

About this task

CLI

The basic command to retrieve table information is the following:

```
/opt/mapr/bin/maprcli table
info -path <tablePath> -json
```

REST

Send a request of type GET to retrieve table details. For example:

```
curl -k -X
GET 'https://<hostname>:8443/rest/
table/info?path=<tablePath>' --user
<username>:<pwd>
```

For more information on the settings, see the `table info` command.

Listing Column Families

Explains how to view the column families for a table using either the Control System or the CLI.

Viewing Table Column Families Using the Control System

About this task

To view the column families for a table:

last-updated: Jun 06, 2024

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click the **Column Families** tab.
   The page displays the default permissions for the column families in the **Default Column Family Authorization** pane, and for each column family, the **All** pane displays:

Column Name	Column Description
Column Family Name	The name of the column family.
JSON Path	The JSON path for the column in the JSON file in dotted notation.
Compression	The compression scheme used for the column family.
Time-to-Live	The amount of time to keep the data in the column family.
In Memory	Whether or not this column value resides in memory.

   Selecting the checkbox associated with the column family makes the **Remove Column Family** button available. You can:

   - Add a column family to the table
   - Remove a column family associated with the table

Viewing Table Column Families Using the CLI or REST API

About this task

The command to list the column families that are in a table is:

```
maprcli table cf list -path <path> -cfname <name_of_column_family>
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  NOTE: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♠=#;{}&()/"  (or)
  maprcli table create -path '/♠=#;{}&()/'
  ```

last-updated: Jun 06, 2024

To use either the **'** or the **"** character in the table name, enclose:

- the **'** character within double quotes (")
- the **"** character within single quote (')

For example:

```
maprcli table create -path "/'♦=#;{}&()/"  (or)
maprcli table create -path '/"♦=#;{}&()/'
```

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the paths
- `adminaccessperm` on the table

For complete reference, see the `table cf list` command.

Viewing Table Regions
Use either the Control System or the CLI to list the regions in which a table's data is located.

About this task

HPE Ezmeral Data Fabric Database tables are split into regions on an ongoing basis. Administrators and developers do not need to manage these regions or restructure data on disk when data is added and deleted. These operations happen automatically. You can view region information for tables to get a sense of the size and location of table data on the data-fabric cluster.

Displaying the Regions Using the Control System

About this task

To display the regions of a table:

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Do one of the following:
   - Click **Regions** to view the list of regions for the table.
   - Click the name of the index in the **Indexes** tab to view the regions for the index.

   For each region, the **Regions** pane displays the following:

Column Name	Column Description
Start Key	Value of the start key for this region. For the first region in a table, this value is exclusive. For all other regions, it is inclusive.
End Key	Value of the end key for this region. This value is always exclusive.
Physical Size	The physical size of the region with data compression (excluding replication).

Column Name	Column Description
Logical Size	The logical size of the region without data compression (excluding replication).
No of Rows	Number of rows in the region.
Primary Node	The host name and port of the primary node for this region.
Secondary Node	The host names and ports of the secondary nodes where this region is replicated.
Last HB	The time since last heartbeat from the region's primary node.
Region Identifier	The region's FID.

Displaying Region Information Using the CLI or the REST API

About this task

The basic command to retrieve the list of regions that make up the table is:

```
maprcli table region list -path <path>
```

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  NOTE: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♠=#;{}&()/"  (or)
  maprcli table create -path '/♠=#;{}&()/'
  ```

  To use either the **'** or the **"** character in the table name, enclose:

  - the **'** character within double quotes (")
  - the **"** character within single quote (')

  For example:

  ```
  maprcli table create -path "/'♠=#;{}&()/"  (or)
  maprcli table create -path '/"♠=#;{}&()/'
  ```

The `json` parameter displays the output as a JSON document.

To run this command, your user ID must have the following permissions:

last-updated: Jun 06, 2024

- `readAce` on the volume
- `lookupdir` on directories in the path

See `table region list` on page 2493.

Displaying the List of Table Replicas
Describes how to view information on the table replicas using the Control System or the CLI.
Displaying the List of Table Replicas Using the Control System

About this task
To view table replicas:

Procedure

1. Log in to the Control System and go to the table information page.
2. Click **Replication**.
   The page displays all the replicas and for each replica, the pane displays the following statistics:

Column Name	Column Description
Paused	Whether replication is paused.
Destination Cluster	The cluster on which the replica resides.
Destination Path	The path to the destination.
Status	The status of the replica. Replicas can be in one of the following states: • In-Synch — indicates replica is in synch with the source table and there are no more bytes to be sent from the source. • Pending — indicates replica is waiting for some bytes to be sent from the source. You can hover over the status to determine the number of bytes, puts, and buckets pending. • Broken — indicates there was an error during replication. If necessary, remove and re-create the replica.
Earliest	The epoch time in milliseconds of the oldest operation that is yet to be replicated to the replica.
Latest	The epoch time in milliseconds of the newest operation that is yet to be replicated to the replica.
Errors	Error ( ) information, if any.
Compression Type	The type of on-wire compression.
Synchronous	Whether replication is synchronous or asynchronous.
Throttled	Whether replication is throttled.
Encrypted	Whether replication is encrypted.

last-updated: Jun 06, 2024

Retrieving List of Table Replicas Using the CLI or the REST API

About this task

To view table replicas and associated replica statistics for a table, run the following command:

```
maprcli table replica list -path <table-path>
```

For more information, see `table replica list` on page 2513

Viewing the List of Change Logs
Explains how to view the list of change logs using the Control System or the CLI.
Viewing the List of Change Logs Using the Control System

Procedure

- Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
  For each change log, the page displays the following:

Column Name	Column Description
Edit Change Log	Shortcut to the **Edit Change Log** window for editing a change log.
Paused	Specifies whether the change propagation is paused for the associated change log.
Destination Cluster	Specifies the destination cluster on which the stream exists.
Destination Stream Topic Name	Specifies the name of the stream associated with the change log.
Up to Date	Specifies whether (**Yes**) or not (**No**) the change log is up to date. If value is **No**, hover the cursor over the value to see the number of pending bytes, puts, and buckets.
Errors	Indicates whether there were any errors during change propagation.
Compression Type	The type of compression for data transfer between file system and gateway for the associated change data log instance
Synchronous	Specifies whether client writes to the table should be acknowledged before the CDC gateway receives the data.
Throttle	Specifies whether data transfer to the stream for the associated change data log is throttled.
Encrypted	Specifies whether the data transfer between file system and gateway for the associated change data log is encrypted.
Field Path	Specifies whether only specific field paths are being published to the stream topic.

Retrieving the List of Change Logs Using the CLI or REST API

About this task

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog list
```

For complete reference, see table changelog list on page 2462.

Listing Secondary Indexes
Describes how to list information about the secondary indexes created on HPE Ezmeral Data Fabric Database JSON tables.

About this task

You can view secondary indexes using the Control System or the `maprcli table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path

NOTE: The mapr user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Listing Indexes in the Control System

Procedure

- Log in to the Control System and go to the **Indexes** tab in the table information page.
  The list of indexes displays in the **All indexes** pane and for each index, the page displays the following:

Column Name	Column Description
Index Name	The name of the index
Fields Indexed	The number of fields on the JSON table that are indexed and used for ordering
Fields Covered	The number of fields on the JSON table that are indexed, but not used for ordering
State	The replication state of the index
Up to Date	Whether the index is up to date
Hashed	Whether the index is hashed
Size	The size of the index

What to do next

To view more details on individual indexes, see Viewing Secondary Index Details on page 1474.
Listing Indexes Using the CLI

About this task

The following is basic command for listing secondary indexes.

```
maprcli table index list
            -path <path>
            -refreshnow < true | false >
```

See `table index list` on page 2481 for more information.

Viewing Table Metrics in the Control System
Explains how to view primary and secondary table index metrics using the Control System.

A subset of the following primary table and secondary index metrics are available as charts and lists in the Control System. For information on how to:

last-updated: Jun 06, 2024

- View these metrics in the Control System, see Monitoring Tables on page 1677.
- Customize the charts you see on the page, see Creating a Custom Board for the Charts on page 1663.
- Customize columns you see on the page, see Adding and Removing Columns from the List View on page 1665.

Chart/Column Name	Metric	Description
Table Bytes Read Per Node	Throughput - bytes read	The number of bytes read from the primary table per node for all RPC types.
Table and Index Bytes Read		The number of bytes read across a primary table and its secondary indexes for all RPC types.
Table Bytes Written Per Node	Throughput - bytes written	The number of bytes written to the primary table per node for all RPC types.
Table and Index Bytes Written		The number of bytes written across a primary table and its secondary indexes for all RPC types.
Table Rows Read Per Node	Throughput - rowCount read	The number of rows read from the primary table per node for all RPC types.
Table and Index Rows Read		The number of rows read across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node.
Table Rows Written Per Node	Throughput - rowCount written	The number of rows written to the primary table per node for all RPC types.
Table and Index Rows Written		The number of rows written across a primary table and its secondary indexes for all RPC types.
All Tables Written Rows Throughput		Number of rows written by RPC operation type.
Table Rows Responded Per Node	Throughput - rowCount returned	The number of rows returned from the primary table per node for all RPC types.
Table and Index Rows Responded		The number of rows returned across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node.
Scan Throughput		Compares the scan throughput for rows read versus rows returned. This is displayed in the default chart view for a node and for a table.

last-updated: Jun 06, 2024

Chart/Column Name	Metric	Description
All Tables Throughput	Throughput - rpcCount/second	Number of RPC operations by type for all tables in the cluster. This is displayed in the default chart view for all the tables.
Throughput by Rpc Type		The combined RPC load for the primary table and its indexes.
All Tables RPC Byte Throughput		The number of bytes processed by RPC operation type.
All Tables Read Rows Throughput		Number of rows processed by RPC operation type.
All Tables Returned Rows Throughput		Number of rows returned by RPC operation type.
Put and Append Operation Throughput		Number of put and append RPC operations for the table, including its indexes.
Table Check and Put Ops Per Node		The number of check and put operations completed for a primary table and for a node.
Table Update and Get Ops Per Node		The number of update and get operations completed for a primary table and for a node.
Table Get and Index Scans		The number of get and index scans completed for a primary table and for a node.
Table Write and Index Maintenance Activity		The number of table writes (puts, appends, increments, check and puts, update and gets) that require puts to the index.
Table Get Ops Per Node		The number of get operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Get Throughput Per Node		The number of get operations completed per second for a table, excluding its secondary indexes, per node. This is displayed in the default chart view for a node and for a table.
Table Increment Ops Per Node		The number of increment operations completed for a primary table and for a node.
Table Put Ops Per Node		The number of put operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Scan Ops Per Node		The number of scan operations completed for a primary table and for a node.
Table Append Ops Per Node		The number of append operations completed for a primary table and for a node.
Table Write Throughput Per Node		The number of put and append

Chart/Column Name	Metric	Description
Table and Index Scan Latency	Latency	The 99th percentile latency of all scan operations across the primary table and its secondary indexes. A bad ratio between rows read and responded with high scan latency may indicate a poorly configured index.
Table and Index Scan Latency Per node		The 99th percentile latency of scan operations completed across the primary table and secondary index per node. Large scans may hit the disks and result in poor performance, or a degrading disk may spike the latency.
Table Append Latency Per Node		The 99th percentile latency of append operations on the primary table per node.
Table Increment Latency Per Node		The 99th percentile latency of increment operations on the primary table per node.
Table Put Latency Per Node		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Get Latency Per Node		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Scan Latency Per Node		The 99th percentile latency of scan operations on the primary table per node.
Table Get Latency Percentiles*		The get operation latency by percentile for the primary table and its secondary indexes.
Primary Table Put & Append Latency Percentiles*		The pure write operation latency by percentile for the primary table and its secondary indexes.
Table Write Throughput Latency Percentiles		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Get Throughput Latency Percentiles		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Check and Put Latency Per Node		The 99th percentile latency of check and put operations on the primary table per node.
Table Update and Get Latency Per Node		The 99th percentile latency of update and get operations on the primary table per node.
Index Put Latency		The 99th percentile latency of put operations per secondary index of the

Chart/Column Name	Metric	Description
All Tables Replication Sent Bytes	Replication - rows/bytes sent	The number of bytes of replication data sent.
All Tables Replication Pending Bytes	Replication - rows/bytes pending	The number of bytes of replication data not yet sent.
All Tables Replication Activity	Replication - rows/bytes sent/pending	Number of bytes of replication data sent vs not yet sent. This is displayed in the default chart view for all the tables.
Index Throughput by RPC Type	Index - Throughput	The combined RPC load for the primary table and its secondary indexes.
Index Put Ops		The number of put operations completed per secondary index of the primary table.
Index Put Ops Per Node		The number of put operations completed per secondary index of the primary table per node.
Index Scan Ops		The number of scan operations completed per secondary index of the primary table.
Index Scan Ops Per Node		The number of scan operations completed per secondary index of the primary table per node.
Index Bytes Read	Index - rows/bytes read	The number of bytes read per secondary index of the primary table for all RPC types.
Index Bytes Read Per Node		The number of bytes read per secondary index of the primary table per node for all RPC types.
Index Bytes Written Per Node		The number of bytes written per secondary index of the primary table per node for all RPC types.
Index Rows Read		The number of rows read per secondary index of the primary table for all RPC types.
Index Rows Read Per Node		The number of rows read per secondary index of the primary table per node for all RPC types.
Index Rows Responded	Index - rows/bytes returned	The number of rows returned per secondary index of the primary table for all RPC types.
Index Rows Responded Per Node		The number of rows returned per secondary index of the primary table per node for all RPC types.
Index Scan Read vs Returned Rows	Index - rows/bytes read	The number of secondary index rows that were read versus returned.

last-updated: Jun 06, 2024

Chart/Column Name	Metric	Description
Index Bytes Written	Index - rows/bytes write	The number of bytes written per secondary index of the primary table for all RPC types.
Index Rows Written		The number of rows written per secondary index of the primary table for all RPC types.
Index Rows Written Per Node		The number of rows written per secondary index of the primary table per node for all RPC types.
All Tables Index Sent Bytes	Index - rows/bytes sent	The number of bytes sent for secondary index updates.
All Tables Index Pending Bytes	Index - rows/bytes pending	The number of bytes of secondary index data remaining to be sent.
All Index Maintenance Activity		Number of bytes of index data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Tables CDC Sent Bytes	CDC - rows/bytes sent	The number of bytes of CDC data sent.
All Tables CDC Pending Bytes	CDC - rows/bytes pending	The number of bytes of CDC data per node not yet sent.
All Tables CDC Propagation Activity		The number of bytes of CDC data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Streams Producer Ops	Streams Throughput, RPCs	The number of Streams producer RPCs.
All Streams Consumer Ops		The number of Streams consumer RPCs.
All Streams Producer Messages	Streams Throughput, messages	The number of Streams messages produced.
All Streams Consumer Messages		The number of Streams messages read by consumers.
Table Value Cache All Lookups	Value Cache Lookups	All operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups		The number of get operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups Per Index		The number of get operations for a primary table and for a node that performed a cache lookup.

last-updated: Jun 06, 2024

Chart/Column Name	Metric	Description
Table and Index Value Cache All Lookups	Value Cache Hits	All operations across the primary table and its secondary indexes that performed a cache lookup.
Table and Index Value Cache Lookups Per Index		The number of get operations across the primary table and its secondary indexes that performed a cache lookup per secondary index.
Table and Index Value Cache Lookups		The number of get operations across the primary table and its secondary indexes that performed a cache lookup.
Table Value Cache All Hits		All operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits Per Index		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table and Index Value Cache All Hits		All operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits Per Index		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit per secondary index.
Value Cache Utilization	Value Cache	Compares the relative distribution of get operations that either hit the cache or require a lookup. This is displayed in the default chart view for a node and for a table.
All Tables Flushes	Bucket Flushes	The number of table flushes that were manually and automatically triggered. Table flushes reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold. This is displayed in the default chart view for all the tables.
All Tables Flushes		The number of total table flushes that were manually versus automatically triggered.
All Tables Force Flushes	Bucket Force Flushes	The number of table flushes that were not automatically triggered.

last-updated: Jun 06, 2024

Chart/Column Name	Metric	Description
All Tables Compactions	Compaction	Number of table compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. This is displayed in the default chart view for all the tables.
All Tables Full Compactions		Number of full compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. Full compactions improve read performance because after compaction, HPE Ezmeral Data Fabric Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files.
All Tables Mini Compactions		Number of partial compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. After a mini compaction, HPE Ezmeral Data Fabric Database needs to read only two spill files.
All Tables TTL Compactions		Number of compactions that result in reclamation of disk space after removal of stale data. You can control the frequency of TTL compactions by configuring the TTL for a table's column families.
All Tables Free Index Memory	Memindex Usage	The number of available MB in the in-memory bucket file cache.

* Percentiles are estimated by linearly interpolating between fixed buckets sizes.

Loading Documents into JSON Tables

There are three command-line utilities for loading documents into JSON tables: `mapr copytable`, `mapr importtable` (which works in conjunction with the `mapr exporttable` utility), and `mapr importJSON`

You can choose whether to have these utilities perform bulk loads or incremental loads.

For bulk loads, the `-bulkload` parameter of the JSON table must be set to `true`. During a bulk load, client applications are unable to access the table. After the utility is finished, you must set the table's `-bulkload` parameter to `false`, so that client applications can access the table again.

When you set the `-bulkload` parameter to true, you cannot enable replication on the table. Since this effectively disables logging on the table, HPE Ezmeral Data Fabric Database also does not capture log data that Elasticsearch can use to index the table.

NOTE: Incremental loads allow client applications to access the table as the documents are loaded. However, incremental loads are slower than bulk loads.

last-updated: Jun 06, 2024

`mapr copytable`

The `mapr copytable` utility copies documents -- all documents or a subset determined by a range of row keys, and all fields or a subset of fields -- directly from oneJSON table to another.

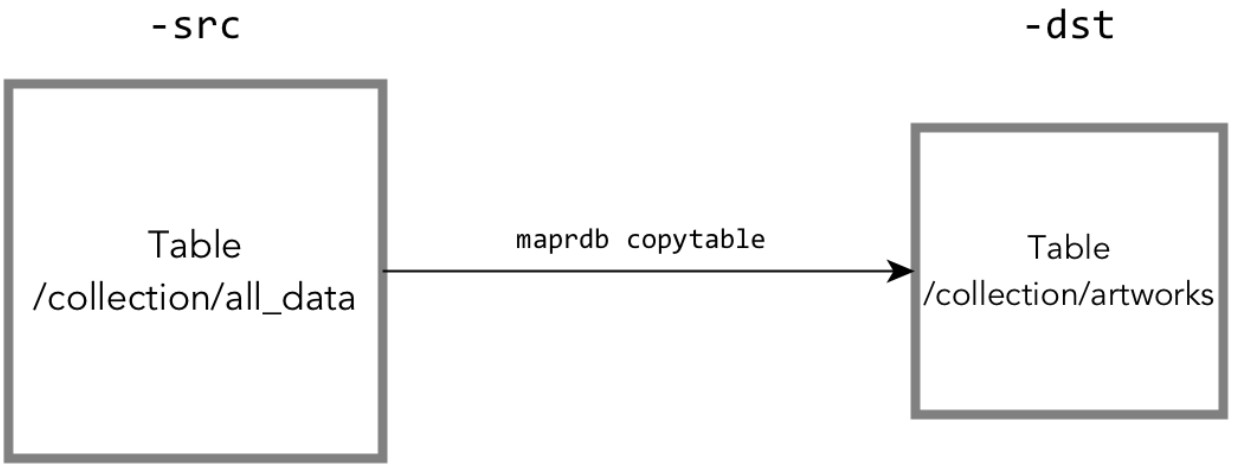


Figure 15: Copying a subset of data from one table to another

For reference information about this utility, see `mapr copytable`.

`mapr exporttable` and `mapr importtable`

The `mapr exporttable` utility exports data from a JSON table to binary sequence files that you can import into another JSON table by using the `mapr importtable` utility.

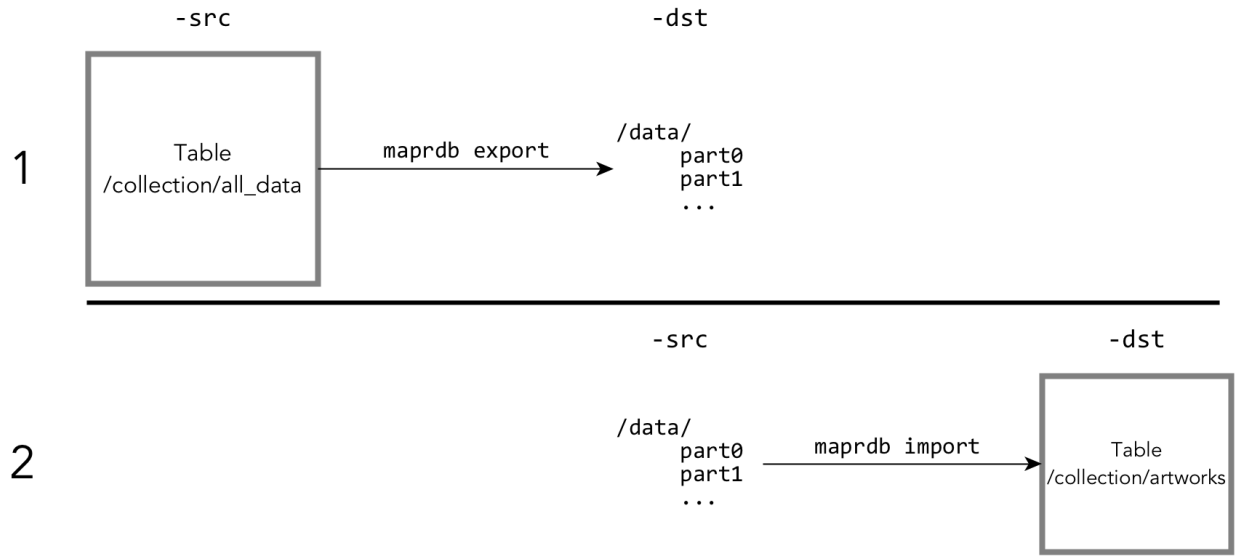

Figure 16: JSON documents exported from a JSON table as binary sequence files and then imported into another JSON table

The destination directory is created by the `mapr exporttable` utility. To prevent accidental overwriting of data, the `mapr exporttable` utility fails if the destination directory already exists.

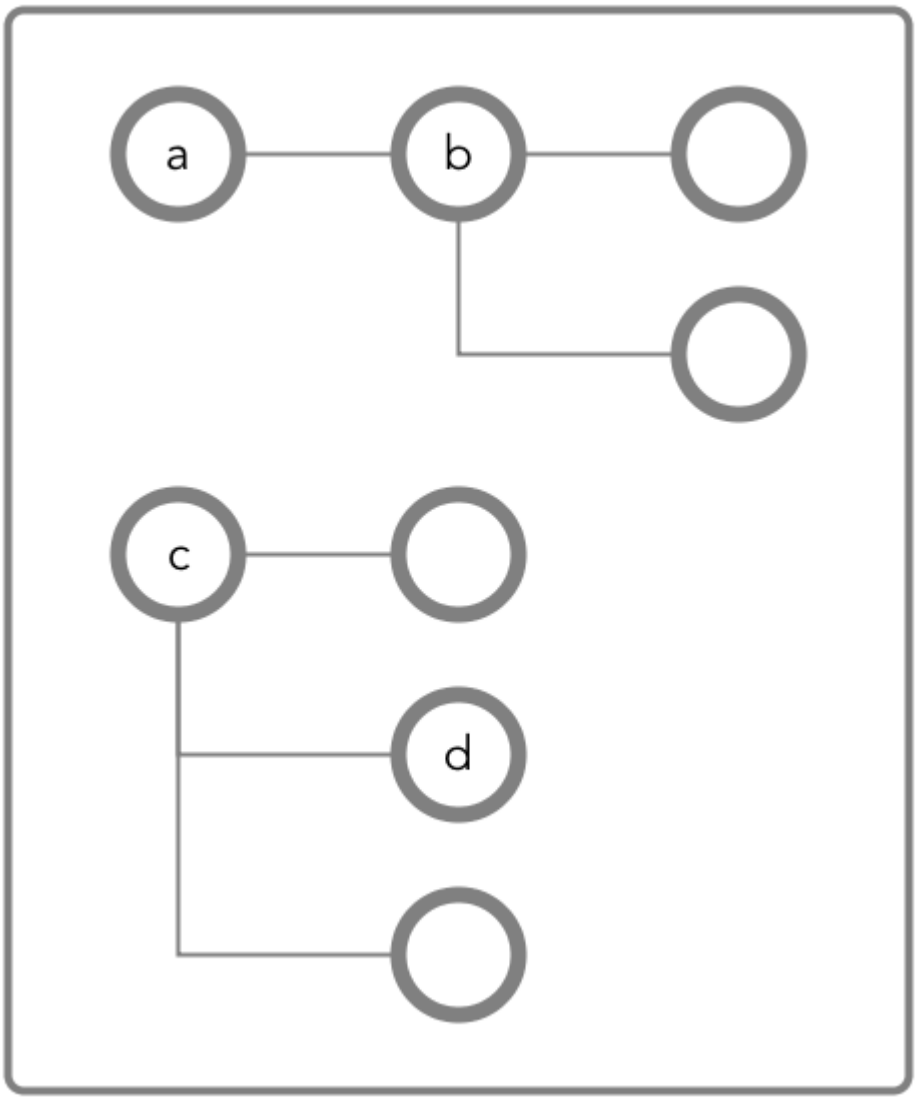
last-updated: Jun 06, 2024

The command for running the `mapr importtable` utility in step 2 of the diagram above would look like this:

```
mapr importtable -src /data/* -dst /collection/artworks
```

The `-columns` parameter of the `mapr exporttable` utility lets you export subsets of the fields in the documents that are in a table. For example, to export field b, the fields under it, and field d from documents with the following structure, the command to run the `mapr exporttable` utility would look like this:

```
mapr exporttable -columns a.b,c.d -src /collection/all_data -dst /data
```



For reference information about these commands, see HPE Ezmeral Data Fabric Database JSON ExportTable and ImportTable on page 5504.

`mapr importJSON`

This utility imports one or more JSON documents that are text files into a JSON table.

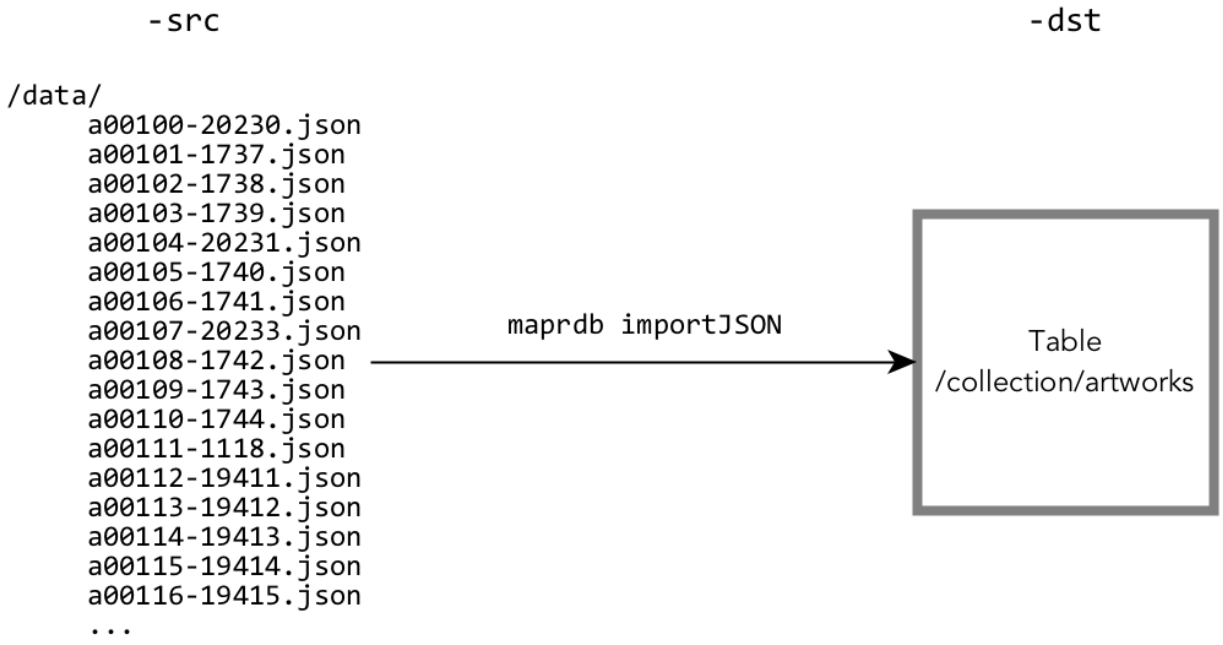


Figure 17: JSON documents in a folder named /data being imported into a JSON table

If the each document does not already contain an `_id` field to use as a document ID, the `mapr importJSON` utility adds an `_id` field during the import. Use the `-idfield` parameter to specify the name of the field that contains the value to copy into the value of the `_id` field.

For example, each document might have a `product_ID` field that contains a universally unique identifier. You could run the utility with this command:

```
mapr importJSON -idfield "product_ID" -src /data/* -dst /collection/artworks
```

For reference information about this command, see the `mapr importJSON` command.

Loading Data into Binary Tables

Bulkload operations can be performed as a full bulkload or as an incremental bulkload.

The most common way of loading data into a HPE Ezmeral Data Fabric Database Binary Tables is with a put operation. However, at large scales, bulk loads offer a performance advantage over put operations.

Bulk loading is supported by the following tools, which can be used for both full and incremental bulkload operations:

- Hbase *HPE Ezmeral Data Fabric Database Binary CopyTable* utility which copies HPE Ezmeral Data Fabric Database binary table data, table metadata, access control expressions, and more to another HPE Ezmeral Data Fabric Database binary table.

  ```
  hbase com.mapr.fs.hbase.tools.mapreduce.CopyTable
  ```

- Hbase `ImportFiles` utility which imports HFile or Result files into HPE Ezmeral Data Fabric Database binary tables. For example:

```
hbase com.mapr.fs.hbase.tools.mapreduce.ImportFiles
   -Dmapred.reduce.tasks=2
   -inputDir < input directory, for example: /test/tabler.kv >
   -table < table name, for example: /table2 >
   [ -format < Result|HFile > ]
   [ -sample < true|false > ]
   [ -mapOnly < true|false > ]
```

Full Bulk Loads

Full bulkload operations offer the best performance advantage because it skips the write-ahead log (WAL) typical of HPE Ezmeral Data Fabric Database binary table operations. Full bulkload operations can only be performed on empty tables that have the `bulkload` attribute set to **true**. This value is set only when creating a table.

When you set the `bulkload` attribute, you cannot enable replication on the table. Since this effectively disables logging on the table, HPE Ezmeral Data Fabric Database also does not capture log data that Elasticsearch can use to index the table.

IMPORTANT: Tables are unavailable for normal client operations, including put, get, and scan operations, while a full bulkload operation is in progress.

To create a HPE Ezmeral Data Fabric Database binary table for bulkloading, use one of the following:

- maprcli table create command with tthe `-bulkload` parameter set to true.
- Apache HBase shell `create` command with the `BULKLOAD` parameter set to `true`. For example:

```
hbase> create '/a0','f1', BULKLOAD => 'true'
```

  If you want to pre-split a table, separate the `BULKLOAD` parameter from the `SPLITS` parameter. For example:

```
hbase> create '/t1', 'f1', {SPLITS => ['10', '20', '30']}, {BULKLOAD =>
'true'}
```

- Control System with **Will table be bulkload?** option set to **Yes** under table **PROPERTIES**.

NOTE: Attempting a full bulkload on a table that does not have the bulkload attribute set to true results in an incremental bulkload being performed instead.

After you perform a full bulkload on a table, you cannot perform a full bulkload on it again. For example:

- You cannot use the `maprcli table edit` command to set the `bulkload` parameter to TRUE again.
- You cannot use the Apache HBase shell `alter` command to set the `BULKLOAD` parameter to TRUE again.
- In the Control System, the **Will table be bulkload?** option cannot be modified after table creation.

Incremental Bulk Loads

Incremental bulk loads can add data to existing tables concurrently with other table operations, with better performance than put operations. This type of bulk load makes use of write-ahead log files.

NOTE: Tables are available for client operations, such as put, get, and scan operations, during incremental bulk loads.

You can use incremental bulk loads to ingest large amounts of data to an existing table. Tables remain available for standard client operations such as put, get, and scan while the bulk load is in process. A table can perform multiple incremental bulk load operations simultaneously.

NOTE: Whether you create a table with the `maprcli table create` command, with the hbase shell's `create` command, or in the Control System, incremental loads are supported by default.

Performing File System Operations on HPE Ezmeral Data Fabric Database Tables

The data-fabric file system stores tables in the same namespace as files. You can move and delete tables in much the same way as you can with files. All file system operations remain accessible with the `hadoop fs` command.

Volume properties, such as replication factor or rack topology, that apply to the specified location also apply to tables stored at that location. You can move a table with the Linux `mv` command or the `hadoop fs -mv` command.

When you use Direct Access NFS or the `hadoop fs -ls` command to access a MapR cluster, tables and files are listed together. Because the client's Linux commands are not table-aware, other Linux file manipulation commands, notably file read and write commands, are not available for HPE Ezmeral Data Fabric Database tables.

This section describes the operations that you can perform on HPE Ezmeral Data Fabric Database tables through a Linux command line when you access the cluster through NFS or with the `hadoop fs` commands.

Setting Permissions

HPE Ezmeral Data Fabric Database tables do not support setting user permissions through the UNIX `chmod` command or the `hadoop fs -chmod` analogue. Instead, HPE Ezmeral Data Fabric Database table access is controlled with Access Control Expressions (ACEs). See Enabling Table and Stream Authorizations with ACEs on page 1363.

Read and Write

You cannot perform read or write operations on a HPE Ezmeral Data Fabric Database table from a Linux file system context. For example, you cannot use the `cat` command to view the content of a table or search through a table with the `grep` command. file system returns an error when an application attempts to read or write to a HPE Ezmeral Data Fabric Database table.

Move

You can move a HPE Ezmeral Data Fabric Database table within a volume with the `mv` command over NFS or with the `hadoop fs -mv` command. These moves are subject to the standard permissions restrictions. Moves across volumes are not currently supported.

Remove

You can remove a table with the `rm` command over NFS or with the `hadoop fs -rm` command. These commands remove the table from the namespace and asynchronously reclaims the disk space. You can remove a directory that includes both files and tables with the `rm -r` or `hadoop fs -rmr` commands.

NOTE: To prevent users from deleting a particular table, you must ensure that users do not have WRITE permission on the folder in which the table is located. Permissions on the table itself are not used in evaluating whether a user can delete the table. This convention follows standard UNIX rules for file and directory permissions.

last-updated: Jun 06, 2024

Copy and Recursive/Directory Copy

Table copying at the file-system level is not supported. See Migrating Between Apache HBase Tables and HPE Ezmeral Data Fabric Database Tables for information on copying tables using the HBase shell.

Managing Column Families and Columns

This section covers overviews of column families in binary tables and JSON tables, how to create column families, alter them, delete them, set permissions on them, and set and display parameter values.

For a conceptual overview of column families in binary tables, see *Column Families in Binary Tables*.

For a conceptual overview of column families in JSON tables, see *Managing Column Families*.

Creating Column Families

Explains how to create column families using either the Control System, the CLI, or the HBase shell.

About this task

There are several methods that you can use to create column families in HPE Ezmeral Data Fabric Database tables. To create column families, you must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path to the table
- `createrenamefamilyperm` on the table

Creating Column Families Using the Control System

About this task

To create a column family from the Control System, under **Data** > **Tables**:

NOTE: This option is not available on the Kubernetes version of the Control System.

Procedure

1. Click:
   - **Take me to Add Column Family** after creating a new table.
   - **Add Column Family** from the **All** pane of **Column Families** tab under the table information page.

     See Viewing Table Information on page 1368.
2. Specify the following properties in the **Properties** pane of the **Add Column Family** page to set up a column family, as needed. See the table below for information on fields shown under the **Properties** pane of the **Add Column Family** page.

JSON Table Properties

Field	Field Description
Column Family Name	The name of the column family.

last-updated: Jun 06, 2024

Field	Field Description
JSON Path	The path to the column family in dotted notation. For example, suppose the table contained JSON documents that were of this general structure: `{ "_id" : "ID", "a" : { "b" : { "c" : "value", }, "e" : "value" } }` If you want to create a column family at the field `d` nested within `b`, your new path would be `a.b.d`. **NOTE:** Ensure that the field at which you want to create the column family does not yet exist. If the field exists, it could become inaccessible after the column family is created.
Compression	The compression setting to use for the column family. Valid options are `off`, `lzf`, `lz4`, and `zlib`. The default setting is the same as the compression setting for the directory where the table is located.

Field	Field Description
In Memory	Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled. **NOTE:** All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family. By default, this is enabled.

last-updated: Jun 06, 2024

Binary Table Properties

Field	Field Description
Column Family Name	The name of the column family.
Version	• Minimum — The minimum number of versions of column values to keep. The default is zero. • Maximum — Maximum number of versions of column values to keep. The default is one.
Compression	The compression setting to use for the column family. Valid options are off, lzf, lz4, and zlib. The default setting is the same as the compression setting for the directory where the table is located.
Time-to-Live	Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever.

last-updated: Jun 06, 2024

Field	Field Description
In Memory	Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled. **NOTE:** All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family. By default, this is enabled.

3. (JSON Tables) Under the **Security Policy** pane, set the security policy for the displayed table column family, as needed:
   a) Open the **Security** pane of the page, if not already opened.
   b) Enter the name of or the first few characters of the name of an existing security policy in the **Search for security policy** field. Available policies matching your entry will be listed below the field.

      NOTE: Tagging for the currently displayed table must be set to **Yes** to be able to use security policy options. All security policies are set up and created from the **Security** page.

   c) Click the checkbox next the name of the needed security policy, if listed. The selected policy is applied to the displayed table column family.
   d) Click **Add** to the apply the security policy with its settings to the currently displayed table column family. The name of the security policy appears above the search box after you click **Add**.
4. Select **Basic** or **Advanced** to set up access controls (shown under the **User Access Control** pane) for the displayed column family, as needed. Note that the page options displayed after selecting **Basic** or **Advanced** differ. These differences are explained below. See the JSON Table Data Access Control Permission Options or Binary Table Data Access Control Permission Options tables below for permission descriptions.

   NOTE: By default, all permissions are given to the user creating the table. You can use either the default permissions that are automatically displayed or proceed to define new permissions for this column family.

   To grant or block access to users, groups, and/or roles, from the:

   - **Basic** settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

     TIP: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

     To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.
   - **Advanced** settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
     - ! — Negation operator.
     - & — AND operation.
     - | — OR operation.

     Use ( ), parentheses, for subexpressions.

     NOTE: You *cannot* specify user, group, or role individually if access is granted to all users (public).

     Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs Using the Access Control Expression Builder on page 1881 for more information.

NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (`&`) and negation (`!`) operations that are supported by advanced settings are not supported in the basic settings.

JSON Table Data Access Control Permission Options

Option	Option Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on `a.b`, but not on `a`. For sjohnson to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family.
Set Compression	Can set or change the compression setting for the column family.

Option	Option Description
Unmasked Data	Check **Unmask Data** to direct the system to show all data for the table column family for this new table. Leaving the **Unmask Data** unchecked directs the system to hide table column data when using this security policy for the selected user type.

Binary Table Data Access Control Permission Options

Option	Option Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

5. Click **Add Column Family** to add the column family to the table. The name of newly created column family appears in the **All** pane of the tables information page.
6. Opt to add field permissions to the newly created column family.

Creating Column Families Using CLI or the REST API

About this task

JSON Table

To create a column family in a JSON table, include the parameters `-jsonpath` and `-force` :

```
maprcli table cf
create -path <path> -cfname
<name_of_column_family> -jsonpath

<path> -force true
```

For the full list of options, see the `table cf create` command.

The `-jsonpath` parameter specifies the path to the column family. The path is in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
     "_id" : "ID",
     "a" :
          {
               "b" :
                    {
                         "c" :
"value",
                    },
               "e" : "value"
          }
}
```

You want to create a column family at the field `d` in the new path `a.b.d` because you plan to store image files in fields in that column family.

IMPORTANT: Ensure that the field at which you want to create the column family does not yet exist. Also ensure that there are no secondary indexes defined on the field. If the field does exist or is a field in an index, the data in the field could become inaccessible after you create the column family.

By default, every time you try to create a non-default column family in a JSON table, this command fails and returns a warning message that you should ensure there is no existing data at the specified path. Set the `-force` parameter to `true` if you want to override this warning mechanism and create a column family.

Binary Table

The command to create a column family for a binary table is:

```
maprcli table cf create -path
<path> -cfname <name_of_column_family>
```

For the full list of options for this command, see the `table cf create` command.

last-updated: Jun 06, 2024

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster.

Creating a Column Family for a Binary Table Using HBase Shell

About this task

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Permission Types for Fields and Column Families in JSON Tables
By using ACEs, you can grant or deny access to fields and column families that are in JSON tables.

There are three types of permission:

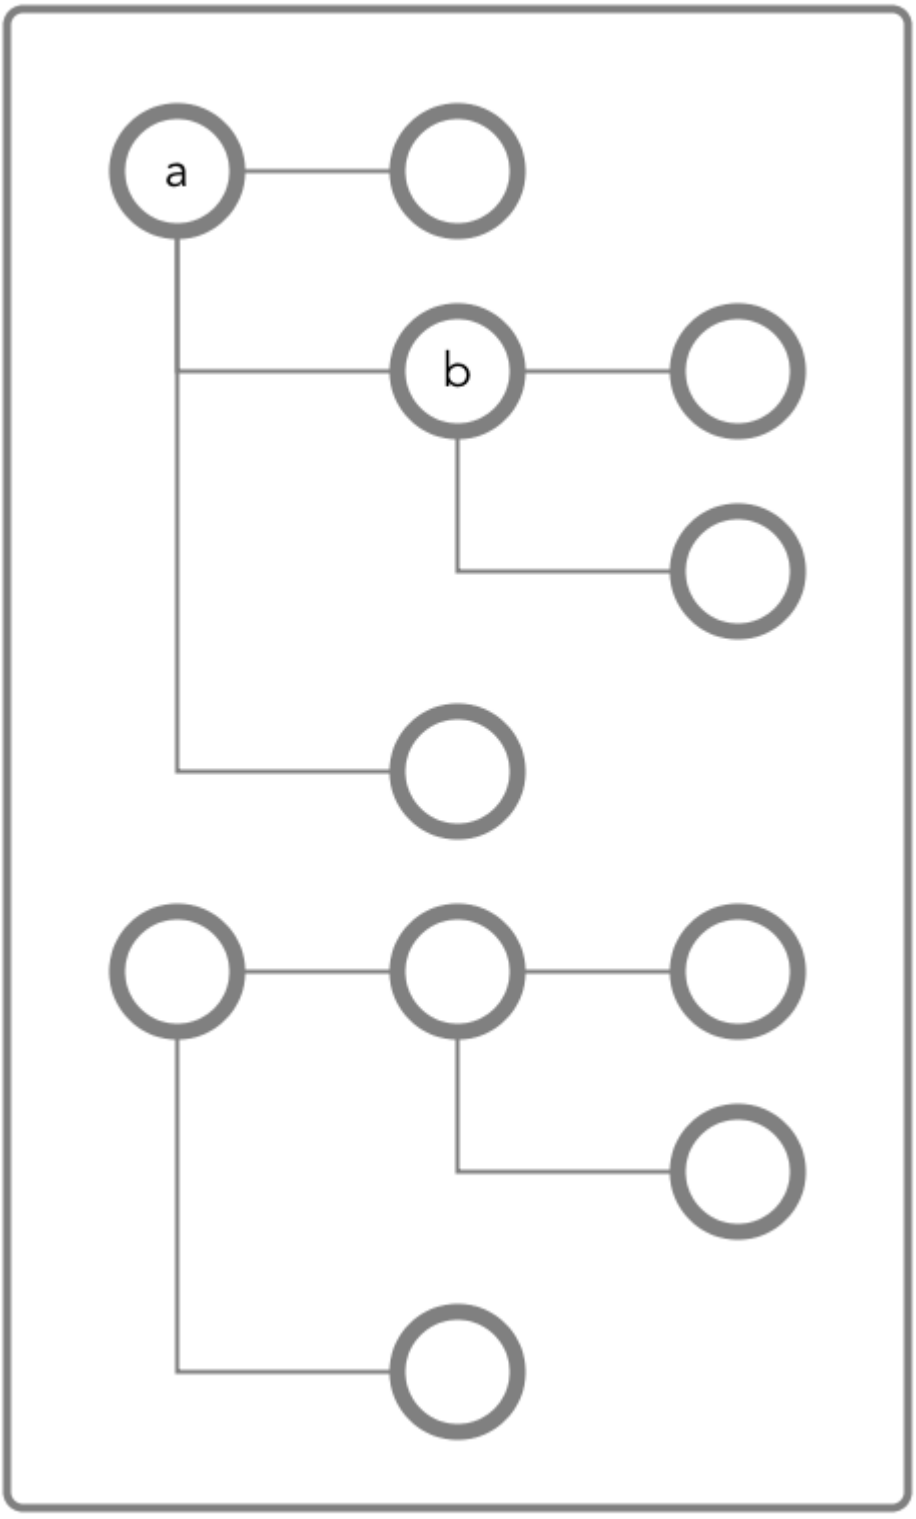
- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access fields on which the grantee has write or read permission.

For example, suppose that a user has read and write access to only field b below.

last-updated: Jun 06, 2024

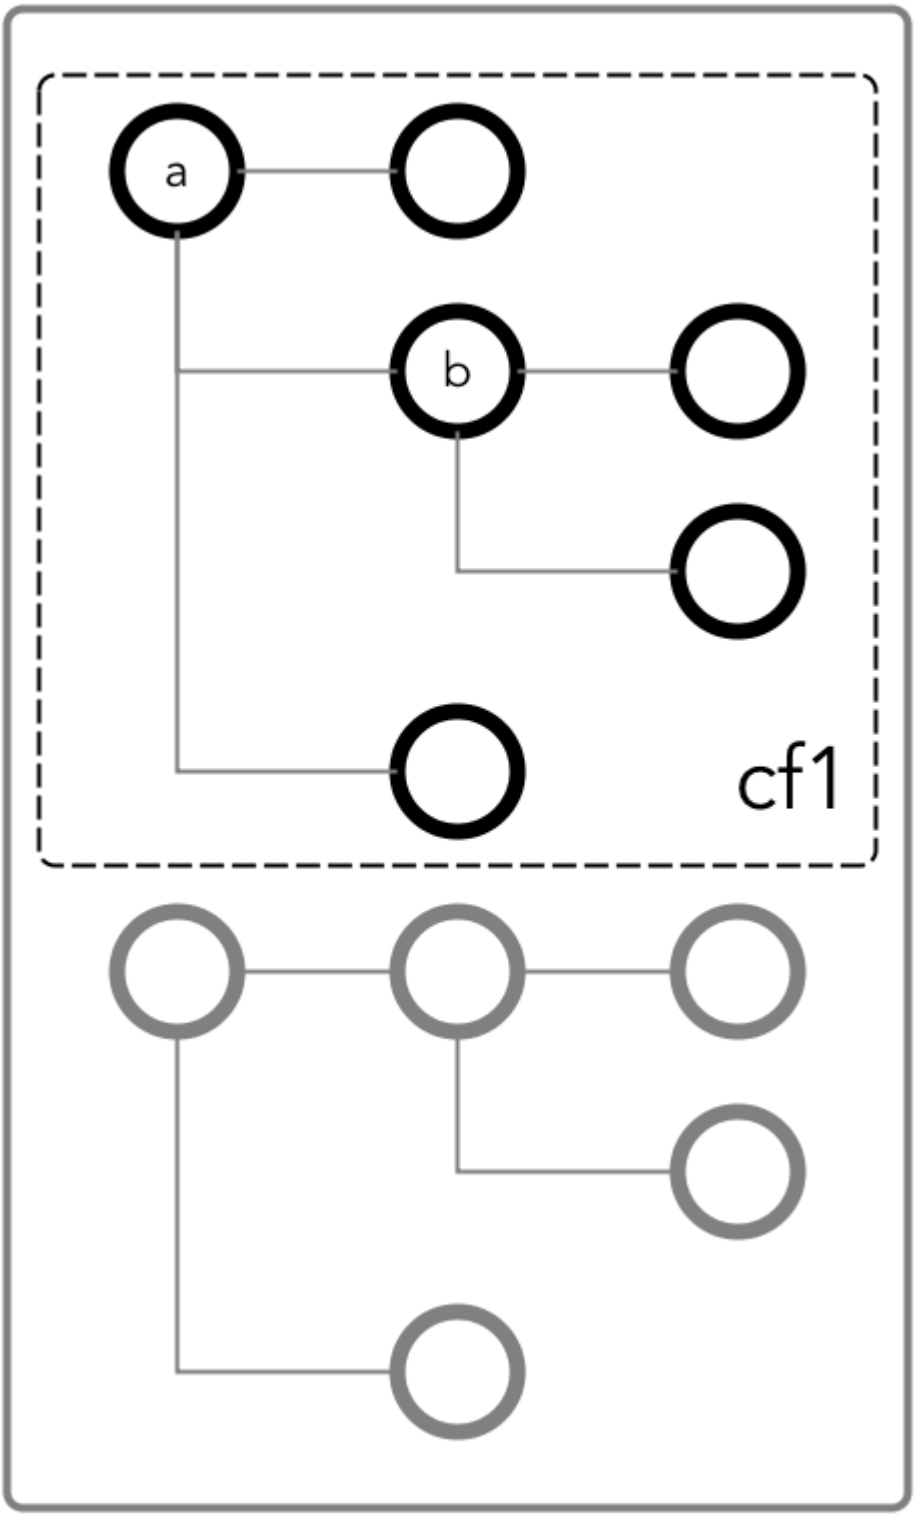


To access field b, the user would need to be able to traverse (pass through) field a. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If a user was denied traverse permission on the default column family, the user would not be able to access field b. Granting traverse permission on field a in this case would have no effect.

last-updated: Jun 06, 2024

In the example below, field a is part of the `cf1` column family.



To be able to read and write at field b, the user could be granted the traverse permission on the column family.

last-updated: Jun 06, 2024

Read (`readperm`)

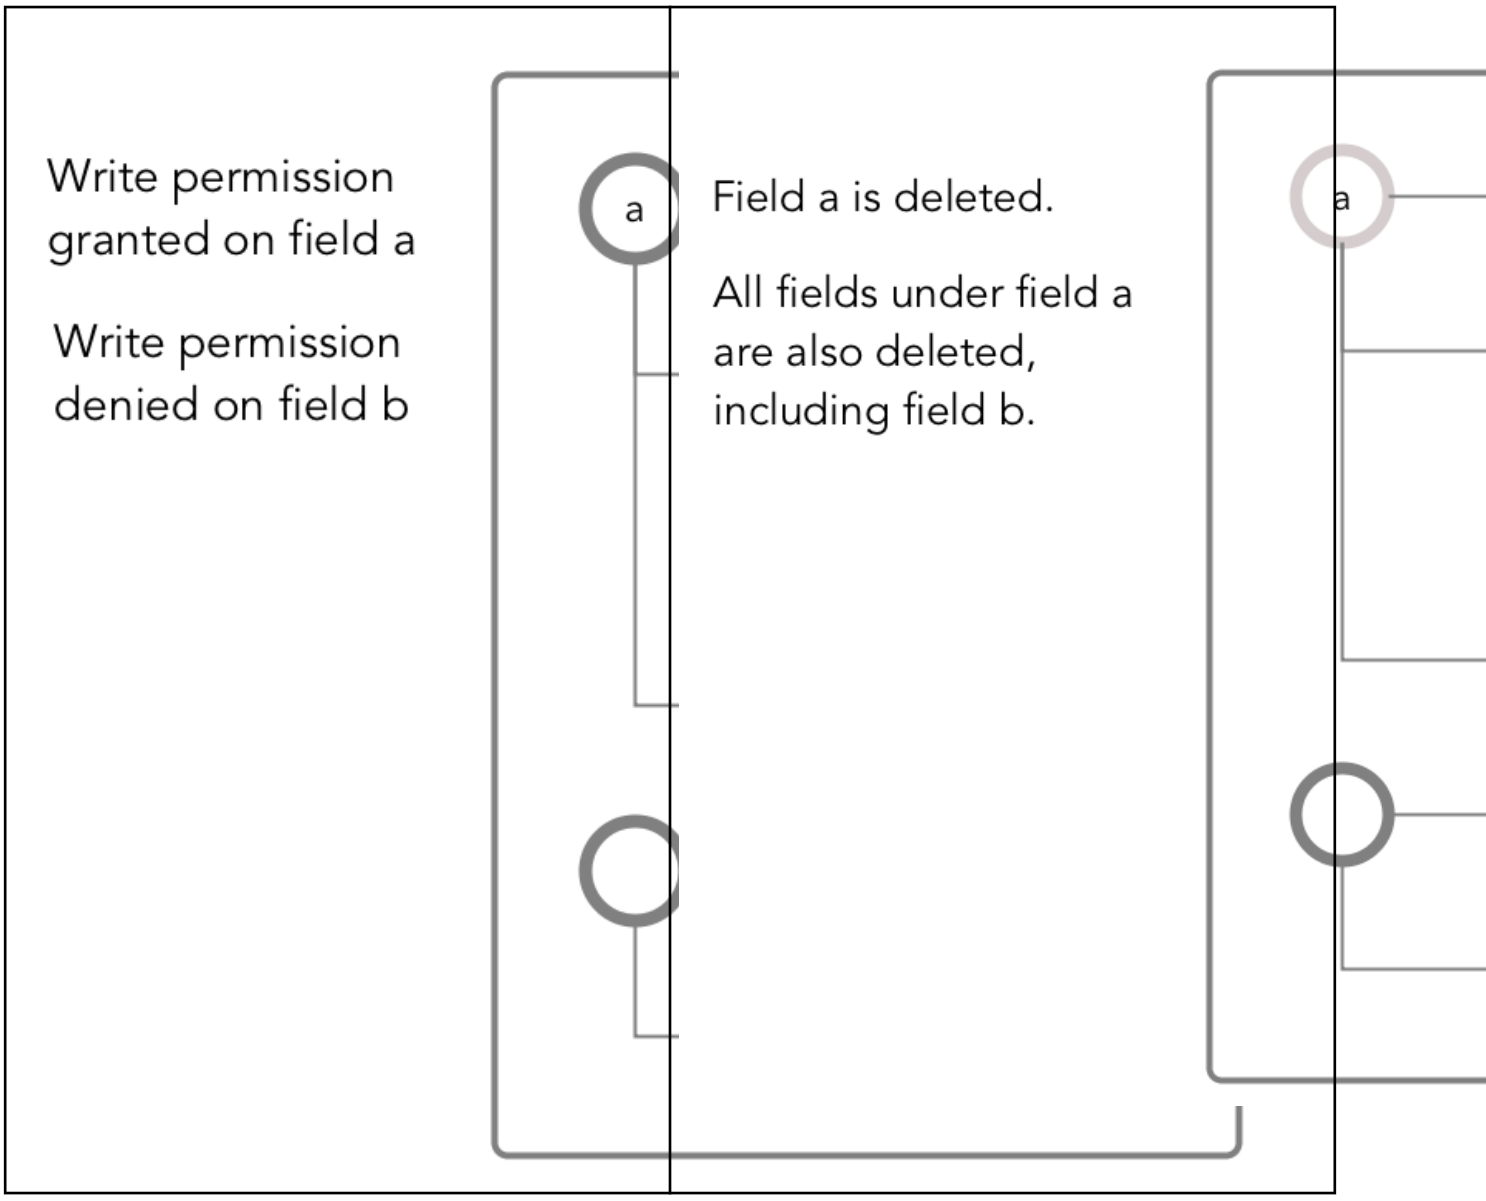
The read permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field on which the permission was granted. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (`writeperm`)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite field value.

As illustrated in the two diagrams below, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.



Obtaining `readperm` and `writeperm` on Fields
In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

last-updated: Jun 06, 2024

If the field is in the default column family

In the document below, you want to perform an operation on field c, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field c.

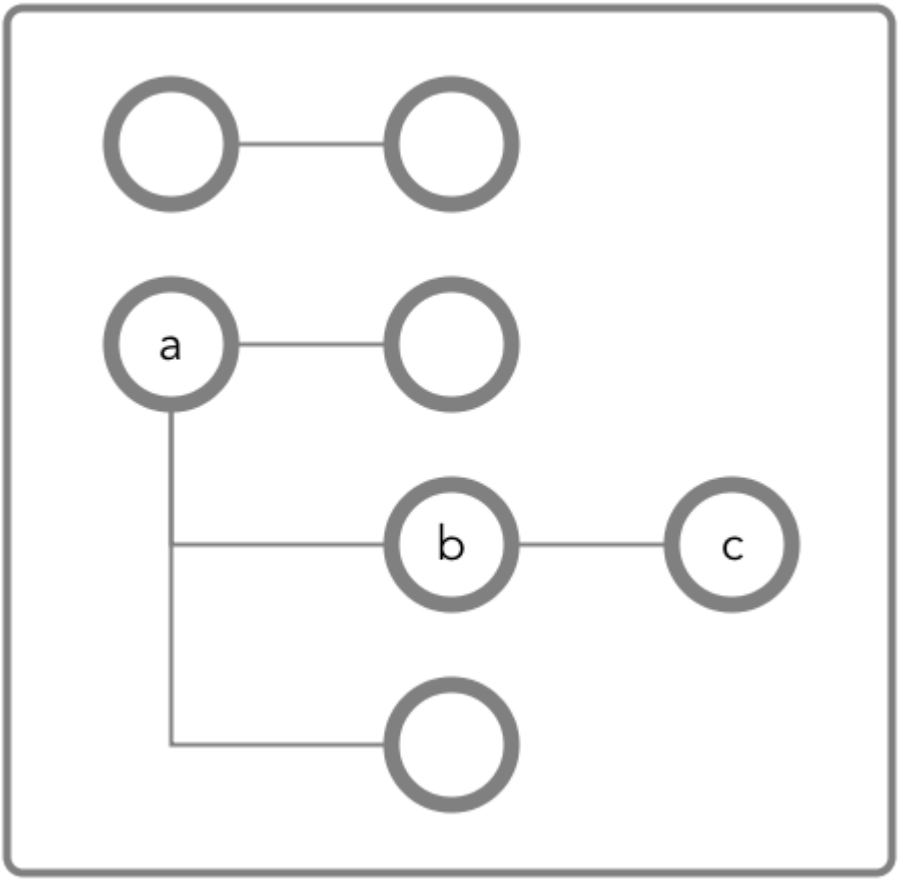


Figure 18: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field c inherits these permissions, assuming that the permissions were not denied on field a or b.

If you do not have `readperm` and `writeperm` on field a or b, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field c. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```
maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
```

last-updated: Jun 06, 2024

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have `readperm` and `writeperm` on the default column family

In this case, you need the `traverseperm` permission on the default column family. Fields a and b inherit this permission. You also need `readperm` and `writeperm` on field c.

You could be granted these permissions with commands similar to these:

```
maprcli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see Column Families in JSON table.

In the following document, you want to perform an operation on field c, which is in the column family `cf1` that is defined at field b with the path `a.b`.

last-updated: Jun 06, 2024

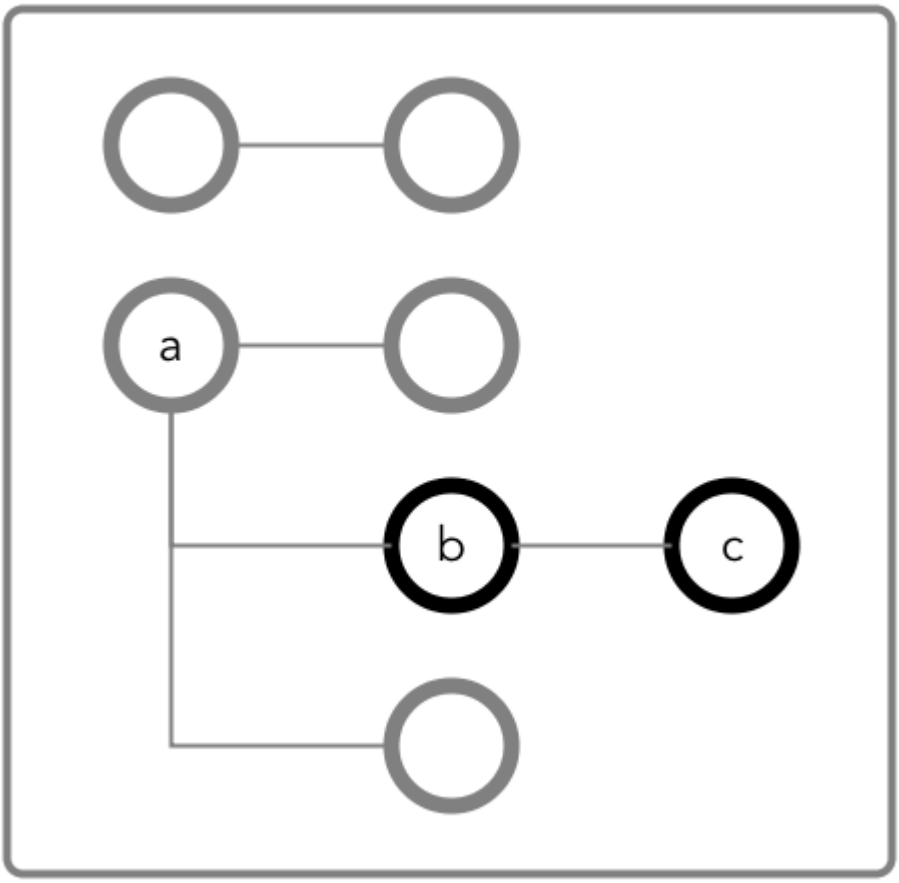

Figure 19: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have `readperm` and `writeperm` on field `b`	You need `traverseperm` on field b and both `readperm` and `writeperm` on field c. You can be granted these permissions with commands similar to these:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field> -writeperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have `readperm` and `writeperm` on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Obtaining `readperm` or `writeperm` on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm or writeperm permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

If the field is in the default column family

In the following document, you want to perform an operation on field `c,` which is in the default column family. The operation requires you to have `readperm` or `writeperm` on field `c`.

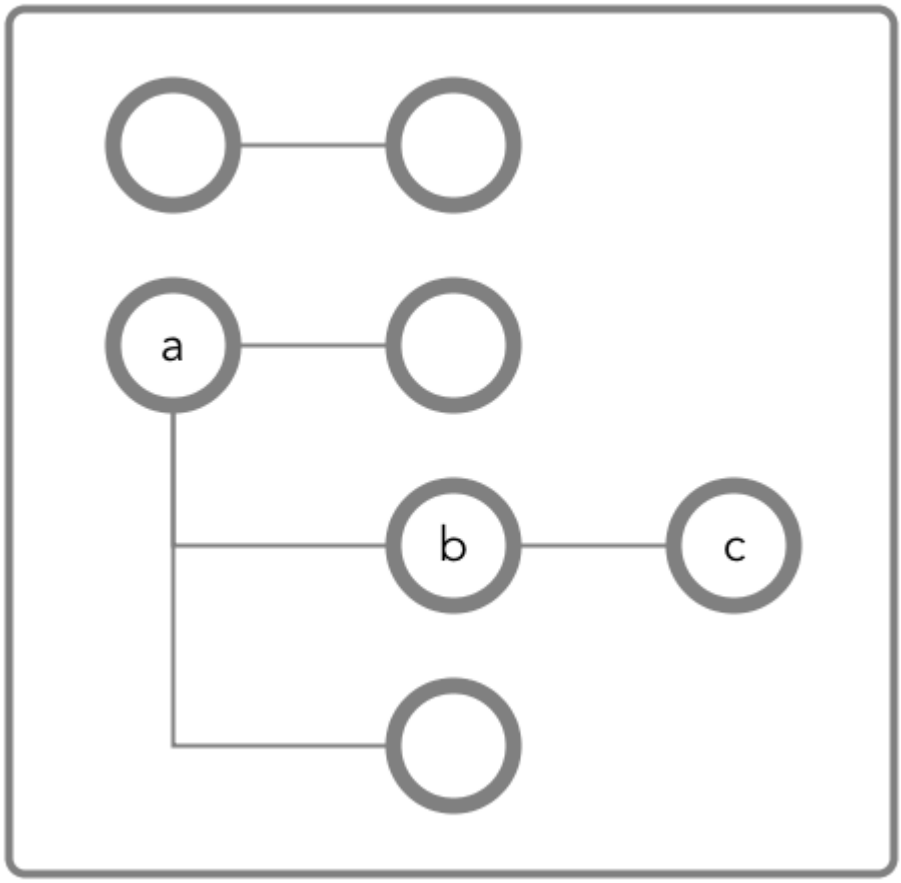

Figure 20: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (`readperm` or `writeperm`) on the default column family	In this case, field `c` inherits the permission, assuming that the permission was not denied on field `a` or `b`. If you do not have `readperm` or `writeperm` on field `a` or `b`, you need `traverseperm` on the field that denied you the permission that you need. You also need `readperm` or `writeperm` explicitly granted to you on field `c`. Example commands to grant these permissions: `/opt/mapr/bin/maprcli table cf colperm set -path <path to JSON table> -cfname`

```
default -name a.b -traverseperm
u:<user ID> | <existing ACE for this
field>
```

The next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (`readperm` or `writeperm`) on the default column family

In this case, you need the `traverseperm` permission on the default column family. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see Column Families in JSON Tables.

In the following document, you want to perform an operation on field `c`, which is in the column family that is defined at field b with the path `a.b`. The operation requires you to have `readperm` or `writeperm` on field `c`.

last-updated: Jun 06, 2024

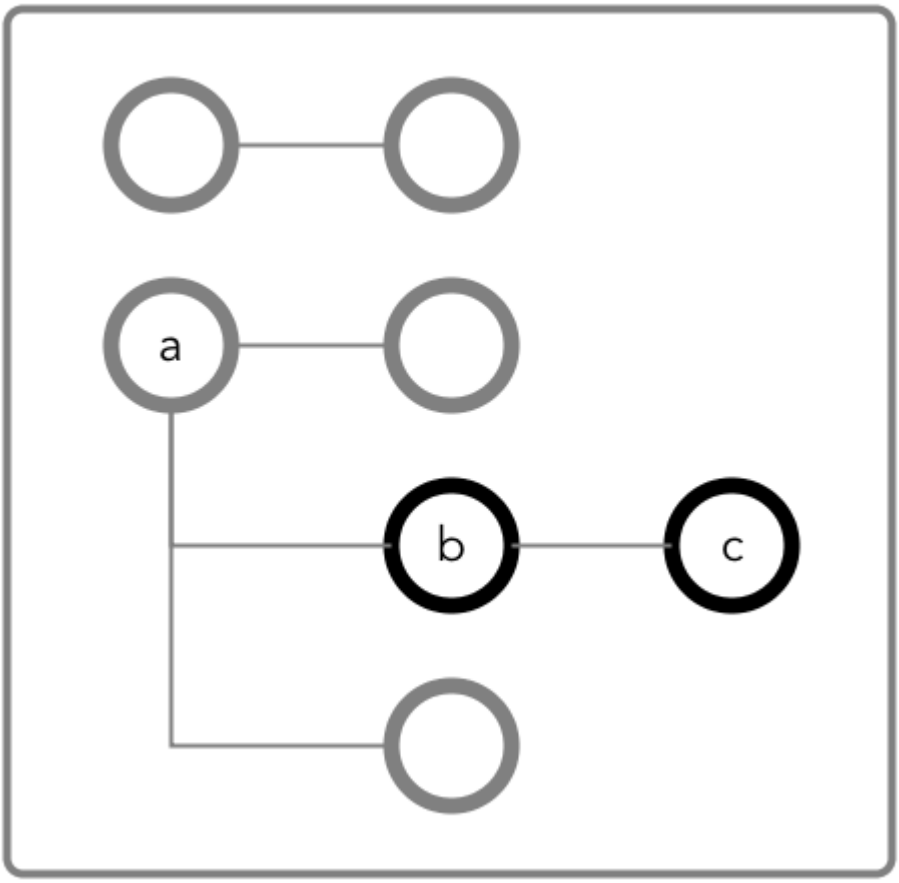

Figure 21: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have the permission you need (`readperm` or `writeperm`) on field `b`	You need `traverseperm` on field b, and you need `readperm` or `writeperm` granted to you explicitly on field c.
	Example commands to grant these permissions:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have the permission you need (`readperm` or `writeperm`) on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Setting Permissions on Arrays

If you are granting permissions on a field and the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and

last-updated: Jun 06, 2024

scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

NOTE: This topic describes the behavior of permissions in HPE Ezmeral Data Fabric Database version 6.1 and later, regardless of the data-fabric version you used to grant the permissions.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
    "_id" : "id001",
    "person" : [
        {"name" : {"last" : "Smith", "first" : "John"}},
        {"name" : {"last" : "Subramanium", "first" : "Ananya"}}
    ]
}
{
    "_id" : "id002",
    "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
    "_id" : "id003",
    "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person` to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

last-updated: Jun 06, 2024

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables
Summarizes the default ACEs for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

Action	Method	Permissions	Default Access-Control Expressions
Set default permissions on new column families when creating a JSON table.	Java API	`-defaultreadperm -defaulttraverseperm -defaultwriteperm`	`u:<ID of the process>`
	`maprcli table create`		`u:<user ID of table creator>`
	mapr dbshell		
	Control System		
Set default permissions on new column families when editing a JSON table.	`maprcli table edit`		Current ACEs
	Control System		
Set permissions on a column family when creating the column family.	`maprcli table cf create`	`-readperm -traverseperm -writeperm -indexperm`	ACEs for `-defaultreadperm`, `-defaulttraverseperm`, and `-defaultwriteperm`
	Control System		
Set permissions on a column family when editing the column family.	`maprcli table cf edit`		Current ACEs
	Control System		
Set permissions on individual fields.	`maprcli table cf colperm set`		Inherited from column family or parent field
	Control System		
Set the dynamic mask	`maprcli table cf column datamask set`	`-defaultunmaskedreadperm -unmaskedreadperm`	Set to the table creator
	`maprcli table cf colperm set`		
	`maprcli table create`		
	`maprcli table edit`		
	`maprcli table cf create`		
	`maprcli table cf edit`		
	`maprcli table cf colperm set`		
	Control System		

last-updated: Jun 06, 2024

Listing Column Families
Explains how to view the column families for a table using either the Control System or the CLI.
Viewing Table Column Families Using the Control System

About this task
To view the column families for a table:

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click the **Column Families** tab.
   The page displays the default permissions for the column families in the **Default Column Family Authorization** pane, and for each column family, the **All** pane displays:

Column Name	Column Description
Column Family Name	The name of the column family.
JSON Path	The JSON path for the column in the JSON file in dotted notation.
Compression	The compression scheme used for the column family.
Time-to-Live	The amount of time to keep the data in the column family.
In Memory	Whether or not this column value resides in memory.

Selecting the checkbox associated with the column family makes the **Remove Column Family** button available. You can:

- Add a column family to the table
- Remove a column family associated with the table

Viewing Table Column Families Using the CLI or REST API

About this task

The command to list the column families that are in a table is:

```
maprcli table cf list -path <path> -cfname <name_of_column_family>
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

NOTE: You cannot use the following characters in the table name:

```
< > ? % \
```

To use the following characters in the table name, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table create -path "/♦=#;{}&()/"  (or)
maprcli table create -path '/♦=#;{}&()/'
```

To use either the **'** or the **"** character in the table name, enclose:

- the **'** character within double quotes (")
- the **"** character within single quote (')

For example:

```
maprcli table create -path "/'♦=#;{}&()/"  (or)
maprcli table create -path '/"♦=#;{}&()/'
```

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the paths
- `adminaccessperm` on the table

For complete reference, see the `table cf list` command.

Removing Column Families
Explains how to delete column families using either the Control System or the CLI.

About this task

IMPORTANT: Starting in the 6.0 release, you cannot delete a column family from a JSON table.

Removing Column Families Using the Control System

About this task
To remove one or more column families:

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click **Column Families** tab.
   The page displays:
   - Default column family permissions
   - All the column families for the table
3. Select the checkbox associated with the column families to delete in the **All** pane.
4. Click **Remove Column Family**.
   The **Remove Column Families** confirmation dialog displays.

5. Verify the list of column families and click **Remove Column Family**.
   If necessary, click ✕ to remove a column family from the list of column families to delete.

Removing a Column Family Using the CLI or the REST API

About this task

To remove a column family by name using the CLI or the REST API, run the following command:

```
maprcli table cf delete -path <path> -cfname <name>
```

See the `table cf delete` command for more information.

Altering Column Families
Explains how to modify the permissions and properties of column families using either the Control System, the CLI, or the HBase shell.

About this task
There are several methods that you can use to edit column families in HPE Ezmeral Data Fabric Database tables. These methods also let you change permissions on column families.
Modifying a Column Family Using the Control System

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click the **Column Families** tab.
   The page displays the:
   - **Default Column Family Authorization** pane
   - **All** pane which lists the column families for the table
3. Click the name of the column family to modify.
   The **Edit Column Family** page appears.
4. Make changes to the following properties (under the **PROPERTIES** pane), as desired.

JSON Table Properties

Field Name	Field Description
Column Family Name	The name of the column family.
Compression	The compression setting to use for the column family. Valid options are `off`, `lzf`, `lz4`, and `zlib`. The default setting is the same as the compression setting for the directory where the table is located.

Field Name	Field Description
In Memory	Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled. **NOTE:** All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family. By default, this is enabled.

last-updated: Jun 06, 2024

Binary Table Properties

Field Name	Field Description
Column Family Name	The name of the column family.
Version	• Minimum — The minimum number of versions of column values to keep. The default is zero. • Maximum — Maximum number of versions of column values to keep. The default is one.
Compression	The compression setting to use for the column family. Valid options are `off`, `lzf`, `lz4`, and `zlib`. The default setting is the same as the compression setting for the directory where the table is located.
Time-to-Live	Specifies whether to purge data when the age of the data in this column family exceeds the value specified here. Data can remain forever or can be purged after specified amount of time (in seconds). Setting the value to 0 is equivalent to allowing data to remain indefinitely or forever.

last-updated: Jun 06, 2024

Field Name	Field Description
In Memory	Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory. For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if this is disabled (No), but preference will be given to column families where this is enabled (Yes). A column family can have more than 32 bytes stored inline if this is enabled. If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have this enabled. **NOTE:** All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data will be stored in-line for that column family. By default, this is enabled.

last-updated: Jun 06, 2024

5. (JSON Tables) Add or remove a security policy, as appropriate:
   - **Add a Policy**:
     a. Enter the first few characters of the name of an existing security policy in the **Search for security policy** field. A list of security policies matching your search criteria are listed below the **Search for security policy** field.
     b. Check the needed policy.
     c. click **Add**. The added security policy appears above the **Search for security policy** field. The policy settings for the selected security policy are now associated with the column family.
   - **Remove a Policy**: Click (Delete) to the right of the displayed security name to remove disassociate the policy from the column family. The security policy is deleted immediately.
6. Do one of the following:
   - Delete a set of user access control permissions:

     Click (Delete) to the right of a displayed set of permissions to delete the set of permissions. The set of user access control permissions are deleted immediately.
   - Change or update one or more sets of existing user access control permissions:

     See the tables below for more information on user access control permission options.

     Use the **Basic** or **Advanced** settings to update existing permissions:

     To grant or block access to users, groups, and/or roles, from the:
     - **Basic** settings, select the type — public, (OR) user, group, or role — from the drop-down menu, specify the name of the user, group, or role, and select one or more checkbox to grant permissions.

       TIP: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

       To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.
     - **Advanced** settings, specify public (p) or user (u), group (g), and/or role (r) who have or do not have the type of access using the following boolean expressions and subexpressions:
       - ! — Negation operator.
       - & — AND operation.
       - | — OR operation.

       Use ( ), parentheses, for subexpressions.

       NOTE: You *cannot* specify user, group, or role individually if access is granted to all users (public).

       Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs Using the Access Control Expression Builder on page 1881 for more information.

last-updated: Jun 06, 2024

NOTE: If you switch from **Basic** to **Advanced**, the basic settings, if any, are carried over to the advanced settings. If you switch from **Advanced** to **Basic**, all the settings are lost because the subexpressions and AND (&) and negation (!) operations that are supported by advanced settings are not supported in the basic settings.

JSON Table Permission Option Descriptions

Modify or update the following user access control permissions for the column family:

Option	Option Permission
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on a.b, but not on a. For sjohnson to read a.b, the user needs the traverse permission on a. The user can then pass over field a to a.b. This permission is inherited by fields within the column family.
Set Compression	Can set or change the compression setting for the column family.

Option	Option Permission
Unmasked Data	Leaving the **Unmask Data** checkbox unchecked hides table column family data from the selected user. Checking the box allows the selected user to see all table data, based on and in coordination with other security and data access settings.

Binary Table Permission Option Descriptions

Modify or set the following permissions for the column family:

Option	Option Permission
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

7. Click **Save Changes** for the changes to take effect.

Modifying a Column Family Using the CLI or REST API

About this task

The basic command to edit a column family is:

```
maprcli table cf edit -path <path> -cfname <name_of_column_family> options
```

last-updated: Jun 06, 2024

For the full list of options, see the `table cf edit` command.

The format of the value of the `-path` parameter depends on whether you are creating a table on a local cluster or a remote cluster:

- For a path on the local cluster, start the path at the volume mount point. For example, for a table named `test` under a volume with a mount point at /volume1, specify the following path: `/volume1/test`
- For a path on a remote cluster, you must also specify the cluster name in the path. For example, for a table named `customer` under `volume1` in the `sanfrancisco` cluster, specify the following path:`/mapr/sanfrancisco/volume1/customer`

  NOTE: You cannot use the following characters in the table name:

  ```
  < > ? % \
  ```

  To use the following characters in the table name, enclose them either in single or double quotes:

  ```
  ; | ( ) /
  ```

  For example:

  ```
  maprcli table create -path "/♦=#;{}&()/"  (or)
  maprcli table create -path '/♦=#;{}&()/'
  ```

  To use either the **'** or the **"** character in the table name, enclose:

  - the **'** character within double quotes (")
  - the **"** character within single quote (')

  For example:

  ```
  maprcli table create -path "/'♦=#;{}&()/"  (or)
  maprcli table create -path '/"♦=#;{}&()/'
  ```

Modifying a Column Family in a Binary Table Using HBase shell

About this task

After starting the HBase shell, run the `alter` command. Type `help` to see a list of commands and their syntax.

Displaying Default Column Family Permissions

Use either the Control System or the `maprcli` command to find out the users, groups, or roles that have permissions on the default column family.

Viewing Default Column Family Permissions in the Control System

Procedure

- Log in to the Control System and go to the **Column Families** tab from the table information page.

  The **Default Column Family Authorization** pane displays the following permissions for users, groups, and roles.

Binary Table Default Column Family Authorization Permissions

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Append Data	Can do column appends. Column appends require permission both at the column-family level and at the column level.
Set Version	Can set or change the maximum and minimum number of versions of column values to keep.
Set Compression	Can set or change the compression setting for the column family.

JSON Table Default Column Family Authorization Permissions

Permission	Permission Description
Read Data	Can do column reads. Reads require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.

Permission	Permission Description
Write Data	Can do column writes. Writes require permission both at the column-family level and at the field level. This permission is inherited by fields within the column family.
Traverse Data	Can pass over fields in JSON documents. For example, suppose that a JSON table contains documents of this general structure: `{ "_id" : "ID", "a" : { "b" : "value", "c" : "value" } }` Suppose further that the user sjohnson has read permission on `a.b`, but not on `a`. For sjohnson to read `a.b`, the user needs the traverse permission on `a`. The user can then pass over field `a` to `a.b`. This permission is inherited by fields within the column family.
Set Compression	Can set or change the compression setting for the column family.
Unmasked Data	Can perform unmasked column reads if the user also has read data permission. Unmasked data require permission both at the column family level and at the field level. This permission is inherited by fields within the column family.

last-updated: Jun 06, 2024

Retrieving the Default Column Family Permissions Using the CLI

About this task

To display the permissions on a column family, run this command:

```
maprcli table cf colperm get -path <path> -cfname <name of column
family> -json
```

To display the permissions on a column, add the `-name` parameter:

```
maprcli table cf colperm get -path <path> -cfname <name of column
family> -name
            <name of column> -json
```

The format of the value of the `-path` parameter depends on whether you are viewing a table on a local cluster or a remote cluster.

The `json` parameter displays the output as a JSON document.

Managing Column Family Fields and Field Permissions for JSON Tables

This sections covers details for working with column family fields. Column family fields can be added to any existing JSON table, and column families comprise optional fields.

Adding Field Permissions to a JSON Table Column Family

Explains how to add fields and field permissions to a column family for a specified JSON table using the Control System.

About this task

Use the Control System to add field permissions to an existing table with a column family.

NOTE: Field and field permissions can be used with and assigned to only JSON tables.

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

   NOTE: This option is not available on the Kubernetes version of the Control System.

2. Click **Data** > **Tables** from the top of the page. The **Tables** page appears.

3. Select the JSON table needing field permissions added from the **Recently Viewed Tables** pane or enter the path to the needed table in the available field, and then click **Go**. The table information page of the selected table appears.

4. Click the **Column Families** tab. A page showing column family information appears.

5. Click the name of column family (under the **All** pane) to which field permissions are to be added, and then click **Field Permission** at the top of the **Edit Column Family** page. A new page appears showing existing fields, if any, in the left pane. If none, the **FIELD AUTHORIZATION - ACCESS CONTROL EXPRESSION** pane allows you to add a field to the column family.

6. Click **Add Field** (if displayed) to add a field. The default `Field` description appears in the **Field Name** field.

7. Replace the `Field` entry in the **Field Name** field by entering a new name for the new field, as applicable.

last-updated: Jun 06, 2024

8. Click the **Data Masking** pull-down menu (shown near to top of the page in the right pane), and then select one of the following data masking options, as needed:
   - Replace all alpha characters with an X and numeric characters with 0,
   - Show only the last 4 characters. Replace all other characters with an 'x',
   - Show only the first 4 characters. Replaces all other characters with an 'x',
   - Show only the first 6 and last 4 characters. Replaces other characters with an 'x',
   - Show the first and last 2 chars of username and part of domain,
   - Show the hash of the data, or
   - Shows only the year portion of the date and default everything else to Jan 1 and 00:00:00
   - None
9. Set user access control permissions for the currently selected field by doing one of the following:
   - Select **Basic**, and then select a user type from the **Type** pull-dow menu, enter a name for the user type in the **Name** field, and check data access permissions, as needed.
   - Select **Advanced**, and then enter the permission details, and, if necessary, click  (the pencil icon) to open the **Edit Data Access Control Expression** window to select additional permission definitions. See Defining ACEs Using the Access Control Expression Builder on page 1881 for more information.

     NOTE: The **AUTHORIZATION - ACCESS CONTROL EXPRESSION** pane of the page displays default column family authorizations as a reference.

Field Permission Descriptions (for JSON Tables)

By default, a field inherits permissions from the column in which the field is located. Permissions set at this level override permissions inherited from the column. You can set the following permissions by selecting the associated checkbox, as described in the table below.

Read Data	Can read from the field. This permission extends to fields that are nested below as well unless explicitly denied on any of the nested fields.
Write Data	Can delete the field, insert a value into the field, or overwrite the field's value. **NOTE:** Deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.

last-updated: Jun 06, 2024

Traverse Data	Can descend a hierarchy of fields to access the fields to read or write.
Unmasked Data	Check **Unmask Data** to allow the specified user to see all field data for field specified of the selected column family. Leaving the **Unmask Data** field unchecked hides field data for the selected column family from the selected user.

By default, all permissions are given to the user creating the table.

10. Opt to repeat the step above to:
    - Add another field by clicking **Add Field**.
    - Add a different set of permissions to a selected field for another public user or another user, group, or role.
11. Click **Save Changes** to save your current additions and changes.

Editing Field Permissions for a JSON Table Column Family

Explains how to edit field permissions for an existing column family for a specified JSON table using the Control System.

About this task

Use the Control System to edit field permissions for fields that are part of a column family within an existing JSON table.

NOTE: Field and field permissions can be used with and assigned to only JSON tables.

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

   NOTE: This option is not available on the Kubernetes version of the Control System.
2. Click **Data** > **Tables** from the top of the page. The **Tables** page appears.

last-updated: Jun 06, 2024

3. Select the JSON table needing field permissions edited by selecting it under the **Recently Viewed Tables** pane or entering the path to the needed table in the available field, and then clicking **Go**. The table information page of the selected table appears.
4. Click the **Column Families** tab.
5. Click the name of the column family (under the **All** pane) to which field permissions are to be edited, and then click **Field Permission** at the top of the **Edit Column Family** page.
6. Opt to:
   - Add additional fields:
     a. Click **Add Field** to add one or more fields, and then select a field listed in the left-hand pane of the screen.
     b. Enter a name for the field in the **Field Name** field, as applicable.
   - Change the name of an existing field of the displayed column family by clicking on the name of the field (in the left panel) and then updating the name in the **Field Name** field.
   - Delete an existing field by clicking (delete) to the right of the field name shown in the left pane of the page. The field name is deleted immediately.
   - Change data masking options for a selected field:

     Select the field to have its masking options modified, and then click the **Data Masking** pull-down menu, and then select one of the following data masking options:
     - Replace all alpha characters with an X and numeric characters with 0,
     - Show only the last 4 characters. Replace all other characters with an 'x',
     - Show only the first 4 characters. Replaces all other characters with an 'x',
     - Show only the first 6 and last 4 characters. Replaces other characters with an 'x',
     - Show the first and last 2 chars of username and part of domain,
     - Show the hash of the data, or
     - Shows only the year portion of the date and default everything else to Jan 1 and 00:00:00
     - None
   - Change existing access permission selections for the currently displayed field or add a new set of access permissions for the selected field by clicking on the name of the field in the left panel and then selecting either of the following:
     - **Basic**. After selecting **Basic**, click **Add Another** and make selections and entries for a new set of permissions. Alternatively, for a listed user type, select a different user type from the **Type** pull-dow menu, , change the name for the user type in the **Name** field, and update access permissions, as needed. See the table below for permission option information.

       NOTE: Alternatively, you can click (Duplicate) to duplicate the previously listed row and then select applicable permissions.
     - **Advanced**. After selecting **Advanced**, enter the permission details, and, if necessary, click (the pencil icon) to open the **Edit Data Access Control Expression** window to select additional permission definitions. See Defining ACEs Using the Access Control Expression Builder on

last-updated: Jun 06, 2024

page 1881 for more information on ACE functionality. See the table below for access permission option information.

NOTE: The **AUTHORIZATION - ACCESS CONTROL EXPRESSION** pane of the page displays default column family authorizations (just below the **Data Masking** pull-down menu) as a reference.

Field Permissions (for JSON Tables)

By default, a field inherits permissions from the column in which the field is located. Permissions set at this level override permissions inherited from the column. You can set the following permissions by selecting the associated checkbox, as described in the table below.

Read Data	Can read from the field. This permission extends to fields that are nested below as well, unless explicitly denied on any of the nested fields.
Write Data	Can delete the field, insert a value into the field, or overwrite the field's value. **NOTE:** Deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.
JSON Traverse	Can descend a hierarchy of fields to access the fields to read or write.
Unmasked Data	Check **Unmask Data** to allow the specified user to see all field data for field specified of the selected column family. Leaving the **Unmask Data** field unchecked hides field data for the selected column family from the selected user.

By default, all permissions are given to the user creating the table. See Permission Types for Fields and Column Families in JSON Tables on page 1400 for more information.

- Delete an existing set of permissions for a created user type of a select field:
  a. Click on the name of the field associated with the permissions to be deleted.

last-updated: Jun 06, 2024

b. Click (Delete) to the far right of the permission options. The set of permissions is deleted immediately.

7. Opt to:

- Add another field by clicking **Add Field**. See the above step for more details.
- Update data masking options for another field. See the above step for more details.
- Add a different set of permissions to a selected field for another public user or another user, group, or role. See the above step for more details.
- Delete another set of permissions for a listed user type. See the above step for more details.

8. Click **Save Changes** to save your current additions and changes.

Viewing Fields and Field Permissions for a JSON Table Column Family

Explains how to view field and field permissions for an existing JSON table.

About this task

This tasks explains how to access JSON table column family fields and field permissions.

NOTE: Field and field permissions can be used with and assigned to only JSON tables.

Procedure

1. Log into the Control System using your login credentials. The Control System **Overview** page appears.

NOTE: This option is not available on the Kubernetes version of the Control System.

2. Click **Data** > **Tables** from the top of the page. The **Tables** page appears.

3. Select the JSON table associated with the fields you want to view by selecting it under the **Recently Viewed Tables** section or entering the path to the needed table in the available field, and then clicking **Go**. The table information page of the selected table appears.

last-updated: Jun 06, 2024

4. Select the **Column Families** tab.
5. Click the name of the column family (under the **All** section). The **Edit Column Family** page appears.
6. Click **Field Permission** at the top of the **Edit Column Family** page. The page displays a listing of fields associated with the selected column family, if any, in the left pane, and all permissions assosicated with the selected field are displayed at the bottom of the page. You can select any listed field to view its permission.

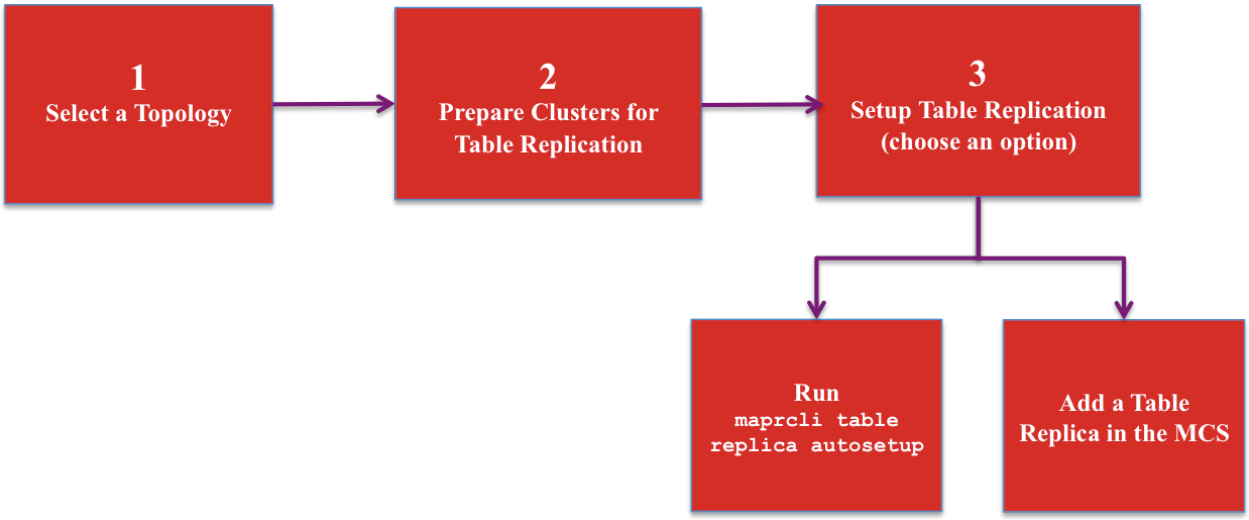
   NOTE: If no column family fields appear, then none have been set up. See Adding Field Permissions to a JSON Table Column Family on page 1424 for more information on setting up fields for a column family.

Managing Table Replication

This section contains topics about setting up table replication and administering existing replicas.

The process to set up table replication consists of the following steps:

1. Select a Topology
2. Prepare Clusters for Table Replication.
3. Set up Table Replication using one of the following options:
   - Run maprcli table replica autosetup.
   - Add a Table Replica in the Control System.



1. Select a Table Topology
2. Prepare Clusters for Table Replication
3. Run maprcli table replica autosetup
4. Add a Table Replica in the MCS

NOTE: After setting up replication, replicas can be administered using either the Control System or the CLI.

Preparing Clusters for Table Replication

Preparing clusters for table replication includes configuring gateways on destination clusters, configuring the `mapr-clusters.conf` file on the source cluster, and, if the clusters are secure, setting up secure communications between the clusters. After you prepare the clusters for table replication, you can setup replication between tables.

Before You Begin

The following topics identify concepts and tasks that you need to do before setting up your environment for table replication.

- Plan which replication topology you want to use. For information about the various topologies, see Supported replication topologies on page 750.

- In general, if you are replicating tables, you should store them in their own volumes to avoid overlap with volume mirroring. Otherwise, if a source volume fails, you may have a scenario where a table in a promoted mirror lags behind the table's replica.

  For example, suppose `/vol` mirrors to `/vol.mirror` and contains a table `srcTab` that replicates to `/replVol/replTab`. If `/vol` fails, `/vol.mirror/srcTab` may lag `/replVol/replTab` when `/vol.mirror` is promoted.

  To avoid this problem, starting with the 6.1 release, after HPE Ezmeral Data Fabric Database promotes a mirror volume, replication terminates with `REPLICA_STATE_UNEXPECTED` for any tables in that volume.

  The following sample output shows this behavior:

```
[mapr]# /opt/mapr/bin/maprcli table replica list -path /vol.mirror/
srcTab -refreshnow true -json
{
  "timestamp":1534805233244,
  "timeofday":"2018-08-20 03:47:13.244 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "cluster":"mirrorSrc",
      "table":"/replVol/replTab",
      "type":"MapRDB",
      "replicaPath":"/replVol/replTab",
      "replicaState":"REPLICA_STATE_UNEXPECTED",
      "paused":false,
      "throttle":false,
      "idx":1,
      "networkencryption":false,
      "synchronous":false,
      "networkcompression":"lz4",
      "propagateExistingData":false,
      "isUptodate":true,
      "minPendingTS":0,
      "maxPendingTS":0,
      "bytesPending":0,
      "putsPending":0,
      "bucketsPending":0,
      "uuid":"8b4563e1-884d-7852-f257-078c397b5b00",
      "copyTableCompletionPercentage":0,
      "errors":{
        "Code":"ErrReplicaTableUpstreamMismatch",
        "Host":"10.10.104.35",
        "Msg":"OpenStream: Upstream table does not match original
Upstream cluster mirrorSrc table /replVol/replTab"
      }
    }
    ]
}
```

  This change in behavior applies to only tables that have replication enabled starting in 6.1. See Table Replication States on page 764 for more details.

- Ensure that your user ID has the `readAce` permission on the volume where the source tables are located and the `writeAce` permission on the volumes where the replicas are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1365.

- Ensure that you have administrative authority on the clusters that you plan to use.

- If you upgraded your source cluster from a previous version of data-fabric, enable table replication by running this `maprcli` command: `maprcli cluster feature enable -name mfs.feature.db.repl.support`
- Depending on your use case, replication requires the installation of gateways and may also require the HBase client. For more information about installation requirements, see Service Layout Guidelines for Replication on page 88

Setting Up Table Replication

The following steps show how to set up your environment for table replication including setup for secure clusters.

1. In the `mapr-clusters.conf` file on every node in your source cluster, add an entry that lists the CLDB nodes that are in the destination cluster. This step is required so that the source cluster can communicate directly with the destination cluster's CLDB nodes. See mapr-clusters.conf for the format to use for the entries.
2. On the destination cluster, configure gateways through which the source cluster sends updates to the destination cluster. See Configuring Gateways for Table and Stream Replication on page 1528.
3. If your clusters are secure, configure each cluster so that you can access them all from one cluster. This way, you need not log into each secure cluster separately and run `maprcli` commands locally on them. See Configuring Secure Clusters for Running Commands Remotely on page 1949 for more information.
4. If your clusters are secure, add a cross-cluster ticket to the source cluster, so that it can replicate data to the destination cluster. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1952.
5. **Optional:** If your clusters are secure, configure your source cluster so that you can use the Control System to set up and administer table replication from the source to the destination cluster.

   These steps make it convenient to use the Control System for setting up and managing replication involving two secure clusters. However, before following them, perform these prerequisite tasks.

   NOTE:

   - Ensure that both clusters are managed by the same team or group. The UIDs and GIDs of the users that are able to log in to the Control System on the source cluster must exactly match their UIDs and GIDs on the destination cluster. This restriction applies only to access to both clusters through the Control System, and does not apply to access to both clusters through the maprcli. If the clusters are managed by different teams or groups, use the maprcli instead of the Control System to set up and manage table replication involving two secure clusters.
   - Ensure that the proper file-system and table permissions are in place on both clusters. Otherwise, any user who can log into the Control System and has the same UID or GID on the destination cluster will be able to set up replication either from the source cluster to the destination cluster or vice versa. A user could create one or more tables on the destination cluster, enable replication to them from the source cluster, load the new tables with data from the source cluster, and start replication. A user could also create tables on the source cluster, enable replication to them from tables in the destination cluster, load the new tables with data from the destination cluster, and start replication.

a. On the source cluster, generate a service ticket by using the `maprlogin` command:

```
maprlogin generateticket -type service -cluster <destination cluster>
-user mapr -duration <duration> -out <output folder>
```

Where `-duration` is the length of time before the ticket expires. You can specify the value in either of these formats:

- `[Days:]Hours:Minutes`
- `Seconds`

b. To every node of the source cluster, add the service ticket to the file `/opt/mapr/conf/maprusertickets` file that was created when you secured the source cluster:

```
at <path and filename of the service ticket> >> /opt/mapr/conf/
maprusertickets
```

c. Restart the web server by running the `maprcli node services` command. For the syntax of this command, see node services on page 2292.

d. Add the following two properties to the `core-site.xml` file. For Hadoop 2.7.0, edit the file `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/core-site.xml`.

```
<property>
      <name>hadoop.proxyuser.mapr.hosts</name>
      <value>*</value>
 </property>
 <property>
      <name>hadoop.proxyuser.mapr.groups</name>
      <value>*</value>
 </property>
```

Setting Up Table Replication Using the CLI

You can run the `maprcli table replica autosetup` command to set up primary-secondary or multi-master replication from an existing source table.

Prerequisites

NOTE: This procedure describes how to use the `maprcli` to automatically set up table replication. As an alternative, you can use the Control System to automatically setup table replication or use the `maprcli` command to manually setup primary-secondary replication or manually setup multi-master replication.

Before you begin, complete the following steps:

- Verify that you have completed the steps to configure the clusters for table replication. For more information, see Preparing Clusters for Table Replication on page 1431.
- On the source table, run the `maprcli table info` command to verify that you have the following permissions:
  - `readperm`, which is required for reading from the table.
  - `replperm`, which is required for replicating from the table.

  On the destination table (if it already exists), run the `maprcli table info` command to verify that you have the following permissions:

- `bulkload`, which is required for the initial copy of source data into the destination table.
- `replperm`, which is required for receiving replicated updates from the source table.

All updates from a source table arrive at a replica after having been authenticated at a gateway. Therefore, access control expressions on the replica that control permissions for updates to column families and columns are irrelevant; gateways have implicit authority to update replicas.

About this task

NOTE: If you are setting up a primary-secondary replication loop for *n* clusters, repeat these steps for *n-1* primary-secondary relationships to set up basic primary-secondary topologies.

Procedure

1. Log into both the source and destination clusters.
2. Run the `maprcli table replica autosetup` command.
   - For primary-secondary replication:

     ```
     maprcli table replica autosetup -path /mapr/<source cluster>/<path to table> -replica /mapr/<destination cluster>/<path to table>
     ```

   - For multi-master replication:

     ```
     maprcli table replica autosetup -path /mapr/<source cluster>/<path to table> -replica /mapr/<destination cluster>/<path to table> -multimaster true
     ```

     NOTE:

     The parameter `-multimaster` is an optional parameter that you use to set up multi-master replication.

   For example, to set up multi-master replication between the `customers` table in the `sanfrancisco` cluster and a new `customers` table in the `newyork` cluster, you could use this command:

   ```
   maprcli table replica autosetup -path /mapr/sanfrancisco/
   customers -replica /mapr/newyork/customers -multimaster true
   ```

   To set up primary-secondary replication between the `customersA` table in the `sanfrancisco` cluster and a new `customersB` table in the same cluster, you could use this command:

   ```
   maprcli table replica autosetup -path /mapr/sanfrancisco/
   customersA -replica /mapr/sanfrancisco/customersB
   ```

   NOTE: For information about additional parameters that you can configure, see table replica autosetup on page 2504.
3. To check the replication status, run table replica list on page 2513.

What to do next

Additional Information:

- With multi-master replication, if one of the tables goes offline, you can direct client applications to the other table. For more information, see Multi-Master Replication on page 755.
- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see Adding a Column Family to a Replica on page 1452
- Check the Control System for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication. See Table-Replication Alarms.

Setting Up Primary-Secondary Replication Manually
You can run `maprcli` commands to set up primary-secondary replication manually.

Procedure

1. Ensure that you have followed these prerequisite steps:
   - Verify that you have complete the steps to configure the clusters for table replication. For more information, see Preparing Clusters for Table Replication on page 1431.
   - Run the `maprcli table info` command on the source table to verify that you have the following permissions:
     - `readperm`, which is required for reading from the table.
     - `replperm`, which is required for replicating from the table.
   - Run the `maprcli table info` command on the destination table (if it already exists) to verify that you have the following permissions:
     - `bulkload`, which is required for the initial copy of source data into the destination table.
     - `replperm`, which is required for receiving replicated updates from the source table.
2. Create the replica manually with the `maprcli` command `table create`. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source table. Metadata includes column families, access control expressions (ACEs), and other attributes.

   ```
   maprcli table create -path <path to the replica> -copymetafrom <path to the source table>
   ```

   For example, to create the replica `customers` in the `newyork` cluster and use the metadata from the source table in the `sanfrancisco` cluster, you could use this command:

   ```
   maprcli table create -path /mapr/newyork/customers -copymetafrom /mapr/sanfrancisco/customers
   ```

3. Register the replica as a replica of the source table by running the `maprcli table replica add` command.

   ```
   maprcli table replica add -path <path to the source table> -replica
   <path to the replica> -paused true
   ```

   For example, to register the `customers` table in the `newyork` cluster as a replica of the `customers` table in the `sanfrancisco` cluster, you could use this command:

   ```
   maprcli table replica add -path /mapr/sanfrancisco/customers -replica /
   mapr/newyork/customers -paused true
   ```

   The `-paused` parameter ensures that replication does not start immediately after you register the source table as a source for this replica. You do this registration in step 4.

   NOTE: For more information about additional parameters that you can configure, see table replica add on page 2500.

4. Verify that you specified the correct replica by running the `maprcli table replica list` command.

   ```
   maprcli table replica list -path <path to the source table>
   ```

   To verify that the customers table in the `newyork` cluster is a replica of the `customers` table in the `sanfrancisco` cluster, you could look at the output of this command:

   ```
   maprcli table replica list -path /mapr/sanfrancisco/customers
   ```

5. Authorize replication between the tables by defining the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

   ```
   maprcli table upstream add -path <path to the replica> -upstream <path
   to the source table>
   ```

   To add the `customers` table in the `sanfrancisco` cluster as an upstream source for the `customers` table in the `newyork` cluster:

   ```
   maprcli table upstream add -path /mapr/newyork/customers -upstream /mapr/
   sanfrancisco/customers
   ```

6. Verify that you specified the correct source table by running the `maprcli table upstream list` command.

   ```
   maprcli table upstream list -path <path to the replica>
   ```

   To verify this in our example scenario, you could use this command:

   ```
   maprcli table upstream list -path /mapr/newyork/customers
   ```

7. If you set `-paused` to `true` when adding the replica, follow these steps:

a) Load the replica with data from the source table by using the HPE Ezmeral Data Fabric Database CopyTable utility for binary tables or the HPE Ezmeral Data Fabric Database JSON CopyTable on page 5496 utility for JSON tables.

b) Start replication with the command `maprcli table replica resume`. Here is the `maprcli` command:

```
maprcli table replica resume -path <path to the source
table> -replica <path to the replica>
```

For our example scenario, you could use this command:

```
maprcli table replica resume -path mapr/sanfrancisco/
customers -replica /mapr/newyork/customers
```

What to do next

- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see Adding a Column Family to a Replica on page 1452
- You can check for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication by looking in the Control System. See Table-Replication Alarms.

Setting Up Multi-Master Replication Manually

You can run `maprcli` commands to set up multi-master replication, first establishing replication in one direction, and then establishing it in the other direction.

Prerequisites

- Verify that you have complete the steps to configure the clusters for table replication. For more information, see Preparing Clusters for Table Replication on page 1431.
- Run the `maprcli table info` command on the source table to verify that you have the following permissions:
  - `readperm`, which is required for reading from the table.
  - `replperm`, which is required for replicating from the table.
- Run the `maprcli table info` command on the destination table (if it already exists) to verify that you have the following permissions:
  - `bulkload`, which is required for the initial copy of source data into the destination table.
  - `replperm`, which is required for receiving replicated updates from the source table.

Procedure

1. For manual setup in one direction, follow these steps:

a) Create the replica manually with the `maprcli table create command`. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source table. Metadata includes column families, access control expressions (ACEs), and other attributes.

```
maprcli table create -path <path to the replica> -copymetafrom <path
to the source table>
```

For example, to create the replica `customers` in the `newyork` cluster and use the metadata from the source table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table create -path /mapr/newyork/customers -copymetafrom /
mapr/sanfrancisco/customers
```

b) Register the replica as a replica of the source table by running the `maprcli table replica add` command.

```
maprcli table replica add -path <path to the source table> -replica
<path to the replica> -paused true
```

For example, to register the `customers` table in the `newyork` cluster as a replica of the `customers` table in the `sanfrancisco` cluster, you could use this command:

```
maprcli table replica add -path /mapr/sanfrancisco/
customers -replica /mapr/newyork/customers -paused true
```

The `-paused` parameter ensures that replication does not start immediately after you register the source table as a source for this replica. You do this registration in step d.

c) Verify that you specified the correct replica by running the `maprcli table replica list` command.

```
maprcli table replica list -path <path to the source table>
```

To verify that the customers table in the `newyork` cluster is a replica of the `customers` table in the `sanfrancisco` cluster, you could look at the output of this command:

```
maprcli table replica list -path /mapr/sanfrancisco/customers
```

d) Authorize replication between the tables by registering the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprcli table upstream add -path <path to the replica> -upstream
<path to the source table>
```

To add the `customers` table in the `sanfrancisco` cluster as an upstream source for the `customers` table in the `newyork` cluster:

```
maprcli table upstream add -path /mapr/newyork/customers -upstream /
mapr/sanfrancisco/customers
```

e) Verify that you specified the correct source table by running the `maprcli table upstream list` command.

```
maprcli table upstream list -path <path to the replica>
```

To verify this in our example scenario, you could use this command:

```
maprcli table upstream list -path /mapr/newyork/customers
```

f) If you set `-paused` to `true` when adding the replica, follow these steps:

1. Load the replica with data from the source table by using the HPE Ezmeral Data Fabric Database CopyTable utility for binary tables or the HPE Ezmeral Data Fabric Database JSON CopyTable on page 5496 utility for JSON tables.
2. Start replication with the command `maprcli table replica resume`. Here is the `maprcli` command:

```
maprcli table replica resume -path <path to the source
table> -replica <path to the replica>
```

For our example scenario, you could use this command:

```
maprcli table replica resume -path mapr/sanfrancisco/
customers -replica /mapr/newyork/customers
```

2. For manual setup in the other direction, follow these steps:

a) Log into both the source and destination clusters.

b) Register the replica as a replica of the source table by running the `maprcli table replica add` command.

```
maprcli table replica add -path <path to the source table> -replica
<path to the replica>
```

c) Verify that you specified the correct replica by running the `maprcli table replica list` command.

```
maprcli table replica list -path <path to the source table>
```

d) Authorize replication between the tables by defining the source table as the upstream table for the replica by running the `maprcli table upstream add` command. Definition of the upstream table ensures that a table cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two tables.

```
maprcli table upstream add -path <path to the replica> -upstream
<path to the source table>
```

What to do next

- With multi-master replication, if one of the tables goes offline, direct client applications to the other table. For more information, see Multi-Master Replication on page 755.

- Be aware that changes to the structure of a source table are not replicated automatically to replicas. For more information, see Adding a Column Family to a Replica on page 1452
- You can check for alarms related to replication and whether synchronous replication is switched temporarily to asynchronous replication by looking in the Control System. See Table-Replication Alarms.

Adding Table Replicas
Explains how to add table replicas using either the Control System, the CLI or the REST API.

About this task

You can register a HPE Ezmeral Data Fabric Database binary or JSON table as a replica of another HPE Ezmeral Data Fabric Database binary or JSON table using the Control System and the CLI. When you add a replica using the Control System, you can also setup and start replication between a source HPE Ezmeral Data Fabric Database Binary or JSON table to a replica HPE Ezmeral Data Fabric Database Binary or JSON table. Before you begin, complete the steps to prepare HPE Ezmeral Data Fabric clusters for table replication.

Adding Table Replica Using the Control System

About this task

To replicate a table:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the table information page.
2. Click **Add Replica** and follow the steps for:
   - Adding JSON Table Replicas on page 1442
   - Adding Binary Table Replicas on page 1444
3. Click **Add Replica**.

Adding Table Replica Using the CLI or the REST API

About this task

To add a replica, run the following command:

```
/opt/mapr/bin/maprcli table replica add -path <table path> -replica
<replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference information, see `table replica add` on page 2500.

NOTE: You also have the option to setup table replication with `maprcli table replica autosetup` which will setup and start replication. For more information, see Setting Up Table Replication Using the CLI on page 1434.

last-updated: Jun 06, 2024

Adding JSON Table Replicas
Explains how to add replicas of JSON tables using either the Control System, the CLI or the REST API.

About this task

You can register a HPE Ezmeral Data Fabric Database JSON table as a replica of another HPE Ezmeral Data Fabric Database JSON table using either the Control System or the CLI. When you add a replica using the Control System, you can also setup and start replication between a source HPE Ezmeral Data Fabric Database JSON table to a replica HPE Ezmeral Data Fabric Database JSON table. Before you begin, complete the steps to prepare HPE Ezmeral Data Fabric clusters for table replication.

Adding JSON Table Replica Using the Control System

About this task
To create a replica:

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click **Replicas** tab.
   The list of replicas associated with the table displays.
3. Click **Add Replica**.
   The **Add Replica** page displays.
4. Specify the following settings:

Destination Cluster	The destination cluster for the replica, where gateways are configured to allow source cluster to send updates.
Path to Replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst` **NOTE:** For replication to a table, the command will fail if the replica path you specify points to table that already exists.
Replication State	Specify whether or not to start replication by choosing one of the following: • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and starts replication. • Pause Replication — Registers the table on the destination cluster as a replica and adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication. **NOTE:** Although visible, this option is not supported if the source or replica is on a remote secure cluster.

last-updated: Jun 06, 2024

Multi-Master Setup	(Available only with **Automatic Setup**) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both the primary and secondary roles. Client applications update both tables and each table replicates updates to the other. See Multi-Master Replication on page 755. If this is not selected, table replication will be basic primary-secondary topology. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located. See Primary-Secondary Replication on page 750. **NOTE:** Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.

5. Set the following optional properties:

Throttle	Specify whether (**Yes**) or not (**No**) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load.
Replicate Synchronously	Specify whether replication is synchronous (**Yes**) or asynchronous (**No**). See Modes of replication on page 750 for more information.
Encrypt On Wire	Specify whether (**Yes**) or not (**No**) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	The type of on-wire compression. Choose one of the following: • Inherited • OFF • LZF • LZ4 • ZLib

6. Choose whether to:
   - **Replicate Entire Document**
   - **Replicate Selected Field Paths** — Specify the full path to the field in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
     "_id" : "ID",
     "a" :
          {
               "b" :
                    {
                         "c" : "value",
                    },
               "e" : "value"
```

last-updated: Jun 06, 2024

```
            }
}
```

To replicate field `c`, you must specify `a.b.c` as the field path. Do not use quotation marks and do not include spaces after each dot. Click:

- **Add Field** to add another field to replicate.
- ⛔ to remove a field.

By default, the entire document in the source table is replicated.

NOTE: If a field is added at a later date, replication for that field will start at that time.

7. Click **Add Replica**.
   A table with the specified fields is created in the destination cluster, the new table is declared to be a replica of the source table, and the source table is registered as an upstream source for the replica.

Adding JSON Table Replica Using the CLI or the REST API

About this task

To add a replica, run the following command:

```
maprcli table replica add -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference information, see `table replica add` on page 2500.

NOTE: You also have the option to use `maprcli table replica autosetup` which will setup and start replication. For more information, see `table replica autosetup` on page 2504.

Adding Binary Table Replicas
Explains how to add replicas of binary tables using either the Control System or the CLI.

About this task

You can register a HPE Ezmeral Data Fabric Database Binary table as a replica of another HPE Ezmeral Data Fabric Database Binary table using the Control System and CLI. When you add a replica using the Control System, you can also setup and start replication between a source HPE Ezmeral Data Fabric Database Binary table to a replica HPE Ezmeral Data Fabric Database Binary table. Before you begin, complete the steps to prepare HPE Ezmeral Data Fabric clusters for table replication.

Adding Binary Table Replica Using the Control System

About this task
To create a replica:

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.

2. Click **Replicas** tab.
   The list of replicas associated with the table displays.
3. Click **Add Replica**.
   The **Add Replica** page displays.
4. Specify the following settings:

Destination Cluster	The destination cluster for the replica, where gateways are configured to allow source cluster to send updates.
Path to Replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfracisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst` **NOTE:** For replication to a table, the command will fail if the replica path you specify points to table that already exists.
Replication State	Specify whether or not to start replication by choosing one of the following: • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and starts replication. • Pause Replication — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication. **NOTE:** Although visible, this option is not supported if the source or replica is on a remote secure cluster.
Multi-Master Setup	(Available only with **Automatic Setup**) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both primary and secondary roles. Client applications update both tables and each table replicates updates to the other. See Multi-Master Replication on page 755. If this is not selected, table replication will be basic primary-secondary topology. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located. See Primary-Secondary Replication on page 750. **NOTE:** Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.

5. Set the following optional properties:

Throttle	Specify whether (**Yes**) or not (**No**) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load.

last-updated: Jun 06, 2024

Replicate Synchronously	Specify whether replication is synchronous (**Yes**) or asynchronous (**No**). See Modes of replication on page 750 for more information.
Encrypt On Wire	Specify whether (**Yes**) or not (**No**) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	The type of on-wire compression. Choose one of the following: • Inherited • OFF • LZF • LZ4 • ZLib

6. Choose whether to:
   - **Replicate all column families**
   - **Replicate Selected Column Families** — Specify the column family name and select:
     - **Include All Columns** — to replicate all the columns associated with the column family.
     - **Assign Columns** — to specify specific columns associated with the column family. To add more columns, click +.

   By default, all columns in the source table are replicated.

   NOTE: While the column families that you specify must already exist in the source table, the columns that you specify do not have to exist in the destination table for replication to succeed. If a column is added at a later date, replication for that column will start at that time.

7. Click **Add Replica**.
   A table with the specified column families is created in the destination cluster, the new table is declared to be a replica of the source table, and the source table is registered as an upstream source for the replica.

Adding Binary Table Replica Using the CLI or the REST API

About this task

To add a replica, run the following command:

```
maprcli table replica add -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference information, see `table replica add` on page 2500.

NOTE: You also have the option to use `maprcli table replica autosetup` which will setup and start replication. For more information, see `table replica autosetup` on page 2504.

Displaying the List of Table Replicas
Describes how to view information on the table replicas using the Control System or the CLI.
Displaying the List of Table Replicas Using the Control System

About this task
To view table replicas:

Procedure

1. Log in to the Control System and go to the table information page.
2. Click **Replication**.
   The page displays all the replicas and for each replica, the pane displays the following statistics:

Column Name	Column Description
Paused	Whether replication is paused.
Destination Cluster	The cluster on which the replica resides.
Destination Path	The path to the destination.
Status	The status of the replica. Replicas can be in one of the following states: • In-Synch — indicates replica is in synch with the source table and there are no more bytes to be sent from the source. • Pending — indicates replica is waiting for some bytes to be sent from the source. You can hover over the status to determine the number of bytes, puts, and buckets pending. • Broken — indicates there was an error during replication. If necessary, remove and re-create the replica.
Earliest	The epoch time in milliseconds of the oldest operation that is yet to be replicated to the replica.
Latest	The epoch time in milliseconds of the newest operation that is yet to be replicated to the replica.
Errors	Error ( ) information, if any.
Compression Type	The type of on-wire compression.
Synchronous	Whether replication is synchronous or asynchronous.
Throttled	Whether replication is throttled.
Encrypted	Whether replication is encrypted.

last-updated: Jun 06, 2024

Retrieving List of Table Replicas Using the CLI or the REST API

About this task

To view table replicas and associated replica statistics for a table, run the following command:

```
maprcli table replica list -path <table-path>
```

For more information, see `table replica list` on page 2513

Modifying Table Replica

Explains how to edit the properties of a replica using the Control System and the CLI.

Modifying a Table Replica Using the Control System

About this task

To modify the properties of a table replica:

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click **Replicas** to go to that tab.
3. Click  associated with the replica to modify.
   The **Edit Replica** page displays.
4. Make changes to the following as desired:

Path to Replica	The path to the replica. • For a table on the local cluster, start the path at the volume mount point. For example, for a table named `testdst` under a volume with a mount point at `/volume1`, specify the following path: `/volume1/testdst` • For a table on another cluster, you must also specify the cluster name in the path. For example, for a table named `customerdst` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customerdst`  **NOTE:** For replication to a table, the command will fail if the replica path you specify points to a table that already exists.
Replication State	Specify whether or not to start replication by choosing one of the following: • Automatic Setup — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, copies the content of the current table into the replica, and start replication. • Pause Replication — Creates the table on the destination cluster, registers the table on the destination cluster as a replica, adds the current table as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current table, after which you can restart replication.
Multi-Master Setup	(Available only with **Automatic Setup**) Multi-master topology, in which there are two primary-secondary relationships, with each table playing both primary and secondary roles. Client applications update both tables and each table replicates updates to the other. See Primary-Secondary Replication on page 750.

	If this is not selected, table replication will be basic primary-secondary topology, which is the default. In this topology, you replicate one way from source tables to replicas. The replicas can be in a remote cluster or in the cluster where the source tables are located. See Primary-Secondary Replication on page 750. **NOTE:** Access control expressions on the replica that control permissions for updates to column families and columns are irrelevant because all updates from a source table arrive at a replica after having been authenticated at a gateway, which has the implicit authority to update replicas.

5. Set the following optional properties:

Throttle	Specify whether (**Yes**) or not (**No**) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load.
Replicate Synchronously	Specify whether replication is synchronous (**Yes**) or asynchronous (**No**).
Encrypt On Wire	Specify whether (**Yes**) or not (**No**) to enable on-wire encryption. If you enable this, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	The type of on-wire compression. Choose one of the following: • Inherited • OFF • LZF • LZ4 • ZLib

6. Choose whether to:
   - For JSON table replica:
     - **Replicate Entire Document**
     - **Replicate Selected Field Paths** — Specify the full path to the field in dotted notation. For example, suppose the table contained JSON documents that were of this general structure:

```
{
     "_id" : "ID",
     "a" :
          {
               "b" :
                    {
                         "c" : "value",
                    },
               "e" : "value"
          }
}
```

       To replicate field `c`, you must specify `a.b.c` as the field path. Do not use quotation marks and do not include spaces after each dot. Click:
       - **Add Field** to add another field to replicate.

last-updated: Jun 06, 2024

- ⛔ to remove a field.

- For Binary table replica:
  - **Replicate All Column Families**
  - **Replicate Selected Column Families** — Specify the column family name and select:
    - **Include All Columns** — to replicate all columns associated with the column family.
    - **Assign Columns** — to specify specific columns associated with the column family. To add more columns, click +.

7. Click **Edit Replica** for the changes to take effect.

Modifying a Table Replica Using the CLI or REST API

About this task

The basic command to modify a table replica is:

```
maprcli table replica edit -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see `table replica edit` on page 2509.

Removing Table Replicas
Explains how to un-register one or more replicas using either the Control System or the CLI.
Removing Replication Using the Control System

About this task

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click **Replication** to go to that tab.
3. Select the replicas to remove by clicking the associated checkbox.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
4. Select **Remove Replica(s)** from the **Actions** drop-down menu.
   The **Remove Replica(s)** confirmation window displays.
5. Verify the list of replicas to remove and click **Remove Replica**.
   If necessary, click ✕ to remove a replica.

   The selected replicas are no longer replicas of the source table and will no longer receive updates from the source table. You must also remove upstream source to remove the association between the source table and the replica table. For more information, see Removing Upstream Sources.

Removing Replication Using the CLI or REST API

About this task

The un-register a replica, run the following command:

```
maprcli table replica remove -path <table path> -replica <replica table
path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see `table replica remove` on page 2517.

Pausing Table Replication

Explains how to pause table replication of data from a source HPE Ezmeral Data Fabric Database binary or JSON table to a replica HPE Ezmeral Data Fabric Database binary or JSON table respectively using either the Control System or the CLI.

Pausing Table Replication Using the Control System

About this task

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click **Replicas** to go to that tab.
3. Select the replicas to pause by clicking the associated checkbox.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
4. Select **Pause Replication** from the **Actions** drop-down menu.
   The **Pause Replication** confirmation window displays.
5. Verify the list of replicas to pause and click **Pause Replication** to pause replication on the selected replicas.
   If necessary, click ✕ to remove a replica from being paused.

Pausing Table Replication Using the CLI or REST API

About this task

The pause replication, run the following command:

```
maprcli table replica pause -path <table path> -replica <replica table path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables

last-updated: Jun 06, 2024

- `readperm` and `replperm` permissions on the source table

For complete reference, see `table replica pause` on page 2516.

Resuming Table Replication
Explains how to resume replication between a source HPE Ezmeral Data Fabric Database binary or JSON table and a replica of that table when the replication state is set to paused from the Control System or by the `maprcli table replica add` or the `maprcli table replica pause` command.
Resuming Replication Using the Control System

About this task

Procedure

1. Go to the table information page.
   See Viewing Table Information on page 1368.
2. Click **Replicas** to go to that tab.
3. Select the replicas in paused state by clicking the associated checkbox.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
4. Select **Resume Replication** from the **Actions** drop-down menu.
   The **Resume Replication** confirmation window displays.
5. Verify the list of replicas for which to resume replication and click **Resume Replication**.
   If necessary, click ✕ to leave the replica in paused state.

Resuming Replication Using the CLI or REST API

About this task

The resume replication, run the following command:

```
maprcli table replica resume -path <table path> -replica <replica table
path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on both the source volume and the target volume
- `lookupdir` on directories in the paths of both tables
- `readperm` and `replperm` permissions on the source table

For complete reference, see `table replica resume` on page 2519.

Adding a Column Family to a Replica
Changes to the structure of a source table are not automatically replicated to replica table. You must complete the following steps to add a column family to a replica.

About this task

When an entire table is being replicated, new column families are not automatically created at the replica. However, once you add the new column family to the replica then updates to the new column family will immediately start being replicated.

When you are replicating a subset of column families and columns, you must add the new column family to the replica and also run the copytable utility to initially populate the new column family in the replica table.

Procedure

1. Pause replication by running the `maprcli table replica pause` command.
2. Add the new column family to the replica by running the `maprcli table replica edit` command.
3. If the replica includes a subset of column families and columns from the source table, copy the data from the new column family from the source table into the replica by using the CopyTable utility. Use the `-columns` parameter to specify the name of the column family.
4. Resume replication by running the `maprcli table replica resume` command.

Viewing Active Table Replication Alarms
Describes how to view active table replication alarms using the Control System and the CLI.

About this task

You can view table replication alarms using the Control System, the log files, and the CLI.

Viewing Active Table Alarms in the Control System

Procedure

- Log in to the Control System and click **Data** > **Tables** to view table replication alarms in the **Active Alarms** pane.

  You can:

  - View information related to the alarm.
  - Dismiss an alarm.
  - Mute an alarm.

  See Table-Replication Alarms on page 3021 for more information on the table alarms.

Retrieving Active Table Replication Alarms Using the CLI or REST API

About this task

Alarms for replication are issued per volume rather than per source table. To retrieve table replication alarms, run the following command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see `alarm list` on page 2023.

Viewing Table Replication Alarms in the Log Files

About this task

The log files `mfs.log-5` and `cldb.log` display these alarms. These files are located in the `/opt/mapr/logs` directory.

Managing Upstream Source for Table Replicas

You can set up a table to be the upstream source for replicas. This is especially useful if you did not set up replication automatically when setting up replicas.

Setting Table as Upstream Source for a Replica
Explains how to set up the current table as the upstream source for a replica if the replica was not configured to automatically re-sync with the current table.
Setting Up Current Table as Upstream Source for a Replica Using the Control System

About this task
To set up a table as the upstream source for replicas:

Procedure

1. Go to the **Replication** tab in the table information page.
2. Select the checkbox beside the replicas that do not have the current table configured as upstream source for automatic re-sync.
   Selecting a checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Set Current Table as Upstream Source** from the **Actions** drop-down menu.
   The **Set Current Table as Upstream Source** dialog displays.
4. Review the list of selected replicas and click **Set Upstream Source**.
   The current table will automatically send updates to the replica(s).

Setting Up Table as Upstream Source for a Replica Using the CLI or REST API

About this task

The basic command to set a table as the upstream source for a replica is:

```
maprcli table upstream add -path <replica table path> -upstream <source
table path>
```

See `table upstream add` on page 2523 for complete reference information.

Adding Upstream Source for Table
Describes how to add an upstream source for a table using either the Control System or the CLI.
Adding Upstream Source Using the Control System

About this task
To add an upstream source for the current table:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the table information page.
2. Click **Add Upstream Source Table** in the **Upstream Sources** pane.
   The **Add Upstream Source Table** window displays.
3. Enter the path to the upstream source table.
   - For a path on the local cluster, start the path at the volume mount point. For example, for a table named `testsrc` under `volume1` which has a mount point at `/volume1`, specify the following path: `/volume1/testsrc`

last-updated: Jun 06, 2024

- For a path on another cluster, you must also specify the cluster name in the path. For example, for a table named `customersrc` under `volume1` in the `sanfrancisco` cluster, specify the following path: `/mapr/sanfrancisco/volume1/customersrc`

4. Click **Add Upstream Source Table**.

Adding Upstream Source Using the CLI or the REST API

About this task

The basic command to add upstream source is:

```
maprcli table upstream add -path <table path> -upstream <upstream table
path>
```

See `table upstream add` on page 2523 for complete reference information.

Listing all Upstream Sources for a Table
Explains how to retrieve and view the list of upstream sources for a table using either the Control System, or the CLI.
Viewing Upstream Sources Using the Control System

About this task
To view the list of upstream sources:

Procedure

- Log in to the Control System and go to the **Replication** tab in the table information page.

  The list of upstream sources for the table displays in the **Upstream Source** pane. For each upstream source, the pane displays the following:

Column Name	Column Description
IDX	The index number of the replica table.
Upstream Source Cluster	The cluster on which the upstream table resides.
Upstream Source Path	The path to the upstream source table.
UUID	The replica table's universally unique identifier.

  Selecting the checkbox beside an upstream source makes the **Remove Upstream Source(s)** button available. You can:

  - Add an upstream source table
  - Remove an upstream source table

Retrieving Upstream Sources Using the CLI or the REST API

About this task

The basic command to retrieving the list of upstream sources for a table is:

```
maprcli table upstream list -path <table path>
```

See `table upstream list` on page 2525 for complete reference information.

Removing Upstream Source
Explains how to remove a table as an upstream source using either the Control System or the CLI.

Removing Upstream Source Using the Control System

About this task
To remove upstream source:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the table information page.
   See Viewing Table Information on page 1368.
2. Select the upstream sources to remove in the **Upstream Source** pane by clicking the associated checkbox.
3. Click **Remove Upstream Source Table** in the **Upstream Source** pane.
   The **Remove Upstream Source Table** confirmation dialog displays.
4. Verify the list of upstream sources to remove and click **Remove Upstream Source Table**.

Removing Upstream Source Using the CLI or the REST API

About this task

The basic command to remove upstream source is:

```
maprcli table upstream remove -path <table path> -upstream <upstream table
path>
```

See `table upstream remove` on page 2526 for complete reference information.

Addressing High Memory File Server Alarm for JSON Table Replication
The topic describes the troubleshooting steps for memory overflow issues with JSON tables where replication has been set up, secondary indexes have been created on the JSON table being replicated, and table row size less than 1 KB.

About this task
When you are working with JSON tables and High File Server Memory alarm is raised during table replication that has been set up between the JSON tables, check if secondary indexes are created on the destination table and the table row size is smaller than 1 KB.

If all the aforementioned conditions are met, follow the steps given below to resolve the memory overflow issue.

Procedure

1. Check the table region size to identify tables with memory overflow by running the table region list on page 2493 command.
2. Use the table region split on page 2499 command to manually split destination table regions with memory overflow or high memory usage. Split until each table region size is equal to or lower than 512 MB. This is a remedial measure for the memory overflow problem.
3. Run the table edit on page 2468 command and reset the `regionsizemb` parameter on the destination table to 512 MB from the default 4 GB value. This is a preventive measure that helps with avoiding the Data Fabric file system from running out of memory during replication of JSON tables, where row size smaller than 1 KB and a secondary index has been created on the JSON table.

Managing Secondary Indexes

Describes how to manage secondary indexes, including adding, deleting, and listing indexes, setting up your cluster for querying, and troubleshooting index usage.

You can add and manage secondary indexes using either the `maprcli table index` commands or the Control System. The `maprcli table index` commands are also available using the REST API. The following diagram provides links to information about managing indexes.

1. Describes the tasks needed to prepare your environment so you can query HPE Ezmeral Data Fabric Database JSON tables using secondary indexes.
2. Describes how to add secondary indexes on HPE Ezmeral Data Fabric Database JSON tables.
3. Describes how to view information about secondary indexes. This includes information about whether an index is lagging its parent JSON table.
4. Describes how to use the HPE Ezmeral Data Fabric Database shell to examine the contents of a secondary index. This includes displaying information about errors encountered inserting into the index.
5. Describes how to verify that the data in a secondary index is consistent with its JSON table.
6. This topic describes how to remove secondary indexes that are no longer needed.
7. Describes how to debug and troubleshoot usage of secondary indexes.

The following permissions are required to add, remove, and list indexes. Indexes share the same volume and topology as its JSON table, so the applicable permissions are on the volume and JSON table path.

- `readAce` on the volume
- `lookupdir` on directories in the table path

NOTE: The `mapr` user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Also, to add or remove an index, the user must be the creator of the table or a user with `indexperm` permission.

Preparing Clusters for Querying using Secondary Indexes on JSON Tables

Describes the tasks needed to prepare your environment so you can query HPE Ezmeral Data Fabric Database JSON tables using secondary indexes.

Installing with the MapR Installer

To install MapR using the MapR installer, follow the steps outlined at Installing with the Installer on page 178.

last-updated: Jun 06, 2024

Starting with MapR 6.0.1, you do not have to enable a separate query service to use secondary indexes. The **Operational Applications with HPE Ezmeral Data Fabric Database** template installs and configures the replication gateways needed to update secondary indexes in HPE Ezmeral Data Fabric Database JSON and includes the components needed to run OJAI queries.

You must enable the OJAI Distributed Query Service on page 640 to use certain features. The following table summarizes the differences in the functionality of OJAI queries when you do and do not have the service enabled:

Service Not Enabled	Service Enabled
• Can run queries that use a single secondary index • Can sort data in your queries up to a configurable limit	• Can run queries that use multiple secondary indexes • Can sort data in your queries without any limit • Can run queries in parallel

Selecting any of the following templates enables the OJAI Distributed Query Service:

- **Operational Applications with HPE Ezmeral Data Fabric Database and Distributed Query Service**
- **MapR Converged Cluster: Batch, interactive and real-time analytics**
- **Analytics with HPE Ezmeral Data Fabric Database**

You can also explicitly enable the OJAI Distributed Query Service by selecting the service in the **Custom Services** template.

For more information about installer templates, see Auto-Provisioning Templates on page 5636.

For more information about how secondary index selection and execution works in HPE Ezmeral Data Fabric Database JSON, see Selection and Execution of Secondary Indexes on page 721.

NOTE: The **OJAI Query Service** has been renamed to the **OJAI Distributed Query Service** in MapR 6.0.1. All information about the OJAI Distributed Query Service applies to the OJAI Query Service, except where noted.

Installing without the MapR Installer

Other sections of the documentation describe the detailed steps for installing and configuring without the MapR installer. Generally, you need to perform the following steps:

1. Install software.

   To install MapR without using the MapR installer, follow the steps outlined at Installing without the Installer on page 179. In addition to installing MapR core packages, you also need to install MapR Drill if you want advanced secondary index selection, sorts on large data sets, and parallel query execution. When installing Drill, make sure to Configure the OJAI Distributed Query Service on page 241.

2. Install and configure replication gateways.

   Updates are propagated from the JSON tables using the Gateways for Replicating HPE Ezmeral Data Fabric Database Tables on page 760. You need to install the replication gateways. Since the source JSON table and the secondary index are on the same volume within a cluster, configure an intracluster gateway. In this type of gateway, the source and destination clusters are the same.

   If your gateways are running on the same nodes as CLDB, then no additional configuration steps are required. See Configuring Gateways for Table and Stream Replication on page 1528 for details about this scenario and other options for configuring your gateways.

Upgrades

Other sections of the documentation describe the detailed steps for upgrades. Generally, you need to perform the following steps:

1. Upgrade your MapR software by following the instructions at Upgrading Core or EEP Components on page 300.
2. Install MapR Drill, if you have not already done so and want to sort large data sets and run queries in parallel.
3. When installing Drill, make sure to Configure the OJAI Distributed Query Service on page 241.
4. If you are upgrading without the MapR installer, follow step 2 in the previous section to install and configure replication gateways.
5. Enable the replication support needed to propagate index updates by running the following command:

   ```
   maprcli cluster feature enable -name mfs.feature.db.streams.v6.support
   ```

   See Step 4: Enable New Features on page 340 for further details.

IMPORTANT: If you are using a Manual Rolling Upgrade Description on page 327, you must upgrade all nodes running replication gateways before performing updates on tables with indexes. Otherwise, the index updates will hang.

Adding Secondary Indexes on JSON Tables

Describes how to add secondary indexes on HPE Ezmeral Data Fabric Database JSON tables.

About this task

You can add secondary indexes using the Control System, or the `maprcli table index` commands.

If you are adding an index on a large table, particularly if it contains complex data, you should consider modifying the `mfs.db.parallel.copyregions` parameter using the maprcli config save command. The parameter controls the degree of parallel processing in your HPE Ezmeral Data Fabric cluster. Increasing parallelism can improve the index build time by optimizing the build's intermediate copy operation.

Permissions

You need the following permissions to add an index:

- `readAce` on the volume
- `lookupdir` on directories in the table path
- `indexperm` permission on the table

If you created the table in version 6.0 or later, you automatically have `indexperm` permission. For tables created before 6.0, even if you are the owner of the table, you must explicitly add `indexperm` permission.

NOTE: The mapr user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the mapr user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

See Restrictions on Secondary Indexes on page 703 for information about other restrictions.

last-updated: Jun 06, 2024

NOTE: If you are configuring secondary index on a JSON table that has replication set up and the JSON table has row size of less than 1 KB, run the `table edit` command to reset the `regionsizemb` parameter to 512 MB from the default 4 GB value. This prevents a memory overflow during the table replication operation.

Adding Indexes Using the Control System

Procedure

1. Log in to the Control System and go to the **Indexes** tab in the table information page.
2. Click **Add Index** to display the **Add Index** page.
3. Specify the following settings:
   a) Specify the name of the index in the **Index Name** field.
   b) Specify whether (**Yes**) or not (**No**) the index is hashed in the **Hashed** field. If **Yes**, specify the number of hash index partitions for distributing the keys.
   See Hashed Indexes on page 693 for information about whether you should create a hashed index.
4. Specify the list of indexed fields under **FIELDS INDEXED**.
   a) Specify the name of the indexed field in the **Field Name** text field.
   b) Select the ordering (**Ascending** or **Descending**) for the field from the **Order** drop-down menu.
   c) Select the function of the field from the **Function** drop-down menu.
   Before defining an index that specifies index keys with CAST functions, see Using Casts in Secondary Indexes on page 695 for more information on creating indexes using CAST functions.

   TIP: To add more indexed fields, click **Add Another** and repeat step 4.
5. Specify the names of the included fields under **INCLUDED FIELDS**.
   For more information, see Covering Indexes on page 698.

   TIP: To add additional included fields, click **Add Another** and repeat step 5.
6. Click **Add Index** to create the index.

Adding Indexes Using the CLI

About this task

The following is the basic command for adding a secondary index on a JSON table.

```
maprcli table index add
  -path <path>
  -index <index name>
  -indexedfields < indexed field names >
```

See `table index add` on page 2473 for a description of the complete syntax.

Troubleshooting Secondary Indexes

Describes how to debug and troubleshoot usage of secondary indexes.

The following table lists problems you may encounter when using secondary indexes. Based on the symptoms listed in the first column, refer to the section in the third column to further troubleshoot the issue.

Symptom	Possible Cause	Troubleshooting Steps
Query performance is slow	Query is not using secondary indexes	1. Determining the Query Execution Path for OJAI Queries on page 1466 2. Determining Secondary Index Usage on page 1467
	Non-optimal OJAI query plan chosen	Examining the OJAI Query Plan on page 1467
	Non-optimal query plan chosen by OJAI Distributed Query Service	Determining Index Use on page 4116
Inconsistent query results	Secondary index update lag	Identifying Secondary Index Lag on page 1468
	Unresolved encoding errors	Troubleshooting Secondary Index Encoding Errors on page 1470
Query runs out of memory	Memory configuration in the OJAI Distributed Query Service set too low	Adjusting Memory Settings in the OJAI Distributed Query Service on page 1471
High File Server Memory alarm is raised when JSON table replication operation runs out of memory, if secondary index has been created on the table.	The table row size less than 1 KB causes memory leak.	Addressing High Memory File Server Alarm for JSON Table Replication on page 1456

Secondary Index Restrictions

When troubleshooting secondary indexes, you should also keep in mind the following restrictions:

Name Restrictions

You cannot use the following characters in the index name and in the indexed fields:

```
< > ? % \
```

To use the following characters in the index name and in the indexed fields, enclose them either in single or double quotes:

```
; | ( ) /
```

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"MYTABLE1_ANALYSIS_1♦=#;{}&()/" \
  -indexedfields "●timestamp":desc,"●
♥,"LOTNo" -includedfields \
  "♥,"♦=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'MYTABLE1_ANALYSIS_1♦=#;{}&()/' \
  -indexedfields "●timestamp":desc,"●
♥,"LOTNo" -includedfields \
  '♦,'♦=#;{}&()/'
```

To use either the **'** or the **"** character in the index name and in the indexed fields, enclose:

last-updated: Jun 06, 2024

- the ' character within double quotes (")
- the " character within single quote (')

For example:

```
maprcli table index
add -path /volume1/MYTABLE -index
"'MYTABLE1_ANALYSIS_1♦=#;{}&()/" \
  -indexedfields "●timestamp":desc,"♦●
♦,"LOTNo" -includedfields \
  "♦","♦=#;{}&()/" (or)

maprcli table index
add -path /volume1/MYTABLE -index
'"MYTABLE1_ANALYSIS_1♦=#;{}&()/' \
  -indexedfields "'●timestamp":desc,"●
♦,"LOTNo" -includedfields \
  '♦','♦=#;{}&()/"
```

Type Restrictions

- If a composite index includes the same subfield in multiple indexed fields, the implied types of the subfields must be consistent.

  For example, you cannot create an index with the following indexed fields:

  ```
  a.b[].c, a.b.d
  ```

  Although subfield b appears in both indexed fields, in the first, it is an array and in the second, it is a nested document.

  See Composite Indexes and Container Field Paths on page 692 for more details.

Size Restrictions

- The maximum size of all indexed fields in an index is 32 KB.

  If the collective size exceeds 32 KB, then an insert of the corresponding document results in an encoding error (`INDEX_ROW_KEY_ENCODER_ERROR_ENCODING_IS_TOO_LONG`).

- The maximum number of indexes that you can create on a JSON table is 32.

Field Definition Restrictions

- You cannot specify individual array elements as indexed fields.
- You cannot specify a table's `_id` field as an indexed field.
- If a field contains an array of nested documents and you want to index on subfields in the nested documents, then you must define the indexed field using a container field path.
- You can include a specific field only once as either an indexed or included field, with the following two exceptions:

- The indexed field is a container field path:

```
maprcli table index add -path /
people \
   -index phoneNumberIdx \
   -indexedfields
Phones[].Number \
   -includedfields
Phones[].Number
```

- The field specifies a cast to another type.

  You can create an index in which the `score` field is an indexed field cast as a `double` type, and `score` is also an included field. The included field retains the original data type of the `score` field:

```
maprcli table index add -path /
castTable \
   -index castIdx1 \
   -indexedfields
'$CAST(score@DOUBLE)' \
   -includedFields score
```

  You can create an index in which the `score` field is an indexed field, cast as a `double` type, and the `score` field is also another indexed field, cast as a `long` type:

```
maprcli table index add -path /
castTable \
   -index castIdx2 \
   -indexedfields
'$CAST(score@DOUBLE)','$CAST(scor
e@LONG)'
```

- You cannot use casts with included fields.

- You cannot specify a field as either an indexed or included field if the field is also specified as a column family JSON path name.

  For example, suppose you have the following JSON table:

  ```
  {
       "_id" : "ID",
       "a" :
            {
                 "b" :
                      {
                           "c" :
  "value",
                           "d" :
  "value"
                      },
                 "e" : "value"
            }
  }
  ```

  If you create a column family at field `c` in the JSON path `a.b.c`, you cannot define field `a.b.c` as either an indexed or included field. You can define the fields `a`, `a.b`, and `a.b.d` as either indexed or included fields.

last-updated: Jun 06, 2024

- You cannot specify an included field in which the data in the field spans more than one column family.

  In the following example, the included field `sl1.sl2` spans column families, `cf2` and `cf3`:

```
maprcli table cf list -path /cftab
compressionperm  readperm
traverseperm  jsonfamilypath
writeperm  minversions
maxversions  compression
ttl         inmemory  cfname
memoryperm
u:root           u:root
u:root
u:root     0
1            lz4
2147483647  false     default
u:root
u:root           u:root
u:root         sl1
u:root     0
1            lz4
2147483647  false     cf1
u:root
u:root           u:root
u:root         sl1.sl2.sl3
u:root     0
1            lz4
2147483647  false     cf2
u:root
u:root           u:root
u:root         sl1.sl2.sl3.sl4
u:root     0
1            lz4
2147483647  false     cf3
u:root

maprcli table index add -path /
cftab -index i1 -indexedfields
sl1.sl2.sl3.sl4.l4a,
sl1.l1a -includedfields

column family."
                }
         ]
}
```

	• You cannot specify a composite index with more than one container field path as your indexed fields, unless the prefixes of the container field paths are the same. See Composite Indexes and Container Field Paths on page 692 for more details. • You cannot specify a composite index with an indexed field that is a subfield of another indexed field. For example, you cannot create an index with the following indexed fields: `a, a.b` The indexed field `a.b` is a subfield of the indexed field `a`.
Option Restrictions	• As indexes are automatically split, you cannot disable splits when you create your index.
Index Use Restrictions	• Indexes do not optimize non-existence filter conditions.

HPE Ezmeral Data Fabric Database JSON verifyindex on page 5508
Describes how to use the HPE Ezmeral Data Fabric Database JSON `verifyindex` command to verify that the data in a secondary index is consistent with its JSON table.

dbshell indexscan on page 5482

Determining the Query Execution Path for OJAI Queries

You can determine whether an OJAI query directly accesses HPE Ezmeral Data Fabric Database JSON or leverages the OJAI Distributed Query Service by enabling Java OJAI tracing. Java OJAI tracing logs information that enables you to determine which execution path your queries use.

Follow the instructions at Enable OJAI Tracing on page 3447 to output tracing messages that include query plans.

If the query does not use the OJAI Distributed Query Service, you will see tracing like the following:

```
2017-07-17 17:35:59 TRACE OjaiDocumentStore:132 -
Query Plan: '[{"streamName":"DBDocumentStream","parameters":
{"queryConditionPath":false,"indexName":"abc_Idx","projectionPath":
["c","b","a"],"primaryTable":"/tmp/test-728918932/ei_suffix_sort"}}]'
```

If a query uses the OJAI Distributed Query Service, you will see tracing like the following instead:

```
2017-07-17 18:51:13 TRACE OjaiDocumentStore:132 - Query
Plan:'[{"streamName":"DrillDocumentStream","parameters":{"sql":"select t.`$
$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from dfs.`/tmp/testTable` t
where (t.`l0_a4_int` = -92) order by t.`l0_a4_int` ASC,t.`_id` DESC"}}]'
```

```
2017-07-17 18:51:14 DEBUG DrillDocumentStream:120 -
DocumentResultsListener[1].queryIdArrived(queryId =
```

```
2692966d-0888-96e2-fa09-0d9befcd3173 ,sql string = select t.`$
$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from dfs.`/tmp/testTable` t
where (t.`l0_a4_int` = -92) order by t.`l0_a4_int` ASC,t.`_id` DESC)
```

Note that the **Query Plan** in the second trace fragment above contains a **DrillDocumentStream** instead of a **DBDocumentStream**. The **sql** parameter in that stream shows a SQL query. This is also missing in the first trace fragment above. The presence of the SQL query indicates that OJAI passes the query to the OJAI Distributed Query Service, as noted in the third trace fragment.

For further information about OJAI query plans, see Examining the OJAI Query Plan on page 1467. For background information about different query execution paths, see OJAI Distributed Query Service on page 640.

Determining Secondary Index Usage
This section describes how to determine whether a query is using secondary indexes, depending on the query execution path used.

Determine whether your query uses the OJAI Distributed Query Service by following the steps outlined at Determining the Query Execution Path for OJAI Queries on page 1466. The following sections describe next steps depending on the execution path.

Simple OJAI Queries

Using the tracing described at Determining the Query Execution Path for OJAI Queries on page 1466, you will see the following in the log output:

```
2017-07-17 17:35:59 TRACE MapRDBTableImplHelper:703 - Scan on Index:
'testIndex', Primary Table is: '/tmp/testTable', Index Scan QueryCondition:
'((field < {"$numberLong":101}))',
Index Scan startRow: '\x0FZ', Index Scan stopRow: '\x0F\x89\xCA\x80\x00'
```

The "**Scan on Index**", highlighted in bold, indicates OJAI used a secondary index to process the query.

Queries Requiring the OJAI Distributed Query Service

The tracing output described at Determining the Query Execution Path for OJAI Queries on page 1466 contains a **queryId**, highlighted in bold:

```
2017-07-17 18:51:14 DEBUG DrillDocumentStream:120 -
DocumentResultsListener[1].queryIdArrived(queryId =
2692966d-0888-96e2-fa09-0d9befcd3173 ,
sql string = select t.`$$ENC00NQYF6YJUL5UW45AAL5UWI`,t.`$$document` from
dfs.`/tmp/testTable` t where (t.`l0_a4_int` = -92) order by t.`l0_a4_int`
ASC,t.`_id` DESC)
```

Use this **queryId** to retrieve more information through the Drill Web Console, including the query plan selected by the OJAI Distributed Query Service. See Query Profile on page 4116 for details.

Examining the OJAI Query Plan
This section describes two ways to access a Java OJAI query plan and provides general information about how to interpret the query plan. You can examine the query plan to determine if the Java OJAI client chooses an appropriate execution path.

Using OJAI Tracing

After following the steps at Determining the Query Execution Path for OJAI Queries on page 1466, if you determine that your query directly accesses HPE Ezmeral Data Fabric Database JSON and does not use the OJAI Distributed Query Service, you can further examine the query plan in the trace output.

As noted in the referenced topic, to enable tracing, set the following property in your `log4j.properties` file, located in the `/opt/mapr/conf` directory:

```
log4j.logger.com.mapr.ojai.store.impl=TRACE, stdout
```

In the following logged output, the query plan uses an index named `i1_idx` and projects field `id1`. It also limits the result to two documents:

```
2017-10-18 11:29:32,876 TRACE
[main] com.mapr.ojai.store.impl.OjaiDocumentStore -
Query Plan: '[{"streamName":"DBDocumentStream","parameters":
{"queryConditionPath":false,"indexName":"i1_idx","projectionPath":
["id1"],"primaryTable":"/tmp/test-728918932/tab"}},
{"streamName":"LimitStream","parameters":{"limit":2}}]'
```

Calling `QueryResult.getQueryPlan`

Instead of using OJAI tracing, you can programmatically retrieve query plans by calling QueryResult.getQueryPlan. The method returns a JSON document that is a list of `Maps`. Each `Map` in the list represents a DocumentStream in the query plan, which corresponds to an operation. The order of the list represents the order the HPE Ezmeral Data Fabric Database client processes each operation. Each `Map` entry contains the name of the DocumentStream (`streamName`) and its parameters. You may see `Map` entries corresponding to the following `DocumentStreams` in a query plan:

- `DBDocumentStream` - Accesses HPE Ezmeral Data Fabric Database without the OJAI Distributed Query Service
- `DrillDocumentStream` - Uses the OJAI Distributed Query Service to process the query
- `LimitStream` - Limits the number of documents to return
- `OffsetStream` - Skips past specified number of documents before reading

IMPORTANT: The `DocumentStream` names and their parameters are subject to change from one release to the next. Take that into consideration if you plan to write tools that interpret the contents of an OJAI query plan

Identifying Secondary Index Lag

This section describes the commands you use to determine if updates to a secondary index are lagging.

Secondary index lag can occur due to aysnchronous secondary index updates. Use maprcli table index list and mapr verifyindex to assess if there is update lag in an index and to see details on the updates that are lagging.

Run maprcli table index list

The `maprcli table index list` command lists information about indexes created on a table. To retrieve the most current status, specify the optional `refreshnow` parameter. Examine the values of the following fields to determine if an index is lagging:

- isUptodate - True if the index is up-to-date
- bytesPending - The number of bytes pending propagation to the index
- putsPending - The number of puts pending propagation to the index
- minPendingTS - The timestamp of the oldest put pending propagation to the index
- maxPendingTS - The timestamp of the most recent put pending propagation to the index

last-updated: Jun 06, 2024

In the sample output below, the index is up-to-date.

```
maprcli table index list -path /demo/business -json
{
        "timestamp":1506617667735,
        "timeofday":"2017-09-28 04:54:27.735 GMT+0000 PM",
        "status":"OK",
        "total":1,
        "data":[
                {
                        "cluster":"my.cluster.com",
                        "type":"maprdb.si",
                        "indexFid":"2049.93.10257820",
                        "indexName":"i1",
                        "hashed":false,
                        "indexState":"REPLICA_STATE_REPLICATING",
                        "idx":1,
                        "indexedFields":"a.b:ASC",
                        "isUptodate":true,
                        "minPendingTS":0,
                        "maxPendingTS":0,
                        "bytesPending":0,
                        "putsPending":0,
                        "bucketsPending":0,
                        "copyTableCompletionPercentage":100,
                        "numTablets":1,
                        "numRows":4,
                        "totalSize":24576
                }
        ]
}
```

Run mapr verifyindex

If `maprcli table index list` shows that an index is lagging, use the mapr verifyindex command to gather more information. The following example illustrates the output in the case where an index is lagging. The following updates have not yet propagated to the index:

- Document with _id=997 not yet inserted into the index.
- Update to the `city` field in document with _id=998 not yet propagated to the index.

```
// Display contents of parent JSON table
# mapr dbshell

maprdb root:> find /t1
{"_id":"1000","city":"city3","misc":{"a":"misc.a","b":2}}
{"_id":"997","city":"city3","misc":{"a":"misc.a","b":2}}
{"_id":"998","city":"city4","misc":{"a":"misc.a","b":2}}
{"_id":"999","city":"city3","misc":{"a":"misc.a","b":2}}
4 document(s) found.

// Display contents of an index that is lagging.
// Document with _id=997 is missing from the index and
// there is a mismatch in the index data for document with _id=998
maprdb root:> indexscan /t1 --indexname i2
{"_id":"1000","city":"city3"}
{"_id":"998","city":"city3"}
{"_id":"999","city":"city3"}
3 document(s) found.
maprdb root:> quit
```

```
// Output of verifyindex
# mapr verifyindex -path /t1 -index i2

Missing Document in Index:
{"_id":"997","city":"city3"}

Mismatch Document Found!!
Table side-->{"_id":"998","city":"city4"}
Index side-->{"_id":"998","city":"city3"}

Number of rows in table but not in index: 1
Number of rows in index but not in table: 0
Mismatch row count: 1
```

Troubleshooting Secondary Index Encoding Errors
This section describes how to locate secondary index encoding errors in log files, and then resolve them.

About this task
Unresolved secondary index encoding errors can result in queries returning incomplete results. See Secondary Index Encoding Error on page 3024 for details.

To troubleshoot secondary index encoding errors, follow these steps:

Procedure

1. Determine whether any table has index encoding alarms by using one of the following two options:
   - Run the following `grep` command, searching for the strings `index` and `encoding` in the `mfs.log-5` file:

     ```
     # grep -i "index.*encoding" /opt/mapr/logs/mfs.log-5
     2018-07-10 11:06:07,7042 INFO DB db/repl/araggregator.cc:524 Table
     2050.43.262440 hit index row-key encoding error
     2018-07-10 11:06:07,7042 INFO DB db/repl/araggregator.cc:914 Raising
     alarm VOLUME_ALARM_TABLE_INDEX_ENCODING_ERROR for volume 195503497
     ```

     The fid, `2050.43.262440`, in the sample output indicates the table corresponding to the alarm. If you are not sure which table this corresponds to, you can convert the fid to a table path by following the instructions at Converting fid and volid on page 3223.

   - Check for any table index encoding alarms in the MapR Control System, as described at Viewing Active Table Replication Alarms on page 1693.

     The alarm details indicate the table corresponding to the alarm.

2. Find the index on the table from step 1 that is causing the error.

   Run dbshell indexscan on page 5482 with `--mode` set to `err` on each index to see the index's error output. You need to run the command multiple times if a table has multiple indexes with errors.

   For example, if `table1` has three secondary indexes and all three secondary indexes have errors, you must run `indexscan` three times:

   ```
   indexscan /table1 --indexname index1 --mode err
   indexscan /table1 --indexname index2 --mode err
   indexscan /table1 --indexname index3 --mode err
   ```

   The following example shows error output from running the `dbshell indexscan` command:

   ```
   maprdb root:> indexscan /IndexEncodingErrorAlarmsTest1/tab1 --indexname
   idx1 --mode err
   {"_id":"100","$ERROR":"Index field 1: INVALID_CAST"}
   ```

3. Address the identified errors by attempting the following suggested resolutions:

Error	Suggested Resolutions
KEY_TOO_LONG: The collective size of the index key is limited to less than 32 KB.	• Reinsert the row in the JSON table so the collective size of all the indexed fields is less than 32 KB. • Redesign the secondary index so fields with large values are included fields instead of indexed fields. • Reduce the number of indexed fields in the secondary index.
INVALID_CAST: An error was encountered applying the CAST function on an indexed field.	• Verify that you have specified the correct types when using the CAST function with indexed fields. • If the types are correct, reinsert the row in the JSON table so the values of indexed fields can be cast to the specified type. See Using Casts in Secondary Indexes on page 695.

Adjusting Memory Settings in the OJAI Distributed Query Service
This section describes how to verify, through log output, that your OJAI query is running out of memory due to memory limits in the OJAI Distributed Query Service. It then describes how to adjust the memory settings in the service.

Procedure

1. Before adjusting the OJAI Distributed Query Service memory settings, first confirm that your query has run out of memory due to limits in the service.

   You should see output like the following in your client application log:

   ```
   15:32:46.465 [Thread-21] - Error caused in scan Drill submissionFailed
   for "select t.`$$ENC00FIAF62LE`,t.`$$document` from dfs.`/tables/
   business` t where ((t.`city` = 'Currie') and (t.`state` = 'PA') and
   (t.`review_count` > 5100)) limit 1
   org.ojai.exceptions.OjaiException: Drill submissionFailed for "select
   t.`$$ENC00FIAF62LE`,t.`$$document` from dfs.`/tables/business` t where
   ((t.`city` = 'Currie') and (t.`state` = 'PA') and (t.`review_count` >
   5100)) limit 128" please ch
           at
   com.mapr.ojai.store.impl.DrillDocumentStream$DocumentResultsListener.subm
   issionFailed(DrillDocumentStream.java:220)
           at

   sListener.java:84)
           at
   com.mapr.ojai.store.impl.RunnableQueue$QueueRunner.run(RunnableQueue.java
   :59)
           at
   java.util.concurrent.ThreadPoolExecutor.runWorker(ThreadPoolExecutor.java
   :1142)
           at
   java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.jav
   a:617)
           at java.lang.Thread.run(Thread.java:745)
   Caused by: org.apache.drill.common.exceptions.UserRemoteException:
   RESOURCE ERROR: One or more nodes ran out of memory while executing the
   query.

   Failure trying to allocate initial reservation for Allocator. Attempted
   to allocate 5000000 bytes and received an outcome of FAILED_LOCAL.
   Fragment 0:0
   ```

   In the OJAI Distributed Query Service, log files are in the `/opt/mapr/drill/<drill-version>/logs/drillbit.log` on each node where the Query Service is running.

   You should see output like the following:

   ```
   2017-10-07 15:32:41,693 [BitServer-3] INFO
   o.a.drill.exec.ops.FragmentContext - User Error Occurred: One or more
   nodes ran out of memory while executing the query. (Failure trying to
   allocate initial reservation for Allocator. Attempted
   org.apache.drill.common.exceptions.UserException: RESOURCE ERROR: One or
   more nodes ran out of memory while executing the query.

   Failure trying to allocate initial reservation for Allocator. Attempted
   to allocate 7000000 bytes and received an outcome of FAILED_LOCAL.
   Fragment 1:1
   ```

2. After confirming, increase the Query Service memory settings by editing the `/opt/mapr/conf/conf.d/warden.drill-bits.conf` file on each Drillbit node. The file contains the following entries:

   ```
   service.env=DRILL_HEAP=3072m,DRILL_MAX_DIRECT_MEMORY=1024m,DRILLBIT_CODE_
   CACHE_SIZE=512m
   ```

```
service.heapsize.min=4608
service.heapsize.max=4608
```

Perform the following steps on **each** Drillbit node:

a) Modify `DRILL_HEAP` and `DRILL_MAX_DIRECT_MEMORY` in the `service.env` entry based on your requirements.

b) Update `service.heapsize.min` and `service.heapsize.max` to reflect the updates you made. The numbers sum to the 3 memory settings in the `service.env` entry.

c) Restart warden on the node by running the following command:

```
service mapr-warden restart
```

Listing Secondary Indexes

Describes how to list information about the secondary indexes created on HPE Ezmeral Data Fabric Database JSON tables.

About this task

You can view secondary indexes using the Control System or the `maprcli table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path

NOTE: The mapr user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Listing Indexes in the Control System

Procedure

- Log in to the Control System and go to the **Indexes** tab in the table information page.
  The list of indexes displays in the **All indexes** pane and for each index, the page displays the following:

Column Name	Column Description
Index Name	The name of the index
Fields Indexed	The number of fields on the JSON table that are indexed and used for ordering
Fields Covered	The number of fields on the JSON table that are indexed, but not used for ordering
State	The replication state of the index
Up to Date	Whether the index is up to date
Hashed	Whether the index is hashed
Size	The size of the index

What to do next

To view more details on individual indexes, see Viewing Secondary Index Details on page 1474.

last-updated: Jun 06, 2024

Listing Indexes Using the CLI

About this task

The following is basic command for listing secondary indexes.

```
maprcli table index list
            -path <path>
            -refreshnow < true | false >
```

See `table index list` on page 2481 for more information.

Viewing Secondary Index Details

Describes how to use the Control System to view more specific details on secondary indexes.

About this task

You can view secondary index details using the Control System.

Procedure

1. Go to the **Indexes** tab in the table information page for the JSON table.
2. Click the name of the index to display the details.
   The page displays **Summary** and **Metrics** tabs.

Summary	The **Summary** tab displays the following:	
	Throughput - By Op Type	See Viewing Throughput by Operation Type Using the Control System on page 1677
	Region Distribution	See Viewing Region Distribution on page 1681.
	SETTINGS AND AUDITING	Displays the index name, whether or not the index is hashed and if hashed, the number of hashed partitions, the status of the index and if the index is current, and the number of bytes, puts, and buckets that are yet to be replicated to the index.
	INCLUDED FIELDS	The fields in the JSON table that are indexed, but not used for ordering.
	FIELDS INDEXED	The fields in the JSON table that are indexed and used for ordering.
Metrics	The **Summary** tab displays charts for the secondary index metrics. For more information, see Viewing Secondary Index Metrics on page 1680.	

Removing Secondary Indexes on JSON Tables

Describes how to remove secondary indexes that are no longer needed.

About this task

You can remove secondary indexes using the Control System or the `maprcli table index` commands. You need the following permissions.

- `readAce` on the volume
- `lookupdir` on directories in the table path
- `indexperm` permission on the table, if you did not create the table

NOTE: The mapr user is not treated as a superuser. HPE Ezmeral Data Fabric Database does not allow the `mapr` user to perform this operation unless that user is given the relevant permission or permissions with access-control expressions.

Removing Indexes Using the Control System

Procedure

1. Log in to the Control System and go to the **Indexes** tab in the table information page.
2. Select the indexes to remove and click **Remove Index**.
   The **Remove Index** confirmation window displays.
3. Review the index(es) to remove and click **Remove Index**.

Removing Indexes Using the CLI

About this task

The following is the basic command for removing a secondary index on a JSON table.

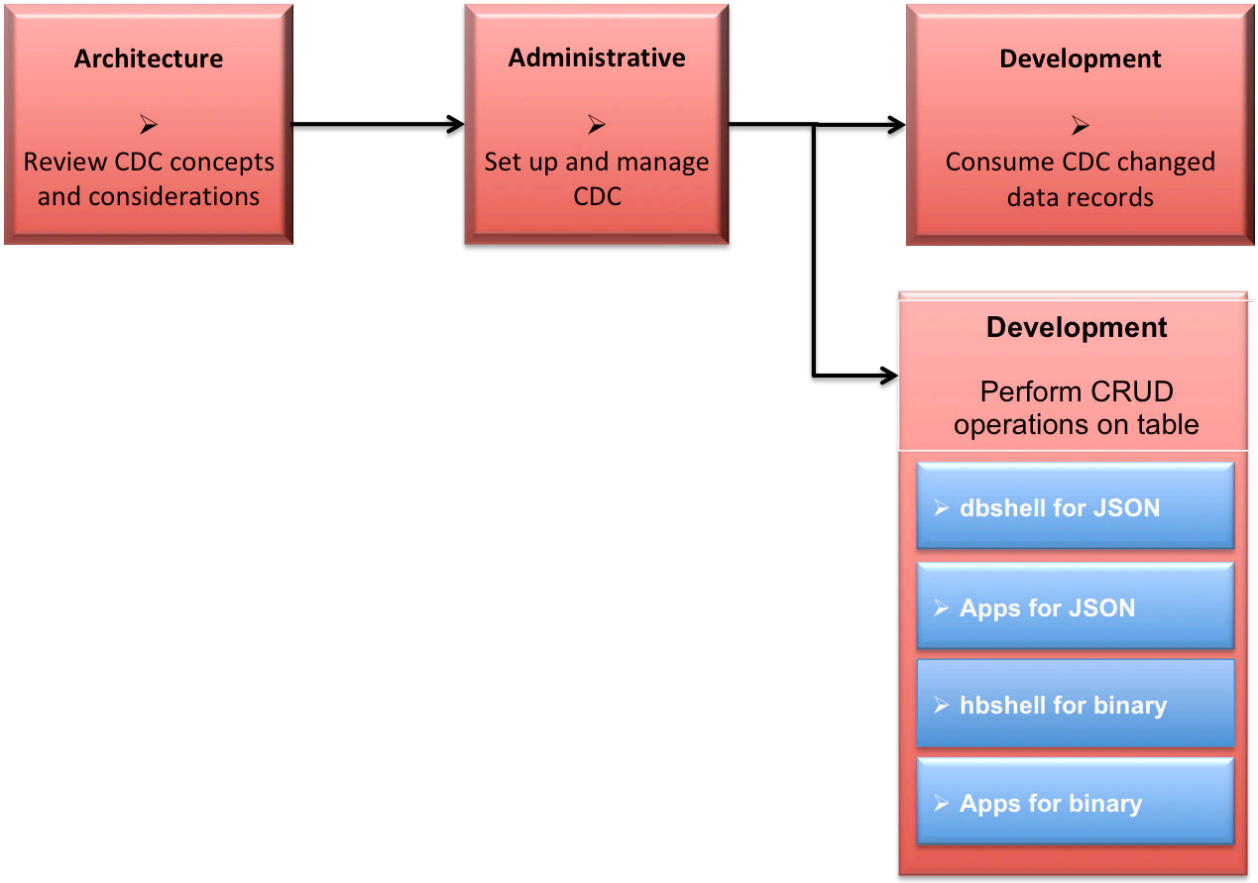
```
maprcli table index remove
  -path <path>
  -index <index name>
```

See `table index remove` on page 2484 for more information.

Administering Change Data Capture

This topic covers the Control System and `maprcli` tools for managing the Change Data Capture (CDC) feature.

The following topics provide information you need to understand the CDC feature, to setup and use CDC and the `maprcli` commands used to perform tasks.



1. Learning about CDC
2. Setting up the CDC environment
3. Consuming CDC changed data records
4. Using dbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database JSON tables
5. Developing client applications for HPE Ezmeral Data Fabric Database JSON tables.
6. Using hbshell to perform CRUD operations on HPE Ezmeral Data Fabric Database binary tables.
7. Developing client applications for HPE Ezmeral Data Fabric Database binary tables.

Additional Information

- table changelog on page 2459: The `maprcli table changelog` commands for managing the changelog relationship between the source table and the destination stream topic.

Setting Up CDC

Describes the requirements and how to set up Change Data Capture (CDC).

To set up the Change Data Capture (CDC) feature, the following must exist or be created:

- HPE Ezmeral Data Fabric Database source table (JSON or binary)
- HPE Ezmeral Data Fabric Streams changelog stream
- HPE Ezmeral Data Fabric Streams stream topic

last-updated: Jun 06, 2024

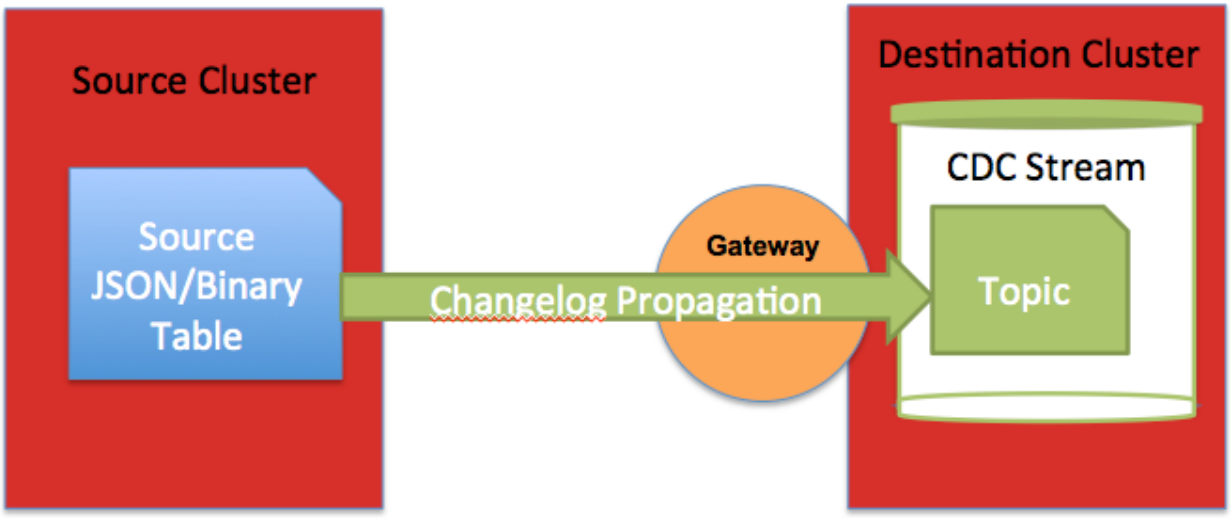
- HPE Ezmeral Data Fabric Database table changelog relationship between the source table and the destination stream topic

Before Setting Up CDC

The destination HPE Ezmeral Data Fabric Streams stream can be in the same cluster as the HPE Ezmeral Data Fabric Database source table or it can be on a remote HPE Ezmeral Data Fabric cluster. Regardless of where the stream is located, propagating changed data requires a gateway.

Typically, gateways are setup by installing the gateway on the destination cluster and specifying the gateway node(s) on the source cluster. However, if the stream and the HPE Ezmeral Data Fabric Database source table are in the same cluster, install the gateway on that cluster and specify the gateway nodes(s) in the cluster. See Administering Data Fabric Gateways on page 1526 and Configuring Gateways for Table and Stream Replication on page 1528.

The following diagram shows a simple CDC data model with one source table to one destination topic on one stream; however, more complex CDC scenarios can be implemented with multiple gateways. See Data Modeling and CDC on page 743.



IMPORTANT: If you have a secure cluster, secure configuration must be setup. See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1952.

Create Table

An HPE Ezmeral Data Fabric Database table (JSON or binary) must be established for the CDC data. You can create a new table and add data or use an existing table with data. See maprcli table create for creating a new table or use the Control System. Example code is provided for completing this task using either the maprcli or REST. Alternatively, depending on whether you are establishing JSON documents or binary files, you can use the following:

- mapr dbshell for HPE Ezmeral Data Fabric Database JSON documents
- hbshell for HPE Ezmeral Data Fabric Database binary data

ATTENTION: Ensure that a volume exists and mounted for both tables and streams. Even though HPE Ezmeral Data Fabric Database tables and HPE Ezmeral Data Fabric Streams stream can exist in the same volume, for organizational purposes, you could create separate volumes for both tables and streams.

The following code examples show how to:

last-updated: Jun 06, 2024

- Create and mount a volume for a source table.
- Create a new binary table. The -tabletype parameter's default setting is binary so you don't need to specify this parameter.
- Create a new JSON table.

CLI

```
// Create Volume for table
maprcli volume create -name
tableVolume -path /tableVolume

// Create Binary table
maprcli table create -path /
tableVolume/cdcTable

// Create JSON table
maprcli table create -path /
tableVolume/cdcTable -tabletype json
```

REST

```
// Create Volume for table
https://10.10.100.17:8443/rest/
volume/create?name=tableVolume&path=/
tableVolume

// Create Binary table
https://10.10.100.17:8443/rest/table/
create?path=/tableVolume/cdcTable

// Create JSON table
https://10.10.100.17:8443/rest/
table/create?path=/tableVolume/
cdcTable&tabletype=json
```

Create Stream

An HPE Ezmeral Data Fabric Streams changelog stream must be created for the propagated changed data records using the `maprcli stream create -ischangelog` parameter. See maprcli stream create or use the Control System.

NOTE: Ensure that a volume exists and mounted for both tables and streams. Even though HPE Ezmeral Data Fabric Database tables and HPE Ezmeral Data Fabric Streams stream can exist in the same volume, for organizational purposes, you could create separate volumes for tables and streams.

IMPORTANT: The changelog stream's default partitions can impact how many partitions a stream topic can have. This is because once you create a stream topic for a changelog stream, the number of topic partitions is *locked*. The number of topic partitions cannot change.

- If the `stream topic create` command is used to create a stream topic, then the number of topic partitions can be set at creation time and then is *locked*.
- If the `table changelog add` command is used to add a stream topic (as well as establish a relationship between the source table and the changelog stream), then the number of topic partitions is inherited from the changelog stream and is *locked*.

The following code examples show how to:

- Create and mount a volume for a changelog stream.
- Create a changelog stream using the default partitions value of one (1).
- Create a changelog stream changing the default partitions to three (3).

CLI

```
// Create Volume for stream
maprcli volume create -name
streamVolume -path /streamVolume

// Create stream (default partitions:
1)
maprcli
stream create -path /streamVolume/
changelogStream -ischangelog true

// Create stream  (default
partitions: 3)
maprcli
stream create -path /streamVolume/
changelogStream -ischangelog
true -defaultpartitions 3
```

REST

```
// Create Volume for stream
https://10.10.100.17:8443/rest/volume/
create?name=streamVolume&path=/
streamVolume

// Create stream (default partitions:
1)
https://10.10.100.17:8443/rest/stream/
create?path=/streamVolume/
changelogStream&ischangelog=true

// Create stream (default partitions:
3)
https://10.10.100.17:8443/rest/stream/
create?path=/streamVolume/
changelogStream&ischangelog=true&defau
ltpartitions=3
```

Create Topic

An HPE Ezmeral Data Fabric Streams stream topic must be created for the changed data records. This can be accomplished in a variety of ways:

- Use the maprcli table changelog add command. This command establishes a changelog relationsip between the source table and the destination stream topic.
- Use the maprcli stream topic create command. I
- Use the REST equivalent of the above maprcli commands.
- Use the Control System.

IMPORTANT: Once a changelog relationship is established between the source table and the destination stream topic, the number of topic partitions is *locked*. (The `maprcli table changelog add` command is used to establish the changelog relationship.) The `stream topic edit` command can not be used to modify the topic's number of partitions.

last-updated: Jun 06, 2024

The following describes when to create a stream topic a specific way.

- If the changelog stream's default partitions are acceptable for the stream topic (because the topic inherits the stream's default partitions), you can either:
  - Go directly to adding the changelog relationship with the `maprcli table changelog add` command and create the topic there.
  - Create the topic with the `stream topic create` command and *not* specify the `-partitions` parameter.
- If you want to change the topic's partitions, create the topic with the `stream topic create` command and set the `-partitions` parameter.
- If you use the Control System, either of the above methods are available.

The following code examples show how to create a stream topic and change the default partition to five (5).

CLI

```
// Create topic (default partitions: 5
maprcli stream topic create -path /
streamVolume/changelogStream -topic
cdcTopic1 -partitions 5
```

REST

```
// Create topic (default partitions: 5
https://10.10.100.17:8443/rest/stream/
topic/create?path=/streamVolume/
changelogStream&topic=cdcTopic1&partit
ions=5
```

Add Changelog

A table changelog relationship must be added between the source table and the destination stream topic by using the maprcli table changelog add command or the Control System. By adding a table changelog relationship, you are creating an environment that propagates changed data records from a source table to an HPE Ezmeral Data Fabric Streams stream topic.

- If you are creating a changelog relationship and the stream topic *does not* exist, specify the stream path and topic.
- If you are creating a changelog relationship and the stream topic *does* exist, specify the stream path and topic AND the `-useexistingtopic` parameter. The `-useexistingtopic` parameter can only be used with a changelog stream's newly created topic or a previous changelog stream topic *for the same source table*.

NOTE: Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is true.

NOTE: Propagation is enabled as soon as the table changelog relationship is added. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See table changelog resume on page 2466 for more information.

The following examples show you how to:

- Create a changelog relationship between the source table and the destination stream topic, where the stream topic *does not* exist.

last-updated: Jun 06, 2024

- Create a changelog relationship between the source table and the destination stream topic, where the stream topic *does* exist.

IMPORTANT: The examples show streams in a local cluster. To specify streams in a destination (remote) cluster, the path format is `/mapr/<remote-cluster>/path/to/stream:topic`.

CLI

```
maprcli table changelog add -path /
tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1

maprcli table changelog add -path /
tableVolume/cdcTable -changelog /
streamVolume/
changelogStream:cdcTopic1 -useexisting
topic true
```

REST

```
https://10.10.100.17:8443/rest/table/
changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/
changelogStream:cdcTopic1

https://10.10.100.17:8443/rest/table/
changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/
changelogStream:cdcTopic1&useexistingt
opic=true
```

The following example verifies that the table changelog relationship exists:

```
maprcli table changelog list -path /tableVolume/cdcTable
```

What's Next: Modifying and Consuming Data

To have CDC changed data records to consume, you need to perform inserts, updates, and deletes on the HPE Ezmeral Data Fabric Database table data. See CRUD operations on documents using mapr dbshell for JSON documents, mapr hbshell for binary data, Java applications for HPE Ezmeral Data Fabric Database JSON, C or Java applications for HPE Ezmeral Data Fabric Database Binary.

An HPE Ezmeral Data Fabric Streams Kafka/OJAI consumer application subscribes to the topic and consumes the change data records. See Consuming CDC Records on page 3515 for more information.

Example: Setting Up CDC with Default Topic Partitions

This example creates the following: a volume for a HPE Ezmeral Data Fabric Database table, a HPE Ezmeral Data Fabric Database JSON table, a HPE Ezmeral Data Fabric Streams changelog stream without changing the default partitions, creates a topic while adding a table changelog relationship from the source table to the destination stream topic and and views the changelog information.

CLI Example

```
// Creating and mounting a volume for the source table
   maprcli volume create -name tableVolume -path /tableVolume

// Creating and mounting a volume for the destination stream
   maprcli volume create -name streamVolume -path /streamVolume

// Creating a new JSON table
   maprcli table create -path /tableVolume/cdcTable -tabletype json
```

last-updated: Jun 06, 2024

```
// Creating a stream for CDC data
   maprcli stream create -path /streamVolume/changelogStream -ischangelog
true

// Creating a changelog relationship between the source table and the stream
   maprcli table changelog add -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1

// Viewing the changelog information
   maprcli table changelog info -changelog  /streamVolume/
changelogStream:cdcTopic1 -json
```

REST Example

```
// Creating and mounting a volume for the source table
   https://10.10.100.17:8443/rest/volume/create?name=tableVolume&path=/
tableVolume

// Creating and mounting a volume for the destination stream
   https://10.10.100.17:8443/rest/volume/create?name=streamVolume&path=/
streamVolume

// Creating a stream for CDC data
   https://10.10.100.17:8443/rest/stream/create?path=/streamVolume/
changelogStream&ischangelog=true

// Creating a changelog relationship between the source table and the stream
   https://10.10.100.17:8443/rest/table/changelog/add?path=/tableVolume/
cdcTable&changelog=/streamVolume/changelogStream:cdcTopic1

// Viewing the changelog information
   https://10.10.100.17:8443/rest/table/changelog/info?changelog=/
streamVolume/changelogStream:cdcTopic1
```

Example: Setting Up CDC with Non-default Topic Partitions
This example creates the following: a volume for a HPE Ezmeral Data Fabric Database table, a HPE Ezmeral Data Fabric Database JSON table, a HPE Ezmeral Data Fabric Streams changelog stream with default partitions, a stream topic with custom partitions, a table changelog relationship from the source table to the destination stream topic, and views the changelog information.

CLI Example

```
// Creating and mounting a volume for the source table
   maprcli volume create -name tableVolume -path /tableVolume

// Creating and mounting a volume for the destination stream
   maprcli volume create -name streamVolume -path /streamVolume

// Creating a new JSON table
   maprcli table create -path /tableVolume/cdcTable -tabletype json

// Creating a stream for CDC data
   maprcli stream create -path /streamVolume/changelogStream -ischangelog
true -defaultpartitions 3

// Creating a stream topic that overrides the stream's default partitions
   maprcli stream topic create -path /streamVolume/changelogStream -topic
cdcTopic1 -partitions 5

// Creating a changelog relationship between the source table and the
```

```
stream plus using an existing topic that has custom partitions
   maprcli table changelog add -path /tableVolume/cdcTable -changelog /
streamVolume/changelogStream:cdcTopic1  -useexistingtopic true

// Viewing the changelog information
   maprcli table changelog info -changelog  /streamVolume/
changelogStream:cdcTopic1 -json
```

REST Example

```
// Creating and mounting a volume for the source table
   https://10.10.100.17:8443/rest/volume/create?name=tableVolume&path=/
tableVolume

// Creating and mounting a volume for the destination stream
   https://10.10.100.17:8443/rest/volume/create?name=streamVolume&path=/
streamVolume

// Creating a stream for CDC data
   https://10.10.100.17:8443/rest/stream/create?path=/streamVolume/
changelogStream&ischangelog=true&defaultpartitions=3

// Creating a stream topic that overrids the stream's default partitions
    https://10.10.100.17:8443/rest/stream/topic/create?path=/streamVolume/
changelogStream&topic=cdcTopic1amp;partitions=5

// Creating a changelog relationship between the source table and the
stream plus using an existing topic that has custom partitions
   https://10.10.100.17:8443/
rest/table/changelog/add?path=/tableVolume/cdcTable&changelog=/streamVolume/
changelogStream:cdcTopic1&useexistingtopic=true

// Viewing the changelog information
   https://10.10.100.17:8443/rest/table/changelog/info?changelog=/
streamVolume/changelogStream:cdcTopic1
```

Managing Table Changelogs
Describes how to manage CDC table changelogs through the Control System and maprcli.

Adding a Change Data Log
Explains how to add a change data log using the Control System and the CLI.

About this task

To add a change data log, you must have the following permissions:

- **Replication Access** (UI) or `replperm` (CLI) on the source table on the source cluster
- **Topic** (UI) or `topicperm` (CLI) on the destination stream in the destination cluster

If you are a normal user and want to create a changelog between your own HPE Ezmeral Data Fabric Database table and someone else's stream topic, you must have **Topic** (UI) permission or `topicperm` (CLI) on the destination stream.

Adding a Change Data Log Using the Control System

Procedure

1. Log in to t he Control System and go to the **Change Data Capture** tab in the table information page.

2. Click **Add Change Log** to display the **Add Change Log** page.
3. Set values for the following.

Destination Cluster	(Required) The path to the cluster on which the changelog stream exists. If the destination stream is on a remote secure cluster, then a gateway and secure configuration must first be setup. For more information, see Table Replication on page 749, Administering Data Fabric Gateways on page 1526, and Configuring Secure Clusters for Cross-Cluster Mirroring and Replication on page 1952.
Destination Stream Topic Name	(Required) The target of the changelog stream, specified as `<stream_path>:<topic_name>`, to which all change data records will be published. The stream must exist as a changelog stream or the operation fails.
Publish to Existing Topic	Whether (**Yes**) or not (**No**) to publish to existing topic. If value is **No** and the topic does not already exist, it will be created.
Publish Existing Data	Whether (**Yes**) or not (**No**) to initiate publishing of the existing data to the stream. If value is **No**, only new changes will be propagated.
Defer Publishing	Whether (**Yes**) or not (**No**) to pause propagation after creating the change log.
Throttle	Whether (**Yes**) or not (**No**) the data transfer to the stream for this change log must be throttled.
Synchronously	Whether (**Yes**) or not (**No**) to acknowledge the client writes to the table before the CDC gateway receives the data.
Encrypt on Wire	Whether (**Yes**) or not (**No**) the data transfer between file system and gateway for this change log is encrypted.
Compress on Wire	The compression scheme of the data transfer between file system and gateway for this change log instance.

4. Choose one of the following:
   - For JSON table:
     - **Publish Entire Document** — to publish the entire document to the stream topic.
     - **Publish Selected Field Path** — to specify the paths to the fields to publish to the stream topic.
   - For Binary table:
     - **Publish Entire Document** — to publish the entire document to the stream topic.
     - **Publish Selected Column Families** — to specify the column families to publish to the stream topic.
5. Click **Add Change Log**.

last-updated: Jun 06, 2024

Adding a Change Data Log Using the CLI and REST API

About this task

The basic command to add a change data log to a table is:

```
maprcli table changelog add
```

For complete reference, see table changelog add on page 2459.

Viewing the List of Change Logs
Explains how to view the list of change logs using the Control System or the CLI.
Viewing the List of Change Logs Using the Control System

Procedure

- Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
  For each change log, the page displays the following:

Column Name	Column Description
Edit Change Log	Shortcut to the **Edit Change Log** window for editing a change log.
Paused	Specifies whether the change propagation is paused for the associated change log.
Destination Cluster	Specifies the destination cluster on which the stream exists.
Destination Stream Topic Name	Specifies the name of the stream associated with the change log.
Up to Date	Specifies whether (**Yes**) or not (**No**) the change log is up to date. If value is **No**, hover the cursor over the value to see the number of pending bytes, puts, and buckets.
Errors	Indicates whether there were any errors during change propagation.
Compression Type	The type of compression for data transfer between file system and gateway for the associated change data log instance
Synchronous	Specifies whether client writes to the table should be acknowledged before the CDC gateway receives the data.
Throttle	Specifies whether data transfer to the stream for the associated change data log is throttled.
Encrypted	Specifies whether the data transfer between file system and gateway for the associated change data log is encrypted.
Field Path	Specifies whether only specific field paths are being published to the stream topic.

Retrieving the List of Change Logs Using the CLI or REST API

About this task

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog list
```

last-updated: Jun 06, 2024

For complete reference, see table changelog list on page 2462.

Viewing Change Log Information
Explains how to view information about a specific change log using the CLI.
Retrieving Change Log Information Using the CLI or REST API

About this task

The basic command to retrieve the list of change data logs is:

```
maprcli table changelog info
```

For complete reference, see table changelog info on page 2461.

Editing a Change Log
Explains how to modify a change log associated with a table using either the Control System or the CLI.
Editing a Change Log Using the Control System

Procedure

1. Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
2. Click  associated with the change log to modify.
   The **Edit Change Log** window displays.
3. Make the necessary changes to any of the following:

Throttle	Whether (**Yes**) or not (**No**) the data transfer must be throttled.
Synchronously	Whether (**Yes**) or not (**No**) to acknowledge the client writes to the table before the CDC gateway receives the data.
Encrypt on Wire	Whether (**Yes**) or not (**No**) the data transfer is encrypted.
Compress on Wire	The compression scheme of the data propagation.

4. Click **Save Changes** for the changes to take effect.

Editing a Change Log Using the CLI or REST API

About this task

The basic command to modify the change log is:

```
maprcli table changelog edit
```

For complete reference, see table changelog edit.

Pausing Data Propagation
Explains how to pause data propagation using either the Control System or the CLI.
Pausing Data Propagation Using the Control System

Procedure

1. Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
2. Select the change log(s) to pause.
   Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.

3. Select **Pause Data Propagation** from the **Actions** drop-down menu to display the **Pause Data Capture** confirmation dialog.
4. Review the change log(s) to pause and click **Pause Data Capture**.

Pausing Data Propagation Using the CLI or REST API

About this task

The basic command to pause change data propagation is:

```
maprcli table changelog pause
```

For complete reference, see table changelog pause.

Resuming Data Propagation
Explains how to resume a paused change log using either the Control System or the CLI.
Resuming Data Propagation Using the Control System

Procedure

1. Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
2. Select the change log(s) to pause.
   Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.
3. Select **Resume Data Propagation** from the **Actions** drop-down menu to display the **Resume Data Capture** confirmation dialog.
4. Review the change log(s) to resume and click **Resume Data Capture**.

Resuming Data Propagation Using the CLI or REST API

About this task

The basic command to resume change data propagation is:

```
maprcli table changelog resume
```

For complete reference, see table changelog resume.

Removing Change Logs
Describes how to remove change logs using either the Control System or the CLI.
Removing Change Logs Using the Control System

Procedure

1. Log in to the Control System and go to the **Change Data Capture** tab in the table information page.
2. Select the change log(s) to remove.
   Selecting the checkbox next to a change log makes the **Actions** drop-down menu available.
3. Select **Remove Change Logs** from the **Actions** drop-down menu to display the **Remove Change Log(s)** confirmation dialog.
4. Review the change log(s) to remove and click **Remove Change Logs**.

Removing Change Logs Using the CLI or REST API

About this task

The basic command to remove a change log is:

```
maprcli table changelog remove
```

For complete reference, see table changelog remove.

Troubleshooting Changelogs

checkandcreate topic failed with error 17

I'm getting a **checkandcreate topic** error while trying to edit a changelog topic.

Because the `maprcli table changelog add` command is an asynchronous command, the CDC relationship (same as replication relationship) involves storing information at both the source and destination sides. This results in the following behavior:

- When the `maprcli table changelog add` operation succeeds, it means that the add request is received. To check whether there is an error during the add operation, run the `maprcli table changelog list` operation.
- The `maprcli table changelog edit` operation only modifies the information on the source side, even if an error is display in the `maprcli table changelog list` output, the changelog can still be modified.

Troubleshooting methods:

- If the stream topic already exists in the destination and you are getting an error, delete the topic. The `maprcli table changelog add` operation automatically retries and finishes.
- If the error can not be fixed, delete the partial relationship from the source side with the `maprcli table changelog remove` operation and retry.

Enabling/Disabling Propagation

Propagation of existing table data is enabled by default. If you do *not* want to propagate existing source table data, set the `-propagateexistingdata` parameter to **false**. The default is true.

Propagation is enabled as soon as the table changelog relationship is added. If you do *not* want propagation to begin, set the `-pause` parameter to **true**. The change data records are stored in a bucket until you resume the changelog relationship; at this point, the stored change data records are propagated to the stream topic. See table changelog resume on page 2466 for more information.

Indexing HPE Ezmeral Data Fabric Database Binary Tables with Elasticsearch

As of with MapR 6.0, HPE Ezmeral Data Fabric Database Elastic Search integration capability is deprecated and no longer available in the HPE Ezmeral Data Fabric Database product.

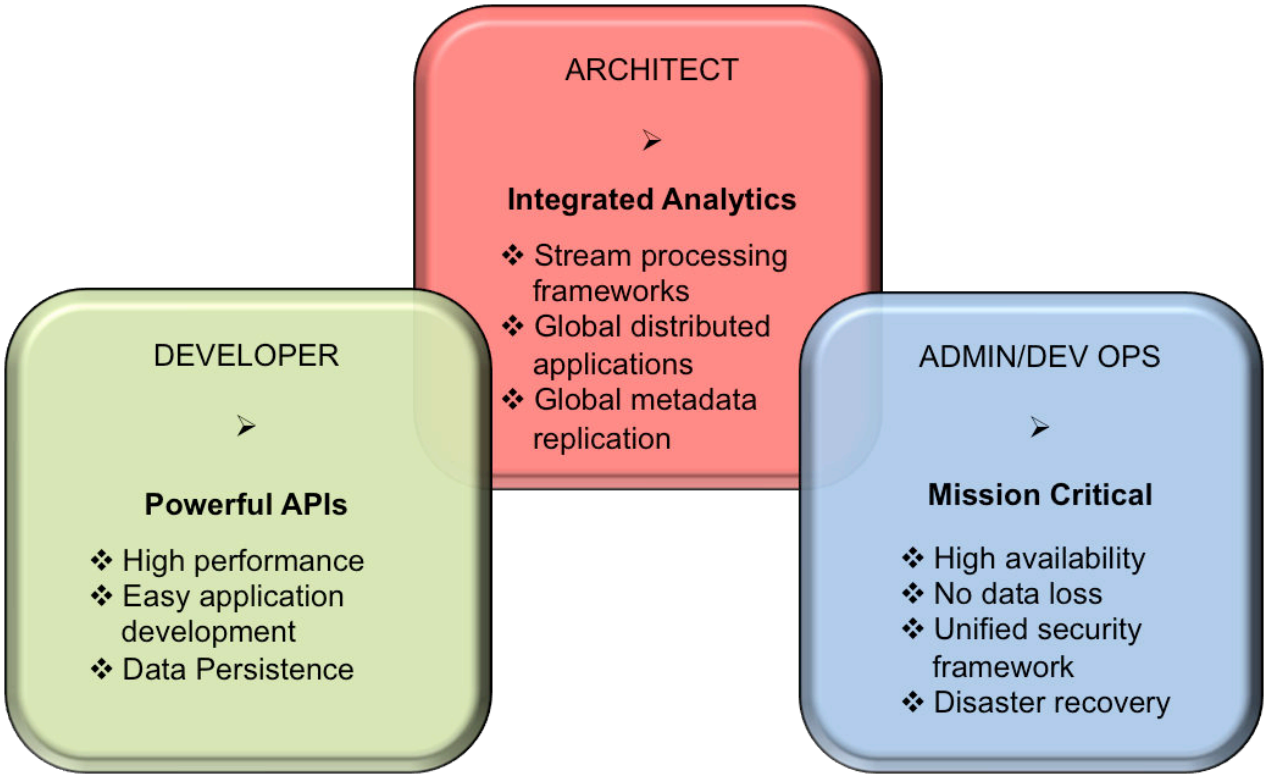
ATTENTION: HPE Ezmeral Data Fabric Database Change Data Capture (CDC) framework can be used to integrate with latest versions of Elasticsearch. See Change Data Capture on page 736 for more information.

Administering Streams

HPE Ezmeral Data Fabric Streams brings integrated publish and subscribe messaging to the HPE Ezmeral Data Fabric. Producer applications can publish messages to topics, which are logical collections of

last-updated: Jun 06, 2024

messages, and Consumer applications can read those messages at their own pace. Topics are grouped into streams, for which administrators can apply security, retention, and replication policies.



1. The HPE Ezmeral Data Fabric Streams and Apps section information and examples for developing Producer and Consumer applications.
2. The HPE Ezmeral Data Fabric Streams section provides conceptual information.
3. The Administering Streams section provides information about creating and managing streams, topics, and stream replication.

Managing Streams

This topic provides information about managing streams in HPE Ezmeral Data Fabric Streams.

Creating a Stream

Explains how to create a stream using the Control System and the CLI.

About this task

Your decision about what streams to create should take into account whatever topics you want to replicate. Replication is between streams, not individual topics.

For example, suppose that you plan to create the stream `pollution_monitors` to collect various measurements about pollution levels in cities in Europe. However, during a planning session, the representative from Amsterdam says that her country wants to perform analyses of the data for its cities, and would like your company to replicate the data to its own HPE Ezmeral Data Fabric cluster, where its own consumers can read the replicated messages.

You would create a separate stream of topics that contain data from only the pollution sensors in the cities in that country. You might even decide to do the same for each center, in case other centers

last-updated: Jun 06, 2024

eventually want to perform their own analyses, too. The streams you might decide to create could be `pollution_monitors_netherlands`, `pollution_monitors_sweden`, and so on.

Creating a Stream Using the Control System

About this task

To create a stream:

Procedure

1. Log in to the Control System and click **Create Stream** under **Data** > **Streams**.

   NOTE: This option is not available in the Kubernetes version of the Control System.

   The **Create New Stream** page displays.

2. Specify the following properties.

Property	Description
Stream Path	The path and name of the stream to create. The path to the stream can include any character allowed by HPE Ezmeral Data Fabric. For example, `/my/path/with:/to/mystream:topic1` is valid, but `/my/path/with:/to/mystream:withcolon:topic1` is invalid. The name of the stream cannot include a colon (`:`) or a forward slash (`/`).
Time To Live	The amount of time to elapse between the publication of a message in a topic in this stream and the expiration of that message. Choose: • Forever to retain messages indefinitely • Seconds to specify the number of seconds. A value of 0 causes messages to be retained indefinitely. Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages on page 776 for details.
Compression	The compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompresses it, and passes it to client applications. Choose one of the following: • Inherited (to inherit from the directory where the stream is stored), which is the default setting • OFF (to disable compression) • LZF • LZF4 • ZLIB

last-updated: Jun 06, 2024

Property	Description
Auto Create Topics	Whether (**Yes**) or not (**No**) to create a topic automatically when a producer tries to write the first message to it.
Default Partitions	The default number of partitions to allocate to new topics in the stream. When deciding how many partitions to create by default for new topics in a stream, consider the expected volume of messages that will be published to the topics in the stream. High message volumes can be handled more efficiently by multiple consumers in consumer groups reading from multiple partitions than by individual consumers reading from a single partition. **NOTE:** You can override the default and specify a different number of partitions for each topic in the stream at the time of creating the topic or after creating the topic.
Use for Change Log	Whether (**Yes**) or not (**No**) to create the stream for changed data records (as a result of inserts, updates, and deletes) in a HPE Ezmeral Data Fabric Database table.

3. Set up access to streams for users, groups, and roles.

   For each user, group, and/or role, you can grant (by selecting the associated check box) or block (by deselecting the associated checkbox) the following types of access:

Administer	Can modify the access-control expressions for the stream, set up replication from the stream, and modify attributes of the stream. This permission includes the topic permission.
Copy Stream	Can copy data from one HPE Ezmeral Data Fabric stream to another HPE Ezmeral Data Fabric stream (using the `mapr copystream` utility) and compare the message IDs, metadata, and data in two HPE Ezmeral Data Fabric streams (using the `mapr diffstreams` utility).
Topic	Can create, edit, or remove topics in the stream.
Producer	Can publish messages to topics in the stream.
Consumer	Can listen to topics in the stream.

   By default, all permissions are given to the user creating the stream. To grant or block access to other users, groups, and/or roles, choose one of the following:

   - Basic Settings: Select the type — public, (OR) user, group, or role — from the drop-down list and grant read and/or write permissions.

     TIP: Click to create a copy of the associated access control setting. Click to remove the associated access control expression.

     Click **Add Another** to add permissions for another user, group, or role.

   - Advanced Settings: Within empty strings (""), specify user (u), group (g), role (r), or public (p) who have and do not have read and/or write access using the following boolean expressions and subexpressions:

     - ! — Negation operator.

last-updated: Jun 06, 2024

- `&` — AND operation.
- `|` — OR operation.

Use `( )`, parentheses, for subexpressions.

Alternatively, click  associated with the type of access to use the **Create Access Control Expression** window to define access for public or users, group, and/or role.

NOTE: If you switch from Basic to Advanced, the basic settings, if any, will be carried over to the Advanced settings. If you switch from Advanced to Basic, all the settings will be lost because the subexpressions and AND (&) and negation (!) operations that are supported by Advanced settings are not supported in the Basic settings.

To add access control expressions for another user, group, or role, click **Add Another** and repeat this step.

4. Click **Create Stream** to create the stream.

Creating a Stream Using the CLI or REST API

About this task

The basic command to create a stream is:

```
maprcli stream create -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

For complete reference information, see `stream create` on page 2368.

Editing a Stream

Describes how to edit streams using the Control System and the CLI.

Editing a Stream Using the Control System

Procedure

1. Log in to the Control System and go to the stream information page.
2. Click **Edit Stream**.
   The **Edit Stream** page displays.
3. Make necessary changes to one or more of the following:

Property	Description
Time To Live	The amount of time to elapse between the publication of a message in a topic in this stream and the expiration of that message. Choose: • Forever to retain messages indefinitely • Seconds to specify the number of seconds. A value of 0 causes messages to be retained indefinitely. Messages that have expired are deleted during the next purge process. See Time-to-Live for Messages on page 776 for details.
Compression	The compression setting to use for the stream. Producer client libraries can bundle messages that are to be published on the same partition and compress them. The messages are sent to the server compressed, are stored compressed, are replicated to other containers compressed, and (if stream replication is configured) replicated to replica streams compressed. Consumer client libraries receive compressed data, decompress it, and pass it to client applications. Choose from one of the following compression settings: • Inherited (to inherit from the directory where the stream is stored), which is the default setting • OFF (to disable compression) • LZF • LZF4 • ZLIB
Auto Create Topics	Whether (**Yes**) or not (**No**) to create a topic automatically when a producer tries to write the first message to it.
Default Partitions	The default number of partitions to allocate to new topics in the stream.
Compact	Enable (**Yes**) or disable (**No**) log compaction. If enabled, obsolete records from topics are detected and deleted. By default, this is disabled (**No**).

4. Add, modify, or remove access to streams for users, groups, and roles.

   For each user, group, and/or role, you can grant (by selecting the associated check box) or deny (by deselecting the associated checkbox) the following types of access:

Administer	Can modify the *ACE* for the stream, set up replication from the stream, and modify attributes of the stream. This permission includes the topic permission.
Copy Stream	Can copy data from one HPE Ezmeral Data Fabric stream to another HPE Ezmeral Data Fabric stream (using the `mapr copystream` utility) and compare the message IDs, metadata, and data in two HPE Ezmeral Data Fabric streams (using the `mapr diffstreams` utility).
Topic	Can create, edit, or remove topics in the stream.
Producer	Can publish messages to topics in the stream.

last-updated: Jun 06, 2024

Consumer	Can listen to topics in the stream.

To grant or deny access to users, groups, and/or roles, choose one of the following:

- Basic Settings: Select the type — public, (OR) user, group, or role — from the drop-down list and grant read and/or write permissions.

  TIP: Click to create a copy of the associated *ACE* setting. Click to remove the associated *ACE*.

  Click **Add Another** to add permissions for another user, group, or role.

- Advanced Settings: Within empty strings (""), specify user (u), group (g), role (r), or public (p) who have and do not have read and/or write access using the following boolean expressions and subexpressions:
  - ! — Negation operator.
  - & — AND operation.
  - | — OR operation.

  Use ( ), parentheses, for subexpressions.

  Alternatively, click associated with the type of access to use the **Access Control Expression** window to define access for public or users, group, and/or role. See Defining ACEs Using the Access Control Expression Builder on page 1881 for more information.

NOTE: If you switch from Basic to Advanced, the basic settings, if any, are carried over to the Advanced settings. If you switch from Advanced to Basic, all the settings are lost because the subexpressions, and AND (&) and negation (!) operations that are supported by Advanced settings are not supported in the Basic settings.

To add *ACE*s for another user, group, or role, click **Add Another** and repeat this step.

5. Click **Save Changes** for the changes to take effect.

Editing a Stream Using the CLI or REST API

About this task

The basic command to edit a stream is

```
/opt/mapr/bin/maprcli stream edit -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `adminperm` permission on the stream

For complete reference information, see `stream edit` on page 2375.

Encrypting a Stream

Apply an additional layer of security to streams by encrypting them.

To set encryption on a stream:

1. Before encrypting a stream, ensure that wire-level security is enabled for the cluster. See Enabling Wire-level Security on page 1797.
2. Determine whether a directory or stream is encrypted by running the following command:

```
hadoop mfs -ls <path>
```

   NOTE: Streams inherit the value of the `-setnetworkencryption` setting from the directory in which they are created.

3. If the directory is not encrypted, set the encryption on the streams with the following command:

```
hadoop mfs -setnetworkencryption on <path of stream>
```

Example

Suppose that the streams that you want to encrypt are all in the `/test` directory. You run this command to discover whether the directory is encrypted:

```
# hadoop mfs -lsd /test
Found 1 items
drwxr-xr-x Z U U   - root root          0 2015-09-07 02:37  268435456 /test
           p 2049.43.131260  localhost:5660
```

The second flag U after the permissions indicates that the directory `test` is unencrypted. Because you want to encrypt your stream to enhance data security, you run this command, which encrypts the entire directory:

```
hadoop mfs -setnetworkencryption on /test
```

If you run the `-lsd` command again, you will see that the U is replaced by an E, indicating that the directory is now encrypted:

```
# hadoop mfs -lsd /test
Found 1 items
drwxr-xr-x Z E U   - root root          0 2015-09-07 02:40  268435456 /test
           p 2049.43.131260  localhost:5660
```

Defining ACEs Using the Access Control Expression Builder

Describes how to build ACEs using the Expression Builder.

About this task

To define access control expressions using the **Access Control Expression** builder in the MapR Control System:

Procedure

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.

   Here:

All	AND (&) operation	Indicates that all of the conditions must be met for public or user, group, and role to access the volume.

Any	OR (|) operation	Indicates that any one of the conditions must be met for public or user, group, and role to access the volume.

2. Click:

+	To add an expression.
( )	To add a subexpression.
x	To remove an expression or subexpression.

3. Select **Public or User**, **Group**, or **Role** from the drop-down menu and:
   a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
   b) Enter the name of the user, group, or role.
4. Click **Save Changes** to create an ACE.

Setting Whole Volume ACEs Using the CLI

About this task
See Setting Whole Volume ACEs on page 1365.
Setting Table ACEs Using the CLI

About this task
See Enabling Table and Stream Authorizations with ACEs on page 1363.
Setting Stream ACEs Using the CLI

About this task
See Enabling Table and Stream Authorizations with ACEs on page 1363.

Removing Streams
Explains how to delete a stream using either the Control System or the CLI.

About this task

Deleted streams cannot be recovered unless they were replicated before deletion. After a stream is deleted, producers will not be able to publish messages to topics in the stream, and consumers will not be able to read messages from topics in the stream.

Removing a Stream Using the Control System

About this task

Procedure

1. Log in to the Control System and go to the stream information page.
2. Click **Remove Stream** to display the **Remove Stream** confirmation dialog.
3. Confirm the action by clicking **Remove Stream**.

Removing a Stream Using the CLI or REST API

About this task

The command to delete a stream is:

```
stream delete -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path

For complete reference, see stream delete on page 2374.

Viewing a List of Streams

Describes how to view the list of streams using the Control System.

Listing Streams by Type

Procedure

1. Log in to the Control System and click **Data** > **Streams**.

   NOTE: This option is not available in the Kubernetes version of the Control System.

2. Choose one of the following HPE Ezmeral Data Fabric Streams stream type:
   - **Multiple Topics** — to display the list of streams with multiple topics
   - **Single Topic** — to display the list of streams with a single topic

Listing Streams in a Volume

Procedure

1. Log in to the Control System and click **Data** > **Streams** to view all the volumes that you have access to.

   NOTE: This option is not available in the Kubernetes version of the Control System.

   For each volume, the pane displays the following:

Column Name	Column Description
Name	The name of the volume.
Type	The type. Value can be: • — Volume • — Directory • — Stream
Owner	The name of the owner.
Last Modified	The last modification date and timestamp.

last-updated: Jun 06, 2024

2. Click the name of the volume (to browse to the path to the stream) or enter the name of the volume in the text field.

   The streams in the selected volume display. If necessary, click  to return to **All** volumes view.

Listing Streams by Stream Path

About this task

Procedure

1. Log in to the Control System and click **Data** > **Streams**.

    **NOTE:** This option is not available in the Kubernetes version of the Control System.

2. Enter the path to the stream in the search field and click **GO**.

Viewing Stream Information

Explains how to view stream information including stream properties, topics, and replication settings using the Control System and the CLI.

Viewing Stream Information Using the Control System

About this task

To view stream information:

Procedure

1. Log in to the Control System and click **Data** > **Streams**.

    **NOTE:** This option is not available in the Kubernetes version of the Control System.

2. Locate the stream (by searching or browsing the volumes or by entering the full path to the stream) and click on the stream name.

   The stream information page displays the following tabs:

   - Summary
   - Topics
   - Replication

   You can:

   - Modify the stream
   - Remove the stream

   The **Summary** tab displays:

   - The active and recent alarms in the **Alarms** pane.
   - The stream settings and permissions in the **Detail** pane.

last-updated: Jun 06, 2024

Retrieving Stream Information Using the CLI or REST API

About this task

The basic command to retrieve stream information is:

```
maprcli stream info -path <Stream Path>
```

To run this command, your user ID must have the following permissions:

- `readAce` on the volume
- `lookupdir` on directories in the path
`adminperm`	When a user with this permission runs the command, the output includes the access-control expressions for the `adminperm` and `topicperm` permissions.
`produceperm`, `consumeperm`, or `topicperm`	When a user with one of these permissions runs the command, the output does not include any access-control expressions.

For complete reference information, see `stream info` on page 2378.

Managing Topics

Topics are logical collections of messages. The following sections describe how to create and manage topics.

Adding a Topic to a Stream

Explains how to add a topic to a stream using either the Control System or the CLI.

Adding a Topic to a Stream Using the Control System

Procedure

1. Log in to the Control System and go to the **Topics** tab in the stream information page.
2. Click **Add Topic** in the **All** topics pane.
3. Specify the name of the topic in the **Topic Name** field.

   A name can include alphanumeric characters and the following characters: `.` (dot), _ (underscore), and `-` (hyphen).
4. Specify the number of partitions to use for the topic.

   After you create the topic, you can increase the number of partitions, but you cannot reduce the number. If the topic is associated with a stream for change log, you cannot modify the partitions after you create the topic.
5. Click **Add Topic** to create the topic.

Adding a Topic to a Stream Using the CLI or the REST API

About this task

The basic command to create a topic is:

```
maprcli stream topic create -path <Stream Path> -topic <Topic Name>
```

For complete reference information, see `stream topic create` on page 2391.

Removing Topics in a Stream

Describes how to delete one or more topics from the stream using either the Control System or the CLI.

About this task

Consumers do not have to stop consuming from a topic before the topic is deleted.

Removing Topics in a Stream Using the Control System

Procedure

1. Log in to the Control System and the go to the **Topics** tab in the stream information page.
2. Select the topics to remove in the **All** topics pane and click **Remove Topic(s)**.
   The **Remove Topic(s)** confirmation window displays.
3. Verify the list of topics and click **Remove Topic**.
   The topic and the messages are immediately deleted.

Removing Topics in a Stream Using the CLI or REST API

About this task

The command to delete a topic is:

```
maprcli stream topic delete -path <Stream Path> -topic <Topic Name>
```

For complete reference information, see `stream topic delete` on page 2393.

Viewing the List of Topics in a Stream

Explains how to view the list of topics in a stream using the Control System and the CLI.

Viewing the List of Topics in a Stream Using the Control System

Procedure

- Log in to the Control System and go to the **Topics** tab in the stream information page.
  The All topics pane displays the list of topics in the stream and for each topic, the pane displays the following:

Column Name	Column Description
Topic Name	The name of the topic.
Maximum Lag	The consumer lag time (in milliseconds).
Partitions	The number of partitions in the topic.
Consumers	The number of consumers for the topic.
Physical Size	The physical size (in MB) of the topic.

You can view a topic from the list of topics by entering the topic name in the search field. You can also:

- Add a topic to the stream.
- Remove one or more topics.
- Modify the number of partitions for a topic.

last-updated: Jun 06, 2024

Viewing the List of Topics in a Stream Using the CLI or REST API

About this task

The command to view the list of topics in a stream is:

```
stream topic list -path <Stream Path>
```

For complete reference information, see stream topic list on page 2397.

Modifying Topic Partitions

Explains how to modify the number of partitions using the Control System and the CLI.

About this task

NOTE: In general, you can increase the number of partitions, but you cannot reduce the number. However, if the topic is associated with a stream for change logs, you *cannot* modify the number of partitions.

Modifying Topic Partitions Using the Control System

Procedure

1. Log in to the Control System and go to the **Topics** tab in the stream information page.
2. Click in the **Partitions** column for the topic.
   The **Edit Partition** window displays.
3. Modify the number of partitions and click **Save Changes** for the changes to take effect.

Modifying Topic Partitions Using the CLI or REST API

About this task

The command to modify topic partitions is:

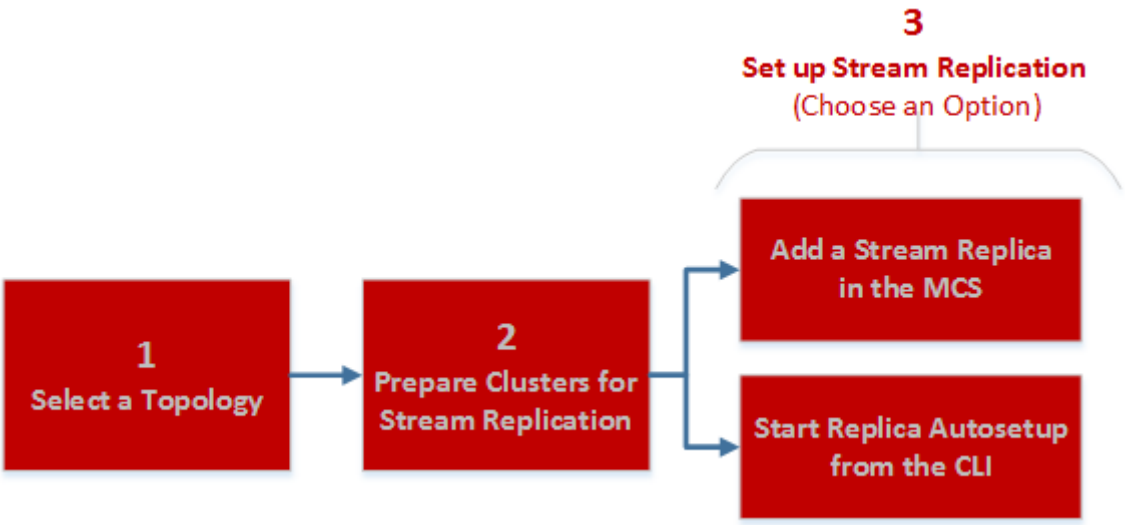
```
stream topic edit -path <stream path> -topic <topic name> -partitions
<number of partitions>
```

For complete reference information, see stream topic edit on page 2394.

Managing Stream Replication

This section contains topics about setting up stream replication and administering existing replicas.

The process to set up stream replication consists of 3



steps:

1. Stream Replication on page 795
2. Preparing Clusters for Stream Replication on page 1502
3. Adding Stream Replicas on page 1503
4. Setting Up Stream Replication Using the CLI on page 1505

After you set up replication, you can administer replicas using the Control System or the CLI. To view the replication status, run stream replica list on page 2385.

Preparing Clusters for Stream Replication
Configuring clusters for participation in the replication of HPE Ezmeral Data Fabric Streams streams involves configuring two or more gateways on destination clusters and, if the clusters are secure, setting up secure communications between the clusters.

Prerequisites

- Plan which replication topology you want to use: basic primary-secondary, multi-master, or a combination of these. For more information about replication topologies, see Stream Replication on page 795.
- Ensure that you have administrative authority on the clusters that you plan to use.
- Replicating streams requires the installation of gateways. For more information about installation requirements, see Service Layout Guidelines for Replication on page 88

Procedure

To configure clusters for replication between streams:

1. In the mapr-clusters.conf file on every node in your source cluster, add an entry that lists the CLDB nodes that are in the destination cluster.

   NOTE:

   This step is required so that the source cluster can communicate directly with the destination cluster's CLDB nodes. See mapr-clusters.conf on page 2983 for the format to use for the entries.

last-updated: Jun 06, 2024

2. Configure gateways on the destination clusters.
   See Configuring Gateways for Table and Stream Replication.
3. **For secure clusters:** Optionally, configure source clusters so that you can locally run maprcli commands that are executed on the destination cluster.
   See Configuring Secure Clusters for Running Commands Remotely.
4. **For secure clusters:** Add one cross-cluster ticket to each source cluster for each cluster that it replicates to.
   See Configuring Secure Clusters for Cross-Cluster Mirroring and Replication.
5. Ensure that the user ID of the person who starts the replication process has the `readAce` permission on the volume where the source streams are located and the `writeAce` permission on the volumes where the replica streams are located. For information about how to set permissions on volumes, see Setting Whole Volume ACEs on page 1365.

Adding Stream Replicas
You can create stream replicas using the Control System and the CLI. When you add a replica using the Control System, you can also set up and start replication between a source and replica stream.

About this task

Before creating a replica:

1. Review the following:
   - Modes of Stream Replication on page 798
   - Security for Stream Replication on page 801
   - Preparing Clusters for Stream Replication on page 1502

NOTE:

- You must replicate all of the topics that are in a stream. You cannot select only a subset of topics to replicate.
- The maximum number of replicas that a stream can replicate to is 64.
- The maximum number of upstream sources that a replica can accept data from is 64.
- In
  - Multi-master replication, names of topics must be unique on all streams. Messages are assigned sequential offsets. The offsets for messages in a topic in one copy could conflict with the offsets for messages in the other copy. As a result, messages could be lost.
  - Many-to-one replication, topics with the same name should not be replicated to an aggregate replica.

Adding a Replica Using the Control System

About this task
To add a replica using the Control System:

last-updated: Jun 06, 2024

Procedure

1. Log in to the Control System and go to the **Replication** tab in the Viewing Stream Information on page 1498.
2. Click **Add Replica**.
   The **Add Replica** page displays.
3. Specify the following settings.

Path to Source Stream	The path and name of the stream that you want to create a replica for.
Destination Cluster	The destination cluster for the replica, where gateways are configured to allow source cluster to send updates.
Path to Replica	The path and name of the replica stream.
Replication State	Specify whether or not to start replication by choosing one of the following: • **Automatic Setup** — Creates the stream on the destination cluster, registers the stream on the destination cluster as a replica, adds the current stream as an upstream source, copies the content of the current stream into the replica, and starts replication. In this case, the replica stream starts empty and accumulates messages over time. • **Pause Replication** — Creates the stream on the destination cluster, registers the stream on the destination cluster as a replica, adds the current stream as an upstream source, but prevents replication from immediately starting after. Pausing replica like this allows you to load the data into the replica from the current stream, after which you can restart replication.  **NOTE:** If you are interested only in the messages that are published to the source stream after replication starts, then you do not need to pause replication initially. However, if you want the full set of messages from the source stream that have not yet been purged or marked for deletion, then pause replication initially.
Multi-Master Setup	(Available only with **Automatic Setup**) Multi-master topology, in which there are two primary-secondary relationships, with each stream playing both the primary and secondary roles. Client applications update both streams and each stream replicates updates to the other. If this is not selected, stream replication will be basic primary-secondary topology. In this topology, you replicate in one direction. See Stream Replication on page 795 for more information.

4. Select values for the following optional settings.

Throttle	Specifies whether (**Yes**) or not (**No**) to throttle replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. By default, throttling is disabled.

last-updated: Jun 06, 2024

	Throttling has two effects, both of which allow HPE Ezmeral Data Fabric Streams to use more system resources to process new messages: • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk.
Replicate Synchronously	Specifies whether replication is synchronous (**Yes**) or asynchronous (**No**). The default value is asynchronous replication.
Encrypt On Wire	Specifies whether (**Yes**) or not (**No**) to enable on-wire encryption. By default, this is disabled (**No**). If you enable on-wire encryption, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	Specifies the type of compression to use when replicating messages.

5. Click **Add Replica** to create the replica.

Adding a Replica Using the CLI or REST API

About this task

The basic command to create a replica is:

```
maprcli stream replica add -path <stream path> -replica <remote stream path>
```

To run this command, your user ID must have the following permissions on the:

- Source cluster:
  - `readAce` and `writeAce` on the volume
  - `lookupdir` on directories in the path
  - `adminperm` and `copyperm` permissions on the source stream
- Target cluster:
  - `readAce` and `writeAce` on the volume
  - `lookupdir` on directories in the path

For complete reference, see `stream replica add` on page 2379.

NOTE: You also have the option to set up replication with `maprcli table replica autosetup` which will set up and start replication. For more information, see Setting Up Stream Replication Using the CLI on page 1505.

Setting Up Stream Replication Using the CLI

Describes how to run the `maprcli stream replica autosetup` command to set up primary-secondary or multi-master replication from an existing source stream.

About this task

NOTE: This procedure describes how to use the maprcli to automatically set up stream replication. As an alternative, you can use the Control System to automatically set up table replication or use the `maprcli` command to manually set up primary-secondary replication.

Before you begin, review the following requirements:

- You must replicate all of the topics that are in a stream. You cannot select only a subset of topics to replicate.
- The maximum number of replicas that a stream can replicate to is 64.
- The maximum number of upstream sources that a replica can accept data from is 64.
- In multi-master replication, names of topics must be unique on all streams. Messages are assigned sequential offsets. The offsets for messages in a topic in one copy could conflict with the offsets for messages in the other copy. As a result, messages could be lost.
- In many-to-one replication, topics with the same name should not be replicated to an aggregate replica.

In general, you should store your streams on their own volumes to avoid overlap with volume mirroring. Otherwise, if a source volume fails, you may have a scenario where a stream in the promoted mirror lags behind the stream's replica. See Preparing Clusters for Table Replication on page 1431 for more details.

Set up replication automatically by following these steps:

Procedure

1. Log into both the source and destination clusters.
2. Run the command `maprcli stream replica autosetup`:
   - For primary-secondary replication:

     ```
     maprcli stream replica autosetup -path <path to source
     stream> -replica <path to replica stream>
     ```

     For example, to set up primary-secondary replication from the `activity` stream in the `sanfrancisco` cluster to a new `activity` stream in the `newyork` cluster, you could use this command:

     ```
     maprcli stream replica autosetup -path
     /mapr/sanfrancisco/activity -replica /mapr/newyork/activity
     ```

   - For multi-master replication:

     ```
     maprcli stream replica autosetup -path <path to source
     stream> -replica <path to replica stream> -multimaster yes
     ```

     For example, to set up multi-master replication between the `activity` stream in the `sanfrancisco` cluster and a new `activity` stream in the `newyork` cluster, you could use this command:

     ```
     maprcli stream replica autosetup -path /mapr/sanfrancisco/activity
     -replica /mapr/newyork/activity -multimaster yes
     ```

     NOTE: The parameter `-multimaster` is an optional parameter that you use to set up multi-master replication.

NOTE: By default, `maprcli stream replica autosetup` sets up asynchronous replication. If you want to set up synchronous replication or use any of the other optional parameters, see `stream replica autosetup` on page 2381.

last-updated: Jun 06, 2024

3. To check the replication status, run stream replica list on page 2385.

Setting Up Primary-Secondary Stream Replication Manually
Describes how to setup a primary-secondary stream replica that replicates in one direction.

About this task

Replica streams can be in a remote data-fabric cluster or in the data-fabric cluster where their source streams are located. All updates from a source stream arrive at a replica stream after having been authenticated at a gateway. Therefore, the `produceperm` access control expressions on the replica stream is irrelevant; gateways have the implicit authority to publish messages to topics in replica streams.

To set up primary-secondary replication of streams:

Procedure

1. Create the replica manually with the `maprcli stream create` command. Use the `-copymetafrom` option to ensure that the metadata for the replica is identical to the metadata for the source stream.

   ```
   maprcli stream create -path <path to replica>
   -copymetafrom <path to source stream>
   ```

   For example, to create the replica `activity` in the `newyork` cluster and use the metadata from the source stream in the `sanfrancisco` cluster, you could use this command:

   ```
   maprcli stream create -path /mapr/newyork/activity
   -copymetafrom /mapr/sanfrancisco/activity
   ```

2. Register the replica as a replica of the source stream by running the `maprcli stream replica add` command.

   ```
   maprcli stream replica add -path <path to source stream>
   -replica <path to replica> -paused true
   ```

   For example, to register the `activity` stream in the `newyork` cluster as a replica of the `activity` stream in the `sanfrancisco` cluster, you could use this command:

   ```
   maprcli stream replica add -path /mapr/sanfrancisco/activity
   -replica /mapr/newyork/activity -paused true
   ```

   The `-paused` parameter ensures that replication does not start immediately after you register the source stream as a source for this replica. You do this registration in step 4.

3. Verify that you specified the correct replica by running the `maprcli stream replica list` command.

   ```
   maprcli stream replica list -path <path to source stream>
   ```

   To verify that the `activity` stream in the `newyork` cluster is a replica of the `activity` stream in the `sanfrancisco` cluster, you could look at the output of this command:

   ```
   maprcli stream replica list -path /mapr/sanfrancisco/activity
   ```

last-updated: Jun 06, 2024

4. Authorize replication between the streams by defining the source stream as the upstream stream for the replica by running the `maprcli stream upstream add` command.

   Definition of the upstream stream ensures that a stream cannot replicate updates to any replica. Replication depends on a two-way agreement between the owners of the two streams.

   ```
   maprcli stream upstream add -path <path to replica> -upstream
   <path to source stream>
   ```

   To add the `activity` stream in the `sanfrancisco` cluster as an upstream source for the `activity` stream in the `newyork` cluster:

   ```
   maprcli stream upstream add -path /mapr/newyork/activity -upstream
   /mapr/sanfrancisco/activity
   ```

5. Verify that you specified the correct source stream by running the `maprcli stream upstream list` command.

   ```
   maprcli stream upstream list -path <path to the replica>
   ```

   To verify this in our example scenario, you could use this command:

   ```
   maprcli stream upstream list -path /mapr/newyork/activity
   ```

6. Load the replica with data from the source stream by using the `mapr copystream` on page 5523 utility.

7. Start replication with the command `maprcli stream replica resume`.

   ```
   maprcli stream replica resume -path <path to the source stream>
   -replica <path to the replica>
   ```

   For our example scenario, you could use this command:

   ```
   maprcli stream replica resume -path mapr/sanfrancisco/activity
   -replica /mapr/newyork/activity
   ```

Viewing the List of Stream Replicas
Explains how to view the list of replicas for a stream using the Control System and the CLI.
Viewing the List of Stream Replicas Using the Control System

Procedure

- Log in to the Control System and go to the **Replication** tab in the stream information page.

  The **Replicas** pane displays the the list of replicas for the selected stream and for each replica, the pane displays the following:

Column Name	Column Description
Paused	Specifies whether replication is paused.
Destination Cluster & Type	The cluster on which the replica stream resides.
Destination Path	Specifies the name and path of the replica stream.

last-updated: Jun 06, 2024

Column Name	Column Description
Status	The status of the replica. Replicas can be in one of the following states: • In-Synch — indicates replica is in synch with the source stream and there are no more bytes to be sent from the source. • Pending — indicates replica is waiting for some bytes to be sent from the source. You can hover over the status to determine the number of bytes, puts, and buckets pending. • Broken — indicates there was an error during replication. If necessary, remove and re-create the replica.
Earliest	The date of the oldest message that has yet to be replicated.
Latest	The date of the newest message that has yet to be replicated.
Errors	Indicates if there were errors during replication.
Compression Type	The type of on-wire compression.
Synchronous	Specifies whether replication is synchronous.
Throttled	Specifies whether replication operations are throttled.
Encrypted	Specifies whether on-wire encryption is enabled.

Selecting the checkbox beside a replica makes the Actions drop-down menu available. You can:

- Add a replica
- Edit a replica
- Pause a replica
- Resume replication
- Un-register replica(s)
- Set current stream as an upstream source

Viewing the List of Stream Replicas Using the CLI or REST API

About this task

The command to pause a replication is:

```
maprcli stream replica pause -path <stream path> -replica <remote stream
path>
```

For complete reference information, see `stream replica pause` on page 2387.

Editing a Stream Replica

Explains how to edit a stream replica using the Control System and the CLI to modify the way in which messages are replicated from the source stream to the replica.

Editing a Stream Replica Using the Control System

About this task
To un-register one or more stream replicas from the Control System:

Procedure
1. Log in to the Control System and go to the **Replication** tab in the stream information page.
2. Click  associated with the replica to edit in the **Replicas** pane.
   The **Edit Replica** page displays.
3. Make necessary changes to any of the following properties.

Path to Replica	Specify path and name of the replica stream.
Throttle	Enable (**Yes**) or disable (**No**) throttling of replication operations. Throttle the replication stream to minimize the impact of the replication process on incoming operations during periods of heavy load. By default, throttling is disabled. Throttling has two effects, both of which allow HPE Ezmeral Data Fabric Streams to use more system resources to process new messages: • Throttling slows down the rate at which changes to a stream are replicated. • Throttling slows down the rate at which messages to be replicated are read from disk.
Replicate Synchronously	Set up synchronous (**Yes**) or asynchronous (**No**) replication.
Encrypt On Wire	Enable (**Yes**) or disable (**No**) on-wire encryption. By default, this is disabled (**No**). If you enable on-wire encryption, the local cluster and any other cluster that is part of the replication process must be enabled for security.
Compress On Wire	Specify type of compression to use when replicating messages.

4. Click **Save Changes** for the changes to take effect.

Editing a Stream Replica Using the CLI or REST API

About this task

The basic command to modify a replica is:

```
stream replica edit -path <stream path> -replica <remote stream path>
```

For complete reference information, see `stream replica edit` on page 2383.

Removing Stream Replicas
Explains how to unregister one or more replicas using the Control System and the CLI.
Removing Stream Replicas Using the Control System

About this task
To un-register one or more stream replicas from the Control System:

Procedure
1. Log in to the Control System and go to the **Replication** tab in the stream information page.

last-updated: Jun 06, 2024

2. Select the replicas to remove in the **Replicas** pane.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Remove Replica(s)** from the **Actions** drop-down menu.
   The **Remove Replica(s)** confirmation window displays.
4. Verify the list of replicas to remove and click **Remove Replica**.
   This action un-registers the stream as the replica of the source stream.

Removing a Stream Replica Using the CLI or REST API

About this task

The command to remove a replica is:

```
stream replica remove -path <stream path> -replica <remote stream path>
```

For complete reference information, see stream replica remove on page 2388.

Pausing Stream Replication

Explains how to pause replication from a source stream to a replica stream using the Control System and the CLI.

Pausing Stream Replication Using the Control System

About this task

To pause one or more replications:

Procedure

1. Log in to the Control System and go to the **Replication** tab in the stream information page.
2. Select the replicas to pause in the **Replicas** pane.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Pause Replication** from the **Actions** drop-down menu.
   The **Pause Replication** confirmation window displays.
4. Verify the list of replicas to pause and click **Pause Replication**.
   This action pauses replication from the source stream to the selected replica stream(s).

Pausing Stream Replication Using the CLI or REST API

About this task

The command to pause a replication is:

```
maprcli stream replica pause -path <stream path> -replica <remote stream
path>
```

For complete reference information, see stream replica pause on page 2387.

Resuming Stream Replication

Explains how to resume replication from one stream to another stream using either the Control System or the CLI.

Resuming Stream Replication Using the Control System

About this task
To resume one or more replications:

Procedure
1. Log in to the Control System and go to the **Replication** tab in the stream information page.
2. Select the replicas (in **Paused** state) in the **Replicas** pane.
   Selecting the checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Resume Replication** from the **Actions** drop-down menu.
   The **Resume Replication** confirmation window displays.
4. Verify the list of replicas to resume and click **Resume Replication**.
   This action resumes replication from the source stream to the selected replica stream(s).

Resuming Stream Replication Using the CLI or REST API

About this task

The command to resume a replication is:

```
maprcli stream replica resume -path <stream path> -replica <remote stream
path>
```

For complete reference information, see `stream replica resume` on page 2388.

Managing Upstream Sources for Stream Replicas

You can set up a stream to be the upstream source for replicas. This is especially useful if you did not set up replication automatically when setting up replicas.

Set up Stream as Upstream Source
Describes how to set up the current stream as the upstream source for a replica if the replica was not set up to automatically resync with the current stream.
Setting Up Current Stream as Upstream Source for a Replica Using the Control System

About this task
To set up a stream as the upstream source for a replica:

Procedure
1. Go to the **Replication** tab in the stream information page
2. Select the checkbox beside the replica(s) that do not have the current stream configured as upstream source for automatic resync.
   Selecting a checkbox next to a replica makes the **Actions** drop-down menu available.
3. Select **Set Current Stream as Upstream Source** from the **Actions** drop-down menu.
   The **Set Current Stream as Upstream Source** dialog displays.
4. Review the list of selected replicas and click **Set Upstream Source**.
   The current stream will automatically send updates to the replica(s).

Setting Up Stream as Upstream Source for a Replica Using the CLI or REST API

About this task

The basic command to set a table as the upstream souce for a replica is:

```
maprcli stream upstream add -path <replica stream path> -upstream <source
stream path>
```

See `stream upstream add` on page 2389 for complete reference information.

Adding Upstream Source for a Stream
Explains how to add an upstream source for a stream using either the Control Panel or the CLI.

About this task

You can register a stream as an upstream source for a stream using the Control System and the CLI. When you register a stream as an upstream source, the registered upstream source stream will send updates to the stream.

Adding Upstream Source for a Stream Using the Control System

About this task
To register a stream as an upstream source:

Procedure

1. Log in to the Control System and go the stream information page.
2. Click **Add Upstream Source** in the **Upstream Sources** pane.
   The **Add Upstream Sources** window displays.
3. Specify the path and name of the source stream in the **Upstream Source** field.
4. Click **Add Upstream Source** to register the source stream as an upstream source for this stream.

Adding Upstream Source for a Stream Using the CLI or REST API

About this task

The command to add an upstream source is:

```
maprcli stream upstream add -path <stream path> -upstream <upstream stream
path>
```

For complete reference information, see `stream upstream add` on page 2389.

Listing all Upstream Sources for a Stream
Describes how to list all the upstream sources for a stream using the Control System and the CLI.
Listing all Upstream Sources for a Stream Using the Control System

Procedure

- Log in to the Control System and go to the **Replication** tab in the stream information page.
  The **Upstream Sources** pane displays the list of upstream sources for the selected stream and for each upstream source, the pane displays the following:

Column Name	Column Description
IDX	The index number of the upstream stream.

Column Name	Column Description
Upstream Source Cluster	The name of the data-fabric cluster in which the upstream stream is located.
Upstream Source Path	The path and name of the upstream stream.
UUID	The upstream stream's universally unique identifier.

You can add an upstream source and by selecting the checkbox beside a stream, you can decouple the selected upstream stream.

Listing all Upstream Sources for a Stream Using the CLI or REST API

About this task

The command to list all upstream sources for a stream is:

```
maprcli stream upstream list -path <stream path>
```

For complete reference information, see `stream upstream list` on page 2390.

Removing Upstream Sources for a Stream
Explains how to un-register a stream as an upstream source for a stream using either the Control System or the CLI.

About this task

When you remove a stream as an upstream source for a stream, the upstream source stream will stop sending updates to the stream.

Removing Upstream Sources for a Stream Using the Control System

Procedure

1. Log in to the Control System and go the **Replication** tab in the stream information page.
2. Select the upstream sources to remove in the **Upstream Sources** pane and click **Remove Upstream Source(s)**.
   The **Remove Upstream Source(s)** confirmation window displays.
3. Verify the list and click **Remove Upstream Source**.
   This action un-registers the selected stream(s) as upstream source(s) for this stream.

Removing Upstream Sources for a Stream Using the CLI or REST API

About this task

The command to decouple upstream sources is:

```
maprcli stream upstream remove -path <stream path> -upstream <upstream
stream path>
```

For complete reference information, see `stream upstream remove` on page 2391.

Preparing Clusters for Log Compaction

Describes how to prepare your environment so you can use log compaction.

Installing with the MapR Installer

When you use the MapR Installer to install HPE Ezmeral Data Fabric Streams, a local gateway is also locally installed so that log compaction can be implemented. To configure for log compaction, see maprcli stream create on page 2368 and stream edit on page 2375.

Installing without the MapR Installer

Other sections of the documentation describe the detailed steps for installing and configuring without the MapR installer. Generally, you need to perform the following steps:

1. Install the MapR software.To install MapR without using the MapR installer, follow the steps outlined at Installing without the Installer on page 179.
2. Install the MapR gateway on your local cluster. Since gateways for log compaction are installed on the local cluster, no configuration is needed. See Gateways and Stream Replication on page 801 for general information about gateways.

Adding Gateways for Load Balancing

Since the number of gateways impacts the compaction process, you might want to increase the number of gateways on the cluster to improve the load distribution. To add gateways for log compaction, you install additional MapR gateways on your local cluster. See Gateways and Stream Replication on page 801 for general information about gateways.

NOTE: No configuration is required because the additional gateways are installed on the local clusster.

For More Information

See the following topics for more information:

- maprcli stream create on page 2368 and stream edit on page 2375
- HPE Ezmeral Data Fabric Streams Java Applications on page 3546, HPE Ezmeral Data Fabric Streams Java API Library on page 3548, and Enabling Log Compaction on page 3556

Mirroring Topics with Apache Kafka MirrorMaker

Use the Apache Kafka MirrorMaker utility either to mirror topics that are in Apache Kafka clusters to streams that are in HPE Ezmeral Data Fabric clusters or to Mirror topics that are in HPE Ezmeral Data Fabric clusters to Apache Kafka clusters.

Mirroring is a type of replication that takes place in this sequence of steps:

1. Messages that are published to topics in a source cluster are read by consumers that MirrorMaker manages.
2. These consumers send the messages to producers that MirrorMaker also manages.
3. The producers publish the messages in topics that are in the destination cluster.

Mirroring can continue indefinitely. Alternatively, you can mirror your data as a way of migrating it from Apache Kafka to HPE Ezmeral Data Fabric Streams. If you use it for this purpose, you can stop mirroring after migrating your producers and consumers to use HPE Ezmeral Data Fabric Streams, as described in Migrating Apache Kafka 0.9.0 Applications to HPE Ezmeral Data Fabric Streams.

ATTENTION: MirrorMaker does not provide the same reliability guarantees as the replication features in HPE Ezmeral Data Fabric Streams. In particular, MirrorMaker does not replicate cursors or message positions, which makes disaster recovery much more difficult than with replication of HPE Ezmeral Data Fabric Streams. Therefore, HPE Ezmeral Data Fabric recommends MirrorMaker for use only for mirroring between HPE Ezmeral Data Fabric Streams and Apache Kafka, not for replication of HPE Ezmeral Data Fabric Streams.

Prerequisites

- Ensure that the destination stream in the HPE Ezmeral Data Fabric cluster exists. To create a stream, run the command `maprcli stream create`.
- Ensure that the ID of the user that runs MirrorMaker has the `produceperm` and `topicperm` permissions on the stream.

Command Syntax and Descriptions of Parameters

```
bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
--whitelist=<Java-style regular expression for specifying the topics to
mirror>
```

Parameter	Description
`consumer.config`	The path and name of the file that lists the consumer properties. See the Consumer Properties and Descriptions on page 1516 section for detailed information.
`num.streams`	Use the --num.streams option to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption).
`producer.config`	The path and name of the file that lists the producer properties. See the Producer Properties and Descriptions on page 1517 section for detailed information.
`whitelist`	A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol ('|'). This parameter is required.

Consumer Properties and Descriptions

```
group.id=<ID>
bootstrap.servers=<IP address>:<port>
shallow.iterator.enable=false
```

Property	Description
`group.id`	A unique string that identifies the consumer group this consumer belongs to. This property is required if the consumer uses either the group management functionality by using `subscribe(topic)` or the Kafka-based offset management strategy. If `group.id` is not set and the value of the `num.streams` option is > 1 , messages might go multiple times to a stream.
`bootstrap.servers`	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form `host1:port1,host2:port2,....` Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).
`shallow.iterator.enable`	Set this value to `false`.

Producer Properties and Descriptions

```
key.serializer=<serializer class>
value.serializer=<serializer class>
streams.producer.default.stream=<Path and name of the stream to copy the
topics to>
auto.create.topics.enable=true
```

Property	Description
`key.serializer`	The name of the appropriate serialization class in the `org.apache.kafka.common.serialization` package or a class that implements the `Serializer` interface for serializing keys.
`value.serializer`	The class that implements the `Serializer` interface for serializing values.
`streams.producer.default.stream`	Specifies the path and name of stream that the topics will be copied to.
`auto.create.topics.enable`	Enables auto-creation of topics within the stream specifed with the `streams.producer.default.stream` parameter.

Mirroring Topics from an Apache Kafka Cluster to the HPE Cluster

You can use MirrorMaker to mirror data continuously from Apache Kafka clusters to streams in HPE Ezmeral Data Fabric Streams clusters.

Prerequisites

- Because this procedure requires that MirrorMaker be run from the HPE Ezmeral Data Fabric cluster, ensure that the mapr-kafka package is installed on the node that you choose to run MirrorMaker from.
- Configure the node as a mapr client.

last-updated: Jun 06, 2024

- Ensure that the ID of the user that runs MirrorMaker has the `produceperm` and `topicperm` permissions on the destination stream.

About this task

Alternatively, you can stop mirroring after you migrate the consumers and producers for your applications from your Apache Kafka cluster to your data-fabric cluster where the stream is located. See in Migrating Apache Kafka 0.9.0 Applications to HPE Ezmeral Data Fabric Streams for details. After you start MirrorMaker, it launches a configurable number of consumer threads to read topics that are in a Kafka cluster and a number of producers to write the messages from those topics into topics in HPE Ezmeral Data Fabric Streams.

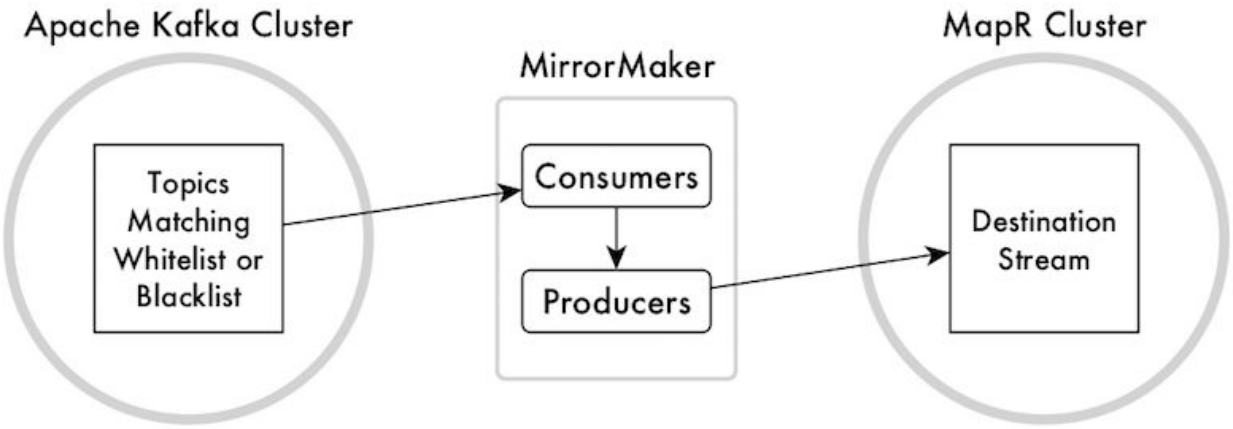


Figure 22: Mirroring from Apache Kafka to HPE Ezmeral Data Fabric Streams

Before running MirrorMaker, you create a file that contains the required configuration parameters for the consumers that read from the Apache Kafka cluster. You also create a file that contains the required configuration parameters for the producers that publish to the stream in the HPE Ezmeral Data Fabric cluster. You point to these files in the MirrorMaker command.

To specify which topics you want to mirror, use the `whitelist` parameter to provide a Java-style regular expression that matches the names of the topics that you want mirrored.

Procedure

1. Create a file that contains the required properties and values for consumers to use. When you run MirrorMaker, you point to this file by using the `consumer.config` parameter.

   The descriptions of these properties, except for the last, are taken from the documentation for Apache Kafka. The last property is not documented.

Property	Description
`group.id`	A unique string that identifies the consumer group the consumers started by MirrorMaker belong to.

Property	Description
`bootstrap.servers`	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form `host1:port1,host2:port2,...`. Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).

2. Create a file that contains the required properties and values for producers to use. When you run MirrorMaker, you point to this file by using the `producer.config` parameter.

Property	Description
`streams.producer.default.stream`	Specifies the path and name of the stream in the HPE Ezmeral Data Fabric cluster that the topics will be mirrored to.
`auto.create.topics.enable`	Set the value to `true`. The producers will therefore be able to create topics in the destination stream automatically.

3. Run MirrorMaker with this command to start mirroring topics from Apache Kafka to HPE Ezmeral Data Fabric Streams:

   Syntax

```
/opt/mapr/kafka/kafka-0.9.0/bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
--whitelist=<Java-style regular expression for specifying the topics to
mirror>
```

Parameter	Description
`consumer.config`	The path and name of the file that lists the consumer properties and their values.
`num.streams`	Use this option to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption).
`producer.config`	The path and name of the file that lists the producer properties and their values.
`whitelist`	A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol ('|'). This parameter is required.

last-updated: Jun 06, 2024

Example

In this example, the file that lists the properties and values for the consumers that will read messages from the topics in Apache Kafka is named `consumers.props`. It contains this list:

```
group.id=cg1
bootstrap.servers=10.10.100.87:9093
shallow.iterator.enable=false
```

The file that lists the properties and values for the producers that will publish messages to topics in HPE Ezmeral Data Fabric Streams is named `producers.props`. It contains this list:

```
streams.producer.default.stream=/newStream
auto.create.topics.enable=true
```

The topics to mirror all have names that begin with `na_west`. When running the command, we can use `"na_west.*"` as the regular expression to use for the `whitelist` parameter.

Here is the command:

```
bin/kafka-mirror-maker.sh --consumer.config consumers.props
--num.streams 2 --producer.config producers.props --whitelist="na_west.*"
```

Mirroring Topics from the HPE Cluster to an Apache Kafka Cluster
You can use MirrorMaker to mirror data continuously from streams in HPE Ezmeral Data Fabric clusters to Apache Kafka clusters.

Prerequisites

- This procedure requires MirrorMaker to run from the HPE Ezmeral Data Fabric cluster. Verify that the mapr-kafka package is installed on the node that you choose to run MirrorMaker on.
- Configure the node as a `mapr` client.
- Ensure that the ID of the user who runs MirrorMaker has the `consumeperm` permission on the stream.

About this task

After you start MirrorMaker, it launches a configurable number of consumer threads to read topics that are in a stream in a HPE Ezmeral Data Fabric cluster and a number of producers to write the messages from those topics into topics in an Apache Kafka cluster.

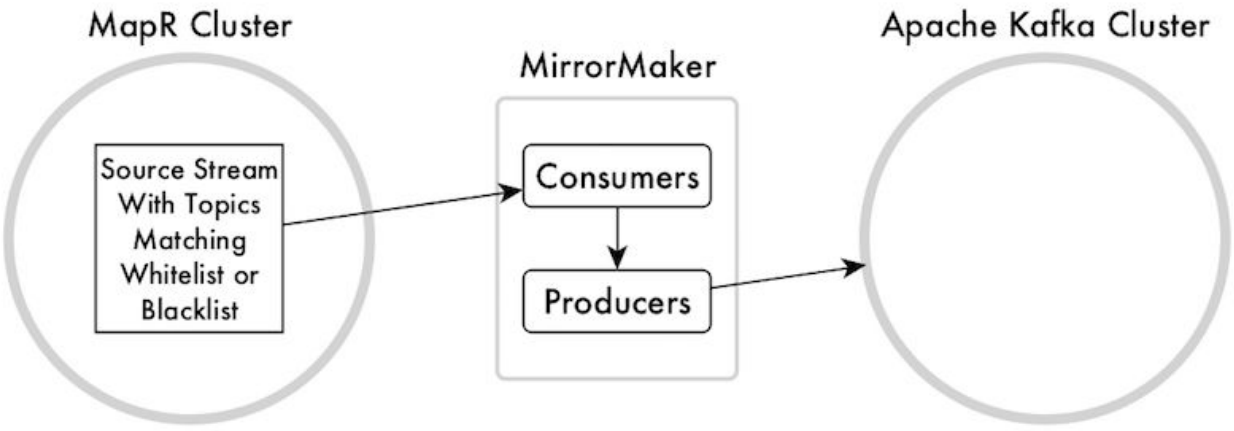

Figure 23: Mirroring from HPE Ezmeral Data Fabric Streams to Apache Kafka

Before running MirrorMaker, you create a file that contains the required configuration parameters for the consumers that read from the stream in the HPE Ezmeral Data Fabric cluster. You also create a file that contains the required configuration parameters for the producers that publish to the Apache Kafka cluster. You point to these files in the MirrorMaker command.

To specify which topics you want to mirror, use the `whitelist` parameter to provide a Java-style regular expression that matches the names of the topics that you want mirrored.

Procedure

1. Create a file that contains the required properties and values for consumers to use. When you run MirrorMaker, you point to this file by using the `consumer.config` parameter.

Property	Description
`streams.record.strip.streampath`	Set the value of this property to true. In messages that are written to streams, the names of topics include the paths and names of the streams in which those topics are located. Apache Kafka needs only the names of the topics. This parameter removes the path and name of the stream that the topics will be mirrored from.
`streams.consumer.default.stream`	Specifies the path and name of the stream that the topics will be mirrored from.
`group.id`	A unique string that identifies the consumer group the consumers started by MirroMaker belong to.

2. Create a file that contains the required properties and values for producers to use. When you run MirrorMaker, you point to this file by using the `producer.config` parameter.

Property	Description
`bootstrap.servers`	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The producers will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form `host1:port1,host2:port2,...`. Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).
`producer.type`	Specifies whether the messages are published asynchronously in batches or as data is received by producers. The values are `async` and `sync`.
`compression.codec`	Specifies the compression codec for all messages that are generated by producers. The possible values are `none`, `gzip`, `snappy`, and `lz4`.

3. Run MirrorMaker with this command to start mirroring topics from HPE Ezmeral Data Fabric Streams to Apache Kafka:

   Syntax

```
bin/kafka-mirror-maker.sh
--consumer.config <File that lists consumer properties and values>
--num.streams <Number of consumer threads>
--producer.config <File that lists producer properties and values>
```

last-updated: Jun 06, 2024

```
--whitelist=<Java-style regular expression for specifying the topics to
mirror>
```

Parameter	Description
`consumer.config`	The path and name of the file that lists the consumer properties and their values.
`new.consumer`	Specifies to use consumers that use the Apache Kafka 0.90 API library.
`num.streams`	Use this parameter to specify the number of mirror consumer threads to create. Note that if you start multiple mirror maker processes then you may want to look at the distribution of partitions on the source cluster. If the number of consumption streams is too high per mirror maker process, then some of the mirroring threads will be idle by virtue of the consumer rebalancing algorithm (if they do not end up owning any partitions for consumption).
`producer.config`	The path and name of the file that lists the producer properties and their values.
`whitelist`	A Java-style regular expression for specifying the topics to copy. Commas (',') are interpreted as the regex-choice symbol ('|'). This parameter is required.

Example

In this example, the file that lists the properties and values for the consumer that will read messages from the topics in HPE Ezmeral Data Fabric Streams is named `consumers.props`. It contains this list:

```
streams.record.strip.streampath=true
streams.consumer.default.stream=/myStream
group.id=cg1
```

The file that lists the properties and values for the producers that will publish messages to topics in Apache Kafka is named `producers.props`. It contains this list:

```
bootstrap.servers =10.10.83.93:9092
producer.type=sync
compression.codec=none
```

The topics to mirror all have names that begin with `na_west`. When running the command, we can use `"na_west.*"` as the regular expression to use for the whitelist parameter.

```
bin/kafka-mirror-maker.sh --new.consumer
--consumer.config consumers.props --num.streams 2 --producer.config
producers.props
--whitelist="na_west.*"
```

Mirroring Topics with HPE Ezmeral Data Fabric MirrorMaker 2

MirrorMaker 2.0 is a multi-cluster, cross-data-center replication engine based on the Kafka Connect framework. MirrorMaker 2 is available starting in EEP 8.0.0.

Mirror Maker 2.0 replicates data in topics from one Kafka cluster to another. HPE Ezmeral Data Fabric Mirror Maker 2 can mirror data:

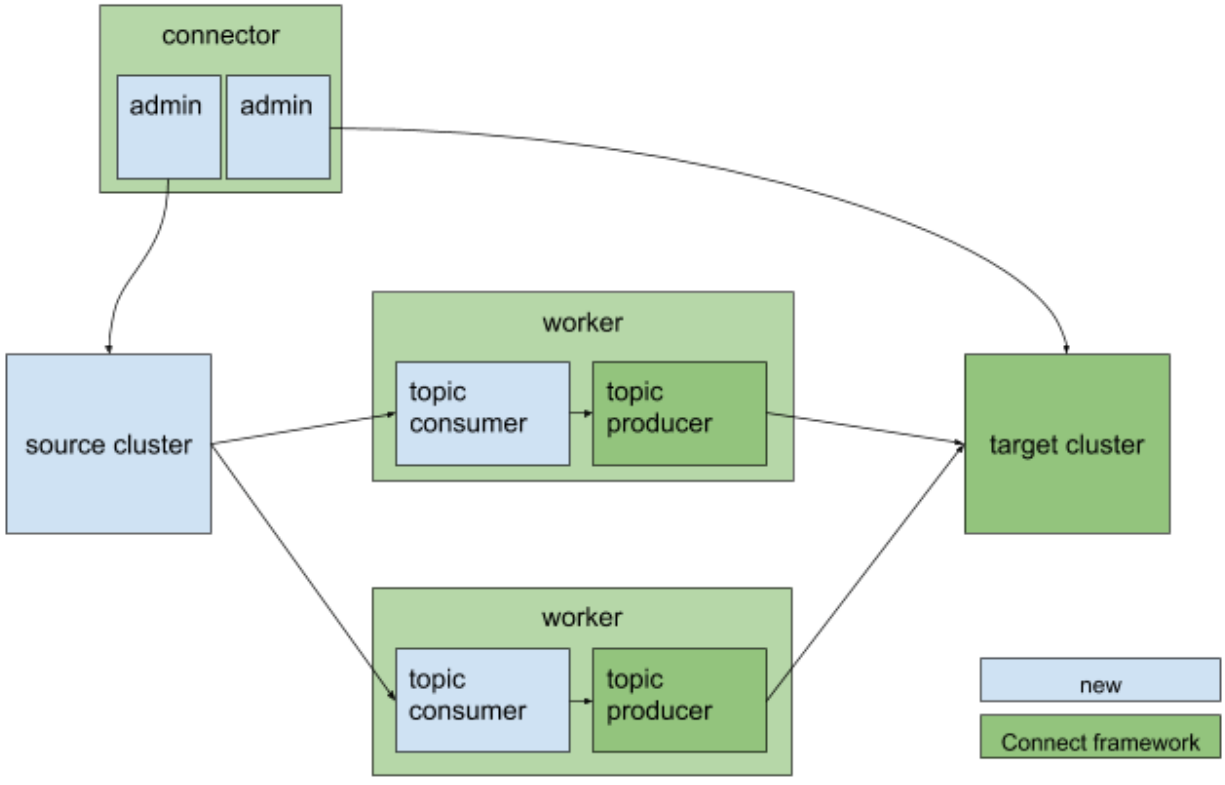
- from Apache Kafka clusters to Apache Kafka clusters.
- from Apache Kafka clusters to streams in HPE Ezmeral Data Fabric clusters.
- from streams in HPE Ezmeral Data Fabric clusters to Apache Kafka clusters.
- between streams in HPE Ezmeral Data Fabric clusters.

MirrorMaker 2 Architecture

MirrorMaker 2 uses the Kafka Connect framework to simplify configuration and scaling. Both source and sink connectors are provided to enable complex flows between multiple Kafka clusters and across data centers via existing Kafka Connect clusters. The main MirrorMaker 2 components are actually Kafka connectors, as described in the following list:

- The MirrorSourceConnector replicates records from local to remote clusters and enables offset synchronization.
- The MirrorCheckpointConnector manages consumer offset synchronization, emits checkpoints, and enables failover.
- The MirrorHeartbeatConnector provides heartbeats, monitoring of replication flows, and client discovery of replication topologies, which can be more complex than for the original MirrorMaker.

As shown in the following MirrorMaker 2 architecture diagram, the source and sink connectors contain a pair of producers and consumers to replicate records, and a pair of AdminClients to propagate configuration changes:



Prerequisites

When using HPE Ezmeral Data Fabric streams as the source or target:

last-updated: Jun 06, 2024

- Ensure that the destination stream in the HPE Ezmeral Data Fabric cluster exists. To create a stream, run the `maprcli stream create` command.
- Ensure that the ID of the user that runs MirrorMaker 2 has the `produceperm` and `topicperm` permissions on the stream.

When using an Apache Kafka cluster as the source or target:

- Verify that a connection to the Apache Kafka cluster exists.

Connector Configuration Properties for MirrorMaker 2

Use the `.stream` property instead of the `.bootstrap.servers` property when an HPE Ezmeral Data Fabric stream is the source or the target.

The following table lists the properties common to the SourceConnectors and SinkConnector:

Property	Default	Description
name	required	name of the connector, e.g. "us-west->us-east"
topics	empty string	regex of topics to replicate, e.g. "topic1|topic2|topic3". Comma-separated lists are also supported.
topics.blacklist	".*\.internal, .*\.replica, __consumer_offsets" or similar	topics to exclude from replication
groups	empty string	regex of groups to replicate, e.g. ".*"
groups.blacklist	empty string	groups to exclude from replication
source.cluster.alias	required	name of the cluster being replicated
target.cluster.alias	required	name of the downstream Kafka cluster
source.cluster.stream	required or can be replaced by bootstrap.servers	stream from upstream HPE Ezmeral Data Fabric cluster to replicate
target.cluster.stream	required or can be replaced by bootstrap.servers	Stream from downstream HPE Ezmeral Data Fabric cluster
source.cluster.bootstrap.servers	required or can be replaced by stream	upstream cluster to replicate
target.cluster.bootstrap.servers	required or can be replaced by stream	downstream cluster
sync.topic.configs.enabled	true	whether or not to monitor source cluster for configuration changes
sync.topic.acls.enabled	true	whether to monitor source cluster ACLs for changes
emit.heartbeats.enabled	true	connector should periodically emit heartbeats
emit.heartbeats.interval.seconds	5 (seconds)	frequency of heartbeats
emit.checkpoints.enabled	true	connector should periodically emit consumer offset information
emit.checkpoints.interval.seconds	5 (seconds)	frequency of checkpoints
refresh.topics.enabled	true	connector should periodically check for new topics

last-updated: Jun 06, 2024

Property	Default	Description
refresh.topics.interval.seconds	5 (seconds)	frequency to check source cluster for new topics
refresh.groups.enabled	true	connector should periodically check for new consumer groups
refresh.groups.interval.seconds	5 (seconds)	frequency to check source cluster for new consumer groups
readahead.queue.capacity	500 (records)	number of records to let consumer get ahead of producer
replication.policy.class	org.apache.kafka.connect.mirror.DefaultReplicationPolicy	use LegacyReplicationPolicy to mimic legacy MirrorMaker
heartbeats.topic.retention.ms	1 day	used when creating heartbeat topics for the first time
checkpoints.topic.retention.ms	1 day	used when creating checkpoint topics for the first time
offset.syncs.topic.retention.ms	max long	used when creating offset sync topic for the first time
replication.factor	2	used when creating remote topics

The following table lists internal client properties that you can override:

Property	Description
source.cluster.consumer.*	overrides for the source-cluster consumer
source.cluster.producer.*	overrides for the source-cluster producer
source.cluster.admin.*	overrides for the source-cluster admin
target.cluster.consumer.*	overrides for the target-cluster consumer
target.cluster.producer.*	overrides for the target-cluster producer
target.cluster.admin.*	overrides for the target-cluster admin

Example Configuration File

The following `mm2.properties` configuration file example shows the configuration for an HPE Ezmeral Data Fabric stream to Apache Kafka cluster workflow.

```
# Datacenters.
clusters = source, target
source.stream = /str
target.bootstrap.servers = 192.168.33.12:9092

# Source and target cluster configurations.
source.config.storage.replication.factor = 1
target.config.storage.replication.factor = 1

source.offset.storage.replication.factor = 1
target.offset.storage.replication.factor = 1

source.status.storage.replication.factor = 1
target.status.storage.replication.factor = 1

source->target.enabled = true
target->source.enabled = false
```

```
# Mirror maker configurations.
offset-syncs.topic.replication.factor = 1
heartbeats.topic.replication.factor = 1
checkpoints.topic.replication.factor = 1

topics = .*
groups = .*

tasks.max = 1
replication.factor = 1
refresh.topics.enabled = true
sync.topic.configs.enabled = true
refresh.topics.interval.seconds = 30

topics.blacklist = .*[\-\.]internal, .*\.replica, __consumer_offsets
groups.blacklist = console-consumer-.*, connect-.*, __.*

# Enable heartbeats and checkpoints.
source->target.emit.heartbeats.enabled = true
source->target.emit.checkpoints.enabled = true
```

Command Syntax

To start the MirrorMaker 2 connectors, run the following command:

```
/opt/mapr/kafka/kafka-<version>/bin/connect-mirror-maker.sh mm2.properties
```

Logs are written to the console instead of log files. You can change where logs are written by editing the `/opt/mapr/kafka/kafka-<version>/config/connect-mirror-maker-log4j.properties` file.

Limitations

There are several limitations that differentiate HPE Ezmeral Data Fabric MirrorMaker 2 from Apache Kafka MirrorMaker 2:

- MirrorCheckpointConnector is not supported by HPE Ezmeral Data Fabric MirrorMaker 2; therefore, mirroring is based only on MirrorSourceConnector and MirrorHeartbeatConnector.
- Access Control Lists (ACLs) synchronization is not supported because HPE Ezmeral Data Fabric streams are not supported ACL.
- Broker configurations that include any of the `log.` properties are not synchronized. For example, if the broker configuration contains the `log.dir` property, the broker configuration is not synchronized across all brokers in the cluster.

Administering Data Fabric Gateways

A HPE Ezmeral Data Fabric gateway mediates one-way communication between a source HPE Ezmeral Data Fabric cluster and a destination cluster. You can replicate HPE Ezmeral Data Fabric Database tables (binary and JSON) and HPE Ezmeral Data Fabric Streams streams. HPE Ezmeral Data Fabric gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

The initial task for setting up your gateways is to decide where you want to put them:

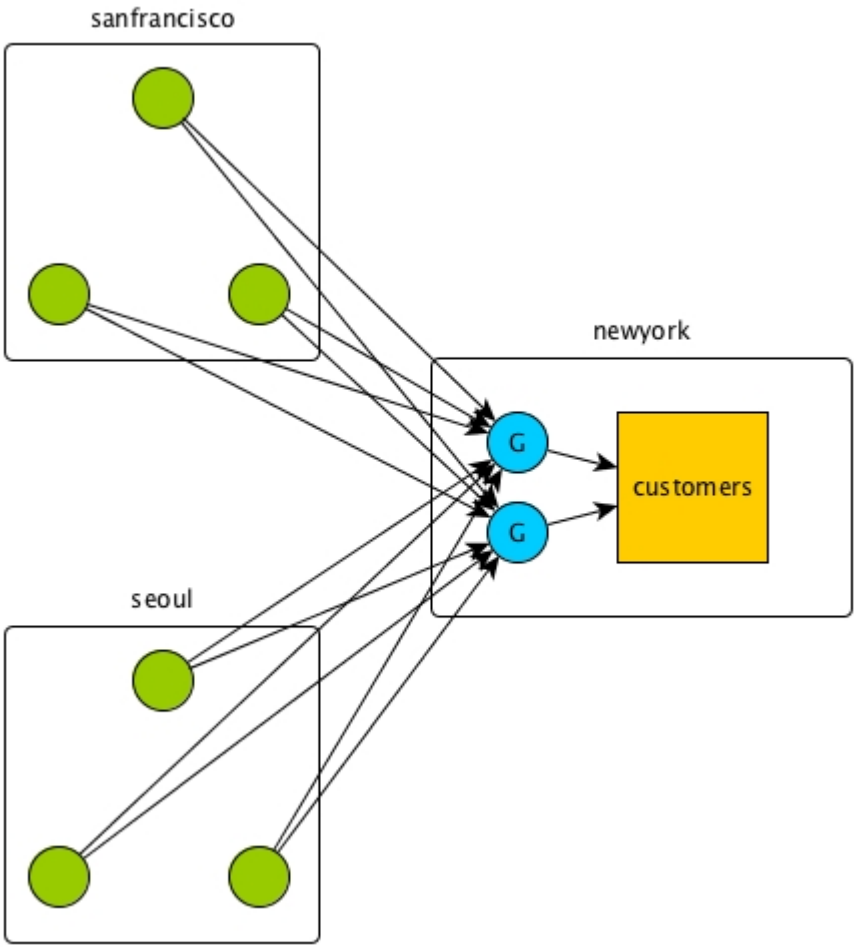
last-updated: Jun 06, 2024

- If you are going to replicate HPE Ezmeral Data Fabric Database tables, see Gateways for Replicating HPE Ezmeral Data Fabric Database Tables on page 760.
- If you are going to replicate streams, see Gateways and Stream Replication on page 801.
- If your HPE Ezmeral Data Fabric Database JSON tables have secondary indexes, see Preparing Clusters for Querying using Secondary Indexes on JSON Tables on page 1457.
- If you are using CDC, see Getting Started with CDC on page 739.

NOTE: Gateways perform negligible disk I/O and use negligible amounts of memory, though gateways require significant CPU usage.

However, the resource that gateways use the most is network bytes. For example, if the peak network throughput for puts is about 40 MB per second per node, in a 10-node source cluster the peak network throughput will be about 400 MB per second. So, the aggregate network throughput required on the nodes running gateways will be 400 MB per second for both incoming and outgoing traffic. The aggregate network throughput for a 50 node cluster would be 2GB per second.

For another example, in the following diagram there are two source clusters of three nodes each and the clusters are replicating to one destination cluster. The peak traffic on the gateways will be 40MB per second per cluster node, which means that these gateways together will experience a peak network load of 240MB per second.



Although the load is balanced across the two gateways, so that each gateway experiences a peak network load of 120MB per second, each gateway should be able to tolerate the full aggregate network load in case the other gateway fails unexpectedly.

Configuring Gateways for Table and Stream Replication

Configuring gateways involves installing the `mapr-gateway` package on nodes on a Data Fabric destination cluster and then configuring the Data Fabric source cluster to communicate with the destination cluster. The Data Fabric source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

How Many Gateways to Configure?

Although it is possible to use a single gateway, the recommended practice is to configure at least two (2) gateways, so that replication can continue if one gateway fails. Data Fabric source clusters distribute requests among the gateways in a round-robin fashion. See Gateways for Replicating HPE Ezmeral Data

Fabric Database Tables on page 760, Table Replication on page 749, and Preparing Clusters for Stream Replication on page 1502 for more information about replication.

For more information about setting up cross-cluster security, including cross-cluster security for table and stream replication, see Setting Up Cross-Cluster Security on page 1948.

Default Gateway Configuration for Replication

If you do not perform any of these options, HPE Ezmeral Data Fabric Database uses the configuration from the `mapr-clusters.conf` file. It uses the cluster name specified in that file as the destination cluster, and the CLDB node addresses as the gateway nodes. You must have gateways running on these CLDB nodes.

Configuration Procedure

TIP: To list the current gateways, see cluster gateway get on page 2051.

1. On the destination cluster, install the `mapr-gateway` package on each node where you want to run a gateway. See Step 4: Install Cluster Service Packages on page 192.

   NOTE: On the gateway nodes in the destination cluster, when you run (or re-run) the `configure.sh` script (in addition to your regular parameters) be sure to specify the `-N` parameter with the name of the cluster to which the gateway belongs. For more information about `configure.sh` usage, options, and examples, see configure.sh on page 2821.

2. To change the port that a gateway uses (by default, gateways use port `7660`):
   a. On the node where the gateway is running, edit the `/opt/mapr/conf/gateway.conf` file, ensure that the line `#gateway.port=7660` is not commented, and change the port number. For more information about `gateway.conf` configuration properties, see gateway.conf on page 2980.
   b. After saving the file, restart the gateway by running this command: `maprcli node services -name gateway -action restart`

3. On the source cluster, specify the destination cluster's name and gateway nodes by using one of the following methods:
   - Run the `maprcli cluster gateway set` command:

     ```
     maprcli cluster gateway set -dstcluster <cluster name> -gateways
     "<space-delimited list of gateways>"
     ```

     The following sample command sets two gateway nodes on the destination cluster `my.cluster.com`:

     ```
     maprcli cluster gateway set -dstcluster my.cluster.com -gateways
     "node1.com node2.com"
     ```

   - Add a DNS record to your DNS server's zone file for your domain.

   See Managing Gateways on page 1530 for more information about using these methods.

Managing Gateways

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

You can run the following commands to perform operations on your gateways.

NOTE: If you have configured an intra-cluster gateway, the source and destination clusters are the same.

- To see a list of the gateways for a particular destination cluster:

  Run the `maprcli cluster gateway get` command on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To see a list of the gateways for all of the destination clusters to which the source cluster is replicating:

  Run the `maprcli cluster gateway list` command on the source cluster. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To remove the list of gateways that you specified for a destination cluster by using the `maprcli cluster gateway set` command:

  Run the `maprcli cluster gateway delete` command on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To find out how HPE Ezmeral Data Fabric Database or HPE Ezmeral Data Fabric Streams is finding gateways (for example, from DNS records, lists created by the `maprcli cluster gateway set` command or the `mapr-clusters.conf` file):

  Run the command `maprcli cluster gateway resolve` on the source cluster. Specify the name of the destination cluster with the `-dstcluster` parameter. If you run the command remotely from your source cluster, specify the name of the source cluster with the `-cluster` parameter.

- To stop and start one or more gateways:

  Run the `maprcli node services -name gateway -action stop|start` on the clusters where the gateways are running.

  ```
  /opt/mapr/bin/maprcli node services -name gateway -action stop -nodes
  <hostnames or IP addresses separated by spaces>
  ```

  ```
  /opt/mapr/bin/maprcli node services -name gateway -action start -nodes
  <hostnames or IP addresses separated by spaces>
  ```

- To check the status of a gateway service on a particular node:

  Run the command maprcli service list on the clusters where the gateways are running.

Running the `maprcli cluster gateway set` command

The syntax of the `maprcli cluster gateway set` command is:

```
/opt/mapr/bin/maprcli cluster gateway set -dstcluster <cluster
name> -gateways "<space-delimited list of gateways>"
```

To generate a list of the existing gateways in a data-fabric cluster, use the `maprcli cluster gateway list` command. You can then copy this list and paste it into the `maprcli cluster gateway set` command. Alternatively, to generate a list of the gateways on a local cluster, run the `maprcli cluster gateway local -format text` command. If you want to run the command from a different cluster and point to the cluster where the gateways are located, use the `-cluster` parameter to provide the name of that cluster.

For example, suppose that you are configuring table replication from the cluster `sanfrancisco` to the cluster `newyork`, and want to use two gateways. The nodes on which these gateways are located are named `gw1` and `gw2`.

The command that you run will be as follows:

```
/opt/mapr/bin/maprcli cluster gateway set -dstcluster newyork -gateways
"gw1.bigcompany.com gw2.bigcompany.com"
```

Adding a DNS record to your DNS server's zone file for your domain

In your DNS server’s zone file for your domain, you can add a record for the cluster where gateways are located, listing the nodes to use as gateways. You can use the Control System to create a record that you

can copy into a DNS configuration file, run a `maprcli` command to generate the record, or create a record manually.

For details, see Specifying the Location of Gateways on page 1085.

If a Gateway Fails

If a gateway fails, the warden service tries three (3) times to restart it automatically. After an interval, the warden tries again three times to start the gateway. You can configure the interval by using the parameter `services.retryinterval.time.sec` in the `warden.conf` file. The default is 30 minutes.

During the time that the gateway is down, source clusters will resend updates to other gateways. Source clusters will also ping the failed gateway with an exponentially increasing backoff.

If all of the gateways fail in a destination cluster, source clusters will ping the failed gateways in the same manner. Updates pending replication are stored on disk in an internal data structure until at least one gateway in the destination cluster comes back online. Therefore, you will see additional storage costs during a gateway outage. The Gateway Service Down alarm in the Control System will notify you when none of the gateways in a destination cluster can be reached.

If the additional storage becomes too costly, you can follow either of these procedures:

If you are replicating to a HPE Ezmeral Data Fabric Database binary table:

1. Run the `maprcli table replica remove` command to stop replicating to the replica. This action deletes the pending updates.
2. Resolve the gateway outage.
3. Recreate the replica and start replicating to it by running the `maprcli table replica autosetup` command.

If you are replicating to a HPE Ezmeral Data Fabric Streams stream:

1. Run the `maprcli stream replica remove` command to stop replicating to the replica stream. This action cancels the pending updates to the replica stream.
2. Resolve the gateway outage.
3. Run the command `maprcli stream replica autosetup` to recreate the replica stream and start replicating to it.

Troubleshooting

You can refer to two log files for each gateway when troubleshooting. Both these files are in the `/opt/mapr/logs` directory on the node where the gateway is running:

- `gateway.log`
- `gatewayinit.log`

HPE Ezmeral Data Fabric Database Lookup Order

HPE Ezmeral Data Fabric Database uses the following order to locate the gateways that are running in a destination cluster.

- Look up the destination cluster's name and gateway addresses in the information specified by the `maprcli cluster gateway set` command. If a list of gateways, then a DNS lookup is performed.
- Perform a DNS lookup of the destination cluster and the addresses of the gateways. If no DNS record for the destination cluster is found, then the lookup goes to the `mapr-clusters.conf` file.

- Look up the destination cluster's name and the CLDB node addresses in the `mapr-clusters.conf` file under the assumption that gateways are running on all of the CLDB nodes and only on those nodes.

Administering Services

The various topics in this section describe how to manage (start, stop, restart, etc.) the various services installed on the MapR cluster using the MapR Control System (click **Services**) and the CLI.

Managing Services

Synopsis on managing services.

Once a role is installed on a node and the warden has been restarted, HPE Ezmeral Data Fabric recognizes the role for that node. You can then start the service. Refer to the following topics for information on managing services on a node using the Control System and the CLI.

Viewing the List of Services
Explains how to view the list of services using either the Control System or the CLI.
Viewing the Services Installed on the Cluster Using the Control System

Procedure

- Log in to the Control System and click **Services**.

  The **Services** pane displays all the services installed on the cluster. On the non-Kubernetes version of the Control System, the pane displays the following:

Column Name	Column Description
Service	The name of the installed service.
Running Nodes	The number of nodes on which the associated service is running. The service can be stopped ( ) or restarted ( ). Click the number in this column to view the nodes on which the service is running.
Standby Nodes	The number of nodes on which the associated service is in standby (available, but not running) state. The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service is in standby state.
Failed Nodes	The number of nodes on which the service has failed. The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service has failed.
Stopped Nodes	The number of nodes on which the associated service is stopped (and not running). The service can be started ( ) or restarted ( ). Click the number in this column to view the nodes on which the service has been stopped.
Log Viewer	(Displays only if Kibana is installed on a node) The link ( ) to the Kibana UI.

  You can filter the list of services displayed by:

  - **EEP**, which includes services such as Hive, Drill, etc.
  - **Core**, which includes services such as CLDB, Hoststats, File server, etc.
  - **Monitoring**, which includes services such as Grafana, Kibana, etc.

Viewing the Services Running on a Node Using the Control System

Procedure

1. Log in to the Control System and click **Nodes**.

   NOTE: The **Nodes** menu is not available in the Kubernetes version of the Control System.

2. You can:

   - Hover the cursor over the number listed in the **Running Services** column in the **Nodes** pane to view the list of services installed on that node.

last-updated: Jun 06, 2024

- Go to the **Summary** tab in the node information page to view detailed information on the services installed on a node.

In the **Summary** tab, for each service running on the node, the **Services** pane displays the following:

Column Name	Column Description
Service	The name of the service.
State	The current state of the service. Value can be: • Running • Stopped
Memory Allocated	The amount of system memory allocated to the service.
System Memory Utilized	The percentage of memory utilized by the service.
CPU Usage	The CPU used by the service.
Log Path	The path to the service log file.
Log Viewer	The link to the Kibana UI (only if Kibana is installed).

You can select the checkbox beside one or more services to take the following actions:

- Start Services
- Stop Services
- Restart Services

NOTE: If Kibana is installed, you can click to view the logs. See Kibana User Guide for more information.

Retrieving the Services Running on a Node Using the CLI or REST API

About this task

The command to list all the services on a node is:

```
maprcli service list -node <node name>
```

For complete reference information, see `service list` on page 2356.

Enabling and Disabling a Service Using the CLI and REST API

Describes how to enable or disable a service using either the REST API or the CLI.

About this task

You can disable a service to prevent it from starting or restarting when Warden starts or restarts, and enable a service to allow it to start or restart when Warden starts or restarts.

last-updated: Jun 06, 2024

Disabling a Service Using the CLI or REST API

About this task

CLI	Run the following command: `maprcli node services -nodes <hostName> -name <serviceName> -action disable`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<hostName>&name=<serviceName>&action=disable' --user mapr:mapr`

NOTE: When you disable a service, the service is stopped and the service is not automatically starrted/restarted when Warden is started/restarted.

See `node services` on page 2292 for more information.

Enabling a Service Using the CLI or REST API

About this task

CLI	Run the following command: `maprcli node services -nodes <hostName> -name <serviceName> -action enable`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<hostName>&name=<serviceName>&action=enable' --user mapr:mapr`

NOTE: When you enable a service, the service is started/restarted when Warden is started/restarted.

See `node services` on page 2292 for more information.

Related tasks

Restarting the Services on page 1141
Describes how to restart a service using either the Control System, the CLI or the REST API.

Starting the Services

Explains how to start services using either the Control System, the CLI or the REST API.

About this task

You can start one or more services using the Control System or the CLI if the service is not disabled. If the service is disabled, you must enable the service first, in order to start the service. See Enabling and Disabling a Service Using the CLI and REST API on page 1138 for more information.

Starting the Services Running on the Nodes Using the Control System

About this task

To start the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Start** radio button for the services you wish to start on the selected nodes and click **Save**.

Starting the Services Running on a Node Using the Control System

About this task

To start one or more services running on a node:

Procedure

1. Go to the **Summary** tab in the node information page.
2. Select the services to start in the **Services** pane.
3. Click **Start Services**.
   The **Start Services** confirmation dialog displays.
4. Verify the list of services to start and click **Start Service**.

Starting the Services on the Cluster Using the Control System

Procedure

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. On the non-Kubernetes version of the Control System, click ▶ for the service to start.
   The **Start Service** confirmation dialog displays.
3. Verify the list of nodes on which to start the service and click **Start Service**.

Starting a Service Using the CLI or REST API

About this task

The basic command to start a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action start
```

For complete reference information, see `node services` on page 2292.

Stopping the Services

Describes how to stop services using either the Control System, the CLI or the REST API.

Stopping the Services Running on the Nodes Using the Control System

About this task

To stop the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   NOTE: The **Nodes** page is not available in the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Stop** radio button for the services you wish to stop on the selected nodes and click **Save**.

Stopping the Services on a Node Using the Control System

About this task

To stop one or more services running on a node:

Procedure

1. Go to the **Summary** tab in the node information page.
2. Select the services to stop in the **Services** pane.
3. Click **Stop Services**.
   The **Stop Services** confirmation dialog displays.
4. Verify the list of services to stop and click **Stop Service**.

Stopping a Service on the Cluster Using the Control System

Procedure

1. Log in to the Control System and click **Services**.
2. On the non-Kubernetes version, click  associated with the service to stop.
   The **Stop Service** confirmation dialog displays.
3. Verify the list of nodes on which to stop the service and click **Stop Service**.

Stopping the Services Using the CLI or REST API

About this task

The basic command to stop a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action stop
```

For complete reference information, see node services on page 2292.

Restarting the Services

Describes how to restart a service using either the Control System, the CLI or the REST API.

last-updated: Jun 06, 2024

About this task

When a HPE Ezmeral Data Fabric system is rebooted, the following services are automatically restarted:

- mapr-warden
- mapr-zookeeper
- mapr-loopbacknfs
- mapr-posix-client-*

These services are also automatically restarted if they are shut down externally (as opposed to being shut down explicitly via `service` or `sysctl` commands).

NOTE: This feature is implemented with `systemd` and is only supported on the following operating systems:

- RHEL 7.0, 7.1
- CentOS 7.0, 7.1
- SLES 12

This feature is not supported on any of the Ubuntu versions that HPE Ezmeral Data Fabric currently supports.

You can restart one or more services using the Control System and the CLI if the services are not disabled. However, if a service is disabled, the service cannot be restarted. To restart a service, make sure the service is enabled. See Enabling and Disabling a Service Using the CLI and REST API on page 1535 for more information.

Restarting the Services Running on the Nodes Using the Control System

About this task

To restart the services running on the nodes:

Procedure

1. Log in to the Control System and click **Nodes** to display the **Nodes** page.

   NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

2. Select the nodes from the list of nodes in the **Nodes** pane and click **Manage Services** to display the **Manage Services** window.
3. Choose the **Restart** radio button for the services you wish to restart on the selected nodes and click **Save**.

Restarting one or more Services on a Node Using the Control System

Procedure

1. Go to the **Summary** tab in the node information page.
2. Select the services to restart in the **Services** pane.
3. Click **Restart Service(s)**.
   The **Restart Service(s)** confirmation dialog displays.

last-updated: Jun 06, 2024

4. Verify the list of services to restart and click **Restart Service**.

Restarting the Services on the Cluster Using the Control System

Procedure

1. Log in to the Control System and navigate to **Services**.
2. On the non-Kubernetes version, click  associated with the service to restart.
   The **Restart Service** confirmation dialog displays.
3. Verify the list of nodes on which to restart the service and click **Restart Service**.

Restarting a Service Using the CLI or REST API

About this task

The basic command to restart a service on a node is:

```
maprcli node services -nodes <node name> -name <service> -action restart
```

For complete reference information, see `node services` on page 2292.

Related tasks

Enabling and Disabling a Service Using the CLI and REST API on page 1535
Describes how to enable or disable a service using either the REST API or the CLI.

Viewing a Service Information Page
Describes how to view the information pages for the installed services using the Control System.

About this task

Procedure

1. Log in to the Control System and click **Services**.

    **NOTE:** The **Services** page is not available on the Kubernetes version of the Control System.

   The **Services** pane displays the list of services that are installed on the cluster.
2. Click the name of the service from the list.
   The information page for the service displays.

Changing the User for Data Fabric Services from the Command-Line
Explains how use the CLI to change the user that data-fabric services run as.

About this task

All services should run with the same uid/gid on all nodes in the cluster.

Running Data Fabric Services as the Root User

Procedure

1. Stop Warden.

   ```
   service mapr-warden stop
   ```

last-updated: Jun 06, 2024

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. Run the script `$INSTALL_DIR/server/config-mapr-user.sh -u root`
4. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

5. Start Warden.

```
service mapr-warden start
```

Running Data Fabric Services as a Non-Root User

Procedure

1. Stop Warden.

```
service mapr-warden stop
```

2. If ZooKeeper is installed on the node, stop it.

```
service mapr-zookeeper stop
```

3. If the MAPR_USER does not exist, create the user/group with the same UID and GID.
4. If the MAPR_USER exists, verify that the uid of MAPR_USER is the same as the value on the CLDB node.
5. Run `$INSTALL_DIR/server/config-mapr-user.sh -u MAPR_USER`.
6. If Zookeeper is installed, start it.

```
service mapr-zookeeper start
```

7. Start Warden.

```
service mapr-warden start
```

8. After clearing NODE_ALARM_MAPRUSER_MISMATCH alarms on all nodes, run `$INSTALL_DIR/server/upgrade2mapruser.sh` on all nodes wherever the alarm is raised.

Viewing the Service Log

Esplains how to view service logs using Kibana.

About this task

If Kibana is installed on the node, you can view the service log in the Kibana UI from the Control System. To view the log in the Kibana UI from the Control System:

Procedure

1. Log in to the Control System and do one of the following:
   - Click **Services** to display the list of services installed on the cluster.
   - Go to the **Summary** tab in the service information page for the service.
2. Click  in the **Log Viewer** column to view the log for the associated service in the Kibana UI. See Kibana User Guide for more information.

Viewing CLDB Information

Describes how to view CLDB information from the CLDB page, and provides an explanation of each field that the page displays.

The CLDB page on the Control Panel provides information about the Container Location Database (CLDB). The CLDB is a management service that tracks container locations and the root of volumes.

To display the CLDB information page, log in to the Control System and go to the service information page for CLDB. Alternatively, you can use the following links to access the CLDB page:

- For a *secure* cluster, access the CLDB view at `https://<cldbmaster>:7443/cldb.jsp`.
- For an *non-secure* cluster, access the CLDB view at `http://<cldbmaster>:7221/cldb.jsp`.

The CLDB page displays the following information:

Container Location Database	*Description:* This section displays: • CLDB Mode: The CLDB node can be in one of the following modes: MASTER_READ_WRITE or SLAVE_READ_ONLY. • CLDB BuildVersion: Lists the build version. • Master for CLDB volume ready: Indicates whether the CLDB volume is ready for use. • CLDB Status: The status of the CLDB node. • Cluster Capacity: The storage capacity for the cluster. • Cluster Used: The amount of storage in use. • Cluster Available: The amount of available storage. • Cluster Used Percentage: The percentage of storage in use.
Active FileServers	*Description:* Displays information about the File Servers in use: • ServerID (Hex): The server's ID in hexadecimal notation. • ServerId: The server's ID in decimal notation. • HostPort: The IP address of the file server. • HostName: The hostname assigned to the file server.

last-updated: Jun 06, 2024

	• Network Location: The network topology for the file server. • Last Heartbeat (s) : The timestamp for the last received heartbeat. • State: Is the file server ACTIVE (in use at present) • Capacity (MB): Total storage capacity on the file server. • Used (MB): Storage used on the file server. • Available (MB): Storage available on the file server. • In Transit (MB): Amount of data in transit
Active NFSServers	*Description:* Displays information about the NFS Servers in use: • ServerID (Hex): The server's ID in hexadecimal notation. • ServerId: The server's ID in decimal notation. • HostPort: The IP address of the NFS server. • HostName: The hostname assigned to the NFS server. • Last Heartbeat (s) : The timestamp for the last received heartbeat. • State: Is the NFS server ACTIVE (in use at present)
Volumes	*Description:* Displays information about the volumes on the container: • Volume Name: The name of the volume. Click the name of the volume to view the containers of the volume (including the container ID, size (in MB), container primary location and container locations, and replication type, which can be S for sequential and C for cascading). • Mount Point: The path in which the volume is mounted over NFS. • Mounted: Specifies whether volume is mounted. Value can be Y or N. • ReadOnly: Specifies whether volume is a read-only or read/write volume. Value can be Y (if volume is read-only) or N (if volume is read/write). • Volume ID: The Volume ID. • Volume Topology: The path describing the topology to which the volume is assigned. • Quota: The total size of the volume's quota. A quota of 0 means no quota is assigned.

last-updated: Jun 06, 2024

- Advisory Quota: The usage level that triggers a disk usage warning.
- Used: Total size of data written to the volume after compression.
- LogicalUsed: Actual size of data written to the volume.
- Root Container ID: The ID of the root container.
- Replication: The number of copies of the volume.
- Guaranteed Replication: The minimum number of copies of the volume.

Accountable Entities

Description: Displays information about users and groups:

- AE Name: The name of the accountable entity.
- AE Type: The type of accountable entity.
- AE Quota: The hard quota allocated to the accountable entity.
- AE Advisory Quota: The advisory quota limit for the accountable entity.
- AE Used: The amount of disk space used by the accountable entity.

Mirrors Information

Description: Contains a link to the Mirrors page, which displays information about volume mirrors:

- Mirror Volume Name: The name of the mirror volume.
- Mirror ID: The ID of the mirror volume used for the last successful mirroring. This ID starts with 1 and is incremented by 1 after each mirroring.
- Mirror NextID: The ID to be used for the next mirroring operation.
- Mirror Status: The status of the mirroring operation.
- Last Successful Mirror Time: The date and time stamp from the last successful mirroring operation.
- Mirror SrcVolume: The source volume for the mirror volume.
- Mirror SrcRootContainerID: The source container ID for the mirror volume.
- Mirror SrcClusterName: The source cluster name for the mirror volume.
- Mirror SrcSnapshot: The source snapshot associated with the mirror volume.

last-updated: Jun 06, 2024

- Mirror DataGenerator Volume: The first volume that generates data (RW Volume) in the mirror chain.

  For example, if the mirror chain is **A** > **B** > **C**, then at C, the Mirror DataGenerator volume is A while the source volume is B.

- Mirror DataGenerator snapshot time: The time at which the last snapshot for the Mirror DataGenerator Volume was generated.

Snapshots Information

Description: Contains a link to the Snapshots page, which displays information about snapshots:

- Snapshot ID: The ID of the snapshot.
- RW Volume ID: The ID of the standard (or read/write) volume associated with the snapshot.
- Snapshot Name: The name of the snapshot.
- Root Container ID: The ID of the container.
- Snapshot Size: The size of the snapshot.
- Snapshot InProgress: The status of the snapshot if it is currently in progress.

The page also displays a list of snapshot containers, and the following information about each:

- Snapshot Container ID: The unique ID of the container.
- Snapshot ID: The ID of the snapshot corresponding to the container.
- RW Container ID: The corresponding source container ID.
- Latest Epoch: The latest sequence number of the snapshot. Higher the number, the newest and most up-to-date is the snapshot.
- SizeMB: The container size, in MB.
- Container Master Location: The location of the container's primary replica.
- Container Locations: The location of the data containers.
- Inactive Locations: The location of inactive containers.

Storage Pools

Description: Displays information about storage pools:

- SP: The ID of the storage pool.
- ServerId: The ID of the server associated with the storage pool.
- SpIdx: The index of the storage pool.
- Last Heartbeat(s): The timestamp for the last received heartbeat.

last-updated: Jun 06, 2024

	• Capacity: The total capacity of the storage pool. • Used: The amount of space used on the storage pool. • Disk Fullness Level (percentage): The percentage of disk space (associated with the storage pool) that is full. • InTransit: Indicates that some containers in the storage pool are being resynced. • OutTransit: Indicates that none of the containers in the storage pool are being resynced.
Active Container Moves	*Description:* Displays information about the containers being moved: • Container ID: The ID of the container being moved. • SizeMB: The size (in MB) of the container being moved. • From Location: The location from where the container is being moved. • From SP: The SP out of which the container is being moved. • To Location: The location to which the container is being moved. • To SP: The SP to which the container is being moved.

Listing CLDB Nodes on page 1546
Describes how to list CLDB nodes in the HPE Ezmeral Data Fabric.

Listing CLDB Nodes

Describes how to list CLDB nodes in the HPE Ezmeral Data Fabric.

Use the nodelist cldbs command to list all the CLDB nodes for a specified cluster.

For example:

```
# maprcli node listcldbs -cluster my.cluster.com -json
{
    "timestamp":1529445021408,
    "timeofday":"2018-06-19 02:50:21.408 GMT-0700 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            "CLDBs":"in111-22.qa.lab,in111-24.qa.lab,in111-21.qa.lab"
        }
    ]
}
```

Alternatively, use the maprcli node list command to find out whether a node is a CLDB node.

SSH into the node as `root` or the Data Fabric admin user, and issue the following command:

```
maprcli node list -columns svc,ip
```

A node is a CLDB node if the service list includes `cldb` as one of the services:. For example:

```
$ maprcli node list -columns svc,ip
hostname
service
                ip
mynode.mycompany.net
s3server,historyserver,resourcemanager,fileserver,cldb,nfs,mastgateway,hosts
tats,apiserver  10.163.167.210
```

Describes how to view CLDB information from the CLDB page, and provides an explanation of each field that the page displays.

Managing Drill

Provides a short description on managing Drill services.

You can install and run a Drillbit service on one node or on all of the nodes on a data-fabric cluster to form a distributed cluster environment. After you have installed Drill and configured connections to your data sources, you can view Drill metrics and manage Drillbits using the Control System.

Viewing Drill Information

Explains how to view Drill information using the Control System.

Viewing Drill Information Using the Control System

Procedure

1. Log in to the Control System and click **Services**.

   NOTE: The **Services** page is not available on the Kubernetes version of the Control System.

2. Click **Drill** in the **Services** pane.

   The **Drill** information page displays the following:

Summary

The **Summary** tab displays the following panes:

Information	Displays the number of Drillbits and the number of completed and in-progress queries.
Resource Utilization	The percentage of CPU, memory, and disk space utilized by Drill.
Running Fragments	The number of query fragments running in the Drillbit during the selected date and time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view. For more information on fragments, see Drill Query Execution.
Memory Used	The amount of direct memory used by the JVM during the selected date and time range. You can select

last-updated: Jun 06, 2024

	a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view. To configure the amount of direct memory allocated to a Drillbit for query processing in a Drill cluster, see Configuring Drill Memory.
Queries	The number of queries during the selected time range. You can select a preset (last 15 minutes, last 1 hour, last 12 hours, last 7 days, last 30 days, last 90 days) or custom time range and zoom in (by clicking and dragging your mouse in the pane) for a more granular view.

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to install the metrics collection infrastructure.

Drill Bits	The **Drill Bits** tab displays the list of Drillbits. See Viewing the List of Drillbits on page 1548.

Viewing the List of Drillbits

Explains how to view the list of Drillbits using the Control System.

About this task

Procedure

- Log in to the Control System and go to the **Drill Bits** tab in the service information page for Drill.
  For each Drillbit, the pane displays the following:

Column Name	Column Description
Drill Bit ID	The ID of the Drillbit.
Node	The node on which the Drillbit is installed.
Service State	The status of the service. Value can be: • Running • Stopped
Queries in Progress	The number of queries currently in progress.
Resource Usage - Memory	The percentage of memory being used.
Resource Usage - CPU	The percentage of CPU being used.

Select the checkbox beside one or more Drillbit IDs to:

- **Stop the Service(s)**

- **Start the Service(s)**
- **Restart the Service(s)**

For more information, see Stopping, Starting, and Restarting Drillbits on page 1549.

Stopping, Starting, and Restarting Drillbits
Explains how to stop, start and restart Drillbits using the Control System.
Stopping Drillbits

Procedure

1. Log in to the Control System and go to the **Drill Bits** tab in the service information page for Drill.
2. Select the checkbox associated with the Drillbit(s) and click **Stop Service(s)** to display the **Stop Service** confirmation dialog.

   You can only stop Drillbits that are currently in running state.
3. Review the list of Drillbits and click **Stop Service** to stop the Drillbits.

Starting Drillbits

Procedure

1. Log in to the Control System and go to the **Drill Bits** tab in the service information page for Drill.
2. Select the checkbox associated with the Drillbit(s) and click **Start Service(s)** to display the **Start Service** confirmation dialog.

   You can only start Drillbits that are currently in stopped state.
3. Review the list of Drillbits and click **Start Service** to start the Drillbits.

Restarting Drillbits

Procedure

1. Log in to the Control System and go to the **Drill Bits** tab in the service information page for Drill.
2. Select the checkbox associated with the Drillbit(s) and click **Restart Service(s)** to display the **Restart Service** confirmation dialog.
3. Review the list of Drillbits and click **Restart Service** to restart the Drillbits.

Managing the HPE Ezmeral Data Fabric NFS Service

Provides an overview of managing the NFS for the HPE Ezmeral Data Fabric service on a licensed cluster.

The data-fabric NFS for the HPE Ezmeral Data Fabric service lets you access data on a licensed HPE Ezmeral Data Fabric cluster using the NFS protocol:

- Community Edition license: one NFS for the HPE Ezmeral Data Fabric node allows you to access your cluster as a standard POSIX-compliant filesystem.
- Enterprise Edition or Enterprise Database Edition license: multiple NFS servers allow each node to mount its own data-fabric filesystem on NFS for the HPE Ezmeral Data Fabric enabled with VIPs for high availability (HA) and load balancing.

You can mount the data-fabric cluster using NFS for the HPE Ezmeral Data Fabric, and use standard shell scripting to read and write live data on the cluster. NFS for the HPE Ezmeral Data Fabric access to cluster

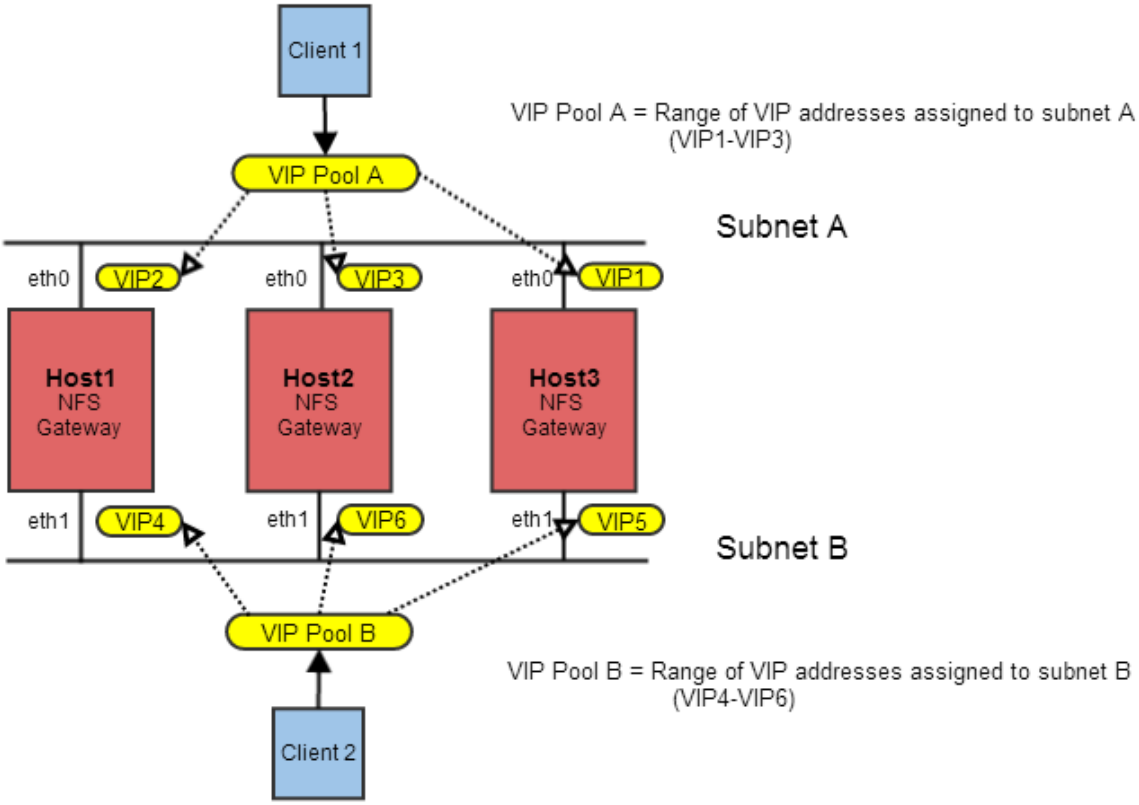
data can be faster than accessing the same data with the `hadoop` commands. To mount the cluster using NFS for the HPE Ezmeral Data Fabric from a client machine, see Accessing Data with NFS v3.

Managing VIPs for NFS
Explains how to use virtual IP addresses (VIPs) on NFS servers.

You can set up a pool of NFS servers on various nodes in your cluster and connect to them using virtual IP addresses (VIPs) to achieve High Availability (HA) with failover; if one node fails, the VIP will automatically be reassigned to another NFS node in the pool. If you do not specify a list of NFS nodes to form a pool, then data-fabric uses any available node running the data-fabric NFS Gateway service. VIPs are not assigned to any nodes that are not on the list, regardless of whether they are running NFS.

NOTE: To add a server to an NFS pool that is not divided into subnets, start the data-fabric NFS service on that server. The data-fabric cluster automatically detects it and adds it to the pool.

The following illustration shows three nodes (Host1, Host2, and Host3) acting as NFS servers. Each node has two NICs whose ports are labeled eth0 and eth1. The NICs are grouped into two subnets, called Subnet A and Subnet B. Clients can access any of the NFS servers through a pool (or range) of VIPs assigned to each subnet. Data Fabric assigns each VIP address in the pool at random to a MAC address in the subnet (with its corresponding physical IP address).



The initial VIP assignment shown above is summarized in the following table. If one NFS server becomes unavailable, the VIP assigned to that server is automatically assigned to another server on the same subnet.

Server	Subnet	VIPs (randomly assigned)
NFS1	A	VIP2
NFS2	A	VIP3
NFS3	A	VIP1

last-updated: Jun 06, 2024

Server	Subnet	VIPs (randomly assigned)
NFS1	B	VIP4
NFS2	B	VIP6
NFS3	B	VIP5

If the cluster's NFS nodes have multiple network interface cards (NICs) connected to different subnets, you should restrict VIP assignment to the NICs that are on the correct subnet: for each NFS server, choose whichever MAC address is on the subnet from which the cluster will be NFS-mounted, then add it to the list.

WARNING: If you add a VIP that is not accessible on the subnet, then failover will not work. Also, do not use duplicate MAC addresses. For example, for bonding interfaces on the cluster nodes, do not use the same MAC address for bond0 and bond0.X, as then the failover of VIP might not work.

You can only set up VIPs for failover between network interfaces that are in the same subnet. In large clusters with multiple subnets, you can set up multiple groups of VIPs to provide NFS failover for the different subnets.

VIPs are evenly distributed across NFS nodes. For example, if six VIP addresses are available for three NFS servers, two VIPs are assigned to each server. If the previous example did not have two separate subnets, the six VIP addresses might be assigned like this:

Server	VIPs (randomly assigned)
N/FS1	VIP1, VIP3
NFS2	VIP4, VIP5
NFS3	VIP2, VIP6

The following sections describe how to set up, edit, and remove VIPs using the Control System and the CLI.

Using Consistent Export Rules
Lists the default NFS export rules.

Export rules (stored in `conf/exports`) should be the same across all NFS nodes that are in the same VIP pool, and for nodes that are configured for the same VIP failover. The default version of `conf/exports` is as follows:

```
# Sample Exports file

# for non /mapr exports
# <Path>  <comma separated cldb addresses=host:port> <exports_control>

# for /mapr exports
# <Path> <exports_control>

#access_control -> order is specific to default
# list the hosts before specifying a default for all
#  a.b.c.d,1.2.3.4(ro) d.e.f.g(ro) (rw)
#  enforces ro for a.b.c.d & 1.2.3.4 and everybody else is rw

# special path to export clusters in mapr-clusters.conf. To disable
exporting,
# comment it out. to restrict access use the exports_control
#
/mapr (rw)

#to export only certain clusters, comment out the /mapr & uncomment.
```

last-updated: Jun 06, 2024

```
# Note: this will cause /mapr to be unexported
#/mapr/clustername (rw)

#to export /mapr only to certain hosts (using exports_control)
#/mapr a.b.c.d(rw),e.f.g.h(ro)

# export /mapr/cluster1 rw to a.b.c.d & ro to e.f.g.h (denied for others)
#/mapr/cluster1 a.b.c.d(rw),e.f.g.h(ro)

# export /mapr/cluster2 only to e.f.g.h (denied for others)
#/mapr/cluster2 e.f.g.h(rw)

# export /mapr/cluster3 rw to e.f.g.h & ro to others
#/mapr/cluster2 e.f.g.h(rw) (ro)
```

Setting Up VIPs for NFSv3
Explains how to set up VIPs for NFS version 3 using either the Control System or the CLI.

About this task

NOTE: The NFSv3 server (`mapr-nfsserver`) nodes cannot failover to NFSv4 server (`mapr-nfs4server`) nodes and vice versa. Ensure that different sets of VIPs are assigned for NFSv3 and NFSv4 server nodes. When running the `maprcli virtualip add` command to set up VIPs, list the MACs of the respective nodes so that the failover works properly (this is necessary when both NFSv3 and NFSv4 are going to be set up on the same cluster). The MACs should be mutually exclusive as both NFSv3 and NFSv4 servers cannot run on the same node.

Adding VIPs Using the Control System

About this task

You can use the Control System to specify a range of virtual IP addresses and assign them to the pool of servers that are running the NFS service. You can also restrict the assignment of virtual IP addresses to certain subnets.

Before following this procedure, make sure:

- You have installed NFS on at least three nodes (recommended).
- You have started the NFS gateway service on the servers to which you plan to assign VIPs.

Procedure

1. Log in to the Control System, click **Services**, and go to the NFS service information page where you can configure VIPs for NFSv3 nodes.

   NOTE: The **Services** page is not available on the Kubernetes version of the Control System.

2. Click **Add Virtual IP** to display the **Add Virtual IP** page.
3. Enter the start of the VIP range in the **Starting Virtual IP** field.

   HPE Ezmeral Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
4. Enter the end of the VIP range in the **Ending Virtual IP** field.

   If you are assigning only one VIP, you can leave the field blank. HPE Ezmeral Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.

5. Enter the Netmask for the VIP range in the **Netmask** field.
   For example: `255.255.255.0`. HPE Ezmeral Data Fabric assigns this netmask to the network interfaces along with the VIPs.
6. Specify whether (**Yes**) or not (**No**) to assign a particular VIP address to a specific server or MAC address. If **Yes**, enter the MAC address for the network interface to be assigned to the Starting Virtual IP address. The remaining VIP addresses from the same pool are assigned randomly.
7. Select one of the following:
   - **Use all network interfaces on all nodes that are running the NFS Gateway service** to set up VIPs that use all network interfaces on all the nodes running the NFS Gateway service.
     If additional NFS Gateway services are started, the network interfaces on their nodes will automatically become candidates for the VIPs in this range.
   - **Select network interfaces** to restrict the assignment of virtual IP addresses to certain subnets:
     A list of available and selected node names, physical IP addresses, and MAC addresses displays. Select from the:
     - Available list and click ▶ to move selection to **Selected** VIPs.
     - Selected list and click ◀ to remove from selected list of VIPs.

     See Designating NICs for HPE Ezmeral Data Fabric on page 1156.
8. Confirm the actual VIP assignment by clicking **Save Changes**.
   It might take up to 40 seconds to assign the VIPs. If necessary, refresh the page in your browser to view the list of VIPs.

Adding VIPs Using the CLI and REST API

About this task

CLI

The basic command to set up VIPs is:

```
maprcli virtualip
add -netmask <netmask> -virtualip
<virtualip> -service nfs3 -json
```

REST

Send a request of type POST. For example:

```
curl -k -X POST 'https://<host>:8443/
rest/virtualip/add?
service=nfs3&netmask=<netmask>&virtual
ip=<vip>' --user mapr:mapr
```

For the complete list of required and optional parameters, see `virtualip add` on page 2559.

Setting Up VIPs for NFSv4
Describes how to setup Virtual IPs (VIPs) for high availability of NFSv4 servers, using either the Control System or the CLI.

About this task

Virtual IP addresses (VIPs) allow you to achieve high availability with failover when the NFS servers use them to connect to your cluster. When configuring VIPs for NFSv4 servers, ensure that you select NFSv4

server nodes only. HPE Ezmeral Data Fabric does not support failing over between NFSv3 and NFSv4 servers.

Adding VIPs Using the Control System

About this task

You can use the Control System to specify a range of virtual IP addresses and assign them to the pool of servers that are running the NFS service. You can also restrict the assignment of virtual IP addresses to certain subnets.

Before following this procedure, make sure that:

- You have installed NFS on at least three nodes (recommended).
- You have started the NFS gateway service on the servers to which you plan to assign VIPs.

Procedure

1. Log in to the Control System and go to the NFS4 service information page where you can configure VIPs for NFSv4 nodes.
2. Click **Add Virtual IP** to display the **Add Virtual IP** page.
3. Enter the start of the VIP range in the **Starting Virtual IP** field.
   HPE Ezmeral Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
4. Enter the end of the VIP range in the **Ending Virtual IP** field.
   If you are assigning only one VIP, you can leave the field blank. HPE Ezmeral Data Fabric distributes the VIPs in this range to the selected network interfaces. VIPs are automatically migrated between the network interfaces when failures occur.
5. Enter the Netmask for the VIP range in the **Netmask** field.
   For example: `255.255.255.0`. HPE Ezmeral Data Fabric assigns this netmask to the network interfaces along with the VIPs.
6. Specify whether (**Yes**) or not (**No**) to assign a particular VIP address to a specific server or MAC address. If **Yes**, enter the MAC address for the network interface to be assigned to the Starting Virtual IP address. The remaining VIP addresses from the same pool are assigned randomly.
7. Select one of the following:
   - **Use all network interfaces on all nodes that are running the NFS Gateway service** to set up VIPs that use all network interfaces on all the nodes running the NFS Gateway service.
     If additional NFS Gateway services are started, the network interfaces on their nodes automatically become candidates for the VIPs in this range.
   - **Select network interfaces** to restrict the assignment of virtual IP addresses to certain subnets:
     The system displays a list of available and selected node names, physical IP addresses, and MAC addresses. Do one of the following:
     - Select from the available list and click ▶ to move the selection to **Selected** VIPs.
     - Choose from the selected list and click ◀ to remove the chosen entries from the selected list of VIPs.

     See Designating NICs for HPE Ezmeral Data Fabric on page 1156.

last-updated: Jun 06, 2024

8. Confirm the actual VIP assignment by clicking **Save Changes**.

   It might take up to 40 seconds to assign the VIPs. If necessary, refresh the page in your browser to view the list of VIPs.

Setting up VIPs for NFSv4 Server from the Command-Line

About this task

To set up VIPs for NFSv4 server:

Procedure

1. Add VIPs to the NFS server nodes in the cluster by running the `virtualip add` on page 2559 command.

   ```
   maprcli virtualip add -virtualip <vip> -virtualipend <vipend> -service
   nfs4 -netmask <netmask> -macs <mac>
   ```

   For example, for a range of virtual IPs use:

   ```
   maprcli virtualip add -virtualip 10.10.104.203 -virtualipend
       10.10.104.206 -service nfs4 -netmask 255.255.255.0 -macs
      "18:e7:28:2e:b0:80 18:e7:28:2e:2d:a0 18:e7:28:2e:2d:a8"
   ```

   For a single virtual IP, do not include the `-virtualipend` parameter. For example:

   ```
   maprcli virtualip add -virtualip 10.10.104.203 -service nfs4 -netmask
   255.255.255.0 -macs
      "18:e7:28:2e:b0:80 18:e7:28:2e:2d:a0 18:e7:28:2e:2d:a8"
   ```

   For the complete list of required and optional parameters, see `virtualip add` on page 2559.

2. Add the hostname for each VIP in the `/etc/hosts` file on all the nodes in the cluster.

3. Add the principal for each VIP and generate the keytab file. That is, repeat this step in the following order for each VIP:

   a) Add the principals for the following:

      - NFS server hostnames in the kerberos server.
      - VIP hostname in the kerberos server.

   b) Generate the keytab file, which contains entries for all the NFS server and VIP hostname principals.

4. Restart the `rpc.gssd` service on all the NFSv4 server nodes.

   To restart, run the following command:

   ```
   service rpcgssd start
   ```

5. Mount the cluster.

Editing a VIP

Explains how to modify the Virtual IP (VIP) range using either the Control System or the CLI.

last-updated: Jun 06, 2024

Editing a VIP Using the Control System

Procedure

1. Log in to the Control System and go to the service information page for NFS.
2. Click the **VIP Range** to modify.
   The **Edit Virtual IP** page displays.
3. Modify changes to one or more of the following as needed.

Preferred MAC Address	The preferred MAC for this virtual IP. When an NFS server restarts, the HPE Ezmeral Data Fabric system attempts to move all of the virtual IP addresses that list a MAC address on this node as a preferred MAC to this node. If the new value is null, this field resets the preferred MAC value.
Select network interfaces	The list of MAC addresses that represent the NICs on the nodes to which the VIPs in the VIP range can be associated. Use this list to limit VIP assignment to NICs on a particular subnet when your NFS server is part of multiple subnets.

4. Click **Save Changes** for the changes to take effect.

Editing a VIP Using the CLI and REST API

About this task

CLI

The basic command to modify a VIP range is:

```
maprcli virtualip edit -netmask
<netmask> -virtualip <virtualip>
```

REST

Send a request of type POST. For example:

```
durl -k -X POST 'https://<host>:8443/
rest/virtualip/edit?
netmast<netmask>&virtualip=<vip>' --us
er mapr:mapr
```

For the complete list of required and optional parameters, see `virtualip edit` on page 2562.

Viewing the List of Virtual IPs

Explains how to view the list of VIPs using either the Control System or the CLI.

Viewing the List of VIPs Using the Control System

Procedure

- Log in to the Control System and go to the service information page for NFS.
  The page displays the following:

Column Name	Column Description
VIP Range	The Virtual IP range.
Virtual IP	The VIP (in the range) of the associated node.
Node Name	The host name of the node.
Physical IP	The physical IP of the associated node.
MAC Address	The MAC address of the network interface that is assigned to the associated VIP.

last-updated: Jun 06, 2024

You can add and remove VIPs.

Retrieving the List of VIPs Using the CLI and REST API

About this task

CLI	The basic command to retrieve a list of VIPs is: `maprcli virtualip list`
REST	Send a request of type GET. For example: `curl -k -X GET 'https://<host>:8443/rest/virtualip/list' --user mapr:mapr`

For complete reference, see `virtualip list` on page 2563.

Removing a VIP
Explains how to remove a VIP range using either the Control System or the CLI.
Removing a VIP Range Using the Control System

Procedure

1. Log in to the Control System and go the service information page for NFS.
2. Select the VIP range(s) to remove and click **Remove Virtual IP**.
   The **Remove Virtual IP** confirmation dialog displays.
3. Review the VIP range(s) to remove and click **Remove Virtual IP**.

Removing a VIP Range Using the CLI or REST API

About this task

The basic command to remove a VIP range is:

```
maprcli virtualip remove -virtualip <virtual IP>
```

For complete reference information, see `virtualip remove` on page 2568.

Accessing Data with NFS v3
Describes how data-fabric works with NFS v3.

Unlike other Hadoop distributions that only allow cluster data import or import as a batch operation, Data Fabric lets you mount the cluster itself using NFS for the HPE Ezmeral Data Fabric so that your applications can read and write data directly. Data Fabric allows direct file modification and multiple concurrent reads and writes using POSIX semantics. With a NFS-mounted cluster, you can read and write data directly with standard tools, applications, and scripts. For example, you could run a MapReduce application that outputs to a CSV file, then import the CSV file directly into SQL using NFS for the HPE Ezmeral Data Fabric.

Data Fabric exports each cluster as the directory `/mapr/<cluster name>` (for example, `/mapr/my.cluster.com`). If you create a mount point with the local path `/mapr`, then Hadoop FS paths and NFS v3 paths to the cluster will be the same. This makes it easy to work on the same files using NFS v3 and Hadoop. In a multi-cluster setting, the clusters share a single namespace, and you can see them all by mounting the top-level `/mapr` directory.

last-updated: Jun 06, 2024

WARNING: Data Fabric uses version 3 of the NFS protocol. NFS version 4 bypasses the port mapper and attempts to connect to the default port only. If you are running NFS on a non-standard port, mounts from NFS version 4 clients time out. Use the `-o nfsvers=3` option to specify NFS v3.

CAUTION: It is observed that NFS v3 clients are caching older `atime` values from previous history. Therefore, you might observe wrong `atime` values. To mitigate, make sure to clear caches, before checking file timestamps.

You can mount the cluster on a Linux, Mac, or Windows client. Before you begin, make sure you know the hostname and directory of the NFS v3 share you plan to mount.

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv3
Explains how to start, stop, and restart NFS version 3 using either the Control System or the CLI.
Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv3 Using the Control System

About this task

See:

- Starting the Services on the Cluster Using the Control System on page 1140
- Stopping a Service on the Cluster Using the Control System on page 1141
- Restarting the Services on the Cluster Using the Control System on page 1142

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv3 Using the CLI and REST API

About this task

NFSv3 Server	The command to stop, start, or restart HPE Ezmeral Data Fabric NFSv3 server is: `maprcli node services -nodes <node names> -nfs stop|start|restart`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<nodeNames>&nfs=stop|start|restart' -- user mapr:mapr`

NOTE: When NFS server is stopped, the VIPs associated with the server are released, and CLDB attempts to reassign the VIPs to other available NFS servers. For the complete list of parameters, see `node services` on page 2292.

Setting Up Aliases for NFS Exports

About this task

When provisioning file system for various tenants, you can set up an alias for the path in file system, rather than exporting the whole path, to mask the path from the users. Once the alias is set up, users will not be able to access or mount the path in file system.

Aliases can be set up for the cluster, volume, and directory, but not for the root of the path in file system (`/mapr`). To set up an alias for a path in file system:

last-updated: Jun 06, 2024

Procedure

1. Open the NFS exports file in `/opt/mapr/conf/` directory.
2. Specify the alias name for the mount path using the following syntax:

   ```
   <path in MFS> /<alias name> <options>
   ```

   Here:

`<path in MFS>`	Refers to the file system mount path. If this points to a: • Volume, the user can access the snapshots associated with the volume. • Directory, the user cannot access the snapshots.
`/<alias name>`	Refers to the alias name to use. If there are duplicate aliases in the file, the last entry will take effect and all other duplicate entries will be ignored. If the alias name is not specified, the path in file system will be exported.
`<options>`	The list of available/supported options.

   For example, suppose a file system mount path of `/mapr/samplecluster/samplevolume` for tenant samplecustomer. To set up an alias, add the following to the exports file:

   ```
   /mapr/samplecluster/samplevolume /samplecustomer (rw)
   ```

   For example, to export a certain cluster, volume, or a subdirectory as an alias, comment out `/mapr` and add the following:

   ```
   /mapr/clustername /alias1 (rw)
   /mapr/clustername/vol /alias2 (rw)
   /mapr/clustername/vol/dir /alias3 (rw)
   ```

   NOTE: Only the alias will be visible/exposed to the NFS client.
3. Run the following command for the file changes to take effect:

   ```
   /opt/mapr/bin/maprcli nfsmgmt refreshexports
   ```

4. Run the following command to export the path:

   ```
   mount -t nfs nfsServer:/<alias_name> /localpath
   ```

   Run this command once for each entry in the file.

What to do next

The same export rules must be set up on all the NFS servers in the cluster to ensure that in the event of a node failure, the same aliases work with VIP failover.

Mounting NFS for the HPE Ezmeral Data Fabric to file system on a Cluster Node

You can *automatically* or *manually* mount NFS for the HPE Ezmeral Data Fabric to the file system on a cluster node.

NOTE: The procedure works only on nodes where NFS service is installed.

Automatically Mount

last-updated: Jun 06, 2024

Use this procedure to *automatically* mount NFS for the HPE Ezmeral Data Fabric to file system on the cluster *my.cluster.com* at the `/mapr` mount point.

1. Set up the mount point by creating the directory.

```
sudo mkdir /mapr
```

2. Add the following line to `/opt/mapr/conf/mapr_fstab:`

```
<hostname>:/mapr /mapr hard,nolock
```

NOTE: The change to `/opt/mapr/conf/mapr_fstab` will not take effect until Warden is restarted.

Every time your system is rebooted, the mount point is automatically re-established according to the `mapr_fstab` configuration file.

Manually Mount

Use this procedure to *manually* mount NFS for the HPE Ezmeral Data Fabric to file system on the cluster *my.cluster.com* at the `/mapr` mount point.

1. Set up a mount point for a NFS for the HPE Ezmeral Data Fabric share.

```
sudo mkdir /mapr
```

2. Mount the cluster via NFS for the HPE Ezmeral Data Fabric.

```
sudo mount -o hard,nolock usa-node01:/mapr /mapr
```

NOTE: When you mount manually from the command line, the mount point does not persist after a reboot.

Mounting NFS on a Linux Client
Explains how to mount NFS on a Linux client either automatically at start up or manually.

You can *automatically* or *manually* mount NFS on a Linux client when your system starts up.

Automatically Mount

Use this procedure to *automatically* mount to NFS on a Linux client when your system starts up.

Add an NFS mount to `/etc/fstab`.

```
# device          mountpoint      fs-type      options      dump fsckorder
...
usa-node01:/mapr  /mapr_nfs/         nfs          rw           0    0
...
```

Manually Mount

Use this procedure to *manually* mount to NFS on a Linux client.

1. Install the NFS client.
   - `sudo yum install nfs-utils` (Red Hat or CentOS)
   - `sudo apt-get install nfs-common` (Ubuntu)

last-updated: Jun 06, 2024

- `sudo zypper install nfs-client` (SLES)

2. List the NFS shares exported on the server. For example:

```
showmount -e usa-node01
```

NOTE: If the NFS protocol is v4 only, the `showmount` command does not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

3. Set up a mount point for an NFS share. For example:

```
sudo mkdir /mapr_nfs/
```

4. Mount the cluster using NFS. Use the command as in the following example:

```
sudo mount -t nfs -o sec=mode vers=NFS_version usa-node01:/mapr /
mapr_nfs/
```

where mode is one of the following:

- krb5 for Kerberos version 5 authentication service.
- krb5i for Kerberos version 5 with integrity.
- krb5p for Kerberos version 5 with privacy.
- none for no authentication.

and NFS_version is either 3 or 4.

RESTRICTION: You can use the `sec=mode` option only for NFS version 4. NFS version 3 does not support this option.

TIP: For the best performance, use NFS v4.0.

Use the `vers=4.0` parameter in the mount command. For example:

```
mount -t nfs -o sec=krb5,vers=4.0 usa-node01:/mapr /mapr_nfs/
```

For NFS v3, use the command as in the following example:

```
mount -t nfs -o vers=3 usa-node01:/mapr /mapr_nfs/
```

NOTE: The mount point does not persist after reboot when you mount manually from the command line.

5. List all mounted file systems to verify that the cluster is mounted. For example:

```
$ mount | grep nfs4
  usa-node01:/mapr on /mapr_nfs (nfs, nodev, nosuid, mounted by testUser)
```

last-updated: Jun 06, 2024

Mounting NFS on a Mac Client

Describes how to mount a NFS server on a Mac client.

About this task

Use this procedure to mount to the cluster *manually* from the command line:

Procedure

1. Open a terminal. For example, you can click on **Launchpad > Open terminal**.
2. At the command line, enter the following command to become the root user:
   ```
   sudo bash
   ```
3. List the NFS shares exported on the server. For example:
   ```
   showmount -e usa-node01
   ```
4. Set up a mount point for an NFS share. For example:
   ```
   sudo mkdir /mapr_nfs/
   ```
5. Mount the cluster using NFS. Use the command as in the following example:
   ```
   sudo mount -t nfs -o vers=3 usa-node01:/mapr /mapr_nfs/
   ```
   NOTE: The mount point does not persist after reboot when you mount manually from the command line.
6. List all mounted file systems to verify that the cluster is mounted. For example:
   ```
   $ mount | grep nfs
   usa-node01:/mapr on /mapr_nfs (nfs, nodev, nosuid, mounted by testUser)
   ```

Mounting NFS on a Windows Client

Describes how to mount an NFS share on a Windows client, and configure the relevant user and group IDs.

About this task

To set up the Windows NFS client, mount the cluster, map a network drive, and configure the user ID (UID) and group ID (GID). The Windows client must access NFS using a valid UID and GID from the Linux domain. Mismatched UID or GID results in permission problems when MapReduce jobs try to access files that were copied from Windows over an NFS share.

Due to Windows directory caching, the `.snapshot` directory may not appear in the root directory of each volume. As a workaround, you can force Windows to re-load the volume's root directory by updating its modification time (for example, by creating an empty file or directory in the volume's root directory).

With Windows NFS clients, use the `-o nolock` option on the NFS server to prevent the Linux NLM from registering with the portmapper. The native Linux NLM conflicts with the HPE Ezmeral Data Fabric NFS server.

Complete the following steps to mount NFS on a Windows client:

last-updated: Jun 06, 2024

Procedure

1. Mount the Cluster.

Windows 10 Enterprise

Complete the following steps for *Windows 10 Enterprise*

a. Open **Start > Control Panel > Programs**.

b. Select **Turn Windows features on or off**.

c. Select **Services for NFS**.

d. Click **OK**.

e. Enable write permissions for the anonymous user as the default options only grant read permissions when mounting a UNIX share using the anonymous user.

   To grant write permissions, make a change to the Windows registry by performing the following steps:

   1. Open `regedit` by typing it in the search box and pressing **Enter**.
   2. Create a new **New DWORD (32-bit) Value** inside the `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default` folder named `AnonymousUid` and `AnonymousGid` and assign the UID and GID found on the UNIX directory as shared by the NFS system.

f. Restart the NFS client or reboot the machine to apply the changes.

g. Mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o anon usa-node01:/mapr z:
```

   For more information, see step 2.

Windows 7 Enterprise

Complete the following steps for *Windows 7 Ultimate* or *Windows 7 Enterprise*

a. Open **Start > Control Panel > Programs**.

b. Select **Turn Windows features on or off**.

c. Select **Services for NFS**.

d. Click **OK**.

last-updated: Jun 06, 2024

e. Mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o nolock usa-node01:/mapr
z:
```

For more information, see step 2.

Other Versions of Windows

Complete the following steps for all other versions of Windows:

a. Download and install Microsoft Windows Services for Unix (SFU). You only need to install the NFS Client and the User Name Mapping.

b. Configure the user authentication in SFU to match the authentication used by the cluster (LDAP or operating system users). You can map local Windows users to cluster Linux users, if desired.

c. Once SFU is installed and configured, mount the cluster and map it to a drive using the Map Network Drive tool or from the command line.

```
mount -o nolock usa-node01:/mapr
z:
```

For more information, see step 2.

2. Map a network drive with the Map Network Drive tool.

a) Open **Start > My Computer**.

b) Select Tools > Map Network Drive.

c) In the Map Network Drive window, choose an unused drive letter from the **Drive** drop-down list.

d) Specify the folder by browsing for the MapR cluster, or by typing the hostname and directory into the text field.

e) Browse for the MapR cluster or type the name of the folder to map. This name must follow UNC. Alternatively, click **Browse…** to find the correct folder by browsing available network shares.

f) Select **Reconnect at login** to reconnect automatically to the MapR cluster whenever you log into the computer.

g) Click **Finish**.

3. Configure the UID and GID for NFS access.

System that is part of Active Directory Domain

For a system that is part of the Active Directory Domain, you must instruct the NFS client to access an AD server to get `uidNumber` and `gidNumber`.

a. Ensure that the AD Users schema has auxiliary class `posixAccount`.

last-updated: Jun 06, 2024

	b. Populate the AD `uidNumber` and `gidNumber` fields with the matching `uid` and `gid` from Linux. **c.** Configure the NFS client to look up `uid` and `gid` in the AD DS store. **d.** Refer to details here: `http://technet.microsoft.com/en-us/library/hh509016(v=ws.10).aspx`.
System not using Active Directory	For a standalone Windows 7 or Vista machine (not using Active Directory), Windows always uses its configured anonymous UID and GID for NFS access, which by default are `-2`. However, you can configure Windows to use specific values, which results in being able to access NFS using those values. The UID and GID values are set in the Windows Registry and are global on the Windows NFS client box. This solution might not work well if your Windows box has multiple users who each need access to NFS with their own permissions, but there is no obvious way to avoid this limitation. The values are stored in the registry path `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default`. The two DWORD values are `AnonymousUid` and `AnonymousGid`. If they do not exist, you must create them. Refer to details here: `https://docs.microsoft.com/en-us/archive/blogs/msdn/sfu/can-i-set-up-user-name-mapping-in-windows-vista`.

4. (Optional) Deactivate the `nlockmgr` service.

   If the `nlockmgr` service is active on a Windows machine, attempts to mount a HPE Ezmeral Data Fabric NFS share fail with the following message:

   ```
   C:\Users\administrator.Client1>mount -o nolock -u:mapr -p:mapr
   ClusterNode1:/mapr / g:
   Network Error - 53
   Type 'NET HELPMSG 53' for more information.
   ```

   a) Run the `rpcinfo` command to confirm that the `nlockmgr` service is active.

   ```
   C:\Users\administrator.Client1>rpcinfo -p ClusterNode1
   program version protocol     port
   -------------------------------------------------
   100000       4      tcp      111    portmapper
   100024       1      udp    60588    status
   100007       2      udp      817    ypbind
   100021       1      udp    47016    nlockmgr
   100021       3      udp    47016    nlockmgr
   100021       4      udp    47016    nlockmgr
   100021       1      tcp    34254    nlockmgr
   100021       3      tcp    34254    nlockmgr
   100021       4      tcp    34254    nlockmgr
   ```

b) Check the output for the presence of `nlockmgr`. To deregister `nlockmgr` services on the node, use the `-d` switch in `rpcinfo` on the HPE Ezmeral Data Fabric node.

```
rpcinfo -d 100021 1
rpcinfo -d 100021 2
rpcinfo -d 100021 3
rpcinfo -d 100021 4
```

c) Re-check `rpcinfo` output to verify that no `nlockmgr` services are registered. The NFS mount completes successfully at this point.

```
C:\Users\administrator.Client1>mount -o nolock -u:mapr -p:mapr
ClusterNode1:/mapr/ Z:
Z: is now successfully connected to ClusterNode1:/mapr/
The command completed successfully.
```

Configuring Access When ACES are set

About this task

Some NFS clients, such as the Microsoft native Windows NFSv3 client, check mode bits to determine if access is allowed even before contacting the NFS server. If *ACE*s are set on a directory or file, the client-side permission checks based solely on mode bits prevent the client from accessing the file or directory. You can set the value for the `WindowsAceSupport` property to `true` in the `nfsserver.conf` on page 2989 file to allow the Windows client access to the file or directory. The default value for this property is `false`, and denies access to the client even before contacting the NFS server.

When the `WindowsAceSupport` property value is set to `true`, HPE Ezmeral Data Fabric returns mode bits 777 to the client if *ACE* is set on the file or directory, thus allowing the client to establish a connection to the server. However, when the client actually tries to read or write from the server, HPE Ezmeral Data Fabric performs permission checks against the mode bits and *ACE*s on the directory and/or file, ensuring proper access.

NOTE: When the `WindowsAceSupport` property value is set to `true`:

- Tools that visually display access information might show read/write access for users who do not have that access.
- Files that are not executables might appear executable.
- You cannot use the NFSv3 to access an NFSv4 server, because the NFSv4 server only supports the v4 protocol.

Configuring the Linux NFS Client
Describes how to set the optimal number of RPC requests to the NFS server.

About this task

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128.

Perform the following steps as the `root` user on each NFS client machine:

last-updated: Jun 06, 2024

Procedure

1. To enable the configuration to persist after a reboot of the NFS client machine, issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
```

2. To enable the configuration to take effect after you remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway, issue the following echo commands:

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

3. Remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway. For example, the following commands unmount and mount NFS for the HPE Ezmeral Data Fabric assuming that the cluster is mounted at `/mapr`:

```
umount /mapr
mount -o hard,nolock <hostname>:/mapr /mapr
```

NOTE: Failure to configure this property may result in the following error in `/opt/mapr/logs/nfsserver.log`:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0]
cannot allocate more OncRpcContexts: [numDropped=2556001]
dropping connection from nfsc=10.13.64.225:0
```

TIP: For CentOS, after the reboot of the node, if the `/proc/sys/sunrpc` directory is not available or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command:

```
service rpcidmapd start
```

Accessing Data with NFS v4

Describes how HPE Ezmeral Data Fabric works with the NFS v4 protocol. Presents an overview of the process flow to read and write HPE Ezmeral Data Fabric processes with NFS v4, and a list of NFS v4 features that HPE Ezmeral Data Fabric does not support.

HPE Ezmeral Data Fabric lets you mount the cluster using NFS v4 so that your applications can read and write data directly. HPE Ezmeral Data Fabric allows direct file modification and multiple concurrent reads and writes using POSIX semantics. With an NFS v4-mounted cluster, you can read and write data directly with standard tools, applications, and scripts. For example, you could run a MapReduce application that outputs to a CSV file, then import the CSV file directly into SQL using NFS v4.

HPE Ezmeral Data Fabric uses NFS Ganesha for supporting NFS v4 features. NFS Ganesha is an Open Source userspace implementation of the NFS v4 server. The following table summarizes the NFS Ganesha versions used by various Ezmeral Data Fabric release versions.

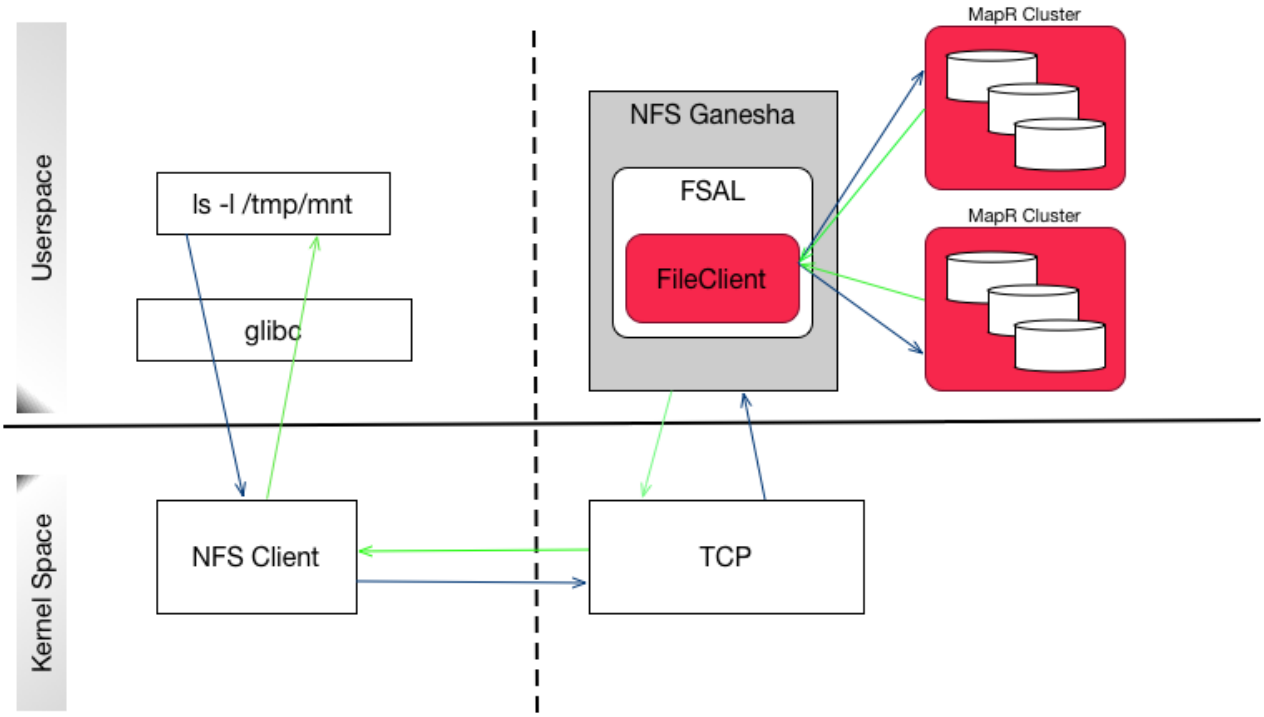
Ezmeral Data Fabric release version	NFS Ganesha release version used
Upto version 6.1	Version 2.3

last-updated: Jun 06, 2024

Ezmeral Data Fabric release version	NFS Ganesha release version used
Version 6.2 to version 7.6	Version 3.3
Version 7.7	Version 5.7

The HPE Ezmeral Data Fabric NFS v4, running as a userspace process, registers callbacks with NFS Ganesha through the File System Abstraction Layer (FSAL), which is a shared library (`libfsalmapr.so`). NFS Ganesha loads and uses this library whenever the file system is exported/mounted. The FSAL, in turn, uses FileClient (`libMapRClient.so`) to connect to the cluster.

The following diagram illustrates how the HPE Ezmeral Data Fabric processes read and write operations to the HPE Ezmeral Data Fabric cluster using NFS v4. When the user enters a command (such as `ls`), the NFS client submits the request over TCP to the HPE Ezmeral Data Fabric NFS v4 server. The NFS v4 server uses the HPE Ezmeral Data Fabric FileClient to perform the requested operation on the cluster and returns the response to the NFS v4 client over TCP.



HPE Ezmeral Data Fabric exports each cluster as the directory `/mapr/<cluster name>` (for example, `/mapr/my.cluster.com`). If you create a mount point with the local path `/mapr`, then Hadoop FS paths and NFS v4 paths to the cluster are the same. This makes it easy to work on the same files using NFS v4 and Hadoop. In a multi-cluster setting, the clusters share a single namespace, and you can see them all by mounting the top-level `/mapr` directory.

For NFS v4, HPE Ezmeral Data Fabric also requires alias or pseudo-path, which when specified masks the mount path from the NFS v4 client. HPE Ezmeral Data Fabric's NFS v4 server provides a pseudo-filesystem where only the exported volumes are visible. This is especially useful in scenarios where one or more volumes in the hierarchy should be hidden and not be visible. For more information, see NFS v4 RFC.

CAUTION: It is observed that NFS v4 clients are caching older `atime` values from previous history. Therefore, you might observe wrong `atime` values. To mitigate, make sure to clear caches, before checking file timestamps.

last-updated: Jun 06, 2024

Unsupported NFS v4 Features

HPE Ezmeral Data Fabric does not currently support the following NFS v4 features:

- pNFS
- Delegations
- Mandatory locking
- Lock upgrades and downgrades
- Deny share
- *ACL*
- Namespaces
- Persistent reply cache
- Data retention
- Attributes such as time_access, FATTR4_ARCHIVE, FATTR4_FILES_AVAIL, FATTR4_FILES_FREE, FATTR4_FILES_TOTAL, FATTR4_FS_LOCATIONS, FATTR4_MIMETYPE, FATTR4_QUOTA_AVAIL_HARD, FATTR4_QUOTA_AVAIL_SOFT, FATTR4_QUOTA_USED, FATTR4_TIME_BACKUP, and FATTR4_ACL

Configuring the NFSv4 Server

You can configure NFSv4 server by setting the values for the parameters in the `/opt/mapr/conf/nfs4server.conf` file. The configuration parameters are defined within blocks in the file. The following sections describe the blocks and required parameters (within each block) for the data-fabric NFSv4 server.

By default, the NFSv4 server is configured to rely on a Kerberos infrastructure. If you don't want or don't have a Kerberos infrastructure, comment out the `SecType` parameter of the EXPORT section.

NFS_CORE_PARAM

Contains the general settings for the daemon. The parameters in this block should not be modified.

`Clustered`	The value is `false`. Do not modify this parameter.
`Plugins_Dir`	The directory for the FSAL libraries. The value is `/opt/mapr/lib`. Do not modify this parameter.
`DRC_TCP_Size`	The maximum number of results stored in the DRC. The default value is `16`.
`DRC_TCP_Recycle_Expire_S`	The amount of time after which to expire results stored in DRC. The default value is `60` seconds.
`Dirent_Entries_Track`	Specifies whether (`true`) or not (`false`) to monitor dirent entries. If `true`, the process restarts if the number of dirent entries exceeds limit.

last-updated: Jun 06, 2024

`Num_Log_Files`	The maximum number of log files. The default value is `1`.
`Max_Logfile_Size`	The maximum amount of space for each log file. The default value is `1073741824`. The total amount of disk space for log files is calculated using the following: `Num_Log_Files * Max_LogFile_Size` For example, suppose `Num_Log_Files = 32` and `Max_LogFile_Size = 1GB`. Then, the total disk space for log files is 32GB.
`Enable_RQUOTA`	Specifies whether (`true`) or not (`false`) to enable support for remote quotas. The default value is `false`.
`NFS_Protocols`	The supported NFS protocols. The only supported value is `4`.

NFSV4

Contains settings for the NFSv4 protocol. The following parameters should not be modified.

`Delegations`	boolean	Specifies whether delegation is supported. The default value is `false` and should not be modified (cannot be set to `true`) as delegation is not supported.

`Dirent_Cache_Threshold`	128	The threshold for caching directory entries. If directory entries exceed threshold, the entries are not cached; caching is enabled only if entries are below this threshold. **NOTE:** This should be used only if `readdirplus` is `true`.

EXPORT_DEFAULTS

Contains default values for all subsequent EXPORT blocks. The settings in subsequent EXPORT blocks can override these default values on a per export basis.

`Anonymous_Uid`	The anonymous UID. The default value is `-2`, which is converted to a 32 bit unsigned integer (4294967294) when root squash is enabled.
`Anonymous_Gid`	The anonymous GID. The default value is `-2`, which is converted to a 32 bit unsigned integer (4294967294) when root squash is enabled.
`Protocols`	The supported NFS protocols. The default value is 4. This cannot be changed.

EXPORT

Contains settings for exporting a file system.

last-updated: Jun 06, 2024

`SecType`	The comma-separated list of supported authentication flavors for the export or the type of security. Value can be comma-separated list of: • krb5 — authentication • krb5i — integrity • krb5p — privacy  **NOTE:** This *must* be specified if you want the clients to use kerberos ticket for secure access.
`Path`	(Required) The (cluster) path to export via NFS. The path should have a leading slash. If just `/mapr` is specified as the path, all the clusters (listed in the `mapr-clusters.conf` file) will be visible. To export only a specific cluster, specify the complete path to the cluster to export.  **NOTE:** Exporting will not be successful if extra forward slash (`/`) characters are in the path. For example, the following path will not be exported because of the extra slash (shown in bold) in the path: `/mapr/Test3//ATS-VOLUME`

`Pseudo`	(Required for NFSv4 protocol for every directory or volume to export) The pseudo path, which when specified, masks the mount path from the NFS client, for the NFSv4 exports. MapR's NFSv4 server provides a pseudo-file system where only the exported volumes are visible. This is especially useful in scenarios where one or more volumes in the hierarchy should be hidden and not be visible. When mounting with NFSv4, use the pseudo path. Value can be the volume or directory path.
`Export_Id`	(Required) The tag used to set the ID for the export or the unique ID to associate with each export. Value should not be 0. **NOTE:** The export ID associated with each export must be the same across all NFSv4 servers on the cluster.
`Clients`	The list of clients these export permissions apply to. Clients may be specified by hostname, IP address, netgroup, CIDR network address, host name wild card, or simply "*" to apply to all clients.

last-updated: Jun 06, 2024

`Squash`	Specifies whether to enable or disable root squashing. By default, root squashing is disabled. If root squash is enabled, the values substituted for the root user will be anonymous user (`Anonymous_Uid` and `Anonymouos_Gid`); that is, the UID and GID of a file created will not be `nfsnobody` because the default value of -2 is converted to a 32 bit unsigned integer (4294967294) instead of the 16 bit equivalent (65534), which is the value of nfsnobody.
`Access_Type`	(Required) The type of access on the mount point. Valid values include: • RO — for read-only mount point • RW — for read/write mount point • MDONLY — for read/write access to metadata only • MDONLY_RO — for read-only access to metadata only
FSAL	(Required) The file system to use. Value must be MAPR to use the file system `libfsalmapr.so` library, which contains the shared library (`libMapRClient`) and the callbacks.

LOG

Contains configuration for logging. The default log level is INFO. Value can be one of the following:

- FATAL
- MAJ
- CRIT
- WARN
- EVENT
- INFO

- DEBUG
- MID_DEBUG
- FULL_DEBUG

MAPRFS

Contains configurations for NFS gateway access to the data-fabric file system.

Parameter	Default Value	Description
`log_path`	`/opt/mapr/logs/nfs4`	Path for the log files.
`ra_sessions`	`5`	Number of parallel read ahead sessions per client library (`libMapRClient.so`). Each open file acts as one read ahead session. For example, if value is set to `5`, up to `5` files can have read ahead sessions per client library (`libMapRClient.so`). To disable read ahead sessions, set value to `0`.  **NOTE:** The number of client libraries is 3 by default and cannot be configured.

last-updated: Jun 06, 2024

Parameter	Default Value	Description
`flush_inline`	`true`	Specifies whether or not to flush all writes inline. Value can be: • `true` — flush all writes inline • `false` — disable inline flushing If enabled (default), writes are sent to server directly. If disabled, for all open files, the buffer is flushed automatically every 3 seconds or when it reaches 64KB.
`fast_local_directio`	`false`	Specifies whether to optimize or disable NFS client for local direct IO. Value can be: • `true` — optimize • `false` — disable
`nfs_track_memory`	`false`	Specifies whether to enable (`true`) or disable (`false`) memory tracking for NFS.

last-updated: Jun 06, 2024

Parameter	Default Value	Description
`hb_interval`	`5`	The interval (in seconds) for sending heartbeat to CLDB to allow CLDB to determine whether server is running. The CLDB will declare the NFS gateway dead when it loses about 8 heartbeats in a row and will trigger a failover.
`req_threshold`	`5`	The amount of time (in seconds) for processing requests. If the threshold is exceeded, warnings will be logged.

last-updated: Jun 06, 2024

Parameter	Default Value	Description
`client_lib_path`	`/tmp/nfs4`	The location for the client library (`libMapRClient`). **NOTE:** To install and use NFSv4 and FUSE-based POSIX client on the same node, ensure that the path for the client library for the NFSv4 and FUSE-based POSIX client is not `/tmp`. Specify a different location for the client libraries. For example, `/tmp/nfs4lib`.
`readdirplus`	`true`	Specifies whether (`true`) or not (`false`) to enable extended read from the directory. If enabled (`true`), each entry returns the name, the file ID, attributes (including the field), and file handle.

last-updated: Jun 06, 2024

NOTE:

- The `libnfsidmap` must be configured to use `nsswitch`, a translation mechanism for mapping names to IDs, in the `/etc/idmapd.conf` file.
- The NFSv3 (mapr-nfsserver) nodes cannot failover to NFSv4 server nodes and vice versa. Ensure that different set of VIPs are assigned for NFSv3 and NFSv4 server nodes. When running the `maprcli virtualip add` command to set up VIPs, list the MACs of the respective nodes so that the failover works properly (this is necessary if both NFSv3 and NFSv4 are going to be set up for same cluster). The MACs should be mutually exclusive as both NFSv4 and NFSv3 servers cannot run on the same node.

Sample Configurations

You can refer to the following sections, which contain blocks for the various required configurations using sample values.

Configuration for Supported NFS Protocols

To specify the supported NFS protocols, set the value for the `NFS_Protocols` parameter in the `/opt/mapr/conf/nfs4server.conf` file. For example, for NFSv4 protocol, in the `/opt/mapr/conf/nfs4server.conf` file, set the value for the `NFS_Protocols` parameter as shown (in bold) below.

```
NFS_CORE_PARAM
{
        Plugins_Dir = /opt/mapr/lib;
        NFS_Protocols = 4;
        Clustered = false;
}
```

NOTE: The only supported protocol is `4`.

For NFSv4, the `showmount` command does not return the list of exported NFS shares.

Configuration for Mounting the Cluster

Add the `MAPRFS` block in the `/opt/mapr/conf/nfs4server.conf` file as shown below.

```
MAPRFS
{
  #Directory path where nfsv4 logs should be stored
  log_path = /opt/mapr/logs/nfs4;

  #Set number of readahead sessions
  ra_sessions = 5;

  #Flush all writes inline
  flush_inline = true;

  #Optimize for local direct writes
  fast_local_directio = false;

  #Set security ticket file
  tkt_location = /tmp/maprticket_XXX;

  #Hearbeat interval for NFSv4 (in seconds)
  hb_interval = 5;

  #Request threshold, logs warning if any request takes more time (in
seconds)
```

last-updated: Jun 06, 2024

```
  req_threshold = 5;
}
```

Configuration for Exporting the File System

Modify the EXPORT block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below. The following sample block shows a standard configuration where the exported path and the actual path are the same.

```
EXPORT
{
     # Export Id (mandatory, each EXPORT must have a unique Export_Id)
     Export_Id = 77;

     # Exported path (mandatory)
     Path = /mapr;

     # Pseudo Path (required for NFS v4)
     Pseudo = /mapr;
     Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
     Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
     SecType = krb5;

    # Exporting FSAL
      FSAL {
      Name = MAPR;
    }

}
```

NOTE: If you change anything in the export block, restart NFSv4 service and remount the path.

Configuration for Pseudo Path

To mask the path to the volume from the client, set the pseudo path. For the pseudo path, you can specify a value that is different from the path parameter to hide the true path name. To hide the full path to volumes and/or directories, specify the complete path in the EXPORT block.

For example, modify the EXPORT block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below to mask the path and show only the name of the volume to the client. Note that the following sample block shows a pseudo path that is different from the exported path.

```
EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
    Pseudo = /vol1;
    Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
```

last-updated: Jun 06, 2024

```
     Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
     SecType = krb5;

   # Exporting FSAL
      FSAL {
      Name = MAPR;
    }

}
```

Configuration for Security

The NFS client to NFS Server can be secured using Kerberos. Before configuring Kerberos to work with MapR, modify the `/opt/mapr/conf/nfs4server.conf` file to specify the security type. For example, modify the `EXPORT` block in the `/opt/mapr/conf/nfs4server.conf` file as shown (in bold) below.

```
EXPORT
{
    # Export Id (mandatory, each EXPORT must have a unique Export_Id)
    Export_Id = 77;

    # Exported path (mandatory)
    Path = /mapr;

    # Pseudo Path (required for NFS v4)
      Pseudo = /vol1;
      Squash = No_Root_Squash;

    # Required for access (default is None)
    # Could use CLIENT blocks instead
      Access_Type = RW;

    # Security type (krb5,krb5i,krb5p)
    SecType = krb5;

    # Exporting FSAL
       FSAL {
        Name = MAPR;
      }

}
```

The NFSv4 server uses the ticket in `/opt/mapr/conf` directory, if it is present, to secure communication between the NFS server and the MapR cluster.

Configuration for Clients

You can add a client block to the NFSv4 server configuration specifying the list of clients to which the export permissions apply. Clients may be specified by hostname, IP address, netgroup, CIDR network address, host name wild card, or simply "*" to apply to all clients. For example:

```
EXPORT
{
     # Export Id (mandatory, each EXPORT must have a unique Export_Id)
     Export_Id = 77;

     # Exported path (mandatory)
     Path = /mapr;
```

last-updated: Jun 06, 2024

```
     # Pseudo Path (required for NFS v4)
     Pseudo = /mapr;

    # Defining the clients who are allowed to export
      CLIENT
    {
     # Required for access (default is None)
     Clients=192.168.0.10, 192.168.1.0/8;
     Access_Type = RW;
     Squash = No_root_squash;
     SecType=krb5;
    }
     # Exporting FSAL
     FSAL{
         Name = MAPR;
     }
}
```

Configuration for NFS Ganesha Debug Logging

Add the following block in the `/opt/mapr/conf/nfs4server.conf` file.

```
LOG {
  COMPONENTS {
    ALL = DEBUG;
  }
}
```

Default NFSv4 Server Configuration File

The `nfs4server.conf` file is available in `/opt/mapr/conf` directory.

```
      LOG
{
  COMPONENTS {
    ALL = INFO;
  }

  FORMAT {
    EPOCH = false;
    CLIENTIP = true;
    HOSTNAME = false;
    PROGNAME = false;
    FILE_NAME = false;
    LINE_NUM = true;
    FUNCTION_NAME = true;
    COMPONENT = false;
    LEVEL = false;
    time_format = syslog_usec;
  }
}

NFSV4
{
  #Delegation is not supported.
  Delegations = false;

  #Dirent cache threshold. Use only when readdirplus is true
  #Dirent_Cache_Threshold = 128;
}
```

```
NFS_CORE_PARAM
{
  Plugins_Dir = /opt/mapr/lib;

  Clustered = false;

  # Max number of results stored in DRC
  DRC_TCP_Size = 16;

  # Expire DRC after 60 seconds (if refcount is zero)
  DRC_TCP_Recycle_Expire_S = 60;

  # Only NFSv4 is supported. showmount will not work
  NFS_Protocols = 4;

  # RQUOTA protocol is not supported
  Enable_RQUOTA = false;

  # To set number of Nfs4server logs
  Num_Log_Files = 1;

  # Total disk space usage for logs = Num_Log_Files * Max_LogFile_Size
  # If Num_Log_Files = 32 and Max_LogFile_Size = 1GB,then disk space used
for logs = 32 GB.
  Max_Logfile_Size = 1073741824;

  # Monitor dirent entries (process restarts if number of entries beyond
limit, if true
  Dirent_Entries_Track = true;
}

MAPRFS
{
  #Set number of readahead sessions
  #ra_sessions = 5;

  #Flush all writes inline
  #flush_inline = true;

  #Optimize for local direct writes
  #fast_local_directio = false;

  #Enable/Disable memory tracking for nfs
  nfs_track_memory = false;

  #Sets client debug level, values are fatal, error, warn, info, debug
  mapr_log_debug_level = error;

  #Hearbeat interval for NFSv4 (in seconds)
  #hb_interval = 5;

  #Request threshold, logs warning if any request takes more time (in
seconds)
  #req_threshold = 5;

  #Specify the folder to copy libMapRClient
  #client_lib_path="/tmp/nfs4";

  #Readdirplus support
  #readdirplus = true;
}

#EXPORT_DEFAULTS
#{
```

last-updated: Jun 06, 2024

```
  #Default value for anonymous uid/gid is -2. Should be configured to
  #nfsnobody/nobody uid/gid if required
  #Anonymous_Uid = -2;

  #Anonymous_Gid = -2;

  #Supported NFS protocols. Currently only v4 is supported.
  #Protocols = 4;
#}

EXPORT
{
  # Export Id (mandatory, each EXPORT must have a unique Export_Id)
  Export_Id = 30;

  # Exported path (mandatory)
  Path = /mapr;

  # Pseudo Path (required for NFS v4)
  Pseudo = /mapr;

  Squash = No_Root_Squash;

  # Required for access (default is None)
  # Could use CLIENT blocks instead
  Access_Type = RW;

  # Security type (krb5,krb5i,krb5p)
  #SecType = krb5;

  # Exporting FSAL
  FSAL {
    Name = MAPR;
  }

  #SuperUser_Uid = 0;
}
```

Configuring NFSv4 Server for Kerberos
Describes how to configure and use NFSv4 on Kerberos.

About this task

You can configure data-fabric NFSv4 server to use Kerberos-based authentication. Data Fabric supports configuration of NFSv4 server for Kerberos with Active Directory server and Kerberos with LDAP. You can also configure data-fabric NFSv4 server to work with other Kerberos installations. Before configuring data-fabric NFSv4 server for Kerberos, you must have performed the following:

- Installed packages for Kerberos server.
- Installed NFSv4 server. See Installing NFS for the HPE Ezmeral Data Fabric on page 401 for more information.
- Installed packages for Kerberos client.

NOTE: The steps in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Please consult with your Kerberos administrator for assistance.

By default, the NFSv4 server is configured to rely on a Kerberos infrastructure. If you don't want or don't have a Kerberos infrastructure, comment out the `SecType` parameter of the EXPORT section of the `/opt/mapr/conf/nfs4server.conf` file.

Configure NFSv4 Server for Kerberos with Active Directory Server

About this task

The following procedure describes how to configure the data-fabric NFSv4 server to work with the Kerberos available with Active Directory server. Before configuring the data-fabric NFSv4 server, ensure that Active Directory server is installed and all the nodes on the cluster have joined that Active Directory server. The following procedure requires the NFSv4 server to run under user `mapr` and group `maprgrp`.

Procedure

1. In an Active Directory server environment, join the cluster nodes to the Active Directory server.

   Follow the sample procedure here or consult with your system administrator for assistance with installing and joining the nodes to Active Directory server.

2. Check if Kerberos tickets for host and NFS service principal are present, by running the following command:

   ```
   # klist
   klist: No credentials cache found (filename: /tmp/krb5cc_0)
   ```

3. Ensure host principal is available by checking to see if existing keys are present on the node.

   For example, when you run the following command, the output should look similar to the following output for `nfs4ad.com` domain:

   ```
   # klist -kt
   Keytab name: FILE:/etc/krb5.keytab
   KVNO Timestamp           Principal
   ---- ------------------- ------------------------------------------------------

      2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
      2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
      2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
      2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
      2 04/10/2018 23:51:24 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
      2 04/10/2018 23:51:24 host/ATSQA4-161@NFS4AD.COM
      2 04/10/2018 23:51:25 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
      2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
      2 04/10/2018 23:51:25 host/atsqa4-161.nfs4ad.com@NFS4AD.COM
      2 04/10/2018 23:51:25 host/ATSQA4-161@NFS4AD.COM
      2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
      2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
      2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
      2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
      2 04/10/2018 23:51:25 ATSQA4-161$@NFS4AD.COM
   ```

last-updated: Jun 06, 2024

4. Generate the host ticket by running the `kinit` command.
   For example:

```
[root@atsqa4-161 ~]# kinit -k ATSQA4-161$
[root@atsqa4-161 ~]# klist
Ticket cache: FILE:/tmp/krb5cc_0
Default principal: ATSQA4-161$@NFS4AD.COM
Valid starting       Expires              Service principal
04/11/2018 03:04:38  04/11/2018 13:04:38  krbtgt/NFS4AD.COM@NFS4AD.COM
        renew until 04/18/2018 03:04:38
```

5. Add NFS service principal entry for the host in the AD server by running the `setspn` command.
   For example, for `nfs4ad.com` domain, run the following command:

```
C:\Users\Administrator>setspn -A nfs/atsqa4-161.nfs4ad.com mapr
Checking domain DC=nfs4ad,DC=com
Registering ServicePrincipalNames for CN=mapr,CN=Users,DC=nfs4ad,DC=com
        nfs/atsqa4-164.nfs4ad.com
Updated object
```

6. Get the latest service ticket for the host from the AD server by running the `kvno` command.
   For example:

```
# kvno nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM
nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM: kvno = 46
kvno nfs/qa108-43.nfs4ad.com@NFS4AD.COM
```

7. Add entry for NFS service principal key in the Kerberos keytab file, `/etc/krb5.keytab`:

```
# ktutil
ktutil:  addent -password -p nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM -k
46 -e RC4-HMAC
Ex: addent -password -p nfs/qa108-43.nfs4ad.com@NFS4AD.COM -k 46 -e
RC4-HMAC
Password for nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM:
( Give mapr user password i.e nfs4AD123 )
ktutil:  l
slot KVNO Principal
---- ---- ---------------------------------------------------------------------

   1   46      nfs/atsqa4-164.nfs4ad.com@NFS4AD.COM
ktutil:  wkt /etc/krb5.keytab
ktutil:  q
```

8. Verify that NFS service principal and host principal are in the `/etc/krb5.keytab` file by running the `klist` command.

   For example, for domain `nfs4ad.com`, run the following command and verify the entries in the file:

```
# klist -kt /etc/krb5.keytab
Keytab name: FILE:/etc/krb5.keytab
KVNO Timestamp           Principal
---- ------------------- ------------------------------------------------------

   4 08/01/2018 00:29:22 ATSQA4-161$@NFS4AD.COM
  46 08/01/2018 02:58:01 nfs/atsqa4-161.nfs4ad.com@NFS4AD.COM
```

9. Ensure that `/etc/krb5.keytab` file is owned by user `mapr` and if necessary, change ownership to user `mapr`.

   For example:

```
[root@qa108-41 ~]# chown mapr:root /etc/krb5.keytab
[root@qa108-41 ~]# ls -l /etc/krb5.keytab
-rw------- 1 mapr root 4175 Jul 22 23:53 /etc/krb5.keytab
```

10. Restart the `rpcgssd` service on the host to establish GSS security contexts.

CentOS	`service rpcgssd start`
Ubuntu	`service gssd restart`

11. Enable security variable, `SecType`, in the NFSv4 server configuration file at `/opt/mapr/conf/nfs4server.conf`.

    For example:

```
  # Security type (krb5,krb5i,krb5p)
  SecType = krb5;
```

12. Start the NFSv4 server.

    For more information, see Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4 on page 1591.

last-updated: Jun 06, 2024

13. List the shares exported on the server by running `showmount -e` command.

    If the protocol is v4 only, the `showmount` command will not return the list of exported NFS shares. Instead, to view the export list, run the following command:

    ```
    /opt/mapr/server/nfs4mgr list-exports
    ```

14. Ensure that the `list-exports` command runs successfully.

    For example:

    ```
    #  maprcli nfs4mgmt list-exports
    Export Id     Path
    30            /mapr
    0             /
    ```

15. (Troubleshooting) Run the following command to restart the services if you see security-related issues.

    CentOS

    ```
    maprcli node services -nfs4
    stop -nodes `hostname` ; service
    rpcgssd restart; sleep 1; service
    rpcbind  restart ; sleep 1;
    service nfs restart ; service
    nfs stop ; sleep 2; maprcli
    node services -nfs4 start -nodes
    `hostname`
    ```

    Ubuntu

    ```
    maprcli node services -nfs4
    stop -nodes `hostname` ; service
    gssd restart; sleep 1; service
    rpcbind  restart ; sleep 1; service
    nfs-kernel-server restart ; service
    nfs-kernel-server stop ; sleep
    2; maprcli node services -nfs4
    start -nodes `hostname`
    ```

16. Set up VIPs for the NFSv4 servers:

    a) Add entries for IPs and names of VIPs in the `/etc/hosts` file on the NFSv4 server host first and then on the AD server host.

       For example:

       ```
       10.10.88.14 nfsvirtualip1
       10.10.88.15 nfsvirtualip2
       ```

    b) Add NFS service principal for the virtual IP by running the `setspn` command.

       For example:

       ```
       C:\Users\Administrator>setspn -A host/nfsvirtualip1 nfsserver
       C:\Users\Administrator>setspn -A nfs/nfsvirtualip1 nfsserver

       C:\Users\Administrator>setspn -A host/nfsvirtualip2 nfsserver
       C:\Users\Administrator>setspn -A nfs/nfsvirtualip2 nfsserver
       ```

last-updated: Jun 06, 2024

c) Restart the `rpcgssd` service on the host to re-establish GSS security contexts.
For example:

```
service rpcgssd restart
```

Configuring NFSv4 Server for Other Kerberos Installations

Procedure

1. Configure NFS server for Kerberos.
   Consult with your system administrator for assistance with the commands for configuring the NFS server for Kerberos-based authentication. For example, you must do the following:
   - Create a service principal with `nfs` as the service name.
     For example: `nfs/host.domain.com@REALM`
   - Generate a keytab for the NFS service principal, store it in the `/etc/krb5.keytab` file, and set correct permissions on the file.
2. Enable the security variable, `SecType`, in the NFSv4 server configuration file at `/opt/mapr/conf/nfs4server.conf`.
   For example:

```
# Security type (krb5,krb5i,krb5p)
SecType = krb5;
```

3. Start the NFSv4 server.
   For more information, see Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4 on page 1591.
4. List the shares exported on the server by running `showmount -e` command.
   If the protocol is v4 only, the `showmount` command will not return the list of exported NFS shares. Instead, to view the export list, run the following command:

```
/opt/mapr/server/nfs4mgr list-exports
```

5. Ensure that the `list-exports` command runs successfully.
   For example:

```
#  maprcli nfs4mgmt list-exports
Export Id     Path
30            /mapr
0             /
```

Configuring NFSv4 Client

Procedure

1. Ensure that NFS client has a `/etc/krb5.keytab` file with a valid principal similar to one of the following: `nfs/<client_fqdn>@<domain>@<REALM>`, `host/<client_fqdn>@<domain>@<REALM>`, or `<HOSTNAME>$@<REALM>`.
   If the principal is not present, create the `keytab` file with the principal, which will be used to mount the share, for the OS (as mentioned in the OS vendor documentation).

2. Mount the cluster by running the `mount` command.

   For example:

   ```
   mount -t nfs4 -o sec=<security-type> <nfs4-server-hostname>:/
   <pseudo-path> <mount-point>
   ```

   For example:

   ```
   # mount -t nfs4 -o sec=krb5 <FQDN>:/mapr /mnt/nfs4mnt
   ```

3. Generate user ticket for the user to access the mount path.

   For example, for user `mapr` on domain `nfs4ad.com`, run one of the following commands to generate the ticket:

   - ```
     kinit mapr@NFS4AD.COM
     <Enter password>
     ```

   - ```
     echo usr2AD123 | kinit user2@NFS4AD.COM
     ```

   NOTE: You must renew the user ticket before it expires; otherwise, the mount path returns permissions denied error after the ticket expires.

4. (Troubleshooting) Restart the services and mount again to avoid security-related issues.

CentOS	`service rpcgssd restart; sleep 1;`
	`service rpcbind  restart ; sleep 1;`
	`service nfs stop`

Ubuntu	`service rpcgssd restart; sleep 1;`
	`service rpcbind  restart ; sleep 1;`
	`service nfs stop`

   TROUBLE: Any running IO on NFSv4 mount (with Kerberos) is stuck if the krb5 ticket expires for the current user. The mount point also hangs and becomes inaccessible.

   Workaround: Restart the `rpcgssd` service with the new ticket to make the mount point accessible and re-trigger the IO to proceed.

Configuring NFSv4 Server Without Kerberos

About this task

To start using NFSv4 server without Kerberos, do the following:

Procedure

1. Start the NFSv4 server.

   For more information, see Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4 on page 1591.

last-updated: Jun 06, 2024

2. Verify that the list-exports command runs successfuly.
   For example:

```
#  maprcli nfs4mgmt list-exports
Export Id     Path
30            /mapr
0             /
```

3. Mount the cluster by running the `mount` command.
   For example:

```
mount -t nfs4 <nfs4-server-hostname>:/<pseudo-path> <mount-point>
```

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4
Describes how to start, stop and restart the NFS version 4 service using either the Control System, the CLI, or the REST API.
Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4 Using the Control System

About this task

See:

- Starting the Services on the Cluster Using the Control System on page 1140
- Stopping a Service on the Cluster Using the Control System on page 1141
- Restarting the Services on the Cluster Using the Control System on page 1142

Starting, Stopping, and Restarting HPE Ezmeral Data Fabric NFSv4 Using the CLI and REST API

About this task

NOTE: On Ubuntu 20, run the following commands before starting NFS4, Else, NFS fails to start, as it cannot find the jemalloc library.

```
apt-get install libjemalloc2

ln /usr/lib/x86_64-linux-gnu/libjemalloc.so.2 /opt/mapr/lib/
libjemalloc.so.1
```

CLI	To stop, start, or restart the HPE Ezmeral Data Fabric NFSv4 server, run: `maprcli node services -nodes <node names> -name nfs4 -action stop|start|restart`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:8443/rest/node/services?nodes=<nodeNames>&nfs4=stop|start|restart' --user mapr:mapr`

NOTE: When the NFS server is stopped, the VIPs associated with the server are released, and CLDB attempts to reassign the VIPs to other available NFS servers.

For the complete list of parameters, see `node services` on page 2292.

Mounting NFS on a Linux Client

Describes how to mount a NFS server on a Linux client.

About this task

You can manually mount NFS on a Linux client when your system starts up.

NOTE: On nodes running CentOS, use the VIP for mounting because, by default, the mount command will use the physical IP of the node.

Procedure

1. List the NFS shares exported on the server.

   For example, run the following command for NFS version 4 servers:

   ```
   maprcli nfs4mgmt list-exports
   ```

   If the NFS protocol is not version 4 only, use the `showmount` command to retrieve the list of exported NFS shares. For example:

   ```
   showmount -e usa-node01
   ```

2. Mount the cluster using NFS.

   For example:

   ```
   mount -t nfs4 -o sec=krb5 usa-node01:/<psuedo_mapr> /mapr
   ```

Results

TIP: For the best performance, use NFS v4.0.

Use the `vers=4.0` parameter in the mount command. For example:

```
mount -t nfs4 -o sec=krb5,vers=4.0 usa-node01:/<psuedo_mapr> /mapr
```

NOTE: When you mount manually from the command line, the mount point does not persist after a reboot.

Configuring the Linux NFS Client

Describes how to set the optimal number of RPC requests to the NFS server.

About this task

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128.

Perform the following steps as the `root` user on each NFS client machine:

last-updated: Jun 06, 2024

Procedure

1. To enable the configuration to persist after a reboot of the NFS client machine, issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration:

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
```

2. To enable the configuration to take effect after you remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway, issue the following echo commands:

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

3. Remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway. For example, the following commands unmount and mount NFS for the HPE Ezmeral Data Fabric assuming that the cluster is mounted at `/mapr`:

```
umount /mapr
mount -o hard,nolock <hostname>:/mapr /mapr
```

NOTE: Failure to configure this property may result in the following error in `/opt/mapr/logs/nfsserver.log`:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0]
cannot allocate more OncRpcContexts: [numDropped=2556001]
dropping connection from nfsc=10.13.64.225:0
```

TIP: For CentOS, after the reboot of the node, if the `/proc/sys/sunrpc` directory is not available or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command:

```
service rpcidmapd start
```

Advisory Locking in NFS v4

Explains NFS v4 support for Advisory Locking.

Data Fabric NFS v4 service includes support for (advisory) file locking. Data Fabric keeps track of the locks on a file in the NFS for the HPE Ezmeral Data Fabric gateway, but does not prevent a client process from writing to a file that is locked by another process. The locks are not shared with other NFS for the HPE Ezmeral Data Fabric gateways. Since the locks are enforced locally, it is the responsibility of the client process to check for write locks on a file before attempting to perform write operations on the file.

To ensure that a file is locked and not available for changes by other processes and to ensure that the lock on a file by a process is honored by other processes, add a program similar to the following for the process.

Sample Program Description	The following program demonstrates how to open a file, check if the file has a write lock, and wait if another process currently has locked the file. Before running this application, ensure that you have access to a cluster running file system.

last-updated: Jun 06, 2024

Opens a file

```
  if (argc > 1) {
    int fd
= open(argv[1],
O_WRONLY);
    if(fd == -1)
{

printf("Unable
to open the
file\n");
      exit(1);
    }
```

Checks if the file is locked for a write operation

```
    lock.l_type
= F_WRLCK;
    lock.l_start
= 0;

lock.l_whence =
SEEK_SET;
    lock.l_len =
0;
    lock.l_pid =
getpid();
```

Gets lock, else waits

```
    int ret
= fcntl(fd,
F_SETLKW,
&amp;lock);

printf("Return
value of
fcntl:%d\n",ret);
    if(ret==0) {
      while (1) {

scanf("%c",
NULL);
      }
    }
```

Sample Program Code

```
#include <stdio.h>
#include <fcntl.h>

int main(int argc, char **argv) {
  if (argc > 1) {
    int fd = open(argv[1], O_WRONLY);
    if(fd == -1) {
      printf("Unable to open the
file\n");
      exit(1);
    }
    static struct flock lock;

    lock.l_type = F_WRLCK;
    lock.l_start = 0;
    lock.l_whence = SEEK_SET;
```

```
    lock.l_len = 0;
    lock.l_pid = getpid();

    int ret = fcntl(fd, F_SETLKW,
&lock);
    printf("Return value of
fcntl:%d\n",ret);
    if(ret==0) {
      while (1) {
        scanf("%c", NULL);
      }
    }
  }
}
```

NFSv4 Troubleshooting

Unable to start the service:

If you or the warden is unable to restart the NFS service, do the following:

1. Review the warden logs (in `$MAPR_HOME/logs/warden.log` file) to determine when the NFSv4 Service Alarm on page 3016 was raised.

last-updated: Jun 06, 2024

2. Review the following NFSv4 server logs in `$MAPR_HOME/logs/nfs4/nfs4server.log-0` and `$MAPR_HOME/logs/nfs4/fsal.log-0`, and other logs under `$MAPR_HOME/logs/nfs4` on the node where the service went down to determine the cause for the error.

   The following example logs show some common causes for NFSv4 service shutting down such as license not present or an issue in the configuration.

```
# tail -f /opt/mapr/logs/nfs4/

3. Take corrective action to rectify the cause for the error.

Viewing the List of NFS Servers

Explains how to view the list of NFS servers using the Control System.

About this task

Procedure

- Log in to the Control System and go to the service information page for CLDB.
  The **Active NFS Servers** section displays the following:

Column Name	Column Description
Server ID-HEX	The server's ID in hexadecimal notation.
Server ID	The server's ID in decimal notation.
Host Port	The IP address of the NFS server host.

Column Name	Column Description
Hostname	The hostname of the NFS server host.
Last heartbeat	The timestamp for the last received heartbeat.
State	The status of the NFS server. Value can be: • Active

Handling Heavy Write Loads on Red Hat Enterprise Linux
Describes a fix to mitigate resource contention between NFS Clients and the NFS Server on Red Hat Linux.

If you are operating on RHEL and have a heavy NFS write load, you might experience resource contention between the NFS client and the NFS server. This resource contention can cause the NFS server to be unresponsive. To avoid this potential problem, try one of following approaches. These approaches work on all versions of Red Hat (5.x, 6.x and 7.x).

- Edit `/etc/sysctl.conf` and apply these settings on each NFS server:

  ```
  vm.dirty_ratio=10
  vm.dirty_background_ratio=5
  ```

  Reboot the server so the changes will take effect. To make the settings take effect immediately, issue the `echo` command as shown:

  ```
  % echo 10 > /proc/sys/vm/dirty_ratio
  % echo 5 > /proc/sys/vm/dirty_background_ratio
  ```

- Separate the NFS client from the NFS server so they do not compete for memory on the same system.

Configure NFS Write Performance
Describes how to set the optimal value for outstanding Remote Procedure Call (RPC) requests to the NFS server.

The default Remote Procedure Call (RPC) requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the NFS server to be 128, for optimal performance. The NFS client uses this value to determine when to send requests to the NFS server, along with the number of parallel requests to send.

- If the value is too small, the NFS client does not send many parallel requests. This scenario results in decreased performance.
- If the value is too high, the NFS client sends a lot of parallel requests, but the NFS server discards some requests, as it has a limit on the number of requests it can handle. This scenario causes the NFS client to resend the requests, and negatively affects performance.

The kernel tunable value `sunrpc.tcp_slot_table_entries` represents the number of simultaneous RPC requests. The default value of this tunable is 16 (on Red Hat versions prior to version 6.3). On Red Hat versions 6.3 and above, the default value of this tunable is set at 65536. Increasing or decreasing this value to 128 (depending on the Red Hat version in use), may improve write speeds. Use the command `sysctl -w sunrpc.tcp_slot_table_entries=128` to set the value. Add an entry to your `sysctl.conf` file to make the setting persist across reboots.

Perform the following steps as the root user, on each NFS client machine:

1. Issue the following commands to create the `sunrpc.conf` file under `/etc/modprobe.d` with the recommended configuration. These commands enable the configuration to persist after a reboot of the NFS client machine.

```
echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
sunrpc.conf
echo "options sunrpc tcp_max_slot_table_entries=128" >>  /etc/modprobe.d/
sunrpc.conf
```

2. Issue the following `echo` commands. These commands enable the configuration to take effect after you remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway.

```
echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
```

3. Remount the NFS client to the NFS for the HPE Ezmeral Data Fabric gateway. Mount the data-fabric NFS server with a rsize and wsize of 128K, as this value significantly cuts down NFS server requests for a given transfer, and improves the overall performance. For example, the following commands unmount and mount the NFS server, assuming that the cluster is mounted at `/mapr`.

```
umount /mapr
mount -o nolock,rsize=131072,wsize=131072 <hostname>:/mapr /mapr
```

4. After rebooting the node, if the `/proc/sys/sunrpc` directory is not available, or if `rpcidmapd` is not running, start the `rpcidmapd` service, using the following command: `service rpcidmapd start`.

Failure to set this tunable to an optimum value, may result in the following error in the `/opt/mapr/logs/nfsserver.log` file:

```
ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0] cannot
allocate more OncRpcContexts: [numDropped=2556001] dropping connection from
nfsc=10.13.64.225:0
```

NFS for the HPE Ezmeral Data Fabric write performance varies between different Linux distributions. The recommended value of this tunable may have no effect, or even a negative effect on your particular cluster.

Adjusting NFS Memory Settings

The memory allocated to each MapR service is specified in the `/opt/mapr/conf/warden.conf` file, which MapR automatically configures based on the physical memory available on the node. You can adjust the minimum and maximum memory used for NFS, as well as the percentage of the heap that it tries to use, by setting the `percent`, `max`, and `min` parameters in the `warden.conf` file on each NFS node. Example:

```
...
service.command.nfs.heapsize.percent=3
service.command.nfs.heapsize.max=1000
service.command.nfs.heapsize.min=64
...
```

The percentages need not add up to 100; in fact, you can use less than the full heap by setting the `heapsize.percent` parameters for all services to add up to less than 100% of the heap size. In general, you should not need to adjust the memory settings for individual services, unless you see specific memory-related problems occurring.

last-updated: Jun 06, 2024

Running NFS on a Non-standard Port

Procedure

1. To run NFS on an arbitrary port, modify the following line in `warden.conf`:

   ```
   service.command.nfs.start=/etc/init.d/mapr-nfsserver start
   ```

   Add `-p <portnumber>` to the end of the line, as in the following example:

   ```
   service.command.nfs.start=/etc/init.d/mapr-nfsserver start -p 12345
   ```

2. After modifying `warden.conf`, restart the MapR NFS server by issuing the following command:

   ```
   maprcli node services -nodes <nodename> -nfs restart
   ```

3. You can verify the port change with the `rpcinfo -p localhost` command.

   WARNING: MapR uses version 3 of the NFS protocol. NFS version 4 bypasses the port mapper and attempts to connect to the default port only. If you are running NFS on a non-standard port, mounts from NFS version 4 clients time out. Use the `-o nfsvers=3` option to specify NFS version 3.

Enabling Debug Logging for NFS Using the CLI

About this task

Debug-level logging is available to help you isolate and identify NFS-related issues.

Enabling Debug Logging for NFSv3

Procedure

1. To enable logging at the debug level, enter this command at the command line:

   ```
   maprcli trace setlevel -port 9998 -level debug
   ```

   where `-port 9998` indicates NFS.

   WARNING: The `debug` log level provides much more information than the default log level of `info`.

2. In default mode, information is logged to a buffer and dumped periodically. To display information immediately instead, enable `continuous` mode by entering:

```
maprcli trace setmode -port 9998 -mode continuous
```

Sample log output from an `ls` command is shown here:

From `/opt/mapr/logs/nfsserver.log`:

```

```

The log shows every operation sent to and received from an NFS client.

3. To return to the default log level and log mode, enter:

```
maprcli trace setlevel -port 9998 -level default
maprcli trace setmode -mode default
```

Enable Debug Logging for NFSv4

Procedure

1. Modify `core-site.xml` file to add the following:

```
<property>
   <name>fs.mapr.trace</name>
   <value>DEBUG</value>
   <description> </description>
</property>
```

2. Save and close the file.

Example

Run the `/opt/mapr/server/nfs4mgr` command for debugging NFS Ganesha.

Unmounting the MapR Cluster from the Command-Line

Procedure

- To unmount the MapR cluster, run the `umount` command.

  For example, to unmount the cluster in `/mapr`, run the following command:

```
umount /mapr
```

  If a process is busy on the mount point, the umount command will fail. To unmount the cluster after the process completes, run the following command:

```
umount -l /mapr
```

Managing HPE Ezmeral Data Fabric POSIX Clients

Provides a brief synopsis of HPE Ezmeral Data Fabric POSIX clients.

The HPE Ezmeral Data Fabric POSIX clients allow app servers, web servers, and other client nodes and apps to read and write data directly and securely to a HPE Ezmeral Data Fabric cluster. The following topics describe the steps for configuring and managing loopback NFS POSIX and FUSE-based POSIX clients.

Apart from the clients that are EOL, all others are supported. However, newer clients might have features that may not be supported in older clients.

Difference between the POSIX loopback NFS client and the FUSE-based POSIX Basic and Platinum clients

The following table summarizes the differences between the POSIX loopback NFS client and the FUSE-based POSIX Basic and Platinum clients:

	HPE Ezmeral Data Fabric POSIX Loopback NFS Client	HPE Ezmeral Data Fabric FUSE-based POSIX Basic/Platinum Client
Throughput	• 500MB/s for remote read/write • 1G/s for local read/write	Greater than 2G/s for remote and local read/write
Client OS	Supported Linux and Ubuntu distributions only.	

last-updated: Jun 06, 2024

	HPE Ezmeral Data Fabric POSIX Loopback NFS Client	HPE Ezmeral Data Fabric FUSE-based POSIX Basic/Platinum Client
Installs On Node Type	• Client node • Cluster node	
Access to Cluster	Must have direct network access to all HPE Ezmeral Data Fabric cluster nodes.	Must have direct network access to all HPE Ezmeral Data Fabric cluster nodes. However, each client only supports up to 16 clusters.
Connection to File System	• Proxied on host to regular HPE Ezmeral Data Fabric client traffic • Direct, no NFS for the HPE Ezmeral Data Fabric gateway • No single point of failure	
Security	Fully secured.	
Caching	Buffered writes are cached in the kernel.	Buffered writes are cached (only in kernel >= 3.15) if writeback option is enabled.

HPE Ezmeral Data Fabric loopbacknfs POSIX Client
Explains the differences between the HPE Ezmeral Data Fabric POSIX client and the Linux native NFS client.

The HPE Ezmeral Data Fabric POSIX Client feature allows app servers, web servers, and other client nodes and apps to read and write directly to a HPE Ezmeral Data Fabric cluster. Starting with the 4.0.2 release, HPE Ezmeral Data Fabric provides single-user `loopbacknfs` licenses that give access to one or more clusters.

The table below summarizes the differences between the basic Linux OS NFS client and the HPE Ezmeral Data Fabric POSIX client:

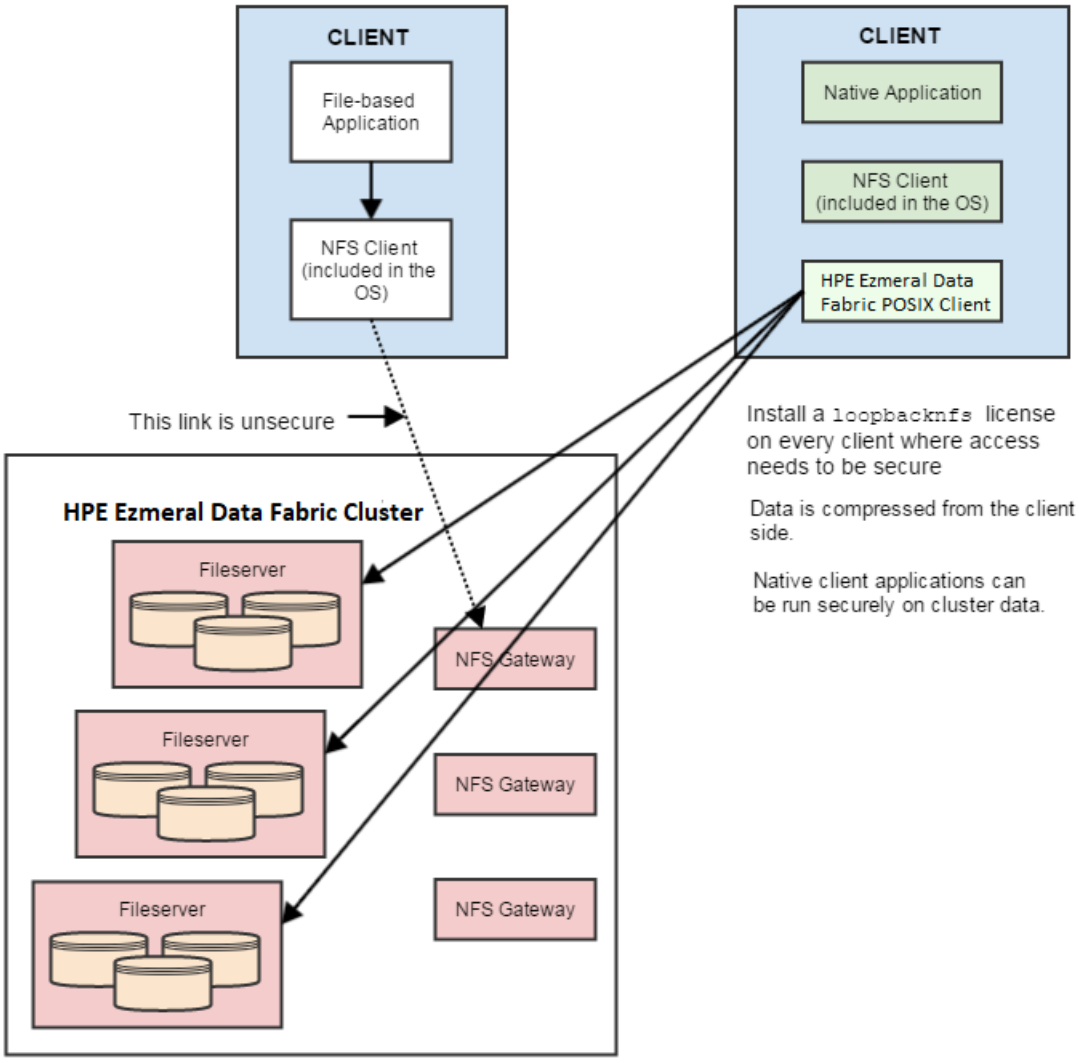
	Linux OS Client	HPE Ezmeral Data Fabric POSIX Client
Client OS	• Supported Linux distributions and desktop systems (Mac OS X and Windows)	• Supported Linux distributions only • No version for Mac OS X
Installs On Node Type	• Client node - not part of the HPE Ezmeral Data Fabric cluster • No mapr-fileserver or other Hadoop services	• Client node • Cluster node
Access to Cluster	• Must have direct network access to NFS Gateways.	• Must have direct network access to all HPE Ezmeral Data Fabric cluster nodes
Supported Interfaces	• POSIX-NFS	• POSIX-NFS

last-updated: Jun 06, 2024

	Linux OS Client	HPE Ezmeral Data Fabric POSIX Client
Connection to File System	• Point to point • Via an NFS gateway • Single point of failure	• Proxied on host to regular HPE Ezmeral Data Fabric client traffic • Direct, no NFS gateway • No single point of failure
Security	• Link to NFS gateway is insecure	• Fully secured

The Linux OS NFS client must go through an NFS gateway, the link to the gateway is not secured, and transmitted data is not compressed.

The following diagram illustrates how the HPE Ezmeral Data Fabric POSIX client (`mapr-loopbacknfs`) works, in comparison with the Linux OS NFS client (left).



The instructions on this page are for the HPE Ezmeral Data Fabric POSIX client. For instructions on setting up NFS on a HPE Ezmeral Data Fabric cluster, see Managing the HPE Ezmeral Data Fabric NFS Service on page 1549.

last-updated: Jun 06, 2024

The table below summarizes the differences in the HPE Ezmeral Data Fabric POSIX client deployment behavior when installed with a HPE Ezmeral Data Fabric cluster where security is disabled or enabled:

	Cluster Security Disabled	Cluster Security Enabled
Client Node	• HPE Ezmeral Data Fabric cluster looks exactly like network attached storage (NAS) • POSIX permissions are enforced	• Single-user authentication • Write access is supported only for applications with UID matching authenticated user
Cluster Node	• HPE Ezmeral Data Fabric cluster looks exactly like NAS • POSIX permissions are enforced	• Secure cluster access is key • Best Practice: Use ticket from *mapr* user

Specifying Environment Variables
Explains how to set environment variables on a client node.

About this task
Some of the environment variables defined on the servers for the HPE Ezmeral Data Fabric cluster must be defined with the same values on the client. You can add environment variables directly to the startup script, or create a local `env.sh` file in `/usr/local/mapr-loopbacknfs/conf`. You cannot simply copy the `env.sh` file from a server node in the cluster because the MAPR_HOME setting would be different.

Complete the following steps to specify environment variables:

Procedure

1. On a server node in the HPE Ezmeral Data Fabric cluster, locate the `env.sh` and `env_override.sh` files in the `/opt/mapr/conf` directory. If the `env_override.sh` file is not present, use the `env.sh` file. For more information about these files, see About env_override.sh on page 3077.
2. Retrieve the MAPR_SUBNETS and JAVA_HOME settings from the server files and clone them to `/usr/local/mapr-loopbacknfs/conf/env.sh` on the client node.
3. (Optional) Set the `NFS_LOOPBACK_HONOUR_SUBNETS` environment variable to avoid re-registration whenever there is a change in any network interface. The value can be:
   - `true` to consider the `MAPR_SUBNETS` while registering with CLDB. If set to `true`, re-registration does not happen when there is a change in any network interface.
   - `false` to ignore the `MAPR_SUBNETS`. If set to `false`, re-registration happens when there is a change in any network interface.

   For example:

   ```
   # export NFS_LOOPBACK_HONOUR_SUBNETS=true
   # export MAPR_SUBNETS=10.10.104.0/24

   # env | grep SUBNET
   NFS_LOOPBACK_HONOUR_SUBNETS=true
   MAPR_SUBNETS=10.10.105.0/24,10.10.104.0/24
   ```
4. Change the `JAVA_HOME` setting to point to the location where Java is installed on the client.

5. Add the following lines to the client node `env.sh` file:

```
export MAPR_HOME=/usr/local/mapr-loopbacknfs
export MAPR_TICKETFILE_LOCATION=<MAPR user ticket path>
```

NOTE: To allow impersonation, set the value for `MAPR_TICKETFILE_LOCATION` to the path to the `mapr` user ticket.

6. Save and close the `env.sh` file.

7. Restart the loopbacknfs service for the changes to take effect.

Copying Configuration Files from a Server Node

About this task
Settings in the `nfsserver.conf` and `mapr-clusters.conf` files on server nodes in the MapR cluster are also needed by the POSIX client. Complete the following steps to copy configuration files from a server node:

Procedure

1. On a server node in the MapR cluster, locate the `nfsserver.conf` and `mapr-clusters.conf` files in the `/opt/mapr/conf/` directory.

2. Copy both of those files to the `/usr/local/mapr-loopbacknfs/conf/` directory on the client machine.

Starting the mapr-loopbacknfs Service to Access a Cluster
Describes the prerequisites and the process of starting the `mapr-loopbacknfs` service to access a secure cluster.

The following instructions explain how to start the loopbacknfs service so you can access either a non-secure or secure cluster.

To access multiple clusters, ensure that the first cluster that you configure is a HPE Ezmeral Data Fabric 4.0.2 or later cluster, with available POSIX client licenses.

Prerequisites for accessing a secure cluster:

- Ensure that the stock Linux NFS service is not running. Linux NFS and HPE Ezmeral Data Fabric NFS cannot run concurrently.
- Disable the lock manager (`nlockmgr`).
- Check that the `rpcbind` service is running on RHEL and CentOS v6.0 and higher. You can use the command `ps ax | grep rpcbind` to check.
- Check that the `portmapper` service is running on RHEL and CentOS v5.x and lower, and on Ubuntu and SLES. You can use the command `ps ax | grep portmap` to check.
- Make sure you have applied a Community Edition (M3) license or an Enterprise Edition (M5) license (paid or trial) to the cluster. See Adding a License on page 1079.
- Enable security for the cluster. See Enabling Wire-level Security on page 1797 and Disabling Wire-level Security on page 1798 wire-level security.

last-updated: Jun 06, 2024

- Generate a user ticket. See Generating a HPE Ezmeral Data Fabric User Ticket on page 1831 for instructions. If you do not already have a HPE Ezmeral Data Fabric user ticket, with full control *ACL* authorization on the cluster, you must have a cluster administrator do this for you.
  - In the HPE Ezmeral Data Fabric cluster, navigate to the server node to which you want to connect.
  - First, run `maprlogin password` to login. The user who logs in must be a privileged user, such as the `mapr` superuser.
  - Next, run `maprlogin generateticket -type service -user <user> -duration 365:0:0 -out <file>` to generate the user ticket. The <user> for whom the ticket is generated can be any user. If the service ticket expires, the POSIX client:
    - Automatically uses the renewed service ticket without requiring a restart, if the ticket is replaced before expiration (ticket expiry time + grace period of 55 minutes). If the ticket is replaced after expiration (which is ticket expiry time + grace period of 55 minutes), the POSIX loopbacknfs client does not refresh the ticket as the mount becomes stale.
    - Allows impersonation if a service ticket is replaced before ticket expiration (which is ticket expiry time + grace period of 55 minutes) with a `servicewithimpersonation` ticket.
    - Honor all changes in user/group IDs of the renewed ticket.
- Copy the user ticket file from the cluster server node where you generated it to the `/usr/local/mapr-loopbacknfs/conf` directory on the client machine where the HPE Ezmeral Data Fabric POSIX client runs.

NOTE: Since the NFS server runs based on a single user's ticket, it can act on behalf of only one user. Therefore, the UID or GID associated with the ticket must match the UID or GID of any user who accesses the NFS server through the HPE Ezmeral Data Fabric POSIX Client.

NOTE: Securing the cluster so that only one user can have secure access provides tight control over cluster access, but it also means that any user on the client who is able to read the generated ticket has read access to all data in the cluster.

Start the mapr-loopbacknfs service and mount the volume

Complete the following steps from your client node, except where noted, to start the `mapr-loopbacknfs` service and mount the volume:

NOTE: If cluster security is enabled, the ticket that you generated using the preceding procedure, must be available or the NFS server does not start.

1. Start the `mapr-loopbacknfs` service from the command line.

```
service mapr-loopbacknfs start
```

2. Create a mount point at `/mapr` and mount the client node to it.

```
mkdir /mapr
mount localhost:/mapr /mapr
```

3. You can also automate the mounting of the volume with every launch of the `mapr-loopbacknfs` service. On the POSIX client node, create `/usr/local/mapr-loopbacknfs/conf/mapr_fstab` and add the following line:

```
localhost:/mapr /mapr hard,nolock
```

Securing the Mountpoint

About this task

POSIX permissions are the only limitation on read access by the MapR POSIX client, whether the cluster connected to has security enabled or disabled. By securing the mountpoint, you can limit access to a single user.

Complete the following steps to secure the mountpoint:

Procedure

1. On the client system, create `/mapr/<clustername>`:

```
mkdir -p /mapr/<clustername>
```

2. Set ownership and permissions:

```
chown user1:<posix_user> /mapr
chmod 700 /mapr
```

3. Mount the cluster:

```
mount localhost:/mapr/<clustername>  /mapr/<clustername>
```

   Now only the `<posix_user>` can access the cluster with the POSIX client.

Registering a POSIX Client with Additional Clusters

The first time you start the `loopbacknfs` service, you edit the `mapr-loopbacknfs` init script by defining the `CLUSTER_NAME` and `CLDB_IPS` variables, then run the script. These actions update the `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf` file.

However, when you want to register a client with a new cluster or an additional cluster, you must add entries directly to the `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf` file. Editing the `mapr-loopbacknfs` script and restarting the `loopbacknfs` service does not update the `mapr-clusters.conf` file.

Configuring the HPE Ezmeral Data Fabric POSIX Client

Explains how to set the number of RPC requests that POSIX clients send to a cluster.

About this task

The default RPC requests configuration can negatively impact performance and memory. To avoid performance and memory issues, configure the number of outstanding RPC requests to the cluster to be 128.

Perform the following steps as the root user on each POSIX client machine:

Procedure

1. Issue the following commands to create the *sunrpc.conf* file under */etc/modprobe.d* with the recommended configuration:

   ```
   echo "options sunrpc tcp_slot_table_entries=128" >> /etc/modprobe.d/
   sunrpc.conf
   echo "options sunrpc tcp_max_slot_table_entries=128" >> /etc/modprobe.d/
   sunrpc.conf
   ```

   These commands enable the configuration to persist after a reboot of the NFS client machine.

2. Issue the following echo commands:

   ```
   echo 128 > /proc/sys/sunrpc/tcp_slot_table_entries
   echo 128 > /proc/sys/sunrpc/tcp_max_slot_table_entries
   ```

   The commands enable the configuration to take effect after you remount the POSIX client to the HPE Ezmeral Data Fabric cluster.

3. Remount the POSIX client to the HPE Ezmeral Data Fabric cluster. For example, the following commands unmount and mount the NFS assuming that the cluster is mounted at */mapr*:

   ```
   umount /mapr
   mount -o hard,nolock 127.0.0.1:/mapr /mapr
   ```

   NOTE: Failure to configure this property may result in the following error in */usr/local/mapr-loopbacknfs/log*: `ERROR nfsserver[38960] fs/nfsd/requesthandle.cc:791 0.0.0.0[0] cannot allocate more OncRpcContexts: [numDropped=2556001] dropping connection from nfsc=10.13.64.225:0`

   CentOS Troubleshooting Tip

   After the reboot of the node, if the */proc/sys/sunrpc* directory is not available, or if `rpcidmapd` is not running, start the `rpcidmapd` service using the following command: `service rpcidmapd start`.

Verifying Data Fabric POSIX Client Licenses
Use the Control System, to check how many data-fabric POSIX client licenses are available and being used.

About this task

Procedure

1. Log in to the Control System and click **Admin** > **Cluster Settings**.
2. Look at the **LICENSES** pane for the number of POSIX Client nodes that are available and currently being used.

Managing the mapr-loopbacknfs Service
Explains how to start/stop and manage the `loopbacknfs` service from the command line.

To manually start or stop the service:

```
service mapr-loopbacknfs [start|stop]
```

last-updated: Jun 06, 2024

To have the service start automatically when the OS starts up:

```
systemctl enable mapr-loopbacknfs
```

To monitor the service:

```
service mapr-loopbacknfs status
showmount -e localhost
```

The showmount command displays:

```
Export list for <host>
/mapr               127.0.0.1
/mapr/<clustername> 127.0.0.1
```

Setting Up Aliases for NFS Exports

About this task

When provisioning file system for various tenants, you can set up an alias for the path in file system, rather than exporting the whole path, to mask the path from the users. Once the alias is set up, users will not be able to access or mount the path in file system.

Aliases can be set up for the cluster, volume, and directory, but not for the root of the path in file system (`/mapr`). To set up an alias for a path in file system:

Procedure

1. Open the NFS exports file in `/opt/mapr/conf/` directory.
2. Specify the alias name for the mount path using the following syntax:

   ```
   <path in MFS> /<alias name> <options>
   ```

   Here:

`<path in MFS>`	Refers to the file system mount path. If this points to a: • Volume, the user can access the snapshots associated with the volume. • Directory, the user cannot access the snapshots.
`/<alias name>`	Refers to the alias name to use. If there are duplicate aliases in the file, the last entry will take effect and all other duplicate entries will be ignored. If the alias name is not specified, the path in file system will be exported.
`<options>`	The list of available/supported options.

   For example, suppose a file system mount path of `/mapr/samplecluster/samplevolume` for tenant samplecustomer. To set up an alias, add the following to the exports file:

   ```
   /mapr/samplecluster/samplevolume /samplecustomer (rw)
   ```

last-updated: Jun 06, 2024

For example, to export a certain cluster, volume, or a subdirectory as an alias, comment out `/mapr` and add the following:

```
/mapr/clustername /alias1 (rw)
/mapr/clustername/vol /alias2 (rw)
/mapr/clustername/vol/dir /alias3 (rw)
```

NOTE: Only the alias will be visible/exposed to the NFS client.

3. Run the following command for the file changes to take effect:

```
/opt/mapr/bin/maprcli nfsmgmt refreshexports
```

4. Run the following command to export the path:

```
mount -t nfs nfsServer:/<alias_name> /localpath
```

Run this command once for each entry in the file.

What to do next

The same export rules must be set up on all the NFS servers in the cluster to ensure that in the event of a node failure, the same aliases work with VIP failover.

Troubleshooting mapr-loopbacknfs Service Issues

Describes solutions for mapr-loopbacknfs issues.

To debug authentication issues, follow these steps:

1. If you receive a standard error (stderr):
   - Make sure `rpcinfo/portmap` is installed and/or run service portmap start.
   - Run service `rpcbind restart`.
2. Examine the log files for error messages:

```
/usr/local/mapr-loopbacknfs/logs/loopbacknfs.log
/usr/local/mapr-loopbacknfs/logs/mount_local_fs.log
```

Error messages in `loopbacknfs.log` file:

Error Message	Solution
`Refresh User tickets failed as security layer could not be initialized with user ticket /tmp/maprticket_0`	`Unset MAPR_TICKETFILE_LOCATION in initscripts/mapr-loopbacknfs.`
`exiting: license only allows 10 NFS/mfs server(s), currently alive=10`	`If you have multiple clusters listed in the mapr-clusters.conf file on the client, make sure the first one listed is a MapR 4.0.2 or later cluster. If that is not the problem, you will probably need to purchase additional licenses, or reduce number of installations of the mapr-loopbacknfs service.`
`mount.nfs: Protocol not supported`	`The NFS directory with mapr-loopbacknfs is already mounted.`

3. Verify that settings in configuration files are correct.

last-updated: Jun 06, 2024

- For all clusters: `/usr/local/mapr-loopbacknfs/conf/mapr-clusters.conf`
- For secure clusters: `MAPR_TICKETFILE_LOCATION`

4. Check for “stale” mounts.
   - The `mount_local_fs.pl` script can cause the initscript wrapper to force unmounts of the mounted file systems.
   - Always check for stale mounts after stopping the service:
     - `df -k` should return instantly.
     - Use `umount -f <mount_point>` to force the unmount.
     - Use `ps -ef | grep mount_local` to confirm that the script is not stuck.

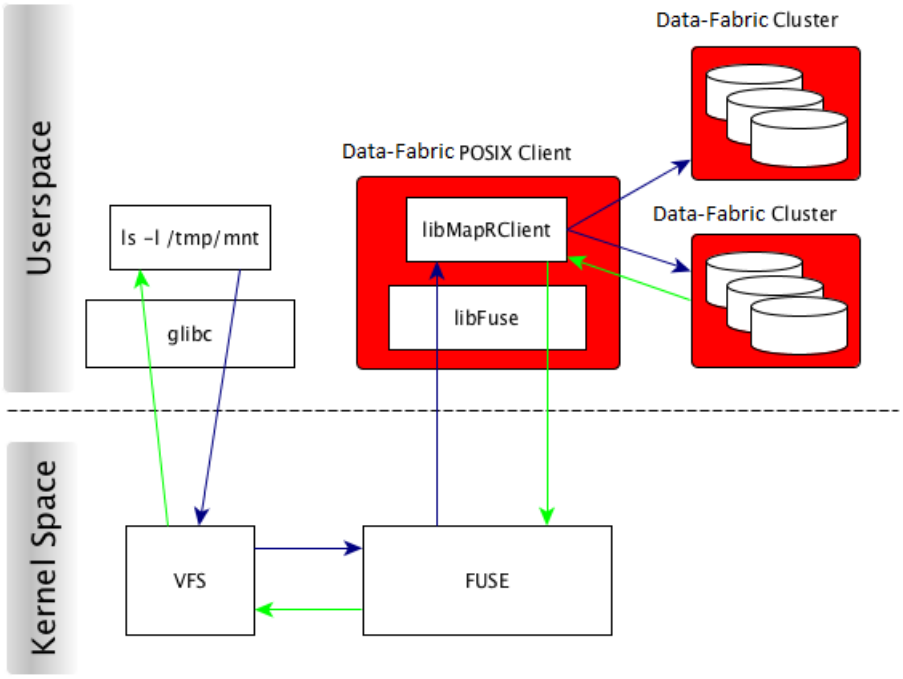
HPE Ezmeral Data Fabric FUSE-Based POSIX Client
Provides a brief description of the FUSE-based POSIX client.

The HPE Ezmeral Data Fabric FUSE-based POSIX client (either *mapr-posix-client-basic* or *mapr-posix-client-platinum*) allows app servers, web servers, and other client nodes and apps to read and write data directly and securely to a HPE Ezmeral Data Fabric cluster like a Linux filesystem.

The same HPE Ezmeral Data Fabric client can access both secure and nonsecure clusters; however, a HPE Ezmeral Data Fabric client that is configured to access a secure cluster can access a nonsecure cluster only if these conditions are met:

1. The secure cluster must be listed in the `mapr-clusters.conf` file.
2. A user must obtain a ticket for the secure cluster even if the user wants to access only the nonsecure cluster.

The FUSE-based HPE Ezmeral Data Fabric POSIX client runs as a userspace process to connect to one or more HPE Ezmeral Data Fabric clusters. The necessary FUSE (Filesystem in Userspace) library (`libfuse`) is bundled with the POSIX client package. With the installation of the POSIX client package, the HPE Ezmeral Data Fabric POSIX client performs operations such as read and write on the filesystem exposed by FUSE. The following diagram illustrates how the HPE Ezmeral Data Fabric FUSE-based POSIX client works.



Example of Mounting FUSE
This example shows you how to mount FUSE and perform operations as a regular user.

The following example is a quick introduction to mounting FUSE and accessing the mount point as a regular user.

Assume that you have a mount point */mapr* that you want to mount on FUSE and access as user *kate*.

Perform the following steps:

1. Create the user *kate*: Run

   ```
   adduser kate
   ```

2. Generate a ticket with impersonation as user *kate*. You will use this ticket to mount and access FUSE. Run:

   ```
   maprlogin generateticket -type servicewithimpersonation -user
   kate -out /var/tmp/sample_ticket
   ```

   NOTE: For more information on generating a ticket with impersonation, see How Impersonation Works on page 1943 and Generating a Service with Impersonation Ticket on page 1833

3. Edit the `/opt/mapr/conf/fuse.conf` file and set `fuse.ticketfile.location=/var/tmp/sample_ticket`

4. The mount point */mapr* is already set in the `fuse.conf` file.

   NOTE: Change `fuse.mount.point=/mapr` if your mount point is different from */mapr*.

5. Create the */mapr* directory. Run:

   ```
   mkdir /mapr
   ```

last-updated: Jun 06, 2024

6. Start the MapR FUSE POSIX client, either *basic* or *platinum* as per your licence. For example:

```
service mapr-posix-client-basic start
```

The */mapr* directory is now mounted on FUSE. You can perform all operations on */mapr/* as the user *kate*.

Introduces impersonation functionality, limitations, and core requirements.

Generating a Service with Impersonation Ticket on page 1833

Configuring the HPE Ezmeral Data Fabric FUSE-Based POSIX Client

Lists FUSE configuration parameters.

FUSE Parameters

You can set the POSIX client configuration values in the `/opt/mapr/conf/fuse.conf` file. After installing the FUSE-based POSIX client, you can edit the configuration file to define the values for the following parameters and save the file.

To retrieve the list of configuration parameters, run the following command:

```
/opt/mapr/bin/posix-client-* --help
```

Here * refers to the basic or platinum client package installed on the system. If necessary, set the shared `LD_LIBRARY_PATH` environment variable to run the `help` option with the command. For example:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/
java-1.7.0-openjdk-1.7.0.79.x86_64/jre/lib/amd64/server/:/opt/mapr/lib
```

NOTE: The HPE Ezmeral Data Fabric FUSE-based POSIX clients support only the configuration parameters in the `fuse.conf` file. All other FUSE configuration parameters are not supported. For more information on the non-mapr configuration parameters, refer to FUSE documentation.

`fuse.access.type`

Default Value: rw

Sets the type of access on the mount point. Value can be:

- `ro` — Read only
- `rw` — Read and write

`fuse.affinity`

Default Value: 0 (Disabled)

Specifies whether to enable (`1`) or disable (`0`) NUMA affinity. If enabled, sets the NUMA affinity for the POSIX client.

`fuse.allow.other`

Default Value: 1

Allow other users to access the mount point. Value can be one of:

- `0` - do not allow other users

- `1` - allow other users

Set this to `1` if the `root` user starts the FUSE service. Set to `0` or comment out this parameter if a non-root user starts the FUSE service . If set to `1`, also add the `user_allow_other` parameter to the `/etc/fuse.conf` file.

`fuse.asyncdirect.io`

Default Value: 1

Specifies whether to enable asynchronous direct IO. Value can be one of:

- `0` - disable
- `1` - enable

`fuse.attr.timeout`

Default Value: 3.0

The timeout value in seconds for file/directory (regular) attributes (such as file size, UID, and GID, which are normally stored inside the inode) cache. This value is used to determine whether to use the cached attribute information (only if within the specified timeout window) or fetch attribute information again. The default is 3.0 seconds, which specifies that cached attribute information must be considered stale and refreshed after 3.0 seconds. You can assign fractions of a second as well (for example, `fuse.attr.timeout=2.8`).

Set the value for this parameter to `0` to compare POSIX (pjd) compliance with the ext3/4 file system. A value of 0 disables caching. For better performance, avoid disabling caching.

`fuse.auto.inval.data`

Default Value: 1

Specifies whether (1) or not (0) to automatically invalidate the kernel FUSE cache for any data change that causes mtime change, on the files. If set to `1`, when the file is read, the correct file data is returned. If set to 0, the kernel cache of the data, which might not have the most current change, is returned.

`fuse.auto.unmount`

Default Value: 1

Specifies whether to automatically unmount the filesystem when the process is terminated. Value can be one of:

- `0` - disable
- `1` - enable

`fuse.big.writes`

Default Value: 1

Specifies whether to enable writes larger than 4KB. Value can be one of:

- `0` - disable
- `1` - enable

Sets the size of the data/buffer that can be transferred from the kernel to the FUSE library, per request. If enabled, FUSE allows writes of 128KB from the kernel. If disabled, FUSE allows writes of 4KB from the kernel.

last-updated: Jun 06, 2024

fuse.client.lib.path

Default Value: `/tmp`

Specifies the path to store the client libraries.

NOTE: To install and use FUSE-based POSIX client and NFS v4 on the same node, ensure that the path for both the client library for the FUSE-based POSIX client, and NFS v4 is not `/tmp`, which is the default. Specify a different location for the client libraries. For example, `/tmp/fuselib`.

fuse.cluster.conf.location

Default Value: `/opt/mapr/conf/mapr-clusters.conf`

The path to the configuration file to use.

fuse.congestion.threshold

Default Value: 10

Specifies the kernel's congestion threshold.

fuse.disable.shardcache

Default Value: 0 (false)

Specifies whether to disable shard cache, which is a cache of lookups. Value can be:

- `0` - false
- `1` - true

If true, more number of lookup calls are used. The FUSE client uses the shard cache to ensure that requests for data related to the same file are served by the same library. This is done using hash to improve performance. In very rare circumstances, it might make sense to disable this cache in conjunction with HPE Ezmeral Data Fabric support.

fuse.disable.writeback

Default Value: 0

Specifies whether (`1`) or not (`0`) to disable the writeback cache. This parameter is applicable only in kernel versions >= 3.15. By default, in kernel versions >= 3.15, writeback is enabled. To disable writeback cache, set the value for this parameter to `1`. If enabled, the writes are buffered in the kernel. However, when multiple FUSE clients work on the same file, writes to a file by one FUSE client might never be seen by other FUSE clients performing a read because the kernel does not update the attributes of the file unless the file is modified locally. You can disable the writeback cache to allow the kernel to perform a write through.

fuse.enforce.core.pattern

Default Value: false

Specifies whether (`true`) or not (`false`) to write to `/proc/sys/kernel/core_pattern` file when the FUSE-based POSIX starts. The default value is `false`. If `true`, the `core_pattern` file contains an `/opt/cores/%e.core.%p.%h` entry and if `false`, the file is not touched.

fuse.entry.timeout

Default Value: 3

The timeout value in seconds for the name lookup cache. Use this parameter to determine whether to use the cached entry for the name lookup (if within the specified timeout window) or lookup the name again. The default is 3 seconds, which specifies that cached name lookup information must be considered stale and refreshed after 3 seconds. For this option, it is possible

last-updated: Jun 06, 2024

to give fractions of a second as well (for example, `fuse.entry.timeout=2.8`).

Set the value for this parameter to `0` to compare POSIX (pjd) compliance with the ext3/4 file system. Avoid retaining this value as 0 as it disables the cache, and impacts performance.

`fuse.evenly.spread.data`

Default Value: 0

Specifies whether (`1`) or not (`0`) to evenly spread writes across the nodes on the cluster. If set to `0`, writes are always sent to the local primary node, from where data is replicated on all the other nodes. If set to `1`, writes are distributed across different nodes. Set the value to `1` in case of reduced performance resulting from a large number of writes on the local primary node.

`fuse.export`

Default Value: `/mapr`

Denotes the fully-qualified cluster path to the volume or directory under the mount point.

When you do not specify a value, all clusters found in `mapr-clusters.conf` are mounted under the entity specified by the `fuse.mount.point` property (`/mapr` by default). If `mapr-clusters.conf` contains two clusters A and B, there are directories pointing to the root directories of those clusters, for example `/mapr/A` and `/mapr/B`.

When you specify a value, it overrides the default behavior, and causes exactly one path from one cluster to be exposed at the entity specified by the `fuse.mount.point` property. You can either fully expose a single cluster, or expose only a subset of a single cluster.

If you set `fuse.export` to the name of a cluster, enclosed within `/`, then that cluster is mounted at `/mapr`. For example if `fuse.export=/A/`, then the path `/mapr` shows the root directory of cluster A.

If you set `fuse.export` to a path within a cluster, then `/mapr` points to that path. For example, if `fuse.export=/A/var/`, then `/mapr` displays the directory contents of `/var` from the HPE Ezmeral Data Fabric cluster A.

NOTE: If the value is not a valid path to the name of a volume or directory, the FUSE service does not start. The value *cannot* be the path to a file.

`fuse.fast.local.directio`

Default Value: 0

Specifies whether to optimize (1) or disable (0) FUSE client for local direct IO. Value can be one of:

- `0` - disable
- `1` - optimize

`fuse.flush.inline`

Default Value: 0

Specifies whether (1) or not (0) to flush all writes inline. Value can be one of:

last-updated: Jun 06, 2024

	• `0` - disable inline flushing • `1` - flush all writes inline If disabled, for all open files, by default, the buffer is flushed automatically every 3 seconds or when it reaches 64KB. If enabled, writes are sent to server directly.
`fuse.fsname`	*Default Value:* FUSE mount point Specifies the filesystem source, which is the first field in the `/etc/mtab` file. The default value is the FUSE mount point that is denoted by the parameter `fuse.mount.point`.
`fuse.hb.interval`	*Default Value:* 5 Specifies the heartbeat interval (in seconds) for the FUSE-based POSIX client.
`fuse.log.debug_level`	*Default Value:* error The FUSE-based POSIX client log level. The value can be one of: • `fatal` • `error` • `warn` • `info` • `debug`
`fuse.log.path`	*Default Value:* `/opt/mapr/logs` Specifies the path to store the log files.
`fuse.max.background`	*Default Value:* 64 Specifies the maximum number of asynchronous requests that can be submitted. IO requests beyond the maximum limit are blocked.
`fuse.max.cache.pages`	*Default Value:* 1048576 (1 Million pages) Specifies the maximum number of pages (each page is 8KB) in the page cache that each HPE Ezmeral Data Fabric Client library in FUSE process can use when working with a large number of open files. This setting limits the amount of memory consumed by FUSE.
`fuse.max.read`	*Default Value:* 131072 Specifies the maximum size (in bytes) of read requests.
`fuse.max.readahead`	*Default Value:* 131072 Specifies the maximum number of bytes to read ahead.
`fuse.max.write`	*Default Value:* 131072 Specifies the maximum number of bytes that is allowed in a single write request.
`fuse.mount.point`	*Default Value:* `/mapr`

last-updated: Jun 06, 2024

This parameter is mandatory. Specifies the mount point where the HPE Ezmeral Data Fabric filesystem must be mounted. Ensure that the specified mount point is empty before starting the service. Once mounted, the POSIX client has access to all the clusters specified in `/opt/mapr/conf/mapr-clusters.conf` file. The value should not be `/mapr` if you wish to mask HPE Ezmeral Data Fabric branding.

NOTE: If NFS server is also running on this node, ensure that the FUSE mount point is different from the NFS server mount point.

`fuse.mount.setuid`

Default Value: `0`

By default, FUSE mounts with the `nosuid` option. This prevents users other than root from running executable files with the SUID bit set, on FUSE. Enable this parameter (set to 1), to allow users other than root to run executable files with the SUID bit enabled, on the HPE Ezmeral Data Fabric Fuse FileSystem.

This parameter works in conjunction with the `allowreadforexecute` parameter in volume create on page 2588 and volume modify on page 2676 commands.

The following table describes how both parameters work together to permit running SUID binaries:

Table

fuse.mount.setuid	allowreadforexecute	Result
Disabled	Does not matter	SUID binaries cannot be executed by users other than *root*.
Enabled	Disabled	Users other than *root* can run the SUID binaries only when the binary has **both read and execute permissions**.
Enabled	Enabled	Users other than *root* can execute the SUID binaries either when the binary has **both read and execute permissions** OR **execute permission alone**.

`fuse.negative.timeout`

Default Value: 3

Applicable for the Container, Basic, and Platinum POSIX clients.

last-updated: Jun 06, 2024

	Indicates the duration in seconds to cache negative lookup results. Negative lookup results that are returned when a file does not exist (lookup retuned ENOENT), are cached for the specified number of seconds. The lookup is performed again, only after this period elapses. The file is deemed to be non-existent till this period elapses. The default value of 3 indicates that negative lookup results are cached for 3 seconds. Set this value to `0` to disable the negative lookup cache. When patching or upgrading the client from an older release, this parameter is automatically applied. However, new parameters are not automatically written to `fuse.conf`. Make sure to copy this parameter from `fuse.conf.new` to `fuse.conf`, only if you want to change the default value, or disable this cache.
`fuse.nonempty`	*Default Value:* 0 Specifies whether FUSE can be mounted on a non-empty mount point (1) or on an empty mount point (0). Value can be: • 0 - indicates that mount point should be empty • 1 - indicates that mount point need not be empty
`fuse.num.libs`	*Default Value:* • Container - 1 • Basic - 1 • Platinum - 5 Specifies the number of client libraries to run with. For: • Container client, value must be 1. • Basic client, value must be 1. • Platinum client, default value is 5 and can be set to a value greater than 5. More than one library allows for more than 1GB/sec throughput on remote operations as each additional library increases the throughput by sharding operations across libraries (for parallelism). **NOTE:** Each additional library will consume additional memory and CPU.
`fuse.num.threads`	*Default Value:* 64 Specifies the number of FUSE threads in userspace per mount point. A higher number allows parallel processing of multiple operations. Recommended value is only up to 64.
`fuse.ra.sessions`	*Default Value:* • Container - 1

last-updated: Jun 06, 2024

- Basic - 1
- Platinum - 5

Specifies the number of parallel read ahead sessions per library. Each open file acts as one read ahead session. For example, for the default value of 5, up to 5 files can have read ahead sessions per library. If value is set to `0`, readahead is disabled.

NOTE: A greater value allows larger number of parallel read ahead sessions, which is useful if more number of files need to be opened simultaneously. However, each additional read ahead session consumes additional memory (512K per read ahead session) and threads.

`fuse.readdirplus`

Default Value: 1

Enables (1) or disables (0) `readdirplus` functionality for high latency networks. The `readdirplus` attribute returns the file handle and attribute information such as the name and the file ID, along with the directory entries, unlike the `readdir` attribute that requires the client to query the server separately for each directory entry. For the best performance, do not disable this parameter.

`fuse.sync.read`

Default Value: 0

Specifies whether to enable or disable synchronized reads. Value can be:

- `0` - disable
- `1` - enable

`fuse.ticketfile.location`

Default Value: `/opt/mapr/conf/maprfuseticket`

Specifies the ticket to use to start the service in secure mode. Generate the required ticket and place it in `/opt/mapr/conf/<maprfuseticket>`.

NOTE: To support impersonation, provide the mapr user ticket file location or the user's servicewithimpersonation ticket file location. You can use the mapr user ticket on the server node, and service with impersonation ticket on client node. The FUSE service must be started by the root user if servicewithimpersonation ticket is specified. In case of non-impersonated ticket, the ticket credentials becomes the identity for all the requests, no matter which user is accessing the fuse mount point.

See also: Setting up a Ticket for the POSIX Client.

`fuse.track.memory`

Default Value: false

Specifies whether to enable (`true`) or disable (`false`) memory tracking for FUSE.

`fuse.use.compressed.inode.format`

Default Value: 0

Specifies whether or not to use compressed inode format. When enabled, a 16-bit unique identifier is used to avoid inode cache collisions when multiple clients are modifying (creating, deleting, and similar

last-updated: Jun 06, 2024

operations) the same directories/files. The value can be one of:

- `0` — (default) do not use compressed inode format
- `1` — use compressed inode format including unique identifier

NOTE: Even when set to `1`, EBUSY errors are returned if client accesses more than 32k volumes at the same time.

Enabling this flag may not completely avoid inode cache collisions when too many modifications such as creation, and deletion are performed on the same directories or files. Give the kernel sufficient time to purge inode cache entries between modifications.

`fuse.xattr.enable`

Default Value: 0 (false)

Specifies whether (true) or not (false) to enable extended attributes through the FUSE client. Value can be one of:

- 0 - false
- 1 - true

The default value is 0 (false). This is disabled by default because if enabled, during operations, the kernel might make a lot of extended attribute calls for security checks resulting in performance degradation even when there are no extended attributes on the inode. When disabled, extended attributes can still be added using the `hadoop fs` command; however, this must be enabled to perform any operations on extended attributes using the FUSE-based POSIX client.

NOTE: Of the five types of extended attribute namespaces in Linux, system, trusted, user, raw, and security, only user namespace is supported. For all other namespaces, EINVAL is returned.

You must start/restart the FUSE-based POSIX client for the changes to take effect. See Starting and Stopping the POSIX Client for more information.

Configuration Backup When Installing/Upgrading POSIX Clients

When you install a patch, the `/opt/mapr/conf/fuse.conf.new` file contains the new settings. You can copy the new parameters (with default values) to your existing `fuse.conf` file and restart FUSE for the settings to take effect.

When you upgrade from a prior release, on all supported OS other than Ubuntu, the old `fuse.conf` file is backed up as `fuse.conf.backup`, before being overwritten with the new settings. This backup is available in the `/opt/mapr/conf` directory.

On Ubuntu, the upgrade process does not create a backup copy of the file. You need to manually backup the `fuse.conf` file before upgrading, as this file is overwritten with the new settings after upgrading.

last-updated: Jun 06, 2024

To continue using FUSE with your custom settings, and take advantage of the new settings, manually copy your custom settings in the `fuse.conf.backup` file to the `fuse.conf` file, set custom values for the new parameters in the `fuse.conf` file where necessary, and restart FUSE for the settings to take effect.

To restart FUSE, use one of the following commands depending on the POSIX client of your choice:

- For POSIX container: `service mapr-posix-client-container restart`
- For POSIX basic: `service mapr-posix-client-basic restart`
- For POSIX platinum: `service mapr-posix-client-platinum restart`

Optimizing FUSE performance when running the Flexible I/O tester (fio tool)

Performance Tips

- With Linux kernels prior to version 4.8, size extending writes are serialized by the kernel, and result in degraded write performance. For optimized write performance, ensure that the Linux kernel in use, is at least version 4.8.
- With kernel 4.8 and above, fio performance improves when using larger block sizes and larger number of jobs (numjobs). Keep numjobs constant and use larger blocksizes (>128k) for enhanced performance.

For example, for optimised performance, the `fio` command could be as follows:

```
fio --ioengine=libaio --direct=1 --gtod_reduce=1 --name=perftest --filename=
perfile
          --bs=16m --iodepth=64 --size=4G --rw=write --numjobs=4
```

Configuring Timeout for Inactive Connections
In cases where the file client connects infrequently to a remote CLDB node that is firewalled, TCP segments on the connection are silently dropped by the firewall due to the long idle time. However, the client keeps waiting for the response till RPC times out. To mitigate this scenario, you can now configure the timeout for inactive connections. Use the `fs.mapr.binding.inactive.threshold` parameter in the *core-site.xml* file to set this threshold in seconds. For example:

```
<property>
<name>fs.mapr.binding.inactive.threshold</name>
<value>600</value>
</property>
```

In this example, when the client tries to send data to the CLDB after a certain idle time, the system checks if the specified time (here 600 seconds, that is 10 minutes) is crossed after the previous request was sent. If so, the system tears down the existing TCP connection and creates a new TCP connection for the file client and CLBD to use for communication.

Tuning the Cache for FUSE-Based POSIX Clients
Describes performance tuning measures for FUSE clients.

The FUSE kernel and the FUSE userspace process caches both data and metadata. When an application performs a read of a file using the FUSE-based POSIX client, data is generally returned from the local FUSE kernel cache if that portion of the file resides in cache from a previous read or write operation. However, if the file has been modified on the HPE Ezmeral Data Fabric cluster by a different client, the data in the local kernel cache may be stale. The following illustration shows the layers of cache — FUSE kernel cache (referred to as kCache), the FUSE userspace cache (referred to as uCache), HPE Ezmeral Data Fabric file system cache (referred to as mfsCache) — and the following sections describe how these affect reads and writes and how the FUSE attributes can be used to tune the caching behavior.

Inode Attribute Cache

Inode attributes are cached in the FUSE kernel cache (kCache) and in the userspace cache (uCache). When the same file is accessed from multiple FUSE clients, writes on the file through one mountpoint may not be seen by other applications performing a read on the file (through a different client). The inode attributes are cached in the kernel because of which another application modifying the file might not see the updates instantly. For example, the inode attributes, to name a few, such as size, or modification timestamp (mtime) of the file, in the kCache and uCache on Node A might be stale if the file is being modified concurrently by an application on Node B.

Tuning the attribute timeout in kCache	The FUSE kernel refreshes inode attributes from the userspace FUSE process once every 3 seconds by default. This can be tuned through the `fuse.attr.timeout` parameter in the `fuse.conf` file. The `fuse.attr.timeout` parameter specifies the interval of time at which to refresh the inode attributes in kernel and can be used to minimize the amount of time it takes to refresh the cache. Even if `fuse.attr.timeout` is set to `0`, Node A might still not see the latest writes from Node B because there is cached metadata in the userspace FUSE process on Node A; metadata can be served from the uCache and the application might not see current updates for attributes like size. To see the latest changes on a file, see Tuning the attribute timeout in uCache on page 1625.
Tuning the attribute timeout in uCache	The userspace FUSE process caches both data and metadata and refreshes the inode attributes from the HPE Ezmeral Data Fabric file system once every 3 seconds; *this is not tunable*. Even if the `fuse.attr.timeout` is set to 0, because there is

	cached data and metadata in the userspace FUSE process (uCache), stale data or metadata can be served from the userspace FUSE process, which only refreshes inode attributes every 3 seconds. However, the userspace FUSE process updates the inode attributes every time a file is opened. To see the latest changes on a file, applications, especially readers on a file, that require to see updates on the file within 3 seconds can close and open the file to refresh the attributes and see instant updates.

Readdir Cache

Directory entries (files within a directory) are not cached in the uCache, but are cached in the kCache. The kCache can be stale on Node A if there are files being created in the directory by an application from the mountpoint on Node B. That is, a user listing directory entries on Node A for a directory (using a command like ls) might not see the files that were just created from Node B.

Tuning the entry timeout in kCache	The `fuse.entry.timeout` parameter specifies the interval of time at which to refresh the readdir (or lookup) cache in the kernel (kCache). The default value is 3 seconds and this can be configured in the `fuse.conf` file.

Data Cache

By default:

- Reads are buffered both in the kCache and the uCache.
- Writes are not buffered in the kCache, but are buffered in the uCache.

An application trying to read a file on Node A might not see the latest updates to the file (written from node B) for the following reasons:

- Reads on Node A might have been served either from the kCache or the uCache of Node A.

  See Tuning the cache for reads on page 1626 for information on invalidating the cache.

- The writes might have been buffered in the uCache of Node B.

  See Tuning the cache for writes on page 1627 for information on disabling buffering at a file level or altogether.

Tuning the cache for reads	**Tuning the kCache**	The `fuse.auto.inval.data` parameter specifies whether or not to automatically invalidate the kCache for any data change, which causes mtime change, on the files. If enabled, any mtime update on the file automatically invalidates the page cache of the file. The mtime is an inode attribute; for information on refreshing the cache for inode attributes, see Inode Attributes.

last-updated: Jun 06, 2024

	Tuning the uCache	Every read cache page is valid for 3 seconds. After 3 seconds, the read cache page is dropped from uCache. *This is not tunable*.
Tuning the cache for writes	**Tuning the kCache**	The `fuse.writeback.cache` parameter specifies whether to buffer writes in the kernel or to perform a write through. If enabled, the writes are buffered in the kernel. If disabled, writes are not buffered in the kernel and are directly sent to the FUSE process. By default, writeback caching is disabled; that is, the kernel sends all writes to the FUSE process directly. If an application does small writes, then the FUSE process might run out of CPU because of the overhead involved in small writes. To mitigate this, the FUSE kernel can be configured to enable caching in the kernel using the `fuse.writeback.cache` attribute. However, this can be enabled only on kernels running version >= 3.15.
	Tuning the uCache	The `fuse.flush.inline` attribute can be used to disable data buffering in the uCache. By default, the userspace FUSE process caches the writes locally. This parameter specifies whether to cache writes (for up to 3 seconds or 64KB in size) or write directly to server. This can be disabled at both the file and FUSE process levels. If the application does buffering before writing to file system, to avoid redundant buffering, you can disable buffering at the FUSE level by setting the

	`fuse.flush.inline` parameter value to `1` in the `fuse.conf` file. Caching can be disabled at a file-level by opening the file in `O_DIRECT` mode.

Caching Negative Lookup Results

FUSE issues thousands of lookup calls for the file, even when the initial lookup call has returned ENOENT, indicating that the file that does not exist, This behaviour is in contrast to NFS for the HPE Ezmeral Data Fabric, which caches the lookup result for a specified time. For example, when running a `git clone` operation on the *mapr-core* repository, testing indicated that FUSE issued 870k calls, while NFS for the HPE Ezmeral Data Fabric issued 82k calls, for files that are non-existent.

To reduce the number of negative lookups, and optimize performance, the FUSE configuration contains the `fuse.negative.timeout` parameter.

By default, this parameter is set to 3 seconds. Negative lookup results that are returned when a file does not exist (lookup retuned ENOENT), are cached for 3 seconds. The lookup is performed again, only after this period elapses. The file is deemed to be non-existent till this period elapses.

For more information on this parameter, check the FUSE configuration.

Configuring HPE Ezmeral Data Fabric FUSE-based POSIX Client for Tenant Environment
Explains the parameters to set to enable tenant user access to tenant shares from the FUSE-based POSIX client.

To enable tenant users to access the tenant share from the FUSE-based POSIX client, set the following configuration parameters in the `fuse.conf` file on the tenant host:

fuse.mount.point	Specifies the local mount path to where the cluster filesystem is going to mount. To mask the HPE Ezmeral Data Fabric branding from the tenant user, do not specify `/mapr` as the value for this parameter.
fuse.export	Specifies the path to the tenant volume mount path or directory under the tenant volume mount point. This is disabled by default, allowing users to access all the clusters specified in the `/opt/mapr/conf/mapr-clusters.conf` file. This must be set to enable the user on the tenant host to directly access only the specified volume or directory.
fuse.ticketfile.location	Specifies the path to the tenant ticket file to start the service in secure mode.

For more information on all other available and supported parameters, see Configuring the MapR FUSE-based POSIX Client.

Sample MapR FUSE-Based POSIX Client Configuration File

```
#Set path to the mount point
fuse.mount.point=/mapr

#Set path where logs shall be stored
fuse.log.path=/opt/mapr/logs

#Set path where client libraries shall be stored
fuse.client.lib.path=/tmp
```

```
#Allow all users to access the filesystem
fuse.allow.other=1

#Enable larger than 4kB writes
fuse.big.writes=1

#Enable NUMA affinity
fuse.affinity=0

#Auto unmount on process termination
fuse.auto.unmount=1

#Set number of libMapRClient libraries to run with
#fuse.num.libs=DEFAULT_NUM_LIBS

#Set number of readahead sessions
#fuse.ra.sessions=1

#Enable/Disable memory tracking for fuse
fuse.track.memory=false

#Set number of FUSE threads
#fuse.num.threads=64

#Enable async direct io
fuse.asyncdirect.io=1

#Set the maximum size of read requests
#fuse.max.read=128

#Set the maximum bytes to readahead
#fuse.max.readahead=128k

#Set the maximum size in a single write request
#fuse.max.write=128

#Enable sync reads
#fuse.sync.read=0

#Set number of maximum background requests
fuse.max.background=64

#Set kernel's congestion threshold
#fuse.congestion.threshold=10

#Flush all writes inline
#fuse.flush.inline=0

#Optimize for local direct writes
#fuse.fast.local.directio=0

#Optimize by evenly distribute data across cluster
#fuse.evenly.spread.data=0

#Disable shard cache
#fuse.disable.shardcache=0

#Sets the filesystem  source  (first  field  in  /etc/mtab).
#The default is the mount program name.
#fuse.fsname=NAME

#Set fuse ticket file
fuse.ticketfile.location=/opt/mapr/conf/maprfuseticket
```

last-updated: Jun 06, 2024

```
#fuse nonempty option to enable mounting at nonempty mount point
#fuse.nonempty=0

#by default, we support user namespace xattr.
#setting below option to 1 will enable the user xattr.
#fuse.xattr.enable=1

#Attribute timeout for inodes
#fuse.attr.timeout=3.0

#Entry timeout for inodes
#fuse.entry.timeout=3.0

#Hearbeat interval for FUSE in seconds
#fuse.hb.interval=5

#fuse sub exports
#fuse.export=/clus.default/vol1

#fuse core pattern
#fuse.enforce.core.pattern=true

#Readonly or readwrite, values are ro,rw
#fuse.access.type=rw

#Auto invalidation of data on mtime change
fuse.auto.inval.data=1

#Disable writeback cache
#If multiple fuse servers are operating on the same file then enabling
#this option will break consistency among different fuse servers i.e.
#writes to file1 on server1 will not be seen by an application reading
#file1 on server2 forever.
fuse.disable.writeback=1

#Set cluster configuration file
#fuse.cluster.conf.location=/opt/mapr/conf/mapr-clusters.conf

#Sets client debug level, values are fatal, error, warn, info, debug
fuse.log.debug_level = error;

#Inode compressed format
fuse.use.compressed.inode.format=0
```

Managing the FUSE-Based POSIX Client
Describes how to use the FUSE-based POSIX client.

Ports Needed for POSIX Clients and File System to Communicate With Each Other

POSIX clients communicate with the CLDB and server components of the HPE Ezmeral Data Fabric file system. You need to open the relevant ports for **TCP** connectivity from POSIX clients to the HPE Ezmeral Data Fabric file-system cluster nodes. Open the CLDB, file-system server, and file-system server instances ports.

- CLDB - Ports 7222 and 7223.
- File-System Server - 5660, 5692, 5724, 5756, and 6660.

For better performance, you can open additional CLDB ports. See Ports Used by HPE Ezmeral Data Fabric Software on page 3079 for more information.

When using Multi-MFS instances, open the relevant ports for these instances to work. For example, instance 0 will use four ports from 5660, 5692 (5660+32), 5724 (5660+64), and 5756 (5660+96), instance

last-updated: Jun 06, 2024

1 will use four ports from 5661, 5693, 5725, 5757, and so on for every additional instance. See Working with Multiple Instances of the File System on page 1096 for more information.

Setting up a Ticket for the POSIX Client

The POSIX client can be accessed using user and service tickets. The service tickets have long lifetimes, by default, for ease of administration. This is useful for running application processes that should not be bounded by the CLDB duration (`cldb.security.user.ticket.duration.seconds`) and renewal (`cldb.security.user.ticket.max.duration.seconds`) properties, which limit the lifetime of user tickets. If you plan to use a user ticket, ensure that the user has read permissions on the ticket file.

Regardless of the ticket type, after generating the ticket, set the `fuse.ticketfile.location` parameter value in the `fuse.conf` file to point to the ticket file to use.

For more information, see:

- Generating a HPE Ezmeral Data Fabric User Ticket on page 1831
- Generating a Service Ticket on page 1832

NOTE: If the UID/GID in the ticket (without impersonation capability) is different from the UID/GID of the logged-in user, all operations are performed using the UID/GID of the ticket and not that of the logged-in user.

Starting and Stopping the POSIX Client

To ensure that the service can be started and stopped and to run the help option, set the shared `LD_LIBRARY_PATH` environment variable. Update the shared library environment variable to include the paths to the following:

- Full path to the directory containing `libjvm.so` file
- `$MAPR_HOME/lib` (that is, `/opt/mapr/lib` directory)

For example:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/
java-1.7.0-openjdk-1.7.0.79.x86_64/jre/lib/amd64/server/:/opt/mapr/lib
```

To allow a non-root user to start this service, as administrator or `root` user, run the following command:

```
chmod u+s /opt/mapr/bin/fusermount
```

Verify that permissions have been set for the non-root user to start the service. For example:

```
ls -l /opt/mapr/bin/fusermount
```

Your output should look similar to the following:

```
-rwsr-xr-x 1 root root 39704 Feb 16 19:41 /opt/mapr/bin/fusermount
```

Ensure that the non-root user has full permissions on the mount point and log files.

To manually start or stop the service:

```
service mapr-posix-client-* [start|stop|status]
```

When you run the command, replace * with basic or platinum, which corresponds with the package that is installed on the system.

last-updated: Jun 06, 2024

NOTE: The POSIX client service cannot be stopped or restarted if any other process is accessing the mount point. With `systemd` (on CentOS/RH 7.x and SLES 12), the service will enter failed state (if you tried to stop) or activating state (if you tried to restart) and you must manually kill the client processes.

Running the POSIX Client in Secure Mode

The POSIX client reads the `mapr-clusters.conf` file to determine whether the process must start in secure or non-secure mode. If security is configured, the `servicewithimpersonation` ticket file must be present in the default `/tmp` directory. If the ticket file is not in the default `/tmp` directory, specify the location of the ticket file using the `fuse.ticketfile.location` configuration parameter in the `fuse.conf` file

TIP: See also: Enabling Impersonation for the HPE Ezmeral Data Fabric Superuser on page 1945 and Enabling Impersonation for any User on page 1946.

If the ticket expires after a connection has been established between the POSIX client and the cluster, the connection can stay alive for up to an hour. No new connections will be allowed. If the access to the ticket was denied, restart POSIX client to refresh the ticket.

Mounting the File System

To mount the HPE Ezmeral Data Fabric file system at the mount point specified in the `/opt/mapr/conf/fuse.conf` file, create the mount point specified in the `fuse.conf` file and start the service. For example:

```
mkdir /mapr
service mapr-posix-client-* start
```

NOTE: If security software blocks the FUSE subsystem or kernel, the mounting process can be inhibited, or access to the FUSE mount using available commands can hang. Examples of such security software include:

- CrowdStrike Falcon Sensor Service
- Vormetric Data Security Manager
- Tripwire file-integrity monitoring solutions
- Symantec Agent for Linux IDS daemon

Contact your HPE customer support representative if you experience related issues.

NOTE: When you run the command, replace * with basic or platinum, which corresponds with the package that is installed on the system.

ATTENTION: Remember the following points when using a FUSE mounted file system:

- When trying to open a FIFO on a FUSE mounted file system, permissions to perform the operation are not checked.
- Any user can set time using `touch -t` for any file on a FUSE mounted file system.

See also: Enabling Soft Mount and Setting the Timeout on page 452

last-updated: Jun 06, 2024

Monitoring the POSIX Client

To determine whether the POSIX client is running, run the following command:

```
service mapr-posix-client-* status
```

NOTE: When you run the command, replace * with basic or platinum, which corresponds with the package that is installed on the system.

Adding and Removing Users

Before you add and/or remove users using the POSIX client, make a note of the following:

- Invalid UID/GID cannot perform operations on the system.
- When you add or remove users, it may take up to 30 minutes for the changes to take effect.

By default, the UID cache will expire in 30 minutes. To disable UID cache, set the value (in seconds) for `fs.mapr.uid.cache.timeout.seconds` parameter in the `core-site.xml` file. You can set the value to:

- `0` to fetch the GID information from the idstore directly
- `>0` to specify the amount of time to keep the UID information in cache

For example, your `core-site.xml` entry would look similar to the following for:

- Disabling cache:

```
<property>
   <name>fs.mapr.uid.cache.timeout.seconds</name>
   <value>0</value>
   <description>disable UID cache</description>
</property>
```

- Setting 3 minutes as the amount of time to keep the UID information in cache:

```
<property>
   <name>fs.mapr.uid.cache.timeout.seconds</name>
   <value>180</value>
   <description>UID cached for 3 minutes</description>
</property>
```

Registering POSIX Client with Additional Clusters

To register the POSIX client with additional clusters, you must add entries directly to the `/opt/mapr/conf/mapr-clusters.conf` file. The clusters will be visible after few minutes.

NOTE: Each client supports up to 16 clusters.

Configuring the FUSE Read Chunk Size

The POSIX FUSE platinum client can break large reads into multiple pieces to be handled in parallel, if you set the FUSE read chunk size of a file. This process is called sharding.

last-updated: Jun 06, 2024

By default, the FUSE read chunk size is set to 2 MB. To change the chunk size used by the FUSE platinum client for parallel reads, set the value (in bytes) for the `fs.mapr.fuseshard.chunksize` configuration field in the `core-site.xml` file. To set the chunksize to 5 MB (5242880 bytes), use:

```
<property>
        <name>fs.mapr.fuseshard.chunksize</name>
        <value>5242880</value>
        <description>setting chunk size</description>
        </property>
```

For example, if the FUSE read chunk size is set to 1 MB, and the FUSE platinum client is configured with 5 libraries, then the platinum client reads 5 MB in parallel.

Unmounting the FUSE Mount

To unmount the mountpoint and kill the FUSE process, run the following command:

```
service mapr-posix-client-* stop
```

NOTE: When you run the command, replace * with basic or platinum, which corresponds with the package that is installed on the system.

Troubleshooting the FUSE-Based POSIX Client

Explains how to enable and collect the stack trace to troubleshoot POSIX client issues.

This section contains information for troubleshooting the FUSE-based POSIX client.

Enabling Traces

To enable traces at system startup, set the property `fs.mapr.trace` in the `core-site.xml` file. For example:

```
<property>
   <name>fs.mapr.trace</name>
   <value>DEBUG | INFO | WARN | ERROR | CRITICAL | OFF</value>
   <description> </description>
</property>
```

Collecting the Stack Trace

If the mountpoint is not responding or if the filesystem operations are taking too much time, collect the stack trace of all the threads to debug. To collect the stack trace of all threads, run the following command:

```
gstack <fuse-process-id> > ./gstack.log
```

If the filesystem commands fail, repeat the filesystem command with `strace` and collect the log file:

```
strace <filesystem command> > ./strace.log
```

Managing the MAST Gateway

About this task

You can start, stop, and restart the MAST Gateway using the MapR Control System and the CLI. You can also configure how frequently MapR runs the load balancer to balance the load on the MAST Gateway.

Configuring the MAST Gateway Service

last-updated: Jun 06, 2024

About this task

After installing MAST Gateway service, perform the following steps on the node if file system is not installed on the node. If file system is (also) installed on the node, start at step 4:

Procedure

1. Run `configure.sh` on page 2821 utility.

   For example:

   ```
   /opt/mapr/server/configure.sh -C <CLDB nodes> -Z <Zookeeper nodes> -N
   <ClusterName>
   ```

2. Start Warden if it is already not running.

   ```
   service mapr-warden start
   ```

3. Run `jps` or `/etc/init.d/mapr-mastgateway status` to check whether MAST Gateway is running on the node.

4. Open the `/opt/mapr/conf/mastgateway.conf` file and set values for the following parameters:

Parameter	Default Value	Description
`mastgateway.port`	8660	The port on which the MAST Gateway process runs. Default value is 8660.
`mastgateway.worker.numthreads`	16	The number of threads to execute tiered data operations such as read and modify part of the offloaded data. The default value is 16. You can modify this based on the machine's configuration.
`mastgateway.cntr.worker.numthreads`	16	The number of threads to use to execute container-based tiered data operations such as offload and recall of file-level and volume-level data in parallel. The default value is 16. **TIP:** For faster offload, modify this value based on the machine's configuration.
`mastgateway.logfile.size.mb`	1024	The maximum size (in MB) of the MAST Gateway log file. When the size limit is reached, the logs get rolled over.

   NOTE: If you modify the `mastgateway.conf` file, you must restart the MAST Gateway for the changes to take effect.

5. (Optional) Add the following parameters in the `/opt/mapr/conf/mastgateway.conf` file only if you wish to customize libcurl.

   The MAST Gateway uses libcurl to perform tiering-related operations. The following table lists the customizable libcurl options and their default values. If these are not set in the `mastgateway.conf` file, the default values are used.

last-updated: Jun 06, 2024

NOTE: In the `mastgateway.conf` file, add only the parameters that you wish to customize.

Parameter	Default Value	Description
`mastgateway.curl.timeout`	300000	Timeout for the entire request.
`mastgateway.curl.connecttimeout`	60000	Timeout for the connection phase.
`mastgateway.curl.nosignal`	0	Do not install signal handlers.
`mastgateway.curl.followlocation`	0	Follow HTTP redirects.
`mastgateway.curl.maxsendspeed`	0	Limit on data upload speed.
`mastgateway.curl.maxrecvspeed`	0	Limit on data download speed.
`mastgateway.curl.maxconnects`	5	Maximum number of connections in the connection pool.
`mastgateway.curl.dnsservers`	null	Preferred DNS servers.
`mastgateway.curl.interface`	null	Bind connection locally to this.
`mastgateway.curl.verifypeer`	1	Verify the SSL certificate.
`mastgateway.curl.verifyhost`	2	Verify the host name in the SSL certificate.
`mastgateway.curl.cainfo`	null	CA cert bundle.
`mastgateway.curl.issuercert`	null	Issuer certificate.
`mastgateway.curl.sslcert`	null	Client cert.
`mastgateway.curl.sslcerttype`	null	Client cert type.
`mastgateway.curl.sslkey`	null	Client key.
`mastgateway.curl.sslkeytype`	null	Client key type.
`mastgateway.curl.sslkeypasswd`	null	Client key password.
`mastgateway.curl.proxy`	null	Proxy to use. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
`mastgateway.curl.preproxy`	null	Socks proxy to use.
`mastgateway.curl.proxyport`	0	Proxy port to use. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.

last-updated: Jun 06, 2024

Parameter	Default Value	Description
`mastgateway.curl.proxytype`	0	Proxy type. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
`mastgateway.curl.httpproxytunnel`	0	Tunnel through the HTTP proxy. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
`mastgateway.curl.proxyuser`	null	Proxy user name. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
`mastgateway.curl.proxypasswd`	null	Proxy password. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
`mastgateway.curl.proxyauth`	1	HTTP proxy authentication methods. **Note:** Specify a value for this parameter to configure MAST Gateway to use a proxy server. See example below this table for more information.
`mastgateway.curl.proxyverifypeer`	1	Verify the proxy's SSL certificate.
`mastgateway.curl.proxyverifyhost`	2	Verify the proxy certificate's name against host.
`mastgateway.curl.proxycainfo`	null	Path to proxy Certificate Authority (CA) bundle.
`mastgateway.curl.proxysslcert`	null	SSL proxy client certificate.
`mastgateway.curl.proxysslcerttype`	null	Type of the proxy client SSL certificate.
`mastgateway.curl.proxysslkey`	null	Private keyfile for TLS and SSL proxy client cert.
`mastgateway.curl.proxysslkeytype`	null	Type of proxy private key file.
`mastgateway.curl.proxysslkeypasswd`	null	Passphrase for proxy private key.

last-updated: Jun 06, 2024

For example, to configure the MAST Gateway for proxy server, your `mastgateway.conf` file settings for proxy server should look similar to the following:

```
mastgateway.curl.proxy=10.20.30.140

mastgateway.curl.preproxy=null

mastgateway.curl.proxyport=3128

mastgateway.curl.proxytype=0

mastgateway.curl.httpproxytunnel=0

mastgateway.curl.proxyuser=proxyuser

mastgateway.curl.proxypasswd=proxyuserpwd

mastgateway.curl.proxyauth=1
```

6. Save and close the `/opt/mapr/conf/mastgateway.conf` file.
7. (Optional) Configure memory for the MAST Gateway in the `/opt/mapr/conf/conf.d/warden.mastgateway.conf` file by setting values for the following parameters:

Parameter	Default Value	Description
`service.heapsize.min`	2048	The minimum amount of node memory (in MB) to allocate.
`service.heapsize.max`	20480	The maximum amount of node memory (in MB) allocate.
`service.heapsize.percent`	10	The percentage of node memory to allocate.

By default, 10% of the node memory or 20GB, whichever is lower, is allocated to MAST Gateway. If the MAST Gateway is processing jobs for both warm and cold tiers, memory consumption can increase up to 7GB or more. If you see high memory alarms for small memory consumption also, tune the percentage of memory allocated for MAST Gateway. Ensure that the percentage of memory allocated through `service.heapsize.percent` is available for MAST Gateway.

8. (Optional) Set the value for `fs.mapr.pool.queue.max_size` parameter to 20000 in the `/opt/mapr/conf/dbclient.conf` file.

   If compression is enabled on the data in a tiering-enabled volume, tiering jobs can fail and return errors because of the large number of operations sent to the DB (where metadata for offloaded data is stored). To prevent errors, add the `fs.mapr.pool.queue.max_size` parameter to the `/opt/mapr/conf/dbclient.conf` file and set the value for this parameter to a large number, such as 20000. For example, your entry in the `/opt/mapr/conf/dbclient.conf` file should look similar to the following:

   ```
   fs.mapr.pool.queue.max_size = 20000
   ```

9. Restart the MAST Gateway for the changes to take effect.
   See Starting, Stopping, and Restarting the MAST Gateway on page 1639 for more information.

Configuring Secure Access

About this task

If the MapR cluster is a secure cluster and the MAST Gateway is installed on a cluster node, no additional configuration is needed for the MAST Gateway to access data. On the other hand, if the MapR cluster is a secure cluster and if MAST Gateway is installed on an edge node, to enable the MAST Gateway to communicate with the secure MapR cluster, do the following:

Procedure

1. Copy the `/opt/mapr/conf/maprserverticket`, `/opt/mapr/conf/ssl_keystore`, and `/opt/mapr/conf/ssl_truststore` files on the CLDB node to the `/opt/mapr/conf` directory on the edge node.
2. Run `configure.sh` as shown below:

   ```
   /opt/mapr/server/configure.sh -C <cldb-node-IP-addresses> -Z
   <zookeeper-node-IP-addresses> -secure -N <cluster-name>
   ```

   See `configure.sh` on page 2821 for more information.

Starting, Stopping, and Restarting the MAST Gateway

About this task

You can start, stop, and restart the MAST Gateway using the Control System and the CLI.

Starting, Stopping, and Restarting the MAST Gateway Using the Control System

About this task

See:

- Starting the Services on the Cluster Using the Control System on page 1140
- Stopping a Service on the Cluster Using the Control System on page 1141
- Restarting the Services on the Cluster Using the Control System on page 1142

Starting, Stopping, and Restarting the MAST Gateway Using the CLI

Procedure

- Run the following command to:
  - Start the MAST Gateway:

    ```
    maprcli node services -nodes <nodename|IP_address> -name
    mastgateway -action start
    ```

  - Stop the MAST Gateway:

    ```
    maprcli node services -nodes <nodename|IP_address> -name
    mastgateway -action stop
    ```

- Restart the MAST Gateway:

```
maprcli node services -nodes <nodename|IP_address> -name
mastgateway -action restart
```

Balancing Gateway Load
Explains how CLDB balances MAST Gateway loads.

About this task

CLDB assigns volumes to MAST Gateways so that any tiering-related operation for a volume is performed by the MAST Gateway assigned to the volume. This assignment is sticky and the volume remains assigned to the same gateway across CLDB, MAST Gateway, and cluster restarts. When a MAST Gateway goes down, volumes assigned to the MAST Gateway are not re-assigned immediately. Instead, when a tiering operation needs to be run and the assigned MAST Gateway is down, CLDB assigns a new MAST Gateway to the volume, and the operation is performed using the newly assigned MAST Gateway.

Volumes are assigned to gateways with the lowest load (or lowest number of volumes currently assigned to it) to ensure equal distribution. Whenever a volume is created or removed or whenever a MAST Gateway is added or removed, the load on the gateways require rebalancing. HPE Ezmeral Data Fabric automatically balances the load on the gateways after a certain (configurable) amount of time since the occurrence of the event that necessitates a rebalance. The delay after which HPE Ezmeral Data Fabric tries to rebalance varies based on the type of event that necessitates a rebalance. See Configuring the Delay After Which Load Balancer runs for Events on page 1641 for more information.

Each volume in the cluster is assigned a weight, which is 1 for all volumes. The load on a gateway is the sum of weights of all the volumes that are assigned to the gateway. Load balancer tries to ensure that the load on a gateway is at least the average weight.

```
avg weight = (sum(weight of all tiered vols) + num active gws - 1) / num
active gws
```

When the balancer needs to pick volumes from a gateway for reassignment, it first picks the volume with max weight and one that currently has no activity (volume level offload, recall, or compaction). To minimize the interruptions in gateway activity, the balancer first considers idle volumes and picks volumes with active tasks after. However, any balancing and/or reassignment is skipped if there is already assignment related flux in the cluster (such as volumes with gateway assignment currently in progress). If this happens, load balancer runs again with a shorter time delay of 10 minutes.

HPE Ezmeral Data Fabric performs load balancing in batches of 5 volumes per run. That is, it assigns 5 volumes to gateways and then after a delay of 10 minutes by default, runs the load balancer again to distribute other volumes (in batches of 5). HPE Ezmeral Data Fabric figures out the next batch of volumes by re-evaluating the current assignment state. When the load on the gateway is balanced, the balancer is disabled and the load balancer is run again only by any of the 4 events.

Configuring Interval Between Load Balancer Runs

Procedure

- HPE Ezmeral Data Fabric assigns 5 volumes to gateways and then after a delay of 10 minutes by default, runs the load balancer again to distribute other volumes (in batches of 5). Run the following command to configure the interval between runs:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.recheck":"<time-in-seconds>"}
```

Configuring the Delay After Which Load Balancer runs for Events

About this task

HPE Ezmeral Data Fabric runs the load balancer automatically for any of the following events. You can configure the delay after which HPE Ezmeral Data Fabric runs the load balancer.

Create Volume

When you create a tiering-enabled volume, it is assigned the gateway with the lowest load. If gateways are not available for the volume at the time of creation, the volume might stay unassigned. To ensure that the volume has an associated gateway for handling the tiering operations, HPE Ezmeral Data Fabric runs the gateway load balancer after a delay of 2 hours (7200 seconds) by default for this event.

To configure the delay, set the value for `cldb.tier.gw.balance.delay.vol.create` property (in seconds) using the `config save` on `page 2106` command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.vol.creat
e":"<time-in-seconds>"}
```

Remove Volume

When you remove a volume, the distribution of volumes across gateways can become uneven, and the balancer must be run to redistribute the volumes. For this event, HPE Ezmeral Data Fabric runs the load balancer to redistribute the volumes and rebalance the gateways after a delay of 2 hours (7200 seconds) by default for this event.

To configure the delay, set the value for the `cldb.tier.gw.balance.delay.vol.delete` property (in seconds) using the `config save` on `page 2106` command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.vol.delet
e":"<time-in-seconds>"}
```

Add Gateway

When you install a new gateway on a cluster, volumes are assigned to the new gateway only if a new volume is created or an existing volume has a pending task, but no active assigned gateway. Volumes that have active gateways are not re-assigned by default. For this event, HPE Ezmeral Data Fabric runs the load balancer to re-distribute the volumes and rebalance the gateway load after a delay of 2 hours (7200 seconds) by default.

To configure the delay, set the value for the `cldb.tier.gw.balance.delay.new.gw` property (in seconds) using the `config save` on `page 2106` command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.new.gw":"
<time-in-seconds>"}
```

Remove Gateway

When you remove a gateway or when a gateway goes down, all the volumes assigned to the gateway

last-updated: Jun 06, 2024

are not re-assigned by default; only volumes with pending tasks are assigned to new gateways. For this event, HPE Ezmeral Data Fabric runs the load balancer to re-distribute the volumes after 6 hours (21600 seconds) by default.

To configure the delay, set the value for the `cldb.tier.gw.balance.delay.dead.gw` property (in seconds) using the `config save` on `page 2106` command. For example:

```
maprcli config save -values
{"cldb.tier.gw.balance.delay.dead.gw":
"<time-in-seconds>"}
```

Determining the Volumes Assigned to MAST Gateways

Procedure

- Run one of the following commands to determine the volumes that are assigned to MAST Gateways:
  - `/opt/mapr/server/mrconfig info mastgateway`
  - `/opt/mapr/server/mrconfig info volume mastgateway`

  For more information, see `mrconfig info` on `page 2933`.

Enabling Debug Logging for MAST Gateway

About this task

The MAST Gateway service log file contains alarm messages, error codes, and information on the errors. When the `mastgateway.log` file reaches `mastgateway.logfile.size.mb/5`, a roll over happens and the `mastgateway.log` file is renamed as `mastgateway.log.1`; also, a new `mastgateway.log` file is created. When the newly created `mastgateway.log` reaches `mastgateway.logfile.size.mb/5`, a roll over happens again and:

- The `mastgateway.log.1` is renamed as `mastgateway.log.2`
- The `mastgateway.log` is renamed as `mastgateway.log.1`
- A new `mastgateway.log` is created

This process continues and up to 5 files, whose size is `mastgateway.logfile.size.mb/5`, are created before the oldest log file, `mastgateway.log.4`, is deleted.

Procedure

- Run the following command to enable debug logging for MAST Gateway:

  ```
  maprcli trace setlevel -module MASTGateway -level Debug -port 8660
  ```

Configuring YARN for Control Groups

Control groups (cgroups) are a Linux kernel feature available through the LinuxContainerExecutor program that you can configure to limit and monitor the CPU resources available to YARN container processes on a node.

last-updated: Jun 06, 2024

To enable cgroups, follow the Apache instructions for Using CGroups with YARN, but note that the default directory for `yarn.nodemanager.linux-container-executor.cgroups.hierarchy` (hadoop-yarn) is created automatically in the default place (`/sys/fs/cgroup/cpu,cpuacct/`) by `mapr-warden`, and permissions are set to the `mapr` user.

If you run Spark jobs, note the following consideration. When deployed in `client` mode, Spark driver programs are not controlled by cgroups, but the tasks are. In `cluster` mode, both the driver and tasks are controlled by cgroups. For more information about these modes, see Deployment Modes on page 4620.

Related tasks

Restarting Services on page 1141
Describes how to restart a service using either the Control System, the CLI or the REST API.

Configuring NodeManager Restart

About this task

NodeManager restart is enabled by default. Active containers will keep running in the event that the NodeManager shuts down.

When the NodeManager restart is enabled, it stores the container state of active containers in a recovery directory;when the NodeManager restarts, it retrieves the container state from the recovery directory.

If you disable NodeManager restart, active containers are shut down when the NodeManager shuts down and containers need to be reallocated when the NodeManager starts again.

To configure NodeManager restart, enable the NodeManager recovery and also specify a port that can be dedicated to run the NodeManager service.

Procedure

1. Add the following parameters to the `yarn-site.xml` on each NodeManager node:
   a) Set `yarn.nodemanager.recovery.enabled` to true.
   b) Set `yarn.nodemanager.address` to include a port that is dedicated to run the NodeManager on this node.
   c) Optionally, set `yarn.nodemanager.recovery.dir` to a different recovery directory for this node.
      By default, the recovery directory is set to`$hadoop.tmp.dir/yarn-nm-recovery` which resolves to `tmp/hadoop-mapr/nm-local-dir/yarn-nm-recovery`. See the following example configuration:

```
<property>
  <name>yarn.nodemanager.recovery.enabled</name>
  <value>true</value>
</property>
<property>
  <name>yarn.nodemanager.address</name>
  <value>0.0.0.0:8099</value>
</property>
```

2. Restart the NodeManager Service.
   For more information, see Managing Services on page 1136.

Managing Jobs and Applications

If you have used Hadoop in the past to run MapReduce applications, then running jobs on the HPE Ezmeral Data Fabric platform will be very familiar to you. HPE Ezmeral Data Fabric is a full Hadoop distribution, API-compatible with all versions of Hadoop. HPE Ezmeral Data Fabric provides additional capabilities not present in any other Hadoop distribution.

You can perform the following procedures to manage applications in a HPE Ezmeral Data Fabric cluster:

Job Scheduling

You can use job scheduling to prioritize the YARN applications that run on your MapR cluster.

The MapReduce system supports a minimum of one queue, named `default`. Hence, this parameter's value should always contain the string `default`. Some job schedulers, like the Capacity Scheduler, support multiple queues.

The default job scheduler is the Fair Scheduler, which is designed for a production environment with multiple users or groups that compete for cluster resources.

The MapR Converged Data Platform supports these job schedulers:

- **FIFO queue-based scheduler**: The FIFO queue scheduler runs jobs based on the order in which the jobs were submitted. You can prioritize a job by changing the value of the `mapred.job.priority` property or by calling the `setJobPriority()` method.
- **Fair Scheduler**: This is the default scheduler. The Fair Scheduler allocates a share of cluster capacity to each user over time. The design goal of the Fair Scheduler is to assign resources to jobs so that each job receives an equal share of resources over time. The Fair Scheduler enforces fair sharing within each queue. Running jobs share the queue's resources.
- **Capacity Scheduler**: The Capacity Scheduler enables users or organizations to simulate an individual hadoop cluster with FIFO scheduling for each user or organization. You can define organizations using *queues*.

The following sections provide more information about job scheduling:

Hadoop 3.x Fair Scheduler

The FairScheduler is a pluggable scheduler for Hadoop that allows YARN applications to share resources in a large cluster fairly. Fair scheduling is a method of assigning resources to applications such that all applications get, on average, an equal share of resources over time. Hadoop 3.x is capable of scheduling multiple resource types.

By default, the Fair Scheduler bases scheduling fairness decisions only on memory. It can be configured to schedule resources based on memory, CPU, and disk usage. When only one application is running, that application uses the entire cluster. When other applications are submitted, resources that free up are assigned to the new applications, so that each application eventually gets approximately the same amount of resources. Unlike the default Hadoop scheduler, which forms a queue of applications, this lets short applications finish in reasonable time while not starving long-lived applications. It is also a reasonable way to share a cluster between a number of users. Finally, fair sharing also uses priorities applied as weights to determine the fraction of total resources that each application should get.

For additional information about Hadoop Fair Scheduler, you can also refer to the open source documentation.

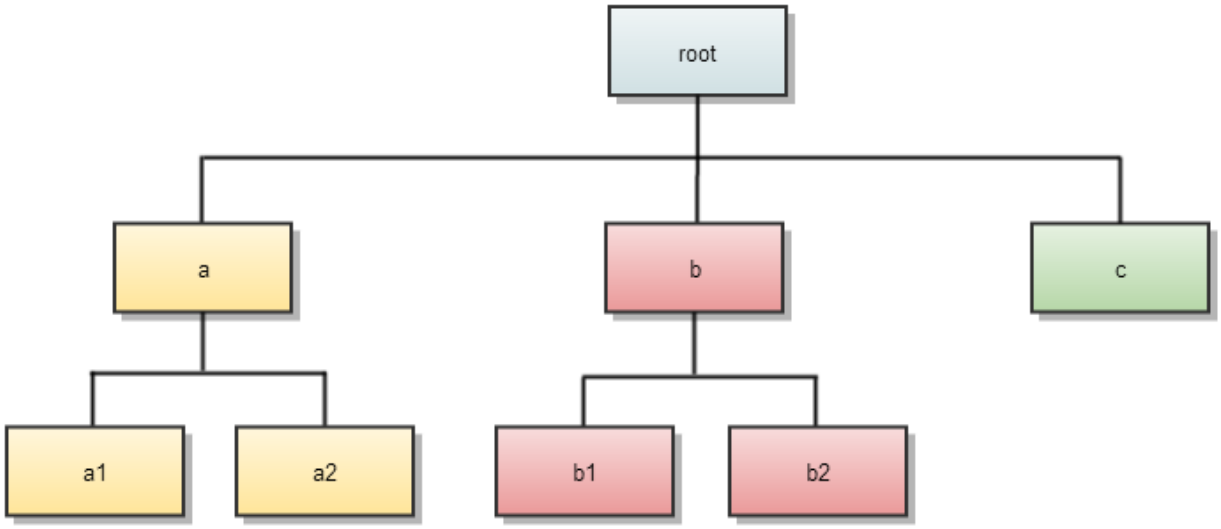
Scheduling Queues

The scheduler organizes applications further into *queues*, and shares resources fairly between these queues. By default, all users share a single queue, named `default`. If an application specifically lists a queue in a container resource request, the request is submitted to that queue. You can also assign queues based on the user name included with the request through configuration. Within each queue, a scheduling

last-updated: Jun 06, 2024

policy is used to share resources between the running applications. The default is memory-based fair sharing, but FIFO and multi-resource with Dominant Resource Fairness can also be configured.

Queues can be arranged in a hierarchy to divide resources, and they can be configured with weights to share the cluster in specific proportions. The Fair Scheduler uses a concept called a *queue path* to configure a hierarchy of queues. The queue path is the full path of the queue's hierarchy, starting at *root.* The following example has three top-level child-queues a, b, and c and some sub-queues for a and b:



In addition to providing fair sharing, the Fair Scheduler allows assigning guaranteed minimum shares to queues, which is useful for ensuring that certain users, groups or production applications always get sufficient resources. When a queue contains apps, it gets at least its minimum share, but when the queue does not need its full guaranteed share, the excess is split between other running apps. This lets the scheduler guarantee capacity for queues while utilizing resources efficiently when these queues do not contain applications.

Configuring the Fair Scheduler

The Fair Scheduler lets all applications run by default, but you can also limit the number of running applications per user and per queue through the configuration file. This can be useful when a user must submit hundreds of applications at once, or in general to improve performance if running too many applications at once would cause too much intermediate data to be created or too much context-switching. Limiting the applications does not cause any subsequently submitted applications to fail; it only causes them to wait in the scheduler's queue until earlier applications finish.

To customize the Fair Scheduler, set the configuration properties in `yarn-site.xml` and update the allocation file to list existing queues and their respective weights and capacities. The allocation file is automatically created during HPE Ezmeral Data Fabric installation in the following directory:

```
{$MAPR_HOME}/hadoop/hadoop-2.x/etc/hadoop/fair-scheduler.xml
```

The allocation file is reloaded every 10 seconds to refresh the scheduler with any modified settings that are specified in the file.

Specifying Fair Scheduler Configuration Properties in yarn-site.xml
Lists the properties in the *yarn-site.xml* file for Fair Scheduler.

The `yarn-site.xml` file contains the following parameters that determine scheduler-wide options.

yarn.scheduler.fair.allocation.file *Default Value*: `fair-scheduler.xml`

	Description: Specifies the path to the allocation file. If a relative path is given, the file is searched for on the classpath.
yarn.scheduler.fair.user-as-default-queue	*Default Value*: `true` *Description*: Determines whether to use the username associated with the allocation file as the default queue name, if a queue name is not specified. **NOTE:** If a queue placement policy is given in the allocations file, this property is ignored.
yarn.scheduler.fair.preemption	*Default Value*: `false` *Description*: Indicates whether to use preemption. **NOTE:** Do not use preemption when `FairScheduler DominantResourceFairness` is in use and node labels are present.
yarn.scheduler.fair.sizebasedweight	*Default Value*: `false` *Description*: Indicates whether to assign shares to individual applications based on their size, rather than providing an equal share to all applications regardless of size. When set to `true`, applications are weighted by *(ln 1 + <application's total requested memory>)/ ln 2*.
yarn.scheduler.fair.assignmultiple	*Default Value*: `false` *Description*: Indicates whether to allow multiple container assignments in one heartbeat.
yarn.scheduler.fair.resources-based-on-labels-enabled	*Default Value*: `false` *Description*: Indicates whether to allow container allocation on all nodes by recomputing fair shares based on labels.
yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled	*Default Value*: `false` *Description*: Indicates whether to enable/disable preemption of the threshold per-label.

Fair Scheduler Allocation File
Describes an allocation file and the entities within an allocation file.

An allocation file is an XML manifest that describes queues and their properties, as well as certain policy defaults. The allocation file is automatically created during HPE Ezmeral Data Fabric installation in the following directory:

```
{$MAPR_HOME}/hadoop/hadoop-3.x/etc/hadoop/fair-scheduler.xml
```

The allocation file is reloaded every 10 seconds to refresh the scheduler with any modified settings that are specified in the file.

The allocation file contains the following types of elements:

Queue Elements

Queue elements represent queues and can contain the following elements:

- `minResources`
- `maxResources`

last-updated: Jun 06, 2024

- `maxRunningApps`

  TIP: The `queueMaxAppsDefault` value is used for any parent queue that does not set a value for the `maxRunningApps` element.

- `weight`
- `schedulingPolicy`
- `aclSubmitApps`
- `aclAdministerApps`
- `minSharePreemptionTimeout`
- `maxContainerAllocation`

  TIP: The `maxContainerAllocation` property sets a limit on the resources a queue can allocate for a single container. The value cannot exceed `maxResources`. If you do not set `maxContainerAllocation`, the value is inherited from a parent queue. The default values are set through the `yarn.scheduler.maximum-allocation-mb`, `yarn.scheduler.maximum-allocation-vcores` properties, which you can modify in `/opt/mapr/hadoop/hadoop-3.x.x/etc/hadoop/yarn-site.xml`. The `maxContainerAllocation` element is not valid for the root queue.

For more information on these elements, see Hadoop: Fair Scheduler.

User Elements

User elements represent settings that govern the behavior of individual users. They can contain a single property, `maxRunningApps`, which limits the number of running applications for a particular user. It contains the following elements:

- `userMaxAppsDefault`
- `queueMaxAppsDefault`
- `fairSharePreemptionTimeout`
- `defaultQueueSchedulingPolicy`
- `queuePlacementPolicy`

For more information on these elements, see Hadoop: Fair Scheduler.

TIP: If you set a value for `queueMaxAppsDefault` and do not set a value for `maxRunningApps` for the root queue, the value of `queueMaxAppsDefault` sets the application limit for all queues under the root queue hierarchy.

Example Allocation File

See example allocation file in Hadoop: Fair Scheduler.

Queue Access Control Lists

Queue Access Control Lists (*ACL*s) allow administrators to control who may take actions on particular queues. They are configured with the `aclSubmitApps` and `aclAdministerApps` properties, which can be set per queue. Currently, the only supported administrative action is killing an application. Anyone who

has permission to administer a queue may also submit applications to it. These properties take values in a format such as user1,user2 group1,group2 or group1,group2. An action on a queue is permitted if its user or group is in the *ACL* of that queue or in the *ACL* of any of that queue's ancestors. Therefore, if queue2 is inside queue1, and user1 is in queue1's *ACL*, and user2 is in queue2's *ACL*, then both users may submit to queue2.

For more information, see Hadoop: Fair Scheduler.

The `yarn.admin.acl and yarn.acl.enable` Properties	By default, on a secure cluster, users cannot kill jobs that do not belong to them.
	On a secure cluster, you do not need to set the `yarn.acl` or the `yarn.admin.acl` properties. By default, they are set as follows. On unsecured clusters, these properties are not set by default.
	`<property>`
	`  <name>yarn.acl.enable</name> >`
	`  <value>true</value> >`
	`</property>`
	`<property>`
	`  <name>yarn.admin.acl</name> >`
	`  <value> </value> >`
	`</property>`
	The `yarn.admin.acl` property is set by default to " ", meaning that an administrator is not specified on a cluster.
	To allow users to kill jobs that do not belong to them, or to get access to their logs, you need to set the `yarn.admin.acl` property with the user or group name.

Fair and Capacity scheduler root queue admins	For both the Fair scheduler and Capacity scheduler, the default value of the administrators for the root queues is " " .

Hadoop 3.x Capacity Scheduler

The `CapacityScheduler` is a pluggable scheduler for Hadoop that allows multiple tenants to securely share a large cluster. Resources are allocated to each tenant's applications in a way that fully utilizes the cluster, governed by the constraints of allocated capacities.

Queues are typically set up by administrators to reflect the economics of the shared cluster. The Capacity Scheduler supports hierarchical queues to ensure that resources are shared among the sub-queues of an organization before other queues are allowed to use free resources.

The following sections provide more information about the CapacityScheduler:

Capacity Scheduler Features

The CapacityScheduler supports these features:

- **Hierarchical Queues** Hierarchical queues ensure that resources are shared among the sub-queues of an organization before other queues are allowed to use free resources, thereby providing more control and predictability.
- **Capacity Guarantees** Queues are allocated a fraction of the capacity of the grid, which means that a certain capacity of resources are at their disposal. All applications submitted to a queue have access to the capacity allocated to the queue. Administrators can configure soft limits and optional hard limits on the capacity allocated to each queue.
- **Security** Each queue has strict Access Control Lists (ACLs). The ACLs control which users can submit applications to individual queues. Also, safeguards ensure that users cannot view or modify applications from other users. Per-queue and system administrator roles are also supported.

last-updated: Jun 06, 2024

- **Elasticity** Free resources can be allocated to any queue beyond its capacity allocation. As tasks scheduled on these resources complete, the resources become available to be reassigned to applications on queues running below their capacity. This ensures that resources are available in a predictable and elastic manner to queues, thus preventing artificial silos of resources in the cluster and improving cluster utilization.
- **Multi-tenancy** A comprehensive set of limits is provided to prevent a single application, user, or queue from monopolizing resources of the queue or the cluster as a whole. This ensures that the cluster is not overwhelmed.
- **Operability**
  - **Runtime Configuration** The queue definitions and properties, such as capacity or ACLs, can be changed in a secure manner by administrators at runtime, which minimizes disruption to users. Also, a console is provided for users and administrators to view the current allocation of resources to various queues in the system. Administrators can add queues at runtime, but queues cannot be deleted at runtime.
  - **Drain applications** Administrators can stop queues at runtime to ensure that while existing applications run to completion, no new applications can be submitted. If a queue is in the STOPPED state, new applications cannot be submitted to that queue or any of its child queues. Existing applications continue to completion, so the queue can be drained gracefully. Administrators can also start the stopped queues.
- **Resource-based Scheduling** Support for resource-intensive applications, where an application can optionally specify higher resource requirements than the default, thereby accommodating applications with differing resource requirements. Currently, *memory* is the only supported resource requirement.

Setting Up ResourceManager to Use CapacityScheduler

To configure the ResourceManager to use the CapacityScheduler, set the following property in the `yarn-site.xml` file:

Property Name	Value
`yarn.resourcemanager.scheduler.class`	`org.apache.hadoop.yarn.server.resourcemanager.scheduler.capacity. CapacityScheduler`

Setting Up Queues

The ResourceManager uses the configuration file `capacity-scheduler.xml`, where you can configure various scheduling parameters related to queues. These parameters include:

- the short queue name
- the full queue path name
- a list of associated child queues and applications
- the guaranteed capacity (expressed as a percentage of total resources in the cluster) available to the jobs in the queue
- the maximum capacity of the queue
- a list of active users and their resource allocation limits
- the state of the queue (running or stopped)
- access control lists that determine who can access the queue

The CapacityScheduler has a pre-defined queue called *root*. All queues in the system are children of the `root` queue. Further queues can be set up by configuring `yarn.scheduler.capacity.root.queues` with a list of comma-separated child queues.

Queue Properties

The `capacity-scheduler.xml` file includes three types of queue properties:

Resource Allocation Properties

The following table lists resource allocation properties:

Property	Description
`yarn.scheduler.capacity.<queue-path>.capacity`	Queue *capacity* in percentage (%) expressed as a float (for example, 12.5). The sum of capacities for all queues, at each level, must equal 100. Applications in the queue may consume more resources than the queue's capacity if there are free resources, which provides elasticity.
`yarn.scheduler.capacity.<queue-path>.maximum-capacity`	Maximum queue capacity in percentage (%) expressed as a float. This property limits the elasticity for applications in the queue. The default is -1 which disables it.
`yarn.scheduler.capacity.<queue-path>.minimum-user-limit-percent`	Sets the minimum value, expressed as an integer, on the percentage of resources allocated to a user, if there is a demand for resources. A value of 100 implies no user limits are imposed. The default is 100. The maximum value depends on the number of users who have submitted applications. For example, if this property is set to 25 and two users have submitted applications to a queue, the maximum percent of queue resources for each user is 50%. If a third user submits an application, no single user can use more than 33% of the queue resources. With four or more users, no user can use more than 25% of the queue resources.
`yarn.scheduler.capacity.<queue-path>.user-limit-factor`	The multiple of the queue capacity that can be configured to allow a single user to acquire more resources. Value is specified as a float. The default is 1, which ensures that a single user can never take more than the queue's configured capacity no matter how idle the cluster is.

last-updated: Jun 06, 2024

Property	Description
`yarn.scheduler.capacity.resource-calculator`	Specifies the `ResourceCalculator` implementation to be used to compare resources in the scheduler. The default value is `DiskBasedResourceCalculator`, which uses memory, CPU and disk. Other values for this parameter include: • `DefaultResourceCalculator`, which uses memory only • `DominantResourceCalculator`, which uses dominant-resource to compare multi-dimensional resources such as memory and CPU • `DiskBasedDominantResourceCalculator`, which uses dominant-resource to compare multi-dimensional resources, such as memory, CPU and disk

Running and Pending Application Limits

Applications are considered active if they are either running or pending. The following table lists properties that specify running and pending application limits:

Property	Description
`yarn.scheduler.capacity.maximum-applications`	Maximum number of applications in the system that can be concurrently active, both running and pending. Limits on each queue are directly proportional to their queue capacities and user limits. This is a hard limit; any applications submitted when this limit is reached will be rejected. The default is 10000. This applies to all queues.
`yarn.scheduler.capacity.<queue-path>.maximum-applications`	Overrides `yarn.scheduler.capacity.maximum-applications` on a per queue basis.
`yarn.scheduler.capacity.maximum-am-resource-percent`	Maximum percent of resources in the cluster that can be used to run application masters - controls the number of concurrent active applications. Limits on each queue are directly proportional to their queue capacities and user limits. Specified as a float. For example, 0.5 = 50%. The default is 0.1. This can be set for all queues with yarn.scheduler.capacity.maximum-am-resource-percent
`yarn.scheduler.capacity.<queue-path>.maximum-am-resource-percent`	Overrides `yarn.scheduler.capacity.maximum-am-resource-percent` on a per queue basis.

Queue Administration and Permissions

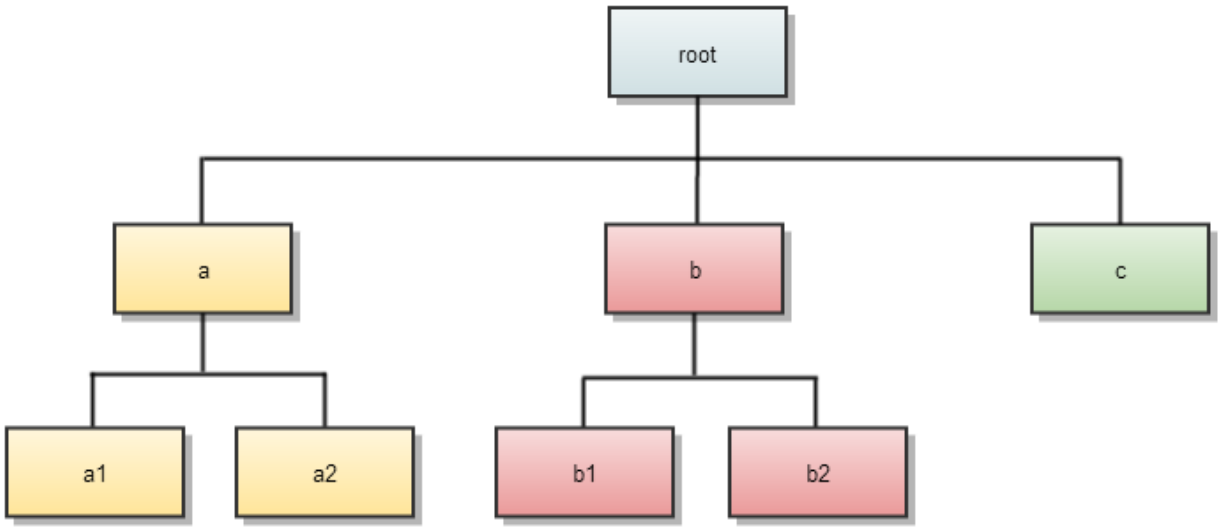
The following table lists queue administration and permission properties:

last-updated: Jun 06, 2024

Property	Description
`yarn.scheduler.capacity.<queue-path>.state`	The *state* of the queue. Possible values are RUNNING or STOPPED. If a queue is in the STOPPED state, new applications cannot be submitted to that queue or any of its child queues. If the *root* queue is STOPPED, no applications can be submitted to the entire cluster. Existing applications continue to completion, so the queue can be *drained* gracefully.
`yarn.scheduler.capacity.root.<queue-path>.acl_submit_applications`	The *ACL* that controls who can *submit* applications to the given queue. If the given user/group belongs to the *ACL* on a given queue or one of the parent queues in the hierarchy, they can submit applications. *ACLs* for this property *are* inherited from the parent queue if not specified.
`yarn.scheduler.capacity.root.<queue-path>.acl_administer_queue`	The *ACL* that controls who can *administer* applications on the given queue. If the given user/group has the necessary ACLs on the given queue or one of the parent queues in the hierarchy, they can administer applications. *ACLs* for this property *are* inherited from the parent queue if not specified.

Setting Up a Hierarchy of Queues

CapacityScheduler uses a concept called a *queue path* to configure a hierarchy of queues. The queue path is the full path of the queue's hierarchy, starting at *root.* The following example has three top-level child-queues a, b, and c and some sub-queues for a and b:



Queue paths are defined for each level under the `root` queue. A queue's children are defined with the parameter `yarn.scheduler.capacity.<queue-path>.queues`, where `<queue-path>` takes the form `root.<child>`, `root.<child>.<child>`, and so on. For example, the queue path to a2 is designated as `root.a.a2`.

WARNING:

Children do not inherit properties directly from the parent unless otherwise noted.

last-updated: Jun 06, 2024

The corresponding queue definition block of the `capacity-scheduler.xml` file is shown below.

```
<property>
  <name>yarn.scheduler.capacity.root.queues</name>
  <value>a,b,c</value>
  <description>The queues at this level (root is the root queue).
  </description>
</property>

<property>
  <name>yarn.scheduler.capacity.root.a.queues</name>
  <value>a1,a2</value>
  <description>The queues at this level (root is the root queue).
  </description>
</property>

<property>
  <name>yarn.scheduler.capacity.root.b.queues</name>
  <value>b1,b2,b3</value>
  <description>The queues at this level (root is the root queue).
  </description>
</property>
```

Changing Queue Configuration

You can change queue properties and add new queues by editing `capacity-scheduler.xml`. Make sure that the updated queue configuration is valid and that the queue-capacity at each level equals 100%.

For the changes to take effect, run the following command:

```
yarn rmadmin -refreshQueues
```

WARNING:

Queues cannot be deleted, only added.

Queue Access Control Lists
Describes how to restrict access to queues using Access Control Lists (ACLs).

Queue *ACL*s allow administrators to control who may take actions on particular queues. They are configured with the following properties:

```
yarn.scheduler.capacity.root.support.acl_submit_applications
yarn.scheduler.capacity.root.support.acl_administer_queue
```

You can set these properties for each queue. Currently, the only supported administrative action is killing an application. Anyone who has permission to administer a queue may also submit applications to it. These properties take values in a format such as `user1,user2 group1,group2` or `group1,group2`. An action on a queue is permitted if its user or group is in the *ACL* of that queue, or in the *ACL* of any of that queue's ancestors. So if queue2 is inside queue1, and user1 is in queue1's *ACL*, and user2 is in queue2's *ACL*, then both users may submit to queue2.

The root queue's *ACL*s are "*" by default. Since *ACL* are passed down, by default, everyone may submit to, and kill applications from every queue. To restrict access, change the root queue's *ACL*s to something other than `*`.

last-updated: Jun 06, 2024

By default, the yarn.admin.acl property in yarn-site.xml is also set to *, which means that any user can be the administrator. If queue *ACL*s are enabled, you also need to set the yarn.admin.acl property to the correct admin user for the YARN cluster. For example:

```
<property>
<name>yarn.admin.acl</name> >
<value>mapr</value> >
</property>
```

If you do not set this property correctly, users can kill YARN jobs even when they do not have access to the queues for those jobs.

Label-based Scheduling

Label-based scheduling provides a way to allocate shared cluster resources on particular nodes in a cluster. First, you assign node labels in a text file. The node labels map to one or more nodes. Next, you can create queue labels and job labels based on the node labels.

When you run jobs, you can place them on specified nodes on a per-job basis (using a job label) or at the queue level (using a queue label). This feature is used in conjunction with schedulers, such as the Fair Scheduler or the Capacity Scheduler.

The following sections provide more information about label-based scheduling:

Label-based Scheduling for YARN Applications

Label-based scheduling provides job placement control on a multi-tenant hadoop cluster. Using label-based scheduling, an administrator can control exactly which nodes are chosen to run jobs submitted by different users and groups. This is useful for data locality and multi-tenancy use cases.

To use label-based scheduling, an administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When you run jobs, you can place them on specified nodes on a per-job basis (using a job label) or at the queue level (using a queue label).

This feature is used in conjunction with schedulers, such as the Fair Scheduler or the Capacity Scheduler.

YARN Resource Calculation Based on Labels

MapR 6.1.0 implements correct steady/instantaneous Fair Scheduler shares, headroom, and maximum resource calculation for queues with label-based scheduling (LBS).

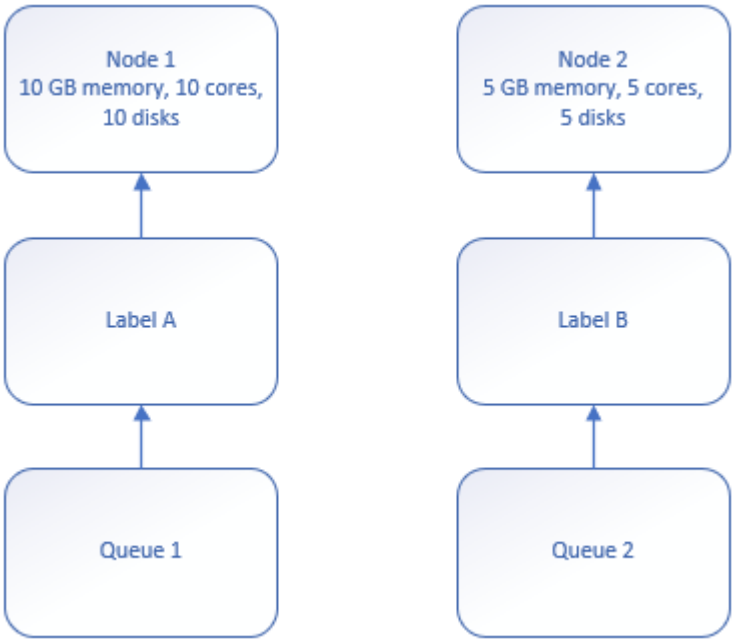
This new approach to YARN resource allocation enables the cluster LBS configuration to compute the resources that are allowed for each queue. It also uses LBS to assign containers to the correct queues to preempt containers, and to prevent resource overuse. The LBS approach to YARN resource allocation relies on:

1. Resource computation (memory, CPU, disks) based on labels for each queue.
2. Per-label preemption threshold.

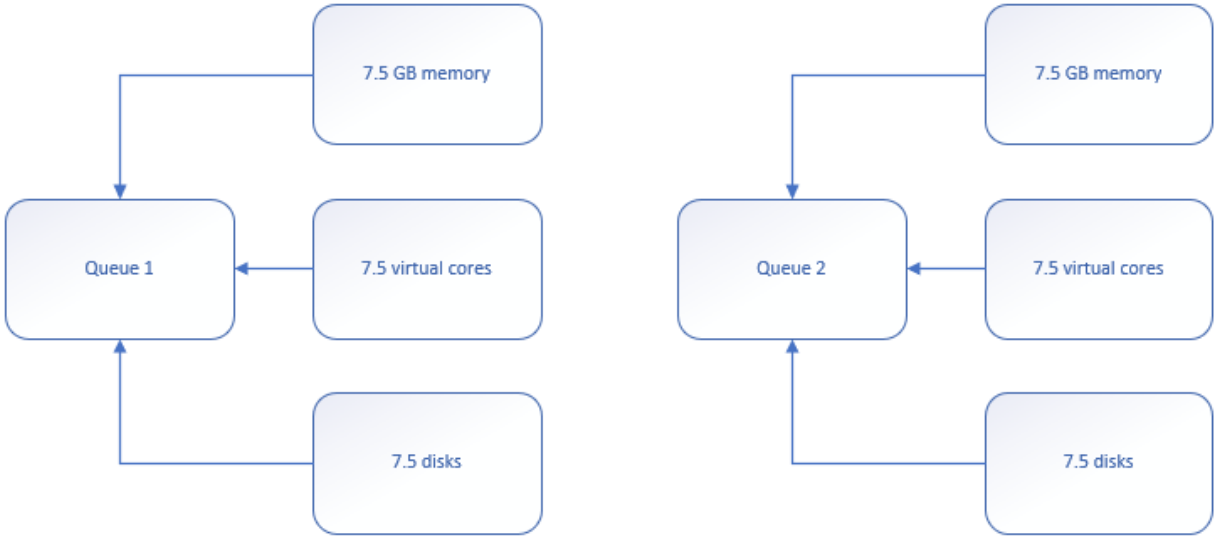
Example of LBS Resource Computation

For example, imagine that you have the following resources:

last-updated: Jun 06, 2024

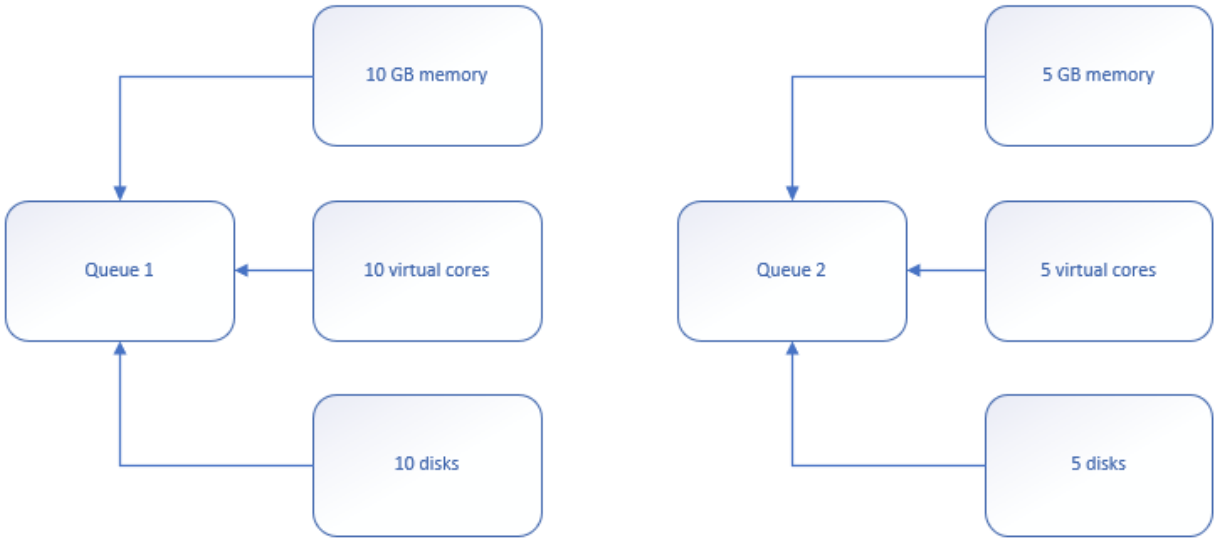


Using the former fair-share resource distribution results in the following:



Using the new LBS resource distribution results in the following:

last-updated: Jun 06, 2024



Understanding LBS preemption thresholds

Before LBS, preemption occurred by default when an entire cluster became 80% full (`yarn.scheduler.fair.preemption.cluster-utilization-threshold=0.8f`). With LBS, preemption occurs per labeled resource, as that resource becomes 80% full.

Descriptions of New Properties When Using LBS

- `defaultQueueLabel`

  Assigned to all new queues and existing queues that do not have a label (excluding the `root` queue).

  For example, `root.%username%` queue is created if you submit a new job without queue information and property `yarn.scheduler.fair.user-as-default-queue` is true.

  You can specify this property in `fair-scheduler.xml`:

```
<allocations>
  <defaultQueueLabel>LabelA</defaultQueueLabel>
  <queue name="root">
          ...
  <queue name="queue1">
  </queue>
  <queue name="queue2">
    <label>LabelB</label>
   </queue>
          ...
  </queue>
</allocations>
```

  See Specifying Fair Scheduler Configuration Properties in yarn-site.xml on page 1645 for more information.

- `yarn.scheduler.fair.resources-based-on-labels-enabled`

  Used to enable or disable recomputing of fair shares based on labels. It allows container allocation on all nodes.

  You can specify this property in `yarn-site.xml`:

  ```
  <property>
    <name>yarn.scheduler.fair.resources-based-on-labels-enabled</name>
    <value>false</value>
  </property>
  ```

- `yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled`

  Allows enabling or disabling (default) preemption of the threshold per-label. To overcome the default and start container preemption when the threshold of the label is exceeded, change this property to `true`.

  You can specify this property in `yarn-site.xml`:

  ```
  <property>

  <name>yarn.scheduler.fair.preemption.cluster-utilization-threshold.based-on-labels-enabled</name>
    <value>false</value>
  </property>
  ```

See Specifying Fair Scheduler Configuration Properties in yarn-site.xml on page 1645 for more information.

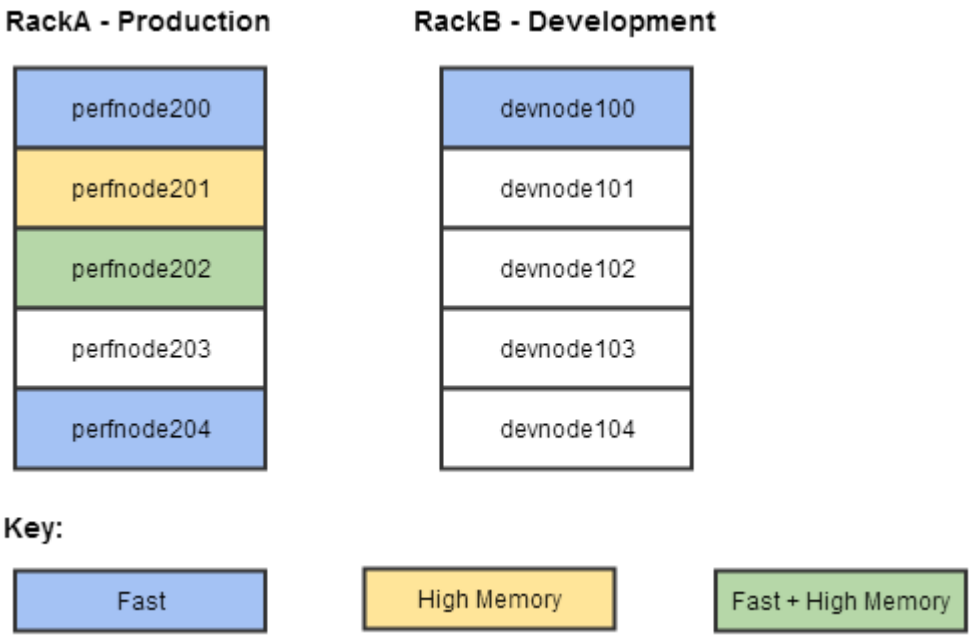
LBS Requirements and Restrictions?

Before you adopt LBS, you should be aware of two issues:

- Multiple labels for a node and label expression at the queue level are not supported.
- Except for `root`, all queues including the default, must be labeled, either independent or through inheritance.

Sample Cluster Configuration

To illustrate the concept of label-based scheduling, consider a cluster with two racks: RackA and RackB. The nodes in RackA are dedicated to the Production group, and the nodes in RackB are dedicated to the Development group. In addition, some nodes are configured with a fast CPU, one node is configured with high memory, and one node is configured with both a fast CPU and high memory. The following diagram illustrates the cluster configuration:



Using Node Labels to Schedule YARN Applications

About this task
To set up node labels for the purpose of scheduling YARN applications (including MapReduce applications) on a specific node or group of nodes:

Procedure

1. Enable the labels by using the following steps:
   a. Add the `yarn.node-labels.enabled` parameter to the `yarn-site.xml` file:

```
<property>
  <name>yarn.node-labels.enabled</name>
  <value>true</value>
</property>
```

   b. Restart the ResourceManager (RM):

```
/opt/mapr/bin/maprcli node services -name resourcemanager -nodes
<node names> -action restart
```

2. Add labels to clusters and nodes:

```
yarn rmadmin -addToClusterNodeLabels "label3, label4"
yarn rmadmin -replaceLabelsOnNode "node3.cluster.com:8099=label3
node4.cluster.com:8099=label4"
```

3. To gather information about the labels, use any of the following commands:
   - To list the node labels:

```
yarn cluster --list-node-labels
Node Labels: <label4:exclusivity=true>,<label3:exclusivity=true>
```

last-updated: Jun 06, 2024

- To reload the queues, states, and scheduler-specific properties:

```
yarn rmadmin -refreshQueues
```

- To show the node status:

```
yarn node -status node3.cluster.com:8099
Node Report :
        Node-Id : node3.cluster.com:8099
        Rack : /default-rack
        Node-State : RUNNING
        Node-Http-Address : node3.cluster.com:8044
        Last-Health-Update : Tue 24/Jan/23 03:16:07:88UTC
        Health-Report :
        Containers : 0
        Memory-Used : 0MB
        Memory-Capacity : 45744MB
        CPU-Used : 0 vcores
        CPU-Capacity : 40 vcores
        Node-Labels : label3
        Node Attributes :
        Resource Utilization by Node : PMem:21544 MB, VMem:21544 MB,
VCores:2.6766665
        Resource Utilization by Containers : PMem:0 MB, VMem:0 MB,
VCores:0.0
```

Creating Queue Labels

Queue labels are optional with label-based scheduling. You can use queue labels to determine which nodes an application or job can run on (subject to the queue label policy). A queue label is created from node labels as explained below.

Defining Queue Labels for Fair Scheduler

Explains how to customize the Fair Scheduler.

By default, all users share a single queue, named *default*.

To customize the Fair Scheduler, create an allocation file that lists existing queues and their respective weights and capacities, as explained in Hadoop 2.x Fair Scheduler. In the allocation file, add the following property within the `queue` section:

```
<label>labelname</label>
```

For example:

```
<queue name="Customer Data Analysis">
   <weight>2.0</weight>
   <label>Fast</label>
</queue>
```

For a hierarchical queue, note that labels and label policies can be defined on any level of the queue. If a child queue does not have its own labels or label policies, the labels and label policies of the closest level are used.

Defining Queue Labels for Capacity Scheduler

EEP 9.0.0 (core 7.1.0) and later use the Apache Hadoop node-label implementation.

For more information about label configuration for the capacity scheduler, see Configuration of Schedulers for Node Labels.

last-updated: Jun 06, 2024

Submitting Jobs and Applications to the Cluster

You can submit YARN applications (MapReduce version 2 and other applications that run on YARN) to the same cluster. An application can be submitted to the cluster in the following ways:

- The `hadoop jar` command submits an MRv2 application.
- The `yarn jar` command submits an application.
- An external application submits an application.
- An ecosystem component generates and submits an application.
- The `hadoop job` command submits an MRv2 application.
- The `mapred job` command submits an MRv2 application.

When you submit a non-MapReduce application to the cluster, such a Spark application, it is automatically processed using `yarn` mode (ResourceManager, NodeManager, and MapReduce ApplicationMaster).

NOTE: The method to submit Hadoop commands from a Windows or Mac client is different, For details, see Setting Up the Client.

Configuration Files for Jobs and Applications

Lists the locations of the MapReduce configuration files.

To override the MapReduce default configuration, use the following MapReduce configuration files:

MapReduce Version	Configuration File Locations
MapReduce Version 2	• `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/mapred-site.xml` • `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml`

To override the default configuration for applications, use the `yarn-site.xml` file that is present in `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`.

YARN Container Resources

Provides an overview of YARN.

A YARN application can be a MapReduce version 2 (MRv2) application or a non-MapReduce application. The Warden on each node calculates the resources that can be allocated to process YARN applications. Each application has an ApplicationMaster that negotiates YARN container resources. For MapReduce applications, YARN processes each map or reduce task in a container. The ApplicationMaster requests resources from the ResourceManager based on memory, CPU, and disk requirements for the YARN containers. For YARN containers that process MRv2 tasks, there are additional considerations. See YARN Container Resources for MapReduce Version 2 Applications on page 1661 for details.

The ApplicationMaster requests YARN container resources based on the values of the following parameters:

yarn.scheduler.minimum-allocation-mb

Default: 1024

Description: Defines the minimum memory allocation available for a container in MB.

To change the value, edit the yarn-site.xml file for the node that runs the ResourceManager. Assign the new value to this property, then restart the ResourceManager.

last-updated: Jun 06, 2024

yarn.scheduler.maximum-allocation-mb

Default: 8192

Description: Defines the maximum memory allocation available for a container in MB.

To change the value, edit the yarn-site.xml file for the node that runs the ResourceManager. Assign the new value to this property, then restart the ResourceManager.

yarn.nodemanager.resource.memory-mb

Default: Variable. This value is calculated by Warden.

Description: Defines the memory available to processing Yarn containers on the node in MB.

Warden uses the following formula to calculate this value: `[total physical memory on node] - [memory required by the operating system, file system, and HPE Ezmeral Data Fabric services installed on the node]`.

To determine the value, go to the ResourceManager UI and view the memory available for that node.

yarn.nodemanager.resource.cpu-vcores

Default: Variable. This value is calculated by Warden.

Description: Defines the number of CPUs available to process YARN containers on this node.

Warden uses the following formula to calculate this value: `[Number of CPU cores on node] - [Number of CPU cores assigned to file system]`.

To determine the value, go to the ResourceManager UI or the YARN pane on the Control System and view the number of CPUs available for that node.

To change the value, edit the yarn-site.xml file for the node, assign the new value to this property, then restart the NodeManager.

yarn.nodemanager.resource.io-spindles

Default: Variable. This value is calculated by Warden.

Description: Defines the number of disks available to process YARN containers. Warden uses the following formula to calculate this value: `[Number of of disks on the node]`.

To determine the value, go to the ResourceManager UI or the YARN pane on the Control System and view the disk information for this node.

YARN Container Resources for MapReduce Version 2 Applications

In addition to the YARN container resource allocation parameters, the MapReduce ApplicationMaster also considers the following container requirements when it sends requests to the ResourceManager for containers to run MapReduce applications:

Parameter	Default	Description
`mapreduce.map.memory.mb`	1024	Defines the container size for map tasks in MB.
`mapreduce.reduce.memory.mb`	3072	Defines the container size for reduce tasks in MB.

last-updated: Jun 06, 2024

Parameter	Default	Description
`mapreduce.reduce.java.opts`	-Xmx2560m --add-opens java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC	Java options for reduce tasks.
`mapreduce.map.java.opts`	-Xmx900m --add-opens java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC	Java options for map tasks.
`mapreduce.map.disk`	0.5	Defines the number of disks a map task requires. For example, a node with 4 disks can run 8 map tasks at a time. **Note:** If I/O intensive tasks do not run on the node, you may want to change this value.
`mapreduce.reduce.disk`	1.33	Defines the number of disks that a reduce task requires. For example, a node with 4 disks can run 3 reduce tasks at a time. **Note:** If I/O intensive tasks do not run on the node, you might want to change this value.

You can use one of the following methods to change the default configuration:

- Provide updated values in the `mapred-site.xml` file on the node that runs the job. You can use central configuration to change this value on each node that runs the NodeManager in the cluster. Then, restart NodeManager on each node in the cluster. The `mapred-site.xml` file for MapReduce ve applications is located in the following directory: `opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`
- Override the default values from the command line for each application that requires a non-default value.

Monitoring the Cluster

This section describes how to monitor the health and performance of a MapR cluster.

Monitoring Using the Control System and the CLI

Describes the Overview page in the Control System, which displays information about the cluster.

The **Overview** displays a summary of information about the cluster in six panes including information on cluster health, activity, and usage.

NOTE: During installation using the Installer, you can configure metrics and logging using settings on the **Monitoring** page of the Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts in the **Overview** page. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the **Overview** page. If you want, you can install metrics collection or logging at any time by selecting the feature during an Incremental Install.

The following sections provide information about each pane.

Setting the Refresh Rate on the Control System
Explains how to configure how frequently you want to refresh the graphs, and data in the Control System.
Setting Refresh Rate for Graphs and Data

About this task

To set the refresh rate:

last-updated: Jun 06, 2024

Procedure

1. Log in to the Control System and click **Settings** from the drop-down menu.
2. Enter the refresh rate in seconds for the following.
   - Data refresh rate
   - Metrics and charts refresh rate

   The default refresh rate is 30 seconds. The minimum refresh rate is:
   - 5 seconds for data.
   - 30 seconds for metrics and charts.
3. Set the User Session Inactivity Timer in minutes. The user is logged out from the Control System after the specified number of minutes if there is no activity on the Control System. The default value is 30 minutes.
4. Click **Save Changes** for the changes to take effect.

Customizing the List of Metric Charts and Columns on the Control System
Explains how to customize the list of metric charts and columns on the Control System.

About this task

You can customize the list of table metric charts and columns that you see on the Control System.

Creating a Custom Board for the Charts

About this task
To view a custom set of charts on the Control System, you can create a custom board. To create a board:

Procedure

1. Log in to the Control System and go to one of the following pages:
   - **Metrics** tab of the node details page.
   - **Metrics** tab in the **Data** > **Tables** page.
   - **Metrics** tab of the table information page.
   - **Metrics** tab of the secondary index details page.
2. Select **Create new Board** from the **Boards** drop-down list to display the **Create New Chart Board** window.
3. Enter a unique name for the new Board in the **Board Name** field.
4. Select the charts from the **Available** list of charts and click to move selection to **Selected** charts to display on page.

   You can select up to six charts to display at a time on the page.
5. (Optional) Click and/or down arrows to sort the order of charts.
6. Click **Create and Apply** to create a new Board and view the selected charts in the Board.

last-updated: Jun 06, 2024

Editing a Chart Board

About this task
You can modify an existing chart Board to add or remove charts from the board:

Procedure

1. Log in to the Control System and go to one of the following pages to view the board to modify:
   - **Metrics** tab of the node details page.
   - **Metrics** tab in the **Data** > **Tables** page.
   - **Metrics** tab of the table information page.
   - **Metrics** tab of the secondary index details page.
2. Click associated with the Board to modify from the **Boards** drop-down list.
   The **Edit Chart Board** window displays.
3. You can make the following changes:
   a) Modify the Board name.
   b) Select the charts from the:
      - Selected list of charts and click to remove selected charts.
      - Available list of charts and click to move selection to **Selected** charts to display on page.

      You can select up to six charts to display at a time on the page.
   c) Click and/or down arrows to sort the order of charts.
4. Click **Save and Apply** for the changes to take effect.

Removing a Chart Board

About this task
To remove charts from a Board, see Editing a Chart Board on page 1664. To remove a chart Board, do the following:

Procedure

1. Log in to the Control System and go to one of the following pages to view the list of Boards:
   - **Metrics** tab of the node details page.
   - **Metrics** tab in the **Data** > **Tables** page.
   - **Metrics** tab of the table information page.
   - **Metrics** tab of the secondary index details page.
2. Click associated with the Board to remove from the **Boards** drop-down list.
   The **Delete Board** window displays.
3. Click **Submit** to remove the Board.

Adding and Removing Columns from the List View

Procedure

1. Log in to the Control System and do one of the following:
   - Go to the **Metrics** tab of the node details page and select **Activity by Tables** from the drop-down menu to view the metrics for all table-related activities on the node.
   - Go to the **Metrics** tab of the table information page and select:
     - **Activity by Nodes** (default selection) from the drop-down menu to view the metrics for table activity across nodes.
     - **Activity by Indexes** from the drop-down menu to view metrics for all index-related activity on the table.
   - Go to the **Metrics** tab of the secondary index details page and select **Activity by Nodes** to view metrics for index-related activity across nodes.
2. Click to switch to a list view.
3. Click to display the **Customize Columns** window.
   In the **Customize Columns** window, the:
   - **Available** list displays the columns available, but currently not displayed.
   - **Selected** list displays the columns currently displayed in the page.
4. Select the columns from the:
   a) Selected list of columns and click to remove selected columns from the view.
   b) Available list of columns and click to move selection to **Selected** columns (for display).
   For the list of metrics that can be viewed in the columns, see Viewing Table Metrics in the Control System on page 1681
5. (Optional) Click and/or down arrows to sort the order of columns.
6. Click **Save** to view the selected columns.

Monitoring the Cluster

Explains how to view the cluster health, disk, memory, CPU utilization metrics, and alarms on the cluster using either the Control System or the CLI.

Monitoring Cluster Health Using the Control System

Procedure

- Log in to the Control System and click **Overview**.
  The **Overview** page displays the following panes:
  - Node Health — the health of the nodes on the cluster, by service (default) or topology
  - Active Alarms — a summary of active alarms for the cluster
  - Cluster Utilization — CPU, memory, and disk space usage
  - Yarn — the number of running and queued applications, number of Node Managers, and percent of memory and CPU's used relative to the amount configured

last-updated: Jun 06, 2024

NOTE: During installation using the Installer, you can configure metrics and logging using settings on the **Monitoring** page of the Installer user interface. The metrics collection infrastructure must be installed because the Control System relies on these metrics to provide graphs and charts in the panes. If the metrics collection infrastructure is not installed, you cannot visualize the metrics in the various panes. If you want, you can install metrics collection or logging by selecting the feature during an Incremental Install.

Viewing Cluster Utilization Information on the Control System

About this task

The **Cluster Utilization** pane in the **Overview** page displays the following for:

- CPU — Percentage of cores currently utilized and total cores
- Memory — Percentage of memory (in GB) currently utlized and total memory (in GB)
- Disk — Percentage of space (in GB) currently utilized and total disk space (in GB)

The **Cluster Utilization** pane also shows the amount of raw data and the savings (in percentage) after compression.

The **Utilization Trend** pane shows CPU, memory, and disk usage trend for the last 24 hours by default. You can select a preset (shown in the following screenshot) or specify a custom time range (shown in the following screenshot).

You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Reset Zoom** to zoom out and return to selected date/time range view. If there were any alarms during the selected date/time range, the **Alarms** pane above shows:

- When the alarm was raised
- The severity of the alarm
  - — an error
  - — a warning
  - — information

Monitoring Cluster Alarms on the Control System

About this task

See Viewing Active Cluster Alarms on page 1691 for more information.

Retrieving Cluster Information Using the CLI or REST API

About this task

The basic command to retrieve cluster health and disk space information is:

```
maprcli dashboard info -cluster <cluster>
```

The `utilization` field in the output shows the total and utilized amount of disk space, memory, and CPU for the cluster, which can also be visualized on the Control System. For example:

```
# /opt/mapr/bin/maprcli dashboard info -json
{
```

last-updated: Jun 06, 2024

```
    "timestamp":1525230746268,
    "timeofday":"2018-05-01 08:12:26.268 GMT-0700 PM",
    "status":"OK",
    "total":1,
    "data":[
        {
            ...
            "utilization":{
                "cpu":{
                    "util":7,
                    "total":8,
                    "active":0
                },
                "memory":{
                    "total":15886,
                    "active":11281
                },
                "disk_space":{
                    "total":273,

                    "offloaded":0,
                    "recalled":0
                }
            },
            ...
        }
    ]
}
```

For information on all the fields returned by this command, see dashboard info on page 2108.

Monitoring Nodes
Explains how to monitor nodes using either the Control System or the CLI.

About this task

You can check the health of the nodes on the cluster in the Control System, organized by service or by topology, or by using the CLI.

NOTE: To visualize the graphs and charts, you must install the metrics collection infrastructure during installation. If the metrics collection infrastructure is not installed, perform an Incremental Install to install the metrics collection infrastructure.

NOTE: The **Nodes** page is not available on the Kubernetes version of the Control System.

Monitoring Node Health Using the Control System

About this task
To monitor the health of nodes:

last-updated: Jun 06, 2024

Procedure

1. Log in to the Control System and click:
   - **Overview** to view the health of the nodes in the **Node Health** pane.
   - **Nodes** to view the health of the nodes in the **Node Health** pane.
2. Select one of the following from the drop-down menu in the **Node Health** pane.
   - **By Service** to organize the display of nodes by services.

     This is the default view in the **Overview** page. This view contains the list of services and the nodes on which the service is running ( ) and is down ( ).

     NOTE: The color of the node (which reflects the status of the service) is even when a service is stopped (not running) on the node.
   - **By Topology** to view the display of nodes by topology.

     This is the default view in the **Nodes** page. This view contains the list of topologies and the health of the nodes (as shown in the following table) in the topology.

Node Color	Description
	Indicates the node is healthy.
	Indicates the node is degraded and/or may need attention. A node is considered to be in degraded state if: • There is no heartbeat from the HPE Ezmeral Data Fabric filesystem/NFS node for over 60 seconds. • One or more services are down on the node. • One or more alarms are raised on the node.
	Indicates the node is in maintenance mode.
	Indicates critical issue(s) on the node. A node is considered to be in critical state if: • There is no heartbeat from the node for more than 5 minutes. • All HPE Ezmeral Data Fabric files system disks on the node are dead or are offline. • All containers on the node are being re-replicated because either the node was removed, unregistered, or there was no heartbeat from the node for more than 1 hour. • File server is dead/inactive because there is no heartbeat for a long time. • NFS server on node is dead. • HPE Ezmeral Data Fabric install directory is full. • Node reported high HPE Ezmeral Data Fabric filesystem memory usage.

last-updated: Jun 06, 2024

Monitoring Node Resource Utilization from the Control System

Procedure

- Log in to the Control System and click **Nodes** to view the nodes that consumed the most CPU and memory (in percentage) in the **Current Resource Utilization** pane. The shade of the bubble indicates node resource utilization with the darker shade indicating the nodes that are nearing disk capacity.

Monitoring Active Node Alarms from the Control System

About this task

See Viewing Active Node Alarms on page 1692 for more information.

Monitoring Node Health Using the CLI or REST API

About this task

You can check general health of the nodes with the following command:

```
maprcli node heatmap -cluster <cluster>
```

This command displays a heatmap for the nodes on the specified cluster; a subset of the output can also be visualized on the Control System. For complete reference information, see `node heatmap` on page 2262.

Viewing Node Metrics

Explains how to view node metrics using the Control System.

About this task

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to visualize the metrics that are desribed in the following section.

Monitoring Node Metrics Using the Control System

Procedure

- Log in to the Control System and go to the **Metrics** tab in the node information page.

  By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

  You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

  - › to shift time window forwards.

last-updated: Jun 06, 2024

- to shift time window backwards.

Click associated with the chart to view information about the graph. Click to display the **Customize Active Charts** window. You can select charts to display and remove from the **Available** and **Selected** lists in the **Customize Active Charts** window. You can view up to 6 charts at a time in the page.

Use the following table when selecting the charts to view in the page. In the following table, the Charts column lists the charts that are available and the Metric column describes that type of metric that can be visualized in the chart:

Metric	Charts
CPU Usage	• Node Active CPU Usage • Node CPU Usage** • Node CPU Usage IDLE • Node CPU Usage NICE • Node CPU Usage SYSTEM • Node CPU Usage USER • Node CPU Usage WAIT • MFS CPU Usage • Allocated vs Available CPU Cores • MapR Process CPU Usage • MAST Gateway CPU Usage • DB Gateway CPU Usage • Data Access Gateway CPU Usage
Memory Usage	• Node Free Memory • Node Utilized Memory*** • Node Memory Free vs Used* • MFS Process Memory Usage • Data Fabric Process Memory Usage
SWAP Space	• Node Swap Free • Node Swap Used • Node Swap Space Available vs Used* • Node Swap IO

last-updated: Jun 06, 2024

Metric	Charts
Node IOs	• Node Network IO* • Node Network Interface Input • Node Network Interface Output • Node Network Interface Error Input • Node Network Interface Error Output
System Disk Throughput	• Disk Read Ops • Disk Write Ops • Disk Reads and Writes*
System Disk Latency	• Disk Avg Read Latency • Disk Avg Write Latency • Disk Read and Write Times
MFS Throughput	• MFS Read Throughput • MFS Write Throughput • MFS Read and Write Throughput • MFS System Disk Activity in Bytes*

* This metric is diplayed in the default chart view for a node.

** This metric is diplayed in the default chart view for a node and in the default list view for a table.

*** This metric is diplayed in the default list view for a table.

For information on viewing metrics for:

- All table activities on a node, see Viewing Per Node Metrics for Table Activities on page 1671.
- All stream activities on a node, see Monitoring Streams Operations Using the Control System on page 1688.

Viewing Per Node Metrics for Table Activities
Describes how to view per node metrics for table activities using the Control System and Grafana.

About this task

This section describes how to view the metrics as charts and lists in the Control System. For information on visualizing the metrics in the Grafana UI, see Metric Visualization on page 1751

NOTE: The metrics collection infrastructure must be installed to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to visualize the metrics as described below.

Procedure

1. Log in to the Control System and go the **Metrics** tab in the node information page.

last-updated: Jun 06, 2024

2. Select **Activity by Tables** from the drop-down menu.

   By default, the page displays charts that show metrics for the last 24 hours. You can select a preset or specify a custom time range.

   You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

   - to shift time window forwards.
   - to shift time window backwards.

   The charts show metrics for the node across tables. Click associated with the chart to view information about the graph. Click to display the **Customize Active Charts** window, where you can select charts to display and remove from the **Available** and **Selected** lists. You can view up to 6 charts at a time in the page.

   You can switch to the list view by clicking . In the list view, you can:

   - Click the table name to go to the metrics page for the table.
   - Select one or more tables and switch to charts view (by clicking) to visualize metrics for the selected tables only.

   For the complete list of metrics that you can view at both the node and table levels, see Viewing Table Metrics in the Control System on page 1681.

Monitoring YARN

Procedure

- Log in to the MapR Control System and:
  - Click **Overview** to view the following in the **YARN** pane:
    - Number of node managers, running applications, and queued jobs.
    - Memory and CPU utilization metrics.
  - Go to the service information page for YARN. The YARN information page displays the following panes:

Summary	Displays: • Total number of nodes and number of active and unhealthy nodes. • Allocated, pending, and reserved number of Resource Manager containers.

Top Queues by CPU Utilization	Displays the queues that utilize the most CPU (in percentage).
Top Queues by Memory Consumption	Displays the queues that consume the most memory (in percentage).
Applications	Displays the number of submitted, completed, running, pending, and failed applications during a selected date and time range. You can select a preset or specify a custom time range.  You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.
Resource Manager (CPU)	The number of cores allocated and used by Resource Manager during a selected date and time range. You can select a preset or specify a custom time range.  You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.
Resource Manager (Memory)	The amount (in MB) of memory allocated and used by Resource Manager during a selected date and time range. You can select a preset or specify a custom time range.  You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view.

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to install the metrics collection infrastructure.

Monitoring Volumes

Explains how to monitor volume parameters using the Control System.

About this task

You can monitor volume:

- Disk usage
- Alarms

last-updated: Jun 06, 2024

Monitoring Volume Disk Usage Using the Control System

Procedure

- You can view:
  - Volumes that use the most amount of allocated disk space in the **Top Volume Utilization** pane under **Data** > **Volumes**.

    NOTE: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

  - Disk usage trend for a volume in the **Usage Trends** pane in the **Summary** tab of the volume information page. You can select a preset (shown in the following screenshot) or specify a custom time range (shown in the following screenshot). You can zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Reset Zoom** to zoom out and return to selected date/time range view.

NOTE: The metrics collection infrastructure must be installed during installation to visualize the metrics in the various panes. If the metrics collection infrastructure is not installed, perform an Incremental Install to view the charts described here.

Monitoring Volume Alarms in the Control System

About this task

See Viewing Active Volume Alarms on page 1693.

Monitoring Local and Remote Storage for Volumes

About this task

You can view the following storage utilization metrics for tiered volumes in the **Data** > **Volumes** > **Local & Remote Usage** pane.

NOTE: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.

- Local — The total disk space (in GB) used (before compression) for the volumes in the HPE Ezmeral Data Fabric cluster. This value does not include erasure-coded backend volumes and cache-volumes because their logical usage is already accounted for by the front-end and parent volumes respectively.
- Cold Offloaded — The total physical data (in GB) offloaded to the cold tier. This is calculated using the following: *amount of data purged from the hot tier (HPE Ezmeral Data Fabric cluster) + amount of data recalled to the hot tier (HPE Ezmeral Data Fabric cluster)*.
- Warm Offloaded — The total physical data (in GB) offloaded to the erasure coded volume (warm tier). This is calculated using the following: *amount of data purged from the hot tier (HPE Ezmeral Data Fabric cluster) + amount of data recalled to the hot tier (HPE Ezmeral Data Fabric cluster)*.

Collecting Volume Metrics

Describes how to enable and collect operational metrics for volumes.

You can collect the following volume metrics on file system after you enable metrics collection as described in Enabling Volume Metric Collection on page 1676:

Read I/Os	Number of reads
Write I/Os	Number of writes

last-updated: Jun 06, 2024

Read throughput	Amount of data read
Write throughput	Amount of data written
Read latency	Time taken by read operations
Write latency	Time taken by write operations

If you enable metrics collection on a volume, for each file system instance, on every node where the volume containers reside, metrics for the volume (for a day) are captured every 10 seconds and logged to files in a local volume, which is two way replicated. The metrics log file, `Metrics.log-<date>-<n>.json`, is available at `/var/mapr/local/<hostname>/audit/<mfs-port>` directory. Here:

- `mfs-port` is the port on which the file system instance listens.
- `date` is the record date in the format yyyy-mm-dd. A new file is created at the beginning of each day.
- n is the iteration of the log file represented by 3 digits. A new file is created every time Warden is restarted on the node. For the first file, <n> is 001 and <n> is incremented every time warden restarts. For example: `Metrics.log-2017-08-18-001.json` and `Metrics.log-2017-08-18-002.json` When a new file is created, the old file is purged based on the CLDB audit log retention period, which is 30 days by default.

Each record in the file looks similar to the following:

```
{
 "ts":1503048590000,
  "vid":35211529,
  "RDT":0.0,
  "RDL":0.0,
  "RDO":0.0,
  "WRT":308085.8,
  "WRL":2434.0,
  "WRO":2192.0
}
```

Here:

- `ts` — timestamp in milliseconds
- `vid` — volume ID
- `RDT` — read throughput in KB (cumulative for 10 seconds)
- `RDL` — amount of time taken by read operations (average for 10 seconds)
- `RDO` — number of read operations (cumulative for 10 seconds)
- `WRT` — write throughput in KB (cumulative for 10 seconds)
- `WRL` — amount of time taken by write operations (average for 10 seconds)
- `WRO` — number of write operations (cumulative for 10 seconds)

The `collectd` service reads up to 16 MB of data every ten seconds from each file, then aggregates and writes one minute worth of data to OpenTSDB. When reading the file, the `collectd` service stores offsets (as to how much has been read) as extended attributes (`trusted.disptachedOffset`) on the file. In addition to the default tags assigned to each metric when collectd writes metrics to OpenTSDB, the following tags are assigned to volume metrics:

last-updated: Jun 06, 2024

- `mapr.volmetrics.[read_|write_][throughput|latency|ops]` — Displays the type of metric
- `volume_name` — Displays the name of the volume

For more information on the default tags, see Metric Collection on page 1699.

For each metrics file, MapR also creates a file, `Vollist_metrics.log-<date>-<n>`, in the `/var/mapr/local/<hostname>/audit/<mfs-port>/` directory. This file is purged based on the CLDB audit log retention period, which is 30 days by default. This file contains a comma separated list of volume name and volume ID (for volumes for which metrics are captured) and is associated with the `Metrics.log-<date><n>.json` file. For example, the record in the file looks similar to the following:

```
<volumeid>,<volume name>,<volumeid>,<volume name>,...
```

You can visualize the metrics in the dashboards on Grafana. See Metric Visualization on page 1751 for more information.

Enabling Volume Metric Collection
Describes how to enable metric collection for a volume, and gather volume statistics.

About this task

On all new installations, this feature is enabled by default and you only need to enable metrics collection for each volume. If you are upgrading from a version prior to MapR version 6.0, to start collecting volume metrics that you can then visualize in Grafana, you must enable the metrics collection feature and then enable metrics collection for each volume.

You can enable metrics collection from the command-line and using the Control System.

Enabling the Metric Collection Feature

Procedure

- Enable the feature by running the following command:

  ```
  /opt/mapr/bin/maprcli cluster feature enable -name
  mfs.feature.metrics.support
  ```

Enabling Metric Collection for New Volumes Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Volumes**.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Click **Create Volume** to display the **Create New Volume** page.
3. Enter values for the required settings and move the slider for **Collect Metrics** to **Yes** to enable metric collection for the volume.

   For more information, see Creating a Volume on page 1177.

4. Click **Create Volume** to create the volume.

Enabling Metric Collection for Existing Volumes Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Volumes**.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. Select the **Volumes** to edit and **Edit Volume** from the **Actions** drop-down menu or go the volume info page and click **Edit Volume**.

3. Move the slider for **Collect Metrics** to **Yes** to enable metric collection for the volume.
   For more information, see Creating a Volume on page 1177.

4. Click **Save Changes** for the changes to take effect.

Enabling Metric Collection for Volumes Using the CLI

Procedure

- Enable metrics collection on:
  - A new volume by running the following command:

    ```
    /opt/mapr/bin/maprcli volume create -name <volume-name> -path
    <volume-mount-path> -type <volume-type> -metricsenabled true
    ```

    For more information, see `volume create` on page 2588.

  - An existing volume by running the following command:

    ```
    /opt/mapr/bin/maprcli volume modify -name <volume-name> -metricsenabled
    true
    ```

    For more information, see `volume modify` on page 2676.

  - All volumes that do not have mapr in the name by running the following script:

    ```
    for i in `/opt/mapr/bin/maprcli volume list -columns n | grep -v
    mapr | grep -v volumename`; do echo $i; /opt/mapr/bin/maprcli volume
    modify -name $i -metricsenabled true; done
    ```

Monitoring Tables
Explains how to monitor table alarms and view table metrics in the Control System.
Monitoring Table Alarms in the Control System

About this task

See Viewing Active Table Replication Alarms on page 1693.

Viewing Throughput by Operation Type Using the Control System

Procedure

- Log in to the Control System and do one of the following:
  - Go to the **Summary** tab in the table information page.

The **Throughput - By Op Type** pane displays a graph for the following operations on the table in the last hour:

- Gets
- Puts
- Scans
- Increments
- Appends
- Checks and Puts
- Updates and Gets

- Go to the **Summary** tab in the index details page.

  The **Throughput - By Op Type** pane displays a graph for the following operations on the index in the last hour:

  - Puts
  - Scans

You can move the cursor over the graph to view the number of operations on the table (across nodes).

Visualizing Table Metrics in the Control System

About this task

In the Control System, you can visualize node-level metrics for table operations on a node. You can view charts that show metrics for all tables across all nodes, metrics per table aggregated across nodes, metrics per table per node, and metrics per node across tables. In addition, you can view metrics for activity by indexes and for the table and its secondary indexes.

For the full list of metrics (and associated charts/columns) that you can view in the Control System, see Viewing Table Metrics in the Control System on page 1681.

Procedure

- Log in to the Control System and do one of the following to view table metrics:
  - Go to the **Metrics** tab in the node information page and select **Activity by Tables** from the drop-down menu.

    In this tab, you can view charts/columns that show metrics for all table operations on the node, operations on streams, and other node metrics described here.

  - Go to the **Metrics** tab in the **Data** > **Tables** page.

    In this tab, you can view charts/columns that show metrics per node for all tables.

  - Go to the **Metrics** tab in the table information page.

    In this tab, you can view charts/columns that show operations on the table and its secondary indexes across nodes.

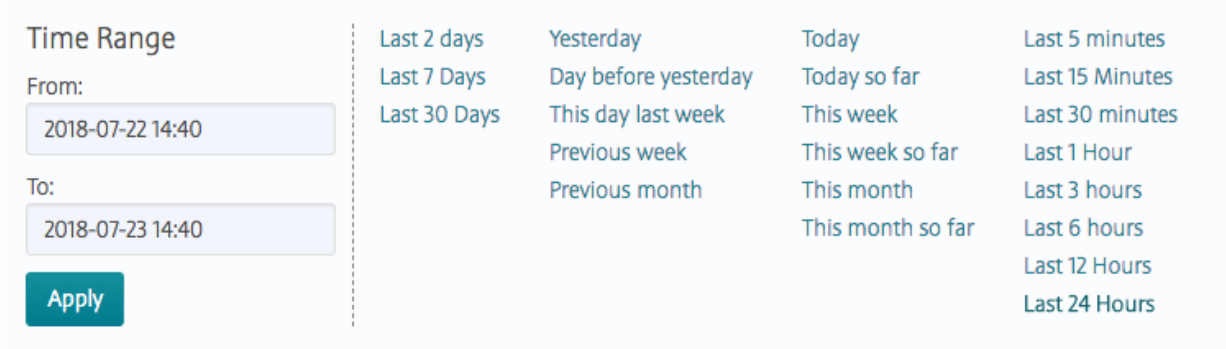
  - Go to the **Metrics** tab in the index details page and select **Activity by Nodes** from the drop-down menu.

    In this tab, you can view charts that show all index operations and index operations per node.

last-updated: Jun 06, 2024

You can select the charts to view by creating a custom chart Board or by modifying an existing Board. See Creating a Custom Board for the Charts on page 1663 or Editing a Chart Board on page 1664 for more information.

The charts on the page show the metrics for the last 24 hours by default. You can select a preset or specify a custom time range.



You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

- to shift time window forwards.
- to shift time window backwards.

NOTE: When you select a granular view, the chart might not show the most accurate data because of the difference between the interval at which the metrics are logged and the downsampling (lowering the sampling rate) for the interval being viewed.

You can switch to a list view, where available, by clicking . In this view, you can select metrics to view by clicking . See Adding and Removing Columns from the List View on page 1665 for more information.

In the list view, you can:

- Filter the list by clicking .
- Click the node name to go to the node-level metrics page.
- Select one or more nodes and switch to charts view by clicking to visualize metrics for the selected nodes only. The legends for the charts reflect the selected nodes.

NOTE: Certain grouping of metrics, available in the charts view, are not available in the list view. All the metric grouping available in the list view are available in the charts view as well. When you switch from charts to list view and vice versa, your selection of metrics in one view is not carried over to the other view.

The chart and list views allow you to detect and diagnose bottlenecks and performance issues on individual tables and nodes. You can use the charts for measuring the throughput and latency of different RPC operations on a table and for determining which operations on a table are slow or which tables are most frequently accessed.

For example:

- Suppose your node is busy and you are noticing intermittent latency spikes on your table. You can compare throughput and latency in the **Metrics** tab of the table information page and investigate if the latency spike is due to node being very busy or node having high CPU utilization by switching to the list view from where you can navigate to the **Metrics** tab of the node details page.

last-updated: Jun 06, 2024

- Suppose your index queries take minutes instead of seconds to complete. You can compare the get latency percentile with the scan read/response in the **Metrics** tab of the table information page by zooming in to the area where you see the spike. Switch to **Activity by Index** to view the index vs primary table scans where you can determine whether excessive scan load went to the primary table.
- Suppose you are noticing latency spikes on one of your table as a result of a lot of activity on another table. Observe the get latency percentile spikes in the **Metrics** tab of the table information page and switch to **Activity by Node** list view to identify the nodes with high overall aggregate table RPC load and node IOps. Select the saturated nodes in the list view and switch to the chart view. Go back to the list view and click the saturated node to navigate to the **Metrics** tab of the node details page. Switch to **Activity by Tables** to determine the most active table.

Viewing Secondary Index Metrics

About this task

You can visualize the secondary index metrics in the Control System.

Procedure

- Log in to the Control System and do one of the following:
  - Go to the **Metrics** tab in the table information page and select **Activity by Indexes** from the drop-down menu to view all index-related activity on the table.
  - Go to the **Metrics** tab in the secondary index page to view metrics for index-related activity across tables or per node.

  By default, the page displays metrics for the last 24 hours. You can select a preset or specify a custom time range.

  You can also zoom in (by clicking and dragging the cursor in the pane) for a more granular view. Click **Zoom Out** to expand time window or click:

  - > to shift time window forwards.
  - < to shift time window backwards.

  The page displays charts by default. When viewing activity by nodes, you can switch to a list view by clicking and return to charts view by clicking .

Charts view	You can select the charts to view by creating a custom chart Board or by modifying an existing Board. See Creating a Custom Board for the Charts on page 1663 or Editing a Chart Board on page

	1664 for more information. Click the  associated with the chart to view information about the graph.
List view	The list view shows the metrics in the columns. You can customize the columns by clicking  . See Adding and Removing Columns from the List View on page 1665 for more information. In addition, you can: • Click the column name to sort the table by that column. • Click the node name to go to the metrics page for the node. • Click one or more checkboxes next to the node name and switch to the charts view to visualize metrics for the secondary index activities on those nodes only.

You can use the charts to diagnose and troubleshoot bottlenecks and performance issues. For the complete list of metrics that you can view for secondary indexes, see Viewing Table Metrics in the Control System on page 1681.

Viewing Region Distribution

Procedure

- Log in to the Control System and go to one of the following pages:
  - **Summary** tab in the table information page to view the region distribution for a table.
  - **Summary** tab in the index details page to view the region distribution for a secondary index.

  The **Region distribution** pane shows the distribution of the table or secondary index regions across the nodes in the cluster. The shade of the node reflects the sum of the physical size of data on the node with the darker shade indicating increased resource utilization on the node. You can move the cursor over a node to view the following:
  - Hostname of the node
  - Number of regions on the node
  - Total size of data (across regions) on the node

  You can click a node to go to the node information page.

Viewing Table Metrics in the Control System

Explains how to view primary and secondary table index metrics using the Control System.

A subset of the following primary table and secondary index metrics are available as charts and lists in the Control System. For information on how to:

- View these metrics in the Control System, see Monitoring Tables on page 1677.
- Customize the charts you see on the page, see Creating a Custom Board for the Charts on page 1663.
- Customize columns you see on the page, see Adding and Removing Columns from the List View on page 1665.

last-updated: Jun 06, 2024

Chart/Column Name	Metric	Description
Table Bytes Read Per Node	Throughput - bytes read	The number of bytes read from the primary table per node for all RPC types.
Table and Index Bytes Read		The number of bytes read across a primary table and its secondary indexes for all RPC types.
Table Bytes Written Per Node	Throughput - bytes written	The number of bytes written to the primary table per node for all RPC types.
Table and Index Bytes Written		The number of bytes written across a primary table and its secondary indexes for all RPC types.
Table Rows Read Per Node	Throughput - rowCount read	The number of rows read from the primary table per node for all RPC types.
Table and Index Rows Read		The number of rows read across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node.
Table Rows Written Per Node	Throughput - rowCount written	The number of rows written to the primary table per node for all RPC types.
Table and Index Rows Written		The number of rows written across a primary table and its secondary indexes for all RPC types.
All Tables Written Rows Throughput		Number of rows written by RPC operation type.
Table Rows Responded Per Node	Throughput - rowCount returned	The number of rows returned from the primary table per node for all RPC types.
Table and Index Rows Responded		The number of rows returned across a primary table and its secondary indexes for all RPC types. This is displayed in the default list view for a node.
Scan Throughput		Compares the scan throughput for rows read versus rows returned. This is displayed in the default chart view for a node and for a table.

last-updated: Jun 06, 2024

Chart/Column Name	Metric	Description
All Tables Throughput	Throughput - rpcCount/second	Number of RPC operations by type for all tables in the cluster. This is displayed in the default chart view for all the tables.
Throughput by Rpc Type		The combined RPC load for the primary table and its indexes.
All Tables RPC Byte Throughput		The number of bytes processed by RPC operation type.
All Tables Read Rows Throughput		Number of rows processed by RPC operation type.
All Tables Returned Rows Throughput		Number of rows returned by RPC operation type.
Put and Append Operation Throughput		Number of put and append RPC operations for the table, including its indexes.
Table Check and Put Ops Per Node		The number of check and put operations completed for a primary table and for a node.
Table Update and Get Ops Per Node		The number of update and get operations completed for a primary table and for a node.
Table Get and Index Scans		The number of get and index scans completed for a primary table and for a node.
Table Write and Index Maintenance Activity		The number of table writes (puts, appends, increments, check and puts, update and gets) that require puts to the index.
Table Get Ops Per Node		The number of get operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Get Throughput Per Node		The number of get operations completed per second for a table, excluding its secondary indexes, per node. This is displayed in the default chart view for a node and for a table.
Table Increment Ops Per Node		The number of increment operations completed for a primary table and for a node.
Table Put Ops Per Node		The number of put operations completed for a primary table and for a node. This is displayed in the default list view for a node and for a table.
Table Scan Ops Per Node		The number of scan operations completed for a primary table and for a node.
Table Append Ops Per Node		The number of append operations completed for a primary table and for a node.
Table Write Throughput Per Node		The number of put and append

Chart/Column Name	Metric	Description
Table and Index Scan Latency	Latency	The 99th percentile latency of all scan operations across the primary table and its secondary indexes. A bad ratio between rows read and responded with high scan latency may indicate a poorly configured index.
Table and Index Scan Latency Per node		The 99th percentile latency of scan operations completed across the primary table and secondary index per node. Large scans may hit the disks and result in poor performance, or a degrading disk may spike the latency.
Table Append Latency Per Node		The 99th percentile latency of append operations on the primary table per node.
Table Increment Latency Per Node		The 99th percentile latency of increment operations on the primary table per node.
Table Put Latency Per Node		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Get Latency Per Node		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default list view for a node and for a table.
Table Scan Latency Per Node		The 99th percentile latency of scan operations on the primary table per node.
Table Get Latency Percentiles*		The get operation latency by percentile for the primary table and its secondary indexes.
Primary Table Put & Append Latency Percentiles*		The pure write operation latency by percentile for the primary table and its secondary indexes.
Table Write Throughput Latency Percentiles		The 99th percentile latency of put operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Get Throughput Latency Percentiles		The 99th percentile latency of get operations on the primary table per node. This is displayed in the default chart view for a node and for a table.
Table Check and Put Latency Per Node		The 99th percentile latency of check and put operations on the primary table per node.
Table Update and Get Latency Per Node		The 99th percentile latency of update and get operations on the primary table per node.
Index Put Latency		The 99th percentile latency of put operations per secondary index of the

Chart/Column Name	Metric	Description
All Tables Replication Sent Bytes	Replication - rows/bytes sent	The number of bytes of replication data sent.
All Tables Replication Pending Bytes	Replication - rows/bytes pending	The number of bytes of replication data not yet sent.
All Tables Replication Activity	Replication - rows/bytes sent/pending	Number of bytes of replication data sent vs not yet sent. This is displayed in the default chart view for all the tables.
Index Throughput by RPC Type	Index - Throughput	The combined RPC load for the primary table and its secondary indexes.
Index Put Ops		The number of put operations completed per secondary index of the primary table.
Index Put Ops Per Node		The number of put operations completed per secondary index of the primary table per node.
Index Scan Ops		The number of scan operations completed per secondary index of the primary table.
Index Scan Ops Per Node		The number of scan operations completed per secondary index of the primary table per node.
Index Bytes Read	Index - rows/bytes read	The number of bytes read per secondary index of the primary table for all RPC types.
Index Bytes Read Per Node		The number of bytes read per secondary index of the primary table per node for all RPC types.
Index Bytes Written Per Node		The number of bytes written per secondary index of the primary table per node for all RPC types.
Index Rows Read		The number of rows read per secondary index of the primary table for all RPC types.
Index Rows Read Per Node		The number of rows read per secondary index of the primary table per node for all RPC types.
Index Rows Responded	Index - rows/bytes returned	The number of rows returned per secondary index of the primary table for all RPC types.
Index Rows Responded Per Node		The number of rows returned per secondary index of the primary table per node for all RPC types.
Index Scan Read vs Returned Rows	Index - rows/bytes read	The number of secondary index rows that were read versus returned.

last-updated: Jun 06, 2024

Chart/Column Name	Metric	Description
Index Bytes Written	Index - rows/bytes write	The number of bytes written per secondary index of the primary table for all RPC types.
Index Rows Written		The number of rows written per secondary index of the primary table for all RPC types.
Index Rows Written Per Node		The number of rows written per secondary index of the primary table per node for all RPC types.
All Tables Index Sent Bytes	Index - rows/bytes sent	The number of bytes sent for secondary index updates.
All Tables Index Pending Bytes	Index - rows/bytes pending	The number of bytes of secondary index data remaining to be sent.
All Index Maintenance Activity		Number of bytes of index data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Tables CDC Sent Bytes	CDC - rows/bytes sent	The number of bytes of CDC data sent.
All Tables CDC Pending Bytes	CDC - rows/bytes pending	The number of bytes of CDC data per node not yet sent.
All Tables CDC Propagation Activity		The number of bytes of CDC data sent vs not yet sent. This is displayed in the default chart view for all the tables.
All Streams Producer Ops	Streams Throughput, RPCs	The number of Streams producer RPCs.
All Streams Consumer Ops		The number of Streams consumer RPCs.
All Streams Producer Messages	Streams Throughput, messages	The number of Streams messages produced.
All Streams Consumer Messages		The number of Streams messages read by consumers.
Table Value Cache All Lookups	Value Cache Lookups	All operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups		The number of get operations for a primary table and for a node that performed a cache lookup.
Table Value Cache Lookups Per Index		The number of get operations for a primary table and for a node that performed a cache lookup.

last-updated: Jun 06, 2024

Chart/Column Name	Metric	Description
Table and Index Value Cache All Lookups	Value Cache Hits	All operations across the primary table and its secondary indexes that performed a cache lookup.
Table and Index Value Cache Lookups Per Index		The number of get operations across the primary table and its secondary indexes that performed a cache lookup per secondary index.
Table and Index Value Cache Lookups		The number of get operations across the primary table and its secondary indexes that performed a cache lookup.
Table Value Cache All Hits		All operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table Value Cache Hits Per Index		The number of get operations for a primary table and for a node that resulted in a cache hit.
Table and Index Value Cache All Hits		All operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit.
Table and Index Value Cache Hits Per Index		The number of get operations across the primary table and its secondary indexes that resulted in a cache hit per secondary index.
Value Cache Utilization	Value Cache	Compares the relative distribution of get operations that either hit the cache or require a lookup. This is displayed in the default chart view for a node and for a table.
All Tables Flushes	Bucket Flushes	The number of table flushes that were manually and automatically triggered. Table flushes reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold. This is displayed in the default chart view for all the tables.
All Tables Flushes		The number of total table flushes that were manually versus automatically triggered.
All Tables Force Flushes	Bucket Force Flushes	The number of table flushes that were not automatically triggered.

last-updated: Jun 06, 2024

Chart/Column Name	Metric	Description
All Tables Compactions	Compaction	Number of table compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. This is displayed in the default chart view for all the tables.
All Tables Full Compactions		Number of full compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. Full compactions improve read performance because after compaction, HPE Ezmeral Data Fabric Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files.
All Tables Mini Compactions		Number of partial compactions. Compactions combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. After a mini compaction, HPE Ezmeral Data Fabric Database needs to read only two spill files.
All Tables TTL Compactions		Number of compactions that result in reclamation of disk space after removal of stale data. You can control the frequency of TTL compactions by configuring the TTL for a table's column families.
All Tables Free Index Memory	Memindex Usage	The number of available MB in the in-memory bucket file cache.

* Percentiles are estimated by linearly interpolating between fixed buckets sizes.

Monitoring Streams
Explains how to monitor streams using either the Control System or the CLI.

About this task

The speed at which messages flow from producers to partitions, and from partitions to consumers depends on the performance of your producers, the cluster nodes hosting partitions, and your consumers.

Monitoring Streams Operations Using the Control System

Procedure

- Log in to the Control System and go to the **Metrics** tab in the node information page to select the charts that show the following when you filter the list of charts by table activities:
  - **All Streams Producer Messages**: The number of Streams messages produced on the node
  - **All Streams Consumer Messages**: The number of Streams messages on the node read by consumers

last-updated: Jun 06, 2024

- **All Streams Producer Ops**: The number of Streams producer RPCs on the node
- **All Streams Consumer Ops**: The number of Streams consumer RPCs on the node

For more information, see Creating a Custom Board for the Charts on page 1663.

Monitoring Active Stream Alarms

About this task

See Viewing Active Stream Alarms on page 1694.

Monitoring Cluster Nodes that Host Partitions

You can find out which nodes in a MapR cluster are being used for topics in a stream by running the command `maprcli stream topic info`. The nodes are listed in the `servers` field.

The `guts` utility can show you whether there are any I/O bottlenecks on these nodes. This utility can also show you whether there is any capacity on other nodes in the cluster that you can take advantage of by creating additional partitions for topics.

To run this utility, issue this command after logging into the MapR cluster that you want statistics for:

```
/opt/mapr/bin/guts
```

You can also use the `guts` utility to show only these statistics from HPE Ezmeral Data Fabric Streams:

Table

Name	Description
`mpr`	The number of RPCs from HPE Ezmeral Data Fabric Streams producers to the server.
`mpm`	The number of messages that have been published to the server.
`mpMB`	The total size in MB of the messages that have been published to the server.
`mlr`	The number of RPCs from HPE Ezmeral Data Fabric Streams consumers to the server.
`mlm`	The number of messages that have been read from the server.
`mcl`	The number of concurrent RPCs from consumers to the server.
`mlMB`	The total size in MB of the messages that have been read from the server.

To see these statistics, run this command:

```
/opt/mapr/bin/guts streams:all
```

NOTE: These statistics are for the most recent sample period at the time the command is run, and are not cumulative. Sample periods are one second.

Monitoring Producers

To get a sense of how quickly producers are sending messages to the producer client library, you can run the command `stream topic info` at intervals.

Doing so will show you changes over time in the rate at which the values for `maxoffset` and `maxtimestamp` increase for the partitions in the topics that your producers are publishing to.

last-updated: Jun 06, 2024

For example, if you have a script that runs the command at intervals of 10 seconds, the change per second would be `(Value at first run - Value at second run)/10`.

This is an indirect measure of the speed of the producers because the producer client library batches messages before publishing them to partitions. The faster the producers send messages to the client, the faster the client publishes message batches, and the greater the change per second.

If producers do not seem to be sending messages quickly enough, and this problem is not caused by server-side I/O bottlenecks, you can spawn more producer threads.

See `stream topic info` for the syntax of this command.

Monitoring Consumers
There are two commands that you can run at intervals to get a sense of how far behind a consumer is in a partition. The consumer must belong to a consumer group, even if the consumer is the only member of that group.

To find the lag in milliseconds between the timestamp of the most recently published message in a stream, topic, or partition and the timestamp of a consumer's most recently committed cursor, run the command `stream cursor list`. The lag is the value of the `consumerlagmillis` parameter.

To find the timestamp of the most recently committed cursor for the consumer that is furthest back in a partition compared to all other consumers reading from the same partition, run the command `stream topic info`. This timestamp is the value of the `mintimestampacrossconsumers` parameter. Use this timestamp together with the values of the following parameters to get a sense of where this cursor is in the partition:

`mintimestamp`	This parameter shows the timestamp of the oldest message in the partition.
`maxtimestamp`	This parameter shows the timestamp of the most recently published message in the partition.

If a consumer's configuration for cursor commits is the default (the configuration parameter `enable.auto.commit` is set to `true` and `auto.commit.interval.ms` is set to 1000 milliseconds), the consumer will be only about one second ahead of the offset and timestamp reported for the consumer's most recently committed cursor.

If it seems that consumers are falling behind and that this problem is not caused by server-side I/O bottlenecks, you can start more consumer threads.

If the current number of consumers in a consumer group is equal to the number of partitions in the topic with the fewest partitions to which the consumer group is subscribed, add a partition to this topic before adding a consumer. The consumer client library dynamically reassigns the existing partitions in the topic to the consumers in the consumer group, as well as assigning the new partition to a consumer.

If the current number of consumers in a consumer group is less than the number of partitions in the topic with the fewest partitions to which the consumer group is subscribed, you don't need to add any partitions before adding a consumer.

Monitoring Alarms
Provides an overview of how to monitor alarms using the Control Panel and the CLI.

On a cluster with an Enterprise Edition or Enterprise Database Edition license, HPE Ezmeral Data Fabric raises alarms to alert you to information about the cluster:

- Cluster health, including disk failures
- Volumes that are under-replicated or over quota
- Services not running

You can see any currently raised alarms in the **Active Alarms** pane and the **Alarm Summary** page of the Control System (click in the Control System) or using the `alarm list on page 2023` command. For a list of all alarms, see the Alarms Reference.

When you click , the **Alarm Summary** page displays all active alarms and for each alarm, the **All** active alarms pane displays the following:

Column Name	Column Description
Severity	The severity of the alarm. Value can be: • — Critical • — Warning • — Information
Status	The status of the alarm. Value can be: • Active • Muted
Time	The date and time stamp from when the alarm was raised.
Name	The name of the alarm.
Info	The notes associated with the alarm, which contains description of the alarm and the recommended action to take.
Entity	The entity on which the alarm was raised.
Type	The type of alarm. Value can be: • CLUSTER • NODE • VOLUME • USER/GROUP

You can select the checkbox beside one or more alarms to:

- Dismiss the alarms
- Mute the alarms

Viewing Active Cluster Alarms
Describes how to view cluster alarms using the Control System and the CLI.

About this task

You can view cluster alarms using the Control System and the CLI.

Viewing Active Cluster Alarms in the Control System

Procedure

- Log in to the Control System and click:

last-updated: Jun 06, 2024

- **Overview** to view all the alarms on the cluster in the **Active Alarms** pane. To view only the cluster alarms, select **Cluster Alarm** from the drop-down menu in the **Active Alarms** pane.
-  (Alarm Summary) to view all the alarms on the cluster in the **All** alarms pane. To view only the cluster alarms, select **Cluster Alarm** from the drop-down menu in the **All** alarms pane.

You can:

- View alarm information
- Dismiss an alarm
- Mute an alarm

Retrieving Cluster Alarms Using the CLI or REST API

About this task

The basic command to retrieve the alarms for a cluster is:

```
maprcli alarm list -cluster <cluster name> -type cluster
```

For complete reference information, see `alarm list` on page 2023.

Viewing Active Node Alarms
Describes how to view active node alarms using the Control System and the CLI.
Viewing Active Node Alarms in the Control System

Procedure

-  **NOTE:** The **Nodes** page is not available in the Kubernetes version of the Control System.

  Log in to the Control System and:

  - Click **Nodes** to view all the node alarms on the cluster in the **Active Alarms** pane.
  - Go to the node information page to view alarms in the **Alarms** pane for the selected node.
  - Click  (in the top navigation bar) to display the **Alarm Summary** page and select **Node Alarms** from the drop-down menu in the **All** alarms pane.
  - Click **Overview** and select **Node Alarms** from the drop-down menu in the **Active Alarms** pane to view all the node alarms on the cluster.

  You can:

  - View alarm notes
  - Mute an alarm
  - Dismiss an alarm

Retrieving Active Node Alarms Using the CLI or REST API

About this task

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type node
```

last-updated: Jun 06, 2024

For complete reference information, see alarm list on page 2023.

Viewing Active Volume Alarms
Describes how to view volume alarms using the Control System and the CLI.

About this task

You can view volume alarms in the Control System and using the CLI.

Viewing Active Volume Alarms in the Control System

Procedure

- Log in to the Control System and:
  - Click **Data** > **Volumes** to view all active volume alarms in the **Active Alarms** pane.

    NOTE: The **Volumes** page is under the **Volumes** menu on the Kubernetes version of the Control System.
  - Go to the **Summary** tab in the volume information page to view the recent and active alarms for the selected volume in the **Alarms** pane.
  - Click  (in the top navigation bar) and select **Volume Alarms** from the drop-down menu in the **All** alarms pane to view all the active volume alarms.
  - Click **Overview** and select **Volume Alarms** from the drop-down menu in the **Active Alarms** pane to view all active volume alarms.

  You can:
  - View information related to the alarm.
  - Dismiss an alarm.
  - Mute an alarm.

  See Volume Alarms on page 3024 for more information on the volume alarms.

Retrieving Active Volume Alarms Using the CLI or REST API

About this task

The basic command to retrieve node alarms is:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see alarm list on page 2023.

Viewing Active Table Replication Alarms
Describes how to view active table replication alarms using the Control System and the CLI.

About this task

You can view table replication alarms using the Control System, the log files, and the CLI.

Viewing Active Table Alarms in the Control System

Procedure

- Log in to the Control System and click **Data** > **Tables** to view table replication alarms in the **Active Alarms** pane.

  You can:

  - View information related to the alarm.
  - Dismiss an alarm.
  - Mute an alarm.

  See Table-Replication Alarms on page 3021 for more information on the table alarms.

Retrieving Active Table Replication Alarms Using the CLI or REST API

About this task

Alarms for replication are issued per volume rather than per source table. To retrieve table replication alarms, run the following command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see `alarm list` on page 2023.

Viewing Table Replication Alarms in the Log Files

About this task

The log files `mfs.log-5` and `cldb.log` display these alarms. These files are located in the `/opt/mapr/logs` directory.

Viewing Active Stream Alarms
Describes how to view active stream alarms using the Control System and the CLI.

About this task

You can view stream alarms using the Control System and the CLI.

Viewing Active Stream Alarms in the Control System

Procedure

- Log in to the Control System and:
  - Click **Data** > **Streams** to view all stream alarms in the **Active Alarms** pane.
  - Go to the **Summary** tab in the stream information page to view the recent and active alarms for the selected stream in the **Active Alarms** pane.

  You can:

  - View information related to the alarm.
  - Dismiss an alarm.
  - Mute an alarm.

  See Alarms Reference on page 3004 for more information on the stream alarms.

last-updated: Jun 06, 2024

Retrieving Active Stream Alarms Using the CLI or REST API

About this task

The basic command:

```
maprcli alarm list -cluster <cluster name> -type volume
```

For complete reference information, see alarm list on page 2023.

Monitoring Errors
Explains how to monitor errors using the Control System.

About this task

To view the errors on the cluster:

Procedure

1. Log in to the Control System and click  to display the **Recent Errors** window.
   The **Recent Errors** window displays only if there are any errors. For each error, the window displays the following:

Column Name	Column Description
Name	The name of the error.
Type	The type of error.
Action	The type of operation during which the error occurred.
Date & Time	The date and time when the error occurred.
Description	A brief description of the error.

2. Choose one of the following from the drop-down menu to filter the list of errors by a specific type:
   - All Types — to display all types of errors.
   - Data — to display errors related to data
   - Disk Usage — to display errors related to disk usage
   - Nodes — to display errors on nodes
   - Schedules — to display errors related to schedules
   - Services — to display service-related errors
   - Snapshots — to display errors during snapshot
   - Volumes — to display errors on volumes
   - Tables — to display errors on tables

Using HPE Ezmeral Data Fabric Monitoring (Spyglass Initiative)

HPE Ezmeral Data Fabric Monitoring (part of the Spyglass initiative) provides the ability to collect, store, and view metrics and logs for nodes, services, and jobs/applications.

Metric Monitoring

Administrators can monitor the current status of the cluster and anticipate future cluster requirements with dashboards. For example, you can use metrics dashboards to visualize the following:

Storage Utilization	Use metrics dashboards to monitor storage trends. For example, you can compare the volume of file system usage at different times to the file system capacity and then allocate resources to the file system accordingly.
Node Utilization	Use metrics dashboards to check for node overload. For example, if the CPU usage is high on a few nodes, you may want to distribute the load across more nodes for better performance and efficiency.
HPE Ezmeral Data Fabric Database Operational Trends	Use metrics dashboards to display historical trends for HPE Ezmeral Data Fabric Database operations. For example, if a user reports HPE Ezmeral Data Fabric Database slowness, the historical trends associated with row scans, get, and put operations can be used to identify the node(s) on which the performance degradation occurs.

Log Monitoring

Administrators can use dashboards to visualize, search, and review logs when troubleshooting issues. For example, you can use log dashboards to troubleshoot the following issues:

Service Failures	When metrics indicate that one or more services are down, use log dashboards to check the logs for each failed service and drill-down to each associated node.
Application Failures	When an application or job fails, use log dashboard to identify possible bottlenecks. For example, you can search the logs for a given application ID across all the nodes in the cluster.
file system Performance	When users experience file system or NFS for the HPE Ezmeral Data Fabric slowness, use log dashboards to search the HPE Ezmeral Data Fabric file system logs for service errors or application issues.

Related Information

- Using HPE Ezmeral Data Fabric Monitoring (Spyglass Initiative) on page 1695
- Data Fabric Monitoring Storage Options on page 89
- Step 9: Install Metrics Monitoring on page 222
- Step 10: Install Log Monitoring on page 225

HPE Ezmeral Data Fabric Monitoring Architecture

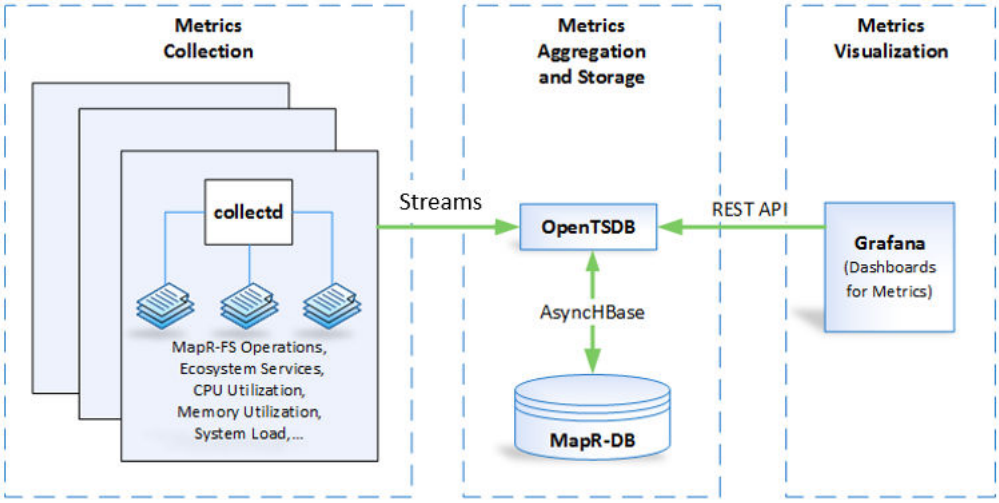
HPE Ezmeral Data Fabric Monitoring integrates with open-source components to collect, aggregate, store, and visualize metrics and logs.

NOTE: The HPE Ezmeral Data Fabric Monitoring architecture is designed for use on HPE Ezmeral Data Fabric cluster nodes. Installing monitoring components on client nodes or edge nodes is not supported.

Metric Monitoring Architecture

To visualize cluster metrics, HPE Ezmeral Data Fabric Monitoring integrates with the following components:

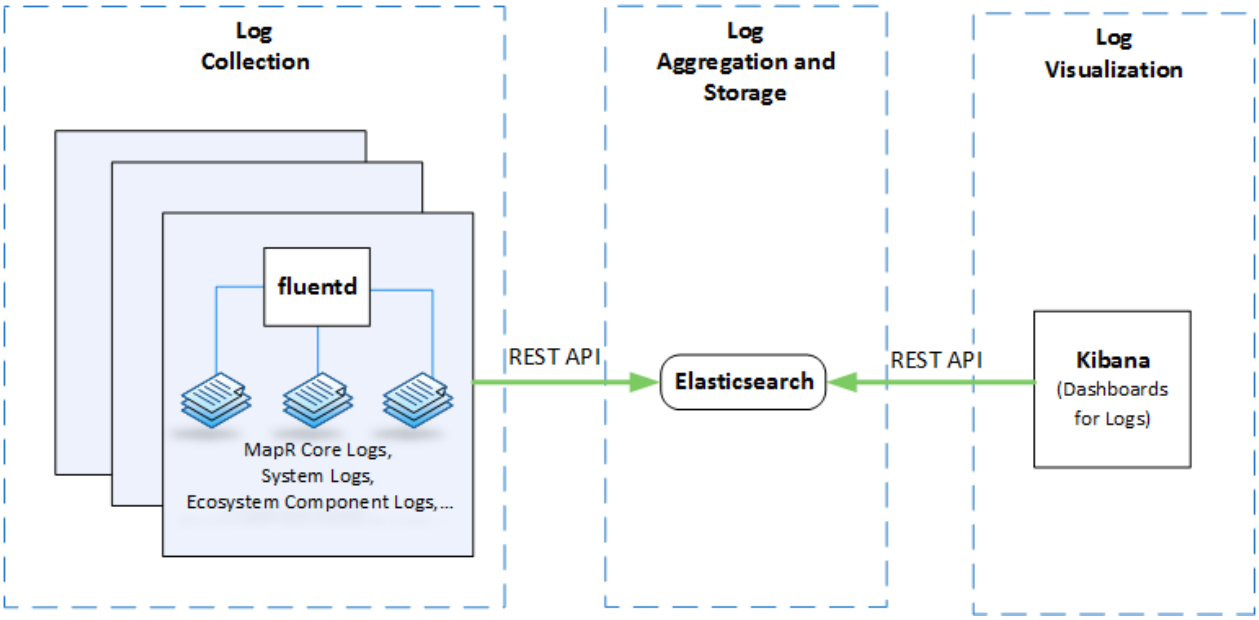
last-updated: Jun 06, 2024



collectd	The collectd service runs on each node in the cluster to collect metrics. It uses streams to send the metrics to opentsdb. For more information, see Metric Collection on page 1699.
OpenTSDB	OpenTSDB aggregates the metrics and runs as the time-series database on top of HPE Ezmeral Data Fabric Database, the metrics data store. Based on your cluster requirements, it runs on one or more nodes in the cluster.
Grafana	Grafana uses REST API to access metrics data from OpenTSDB. Using a single instance of Grafana, users can build custom dashboards or use sample dashboards to visualize the metric. For more information about dashboards, see Metric Visualization on page 1751.

Log Monitoring Architecture

To visualize logs, MapR Monitoring integrates with the following components:



last-updated: Jun 06, 2024

fluentd	fluentd runs on each node in the cluster to collect and parse logs. It uses REST API to send the logs to ElasticSearch. For more information, see Log Collection on page 1756.
Elasticsearch	Elasticsearch indexes the logs so that they are easily accessed and searchable. Based on your cluster requirements, it runs on one or more nodes in the cluster. For more information, see Log Aggregation and Storage on page 1761.
Kibana	Kibana uses REST API to access and search the logs available in Elasticsearch. Using a single instance of Kibana, users can create visualizations and dashboards to analyze their logs. For more information, see Log Visualization on page 1766.

Spyglass on Streams

Release 6.0 of the HPE Ezmeral Data Fabric introduced Spyglass on Streams. When you install release 6.0 or later, Streams is the default mechanism through which metrics flow from the Collectd service to OpenTSDB. Moving metrics through streams secures the data and provides a mechanism to perform real-time data analytics.

NOTE: Currently, Spyglass on Streams is not available for logs. Fluentd continues to use the REST API to send logs to ElasticSearch for the indexing of logs.

The Flow of Metrics via Streams

The Collectd service collects node-level and service-level metrics from each node in the cluster. The Collectd service hashes metrics to a stream and writes the metrics into topics in that stream.

In release 6.1.0 and later, Collectd creates one stream per cluster: `/var/mapr/mapr.monitoring/metricstreams/0`. Topic names use the format `<hostname>`. For example: `mfs81.qa.lab`.

The Streams server distributes metrics to the available OpenTSDB nodes, and OpenTSDB consumes the metrics.

NOTE: Writing to an external OpenTSDB is not supported from release 6.0 onwards. In addition, inserting non-data-fabric data into the provided OpenTSDB is not supported. Any custom data added to the provided OpenTSDB will be removed by the purge script (`tsdb_cluster_mgmt.sh`) that runs periodically.

NOTE: Dedicated metrics volumes should be appropriately paired with a topology that has OpenTSDB nodes. Change topology accordingly if OpenTSDB begins using more than 10% of the file-system write capacity.

Determining How Many OpenTSDB Nodes to Install

Having multiple OpenTSDB nodes in the cluster distributes the workload. The number of partitions and OpenTSDB nodes determines the level of parallelism for consumption.

Each OpenTSDB node can consume one partition at a time. By default, metrics data is divided across 12 partitions in each topic and optimal parallelism is reached if there are five OpenTSDB nodes to consume the partitions. See Parallelism When Consuming Messages. Note that the term “consumer” in the topic equates to an OpenTSDB node in Spyglass on Streams.

A general guideline for the minimum number of OpenTSDB nodes in a cluster is one for every 10x increase in nodes beyond 10, for example:

- Three OpenTSDB nodes in a 10-node cluster
- Four OpenTSDB nodes in a 100-node cluster

last-updated: Jun 06, 2024

- Five OpenTSDB nodes in a 1000-node cluster

If your cluster has 10 or more nodes, at least three OpenTSDB nodes should be available to consume metrics. Typically, for every 10x increase in nodes, you should add another OpenTSDB node. For example, if your cluster reaches a size of 100 nodes, have four OpenTSDB nodes available for consumption.

These guidelines do not guarantee optimal performance. Evaluate the performance of the streams to determine if your cluster would benefit from additional OpenTSDB nodes.

NOTE: If all configured OpenTSDB nodes have been offline for several hours, you may notice an initial spike in memory and CPU usage by OpenTSDB processes as they aggressively try to keep up with the metrics. You can reduce the number of AsynchHBase threads to reduce the CPU and memory usage. By default, AsynchHBase runs 128 threads. To modify the number of threads, add or modify the following property in the `/opt/mapr/asynchbase/asynchbase-<version>/conf/asynchbase.conf` file on the OpenTSDB nodes:

```
"fs.mapr.async.worker.threads=<value>"
```

Increasing the Number of Streams

For release 6.1 and later, the default setting for the number of streams is one. Even if your cluster grows to 1000 nodes or more, you do not need to increase the number of streams. For release 6.0.x, increasing the number of streams is recommended as you add more nodes (see the release 6.0 documentation), but this practice is not required in release 6.1 and later.

Changing the Automatic Stream Cursor Commits

You can adjust the frequency of automatic stream cursor commits for OpenTSDB. Modify the `tsd.streams.autocommit.interval` in `opentsdb.conf` The unit is thousands of seconds. The default value is '60000' which is 60 secs. For a system with heavy loads, consider changing the value to something like 5 minutes.

Metric Collection

Metrics are collected from each node in the cluster so that administrators can use the data to monitor the cluster. In general, the `collectd` service collects metrics every 10 seconds. The exception is volume metrics which are collected every 10 minutes.

When `collectd` writes metrics to streams, tags are assigned to each metric so that administrators can filter metric data to create dashboards that are specific to their needs.

By default, each metric contains the following tags:

- `fqdn`: Displays values for a specified node.
- `clusterid`: Displays values for a specific cluster.
- `clustername`: As of EEP 3.0, displays values for a specific cluster.

However, many metrics have additional tags that you can use to filter metric data.

Streams store metrics in OpenTSDB with the following schema:

```
<metrictype.name> <fqdn:fqdnvalue> <clusterid:clusteridvalue>
<clustername:clusternamevalue>[<AdditionalTagA:AdditionalTagAvalue>
<AdditionalTagB:AdditionalTagBvalue>...] <metricvalue> <timestamp>
```

NOTE: A negative value shown in the metrics indicates that the maximum value configured for that metric is exceeded. The maximum value for GUT metrics is int32 (2^31-1).

last-updated: Jun 06, 2024

For more information on using tags and dashboards, see Metric Visualization on page 1751.

Configure Metric Retention
By default, OpenTSDB stores two weeks of metrics. Based on your requirements, you can change metric retention period.

The following cron job runs each day to purge metrics based on the retention period.

```
$min $hour * * * $OTSDB_HOME/bin/tsdb_cluster_mgmt.sh -purgeData >>
$OTSDB_HOME/var/log/opentsdb/purgeData.log 2>&1
```

Complete the following steps to edit the metric retention period:

1. Open the `/opt/mapr/opentsdb/opentsdb-<version>/bin/tsdb_cluster_mgmt.sh` file.
2. In the following line, update the value of `'2 weeks ago'` to the new retention period.

   ```
   $OT_HOME/bin/tsdb scan --delete 2000/01/01 $(date --date='2 weeks ago'
   +'%Y/%m/%d') sum $metric
   ```

   For example, to delete metrics from 1/1/2000 to [current date - 2 days]:

   ```
   $OT_HOME/bin/tsdb scan --delete 2000/01/01 $(date --date='2 days ago'
   +'%Y/%m/%d') sum $metric
   ```

WARNING: MapR monitoring uses 2 MB disk space per minute per node when HPE Ezmeral Data Fabric Streams metrics is enabled. This is approximately 3 GB per day on a single node or 7 GB per node per day with a 3X replication. This stream metrics data is automatically deleted every 30 days.

NOTE: For more information, see the OpenTSDB scan command documentation.

Configure Queue Filters for `mapr.rm.<value>` Metrics
The YARN application metrics that are collected by JMX have the metric name syntax `mapr.rm.<metric_name>` and the metric values are aggregated among all the queues in the default queue. However, you can configure collectd to create a filter for each queue. As an alternative, you can use the REST API queue metrics (`mapr.rm_queue.<metric_name>`) which are by default set up for filtering by queue.

About this task

To configure collectd to create queue filters for `mapr.rm.*` metrics, define each queue that you want to create filters for in the `/opt/mapr/collectd/collectd-<version>/etc/collectd.conf` file. You can configure collectd to generate filters for every queue or only for specific queues. Changes that you make to the collectd.conf file only apply to metrics collected after you restart the collectd service.

Procedure

1. Open the collectd.conf file and locate the MBean "QueueMetrics" block.

```
<MBean "QueueMetrics">
      ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root"
      InstancePrefix "rm"

      <Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "default-queue"
      </Value>

      <Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "default-queue"
      </Value>

      ...
    </MBean>
```

   This block specifies that there is one queue named `root` and that the filter for this queue is named `default-queue`.

2. Create copy of the MBean "QueueMetrics" block.

3. Configure the ObjectName option in the MBean "QueueMetrics" block copy, with the queue path for the queue that you want to create a filter for.

   - To define the a child queue named `alpha` under the `root` queue:

```
ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha"
```

   - To define a child queue named beta which is under a child queue named alpha:

```
ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha,q2=b
eta"
```

4. For each Value block within the MBean "QueueMetrics" block you are defining, replace `default-queue` with the queue name that you want to create a filter for.

last-updated: Jun 06, 2024

- To define filter value `alpha` for the rm_queue tag, set the InstancePrefix to `alpha:`

```
 <MBean "QueueMetrics">
      ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha"
      InstancePrefix "rm"
<Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "alpha"
      </Value>
<Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "alpha"
      </Value>
...
    </MBean>
```

- To define a filter value `beta` for the rm_queue tag, set the InstancePrefix to `beta:`:

```
 <MBean "QueueMetrics">
      ObjectName
"Hadoop:service=ResourceManager,name=QueueMetrics,q0=root,q1=alpha,q2=b
eta"
      InstancePrefix "rm"
<Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "beta"
      </Value>
<Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "beta"
      </Value>
...
    </MBean>
```

5. Repeat steps 2 and 3 for each queue that you want to create a filter value for.
6. Save the collectd.conf file.
7. Repeat steps 1 through 6 on each ResourceManager node.
8. Restart the collectd service.

```
maprcli node services -name collectd -nodes <space separated list of
ResourceManager Nodes> -action restart
```

Example

In the following example, rm_queue tag will have the following filter values: `alpha` , `beta` (child of alpha), and `highpriority` (child of root):

```
<MBean "QueueMetrics">
      ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=alpha"
      InstancePrefix "rm"

      <Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "alpha"
      </Value>
```

last-updated: Jun 06, 2024

```
      <Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "alpha"
      </Value>
      ...
      <Value "ReservedVCores">
        Type "reserved_vcores"
        InstancePrefix "alpha"
      </Value>
    </MBean>

<MBean "QueueMetrics">
      ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=alpha q2=beta"
      InstancePrefix "rm"

      <Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "beta"
      </Value>

      <Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "beta"
      </Value>
      ...
      <Value "ReservedVCores">
        Type "reserved_vcores"
        InstancePrefix "beta"
      </Value>
    </MBean>

<MBean "QueueMetrics">
      ObjectName "Hadoop:service=ResourceManager,name=QueueMetrics,q0=root
q1=highpriority"
      InstancePrefix "rm"

      <Value "AppsRunning">
        Type "apps_running"
        InstancePrefix "highpriority"
      </Value>

      <Value "ActiveApplications">
        Type "active_applications"
        InstancePrefix "highpriority"
      </Value>
      ...
      <Value "ReservedVCores">
        Type "reserved_vcores"
        InstancePrefix "highpriority"
      </Value>
    </MBean>
```

Configure the Collectd Service Heap Size

The `collectd` service uses an embedded JVM when it gathers metrics from the CLDB, Node Manager, Resource Manager, and Drill. You can edit the Plugin Java section of *collectd.conf* to configure limits to the collectd virtual memory footprint.

last-updated: Jun 06, 2024

About this task

NOTE: The Plugin Java section of the collectd.conf file may be commented or uncommented. The configure.sh utility will uncomment the Plugin Java section when `collectd` runs on a node that requires an embedded JVM. Therefore, when you update the file, do not add or remove comment symbols (#) in the Plugin java section

Complete the following steps on each `collectd` node:

Procedure

1. Open the `/opt/mapr/collectd/collectd-<version>/etc/collectd.conf` file.
2. Look for the following section:

```
## **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
 <Plugin java>
JVMArg "-Djava.class.path=......
```

3. Update `Xms` and `Xmx` options in the Plugin java section.

   `Xms` defines the amount of memory allocated to the service when it starts. `Xmx` defines the maximum amount of memory allocated to the service.

   If the <Plugin java> section is not commented out, the configuration may look like this:

```
## **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
<Plugin java>
JVMArg "-Djava.class.path=......
JVMArg "-Xms32m"
JVMArg "-Xmx128m"
```

   If the <Plugin java> section is commented out, the configuration may look like this:

```
### **** MAPR_CONF_JMX_TAG: MAPR CONFIGURATION - DO NOT EDIT or REMOVE
TAG/BLOCK ***
#<Plugin java>
# JVMArg "-Djava.class.path=......
# JVMArg "-Xms32m"
# JVMArg "-Xmx128m"
```

4. Restart the `collectd` service.

```
maprcli node services -name collectd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

CPU Metrics

Every 10 seconds, the collectd service uses the cpu plugin to gather the following CPU metrics on each node in the cluster.

last-updated: Jun 06, 2024

Name	Description	Additional Tag(s)
`cpu.percent`	The aggregate percentage of all CPUs.	• `cpu_core`: Display values specified core. Core values: 0,1, and 2 • `cpu_class`: Display values for a specified class of CPU. CPU class values: idle, user, nice, system.
`thread.cpu_usage`	The percentage of CPU used by each thread.	• `thread_name`: Indicates if thread belongs to RPC, HPE Ezmeral Data Fabric Database, file system, or an instance of file system.

Disk Free Metrics
Every 10 seconds, the collectd service uses the df plugin to gather the following disk free metrics on each node in the cluster.

Name	Description	Additional Tag(s)
df.df_complex	The aggregate number of bytes for disk partitions.	• `df_partition`: Display values for a specified disk. Disk values: dev or boot. • `df_type`: Display values for a certain type. Type values: free, reserved, and used.
df.percent_bytes	The aggregated percentage of disk partitions.	• `df_partition`: Display values for a specified disk. Disk values: dev or boot. • `df_type`: Display value for a certain type. Type values: free, reserved, and used.

Disk Metrics
Every 10 seconds, the collectd service uses the disk plugin to gather the following disk metrics on each node in the cluster.

Name	Description	Additional Tag(s)
disk.disk_await	The average time in milliseconds to complete I/O requests. This includes the time request are waiting in queue and the time spent processing the request. This metric is available as of EEP 3.0.	• `disk_name:` Display values for a specified disk.
disk.disk_avg_requests_size	The average size in kilobytes for I/O requests issued to the disk. This metric is available as of EEP 3.0.	• `disk_name:` Display values for a specified disk.
disk.disk_avg_queue_size	The average number of requests issued to the disk. This metric is available as of EEP 3.0.	• `disk_name:` Display values for a specified disk.
disk.disk_io_time.io_time	The disk I/O time in milliseconds (ms).	• `disk_name:` Display values for a specified disk.

last-updated: Jun 06, 2024

Name	Description	Additional Tag(s)
disk.disk_io_time.weighted_io_time	The aggregate time in milliseconds (ms) spent on I/O operations that are either in progress or have completed	• `disk_name`: Display values for a specified disk.
disk.disk_merged.read	The number of physical read operations.	• `disk_name`: Display values for a specified disk.
disk.disk_merged.write	The number of physical write operations.	• `disk_name`: Display values for a specified disk.
disk.disk_octets.read	The number of bytes read from disk.	• `disk_name`: Display values for a specified disk.
disk.disk_octets.write	The number of bytes written to disk.	• `disk_name`: Display values for a specified disk.
disk.disk_ops.read	The number of completed read operations.	• `disk_name`: Display values for a specified disk.
disk.disk_ops.write	The number of completed write operations.	• `disk_name:` Display values for a specified disk.
disk.disk_time.read	The average time in milliseconds(ms) to read from disk.	• `disk_name:` Display values for a specified disk.
disk.disk_time.write	The average time in milliseconds(ms) to write to disk.	• `disk_name:` Display values for a specific disk.
disk.disk_utilization	The disk utilization percentage. This metric is available as of EEP 3.0.	• `disk_name:` Display values for a specific disk.
disk.pending_operations	The number of pending disk operations.	• `disk_name:` Display values for a specific disk.

Drill Metrics

Every 10 seconds, the collectd service uses the plugin to gather the following Drill metrics on each node in the cluster.

Name	Description
mapr.drill.allocator_root_used	The amount of memory used in bytes by the internal memory allocator.
mapr.drill.allocator_root_peak	The peak amount of memory used in bytes by the internal memory allocator.
mapr.drill.blocked_count	The number of threads that are blocked because they are waiting for a monitor lock.
mapr.drill.count	The number of live threads (including both daemon and non-daemon threads).
mapr.drill.fd_usage	The ratio of used to total file descriptors.
mapr.drill.fragments_running	The number of query fragments currently running in the drillbit.
mapr.drill.heap_used	The amount of heap memory used in bytes by the JVM.

last-updated: Jun 06, 2024

Name	Description
mapr.drill.non_heap_used	The amount of non-heap memory used in bytes by the JVM.
mapr.drill.queries_completed	The number of completed, canceled or failed queries for which this drillbit is the foreman.
mapr.drill.queries_running	The number of running queries for which this drillbit is the foreman.
mapr.drill.runnable_count	The number of threads executing in the JVM.
mapr.drill.waiting_count	The number of threads that are waiting to be executed. This can occur when a thread must wait for another thread to perform an action before proceeding.

Hive JMX Metrics

Every 10 seconds, the `collectd` service uses the Hive plug-in to gather the following Hive JMX metrics on each node in the cluster. Descriptions for the Hive metrics are not currently available.

Metric Collection

Metrics collected in Hive relate specifically to the HiveServer2 and Hive metastore processes. Each process runs in a separate JVM, and the JVMs provide values for the metrics.

Starting in EEP 6.3.2 and EEP 7.0.1, the `hive.exec.submit.local.task.via.child` option (in hive-site.xml) is set to `true`, by default, and enables HiveServer2 to spawn local tasks (typically mapjoin hashtable generation phase) in child JVMs. The system does not collect metrics for the child JVMs. The system only collects metrics for the HiveServer2 and Hive metastore processes.

Hive Metastore Metrics

The following are the JMX metrics provided for the Hive metastore:

- mapr.hivemetastore.hivemetastore_buffers_direct_capacity
- mapr.hivemetastore.hivemetastore_buffers_direct_count
- mapr.hivemetastore.hivemetastore_buffers_direct_used
- mapr.hivemetastore.hivemetastore_buffers_mapped_capacity
- mapr.hivemetastore.hivemetastore_buffers_mapped_count
- mapr.hivemetastore.hivemetastore_buffers_mapped_used
- mapr.hivemetastore.hivemetastore_class_loading_loaded
- mapr.hivemetastore.hivemetastore_class_loading_unloaded
- mapr.hivemetastore.hivemetastore_gc_ps_mark_sweep_count
- mapr.hivemetastore.hivemetastore_gc_ps_mark_sweep_time
- mapr.hivemetastore.hivemetastore_gc_ps_scavenge_count
- mapr.hivemetastore.hivemetastore_gc_ps_scavenge_time
- mapr.hivemetastore.hivemetastore_init_total_count_dbs
- mapr.hivemetastore.hivemetastore_init_total_count_partitions

last-updated: Jun 06, 2024

HiveServer2 Metrics

The following are the JMX metrics provided for HiveServer2 (hs2):

- mapr.hiveserver2.hiveserver2_buffers_direct_capacity
- mapr.hiveserver2.hiveserver2_buffers_direct_count
- mapr.hiveserver2.hiveserver2_buffers_direct_used
- mapr.hiveserver2.hiveserver2_buffers_mapped_capacity
- mapr.hiveserver2.hiveserver2_buffers_mapped_count
- mapr.hiveserver2.hiveserver2_buffers_mapped_used
- mapr.hiveserver2.hiveserver2_class_loading_loaded
- mapr.hiveserver2.hiveserver2_class_loading_unloaded
- mapr.hiveserver2.hiveserver2_exec_async_pool_size
- mapr.hiveserver2.hiveserver2_exec_async_queue_size
- mapr.hiveserver2.hiveserver2_gc_ps_mark_sweep_count
- mapr.hiveserver2.hiveserver2_gc_ps_mark_sweep_time
- mapr.hiveserver2.hiveserver2_gc_ps_scavenge_count
- mapr.hiveserver2.hiveserver2_gc_ps_scavenge_time
- mapr.hiveserver2.hiveserver2_active_sessions
- mapr.hiveserver2.hiveserver2_open_sessions
- mapr.hiveserver2.hiveserver2_init_total_count_dbs
- mapr.hiveserver2.hiveserver2_init_total_count_partitions
- mapr.hiveserver2.hiveserver2_init_total_count_tables
- mapr.hiveserver2.hiveserver2_memory_heap_committed
- mapr.hiveserver2.hiveserver2_memory_heap_init
- mapr.hiveserver2.hiveserver2_memory_heap_max
- mapr.hiveserver2.hiveserver2_memory_heap_usage

- mapr.hiveserver2.hiveserver2_memory_heap_used
- mapr.hiveserver2.hiveserver2_memory_non_heap_committed
- mapr.hiveserver2.hiveserver2_memory_non_heap_init
- mapr.hiveserver2.hiveserver2_memory_non_heap_max
- mapr.hiveserver2.hiveserver2_memory_non_heap_usage
- mapr.hiveserver2.hiveserver2_memory_non_heap_used
- mapr.hiveserver2.hiveserver2_memory_pools_code_cache_usage
- mapr.hiveserver2.hiveserver2_memory_pools_compressed_class_space_usage
- mapr.hiveserver2.hiveserver2_memory_pools_metaspace_usage
- mapr.hiveserver2.hiveserver2_memory_pools_ps_eden_space_usage
- mapr.hiveserver2.hiveserver2_memory_pools_ps_old_gen_usage
- mapr.hiveserver2.hiveserver2_memory_pools_ps_survivor_space_usage
- mapr.hiveserver2.hiveserver2_memory_total_committed
- mapr.hiveserver2.hiveserver2_memory_total_init
- mapr.hiveserver2.hiveserver2_memory_total_max
- mapr.hiveserver2.hiveserver2_memory_total_used
- mapr.hiveserver2.hiveserver2_threads_blocked_count
- mapr.hiveserver2.hiveserver2_threads_count

Kafka JMX Metrics
Starting in EEP 9.0.0, you can enable metrics collection for Kafka consumers and producers. When enabled, JMX collects Kafka producer and consumer metrics from client applications. You can view the metrics through the JConsole UI or JMXTerm CLI.

Metrics Collected

When you enable Kafka JMX metrics, you can view the following producer and consumer metrics through the JConsole UI or JMXTerm CLI :

Producer Metrics Collected	*Global* metrics collected: • record-send-rate • record-send-total • record-error-rate • record-error-total • record-size-max • record-size-avg **NOTE:** Record size is computed as the sum of topic length, key size, value size, and sizes of keys and values of all headers if any exist. *Per-topic* metrics collected: • record-send-rate • record-send-total • byte-rate • byte-total • record-error-rate • record-error-total
Consumer Metrics Collected	• fetch-size-avg • fetch-size-max • bytes-consumed-rate • bytes-consumed-total • records-consumed-rate • records-consumed-total

NOTE: This list of supported metrics is a subset of all the Kafka JMX metrics. The unsupported metrics are either not registered or have default values such as 0 or NaN. A full list of Kafka JMX metrics is available here.

last-updated: Jun 06, 2024

Enabling Metrics Collection

To enable metrics collection, set `metrics.enabled=true` in the producer and consumer configuration.

The following sections provide steps to enable metrics collection and view metrics in the JConsole UI and JMXTerm CLI.

Using the JConsole UI to View Metrics

Complete the following steps to enable metrics collection and view metrics in the JConsole UI:

1. Start the console producer with metrics collection enabled:

   ```
   bin/kafka-console-producer.sh --broker-list
   localhost:9092 --topic /s:t --producer-property metrics.enabled=true
   ```

2. Enter and send data.

3. In another terminal, run the following command to start JConsole:

   ```
   jconsole
   ```

4. In JConsole, select the console producer process and connect to it.

5. Select **Insecure Connection**.

6. In the MBeans section, look at kafka.producer or kafka.producer domain, and select the MBean of interest to view its attributes.

7. Click **Refresh** to update attribute values.

Using the JMXTerm CLI to View Metrics

JMXTerm is the CLI analog of JConsole. To download JMXTerm, go to https://docs.cyclopsgroup.org/jmxterm.

Complete the following steps to enable metrics collection and view metrics through the JMXTerm CLI:

1. Start the console producer with metrics collection enabled:

   ```
   bin/kafka-console-producer.sh --broker-list
   localhost:9092 --topic /s:t --producer-property metrics.enabled=true
   ```

2. Run the following command to start JMXTerm in interactive mode:

   ```
   java -jar jmxterm-1.0.2-uber.jar
   ```

3. Run the `jvms` command to identify which process is running the Kafka console producer:

```
jvms

WARNING: An illegal reflective access operation has occurred
WARNING: Illegal reflective access
by org.cyclopsgroup.jmxterm.utils.WeakCastUtils$2 (file:/
home/mapr/jmxterm-1.0.2-uber.jar) to method
sun.tools.jconsole.LocalVirtualMachine.getAllVirtualMachines()
WARNING: Please consider reporting this to the maintainers of
org.cyclopsgroup.jmxterm.utils.WeakCastUtils$2
WARNING: Use --illegal-access=warn to enable warnings of further illegal
reflective access operations
WARNING: All illegal access operations will be denied in a future release
4113     ( ) - com.mapr.admin.AdminApplication
18946    (m) - org.apache.hadoop.yarn.server.nodemanager.NodeManager
3045     (m) -
org.apache.hadoop.yarn.server.resourcemanager.ResourceManager
23286    ( ) - org.apache.zookeeper.server.quorum.QuorumPeerMain /opt/
mapr/zookeeper/zookeeper-3.5.6/conf/zoo.cfg
29545    (m) - com.mapr.fs.cldb.CLDB /opt/mapr/conf/cldb.conf
4090     ( ) - jmxterm-1.0.2-uber.jar
26491    ( ) - com.mapr.warden.WardenMain /opt/mapr/conf/warden.conf
13003    (m) - org.apache.hadoop.mapreduce.v2.hs.JobHistoryServer
2286     (m) - kafka.tools.ConsoleProducer --broker-list
localhost:9092 --topic /s:t --producer-property metrics.enabled=true
```

NOTE: In this example, the process is 2286. On your system, the process number may differ. Use the process number provided by your system.

4. Run the `open` command with the process number to open the connection:

```
open 2286
```

5. Run the following command to set the domain to kafka.producer:

```
domain kafka.producer
```

6. Run the `beans` command to see the beans available in the kafka.producer domain:

```
beans

#domain = kafka.producer:
kafka.producer:client-id=console-producer,topic="/
s:t",type=producer-topic-metrics
kafka.producer:client-id=console-producer,type=kafka-metrics-count
kafka.producer:client-id=console-producer,type=producer-metricseans
```

7. Set the bean to kafka.producer:client-id=console-producer,type=producer-metrics:

```
bean kafka.producer:client-id=console-producer,type=producer-metrics
```

last-updated: Jun 06, 2024

8. Run the following command to get all the metrics for the kafka.producer:client-id=console-producer,type=producer-metrics bean:

```
get *

#mbean = kafka.producer:client-id=console-producer,type=producer-metrics:
record-send-rate = 0.0;
record-retry-total = 0.0;
record-size-avg = NaN;
batch-split-total = 0.0;
record-queue-time-avg = NaN;
request-latency-avg = NaN;
record-error-total = 0.0;
batch-split-rate = 0.0;
record-error-rate = 0.0;
record-send-total = 3.0;
batch-size-max = NaN;
compression-rate-avg = NaN;
record-queue-time-max = NaN;
record-retry-rate = 0.0;
request-latency-max = NaN;
record-size-max = NaN;
batch-size-avg = NaN;
records-per-request-avg = NaN;
```

Load Metrics

Every 10 seconds, the collectd service uses the load plugin to gather the following load metrics on each node in the cluster.

Name	Description
load.load.longterm	The number of tasks running on the node every 15 minutes.
load.load.midterm	The number of tasks running on the node every 10 minutes.
load.load.shortterm	The number of tasks running on the node every minute.

Alarm Metrics

Every 10 seconds, the collectd service uses a plugin to gather the cluster alarms.

Name	Description	Additional Tag(s)
mapr.alarms.alarm_raised	The number of alarms raised. The timestamp for each alarm is based on the time that MapR raised the alarm, not the time when the collectd service gathered the alarm data.	• `alarm_name:` Display values for a specified alarm name. • `alarm_entity:.` Display values for a specified volume, node, user, or group.

Cache Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following Data Fabric file system cache metrics on each node in the cluster.

Name	Description
mapr.cache.lookups_data	The number of cache lookups in the block cache.
mapr.cache.lookups_dir	The number of cache lookups in the table LRU cache. The table LRU is used for storing internal B-Tree leaf pages.

last-updated: Jun 06, 2024

Name	Description
mapr.cache.lookups_inode	The number of cache lookups in the inode cache.
mapr.cache.lookups_largefile	The number of cache lookups in the large file LRU cache. The large file LRU is used for storing files with size greater than 64K and also HPE Ezmeral Data Fabric Database data pages.
mapr.cache.lookups_meta	The number of cache lookups on the meta LRU cache. The meta LRU is used for storing internal B-Tree pages.
mapr.cache.lookups_smallfile	The number of cache lookups on the small file LRU cache. This LRU is used for storing files with size less than 64K and also HPE Ezmeral Data Fabric Database index pages.
mapr.cache.lookups_table	The number of cache lookups in the table LRU cache. The table LRU is used for storing internal B-Tree leaf pages.
mapr.cache.misses_data	The number of cache misses in the block cache.
mapr.cache.misses_dir	The number of cache misses on the table LRU cache.
mapr.cache.misses_inode	The number of cache misses in the inode cache.
mapr.cache.misses_largefile	The number of cache misses on the large file LRU cache.
mapr.cache.misses_meta	The number of cache misses on the meta LRU cache.
mapr.cache.misses_smallfile	The number of cache misses on the small file LRU cache.
mapr.cache.misses_table	The number of cache misses on the table LRU cache.

CLDB Metrics

Every 10 seconds, the collectd service uses a HPE Ezmeral Data Fabric plugin to gather the following CLDB metrics on the primary CLDB node in the cluster.

Name	Description
mapr.cldb.cluster_cpu_total	The number of physical CPUs in the cluster.
mapr.cldb.cluster_cpubusy_percent	The aggregate percentage of busy CPUs in the cluster.
mapr.cldb.cluster_disk_capacity	The storage capacity for HPE Ezmeral Data Fabric disks in GB.
mapr.cldb.cluster_diskspace_used	The amount of HPE Ezmeral Data Fabric disks used in GB.
mapr.cldb.cluster_memory_capacity	The memory capacity in MB.
mapr.cldb.cluster_memory_used	The amount of used memory in MB.
mapr.cldb.containers	The number of containers currently in the cluster.
mapr.cldb.containers_created	The cumulative number of containers created in the cluster. This value includes containers that have been deleted.
mapr.cldb.containers_unusable	The number of containers that are no longer usable. The CLDB marks a container as unusable when the node that stores the container is offline for 1 hour or more.
mapr.cldb.disk_space_available	The amount of disk space available in GB.
mapr.cldb.nodes_in_cluster	The number of nodes in the cluster.
mapr.cldb.nodes_offline	The number of nodes in the cluster that are offline.

last-updated: Jun 06, 2024

Name	Description
mapr.cldb.rpc_received	The number of RPCs received.
mapr.cldb.rpcs_failed	The number of RPCs failed.
mapr.cldb.storage_pools_cluster	The number of storage pools.
mapr.cldb.storage_pools_offline	The number of offline storage pools.
mapr.cldb.volumes	The number of volumes created, including system volumes.

HPE Ezmeral Data Fabric Database Metrics

Every 10 seconds, the collectd service uses a plugin to gather HPE Ezmeral Data Fabric Database metrics on each node in the cluster. HPE Ezmeral Data Fabric Database provides both node and table metrics.

Node metrics capture data for operations across a MapR node. You can use them to assess the performance of individual nodes in your MapR cluster.

Starting in MapR 6.1, HPE Ezmeral Data Fabric Database supports table metrics. Table metrics provide more granular metrics. They allow you detect and diagnose bottlenecks and performance issues that are specific to individual tables. For example, suppose a node metric shows a spike in a particular RPC. Knowing this, you can use the corresponding table metric to determine if the spike originates from a single table.

Examples of other use cases that benefit from table metrics are the following:

- You want to measure the latency of different RPC operations on a table
- You want to determine which operations on a table are slow
- You want to determine which tables are most frequently accessed

HPE Ezmeral Data Fabric Database Node Metrics

This section describes the available HPE Ezmeral Data Fabric Database node metrics.

The following table lists HPE Ezmeral Data Fabric Database node metrics:

last-updated: Jun 06, 2024

Metric Category	Name	Description
Throughput - RPC counts	mapr.db.append_rpcs	The number of HPE Ezmeral Data Fabric Database append RPCs completed
	mapr.db.checkandput_rpcs [1]	The number of HPE Ezmeral Data Fabric Database check and put RPCs completed
	mapr.db.get_currpcs	The number of HPE Ezmeral Data Fabric Database get RPCs in progress
	mapr.db.get_rpcrows	The number of get rows completed. Each get RPC can include multiple get rows.
	mapr.db.get_rpcs	The number of HPE Ezmeral Data Fabric Database get RPCs completed
	mapr.db.increment_rpcs [1]	The number of HPE Ezmeral Data Fabric Database increment RPCs completed
	mapr.db.put_currpcs	The number of HPE Ezmeral Data Fabric Database put RPCs in progress
	mapr.db.put_rpcs	The number of HPE Ezmeral Data Fabric Database put RPCs completed
	mapr.db.scan_currpcs	The number of HPE Ezmeral Data Fabric Database scan RPCs in progress
	mapr.db.scan_rpcrows	The number of scan rows completed. Each scan RPC can include multiple scan rows.
	mapr.db.scan_rpcs	The number of HPE Ezmeral Data Fabric Database scan RPCs completed
	mapr.db.updateandget_rpcs	The number of HPE Ezmeral Data Fabric Database update and get RPCs completed
Throughput - Row count written	mapr.db.append_rpcrows [1]	The number of rows written by append RPCs
	mapr.db.checkandput_rpcrows [1]	The number of rows written by check and put RPCs
	mapr.db.increment_rpcrows [1]	The number of rows written by increment RPCs
	mapr.db.put_rpcrows	The number of rows written by put RPCs. Each HPE Ezmeral Data Fabric Database put RPC can include multiple put rows.
	mapr.db.updateandget_rpcrows [1]	The number of rows written by update and get RPCs
Throughput - Rows returned	mapr.db.get_resprows [1]	The number of rows returned from get RPCs
	mapr.db.scan_resprows [1]	The number of rows returned from scan RPCs
Throughput - Row count read	mapr.db.get_readrows [1]	The number of rows read by get RPCs
	mapr.db.put_readrows [1]	The number of rows read by put RPCs
	mapr.db.scan_readrows [1]	The number of rows read by scan RPCs

last-updated: Jun 06, 2024

Metric Category	Name	Description
Throughput - Bytes written	`mapr.db.append_bytes` [1]	The number of bytes written by append RPCs
	`mapr.db.checkandput_bytes` [1]	The number of bytes written by check and put RPCs
	`mapr.db.put_bytes`	The number of bytes written by put RPCs
	`mapr.db.increment_bytes` [1]	The number of bytes written by increment RPCs
	`mapr.db.updateandget_bytes` [1]	The number of bytes written by update and get RPCs
Throughput - Bytes read	`mapr.db.get_bytes` [1]	The number of bytes read by get RPCs
	`mapr.db.scan_bytes` [1]	The number of bytes read by scan RPCs
Value cache usage	`mapr.db.valuecache_hits`	The number of HPE Ezmeral Data Fabric Database operations that utilized the HPE Ezmeral Data Fabric Database value cache
	`mapr.db.valuecache_lookups`	The number of HPE Ezmeral Data Fabric Database operations that performed a lookup on the HPE Ezmeral Data Fabric Database value cache
	`mapr.db.valuecache_usedSize`	The HPE Ezmeral Data Fabric Database value cache size in MB
Compactions	`mapr.db.fullcompacts` [1]	The number of compactions that combine multiple HPE Ezmeral Data Fabric Database data files containing sorted data (known as spills) into a single spill file. HPE Ezmeral Data Fabric Database creates a spill file each time it flushes files containing unsorted data (known as buckets). Full compactions improve read performance because after compaction, HPE Ezmeral Data Fabric Database needs to read only the single resulting sorted spill file. But they incur I/O costs because the compaction must read, sort, and rewrite all data in the spill files.
	`mapr.db.minicompacts` [1]	The number of compactions that combine multiple small data files containing sorted data (known as spills) into a single spill file. HPE Ezmeral Data Fabric Database creates a spill file each time it flushes files containing unsorted data (known as buckets). After a mini compaction, HPE Ezmeral Data Fabric Database needs to read only two spill files.
	`mapr.db.ttlcompacts` [1]	The number of compactions that result in reclamation of disk space due to removal of stale data. You can configure the TTL for a table if it has only a default column family. See table cf edit on page 2444 for details.

last-updated: Jun 06, 2024

Metric Category	Name	Description
Table flushes	`mapr.db.flushes` [1]	The number of flushes that reorganize data from bucket files (unsorted data) to spill files (sorted data) when the bucket size exceeds a threshold
	`mapr.db.forceflushes` [1]	The number of flushes that reorganize data from bucket files (unsorted data) to spill files (sorted data) when the in-memory bucket file cache fills up
CDC - Data sent	`mapr.db.cdc.sent_bytes` [1]	The number of bytes of CDC data sent
	`mapr.db.cdc.sent_rows` [1]	The number of rows of CDC data sent
Secondary indexes - Data sent	`mapr.db.index.sent_bytes` [1]	The number of bytes sent for secondary index updates
	`mapr.db.index.sent_rows` [1]	The number of rows sent for secondary index updates
Replication - Data sent	`mapr.db.repl.sent_bytes` [1]	The number of bytes sent to replicate data
	`mapr.db.repl.sent_rows` [1]	The number of rows sent to replicate data
CDC - Data pending	`mapr.db.cdc.pending_bytes` [1]	The number of bytes of CDC data remaining to be sent
	`mapr.db.cdc.pending_rows` [1]	The number of rows of CDC data remaining to be sent
Secondary indexes - Data pending	`mapr.db.index.pending_bytes` [1]	The number of bytes of secondary index data remaining to be sent
	`mapr.db.index.pending_rows` [1]	The number of rows of secondary index data remaining to be sent
Replication - Data pending	`mapr.db.repl.pending_bytes` [1]	The number of bytes of replication data remaining to be sent
	`mapr.db.repl.pending_rows` [1]	The number of rows of replication data remaining to be sent

[1] Available starting in MapR 6.1

HPE Ezmeral Data Fabric Database Table Metrics

Starting in MapR 6.1, HPE Ezmeral Data Fabric Database supports table metrics. This section describes the available HPE Ezmeral Data Fabric Database table metrics. It also describes how to configure metrics per table, disable them in your cluster, and how to filter them by operation and table.

Table metrics are collected per node. By default, these metrics are written to OpenTSDB every minute. Pre-existing tables in your HPE Ezmeral Data Fabric cluster inherit this default setting. You can change this default per table using either the table create on page 2412 or table edit on page 2468 command. Secondary indexes inherit their metric configuration from their parent table.

You cannot disable metrics on individual tables. During installation, you can disable table metrics across your entire cluster. If you are using the installer, select the minimum metrics collection configuration option.

The following table lists HPE Ezmeral Data Fabric Database table metrics:

mapr.db.table.latency	The latency of RPC operations on tables, represented as a histogram. Endpoints identify histogram bucket boundaries. **NOTE:** Put latency metrics for indexes reflect only the index update time. They do not include lag time due to asynchronous index updates.

last-updated: Jun 06, 2024

mapr.db.table.read_bytes	The number of bytes read from tables.
mapr.db.table.read_rows	The number of rows read from tables.
mapr.db.table.resp_rows	The number of rows returned from tables.
mapr.db.table.rpcs	The number of RPC calls completed on tables.
mapr.db.table.value_cache_hits	The number of HPE Ezmeral Data Fabric Database operations on tables that utilized the HPE Ezmeral Data Fabric Database value cache.
mapr.db.table.value_cache_lookups	The number of HPE Ezmeral Data Fabric Database operations on tables that performed a lookup on the HPE Ezmeral Data Fabric Database value cache.
mapr.db.table.write_rows	The number of rows written to tables.
mapr.db.table.write_bytes	The number of bytes written to tables.

Tags for Table Metrics

Each table metric collects data across all operations on tables and secondary indexes in a HPE Ezmeral Data Fabric node. To view metrics for a particular RPC operation on a specific table, you must filter the metric by RPC type and table path, as described in the following list:

rpc_type

The name of the RPC:

- `append`
- `check_and_put`
- `get`
- `increment`
- `put`
- `scan`
- `update_and_get`

table_path

The path of the HPE Ezmeral Data Fabric Database table.

OpenTSDB supports only the following characters:

- Alphanumeric characters
- Dot (.)
- Underscore (_)
- Dash (-)
- Slash (/)
- Space ( )
- Unicode letters

last-updated: Jun 06, 2024

	If a table path contains characters that are not in this list, HPE Ezmeral Data Fabric cannot collect those table metrics.
index	The name of the secondary index defined on the table specified in `table_path`, if you want to filter on a specific index. When you specify this tag, you cannot specify the `noindex` tag. **NOTE:** You can use regular expressions when specifying the index name to filter for a group of indexes.
noindex	Set to `"//primary"` if you want to filter metrics for only the primary table and exclude metrics for secondary indexes defined on the table. When you specify this tag, you cannot specify the `index` tag.

The following list shows examples of the table-specific tags to use to filter different table metrics:

mapr.db.table.write_rows	*Tag Name*: `table_path` *Tag Value*: `/var/mapr/mapr.monitoring/tsdb-meta` *Description*: The number of rows written to a table in the path `/var/mapr/mapr.monitoring/tsdb-meta`, including writes to its secondary indexes.
mapr.db.table.rpcs	• *Tag Name*: `rpc_type` • *Tag Value*: `get` • *Tag Name*: `table_path` • *Tag Value*: `/var/mapr/mapr.monitoring/tsdb-meta` • *Tag Name*: `noindex` • *Tag Value*: `//primary` *Description*: The number of completed *get* RPCs for a table in the path `/var/mapr/mapr.monitoring/tsdb-meta`, excluding metrics on the table's secondary indexes.
mapr.db.table.read_rows	• *Tag Name*: `table_path` • *Tag Value*: `/var/mapr/mapr.monitoring/tsdb-meta` • *Tag Name*: `index` • *Tag Value*: `tsdbIdx` *Description*: The number of rows read from a secondary index named `tsdbIdx`, defined on the table in the path `/var/mapr/mapr.monitoring/tsdb-meta`.

NOTE: In addition to these table-specific tags, Metric Collection on page 1699 describes other available tags.

HPE Ezmeral Data Fabric Streams Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following Streams metrics on each node in the cluster.

WARNING: MapR monitoring uses 2 MB disk space per minute per node when HPE Ezmeral Data Fabric Streams metrics is enabled. This is approximately 3 GB per day on a single node or 7 GB per node per day with a 3X replication. This stream metrics data is automatically deleted every 3 days.

Name	Description
mapr.streams.produce_rpcs	The number of Streams producer RPCs. This metric is available as of EEP 2.0.
mapr.streams.produce_msgs	The number of Streams messages produced. This metric is available as of EEP 2.0.
mapr.streams.produce_bytes	The number of megabytes produced by Streams messages. This metric is available as of EEP 2.0.
mapr.streams.listen_rpcs	The number of Streams consumer RPCs. This metric is available as of EEP 2.0.
mapr.streams.listen_msgs	The number of Streams messages read by the consumer. This metric is available as of EEP 4.0. **NOTE:** If you upgrade to EEP 4.0, all Streams messages are consumed, however this metric only reports a count on messages that were produced in EEP 4.0. Messages produced prior to EEP 4.0 are consumed, but not counted. In this scenario, the metric reports a partial count or a zero count if all messages were produced prior to EEP 4.0.
mapr.streams.listen_currpcs	The number of concurrent Stream consumer RPCs. This metric is available as of EEP 2.0.
mapr.streams.listen_bytes	The number of megabytes consumed by Streams messages. This metric is available as of EEP 2.0.

file system Metrics

Every 10 seconds, the collectd service uses a HPE Data Fabric plugin to gather the following file system metrics on each node in the cluster.

Name	Description
mapr.fs.bulk_writes	The number of bulk-write operations. Bulk-write operations occur when the primary file system container aggregates multiple small file writes from one or more clients into one big RPC, before replicating the writes.
mapr.fs.bulk_writesbytes	The amount of MB written by bulk-write operations. Bulk-write operations occur when the primary file system container aggregates multiple small file writes from one or more clients into one big RPC, before replicating the writes.
mapr.fs.kvstore_delete	The number of delete operations on key-value store files which are used by the CLDB and HPE Ezmeral Data Fabric Database.
mapr.fs.kvstore_insert	The number of insert operations on key-value store files which are used by the CLDB and HPE Ezmeral Data Fabric Database.

last-updated: Jun 06, 2024

Name	Description
mapr.fs.kvstore_lookup	The number of lookup operations on key-value store files which are used by the CLDB and HPE Ezmeral Data Fabric Database.
mapr.fs.kvstore_scan	The number of scan operations on key-value store files which are used by the CLDB and HPE Ezmeral Data Fabric Database.
mapr.fs.local_readbytes	The amount of MB read by applications that are running on the file system node where the data resides.
mapr.fs.local_reads	The number of file read operations by applications that are running on the file system node where the data resides.
mapr.fs.local_writebytes	The amount of MB written by applications that are running on the file system node where the data resides.
mapr.fs.local_writes	The number of file write operations by applications that are running on the file system node where the data resides.
mapr.fs.read_bytes	The amount of data (in MB) read remotely.
mapr.fs.read_cachehits	The number of cache hits for file reads. This value includes pages that file system populates using the readahead mechanism.
mapr.fs.read_cachemisses	The number of cache misses for file read operations.
mapr.fs.reads	The number of remote reads.
mapr.fs.statstype_create	The number of file create operations.
mapr.fs.statstype_lookup	The number of lookup operations.
mapr.fs.statstype_read	The number of file read operations.
mapr.fs.statstype_write	The number of file write operations.
mapr.fs.write_bytes	The amount of data (in MB) written remotely.
mapr.fs.writes	The number of remote writes.

Process Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following process metrics on each node in the cluster.

Name	Description	Additional Tag(s)
mapr.process.context_switch_involuntary	The number of involuntary context switches for MapR processes. An involuntary context switch occurs when a process consumes more CPU time than what it was allocated by the kernel. When an involuntary context switch occurs, the kernel stops a process to provide resources to another process.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.

last-updated: Jun 06, 2024

Name	Description	Additional Tag(s)
mapr.process.context_switch_voluntary	The number of voluntary context switches for MapR processes. A voluntary context switch occurs when a process does not require the entire CPU time it was allocated by the kernel or when a process is suspended. When a voluntary context switch occurs, the kernel provides CPU resources to another process.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.cpu_percent	The percentage of CPU used for MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.cpu_time.syst	The amount of time, measured in seconds, that the process has been in kernel mode.	
mapr.process.cpu_time.user	The amount of time, measured in seconds, that the process has been in user mode	
mapr.process.data	The amount memory, in MB, used by the data segments of MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.disk_octets.read	The number of bytes read from disk for MapR processes.	
mapr.process.disk_octets.write	The number of bytes written to disk for MapR processes.	
mapr.process.disk_ops.read	The number of read operations for MapR processes.	
mapr.process.disk_ops.write	The number of write operations for MapR processes.	
mapr.process.mem_percent	The percentage of total system memory (not capped by MapR processes) used for MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.page_faults.majflt	The number of major MapR process faults that required loading a memory page from disk.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.page_faults.minflt	The number of minor MapR process faults that required loading a memory page from disk.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.rss	The actual amount of memory, in MB, used by MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.
mapr.process.vm	The amount of virtual memory, in MB, used by MapR processes.	• `process_name`: Display values for a specified process. Process values: hoststats,mfs,warden,.etc.

last-updated: Jun 06, 2024

I/O Metrics
Every 10 seconds, the collectd service uses a plugin to gather the following I/O metrics on each node in the cluster.

Name	Description
mapr.io.read_bytes	The number of MB read from disk.
mapr.io.reads	The number of file system disk read operations.
mapr.io.write_bytes	The number of MB written to disk.
mapr.io.writes	The number of file system disk write operations.

RPC Metric
Every 10 seconds, the collectd service uses a plugin to gather the following RPC metrics on each node in the cluster.

Name	Description
mapr.rpc.bytes_recd	The number of bytes received by the file system over RPC.
mapr.rpc.bytes_sent	The number of bytes sent by the file system over RPC.
mapr.rpc.calls_recd	The number of RPC calls received by the file system.

Spark JMX Metrics
Every 10 seconds, the `collectd` service gathers the following Spark JMX metrics on each node in the cluster.

For detailed information about Spark metrics, see the Apache Spark documentation.

- mapr.spark.driver_block_manager_disk_space_used_mb
- mapr.spark.driver_block_manager_memory_max_mem_mbb

Topology Metrics
Every 60 seconds, the collectd service uses a plugin to gather the following topology metrics on each node in the cluster. Use these metrics to understand disk utilization across a topology or rack. By default, these

last-updated: Jun 06, 2024

metrics include all racks and topologies associated with the cluster. However, you can use tags to specify which rack(s) or topologies(s) to include. **Note:** Racks and topologies can span multiple nodes and one rack can be associated with multiple topologies.

Name	Description	Tag
mapr.topology.disks_total_capacity	The disk capacity in gigabytes. This metric is available as of EEP 3.0.	• `rack_name:` Display values for a specified rack. • `topology_name`: Display values for a specified topology. Provide the full topology path.
mapr.topology.disks_used_capacity	The amount disk space used in gigabytes. This metric is available as of EEP 3.0.	• `rack_name:` Display values for a specified rack. • `topology_name`: Display values for a specified topology. Provide the full topology path.
mapr.topology.utilization	The aggregate percentage of CPU utilization. This metric is available as of EEP 3.0.	• `rack_name:` Display values for a specified rack. • `topology_name`: Display values for a specified topology. Provide the full topology path.

Volume Metrics

Every 10 seconds, the collectd service uses a plugin to gather the following volume metrics on each CLDB node in the cluster.

For volumes prefixed with `mapr.internal*`, the reported volume metrics are not meaningful.

Name	Description	Tag(s)
mapr.volume.logical_used	The number of MBs used for logical volumes before compression is applied to the files.	• `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.
mapr.volume.snapshot_used	The number of MBs used for snapshots.	• `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.
mapr.volume.total_used	The number of MB used for volumes and snapshots.	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.

last-updated: Jun 06, 2024

Name	Description	Tag(s)
mapr.volume.used	The number of MB used for volumes after compression is applied to the files.	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.
mapr.volume.quota	The number of megabytes(MB) used for volume quota.	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `entity_name`: Display values for a specified user or group.

Every 10 seconds, the collectd service uses a plugin to gather the following MapR volume metrics on each CLDB node in the cluster.

Name	Description	Tag(s)
mapr.volmetrics.read_throughput	The per volume read throughput in KB	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.
mapr.volmetrics.write_throughput	The per volume write throughput in KB	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.
mapr.volmetrics.read_latency	The per volume read latency in milliseconds	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.

last-updated: Jun 06, 2024

Name	Description	Tag(s)
mapr.volmetrics.write_latency	The per volume write latency in milliseconds	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.
mapr.volmetrics.read_ops	A count of the read operations per volume	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.
mapr.volmetrics.write_ops	A count of the write operations per volume	• `fqdn`: Display values for a specified node. • `volume_name`: Display values for a specified volume. • `clusterid`: Display values for a cluster specified by ID. • `clustername`: Display values for a cluster specified by name.

Virtual Memory Metrics
Every 10 seconds, the collectd service uses the vmem plugin to gather the following memory metrics on each node in the cluster.

Name	Description
vmem.vmpage_faults.majflt	The number of major page faults. Major page faults require pages to be accessed from disk.
vmem.vmpage_faults.minflt	The number of minor page faults. Minor page faults can be resolved by sharing pages that are already in memory.

Memory Metrics
Every 10 seconds, the collectd service uses the memory and swap plugins to gather the following memory metrics on each node in the cluster.

Name	Description	Additional Tag(s)
memory.memory	The amount of physical memory in bytes.	• `memory_type`: Display values for a specified memory type. Memory type values: free, used, buffered, etc.

last-updated: Jun 06, 2024

Name	Description	Additional Tag(s)
swap.swap	The amount of swap space in bytes.	• `swap_type`: Display values for a specified swap type. Swap type values: used and free.
swap.swap_io	The amount of swap I/O in bytes.	

Network Metrics
Every 10 seconds, the collectd service uses the interface plugin to gather network metrics on each node in the cluster.

Name	Description	Additional Tag(s)
interface.if_errors.rx	The number of network errors received.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_errors.tx	The number of network errors transmitted.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_octets.rx	The number of bytes received over the network per second.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_octets.tx	The number of bytes transmitted over the network per second.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_packets.rx	The number of packets received over the network per second.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.
interface.if_packets.tx	The number of packets transmitted over the network per second.	• `interface_name`: Display values for a specified interface. Interface values: eth0, eth1, etc.

Node Manager Metrics
Every 10 seconds, the collectd service uses a plugin to gather the following Node Manager metrics on each node in the cluster.

Name	Description
mapr.nm.allocated_GB	The amount of memory allocated to the Node Manager in GB.
mapr.nm.allocated_containers	The number of containers allocated to the Node Manager.
mapr.nm.allocated_vcores	The number of CPUs allocated to the Node Manager.
mapr.nm.available_vcores	The number of CPUs available to the Node Manager.
mapr.nm.available_GB	The amount of memory available to the Node Manager in GB.
mapr.nm.containers_completed	The number of containers that have completed.
mapr.nm.containers_failed	The number of containers that have failed.

last-updated: Jun 06, 2024

Name	Description
mapr.nm.containers_initing	The number of containers that are initializing.
mapr.nm.containers_killed	The number of containers that have been killed by the Node Manager.
mapr.nm.containers_running	The number of containers that are running.
mapr.nm.containers_launched	The number of containers started by the Node Manager.
mapr.nm.jvm.gc_count	The number of garbage collections.
mapr.nm.jvm.gc_count_ps_mark_sweep	The number of parallel scavenge mark sweep collections.
mapr.nm.jvm.gc_count_ps_scavenge	The number of parallel scavenge collections.
mapr.nm.jvm.gc_time_millis	The amount of time spent on garbage collection in milliseconds.
mapr.nm.jvm.gc_time_millis_ps_mark_sweep	The amount of time spent on parallel scavenge mark sweep collection in milliseconds.
mapr.nm.jvm.gc_time_millis_ps_scavenge	The amount of time in milliseconds spent on parallel scavenge collection.
mapr.nm.jvm.log_error	The total number of ERROR logs.
mapr.nm.jvm.log_fatal	The total number of FATAL logs.
mapr.nm.jvm.log_info	The total number of INFO logs
mapr.nm.jvm.log_warn	The total number of WARN logs.
mapr.nm.jvm.mem_heap_committed_m	The amount of heap memory committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_heap_max_m	The maximum amount of heap memory that can be committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_heap_used_m	The amount of heap memory used by the Node Manager in megabytes.
mapr.nm.jvm.mem_max_m	The maximum amount of memory that can be committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_non_heap_committed_m	The amount of non-heap memory committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_non_heap_max_m	The maximum amount of non-heap memory that can be committed to the Node Manager in megabytes.
mapr.nm.jvm.mem_non_heap_used_m	The maximum amount of non-heap memory that can be used by the Node Manager in megabytes.
mapr.nm.jvm.threads_blocked	The number of Node Manager threads in BLOCKED state.
mapr.nm.jvm.threads_new	The number of Node Manager threads in NEW state.
mapr.nm.jvm.threads_runnable	The number of Node Manager threads in RUNNABLE state.
mapr.nm.jvm.threads_terminated	The number of Node Manager threads in TERMINATED state.
mapr.nm.jvm.threads_time_waiting	The number of Node Manager threads in TIMED_WAITING state.
mapr.nm.jvm.threads_waiting	The number of Node Manager threads in WAITING state.
mapr.nm.shuffle.shuffle_connection	The number of Node Manager shuffle connections.

last-updated: Jun 06, 2024

Name	Description
mapr.nm.shuffle.shuffle_output_bytes	The amount of Node Manager shuffle output in bytes.
mapr.nm.shuffle.shuffle_outputs_failed	The number of failed Node Manager shuffle outputs.
mapr.nm.shuffle.shuffle_outputs_ok	The number of completed Node Manager shuffle outputs.
mapr.nm.ugi.get_groups_avg_time	The average amount of time spent by Node Manager on group resolution.
mapr.nm.ugi.get_groups_num_ops	The number of group resolutions completed by the Node Manager.
mapr.nm.ugi.login_failure_avg_time	The average amount of time spent by Node Manager on failed login attempts.
mapr.nm.ugi.login_failure_num_ops	The number of failed login attempts by the Node Manager.
mapr.nm.ugi.login_success_avg_time	The average amount of time spent by Node Manager to successfully login.
mapr.nm.ugi.login_success_num_ops	The number of successful logins by the Node Manager.

Resource Manager Metrics

Every 10 seconds, the `collectd` service uses a HPE Ezmeral Data Fabric plugin to gather Resource Manager metrics on the active Resource Manager. `Collectd` gathers metrics on the Resource Manager JVM process, YARN applications, and nodes that are managed by the Resource Manager. The method used to gather the metrics differs based on the metric type.

YARN Application Metrics

`Collectd` gathers YARN application metrics via JMX and REST API. The application metrics that are collected by JMX have the metric name `mapr.rm.<metric_name>`. Application metrics collected via REST API have the metric name `mapr.rm_queue.<metric_name>`.

Metrics Collected Using JMX

The following metrics are collected using JMX. To filter these metrics by queue using the *rm_queue* tag, see Configure Queue Filters for mapr.rm.<value> Metrics on page 1700.

mapr.rm.active_applications

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The number of active applications.

mapr.rm.active_users

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The number of users with active applications.

mapr.rm.aggregate_containers_allocated

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The number of allocated containers.

mapr.rm.aggregate_containers_released

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The number of released containers.

mapr.rm.allocated_MB

Additional Tags: `rm_queue`: Display values for a specified queue.

Description: The amount of memory allocated to the Resource Manager in MB.

last-updated: Jun 06, 2024

mapr.rm.allocated_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs allocated to the Resource Manager.
mapr.rm.apps_completed	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of completed applications.
mapr.rm.apps_failed	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of failed applications.
mapr.rm.apps_killed	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of killed applications.
mapr.rm.apps_pending	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of pending applications.
mapr.rm.apps_running	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of running applications.
mapr.rm.apps_submitted	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of submitted applications.
mapr.rm.available_MB	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The amount of memory available to the Resource Manager in MB.
mapr.rm.available_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of disks available to the Resource Manager.
mapr.rm.available_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs available to the Resource Manager.
mapr.rm.pending_MB	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The amount of memory, in MB, waiting to be allocated by the Resource Manager.
mapr.rm.pending_containers	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of containers waiting to be allocated by the Resource Manager.
mapr.rm.pending_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue.

last-updated: Jun 06, 2024

	Description: The number of disks waiting to be allocated by the Resource Manager.
mapr.rm.pending_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs waiting to be allocated by the Resource Manager.
mapr.rm.reserved_MB	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The amount of memory reserved by the Resource Manager in MB.
mapr.rm.reserved_containers	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of containers reserved by the Resource Manager.
mapr.rm.reserved_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of disks reserved by the Resource Manager.
mapr.rm.reserved_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs reserved by the Resource Manager.

Metrics Collected Using REST API

The following YARN application metrics are collected using REST API.

mapr.rm_queue.aggregate_containers_allocated	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of containers allocated for applications in the default and custom queues.
mapr.rm_queue.appmaster_used_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of disks used by the Application Master for applications in the default and custom queues.
mapr.rm_queue.appmaster_used_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory, in MB, used by the Application Master for applications in the default and custom queues.
mapr.rm_queue.appmaster_used_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs used by the Application Master for applications in the default and custom queues.

last-updated: Jun 06, 2024

mapr.rm_queue.apps_pending	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of pending applications in the default and custom queues.
mapr.rm_queue.apps_running	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of applications running in the default and custom queues.
mapr.rm_queue.fairshare_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter is the number of disks allocated to default and custom queues.
mapr.rm_queue.fairshare_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the amount of memory, in MB, allocated to default and custom queues.
mapr.rm_queue.fairshare_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the number of CPUs used by applications in the default and custom queues.
mapr.rm_queue.used_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of disks used by applications in the default and custom queues.
mapr.rm_queue.used_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The amount of memory, in MB, used by applications in the default and custom queues.
mapr.rm_queue.used_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: The number of CPUs used by applications in the default and custom queues.
mapr.rm_queue.max_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the maximum number of disks available to default and custom queues.
mapr.rm_queue.max_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the maximum amount of memory, in MB, available to default and custom queues.

last-updated: Jun 06, 2024

mapr.rm_queue.max_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Fair Scheduler, this parameter denotes the maximum number of CPUs available to default and custom queues.
mapr.rm_queue.user_allocated_disks	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of disks allocated to the queues.
mapr.rm_queue.user_allocated_memory	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory, in MB, allocated to the queues.
mapr.rm_queue.user_allocated_vcores	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs allocated to queues.
mapr.rm_queue.user_appmaster_used_disks	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of disks used by the queues.
mapr.rm_queue.appmaster_used_memory	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory used by the queues.
mapr.rm_queue.appmaster_used_vcores	*Additional Tags*: `rm_queue`: Display values for a specified queue. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs used by the queues.
mapr.rm_queue.user_apps_pending	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of applications pending in the queues.

last-updated: Jun 06, 2024

mapr.rm_queue.user_apps_running	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of applications running in the queues.
mapr.rm_queue.user_used_disks	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of number of disks used by the queues.
mapr.rm_queue.user_used_memory	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the amount of memory, in MB, used by the queues.
mapr.rm_queue.user_used_vcores	*Additional Tags*: • `rm_queue`: Display values for a specified queue. • `rm_user`: Display values for a specified user. *Description*: When queue resources are managed by the Capacity Scheduler, this parameter denotes the number of CPUs used by the queues.

Resource Manager Node Metrics

The following are the Node metrics:

mapr.rm_cluster.active_nodes	The number of nodes in the cluster where containers are running.
mapr.rm_cluster.total_nodes	The number of nodes in the cluster.
mapr.rm_cluster.unhealthy_nodes	The number of nodes in the cluster that are unable to accept applications.

Resource Manager JVM Metrics

The following Resource Manager metrics are collected using JMX:

mapr.rm.jvm.gc_count	The number of garbage collections.
mapr.rm.jvm.gc_count_ps_mark_sweep	The number of parallel scavenge mark sweep collections.
mapr.rm.jvm.gc_count_ps_scavenge	The number of parallel scavenge collections.

mapr.rm.jvm.gc_time_millis	The amount of time, in milliseconds, spent on garbage collection.
mapr.rm.jvm.gc_time_millis_ps_mark_sweep	The amount of time, in milliseconds, spent on parallel scavenge mark sweep collection.
mapr.rm.jvm.gc_time_millis_ps_scavenge	The amount of time, in milliseconds, spent on parallel scavenge collection.
mapr.rm.jvm.log_error	The total number of ERROR logs.
mapr.rm.jvm.log_fatal	The total number of FATAL logs.
mapr.rm.jvm.log_info	The total number of INFO logs.
mapr.rm.jvm.log_warn	The total number of WARN logs.
mapr.rm.jvm.mem_heap_committed_m	The amount of heap memory, in megabytes, committed to the Resource Manager.
mapr.rm.jvm.mem_heap_max_m	The maximum amount of heap memory, in megabytes, that can be committed to the Resource Manager.
mapr.rm.jvm.mem_heap_used_m	The amount of heap memory, in megabytes, used by the Resource Manager.
mapr.rm.jvm.mem_max_m	The maximum amount of memory, in megabytes, that can be committed to the Resource Manager.
mapr.rm.jvm.mem_non_heap_committed_m	The amount of non-heap memory, in megabytes, committed to the Resource Manager.
mapr.rm.jvm.mem_non_heap_max_m	The maximum amount of non-heap memory, in megabytes, that can be committed to the Resource Manager.
mapr.rm.jvm.mem_non_heap_used_m	The maximum amount of non-heap memory, in megabytes, that can be used by the Resource Manager.
mapr.rm.jvm.threads_blocked	The number of Resource Manager threads in BLOCKED state.
mapr.rm.jvm.threads_new	The number of Resource Manager threads in NEW state.
mapr.rm.jvm.threads_runnable	The number of Resource Manager threads in RUNNABLE state.
mapr.rm.jvm.threads_terminated	The number of Resource Manager threads in TERMINATED state.
mapr.rm.jvm.threads_time_waiting	The number of Resource Manager threads in TIMED_WAITING state.
mapr.rm.jvm.threads_waiting	The number of Resource Manager threads in WAITING state.

Configure the OpenTSDB Service Heap Size

By default, the OpenTSDB service is configured to use a default heap size of 6 gigabytes. The default heap size can be adjusted by modifying certain configuration files.

last-updated: Jun 06, 2024

In EEPs 6.0.1 and later, the OpenTSDB service is configured to use a default heap size of 6 GB. In earlier EEPs, the default was configured to be 2 GB. If you configure a custom value for the OpenTSDB service heap size and then upgrade to EEPs 6.0.1 or later, you will see the 6-GB default implemented in the `/opt/mapr/conf/conf.d/warden.opentsdb.conf` file.

To change the heap size to a different setting, edit the configuration files on all OpenTSDB nodes as follows. The following steps change the heap size from 2 GB to 6 GB. The default heap size might need further adjustment if your cluster grows to a large number of nodes. If the 6-GB heap size is insufficient, you can use these same steps to adjust it:

1. Edit the `/opt/mapr/conf/conf.d/warden.opentsdb.conf` file to change:

   ```
   service.heapsize.max=2000
   service.heapsize.min=2000
   ```

   to

   ```
   service.heapsize.max=6000
   service.heapsize.min=6000
   ```

2. Edit the `/opt/mapr/opentsdb/opentsdb-*/etc/init.d/opentsdb` file to change:

   NOTE: Step 2 is not required for EEPs 6.0.1 and later, which contain logic to edit the `opentsdb` file automatically.

   ```
   $
   {JVMXMX:=-Xmx2000m -Xss1m -XX:MaxMetaspaceSize=128m}
   ```

   to

   ```
   $
   {JVMXMX:=-Xmx6000m -Xss1m -XX:MaxMetaspaceSize=128m}
   ```

3. Restart the OpenTSDB service:

   ```
   maprcli node services -name opentsdb -nodes <space-separated list of
   OpenTSDB nodes> -action restart
   ```

Metric Visualization
Use dashboards to visualize metrics across multiple nodes and clusters.

You can use a single dashboard to visualize metrics for multiple nodes in the cluster, for an entire cluster, or for multiple clusters. In a dashboard, you can use metric tags to filter the type of data that you want to see. To learn more about the tags available for each metric, see Metric Collection on page 1699.

Before you start visualizing metrics, review the following notes:

Sample Dashboards

As of EEP 1.1, the Grafana UI includes sample CLDB, node, and volume dashboards. For more information, see Sample Dashboards in Grafana on page 1754.

Grafana Documentation

For information about creating and using dashboards, see the Grafana documentation.

The Embedded Grafana Database

Grafana uses an embedded database to store configuration data such as users, data sources, and dashboards. When used with the HPE Ezmeral Data Fabric, Grafana uses SQLite for its embedded database. Other databases, such as MySQL and PostgreSQL, are not supported for use with the data-fabric implementation of Grafana.

Note also that in a data-fabric cluster, each instance of Grafana has its own embedded SQLite database. Therefore, if you make a change to the Grafana configuration data (for example, if you add a new user) on one node, you must repeat the change on all other nodes where Grafana is installed.

Access the Grafana UI

You can launch the Grafana UI from the Control System or directly from a web browser.

About this task

Procedure

1. Use one of the following methods to launch the Grafana UI:
   - In the Control System, go to the **Services** page and click **Grafana** to launch the Grafana UI in another tab.
   - From a web browser, launch the following URL: `http://<IPaddressOfGrafanaNode>:3000`
2. Provide user credentials. See Logging on to Grafana on page 1752.
3. Click **Log in**.

Logging on to Grafana

This page describes the credentials needed to log on to Grafana for secure and nonsecure clusters for HPE Ezmeral Data Fabric 6.0 and later.

EEP 5.0.0 and Installer 1.9.0 implemented some changes in security that affect the user IDs and passwords you need to log on to Grafana. Beginning with EEP 5.0.0, Grafana no longer uses its own database to authenticate on secure HPE Ezmeral Data Fabric clusters. On secure clusters, when you enter your user name and password into the browser, the Grafana server sends the user name and password to the CLDB, and the CLDB authenticates using the Pluggable Authentication Module (PAM) and HTTPS. Grafana still relies on its database for some user information. However, because authentication relies on the CLDB, any new user that you add to Grafana must also exist on the HPE Ezmeral Data Fabric cluster.

EEP 4.x.x (Grafana 4.4.2) and Earlier

To log on, enter the default Grafana `admin` user and password:

- **User:** `admin`
- **Password:** `admin`

EEP 5.x.x (Grafana 4.6.1) and Later

To log on, specify the user and password as follows:

	Secure Cluster	Nonsecure Cluster
User	Type the HPE Ezmeral Data Fabric cluster admin user ID.	Type the Grafana `admin` user ID.

	Secure Cluster	Nonsecure Cluster
	NOTE: If the cluster admin user has no password or is not able to log in, see Logging on to Grafana Without Using the Cluster Admin on page 1753.	
Password	Type the HPE Ezmeral Data Fabric cluster admin password that you specified during cluster installation.	Type the password for the Grafana `admin` user that you specified during cluster installation. (During cluster installation, the Installer web interface asks you to provide this password. You can also provide the password by using `configure.sh` during a manual installation.)

For More Information

To change the Grafana password, see Changing the Password for Grafana on page 1753.

For more information about the Grafana versions supported by each EEP, see EEP Components and OS Support on page 5734.

For information about the EEPs supported by different HPE Ezmeral Data Fabric Core versions, see EEP Support and Lifecycle Status on page 5728.

Logging on to Grafana Without Using the Cluster Admin
In secure Grafana installations where the cluster admin (typically `mapr`) has no password and is not allowed to log in as a user, special steps are required to enable login with a user other than the cluster admin.

Use this procedure only if the cluster admin has no password. After an upgrade or a new installation of Grafana, perform these steps on the Grafana nodes:

1. Remove the old Grafana database. You will be able to access the Grafana database later using the new Grafana admin user:

   ```
   cd /opt/mapr/grafana/grafana-<version>/var/lib/grafana
   mv grafana.db grafana.db.sv
   ```

2. Use the `export` command to specify the new Grafana admin user:

   ```
   export GRAFANA_ADMIN_ID=<username>
   ```

3. Run `configure.sh` with the `-R` option:

   ```
   configure.sh -R
   ```

4. Restart Grafana.

Changing the Password for Grafana
Describes how to change the Grafana password for secure and nonsecure clusters.

Secure Clusters

To change the Grafana password for a secure cluster, you must change the password for the data-fabric cluster admin user. The security implementation determines how you change the password. For example, if your security implementation is PAM and LDAP, you need to use LDAP to change the cluster admin password.

last-updated: Jun 06, 2024

NOTE: If the cluster is secure, attempting to change the Grafana password using the Grafana interface has no effect.

Nonsecure Clusters

For a nonsecure cluster:

1. Log in to the interface using the `admin` user ID and the password that you specified for the `admin` user ID when you installed the cluster.
2. Select **Home > Admin > Profile**.
3. On the **User Profile** screen, click **Change Password**, located near the bottom of the screen.
4. Enter and save the new password.

Adding a New Grafana User to a Secure Data Fabric Cluster
In a secure Data Fabric cluster, adding a new Grafana user requires an extra step to ensure that the user can be authenticated through the CLDB.

Beginning with EEP 5.0.0, Grafana no longer uses its own database to authenticate on secure Data Fabric clusters. On secure clusters, when you enter your user name and password into the browser, the Grafana server sends the user name and password to the CLDB, and the CLDB authenticates using the Pluggable Authentication Module (PAM) and HTTPS.

Because authentication relies on the CLDB, any new user that you add to Grafana must also exist on the Data Fabric cluster. Therefore, to add a new Grafana user in a secure Data Fabric cluster:

1. Add the user to the Linux system first. This user must have the same Linux UID and GID on every node in the Data Fabric cluster.
2. Add the same user to Grafana, making sure that you use the user ID you added to the Linux system. In Grafana: **Settings > ServerAdmin > Users > Add new user**.

Sample Dashboards in Grafana

Use the sample dashboards to get familiar with the types of graphs you can create. As of EEP 1.1, sample dashboards are available by default in Grafana.

Displaying the Sample Dashboards

For Grafana 4.x, 5.x, and 6.x, navigate to the **Welcome to Grafana** page, and click the **Home** drop-down menu to display the sample dashboards. Once you select a dashboard, it displays in the **Recently viewed dashboards** list on the Home page.

In Grafana 7.5.x and later, use these steps to display the dashboards:

1. Navigate to the **Welcome to Grafana** page.
2. On the left-side icon menu, click **Dashboard > Manage**. The list of dashboards is displayed.
3. Click a dashboard in the list to load the dashboard. The **General / Node Dashboard** page is displayed.
4. Loading the dashboard adds the dashboard to the **Recently viewed dashboards** list on the **General / Home** page.

Sample Dashboard Descriptions

CLDB Dashboard	The CLDB dashboard provides a high-level view of the data-fabric cluster. It displays the following information about the cluster: number of nodes, status of nodes, number of volumes, container information,

last-updated: Jun 06, 2024

	disk capacity, and the utilization of CPU, memory, and disks across the cluster.
Node Dashboard	The Node dashboard provides node-specific information. It displays the following information for the selected node: CPU, memory, network I/O, file system I/O, HPE Ezmeral Data Fabric Database operations, and Node Manager metrics. All the metrics are tagged with node hostname and the `fqdn` drop-down menu on the top left can be used to switch between nodes.
Volume Dashboard	The Volume dashboard provides volume-specific information. It displays the following information for the selected volume: raw data size, snapshot size, total size (including the snapshot size), volume utilization trends, read/write latency, number of reads/writes, and read/write throughput. All the metrics are tagged with volume name. Use the `VolumeName` drop-down menu on the top left to switch between volumes.

Troubleshooting Sample Dashboards

The sample dashboards should display metrics automatically. However, with certain EEPs, some manual configuration may be required to view sample dashboard metrics.

Configure the ClusterID in the CLDB dashboard	When the `ClusterID` drop-down menu on the CLDB dashboard is set to `None`, you must manually enter the ClusterID. You can determine the ClusterID from the Manage Licenses page on the Control System. ClusterID is usually an eighteen digit number.
Configure the Hostname in the Node dashboards	When the `fqdn` drop-down menu on the Node dashboard is set to `None`, you must manually enter the hostname for the node that you want to view metrics for.
Configure the Volume in the Volume dashboard	When the `VolumeName` drop-down menu on the Volume dashboard is set to `None`, you must manually enter the volume name for the volume that you want to view metrics for. The Volumes page on the Control System lists the volume names in the format required by the field. For example, you can enter `mapr.cluster.root` in the `VolumeName` drop-down menu.

NOTE: You must apply the manual configuration each time you view a dashboard.

Update the OpenTSDB Data Source For Grafana

Grafana connects to a single OpenTSDB node to read metrics. If Grafana cannot read the metrics because an OpenTSDB node has failed, you must configure Grafana to connect to a different OpenTSDB node.

About this task

NOTE: The OpenTSDB node that Grafana connects to by default is determined by the first OpenTSDB node that was specified when the cluster was configured to use metrics monitoring.

Procedure

1. Use one of the following methods to launch the Grafana user interface:
   - From the Control System, select the **Grafana** view. After you select the **Grafana** view, you might also need to select the **Pop-out page into a tab** option.

last-updated: Jun 06, 2024

- From a web browser, launch the following URL: `http://<IPaddressOfGrafanaNode>:3000`

2. Click the Grafana icon in the upper left corner to toggle the side-menu bar.
3. Select **Data Sources** from the menu.
4. Click the **MapRMonitoringOpenTSDB** data source.
5. In the **Http setting** section, update the **Url** field to point to an active OpenTSDB node.
6. Click **Save & Test**.

Log Collection
Fluentd collects log events from each node in the cluster and stores them in a centralized location so that administrators can search the logs when troubleshooting issues in the cluster. The process that fluentd uses to parse and send log events to Elasticsearch differs based on the formatting of log events in each log file.

Fluentd uses one or both of the following mechanisms to parse logs:

multi-line matching	Using the log time stamp as a delimiter, multi-line matching uses the `tail` plugin to read logs and determine the end of a log event. Each log event is sent to Elasticsearch when the next log event is written to the log file. This mechanism is often used when each log event starts with a timestamp and then includes a stack trace.
multi-pattern matching	Multi-pattern matching uses the `grok` plugin to parse logs events using complex expressions. This mechanism is often used to parse logs events that have non-uniform log formatting.

Before Fluentd sends the log entries to Elasticsearch, Fluentd assigns the following columns to each log event:

Tag	Description
level	The message level of the log entry. For example, info, warning, or error.
class	Java or C++ process name associated with the log entry.
message	The log message.
event_time	The time, with millisecond precision, when the log entry was written to the log file.
service_name	The name of the service that generated the log entry.
@timestamp	The time, with second precision, when fluentd read the message.
fqdn	The node on which the log entry was written.
clusterid	The clusterid of the cluster on which the log was written.

NOTE: The log event contents differs based on the service that logs it and the type of log. Therefore, the log events sent to Elasticsearch may include empty columns.

For more information about Elasticsearch, see the Elasticsearch website.

Configure Logs to Index
Edit the *fluentd.conf* file (`/opt/mapr/fluentd/fluentd-<version>/etc/fluentd/fluentd.conf`) to enable or disable the indexing of a specific log.

About this task

The *fluentd.conf* file includes a source parameter for each log file that it indexes.

Procedure

1. To disable the indexing of a log, comment all lines for the associated source parameter.
2. To enable the indexing of a log, for example syslogs, uncomment the lines for the associated source parameter.
3. Restart `fluentd` on each node in the cluster which is impacted by changes to the index configuration. For example, if you disable the indexing of Kibana logs, restart `fluentd` on the node that runs Kibana.

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> \
 -action restart
```

Example

For example, in this excerpt of the *fluentd.conf* file, NodeManager error logs are disabled and ResourceManager logs are enabled:

```
# yarn nodemanager log
# <source>
#  @type tail
#  @id yarn_nodemanager_input
#  format multiline
#  format_firstline /\d{4}-\d{1,2}-\d{1,2}/
#  format1 /^(?<my_event_time>[^ ]* [^ ]*) (?<level>[^ ]*) (?<class>[^:]*):
(?<message>.*)$/
#  time_key my_event_time
#  keep_time_key true
#  path /opt/mapr/hadoop/hadoop-*/logs/yarn-*-nodemanager-*.log
#  tag nodemanager
#  pos_file /opt/mapr/fluentd/fluentd-0.14.00/var/log/fluentd/tmp/
nodemanager.pos
# </source>

# yarn resourcemanager log
<source>
  @type tail
  @id yarn_resourcemanager_input
  format multiline
  format_firstline /\d{4}-\d{1,2}-\d{1,2}/
  format1 /^(?<my_event_time>[^ ]* [^ ]*) (?<level>[^ ]*) (?<class>[^:]*):
(?<message>.*)$/
  time_key my_event_time
  keep_time_key true
  path /opt/mapr/hadoop/hadoop-*/logs/yarn-*-resourcemanager-*.log
  tag resourcemanager
  pos_file /opt/mapr/fluentd/fluentd-0.14.00/var/log/fluentd/tmp/
resourcemanager.pos
</source>
```

Forward Logs to Syslog Server

You can configure `fluentd` to send logs to a syslog server in addition to Elasticsearch. This topic provides instructions for configuring `fluentd` to send logs to syslog compatible collectors. However, it only provides guidelines for the syslog configuration, as syslog parameters differ by version. Knowledge of how to configure a syslog compatible collector is required to complete this configuration.

last-updated: Jun 06, 2024

Complete the following steps:

1. Configure `fluentd` to send logs to the syslog server.
2. Configure `syslog` server to accept logs from `fluentd`.

Step 1: Configure fluentd to send logs to the syslog server

Complete the following steps on each `fluentd` node.

1. Open the `fluentd.conf` file (*/opt/mapr/fluentd/fluentd-<version>/etc/fluentd/fluentd.conf*).
2. Remove the # to uncomment the following store section:

```
# <store>
# @type remote_syslog
# host 10.10.100.92
# port 51400
# severity debug
# tag fluentd
# </store>
```

3. Update the `host` parameter to the hostname/IP address of the receiving `syslog` server.
4. Update the `port` parameter to match the port that the receiving `syslog` server is expecting remote logging information on.
5. Restart the `fluentd` service:

```
maprcli node services -name fluentd -nodes <space separated list of
hostname/IPaddresses> -action restart
```

NOTE: You can run this command after completing the steps on a node or run this command with a list of nodes once you have configured each `fluentd` node.

Step 2: Configure syslog to accept logs from fluentd

In general, you need to perform the following steps on the `syslog` collection server:

- Configure `syslogd` to listen for logs outside of the `syslog` node.
- Set up rules for how `syslog` handles the logs once it receives it.

1. In */etc/rsyslog.d/listen.conf*, comment out the following parameter:

```
$SystemLogSocketName /run/systemd/journal/syslog
```

2. In */etc/rsyslog.conf*, uncomment the following properties:

```
#$ModLoad imudp
#$UDPServerRun 514
```

3. In */etc/rsyslog.conf*, update the UDPServerRun to a value above 1000 that matches the port you configured in *fluentd.conf*. For example: `Set UDPServerRun` to 51400

last-updated: Jun 06, 2024

4. In */etc/rsyslog.conf*, configure rules for handling logs. For example, add the following before the RULES section to route messages from the `fluentd` node to a log file named *qa-node91.log*.

```
if $fromhost-ip == '10.10.100.91' then /var/log/qa-node91.log
& ~
```

NOTE: In this example, the IP address must match the IP address of the `fluentd` node.

Data Fabric Core Logs
The `fluentd` component reads and parses the following Data Fabric Core log files on each node in the cluster.

Service Name	Parsing Method	Description
adminuiapp	Multi-line	Control System logs from `/opt/mapr/apiserver/logs/apiserver.log`.
cldb	Multi-line	CLDB server logs from `$MAPR_HOME/logs/cldb.log`.
cldbfssummary	Multi-line	Summary of the CLDB server logs from `$MAPR_HOME/logs/cldbfssummary.log`
mfs_maprdb	Multi-line	HPE Ezmeral Data Fabric Database logs from `$MAPR_HOME/logs/mfs.log-5`. **NOTE:** If nodes in the cluster run two filesystem instances, Fluentd only reads and parses logs from primary fileserver instance. Therefore, logs from the secondary fileserver instance will not be indexed by Elasticsearch.
mfs	Multi-line	Data Fabric filesystem logs from `$MAPR_HOME/logs/mfs.log-3`. **NOTE:** If nodes in the cluster run two filesystem instances, Fluentd only reads and parses logs from primary fileserver instance. Therefore, logs from the secondary fileserver instance will not be indexed by Elasticsearch.
nfsserver	Multi-line and Multi-pattern	NFS for the HPE Ezmeral Data Fabric server log from `$MAPR_HOME/logs/nfsserver.log`
nodemanager	Multi-line	Node Manager logs from `$MAPR_HOME/hadoop/hadoop-*/logs/yarn-*-nodemanager-*.log`.
resourcemanager	Multi-line	ResourceManager logs from `$MAPR_HOME/hadoop/hadoop-*/logs/yarn-*-resourcemanager-*.log`

last-updated: Jun 06, 2024

Service Name	Parsing Method	Description
warden	Multi-line and Multipattern	Warden logs from `$MAPR_HOME/logs/warden.log`.
zookeeper	Multi-line	Zookeeper logs from `$MAPR_HOME/zookeeper/zookeeper-*/logs/zookeeper.log`

Data Fabric Ecosystem Logs

The `fluentd` component reads and parses the following data-fabric ecosystem component logs on each node in the cluster.

Service Name	Parsing Method	Description
drill	Multi-line	Drill logs from `$MARP_HOME/drill-*/logs/drillbit.log`.
drillbitsSqlline	Multi-line	Drill SQL query logs from `$MAPR_HOME/drill/drill-*/logs/sqlline.log`.
hbaserest	Multi-line and Multipattern	HBase REST Server logs from `$MAPR_HOME/hbase/hbase-*/logs/hbase-*-rest-*.log`.
hbasethriftserver	Multi-line	Hbase Thrift Server logs from `$MAPR_HOME/hbase/hbase-*/logs/hbase-*-thrift-*.log`.
hive	Multi-line	HiveServer logs from `$MAPR_HOME/hive/hive-*/logs/root/hive.log`.
httpfs	Multi-line	HttpFS logs from `$MAPR_HOME/httpfs/httpfs-*/logs/httpfs.log`.
hue	Multi-line	Hue logs from `$MAPR_HOME/hue/hue-*/logs/hue-mapr-runcpserver-*.out`.
oozie	Multi-line	Oozie logs from `$MAPR_HOME/oozie/oozie-*/logs/oozie.log` .
oozieOps	Multi-line	Oozie operation logs from `$MAPR_HOME/oozie/oozie-*/logs/oozie-ops.log`.
oozieCatalina	Multi-line and Multipattern	Oozie Catalina logs from `$MAPR_HOME/oozie/oozie-*/logs/catalina.out`.
sparkhistory	Multi-line	Spark HistoryServer logs from `$MAPR_HOME/spark/spark-*/logs/spark-mapr-org.apache.spark.deploy.history.HistoryServer-1-*.out`.

System Logs

The `fluentd` component does not collect the following system logs by default because they require the configuration of additional permissions for the *$MAPR_USER*.

last-updated: Jun 06, 2024

Service name	Parsing Method	Description
kernlog	Multi-line	Kernel logs from `/var/log/kern.log`.
syslog	Multi-line	System logs from `/var/log/syslog` and `/var/log/messages`.
mysql_errors	Multi-line	MySQL errors from `/var/log/mysql/error.log`.

NOTE: To enable `fluentd` to read and parse these logs, see Configure Logs to Index on page 1756 and also perform the following:

- On Ubuntu and RHEL/CentOS, add *$MAPR_USER* to the `admin` group.
- On RHEL/CentOS, change the ownership of the log file so that it is owned by both the `root` user and the `admin` group.

MapR Monitoring Logs

The `fluentd` component reads and parses the following MapR Monitoring component logs on each node in the cluster.

Service Name	Parsing Method	Description
collectd	Multi-line	The collectd component logs from `$MAPR_HOME/collectd/collectd-*/var/log/collectd/collectd_daemon.log`
fluentd	Multi-line	The fluentd component logs from `$MAPR_HOME/fluentd/fluentd-*/var/log/fluentd/fluentd.log`,
grafana	Multi-line	Grafana logs from `$MAPR_HOME/grafana/grafana-*/var/log/grafana/grafana.log`.
kibana	Multi-line	Kibana logs from `$MAPR_HOME/kibana/kibana-*/var/log/kibana/kibana.log`.

Log Aggregation and Storage

`Fluentd` uses a round-robin approach when writing logs to Elasticsearch nodes. If an Elasticsearch node in unavailable, `Fluentd` can fail over log storage to another Elasticsearch node.

Each `Fluentd` service connects to each Elasticsearch node that you configure to aggregate and store logs. The Elasticsearch nodes are set when you configure Monitoring with the Installer or when you run configure.sh with the `-ES` parameter.

The Elasticsearch index directory is shared among all the Elasticsearch nodes in the cluster. When you use the Installer to install Elasticsearch, each Elasticsearch node writes index data to `/opt/mapr/es_db`, unless you specified a different location during the installation. When you manually install Elasticsearch, each Elasticsearch node writes index data to `/opt/mapr/elasticsearch/elasticsearch-<version>/var/lib/MaprMonitoring/`, unless you specified a different location using the `configure.sh -ESDB` option. For a cluster with one Elasticsearch node, the index directory is allocated 5 shards. For clusters with 2 or more Elasticsearch nodes, the index directory is allocated a number of shards equal to 3 times the number of Elasticsearch nodes in the cluster.

last-updated: Jun 06, 2024

`Fluentd` does not require additional configuration to enable automatic failover to an available Elasticsearch node. However, it is important that at least three Elasticsearch nodes are configured to aggregate and store logs so that failure of one node does not prevent logs from being used for monitoring purposes. Based on your environment, more Elasticsearch nodes may be required. Service Layout Guidelines for Large Clusters on page 87.

For more information about Elasticsearch, see the Elastic website.

Configure Log Retention
By default, Elasticsearch indexes 2 days of logs. Based on your requirements, you can configure a different retention period for Elasticsearch.

The following cron job runs each day to purge logs based on the retention period.

```
$min $hour * * * $ES_HOME/bin/curator --config $ES_HOME/etc/elasticsearch/
curator.yml \
 $ES_HOME/etc/elasticsearch/curator_actions/delete_indices.yml >>
$ES_HOME/var/log/elasticsearch/purgeData.log 2>&1 "
```

Log Retention for Elasticsearch

Complete the following steps to edit the log retention period for Elasticsearch:

1. Open the `/opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/curator_actions/delete_indices.yml` file.
2. Update the `unit` and `unit_count` to the new retention period.

unit	The unit of measure for the retention period. Valid parameter values: `days` and `weeks`.
unit_count	The number of days or weeks.

For example, this version of the *delete_indices.yml* file retains logs for 2 days.

```
actions:
  1:
    action: delete_indices

last-updated: Jun 06, 2024

Log Retention for Kibana

Each time you start Kibana, it logs data to its log file. You cannot delete the log file while Kibana is running.

To purge the log files:

1. Restart Kibana so that a new log file is created.

   ```
   maprcli node services -name kibana -nodes <kibana hostname/
   IPaddress> -action restart
   ```

2. Delete all the old log files (`kibana.*.<#>`) from the following location: `/opt/mapr/kibana/kibana-<version>/var/log/kibana/`.

Configure Purge Duration
Based on your requirements, you can configure a purge duration for Elasticsearch.

To update the purge duration on node with installed Elasticsearch 6.5.3, run the following command:

```
/opt/mapr/elasticsearch/elasticsearch-<Version>/usr/share/elasticsearch/bin/
es_cluster_mgmt.sh --purgeAge <newValue>
```

This command will automatically update the `delete_indices.yml` file. This change updates only the `unit_count` value to `newValue`, without changing the unit value.

Configure Log Rotation Policies for Monitoring Services
New log files are created based on the log rotation policy. By default, each Monitoring service has a log rotation policy. In most cases, you can change the policy based on your requirements.

OpenTSDB Log Rotation Policy

By default, OpenTSDB creates a new log file when each log file reaches the maximum file size of 128MB. After 4 log files are generated, it deletes the oldest log file.

To change the log rotation policy, edit the following file: `/opt/mapr/opentsdb/opentsdb-<version>/etc/opentsdb/logback.xml`. For more information, see the OpenTSDB Logging documentation.

Fluentd and CollectD Log Rotation Policy

By default, `Fluentd` and `Collectd` create a new log file each day and they both retain 30 log files. Log rotation for `Fluentd` and `Collectd` logs is managed by `logrotate`.

To change the log rotation policies, edit the following files: `/etc/logrotate.d/fluentd` and `etc/logrotate.d/collectd`. For details on how to update the log rotation policy, see the logrotate documentation.

Elasticsearch Log Rotation Policy

By default, Elasticsearch creates a new log file each day and it retains 7 days of logs.

To change the log rotation policy, edit the following file `/opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch/logging.yml`. For details on how to update logging.yml, see the Elasticsearch documentation.

Grafana Log Rotation Policy

By default, Grafana creates a new log file whenever the current log file exceeds the 256MB. It retains log files that were generated in the last 7 days.

To change the log rotation policy, edit the `[log]` section of the following file: `/opt/mapr/grafana/grafana-<version>/etc/grafana/grafana.ini`. For details on how to update the grafana.ini, see the Grafana documentation.

Kibana Log Rotation Policy

Each time you start Kibana, it logs data to its log file and it does not automatically delete old log files. A new log file is created when you restart Kibana. To purge the log files, see Configure Log Retention on page 1762.

Configure the Elasticsearch Service Heap Size

The Elasticsearch service is memory-intensive. By default, the Elasticsearch service is configured to use a minimum and maximum heap size of 2 GB. You can override these default values by making changes in the Elasticsearch Warden configuration file and the `jvm.options` file. Restart Elasticsearch after you modify the settings.

Configuring Memory in the Warden Configuration File

You can enable memory settings in the ElasticSearch Warden configuration file, located in the `/opt/mapr/conf/conf.d/warden.elasticsearch.conf` directory. Modify the `service.heapsize.min` and `service.heapsize.max` values set in `warden.elasticsearch.conf`, as shown:

```
service.heapsize.min=2000
service.heapsize.max=2000
```

The `service.heapsize.min` and `service.heapsize.max` values are set in megabytes as an integer. For older EEPs, you must make sure that the `-Xms` and `-Xmx` values in the jvm.options file match the settings in the Warden configuration file.

About the jvm.options File

The `jvm.options` file centralizes arguments to the Java Virtual Machine to simplify the management of the JVM options. You can no longer set the JVM options through the ES_MIN_MEM, ES_MAX_MEM, ES_HEAP_SIZE, ES_HEAP_NEWSIZE, ES_DIRECT_SIZE, ES_USE_IPV4,ES_GC_OPTS, ES_GC_LOG_FILE, and JAVA_OPTS environment variables.

If you installed the Elasticsearch service from the TAR or ZIP distributions, you can locate the `jvm.options` file in `config/jvm.options`. If you installed ElasticSearch from the Debian or RPM packages, you can locate the `jvm.options` file in the `$ES_HOME/etc/elasticsearch/jvm.options` directory, for example:

```
/opt/mapr/elasticsearch/elasticsearch-<version>/etc/elasticsearch
```

To specify an alternative location, set the ES_JVM_OPTIONS environment variable to the file path.

Configuring Memory in the jvm.options File

NOTE: If you configured Elasticsearch memory in the Warden configuration file, configuring memory in the `jvm.options` file is not required for EEPs 6.2.0, 6.1.1, 6.0.2 and later, which contain logic to edit the `jvm.options` file automatically. For other EEPs, you must ensure that memory-configuration changes are made *both* in the Warden configuration file and in the`jvm.options` file.

The `-Xms` and `-Xmx` values in the `jvm.options` file set the Elasticsearch heap size, as shown:

```
-Xms2g
-Xmx2g
```

The `-Xms` parameter sets the minimum heap size in gigabytes. The `-Xmx` parameter sets the maximum heap size in gigabytes. Elasticsearch recommends that both parameters have the same value.

Restarting the Elasticsearch Service

After you modify memory settings, issue the following command to restart the Elasticsearch service:

```
maprcli node services -name elasticsearch -nodes <space separated list of
Elasticsearch nodes> -action restart
```

TIP:

- On a production cluster, you can lock Elasticsearch memory to improve performance. To lock Elasticsearch memory, set the `bootstrap.mlockall: true` option in `$ES_HOME/etc/elasticsearch/elasticsearch.yml`.
- If Elasticsearch uses more than 75% of the configured heap size, you may want to increase the maximum heapsize value.

  For more information, see the Elasticsearch documentation.

Configure Fluentd Services to Write to Elasticsearch Nodes on the Same Rack

On clusters with high-density racks, ensure you have at least one Elasticsearch server per rack and configure each Fluentd service to write to Elasticsearch nodes that run on the same rack as the Fluentd service. This configuration minimizes the impact of log aggregation on other processes that run on the cluster and in particular, minimizes the amount of backbone bandwidth used by the log aggregation.

About this task

Complete the following steps on each node that runs the Fluentd service.

Procedure

1. Open the `/opt/mapr/fluentd/fluentd-<version>/etc/fluentd/es_config.conf` file.
2. Edit the `hosts` property to only include Elasticsearch nodes that are on the same rack as the Fluentd service.
   Example:

   ```
   hosts qa-node90:9200,qa-node91.qa.lab:9200,qa-node92.qa.lab:9200
   ```

3. Restart Fluentd.

   ```
   maprcli node services -name fluentd -nodes <space separated list of
   fluentd nodes> -action restart
   ```

What to do next

WARNING: Changes to the es_config.conf files are overridden by configure.sh. Therefore, you will need reconfigure the hosts property in the es_config.conf file after configure.sh is run on Fluentd nodes.

60-mapr_elasticsearch.conf

The `/etc/sysctl.d/60-mapr_elasticsearch.conf` file is created when you install Elasticsearch. This file specifies a Docker host setting for Elasticsearch.

last-updated: Jun 06, 2024

The `vm.max_map_count` setting is a tuning parameter that limits the number of discrete mapped memory areas for the Linux VM:

Example

```
vm.max_map_count=262144
```

For more information about the `max_map_count` parameter, see the Linux Kernel documentation.

60-mapr_fluentd.conf

The `/etc/sysctl.d/60-mapr_fluentd.conf` file is created when you install Fluentd. This file contains Linux kernel tuning parameters.

The `tcp_tw_reuse` parameter allows you to reuse sockets in the TIME_WAIT state for new connections.

The `ip_local_port_range` parameter defines the local port range that is used by TCP and UDP to choose the local port.

Example

```
net.ipv4.tcp_tw_reuse = 1
net.ipv4.ip_local_port_range = 10240    65535
```

Log Visualization
Use dashboards to visualize the logs across multiple nodes and clusters.

For information about creating and using dashboards, see the Kibana documentation.

Access the Kibana UI
You can launch the Kibana UI from the Control System or directly from a web browser.

About this task

Procedure

1. Use one of the following method to launch the Kibana UI:
   - In the Control System, go to **Services** and click **Kibana** to launch the Kibana UI in another tab.
   - From a web browser, launch the following URL: `http://<IPaddressOfKibanaNode>:5601`
2. Log on as needed. See Logging on to Kibana on page 1766.

Logging on to Kibana
This page describes the credentials needed to log on to Kibana for secure and nonsecure clusters for HPE Ezmeral Data Fabric 6.0 and later.

Elasticsearch has its own user database, which also serves Kibana. EEP 5.0.0 and Installer 1.9.0 implemented some changes in security that affect the user IDs and passwords you need to log on to Kibana.

IMPORTANT: The Kibana version included in HPE Ezmeral Ecosystem Packs (EEPs) is a free version that does not support the integration of LDAP/AD users. Integrating LDAP/AD users requires a paid subscription to Elasticsearch. The paid subscription is not supported for use with the HPE Ezmeral Data Fabric. Therefore, you must use the Kibana `admin` user, as described later on this page, to access the Kibana web UI for use with the Data Fabric.

EEP 4.x.x

To log on, specify the user and password as follows:

	Secure Cluster	Nonsecure Cluster
User	Type the Kibana `admin` user.	No logon required.
Password	Type `admin`.	No logon required.

EEP 5.0.0 and Later

To log on, specify the user and password as follows:

	Secure Cluster	Nonsecure Cluster
User	Type the Kibana `admin` user ID.	No logon required.
Password	Type the ElasticSearch/Kibana password that you specified during cluster installation.	No logon required.

For More Information

To change the Elasticsearch/Kibana password, see Changing the Password for Elasticsearch and Kibana on page 1767.

For more information about the Grafana versions supported by each EEP, see EEP Components and OS Support on page 5734.

For information about the EEPs supported by different HPE Ezmeral Data Fabric Core versions, see EEP Support and Lifecycle Status on page 5728.

Changing the Password for Elasticsearch and Kibana
Describes how to change the password for Elasticsearch / Kibana.

Kibana gets its password from Elasticseach. To change the password for the `admin` user for Elasticsearch and Kibana:

1. On one of the Elasticsearch nodes, run these commands:

```
ESHOME=/opt/mapr/elasticsearch/elasticsearch-<es_version>
cd $ESHOME/usr/share/elasticsearch/plugins/search-guard-6
bash tools/hash.sh -p "NewPasswordYouWantForAdmin"
  $2a$12$6ASxMQEBKYPyGUc10RyleOhz3c8RrvPGb7oqLC9xGGwPxJFwOLJtq
```

   The `es_version` depends on the EEP that you have installed. To determine the `es_version`, use the following table, or refer to Component Versions for Released EEPs on page 5750:

Core Version	EEP Version	`<es_version>`
7.7.0	9.2.2	6.8.8
7.6.1	9.2.1	6.8.8
7.5.0	9.2.x	6.8.8
7.4.0	9.x.x	6.8.8
7.3.0	9.x.x	6.8.8
7.2.0	9.x.x	6.8.8
7.1.0	9.0.0	6.8.8
7.0.0	8.0.0	6.8.8
6.2.0	8.0.0	6.8.8
6.2.0	7.1.1	6.8.8

last-updated: Jun 06, 2024

Core Version	EEP Version	<es_version>
6.2.0	7.1.0	6.8.8
6.2.0	7.0.1	6.8.8
6.2.0	7.0.0	6.8.8
6.1.1	6.3.5	6.8.8
6.1.1 or 6.1.0	6.3.4	6.8.8
6.1.1 or 6.1.0	6.3.3	6.8.8
6.1.0	6.3.2	6.8.8
6.1.0	6.3.1	6.8.8
6.1.0	6.3.0	6.5.3
6.1.0	6.2.0	6.5.3
6.1.0	6.1.1	6.5.3
6.1.0	6.1.0	6.5.3
6.1.0	6.0.2	6.2.3
6.1.0	6.0.1	6.2.3
6.1.0	6.0.0	6.2.3

2. Using the hash generated in step 1, edit the `sgconfig/sg_internal_users.yml` file. Change this:

```
admin:
hash: $2a$12$VcCDgh2NDk07JGN0rjGbM.Ad41qVR/YFJcgHp0UGns5JDymv..TOG
#password is: <PasswordSpecifiedAtClusterInstallation>
```

   to this:

```
admin:
hash: $2a$12$6ASxMQEBKYPyGUc10RyleOhz3c8RrvPGb7oqLC9xGGwPxJFwOLJtq
#password is: <NewPasswordYouWantForAdmin>
#hash: $2a$12$VcCDgh2NDk07JGN0rjGbM.Ad41qVR/YFJcgHp0UGns5JDymv..TOG
#password is: <PasswordSpecifiedAtClusterInstallation>
```

3. Save the file.

4. Load the new users database into Elasticsearch:

```
./tools/sgadmin.sh -h <esHostname> -f sgconfig/
sg_internal_users.yml -t internalusers -cacert ../../../../../etc/
elasticsearch/certs/ca/chain-ca.pem -cert ../../../../../etc/
elasticsearch/certs/admin-usr-clientCert.pem -key ../../../../../etc/
elasticsearch/certs/admin-usr-private-key.pem -cn MaprMonitoring
```

Related concepts

Checking the EEP Version on page 5598
Some Installer operations require you to know the version of the currently installed Ecosystem Pack (EEP). You can check the EEP version easily from within the Installer user interface or derive the EEP version from your repository information.

last-updated: Jun 06, 2024

Related tasks

Checking the Installer Version on page 5597
Some Installer features require you to use the latest version of the Installer. You can check the Installer version easily from within the user interface.

Display Logs Chronologically
To display logs chronologically in Kibana, sort the log events by the event_time column.

@timestamp indicates the time with second precision and is not as precise as event_time which indicates the time with millisecond precision. Therefore, if you want to display logs chronologically in Kibana, sort the log events by the event_time column, not the @timestamp column.

Update the Elasticsearch URL for Kibana
Kibana connects to a single Elasticsearch node to read logs. In the event that Kibana is unable to read logs due to the failure of an Elasticsearch node, configure Kibana to connect to an available Elasticsearch node.

About this task

NOTE: The Elasticsearch node that Kibana connects to by default is determined by the first Elasticsearch node that was specified when the cluster was configured to use Monitoring

Procedure

1. Open `/opt/mapr/kibana/kibana-<version>/config/kibana.yml`.
2. Update the `elasticsearch.url` parameter to point to an available Elasticsearch node.

   TIP: If you want to configure Kibana to work even if the Elasticsearch node is unavailable, see the Kibana documentation for the steps to configure Kibana to load balance across multiple Elasticsearch nodes.

HPE Ezmeral Data Fabric Monitoring Tips and Troubleshooting
Lists the nuances of monitoring clusters.

Monitoring a Secure Cluster

After regenerating the HPE Ezmeral Data Fabric user ticket, service failures occur for `collectd` and OpenTSDB	If you delete or regenerate the HPE Ezmeral Data Fabric user ticket, the running `collectd` and OpenTSDB services will fail. After updating the HPE Ezmeral Data Fabric user ticket, restart `collectd` and OpenTSDB services.

Monitoring Logs

I notice a sudden increase in `fluentd` logs. What can I do?	A sudden increase in the log file for `fluentd` could mean that a feedback loop is occurring where `fluentd` logs an error in the log file for a `fluentd` issue and that log entry causes yet another error when `fluentd` tries to parse it. In this case, consider disabling the index of `fluentd` logs. See Configure Logs to Index on page 1756.
I see "400 - Rejected by Elasticsearch" messages in the fluentd logs. What can I do?	Messages such as the following can accumulate in the `fluentd` log when a process does not produce logs with valid UTF-8 output: `2019-04-25 17:00:11 -0700 [warn]: #0 dump an error event: error_class=Fluent::Plugin::Elasticsea`

```
rch
ErrorHandler::ElasticsearchError
error="400 - Rejected by
Elasticsearch" location=nil
after setting this option in
es_config.conf
```

In a message such as the following, you might see invalid characters represented as a diamond with a question mark:  . The `"service_name":"collectd"` part of the message indicates that `collectd` is generating the invalid UTF-8 output:

```
[2019-04-30T19:06:29,495][DEBUG]
[o.e.a.b.TransportShardBulkAction]
[mfs73] [mapr_monitoring-2019.05.01]
[4] failed
to execute bulk item (index) index
{[mapr_monitoring-2019.05.01]
[mapr_monitoringv1]
[taQkcWoBCeW3tMAsn1cW],
source[{"my_event_time":"2019-04-30
18:36:39","level":"info","message":"wr
ite_maprstreams plugin: Produced:
Offset: 1247132; Size: 152;
[{\"metric\":\"mapr.streams.produce_ms
gs\",\"value\":448,\"tags\":
{\"fqdn\":\
"qa-node91.qa.lab\",\"clusterid\":\"63
78079583755418855\",\"clustername\":\"
my.cluster.com\"}}]
n","@timestamp":"2019-04-30T18:36:39.
000000000-07:00","service_name":"colle
ctd"}]}
org.elasticsearch.index.mapper.MapperP
arsingException: failed to parse
field [message] of type [text]
Caused by:
com.fasterxml.jackson.core.JsonParseEx
ception: Invalid UTF-8 middle byte
0x5c
```

One workaround is to comment out the log producing the invalid character. You can do this in the `fluentd.conf` file. For more information, see Configure Logs to Index on page 1756.

Another workaround is to fix the application that produces the error message. If the log file is produced by an application that you control, change the output of the log producing the invalid character.

Monitoring Metrics

Where should I store the Elasticsearch index?

Elasticsearch requires a lot of disk space. Also, when you upgrade Elasticsearch, the default index directory is removed along with the package update. Therefore, it is recommended to configure a separate filesystem for the index data. It is not recommended to store index data under the `/` or the `/var` filesystem.

NOTE: If you store the Elasticsearch index on a filesystem that is locally hosted, you will be able to access logs in the event that the HPE Ezmeral Data Fabric cluster is not available.

For more information about the Elasticsearch index and the default index directory, see Log Aggregation and Storage on page 1761.

I see a "Bad Request" error message for my HPE Ezmeral Data Fabric Database metrics? What can I do?

If you have more than 1000 active tables in HPE Ezmeral Data Fabric Database and the HPE Ezmeral Data Fabric monitoring request size to OpenTSDB is more than 4 KB, you may see the following error message:

```
"Sorry but your request was rejected
as being invalid.
The reason provided was: Chunked
request not supported."
```

You can increase the maximum request size of OpenTSDB to up to 64 KB by setting the following parameters in the `opentsdb.conf` file:

```
tsd.http.request.enable_chunked=true
tsd.http.request.max_chunk=65536
```

For more information, see the OpenTSDB configuration guide.

Installation and Configuration Errors

See Troubleshoot Monitoring Installation Errors on page 229

Reconfiguring MapR Monitoring

Changes to an existing cluster, such as the addition of services, may require additional steps to enable the collection of metrics and logs.

Configure Monitoring for Additional Services

When you add services to a cluster where MapR Monitoring is already configured, you must restart collectd and Fluentd services to enable the collection of logs and metrics for the newly added services.

About this task

Procedure

1. Restart the collectd service on each node that runs the service that was added to the cluster.

   ```
   maprcli node services -name collectd -nodes <space separated list of
   hostname/IPaddresses> -action restart
   ```

2. Restart the Fluentd service on each node that runs the service that was added to the cluster.

   ```
   maprcli node services -name fluentd -nodes <space separated list of
   hostname/IPaddresses> -action restart
   ```

Update the Monitoring Storage Nodes

You must reconfigure HPE Ezmeral Data Fabric Monitoring when you add additional OpenTSDB or Elasticsearch nodes, or when you change the OpenTSDB or Elasticsearch node locations.

last-updated: Jun 06, 2024

About this task

Procedure

1. Run configure.sh on each node in the HPE Ezmeral Data Fabric cluster with the `-R`, `-ES`, and `-OT` parameters. Optionally, you can include the `-ESDB` parameter.

   ```
   /opt/mapr/server/configure.sh -R -ES <comma-separate list of
   Elasticsearch nodes> \
    -OT <comma-separate list of OpenTSDB nodes> [-ESDB <filepath>]
   ```

   For the entire list of available `configure.sh` parameters, see configure.sh

   If you encounter any errors after running `configure.sh`, see Troubleshoot Monitoring Installation Errors on page 229

2. If you updated the list of Elasticsearch nodes, restart the all the Fluentd, Elasticsearch, and Kibana services.

   ```
   maprcli node services -name fluentd -nodes <space separated list of
   Fluentd nodes> -action restart
   ```

   ```
   maprcli node services -name elasticsearch -nodes <space separated list
   of Elasticsearch nodes> -action restart
   ```

   ```
   maprcli node services -name kibana -nodes <space separated list of
   Kibana nodes> -action restart
   ```

3. If you updated the list of OpenTSDB nodes, restart the collectd, OpenTSDB, and Grafana services.

   ```
   maprcli node services -name opentsdb -nodes <space separated list of
   OpenTSDB nodes> -action restart
   ```

   ```
   maprcli node services -name collectd -nodes <space separated list of
   collectd nodes> -action restart
   ```

   ```
   maprcli node services -name grafana -nodes <space separated list of
   Grafana nodes> -action restart
   ```

Configuring Data Fabric to Track User Behavior

Describes how to configure Data Fabric to be able to track user behavior.

When auditing is enabled in Data Fabric, files, streams and tables can be audited for cluster administration and/or data access operations.

Data Fabric audit logs provide insights into the activity that has taken place in relation to the cluster.

Auditing is useful to record user behavior and assists in tracking anomalies or potential data security threats with respect to Data Fabric.

Data Fabric stores audit logs in files and the audit logs can be directed to streams. However, it was not possible to run queries on streams in the earlier versions on Data Fabric.

Data Fabric provides a utility by the name, `update_insights.sh`, to copy audit logs onto Apache Iceberg (Iceberg), so that the data that is copied or added to Iceberg tables can be queried.

last-updated: Jun 06, 2024

TIP: HPE recommends that you run the `expandaudit` utility before updating Iceberg. This is because there can be different FIDs that belong to the same file. Running `expandaudit` ensures that the filename is the same for different audit log entries that refer to different fids of a given file. The `expandaudit` utility makes the audit log contents more user-friendly by replacing ids with names.

You can use tools like Spark and Zeppelin to run queries on the Iceberg tables to generate various reports and charts required by you to detect any anomalies in user behavior related to the data access operations and cluster administration.

Iceberg requires Hive metastore to store and manage the Iceberg catalog. Hive must be accessible to Iceberg for proper working of Iceberg.

Hive metastore requires a relational database management system like MySQL in production setups. See Using MySQL for the Hive Metastore to use MySQL with Hive metastore.

To set up MySQL to work with the Hive metastore and Data Fabric, see Configuring a Remote MySQL Database for Hive Metastore.

Configuring Security

Describes how to configure security and manage secure clusters.

Configuring Data Fabric Security

Provides usage information for frequently used security functionality, including Access Control Lists (ACLs), Access Control Expressions (ACEs), file permissions, and subnet allowlisting.

NOTE: Release 6.1 makes it easier to secure new Data Fabric installations. See Using the Enable Secure Cluster Option on page 5611 in the Installer on page 5579.

Wired encryption and authentication (including impersonation) for the Data Fabric platform and for all supported ecosystem products are enabled on all new installations through Installer on page 5579. Alternatively, enable security manually by running the `configure.sh on page 2821` command with the `-secure` option.

Enable security features at any time, but additional configuration is required for the individual components to work with security enabled. This section discusses initial configuration of a secure cluster as well as other forms of security.

The following access control elements are available irrespective of whether security features are enabled for your cluster. After security features are enabled, these elements benefit from encrypted traffic within the cluster and strong authentication to the cluster.

- ACLs for the cluster, the volumes in the cluster, and the MapReduce application queue
- *ACE*s control user permissions for directories, files, and HPE Ezmeral Data Fabric Database tables that are stored natively
- File permissions for objects in the file system layer
- Subnet allowlisting restricts access to the cluster's FileServer service

On clusters with security features enabled, ecosystem components may require additional configuration. For example, Hive functionality has different security requirements depending on the interaction between the HiveServer2 component, the Hive command-line interface, and the Hive metastore.

See the Security Support Matrix on page 5775 for more information about supported security options for Ecosystem components. See the specific Ecosystem component in Ecosystem Components on page 3893 for information on security configuration.

last-updated: Jun 06, 2024

See Security Vulnerabilities on page 6184 for a list of known vulnerabilities.

Verifying if Files Needed for Security are Present

When you run `configure.sh` with the `-secure` option, the following files are automatically created in the `/opt/mapr/conf` directory. To ensure that security is properly configured, navigate to the `/opt/mapr/conf` directory and verify that the files are present.

Master value controlling the cluster secure or non-secure state	*File or command:* `/opt/mapr/conf/mapr-clusters.conf` `maprcli dashboard info -cluster <clusterName> -json | grep secure` *Default secure setting:* `secure=true` *Alternate possible values/notes:* `secure=false` disables security on restarting the cluster.
Data Fabric service account	*File or command:* `sudo passwd -S mapr` *Default secure setting:* Site Specific Password. *Alternate possible values/notes:* No password. Use `su` to access.
CLDB key file	*File or command:* `/opt/mapr/conf/cldb.key` *Default secure setting:* Created at install. Do not change. *Alternate possible values/notes:* Must exist on all CLDB nodes and be identical.
Server ticket	*File or command:* `/opt/mapr/conf/maprserverticket` *Default secure setting:* Created at install, do not change. *Alternate possible values/notes:* Must exist on all cluster nodes and be identical.
User ticket	*File or command:* `/opt/mapr/conf/mapruserticket` *Default secure setting:* Created at install, do not change. *Alternate possible values/notes:* Must exist on all cluster nodes and be identical. This ticket is owned and used by the service account as needed.
SSL keys	*File or command:* `/opt/mapr/conf/ssl_truststore` `/opt/mapr/conf/ssl_keystore` *Default secure setting:* Created at install, and should rarely change. These keys are used by web and REST HTTPS interfaces. *Alternate possible values/notes:* How to import CA (Certificate Authority) signed certificates to Ezmeral Data Fabric 7.
Java (JAAS) authentication service settings	*File or command:* `/opt/mapr/conf/mapr.login.conf` *Default secure setting:* Created at install. Do not change.

last-updated: Jun 06, 2024

	Alternate possible values/notes: Must exist on all cluster nodes and be identical.
Roles for use with ACEs	*File or command:* `/opt/mapr/conf/m7_permissions_roles_refimpl.conf` *Default secure setting:* Specific roles defined using automation. *Alternate possible values/notes:* Use should be deprecated. Linux groups are a much better method, centralized and consistent with enterprise standards.
Default security settings for some Data Fabric services	*File or command:* `/opt/mapr/conf/env.sh` *Default secure setting:* Created at install, do not change. *Alternate possible values/notes:* Must exist on all cluster nodes and be identical. View the list of settings by using this command: `grep -i secure env.sh`
ZooKeeper security setting	*File or command:* `/opt/mapr/zookeeper/zookeeper-$zkver/conf/zoo.cfg` *Default secure setting:* `authMech=MAPR-SECURITYauthProvider.1=org.apache.zookeeper.server.auth.SASLAuthenticationProvide` *Alternate possible values/notes:* `authMech=SIMPLE-SECURITY`
JMX remote access (debug and metrics monitoring)	*File or command:* `/opt/mapr/conf/jmxremote.{access,password}` *Default secure setting:* `read-only` and with the password limited to the Data Fabric service account. *Alternate possible values/notes:* `read-write` but is not recommended.

Determining if Wire-Level Security is Enabled Using the CLI

If you run `configure.sh` with the `-secure` option, wire-level security is automatically enabled at the cluster level. You can, optionally, disable wire-level security at the individual volume-level. To determine if wire-level security is enabled for a volume, run the following command:

```
/opt/mapr/bin/maprcli volume list -json |grep wire
```

This command returns the value of `wireSecurity` as `1` if wire-level security is enabled for the volume; `0` otherwise.

Enabling Cluster Wide Data Access Auditing

To enable auditing data access operations at a cluster level, run:

```
/opt/mapr/bin/maprcli audit data -enabled
```

Determining if per Volume Data Access Auditing is Enabled

To determine if auditing data access operations is enabled for a volume, run:

```
/opt/mapr/bin/maprcli volume info -name <volume_name> -json | grep -i
'audited\|coalesce'
```

last-updated: Jun 06, 2024

This command returns the value of `audited` as `1` if data access auditing is enabled for the volume; `0` otherwise.

Getting Started with HPE Ezmeral Data Fabric Security
Describes quick implementation of security.

MapR 6.1 introduced enhanced security settings that simplify the process of creating secure clusters. For a brief introduction, see Security. To learn how to secure a cluster, see this course.

To set up a secure cluster:

1. Enable cluster security, authentication, and wire-level encryption by running configure.sh if you performed a manual installation.

   See Enabling Security on page 1776 for more information.

   NOTE: If you selected the Using the Enable Secure Cluster Option on page 5611 after installing with the Installer on page 5579, proceed to the next step.

2. Generate HPE Ezmeral Data Fabric user tickets to authenticate with your username and password.

   See Generating a HPE Ezmeral Data Fabric User Ticket on page 1831 for more information.

3. Configure each Ecosystem component, where necessary, for security.

   See Security and Ecosystem Components on page 987 for more information.

4. (Optional) Enable encryption of data at rest at the cluster level and selectively for volumes as well.

   See Enabling Encryption of Data at Rest on page 1799 for more information.

5. (Optional) Turn on auditing for the cluster and for directories that contain sensitive data.

   See Enabling and Disabling Auditing of Cluster Administration on page 1058 and Enabling and Disabling Auditing of Data Access Operations on page 1059 for more information.

6. (Optional) Enable authorization using ACEs for files, tables, streams, or volumes; and ACLs for administrative activities that can be performed on the cluster.

   See Managing Access Control Expressions on page 1855 and Managing Access Control Lists on page 1852 for more information.

TIP: After you enable security, review the System Behavior Changes After Enabling Security on page 1796.

Enabling Security
Describes how to enable security for the cluster, platform, ecosystem components, and network-based connections.

About this task

The following steps enable:

- Security for the cluster nodes
- Wire-level encryption for the platform and ecosystem components
- Authentication for all network-based connections
- (Optional) Data-at-rest encryption on the cluster

These steps DO NOT enable security for client nodes. For client-installation information, see Setting Up Clients and Services on page 400.

last-updated: Jun 06, 2024

Use *one* of the following procedures based on the composition of nodes in your cluster:

- Enabling Security When All Nodes Are Non-FIPS on page 1777
- Enabling Security When All Nodes Are FIPS on page 1781
- Enabling Security for a Mix of FIPS and Secure Non-FIPS Nodes on page 1785

Enabling Security When All Nodes Are Non-FIPS

About this task

Use these steps to enable security for a cluster in which all nodes are non-FIPS-enabled nodes:

Procedure

1. If the cluster is running, shut it down.
2. If you are re-running the `configure.sh` script because of an invocation error from a previous run, remove the following files from `${MAPR_HOME}/conf` (if they are present) if you want to re-generate the CLDB key, server ticket, and certificates:
   - All key and trust stores. The files differ depending on whether the node is FIPS enabled. FIPS-enabled nodes use BCFKS key and trust stores, while secure non-FIPS nodes use JKS/JCEKS/P12 key and trust stores:
     - `maprkeycreds.jceks`
     - `maprtrustcreds.jceks`
     - `ssl_keystore, ssl_keystore.p12`
     - `ssl_truststore, ssl_truststore.p12`
     - `ssl_userkeystore`
     - `ssl_usertruststore`
   - All other files in `${MAPR_HOME}/conf` that are generated and configured on the first CLDB node:
     - All PEM files: `ssl_keystore-signed.pem` and `ssl_userkeystore-signed.pem`
     - All files in the `${MAPR_HOME}/conf/tokens` directory (but not the `tokens/` directory itself)
     - `maprserverticket`
     - `mapruserticket`
     - The `store-passwords.txt` file containing the clear-text passwords, if not already removed

   For example:

```
cd /opt/mapr/conf
rm -rf cldb.key maprserverticket mapruserticket ssl-client.xml \
ssl_keystore ssl_truststore ssl-server.xml *.bcfks *.pem tokens/* \
store-passwords.txt
```

last-updated: Jun 06, 2024

3. Run the `configure.sh` script with the `-secure -genkeys -dare` options on the first CLDB node in your cluster:

   ```
   /opt/mapr/server/configure.sh -secure -dare -genkeys -Z
   <Zookeeper_node_list> -C <CLDB_node_list> -N <cluster_name>
   ```

   where both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]` and `-N <cluster_name>` specifies the cluster name. For the hostname, specify an FQDN as described in Connectivity on page 171. Do not specify an alias or IP address. The `-dare` option is required only if you wish to enable data-at-rest encryption at the cluster-level.

   

   IMPORTANT: You must run `configure.sh` with the `-genkeys` option only *after* it is on one CLDB node. The resulting files should be generated only once and then copied to other nodes.

   

   NOTE: The DARE master key is generated in the `tokens/` directory only if data at rest encryption is enabled on the cluster using the `-dare` option with `configure.sh`.

   TIP: For a comprehensive listing of the Trust and Key Store files, see Understanding the Key Store and Trust Store Files on page 1793.

4. Copy files to the destination nodes as follows:

   - If your cluster consists of all secure non-FIPS-enabled nodes, use the following table as a guide to copy files to the destination nodes which are the nodes where the `-genkeys` option is not used to generate keys.

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper Nodes	• conf/maprhsm.conf • conf/maprkeycreds.conf • conf/maprkeycreds.jceks • conf/maprserverticket • conf/maprtrustcreds.conf • conf/maprtrustcreds.jceks • conf/private.key[1] • conf/public.crt[1] • conf/ssl_keystore • conf/ssl_keystore.p12 • conf/ssl_keystore.pem • conf/ssl_keystore-signed.pem • conf/ssl_truststore • conf/ssl_truststore.p12 • conf/ssl_truststore.pem • conf/ssl_userkeystore • conf/ssl_userkeystore.p12 • conf/ssl_userkeystore.pem • conf/ssl_userkeystore-signed.pem • conf/ssl_usertruststore • conf/ssl_usertruststore.p12 • conf/ssl_usertruststore.pem • conf/tokens (use a command such as scp -r to copy everything in this folder)

last-updated: Jun 06, 2024

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
All other cluster nodes, including MFS-only nodes	• conf/maprhsm.conf • conf/maprkeycreds.conf • conf/maprkeycreds.jceks • conf/maprserverticket • conf/maprtrustcreds.conf • conf/maprtrustcreds.jceks • conf/private.key[1] • conf/public.crt[1] • conf/ssl_keystore • conf/ssl_keystore.p12 • conf/ssl_keystore.pem • conf/ssl_keystore-signed.pem • conf/ssl_truststore • conf/ssl_truststore.p12 • conf/ssl_truststore.pem • conf/ssl_userkeystore • conf/ssl_userkeystore.p12 • conf/ssl_userkeystore.pem • conf/ssl_userkeystore-signed.pem • conf/ssl_usertruststore • conf/ssl_usertruststore.p12 • conf/ssl_usertruststore.pem

[1]If you are running Data Fabric 7.0.0.5 or later, the `private.key` and `public.crt` are not present and do not need to be copied to all other nodes. On Data Fabric 7.0.0.5, the `/opt/mapr/conf/ssl_usertruststore` performs this function and is present on all nodes.

5. Run `configure.sh` on each existing node in the cluster using the same arguments as in Step 3 but without the `-genkeys` option.

```
/opt/mapr/server/configure.sh -secure -dare -Z <Zookeeper_node_list> -C
<CLDB_node_list> -N <cluster_name>
```

The `-secure` option indicates that security must be enabled on the node where the command is run. The `-dare` option indicates that data at rest encryption must be enabled on the node and must be specified only if it was specified in Step 3.

last-updated: Jun 06, 2024

IMPORTANT:

- You must also do this on any nodes that you add to the cluster in the future.
- If you run `configure.sh -secure` on a node *before* you copy the necessary files to that node, the command fails.

6. Optionally, enable encrypted quorum ZooKeeper communication. See zoo.cfg on page 3002 for more information.

Enabling Security When All Nodes Are FIPS

About this task

Use these steps to enable security for a cluster in which all nodes are FIPS-enabled:

Procedure

1. If the cluster is running, shut it down.
2. If you are re-running the `configure.sh` script because of an invocation error from a previous run, remove the following files from `${MAPR_HOME}/conf` (if they are present) if you want to re-generate the CLDB key, server ticket, and certificates:
   - All key and trust stores. The files differ depending on whether the node is FIPS enabled. FIPS-enabled nodes use BCFKS key and trust stores, while secure non-FIPS nodes use JKS/JCEKS/P12 key and trust stores:
     - `maprkeycreds.bcfks`
     - `maprtrustcreds.bcfks`
     - `ssl_keystore (symlink), ssl_keystore.bcfks`
     - `ssl_truststore (symlink), ssl_truststore.bcfks`
     - `ssl_userkeystore (symlink), ssl_userkeystore.bcfks`
     - `ssl_usertruststore (symlink), ssl_usertruststore.bcfks`
   - All other files in `${MAPR_HOME}/conf` that are generated and configured on the first CLDB node:
     - All PEM files: `ssl_keystore-signed.pem` and `ssl_userkeystore-signed.pem`
     - All files in the `${MAPR_HOME}/conf/tokens` directory (but not the `tokens/` directory itself)
     - `maprserverticket`
     - `maprusertickt`
     - The `store-passwords.txt` file containing the clear-text passwords, if not already removed

   For example:

```
cd /opt/mapr/conf
rm -rf cldb.key maprserverticket maprusertickt ssl-client.xml \
ssl_keystore ssl_truststore ssl-server.xml *.bcfks *.pem tokens/* \
store-passwords.txt
```

last-updated: Jun 06, 2024

3. Run the `configure.sh` script with the `-secure -genkeys -dare` options on the first CLDB node in your cluster:

   ```
   /opt/mapr/server/configure.sh -secure -dare -genkeys -Z
   <Zookeeper_node_list> -C <CLDB_node_list> -N <cluster_name>
   ```

   where both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]` and `-N <cluster_name>` specifies the cluster name. For the hostname, specify an FQDN as described in Connectivity on page 171. Do not specify an alias or IP address. The `-dare` option is required only if you wish to enable data at rest encryption at the cluster-level.

   IMPORTANT: You must run `configure.sh` with the `-genkeys` option only *once* on one CLDB node, since the resulting files should be generated only once and then copied to other nodes.

   NOTE: The DARE master key is generated in the `tokens/` directory only if data at rest encryption is enabled on the cluster using the `-dare` option with `configure.sh`.

   TIP: For a comprehensive listing of the Trust and Key Store files, see Understanding the Key Store and Trust Store Files on page 1793.

4. Copy files to the destination nodes as follows:

   - If your cluster consists of all FIPS-enabled nodes, use the following table as a guide to copy files to the destination nodes (the nodes where the `-genkeys` option is not used to generate keys):

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper Nodes	• `conf/maprhsm.conf` • `conf/maprkeycreds.bcfks` • `conf/maprkeycreds.conf` • `conf/maprserverticket` • `conf/maprtrustcreds.bcfks` • `conf/maprtrustcreds.conf` • `conf/private.key`[2] • `conf/public.crt`[2] • `conf/ssl_keystore.bcfks`[1] • `conf/ssl_keystore-signed.pem`[1] • `conf/ssl_keystore.p12`[1] • `conf/ssl_keystore.pem`[1] • `conf/ssl_truststore.bcfks`[1] • `conf/ssl_truststore.p12`[1] • `conf/ssl_truststore.pem`[1] • `conf/ssl_userkeystore.bcfks`[1] • `conf/ssl_userkeystore.pem`[1] • `conf/ssl_userkeystore-signed.pem`[1] • `conf/ssl_usertruststore.bcfks`[1] • `conf/ssl_usertruststore.pem`[1] • `conf/tokens` (use `scp -r` to copy everything in this folder)

last-updated: Jun 06, 2024

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
All other cluster nodes, including MFS-only nodes	• `conf/maprhsm.conf` • `conf/maprkeycreds.bcfks` • `conf/maprkeycreds.conf` • `conf/maprserverticket` • `conf/maprtrustcreds.bcfks` • `conf/maprtrustcreds.conf` • `conf/private.key`[2] • `conf/public.crt`[2] • `conf/ssl_keystore.bcfks`[1] • `conf/ssl_keystore.p12`[1] • `conf/ssl_keystore.pem`[1] • `conf/ssl_keystore-signed.pem`[1] • `conf/ssl_truststore.bcfks`[1] • `conf/ssl_truststore.p12`[1] • `conf/ssl_truststore.pem`[1] • `conf/ssl_userkeystore.bcfks`[1] • `conf/ssl_userkeystore.p12`[1] • `conf/ssl_userkeystore.pem`[1] • `conf/ssl_userkeystore-signed.pem`[1] • `conf/ssl_usertruststore.bcfks`[1] • `conf/ssl_usertruststore.p12`[1] • `conf/ssl_usertruststore.pem`[1]

[1]Do NOT copy the `ssl_` symlink files contained in the `conf/` directory. The symlinks are:

- `ssl_keystore` (symlink)
- `ssl_truststore` (symlink)
- `ssl_userkeystore` (symlink)
- `ssl_usertruststore` (symlink)

[2]If you are running Data Fabric 7.0.0.5 or later, the `private.key` and `public.crt` are not present and do not need to be copied to all other nodes. On Data Fabric 7.0.0.5, the `/opt/mapr/conf/ssl_usertruststore` performs this function and is present on all nodes.

last-updated: Jun 06, 2024

5. Run `configure.sh` on each existing node in the cluster using the same arguments as in Step 3 but without the `-genkeys` option.

   ```
   /opt/mapr/server/configure.sh -secure -dare -Z <Zookeeper_node_list> -C
   <CLDB_node_list> -N <cluster_name>
   ```

   The `-secure` option indicates that security must be enabled on the node where the command is run. The `-dare` option indicates that data at rest encryption must be enabled on the node and must be specified only if it was specified in Step 3.

   IMPORTANT:

   - You must also do this on any nodes that you add to the cluster in the future.
   - If you run `configure.sh -secure` on a node *before* you copy the necessary files to that node, the command fails.

6. Optionally, enable encrypted quorum ZooKeeper communication. See zoo.cfg on page 3002 for more information.

Enabling Security for a Mix of FIPS and Secure Non-FIPS Nodes

About this task

A mixed cluster is a cluster consisting of both FIPS-enabled and secure non-FIPS enabled nodes. Since the key and trust store formats are different between FIPS-enabled and secure non-FIPS enabled nodes, the BCFKS stores from FIPS-enabled nodes cannot be copied directly to secure non-FIPS enabled nodes, or vice versa. The Hadoop Credential stores also cannot be copied between FIPS-enabled and secure non-FIPS enabled nodes.

For a mixed configuration, you must:

- Generate the key and trust store, and user key and trust stores if required, on the secure non-FIPS node using the new `${MAPR_HOME}/server/manageSSLKeys.sh convert` utility:
  - After adding a FIPS-enabled node to a cluster consisting of only non-FIPS enabled nodes, generate the BCFKS key and trust stores on the non-FIPS enabled node. Copy them to the `${MAPR_HOME}/conf` directory of the FIPS-enabled node before running `configure.sh`.
  - After adding a secure non-FIPS enabled node to a cluster consisting of only FIPS-enabled nodes, copy the BCFKS key and trust stores from the FIPS-enabled node to a temporary location in the secure non-FIPS enabled node. Generate the JKS key and trust store on the secure non-FIPS enabled node.
- Run the `configure.sh` with the `-storepasswds` option on the node being configured to generate the credential stores.

Enabling Security for the First CLDB Node

About this task

The following steps describe how to enable security for the first CLDB node in the cluster. Note that the data-fabric core platform is installed as secure by default on FIPS-enabled hosts. Security is enabled even if the `-secure` flag is not specified to the `configure.sh` script.

Procedure

1. If the cluster is running, shut it down.

last-updated: Jun 06, 2024

2. If you are re-running the `configure.sh` script because of an invocation error from a previous run, remove the following files from `${MAPR_HOME}/conf` (if they are present) if you want to re-generate the CLDB key, server ticket, and certificates:
   - All key and trust stores. The files differ depending on whether the node is FIPS enabled. FIPS-enabled nodes use BCFKS key and trust stores, while secure non-FIPS nodes use JKS/JCEKS/P12 key and trust stores:

FIPS	Secure Non-FIPS
`maprkeycreds.bcfks`	`maprkeycreds.jceks`
`maprtrustcreds.bcfks`	`maprtrustcreds.jceks`
`ssl_keystore (symlink), ssl_keystore.bcfks`	`ssl_keystore, ssl_keystore.p12`
`ssl_truststore (symlink), ssl_truststore.bcfks`	`ssl_truststore, ssl_truststore.p12`
`ssl_userkeystore (symlink), ssl_userkeystore.bcfks`	`ssl_userkeystore`
`ssl_usertruststore (symlink), ssl_usertruststore.bcfks`	`ssl_usertruststore`

   - All other files in `${MAPR_HOME}/conf` that are generated and configured on the first CLDB node:
     - All PEM files: `ssl_keystore-signed.pem` and `ssl_userkeystore-signed.pem`
     - All files in the `${MAPR_HOME}/conf/tokens` directory (but not the `tokens/` directory itself)
     - `maprserverticket`
     - `maprusertic ket`
     - The `store-passwords.txt` file containing the clear-text passwords, if not already removed

   For example:

```
cd /opt/mapr/conf
rm -rf cldb.key maprserverticket maprusertic ket ssl-client.xml \
ssl_keystore ssl_truststore ssl-server.xml *.bcfks *.pem tokens/* \
store-passwords.txt
```

3. Run the `configure.sh` script with the `-secure -genkeys -dare` options on the first CLDB node in your cluster:

   ```
   /opt/mapr/server/configure.sh -secure -dare -genkeys -Z
   <Zookeeper_node_list> -C <CLDB_node_list> -N <cluster_name>
   ```

   where both `<Zookeeper_node_list>` and `<CLDB_node_list>` have the form `hostname[:port_no][,hostname[:port_no]...]` and `-N <cluster_name>` specifies the cluster name. For the hostname, specify an FQDN as described in Connectivity on page 171. Do not specify an alias or IP address. The `-dare` option is required only if you wish to enable data at rest encryption at the cluster-level.

   IMPORTANT: You must run `configure.sh` with the `-genkeys` option only *once* on one CLDB node, since the resulting files should be generated only once and then copied to other nodes.

   NOTE: The DARE master key is generated in the `tokens/` directory only if data at rest encryption is enabled on the cluster using the `-dare` option with `configure.sh`.

Enabling Security for Additional Cluster Nodes

About this task

To enable security for additional cluster nodes, run `configure.sh` without the `-genkeys` option after copying the required files to the node. For a mixed configuration, first create the key and trust stores on the secure non-FIPS node using the `${MAPR_HOME}/server/manageSSLKeys.sh convert` utility. Then copy these stores to the key and trust stores of the additional cluster node:

- If you are connecting an additional secure non-FIPS cluster node to the first FIPS-enabled cluster node, copy the `ssl_keystore.bcfks` and `ssl_truststore.bcfks` from the `${MAPR_HOME}/conf` directory of the first FIPS-enabled cluster node to the node being configured. Then run the `manageSSLKeys.sh convert` utility from the secure non-FIPS node. Copy the converted JKS key and trust stores to the additional secure non-FIPS cluster node (or simply specify the destination key/trust store as `${MAPR_HOME}/conf/ssl_keystore` and `${MAPR_HOME}/conf/ssl_truststore` respectively in the `${MAPR_HOME}/server/manageSSLKeys.sh convert` utility).
- If you are connecting an additional FIPS-enabled cluster node to the first secure non-FIPS cluster node, copy the JKS `ssl_keystore` and `ssl_truststore` from the `${MAPR_HOME}/conf` directory of the first secure non-FIPS cluster node to a temporary directory of the first node. Then run the `manageSSLKeys.sh convert` utility from the first secure non-FIPS node. Copy the converted BCFKS key and trust stores to the `${MAPR_HOME}/conf` directory of the additional FIPS-enabled cluster node.

Adding a FIPS-Enabled Server to a FIPS Cluster

About this task

To connect a FIPS-enabled server to a cluster consisting of at least one FIPS-enabled node.

Procedure

1. Copy the following files from the existing FIPS-enabled server to the new FIPS server:

last-updated: Jun 06, 2024

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper nodes	• `conf/ssl_keystore.bcfks` • `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.bcfks` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.bcfks` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.bcfks` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/tokens` (use `scp -r` to copy everything in this folder)
All other cluster nodes, including MFS-only nodes	• `conf/ssl_keystore.bcfks` • `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.bcfks` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreeds.bcfks` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.bcfks` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/ca` (use a command such as `scp -r` to copy everything in this folder)

CAUTION: Do NOT copy `conf/ssl_keystore` and `conf/ssl_truststore`. These are symbolic links to `ssl_keystore.bcfks` and `ssl_truststore.bcfks`, which will be generated by configure.sh.

last-updated: Jun 06, 2024

CAUTION: When adding a non-FIPS node to a FIPS cluster, DO NOT copy the Hadoop `ssl*.xml` files to the other cluster nodes. The `manageSSLKeys.sh` script (invoked by `configure.sh`) uses the store type to determine if FIPS is enabled and assumes the system is FIPS-enabled if the store type is BCFKS. Copying the Hadoop `ssl*` files that are set to the BCFKS store type from a FIPS node to a non-FIPS node causes the `configure.sh` script to fail.

2. Run `configure.sh` without the `-genkeys` option. For example, if the cluster name is `fips0.cluster.com` and the CLDB and ZooKeeper nodes are at `m2-mapreng-vm166250`, then the command is:

```
/opt/mapr/server/configure.sh -secure -N fips0.cluster.com \
    -C m2-mapreng-vm166250:7222
```

Adding a Secure Non-FIPS Server to a FIPS Cluster

About this task

Non-FIPS enabled nodes do not support the BCFKS trust store format. Copying the BCFKS trust store from a FIPS-enabled server to the non-FIPS enabled server that is being added will not work. Create the JKS trust store on the non-FIPS server by importing the same keys and certificates that are in the BCFKS key and trust stores on the existing FIPS-enabled server host. Different configuration procedures apply depending on whether you are configuring for the first cluster or for subsequent clusters.

Procedure

1. Copy the following files from an existing FIPS-enabled node in the cluster to the new non-FIPS node being added:

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper nodes	• `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/tokens` (use `scp -r` to copy everything in this folder)

last-updated: Jun 06, 2024

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
All other cluster nodes, including MFS-only nodes	• `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/ca` (use a command such as `scp -r` to copy everything in this folder)

CAUTION: When adding a non-FIPS node to a FIPS cluster, DO NOT copy the Hadoop `ssl*.xml` files to the other cluster nodes. The `manageSSLKeys.sh` script (invoked by `configure.sh`) uses the store type to determine if FIPS is enabled and assumes the system is FIPS-enabled if the store type is BCFKS. Copying the Hadoop `ssl*` files that are set to the BCFKS store type from a FIPS node to a non-FIPS node causes the `configure.sh` script to fail.

2. Copy the following key store, trust store, userkey store, and usertrust store files from the FIPS-enabled server to a temporary directory of the secure non-FIPS enabled server being added:
   - `${MAPR_HOME}/conf/ssl_keystore.bcfks`
   - `${MAPR_HOME}/conf/ssl_truststore.bcfks`
   - `${MAPR_HOME}/conf/ssl_userkeystore.bcfks`
   - `${MAPR_HOME}/conf/ssl_usertruststore.bcfks`
3. Run the `manageSSLKeys.sh convert` utility to convert the key and trust store (and userkey and usertruststore) from BCFKS format to JKS format. The destination key and trust store will be set to the same password as the source key/trust store. You can obtain the key and trust store passwords from the `store-passwords.txt` file. For example:

```
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType bcfks -dstType JKS \
    -p VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC \
    /tmp/ssl_keystore.bcfks /opt/mapr/conf/ssl_keystore
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType bcfks -dstType JKS \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /tmp/ssl_truststore.bcfks /opt/mapr/conf/ssl_truststore
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType bcfks -dstType JKS \
    -p VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC \
    /tmp/ssl_userkeystore.bcfks /opt/mapr/conf/ssl_userkeystore
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType bcfks -dstType JKS \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /tmp/ssl_usertruststore.bcfks /opt/mapr/conf/ssl_usertruststore
```

last-updated: Jun 06, 2024

4. Run the `configure.sh` script without the `-genkeys` option on the secure non-FIPS enabled server being added, using the `-storepasswds` option to specify the key and trust store passwords. Since the converted key and trust stores are set to the same password as the source, the passwords must be the same as the passwords you specified using the `-p` option in step 3. For example:

```
# /opt/mapr/server/configure.sh -secure \
    -N hpe186.cluster.com \
    -C m2-mapreng-vm167186:7222 \
    -Z m2-mapreng-vm167186:5181 \
    -storepasswds \
    VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC:1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA
```

Adding a FIPS Server to a Secure Non-FIPS Cluster

About this task

Use the following steps to connect a FIPS-enabled server to a cluster consisting of only secure non-FIPS enabled nodes:,

Procedure

1. Copy the following files from an existing secure non-FIPS node in the cluster to the FIPS-enabled server being added:

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
CLDB and/or ZooKeeper nodes	• `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/tokens` (use `scp -r` to copy everything in this folder)

Destination Node Type	Copy these files under ${MAPR_HOME} to the destination node . . .
All other cluster nodes, including MFS-only nodes	• `conf/ssl_keystore.p12` • `conf/ssl_keystore.pem` • `conf/ssl_truststore.p12` • `conf/ssl_truststore.pem` • `conf/maprkeycreds.conf` • `conf/maprtrustcreds.conf` • `conf/maprhsm.conf` • `conf/maprserverticket` • `conf/ca` (use a command such as `scp -r` to copy everything in this folder)

CAUTION: When adding a non-FIPS node to a FIPS cluster, DO NOT copy the Hadoop `ssl*.xml` files to the other cluster nodes. The `manageSSLKeys.sh` script (invoked by `configure.sh`) uses the store type to determine if FIPS is enabled and assumes the system is FIPS-enabled if the store type is BCFKS. Copying the Hadoop `ssl*` files that are set to the BCFKS store type from a FIPS node to a non-FIPS node causes the `configure.sh` script to fail.

2. On the secure non-FIPS enabled server in the existing cluster, run the `manageSSLKeys.sh convert` utility to convert the key and trust store (and userkey and usertruststore) from JKS to BCFKS format. You can obtain the key and trust store passwords from the `store-passwords.txt` file. For example:

```
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType JKS -dstType bcfks \
    -p VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC \
    /opt/mapr/conf/ssl_keystore /tmp/ssl_keystore.bcfks
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType JKS -dstType bcfks \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /opt/mapr/conf/ssl_truststore /tmp/ssl_truststore.bcfks
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType JKS -dstType bcfks \
    -p VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC \
    /opt/mapr/conf/ssl_userkeystore /tmp/ssl_userkeystore.bcfks
# /opt/mapr/server/manageSSLKeys.sh convert \
    -srcType JKS -dstType bcfks \
    -p 1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA \
    /opt/mapr/conf/ssl_usertruststore /tmp/ssl_usertruststore.bcfks
```

3. Copy the converted `.bcfks` files from the secure non-FIPS server to the FIPS server being added as follows:

Copy this converted file . . .	To this location on the FIPS server . . .
`ssl_keystore.bcfks`	`/opt/mapr/conf/ssl_keystore.bcfks`
`ssl_userkeystore.bcfks`	`/opt/mapr/conf/ssl_userkeystore.bcfks`
`ssl_truststore.bcfks`	`/opt/mapr/conf/ssl_truststore.bcfks`

last-updated: Jun 06, 2024

Copy this converted file . . .	To this location on the FIPS server . . .
`ssl_usertruststore.bcfks`	`/opt/mapr/conf/ssl_usertruststore.bcfks`

4. Run `configure.sh` without the `-genkeys` option on the FIPS enabled server being added, using the `-storepasswds` option to specify the key and trust store passwords. Since the converted BCFKS key and trust store is set to the same password as the source, the passwords must be the same as the passwords specified using the `-p` option in step 2. For example:

```
/opt/mapr/server/configure.sh -secure \
  -N hpe186.cluster.com \
  -C m2-mapreng-vm167186:7222 \
  -Z m2-mapreng-vm167186:5181 \
  -storepasswds \
VccOl_Qhg3Ix6tLaRJhzr_b53judiaKC:1IB_wtxT5Lbj6OU8xFpWpQiZ0SjE6BrA
```

Understanding the Key Store and Trust Store Files
Provides a comprehensive listing of the key store and trust store files.

Key Stores and Trust Stores Added for Release 7.0.0

Release 7.0.0 added the following key store and trust store files to support FIPS compliance. For Java applications, the Bouncy Castle BCFKS key and trust stores are used. This is new for release 7.0.0. For non-Java applications, the existing PKCS#12 key and trust stores, as well as PEM files are used.

As part of Enabling Security on page 1776, you must copy the key and trust stores, as well as the associated key and trust store credentials, from the `/opt/mapr/conf` directory of the first CLDB node to the `/opt/mapr/conf` directory on all other server nodes. For client-only nodes, only copy the trust stores and the associated trust store credentials.

maprkeycreds.bcfks

Location: `/opt/mapr/conf`

Description: On FIPS-enabled nodes, the encrypted key store that contains passwords used to access the `ssl_keystore` and `ssl_userkeystore`.

maprkeycreds.jceks

Location: `/opt/mapr/conf`

Description: On non-FIPS-enabled nodes, the encrypted key store that contains passwords used to access the `ssl_keystore` and `ssl_userkeystore`.

maprtrustcreds.bcfks

Location: `/opt/mapr/conf`

Description: On FIPS-enabled nodes, the encrypted trust store that contains passwords used to access the `ssl_truststore` and `ssl_usertruststore`.

maprtrustcreds.jceks

Location: `/opt/mapr/conf`

Description: On non-FIPS-enabled nodes, the encrypted trust store that contains passwords used to access the `ssl_truststore` and `ssl_usertruststore`.

ssl_keystore.bcfks

Location: `/opt/mapr/conf`

Description: On FIPS-enabled nodes, the encrypted key store that is generated by configure.sh and used by various data-fabric server-side components for TLS 1.2 communication.

ssl_truststore.bcfks

Location: `/opt/mapr/conf`

	Description: On FIPS-enabled nodes, the encrypted trust store that is generated by configure.sh and used by various data-fabric server-side components for TLS 1.2 communication.
ssl_userkeystore.bcfks	*Location:* `/opt/mapr/conf` *Description:* On FIPS-enabled nodes, the encrypted key store containing the private keys and the certificates for log-monitoring users.
ssl_usertruststore.bcfks	*Location:* `/opt/mapr/conf` *Description:* On FIPS-enabled nodes, the encrypted trust store containing the public keys, and no private keys, for log-monitoring users.

Key Stores and Trust Stores Added for Release 6.2.0

The following key store and trust store files were added at release 6.2.0 to support SSL security for the log stack (Kibana, Elasticsearch, and Fluentd). As part of Enabling Security on page 1776, you must copy these files from the `/opt/mapr/conf` directory of the security master node to the `/opt/mapr/conf` directory on all other nodes, and assign the appropriate ownership and permissions.

ssl_userkeystore	*Location:* `/opt/mapr/conf` *Description:* The key store containing the private keys and the certificates for log-stack users.
ssl_userkeystore.csr	*Location:* `/opt/mapr/conf` *Description:* The certificate-signing request created when the certs are signed using the CA chain.
ssl_userkeystore.p12	*Location:* `/opt/mapr/conf` *Description:* The PKCS#12 version of the `ssl_userkeystore`. The `.p12` version of the file is reserved for future use.
ssl_userkeystore.pem	*Location:* `/opt/mapr/conf` *Description:* The key store containing all of the certs from the `ssl_userkeystore` in the `.pem` format.
ssl_userkeystore-signed.pem	*Location:* `/opt/mapr/conf` *Description:* The key store containing all of the signed certs from the `ssl_userkeystore` in the .pem format.
ssl_usertruststore	*Location:* `/opt/mapr/conf` *Description:* The trust store containing the public keys, and no private keys, for the log-stack users.
ssl_usertruststore.p12	*Location:* `/opt/mapr/conf` *Description:* The PKCS#12 version of the `ssl_usertruststore`. The `.p12` version of the file is reserved for future use.
ssl_usertruststore.pem	*Location:* `/opt/mapr/conf` *Description:* The key store containing all of the certs from the `ssl_usertruststore` in the .pem format.

Certificate Files in 6.2.0

The following files were added at release 6.2.0 to facilitate self-signing of data-fabric certificates. Previously, data-fabric certificates were unsigned. As part of Enabling Security on page 1776, you must

last-updated: Jun 06, 2024

copy these files from the `/opt/mapr/conf` directory of the security master node to the `/opt/mapr/conf` directory on all other nodes, and assign the appropriate ownership and permissions:

root-ca.pem	*Location:* `/opt/mapr/conf/ca` *Description:* The root signing certificate authority.
chain-ca.pem	*Location:* `/opt/mapr/conf/ca` *Description:* The chain certificate authority, which contains both the root CA and signing CA.
signing-ca.pem	*Location:* `/opt/mapr/conf/ca` *Description:* The signing certificate authority.

KMIP Tokens Added in 6.2.0

External key store (KMIP) tokens were also added as part of release 6.2.0. The KMIP tokens are used for authentication and communication with an external key store. The tokens are contained in `/opt/mapr/conf/tokens`. Tokens must be copied to all the CLDB nodes in the cluster.

Key Stores and Trust Stores in Release 6.1.0

The following files are generated by running `configure.sh -dare -genkeys` on a CLDB node. Alternatively, you can generate them by running the manageSSLKeys.sh on page 2897 script. The `ssl_keystore`, `ssl_keystore.p12`, `ssl_keystore.pem`, `ssl_truststore`, `ssl_truststore.p12`, and `ssl_truststore.pem` files are also generated during installation of the Web server, even if you did not enable security. For more information, see Enabling Security on page 1776.

cldb.key	*Location:* `/opt/mapr/conf` *Description:* The CLDB key file. This file must exist on all CLDB nodes and be identical. Releases 7.0.0 and later no longer use this key file. For more information, see Protection of CLDB and DARE Master Keys on page 1815.
dare.master.key	*Location:* `/opt/mapr/conf` *Description:* The key file that enables data-at-rest encryption. The `dare.master.key` file is generated only if data-at-rest encryption is enabled on the cluster. This file must be copied to all the nodes with the CLDB service installed.
maprserverticket	*Location:* `/opt/mapr/conf` *Description:* The server ticket. This file must exist on all cluster nodes and be identical.
ssl-client.xml	*Location (symlink):* `/opt/mapr/conf` *Location (file):* `${MAPR_HOME}/hadoop/hadoop-<version>/etc/hadoop/ssl-client.xml` *Description:* Contains the SSL configuration for the client in XML format.
ssl_keystore	*Location:* `/opt/mapr/conf` *Description:* This file is needed on all nodes where the webserver is running.
ssl_keystore.p12	*Location:* `/opt/mapr/conf` *Description:* When upgrading from Core 5.2.2 or Core 6.0.x to data-fabric 6.1 or later, create the `ssl_keystore.p12` and `ssl_truststore.p12`

	files. Copy them to the `/opt/mapr/conf` directory on all nodes in the cluster. The `.p12` files are required to generate the `.pem` files needed by Grafana and the Data Access Gateway. This step is necessary only for manual upgrades.
ssl_keystore.pem	*Location:* `/opt/mapr/conf` *Description:* When upgrading from Core 5.2.2 or Core 6.0.x to data-fabric 6.1 or later, create the `ssl_truststore.pem` and `ssl_keystore.pem` files. Copy them to the `/opt/mapr/conf` directory on all nodes in the cluster. The Data Access Gateway, Grafana, and Hue components use these files. This step is necessary only for manual upgrades.
ssl-server.xml	*Location (symlink):* `/opt/mapr/conf` *Location (file):* `${MAPR_HOME}/hadoop/hadoop-<version>/etc/hadoop/ssl-server.xml` *Description:* Contains the SSL configuration for the server in XML format.
ssl_truststore	*Location:* `/opt/mapr/conf` *Description:* contains the certificates required by nodes initiating communication over TLS.
ssl_truststore.p12	*Location:* `/opt/mapr/conf` *Description:* When upgrading from Core 5.2.2 or Core 6.0.x to data-fabric 6.1 or later, create the `ssl_keystore.p12` and `ssl_truststore.p12` files, and copy them to the `/opt/mapr/conf` directory on all nodes in the cluster. The `.p12` files are required to generate the `.pem` files needed by Grafana and the Data Access Gateway. This step is necessary only for manual upgrades.
ssl_truststore.pem	*Location:* `/opt/mapr/conf` *Description:* When upgrading from Core 5.2.2 or Core 6.0.x to data-fabric 6.1 or later, create the `ssl_truststore.pem` and `ssl_keystore.pem` files. Copy them to the `/opt/mapr/conf` directory on all nodes in the cluster. The Data Access Gateway, Grafana, and Hue components use these files. This step is necessary only for manual upgrades.

System Behavior Changes After Enabling Security

After enabling security features for a cluster, the following behaviors change:

- Users must authenticate with the `maprlogin` utility.
- Components that have web UIs, such as the Control System, Hive, and Oozie, require authentication.

  WARNING: Note that you must also complete the PAM configuration to set up user authentication for the Control System logins.
- Several components that communicate over HTTP use HTTPS instead.
- Encryption is used for network traffic.

last-updated: Jun 06, 2024

- Access to a cluster using URIs that use the CLDB node's name or IP address, instead of the cluster name, is no longer supported, as in the following examples. The following URIs no longer work after enabling security:

  ```
  http://cldb1.cluster.com:7222/f1
  ```

  ```
  http://10.10.20.10:7221/f1
  ```

  The following URIs work after enabling security:

  ```
  http:///f1 <access f1 in default cluster>
  ```

  ```
  http://my.cluster.com/f1
  ```

Managing Encryption
Provides information that allows you to use encryption across the HPE Ezmeral Data Fabric platform.

This section describes how to enable security for data at rest and on the wire as well as general security components and system changes.

Enabling Wire-level Security

About this task

Wire-level security encrypts data transmission between the nodes in your cluster.

Enable encryption for data on the wire at the volume level only if security is enabled at the cluster level. If necessary, refer to Determining if a Cluster is Secure Using the CLI and REST API on page 1804 to determine if the cluster is secure before enabling wire-level encryption on a volume. If your cluster is enabled for security, wire-level security is enabled by default on all new volumes and no additional steps are required. This section describes how to enable wire-level security on new and existing volumes (if the volume is already not enabled for wire-level security).

Enabling Wire-level Security for a Volume Using the Control System

About this task

Procedure

1. Log in to the Control System and click **Data** > **Volumes**.
2. Click **Create Volume** to display the **Create New Volume** page or go to the Edit Volume page.
3. Set the value for the **Data on Wire Encryption** property to **Yes** (to enable).
   See Creating a Volume on page 1177 or Modifying a Volume on page 1207 for more information.
4. Complete the steps to create or modify the volume.
   See Creating a Volume on page 1177 or Modifying a Volume on page 1207 for more information.

Enabling Wire-Level Security for a Volume Using the CLI and REST API

About this task

CLI	Set the value for the `wiresecurityenabled` parameter to `true` when you:

last-updated: Jun 06, 2024

- Create the volume. For example:

```
maprcli volume create -name
<volName> -path
<volMountPath> -wiresecurityenabled
 true
```

- Modify the volume. For example:

```
maprcli volume modify -name
<volName> -wiresecurityenabled true
```

REST

Send a request of type POST and set the value for the `wiresecurityenabled` parameter to `true` when you:

- Create the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/create?
name=<volName>&path=<volMountPath>&
wiresecurityenabled=true' --user
mapr:mapr
```

- Modify the volume. For example:

```
curl -k -X POST 'https://
abc.sj.us:8443/rest/volume/modify?
name=<volName>&wiresecurityenabled=
true' --user mapr:mapr
```

See `volume create` on page 2588 and `volume modify` on page 2676 for more information.

Disabling Wire-level Security

About this task

Disable wire encryption for a volume using the Control System, the CLI, and REST API.

Disabling Wire-level Security for a Volume Using the Control System

Procedure

1. Log in to the Control System and click **Data** > **Volumes**.
2. Click **Create Volume** to display the **Create New Volume** page or go to the Edit Volume page.
3. Set the value for the **Data on Wire Encryption** property to **No** (to disable).
   See Creating a Volume on page 1177 or Modifying a Volume on page 1207 for more information.
4. Complete the steps to create or modify the volume.
   See Creating a Volume on page 1177 or Modifying a Volume on page 1207 for more information.

Disabling Wire-Level Security for a Volume Using the CLI and REST API

About this task

You can disable encryption of data on wire at the volume level.

CLI	Set the value for the `wiresecurityenabled` parameter to `false` when you:
	• Create the volume. For example:
	`maprcli volume create -name <volName> -path <volMountPath> -wiresecurityenabled false`
	• Modify the volume. For example:
	`maprcli volume modify -name <volName> -wiresecurityenabled false`

REST	Send a request of type POST and set the value for the `wiresecurityenabled` parameter to `false` when you:
	• Create the volume. For example:
	`curl -k -X POST 'https://abc.sj.us:8443/rest/volume/create?name=<volName>&path=<volMountPath>&wiresecurityenabled=false' --user mapr:mapr`
	• Modify the volume. For example:
	`curl -k -X POST 'https://abc.sj.us:8443/rest/volume/modify?name=<volName>&wiresecurityenabled=false' --user mapr:mapr`

See `volume create` on page 2588 and `volume modify` on page 2676 for more information.

Enabling Encryption of Data at Rest

About this task

Enable or disable data-at-rest encryption at the volume level using the Control System, CLI, and REST API if encryption of data at rest is enabled at the cluster level. If you installed using the Installer on page 5579 and selected the **Enable DARE** option, the cluster is automatically enabled for data-at-rest encryption during installation.

NOTE: Conversion of existing HPE Ezmeral Data Fabric clusters to data-at-rest encryption is not currently supported. If you need to convert an existing non-DARE cluster to DARE, contact HPE support.

If encryption is enabled at the cluster level, data-at-rest encryption is also enabled at the volume level by default through the `mapr.volume.dare.default` configuration parameter. If you do not wish to encrypt data at rest in a volume, you can disable encryption when you create a volume. You cannot modify the data-at-rest encryption setting on a volume after the volume is created. For more information, see the following later on this page:

• Enabling or Disabling Data-at-Rest Encryption at the Volume Level Using the Control System on page 1800

last-updated: Jun 06, 2024

- Enabling or Disabling Data-at-Rest Encryption at the Volume Level Using the CLI and REST API on page 1800

Standard volumes inherit the data-at-rest encryption setting from a volume by default if the `inherit` property is specified. If you create a mirror volume for a source volume enabled for data-at-rest encryption, the mirror volume:

- Inherits the data-at-rest encryption setting from the source volume if the mirror volume is in the same cluster as the source volume or if the mirror volume is on a remote cluster enabled for encryption of data at rest.
- Does not inherit the data-at-rest encryption setting from the source volume if the mirror volume is on an unsecure cluster, or if the mirror volume is on secure cluster that is not enabled for encryption of data at rest.

NOTE: If you want to create a mirror volume enabled for data-at-rest encryption for a source volume not enabled for data-at-rest encryption, set the value to `true` for the `dare` property after creating the mirror volume.

This section describes how to enable data-at-rest encryption at the volume level.

Enabling or Disabling Data-at-Rest Encryption at the Volume Level Using the Control System

About this task

You can enable data-at-rest encryption at the volume level only if data-at-rest encryption is enabled at the cluster level. If necessary, refer to Determining if a Secure Cluster is Enabled for Encryption Using the Control System on page 1803 to determine if the cluster is enabled for encryption of data at rest before enabling data-at-rest encryption on a volume.

NOTE: If you do not want to encrypt data at rest in a volume, disable encryption after you create a volume. You cannot modify data-at-rest encryption setting on a volume after the volume is created.

To enable or disable data-at-rest encryption for a new volume using the Control System:

Procedure

1. Log in to the Control System and click **Data** > **Volumes**.
2. Click **Create Volume** to display the **Create New Volume** page.
3. Select volume type, specify values for required and optional properties, and set the value for the **Data at Rest Encryption** property to **Yes** (to enable) or **No** (to disable).
   See Creating a Volume on page 1177 for more information.
4. Click **Create Volume** to create a volume enabled for encryption of data at rest.

Enabling or Disabling Data-at-Rest Encryption at the Volume Level Using the CLI and REST API

About this task

You can enable DARE at the volume level only if data-at-rest encryption is enabled at the cluster level. If necessary, refer to Determining if a Secure Cluster is Enabled for Encryption of Data at Rest Using the CLI and REST API on page 1805 to determine if the cluster is enabled for encryption of data at rest before enabling a volume for data-at-rest encryption.

NOTE: If you do not want to encrypt data at rest in a volume, disable encryption after you create that volume. You cannot modify data-at-rest encryption setting on a volume after the volume is created.

CLI	Set the value for the `dare` parameter to one of the following when you create the volume:
	• `true` to enable data-at-rest encryption.
	NOTE: `true` is the default value.
	For example:
	`maprcli volume create -name <volName> -path <volMountPath> [-dare true]`
	• `false` to disable data-at-rest encryption.
	For example:
	`maprcli volume create -name <volName> -path <volMountPath> -dare false`

REST	Send a request of type POST and set the value for the `dare` parameter to one of the following when you create the volume:
	• `true` to enable data-at-rest encryption.
	NOTE: This is the default value.
	For example:
	`curl -k -X POST 'https://abc.sj.us:8443/rest/volume/create?name=<volName>&path=<volMountPath>[&dare=true]' --user mapr:mapr`
	• `false` to disable data-at-rest encryption.
	For example:
	`curl -k -X POST 'https://abc.sj.us:8443/rest/volume/create?name=<volName>&path=<volMountPath>&dare=false' --user mapr:mapr`

See `volume create` on page 2588 for more information.

Converting to Cluster Enabled for Data-at-Rest Encryption

Enable data-at-rest encryption for a cluster.

About this task

Conversion of existing HPE Ezmeral Data Fabric clusters to data-at-rest encryption is not currently supported. If you need to convert an existing non-DARE cluster to DARE, contact HPE support.

Managing SSL Certificates

This section decribes how to manage certificates and keystores such as when encryption is initially not enabled or when a custom certificate is used.

Using Custom Signed Certificates with Object Store on page 589

Re-running configure.sh after Configuration

last-updated: Jun 06, 2024

If the `configure.sh` script is initially run without the `-genkeys` option, the script generates a `ssl_keystore` file for use by the web server for the Control System.

Then if the `configure.sh` script is re-run with the `-genkeys` option, the system detects the existing `ssl_*` files and exits with an error to prevent inadvertent deletion or reuse of the `ssl_keystore` file.

NOTE: For general information on certificates, see SSL Certificates on page 838.

To re-run `configure.sh` on clusters without security features enabled:

1. Manually delete the `ssl_keystore` file on each node.
2. Run the `configure.sh -genkeys -R` command.

NOTE: The contents of the `ssl_keystore` file are unique to each node.

To re-run `configure.sh` on clusters where the contents of the `ssl_keystore` file are customized:

1. Run the `configure.sh -genkeys -nocerts -R` command to preserve your customizations.

SSL Keys Error Message

The error message will look like the following example:

```
/opt/mapr/server/configure.sh
        -secure -genkeys -C $CLDB_GRP -Z $ZK_GRP -RM $RM -HS
        $HISTORYSERVER
        <hostname1>: Configuring Hadoop-2.x at
        /opt/mapr/hadoop/hadoop-2.x
        <hostname1>: Done configuring Hadoop
        <hostname1>: CLDB node list:
        <hostname1>:7222,<hostname2>:7222,<hostname3>:7222

        <hostname1>: Zookeeper node
        list: <hostname1>:5181,<hostname2>:5181,<hostname3>:5181

        <hostname1>: Node setup configuration: cldb fileserver
        historyserver nfs nodemanager resourcemanager webserver
        zookeeper
        <hostname1>: Log can be found at:
        /opt/mapr/logs/configure.log
        <hostname1>: /opt/mapr/conf/ssl_keystore already exists
        <hostname1>: ERROR: could not generate ssl keys. See log file
        for more details
        clush: <hostname1>: exited with exit code 1
```

General Security for Ecosystem Components

Ecosystem components in the MapR Converged Data Platform use the Java Authentication and Authorization Service (JAAS) for security configuration.

- **`/opt/mapr/conf/mapr.login.conf`** file-defines JAAS configurations
- **`MAPR_ECOSYSTEM_LOGIN_OPTS`** environment variable in the `/opt/mapr/conf/env.sh` file-specifies the JAAS configuration used by installed Ecosystem components

NOTE: See the Ecosystem Guide for component-specific security configuration information.

When security is enabled, the value of the `MAPR_ECOSYSTEM_LOGIN_OPTS` is modified to include the `hybrid` JVM option for `hadoop.login`. This is equivalent to setting the `-Dhadoop.login=hybrid` flag at the command line. This setting specifies a mixed security environment using Kerberos and MapR tickets.

last-updated: Jun 06, 2024

The `mapr.login.conf` file has two stanzas for hybrid security:

```
 /**
 * authenticate using hybrid of kerberos and MapR
 * maprticket must already exist on filesystem as MapR login module
 * cannot get kerberos identity from subject for implicit login.
 */

hadoop_hybrid {
  org.apache.hadoop.security.login.KerberosBugWorkAroundLoginModule optional
      useTicketCache=true
      renewTGT=true
      doNotPrompt=true;
  com.mapr.security.maprsasl.MaprSecurityLoginModule required
      checkUGI=false;
  org.apache.hadoop.security.login.GenericOSLoginModule required;
  org.apache.hadoop.security.login.HadoopLoginModule required
      principalPriority=com.mapr.security.MapRPrincipal;
};

hadoop_hybrid_keytab {
  org.apache.hadoop.security.login.KerberosBugWorkAroundLoginModule optional
      refreshKrb5Config=true
      doNotPrompt=true
      useKeyTab=true
      storeKey=true;
  com.mapr.security.maprsasl.MaprSecurityLoginModule required
      checkUGI=false
      useServerKey=true;
  org.apache.hadoop.security.login.GenericOSLoginModule required;
  org.apache.hadoop.security.login.HadoopLoginModule required
      principalPriority=com.mapr.security.MapRPrincipal;
};
```

Determining if a Cluster is Secure and Enabled for Encryption
Explains how to use the Control System, the CLI, and REST API to determine whether a cluster is secure and whether on-wire encryption and data-at-rest encryption are enabled at the cluster and volume levels.
Determining if a Cluster is Secure Using the Control System

Procedure

- Log in to the Control System and click  to display the **Security** page.
  The **Security** page contains information for determining whether the cluster is secure and enabled for on-wire encryption and/or data-at-rest encryption.

Determining if a Secure Cluster is Enabled for Encryption Using the Control System

Procedure

- Log in to the Control System on a secure cluster and click  to display the **Security** page.
  The page displays the following:
  - **Cluster-level Settings**—whether on-wire encryption and authentication, and data-at-rest encryption is enabled at the cluster-level. The pane shows:
    -  —if enabled
    -  —if disabled
  - **Volume Settings**—the number of volumes that are not enabled for:

- Data On-Wire Encryption
- Data-at-Rest Encryption

Click the number associated with Data On-Wire Encryption or Data-at-Rest Encryption to display the list of volumes filtered.

Determining if a Cluster is Secure Using the CLI and REST API

About this task

CLI

Run the following command to determine if a cluster is secure or unsecure:

```
/opt/mapr/bin/maprcli dashboard
info -cluster <clusterName> -json |
grep secure
```

The value for `secure` is `true` if secure and `false` if unsecure in the command output.

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://
10.10.82.24:8443/rest/dashboard/
info' --user mapr:mapr
{"timestamp":1525198793701,"timeofday"
:"2018-05-01 11:19:53.701 GMT-0700
AM","status":"OK","total":1,"data":
[{"version":"6.1.0.20180501072815.GA",
"cluster":
{"name":"ksTest","secure":true,"dare":

```

The value for `secure` is `true` if secure and `false` if unsecure.

If the value for `secure` is `true`, your cluster is enabled for on-wire encryption. See `dashboard info` on page 2108 for more information.

Determining if a Secure Cluster is Enabled for Encryption of Data at Rest Using the CLI and REST API

About this task

CLI

Run the following command to determine if a cluster is enabled or disabled for data-at-rest encryption:

```
/opt/mapr/bin/maprcli dashboard
info -name <clusterName> -json | grep
dare
```

The value for `dare` is `true` if enabled and `false` if disabled in the command output.

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://
10.10.82.24:8443/rest/dashboard/
info' --user mapr:mapr
{"timestamp":1525198793701,"timeofday"
:"2018-05-01 11:19:53.701 GMT-0700
AM","status":"OK","total":1,"data":
[{"version":"6.1.0.20180501072815.GA",

```

The value for `dare` is `true` if enabled and `false` if disabled.

See `dashboard info` on `page 2108` for more information.

Managing FIPS Security
The topics in this section describe how to learn about and manage your FIPS configuration.

Determining if a Host Is in FIPS Mode
Explains how to use the CLI, REST commands, or the Control System to determine if a host is in FIPS mode.
Determining if a Host Is in FIPS Mode Using the CLI and REST API

About this task
FIPS is a host-specific property, not a cluster-wide property. It is possible to have a mix of FIPS-compliant and non-FIPS compliant nodes in the same cluster.

Release 7.0.0 enhanced the output of the maprcli node list command to include a new `isFips` field name. When the value of `isFips` is `1`, the data-fabric core platform is in FIPS mode on the specified host. If the value is `0`, the core platform is in non-FIPS mode.

CLI

Run the `maprcli node list -json` command to determine if a node is in FIPS or non-FIPS mode:

```
$ maprcli node list -json
{
  "timestamp":1629755217258,
```

```
  "timeofday":"2021-08-23
02:46:57.258 GMT-0700 PM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "id":"3229336703213394432",
      "ip":"10.163.166.250",

"hostname":"fips0.storage.hpecorp.net"
,
      "racktopo":"/data/default-rack/
fips0.storage.hpecorp.net",
      "labels":[
        "default"
      ],
      "isFips":1,
      "health":0,
      ...
```

Another option is to run the `sysctl crypto.fips_enabled` command. This is the command that the `configure.sh` script uses to determine if the operating system is FIPS-enabled:

```
sudo sysctl crypto.fips_enabled
crypto.fips_enabled = 1
```

Another option is to run the following command:

```
fips-mode-setup --check
FIPS mode is enabled.
```

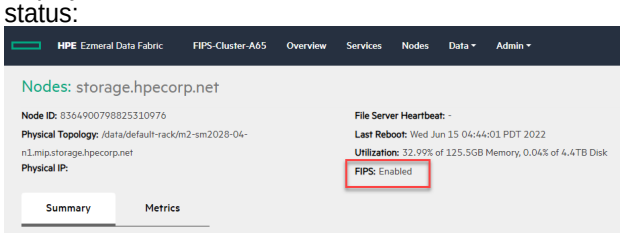
REST

Use the REST equivalent of the `maprcli node list` command, which returns the `isFips` value for each node:

```
curl -u mapr:mapr -X GET -k "https://
host:8443/rest/node/list"
```

Control System

On the **Nodes** page, double-click a **Hostname** to display node-detail information that includes the FIPS status:



You can also customize the **Nodes** pane on the **Nodes** page to include the FIPS status. See Viewing the list of Nodes on page 1104 and Customizing the List of Columns/Fields on page 1105.

Using the Java keytool with Bouncy Castle Key and Trust Stores

Use the Java `keytool` command to manipulate key and trust stores, which includes listing the aliases or contents, exporting certificates, and merging trust stores.

keytool Requires Additional Parameters

The Bouncy Castle BCFKS provider is not installed as part of the JDK but is bundled with the HPE Ezmeral Data Fabric core distribution. The Java `keytool` command needs additional options to specify the BCFKS provider and path. The following example of the keytool command shows how to view the `fips9.cluster.com` alias. Boldface items are additional, required, and highlighted parameters.

```
{JAVA_HOME}/bin/keytool -list -alias fips9.cluster.com \
    -storepass JNMdxFTlFZ5iMlusFE4l0oaqV06InHYr \
    -keystore /opt/mapr/conf/ssl_keystore.bcfks \
    -storetype bcfks \
    -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
    -providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
    -providername BCFIPS \
```

FIPS-Approved Key and Trust Stores

Two key and trust stores are approved for hosts in FIPS mode:

- For Java applications, the Bouncy Castle BCFKS key and trust stores are used. This is new for release 7.0.0.
- For non-Java applications, the existing PKCS#12 key and trust stores, as well as PEM files are used. The `keytool` command cannot be used for the PKCS#12 key and trust stores in FIPS mode. You must use the openssl PKCS 12 commands.

Key and Trust Stores for Java Applications

The Bouncy Castle FIPS-approved BCFKS store format is the only store type that is used by the HPE Ezmeral Data Fabric core platform if FIPS mode is enabled. In addition to the regular parameters for manipulating BCFKS key and trust stores, you must specify the boldface parameters shown in the following examples.

For example, supposing the key store password is `4HHXZzoU665Lt_ZOyLNMAtqnW_t7SQcT`. (Obtain key and trust store passwords from the key or trust store property in `${MAPR_HOME}/conf/store-passwords.txt` after installation.) Use a new `keytool` to generate a key pair, and add it to the key store as shown below:

```
# keytool -keystore /opt/mapr/conf/ssl_keystore.bcfks \
  -storetype BCFKS \
  -providername BCFIPS \
  -providerclass org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
\
  -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
  -providerpath bc-fips-1.0.2.jar \
  -alias hpe188.cluster.com \
  -genkeypair -sigalg SHA512withRSA -keyalg RSA -storepass
4HHXZzoU665Lt_ZOyLNMAtqnW_t7SQcT \
  -dname CN=hpe188.cluster.com -keypass 4HHXZzoU665Lt_ZOyLNMAtqnW_t7SQcT
```

To import a certificate into the key store manually:

```
# keytool -keystore /opt/mapr/conf/ssl_keystore.bcfks \
  -storetype BCFKS \
  -providername BCFIPS \
  -providerclass org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
\
  -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
  -providerpath bc-fips-1.0.2.jar \
  -alias qaclient \
```

last-updated: Jun 06, 2024

```
  -storepass 4HHXZzoU665Lt_ZOyLNMAtqnW_t7SQcT \
  -keypass 4HHXZzoU665Lt_ZOyLNMAtqnW_t7SQcT \
  -import \
  -file <path-to-certificate-file>
```

To view the contents of the keystore, use the `keytool` command. The `storetype, providername, providerclass, provider, providerpath, alias` and `storepass` options are required. The `storetype, providername, providerclass, provider,` and `providerpath` fields must always be set to the boldface values as shown below:

```
# keytool -keystore /opt/mapr/conf/ssl_keystore.bcfks \
  -storetype BCFKS \
  -providername BCFIPS \
  -providerclass org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
\
  -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
  -providerpath bc-fips-1.0.2.jar \
  -alias hpe186.cluster.com\
  -storepass 4HHXZzoU665Lt_ZOyLNMAtqnW_t7SQcT \
  -list
hpe186.cluster.com, Mar 1, 2021, trustedCertEntry,
Certificate fingerprint (SHA-256):
69:30:5A:50:6F:4C:17:7F:CD:EA:B3:F9:FE:FE:96:A5:40:05:C2:FF:76:C0:86:35:1E:9
3:E9:A5:2C:12:96:C3
```

Key and Trust Store Password Protection

This section describes how keystore and truststore passwords are protected.

Password Protection in Release 6.2.0 and Earlier Releases

In release 6.2.0 and earlier releases of the HPE Ezmeral Data Fabric, key and trust store passwords are stored in clear text in the Hadoop `ssl-server.xml` and `ssl-client.xml` configuration files. They are the same for both key and trust stores. The following example shows how the passwords (in **boldface**) are configured in `${MAPR_HOME}/hadoop/hadoop-${HADOOP_VERSION}/etc/hadoop/ssl-server.xml`.

```
<configuration>
...
<property>
  <name>ssl.server.truststore.password</name>
  <value>AB8F93FAA45393F84BD358d0</value>
  <description>Optional. Default value is "".
  </description>
</property>
...
<property>
  <name>ssl.server.keystore.password</name>
  <value>AB8F93FAA45393F84BD358d0</value>
  <description>Must be specified.
  </description>
</property>
<property>
  <name>ssl.server.keystore.keypassword</name>
  <value>AB8F93FAA45393F84BD358d0</value>
  <description>Must be specified.
  </description>
</property>
...
</configuration>
```

Key store protection for release 6.2.0 and earlier is by file permissions. There is no protection for trust store passwords since the file permissions are world readable. Using the same password for both key and trust stores is undesirable. Key stores contain sensitive private keys that should be made available only to server applications that need them. Trust stores contain certificates that should be made available to server and client applications.

=

Password Protection in Release 7.0.0 and Later

In release 7.0.0, distinct passwords are generated: One for the key store and one for the trust store. Note that the key store password (used to protect the entire keystore) and key store key password (used to protect the keys in the keystore) are the same. Many applications expect them to be the same, especially for P12 key stores.

The following example shows how passwords (shown in **boldface**) are configured in release 7.0.0 in `${MAPR_HOME}/hadoop/hadoop-${HADOOP_VERSION}/etc/hadoop/ssl-server.xml` in a non-secure installation. (In secure installations, the clear-text passwords are removed from these configuration files and kept in the Hadoop Credentials stores.)

```
<configuration>
...
<property>
  <name>ssl.server.truststore.password</name>
  <value>895FA43FE91344DB98/_K35</value>
  <description>Optional. Default value is "".
  </description>
</property>
...
<property>
  <name>ssl.server.keystore.password</name>
  <value>AB8F93FAA45393F84BD358d0</value>
  <description>Must be specified.
  </description>
</property>
<property>
  <name>ssl.server.keystore.keypassword</name>
  <value>AB8F93FAA45393F84BD358d0</value>
  <description>Must be specified.
  </description>
</property>
...
</configuration>
```

Password Protection with the Hadoop Credential Provider API
This section describes the credential stores on FIPS-enabled and secure non-FIPS-enabled hosts.

The previous section shows how distinct key and trust store passwords are stored on a non-secure host. On a secure host, the passwords are encrypted, and the passwords no longer appear in the Hadoop configuration files (`ssl-client.xml` and `ssl-server.xml`). They are stored in the credential stores and protected using the Hadoop Credential Provider API.

Credential Stores on a FIPS-Enabled Host

On a FIPS-enabled host, the credential stores are in BCFKS format.

Key Store Passwords	The key store passwords are encrypted in the BCFKS key credential store: `${MAPR_HOME}/conf/`

`maprkeycreds.bcfks`. To view the list of aliases in the BCFKS key credential store:

```
hadoop credential list -provider \
         localbcfks://file/opt/mapr/
conf/maprkeycreds.bcfks
ssl.server.keystore.password
ssl.server.keystore.keypassword
ssl.client.keystore.password
ssl.client.keystore.keypassword
```

Trust Store Passwords

The trust store passwords are encrypted in the BCFKS trust credential store: `${MAPR_HOME}/conf/maprtrustcreds.bcfks`. To view the aliases in the BCFKS trust credential store:

```
hadoop credential list -provider \
         localbcfks://file/opt/mapr/
conf/maprtrustcreds.bcfks
ssl.server.truststore.password
ssl.client.truststore.password
```

If you omit the `-provider` option, the `hadoop credential list` command returns the aliases for the trust store passwords by default, since they are configured in `core-site.xml`. You must specify the `-provider` argument only if you want to view the aliases in the key store.

Key and Trust Store Providers

The Hadoop `${MAPR_HOME}/hadoop/hadoop-${HADOOP_VERSION}/etc/hadoop/core-site.xml` is configured with the BCFKS key and trust store providers:

```
<configuration>
  <property>

<name>hadoop.security.credential.provi
der.path</name>

    <value>localbcfks://file/opt/mapr/
conf/maprkeycreds.bcfks,localbcfks://
file/opt/mapr/conf/
maprtrustcreds.bcfks</value>
    <description>Location of key and
trust store credential file</
description>
  </property>
</configuration>
```

Credential Stores on a Non-FIPS-Enabled Host

On a non-FIPS-enabled host, the credential stores are in JCEKS format.

Key Store Passwords

The key store passwords are encrypted in the JCEKS key credential store: `${MAPR_HOME}/conf/`

`maprkeycreds.jceks`. To view the list of aliases in the JCEKS key credential store:

```
hadoop credential list -provider \
         localjceks://file/opt/mapr/
conf/maprkeycreds.jceks
ssl.server.keystore.password
ssl.server.keystore.keypassword
ssl.client.keystore.password
ssl.client.keystore.keypassword
```

Trust Store Passwords

The trust store passwords are encrypted in the JCEKS trust credential store: `${MAPR_HOME}/conf/maprtrustcreds.jceks`. To view the aliases in the JCEKS trust credential store:

```
hadoop credential list -provider \
         localjceks://file/opt/mapr/
conf/maprtrustcreds.jceks
ssl.server.truststore.password
ssl.client.truststore.password
```

If you omit the `-provider` option, the `hadoop credential list` command returns aliases for trust store passwords by default since they are configured in `core-site.xml`. Specify the `-provider` argument only to view aliases in the key store.

Key and Trust Store Providers

The Hadoop `${MAPR_HOME}/hadoop/hadoop-${HADOOP_VERSION}/etc/hadoop/core-site.xml` is configured with the JCEKS key and trust store providers:

```
<configuration>
  <property>

<name>hadoop.security.credential.provi
der.path</name>

    <value>localjceks://file/opt/mapr/
conf/maprkeycreds.jceks,localjceks://
file/opt/mapr/conf/
maprtrustcreds.jceks</value>
    <description>Location of key and
trust store credential file</
description>
  </property>
</configuration>
```

Password Protection for Non-Java Applications

This section describes an alternative mechanism that non-Java applications can use to access the key and trust store passwords.

As described in the previous section, the Hadoop Credential Provider API protects key and trust store passwords by storing them in an encrypted Java credential store. Non-Java applications cannot access the Hadoop credential store. An alternative mechanism is needed for non-Java applications to retrieve:

- Passwords needed to access the PKCS#12 key and trust stores
- Private keys that are encrypted with a key store password

To protect passwords for non-Java applications, store key store passwords in `maprkeycreds.conf` and trust store passwords in `maprtrustcreds.conf` in `${MAPR_HOME}/conf`. `${MAPR_HOME}/conf` is created by the `${MAPR_HOME}/conf/configure.sh -genkeys` script.

The format of each line of the `maprkeycreds.conf` and `maprtrustcreds.conf` file is is shown below.

```
<password property>=ENC:<code>:<checksum>:<Base64 encrypted password>
```

The table below list keys and provide and key escriptions.

Key	Description
`password property`	The password property in `ssl-client.xml` or `ssl-server.xml`. For example: `ssl.server.keystore.password`
`ENC`	Indication that the password is encrypted.
`code`	Encryption code to denote the type of algorithm used for encryption. For release 7.0.0, the code is always `1` to denote AES-256-CTR using PBKDF2 with 20000 iterations. The password used to derive the encryption key is obtained in an identical way from the Hadoop Credential Provider API (it is obtained from the value of the environment variable `HADOOP_CREDSTORE_PASSWORD` and defaults to `none` if `HADOOP_CREDSTORE_PASSWORD` is not set).
`checksum`	The SHA-256 checksum used to verify that the password is correctly decrypted. Upon decryption, the application should compute the SHA-256 checksum on the decrypted password and verify that it matches this checksum.
`Base-64 encrypted password`	The encrypted password in Base-64 encoding.

For example:

```
pwd
/opt/mapr/conf
cat maprkeycreds.conf
ssl.server.keystore.password=ENC:1:b8f9933aa5af6d9d2c0706fec5156fba5233546ac
3bce8213524353b5c70c42f:U2FsdGVkX1+OYGv5p/
2c3nYXw3u2EYax2N9Y7GpfQKeifFkskdDYA17XEqUkinAf7Q==
ssl.server.keystore.keypassword=ENC:1:b8f9933aa5af6d9d2c0706fec5156fba523354
6ac3bce8213524353b5c70c42f:U2FsdGVkX18LDAUdN66mdVxmt8k8xQo2vAnQJ5xw7V/
enAOq3fQ1NVXOPpi1J027Bg==
ssl.server.truststore.password=ENC:1:e7a15c233a1252a17e6a8a07c2cb397017ecd93
9224593d2327d381cbb56ab54:U2FsdGVkX1+sPmXLhP26sPWC3mi2MD6yRYeVnFOauBEnPVd69+
rGuPE2qoxFcXoJ9A==
```

Applications can use the `openssl` command to decrypt the password. In the following example, replace the default decryption key of `none` with the actual decryption key, which is either the value of the environment variable `HADOOP_CREDSTORE_PASSWORD` or the default value `none`. For example:

```
echo
"U2FsdGVkX18Qbi4OXoFrPDjQhVtJAzzP+fsyHmAgXKcz5OanmpaQZIOfpNENlZPwIw==" |
openssl enc -aes-256-ctr -iter 20000 -pass pass:none -base64 -md
sha256 -A -d
8M2HdpkZxjb1QLVHG2lx_Dtg_bg870gS
```

To verify that the password is correctly decrypted, use the `openssl dgst` command to obtain the SHA-256 signature of the decrypted password. Then verify that it matches the value configured in the checksum field in `maprkeycreds.conf` or `maprtrustcreds.conf`. For example:

```
echo "8M2HdpkZxjb1QLVHG2lx_Dtg_bg870gS" | \
  openssl dgst -sha256 | awk '{print $2}'
b8f9933aa5af6d9d2c0706fec5156fba5233546ac3bce8213524353b5c70c42f
```

To reduce the duplication of code to retrieve these passwords for non-Java applications, `common-ecosystem.sh`, which is already used by most MEP/EEP components, now includes a routine that implements the above steps. Its interface looks like the following:

```
getStorePw() {
    # routine expects 2 or 3 inputs
    # key to lookup - like ssl.server.keystore.password
    # file to look in - like /opt/mapr/conf/maprkeycreds.conf
    # optional password, if not provided, $HADOOP_CREDSTORE_PASSWORD is
used if set,
    # otherwise none
    #
    # returns pw on success otherwise error messages
    # rc=0 on success - 1 otherwise
    #
    # called like:
    #  pw=$(getStorePw ssl.server.keystore.password /opt/mapr/conf/
maprkeycreds.conf)
    #  if [ $? -ne 0 ]; then
    #      echo "got an error: $pw"
    #      ...
    #  fi
```

Since many ecosystem components need to work in both core 6.2.0- and core 7.0.0 environments, an ecosystem `configure.sh` (or supporting script) must deal with both environments. Example usage would look like the following (assume `maprKeyCredsConf` is set to `$MAPR_HOME/conf/maprkeycreds.conf`):

```
keystorePass="$(grep -F -A 1 ssl.server.keystore.password $sslServerConf |
tail -1 | sed 's/ *<value>//;s/<\/value>//')"

if [ "$keystorePass" = "__##CREDENTIALS_STORE##__" ] || [ -z
"$keystorePass" ] && [ -e "$maprKeyCredsConf" ]; then

    keystorePass=$(getStorePw ssl.server.keystore.password
$maprKeyCredsConf
    rc=$?
    if [ $rc -ne 0 ]; then
        echo "Failed to extract keystore password: $keystorePass"
    fi
fi
```

Similar code is expected to be done for the trust store password.

In addition, if a non-Java EEP component requires a private key in PEM format, additional work is required to protect the unencrypted private key or the password for the encrypted private key.

For a component that requires an unencrypted private key pem file, the requirement is that its init/start script must generate the pem key, start the process, and then remove the key after the process is up and running. This assumes that the service does not negatively react to the change in the key file (from containing the key to empty).

last-updated: Jun 06, 2024

Using Grafana, which needs an unencrypted private key, as an example, you can generate an empty key PEM file during `configure.sh` stage. After Warden starts Grafana, the Grafana init/start script extracts the keystore password, and uses that to decrypt the encrypted pem key. Then it puts the unencrypted private key into the `key.pem` file that Grafana requires right before it is started. Additional code is added to the init/start script to detect when the service is fully up and has read the pem key, before zeroing out the file. On an unsuccessful start, the pem key file is also zeroed out.

Similarly, for a service that can use an encrypted private key, but reasonably requires the password for the key in a config file, the password in the config file should only be there during startup. The init/start script must then aquire the required password, edit the config file to fill it in, start the process, and then remove it from the config file. (This only works for processes that do not monitor changes in the config file and restart.)

Protection of CLDB and DARE Master Keys
This section describes how the CLDB key and DARE master keys are encrypted and stored during normal operations.

In release 6.2, if used without HSM integration, the CLDB key is encrypted using a weak hard-coded key and stored in Base-64 format in `${MAPR_HOME}/conf/cldb.key`. The DARE master key is stored in clear text in hexadecimal format in `${MAPR_HOME}/conf/dare.master.key`. Both files are protected only by file permissions. The files need to be encrypted and protected using FIPS-approved algorithms.

Release 7.0.0 and later encrypt and store these keys using the PKCS#11 interface and the `mrhsm` tool. Using `configure.sh` with the `-genkey` option automatically generates the keys inside the HSM. In this case, the HSM could be the HSM that was introduced in release 6.2.0 or the HSM inside the newly introduced file store, which is `${MAPR_HOME}/conf/tokens`. Upgrades also automatically upgrade `mrhsm` configurations to support the file store and store existing keys inside the PKCS #11 file store if the legacy `cldb.key` or `dare.master.key` are found.

Note these important considerations:

- Instead of backing up the `cldb.key` and `dare.master.key` as recommended in previous versions, users are encouraged to back up the `${MAPR_HOME}/conf/tokens` directory as well as the `${MAPR_HOME}/conf/maprhsm.conf` file. These are both essential to retrieve the keys.
- During configuration, instead of copying key files, users must copy the `${MAPR_HOME}/conf/tokens` directory as well as the `${MAPR_HOME}/conf/maprhsm.conf` file to other CLDB nodes in the cluster.
- MFS-only nodes still need an empty `${MAPR_HOME}/conf/dare.master.key` file to detect that DARE is enabled. This file does NOT need to contain the actual key.
- During an upgrade, the `cldb.key` and `dare.master.key` are left intact and untouched even though we expect to have them stored in the PKCS#11 file store. It is a best practice to remove them from the node and store them in a safe location in case they are needed again.

Removing Clear-Text Passwords After Upgrade
Upon upgrade to release 7.0.0 or later, any clear-text passwords that existed in `ssl-client.xml` and `ssl-server.xml` in a pre-7.0.0 release are preserved by default. Remove these passwords by using a `configure.sh` command option.

Preserving the clear-text passwords during an upgrade maintains backward compatibility for any existing custom applications that rely on the passwords. However, data-fabric core components do not use any of these clear-text passwords.

In release 7.0.0, performing a new installation removes all clear-text passwords from the `ssl-client.xml` and `ssl-server.xml` files. On upgrade, the clear-text passwords are retained by default, but you can override this default to remove the passwords as well.

Passwords are stored in encrypted format in the Hadoop Credential Provider stores which is already configured in `ssl-server.xml`. Client applications should add the `core-site.xml` resource using the `Configuration.addResource()` Hadoop API to access the trust store credential provider.

Users who upgrade from a previous installation might have written custom applications that use `ssl-client.xml` and `ssl-server.xml` that they are unable to change. You can still proceed with the upgrade. Confirm that any custom applications continue to run correctly with encrypted credential files, and remove a clear-text password using the following configure.sh on page 2821 command:

```
/opt/mapr/server/configure.sh -R -removePasswordsInXML
```

Manipulating Key and Trust Stores

This section describes how the key and trust stores can be used in the Java `keytool` utility and how they can be manipulated using the `manageSSLKeys.sh` command.

Merging Trust Stores

Use the `manageSSLKeys.sh merge` command to merge two trust stores. This operation is required if you configure cross-cluster connectivity for server nodes or for client nodes that connect to multiple clusters.

Parameters for the `manageSSLKeys.sh merge` command are as shown below.

```
/opt/mapr/server/manageSSLKeys.sh merge \
    <in trust store> <out trust store> [inPassword [outPassword]]
```

The following table describes each `manageSSLKeys.sh merge` parameter:

Parameter	Description
`In trust store`	The input trust store for the destination cluster. Before running the command, copy the trust store from the destination cluster to a file in the current cluster.
`Out trust store`	The output trust store for the current cluster. This is typically `/opt/mapr/conf/ssl_truststore.bcfks` for FIPS-enabled nodes or `/opt/mapr/conf/ssl_truststore` for secure non-FIPS nodes.
`inPassword`	The password for `in trust store` or the path to a file containing the password.
`outPassword`	The password for `out trust store` or the path to a file containing the password.

The following example shows how to use the `manageSSLKeys.sh merge` command. Before merging the trust stores, note the two certificates: one for the root CA and the other for the server certificate.

```
# keytool -list -keystore /opt/mapr/conf/ssl_truststore.bcfks \
    -storepass eEJz0u2_Bmp46UrH_gH90rjjqT_LJu0u \
    -storetype bcfks \
    -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
    -providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
    -providername BCFIPS
Keystore type: BCFKS
Keystore provider: BCFIPS

4:BC:2C:48:28:60:1C
```

last-updated: Jun 06, 2024

First copy the trust store for the other cluster to a location in the directory path. Use the `keytool` command to verify the contents of the trust store to be merged. You will need the trust store password of the remote cluster.

```
# keytool -list -keystore ssl_truststore.bcfks.fips1 \
    -storepass xjxL_K9qfrbsfH6TSscizoSiFSVMLECg \
    -storetype bcfks \
    -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
    -providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
    -providername BCFIPS

Keystore type: BCFKS
Keystore provider: BCFIPS

Your keystore contains 2 entries

fips1.cluster.com, Sep 17, 2021, trustedCertEntry,
Certificate fingerprint (SHA-256):
BD:BB:7B:C2:2F:2E:C7:26:7E:D2:BF:DF:CA:8B:CA:D5:2A:01:7C:CC:4D:46:45:22:7C:9
8:07:9A:51:80:21:EB
fips1.cluster.com-root-ca-chain, Sep 17, 2021, trustedCertEntry,
Certificate fingerprint (SHA-256):
46:45:28:69:73:CB:10:06:42:B9:9C:55:F2:44:0F:70:4D:A2:1D:8B:20:45:17:C4:47:D
0:51:F8:30:74:7D:9A
```

Next merge the trust stores. In this example, `ssl_truststore.bcfks.fips1` is the trust store for the remote cluster to be connected.

```
# /opt/mapr/server/manageSSLKeys.sh merge \
    ssl_truststore.bcfks.fips1 /opt/mapr/conf/ssl_truststore.bcfks \
    xjxL_K9qfrbsfH6TSscizoSiFSVMLECg \
    eEJz0u2_Bmp46UrH_gH90rjjqT_LJu0u
Merging certificates from ssl_truststore.bcfks.fips1 into existing /opt/
mapr/conf/ssl_truststore.bcfks
```

After the command completes successfully, use the `keytool` command to verify that the trust stores are successfully merged.

```
# keytool -list -keystore ssl_truststore.bcfks \
    -storepass eEJz0u2_Bmp46UrH_gH90rjjqT_LJu0u \
    -storetype bcfks \
    -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
    -providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
    -providername BCFIPS

Using Key and Trust Store Passwords in Keytool
Use the Java `keytool` command to manipulate key and trust stores.

To manipulate key and trust store passwords in `keytool`, use both passwords. Passwords saved in the Hadoop Credential Provider stores cannot be retrieved by using command-line utilities. They can only be retrieved from within Java applications.

Running the `configure.sh` utility with the `-genkeys` option creates the `${MAPR_HOME}/conf/store-passwords.txt` file containing the clear-text key and trust store passwords. You need these passwords if you want to manipulate the key and trust stores using the Java `keytool` utility. It is a best practice to copy the `${MAPR_HOME}/conf/store-passwords.txt` file to a safe place, and then delete it from the `${MAPR_HOME}/conf` directory.

Each line of the `${MAPR_HOME}/conf/store-passwords.txt` file contains the password in the following syntax:

`password-property=password-value`

The `password-property` is the value of the password property in `ssl-server.xml` and `ssl-client.xml`. The `password-value` is the clear-text password. For example:

```
# cat /opt/mapr/conf/store-passwords.txt
ssl.server.keystore.password=AxWJOT4K_Arc2apgcypzZps_hr5lyYNQ
ssl.server.keystore.keypassword=AxWJOT4K_Arc2apgcypzZps_hr5lyYNQ
ssl.server.truststore.password=4i0upzuDDUpvwpxb9_417gmfH0kvlB1w
ssl.client.truststore.password=4i0upzuDDUpvwpxb9_417gmfH0kvlB1w
ssl.client.keystore.password=AxWJOT4K_Arc2apgcypzZps_hr5lyYNQ
ssl.client.keystore.keypassword=AxWJOT4K_Arc2apgcypzZps_hr5lyYNQ
```

Converting Between Key and Trust Store Formats
Describes enhancements to the `manageSSLKeys.sh convert` command to enable the conversion of key and trust stores from JKS to BCFKS format or vice versa.

Release 7.0.0 enhanced the `convert` command in the `${MAPR_HOME}/server/manageSSLKeys.sh` utility to support the conversion of key and trust stores from JKS to BCFKS format and vice versa. Key- and trust-store conversion is required if you configure mixed clusters containing both FIPS and non-FIPS enabled nodes. For example:

- Adding a secure non-FIPS node to an existing cluster consisting of only FIPS-enabled nodes.
- Adding a FIPS-enabled node to an existing cluster consisting of only secure non-FIPS enabled nodes.

The node being added can be a server node, such as a CLDB, MFS-only, or another server or client node. Since the JKS store type is not supported on FIPS-enabled node, this command must be run on a secure non-FIPS node.

- If you are adding a secure non-FIPS node to an existing cluster consisting of only FIPS-enabled nodes, copy the BCFKS key or trust store from the `${MAPR_HOME}/conf` directory of the FIPS-enabled node to a temporary location in the secure non-FIPS node. Do so before running the `manageSSLKeys.sh convert` command. Specify the destination location as `${MAPR_HOME}/conf/<store>` in the `manageSSLKeys.sh convert` command so that the newly converted JKS key or trust store is written to the `${MAPR_HOME}/conf` directory.

- If you are adding a FIPS-enabled node to an existing cluster consisting of only secure non-FIPS-enabled nodes, the source JKS-format key or trust store already exists in the `${MAPR_HOME}conf` directory of the secure non-FIPS node. It can then be used directly as the source file in `manageSSLKeys.sh convert`. There is no need to copy it. After the key/trust store is converted to BCFKS format, copy the newly converted BCFKS key/trust store from the temporary location in the secure non-FIPS enabled node to the `${MAPR_HOME}/conf` directory of the FIPS enabled node.

After the converted JKS (for secure non-FIPS) or BCFKS (for FIPS) is added to the `${MAPR_HOME}/conf` directory, run `configure.sh` with the `-storepasswds` parameter to generate the credential stores and complete the configuration. This process is described in greater detail in Enabling Security on page 1776.

The basic syntax for the `manageSSLKeys.sh convert` command with new arguments in bold face is shown below.

```
/opt/mapr/server/manageSSLKeys.sh convert \
    [-N <clustername> ] [-k] [-n] [-p <passwd>]
    [-srcType JKS|bcfks|pkcs12] [-dstType JKS|bcfks|pkcs12]
    <in key/trust store> <out key/trust store>
```

Conversion between JKS and BCFKS key and trust stores require the arguments listed in the table below.

Parameter	Description
`-p <passwd>`	The password for the source key or trust store. The destination key or trust store is set to the same password.
`-srcType`	The type of the source key or trust store. Supported types for conversion are `JKS` or `bcfks`. The value of the `-srcType` argument must be different from the `-dstType` argument. That is, if the `-srcType` is `JKS`, then the `-dstType` should be `bcfks`, and vice versa.
`-dstType`	The type of the destination key or trust store. Supported types for conversion are `JKS` or `bcfks`. The value of the `-dstType` argument must be different from the `-srcType` argument. For example, if the `-dstType` is `JKS`, then the `-srcType` should be `bcfks`, and vice versa.
`In key/trust store`	Full or relative path name of the source key or trust store to convert from. This store must exist.
`Out key/trust store`	Full or relative path name of the destination key or trust store which holds the same contents as the source key or trust store but in a different store format. If this file does not exist, it is created. If the file already exists, the contents are overwritten.

Example: Converting JKS to BCFKS Store

The following example converts the JKS trust store in `/opt/mapr/conf/ssl_truststore` to BCFKS format, and places the BCFKS trust store in `ssl_truststore.bcfks` in the current directory. This conversion is the case if you are adding a FIPS-enabled node to a cluster containing only secure non-FIPS nodes. Upon successful creation of the BCFKS key or trust store, copy it to the FIPS-enabled node before running `configure.sh` on that node to complete the configuration.

```
# /opt/mapr/server/manageSSLKeys.sh convert \
    -p BrqLhVcjGmYo8y5_qABS6YZetRpKfpqB \
    -srcType JKS \
    -dstType bcfks \
    /opt/mapr/conf/ssl_truststore \
    ssl_truststore.bcfks
```

last-updated: Jun 06, 2024

Verify that the BCFKS trust store is correctly converted by verifying that both source JKS and destination BCFKS trust stores have the same contents with the same fingerprints.

```
# keytool -list -keystore /opt/mapr/conf/ssl_truststore -storepass
BrqLhVcjGmYo8y5_qABS6YZetRpKfpqB
Keystore type: JKS
Keystore provider: SUN

C:62:9B:81:B8:78:7F
```

Example: Converting BCFKS to JKS Store

The following example converts the BCFKS trust store to JKS format when adding a secure non-FIPS node to a cluster containing only FIPS-enabled nodes. Only secure non-FIPS nodes can support both the JKS and BCFKS store formats. First, copy the BCFKS store from the FIPS-enabled node to a temporary directory in the secure non-FIPS node. Upon successful creation of the JKS key or trust store, run `configure.sh` to complete the configuration.

```
# /opt/mapr/server/manageSSLKeys.sh convert \
    -p 4hmQRWSpkMj0oWNT_0UEa_kD9djXpgb4 \
    -srcType bcfks \
    -dstType JKS \
    ssl_truststore.bcfks \
    /opt/mapr/conf/ssl_truststore
```

last-updated: Jun 06, 2024

Verify that the JKS trust store is correctly converted by verifying that both source BCFKS and destination JKS trust stores have the same contents with the same fingerprints.

```
# keytool -list -keystore ssl_truststore.bcfks \
    -storepass 4hmQRWSpkMj0oWNT_0UEa_kD9djXpgb4 \
    -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
     -providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
    -providername BCFIPS -storetype bcfks
Keystore type: BCFKS
Keystore provider: BCFIPS

Creating Credential Stores
Describes the `manageSSLKeys.sh createcreds` command that can be used to create credential stores that are compatible with the Hadoop Credential Provider API.

A new command `createcreds` is provided in the `${MAPR_HOME}/server/manageSSLKeys.sh` utility to create credential stores compatible with the Hadoop Credential Provider API. This command is normally invoked internally from the `${MAPR_HOME}/server/configure.sh` script when configuring a mixed cluster consisting of FIPS and non-FIPS nodes. The command can also be used independently to recreate credential stores that are somehow missing or corrupted.

Here is the command syntax:

```
${MAPR_HOME}/server/manageSSLKeys.sh createcreds \
    [-k <password>] \
    -t <trustpass> \
    -ug <maprUserGroup>
```

The following table describes the command parameters.

Parameter	Description
`-k`	Key store password. If not specified, the key credential file is not created.
`-t`	Trust store password for creating the trust credential file. This parameter is required.
`-ug`	Data-fabric user and group. For example: `mapr:mapr`. This parameter is required.

Changing Key and Trust Store Passwords
Change key and trust store passwords by using the `${MAPR_HOME}/server/manageSSLKeys` utility.

Release 7.0.0 added a new `changepassword` command to the `${MAPR_HOME}/server/manageSSLKeys` utility. The existing `copywithconfiguredpassword` and `createrandompassword` commands remain for upgrade purposes but are deprecated starting with release 7.0.0.

To change the key store password, you must provide the current key store password with the `-k` option. To change the trust store password, you must provide the current trust store password with the `-t` option. To set the new user-selectable password, use the `-kp` or `-tp` option. Otherwise, a random password is created. Note that you must pair the `-kp` and/or `-tp` options with the `-k` and/or `-t` options, respectively. For example:

```
# /opt/mapr/server/manageSSLKeys.sh changepassword  \
                      -k 8zVMhs8RtLDXpnTTIBqQkt_q_pFFV3I_ \
                      -t 5eqHoTrLRaiev6dwxJhfzm3qpPqW_0J2
```

To change the password:

1. Run the `manageSSLKeys.sh changepassword` command on the first node in the cluster. Running the command creates a directory under `/tmp`, with new password files and a script. A new `store-passwords.txt` is also created in this directory. It is a best practice to keep the passwords in this file and delete `store-passwords.txt` from the `/tmp` directory.

2. Stop ZooKeeper and Warden on all nodes in the cluster.

3. Distribute the above directory to all nodes in the cluster.

   NOTE: Instead of distributing the directory to all nodes in the cluster, run the `manageSSLKeys.sh changepassword` command used in step 1 on each node. This option eliminates file type and format issues in a cluster on both FIPS and non-FIPS nodes.

4. On each node in the cluster, make sure they have the correct ownership and permissions, and then run `copyPasswordFiles.sh` from this directory.

5. Run `configure.sh -R` on all nodes to allow all services to update their configuration.

6. Start ZooKeeper and Warden on all nodes in the cluster.

The security-file type and format are different on FIPS- and non-FIPS-enabled nodes. You cannot copy the modified passwords across FIPS to non-FIPS or vice versa. To change a password with both FIPS and non-FIPS nodes in a cluster, run the procedure twice: once on the FIPS node and once on the non-FIPS node. Only copy the generated files to, and run the script on, nodes with the same FIPS or non-FIPS type.

Application Development with Encrypted Key and Trust Stores

This section describes application development requirements for users writing custom applications for encrypted key and trust stores in both FIPS and non-FIPS modes.

Support for Encrypted Key and Trust Stores

Release 7.0.0 uses Hadoop 2.7.6, so by default HADOOP_HOME is `${MAPR_HOME}/hadoop/hadoop-2.7.6`.

Beginning with release 7.0.0, clear-text passwords are removed from the Hadoop `ssl-server.xml` and `ssl-client.xml` configuration files. For Java applications, key and trust store passwords are now protected in credential stores accessible through the Hadoop Credential Provider API.

Credential store provider settings differ depending on whether the node is a non-FIPS secure node or a FIPS-enabled node., due to the difference in store types. In addition, the provider settings differ depending on whether the application requiring access is a client or server application. Client applications only require access to trust stores to retrieve both keys and certificates. Server applications require access to both key and trust stores so that they can retrieve private keys as well as certificates.

Credential Provider Configuration for Client Applications

After running `configure.sh`, the Hadoop global configuration file `${HADOOP_HOME}/etc/hadoop/core-site.xml` is configured with the location of the trust-store provider. Secure non-FIPS nodes use the JCEKS credential store type. FIPS-enabled nodes use the BCFKS credential store type. Therefore, on a secure non-FIPS node, the client-side credential provider setting in `core-site.xml` looks like this:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>localjceks://file/opt/mapr/conf/maprtrustcreds.jceks</value>
  <description>File-based trust store credential provider.</description>
</property>
```

On a FIPS-enabled node, the client-side credential provider setting in core-site.xml looks like this:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>localjceks://file/opt/mapr/conf/maprtrustcreds.bcfks</value>
```

```
  <description>File-based trust store credential provider.</description>
</property>
```

Credential Provider Configuration for Server Applications

For server-side custom applications using `ssl-server.xml`, the credential provider property is configured in `ssl-server.xml` itself. For a secure non-FIPS node, the credential provider setting in `ssl-server.xml` looks like this:

```
<property>
  <name>hadoop.security.credential.provider.path</name>

  <value>localjceks://file/opt/mapr/conf/maprkeycreds.jceks,localjceks://
file/opt/mapr/conf/maprtrustcreds.jceks</value>
  <description>File-based key and trust store credential provider.</
description>
</property>
```

Using the Hadoop Configuration API

Custom client applications that need access to the trust-store password to access `${MAPR_HOME}/conf/ssl_truststore` need to be enhanced to add the `${HADOOP_HOME}/etc/hadoop/core-site.xml` to the Configuration resource. For example:

```
import org.apache.hadoop.conf.Configuration;
...
try {
  final Configuration conf = new Configuration(false);
  conf.addResource("core-site.xml", false);
   ...
}
```

Server-side custom applications that need the key-store password to access `${MAPR_HOME}/conf/ssl_keystore` need to add `ssl-server.xml` to the Configuration resource. For example:

```
import org.apache.hadoop.conf.Configuration;
...
try {
  final Configuration conf = new Configuration(false);
  conf.addResource("ssl-server.xml", false);
   ...
}
```

Additional Requirements for FIPS 140-2 Application Development

FIPS Security Policy

The HPE Ezmeral FIPS-compliant `java.security` configuration is available in `${MAPR_HOME}/conf/java.security` for use by Java applications. To ensure that only FIPS-compliant cryptography and security providers are used in custom Java applications, use this security file to override the `master java.security` file that is installed by default with JDK 11 using the `java.security.properties==${MAPR_HOME}/conf/java.security.fips` option. Perform this task while running your Java application in FIPS mode.

If you choose to use alternative FIPS-compliant Java security providers, Hewlett Packard Enterprise recommends that you make a copy of the configuration in `java.security.properties==${MAPR_HOME}/conf/java.security.fips` instead of modifying this directly. Hewlett Packard Enterprise recommends this option because the correct functionality of the HPE Ezmeral core components

last-updated: Jun 06, 2024

depend on this configuration. It is also the user's responsibility to ensure that any security providers used in a `modified java.security` configuration are FIPS compliant. For example:

```
JAVA_SECURITY_FIPS=
#
# Options required for running your custom Java application
YOUR_CUSTOM_JAVA_OPTS=""
#
# Determine FIPS mode, and add the MAPR_ALTERNATE_JAVA_SECURITY option
get_fips_mode=$(sysctl crypto.fips_enabled 2> /dev/null)
fips_enabled='crypto.fips_enabled = 1'
if [ "$get_fips_mode" == "$fips_enabled" ]; then
 # Override the default java.security when in FIPS mode
 JAVA_SECURITY_FIPS=-Djava.security.properties==${MAPR_HOME}/conf/
java.security.fips
fi
# Run your custom Java application
"$JAVA_HOME"/bin/java ${JAVA_SECURITY_FIPS} \
     -classpath ${YOUR_CUSTOM_CLASSPATH} com.example.yourapp $args
```

Bouncy Castle FIPS Provider

For Java applications, HPE Ezmeral Data Fabric release 7.0.0 uses the Bouncy Castle FIPS Java API. The Bouncy Castle JAR files are bundled with the release 7.0.0 distribution in `/opt/mapr/lib`:

- `bc-fips-1.0.2.1.jar`
- `bctls-fips-1.0.11.4.jar`

To write FIPS-compliant Java applications using the Bouncy Castle Java FIPS API, see the Bouncy Castle FIPS Java website. For examples, see this document.

TLS Communication

For TLS communication in FIPS mode, the following changes are required.

1. Look for the key store type in the `ssl-server.xml` or `ssl-client.xml`.
2. For the BCFKS store type:
   a. Set the key manager factory algorithm to `PKIX`.
   b. Set the security provider to `BCJSSE`.
   c. Set the key store type to `BCFKS`.

   Here is an example using `SslContextFactory`:

```
SslContextFactory.Server sslContextFactory =
                         new SslContextFactory.Server();
if (keyStoreType.equalsIgnoreCase(BCFKS_FIPS_KEYSTORE_TYPE)) {
  sslContextFactory.setKeyManagerFactoryAlgorithm("PKIX");
  sslContextFactory.setProvider("BCJSSE");
  sslContextFactory.setKeyStoreType("BCFKS");
}
```

Troubleshooting Tips for FIPS Installations

Answers frequently asked questions and provides troubleshooting tips for FIPS installations.

Release 7.0.0 provides support for FIPS 140-2 Level 1 compliance and many new and upgraded security features, as well as modified functionality. If you are used to configuring and running applications on the core platform before release 7.0.0, you will encounter behavioral differences. These differences can lead to

incorrect or unexpected functionality, which might not be a bug. The following is a partial list of answers to frequently asked questions and troubleshooting tips.

1. Can I upgrade an existing installation to FIPS mode?

FIPS is supported only for fresh installations. However, users with pre-7.0.0 installations can take advantage of FIPS functionality while still maintaining access to critical data. You can do this by adding new FIPS nodes to an already-installed secure non-FIPS cluster and then gradually decommissioning the non-FIPS nodes. Be aware, however, that if any existing user data is encrypted using non-secure cryptographic algorithms (such as DES), the data will first have to be re-encrypted using a secure cryptographic algorithm (such as AES-256) in order to decrypt the data from a FIPS-enabled node.

2. When I enable FIPS on a node, does it mean my entire cluster is FIPS-enabled? Can I just enable FIPS for the whole cluster? After I enable FIPS, can I disable it?

The data-fabric approach to FIPS compliance is a combination of the following strategies:

- Leveraging our partner's FIPS certification for OpenSSL 1.1.1 for C/C++ components.
- Bundling the Bouncy Castle Java FIPS API with the HPE Ezmeral Data Fabric distribution.

The first part means that FIPS has to be enabled at an operating-system level, on a per-node basis. This needs to be done on each cluster node before the HPE Ezmeral Data Fabric is installed. Although you can technically disable FIPS after enabling it at an operating system level, this is not supported by the HPE Ezmeral Data Fabric and will result in incorrect functionality.

The second part regarding the bundling of the Bouncy Castle JARs results in the use of BCFKS key and trust stores if the node is FIPS-enabled, and JKS key and trust stores for secure non FIPS-enabled nodes. FIPS is not just a flag, and there is no concept of a cluster-wide FIPS setting. Also, the entire cluster is FIPS-enabled if every node in the cluster is FIPS-enabled. You can use the new `isFips` property in the enhanced `maprcli node list` command to determine the FIPS setting of each server node in the cluster. See Determining if a Host Is in FIPS Mode on page 1806.

3. Can a non-FIPS client communicate with a FIPS server? Can a non-FIPS server communicate with a FIPS server? How do I set this up

Yes, non-FIPS nodes can communicate with FIPS nodes, whether they are servers or clients. The TLS 1.2 communication between the nodes already uses FIPS-compliant cryptography, so no additional setup is required.

4. I want to set up a cross-cluster trust relationship. Can I still use the configure-crosscluster.sh script to configure FIPS and non-FIPS clusters?

You can use the `configure-crosscluster.sh` script to configure local and remote clusters if they consist of entirely FIPS nodes or entirely non-FIPS nodes. If you want to configure a cross-cluster relationship where either the local or remote clusters consist of a combination of FIPS and non-FIPS nodes, `configure-crosscluster.sh` provides some limited support, but some additional manual steps are required, as outlined in Configuring Cross-Cluster Security for a Mixed (FIPS and Non-FIPS) Configuration on page 1958.

5. Why doesn't keytool work the same way on a FIPS node and a non-FIPS node?

The `keytool` command that comes as part of the JDK supports JKS key and trust stores by default since the JKS key and trust store type is packaged with the JDK distribution. JKS is also the default store type, so the `-storetype` parameter is optional. The JKS store type is insecure, and does not require a

password for store operations such as listing the contents. For example, to list the contents of the trust store in a secure non-FIPS node:

```
keytool -list -keystore /opt/mapr/conf/ssl_truststore
```

For FIPS-enabled nodes, the HPE Ezmeral Data Fabric uses the FIPS-compliant BCFKS store type, which is part of the Bouncy Castle Java FIPS API. Since this is not packaged with the JDK distribution, you need to tell `keytool` where to find the Bouncy Castle provider. In addition, BCFKS stores require that you specify the password for all store operations. So, for the same example of listing the contents of the trust store in a FIPS-enabled node:

```
keytool -list -keystore /opt/mapr/conf/ssl_truststore.bcfks \
         -storepass B28_Xqpcu7_srB8So2T_egUiFn0q9zqZ \
         -provider
org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \
         -providerpath /opt/mapr/lib/bc-fips-1.0.2.1.jar \
         -providername BCFIPS -storetype bcfks
```

6. My custom application runs successfully on a FIPS-enabled node. Does that means my application is FIPS 140-2 Level 1 compliant?

Not necessarily. An application is considered FIPS 140-2 Level 1 compliant if all of the following are true:

- The application runs successfully on a FIPS-enabled node such as RedHat 8.
- All sensitive data is encrypted.
- The application uses only cryptography from FIPS-compliant cryptographic libraries.

If, for example, your application is written in C/C++ and it statically linked a non FIPS-validated cryptographic library, such as CryptoPP, instead of using the FIPS-compliant OpenSSL 1.1.1 from RedHat, or if sensitive data in the application, such as password data, is not encrypted, the application is not considered FIPS-compliant, even if it runs on a FIPS node.

7. My custom application runs successfully on a release 7.0.0 secure non-FIPS enabled node. Why does it fail on a FIPS-enabled node?

There are multiple reasons for this. FIPS enforces the use of strong cryptographic algorithms from FIPS-approved cryptographic libraries such as RedHat's OpenSSL 1.1.1 and the Bouncy Castle Java FIPS API. It disables weak cryptographic algorithms such as DES. Following is a partial list of reasons that your application will fail on a FIPS-enabled node:

- The application uses weak cryptographic algorithms, such as DES and MD-5.
- The application is written in C/C++ and uses a version of OpenSSL other than 1.1.1.
- The application is written in Java and needs to communicate over TLS, but is unable to access the private keys and/or certificates because it does not support the BCFKS store type.
- The application is trying to access data that was previously encrypted using nonsecure cryptographic algorithms such as DES.
- There is insufficient entropy.

8. I have data stored in the file system or database that was previously encrypted using DES. My application on my FIPS-enabled node fails when I try to access the data. How can I retrieve the data?

FIPS-enabled nodes do not support nonsecure algorithms such as DES. If you stored encrypted data in the file system or database from a non-FIPS node, then you must migrate your data. That is, you must decrypt your DES-encrypted data and re-encrypt your data using a stronger cryptographic algorithm – such as AES – on a non-FIPS node before you can access the data on a FIPS-enabled node. To improve your security infrastructure, Hewlett Packard Enterprise recommends that you upgrade your application to support stronger cryptographic algorithms, such as AES.

9. After installing a new FIPS node, running configure.sh results in a hang (specifically, the call to "keytool" hangs for many minutes). What can be done?

The likely reason is low system entropy on the node. Low system entropy is more common on virtual machines; physical machines generate better random numbers from various hardware sources. The `keytool` command reads random bits from `/dev/random`, which blocks while trying to generate new random bits.

Having good entropy available is a pre-requirement for installing the HPE Ezmeral Data Fabric. It is not a feature that the Data Fabric can provide or test for. To see the current entropy level, use this command:

```
sudo cat /proc/sys/kernel/random/entropy_avail
```

Numbers near 3000 or higher are preferable. Some VMs show low entropy (for example, 50). You can search online for possible ways to increase the entropy. These include using the `rng-tools` or `haveged` packages. For example: see these references:

- https://wiki.archlinux.org/title/Rng-tools
- https://wiki.archlinux.org/title/Haveged
- https://www.techrepublic.com/article/how-to-add-more-entropy-to-improve-cryptographic-randomness-on-linux/

Configuring Authentication
Provides information about Data Fabric tickets, Kerberos, Pluggable Authentication Module (PAM) authentication.

Robust authentication prevents third parties from representing themselves as legitimate users. The core component of user authentication in Data Fabric is the *ticket*. A ticket is an object that contains specific information about a user, an expiration time, and a key. Tickets uniquely identify a user and are encrypted to protect their contents. Tickets are used to establish sessions between a user and the cluster.

Data Fabric supports two methods of authenticating a user and generating a ticket:

- Kerberos
- Username/password pairing with PAM

Both of these methods are mediated by the maprlogin on page 2911 utility. When you authenticate with a username/password pair, the system verifies credentials using Pluggable Authentication Modules (PAM). Configure the cluster to use any registry that has a PAM module.

Managing Tickets
Introduces authentication using tickets for users and HPE Ezmeral Data Fabric servers.

HPE Ezmeral Data Fabric implements authentication with tickets. *Tickets* contain keys and are used to authenticate users and HPE Ezmeral Data Fabric servers. In addition, *certificates* are used to implement server authentication. Every user who wants to access a cluster must have a HPE Ezmeral Data Fabric

last-updated: Jun 06, 2024

user ticket (`maprticket_<uid>`). Every node in the cluster must have an HPE Ezmeral Data Fabric server ticket (`maprserverticket`).

A ticket is an object that contains specific information about a user and a key. A ticket authenticates a user to the cluster. Tickets are encrypted to protect their contents. The following table describes the tickets used by HPE Ezmeral Data Fabric for internal cluster operations, the user who can generate the ticket, and the command used to generate the ticket. This type of ticket should only be placed on cluster nodes.

Ticket Type	Description	Permissions/Command to Generate Ticket
`maprserver`	For (internal) cluster operations. This type of ticket can be long lasting.	User root using the `configure.sh` on page 2821 utility
`crosscluster`	For (internal) cross-cluster operations, such as mirroring and replication. This type of ticket can be long lasting.	User mapr using the `maprlogin` on page 2911 utility. The UID of the ticket (mapr) is always used as the identity of the entity using this ticket.

The following table describes the type of tickets supported by HPE Ezmeral Data Fabric for users and services, and whether the ticket can be used to impersonate another user. All of these tickets, except the user ticket, can only be generated by the cluster administrator using the `maprlogin` on page 2911 utility. The user ticket can be generated by any valid user using the `maprlogin` on page 2911 utility. These type of tickets can be placed on both cluster and client nodes and support (FUSE-based and loopbacknfs) POSIX clients and HDFS APIs.

Ticket Type	Description	Impersonation support	Notes
user	For granting access to individual users. This type of ticket has a short duration.	N/A*	The UID of the ticket (implicit or explicit value of the `-user` parameter to `maprlogin` command) is used as the identity of the entity using this ticket, except for the exceptions noted here for user `root` and user `mapr`.
service	For accessing services running on client nodes. This type of ticket can have long duration.	N/A*	The UID of the ticket (explicit value of the `-user` parameter to `maprlogin` command) is used as the identity of the entity using this ticket, except for the exceptions noted here for user `root` and user `mapr`.
servicewithimpersonation (not scoped)	For accessing services running on client nodes to run jobs on behalf of any user (except user `mapr`). This type of ticket can have long duration.	Yes	The ticket cannot be used to impersonate user `root` or user `mapr`.

last-updated: Jun 06, 2024

Ticket Type	Description	Impersonation support	Notes
servicewithimpersonation (scoped)	For accessing services running on client nodes to run jobs on behalf of the users (except user `root` and user `mapr`) specified in the ticket. This type of ticket can have long duration.	Yes	At ticket generation time, you cannot specify UID/GID of user `root` or user `mapr` to impersonate user root or user mapr respectively. **NOTE:** In release 6.0.1, scoped impersonation works with FUSE-based POSIX clients. Scoped impersonation cannot be used with NFS and loopbacknfs POSIX clients. To use scoped impersonation in release 6.0.1, obtain the 6.0.1 EBF patch for RPM or DEB-based distributions from HPE Ezmeral Data Fabric Support, and install the patch.
servicewithimpersonationandticket	Allows some ticket holders to generate tickets subject to their impersonation authority. This type of ticket can have long duration.	Yes	Can be scoped or not scoped. See Generating an Impersonation Ticket with Ticket Generation Privileges on page 1834. Supported in release 7.0.0 and later.
tenant	For tenant user(s) to access tenant volume(s) in a multi-tenant environment. This type of ticket can have long duration.	Yes	The ticket can be used to impersonate user `root` but cannot be used to impersonate user `mapr`.

* Exceptions:

- User `mapr` can impersonate other users (including user `root`)
- User `root` can impersonate other users (excluding user `mapr`)

IMPORTANT: The identity of the user that authenticates with the `maprlogin` utility is independent from the identity of the user of the client OS.

HPE Ezmeral Data Fabric tickets contain the following information:

- UID (generated from the UNIX user ID)
- GIDs (group IDs for each group to which the user belongs)
- Ticket creation time
- Ticket expiration time (initial duration of the ticket)
- Renewal expiration time (maximum lifetime of the ticket)

last-updated: Jun 06, 2024

- Whether user can (true) or cannot (false) impersonate another user

Since a ticket contains the GIDs for a user at the time the ticket is generated, the user must re-generate their ticket after changing group memberships.

Syntax and Examples of Creating and Managing User Tickets

For complete syntax, see The maprlogin Utility. For examples of creating and managing user tickets, see maprlogin Command Examples on page 2915

How Tickets Work
Explains the concept of tickets and how they work.

When an authenticated user runs a client, the client uses that user's ticket to communicate securely with the server. After Enabling Wire-level Security on page 1797, supported communications channels between client and server are encrypted.

Nodes use tickets to identify themselves to one another in order to prevent *spoofing*. Spoofing is a condition where an untrusted machine presents itself as a trusted machine to gain access to the cluster.

User Blocking

System administrators can use the command line interface to *block* a user. The command to block invalidates all of a user's tickets. After a block command is received by the CLDB, the name of the blocked user is sent to all FileServer nodes. These nodes reject any request sent by that user that has a ticket older than the block time stamp. Due to the nature of this check, there is no explicit removal of a blocked user. Issuing a new ticket with a time stamp more recent than the block time stamp implicitly permits the user. To permanently prevent a user from logging in again, revoke the user's credentials in the PAM registry.

What Blocking Affects

A blocked user cannot access the HPE Ezmeral Data Fabric file system or the CLDB. Blocking only revokes a user's *existing valid tickets*, be aware of the following interactions:

- Blocking does not affect a new authentication with user ID and password or with existing Kerberos credentials.
- Since NFS does not use HPE Ezmeral Data Fabric tickets, blocking does not affect NFS access.
- Blocked users can still be impersonated as impersonation does not check whether a user is blocked or not.
- Blocking has no effect on ZooKeeper. Blocked users can still connect to the ZooKeeper server and execute commands. The workaround to resolve this issue is to delete the ticket file.

Generating a HPE Ezmeral Data Fabric User Ticket
Describes what a user ticket is, and how to generate a user ticket.

A user ticket file is stored in `/tmp` and can only be read by that user. To generate a HPE Ezmeral Data Fabric user ticket, run the following command:

```
maprlogin password
```

This command prompts for the user's password, then generates a HPE Ezmeral Data Fabric user ticket associated with the UNIX user ID. By default, tickets on Linux systems are generated in the `/tmp` directory and are named in the form `maprticket_<UID>` . Tickets on Windows systems are generated in the `%TEMP%/` directory and are named in the form `maprticket_<username>` . To change the default location, change the value of the `MAPR_TICKETFILE_LOCATION` environment variable.

NOTE: The `mapr` user can impersonate any user, including user `root`.

last-updated: Jun 06, 2024

NOTE: There are no notifications to indicate that a ticket is about to expire. Use the `maprlogin print` command, with the ticket file, to see when the ticket expires. You can renew the ticket until the renewal date mentioned.

To illustrate a typical work flow, suppose a user wants to access two clusters, cluster1 and cluster2. During this session, a user logs in as `root` to cluster1, gets a HPE Ezmeral Data Fabric user ticket, and displays the ticket contents with the `maprlogin print` command.

```
root@qa-node113:~/SecurityInstall# maprlogin password
[Password for user 'root' at cluster 'cluster1': ]
MapR credentials of user 'root' for cluster 'cluster1' are written to '/tmp/
maprticket_0'
root@qa-node113:~/SecurityInstall#
```

First Ticket for Cluster 1

```
root@qa-node113:~/SecurityInstall# maprlogin print
Opening keyfile /tmp/maprticket_0
qasecurity1: user = root, created = 'Wed Sep 11 14:19:02 PDT 2013', expires
= 'Wed Sep 25 14:19:02 PDT 2013', RenewalTill = 'Fri Oct 11 14:19:02 PDT
2013', uid = 0, gids = 0, 42
root@qa-node113:~/SecurityInstall#
```

Now the `root` user logs in to cluster2. The `maprlogin` command returns a ticket for cluster2. This ticket is stored in the common ticket file. Commands now have access to both tickets.

```
root@qa-node113:/opt/mapr/conf# maprlogin password -cluster cluster2
[Password for user 'root' at cluster 'cluster2': ]
MapR credentials of user 'root' for cluster 'cluster2' are written to '/tmp/
maprticket_0'
```

Showing Tickets for both Clusters

```
root@qa-node113:/opt/mapr/conf# maprlogin print
Opening keyfile /tmp/maprticket_0
qasecurity1: user = root, created = 'Thu Sep 12 11:07:54 PDT 2013', expires
= 'Thu Sep 26 11:07:54 PDT 2013', RenewalTill = 'Sat Oct 12 11:07:54 PDT
2013', uid = 0, gids = 0, 42
qasecurity2: user = root, created = 'Thu Sep 12 15:20:49 PDT 2013', expires
= 'Thu Sep 26 15:20:49 PDT 2013', RenewalTill = 'Sat Oct 12 15:20:49 PDT
2013', uid = 0, gids = 0, 500
root@qa-node113:/opt/mapr/conf#
```

Generating a Service Ticket

Applications may have service processes that run outside the Data Fabric cluster but need to access the cluster to run Data Fabric commands. For security reasons, you decide not to run these services as a `mapr` user. Instead, you can use the `maprlogin` utility to generate a "service ticket" that can be used to access the cluster for the user account that runs the service. The `maprlogin` utility uses the current user's ticket (the user running the `maprlogin` command) to send an authenticated request for a newly generated service ticket.

This type of ticket has a specified duration (expiration), a renewal period (maximum lifetime), and a designated location where the ticket is safely stored. The service process that uses the ticket can access it based on the definition of the `MAPR_TICKETFILE_LOCATION` environment variable. This variable points to the location of the ticket and should be set for the service process after it starts. Short duration and renewal values may be used for security reasons, but much longer lifetimes are supported for ease of administration.

last-updated: Jun 06, 2024

For example:

```
# maprlogin generateticket -type service -out /tmp/
longlived_ticket -duration 30:0:0 -renewal 90:0:0 -user mapr
MapR credentials of user 'mapr' for cluster 'xxxx' are written to '/tmp/
longlived_ticket'
```

This command generates a service ticket that expires after 30 days and is stored in `/tmp/longlived_ticket`. The ticket may be renewed at any time before the 30 days pass, extending its lifetime to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically after it expires.

NOTE: This type of ticket can only be generated by a user with full control on a cluster's ACL.

Generating a Service with Impersonation Ticket

Impersonation allows a user to access data and submit jobs on behalf of another user. Consider allowing users, other than the mapr user, to impersonate other users. Use the `maprlogin` utility to generate a "servicewithimpersonation ticket" that is optionally used to access a secure cluster impersonating another user. The servicewithimpersonation ticket provides the user the ability to impersonate other users (except the mapr user) in addition to the ability to access a secure cluster. This type of ticket can only be generated by a user with full control on a cluster's ACL.

If this type of ticket is generated and saved in the location specified with the `-out` option, after generating the ticket, do the following:

1. Reset the permissions on the ticket to grant the user for whom the ticket was generated read permissions on the ticket.
2. Set the `MAPR_TICKETFILE_LOCATION` environmental variable to point to the ticket file location if the path specified for the `-out` option was not `/tmp/maprticket_<uid>`.

This type of ticket, similar to a service ticket, has a specified duration (expiration), a renewal period (maximum lifetime), and a location where the ticket is safely stored. It grants the specified user the ability to impersonate other users, except the mapr user.

The default duration for this type of ticket is LIFETIME and the duration is not bounded by the CLDB duration properties. Short duration and renewal values may be used for security reasons, but much longer lifetimes are supported for ease of administration.

For example:

```
# maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -out /var/tmp/impersonation_ticket -duration 30:0:0 -renewal
90:0:0
```

The above command generates a service with impersonation ticket that expires after 30 days and is stored in `/var/tmp/impersonation_ticket`. The ticket may be renewed at any time before the 30 days and can be extended up to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires. The ticket allows the user to impersonate all users on the cluster.

To allow a user to impersonate only specific users and/or groups, use the `impersonateduids` and/or `impersonatedgids` options with the `maprlogin` command. For example:

```
# maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -out /var/tmp/impersonation_ticket -duration
30:0:0 -impersonateduids 1002,1003 -impersonatedgids 1005,1006 -renewal
90:0:0
```

The above command generates a service with impersonation ticket. The ticket holder can impersonate users whose UIDs are 1002 and 1003 and users in the groups with GIDs 1005 and 1006. The ticket expires after 30 days and is stored in `/var/tmp/impersonation_ticket`. The ticket may be renewed at any time before the 30 days and can be extended up to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires.

Generating an Impersonation Ticket with Ticket Generation Privileges
Describes a ticket option that allows some ticket holders to generate tickets subject to their impersonation authority.

Cases exist where an arbitrary process started by another process needs a ticket for a particular user. Before release 7.0.0, such tickets could be created by users with cluster-level “Full Control” capability. For example, in release 6.2.0, we can give the `fc` privilege to user `m7server1`:

```
# maprcli acl set -type cluster -user root:login,ss,cv,a,fc,cp \
    mapr:login,ss,cv,a,fc,cp m7server1:login,fc
# maprcli acl show -type cluster
Allowed actions             Principal
[login, ss, cv, a, fc, cp]  User root
[login, ss, cv, a, fc, cp]  User mapr
[login, ss, cv, fc]         User m7server1
```

With the `fc` privilege, the `m7server1` user can create tickets for any user:

```
[m7server1@m2-mapreng-vm166251 ~]$ maprlogin generateticket -user
m7user1 -type service -out m7user1ticket.out
MapR credentials of user 'm7user1' for cluster 'fips1.cluster.com' are
written to 'm7user1ticket.out'
```

Although this meets the literal requirement, the “Full Control” capability is far too powerful, since the ability to create tickets is unrelated to cluster-level “Full Control” capability.

Release 7.0.0 enhanced the `maprlogin generateticket` command to allow the generation of a new type of ticket called `servicewithimpersonationandticket`:

```
# maprlogin generateticket
The -user parameter is required. Specify the user name of the service
identity.
generateticket
-type service|crosscluster|servicewithimpersonation|
servicewithimpersonationandticket|tenant
-user UNIX user name of service identity.
[ -clusters comma seperated list of clusters OR 'all' for all clusters
present in mapr-clusters.conf]
[ -cluster mapr cluster name ]
-out ticket location
[ -duration [Days:]Hours:Minutes OR -duration Seconds.default: cluster's
ticket duration setting ]
[ -renewal [Days:]Hours:Minutes OR -duration Seconds.default: cluster's
ticket duration setting ]
[-ips comma separated list of ips on which ticket should be valid]
[-impersonateduids comma separated list of uids for impersonation]
[-impersonatedgids comma separated list of gids for impersonation]
```

In addition to users with cluster-level “Full Control” capability being able to generate tickets, holders of tickets of the type `servicewithimpersonationandticket` can also generate tickets subject to their impersonation authority. Therefore, for users without cluster-level “Full Control” capability, ticket generation is allowed if the caller holds a ticket with `CanImpersonate = true` and `CanGenerateTicket = true`, and either of the following conditions is true:

last-updated: Jun 06, 2024

- The ticket is not a scoped impersonation ticket. No `impersonatedUids` or `impersonatedGids` ID references are in the ticket. Below is an example of how to generate an unscoped impersonation ticket with ticket-generation permission for user `m7server2`:

```
# maprlogin generateticket -type servicewithimpersonationandticket \
      -user m7server2 -out m7server2ticket.out
MapR credentials of user 'm7server2' for cluster 'fips1.cluster.com' are
written to 'm7server2ticket.out'
# maprlogin print -ticketfile m7server2ticket.out
Opening keyfile m7server2ticket.out
fips1.cluster.com: user = m7server2, created = 'Tue Jan 04 18:00:38 PST
2022', expires = 'Tue Jan 04 18:00:38 PST 12022', RenewalTill = 'Tue Jan
04 18:00:38 PST 12
022', uid = 5004, gids = 5005, CanImpersonate = true, CanGenerateTicket =
true, isExternal = true
```

- If the ticket is a scoped impersonation ticket, the caller is allowed to generate a ticket for the target user if either of the following is true:
  - The target user UID is in the list of impersonated UIDs.
  - At least one group that the target user belongs to is in the list of impersonated GIDs.

Below is an example of how to generate a scoped impersonation ticket with ticket-generation permission for user `m7user2`:

```
# maprlogin generateticket -type servicewithimpersonationandticket -user
m7server2 -out m7server2ticket-imp.out -impersonateduids
5001 -impersonatedgids 5003
[root@m2-mapreng-vm166251 ~]# maprlogin print -ticketfile
m7server2ticket-imp.out
Opening keyfile m7server2ticket-imp.out
fips1.cluster.com: user = m7server2, created = 'Thu Jan 06 00:15:47 PST
2022', expires = 'Thu Jan 06 00:15:47 PST 12022', RenewalTill = 'Thu Jan
06 00:15:47 PST 12022', uid = 5004, gids = 5005, CanImpersonate = true,
CanGenerateTicket = true, isExternal = true, impersonatedUids = 5001,,
impersonatedGids = 5003,
```

User `m7server2` is allowed to generate tickets for user `m7user1` (UID 5001, GID 5002) because its UID is within the list of `impersonatedUids` for this ticket:

```
[m7server2@m2-mapreng-vm166251 ~]$ export MAPR_TICKETFILE_LOCATION=/home/
m7server2/m7server2ticket.out
[m7server2@m2-mapreng-vm166251 ~]$ maprlogin generateticket -user
m7user1 -type service -out m7user1ticket.out
MapR credentials of user 'm7user1' for cluster 'fips1.cluster.com' are
written to 'm7user1ticket.out'
```

The user `m7server2` also is allowed to generate tickets for user `m7user2` (UID 5002, GID 5003) because the GID for `m7user2` is within the list of `impersonatedGid` for this ticket:

```
[m7server2@m2-mapreng-vm166251 ~]$ export MAPR_TICKETFILE_LOCATION=/home/
m7server2/m7server2ticket.out
[m7server2@m2-mapreng-vm166251 ~]$ maprlogin generateticket -user
m7user2 -type service -out m7user2ticket.out
MapR credentials of user 'm7user2' for cluster 'fips1.cluster.com' are
written to 'm7user2ticket.out'
```

User `m7server2` is not allowed to generate tickets for user `m7user3` (UID 5005, GID 5006) since `m7user3` UID (5005) is not in the list of `impersonatedUids` for this ticket. Neither is its GID (5006) in the list of `impersonatedGids`:

```
[m7server2@m2-mapreng-vm166251 ~]$ maprlogin generateticket \
 -user m7user3 -type service -out m7user3ticket.out
User m7server2 does not have permission to impersonate user m7user3(UID:
5005), and cannot generate ticket
```

Generating a Ticket for a Tenant
Explains what tenant tickets are and how to generate one.

About this task

Tenant tickets allow tenant users to access the tenant volume on the cluster if you have a multi-tenant environment on file system. Generate the tenant ticket on the cluster and copy it to tenant hosts to grant tenant users access to provisioned storage.

Procedure

- To generate a tenant ticket, run one of the following commands on the cluster:

  ```
  maprlogin generateticket -type tenant -cluster <cluster_name> -user
  <tenant_admin_user> \
  -duration <seconds> -out <ticket_file_path>.txt
  ```

  NOTE: For more information, see the `maprlogin` command.

  By default, the tenant ticket:

  - Is stored in `/tmp` and can only be read by that user. To change the default location, specify the path to the desired location with the `out` parameter.
  - Has no expiration. To change the expiration time, specify `duration` for the ticket with the command.

  With tenant tickets, the value for `CanImpersonate` and `tenant` is always `true`. For example, if you run the `maprlogin print` command, the output should look similar to the following example.

  ```
  Opening keyfile /user/clstrAdmin/tenant_user_ticket.txt
  tenantHost: user = tenant_user, created = 'Mon Jul 11 07:14:53 UTC 2016',
  expires = 'Mon Jul 11 07:14:53 UTC 12016', RenewalTill = 'Mon Jul 11
  07:14:53 UTC 12016',
  uid = 500, gids = 500, 42, CanImpersonate = true, tenant = true
  ```

  To grant access to tenant users, the tenant ticket must be copied over to the tenant hosts.

What to do next

After generating the ticket:

1. Reset the permissions on the ticket to grant the tenant admin read permissions on the ticket.
2. Move the ticket out of the default `/tmp` directory to a secure location on one or more tenant hosts.

last-updated: Jun 06, 2024

Generating a Data Fabric Ticket from a Kerberos Ticket

About this task

On clusters that use Kerberos for authentication, a Data Fabric ticket is implicitly obtained for a user that runs a Data Fabric command without first using the `maprlogin` utility.

If you want to use a Kerberos ticket to generate a `maprticket`, follow these procedure below.

Procedure

1. Obtain a Kerberos identity by running `kinit` or by another mechanism.
2. Run `maprlogin kerberos` to indicate that you have an existing Kerberos ticket. You can also specify these options: `[ -cluster ]` The name of the cluster. `[ -duration ]` The ticket duration in seconds.

Configuring PAM Authenticator

The HPE Ezmeral Data Fabric supports Pluggable Authentication Modules (PAM) in the UNIX authentication stack. HPE Ezmeral Data Fabric provides a PAM Authenticator module that generates data-fabric tickets in conjunction with the `maprlogin` utility. After you install the platform, the PAM Authenticator module is located at *`$INSTALL_DIR`*`/lib/libmapr_pam.so`. Configuration files for PAM are located in the `/etc/pam.d` directory. Each UNIX operation, such as `su`, `login`, or `ssh`, has a specific PAM configuration file in that directory.

Configure the PAM Authenticator on Ubuntu or SLES

To configure the PAM Authenticator, append the following line to the end of the `/etc/pam.d/common-auth` file:

```
auth optional /opt/mapr/lib/libmapr_pam.so # MapR PAM module
```

WARNING: An absolute path to the location of the `libmapr_pam.so` file is required. By default, this location is `$MAPR_HOME/lib/libmapr_pam.so`.

Configure the PAM Authenticator on RHEL or CentOS

1. Insert the following line in the `/etc/pam.d/system-auth` file immediately before the first module that uses the `auth sufficient` configuration:

```
auth optional libmapr_pam.so # MapR PAM module
```

last-updated: Jun 06, 2024

2. Append the string `try_first_pass` to the end of the module that uses `auth sufficient`, as in this example:

   Before modification:

   ```
   auth required pam_env.so
   auth sufficient pam_unix.so nullok
   auth requisite pam_succeed_if.so uid >= 500 quiet
   auth required pam_deny.so
   ```

   After modification, changes in **bold**:

   ```
   auth required pam_env.so
   auth optional libmapr_pam.so # MapR PAM module
   auth sufficient pam_unix.so nullok try_first_pass
   auth requisite pam_succeed_if.so uid >= 500 quiet
   auth required pam_deny.so
   ```

Enable Debugging for PAM

To enable debugging for the client traffic used by the `maprlogin` utility, update the `/opt/mapr/conf/log4j.properties` file with the following line:

`log4j.logger.com.mapr.login=DEBUG`

After updating the `log4j.properties` file, trace the `com.mapr.login` package at the DEBUG level.

Be sure to update the correct instance of the `log4j.properties` file. Traffic specific to HPE Ezmeral Data Fabric, such as `maprlogin` and Control System traffic, uses the instance in the `/opt/mapr/conf` directory. Hadoop applications use the `log4j.properties` file in the `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop` directory.

To perform the same tracing activity on the server side, modify the appropriate instance of the `log4j.properties` file on the server. Alternatively, specify the page `com.mapr.login` in the Control System UI's tracing/logger settings. To trace PAM activity from the server, add the following line to the server's `log4j.properties` instance:

```
log4j.logger.net.sf.jpam=DEBUG
```

After modifying this setting, the server log will contain a message similar to the following:

`2013-07-23 16:05:25,200 DEBUG Pam [1068409264@qtp-874242484-3]: Debug mode active.`

Detailed information about PAM activity is written to the `/opt/mapr/logs/pam_<username>.log` where `username` is the user name that Linux reports in response to the `getpwuid(geteuid())` call for the process. In this case, Linux returns the *effective user ID*, which can be different from the real user ID or saved user ID. For more information, see Difference between Real User ID, Effective User ID and Saved User ID.

Other Packages

The following packages are not directly related to PAM, but can provide useful insights for subtler errors.

- `org.apache.hadoop.security` - This package contains Apache security code, including HPE Ezmeral Data Fabric enhancements. Tracing this package can provide information about what login configuration is in use.
- `com.mapr.fs.cldb.http.login` - This package contains code that the CLDB uses to validate `maprlogin` calls.

last-updated: Jun 06, 2024

Common Issues

The Linux Documentation Project's HOWTO on LDAP Implementation has a section on PAM and NSS that may prove helpful.

If a user's credentials appear valid, for example where the `su` and `ssh` commands work normally but PAM does not correctly authenticate, the issue may relate specifically to HPE Ezmeral Data Fabric's use of PAM as a normal user. PAM consumers run as the root user, causing permissions issues. The two most common issues relating to this condition are:

- The `/etc/shadow` directory is not readable to the `mapr` user. This directory is made readable to the `mapr` user during install, but some secure environments and configuration management tools undo these changes.
- A Kerberos PAM module is attempting to create and change the ownership of a Kerberos ticket file. This attempt fails, since these changes require root privileges. Different Kerberos PAM modules can report errors differently, leading to difficulty tracking down root causes of errors. To address permissions problems with Kerberos PAM modules, configure the Kerberos PAM module to skip creating a ticket file, using the KDC only to validate the password. PAM configuration information is located in the `/etc/pam.d` directory. HPE Ezmeral Data Fabric can use a custom PAM configuration specified in the `web.conf` file.

Configuring Kerberos

Describes how Kerberos works with HPE Ezmeral Data Fabric tickets.

HPE Ezmeral Data Fabric does not directly support Kerberos. However, Kerberos is indirectly supported through the HPE Ezmeral Data Fabric login utility, which is used to generate HPE Ezmeral Data Fabric tickets. This topic describes how Kerberos works with HPE Ezmeral Data Fabric tickets.

Kerberos Compatibility with RHEL 8

If you install Kerberos out of the box with RHEL 8, it uses a new and default Kerberos Cache Manager (KCM) credentials cache type, which fails to work with the `maprlogin kerberos` command. To resolve this issue, disable KCM.

Open the file `/etc/krb5.conf.d/kcm_default_ccache`, and comment out the following lines:

```
[libdefaults]
        default_ccache_name = KCM:
```

Alternatively, remove this file.

Configuring Kerberos for Authentication Using HPE Ezmeral Data Fabric Tickets

To use Kerberos to generate HPE Ezmeral Data Fabric tickets for users, enable Kerberos on CLDB. Do so by creating a Kerberos identity on the Kerberos server used by the cluster and distributing that identity to the other CLDB nodes in the cluster.

NOTE: You must enable wire-level security on your clusters before using Kerberos. See Enabling Wire-level Security.

HPE Ezmeral Data Fabric clusters do not provide Kerberos infrastructure. This section assumes you have a functioning Kerberos realm and your systems have the Kerberos client installed. The tips in this section assume a Linux-based Kerberos environment. The specific commands for your environment may vary. Please consult with your Kerberos administrator for assistance.

IMPORTANT: If you are using strong encryption with Kerberos with the Oracle JDK, a new Java Cryptography Extension (JCE) policy file is required.

last-updated: Jun 06, 2024

Creating a Kerberos Identity for the CLDB

The CLDB requires a Kerberos server identity, but no other nodes do. By default, this identity takes the `mapr/<cluster name>` form . Use `configure.sh` on page 2821 or edit the `mapr-clusters.conf` file to change this default. Use the following commands in a Linux-based Kerberos environment to set up the identity:

```
kadmin
        : addprinc -randkey mapr/my.cluster.com
        : ktadd -k /opt/mapr/conf/mapr.keytab mapr/my.cluster.com
```

Copy the resulting `mapr.keytab` file to the same location on every CLDB node. The `mapr.keytab` file must be owned and readable only by the `mapr` user. Optionally specify the location of the `mapr.keytab` file in the `conf/mapr.login.conf` file. The default location for `mapr.keytab` is `/opt/mapr/conf`.

Updating the keytab File

Use the `kadmin` tool to update the server keys that are stored in the keytab file. Because the server tickets used to authenticate to the CLDB use the new keys immediately, you must copy the new keytab file to all the CLDB servers in the cluster immediately after updating the server keys.

To update the keytab file with a new key, run the following command:

```
kadmin
        : ktadd -k /opt/mapr/conf/mapr.keytab mapr/my.cluster.com
```

The CLDB automatically detects changes to the keytab file on systems that use Java 7 or later. Systems that use Java 6 require a CLDB restart to detect changes to the keytab file.

NOTE: Starting with the 4.0.1 release of the MapR software, Java 6 is deprecated in favor of Java 7 and Java 8.

Running configure.sh

After a Kerberos principal is created for the CLDB, it is added to the `mapr.keytab` file and the `mapr.keytab` file is copied to all the CLDB servers, Kerberos user authentication is then fully enabled for the HPE Ezmeral Data Fabric cluster.

Two `configure.sh` parameters are important for Kerberos:

- `-K|-kerberosEnable`—lets the rest of the cluster know that Kerberos is enabled, so that clients can auto detect Kerberos tickets and use them to get HPE Ezmeral Data Fabric tickets.
- `-P "<cldbPrincipal>"`—specifies the Kerberos instance which is used to form the CLDB Kerberos principal in the form of `mapr/<instance-name>@<realm-name>`. Enclose this value in quotes (").

Run `configure.sh` on each HPE Ezmeral Data Fabric cluster node and on each HPE Ezmeral Data Fabric client node that will communicate with one or more clusters. For more information, see `configure.sh` on page 2821.

```
configure.sh -K -P "<cldbPrincipal>"
```

Running `configure.sh` on each node enters the Kerberos information into the local `clusters.conf` file, so that the following command is all that is required for the client to access the cluster:

```
hadoop fs -ls
```

last-updated: Jun 06, 2024

If you do not run `configure.sh` on each node, the following two commands are required from the client:

```
maprlogin kerberos
hadoop fs -ls
```

Kerberos Command Summary

- **kinit**: Creates a Kerberos ticket. Prompts the user for the userid and password. After validating, Kerberos creates a ticket file in `/tmp` which is owned by the user. Use the `-R` option to renew an existing ticket. Kerberos credentials expire in 8-10 hours. Expired credentials must be renewed or replaced. By default, tickets can be renewed for up to 24 hours.
- **klist**: Lists the contents of the user's ticket file.
- **kdestroy**: Destroys the contents of the user's ticket file. The user is no longer authenticated.
- **kadmin**: Used to administer Kerberos. The login for this command is implicitly `<userid>/admin` since administrator IDs typically end in `/admin`.
- **ktutil**: As the Kerberos keytab maintenance utility, combines or alters Kerberos keytabs.

Disabling Replay Detection for Kerberos Authentication

You can set an option, as shown below, in `mapr-clusters.conf` file to disable replay detection for Kerberos runtime authentication.

```
disableReplayDetection=true
```

By default, this parameter is set to `false`, meaning that HPE Ezmeral Data Fabric clients enable Kerberos replay detection. Replay detection is enabled to prevent potential attacks, such as the replay of Kerberos packets or multiple login attempts with the same user ID. Set this parameter to `true` only if you do not want HPE Ezmeral Data Fabric clients to enforce this detection.

This parameter applies if users attempt an implicit or explicit `maprlogin`, using the `maprlogin kerberos` command, or by submitting jobs and other operations with `kerberosEnable=true` set in the `mapr-clusters.conf` file.

This parameter is used if applications connect to the cluster using Kerberos. `mapr-clusters.conf` only needs to be updated if it is used by such applications. If all Kerberos access to the cluster is from clients outside the cluster, only the `mapr-clusters.conf` file on those client machines must be updated. If Kerberos is used from applications running on the cluster, `mapr-clusters.conf` file should be updated there as well.

Configuring YARN with Kerberos
Lists the process to use YARN with Kerberos.

Make sure that the following tasks are already completed, as directed in earlier sections of this guide:

- Enabling Wire-level Security on page 1797 by running `configure.sh` with the security options.
- Configuring Kerberos on page 1839 by creating a Kerberos principle and keytab file.

NOTE: To enable YARN REST SPNEGO, see Configuring SPNEGO on Data Fabric on page 1843.

Now complete the following tasks.

last-updated: Jun 06, 2024

Configure the yarn-site.xml File

Add the following properties to the `yarn-site.xml` file on every node in the cluster.

```
/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml
```

NOTE: You need to use `/opt/mapr/conf/mapr.keytab` for the `keytab` property, and `mapr` instead of `yarn` for the `principal` property.

```
<!-- ResourceManager security configs -->
<property>
 <name>yarn.resourcemanager.keytab</name>
 <value>/opt/mapr/conf/mapr.keytab</value>    <!-- path to the YARN
keytab -->

</property>
<property>
 <name>yarn.resourcemanager.principal</name>
 <value>mapr/clustername@YOUR-REALM.COM</value>
</property>

<!-- NodeManager security configs -->
<property>
 <name>yarn.nodemanager.keytab</name>
<value>/opt/mapr/conf/mapr.keytab</value>    <!-- path to the YARN
keytab -->

</property>
<property>
 <name>yarn.nodemanager.principal</name>
 <value>mapr/clustername@YOUR-REALM.COM</value>
</property>
<property>
 <name>yarn.nodemanager.container-executor.class</name>
 <value>org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor</
value>
</property>
<property>
 <name>yarn.nodemanager.linux-container-executor.group</name>
 <value>mapr</value>
</property>
```

Configure the mapred-site.xml File

Add the following properties to the `mapred-site.xml` file on every node in the cluster.

```
/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/mapred-site.xml
```

Note that you need to use `/opt/mapr/conf/mapr.keytab` for the `keytab` property and `mapr` instead of `yarn` for the `principal` property.

```
<!-- MapReduce Job History Server security configs -->
<property>
  <name>mapreduce.jobhistory.address</name>
  <value>host:port</value> <!-- Host and port of the MapReduce Job History
Server; default port is 10020  -->
</property>
<property>
  <name>mapreduce.jobhistory.keytab</name>
  <value>/opt/mapr/conf/mapr.keytab</value><!-- path to the YARN
keytab -->
```

last-updated: Jun 06, 2024

```
</property>
<property>
  <name>mapreduce.jobhistory.principal</name>
  <value>mapr/clustername@YOUR-REALM.COM</value>
</property>
```

Modifying the env_override.sh File

Either the `/opt/mapr/conf/env.sh` file or the `/opt/mapr/conf/env_override.sh` file contains a setting for HPE Ezmeral Data Fabric login option that defaults to the value `maprsasl`. Change this value to `hybrid`, which includes Kerberos and other security protocols. For more information about the `env_override.sh` file, see About env_override.sh on page 3077.

The new line (after the change) should be as follows:

```
MAPR_LOGIN_OPTS="-Dhadoop.login=hybrid ${MAPR_JAAS_CONFIG_OPTS} $
{MAPR_ZOOKEEPER_OPTS}"
```

Restart ResourceManager, NodeManager, and JobHistoryServer

Restart the NodeManager, ResourceManager, and JobHistoryServer services, using either the `maprcli node services` command (with the `name` option) or the Control System. After restarting the services, make sure you can run simple Hadoop jobs by running:

```
hadoop jar /opt/mapr/hadoop/hadoop-<version>/share/hadoop/mapreduce/
hadoop-mapreduce-examples-<version>.jar pi
```

Configuring SPNEGO on Data Fabric

About this task

HPE Ezmeral Data Fabric uses the Simple and Protected GSSAPI Negotiation Mechanism (SPNEGO) to secure several web UIs in a secure cluster, as well as the REST calls to the Control System.

Configuring SPNEGO for the Web Server Nodes on Secure Clusters

About this task

The following procedure configures SPNEGO support for the apiserver nodes on your secure cluster.

Procedure

1. Generate a Kerberos principal with the user name HTTP, of the form `HTTP/<webserver name>`, on each node in the secure cluster that will receive inbound SPNEGO traffic.

   Use the FQDN as the name in the principal. Although you could also use a short name or the IP address for the principal name, using the FQDN keeps the name consistent with principal names that `configure.sh` generates and includes in the `mapr.login.conf` file.

   Whatever you use as the principal name is what users must match exactly in a browser to access the webpagess that are protected.

   NOTE: Several services and components in a HPE Ezmeral Data Fabric cluster handle SPNEGO traffic, including the Control System. Name the `mapr.keytab` keytab file if the file does not already exist. If the `mapr.keytab` file already exists, generate the new principal to a different file name and merge it to the `mapr.keytab` file using the `ktutil` tool. For example:

   ```
   kadmin
    : addprinc -randkey HTTP/<webserver name>
    : ktadd -k /opt/mapr/conf/mapr.keytab HTTP/<webserver name>
   ```

last-updated: Jun 06, 2024

2. Verify that the `/opt/mapr/conf/mapr.login.conf` file lists the correct principal in the `MAPR_WEBSERVER_KERBEROS` section.

   To enable SPNEGO for the Control System UI or for the Control System REST, all nodes with the webserver role, add the following line to the `/opt/mapr/apiserver/conf/properties.cfg` file. For example:

   ```
   mapr.rest.auth.methods=kerberos,basic
   ```

   IMPORTANT: The `mapr.rest.auth.methods=kerberos,basic` option shown above is valid only on a secure cluster. If a cluster is not secure, only basic authentication (`WWW-Authenticate: Basic`) is available to clients.

3. Restart the Control System for the changes to take effect.

Testing SPNEGO With curl

About this task
This example tests that the Control System is using GSS for REST calls made with `curl`.

Use the following command to verify that your version of `curl` supports SPNEGO. Under the **Features** header, output of the command should show either **GSS-Negotiate** or SPNEGO. For example:

```
# curl --versioncurl 7.22.0 (x86_64-pc-linux-gnu) libcurl/7.22.0
OpenSSL/1.0.1 zlib/1.2.3.4 libidn/1.23 librtmp/2.3Protocols:
dict file ftp ftps gopher http https imap imaps ldap pop3 pop3s rtmp rtsp
smtp smtps telnet tftp
Features: GSS-Negotiate IDN IPv6 Largefile NTLM NTLM_WB SSL libz TLS-SRP
```

Verify that you have a valid Kerberos ticket-granting-ticket (TGT) with the `kinit -p <user>` command. Then, test `curl` with the following command:

```
curl --negotiate -u : -b ~/cookiejar.txt -c ~/cookiejar.txt
https://<web server node>:8443/rest/<API call> -k -v
```

This command returns HTTP/1.1 200 OK if `curl` is working correctly with SPNEGO.

Configuring Browsers for SPNEGO

About this task
Use the following processes to configure browsers for SPNEGO connections.

Firefox

The process below configures your Firefox browser for SPNEGO connections.

NOTE: These instructions are specific for Firefox version 40.0.3xj. The details may differ slightly if you are using a different Firefox version.

1. Open the Firefox configuration page by navigating to the `about:config` address.
2. In the **Search** text field, enter `network.negotiate-auth.trusted-uris` to bring up that property.
3. Right-click on `network.negotiate-auth.trusted-uris`, select **Modify** to edit the property, and then enter the hostnames of the web server nodes in the cluster as a comma-separated list.
4. Click **OK**.

Chromium on Ubuntu

last-updated: Jun 06, 2024

To configure the Chromium browser on Ubuntu for SPNEGO, edit the `/etc/chromium-browser/default` file, and add the following property:

```
CHROMIUM_FLAGS="--user-data-dir --auth-server-whitelist=<web server host
names>"
```

The `--user-data-dir` flag enables the root user to launch the browser.
The `--auth-server-whitelist` flag specifies the web servers that support SPNEGO authentication.

Troubleshooting Kerberos

Java errors from Kerberos problems can be obscure and difficult to interpret. To see the Kerberos error messages, enable Kerberos debugging by adding these settings to the JVM:

```
-Dsun.security.krb5.debug=true -Dsun.security.spnego.debug=true -Djavax.net.
debug=all
```

Enable Kerberos debugging for the HPE Ezmeral Data Fabric-provided `maprcli` and Hadoop clients by adding the following line to the `/opt/mapr/conf/env_override.sh` shell script:

```
#MAPRLOGIN_OPTS="$
{MAPRLOGIN_OPTS} -Dsun.security.krb5.debug=true -Dsun.security.spnego.debug=
true -Djavax.net.debug=all"
```

The `env.sh` script reads this file as part of its execution. For more information, see About env_override.sh on page 3077.

Capture the Kerberos error to research the issue.

The following sections list common Kerberos error conditions.

Incorrect JVM

Nodes often have multiple JVMs installed. The HPE Ezmeral Data Fabric `env.sh` script automatically configures a JVM to use. To change the automatically-configured JVM, set the value of the `JAVA_HOME` environment variable in the `/opt/mapr/conf/env_override.sh` file. The `env.sh` script reads this file as part of its execution. For more information, see About env_override.sh on page 3077.

Incorrect Server Name

The following error message is caused by an incorrect CLDB server name in the `mapr.login.conf` file. The error message mentions passwords, but the error condition is unrelated to password authentication.

```
2018-04-25 16:46:02,324 ERROR MapRLoginServlet [185087767@qtp-648535353-2]:
Failed to obtain kerberos identity, continuing anyway...

Invalid or missing keytab file

The `keytab` file must be consistent with the key versions of the Kerberos principal. The following example shows an inconsistent keytab file:

```
kadmin:  getprinc mapr/realm1
        Principal: mapr/realm1@mapr
        Expiration date: [never]
        Last password change: Thu May 23 15:36:01 PDT 2013
        Password expiration date: [none]
        Maximum ticket life: 0 days 10:00:00
        Maximum renewable life: 7 days 00:00:00
        Last modified: Thu May 23 15:36:01 PDT 2013 (mapr/admin@mapr)
        Last successful authentication: Thu May 23 19:31:59 PDT 2013
        Last failed authentication: Thu May 23 15:35:41 PDT 2013
        Failed password attempts: 0
        Number of keys: 8
        Key: vno 15, aes256-cts-hmac-sha1-96, no salt
        Key: vno 15, arcfour-hmac, no salt
        Key: vno 15, des3-cbc-sha1, no salt
        Key: vno 15, des-cbc-crc, no salt
        Key: vno 15, des-cbc-md5, Version 4
        Key: vno 15, des-cbc-md5, Version 5 - No Realm
        Key: vno 15, des-cbc-md5, Version 5 - Realm Only
        Key: vno 15, des-cbc-md5, AFS version 3
        MKey: vno 1

        ktutil:  rkt mapr.keytab
        ktutil:  l
        slot KVNO Principal

 ---- ---- ---------------------------------------------------------------------

        1   14            mapr/realm1@mapr
        2   14            mapr/realm1@mapr
        3   14            mapr/realm1@mapr
        4   14            mapr/realm1@mapr
        ktutil:  q
```

Note that the key versions in the Kerberos principal `/realm1` are 15, and the versions in the `keytab` file are 14. This mismatch can result in errors about missing keys or mismatched encryption.

NOTE:

This error state can also be caused by the `/opt/mapr/conf/mapr.keytab` file not being owned by the user `mapr` or not being present. The `keytab` file is owned by `root` at generation. Be sure to use the `chown` command to set the `mapr` user as the owner:

```
$ chown mapr:mapr /opt/mapr/conf/mapr.keytab
```

Incompatible encryption on Java runtime

Incompatible cryptography between the KDC and the JDK results in failed handshakes, leading to errors similar to the following:

```
Caused by: javax.security.auth.login.LoginException: Unable to obtain
Principal Name for authentication
```

last-updated: Jun 06, 2024

With debugging active, the following message is displayed:

```
>>>DEBUG <CCacheInputStream>  client principal is username@hostname
        >>>DEBUG <CCacheInputStream> server principal is X-CACHECONF:/
krb5_ccache_conf_data/fast_avail/krbtgt/user@hostname
        >>>DEBUG <CCacheInputStream> key type: 0
        >>>DEBUG <CCacheInputStream> auth time: Wed Dec 31 16:00:00 PST 1969
        >>>DEBUG <CCacheInputStream> start time: null
        >>>DEBUG <CCacheInputStream> end time: Wed Dec 31 16:00:00 PST 1969
        >>>DEBUG <CCacheInputStream> renew_till time: null
        >>> CCacheInputStream: readFlags()
        >>> unsupported key type found the default TGT: 18
        Negotiate support not initiated, will fallback to other scheme if
allowed. Reason:
```

This debug message indicates that the problem is an unsupported key type.

Incompatible encryption errors can occur due to a `keytab` file that is not present or contains outdated keys.

Be sure to update the Java jurisdiction policy file. Jurisdiction policy files are available from Oracle.

A persistent encryption incompatibility problem may require you to edit the `krb5.conf` file to ensure compatible algorithms between Java and Kerberos.

Bugs in Java

The following error occurs in Java version 1.6.0_25. Upgrade to 1.6.0_45 to resolve the error.

```

```

NOTE:

Starting with the 4.0.1 release of the HPE Ezmeral Data Fabric software, Java 6 is deprecated in favor of Java 7 and Java 8.

Kerberos and PAM validation

Standard Kerberos implementations are predicated on access to elevated user privileges that are not present on secure HPE Ezmeral Data Fabric clusters. In a HPE Ezmeral Data Fabric cluster, the Control System console and other components call PAM as an ordinary user process. This discrepancy in expected and actual privileges can cause a variety of obscure file permisson errors. Since different Kerberos PAM modules are available, error reports can vary.

To diagnose this issue, attempt starting the Control System as the root user, or clear out the `/tmp` folder. If there are no problems when starting the Control System as root, or if clearing out the `/tmp` folder enables a single login before errors appear again, the problem may lie in the Kerberos PAM configuration.

To resolve this condition, prevent Kerberos from creating a ticket file. HPE Ezmeral Data Fabric security does not use Kerberos tickets. The Kerberos KDC is used to validate passwords. Typically the configuration file for PAM is in the `/etc/pam.d` directory. See the documentation for your specific Kerberos PAM module for more information.

Configuring PAM
Describes how PAM works with MapR.

last-updated: Jun 06, 2024

MapR uses Pluggable Authentication Modules (PAM) for password verification in a variety of places. Make sure PAM is installed and configured on the node running the `mapr-apiserver` and other components that will use PAM to verify passwords.

Several PAM modules (profiles), configurable through configuration files in the `/etc/pam.d/` directory, are typically available. Any component verifying user passwords tries the following three profiles in order:

1. sudo (`/etc/pam.d/sudo`)
2. sshd (`/etc/pam.d/sshd`)
3. mapr-admin (if you created the `/etc/pam.d/mapr-admin` profile and the component checks beyond the first two profiles).

```
auth    sufficient      pam_unix.so  # For local OS Auth
```

Component-specific PAM Configurations

Some ecosystem components have unique requirements that require setup of a component-specific PAM configuration. See the Ecosystem Guide for the specific ecosystem component.

Configuring PAM for the Control System and the REST API
Describes how to create a custom PAM profile and use a specific PAM file for authentication.

About this task

Starting in HPE Ezmeral Data Fabric v6.0, no additional configuration is needed to use PAM files for authentication. The apiserver supports PAM and automatically loads the following PAM files, if they exist, in the following order for authentication:

```
/etc/pam.d/mapr-admin
/etc/pam.d/sudo
/etc/pam.d/sshd
/etc/pam.d/chkpasswd
/etc/pam.d/passwd
```

You can create a custom PAM profile and set the admin server property to point to a specific PAM file to use for authentication.

Procedure

1. Open the `/opt/mapr/apiserver/conf/properties.cfg` file and set the PAM file as the value for the `authentication.pam.service` property.

   For example, to set `mapr-admin` as the file to use for authentication, your entry in the file should look similar to the following:

   ```
   ojai.cache.size=64
   mapr.webui.https.port=8443
   doc.url=https://docs.datafabric.hpe.com/home
   proxy.zkservices=elasticsearch,opentsdb
   authentication.pam.service=mapr-admin
   ```

2. Save and close the file.

Configuring PAM to use LDAP

About this task

For instructions, refer to your operating system vendor documentation.

Configuring PAM to use Kerberos

About this task
To configure PAM with Kerberos:

Procedure

1. Install the `krb5` packages and configure the Kerberos client as per the configuration for your environment.
2. Install the appropriate PAM packages:
   - On Redhat/Centos, `sudo yum install pam_krb5`
   - On Ubuntu, `sudo apt-get install -krb5`

Creating a Custom PAM Profile

To ensure that MapR uses a MapR-unique PAM configuration:

- Leave the `/etc/pam.d/sudo` file as is. Editing the `/etc/pam.d/sudo` file is not recommended.
- Create your own PAM profile in `/etc/pam.d`, naming it `mapr-admin`.
- Manually edit `mapr.login.conf` and other ecosystem component configuration files to use `mapr-admin` only.

Example /etc/pam.d/mapr-admin File

Below are some simple examples of what might work in the PAM profile by editing `mapr-admin` or a different PAM profile.

NOTE: Be sure to consult a Linux administrator before modifying PAM profiles.

```
account     required      pam_unix.so
account     sufficient    pam_succeed_if.so uid < 1000 quiet
account     [default=bad success=ok user_unknown=ignore] pam_ldap.so
account     required      pam_permit.so

auth    sufficient      pam_unix.so nullok_secure
auth    requisite       pam_succeed_if.so uid >= 1000 quiet
auth    sufficient      pam_ldap.so use_first_pass
auth    required        pam_deny.so

password    sufficient    pam_unix.so md5 obscure min=4 max=8 nullok
try_first_pass
password    sufficient    pam_ldap.so
password    required      pam_deny.so

session     required      pam_limits.so
session     required      pam_unix.so
session     optional      pam_ldap.so
```

NOTE: The file `/etc/pam.d/sudo` should be modified only with care and if absolutely necessary.

last-updated: Jun 06, 2024

Example for Hue

- Set which PAM profiles to use by modifying the `pam_service` option in the `<HUE_HOME>/desktop/conf/hue.ini` file:

```
[desktop]
  ...
# Configuration options for user authentication into the web application
# ------------------------------------------------------------------------
 [[auth]]
# Authentication backend...
backend=desktop.auth.backend.PamBackend
  ...
# The service to use when querying PAM.
## pam_service=sudo sshd login
```

NOTE: The `mapr-admin` profile is not used in the default Hue configuration.

NOTE: Hue respects only the `auth` section from the PAM profiles.

Example for Livy

- Authenticate users with PAM only by using MapR MultiMechs authentication, so it uses the configuration from `/opt/mapr/conf/mapr.login.conf`.

Managing Access Controls
Describes how to create, enable, and use ACLs and ACEs.

ACLs specify users or system processes that can perform specific actions on an object. ACEs are Boolean expressions that defines a combination of users, groups, or roles that have access to an object.

Managing Access Control Lists
Defines and describes how to create ACLs.

An access control list (ACL) specifies users or system processes that can perform specific actions on an object.

Creating Cluster-Level ACLs

About this task

A cluster-level ACL determines who has access to a cluster and which actions users are allowed to perform. ACLs on a secure HPE Ezmeral Data Fabric cluster are predicated on a locally-managed OS registry.

IMPORTANT: Before you create an ACL that applies to a particular group, you must create that group and assign users to it.

For example, the Red Hat Linux commands for creating a group called `developers` and adding a user named `jsmith` on a locally-managed OS registry are:

```
groupadd developers
useradd -g developers jsmith
```

After users and groups are defined, an administrator can create a cluster-level ACL using the Control System and CLI.

Creating an ACL from the Control System

last-updated: Jun 06, 2024

Procedure

1. Click **Admin** > **User Settings** > **Permissions**.
2. Follow steps for Adding Cluster Permissions on page 1054.

   Each allowed action has a permission code associated with it. The codes are explained below.

Permission Code	Allowed Action
login	Log in to the Control System, use the API, command-line interface, and read access on cluster and volumes. **NOTE:** Read access allows you to only view file-system objects that already exist. You cannot create volumes, policies, schedules, snapshots, or other file-system objects.
ss	Start/stop services
cv	Create volumes
cp	Create security policies
a	Provides administrative access to cluster ACLs. Grants no other permissions.
fc	Provides full control over the cluster. Enables all cluster-related administrative options, with the exception of changing the cluster ACLs.

Creating an ACL from the Command Line

About this task

To create an ACL at the command line, use the `acl set` command. Include spaces between multiple entries, such as a list of usernames and their associated permission levels (or *actions*).

The syntax is:

```
maprcli acl set -type volume -name <volume name>
                [-group <groupname>:<action> -user <username>:<action>]
```

NOTE: The `acl set` command *removes* previously set permissions if they are not explicitly called out in the command line.

Other ACL commands include:

- acl edit - To modify permissions in an ACL. Use this command instead of `acl set` to change some permissions while leaving others intact.
- acl show - To display permissions in an ACL.

Example

To create an ACL for a cluster named `my.cluster.com` that allows administration of cluster ACLs to user `root` and control over all other aspects of the cluster to all users in the `developers` group, enter this command:

```
maprcli acl set -type cluster -cluster my.cluster.com -user root:a -group
developers:fc
```

last-updated: Jun 06, 2024

To change the `developers` group permissions so they can only log in and start or stop services, use the `acl edit` command:

```
maprcli acl edit -type cluster -cluster my.cluster.com -group
developers:login,ss
```

Note that only the `developers` group's permissions change, while the `root` user retains control over cluster ACL settings.

Creating Job Queue ACLs

About this task

A job queue ACL controls who can submit jobs to a queue, kill jobs, or modify their priority. The default behavior is that any user can submit a job, and jobs can only be seen and killed by the administrator or the user that submitted those jobs.

To create a job queue ACL, specify the following parameters in the `mapred-queue-acls.xml` file.

Parameter	What it does
`mapred.queue.names` *`queue1,queue2,...`*	Names the queues to which jobs can be submitted.
`mapred.acls.enabled=true`	Indicates that ACLs are checked whenever a user or group submits a job, tries to kill a job, or tries to change its priority. This parameter is set to true by default if security features for the cluster are enabled.
`mapred.queue.<queue-name>.acl-submit-job` *`user1,user2,... group1,group2,...`*	Identifies the users and groups that can submit jobs to the specified *queue-name*.
`mapred.queue.<queue-name>.acl-administer-job` *`user1,user2,... group1,group2,...`*	Identifies users and groups that can change the priority or kill jobs submitted to the specified *queue-name*. Note that the job owner can always kill his own job or change its priority.

Results

For information on configuring queue properties, see Configuring Properties for Queues. You can also set job initialization parameters for a queue.

Creating Volume-level ACLs

About this task

MapR provides volumes as a way to organize data and manage cluster performance. For example, to create a volume for each user, department, or project. Create a volume-level ACL that controls which users and groups have access to that volume, and what actions they may perform.

You can create volume-level ACLs from the Control System or from the command line.

Creating Volume-level ACLs from the Control System

Procedure

- For:
  - New volumes, see Creating a Volume on page 1177 to set volume-level ACLs.
  - Existing volumes, see Modifying a Volume on page 1207 to modify volume-level ACLs.

Creating Volume-level ACLs from the Command Line

last-updated: Jun 06, 2024

About this task

To create an ACL at the command line, use the `acl set` command to specify a list of authorized users (or groups) and the actions they are allowed to perform.

The syntax is:

```
maprcli acl set -type volume -name <volume name> [-user
<username>:<action> -group <groupname>:<action>]
```

Include spaces between multiple entries, such as a list of usernames and their associated permission levels (or *actions*). Each allowed action has a permission code associated with it. The codes are explained below.

Permission Code	Allowed Action
dump	Dump or back up the volume
restore	Restore or mirror the volume
m	Modify the volume's properties
d	Delete the volume
a	Administrator (can edit and view ACLs but cannot perform volume operations)
fc	Full control over the volume (This enables all volume-related administrative options with the exception of changing the volume ACLs.)

Example

This example shows how to create an ACL for a volume named `test-volume` that allows full control over volume ACLs for user `rjones`. In addition, all users in the `developers` group are given permission to dump, restore, and modify volume properties.

```
maprcli acl set -type volume -name test-volume -user rjones:fc
-group developers:dump,restore,m
```

Managing Access Control Expressions
Defines and describes how to create, enable, and use ACEs.

ACEs are defined by a combination of user, group, or role definitions.

ACE Syntax
Describes how to construct ACEs.

An *ACE* is defined by a combination of user, group, or *role* definitions. You can combine these definitions using the following syntax:

Operator	Description
u	Username or user ID, as they appear in `/etc/passwd`, of a specific user. Usage: `u:<username or user ID>`
g	Group name or group ID, as they appear in /etc/group, of a specific group. Usage: `g:<group name or group ID>`
r	Name of a specific role. Usage: `r:<role name>`.
p	Public. Specifies that this operation is available to the public without restriction. Cannot be combined with any other operator. API request or CLI command to save such settings will return an error.

last-updated: Jun 06, 2024

Operator	Description
!	Negation operator. Usage: `!<operator>`.
&	AND operation.
|	OR operation
()	Delimiters for subexpressions.
""	The empty string indicates that no user has the specified permission.

An example definition is `u:1001 | r:engineering`, which restricts access to the user with ID 1001 or to any user with the role `engineering`.

In this next example, members of the group `admin` are given access, and so are members of the group `qa`:

`g:admin | g:qa`

Another example is to have a list of groups to which you want to give read permissions:

- The `admin` group as a whole, but not the admins for a particular cluster (which is named `cl3`).
- Members of the `qa` group who are responsible for testing the two applications (named `app2` and `app3`).
- The business analysts (group `ba`) in department 7A (group `dept_7a`)
- All of the data scientists (group `ds`) in the company.

To grant the read permission, you construct this boolean expression:

```
u:cfkane | (g:admin & !g:cl3) | (g:qa & (g:app2 | g:app3)) | (g:ba &
g:dept_7a) | g:ds
```

This expression is made up of five subexpressions which are separated by OR operators:

- The first subexpression `u:cfkane` grants the read permission to the username `cfkane`.
- The subexpression `(g:admin & !g:cl3)` grants the read permission to the admins for all clusters except cluster `cl3`. The operator `g` is the group operator, the value `admin` is the name of the group of all admins. The `&` operator limits the number of administrators who have read permission because only those administrators who meet the additional condition will have it.

  The condition `!g:cl3` is a limiting condition. The operator `!` is the NOT operator. Combined with the group operator, this operator means that this group is excluded and does not receive the read permission.

  WARNING: Be careful when using the NOT operator. You might exclude fewer people than you intended. For example, suppose that you do not want anyone in the group `group_a` to have access. You therefore define this *ACE*: `!g:group_a` You might think that the data is now protected because members of `group_a` do not have access to it. However, you have not restricted access for anyone else except the members of `group_a`. The rest of the world can access the data. You should not define *ACE*s through exclusion by using the NOT operator. You should define them by inclusion and use the NOT operator to limit further the access of the groups or roles that you have included.

  In the subexpression `(g:admin & !g:cl3)`, the NOT operator limits the number of members within the admin group who have access. The `admin` group is included, and all users who are also part of the `cl3` group are excluded.

last-updated: Jun 06, 2024

- The subexpression `(g:qa & (g:app2 | g:app3))` demonstrates use of a subexpression within a subexpression. The larger subexpression means that only members of group `qa` who are also members of group `app2` or `app3` have read access to the data. The smaller subexpression limits the number of people who have this permission in the `qa` group.
- The next two subexpressions -- `(g:ba & g:dept_7a)` and `g:ds` -- grant the read permission to the members of group `ba` who are also in the group `dept_7a`. It also grants permission to the members of the group `ds`.

Creating User Roles for ACEs
Describes how to create and use roles for access control.

NOTE: MapR recommends that you use Unix groups over roles whenever possible for centralized maintenance. Use Roles only if you are unable to modify LDAP or AD groups easily.

A role is a label attached to a set of users and defines a common task or set of behaviors for those users. Roles enable you to use functionality similar to Unix groups for your users without requiring you to alter the existing group hierarchy of your system. Role names can be up to 64 characters long and cannot use the `:`, `&`, `|`, or `!` characters.

Standard Reference Implementation
User Information

The standard reference implementation is a library called `libmapr_roles_refimpl.so`. This library is located at `/opt/mapr/server/permissions`. This library opens a configuration file named `m7_permissions_roles_refimpl.conf`, which should contain a list of all the roles and the users associated with them. This configuration file is located at `/opt/mapr/conf` and should be identical across all clusters.

The structure of the configuration file is shown below. Roles end with `:` and user names are written on each subsequent line. For example:

```
Role_1:
            user_a
            user_b
```

```
Role_2:
            user_b
            user_c
            user_d
            #comment
```

The above example file states that there are two roles from which to choose while assigning permissions: `Role_1` and `Role_2`. The users located under `Role_1` are `user_a`and `user_b`. `Role_2` contains `user_b`, `user_c`, and `user_d`. Blank lines and lines beginning with # are ignored.

Assume a table has permissions `r:Role_2`. `user_b` has access to this table while `user_a` does not have access.

After adding a new role to the `m7_permissions_roles_refimpl.conf` file, you must issue the following command to enable the file system layer to pick up the new role: `$ /opt/mapr/server/mrconfig dbrolescache invalidate`

Run this command on all the nodes whenever a change is needed in the roles configuration file.

Developer Information

The functions that the `libmapr_roles_refimpl.so` exposes are found in the extensibility implementation. If the library is called initially through `GetSecurityMembership`, it parses the `m7_permissions_roles_refimpl.conf` file and loads it into memory. All user names are read and parsed into user IDs (uid_t). If a user ID is not found, the ID is skipped.

The library uses a HashTable. The roles are the keys. The values are a Binary Tree of user IDs.

Each call checks the given user ID and role. The HashTable keys off the role and then searches the Binary Tree for the user ID. If the HashTable finds a user ID, it sets the boolean value of that role to `true`. If the HashTable does not find a user ID or if any errors occur, such as `Role not found`, it sets the boolean value to `false`.

A cleanup method frees the memory allocated to the HashTable along with all of its children. If the `GetSecurityMembership` method is called again, the library reloads the configuration file and loads all the values into memory.

Extensible Implementation

If users decide not to use the reference implementation, they can replace the shared library with their own. In the `mfs.conf` file, add a parameter that specifies the name of the file. If the name of the file is changed, then MFS searches `/opt/mapr/server/permissions` for the new file. If the file is found, it is loaded into memory. If not, then all roles become `false`.

The user's shared library should contain two functions specified under the `mapr::fs` namespace:

```
extern "C"
            void GetSecurityMembership(uid_t uid, const char *roles[], int
numRoles, bool truthValue[]) {
            }
```

```
extern "C"
            void cleanup() {
            }
```

`GetSecurityMembership` takes the given user ID with a list of all the roles, the amount of roles in the array, and an array of all the results, as booleans.

Users must code their own implementation of populating the `truthValue` array with either `true` or `false`. The `truthValue` array has the same length as `numRoles` and is initialized. Do not modify any other variables.

Use the `cleanup` method to reset the shared library to an initialized state. This method resets all values and frees memory since the shared library is not closed until the class that is calling it is destructed.

Invoke Shared Library from MFS

The `TablePermissions` class opens and closes the shared library. During class initialization, the name of the shared library that is read from the `mfs.conf` file is passed to the constructor. The constructor loads the shared library into memory using the `LoadSO` method from `filterutils.cc`. The constructor also loads the `GetSecurityMembership` method with the `cleanup` method and are variables that can be called.

`TablePermissions` contains two methods that can be called to access the shared library:

- The `GetSecurityMembership` method. This method takes three arguments: the user ID, the array of roles, and the amount of roles in the array. This method returns a `RolePermission` structure, which contains all the same data, as well as the boolean of the successful roles for that given user ID. To evaluate the user roles, pass this `RolePermission` structure to the `TablePermission::checkTablePermissions` method.

last-updated: Jun 06, 2024

- The `cleanup` method. This method calls the `cleanup` method in the shared library. This method takes no arguments.

The entity that allocates the `RolePermission` structure into memory also needs to deallocate this structure. Deallocating the `TablePermissions` class calls the `cleanup` method, and closes the shared library.

Shared Library Security

The `/opt/mapr/server/permissions` folder is initialized with `755` permissions. This implies that only the user who installed MapR has access to writing to that folder. These permissions prevent a user from replacing a shared library with a malicious file.

The `m7_permissions_roles_refimpl.conf` file has `755` permission. This permission allows only an administrator to make changes to the file.

The Roles Library Shared Object and ACEs

If you access an object that is secured by an *ACE* , the file system layer calls the roles library a shared object and checks the permissions of the entity requesting access against the contents of the roles file. The roles library shared object reads the roles file every 600 seconds. You can specify your own roles library shared object and specify the location of that object by using the `mfs.dbroles.sopath` parameter in the `/opt/mapr/conf/mfs.conf` file.

Enabling Volume, Directory, and File Authorizations with ACEs
Describes how to set access control expressions for volumes, directories and files.

*ACE*s allow you to define allowlists (to grant access) and denylists (to deny access) for a combination of users, roles, and groups. You can grant different permissions to multiple users, groups, and roles for file system files, directories, and whole volume data using boolean expressions and subexpressions.

ACEs for Files, Directories, and Whole Volume

An *ACE* is defined by a combination of user, group, and/or role definitions. Combine these definitions using the supported syntax. For more information, see Syntax of Access Control Expressions.

The examples in the following table demonstrate how *ACE*s can be used to create allowlists to grant access, and denylists to deny access.

This Access Control Expression...	Grants access to...	Denies access to...
`(u:u1&g:g1)`	only user 'u1', if user 'u1' is a member of group 'g1'	users who are not 'u1' and members of group 'g1'
`(g:g1&g:g2)|r:r1`	only users who are in both the groups 'g1' and 'g2', or users who are assigned role 'r1'	users who are not in both the groups 'g1' and 'g2', and users who are not assigned role 'r1'
`(g:g1&!g:g2)`	only users who are in group 'g1' and not in group 'g2'	users who are in group 'g2', even if they are in group 'g1', and all other users
`(g:g1|g:g2)`	users who are in groups 'g1' or 'g2' only	users who are not in groups 'g1' or 'g2'
`(g:g1|g:g2)&!r:r1`	only users in groups 'g1' or 'g2' and who are not assigned role 'r1'	users who are not members of groups 'g1' or 'g2', users who are assigned role 'r1', even if they are in group 'g1' or 'g2', and all other users
`(p)`	everyone	none
`(!g:g1&!g:g2&!g:g3)`	users who are not in groups 'g1', 'g2', and 'g3'	only users who are in groups 'g1', 'g2', or 'g3'

last-updated: Jun 06, 2024

This Access Control Expression...	Grants access to...	Denies access to...
`((u:u1|u:u2|u:u3)&g:g1&g:g2)&!r:r1`	only users 'u1', 'u2', or 'u3', who are also members in groups 'g1' and 'g2', but not assigned role 'r1'	users who are not 'u1', 'u2', or 'u3' and members of groups 'g1' and 'g2', and users who are assigned role 'r1'
`(u:u1|u:u2|u:u3)&g:g1|g:g2`	only users who are 'u1', 'u2', or 'u3' and who are members in groups 'g1' or 'g2'	users who are not 'u1', 'u2', or 'u3' and members of groups 'g1' or 'g2'

NOTE: The entities — user, group, role, and public — must be the same for file system and HPE Ezmeral Data Fabric Database *ACE*s.

Managing File and Directory ACEs

Describes the implications of setting access control expressions (ACEs) on files and directories.

A file *ACE* allows you to define access (allowlist and denylist) to files and directories for a combination of users, groups, and roles. If ACEs are not set, POSIX mode bits for the file or directory are used to grant or deny access to the file or directory.

When you set ACEs, Data Fabric software sets or resets the corresponding POSIX mode bits to match the permissions granted through ACEs. For more information, see Setting/Modifying File and Directory ACEs.

- If both ACEs and POSIX mode bits are set, access is granted if access is allowed through ACEs or POSIX mode bits.
- If ACEs are not set, POSIX mode bits are used to grant access.
- If neither ACEs nor POSIX mode bits is set, access is denied.

The owner of the file or directory (and `mapr` and `root` users) can set, modify, and remove ACEs for that file or directory using `hadoop mfs` commands.

File ACEs

You can set and modify permissions to read, write, and execute files by using the `hadoop mfs` command or the FileACE Java APIs on page 1864 and FileACE C APIs on page 1864. Specifically, the following access types are supported:

Access Type		
Command Line	**Java API (Enum)**	**Description**
`-readfile`	`READFILE`	Read a file.
`-writefile`	`WRITEFILE`	Write to a file.
`-executefile`	`EXECUTEFILE`	Execute a file.

For more information, see `hadoop mfs`, FileACE Java APIs on page 1864, and FileACE C APIs on page 1864.

Directory ACEs

You can set the same ACEs on directories that you set on files. In addition, directory ACEs support permissions to list, add child, delete child, and lookup directories using the `hadoop mfs` command. Specifically, the following access types are supported:

Access Type		
Command Line	**Java API (Enum)**	**Description**
`-readfile`	`READFILE`	Read a file.

last-updated: Jun 06, 2024

Access Type		Description
Command Line	**Java API (Enum)**	
`-writefile`	`WRITEFILE`	Write to a file.
`-executefile`	`EXECUTEFILE`	Execute a file.
`-readdir`	`READDIR`	List the contents of a directory. This access is required to write and/or execute files in the directory.
`-lookupdir`	`LOOKUPDIR`	Lookup a file in a directory. This access is required to find, read, write, and/or execute files in the directory.
`-addchild`	`ADDCHILD`	Add a file or subdirectory.
`-deletechild`	`DELETECHILD`	Delete a file or subdirectory.

Although you can set both file and directory ACEs on directories, only the directory ACEs are used for determining access to the directory. The file ACE on the directory is used as the default ACE setting for new files under that directory.

By default, when you set ACEs on a parent directory:

- Permissions for existing files and subdirectories under that parent remain unchanged.
- New files under that parent inherit the file ACEs and corresponding POSIX mode bits of the parent directory, if available. Otherwise, new files get the default ACE, the empty string (""), which indicates that no one has permissions to read, write, or execute the file. POSIX mode bits are set on the file in the traditional way.
- New subdirectories under the parent inherit both the directory and file ACEs and corresponding POSIX mode bits from the parent directory.

NOTE: When accessing files and directories, the ACEs on files have no effect on accessing the parent directory.

Workaround for Execute Operation when ACES are set on an executable file

When ACEs are set on any file, mode bits are cleared. For a binary to execute, the kernel checks whether the execute bit is set or not, and restricts execution if it is not set. To run an executable file with ACEs set on it, use one of the following workarounds:

1. Set owner mode exec bit on binaries/shell scripts.
2. Set group mode exec bit on binaries/shell scripts.
3. Change owning group for the files to the group used in MapRAces, and set the executable group mode bit.

Setting File and Directory ACEs

Describes how to set ACEs for files and directories.

For files and directories, run the `hadoop mfs` command to set *ACE*s. After *ACE*s are set, by default, the corresponding POSIX mode bits are also set. POSIX mode bits for owner and owning group are deduced by evaluating the corresponding *ACE*s. POSIX mode bits for others is set only if `"p"` is given as the value for an *ACE*.

The following table lists POSIX mode bits and corresponding access types.

last-updated: Jun 06, 2024

	ACE	POSIX Mode Bits
File	`readfile`	r
	`writefile`	w
	`executefile`	x
Directory	`readdir`	r
	`addchild`	w
	`deletechild`	w
	`lookupdir`	x

The POSIX mode bit that grants write (`w`) access to a directory is set only if the user, role, or group is granted permission for both access types (`addchild` and `deletechild`).

The `hadoop` command, by default, sets the POSIX mode bits that correspond to the given *ACE*s, and:

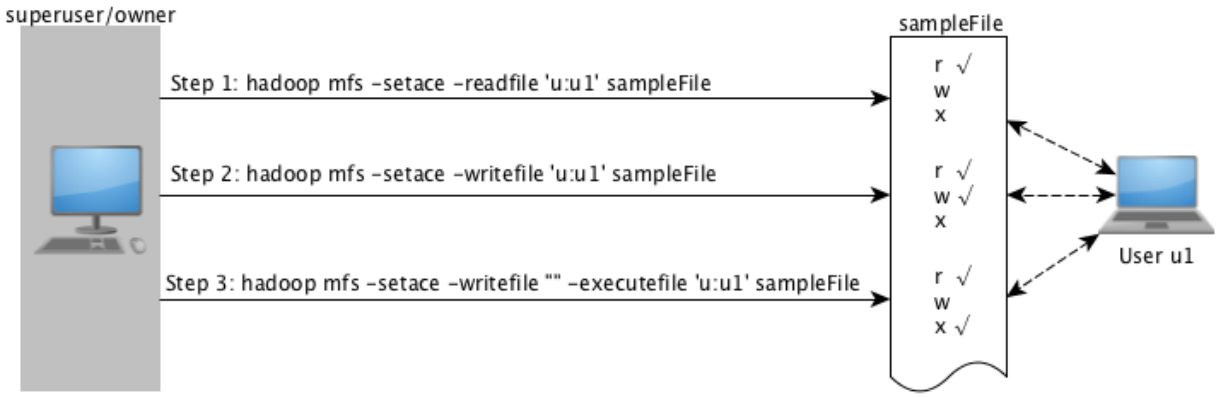
- Overwrites existing *ACE* values with new values, if specified, for access types that were previously set.
- Sets *ACE* values for access types that have not yet been set, if specified.
- Does not modify access types that are not specified with the command, regardless of how they were previously set.

WARNING: Changing the POSIX mode bits using `chmod` does not change the corresponding *ACE* setting and may result in different, conflicting permissions to files and directories.

File ACE Example

Illustrates setting access control expressions for files.

Suppose the following sequence of file *ACE* settings and corresponding POSIX mode bits are set for user u1.



As shown in the preceding illustration, in:

Step 1:

User u1 is granted permissions to read a file, `sampleFile`.

After the command runs, user u1 has permissions to (only) read the file. The POSIX mode bit for reading the file is set to u1 for owner/users.

There is no change in *ACE*s or POSIX mode bits for all other (write and execute) access types.

last-updated: Jun 06, 2024

Step 2:

User u1 is granted permissions to write to the same file.

After the command runs, user u1 has permissions to write to the file. The POSIX mode bit for writing to the file is set to u1 for owner/users.

There is no change in *ACE*s or POSIX mode bits for all other (read and execute) access types.

Step 3:

User u1's permissions are modified to remove write permission (using the empty string) and to grant access to execute file.

After the command runs, user u1 has permissions to execute the file, but user u1 can no longer write to the file. The POSIX mode bit for:

- Writing to the file is set to 0 for owner/users, groups, and others.
- Executing the file is set to u1 for owner/users.

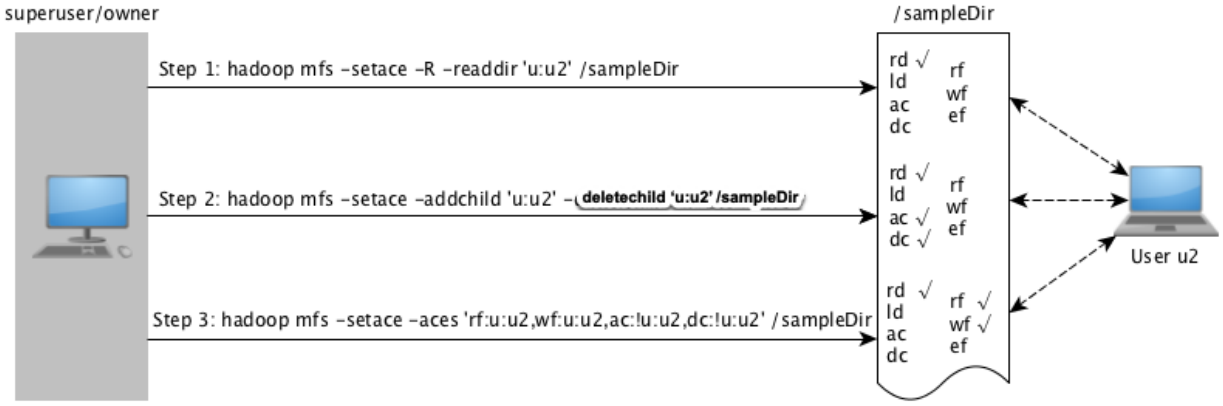
NOTE: When the empty string ("") is used to deny a specific type of file access, that type of file access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`).

There is no change in *ACE*s or POSIX mode bits for all other (read) access types.

Directory ACEs Example

Explains how to set access control expressions for directories.

For example, suppose the following diagram depicts the (command-line) sequence of directory *ACE* settings for user u2:



As shown in the preceding illustration, in:

Step 1:

User u2 is granted access to read directory and sampleDir, while all other directory/file *ACE*s are not specified.

After the command runs, user u2 has permissions to list the contents of the directory. The POSIX mode bits for listing the contents of the directory (`r`) is set to u2 for owner/users.

last-updated: Jun 06, 2024

	There is no change in *ACE*s or POSIX mode bits for all other (file- and directory-level) access types.
Step 2:	User u2 is granted permission only to add and delete child directories, while all other directory/file *ACE*s are not specified. After the command runs, user u2 has permissions to create and delete child directories. The POSIX mode bit for writing (`w`) to the directory for owner/user is set to u2 because user u2 is granted access for both (`addchild` and `deletechild`) access types. If user u2 creates child directories, by default, they inherit the *ACE* settings of the parent directory. There is no change in *ACE*s or POSIX mode bits for all other (file- and directory-level) access types.
Step 3:	User u2's permissions are modified to grant access to read and write to files in the directory. User u2's permissions for adding and deleting child directories are removed (using the negation operator). All other directory/file *ACE*s are not specified. After the command runs, user u2 can read and write to files in the directory, but user u2 can no longer add and delete child directories. The POSIX mode bits for directory write access (`w`) is set to 0 for owner/user. Although at the directory level, user u2 has permissions to read and write to files in the directory for existing files, the file level *ACE*s or the POSIX mode bits for the file are used to determine access. By default, user u2 gets read and write permissions to all new files created under the directory. If user u2 creates new files under the directory, the files inherit the file *ACE*s from the parent directory by default, and the POSIX mode bits for read (`r`) and write (`w`) access are set to u2 for owner/user. There is no change in *ACE*s or POSIX mode bits for all other (`lookupdir` and `executefile`) access types.

Deleting File and Directory ACEs
: Describes how to delete file and directory ACEs using the CLI.

  You can remove all *ACE* associated with a file or directory using the `hadoop mfs -delace` command. After you delete all the *ACE*s, the system sets the *ACE* for the file or directory to the default value, which is the empty string (""). The POSIX mode bits are not reset; if necessary, run the `chmod` command to reset POSIX mode bits.

  You cannot remove specific access types that have been set. Use the empty string to deny specific types of access. After the empty string ("") is used to deny a specific type of access, that type of access is denied to all users, groups, and roles. To deny access to specific users only, use the negation operator (`!`). If you use the empty string ("") or the negation operation (`!`) to deny a specific type of access, the corresponding POSIX mode bit are also reset to match the *ACE* setting.

FileACE Java APIs
: Contains the path to the Java FileACE APIs.

  The Java FileACE APIs are located at File ACE APIs.

FileACE C APIs
: Describes the FileACE C APIs.

  The FileACE C APIs are defined in the `hdfs.h` header file and are as described below.

hdfsSetAces

Sets the ACEs for a file or directory.

Syntax

```
int hdfsSetAces(hdfsFS fs, const char *path, hdfsFileAces *faces, int
isSet, int isRecursive);
```

Parameters

- **fs**: The configured filesystem handle.
- **path**: The path to the file or directory for which the ACEs need to be set.
- **faces**: The ACEs to set.
- **isSet**: Set to 0 to merge with any existing ACEs. Set to 1 to replace all existing ACEs.
- **isRecursive**: Set to 1 to apply ACEs recursively if set on a directory.

Return Value

0 on success, else an error code.

hdfsGetAces

Gets the ACEs from a file or directory.

Syntax

```
int hdfsGetAces(hdfsFS fs, const char *path, void *aceBuf, int bufLen,
hdfsFileAces *faces);
```

Parameters

- **fs**: The configured filesystem handle.
- **path**: The path to the file or directory from which the ACEs need to be fetched.
- **aceBuf**: The buffer to hold the ACEs.
- **bufLen**: Length of the ACE buffer (*aceBuf*).
- **faces**: The structure that contains the returned ACEs.

Return Value

The value is 0 upon success. Otherwise, the `ERANGE` error occurs, which indicates that the buffer is too small to hold the ACE entries.

hdfsDeleteAces

Deletes all ACEs from a file or directory.

Syntax

```
int hdfsDeleteAces(hdfsFS fs, const char *path);
```

Parameters

- **fs**: The configured filesystem handle.

last-updated: Jun 06, 2024

- **path**: The path to the file or directory from which the ACEs need to be deleted.

Return Value

The value is 0 upon success. Otherwise, an error occurs, as appropriate.

Managing Whole Volume ACEs

Describes how to grant permissions to users, groups, and roles for the volume data using whole volume ACEs.

Whole volume *ACE*s allow you to define allowlists to grant access and denylists to deny access for files and tables within a volume.

Volume administrators and mapr user can set and modify whole volume *ACE*s. By default, *ACE*s grant everyone access to read and write to files and tables in the volume at the volume-level. Inside the volume, to determine access for:

- Files, the file *ACE*s or POSIX mode bits are used.
- Tables, the table *ACE*s are used.

Supported Access Types

At the volume level, the following access types are supported:

Access Type	Description
`-readAce`	Read files, HPE Ezmeral Data Fabric Database binary tables, HPE Ezmeral Data Fabric Database JSON tables, and MapR streams in the volume. By default, this is set to p to grant all users this permission.
`-writeAce`	Write to files, HPE Ezmeral Data Fabric Database binary tables, HPE Ezmeral Data Fabric Database JSON tables, and MapR streams in the volume. By default, this is set to p to grant all users this permission.

ACE Behavior on Snapshots and Mirrors

Volume Snapshots

Volume snapshots reflect the *ACE*s of the volume at that point in time. Changes in volume *ACE*s:

- Are carried over to a new snapshot of the volume.
- Do not propagate to older snapshots of the volume.

Volume Mirrors

*ACE*s of a volume are propagated to mirror volumes. After each mirroring operation, mirror volumes reflect the current *ACE* setting of their source volume. After a mirror volume is promoted to a read-write volume, you can modify the *ACE*s on the mirror volume from the command line. *ACE*s on the promoted mirror volume can be different from the source volume.

Setting Whole Volume ACEs

Describes how to set ACE expressions when creating or modifying volumes.

You can set *ACE*s at the time of volume creation using the `volume create` on page 2588 command and modify them at a later time using the `volume modify` on page 2676 command. When you run the command to set or modify *ACE*s, the command does the following:

- Overwrites existing values with new values, if specified, for access types that were previously set.
- Sets values for access types that have not yet been set, if specified.

last-updated: Jun 06, 2024

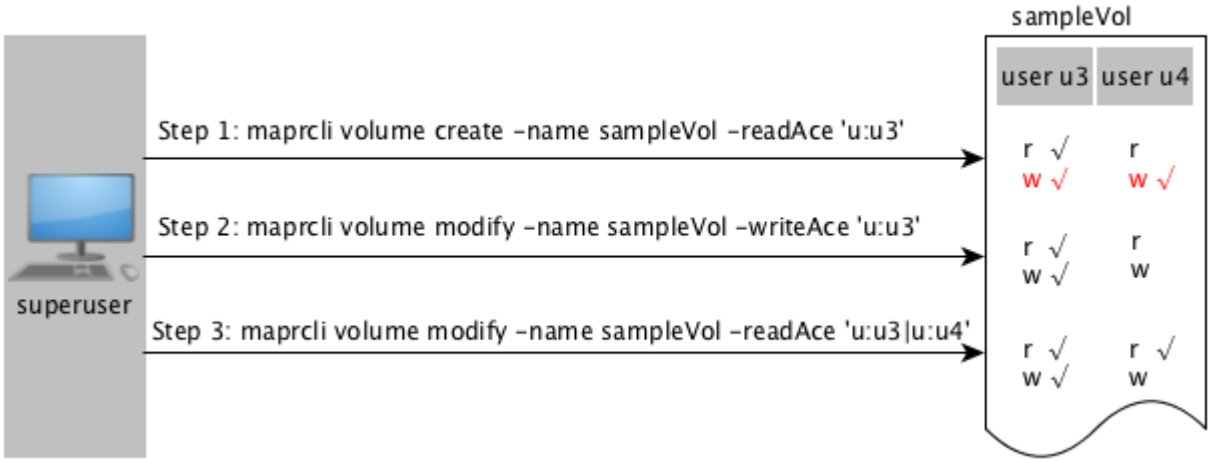
- Does not modify access types that were not specified with the command, whether they were previously set or are unset.

When you set whole volume *ACE*s, permissions on files and tables under that volume remain unchanged. Also, new files and tables in the volume do not inherit the whole volume *ACE*s of that volume. Instead, whole volume *ACE*s, if set, are used to determine volume level access to tables and files within the volume. To gain access to volume data, the user must have access at both the volume and file/table levels.

Whole Volume *ACE* Example

For example, suppose the following sequence of whole volume *ACE* settings for users u3 and u4 is as follows.

NOTE: In the following illustration, default *ACE* values are shown in red.



As shown in the illustration above, in:

Step 1:

User u3 is granted permissions to read.

User u3: User u3 has permissions to read files and tables at the volume level and by default, user u3 has write permission (shown in red) at the volume level. However, for:

- Files in the volume, file *ACE* or POSIX mode bits are used to determine read and write access for user u3.
- Tables in the volume, table *ACE*s are used to determine read and write access for user u3.

User u4: User u4 cannot read files and tables within the volume because the *ACE* for the volume does not explicitly grant access to user u4. Although user u4 has write permission by default, user u4 cannot write to files/tables in the volume because user u4 does not have read permission.

Step 2:

User u3 is granted permissions to write.

User u3: User u3's read access remains unchanged and although user u3 has permissions to write to files and tables, for:

last-updated: Jun 06, 2024

	• Files in the volume, file *ACE* or POSIX mode bits are used to determine write access for user u3. • Tables in the volume, table *ACE*s are used to determine write access for user u3. **User u4:** User u4 cannot write to files/tables in the volume.
Step 3	User u4 is granted read access. **User u3:** User u3's read and write access remains unchanged. **User u4:** User u4 has permissions to read files and tables at the volume-level; however, for: • Files in the volume, file *ACE* or POSIX mode bits are used to determine read access for user u4. • Tables in the volume, table *ACE*s are used to determine read access for user u4.

Deleting Whole Volume ACEs

You cannot remove ACEs that have been set. If you must remove ACEs, use the empty string (`""`) to deny specific types of access. If the empty string is used to deny a specific type of access, that type of access is denied to all users. To deny access to specific users only, use the negation operator (`!`).

Enabling Table and Stream Authorizations with ACEs

About this task

Permissions for MapR tables, column families, and columns are defined by ACEs. Set permissions for tables after you create or edit tables. Set default permissions for column families when you create or edit tables, and you can override these defaults when you create column families.

For the syntax to use when creating Access Control Expressions, see ACE Syntax on page 1855.

If a user, group, or role requests to read data from, write data to, or append data to a column, HPE Ezmeral Data Fabric Database checks whether that user, group, or role has read or write permission for the column family AND read or write permission for the column. By default, columns allow read and write access to all users; in such cases, only the read or write permission for the column family matters.

However, suppose that a table contains columns `col1` and `col2` in column family `cf1`, and these columns grant read and write permission only to the table creator. A different user tries to write data to these columns. HPE Ezmeral Data Fabric Database checks whether this user has write permission on `cf1` AND `col1` AND `col2`. If the user does not have all three permissions, HPE Ezmeral Data Fabric Database returns an error that says access for the write is denied.

If this user were to try to read from the same two columns, HPE Ezmeral Data Fabric Database would simply not return the data. If the user tried to read from those two columns and additional columns on which he had read permissions, the results would contain the data for those additional columns but exclude the data for `col1` and `col2`.

NOTE: Table Permissions for Older Releases: Because MapR tables are stored at the file-system level, you can also set permissions for HPE Ezmeral Data Fabric Database tables directly in the file system, if your version of MapR does not support ACEs. Support for ACEs was introduced in version 3.1.

To set permissions directly in the filesystem, see Performing File System Operations on HPE Ezmeral Data Fabric Database Tables on page 1390.

Setting Table ACEs Using the CLI

About this task

You can set ACEs with the following commands:

- `table create` on page 2412 — Creates a new MapR table.
- `table edit` on page 2468 — Edits a MapR table.
- `table cf create` on page 2438 — Creates a column family for a MapR table.
- `table cf edit` on page 2444 — Edits a column-family definition.
- `table cf colperm set` on page 2420 — Set Access Control Expressions (ACEs) for a specified column.

Setting Stream ACEs Using the CLI

About this task

You can set ACEs with the following commands:

- `stream create` on page 2368 — Creates a new MapR stream.
- `stream edit` on page 2375 — Edits a MapR stream.

Permission Types for Fields and Column Families in JSON Tables

By using ACEs, you can grant or deny access to fields and column families that are in JSON tables.

There are three types of permission:

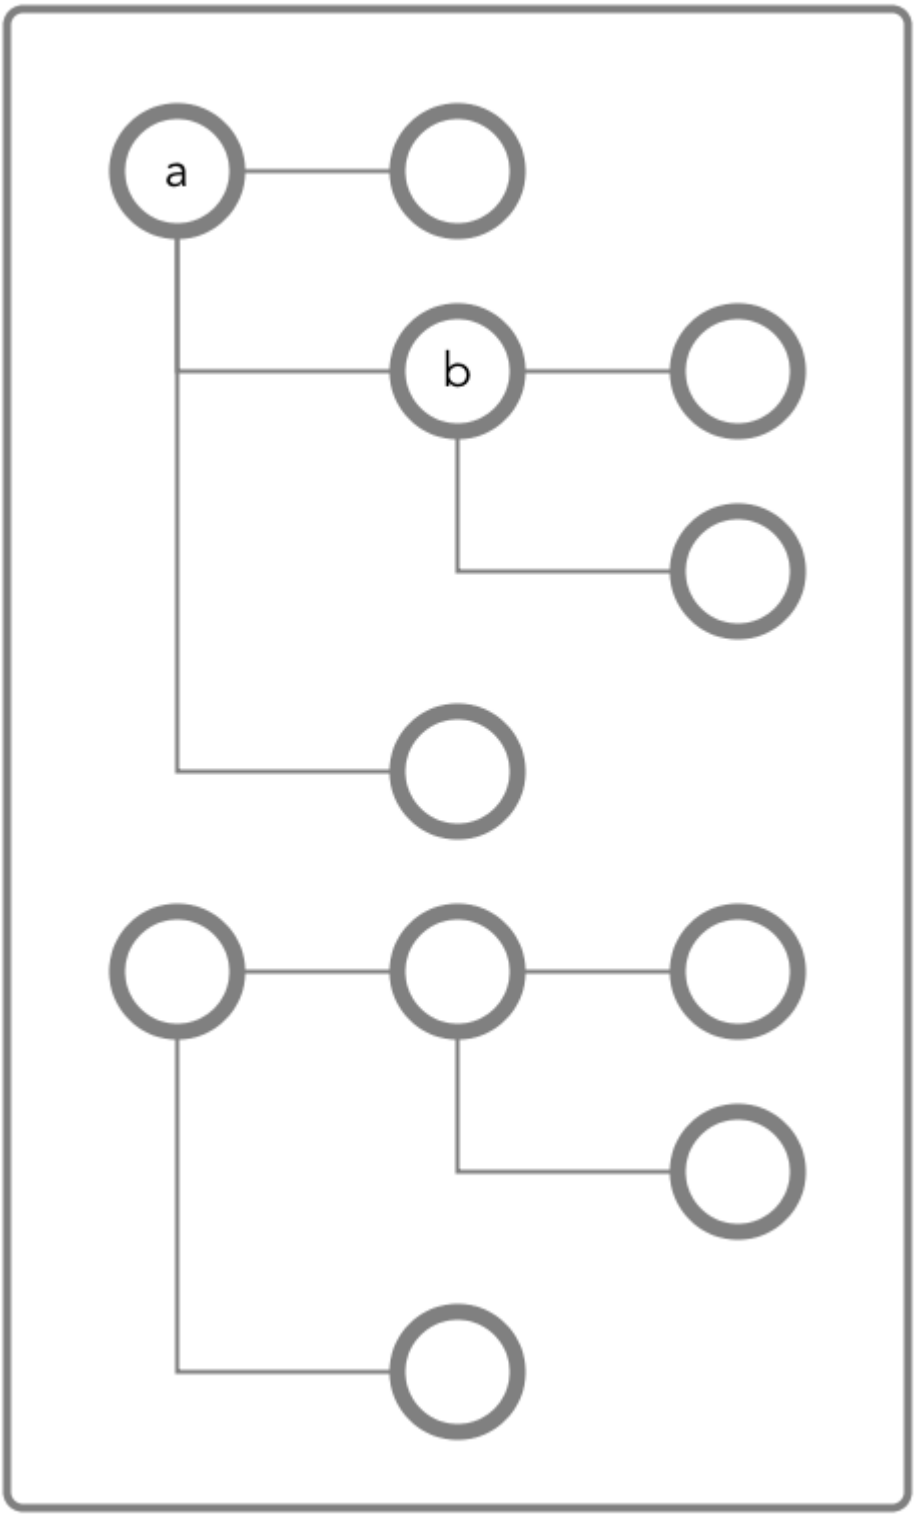
- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (`traverseperm`)

This permission allows the grantee to descend a hierarchy of fields to access fields on which the grantee has write or read permission.

For example, suppose that a user has read and write access to only field b below.

last-updated: Jun 06, 2024

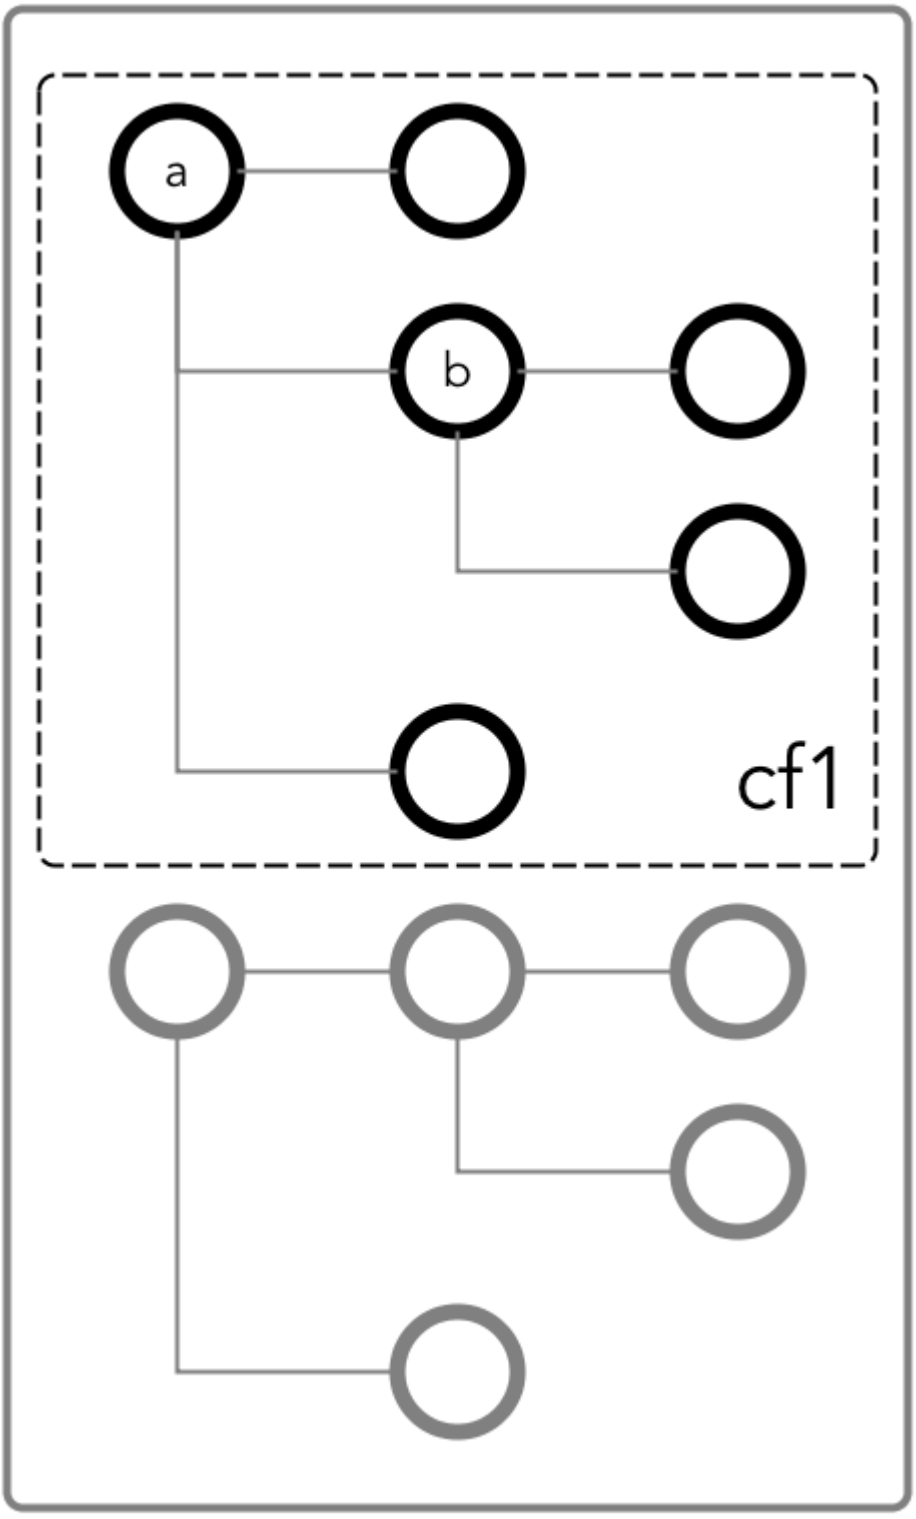


To access field b, the user would need to be able to traverse (pass through) field a. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If a user was denied traverse permission on the default column family, the user would not be able to access field b. Granting traverse permission on field a in this case would have no effect.

last-updated: Jun 06, 2024

In the example below, field a is part of the `cf1` column family.



To be able to read and write at field b, the user could be granted the traverse permission on the column family.

Read (`readperm`)

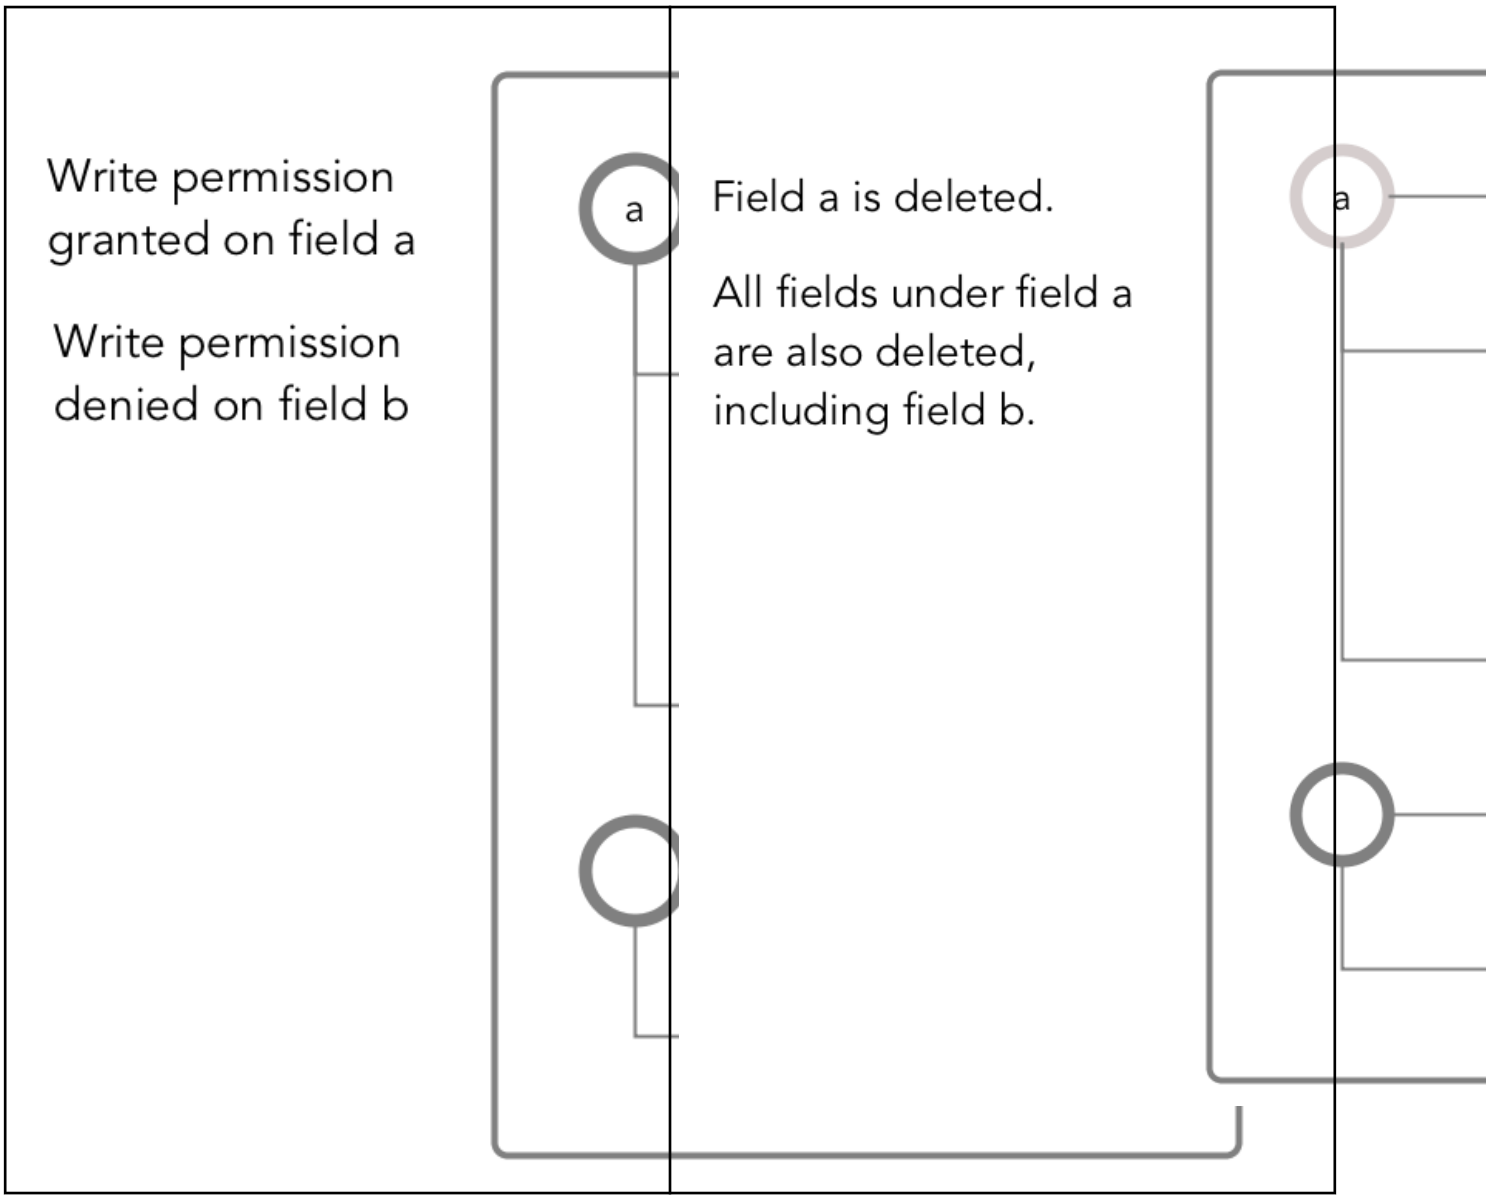
The read permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field on which the permission was granted. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (`writeperm`)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite field value.

As illustrated in the two diagrams below, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.



Obtaining `readperm` and `writeperm` on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

last-updated: Jun 06, 2024

If the field is in the default column family

In the document below, you want to perform an operation on field c, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field c.

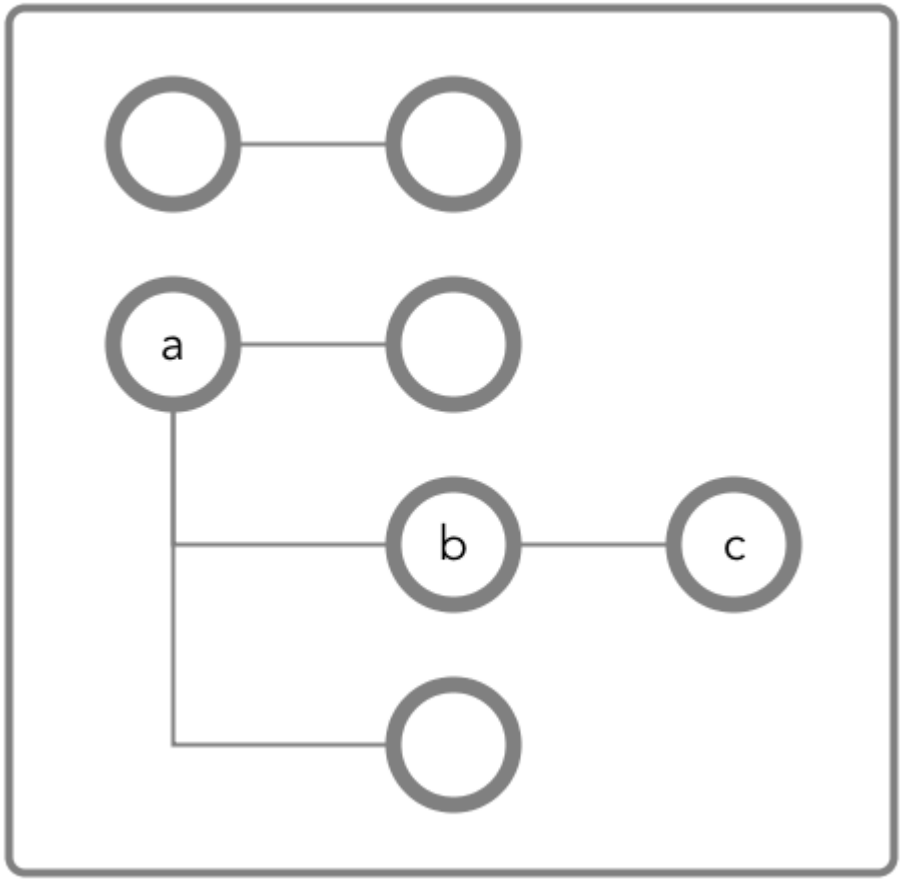


Figure 24: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field c inherits these permissions, assuming that the permissions were not denied on field a or b.

If you do not have `readperm` and `writeperm` on field a or b, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field c. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```
maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
```

last-updated: Jun 06, 2024

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have `readperm` and `writeperm` on the default column family

In this case, you need the `traverseperm` permission on the default column family. Fields a and b inherit this permission. You also need `readperm` and `writeperm` on field `c`.

You could be granted these permissions with commands similar to these:

```
maprcli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see Column Families in JSON table.

In the following document, you want to perform an operation on field `c`, which is in the column family `cf1` that is defined at field b with the path `a.b`.

last-updated: Jun 06, 2024

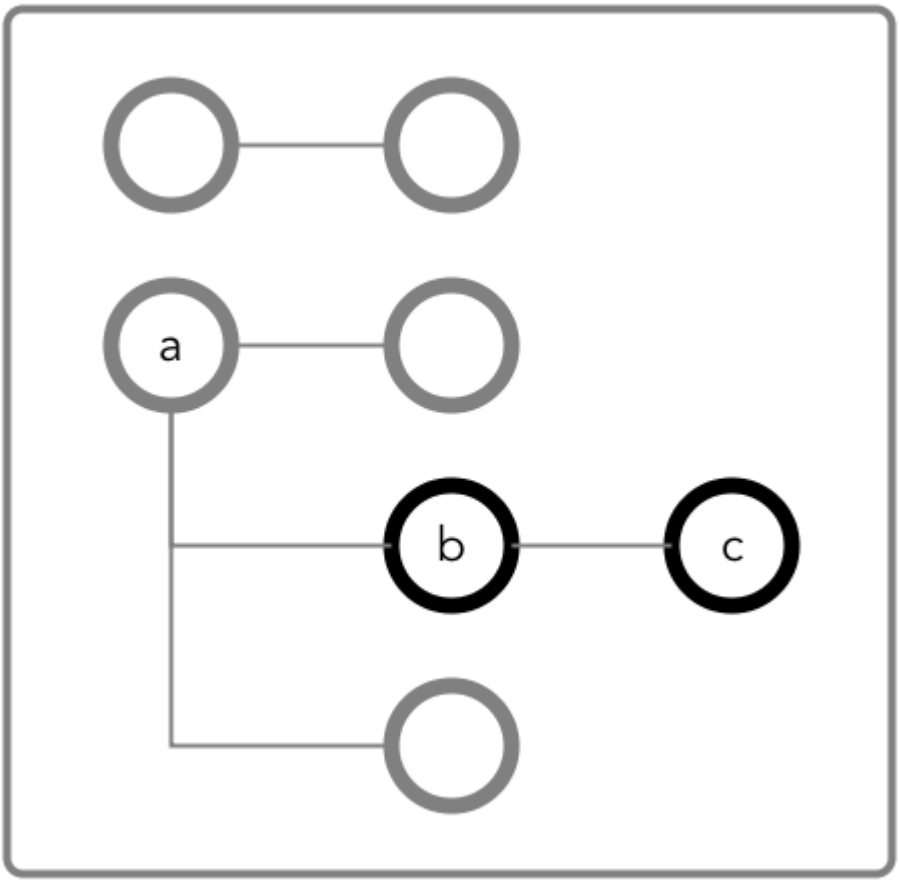

Figure 25: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have `readperm` and `writeperm` on field `b`	You need `traverseperm` on field b and both `readperm` and `writeperm` on field c. You can be granted these permissions with commands similar to these:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field> -writeperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have `readperm` and `writeperm` on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Obtaining `readperm` or `writeperm` on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm or writeperm permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

If the field is in the default column family

In the following document, you want to perform an operation on field `c,` which is in the default column family. The operation requires you to have `readperm` or `writeperm` on field `c`.

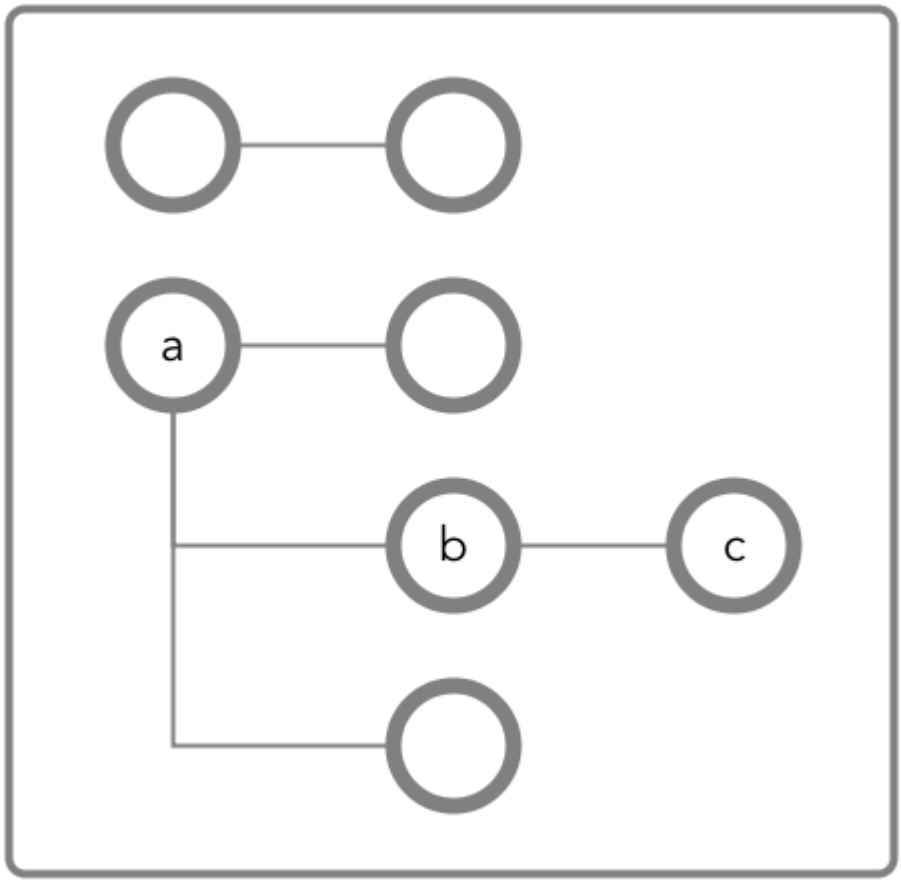

Figure 26: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (`readperm` or `writeperm`) on the default column family

In this case, field `c` inherits the permission, assuming that the permission was not denied on field `a` or `b`.

If you do not have `readperm` or `writeperm` on field `a` or `b`, you need `traverseperm` on the field that denied you the permission that you need. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b -traverseperm
```

last-updated: Jun 06, 2024

```
u:<user ID> | <existing ACE for this
field>
```

The next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (`readperm` or `writeperm`) on the default column family

In this case, you need the `traverseperm` permission on the default column family. You also need `readperm` or `writeperm` explicitly granted to you on field `c`.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants `readperm`:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Ezmeral Data Fabric Database's native JSON support. For information about them, see Column Families in JSON Tables.

In the following document, you want to perform an operation on field `c`, which is in the column family that is defined at field `b` with the path `a.b`. The operation requires you to have `readperm` or `writeperm` on field `c`.

last-updated: Jun 06, 2024

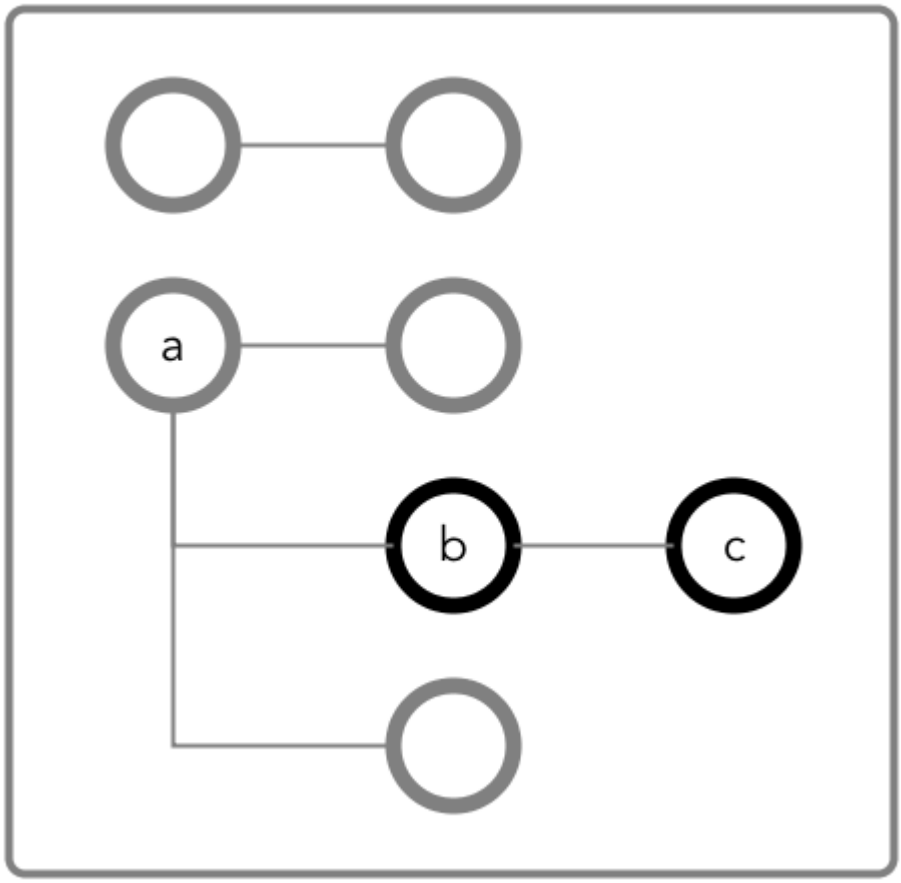

Figure 27: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path `a.b`

Case 1: You do not have the permission you need (`readperm` or `writeperm`) on field `b`	You need `traverseperm` on field b, and you need `readperm` or `writeperm` granted to you explicitly on field c.
	Example commands to grant these permissions:
	`/opt/mapr/bin/maprcli table cf edit -path <path to JSON table> -cfname cf1 -traverseperm u:<user ID> | <existing ACE for this field>`
	`maprcli table cf colperm set -path <path to JSON table> -cfname cf1 -name a.b.c -readperm u:<user ID> | <existing ACE for this field>`

Case 2: You do have the permission you need (`readperm` or `writeperm`) on field `b`	You do not need any further permissions. Field c inherits your `readperm` and `writeperm` permissions from field b.

Setting Permissions on Arrays

If you are granting permissions on a field and the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and

scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

NOTE: This topic describes the behavior of permissions in HPE Ezmeral Data Fabric Database version 6.1 and later, regardless of the data-fabric version you used to grant the permissions.

Granting Permissions on Array Elements

Suppose you have the following documents where `person` is:

- An array of nested documents in document `id001`
- A single nested document in document `id002`
- A scalar value in document `id003`

```
{
    "_id" : "id001",
    "person" : [
        {"name" : {"last" : "Smith", "first" : "John"}},
        {"name" : {"last" : "Subramanium", "first" : "Ananya"}}
    ]
}
{
    "_id" : "id002",
    "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
    "_id" : "id003",
    "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document `id001`. The permission also enables the user to read the `person` field in documents `id002` and `id003`.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person` to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents `id001` and `id002`.

last-updated: Jun 06, 2024

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables

Summarizes the default ACEs for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

Action	Method	Permissions	Default Access-Control Expressions
Set default permissions on new column families when creating a JSON table.	Java API	`-defaultreadperm -defaulttraverseperm -defaultwriteperm`	`u:<ID of the process>`
	`maprcli table create`		`u:<user ID of table creator>`
	mapr dbshell		
	Control System		
Set default permissions on new column families when editing a JSON table.	`maprcli table edit`		Current ACEs
	Control System		
Set permissions on a column family when creating the column family.	`maprcli table cf create`	`-readperm -traverseperm -writeperm -indexperm`	ACEs for `-defaultreadperm`, `-defaulttraverseperm`, and `-defaultwriteperm`
	Control System		
Set permissions on a column family when editing the column family.	`maprcli table cf edit`		Current ACEs
	Control System		
Set permissions on individual fields.	`maprcli table cf colperm set`		Inherited from column family or parent field
	Control System		
Set the dynamic mask	`maprcli table cf column datamask set`	`-defaultunmaskedreadperm -unmaskedreadperm`	Set to the table creator
	`maprcli table cf colperm set`		
	`maprcli table create`		
	`maprcli table edit`		
	`maprcli table cf create`		
	`maprcli table cf edit`

Defining ACEs Using the Access Control Expression Builder
Describes how to build ACEs using the Expression Builder.

About this task

To define access control expressions using the **Access Control Expression** builder in the MapR Control System:

Procedure

1. Choose **All** or **Any** (from the drop-down menu) of the settings to match for access.
   Here:

All	AND (&) operation	Indicates that all of the conditions must be met for public or user, group, and role to access the volume.
Any	OR (|) operation	Indicates that any one of the conditions must be met for public or user, group, and role to access the volume.

2. Click:

+	To add an expression.
( )	To add a subexpression.
x	To remove an expression or subexpression.

3. Select **Public or User**, **Group**, or **Role** from the drop-down menu and:
   a) Choose **Is** to grant or **Is not** to block access to the user, group, or role.
   b) Enter the name of the user, group, or role.
4. Click **Save Changes** to create an ACE.

Setting Whole Volume ACEs Using the CLI

About this task
See Setting Whole Volume ACEs on page 1365.
Setting Table ACEs Using the CLI

About this task
See Enabling Table and Stream Authorizations with ACEs on page 1363.
Setting Stream ACEs Using the CLI

About this task
See Enabling Table and Stream Authorizations with ACEs on page 1363.
Setting Data ACEs
Describes how to set ACEs using both the GUI and the CLI.

About this task

To set data *ACE* using the **Add Access Permission** window in the MapR Control System:

Procedure

1. Specify the entities to set permissions for by doing one of the following:

last-updated: Jun 06, 2024

- Move the slider associated with **Public** to **Yes** to grant access to all users or to **No** to set permissions for individual users, groups, and/or roles.
- Specify the users, groups, and/or roles to set permissions for in the associated fields.
- Select the **Custom ACE** checkbox and enter the access control expression in the field.

2. Click **Add** to set permissions for all or for the specified users, groups, and/or roles.
3. Select the permissions to grant the specified users, groups, and/or roles from the **Permissions** column associated with the entities.
4. Click **Save Changes** to save the *ACE* settings.

Setting Whole Volume ACEs Using the CLI

About this task

See Setting Whole Volume ACEs on page 1365.

Setting Table ACEs Using the CLI

About this task

See Enabling Table and Stream Authorizations with ACEs on page 1363.

Setting Stream ACEs Using the CLI

About this task

See Enabling Table and Stream Authorizations with ACEs on page 1363.

Granting Access Using Security Policy

Describes how to grant access to objects using ACEs in a security policy.

About this task

You can define access controls in a security policy using the Control System, CLI, and REST API.

Defining Access Controls in Security Policy Using the Control System

Procedure

1. Log in to the Control System and go to the **Create Security Policy** page.

   See Creating a Security Policy on page 1893 for more information.

2. Grant or deny access to all users (Public) or to specific users or groups in the **Data Access Control** Section.

   The following types of access can be granted to all (Public) or specific users or groups:

last-updated: Jun 06, 2024

Object	Permission
Directories	• **Read** the contents of a directory. If you do not select this permission, mode bits are used to determine read access. To read the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume, the parent directory (if any), and the file. • **Lookup** or list the contents in a directory. If you do not select this permission, mode bits are used to determine lookup access. To lookup a file of directory that is tagged with this security policy, the user must also have read permissions on the volume and the lookup permission on the directory. • **List** the contents of a directory. If you do not select this permission, mode bits are used to determine **directorylist** access. To **list** the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume, and lookup permission on all directories in the path (if any). • **Add** a file or subdirectory. If you do not select this permission, mode bits are used to determine permissions to create files or subdirectories. To add a child to a directory that is tagged with this security policy, the user must also have write permissions on the volume and the parent directory, add child permission on the parent directory, and read and execute permissions on all directories in the path. • **Delete** a file or subdirectory. If you do not select this permission, mode bits are used to determine permissions to create files and/or subdirectories. To delete a child of a directory that is tagged with this security policy, the user must also have write permissions on the volume and delete child permission on the parent directory, and lookup permissions on all directories in the path. For more information, see Managing File and Directory ACEs on page 1860.
Files	• **Read** a file. If you do not select this permission, mode bits are used to determine read access to file. To read a file that is tagged with this security policy, the user must also have read permissions on the volume, and lookup permission on all directories in path. • **Write** to a file. If you do not select this permission, mode bits are used to determine read access to the file. To write to a file that is tagged with this security policy, the user must also have write permissions on the volume, and lookup permission on all directories in the path. • **Execute** a file. If you do not select this permission, mode bits are used to determine execute access to the file. To execute a file that is tagged with this security policy, the user must also have read permissions on the volume, and lookup permission on all directories in the path. For more information, see Managing File and Directory ACEs on page 1860.

last-updated: Jun 06, 2024

Object	Permission
Tables	• **Read** new column families that are created in the table. • **Traverse** to descend a hierarchy of column families. • **Write** to new column families that are created in the table. • **Mask** information when retrieved from the table. For more information, see Enabling Table and Stream Authorizations with ACEs on page 1363 and Dynamic Data Masking on page 884.

3. Complete the steps to create the security policy.
   See Creating a Security Policy on page 1893 for more information.

Granting Access Using the CLI and REST API

About this task
You can grant access to file system and HPE Ezmeral Data Fabric Database data objects using a security policy at the time of creating or modifying a security policy.

CLI

Use the following command to set access controls when creating a security policy:

```
/opt/mapr/bin/maprcli security policy
create -<ACEparam> <ACEsyntax>
```

Use the following command to specify *ACE*s when modifying a security policy:

```
/opt/mapr/bin/maprcli security policy
modify -<ACEparam> <ACEsyntax>
```

REST

Send a request of type POST. For example:

```
curl -k -X POST ''https://
<hostname>:8443/rest/security/policy/
create?
name=<policyName>&<ACEparam>=<ACEsynta
x>' --user <username>:<pwd>
```

```
curl -k -X POST 'https://
<hostname>:8443/rest/security/policy/
modify?
name=<policyName>&<ACEparam>=<ACEsynta
x>' --user <username>:<pwd>
```

Refer to the ACE Syntax on page 1855 for more information. The following sections describe the *ACE* parameter to specify for a specific type of access on a data object.

Directories

- `readdirace` to read the contents of a directory. See **Read** for Directories in the *Defining Access Controls in Security Policy Using the Control System* section for more information.

last-updated: Jun 06, 2024

	• `lookupdirace` to lookup or list the contents in a directory. See **Lookup** for Directories in the *Defining Access Controls in Security Policy Using the Control System* section for more information. • `addchildace` to add a file or subdirectory. See **Add** for Directories in the *Defining Access Controls in Security Policy Using the Control System* section for more information. • `deletechildace` to delete a file or subdirectory. See **Delete** for Directories in the *Defining Access Controls in Security Policy Using the Control System* section for more information. For more information, see Managing File and Directory ACEs on page 1860.
Files	• `readfileace` to read a file. See **Read** for Files in the *Defining Access Controls in Security Policy Using the Control System* section for more information. • `writefileace` to write to a file. See **Write** for Files in the *Defining Access Controls in Security Policy Using the Control System* section for more information. • `executefileace` to execute a file. See **Execute** for Files in the *Defining Access Controls in Security Policy Using the Control System* section for more information. For more information, see Managing File and Directory ACEs on page 1860.
JSON Tables	• `readdbace` to read new column families that are created in the table. • `traversedbace` to descend a hierarchy of column families. • `writedbace` to write to new column families that are created in the table. • `unmaskedreaddbace` to read data masked. For more information, see Enabling Table and Stream Authorizations with ACEs on page 1363 and Dynamic Data Masking on page 884.

Creating Subnet Whitelists

Provides the procedure necessary to restrict access to cluster data.

About this task

To provide additional cluster security, limit cluster data access to a whitelist of trusted subnets. The `mfs.subnets.whitelist` parameter in `mfs.conf` accepts a comma-separated list of subnets in CIDR notation. If this parameter is set, the FileServer service only accepts requests from the specified subnets.

Procedure

1. Edit `/opt/mapr/conf/mfs.conf` and modify the `mfs.subnets.whitelist` parameter.

last-updated: Jun 06, 2024

2. Add a comma-separated list of subnets in CIDR notation.
3. Restart the FileServer.

Configuring Policy-Based Security
Starting in HPE Ezmeral Data Fabric 6.2.0 (EEP 7.0.0), HPE Ezmeral Data Fabric supports Policy-Based Security. Policy-Based Security is a mechanism that enables administrators to create security policies for simplified data management. Administrative users can create and manage security policies through the control system, maprcli, REST API, Hadoop and Linux commands, and Java APIs.

IMPORTANT: Some setup and configuration is required before you can create and manage security policies in a cluster. Read Policy-Based Security on page 854 for an overview of the process.

The following sections provide information and instruction for several tasks related to security policies:

Setting Global Configuration Options for Policy-Based Security
The CLDB stores global configuration settings for Policy-Based Security. Before creating security policies, an administrator must designate a master security policy cluster through the `cldb.pbs.global.master` option.

You can modify global configuration settings through the `maprcli config save` command and the REST API.

The following table describes the global configuration settings related to Policy-Based Security.

Parameter	Default	Description
`cldb.pbs.max.security.policy`	`10000`	Maximum number of configured security policies allowed. Prevents users from arbitrarily creating numerous security policies which could impact performance.
`cldb.pbs.global.master`	`0`	**(Required)** Sets the master security policy cluster for the global namespace. Configure a cluster to perform one of the following roles: • Master—A master security policy cluster is required to create and manage security policies. Only one master security policy cluster should be chosen among clusters sharing data (using mirroring). • Member—On a cluster designated as a member, you can view security policies available for tagging and tag data objects. By default, the host is set to member (0) upon a new installation or upgrade. To set the host to master and enable the creation and modification of security policies, set the value of this property to 1. **NOTE:** Policy creation or modification on a member cluster is not allowed.
`cldb.pbs.audit.only.policy.check`	`0`	Set the value to 1 to enforce permissive mode across all volumes in the cluster. In permissive mode, the system only enforces resource-level ACEs and POSIX mode bits. The system checks the security policies for access and audits denied access events. (It does not actually deny access.) See Volume-Level Security Policy Enforcement Mode on page 861.

last-updated: Jun 06, 2024

`cldb.pbs.access.control.enabled`	`1`	Enables and disables policy ACEs set in security policies at the cluster-level. It is set to **0** to disable policy access checks across all volumes in the cluster. The DataAce enforcement mode is automatically enabled. See Disabling Policy Access Controls at the Cluster-Level on page 1887 and Volume-Level Security Policy Enforcement Mode on page 861 for additional information.

Setting the Policy-Based Security Mode Using the CLI and REST API

CLI

Run the following command to set a cluster as the Master for security policies:

```
maprcli config save -values
'{"cldb.pbs.global.master":"1"}'
```

REST

Send a request of type POST. For example, to designate a cluster as the Master for policy-based security creation and management, send a request similar to the following:

```
curl -k -X POST 'https://
<hostname>:8443/rest/config/save?
values={"cldb.pbs.global.master":"1"}'
 --user mapr:mapr
```

Setting the Policy-Based Security Mode Using the Control System

From the Control System, to set the cluster as the Master for security policies:

1. Click the **Security Settings** icon.
2. Click the **PBS Mode** setting.
3. Select **PBS Mode** as **Master** from the drop-down.
4. Click **Submit** to save the setting.

Changing the Policy-Based Security Global Master

To elect a new PBS master:

1. Make sure that the cluster to be set as the master is still a member and not a master already. The value of `cldb.pbs.global.master` on this cluster should be `0`.
2. Ensure that no policies are being created or modified on the current master cluster.
3. Export all policies from the current master cluster, and then import them to the cluster you want to set as the new master.
4. Demote the current master cluster to a member by setting `cldb.pbs.global.master` to `0`.
5. Promote the cluster to be set as the master to be the global master by setting `cldb.pbs.global.master` to `1`.

Disabling Policy Access Controls at the Cluster-Level
Disable policy ACEs that are set in security policies at the cluster-level through the `cldb.pbs.access.control.enabled` option in the CLI and REST API and through the Ignore Policy Access Control option in the Control System.

last-updated: Jun 06, 2024

About this task

Typically, you would only disable security policies at the cluster-level if they are causing issues. The `cldb.pbs.access.control.enabled` option is the fastest way for administrators to turn security policies off in a cluster.

CAUTION: Before you disable policy access controls at the cluster-level, verify that POSIX mode bits or ACEs are directly applied to data objects to prevent unauthorized access to data. See hadoop mfs on page 5557, and refer to the `-getace` parameter.

The following table summarizes how security policy enforcement works when policy access controls are enabled and disabled in a cluster:

Policy Access Controls	Description
Enabled	• Default. • The system enforces all policy access controls (ACEs set in security policies).

Disabled	• The system does not enforce any policy access controls (ACEs set in security policies). ACEs set in security policies are not applied during any data operations in the cluster.
	• Policy access controls (ACEs set in the security policies) are disabled only for the indicated cluster. It does not matter if the cluster is a master or member security policy cluster; disabling the access controls does not affect the security policy settings and behaviors in any other cluster.
	• The system still enforces:
	  • Resource controls (POSIX mode bits and ACEs) directly applied to data objects to determine data access.
	  • Wire-level encryption and auditing settings in the security policies.

The following sections describe how to enable and disable policy access controls (ACEs set in security policies) at the cluster-level:

Disable Policy Access Controls Using the Control System

Procedure

1. Log in to the Control System and click to display the **Security** settings page.
2. Move the slider associated with **Ignore Policy Access Control** to **Yes** to disable access control or **No** to enable access control using security policies.

   If set to **Yes**, access control enforcement is disabled for all the security policies on the cluster. If set to **No**, you can set the enforcement mode setting at the volume level to **Policy Ace and Data Ace** or **Policy Ace Only** to enable access control enforcement using security policy ACEs.

Disable Policy Access Controls Using the CLI

Procedure

- Run the `config save` on page 2106 command and set the `cldb.pbs.access.control.enabled` property to one of the following values:
  - `0` — disables security policy ACE enforcement for data operations in the cluster
  - `1` — enables security policy ACE enforcement for data operations in the cluster

last-updated: Jun 06, 2024

Example:

```
/opt/mapr/bin/maprcli config save -values
'{"cldb.pbs.access.control.enabled":"0"}'
/opt/mapr/bin/maprcli config save -values
'{"cldb.pbs.access.control.enabled":"1"}'
```

Granting Security Policy Permissions

Permissions define which administrative users can create, view, and modify security policies. Administrators set the permissions on security policies through cluster-level and security policy-level ACLs.

Permission Levels

Policy-Based Security supports cluster-level and policy-level permissions.

The following table describes the two permission levels:

Permission Level	Description
Cluster-level	• Controls which administrators can create and view security policies in a cluster. • Administrators with cluster-level `cp` permission can create security policies. • Administrators with cluster-level `fc` permission can view all the security policies created.
Policy-level	• Controls which administrators can view and modify security policies. • Policy-level permissions are set on a per-policy basis. • Permissions set on one security policy do not apply to other security policies.

Administrators with cluster-level permissions can set cluster-level and security policy-level permissions through any of the following tools:

- Control System
- REST API commands
- `maprcli acl set|edit` commands
- `maprcli security policy create` commands

For additional information, refer to the section Setting Permissions on Security Policies on page 1893.

last-updated: Jun 06, 2024

IMPORTANT: Note these important considerations for security-policy permissions:

- On a fresh cluster install, the `root` user and the data-fabric user (typically named `mapr` or `hadoop` on each node) have `cp` permission. On an upgraded cluster, only the data-fabric user user has `cp` permission.
- As the cluster owner, the data-fabric user (typically named `mapr` or `hadoop` on each node), has overriding permission on security policies, including the administrative ACLs. The data-fabric user can create, view, and modify security policies, regardless of the cluster-level and policy-level permission specified.
- By default, administrators do not have permission to create security policies. Administrators need cluster-level `cp (create security policy)` permission to create security policies. Administrators with cluster-level `a (admin)` permission can grant `cp` permission to themselves or other administrators.

  TIP: You must designate a cluster as the global policy master before you create security policies. Setting a global policy master creates a global namespace for security policies. See Security Policy Domain and Policy Management on page 857.
- Any user with a valid data-fabric ticket can view security policy IDs and names. This allows non-administrative users to determine which security policies to apply to data objects.

Permission Codes

Cluster-level and security policy-level permission codes that are set through ACLs grant security policy access to administrators. An administrator (with cluster-level `a (admin)` and `cp (create security policy)` permissions) that creates a security policy has full control over the security policy unless they specifically grant other administrators access to the security policy through policy-level permissions.

The following sections describe the cluster-level and policy-level permission codes for security policy access:

Cluster-Level Permission Codes

The following table lists some cluster-level permission codes and how they relate to security policies. For a complete list of cluster-level permission codes, see acl.

Cluster-level permission code	Description
`a (admin)`	• Grants administrative access to cluster ACLs. • Can grant `create security policy (cp)` permission to themselves or other administrators. • Cannot view or edit the details of any security policy created by other admins. Can only view the security policy ID and name. • Needs security policy-level permissions to view or edit security policies created by other admins.

last-updated: Jun 06, 2024

Cluster-level permission code	Description

`cp (create security policy)`	**ATTENTION:** Administrators need this permission to create security policies.
	• Administrators with a `(admin)` cluster-level permission can grant `cp` permission to themselves or other administrators.
	• Administrators can view and edit all parts of the security policies they create, including the ACEs and permissions on the security policies.
	• Grants the administrator that creates a security policy the following security *policy-level* permissions on the security policy:
	  • `Full Control (fc)`
	  • `Admin (a)`
	  • `Read (r)`
	• Administrators who create security policies can override their access to the security policies by designating policy owners who can then manage the security policies. See policy create on page 2316, policy modify on page 2346, and refer to the `-user` parameter.

`fc (full control)`	• Grants full control over the cluster and enables all cluster-level administrative options. • Cannot change the cluster-level ACLs. • Can view all security policies. • Cannot create security policies. • Cannot edit the details of any security policy unless specifically granted access to a security through policy-level permissions.

Policy-Level Permission Codes

Separate read `(r)` and edit `(fc)` permissions for policy owners allow some policy owners to view policy information while others can edit policy information. This allows most administrators to administer the system without seeing the data and also prevents some policy owners from adding their credentials to the administrative ACLs to manipulate the data access ACEs.

last-updated: Jun 06, 2024

Policy-level permissions are set on a per-policy basis. Permissions set on one security policy do not apply to other security policies.

The following table lists the policy-level permission codes needed to perform actions on security policies.

Policy-level permission code	Description
`a (admin)`	• Can view and modify permissions on the security policy. • Cannot view or modify the security policy; can only view the security policy name and ID.
`fc (full control)`	• Can view and edit any part of the security policy, including the data access ACEs. • Cannot view or modify permissions on the security policy.
`r (read)`	Can view all parts of a security policy, but cannot modify any part of the security policy.

Permissions Table

The following table lists the cluster-level and policy-level permissions needed to perform specific actions on security policies:

NOTE: Administrators who create a security policy have policy-level `r`, `a`, and `fc` permission on the security policy.

Action	Cluster-Level	Policy-Level
Create a security policy	`cp`	--
View details of all security policies	`fc`	--
View details of a security policy	--	`r`
View and edit permissions on a security policy (ACLs)	--	`a`
View and edit the details of a security policy (ACEs, auditing, wire-level encryption)	--	`fc`

last-updated: Jun 06, 2024

Setting Permissions on Security Policies

An administrator with cluster-level permissions can set security policy permissions during policy creation. Administrators with proper edit permissions on a security policy can modify security policy permissions.

Setting Permissions from the Control System

- To set permissions during security policy creation, see Creating a Security Policy on page 1893.
- To modify permissions on existing security policies, see Modifying a Security Policy on page 1902.

Setting Permissions from the CLI and REST API

- To grant cluster-level (`cp`) permission to a cluster administrator, see acl on page 1999.
- To set permissions during security policy creation, see policy create on page 2316.
- To modify permissions on existing security policies, see policy modify on page 2346, acl set on page 2001, and acl edit on page 2000.

Viewing Security Policy Permissions

To display cluster-level permissions, run:

```
/opt/mapr/bin/maprcli acl show -type cluster
```

To display policy-level permissions, run:

```
/opt/mapr/bin/maprcli security policy info -name <policy name> \
[-cluster cluster name ] [ -output terse|verbose ] \
[ -columns <comma-separated list of column names> ] \
[ -expandaces true|false ] -json
```

Related concepts

Example Using Security Policies on page 873
This example demonstrates how to secure data, set permissions, and create, view, and modify a security policy.

Creating a Security Policy

Describes how to create a security policy using the Control System, CLI, and REST API.

About this task

Administrators with cluster-level `cp (create security policy)` permission can create security policies from the Control System, CLI, and REST API. Before creating security policies, first set a cluster as the global policy master. After creating the policy as its owner, edit all parts of the policy, including the policy *ACE*s. After creating a security policy, the policy is disarmed with the tagging set to `false` (or **No** in the Control System), by default, which makes the policy unavailable for tagging. You can modify the policy state to make it available for tagging. See Changing the State of a Security Policy on page 1910 for more information.

Creating a Security Policy Using the Control System

Procedure

1. Log in to the Control System, and click  (Security Settings) to display the **Security** page.
2. Click **Create PolicyCreate New Policy** to display the **Create Security Policy** page.

   NOTE: You must have appropriate permissions to create security policies.

3. Specify the security properties under the **Properties** pane of the page:
   a) Specify a name for the policy in the **Name** field, and enter a brief description of the policy in the **Description** text box.
      Security policy names must be unique within the cluster and must contain only alphanumeric characters, hyphens (`-`), and underscores (_). The maximum length of the security policy name is 32 characters.
   b) Specify **Yes** to enable wire-level encryption by moving the slider. Otherwise, click **No**.
      By default, this setting is enabled on secure clusters and disabled on insecure clusters.
   c) Specify **Yes** to enable auditing by moving the slider. Otherwise, click **No**.
      If auditing is enabled, choose **Default** to accept the default list of operations to audit, or choose **Custom** to select or deselect the operations to audit. Note that including `setattr` automatically enables the following operations:
      - `chown`
      - `chgrp`
      - `chperm`

      If you exclude `setattr`, these operations are automatically disabled. If you do nothing with `setattr` (neither enable nor disable), you can enable or disable `chown, chgrp,` and `chperm` in any combination.
   d) Specify whether (**Yes** or **No**) to allow data-fabric data objects to be tagged with this security policy.

      NOTE: Tagging must be set to **Yes** to allow users to associate the security policy with a table, column family, or field. Security policies preside over chosen tables and their related column families and field data by default.

      For more information, see Changing the State of a Security Policy on page 1910.
4. Select one of the following access control states from the Access Control pull-down menu in the **Data Access Control** pane:
   - **Armed**—Enforce the *ACE*s in the security policy on the data-fabric data objects tagged with the policy.
   - **Disarmed**—Do not enforce the *ACE*s, if any, in the policy on the data-fabric data objects tagged with the policy.
   - **Denied**—Deny all access to the data-fabric data objects tagged with the policy and log any attempt to access.

   For more information, see Changing the State of a Security Policy on page 1910.
5. Click **Add Access Permissions** in the **Data Access Control** pane to set data access controls. The **Add Access Permission** window appears.
6. Do one of the following from the **Add Access Permission** window:
   - Set the policy to `Public`. Setting the **Public** slider to `Yes` makes this policy accessible to everyone.
   - Leave this slider at its default setting of `No` to customize access permissions, and then enter the comma-separated list of users, groups, or roles to be granted to in the **Users**, **Groups**, and **Roles** text boxes respectively.

- Select the **Custom ACE** checkbox to manually enter the ACE in the appropriate text box shown.

  For more information on how to build the custom ACE, see Managing Access Control Expressions on page 1855.

7. Click **Next: Select Permissions** to display the **Add Access Permissions** window.
8. Select and check options, as needed, from the **Add Access Permissions** window. The following table describes the permissions that can be granted to specified users, groups, and roles.

   NOTE: If you opt to select **Reads**, **Writes**, and/or **Executes** at the top of the **Add Access Permissions** window, the system automatically checks appropriate options beneath the Directories, Files, and Tables headings of the **Add Access Permissions** window.

   - Select **Reads** to grant:
     - read permission on directories and files
     - lookup permission on directories

     This is the same as the `readaces` property in the CLI.
   - Select **Writes** to grant:
     - write permission on files
     - add and delete child permissions on directories

     This is the same as the `writeaces` property in the CLI.
   - Select **Executes** to grant execute permission on files. This is the same as the `executefileace` property in the CLI.

Object	Permission
Directories	• **Read** the contents of a directory. If this is not selected, mode bits are used to determine read access. To read the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume, the parent directory (if any), and the file. This is the same as the `readdirace` property in the CLI. • **Lookup** or list the contents in a directory. If this is not selected, mode bits are used to determine lookup access. To read the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume and the directory. This is the same as the `lookupdirace` property in the CLI. • **Add Child** to add a file or subdirectory. If this is not selected, mode bits are used to determine permissions to create files and subdirectories. To add a child to a directory that is tagged with this security policy, the user must also have write permissions on the volume and parent directories, add child permission on the parent directory, and read and execute permissions on all directories in the path. This is the same as the `addchildace` property in the CLI. • **Delete Child** to delete a file or subdirectory. If this is not selected, mode bits are used to determine permissions to create files and/or subdirectories. To delete a child of a directory that is tagged with this security policy, the user must also have write permissions on the volume and parent directories, delete child permission on the parent directory, and read and execute permissions on all directories in the path. This is the same as the `deletechildace` property in the CLI. For more information, see Managing File and Directory ACEs on page 1860.

last-updated: Jun 06, 2024

Object	Permission
Files	• **Read** a file. If this is not selected, mode bits are used to determine read access to file. To read a file that is tagged with this security policy, the user must also have read permissions on the volume. This is the same as the `readfileace` property in the CLI. • **Write** to a file. If this option is not selected, mode bits are used to determine read access to the file. To write to a file that is tagged with this security policy, the user must also have write permissions on the volume. This is the same as the `writefileace` property in the CLI. • **Execute** a file. If this is not selected, mode bits are used to determine execute access to the file. To execute a file that is tagged with this security policy, the user must also have read permissions on the volume. This is the same as the `executefileace` property in the CLI. For more information, see Managing File and Directory ACEs on page 1860.
Tables	• **Read** a table. If this is not selected, mode bits are used to determine read access to table. To read a table that is tagged with this security policy, the user must also have read permissions on the volume. This is the same as the `readtableace` property in the CLI. • **Traverse CF** a table. Allows the grantee to descend a hierarchy of fields to access fields on which the grantee has write or read permission. This is the same as the `traverseperm` property in the CLI. • **Write** to a table. If this is not checked, mode bits are used to determine read access to the table. To write to a table that is tagged with this security policy, the user must also have write permissions on the volume. This is the same as the `writetableace` property in the CLI. • **Unmasked Data** a table. If this checkbox is not checked, it disallows the grantee to see all table data.

9. Click **Add** to add the data access permissions to the policy.
10. Opt to do one of the following, or proceed to the next step.
    - **Add Another**, and repeat the initial step for adding access permissions through to the final step for other users, groups, and roles.
    - to create a copy of the data access controls, which can then be modified by clicking .

last-updated: Jun 06, 2024

11. Grant users and/or groups permissions to perform administrative operations on the policy in the **Policy Administration Control** pane:
    a) Select the entity type, user or group, from the **Type** drop-down list, and enter the entity name in the **Entities** field.
    b) Check the checkbox associated with the following permissions to grant the entity the type of permission:
       - Read access for the policy.
       - Admin access to set and modify ACLs on the policy.
       - Full control over the policy.
    c) Proceed to the next step, or click one of the following to add access controls for other users and groups:
       - **Add Another** and repeat the the initial step through the final step of the add access control procedure for other users and groups.
       - (Duplicate) to create a copy of the access control.
       - (Delete) to delete a listed permission.
12. Click **Save** to create the security policy.

Creating a Security Policy Using the CLI and REST API

About this task

CLI	The basic command to create a security policy: `/opt/mapr/bin/maprcli security policy create -name <policyName>`
REST	Send a request of type POST. For example: `curl -k -X POST 'https://<hostname>:8443/rest/security/policy/create?name=<policyName>" --user mapr:mapr`

For more information, see `policy create` on page 2316.

Related reference

table securitypolicy set on page 2522
Replaces a security policy on a HPE Ezmeral Data Fabric Database JSON table with a new security policy.

table cf securitypolicy set on page 2458
Replaces a security policy associated with a column family for a HPE Ezmeral Data Fabric Database JSON table with a new security policy.

Viewing the List of Security Policies
View the list of security policies using the Control System and extended attributes.

About this task

You can retrieve and view the list of security policies using the Control System, the CLI, and REST API.

Viewing the List of Security Policies Using the Control System

Procedure

- Log in to the Control System, and click the **Security Policies** tab and then **Admin** > **Cluster Settings**.

  The list of security policies display in the **Security Policies** pane. Filter the list of policies by one of the following Access Control statuses: All, Armed, Disarmed, Denied. For each security policy, the page displays the following fields.

Column Name	Description
Policy Name	Shows the name of the policy.
Access Control	Indicates whether access control is enforced by the *ACE* setting in the policy: • Armed • Disarmed • Denied See Changing the State of a Security Policy on page 1910.
Tagging	Indicates whether data objects can be tagged with the policy. See Changing the State of a Security Policy on page 1910.
Description	Displayes the description of the policy.
Date Created	Displays the date when the policy was created.
Date Modified	Displays the date when the policy was last modified.

Viewing the List of Security Policies Using the CLI and REST API

About this task

CLI

The basic command to retrieve the list of security policies that you are allowed to view is:

```
/opt/mapr/bin/maprcli security policy
list -json
```

REST

Send a request of type GET. For example:

```
curl -k -X GET 'https://<host>:8443/
rest/security/policy/list' --user
mapr:mapr
```

For more information, see `policy list` on page 2336.

Retrieving Security Policies Using Extended Attributes

About this task

Describes how to retrieve security policies that are tagged using extended attributes.

Linux Commands

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To retrieve extended attributes, run one of the following commands:

last-updated: Jun 06, 2024

- `getfattr [-hRLP] -n name pathname...`
- `getfattr [-hRLP] -d [-m pattern] pathname...`

The above commands retrieve both policy tags, as well as other extended attributes.

For example, to retrieve all extended attributes for the `/mapr/lab/foo.txt` file, use:

```
getfattr -d /mapr/lab/foo.txt
 # file: /mapr/lab/foo.txt

security.mapr.policy="Lab_Security_Pol
icy,Sensitive_data" ●policy tag

user.test="test"
                ●other
attributes
```

To retrieve the security policy tags without retrieving the rest of the extended attributes, use the `-n` option to match the security policy extended attribute name:

```
getfattr -d -n security.mapr.policy /
mapr/lab/foo.txt
 # file: /mapr/lab/foo.txt

security.mapr.policy="Lab_Security_Pol
icy,Sensitive_Data"
```

Hadoop Commands

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To retrieve security policy attributes, use the command:

`hadoop fs -getfattr [-R] -n security.mapr.policy | -d <pathname>`

For example, to retrieve security policy attributes for the `/mapr/lab/foo.txt` file, use:

`hadoop fs -getfattr -n security.mapr.policy | -d /mapr/lab/foo.txt`

Alternatively, use the Hadoop MFS command to retrieve security policy attributes:

```
hadoop mfs -getsecuritypolicytag [-R]
<path>
```

Java APIs

To retrieve security policy attributes, use the following Java APIs:

- `public byte[] getXAttr(Path path, String name) throws IOException` Gets an extended attribute name and value for a file or directory. The name must be prefixed with the namespace, followed by `.` (period). For security policy tags, the extended attribute name is `security.mapr.policy`.
- `public Map<String,byte[]> getXAttrs(Path path) throws IOException` Gets all the extended attribute name/value pairs for a file or directory. Only those extended attributes that the logged-in user has permissions to view are returned.
- `public Map<String,byte[]> getXAttrs(Path path, List<String> names) throws IOException` Gets the extended attributes specified by the given list of names. Only those extended attributes that the logged-in user has permissions to view are returned.
- `public List<String> listXAttrs(Path path) throws IOException` Gets all the extended attribute names for a file or directory. Only those extended attribute names that the logged-in user has permissions to view are returned.

C APIs

Security policies use a special format for the extended attribute name and is always set to the keyword `security.mapr.policy`.

Retrieve extended attribute values

The `getxattr`, `lgetxattr`, and `fgetxattr` system calls are used to retrieve an extended attribute value associated with a file system object, which may be either a file or directory. The synopsis of these commands are shown below. For additional details, refer to the `getxattr(2)` Linux manual page.

NAME

```
getxattr, lgetxattr, fgetxattr -
retrieve an extended attribute value
```

SYNOPSIS

```
#include <sys/types.h>
#include <attr/xattr.h>
 ssize_t getxattr (const char *path,
const char *name, void *value,

  size_t size);
 ssize_t lgetxattr (const char *path,
const char *name, void *value,

  size_t size);
 ssize_t fgetxattr (int filedes,
const char *name, void *value,

  size_t size);
```

List extended attribute values

Use the `listxattr`, `llistxattr`, and `flistxattr` to list extended attribute names. For more details, refer to the `listxattr`(2) Linux manual page.

NAME

```
listxattr, llistxattr, flistxattr - list
extended attribute names
```

```
#include <sys/types.h>
#include <attr/xattr.h>
 ssize_t listxattr (const char *path,
char *list, size_t size);
 ssize_t llistxattr (const char
*path, char *list, size_t size);
 ssize_t flistxattr (int
filedes, char *list, size_t
size);
```

Modifying a Security Policy
Describes how to modify a security policy.

About this task

You can modify a security policy using the Control System, the CLI, and REST API. You can change the following settings if you edit a security policy:

- Security policy state
- Wire-level encryption and auditing
- Data access control
- Security policy administration control

If you modify a security policy that is currently tagged (or in use), changes to the policy are enforced within **5** minutes.

Modifying a Security Policy Using the Control System

Prerequisites

If not already done, you must first set the related cluster as the global policy master node for the Container Location Database (CLDB) associated with the security policy being modified. See Configuring the Global Policy Master on page 860 for more information.

Procedure

1. Log in to the Control System and go to the **Security Policies** tag in the **Admin** > **Cluster Settings** page to view the list of security policies that you are allowed to see.
2. Click the name of the security policy to display the **Edit Security Policy page**.
3. Make changes to the security policy status by selecting the state to transition to from the drop-down list of statuses next to the **Edit Security Policy** label.

   See Changing the State of a Security Policy on page 1910 for more information on the various states and the valid state to which you need to transition a security policy.
4. Modify any of the following properties:

Description	The description of the policy. The maximum length of the description is **128** characters.
Enable Wire-level Encryption	The wire-level encryption setting. Enable (**Yes**) or disable (**No**) wire-level encryption by moving the slider.
Enable Audit Operations	The audit setting for files, directories, tables, and streams. Enable (**Yes**) or disable (**No**) auditing of operations on files, directories, tables, and streams by moving the slider.
Audit Operations	(Visible only if auditing is enabled) The list of file, directory, table, and stream operations to audit. Select the default list of operations to audit by choosing the **Default** radio button. Select specific file, directory, table, and streams operations to audit by choosing the **Custom** radio button. Enabling `setattr` automatically enables the following operations: • `chown` • `chgrp` • `chperm` If you disable `setattr`, these operations are automatically disabled. If you do nothing with `setattr` (neither enable nor disable), you can enable or disable `chown`, `chgrp`, and `chperm` in any combination and they will not affect `setattr`.
Allow Tagging (For JSON Tables)	The setting to enable (**Yes**) or disable (**No**) tagging of JSON tables for this security policy. If **Yes**, users can tag data objects of JSON tables with this policy. If **No**, users cannot tag data objects of JSON tables with this security policy. See Changing the State of a Security Policy on page 1910 for more information.

5. Make changes to data access control as needed in the **Data Access Control** section.
   a) Select one of the following state for access control.
      - **Disarmed**—Indicates access control is not enforced by the *ACE* settings defined in the policy
      - **Armed**—Indicates access control is enforced by the *ACE* settings defined in the policy
      - **Denied**—Indicates access control is always denied.

      For more information on access control states, see Changing the State of a Security Policy on page 1910.

   b) Set new or modify existing *ACE*s for users, groups, and/or roles.
      You can:
      - Create a copy of an existing *ACE* setting for an entity (user, group, or role) by clicking , which you can then modify.
      - Remove *ACE*s for an entity (user, group, or role) by clicking .
      - Set new *ACE*s if you have not set *ACE*s before for users, groups, or roles by clicking **Add Access Permission**.
      - Add *ACE*s for another user, group, or role by clicking **Add Another**.

last-updated: Jun 06, 2024

- Modify an existing *ACE* setting for an entity (user, group, or role) by clicking  .

After you click **Add Access Permission**, **Add Another**, or  , the **Add Access Permission** window displays. You can:

1. Enter new or modify the existing comma-separated list of users, groups, or roles to grant access to in the **Users**, **Groups**, and **Roles** text boxes respectively. Select the **Custom ACE** checkbox to manually enter the *ACE* in the text box that appears.

   For more information on how to build the custom access control expression, see Managing Access Control Expressions on page 1855.

2. Click **Next: Select Permissions** to display the **Add Access Permissions** page.

   The following table describes the permissions that can be granted to the specified users, groups, or roles in this page:

Object	Permission
Directories	• **Read** the contents of a directory. If you do not select this option, mode bits are used to determine read access. To read the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume, the parent directory (if any), and the file. This is the same as the `readdirace` property in the CLI. • **Lookup** or list the contents in a directory. If you do not select this option, mode bits are used to determine lookup access. To read the contents of a directory that is tagged with this security policy, the user must also have read permissions on the volume and the directory. This is the same as the `lookupdirace` property in the CLI. • **Add** a file or subdirectory. If you do not select this option, mode bits are used to determine permissions to create files or subdirectories. To add a child to a directory that is tagged with this security policy, the user must also have write permissions on the volume and the parent directory, add child permission on the parent directory, and read and execute permissions on all directories in the path. This is the same as the `addchildace` property in the CLI. • **Delete** a file or subdirectory. If you do not select this option, mode bits are used to determine permissions to create files or subdirectories. To delete a child of a directory that is tagged with this security policy, the user must also have write permissions on the volume and the parent directory, delete child permission on the parent directory, and read and execute permissions on all directories in the path. This is the same as the `deletechildace` property in the CLI. For more information, see Managing File and Directory ACEs on page 1860.

last-updated: Jun 06, 2024

Object	Permission
Files	• **Read** a file. If you do not select this option, mode bits are used to determine read access to the file. To read a file that is tagged with this security policy, the user must also have read permissions on the volume. This is the same as the `readfileace` property in the CLI. • **Write** to a file. If you do not select this option, mode bits are used to determine read access to the file. To write to a file that is tagged with this security policy, the user must also have write permissions on the volume. This is the same as the `writefileace` property in the CLI. • **Execute** a file. If you do not select this option, mode bits are used to determine execute access to the file. To execute a file that is tagged with this security policy, the user must also have read permissions on the volume. This is the same as the `executefileace` property in the CLI. For more information, see Managing File and Directory ACEs on page 1860.
Tables	• **Read** new column families that are created in the table. This the same as the `readdbace` property in the CLI. See Security on JSON Tables on page 665 for more information. • **Traverse CF** to descend a hierachy of column families. This is the same as the `traversedbace` property in the CLI. See Security on JSON Tables on page 665 for more information. • **Write** to new column families that are created in the table. This is the same as the `writedbace` property in the CLI. See Security on JSON Tables on page 665 and Enabling Table and Stream Authorizations with ACEs on page 1363 for more information. • **Unmasked Data**. If you do not select this option, disallows the viewing of select and sensitive table fields of a column family. See Dynamic Data Masking on page 884 for more information on data masking.

3. Select the checkbox associated with the individual permission to grant that type of permission to the user, group, or role, or click the following:
   - **Reads** to grant:

last-updated: Jun 06, 2024

- read permission on directories, files, and tables
- lookup permission on directories
- traverse column family permission on tables

This is the same as the `readaces` property in the CLI.

- **Writes** to grant:
  - write permission on files and tables
  - add and delete child permissions on directories

  This is the same as the `writeaces` property in the CLI.
- **Executes** to grant execute permission on files.

  This is the same as the `executefileace` property in the CLI.

4. Click **Add** to add the data access permissions to the policy.

6. Make changes as needed to perform administrative operations on the policy in the **Policy Administration Control** section.

   You can:

   - Create a copy of an existing policy administration control setting for an entity by clicking , which you can then modify.
   - Remove a policy administration control setting for an entity by clicking .
   - Add a policy administration control setting for another user or group by clicking **Add Another**.
   - Modify an existing policy administration control setting for an entity.

   To add or modify an existing policy administration control setting for an entity, you can:

   a) Select new or modify an existing entity type, user or group, from the **Type** drop-down list, or enter a new or modify an existing entity name in the **Entities** field.

   b) Select or deselect the checkbox associated with the following permissions to grant or deny (respectively) that type of permission for the entity:
      - Read access for the policy
      - Admin access to set and modify ACLs on the policy
      - Full control over the policy

7. Click **Save** for the changes to take effect.

Modifying a Security Policy Using the CLI and REST API

About this task

CLI

The basic command to modify an existing security policy is:

```
/opt/mapr/bin/maprcli security policy
modify -name <policyName> -json
```

last-updated: Jun 06, 2024

REST	Send a request of type POST. For example: `curl -k -X POST 'https://<host>:port/rest/security/policy/modify?name=<policyName>' --user mapr:mapr`

For more information, see policy modify on page 2346.

Removing Tagged Security Policies from Data Objects

You can remove security policies associated with data objects using the Control System, CLI, or REST API.

About this task

WARNING: Remove a security policy from data objects before retiring the policy. The system denies all access to data objects tagged with a retired security policy afterwards. See Changing the State of a Security Policy on page 1910.

The following table lists the methods for removing security policies for each type of data object and provides links to command references, where applicable:

HPE Ezmeral Data Fabric Component	Data Object	How to Remove Security Policies
HPE Ezmeral Data Fabric Filesystem	Volume	• Control System (See Removing Security Policies from Objects Using the Control System on page 1908 below) • `maprcli volume modify -securitypolicy ""`
	Directory	• Extended attributes using Linux, Hadoop, Java API, or C API commands (See Removing Security Policies Using Extended Attributes on page 1909 below) • `hadoop mfs -removeallsecuritypolicytag [-R] <path>` • `hadoop mfs -removesecuritypolicytag [-R] <comma-separated list of security policy tags> <path>`
	File	• Same as directory
HPE Ezmeral Data Fabric Database	JSON Table	• Control System (See Removing Security Policies from Objects Using the Control System on page 1908 below) • `maprcli table securitypolicy remove -path <path> -securitypolicy <comma-delimited list of policies>`
	Column family	• Control System (See Removing Security Policies from Objects Using the Control System on page 1908 below) • `maprcli table cf securitypolicy remove -path <path> -cfname <column family name> -securitypolicy <comma-delimited list of policies>`

last-updated: Jun 06, 2024

HPE Ezmeral Data Fabric Component	Data Object	How to Remove Security Policies
	Field	• Control System (See Removing Security Policies from Objects Using the Control System on page 1908 below) • `maprcli table cf column securitypolicy remove -path <path> -cfname <column family name> -column <JSON table field> -securitypolicy <comma-delimited list of policies>`

The following sections describe how to remove security policies from data objects through the Control System and extended attributes.

Removing Security Policies from Objects Using the Control System

About this task

You can remove security policies from volumes, JSON tables, JSON column families, and JSON fields using the Control System.

Removing Security Policies from Volumes

1. Log in to the Control System, and click **Data** > **Volumes**.

   NOTE: The **Volumes** page is under the **Volumes** menu in the Kubernetes version of the Control System.

2. On the **Volumes** page, locate and select the volume that is tagged with the security policy to be removed.
3. Click **Edit Volume**.
4. In the **Security** section, click ⛔ next to the security policy associated with the volume to remove the security policy.
5. Click **Save Changes**.

Removing Security Policies from Tables, Column Families, and Fields

1. Log in to the Control System, and click **Data** > **Tables**.
2. In the **Tables** view, locate and select the table with the security policy to be removed. To remove a security policy from a column family or field, select the table that contains the column family or field.
3. On the **Summary** tab, locate the **Security** section.
4. In the **Security** section, click ⛔ next to the security policy associated with the table to remove the security policy.
   - To remove a security policy from a column family, click on the table to expand the view. Click ⛔ next to security policy associated with the column family to remove the security policy.

last-updated: Jun 06, 2024

- To remove a security policy from a field, click the column family name to expand the view, and remove the security policy.

Removing Security Policies Using Extended Attributes

About this task

The following sections describe how to use extended attributes to remove security policies.

Linux Commands

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To remove the extended attribute by name, run the `setfattr` command with the `-x` option:

```
setfattr [-h] -x name pathname...
```

Remove all security policy tags

Use the `-x` option to remove *all* security policy tags from the specified File Store object. For example, to remove all security policies for the file `/mapr/lab/foo.txt`, use the following command:

```
setfattr -x security.mapr.policy /
mapr/lab/foo.txt
```

Replace a security policy tag

The `setfattr` command replaces any existing security policy tags with the specified policy tags. For example, to remove a security policy named `Sensitive_Data` tagged to a data object but keep the security policy named `Lab_Security_Policy` tagged to the data object, specify the `Lab_Security_Policy` tag in the `-v` argument without the `Sensitive_Data` policy tag:

```
setfattr -n security.mapr.policy -v
"Lab_Security_Policy" /mapr/lab/foo.txt
```

Hadoop Commands

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To remove security policy tags, run the `hadoop fs -setfattr` command with one of the following parameters:

- `-x` to remove all security policy tags
- `-v` to remove the specified security policy tags

For example, to remove all the security policy tags for the file `/mapr/lab/foo.txt`, use:

```
hadoop fs -setfattr -x
security.mapr.policy /mapr/lab/foo.txt
```

To remove some security policy tags, and keep the rest, use the `-v` parameter.

This parameter replaces existing security policy tags with the ones specified.

For example, if two security policies are tagged to the file `/mapr/lab/foo.txt` (namely, `Sensitive_Data` policy and

`Lab_Security_Policy`) and you want to remove the `Sensitive_Data` policy tag, specify just the `Lab_Security_Policy` tag in the `-v` parameter:

```
hadoop fs -setfattr -n
security.mapr.policy -v
"Lab_Security_Policy,Sensitive_Data" /
mapr/lab/foo.txt
```

Alternatively, use the `hadoop mfs` command to remove security policies.

For example, to remove particular security tags, use the format:

```
hadoop mfs [-removesecuritypolicytag
[-R] <comma-separated list of
security policy tags> <path>]
```

To remove all security tags, use the format:

```
hadoop mfs
[-removeallsecuritypolicytags [-R]
<path>]
```

Java APIs

To remove an extended attribute associated with a file or directory, use the following Java API:

```
public void removeXAttr(Path path,
String name) throws IOException
```

The name must be prefixed with the namespace, followed by `.` (period). For data-fabric security policy tags, the attribute name is `security.mapr.policy`.

C APIs

Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

To remove an extended attribute value, use the `removexattr` or `fremovexattr` system calls. The brief synopsis is as follows. For more details, refer to the `removexattr`(2) Linux manual page.

NAME

```
removexattr, fremovexattr -- remove an
extended attribute value
```

SYNOPSIS

```
#include <sys/xattr.h>
int removexattr(const char *path,
const char *name, int options);
int fremovexattr(int fd, const char
*name, int options);
```

Changing the State of a Security Policy

The security policy state indicates whether users can apply a security policy to data objects and whether the system enforces the ACEs set in the security policy. An administrator can change the state of a security policy through the `allowtagging` and `accesscontrol` parameters when creating or modifying a security policy from the `maprcli` or equivalent REST API comands.

The following table describes the `allowtagging` and `accesscontrol` parameters.

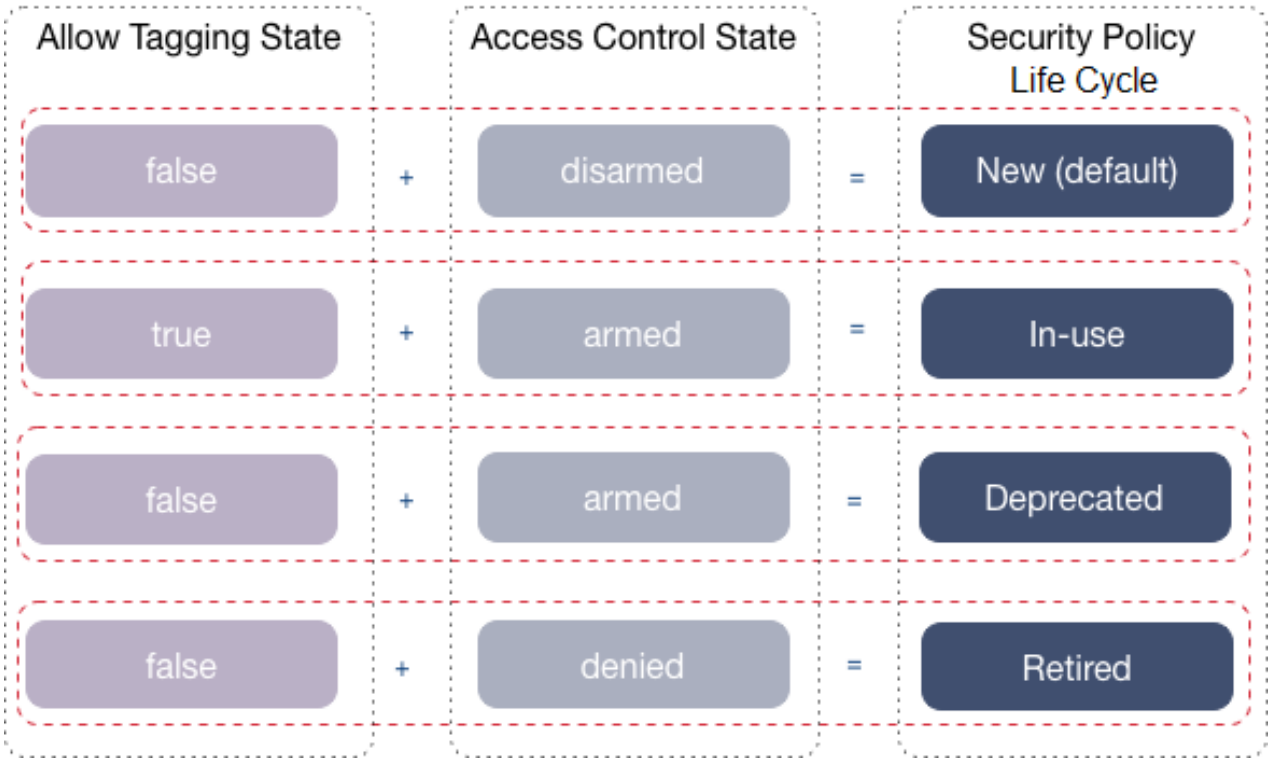
last-updated: Jun 06, 2024

Parameter	Default	Accepted Values and Descriptions
allowtagging	false	false • Disables tagging; users cannot apply the security policy to data objects. • This is the default setting if the administrator creates a security policy, unless the administrator changes the setting when creating the security policy. • In cases where a security policy is active (`allowtagging=true`) but needs to be deprecated, modify the policy and set `allowtagging=false`. This prevents users from tagging any other data objects with the policy. Note that the system continues to enforce the security controls set in the security policy for data objects that were already tagged with the security policy. true • Enables tagging; users can apply the security policy to data objects. • When creating or modifying a security policy, an administrator can set `allowtagging=true`. • When creating a security policy, the administrator may want to set this parameter to true to test the security settings in the policy or to use tagging tools to discover data content and tag the data. • An administrator can set `allowtagging=true` to enable a deprecated security policy.
accesscontrol	Disarmed	Disarmed • This is the default setting if the administrator creates a security policy, unless the administrator changes the setting when creating the security policy. • The system does not enforce the ACEs set in the security policy during data operations on the data objects tagged with the security policy. Armed • The system enforces the ACEs set in the security policy during data operations on the data objects tagged with the security policy. • When creating or modifying a security policy, the administrator can set `accesscontrol=Armed`. • When creating a security policy, the administrator may want to set this parameter to `Armed` to verify that ACEs are correctly defined in the policy and the system correctly enforces them. • The administrator can set `accesscontrol=Armed` to enforce ACEs set in a deprecated security policy. The system continues to enforce ACEs set in the security policy for all data operations on the data objects tagged with the policy. Denied • Denies all access to data objects tagged with the security policy.

Changing the State of a Security Policy

An administrator can change the state of a security policy through the `allowtagging` and `accesscontrol` parameters to move a security policy through a life cycle, as shown in the following image where the security policy moves from new to retired.

last-updated: Jun 06, 2024



The following table describes each of the stages in the security policy life cycle:

Stage	Description
New (default)	• Default upon security policy creation. • Users cannot tag data objects with the security policy. • The system does not enforce ACEs set in the security policy.
In-use	• Users can tag data objects with the security policy. • The system enforces all security controls set in the security policy during data operations on data objects tagged with the security policy. Security controls set in the policy can include ACEs, auditing, and wire-level encryption.
Deprecated	• Users can no longer tag the security policy to data objects. • The system still enforces the security controls set in the security policy for all data operations on the data objects tagged with the policy. Users cannot tag any additional data objects with the policy.
Retired	• Users cannot tag the security policy to data objects. • All data operations on the data objects tagged with the security policy are denied by the system. **WARNING:** Remove a security policy from data objects before retiring it. The system denies all access to data objects tagged with a retired security policy. See Removing Tagged Security Policies from Data Objects on page 1907.

Tagging Data Objects with Security Policies

Once security policies are configured (with tagging enabled), permitted users can associate the security policies with data objects through the Control System, CLI, and REST API. A data object can be associated with one or multiple security policies.

ATTENTION: Verify that the security policy state is set to allow tagging. By default, a security policy has `allowtagging=false` and `accesscontrol=Disarmed` when created. See Changing the State of a Security Policy on page 1910.

Supported Data Objects

The following table lists the data objects in the data-fabric platform that users can tag with security policies:

file system	HPE Ezmeral Data Fabric Database
• Volumes • Directories • Files	• JSON tables • JSON table column families • JASON table fields **NOTE:** If you upgrade your data-fabric cluster to version 6.2.x from a pre-6.2.0 version, you can apply security policies to existing tables if Policy-Based Security is enabled. See Policy-Based Security Quick Reference on page 1934.

Permissions Required to Tag Data Objects

Users must have the required permissions to tag security policies to data objects. Permission requirements vary depending on the data-fabric platform core component.

The following table lists the users that can tag data objects in the data-fabric filesystem and database:

file system	HPE Ezmeral Data Fabric Database
• Owner of the data object • Data Fabric administrator (typically `mapr`) • Superuser (`root`) The superuser cannot tag filesystem objects when the `cldb.reject.root` flag is set.	• Data Fabric administrator (typically `mapr`) • User with ACE administrative access (`adminaccessperm` permission)

The following sections describe how to tag data objects in the file system and HPE Ezmeral Data Fabric Database with security policies

Tagging Volumes, Directories, and Files with Security Policies
Associate security policies with data objects in the file system, including volumes, directories, and files. Associate up to sixteen security policies with a data object in the file system.

Tagging Volumes

About this task

Associate security policies after you create or modify a volume from the Control System, CLI, or REST API. Note that security policies are not supported with tenant volumes and tenant volume resources, and tagging via nfsv3/nfsv4 is not supported since these protocols do not support extended attributes.

Associate security policies with a volume, the volume mount path, or both the volume and the volume mount path. You can only tag a volume mount path through the `maprcli create volume` command with the `rootdirsecuritypolicy` option. You cannot tag a volume mount path through the Control System.

IMPORTANT: A snapshot contains the security policy that was tagged on the volume after the snapshot was taken. If you modify the security policy on the volume after creating the snapshot, the snapshot continues to use the older security policy.

CLI

The basic command to tag a volume with a security policy is:

```
/opt/mapr/bin/maprcli volume
create -name <volName> -path
<mountPath> -securitypolicy
<policy1,policy2,...>
```

REST API

Send a request of type POST. For example:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<volPath>&security
Policy=<policy>' --user mapr:mapr
```

TIP: For more information, including a complete list of required and optional properties, see `volume create` on page 2588.

Control System

1. Log in to the Control System and go to the Create New Volume page or the Edit Volume page.

last-updated: Jun 06, 2024

2. Enter or select the name of the security policies to associate with the volume in the **SECURITY POLICIES** field under the **Security** section.
3. Complete the steps to create or modify the volume.

   TIP: See Creating a Volume on page 1177 or Modifying a Volume on page 1207 for more information.

Tagging Directories and Files

About this task

Associate security policies with directories and files using `hadoop mfs`, extended attributes, and Java APIs.

hadoop mfs

Use the following command syntax to tag a directory or file with one or more security policies:

```
hadoop mfs -setsecuritypolicytag
<policyName> <filePath>
```

TIP: For more information, see `hadoop mfs` on page 5557.

Extended attributes

- For **Linux**, use the `setfattr` command to tag and restore security attributes. Security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.
- For **Hadoop**, security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.
- For **Java and C APIs**, security policies use a special format for the extended attribute name, which is always set to the keyword `security.mapr.policy`.

last-updated: Jun 06, 2024

Command Type		
Linux	**Tag an extended attribute name**	Use the following command to set an extended attribute name on a file/directory and/or a FUSE-mounted file path: `setfattr {-n attribute-name} [-v value] [-h] pathToDataObject`
	Associate one or more security policies	To associate one or more security policies with the file `/mapr/lab/foo.txt`, specify a comma-separated list of security policy names. For example, to associate two security policies named `Lab_Security_Policy` and `Sensitive_Data` to `/mapr/lab/foo.txt`, use: `setfattr -n security.mapr.policy -v "Lab_Security_Policy,Sensitive_Data" /mapr/lab/foo.txt`
	Replace security policies	The `setfattr` command replaces any existing security policies with the specified policies. To remove the `Sensitive_Data` policy and keep the `Lab_Security_Policy`, specify the `Lab_Security_Policy` in the `-v` argument without the `Sensitive_Data` policy: `setfattr -n security.mapr.policy -v "Lab_Security_Policy" /mapr/lab/foo.txt`
	Associate a security policy with a directory	Use a similar command to associate a security policy to a directory: `setfattr -n security.mapr.policy -v "Lab_Security_Policy,Sensitive_Data" /mapr/lab`

Command Type		

Hadoop	**Set security policy attributes**	`hadoop fs -setfattr -n security.mapr.policy -v` *`comma-separated list of policy names path`*
		
		The `-v` parameter is mandatory, and is a comma-separated list of security policy tags.
		
		For example, to associate a security policy `Lab_Security_Policy` with the file `/mapr/lab/foo.txt`, use the command:
		
		`hadoop fs -setfattr -n security.mapr.policy -v "Lab_Security_Policy" /mapr/lab/foo.txt`
		
		If security policy tags already exist for the specified object, this command replaces any existing security policies with the specified policies. Assume that there are two security policies - `Sensitive_Data_Policy` and `Lab_Security_Policy` tagged to the file `/mapr/lab/foo.txt`.
		
		To remove `Sensitive_Data_Policy`, and keep `Lab_Security_Policy`, specify only `Lab_Security_Policy` in the `-v` parameter:
		
		`hadoop fs -setfattr -n security.policy -v "Lab_Security_Policy" /mapr/lab/foo.txt`
		
		You can use the hadoop mfs command as well.
		
		To add policies to an already exisitng set of policies, use the format:
		
		`hadoop mfs [-addsecuritypolicytag [-R] <comma-separated list of security policy tags> <path>]`

last-updated: Jun 06, 2024

Command Type		

Java API	**Tag security policy attributes**	`public void setXAttr(Path path, String name, byte[] value) throws IOException`
		
		The following example demonstrates how to use the Java API to tag the security policy as an extended attribute `security.mapr.policy` with the value `Lab_Security_Policy` for the file `/mapr/lab/foo.txt`:
		
		`import java.net.*;`
		`import org.apache.hadoop.fs.*;`
		`import org.apache.hadoop.conf.*;`
		`…`
		`Configuration conf = new Configuration();`
		`FileSystem fs = FileSystem.get(conf);`
		`Path path = Paths.get("/mapr/lab/foo.txt");`
		`fs.setXAttr(path, "security.mapr.policy", "Lab_Security_Policy");`

last-updated: Jun 06, 2024

Command Type		

C APIs	**Associate a security policy with a file system object in C**	Use the `setxattr` or `fsetxattr` system call. The brief synopsis is as follows. For more details, refer to the `setxattr`(2) Linux manual pages.
		NAME
		`setxattr, fsetxattr -- set an extended attribute value`
		SYNOPSIS
		`#include <sys/xattr.h>`
		`int setxattr (const char *path, const char *name, void *value, size_t size, u_int32_t position, int options);`
		`int fsetxattr (int fd, const char *name, void *value, size_t size, u_int32_t position, int options);`

Java APIs		Associate security policies with data objects using the file system Java APIs. See Security Policy Java APIs on page 1925 for more information.

More information

Security Policy Inheritance and Replication on page 870
Security policies are inherited during data-object creation and copied over during mirroring and replication.

Tagging JSON Tables, Column Families, and Fields with Security Policies
Associate security policies with HPE Ezmeral Data Fabric Database JSON tables, column families, and fields.

About this task

You can apply security policies to HPE Ezmeral Data Fabric Database objects from the Control System, CLI, and the REST API. Tagging through nfsv3/nfsv4 is not supported since these protocols do not support extended attributes. No limit exists on the number of policies tagged to a database object, but be cautious of issues than can occur due to conflicting settings in the policies.

NOTE: You cannot tag binary tables or stream topics. If you apply a policy to a volume, the rules set in the policy apply to all the content in the volume.

last-updated: Jun 06, 2024

Tagging JSON Tables

About this task
Associate security policies with JSON tables.

CLI

To associate a comma-separated list of security policies with a table at the time of table creation:

```
maprcli table create -path
<tablePath> -securitypolicy
<policyName,...>
```

To associate a comma-separated list of security policies with a table without replacing existing security policies, run the following command:

```
maprcli table securitypolicy
add -path <tablePath> -securitypolicy
<policyName,...>
```

To replace security policies on a table with a comma-separated list of new security policies, run the following command:

```
maprcli table securitypolicy
set -path <tablePath> -securitypolicy
<policyName,...>
```

To remove one or more security policies from a table, run the following command:

```
maprcli table
securitypolicy remove -path
<tablePath> -securitypolicy
<policyName,...>
```

REST API

Send a request of type POST. For example, to associate a comma-separated list of security policies with a table at the time of table creation, send a request similar to the following:

```
https://<hostname>:8443/rest/table/
create?
path=<tablePath>&securitypolicy=<polic
yName,...>
```

To associate a comma-separated list of security policies with a table without replacing existing security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/
securitypolicy/add?
path=<tablePath>&securitypolicy=<polic
yName,...>
```

To replace security policies on a table with a comma-separated list of new security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/
securitypolicy/set?
```

```
path=<tablePath>&securitypolicy=<policyName,...>
```

To remove one or more security policies from a table, run the following command:

```
https://<hostname>:8443/rest/table/securitypolicy/remove?path=<tablePath>&securitypolicy=<policyName,...>
```

Control System

1. Log in to the Control System and go to the **Create New Table** page or the **Edit Table** page.
2. Select the security policies to associate with the table in the **Security** section.
3. Specify all other required settings and click **Save Changes**.

TIP: For more information, see:

- table create on page 2412
- table securitypolicy add on page 2520
- table securitypolicy set on page 2522
- table securitypolicy remove on page 2521

Tagging Column Families

About this task
Associate security policies with JSON table column families.

CLI

To associate a comma-separated list of security policies with a column family when the column family is created:

```
maprcli table cf
create -path <tablePath> -cfname
<column-family-name> -jsonpath
<family path> -securitypolicy
<policyName,...> -force true
```

To associate a comma-separated list of security policies with a column family without replacing existing security policies, run the following command:

```
maprcli table cf securitypolicy
add -path <tablePath> -cfname
<column-family-name> -securitypolicy
<policyName,...>
```

To replace security policies on a column family with a comma-separated list of new security policies, run the following command:

```
maprcli table cf securitypolicy
set -path <tablePath> -cfname
<column-family-name> -securitypolicy
<policyName,...>
```

To remove one or more security policies from a column family, run the following command:

```
maprcli table cf securitypolicy
remove -path <tablePath> -cfname
<column-family-name> -securitypolicy
<policyName,...>
```

REST API

Send a request of type POST. For example, to associate a comma-separated list of security policies with a column family at the time of table creation, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
create?
path=<tablePath>&cfname=<column-famil
y-name>&securitypolicy=<policyName,...
>
```

To associate a comma-separated list of security policies with a column family without replacing existing security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
securitypolicy/add?
path=<path>&cfname=<column-family-name
>&securitypolicy=<policyName,...>
```

To replace security policies on a column family with a comma-separated list of new security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
securitypolicy/set?
path=<path>&cfname=<column-family-name
>&securitypolicy=<policyName,...>
```

To remove one or more security policies from a column family, run the following command:

```
https://<hostname>:8443/rest/table/cf/
securitypolicy/remove?
path=<path>&cfname=<column-family-name
>&column=<JSON-table-field>&securitypo
licy=<policyName,...>
```

Control System

1. Log in to the Control System, and click **Data** > **Tables**.

last-updated: Jun 06, 2024

2. Locate and select the table that contains the column family you want to secure.
3. On the **Summary** tab, locate the **Security** section.
4. In the **Security** section, click on the table name to expand the list of column families associated with the table.
5. Click the **+** icon in the **Security Policy** column next to the column family you want to secure with a security policy.
6. In the **Tag Security Policy to Column Family:** window, select the security policy you want to apply to the column family.
7. Click **Add**.

TIP: For more information, see:

- table cf create on page 2438
- table cf securitypolicy add on page 2455
- table cf securitypolicy set on page 2458
- table cf securitypolicy remove on page 2456

Tagging Fields

About this task
Associate security policies with JSON fields.

CLI

To associate a comma-separated list of security policies with a JSON table field, without replacing existing security policies, run the following command:

```
maprcli table cf
column securitypolicy
add -path <tablePath> -cfname
<column-family-name> -column
<column-name> -securitypolicy
<policyName,...>
```

To replace security policies on a JSON table field with a comma-separated list of new security policies, run the following command:

```
maprcli table cf
column securitypolicy
set -path <tablePath> -cfname
<column-family-name> -column
<column-name> -securitypolicy
<policyName,...>
```

To remove one or more security policies from a JSON table field, run the following command:

```
maprcli table cf
column securitypolicy
```

```
remove -path <tablePath> -cfname
<column-family-name> -column
<column-name> -securitypolicy
<policyName,...>
```

REST API

Send a request of type POST. For example, to associate a comma-separated list of security policies with a column family at the time of table creation, send a request similar to the following:

```
https://<hostname>:8443/rest/table/
create?
path=<tablePath>&securitypolicy=<polic
yName,...>
```

To associate a comma-separated list of security policies with a JSON table field without replacing existing security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
column/securitypolicy/add?
path=<path>&cfname=<col-family-name>&s
ecuritypolicy=<policyName,...>
```

To replace security policies on a JSON table field, with a comma-separated list of new security policies, send a request similar to the following:

```
https://<hostname>:8443/rest/table/cf/
column/securitypolicy/set?
path=<path>&cfname=<column-family-name
>&securitypolicy=<policyName,...>
```

To remove one or more security policies from a JSON table field, run the following command:

```
https://<hostname>:8443/rest/table/cf/
column/securitypolicy/remove?
path=<path>&cfname=<column-family-name
>&column=<JSON-table-field>&securitypo
licy=<policyName,...>
```

Control System

1. Log in to the Control System, and click **Data** > **Tables**.
2. Locate and select the table that contains the field you want to secure.
3. On the **Summary** tab, locate the **Security** section.
4. In the **Security** section, click on the table name to expand the list of column families, and then click on the column family that contains the field you want to secure.
5. Click the **+** icon in the **Security Policy** column next to the field you want to secure with a security policy.

last-updated: Jun 06, 2024

6. In the **Tag Security Policy to Column Family:** window, select the security policy you want to apply to the column family.
7. Click **Add**.

TIP: For more information, see:

- table cf column securitypolicy add on page 2424
- table cf column securitypolicy set on page 2436
- table cf column securitypolicy remove on page 2435

Related tasks

Removing Tagged Security Policies from Data Objects on page 1907
You can remove security policies associated with data objects using the Control System, CLI, or REST API.

Security Policy Java APIs

You can create, retrieve, and remove security policies, and associate security policies with a data object using file system APIs.

The standard Linux extended attributes to tag file system objects are POSIX-compliant. You can use these attributes on any Linux or POSIX-compliant client without installing additional MapR software.

With the extended attribute syntax, applications need to ensure that to combine tags, they first retrieve the old tags and then combine them with the new tags. Otherwise, the new tags replace the old tags. Alternatively, applications can use an API with the following features:

1. Setting tags should be additive: new tags should be added to the existing tags, and not replace the existing tags.
2. Set multiple tags for the same resource in a single API.
3. Set tags for multiple file system resources in a single operation.

The extended `MapRFileSystem` Java class provides such an API for setting policy tags.

The list of `MapRFileSystem` API methods for data tagging is as follows:

```
public class MapRFileSystem extends FileSystem;
```

Method and Description	Modifier and Type
Add a Security Policy Tag	
`addSecurityPolicyTag (Path path, String securityPolicyTag) throws IOException;` Use this method to add a single security policy tag to the list of existing security policy tags (if any) for the file or directory specified in *path*. The *securityPolicyTag* parameter contains a security policy tag.	`public int`
`addSecurityPolicyTag (Path path, List<String> securityPolicyTags) throws IOException;` Use this method to add one or more security policies to the list of existing security policies (if any) for the file or directory specified in *path*. The *securityPolicyTags* parameter contains a list of one or more security policy tags.	`public int`
Replace a Security Policy Tag	

Method and Description	Modifier and Type
`setSecurityPolicyTag (Path path, String securityPolicyTag) throws IOException;` Use this method to set the security policy tag to the file or directory specified in *path*, replacing all existing tags. The *securityPolicyTag* parameter contains a security policy tag.	`public int`
`setSecurityPolicyTag (Path`*path*`, List<String>`*securityPolicyTags*`) throws IOException;` Use this method to set one or more security policy tags for the file or directory specified in *path*, replacing any existing security policy tags. The *securityPolicyTags* parameter contains a list of one or more security policy tags.	`public int`
Remove a Security Policy Tag	
`removeSecurityPolicyTag (Path` *path*`, String` *securityPolicyTag*`) throws IOException;` Use this method to remove the security policy tag contained in the *securityPolicyTag* parameter from the list of existing security policy tags (if any) for the file or directory specified in *path*.	`public int`
`removeSecurityPolicyTag (Path`*path*`, List<String>`*securityPolicyTags*`) throws IOException;` Use this method to remove one or more security policy tags from the list of existing security policy tags (if any) for the file or directory specified in *path*. The *securityPolicyTags* parameter contains a list of one or more security policy tags.	`public int`
`removeAllSecurityPolicyTags (Path` *path*`) throws IOException;` Use this method to remove all security policies tagged to the file or directory specified by *path*.	`public int`
Retrieve Security Policy Tags	
`getSecurityPolicyTag (Path`*path*`, List<String>`*securityPolicyTags*`) throws IOException;` Use this method to retrieve the security policy tags associated with the file or directory specified in *path*. The *securityPolicyTags* parameter contains a list of one or more security policy tags.	`public int`

The following example illustrates the usage of file system APIs, and the interchangeability of using the file system API with the extended attribute APIs:

1. Set three security policy tags: `general`, `hipaa`, and `pci`, on the file `/mapr/lab/foo.txt`.
2. Retrieve these security policy tags using the extended attribute commands and the `getSecurityPolicyTag` API.
3. Remove the tag `pci`. Two tags remain: `hipaa` and `general`.
4. Add a new tag `topsecret`.

   The two existing tags, `general` and `hipaa`, are preserved. Finally, there are three tags: `general`, `hipaa`, and `topsecret`.

Step 1: Set Security Policy Tags

Use the Java `addSecurityPolicyTag` API to set three security policies, `pci`, `general`, and `hipaa`, for the file `/mapr/lab/foo.txt` as follows.

```
import java.net.*;
import org.apache.hadoop.fs.*;
```

last-updated: Jun 06, 2024

```
import org.apache.hadoop.conf.*;
import com.mapr.fs.MapRFileSystem;
import java.util.List;
import java.util.ArrayList;
…
Configuration conf = new Configuration();
FileSystem fs = FileSystem.get(conf);
Path path = Paths.get("/mapr/lab/foo.txt");
List<String> securityPolicies = new ArrayList<String>();
securityPolicies.add ("pci");
securityPolicies.add ("general");
securityPolicies.add ("hipaa");
((MapRFileSystem fs).addSecurityPolicyTag (path, securityPolicies);
```

Step 2: Retrieve Security Policy Tags

The `getSecurityPolicyTag` API returns the same set of security policies `general`, hipaa, and `pci` in a List of String object, instead of a comma-separated list:

```
List<String> securityPolicies = new ArrayList<String>();
int status = getSecurityPolicyTag (path, securityPolicies);
```

Alternatively, use the `getfattr` extended attribute API, to retrieve the three security policy tags:

```
getfattr -d /mapr/lab/foo.txt
# file: /mapr/lab/foo.txt
security.mapr.policy="general,hipaa,pci"
```

The tags are always returned in alphabetical order regardless of the tags that you set first. All security policies are considered equal in terms of determining access rights.

Use the extended attribute Java API `getXAttr` to obtain the same result: retrieve the three security policy tags. The following segment prints the comma-separated list: `general,hipaa,pci`.

```
import java.net.*;
import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;
…
Configuration conf = new Configuration();
FileSystem fs = FileSystem.get(conf);
Path path = Paths.get("/mapr/lab/foo.txt");
byte[] securityPolicyBytes = fs.getXAttr(path, "security.mapr.policy");
System.out.println ("Security Policies: " + securityPolicyBytes.toString());
```

Step 3: Remove a Security Policy Tag

At this point, the example has three tags for `/mapr/lab/foo.txt`: `general`, `hipaa`, and `pci`. Now, remove the tag `pci` using the `removeSecurityPolicyTag` API:

```
Configuration conf = new Configuration();
FileSystem fs = FileSystem.get(conf);
Path path = Paths.get("/mapr/lab/foo.txt");
…
((MapRFileSystem fs).removeSecurityPolicyTag (path, "pci");
```

Use any of the methods listed in step 2, to see that the `pci` tag is removed.

Step 4: Add a Security Policy Tag

Add a tag `topsecret` using the `addSecurityPolicyTag` API:

```
FileSystem fs = FileSystem.get(conf);
Path path = Paths.get("/mapr/lab/foo.txt");
…
((MapRFileSystem fs).addSecurityPolicyTag (path, "topsecret");
```

Since this API sets the tags in an additive fashion, it preserves the two existing tags `general` and `hipaa`. The final output is three tags: `general`, `hipaa` and `topsecret`.

Complete Example of Setting and Retrieving Security Policies

The following sample program uses the tagging APIs on the file `/user/root/disks.txt`.

This program does the following tasks:

1. Tags the file with two tags, namely `general`, and `pci`.
2. Retrieve the tags. The output should display `general`, and `pci`.
3. Remove the tag `pci`.
4. Retrieve the tags. The output should display `general`.
5. Add the tag `hipaa`.
6. Retrieve the tags. The output should display `general`, and `hipaa`.

```
package com.mapr.fs;
import java.net.*;
import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;
import java.io.*;
import com.mapr.fs.MapRFileSystem;
import java.util.List;
import java.util.ArrayList;

class SecurityPolicyTest
  {
   public static void main (String [] args) throws IOException
     {
      Configuration conf = new Configuration();
      if (args.length != 1) {
      System.out.println ("Usage: com.mapr.fs.SecurityPolicyTest <path>");
      System.exit(-1);
                    }
       String pathName = args[0];
       System.out.println ("Path name: " + pathName);
       FileSystem fs = FileSystem.get(conf);
       Path path = new Path (pathName);
       List<String> securityPolicies = new ArrayList<String>();
       System.out.println ("Adding general,pci");
       securityPolicies.clear();
       securityPolicies.add ("general");
       securityPolicies.add ("pci");
       ((MapRFileSystem)fs).setSecurityPolicyTag(path, securityPolicies);
       List<String> tags = new ArrayList<String>();
       int status = ((MapRFileSystem)fs).getSecurityPolicyTag(path, tags);
       if (status == 0) {
                         System.out.println ("Tags:");
```

```
                            for (int i=0; i<tags.size(); i++) {
                            System.out.println (tags.get(i));
                           }
                           }
            System.out.println ("Removing pci");
            ((MapRFileSystem)fs).removeSecurityPolicyTag (path,"pci");
            tags.clear();
            status = ((MapRFileSystem)fs).getSecurityPolicyTag(path, tags);
            if (status == 0) {
                                System.out.println ("Tags:");
                                for (int i=0; i<tags.size(); i++) {
                                 System.out.println (tags.get(i));
                                }
                             }
               System.out.println ("Add hipaa");
               ((MapRFileSystem)fs).addSecurityPolicyTag(path, "hipaa");
               tags.clear();
               status = ((MapRFileSystem)fs).getSecurityPolicyTag(path,
tags);
               if (status == 0) {
                                 System.out.println ("Tags:");
                                 for (int i=0; i<tags.size(); i++) {
                                 System.out.println (tags.get(i));
                                    }
                                 }
         }
   }
```

Enforcing Security Policies at the Volume-Level
Describes how to set enforcement modes for security policies at the volume-level.

About this task

The system enforces data access controls during data operations. Data access controls are the ACEs defined in security policies and ACEs and POSIX mode bits directly defined on data objects. The enforcement mode tells the system which of these data access controls to evaluate and enforce during data operations.

You can set the enforcement mode to one of the following values from the Control System, CLI, or REST API:

Enforcement Mode	Enforce Security Policies	Enforce Data ACEs and POSIX Mode Bits
PolicyAceAndDataAce (Default)	Yes	Yes
PolicyAceOnly	Yes	No

last-updated: Jun 06, 2024

Enforcement Mode	Enforce Security Policies	Enforce Data ACEs and POSIX Mode Bits
DataAceOnly	No	Yes
PolicyAceAuditAndDataAce (Permissive mode)	Performs checks but does not fail; audits instead	Yes

For detailed information about the enforcement mode options, see Volume-Level Security Policy Enforcement Mode on page 861.

Set the Enforcement Mode from the Control System

Procedure

1. Log in to the Control System, and go to the volume information page.
2. In the **Security** pane, click  associated with **Enforcement Mode** to display the **Change Enforcement Mode** window.
3. Select the enforcement mode to apply to the volume.
4. Click **Save Changes** for the changes to take effect.

Set the Enforcement Mode from the CLI or REST API

About this task

CLI

Set the enforcement mode when you create a volume:

```
/opt/mapr/bin/maprcli volume
create -name <volName> -path
<mountPath> -securitypolicy
<policyName> -enforcementmode
PolicyAceAndDataAce|PolicyAceOnly|
DataAceOnly
```

Set the enforcement mode when you modify a volume:

```
/opt/mapr/bin/maprcli
volume modify -name
<volName> -enforcementmode
PolicyAceAndDataAce|PolicyAceOnly|
DataAceOnly
```

REST

Send a POST request to set the enforcement mode when you create a volume:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/create?
name=<volName>&path=<mountPath>&securi
typolicy=<policyName>&enforcementmode=
PolicyAceAndDataAce|PolicyAceOnly|
DataAceOnly' --user <username>:<pwd>
```

Send a request of type POST to set enforcement mode when you edit a volume:

```
curl -k -X POST 'https://
<hostname>:8443/rest/volume/modify?
```

last-updated: Jun 06, 2024

```
name=<volName>&enforcementmode=PolicyA
ceAndDataAce|PolicyAceOnly|
DataAceOnly' --user <username>:<pwd>
```

For more information, see `volume create` on page 2588 and `volume modify` on page 2676.

Troubleshooting Security Policies

This topic describes problems that you may encounter when creating and using security policies. It includes recommendations on how to troubleshoot and resolve problems.

Cannot Create a Security Policy

You encounter the following error when attempting to create a security policy:

```
ERROR (1) -  Security policy create of XXX failed: Security policy creation
failed: No privileges to create a security policy
```

You must have cluster-level create/delete security policy (`cp`) permission to create a security policy.

To check your cluster-level permissions, assuming you have cluster-level `login` permission, run the following command:

```
maprcli acl show -type cluster
```

The following shows sample output for a user with the necessary `cp` permission:

```
Allowed actions              Principal
[login, cp]              User PolicyAdmin
```

Cannot view a Security Policy

If you receive an error when running the `maprcli security policy info` command, the root cause depends on the error you encounter:

No MapR Ticket

```
ERROR (22) -  You do not
have a ticket to communicate
with 10.10.20.40:7222. Retry after
obtaining a new ticket using maprlogin
```

This indicates that you do not have a MapR ticket to access the secure MapR cluster.

Create a MapR ticket by running `maprlogin password`.

No Policy-Level Permission

```
ERROR (2) -  Security policy lookup
of XXX failed, Operation not permitted
```

The possible reasons for this error are as follows:

Possible Cause	Troubleshooting Steps
Either you or the group that you belong to does not have the policy-level `read` permission.	1. Ask the user who granted you access to confirm your policy-level permission by running: `maprcli security policy info \ -name XXX \ -columns acl -json` 2. Request access if you do not have the `read` permission.
You are not a member of a group that has policy-level permission.	1. Run the `id` command to verify your group membership. 2. If you are not a member of the group, request an administrator to add you. 3. If you are using MapR tickets, recreate your ticket after updating your group membership.
Your MapR ticket does not reflect your updated group membership because you created the ticket before changing your group membership.	1. Verify your MapR ticket by examining the output from `maprlogin print`. 2. If the ticket does not include the group that has policy-level permission, then recreate your MapR ticket.

Cannot Modify a Security Policy

Depending on the property you are trying to modify, you must have certain policy-level permissions:

Update Non-Permission Properties of a Policy

If you encounter the following error:

```
ERROR (1) -  Security policy
update of XXX failed: Insufficient
privileges to update general section
for security policy XXX
```

last-updated: Jun 06, 2024

	You must have one of the following cluster-level or policy-level permissions: • Cluster-level `cp`, `a`, or `fc` permission • Policy-level `a` or `fc` permission
Update Permission Properties of a Policy	If you encounter the following error: `ERROR (1) - Security policy update of XXX failed: Insufficient privileges to update ACL for security policy XXX` You must have one of the following cluster-level or policy-level permissions: • Cluster-level `cp` or `admin` permission • Policy-level `admin` permission
Cannot tag a security policy to a data object	If you cannot tag a policy to a data object or the volume page search in the Control System is not displaying a security policy, verify that `allowtagging` is set to `true`, as described in Changing the State of a Security Policy on page 1910.
Policies not visible after the CLDB starts	After the CLDB master starts, it can take a couple of minutes for the policyserver to come up. Currently, only the policy server on the cluster designated as the global policy master serves operations. Member clusters standby and do not serve operations. Wait for the policyserver to come up.
Mirroring/Restore fails due to no policies	If mirroring or restore fails due to no policies, import the policies from the global policy master or a member cluster that has the policies, as described in Security Policy Domain and Policy Management on page 857.
Access check on mirror source and destination clusters differ	The policies may have been modified on the global policy master and not propagated to either of them. Get the latest policies, as described in Security Policy Domain and Policy Management on page 857.
Access checks fail	View the file system audit logs on the master node.
Where are the logs?	The following table lists the log locations for components related to security policies:

Component	Location
PolicyServer	cldb.log
Access Check	MFS
Audit Logs	NC master node FS Audit Logs
Client (For tagging)	Regular Client logs (ffs.log or enable Hadoop debug then stdout)

Granting Security Policy Permissions on page 1889

last-updated: Jun 06, 2024

Permissions define which administrative users can create, view, and modify security policies. Administrators set the permissions on security policies through cluster-level and security policy-level ACLs.

Policy-Based Security Quick Reference
This quick reference provides tips and `maprcli` commands for the most common tasks related to Policy-Based Security.

Task	Commands
Enable PBS (Required for upgrades from pre-6.2.0 versions of data-fabric)	If upgrading from a data-fabric version that does not support extended attributes, ena `/opt/mapr/bin/maprcli cluster feature enable -name mfs.featur` Enable PBS: `/opt/mapr/bin/maprcli cluster feature enable -name mfs.featur` Related documentation: • Upgrade Workflows (Releases 6.x or 7.x to 7.7.0) on page 301 • Installer on page 5579

Designate a master security policy cluster
(Required to create and modify security policies)
	You must designate a master security policy cluster to set the security policy global r member clusters. Master and member security policies form a security policy domain
	`maprcli config save -values '{"cldb.pbs.global.master":"1"}'`
	`#1 = master security policy cluster`
	`#0 = member of the security policy cluster`
	To identify which cluster is master, run:
	`maprcli dashboard info -json | grep -i global "globalPolicyMa`
	Related Documentation:
	• Configuring the Global Policy Master on page 860

Customizing Security in HPE Ezmeral Data Fabric
Describes the `.customSecure` file and how HPE Ezmeral Data Fabric 6.x handles custom security settings.

This topic contains the following subsections:

last-updated: Jun 06, 2024

NOTE: Implementing custom security is not recommended unless your installation demands it. Using the custom security option means that HPE Ezmeral Data Fabric software does not ensure that your system is secure by default, and that you need to manually perform all security configuration.

In HPE Ezmeral Data Fabric 6.x, the configure.sh script detects that a cluster is in one of three security states:

Secure	The cluster is configured with the default HPE Ezmeral Data Fabric security settings.
Custom secure	The cluster has a mixture of HPE Ezmeral Data Fabric security settings and custom settings.

Understanding how `configure.sh` handles custom security settings is important when you upgrade a cluster, add services, add nodes, or change security settings.

What is Custom Security?

Any change to the default HPE Ezmeral Data Fabric configuration for authentication, authorization, or encryption represents a "custom security" change. Users who make such changes are encouraged to create a `.customSecure` file to ensure that `configure.sh` does not remove these changes. Custom security changes include any change to the keystore or truststore passwords or the number of keys in those files or the names of the keys.

Other examples of custom security changes include:

- Implementing Kerberos security
- Changing the Hive authorization model
- Changing the Oozie authorization model

Identifying the Current Security State of the Cluster

If the current security state of the cluster (secure or custom secure) is unknown, you can use one of these checks to identify which state the cluster is in:

- Check the security value in the `/opt/mapr/conf/mapr-clusters.conf` file. For example:

  ```
  <clustername1> secure=true <CLDB> <CLDB> … <CLDB>
  ```

  For more information, see mapr-clusters.conf on page 2983.

- Check for the presence of the `.customSecure` file:

  ```
  /opt/mapr/conf/.customSecure
  ```

  If the file is present, `configure.sh` treats the cluster as custom secure.

About the .customSecure File

If you customized the security settings for cluster and you want to ensure that `configure.sh` does not change any of the settings, create a `.customSecure` file. Create the file in the following location on every node:

```
/opt/mapr/conf/.customSecure
```

The `.customSecure` file does not contain any information. The presence of the file tells `configure.sh` that the cluster has security settings that must not be changed by `configure.sh`.

Typically, you create the `.customSecure` file manually. However, in some cases, `configure.sh` creates or removes the `.customSecure` file for you. For example, if `configure.sh` detects that it is being run after an upgrade from a MapR 5.x secure cluster, it creates the `.customSecure` file automatically. If you use the `-forceSecurityDefaults` option and `-secure` with `configure.sh`, the script removes the `.customSecure` file because you are forcing the removal of custom security settings.

Forcing a Change to the Security Configuration

If your HPE Ezmeral Data Fabric 6.x cluster has custom security settings (the `.customSecure` file is present), and you want to change to the default HPE Ezmeral Data Fabric secure or non-secure settings, use the `-forceSecurityDefaults` option of `configure.sh` to make the change. Note these considerations:

- Using the `-forceSecurityDefaults` option removes the `.customSecure` file. You must specify the `-secure` option with `-forceSecurityDefaults`. Otherwise, the command will have no effect.
- The `-forceSecurityDefaults` option might not remove all custom settings. Some manual editing might be necessary to return the cluster to a usable state.
- If you are forcing a custom-secured cluster to be HPE Ezmeral Data Fabric secure, you still must include other `configure.sh` options that are required for security. You must perform any steps required to add security. For example, see Enabling Wire-level Security on page 1797.

Custom Security and the HPE Ezmeral Data Fabric Installer

Using the HPE Ezmeral Data Fabric Installer or HPE Ezmeral Data Fabric Installer Stanzas is not supported on clusters with custom security or customized configurations.

Adding a Node to a Cluster with Custom Security

Adding a node to a cluster with custom security is similar to adding a node to a cluster with HPE Ezmeral Data Fabric security, but there are some additional steps:

1. Add the node with default HPE Ezmeral Data Fabric security as described in Adding Nodes to a Cluster on page 1114.
2. To support your custom security mode, copy any custom resources or settings as needed from existing nodes to the added node.
3. Create the `/opt/mapr/conf/.customSecure` file on the added node:

   ```
   /usr/bin/touch /opt/mapr/conf/.customSecure
   ```

Adding a Service to a Cluster with Custom Security

If you add a new service (ecosystem component) to a secure or custom-secure cluster, `configure.sh` configures the service for HPE Ezmeral Data Fabric security automatically. If the cluster is custom secure,

you need to change the security settings for the service to be compatible with the current cluster settings and restart the service. Any subsequent use of `configure.sh -R` will leave the customization in place.

Managing Impersonation

Provides instructions for enabling and using Data Fabric impersonation features.

Impersonation, also known as identity assertion, is one user accessing data and submitting jobs on behalf of another user. Impersonation in Data Fabric allows centralized control of access to resources in the file system and HPE Ezmeral Data Fabric Database.

Example: Access Control and Impersonation

As an example of impersonation, consider user Bob and a generic Service X:

1. Bob launches a client for the service and may or may not provide credentials.
2. Service X authenticates Bob and establishes a connection for him to use.
3. Bob issues a command to the service that will produce a query.
4. The service uses any user's servicewithimpersonation ticket to authenticate with the datastore - file system/HPE Ezmeral Data Fabric Database.
5. The datastore authenticates the user with the impersonation ticket. The service can now proceed.
6. The service sends the datastore a query, as user Bob.
7. The datastore checks permissions for Bob on the assets that the query will access.
8. If Bob has permissions, the datastore returns the query results to the service, which relays the results to the client, and the query succeeds.
9. If Bob does not have permissions, the datastore sends an access error to the service, which relays the error to the client, and the query fails.

When you use impersonation in Data Fabric:

- The datastore permissions are authoritative.
- The process has end-to-end security.
- Users can do nothing more and nothing less than what they are authorized to do.
- This control is independent of remote authentication and security mechanisms that control user access to application features.
- Any permissions set up within applications, or within the UNIX filesystem permissions on servers where Data Fabric components reside, have no effect on user access to Data Fabric resources.
- The `mapr` superuser is allowed to impersonate any Data Fabric user in any group, connecting from any host. Other users with impersonation capability can impersonate any Data Fabric user in any group, except the `mapr` superuser and the `root` user.

Using Impersonation without Security

Although it is possible to enable impersonation in a non-secure Data Fabric installation, HPE strongly recommends against doing this. The implementation rules are different. Setting up the Data Fabric environment with impersonation operating under those rules makes it very difficult to enable security later. Disabling security in a secure Data Fabric installation is easy, if the need arises.

last-updated: Jun 06, 2024

If you choose to implement impersonation in a non-secure Data Fabric cluster, see Configuring Impersonation when Cluster Security is not Enabled.

Using Impersonation with Security

In general, this documentation assumes that security is enabled in your Data Fabric installation. See Enabling Wire-level Security on page 1797 and Enabling Encryption of Data at Rest on page 1799.

You can use the `maprlogin` utility to generate a **servicewithimpersonation** ticket that can be used to access a secure cluster impersonating another user. That is, the **servicewithimpersonation** ticket provides the user the ability to impersonate other users (except the `mapr` user) in addition to the ability to access a secure cluster. The servicewithimpersonation ticket generated with the list of `impersonatedgids` and `impersonateduids` cannot be used to impersonate user `root` or user `mapr`. If the user is other than `root` or `mapr`, CLDB resolves the username to UID locally. It then checks if the resolved UID can be impersonated (that is, if it is a part of the ticket's `impersonateduids`) or at least one of the GIDs of the resolved UID can be impersonated (i.e., if at least one of the GIDs should be part of the ticket's `impersonatedgids`). The servicewithimpersonation ticket can only be generated by a user with full control on a cluster's ACL.

If you are setting up user impersonation in a secure cluster, you need to generate an impersonation ticket. See the *Generating and Printing Service with Impersonation Ticket* section in the maprlogin Command Examples on page 2915 topic and Generating a Service with Impersonation Ticket on page 1833 for information.

After generating the ticket:

1. Ensure that user1 has read permissions on the ticket.
2. If you moved the ticketfile to a different location, set the `$MAPR_TICKETFILE_LOCATION` environment variable.

How Impersonation Works

Introduces impersonation functionality, limitations, and core requirements.

If a user attempts to impersonate another user to the file system or HPE Ezmeral Data Fabric Database systems and the configuration parameters for resolving the UID and GIDs on the server (see Resolving Username with UID and GIDs During Impersonation) are disabled:

1. The Data Fabric client looks for that user name in the local operating system registry.
2. If the user name is:
   - Found, Data Fabric sends the user's UID and GID to the server for impersonation.
   - Not found in the local operating system registry, the user action is not processed.

If a user attempts to impersonate another user to the file system or HPE Ezmeral Data Fabric Database systems and if the configuration parameters for resolving the UID and GIDs on the server (see Resolving Username with UID and GIDs During Impersonation) are enabled:

1. The Data Fabric client asks CLDB to look for that user name and resolve the UID and GIDs for that user on the server.
2. If the user name is:
   - Found on the server, the server allows the user to proceed with the impersonation.
   - Not found, the user action is not processed.

NOTE: If the configuration property for resolving the username is set on the client, and the configuration property for resolving the username is not set on CLDB, the operation fails with an error.

Limitations on Impersonation

Service with impersonation tickets cannot be used to impersonate the `mapr` or `root` users. A scoped service with impersonation ticket cannot contain the UID of the `root` or `mapr` user (in the impersonated UIDs) and the GID of the `root` or `mapr` user (in the impersonated GIDs). The `mapr` user can impersonate any user, including `root`.

Core Requirements for Impersonation

The `mapr` superuser is allowed to access to the file system and HPE Ezmeral Data Fabric Database systems. The following conditions must be met for the `mapr` superuser to be able to impersonate another Data Fabric user:

1. The `hadoop.proxyuser.mapr.groups` and `hadoop.proxyuser.mapr.hosts` parameters must be set correctly in the `core-site.xml` file.

   See Enabling Impersonation for the mapr Superuser.

   These settings are not always required. The hadoop proxy user functionality is only applicable to ecosystem components included in the Data Fabric distribution for Apache Hadoop. If the Data Fabric client accesses an ecosystem component, such as HiveServer2, these settings may be required. These settings are never needed if the Data Fabric client accesses the file system or HPE Ezmeral Data Fabric Database directly. Enabling impersonation here ensures that the correct settings are in place if they are needed.

2. The name of the Data Fabric user that you want the `mapr` superuser to be able to impersonate must appear in the local operating system registry where the Data Fabric client is running if server-side resolution of UID and GIDs is not enabled.

3. The UID and GUID of the user name under which the Data Fabric client is running must match exactly the UID and GUID for that user name on the server.

NOTE: The `mapr` user can impersonate any user, including user root.

For all other users with access to the file system and HPE Ezmeral Data Fabric Database systems, the following conditions must be met for the user to impersonate another user.

1. A valid servicewithimpersonation ticket must be present for the user who intends to impersonate on the system.

2. The name of the user to impersonate must appear in the local operating system registry where the Data Fabric client is running if the server-side resolution of UID and GIDs is not enabled.

3. The UID and GUID of the user name under which the Data Fabric client is running must match exactly the UID and GUID for that user name on the server.

NOTE: If a user is not authorized to impersonate, then the operations proceeds as the user, not the target user. Some operations succeed and some do not, even if the user has all the permissions for these operations. Also, if a user with full access and impersonating capability tries to impersonate another user, the operations succeeds only if the target user has permissions on the directory.

Component Requirements for Impersonation

Some Data Fabric ecosystem components have additional requirements to enable impersonation.

last-updated: Jun 06, 2024

The following components must have settings that support impersonation in the configuration files indicated, on each node where the component resides:

- **Drill**: Edit the `drill-env.sh` file. See Configuring User Impersonation in the Apache Drill documentation.
- **HBase**: Edit the `hbasesite.xml` file. See Impersonation through the HBase REST Gateway.
- **HiveServer2**: Edit the `hive-site.xml` file. See Hive User Impersonation.
- **Hue**: Edit the `hue.ini` file.
- **Spark**: No special settings are required for Spark in MapReduce 2 (YARN) mode since Spark automatically inherits the correct behavior from YARN. If running standalone, Spark cannot perform impersonation and should not be used if security is important.

Application Development Requirements

You can set up impersonation in an application programmatically.

- **C/C++**: Use `hb_connection_create_as_user()`. See Creating C Apps - Binary Tables on page 3238 and Impersonation Example on page 3241 for more information.
- **Java**: Use `UserGroupInformation.doAs()`. See Class UserGroupInformation in the Hadoop documentation for more information.

Enabling Impersonation for the HPE Ezmeral Data Fabric Superuser

Provides a procedure necessary to implement superuser impersonation.

About this task

To enable impersonation in your HPE Ezmeral Data Fabric installation:

Procedure

1. Open the following file in a text editor:

   ```
   /opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml
   ```

2. Add the following `hadoop.proxyuser` properties:

   ```
   <property>
           <name>hadoop.proxyuser.mapr.hosts</name>
           <value>*</value>
   </property><property>
           <name>hadoop.proxyuser.mapr.groups</name>
           <value>*</value>
   </property>
   ```

   The `hosts` setting (`*`) allows the `mapr` superuser to connect from any host to impersonate a user.

   The `groups` setting (`*`) allows the `mapr` superuser to impersonate any user in any group.

   NOTE: Do not use anything other than a single asterisk here. Other parts of HPE Ezmeral Data Fabric ignore the values here and treat them as if each is set to a single asterisk.

3. Close the file, saving any changes that you made.

last-updated: Jun 06, 2024

Enabling Impersonation for any User

Provides the procedure necessary to implement impersonation for any data-fabric user.

About this task

To enable impersonation for any data-fabric user:

Procedure

1. Log in to the system as root, mapr user, or any user with full control.
2. Generate a servicewithimpersonation ticket for the data-fabric user.

   For example:

   ```
   $ maprlogin generateticket -type servicewithimpersonation -user
   mapruser1 -out /var/tmp/sample_ticket
   ```

   WARNING: The `mapr` user ticket can be used to impersonate any user, including user root.

   You can generate a scoped servicewithimpersonation ticket for the user. Scoped impersonation tickets allow the user using the ticket to impersonate only the UIDs and or GIDs specified in the ticket. For example:

   ```
   $ maprlogin generateticket -type servicewithimpersonation -user
   mapruser1 -impersonateduids 550 -impersonatedgids 500 -out /var/tmp/
   sample_ticket
   ```

   NOTE: If you generate a scoped impersonation ticket, the impersonated UIDs cannot contain the UID of user `root` or user `mapr`, and the impersonated GIDs cannot contain the GID of user `root` or user `mapr`.

   For more information, see `maprlogin` on page 2911.
3. Move the ticket to a secure location, and share the ticket with the user (for whom this ticket is generated).
4. (Optional) Copy the file to a permanent directory.

Configuring Impersonation without Cluster Security

Describes how to use impersonation on a non-secure cluster.

About this task

To configure impersonation without enabling cluster security, perform the following steps on the client.

Procedure

1. Enable impersonation for each ecosystem component you will use that supports impersonation. See *Component Requirements for Impersonation* in How Impersonation Works.
2. Enable impersonation for the data-fabric core components. See Enabling Impersonation for the mapr Superuser.
3. On each client system from which you want to use impersonation:
   a) Set a `MAPR_IMPERSONATION_ENABLED` environment variable with the value `true`. This value must be set in the environment of any process you start that does impersonation.

b) Create a file in `/opt/mapr/conf/proxy/` that has the name of the data-fabric superuser or any other user. For the data-fabric superuser, the default file name would be `mapr`. For all other users, use their username for the proxy file.

If the data-fabric superuser has a different name in your cluster, use that name for the proxy file. To verify the data-fabric superuser name, check the `mapr.daemon.user=` line in the `/opt/mapr/conf/daemon.conf` file on a data-fabric cluster server.

Resolving Username with UID and GIDs During Impersonation
Lists parameters for configuring impersonation.

To resolve username with UID and GIDs on the server (and not the local operating system registry) during impersonation, set the following configuration parameters on the client and CLDB:

Parameter	Description

`fs.mapr.server.resolve.user`	Must be set in `core-site.xml` file on the client machine. Value can be one of the following:
	• `true` - enable
	• `false` - disable
	By default, this parameter is disabled. If enabled, the client requests the CLDB to resolve the user with UID/GIDs. For example, to enable this property, your entry in the `core-site.xml` file should be as shown below:
	`<configuration>`
	`  <property>`
	`  <name>fs.mapr.server.resolve.user</name>`
	`  <value>true</value>`
	`  </property>`
	`</configuration>`

`cldb.security.resolve.user`	Must be set using the `config` command. Value can be one of the following: • `0` - disable • `1` - enable By default, this is disabled. If enabled, CLDB resolve thes user with UID/GIDs for all incoming client requests. For example, to enable this property, run the following command: `maprcli config save -values {cldb.security.resolve.user:1}`

NOTE: Both configuration parameters must be set to enable support for UID/GID resolution on the server. If the configuration parameter is set on the client to resolve on the server and if the configuration parameter is not set on CLDB, the operation fails with an error.

Managing Secure Clusters

Provides procedures that will enable you to use MapR clusters securely.

last-updated: Jun 06, 2024

Administrative topics such as configuring cross-cluster security, managing mirror volumes in secure clusters, running commands on remote secure clusters are discussed. In addition, access scenarios for secure and non-secure MapR clusters and HDFS clusters are described.

Setting Up Cross-Cluster Security

Provides an overview of the `configure-crosscluster.sh` utility that is used to set up security between two clusters.

About this task

When all local and remote CLDB nodes are reachable from the local node, you can run the `configure-crosscluster.sh` on page 2835 utility on any CLDB node to automatically set up a trust relationship between clusters.

For two or more HPE Ezmeral Data Fabric clusters to communicate with one another, a secure trust relationship must exist between the clusters. A secure trust relationship between clusters is required for running commands remotely, creating remote replicas and mirror copies of volumes, and accessing data using NFS on the other cluster. The following sections describe the quick way to configure both the clusters for mirroring, replication, and remote access, and the advanced manual way to configure the clusters for mirroring, replication, remote access, and/or NFS server access.

Quick Configuration

About this task

You can run the `configure-crosscluster.sh` on page 2835 utility on any CLDB node in a cluster to automatically set up a trust relationship between the cluster and another cluster. To automatically configure two clusters for remote access, mirroring, and replication in both directions:

Procedure

1. Log in to the CLDB node on a cluster.
2. Run the `configure-crosscluster.sh` on page 2835 utility with the `all` parameter.
   For example:

   ```
   # /opt/mapr/server/configure-crosscluster.sh create all -remoteip
   <remote_node_IP>
   ```

   When the utility runs, it performs the following actions on all the clusters:

   a. Updates the `/opt/mapr/conf/mapr-clusters.conf` file to include the first entry from the `/opt/mapr/conf/mapr-clusters.conf` file on the other cluster.

   b. Imports the certificate of the other cluster in the `/opt/mapr/conf/ssl_truststore` file, and copies the updated `/opt/mapr/conf/ssl_truststore` file to all the other nodes on the cluster.

   c. Generates a cross-cluster ticket for the other cluster, copies the ticket to the CLDB node on the other cluster, merges the ticket with the `/opt/mapr/conf/maprserverticket` file on the node in the other cluster, and copies the updated `/opt/mapr/conf/maprserverticket` file to all other CLDB nodes on the other cluster.

   For more information on the arguments, syntax, and options, see the `configure-crosscluster.sh` on page 2835 utility.
3. Verify access to the remote cluster by:

- Running remote commands on a node in either cluster.
- Creating mirror volumes on any node in the destination cluster.
- Setting up table and stream replication on tables and streams in the source cluster.

To configure access over NFS, see Configuring Secure Clusters for Cross-Cluster NFS Access on page 1957.

Advanced Configuration

About this task

Using the `configure-crosscluster.sh` on page 2835 utility with the default configuration works only when all local and remote CLDB nodes are reachable from the local node. It does not work, for example, if you set up multi-homed clusters as documented in the MAPR_SUBNETS section in Designating NICs for HPE Ezmeral Data Fabric on page 1156, because the `configure-crosscluster.sh` on page 2835 utility cannot traverse between local and remote IPs (for example, from the external IP 23.21.203.95 to internal IP 10.10.100.100). In such environments, run the `configure-crosscluster.sh` on page 2835 utility with the `-remotehosts` parameter.

You can configure the clusters manually for unidirectional or bidirectional remote access, mirroring, or replication only. The following sections describe the manual steps for:

Configuring Secure Clusters for Running Commands Remotely
Describes how to configure secure clusters to access them all from a single cluster and run commands remotely on them.

About this task

You can configure a number of secure clusters to access them all from one cluster. You need not log into each secure cluster separately and run `maprcli` commands locally on them.

For example, suppose you need to manage two secure clusters, clusterA and clusterB. One method is to log into each cluster separately and run commands locally on each. However, it is possible to log into clusterA only and manage both clusters from clusterA, running commands locally for clusterA and remotely for clusterB. When you type the `maprcli` commands, you must use the `-cluster` parameter in those commands to specify the cluster on which you want the commands to run.

You can configure the secure clusters for remote access manually (as described in the following section) or automatically by running the `configure-crosscluster.sh` utility. If you run the `configure-crosscluster.sh` utility, the utility configures the clusters for running commands remotely in both directions. See `configure-crosscluster.sh` on page 2835 for more information.

Prerequisite

About this task

Ensure that you have the relevant ports open for secure cluster communication.

Setting Up Secure Clusters Manually for Cross-Cluster Access

About this task

To manually configure two secure clusters for remote access:

Procedure

1. Log in to the secure cluster from which you want to run commands.
   In the rest of this procedure, this cluster is referred to as clusterA and the remote cluster is referred to as clusterB.

2. Configure clusterA for communicating with the other clusters by editing `mapr-clusters.conf` file on each node clusterA to specify the hostname or IP address of the CLDB nodes on the other clusters.
   For example, suppose:
   - clusterA's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

     ```
     clusterA.cluster.com secure=true perfnode50.lab:7222
     ```

   - clusterB's `/opt/mapr/conf/mapr-clusters.conf` file contains the following:

     ```
     clusterB.cluster.com secure=true perfnode100.lab:7222
     ```

   Perform the following steps to configure the nodes on the clusters:
   a) On any node in clusterA, append the first entry from clusterB's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of clusterA's `mapr-clusters.conf` file.
      Note that clusterA's entry must be the first line of the `mapr-clusters.conf` file:

      ```
      clusterA.cluster.com secure=true perfnode50.lab:7222
      clusterB.cluster.com secure=true perfnode100.lab:7222
      ```

      The clusterA's `mapr-clusters.conf` file now contains two entries.

   b) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the other nodes in clusterA.

   c) On any node in clusterB, append the first entry from clusterA's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of the remote cluster's `mapr-clusters.conf` file.
      Note that clusterB's entry must be the first line of mapr-clusters.conf file:

      ```
      clusterB.cluster.com secure=true perfnode100.lab:7222
      clusterA.cluster.com secure=true perfnode50.lab:7222
      ```

      The clusterB's `mapr-clusters.conf` file now contains two entries.

   d) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the nodes in clusterB.

   See `mapr-clusters.conf` on page 2983.

3. Perform the following steps on clusterA to ensure that the `ssl_truststore` file has signers for all the clusters:
   a) Copy the `ssl_truststore` from the `/opt/mapr/conf` directory of clusterB into a temporary directory on clusterA.
      For example:

      ```
      # scp mapr@<remote-ip>:/opt/mapr/conf/ssl_truststore /tmp/
      clusterB_ssl_truststore
      ```

b) Merge the `ssl_truststore` of clusterB with the `ssl_truststore` of clusterA using the `/opt/mapr/server/manageSSLKeys.sh` utility.

For example, if you copied the `ssl_truststore` file of clusterB as `/tmp/clusterB_ssl_truststore`, run the following command to merge the files:

```
/opt/mapr/server/manageSSLKeys.sh merge /tmp/
clusterB_ssl_truststore /opt/mapr/conf/ssl_truststore
```

c) Copy the merged `ssl_truststore` file to every node on clusterA.

4. Perform the following steps on clusterB *only* if you want to set up access to clusterA from clusterB:

a) Copy the `ssl_truststore` from the `/opt/mapr/conf` directory of clusterA into a temporary directory on clusterB.

For example:

```
# scp mapr@<remote-ip>:/opt/mapr/conf/ssl_truststore /tmp/
clusterA_ssl_truststore
```

b) Merge the `ssl_truststore` of clusterB with the `ssl_truststore` of clusterA using the `/opt/mapr/server/manageSSLKeys.sh` utility.

For example, if you copied the `ssl_truststore` file of clusterA as `/tmp/clusterA_ssl_truststore`, run the following command to merge the files:

```
/opt/mapr/server/manageSSLKeys.sh merge /tmp/
clusterA_ssl_truststore /opt/mapr/conf/ssl_truststore
```

c) Copy the merged `ssl_truststore` file to every node on clusterB.

5. For crossclusters to work using the Control System, place the mapruserticket of the remote cluster into the local cluster.

a) Generate a mapruserticket for the remote cluster as `mapr` user:

```
maprlogin password -cluster demo
[Password for user 'mapr' at cluster 'demo': ]
MapR credentials of user 'mapr' for cluster 'demo' are written to
'/tmp/maprticket_5000'
```

b) Merge the generated maprticket:

```
cat /tmp/maprticket_5000 >>/opt/mapr/conf/
maprusertícket
```

6. Verify access by running remote commands on clusterA.

See Verifying Access to run Remote Commands on page 1952.

Verifying Access to run Remote Commands

Procedure

1. Log in to any node on clusterA and run the `maprlogin` on page 2911 utility from clusterA to obtain user ticket for accessing the remote cluster.

   For example, to obtain tickets for managing the remote cluster from clusterA, run the following command::

   ```
   # /opt/mapr/bin/maprlogin password -cluster clusterB.cluster.com
   ```

2. Verify access by running remote commands on clusterA.

   For example, the following command, executed from a node in clusterA, lists the volumes on clusterB:

   ```
   # /opt/mapr/bin/maprcli volume list -cluster clusterB.cluster.com
   ```

Configuring Secure Clusters for Cross-Cluster Mirroring and Replication

Describes configuring clusters for cross-cluster operations such as mirroring and replication.

About this task

Cross-cluster tickets are required on secure clusters that need to pull data from another secure cluster and on secure clusters that need to push data to another secure cluster. For example:

- Volume mirroring is a pull operation. The destination cluster pulls the volume data from the source cluster. Since the destination cluster performs the operation, the destination cluster receives a ticket that is generated on the source cluster.
- Table and streams replication is a push operation. The source cluster pushes table or stream data to the destination cluster. Since the source cluster performs the operation, the source cluster receives a ticket that is generated on the destination cluster.

You can configure secure clusters for cross-cluster mirroring and replication manually (as described in Manually Setting up Secure Clusters for Cross-Cluster Mirroring on page 1952 and Manually Setting up Secure Clusters for Cross-Cluster Replication on page 1956). You can configure secure clusters automatically, by running the `configure-crosscluster.sh` utility. This utility configures the clusters for both mirroring and replication in both directions. For more information, see `configure-crosscluster.sh` on page 2835.

Manually Setting up Secure Clusters for Cross-Cluster Mirroring

About this task

To set up secure clusters for cross-cluster mirroring:

Procedure

1. Verify that the user for whom you are configuring access, exists in the registry on both the clusters and has the following permissions:
   - Permissions to create volumes on the source cluster.
   - Permissions to mirror volumes on the destination cluster.

   You can set up access for the *mapr* user, who already has permissions to create volumes and mirror volumes.

last-updated: Jun 06, 2024

2. Configure source cluster (clusterA) to communicate with the other clusters by editing the `mapr-clusters.conf` file on each node of clusterA to specify the hostname or IP address of the CLDB nodes on the other clusters.

   For example, suppose:

   - The `/opt/mapr/conf/mapr-clusters.conf` file on the source cluster (clusterA) contains the following:

     ```
     clusterA.cluster.com secure=true perfnode50.lab:7222
     ```

   - The `/opt/mapr/conf/mapr-clusters.conf` file on the destination cluster (clusterB) contains the following:

     ```
     clusterB.cluster.com secure=true perfnode100.lab:7222
     ```

   Perform the following steps to configure the nodes on the clusters:

   a) On any node in clusterA, append the first entry from clusterB's `mapr-clusters.conf` file, the entry which is prefixed with the cluster name, to the end of clusterA's `mapr-clusters.conf` file.

      Note that clusterA's entry must be the first line of the `mapr-clusters.conf` file:

      ```
      clusterA.cluster.com secure=true perfnode50.lab:7222
      clusterB.cluster.com secure=true perfnode100.lab:7222
      ```

      The `mapr-clusters.conf` file for clusterA now contains two entries.

   b) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the other nodes in clusterA.

   c) On any node in the destination cluster (clusterB), append the first entry from clusterA's `mapr-clusters.conf` file, entry which is prefixed with the cluster name, to the end of the remote cluster's `mapr-clusters.conf` file.

      Note that clusterB's entry must be the first line of the `mapr-clusters.conf` file:

      ```
      clusterB.cluster.com secure=true perfnode100.lab:7222
      clusterA.cluster.com secure=true perfnode50.lab:7222
      ```

      The `mapr-clusters.conf` file for clusterB now contains two entries.

   d) Copy the updated `/opt/mapr/conf/mapr-clusters.conf` file to all the nodes in clusterB.

   See `mapr-clusters.conf` on page 2983.

3. Log in to any node on the source cluster (ClusterA) and perform the following steps:

   a) Generate a cross-cluster ticket for the destination cluster (clusterB) for the mapr user.

      For example, to generate a cross-cluster for the destination cluster (clusterB), run the following command on the source cluster (clusterA):

      ```
      /opt/mapr/bin/maprlogin generateticket -type crosscluster -out /tmp/
      crossclusterticket -user destinationclusteruser
      ```

b) Copy the cross-cluster ticket file to any node on the destination cluster (clusterB).

For example:

```
scp /tmp/crossclusterticket mapr@<dest-ip>:/tmp/
sourceClusterTicketFile
```

4. Log in to the node on the destination cluster (clusterB) where the cross-cluster ticket was copied, and perform the following steps:

a) Merge the cross-cluster ticket file with the `/opt/mapr/conf/maprserverticket` file on the node.

For example, to merge, run the following command:

```
cat /tmp/sourceClusterTicketFile >> /opt/mapr/conf/maprserverticket
```

b) Copy the `/opt/mapr/conf/maprserverticket` file to all the CLDB nodes on the destination cluster.

5. Merge the `ssl_truststore` files by using the `/opt/mapr/server/manageSSLKeys.sh` tool.

In this step, you use the `copytruststore` option of manageSSLKeys.sh on page 2897 to create a copy of the truststore. Then you copy it to the destination node using SCP, and finally run `merge` without any additional options. For example:

a. On clusterA, create a new `ssl_truststore` by using the `copytruststore` option:

```
/opt/mapr/server/manageSSLKeys.sh copytruststore /tmp/
clusterA_ssl_truststore <ssl.server.truststore.password>
<ssl.server.truststore.password>
```

You can obtain the `ssl.server.truststore.password` password from the `/opt/mapr/conf/store-passwords.txt` file for the key `ssl.server.truststore.password` on the CLDB master node for clusterA.

b. Copy the `ssl_truststore` from clusterA to clusterB:

```
scp mapr@<remote-ip>:/opt/mapr/conf/clusterA_ssl_truststore /tmp/
clusterA_ssl_truststore
```

c. Merge the `ssl_truststore` on clusterB:

```
/opt/mapr/server/manageSSLKeys.sh merge /tmp/
clusterA_ssl_truststore /opt/mapr/conf/ssl_truststore
<ssl.server.truststore.password on ClusterA>
<ssl.server.truststore.password on clusterB>
```

You can obtain the password for `ssl.server.truststore.password` from the `/opt/mapr/conf/store-passwords.txt` file for the key `ssl.server.truststore.password` on the CLDB master node for clusterA.

You can obtain the password for `ssl.server.truststore.password` from the `/opt/mapr/conf/store-passwords.txt` file for the key `ssl.server.truststore.password` on the CLDB master node for clusterB.

6. Copy the merged `ssl_truststore` file to every node on clusterB.

7. Generate ticket for `root` user to clusterA from clusterB by using the following command:

   ```
   maprlogin password -cluster clusterA
   ```

8. **Optional:** If your clusters are secure, configure your source cluster so that you can use the Control System to set up and administer table replication from the source to the destination cluster.

   These steps make it convenient to use the Control System for setting up and managing replication involving two secure clusters. However, before following them, perform these prerequisite tasks.

   NOTE:

   - Ensure that both clusters are managed by the same team or group. The UIDs and GIDs of the users that are able to log in to the Control System on the source cluster must exactly match their UIDs and GIDs on the destination cluster. This restriction applies only to access to both clusters through the Control System, and does not apply to access to both clusters through the maprcli. If the clusters are managed by different teams or groups, use the maprcli instead of the Control System to set up and manage table replication involving two secure clusters.
   - Ensure that the proper file-system and table permissions are in place on both clusters. Otherwise, any user who can log into the Control System and has the same UID or GID on the destination cluster will be able to set up replication either from the source cluster to the destination cluster or vice versa. A user could create one or more tables on the destination cluster, enable replication to them from the source cluster, load the new tables with data from the source cluster, and start replication. A user could also create tables on the source cluster, enable replication to them from tables in the destination cluster, load the new tables with data from the destination cluster, and start replication.

   a. On the source cluster (clusterA), generate a service ticket by using the `maprlogin` command:

      ```
      maprlogin generateticket -type service -cluster <destination cluster>
      -user mapr -duration <duration> -out <output folder>
      ```

      Where `-duration` is the length of time before the ticket expires. You can specify the value in either of these formats:

      - `[Days:]Hours:Minutes`
      - `Seconds`

   b. To every node of the destination cluster (clusterB), add the service ticket to the file `/opt/mapr/conf/maprusertickt` file:

      ```
      cat <path and filename of the service ticket> >> /opt/mapr/conf/
      maprusertickt
      ```

   c. Restart the web server by running the `maprcli node services` command. For the syntax of this command, see node services on page 2292.

9. Perform the steps to verify configuration for mirroring.

Results

You can now create mirror volumes on the destination cluster and set up a schedule to pull data from the volumes on the source cluster. However, you cannot create volumes on the source cluster that pull data from volumes in the destination cluster, because the setup described above is unidirectional. To configure

last-updated: Jun 06, 2024

the clusters for bidirectional mirroring, repeat the steps above, by switching the source and destination clusters.

For example, suppose there are two clusters, clusterA and clusterB, and you performed the steps above for clusterA as the source cluster and clusterB as the destination cluster. After you complete the steps above, your destination cluster, clusterB can pull data from volumes on clusterA. For clusterA to mirror data on clusterB, perform the steps above with clusterB as the source cluster and clusterA as the destination cluster.

Manually Setting up Secure Clusters for Cross-Cluster Replication

About this task
To set up secure clusters for cross-cluster replication:

Procedure

1. Verify that the user, for whom you are configuring access, exists in the registry on the destination cluster.
2. Log in to any node on the destination cluster and perform the following steps:
   a) Generate a cross-cluster ticket for the source cluster.
      For example, to generate a cross-cluster for the source cluster, run the following command on the destination cluster:
      ```
      /opt/mapr/bin/maprlogin generateticket -type crosscluster -out /tmp/
      crossclusterticket -user destinationclusteruser
      ```
   b) Copy the cross-cluster ticket file to any node on the source cluster.
      For example:
      ```
      scp /tmp/crossclusterticket mapr@<source-ip>:/tmp/
      sourceClusterTicketFile
      ```
3. Log in to the node in the source cluster where the cross-cluster ticket was copied, and perform the following steps:
   a) Merge the cross-cluster ticket file with the `/opt/mapr/conf/maprserverticket` file on the node.
      For example, to merge, run the following command:
      ```
      cat /tmp/destinationClusterTicketFile >> /opt/mapr/conf/
      maprserverticket
      ```
   b) Copy the `/opt/mapr/conf/maprserverticket` file to all the nodes on the source cluster.
4. Configure the Gateway for table and streams replication.
   See Configuring Gateways for Table and Stream Replication on page 1528 for more information.
5. Perform the steps to verify configuration for replication.

Results
You can now set up volumes on the source cluster to push data to replicas on the destination cluster. However, you cannot create replicas on the source cluster that get data from volumes in the destination cluster because the setup described above is unidirectional. To configure the clusters for bidirectional replication, repeat the steps above by switching the source and destination clusters.

For example, suppose there are two clusters, clusterA and clusterB, and you performed the steps above for clusterA as the source cluster and clusterB as the destination cluster. After you complete the steps above, your source cluster, clusterA can push data to replicas on clusterB. For clusterB to replicate data on clusterA, perform the steps above with clusterB as the source cluster, and clusterA as the destination cluster.

Verifying Cross-Cluster Configuration for Mirroring and Replication

About this task
You can verify the cross-cluster configuration for:

Procedure

1. Mirroring by logging in to a node on the destination cluster as the user for whom access was configured, and creating a mirror volume on the destination cluster for a volume on the source cluster.

   You can create mirror volumes using the Control System and/or the CLI.

2. Replication by logging in to a node on the source cluster as the user for whom access was configured and creating a replica in the destination cluster for a volume, table, and stream on the source cluster.

   You can create replicas using the Control System and the CLI. To set up replication on secure clusters for:

   - Tables, refer to the documentation for the Control System and/or the CLI.
   - Streams, refer to the documentation for the Control System and/or the CLI.

Configuring Secure Clusters for Cross-Cluster NFS Access
Describes how to manually set up cross-cluster NFS access.

About this task

HPE Ezmeral Data Fabric-NFS offers many usability and interoperability advantages to the customer, and makes big data radically easier and less expensive to use. In a secure environment, however, you must configure NFS carefully because the NFS protocol is inherently insecure. Running the NFS server on any cluster node might expose the file system to be world readable and writeable to any machine that knows the IP address of the cluster node running the NFS server and has access to the network, regardless of the permissions, passwords and other security mechanisms. At the minimum, you should configure iptables firewall rules for all the cluster nodes where the NFS server is running, to restrict incoming NFS traffic to authorized client IP addresses.

Configuring cross-cluster NFS access might expose the entire file system of the other cluster to be world readable and writeable as well. Therefore, automated configuration for cross-cluster NFS access is not available with the `configure-crosscluster.sh` on page 2835 utility. You should manually configure cross-cluster NFS access only if you are fully aware of the security risks, and taken appropriate steps to mitigate the risks by securing both your NFS gateway, and incoming client traffic.

This section describes the manual configuration process on a secure cluster for accessing another secure cluster using NFS. There are two methods by which an NFS client can access file systems from multiple clusters:

1. Run the NFS server on one cluster.

   For this method, configure cross-cluster NFS security for the NFS gateway on one cluster, so that the NFS client can mount the file system once from the NFS gateway, and then access the file systems for both clusters.

last-updated: Jun 06, 2024

2. Run the NFS server on both clusters.

   For this method, cross-cluster NFS configuration is not needed. The NFS client can mount the HPE Ezmeral Data Fabric file system individually for each cluster. This method requires that the NFS gateway to be run on each cluster, and the client performs one NFS mount for each NFS file system to be accessed.

The following procedure describes how to setup NFS for the first method:

Procedure

1. Log in to any node on the secure cluster where the NFS server is running.

   In the rest of this procedure, this cluster is referred to as clusterA.cluster.com and the remote cluster is referred to as clusterB.cluster.com.

2. Set up the `/opt/mapr/conf/maprserverticket` file on clusterA.cluster.com to include the server ticket from clusterB.cluster.com. To set up:
   a) Copy the `/opt/mapr/conf/maprserverticket` file from any node on clusterB.cluster.com to any directory on the node you are logged into on clusterA.cluster.com.

   b) Append maprserverticket entry in the `maprserverticket` file from clusterB.cluster.com to the `/opt/mapr/conf/maprserverticket` file on the node you are logged into on clusterA.cluster.com.

      NOTE: If you configured cross-cluster security either automatically using the `configure-crosscluster.sh` on page 2835 utility or manually before, there can be multiple entries in the `maprserverticket` file; copy the first entry with the alias matching the remote cluster name.

      For example, to add maprserverticket of clusterB.cluster.com into the `/opt/mapr/conf/maprserverticket` file of clusterA.cluster.com, run the following command:

      ```
      cat /tmp/remoteclusterticketfile | grep B.cluster.com |
      head --lines=+1 >> /opt/mapr/conf/maprserverticket
      ```

   c) Copy the `/opt/mapr/conf/maprserverticket` file (on the node you are logged into in clusterA.cluster.com) to all the other nodes running NFS server on clusterA.cluster.com.

3. Verify data access on both clusters using NFS.

   Users with access to the NFS servers must be able to access data in both clusters by providing the correct path. For example, users with NFS server access can verify access by running commands similar to the following:

   ```
   # ls /mapr
   clusterA.cluster.com  clusterB.cluster.com
   # ls /mapr/clusterB.cluster.com/
   apps  file  CLUSTERB hbase  opt  tmp  user  var
   ```

Configuring Cross-Cluster Security for a Mixed (FIPS and Non-FIPS) Configuration
Describes how to configure cross-cluster security when the clusters include FIPS and non-FIPS-enabled nodes.

The `configure-crosscluster.sh` script does not support mixed configurations consisting of FIPS and non-FIPS-enabled nodes. However, you can use manual steps to enable cross-cluster security in this scenario.

last-updated: Jun 06, 2024

The following is an example for configuring mixed clusters consisting of a combination of FIPS-enabled and secure non-FIPS-enabled nodes. Suppose you have a five-node local cluster, and three of the nodes are FIPS-enabled nodes:

- AF1.example.com (CLDB)
- AF2.example.com (CLDB)
- AF3.example.com (CLDB)

Suppose the other two nodes are secure non-FIPS nodes:

- AS4.example.com
- AS5.example.com

In addition, suppose the remote cluster is a five-node cluster, and three of the nodes are FIPS-enabled nodes:

- BF1.example.com (CLDB)
- BF2.example.com (CLDB)
- BF3.example.com (CLDB)

Suppose the other two nodes in the remote cluster are secure non-FIPS nodes:

- BS4.example.com
- BS5.example.com

You can use the following steps to configure cross-cluster security:

1. Run the `configure-crosscluster.sh` script on the FIPS-enabled CLDB nodes:

```
$ cat localhostsfile
AF1.example.com
AF2.example.com
AF3.example.com
$ cat remotehostsfile
BF1.example.com
BF2.example.com
BF3.example.com
$ /opt/mapr/server/configure-crosscluster.sh create all \
     -localtruststorepassword localtrustpass \
     -remotetruststorepassword remotetrustpass \
     -localhosts localhostfile \
     -remotehosts remotehostsfile
```

2. Copy the `/opt/mapr/conf/ssl_truststore.bcfks` to a temporary location of the first non-FIPS node in the local cluster (AF4.example.com in the example). Then use the `manageSSLKeys.sh convert` utility to convert the updated local trust store from BCFKS to JKS format. After confirming that the conversion is successful, copy the trust store to `/opt/mapr/conf`. For example:

```
$ /opt/mapr/server/manageSSLKeys.sh convert \
    -p localtrustpass -srcType bcfks -dstType JKS \
    /opt/mapr/conf/ssl_truststore.bcfks /tmp/ssl_truststore
$ cp /tmp/ssl_truststore /opt/mapr/conf/.
```

last-updated: Jun 06, 2024

3. Copy the the `mapr-clusters.conf` and `maprserverticket` (for `all` or `server` mode) from the local FIPS node (AF1.example.com) to the secure non-FIPS node of the local cluster (AF4.example.com). For example, on AF1.example.com:

```
$ cd /opt/mapr/conf
$ scp mapr-clusters.conf \
      mapr@AS4.example.com:/opt/mapr/conf/mapr-clusters.conf
$ scp maprserverticket \
      mapr@AS4.example.com:/opt/mapr/conf/maprserverticket
```

4. Use `pscp` to copy the `ssl_truststore`, `mapr-clusters.conf`, and `maprserverticket` to all the other secure non-FIPS nodes in the cluster.

5. Repeat steps 2 and 3 for the non-FIPS hosts in the remote cluster, starting with the first non-FIPS remote node (BF4.example.com):

   a. On BF4.example.com, use the `manageSSLKeys.sh convert` utility to convert the updated remote trust store from BCFKS to JKs format, and copy it to `/opt/mapr/conf`.

   b. Copy the `mapr-cluster.conf` and `maprticket` files from the remote FIPS node (BF1.example.com) to all the non-FIPS nodes in the remote cluster (BF4.example.com and BF5.example.com).

configure-crosscluster.sh on page 2835
Use the `configure-crosscluster.sh` utility to set up cross-cluster security between two clusters.

Accessing External HDFS Clusters

Outlines how to use protocols to connect to other clusters.

HPE Ezmeral Data Fabric clusters can access an external HDFS cluster with the `webhdfs://` protocols.

Prerequisites

Before you begin, verify the following:

- The HPE Ezmeral Data Fabric node accessing the HDFS cluster must have the `mapr-core` or `mapr-client` package installed.
- The HDFS cluster is installed and configured according to the vendor's specifications.
- To use the `hdfs://` protocol, edit the `fs.hdfs.impl` property in the `$HADOOP_HOME/conf/core-site.xml` file to include the value `org.apache.hadoop.hdfs.DistributedFileSystem`.

The following cases provide information about HPE Ezmeral Data Fabric and accessing HDFS clusters.

Configuring Access Between Non-Secure MapR and HDFS Clusters

If the MapR and HDFS clusters are both non-secure, verify that the `fs.hdfs.impl` property in the `$HADOOP_HOME/conf/core-site.xml` file has the following value:

```
org.apache.hadoop.hdfs.DistributedFileSystem
```

No additional configuration is required.

Verifying access to HDFS cluster

Use the following commands to verify access to the remote HDFS cluster from the MapR cluster.

CDH3 Only

```
hadoop fs -ls hdfs://<namenode_host:port>/
```

Other HDFS Versions

```
hadoop fs -ls webhdfs://<namenode_host_running_webhdfs_service>/
```

Using Java Applications with Secure Clusters

Describes ramifications associated with using Java applications in a MapR secure environment.

A secure computing environment places additional requirements on the Java Virtual Machine (JVM) properties of Java clients. The JVMs launched by MapR with scripts, such as those used by the `maprcli`, `hadoop`, or `hbase` commands, have those properties automatically set by the MapR software. The MapR software attempts to set useful values for these properties.

When a JVM is used or launched directly, such as when you write a stand-alone Java program, any Java code that sets values for the following properties may cause issues on your cluster.

Property	Default Value	Description
java.security.auth.login.config	`/opt/mapr/conf/mapr.login.conf`	Path to the file that specifies JAAS configurations used by MapR.
javax.net.ssl.trustStore	`/opt/mapr/conf/ssl_truststore`	Controls the truststore used by MapR clients for HTTPS connections.
http.auth.preference	`basic`	The default setting disables JVM's default handling of SPNEGO, enabling MapR's Hadoop code to handle SPNEGO authentication.
zookeeper.saslprovider	`com.mapr.security.maprsasl.MaprSaslProvider`	Enables ZooKeeper security.
hadoop.login	`hadoop_default`	Controls the JAAS configuration used by MapR security.

Administering the Data Access Gateway

The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Installing the Data Access Gateway Service

The HPE Ezmeral Data Fabric Data Access Gateway is installed when you install the HPE Ezmeral Data Fabric Database using the HPE Ezmeral Data Fabric Installer. To manually install the service, see Installing Data Access Gateway on page 262. For conceptual information, see Understanding the HPE Ezmeral Data Fabric Data Access Gateway on page 1024.

Shutting Down and Upgrading the Data Access Gateway Service

When the Data Access Gateway receives a shutdown request, it stops accepting new requests and returns an error to the client. Any in-progress requests are allowed to complete before shutting down the service. This allows you to perform rolling upgrades.

Modifying Configuration Settings for the Data Access Gateway Service

Logging Properties

The HPE Ezmeral Data Fabric Data Access Gateway uses standard Log4J configuration to control its logging. The log4j properties are in the `/opt/mapr/data-access-gateway/conf/log4j2.xml` file on nodes where you have installed the service. After modifying any properties on a node, restart the service. For details, see Administering the Data Access Gateway Service on page 1963.

Log data is stored in the `/opt/mapr/data-access-gateway/logs/data-access-gateway.log` file.

Application Properties

To configure HPE Ezmeral Data Fabric Data Access Gateway properties, modify `/opt/mapr/data-access-gateway/conf/properties.cfg` on nodes where you have installed the service.

The following table lists the properties you can configure:

auth.token.expiration	*Default*: 1800 seconds *Description*: Expiration time (in seconds) for the authentication token.
grpc.service.max-message-size	*Default*: 32MB *Description*: The maximum message size that the gRPC service accepts. The default is set to 32MB, as this is the default maximum document size for HPE Ezmeral Data Fabric Database JSON tables. This property is available in Data Access Gateway 2.0.202104302209 and later or 3.0.0.0.202104302219 and later.
grpc.service.ojai.query.result-limit	*Default*: 5000 *Description*: Limit on the number of documents returned in retrieval requests using the Node.js and Python OJAI clients.
grpc.service.port	*Default*: 5678 *Description*: Port number gRPC clients use to connect to the Data Access Gateway. The Node.js and Python OJAI clients are gRPC clients.
grpc.service.ssl.enabled	*Default*: cluster *Description*: Controls whether TLS is enabled for the gRPC Service. Values: `cluster|true|false` If set to `cluster`: • TLS is enabled if your HPE Ezmeral Data Fabric cluster is secure. • TLS is disabled if your HPE Ezmeral Data Fabric cluster is not secure.
rest.https.port	*Default*:8243 *Description*: Port number used to connect to the Data Access Gateway using HTTPS.
rest.result.limit	*Default*:5000 *Description*: Limit the number of documents returned in retrieval requests using the HPE Ezmeral Data Fabric Database JSON REST API.

There is also a configuration file `/opt/mapr/data-access-gateway/conf/ojai-config.json` for parameters used by Data Access Gateway clients:

- HPE Ezmeral Data Fabric Database JSON REST API
- Node.js OJAI
- Python OJAI
- C# OJAI
- Go OJAI
- Java OJAI Thin Client

A parameter you can modify is the client sort limit:

```
{
    "ojai": {
        "mapr": {
            "query": {
                "max-client-sort-limit": 6000
            }
        }
    }
}
```

To understand why you might want to modify this parameter, see Comparisons and Sorts in OJAI Queries on page 3366.

After modifying any parameters on a node, restart the service as described in Administering the Data Access Gateway Service on page 1963.

Warden Configuration

The Warden configuration for the HPE Ezmeral Data Fabric Data Access Gateway is in the `/opt/mapr/data-access-gateway/conf/warden.data-access-gateway.conf` file on nodes where you have installed the Data Access Gateway. To control the amount of memory allocated to the service, modify the following settings:

service.heapsize.max	*Default*:3000 *Description*: Defines the maximum heap size (in MB) for the service.
service.heapsize.min	*Default*:3000 *Description*: Defines the minimum heap size (in MB) for the service.

After modifying the warden configuration file on a node, run `configure.sh -R`, and restart the service:

```
/opt/mapr/server/configure.sh -R
maprcli node services -nodes <node name> -name data-access-gateway -action
restart
```

NOTE: Starting from version 5.0, DAG includes Apache Kafka Wire Protocol Service. See Configuring Apache Kafka Wire Protocol Service on page 3507 for configuration details.

Administering the Data Access Gateway Service

The HPE Ezmeral Data Fabric Data Access Gateway is a service that you administer in the same manner as other HPE Ezmeral Data Fabric services. The name of the service is `data-access-gateway`.

last-updated: Jun 06, 2024

To restart the service through the CLI, run the following command:

```
maprcli node services -nodes <node name> -name data-access-gateway -action
restart
```

For details about other operations you can perform on the service, see Managing Services on page 1136.

Related concepts

Understanding the HPE Ezmeral Data Fabric Data Access Gateway on page 1024
The HPE Ezmeral Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Ezmeral Data Fabric cluster.

Using the HPE Ezmeral Data Fabric Database JSON REST API on page 3478
Starting in the EEP 5.0 release, you can use a REST API to access HPE Ezmeral Data Fabric Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on HPE Ezmeral Data Fabric Database JSON tables.

Using the Node.js OJAI Client on page 3453
Starting with EEP 6.0, you can use the Node.js OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON from middleware components, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Using the Python OJAI Client on page 3458
Starting with EEP 6.0, you can use the Python OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Using the C# OJAI Client on page 3468
Starting with EEP 6.1.0, you can use the C# OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Using the Go OJAI Client on page 3473
Starting with EEP 6.0.0, you can use the Go OJAI client to write HPE Ezmeral Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

Using the Java OJAI Thin Client on page 3450
Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write HPE Ezmeral Data Fabric Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the OJAI API. You can connect to HPE Ezmeral Data Fabric Database JSON, and add, update, and query documents in a HPE Ezmeral Data Fabric Database JSON table.

L3/L4 Load Balancing with the MapR Data Access Gateway

You can use `haproxy` for L3/L4 load balancing of clients that use the MapR Data Access Gateway. This topic describes how to install, configure, and run `haproxy`, and how to set your client connection string to connect to the load balancing service.

Prerequisites

Determine the server where you want to run the load balancing service. The server must be reachable by the clients using the Data Access Gateway. It also must be able to connect to the Data Access Gateway.

Procedure

1. Install the `haproxy` service on the server you have identified:

CentOS	`sudo yum install haproxy`

Ubuntu	`sudo add-apt-repository ppa:vbernat/haproxy-1.7`
	`sudo apt update`
	`sudo apt install haproxy`

SLES	`sudo zypper install haproxy`

2. Configure the `haproxy` service by setting the following parameters in the configuration file at `/etc/haproxy/haproxy.cfg`:
   a) Create a `frontend` section with the following parameters:

```
frontend <section_name>
   mode tcp
   bind *:<port_to_use_in_the_client_connection_string>
   default_backend <backend_section_name>
```

   b) Create a `backend` section with one `server` entry for each Data Access Gateway server:

```
backend <backend_section_name>
   mode tcp
   server <DAG_server_name1> <DAG_server_host1>:<DAG_server_port1>
   server <DAG_server_name2> <DAG_server_host2>:<DAG_server_port2>
   ...
   server <DAG_server_nameN> <DAG_server_hostN>:<DAG_server_portN>
```

   The <*backend_section_name*> is the parameter you specified in Step 2a.

3. Restart the `haproxy` service:

```
sudo service haproxy restart
```

What to do next

Setting Your Client Connection String

Assume you have the following `haproxy` configuration settings and you have installed `haproxy` on `node1.cluster.com`:

```
frontend connection_input
  mode tcp
  bind *:8553
  default_backend maprdb_servers

backend maprdb_servers
  mode tcp
  server srv01 node1.cluster.com:5678
  server srv02 node2.cluster.com:5678
```

You can use the following client connection string with this sample configuration:

last-updated: Jun 06, 2024

DAG with HTTPS | TLS	`node1.cluster.com:8553?auth=basic;user=mapr;password=mapr;ssl=true;sslCA=/opt/mapr/conf/ssl_truststore.pem;sslTargetNameOverride=node1.cluster.com`
DAG with HTTP	`node1.cluster.com:8553?auth=basic;user=mapr;password=mapr;ssl=false`

L7 Load Balancing with the Data Access Gateway

You can use `nginx` for L7 load balancing of clients that use the Data Access Gateway. This topic describes how to install, configure, and run `nginx`, and how to set your client connection string to connect to the load balancing service.

Prerequisites

Determine the server where you want to run the load balancing service. The server must be reachable by the clients using the Data Access Gateway. It also must be able to connect to the Data Access Gateway.

Procedure

1. Install the `nginx` service on the server you have identified:

CentOS	`sudo yum install nginx`
Ubuntu	`sudo apt install nginx`
SLES	`sudo zypper install nginx`

2. Configure the `nginx` service by setting the following parameters in the configuration file at `/etc/nginx/nginx.conf`:
   a) In the `http` section, create an `upstream` block with one `server` entry for each Data Access Gateway server:

```
upstream <upstream_name> {
    server <DAG_server_host1>:<DAG_server_port1>;
    server <DAG_server_host2>:<DAG_server_port2>;
    ...
    server <DAG_server_hostN>:<DAG_server_portN>
    }
```

   b) Create (or modify) the `server` block:

Secure Cluster	For a secure cluster, you must specify the following SSL parameters: • Listen port and protocol • Path to the SSL certificate

last-updated: Jun 06, 2024

- Path to the SSL key
- Path to the file containing the SSL password

```
server {
    listen 80 ssl http2;
    listen [::]:80;

    ssl_certificate
<path_to_certificate>;
    ssl_certificate_key
<path_to_key>;
    ssl_password_file
<path_to_password_file>;

    access_log logs/access.log
main;

    location / {
            grpc_pass grpcs://
<upstream_name>;
    }
}
```

The <*upstream_name*> is the parameter you specified in Step 2a.

3. Restart the `nginx` service:

```
sudo service nginx restart
```

What to do next

Setting Your Client Connection String

Assume you have the following `nginx` configuration settings and you have installed `nginx` on `node1.cluster.com`:

Secure Cluster

```
user mapr;
worker_processes 1;
error_log /var/log/nginx/error.log
warn;
pid /var/run/nginx.pid;
events {
    worker_connections  1024;
}
http {
    log_format  main  '$remote_addr -
$remote_user [$time_local] "$request"'
                      '$status
$body_bytes_sent "$http_referer"'

'"$http_user_agent"';
    upstream servers {
        server node1.cluster.com:5678;
        server node2.cluster.com:5678;
    }
    server {
        listen 80 ssl http2;
        listen [::]:80;
```

```
        ssl_certificate /opt/mapr/
conf/ssl_keystore.pem;
        ssl_certificate_key /opt/mapr/
conf/ssl_keystore.pem;
        ssl_password_file /root/
passwd;

        access_log logs/access.log
main;

        location / {
            grpc_pass grpcs://servers;
        }
    }
}
```

You can use the following client connection string with this sample configuration:

```
node1.cluster.com:80?
auth=basic;user=mapr;password=mapr;ssl
=true;sslCA=/opt/mapr/conf/
ssl_truststore.pem;sslTargetNameOverri
de=node1.cluster.com
```

Planning for High Availability

Configuring a cluster for HA (High Availability) involves running redundant instances of specific services, and configuring NFS properly. When properly licensed and configured for HA, the MapR cluster provides *automatic failover* for continuity throughout the stack.

The following table provides the minimum number of instances of each core service required for HA:

Service	Minimum Number of Instances	Comments
CLDB	2	
ZooKeeper	3	At least 3 are needed to maintain a quorum in case one instance fails.
NFS	2	NFS can be configured for HA using virtual IP addresses (VIPs).
ResourceManager	2	

In HA clusters, it is appropriate to run more than one instance of the WebServer with a load balancer to provide failover. NFS can be configured for HA using VIPs.

The following sections provide information about HA planning:

CLDB Failover

Explains the concept of CLDB failover, and its advantages.

The CLDB service automatically replicates its data to other nodes in the cluster, preserving at least two (and generally three) copies of the CLDB data. If the CLDB process dies, it is automatically restarted on the node. All jobs and processes wait for the CLDB to return, and resume from where they left off, with no data or job loss.

If the node itself fails, the CLDB data is still safe, and the cluster can continue normally as soon as the CLDB is started on another node. In an Enterprise Edition-licensed cluster, a failed CLDB node automatically fails over to another CLDB node without user intervention, and without data loss. It is possible to recover from a failed CLDB node on a Community Edition cluster, but the procedure is different.

Complete the following steps to recover from a failed CLDB node on a community edition cluster:

1. Restore ZooKeeper

If the CLDB node that failed was also running ZooKeeper, install ZooKeeper on another node to maintain the minimum required number of ZooKeeper nodes. Before installing ZooKeeper on another node, ensure that the ZooKeeper role is deleted on the failed node. See Removing ZooKeeper Role for more information.

2. Locate the CLDB Data

About this task

After restoring the ZooKeeper service on the HPE Ezmeral Data Fabric cluster, use the `maprcli dump zkinfo` command to identify the latest epoch of the CLDB, identify the nodes where replicates of the CLDB are stored, and select one of those nodes to serve the new CLDB node.

Secure cluster must first be converted to non-secure cluster before running the `maprcli dump zkinfo` command. Perform the following steps as root or use sudo:

NOTE: For non-secure clusters, skip to step 4.

Procedure

1. On the ZooKeeper nodes, stop Warden and ZooKeeper by running the following commands:

```
service mapr-warden stop
service mapr-zookeeper stop
```

2. Convert the secure cluster to non-secure cluster by running the following command on the ZooKeeper nodes:

   NOTE: The script `configure.sh` takes comma-separated lists of cluster names and ZooKeeper host names (and optionally ports) or IP addresses.

```
/opt/mapr/server/configure.sh -C <host>[:<port>][,<host>:
[<port>]...]|<IP>[,<IP>...] -Z <host>[:<port>][,<host>:[<port>]...]|
<IP>[,<IP>...] -unsecure -R
```

3. Restart ZooKeeper:

```
service mapr-zookeeper restart
```

4. Issue the `maprcli dump zkinfo` command using the `-json` flag.

   ```
   maprcli dump zkinfo -zkconnect localhost:5181 -json | grep -i "Container
   ID"
   ```

   The output displays the ZooKeeper znodes. For example:

   ```
   maprcli dump zkinfo -zkconnect localhost:5181 -json |grep -i "Container
   ID" | more
      "/datacenter/controlnodes/cldb/epoch/1/KvStoreContainerInfo":"
   Container ID:1
      VolumeId:1 Master:10.10.104.34:5660-10.10.105.34:5660--9-VALID
   Servers:
      10.10.104.34:5660-10.10.105.34:5660--9-VALID
      10.10.104.33:5660-10.10.105.33:5660--9-VALID
      10.10.104.32:5660-10.10.105.32:5660--9-VALID
      Inactive Servers:  Unused Servers:  Latest epoch:9"
   ```

   In the above example output, the latest epoch is *9*.

5. In the `/datacenter/controlnodes/cldb/epoch/1` directory, locate the CLDB with the latest epoch.

   The Latest Epoch field identifies the current epoch of the CLDB data.

6. Select a CLDB from among the copies at the latest epoch. For example, `10.10.105.32:5660--9-VALID` indicates that the node has a copy at epoch 9 (the latest epoch).

Results
You can now install a new CLDB on the selected node.

What to do next
To convert the non-secure cluster to a secure cluster, run the the following command:

NOTE: The script `configure.sh` takes comma-separated lists of cluster names and ZooKeeper host names (and optionally ports) or IP addresses.

```
/opt/mapr/server/configure.sh -C <host>[:<port>][,<host>:
[<port>]...]|<IP>[,<IP>...] -Z <host>[:<port>][,<host>:[<port>]...]|
<IP>[,<IP>...] -secure -R
```

3. Stop the Selected Node

About this task
Perform the following steps on the node you have selected for installation of the CLDB:

Procedure

1. Change to the root user (or use sudo for the following commands).
2. Stop the Warden:

   ```
   service mapr-warden stop
   ```

4. Remove the CLDB Role on the Failed Node

About this task

To remove the CLDB role on the failed node, perform the following steps:

Procedure

1. Stop Warden on the node.

```
service mapr-warden stop
```

2. Purge the CLDB package mapr-cldb with the `apt-get`, `yum`, or `zypper` commands, depending on your operating system.

5. Install the CLDB on the Selected Node

About this task

Perform the following steps on the node you have selected for installation of the CLDB:

Procedure

1. Login as `root` or use `sudo` for the following commands.
2. Install the CLDB service on the node:
   - RHEL/CentOS: `yum install mapr-cldb`
   - Ubuntu: `apt-get install mapr-cldb`

6. Configure the Selected Node

The script configure.sh configures a node to be part of a HPE Ezmeral Data Fabric cluster, or modifies services running on an existing node in the cluster. The script creates (or updates) configuration files related to the cluster and the services running on the node.

Before you run configure.sh, make sure you have a list of the hostname of the ZooKeeper nodes. You can optionally specify the ports for the CLDB and ZooKeeper nodes as well. The default ports are:

Service	Default Port #
CLDB	7222
ZooKeeper	5181

The script configure.sh takes an optional cluster name and log file, the CLDB hostname, and comma-separated list of ZooKeeper host names or IP addresses (and optionally ports), using the following syntax:

```
/opt/mapr/server/configure.sh -C <host>[:<port>] -Z <host>[:<port>]
[,<host>[:<port>]...] \
 [-L <logfile>][-N <cluster name>]
```

NOTE: Each time you specify the `-Z <host>[:<port>]` option, you must use the *same order* for the ZooKeeper node list. If you change the order for any node, the ZooKeeper leader election process will fail.

Example

```
/opt/mapr/server/configure.sh -C r1n1.sj.us:7222 \
-Z
```

last-updated: Jun 06, 2024

```
r1n1.sj.us:5181,r2n1.sj.us:5181,r3n1.sj.us:5181,r4n1.sj.us:5181,r5n1.sj.us:5
181 -N MyCluster
```

7. Start the Nodes

About this task
Perform the following steps on the node you have selected for installation of the CLDB:

Procedure

Start the Warden:

```
service mapr-warden start
```

Results
After the CLDB restarts, there is a 15-minute delay before replication resumes, in order to allow all nodes to register and heartbeat. This delay can be configured using the `config save` command to set the `cldb.replication.manager.start.mins` parameter.

8. Restart All Nodes

To restart all nodes in the cluster, stop each node, configure the node with the new CLDB and ZooKeeper addresses, and start the node.

Complete the following steps on each node in the cluster:

1. Stop the node.
   a. Change to the root user (or use sudo for the following commands).
   b. Stop the Warden:

      ```
      service mapr-warden stop
      ```

2. Configure all the nodes with the new CLDB and ZooKeeper addresses.

   The script `configure.sh` configures a node to be part of a HPE Ezmeral Data Fabric cluster, or modifies services running on an existing node in the cluster. You must run this script to configure a node. The script creates (or updates) configuration files related to the cluster and the services running on the node.

   Before you run `configure.sh`, make sure you have the hostname of the CLDB node and the hostnames of the ZooKeeper nodes. You can, optionally, specify the ports for the CLDB and ZooKeeper nodes as well. The default ports are:

Service	Default Port #
CLDB	7222
ZooKeeper	5181

   The script `configure.sh` takes an optional cluster name and log file, the CLDB hostname, and comma-separated list of ZooKeeper host names or IP addresses (and optionally ports), using the following syntax:

   ```
   /opt/mapr/server/configure.sh -C <host>[:<port>] -Z <host>[:<port>]
   [,<host>[:<port>]...] [-L <logfile>][-N <cluster name>]
   ```

last-updated: Jun 06, 2024

NOTE: Each time you specify the `-Z <host>[:<port>]` option, you must use the same order for the ZooKeeper node list. If you change the order for any node, the ZooKeeper leader election process will fail.

Example:

```
/opt/mapr/server/configure.sh -C r1n1.sj.us:7222 -Z
r1n1.sj.us:5181,r2n1.sj.us:5181,r3n1.sj.us:5181,r4n1.sj.us:5181,r5n1.sj.u
s:5181 -N MyCluster
```

3. Start Warden.

```
service mapr-warden start
```

Best Practices for Running a Highly Available Cluster

Lists high availability cluster replication types, and the best practices for running such a cluster.

Data Fabric runs a wide variety of concurrent applications in a highly available fashion. Node failures do not have cluster-wide impact, and activities on other nodes in the cluster can continue normally. In parallel, data-fabric components detect failures and automatically recover from them. During the recovery process, clients may experience latency, the duration of which depends on the nature of the failure.

Node Shutdown Instances

The cause of a service failure can be one of the following:

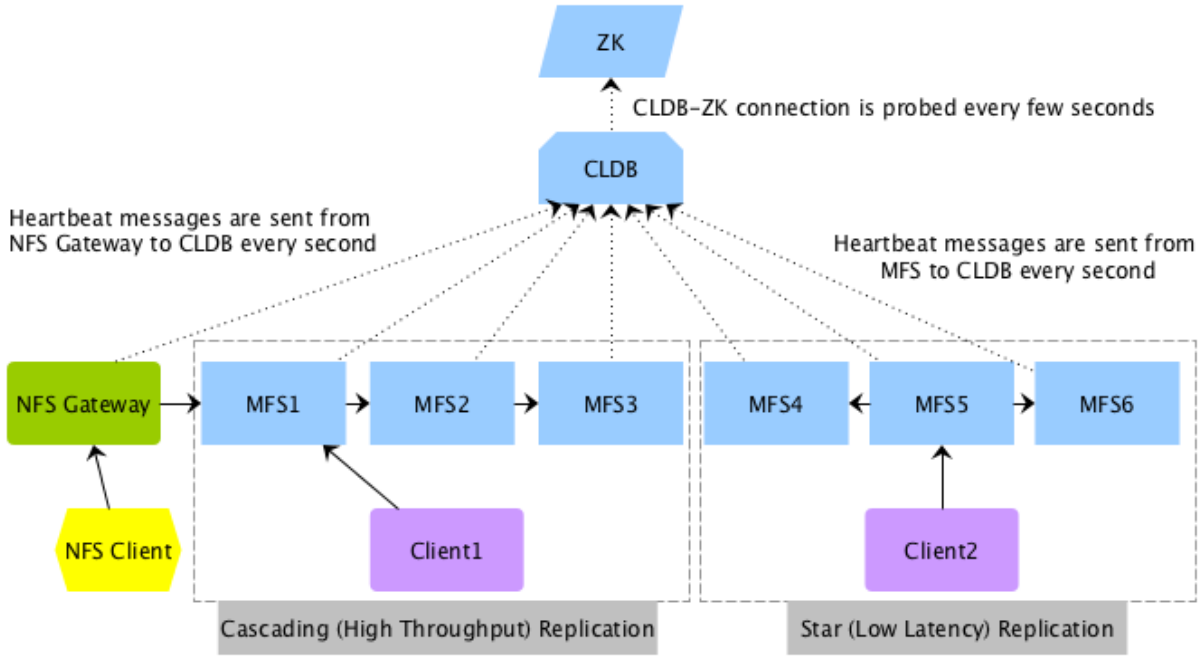
Planned shutdown	A planned/controlled failure. In this case, data-fabric is informed that a file server will be stopped. Data Fabric services use this information to improve recovery behavior.
Unexpected shutdown	Data Fabric services (file system, NFS server etc.,) are stopped. However, the host operating system continues to run and failure detection is fast.
Hard unplanned shutdown	A power off, network down, or some other kind of unplanned stop. A node is stopped in a way that it is no longer reachable. Packets sent to this node do not get an error response and failure is detected through network layer's timeout mechanism. This results in longer failure detection times.

In all of these instances, the recovery process typically involves detecting that a node is unreachable, and contacting another available node for the same piece of information (either for reads, writes, or administrative operations).

How file system and Associated Services Work

Let's review how file system and associated services typically work, using the following illustration.

last-updated: Jun 06, 2024



High-throughput or Cascading Replication Type: As shown in the illustration, the client, Client1, writes to a data-fabric filesystem, MFS1, which in turn talks to MFS2, which in turn talks to MFS3 for cascading (high throughput) replication. The replication is inline and synchronous, which means MFS1 replies to the client only after it receives a response from MFS2. MFS2, in turn, only responds to MFS1 after MFS3 has replied to it. Client1 can read from any MFS, but write only to MFS1.

Low-latency or Star Replication Type: As shown in the illustration, the client, Client2, writes to MFS5. This illustration shows an example of star (low latency) replication where MFS5 replicates to both MFS4 and MFS6 in parallel. Again, the replication is inline and synchronous, which means that MFS5 responds to Client2 only after it has received responses from both MFS4 and MFS6.

Recommended Settings for Running a Cluster with Low Latency and Fast Failover Characteristics

A well designed cluster provides automatic failover for continuity throughout the stack. For an example of a large, high-availability Enterprise Edition cluster, see Example Cluster Designs on page 91. On a large cluster designed for high availability, services should be assigned according to the service layout guidelines. For more information, see Service Layout Guidelines for Large Clusters on page 87. In general, services, specifically CLDB and ZooKeeper, should be installed on separate nodes to prevent the failure of multiple services at the same time and to enable the cluster to recover quickly.

Recommended Settings to Recover from Unplanned Shutdown

Latencies as a result of unplanned or unexpected failures/shutdowns can be improved by performing the following:

Enabling Fast Failover of Services
Describes the Fast Failover feature that allows a cluster to rapidly detect and recover from network failures.

For running a cluster with Fast Failover characteristics, enable the Fast Failover feature:

```
/opt/mapr/bin/maprcli config save -values {mfs.feature.fastfailover:1}
```

If you have enabled the fast failover feature, when the file system detects a failed node, it very quickly declares the node as being down. Clients experience a short latency period while the failure is being detected. Once MapR detects the failure, MapR redirects clients of the failed node to an alternate location

last-updated: Jun 06, 2024

(a replica container) for the data. If you have not enabled the fast failover feature, the file system repeatedly contacts the failed node.

This feature is enabled on all new installations. For upgrade installations, this feature is not enabled by default. You need to evaluate whether this feature works well with your existing infrastructure, before enabling it. You cannot turn this feature off after turning it on.

Tuning the TCP for Fast Failure Detection
Describes how to tune the TCP stack to detect node or network failures rapidly.

An unplanned failure chiefly takes the form of a node failure or a network failure. In both instances, the network layer retries to connect to the failed node. The number of retry attempts is dictated by the TCP parameter `/proc/sys/net/ipv4/tcp_syn_retries`. The default value of that parameter is 5 (in Linux), resulting in a latency of more than a minute to detect the node failure. The problem is compounded when the same failed node is contacted repeatedly in the context of a long operation, such as when a client accesses multiple data objects present on that node.

The data-fabric stack solves the problem by remembering (caching) the information about a node's failure, and by not contacting that node for subsequent operations on data objects present on that node. Since all form of data is replicated, data-fabric services find alternative locations for a data object. This feature is in-built into the current software and does not have to be enabled explicitly. Hence, the communication between a client and a recently failed node incurs a one-time long-duration latency. As mentioned before, that latency is governed by the number of retries at the TCP level. Hence, to further improve the one-time longer latency of an operation between a pair of nodes, it is recommended that the number of TCP retries be decreased from 5 to 4, resulting in a latency of about 30 seconds.

Setting the Timeout for TCP Connections

To set the TCP retry count, set the value of `tcp_syn_retries` to 4 in the `/proc/sys/net/ipv4/` directory (for IPv4 connections). For example:

```
echo 4 > /proc/sys/net/ipv4/tcp_syn_retries
```

Similarly for IPv6 connections, set:

```
echo 4 > /proc/sys/net/ipv6/tcp_syn_retries
```

This TCP setting of 4 ensures that the TCP stack takes about 30 seconds to detect failure of a remote node. To ensure that this setting is persistent across system reboots, set this value in the `/etc/sysctl.conf` file.

WARNING: This setting impacts all TCP connections to and from a node. Hence, caution must be exercised when lowering this further. Also, in some instances, reducing this further may result in a node being incorrectly flagged as unavailable.

Reducing Failure Detection Time for File Clients
Describes how to set the time for Hadoop and POSIX clients to detect node failures.

To reduce the amount of time it takes (Hadoop and FUSE-based POSIX) clients to detect (CLDB and data node) failure, define the property, `fs.mapr.connect.timeout`, in the `core-site.xml` file. The value for this property can be set in 100 milliseconds and will be rounded up to the nearest 100 milliseconds. The minimum value for this property is 100 milliseconds, which can be incremented only by units of 100 milliseconds. Suppose a value of 260 milliseconds is specified, by default, the value will automatically be rounded up to 300 milliseconds. The default value for this property is `0`, which means that the Linux TCP timeout setting will be used for connections if this property is not set.

Your entry in `core-site.xml` file should look similar to the following:

```
<property>
  <name>fs.mapr.connect.timeout</name>
```

```
  <value>200</value>
  <description>file client wait time of 200 milliseconds</description>
</property>
```

This setting (for hadoop and FUSE-based POSIX clients) ensures that the clients wait only for the specified amount of time to establish a connection. That is, it is used only for the first request sent to CLDB or a data node before or after a failure. For subsequent requests, the default system connection timeout value is used. In the event of a failure after a connection has been established, the client will wait for the connection to timeout (based on the system timeout value) before it contacts the next (CLDB or data) node to process the request.

For example, suppose the value for this parameter is 100 milliseconds and the Linux TCP connection timeout value is 30 seconds. When a hadoop or FUSE-based POSIX client contacts CLDB or a data node for the first time to establish a connection, the client will wait for 100 milliseconds before trying the next CLDB or data node. After a connection is established, for subsequent requests, the client will wait for 30 seconds for a response. If the node goes down after a connection has been established, the client will wait for 30 seconds before trying the next node. If the client contacts a recovered node for the first time, it will wait for 100 milliseconds to establish the connection.

NOTE: HPE Ezmeral Data Fabric filesystem does not use this property internally; it is used by Hadoop and FUSE-based POSIX clients only. This setting is not applicable to NFS gateway and loopbacknfs POSIX clients.

Detecting CLDB failures

When a connection with CLDB is established, CLDB returns the list of reachable and unreachable CLDB nodes on the cluster.

Populating the cache

The client stores information about the unreachable CLDB nodes in `/tmp/cldbinfo/unreachableCldbs` file on the client host. The format of this file is the same as the `mapr-clusters.conf` file (i.e., "`clustername ip:port`"). For example:

```
cat /tmp/cldbinfo/unreachableCldbs
  object_pools 10.10.104.33:7222
10.10.104.34:7222
```

The client reads the `mapr-clusters.conf` file and the `unreachableCldbs` file to determine the CLDB to connect to. It then tries to reach the available CLDB nodes first; it tries the unreachable CLDB nodes only if the available CLDB is unable to service its request.

Invalidating the cache

If the available CLDB is unable to service the client request, the client tries the unreachable CLDB. If an unreachable CLDB becomes reachable again, it is removed from the `/tmp/cldbinfo/unreachableCldbs` file, making it reachable for all subsequent IOs and if a reachable CLDB becomes unreachable, it is added to the `/tmp/cldbinfo/unreachableCldbs` file.

Recommended Settings for Planned Shutdown

Explains the modalities of a planned shutdown.

The HPE Ezmeral Data Fabric stack improves the latencies for planned shutdowns by implementing a fast failover mechanism where different services respond to the intimation of a failure.

last-updated: Jun 06, 2024

Notifying CLDB to Allow Fast Failover

When planning to shutdown a node, notifying CLDB of an impending shutdown allows CLDB to update the replication chain such that primary and intermediate containers, if any, are not on the node and re-assign VIPs on the node when the node actually goes down. This, in turn, allows clients to continue activities on available nodes.

MapR (v5.1) includes an argument, `node failover`, to the `maprcli` command that notifies CLDB of impending node shutdown so that CLDB can ensure that the specified node does not have any primary containers and intermediate containers (in a cascaded chain), and VIPs are re-assigned.

Shutting Down a Node

To notify CLDB of a planned shutdown of a node:

1. Enable the fast failover behavior.

   Refer to Enabling Fast Failover for more information.

2. Reset the value of tcp_syn_retries parameter.

   Refer to Tuning TCP for more information.

3. (Optional) Get the hostname of the node to put in maintenance mode by running the following command:

   ```
   /opt/mapr/bin/maprcli node list -columns hostname
   ```

4. Run the `failover` command for that node.

   For example:

   ```
   /opt/mapr/bin/maprcli node failover -nodes <node-hostname>
   ```

   Wait for few minutes (to allow containers to failover) before proceeding to the next step.

5. Stop warden on that node by running the following command:

   ```
   service mapr-warden stop
   ```

6. Notify HPE Ezmeral Data Fabric that the node is in maintenance mode and when the maintenance task is complete, remove the node from maintenance mode.

   See Performing Maintenance on a Node for the commands to run to put and take a node out of maintenance mode.

WARNING: Shut down only one node at a time. Do not take down multiple nodes for maintenance at the same time.

ResourceManager High Availability

Provides an overview of how high availability for Resource Manager works.

The ResourceManager service tracks a cluster's resources and schedules YARN applications.

Configure high availability for the ResourceManager so that the failure of the ResourceManager service is not a single point of failure for the cluster. The high availability of ResourceManager is based on the cluster configuration for restart, recovery, and failover.

last-updated: Jun 06, 2024

Restart

The restart settings are configured on the warden.conf file.

By default, the Warden attempts to restart a failed service three times. You can configure the frequency that Warden attempts to restart failed services before initializing failover in the warden.conf file.

Recovery

By default, ResourceManager recovery is enabled and it uses the `FileSystemRMStateStore` implementation to store the ResourceManager state in the file system.

When a ResourceManager restarts or fails over, the active ResourceManager can recover the state of the previously running ResourceManager. You can configure the ResourceManager to have no recovery. You can also configure the state store implementation that you want to use. For more information, see Recovery for the ResourceManager.

Failover

To configure failover, the cluster must have one or more nodes with the ResourceManager role.

You can select one of the following failover implementations when you use the `configure.sh` utility to configure each node:

- **Zero Configuration Failover** - In this failover mechanism, Warden manages the ResourceManager failover. When the active ResourceManager fails, one of the standby ResourceManager nodes automatically loads the working state from the state store and continues providing services to the cluster. It can be configured with a fresh `configure.sh` without **-RM** property in command.

  Zero configuration failover is the default and recommended setting for the following reasons:

  - **Only one ResourceManager process consumes cluster resources.** With the manual or automatic failover option, the active and standby ResourceManagers consume cluster resources.
  - **Warden initiates failover automatically.** With the manual failover, you need to manually run the yarn rmadmin command for failover to occur.
  - **Simplified clients connectivity.** Clients identify the active ResourceManager with a single request to the Zookeeper. With the manual or automatic failover option, ResourceManager clients connect to each ResourceManager in a round-robin fashion until they locate the active ResourceManager; this results in delays when launching or querying jobs.
  - **Consistent Configuration.** All cluster nodes and clients can use the same yarn-site.xml configuration file. With manual or automatic failover, you must maintain a customized yarn-site.xml file for each node that runs the ResourceManager.

  For information, see Zero Configuration Failover for the ResourceManager. For information on enabling zero configuration failover, see Enabling Zero Configuration Failover for the ResourceManager on page 1983

- **Manual or Automatic Failover** - For information on the manual or automatic failover, see Manual or Automatic Failover for the ResourceManager.

  For information on changing to manual failover from automatic failover, see Manual Failover Administration on page 1982.

  For information on configuration of automatic failover, see Configuring Automatic Failover for the ResourceManager.

  IMPORTANT: The ResourceManager configuration properties can be set in yarn-site.xml if you wish to override any of the default values. See ResourceManager Failover Properties and ResourceManager Recovery Properties for property details.

last-updated: Jun 06, 2024

Manual or Automatic Failover for the ResourceManager

With the manual or automatic failover mechanism, an active ResourceManager and one or more standby ResourceManager processes run in the cluster. The standby ResourceManager nodes run the ResourceManager process without loading the working state. When the active ResourceManager fails, one of the standby ResourceManager nodes can load the working state from the ZooKeeper and continue providing services to the cluster.

ResourceManager clients (HPE Ezmeral Data Fabric client nodes, ApplicationMaster processes, and NodeManager nodes) attempt connections to the ResourceManager nodes in a round-robin fashion until they hit an active ResourceManager node. If the active ResourceManager node is down, ResourceManager clients resume round-robin polling until an active ResourceManager node is detected.

For web requests, including REST API requests, standby ResourceManager nodes automatically redirect web requests to the active ResourceManager node.

Difference between Manual Failover and Automatic Failover

The difference between manual failover and automatic failover is how the transition from standby to active occurs for the ResourceManager process.

- With manual failover, you manually invoke the transition of the ResourceManager from standby to active with the yarn rmadmin command.
- With automatic failover, the ResourceManager processes have an embedded ZooKeeper-based ActiveStandbyElector, which chooses the active ResourceManager. This ActiveStandbyElector detects failures in the currently active ResourceManager and automatically transitions one of the standby ResourceManagers to an active state.

If you specify multiple ResourceManagers when you run configure.sh, automatic failover is configured. However, you can edit the yarn-site.xml file to enable manual failover instead.

Automatic Failover Administration

The Zookeeper-based ActiveStandbyElector on each ResourceManager node detects failures in the currently active ResourceManager and automatically transitions one of the standby ResourceManagers to an active state. Therefore, `rmadmin -transitionToStandby` and `-transitionToActive` are disabled.

Configuring Automatic Failover for the ResourceManager

To use automatic failover, specify multiple ResourceManagers when you run configure.sh on each node in the cluster.

The following configure.sh script syntax configures three ResourceManager nodes (one active and two standby) and one HistoryServer node:

```
/opt/mapr/server/configure.sh -C <CLDB node list> -Z <ZK node list> -RM
<hostname1,hostname2,hostname3> -HS <hostname1> [additional parameters]
```

NOTE: After you run configure.sh, each ResourceManager node contains a different value for the `yarn.resourcemanager.ha.id` property in the yarn-site.xml.

last-updated: Jun 06, 2024

Example yarn-site.xml file

The following configure.sh syntax specifies three ResourceManager nodes (nodeA, nodeB, and nodeC) and a HistoryServer node (nodeA):

```
/opt/mapr/server/configure.sh -C node1,node2,node3 -Z node1,node2,node3 -RM
nodeA,nodeB,nodeC -HS nodeA [additional parameters]
```

```

Manual Failover Administration

Configure manual failover for the ResourceManager if you want to manually transition the state of ResourceManagers in the cluster. In the event of a ResourceManager failure, you use `rmadmin` commands to check the status of each ResourceManager and then transition a standby ResourceManager to the active state.

Configuring Manual Failover for the ResourceManager

About this task

To configure manual failover, specify multiple ResourceManagers when you run `configure.sh` on each node in the cluster and then edit `yarn-site.xml` to disable automatic failover.

Procedure

1. Specify multiple ResourceManagers when you run configure.sh on each cluster and client node. The following the `configure.sh` script syntax configures three ResourceManager nodes (one active and two standby):

   ```
   /opt/mapr/server/configure.sh -C <CLDB node list> -Z <ZK node list> -RM
   <hostname1,hostname2,hostname3> -HS <hostname1> [additional parameters]
   ```

   NOTE: After you run `configure.sh`, each ResourceManager node contains a different value for the `yarn.resourcemanager.ha.id` property in the `yarn-site.xml`.

2. Disable the following automatic failover properties in the `yarn-site.xml` on each node with the ResourceManager role:
   - `yarn.resourcemanager.ha.automatic-failover.enabled`
   - `yarn.resourcemanager.ha.automatic-failover.embedded`
3. Restart the ResourceManager service. For more information, see Restarting the Services on page 1141.

Transitioning a Standby ResourceManager to Active

About this task

The `yarn rmadmin` command includes options to manage high availability for the ResourceManager, including transitioning a ResourceManager node between active and standby modes. These commands take the ResourceManager service ID as an argument and can be run on any node in the cluster. The *serviceID* of a ResourceManager is set in the `yarn.resourcemanager.ha.rm-ids` property of the *yarn-site.xml* file.

Transition a standby ResourceManager to the active state when the active ResourceManager process has failed or the node that runs the process is no longer accessible.

Procedure

1. Determine if an active ResourceManager is running in the cluster. See Checking the ResourceManager State.
2. Run the following command to set the current active ResourceManager to standby:

   ```
   yarn rmadmin -transitionToStandby <serviceID>
   ```

3. Run the following command to transition the standby ResourceManager to the active state:

   ```
   yarn rmadmin -transitionToActive <serviceID>
   ```

Checking the ResourceManager State

About this task

When you configure manual or automatic failover, the ResourceManager is either in active or standby state. Each ResourceManager has a serviceID that identifies the service.

Procedure

- To check the state of a ResourceManager, run the following command with the serviceID:

  ```
  yarn rmadmin -getServiceState <serviceID>
  ```

  The command returns `active` or `standby` based on the state of the ResourceManager associated with the serviceID that you provide.

  NOTE: Tip To determine the serviceIDs associated with the ResourceManagers in the cluster, run `hadoop conf | grep yarn.resourcemanager.ha.rm-ids`

Zero Configuration Failover for the ResourceManager

As of MapR 4.0.2, you can use zero configuration failover. With zero configuration failover, the ResourceManager role is installed on two or more nodes but the ResourceManager process only runs on one node in the cluster.

If the node running the ResourceManager process fails and the Warden on that node is unable to restart it, the Warden on each node and Zookeeper work together to start a ResourceManager process on the cluster. ResourceManager clients connect to the Zookeeper to determine which ResourceManager node is active. Therefore, when failover occurs, the Resource Manager clients are not affected as they automatically connect to the active ResourceManager.

NOTE: When you run `maprcli service list` command, the state of the active ResourceManager process displays as 2 (running) but the other ResourceManagers displays as 5 (stand by).

Enabling Zero Configuration Failover for the ResourceManager

To enable zero configuration failover, do not specify the -RM parameter when you run configure.sh on each node in the cluster. However, for failover to occur, at least two nodes in the cluster must have the ResourceManager role.

For example, if the cluster includes multiple nodes with the ResourceManager role, you can run the following configure.sh command on each cluster node and no further configuration is required:

```
/opt/mapr/server/configure.sh -N mycluster -C centos21 -Z centos21 -HS
centos22 -F /tmp/disks.txt -disk-opts F
```

last-updated: Jun 06, 2024

configure.sh automatically populates yarn-site.xml with the following configuration:

```
<configuration>
<!-- Resource Manager MapR HA Configs -->
<property>
        <name>yarn.resourcemanager.ha.custom-ha-enabled</name>
        <value>true</value>
        <description>MapR Zookeeper based RM Reconnect Enabled.
If this is true, set the failover proxy to be the class
MapRZKBasedRMFailoverProxyProvider</description>
</property>
<property>
        <name>yarn.client.failover-proxy-provider</name>

<value>org.apache.hadoop.yarn.client.MapRZKBasedRMFailoverProxyProvider</
value>
        <description>Zookeeper based reconnect proxy provider. Should
be set if and only if mapr-ha-enabled property is true.</description>
</property>
<property>
        <name>yarn.resourcemanager.recovery.enabled</name>
        <value>true</value>
        <description>RM Recovery Enabled</description>
</property>
<!-- :::CAUTION::: DO NOT EDIT ANYTHING ON OR ABOVE THIS LINE -->
</configuration>
```

For more information about the ResourceManager properties in yarn-site.xml, see ResourceManager Configuration Properties.

Updating ResourceManager Ports

About this task

To simplify the failover configurations in the *yarn-site.xml* file, Warden maintains the list of ResourceManager ports in the *warden.resourcemanager.conf* file. For a list of the default port numbers, see Ports Used by HPE Ezmeral Data Fabric Software on page 3079. If you want to edit the default ResourceManager ports, edit the *warden.resourcemanager.conf* file and the *yarn-site.xml* file on each ResourceManager node.

NOTE: If each node requires different ResourceManager ports, you must maintain a separate *yarn-site.xml* file for each node. Therefore, to you use Central Configuration, you must create a customized configuration file for each ResourceManager node in the cluster.

To update the port numbers, edit the values in the *warden.resourcemanager.conf* file and add the values in the *yarn-site.xml* file.

Procedure

1. Open the warden.resourcemanager.conf file (`/opt/mapr/conf/conf.d/warden.resourcemanager.conf`).

last-updated: Jun 06, 2024

2. Edit the port numbers, which are listed using the following format: `service.extinfo.<port>=<port number>`

Port Name	Property Name in warden.resourcemanager.conf
ResourceManager Scheduler RPC (for ApplicationMasters)	service.extinfo.SCHEDULER_PORT
ResourceManager Resource Tracker RPC (for NodeManagers)	service.extinfo.RESOURCETRACKER_PORT
ResourceManager Client RPC	service.port
ResourceManager Admin RPC	service.extinfo.ADMIN_PORT
ResourceManager Web UI (HTTP)	service.extinfo.WEBAPP_PORT
ResourceManager Web UI (HTTPS)	service.extinfo.WEBAPP_HTTPS_PORT

3. Open the *yarn-site.xml* file (`/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml`).

4. For each port that you edited, add the associated property to the *yarn-site.xml* file:

Port Name	Property Name in yarn-site.xml
ResourceManager Scheduler RPC (for ApplicationMasters)	yarn.resourcemanager.scheduler.address
ResourceManager Resource Tracker RPC (for NodeManagers)	yarn.resourcemanager.resource-tracker.address
ResourceManager Client RPC	yarn.resourcemanager.address
ResourceManager Admin RPC	yarn.resourcemanager.admin.address
ResourceManager Web UI (HTTP)	yarn.resourcemanager.webapp.address
ResourceManager Web UI (HTTPS)	yarn.resourcemanager.webapp.https.address

   For example, to update the port number for the ADMIN_PORT to 9000 on each node, enter the following in the *yarn-site.xml* file on each node:

```
<property>
   <name>yarn.resourcemanager.adminaddress</name>
   <value>10.10.30.140:9000</value>
</property>
```

5. Restart the Warden and the ResourceManager services.

Switching from Zero Configuration to Manual or Automatic Failover

You can change your ResourceManager failover implementation from zero configuration to manual or automatic failover by re-configuring all the cluster and client nodes.

For more information, see Configuring Manual Failover for the Resource Manager or Configuring Automatic Failover for the Resource Manager.

Recovery for the ResourceManager

After a restart or failover, the active ResourceManager recovers the ResourceManager state based on the checkpoints provided in the ResourceManager state store. During recovery, the ResourceManager resumes applications and tasks that were running prior to the failover but were not completed.

Two implementations of the ResourceManager state store are available:

last-updated: Jun 06, 2024

- **FileSystemRMStateStore.** Enables implicit write access to a single ResourceManager node. file system provides fencing implicitly and its state store implementation provides better scalability and failover performance than the ZKRMStateStore. The state store is also naturally protected by file system replication. By default, FileSystemRMStateStore is the state store implementation for the ResourceManager and the ResourceManager state store is maintained in the following MapR filesystem volume: `/var/mapr/cluster/yarn/rm/system`.
- **ZKRMStateStore.** Enables implicit write access to a single ResourceManager node. This is usually recommended for HA implementations where YARN is running on HDFS. However, FileSystemRMStateStore is recommended in a MapR cluster.

NOTE: For recovery to occur,all ResourceManager nodes must have access to the ResourceManager state store.

ResourceManager Recovery Administration

To change the default behavior, update the ResourceManager configuration in the yarn-site.xml files and restart the ResourceManager(s). The yarn-site.xml is located in the following directory: `/opt/mapr/hadoop/hadoop-3.x.x/etc/hadoop/`

Disabling the restart of applications after failover

You can configure the ResourceManager to not recover its state after a restart or failover occurs.

- Set the value of `yarn.resourcemanager.recovery.enabled` to `false` in `yarn-site.xml` on each ResourceManager node.

Configuring Maximum Attempts for Applications
Describes how to set the maximum number of restart attempts for all applications run by the data-fabric ResourceManager and the ApplicationMaster.

About this task
When an ApplicationMaster fails, the ResourceManager restarts the ApplicationMaster as long as the number of restart attempts does not exceed the max-attempt values set at the ResourceManager and ApplicationMaster level . By default, the maximum attempt value is set to 2.

Procedure

- To configure the maximum number of ApplicationMaster attempt retries for all applications run by the ResourceManager:

  Set the value of `yarn.resourcemanager.am.max-attempts` in the `yarn-site.xml` file. The value defaults to 2.
- To configure the number of ApplicationMaster attempts allowed for the MapReduce ApplicationMaster:

  Set the value of `mapreduce.am.max-attempts` in the `mapred-site.xml` file. The value defaults to 2.

Configuring the file system State Store
Describes the configuration of the data-fabric state store.

About this task
By default, the Resource Manager stores its state in the data-fabric filesystem. However, you can change the values for the following properties related to the data-fabric filesystem state store:

last-updated: Jun 06, 2024

Procedure

- To configure the URI to the state store location:
  Set the value of `yarn.resourcemanager.fs.state-store.uri` in the `yarn-site.xml` file. The value defaults to the ResourceManager volume (`/var/mapr/cluster/yarn/rm/system`).
- To configure the retry policy used by the state store client to connect with data-fabric file system:
  Set the value of `yarn.resourcemanager.fs.state-store.retry-policy-spec` in the `yarn-site.xml` file. The value defaults to (2000,500).
- To configure the number of completed applications retained by the state store:
  Set the value of `yarn.resourcemanager.state-store.max-completed-applications` in the `yarn-site.xml` file. The value defaults to 10000.

Enabling ZooKeeper Based State Store

About this task
By default, the Resource Manager stores its state in the file system. However, you can use the Zookeeper based state store instead. To configure the ResourceManager to use the Zookeeper state store:

Procedure

- Set the value of `yarn.resourcemanager.store.class` to `org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore` in the yarn-site.xml.
- Set the value of `yarn.resourcemanager.zk-address` to a comma-separated list of host:port pairs for each ZooKeeper server used by the ResourceManager. This property needs to be set in yarn-site.xml.

ResourceManager Configuration Properties

You can configure the failover and recovery properties for the ResourceManager. The default values for the failover and recovery properties are defined in the yarn-default.xml or by Data Fabric. You can configure overrides to the default by adding to or editing the properties in yarn-site.xml.

ResourceManager Failover Properties

The following table describes the configuration properties for ResourceManager failover:

Property	Description
yarn.resourcemanager.ha.custom-ha-enabled	When yarn.client.failover-proxy-provider is set to org.apache.hadoop.yarn.client.MapRZKBasedRMFailoverProxyProvider, this property must `true`. The default, set by configure.sh in yarn-site.xml when the cluster uses zero configuration failover for the ResourceManager, is `true`.
yarn.resourcemanager.ha.enabled	Enables high availability for the ResourceManager. The default, set by MapR in the yarn-site.xml, is `true`. This property must be set to `true` for failover to occur.
yarn.resourcemanager.ha.automatic-failover.enabled	When yarn.resourcemanager.ha.enabled is true, this property enables the ResourceManager to automatically failover. The default, set in yarn-default.xml, is `true`.

Property	Description
yarn.resourcemanager.ha.automatic-failover.embedded	When yarn.resourcemanager.ha.enabled is true, this property enables the ResourceManager to use the embedded automatic failover. The default, set in yarn-default.xml, is `true`.
yarn.resourcemanager.cluster-id	Specifies the cluster that the ResourceManager belongs to. This value is originally set by configure.sh in the yarn-site.xml and the value is required for failover to occur.
yarn.resourcemanager.ha.rm-ids	The ResourceManager service ID. Configure.sh adds this property to each node with the ResourceManager role.
yarn.resourcemanager.ha.id	Specifies the serviceID of the ResourceManager on the current node.
yarn.resourcemanager.zk-address	Specifies the zookeeper quorum that the ResourceManager belongs to. This value is originally set by configure.sh in the yarn-site.xml when you configure failover.
yarn.client.failover-proxy-provider	Specifies the ResourceManager failover implementation used by clients, ApplicationMasters, and NodeManagers. configure.sh sets this value based on the type of failover that you configure. • For automatic or manual failover, configure.sh sets this value to org.apache.hadoop.yarn.client.ConfiguredRMFailoverProxyProvider • For zero configuration failover, configure.sh sets this value to org.apache.hadoop.yarn.client.MapRZKBasedRMFailoverProxyProvider This value is set by configure.sh in yarn-site.xml when you configure failover. Otherwise, the default, set in yarn-default.xml is org.apache.hadoop.yarn.client.DefaultFailoverProxyProvider.
yarn.resourcemanager.scheduler.address[.<serviceID>]	The address of the scheduler interface This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.

last-updated: Jun 06, 2024

Property	Description
yarn.resourcemanager.resource-tracker.address[.<serviceID>]	The address of the resource tracker interface. ResourceManager listens for container requests and heartbeats from the NodeManagers on this port. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.resourcemanager.address[.<serviceID>]	The address of the client interface. The ResourceManager listens for client requests on this port. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.resourcemanager.admin.address[.<serviceID>]	The address of the administrative interface. ResourceManager listens for administrative requests from the yarn rmadmin command on this port. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.resourcemanager.webapp.address[.<serviceID>]	The address of the ResourceManager web UI. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.resourcemanager.webapp.https.address[.<serviceID>]	The address of the secure ResourceManager web UI. This value, including the serviceID, is set by configure.sh in yarn-site.xml when you configure manual or automatic failover. For zero configuration failover, this property in not needed unless you have configure custom port values. When you specify the custom port number, the serviceID is not required.
yarn.client.failover-max-attempts	The max number of times FailoverProxyProvider should attempt failover. The default is -1.

last-updated: Jun 06, 2024

Property	Description
yarn.client.failover-sleep-base-ms	The sleep base (in milliseconds) to be used for calculating the exponential delay between failovers. The value defaults to the value set by yarn.resourcemanager.connect.retry-interval.ms, which is 30000 ms.
yarn.client.failover-sleep-max-ms	The maximum sleep time (in milliseconds) between failovers. The value defaults to the value set by yarn.resourcemanager.connect.retry-interval.ms, which is 30000 ms.
yarn.client.failover-retries	The number of times a client attempts to reconnect to a ResourceManager. The default, set in yarn-default.xml, is 0 (infinite).
yarn.client.failover-retries-on-socket-timeouts	The number of times a client attempts to reconnect to a ResourceManager on socket timeouts. The default, set in yarn-default.xml, is 0 (infinite).

ResourceManager Recovery Properties

The following table describes the configuration properties for ResourceManager recovery:

Property	Description
yarn.resourcemanager.recovery.enabled	Enables the Resourcemanager to recovery based on the information in the ResourceManager state store. The default, set by configure.sh, is `true`.
yarn.resourcemanager.am.max-attempts	The maximum number of application attempts. This is a global setting for all ApplicationMaster nodes. You can configure an individual maximum number of application attempts for each ApplicationMaster node, but this property sets a global upper bound that overrides the individual node configuration. The default, set in yarn-default.xml, is 2.
mapreduce.am.max-attempts	The maximum number of MapReduce application attempts. If this value is larger than the value set by the ResourceManager, the ResourceManager value will override this value. The default number is set to 2, to allow at least one retry for AM. This property is set in mapred-default.xml.
