The IN operator prevents Drill from returning duplicate rows. For example, when an array is flattened into a table, duplicate values may exist for a particular `_id` (rowkey). Using IN prevents Drill from returning rows with duplicate values.

### Example

Suppose a JSON primary table named CUSTOMERS exists in HPE Ezmeral Data Fabric Database with the following data:

```
{ "_id": "001",
  "NAME": "ALICE",
  "PHONE": "408-555-1212",
  "ADDRESSES": [{"CITY": "SAN JOSE", "ZIPCODE": 95124, "STATE": "CA", "UNITS": [{"UNIT_NO": 555, "FLOOR": 5}, {"UNIT_NO": 777, "FLOOR": 7}]}, {"CITY": "PALO ALTO", "ZIPCODE": 94020, "STATE": "CA", "UNITS": [{"UNIT_NO": 555, "FLOOR": 5}, {"UNIT_NO": 777, "FLOOR": 7}]}, {"CITY": "SANTA CLARA", "ZIPCODE": 95050, "STATE": "CA", "UNITS": [{"UNIT_NO": 555, "FLOOR": 5}, {"UNIT_NO": 777, "FLOOR": 7}]}],
  "QTY": [11, 25, 16, 2, 10, 39, 5, 8, 7, 11]
}
{ "_id": "002",
  "NAME": "BOB",
  "PHONE": "408-555-1313",
  "ADDRESSES": [{"CITY": "SAN JOSE", "ZIPCODE": 95132, "STATE": "CA", "UNITS": [{"UNIT_NO": 838, "FLOOR": 8}, {"UNIT_NO": 888, "FLOOR": 8}]}, {"CITY": "SAN JOSE", "ZIPCODE": 95127, "STATE": "CA", "UNITS": [{"UNIT_NO": 555, "FLOOR": 5}, {"UNIT_NO": 777, "FLOOR": 7}]}, {"CITY": "SAN RAMON", "ZIPCODE": 94582, "STATE": "CA", "UNITS": [{"UNIT_NO": 123, "FLOOR": 1}, {"UNIT_NO": 124, "FLOOR": 1}]}],
  "QTY": [2, 8, 1, 4, 3, 10, 2, 23]
}
{ "_id": "003",
  "NAME": "CHRIS",
  "PHONE": "408-555-1414",
  "ADDRESSES": [{"CITY": "MOUNTAIN VIEW", "ZIPCODE": 94043, "STATE": "CA", "UNITS": [{"UNIT_NO": 922, "FLOOR": 9}, {"UNIT_NO": 958, "FLOOR": 9}]}, {"CITY": "PALO ALTO", "ZIPCODE": 94020, "STATE": "CA", "UNITS": [{"UNIT_NO": 666, "FLOOR": 6}, {"UNIT_NO": 728, "FLOOR": 7}]}, {"CITY": "SUNNYVALE", "ZIPCODE": 94086, "STATE": "CA", "UNITS": [{"UNIT_NO": 226, "FLOOR": 2}, {"UNIT_NO": 333, "FLOOR": 3}]}],
  "QTY": [56, 19, 45, 25, 4, 77, 110, 3, 2, 1]
}
```

 **NOTE:** The QTY field is an array. The ADDRESSES field is an array of maps.

The following query on the CUSTOMERS table returns the result of flattening the “ADDRESSES” array field into a column aliased as “f” where each element in the array is flattened into individual rows:

 **NOTE:** In the results, notice that Bob has two addresses where the “CITY” is “SAN JOSE”. Later in this example, you will see that using the IN operator prevents the query from returning duplicate rows.

```
SELECT NAME, PHONE, f FROM (SELECT NAME, PHONE, FLATTEN(ADDRESSES) AS f
FROM CUSTOMERS);
```

```
+-----+-----+-----+
| NAME   | PHONE   |      |
| f      |         |      |
+-----+-----+-----+
```

```

| ALICE | 408-555-1212 | {"CITY": "SAN JOSE", "STATE": "CA", "UNITS":
[{"FLOOR": 5, "UNIT_NO": 555},
{"FLOOR": 7, "UNIT_NO": 777}], "ZIPCODE": 95124}
|
| ALICE | 408-555-1212 | {"CITY": "PALO ALTO", "STATE": "CA", "UNITS":
[{"FLOOR": 5, "UNIT_NO": 555},
{"FLOOR": 7, "UNIT_NO": 777}], "ZIPCODE": 94020}
|
| ALICE | 408-555-1212 | {"CITY": "SANTA CLARA", "STATE": "CA", "UNITS":
[{"FLOOR": 5, "UNIT_NO": 555},
{"FLOOR": 7, "UNIT_NO": 777}], "ZIPCODE": 95050}
|
| BOB | 408-555-1313 | {"CITY": "SAN JOSE", "STATE": "CA", "UNITS":
[{"FLOOR": 8, "UNIT_NO": 838},
{"FLOOR": 8, "UNIT_NO": 888}], "ZIPCODE": 95132}
|
| BOB | 408-555-1313 | {"CITY": "SAN JOSE", "STATE": "CA", "UNITS":
[{"FLOOR": 5, "UNIT_NO": 555},
{"FLOOR": 7, "UNIT_NO": 777}], "ZIPCODE": 95127}
|
| BOB | 408-555-1313 | {"CITY": "SAN RAMON", "STATE": "CA", "UNITS":
[{"FLOOR": 1, "UNIT_NO": 123},
{"FLOOR": 1, "UNIT_NO": 124}], "ZIPCODE": 94582}
|
| CHRIS | 408-555-1414 | {"CITY": "MOUNTAIN VIEW", "STATE": "CA", "UNITS":
[{"FLOOR": 9, "UNIT_NO": 922},
{"FLOOR": 9, "UNIT_NO": 958}], "ZIPCODE": 94043}
|
| CHRIS | 408-555-1414 | {"CITY": "PALO ALTO", "STATE": "CA", "UNITS":
[{"FLOOR": 6, "UNIT_NO": 666},
{"FLOOR": 7, "UNIT_NO": 728}], "ZIPCODE": 94020}
|
| CHRIS | 408-555-1414 | {"CITY": "SUNNYVALE", "STATE": "CA", "UNITS":
[{"FLOOR": 2, "UNIT_NO": 226},
{"FLOOR": 3, "UNIT_NO": 333}], "ZIPCODE": 94086}
+-----+-----+-----+

```

The following query returns the results of filter conditions on the fields "CITY" and "STATE" if the CITY is SAN JOSE and STATE is CA.

```

SELECT NAME, PHONE, f FROM (SELECT NAME, PHONE, FLATTEN(ADDRESSES) AS f
FROM CUSTOMERS) AS t WHERE t.f.CITY = 'SAN JOSE' and t.f.STATE = 'CA';
+-----+-----+-----+
| NAME | PHONE |
| f |
|
+-----+-----+-----+
| ALICE | 408-555-1212 | {"CITY": "SAN JOSE", "STATE": "CA", "UNITS":
[{"FLOOR": 5, "UNIT_NO": 555},
{"FLOOR": 7, "UNIT_NO": 777}], "ZIPCODE": 95124}
|
| BOB | 408-555-1313 | {"CITY": "SAN JOSE", "STATE": "CA", "UNITS":
[{"FLOOR": 8, "UNIT_NO": 838},
{"FLOOR": 8, "UNIT_NO": 888}], "ZIPCODE": 95132}
|
| BOB | 408-555-1313 | {"CITY": "SAN JOSE", "STATE": "CA", "UNITS":
[{"FLOOR": 5, "UNIT_NO": 555},
{"FLOOR": 7, "UNIT_NO": 777}], "ZIPCODE": 95127}

```

Suppose a composite index exists on `ADDRESSES[ ].CITY` and `ADDRESSES[ ].STATE` with "NAME" as an included field. For the query planner to use the index, you must write the query using the specific SQL syntax that indicates that the query is eligible for an index-based query plan, as shown:

```
SELECT NAME, PHONE
FROM CUSTOMERS
WHERE _id IN ( SELECT _id
              FROM ( SELECT _id, FLATTEN(ADDRESSES) as f
                    FROM CUSTOMERS) as t
              WHERE t.f.CITY = 'SAN JOSE' and t.f.STATE = 'CA' );

//Issuing this query against the data in the CUSTOMERS table returns the
following results:
+-----+-----+
|  NAME  |  PHONE  |
+-----+-----+
| ALICE  | 408-555-1212 |
| BOB    | 408-555-1313 |
+-----+-----+
```

 **NOTE:** Although Bob has two addresses where the "CITY" is "SAN JOSE", the query returns only one result. The IN operator prevents the query from returning duplicate rows.

The following list summarizes key points about this query:

- The innermost subquery projects on the `_id` field (rowkey) and includes the `FLATTEN` function to separate the array elements in the "ADDRESSES" field. The field "ADDRESSES" is flattened into a table aliased as "t", in a column aliased as "f".
- The query uses the IN operator to ensure that the results returned contain unique values only; no duplicates. `DISTINCT` on the subquery to the right of IN is implicit. The SQL query pattern indicates to the query planner that the query is eligible for an index-based query plan.
- The query projects on column "NAME" and "PHONE". "PHONE" requires a join back to the primary table on the `_id` field (rowkey) because it is not included in the composite index.
- The query planner recognizes that `t.f.CITY` references `t.ADDRESSES[ ].CITY` and `t.f.STATE` references `t.ADDRESSES[ ].STATE` and creates an index-based query plan.
- The index table in HPE Ezmeral Data Fabric Database is already flattened for the array field, "ADDRESSES". Flatten is not evaluated in Drill. Drill pushes the filter conditions on the array field into HPE Ezmeral Data Fabric Database.

### Filter Conditions on Various Types of Array Fields

The following table shows examples of filter conditions on various types of array fields and includes the HPE Ezmeral Data Fabric Database notation for the array field with the filter condition, as well as the SQL syntax for writing queries against the array fields.

 **NOTE:** The queries in the table are written against the CUSTOMERS data used in the previous example.

Filter condition on ...	Example using HPE Ezmeral Data Fabric Database notation (not SQL notation)	SQL
-------------------------	--	-----

<p>Array of scalar values</p>	<p>QTY[] &lt; 10</p>	<pre>SELECT NAME, PHONE FROM CUSTOMERS WHERE _id IN ( SELECT _id                 FROM ( SELECT _id, FLATTEN(Q                         FROM CUSTOMERS) as t                         WHERE t.f&lt;10);</pre> <p>This query returns the following results:</p> <pre>+-----+-----+   NAME   PHONE   +-----+-----+   ALICE   408-555-1212     BOB     408-555-1313     CHRIS   408-555-1414   +-----+-----+</pre>
<p>Map field within an array of maps</p>	<p>ADDRESSES[].ZIPCODE &gt; 94000 and ADDRESSES[].ZIPCODE &lt; 95000</p>	<pre>SELECT NAME, PHONE FROM CUSTOMERS WHERE _id IN ( SELECT _id                 FROM ( SELECT _id, FLATTEN(ADDR                         FROM CUSTOMERS) as t                         WHERE t.f.ZIPCODE BETWEEN 94000</pre> <p>This query returns the following results:</p> <pre>+-----+-----+   NAME   PHONE   +-----+-----+   ALICE   408-555-1212     BOB     408-555-1313     CHRIS   408-555-1414   +-----+-----+</pre>
<p>AND-ed condition on 2 fields of the same array element</p>	<p>elementAND(ADDRESSES[], CITY=SAN JOSE, STATE = CA)</p>	<pre>SELECT NAME, PHONE FROM CUSTOMERS WHERE _id IN ( SELECT _id                 FROM ( SELECT _id, FLATTEN(ADDR                         FROM CUSTOMERS) as t                         WHERE t.f.CITY = 'SAN JOSE' and</pre> <p>This query returns the following results:</p> <pre>+-----+-----+   NAME   PHONE   +-----+-----+   ALICE   408-555-1212     BOB     408-555-1313   +-----+-----+</pre>

<p>AND-ed condition on 2 fields of different array elements</p>	<p>ADDRESSES[].CITY = SAN JOSE AND ADDRESSES[].ZIPCODE = 94020</p>	<pre>SELECT NAME, PHONE FROM CUSTOMERS WHERE _id IN ( SELECT _id                 FROM ( SELECT _id, FLATTEN(ADDR                 FROM CUSTOMERS) as t                 WHERE t.f1.CITY = 'SAN JOSE' and</pre> <p>This query returns the following results:</p> <pre>+-----+-----+   NAME   PHONE   +-----+-----+   ALICE   408-555-1212   +-----+-----+</pre>
<p>AND-ed condition on scalar field and array field</p>	<p>PHONE = 408-555-1212 AND ADDRESSES[].ZIPCODE = 94020</p>	<pre>SELECT NAME, PHONE FROM CUSTOMERS WHERE _id IN ( SELECT _id                 FROM ( SELECT _id, FLATTEN(A                 FROM CUSTOMERS) as t                 WHERE t.f.ZIPCODE = 94020 AN</pre> <p>This query returns the following results:</p> <pre>+-----+-----+   NAME   PHONE   +-----+-----+   ALICE   408-555-1212   +-----+-----+</pre>
<p>Map field within nested array of maps</p>	<p>ADDRESSES[].UNITS[].FLOOR &lt; 5</p>	<pre>SELECT NAME, PHONE FROM CUSTOMERS WHERE _id IN ( SELECT _id                 FROM ( SELECT t1._id, flatten(t                 FROM (SELECT _id, FLATT                 FROM CUSTOMERS) a                 WHERE t2.u.`FLOOR` &lt;5);</pre> <p>This query returns the following results:</p> <pre>+-----+-----+   NAME   PHONE   +-----+-----+   BOB     408-555-1313     CHRIS   408-555-1414   +-----+-----+</pre>

<p>Exact match for lists or maps</p>	<pre>col = ADDRESSES[].UNITS[]. {"FLOOR":7,"UNIT_NO":777}</pre>	<pre>SELECT NAME, PHONE FROM CUSTOMERS WHERE _id IN ( SELECT _id                 FROM ( SELECT t1._id, flatten(t                         FROM (SELECT _id, FLATT                               FROM CUSTOMERS) a                         WHERE t2.u = CAST('{"FLOOR":7,"</pre> <p>This query returns the following results:</p> <table border="1"> <thead> <tr> <th>NAME</th> <th>PHONE</th> </tr> </thead> <tbody> <tr> <td>ALICE</td> <td>408-555-1212</td> </tr> <tr> <td>BOB</td> <td>408-555-1313</td> </tr> </tbody> </table>	NAME	PHONE	ALICE	408-555-1212	BOB	408-555-1313
NAME	PHONE							
ALICE	408-555-1212							
BOB	408-555-1313							

### Performance Considerations

When writing queries that leverage indexes on array fields, consider the following points about performance:

- Query patterns that match those described previously in this document are pushed down to HPE Ezmeral Data Fabric Database. Drill does not evaluate the filter conditions, which adds considerable performance benefits even when the query planner does not select an index-based query plan.
- Deduplication on the `_id` is an extra operation (compared to regular, non-complex, indexes) that requires the overhead of hash aggregation.
- Try to avoid array columns in included fields within an index table, as they add a significant amount of storage overhead. However, this may result in the query planner selecting non-covering plans.
- Indexes with deeply nested array elements, such as `a[].b[].c[]...x.y`, can add to the HPE Ezmeral Data Fabric Database storage overhead and can potentially make Drill queries longer and more complex.

### Limitations

Drill queries that leverage indexes on array fields have the following limitations:

- Only queries with patterns similar to those described previously in this document are eligible for index planning, assuming that the index is defined on an array field.
- The following conditions do not produce a covering index plan:
  - Pushdown conditions on indexed fields and included fields on same array element. For example, if an index has indexed fields `a[].b` and included fields `a[].c`, `elementAND(a[], b > 10, c > 20)` does not produce a covering index plan.
  - Pushdown conditions on scalar indexed fields and included fields containing an array element. For example, an index with indexed field `m` and included fields `a[].b`, `m = 10 AND a[].b > 20` does not produce a covering index plan.
- For included array fields, the element must be provided without the `[]` for the query planner to pick covering plans. For example, `a` and not `a[]`. Note that HPE Ezmeral Data Fabric Database considers both `a` and `a[]` syntaxes as equivalent for included fields.
- Index planning is disabled for queries with multi-level flattens and intermediate filters that reference multi-level flattens. A filter can reference the root level flatten, but not the intermediate flattens.

## Determining Index Use

Evaluate the query plan to analyze query performance and determine if Drill uses indexes. You can view query plans in the Drill Web Console or through the command line using the EXPLAIN command. You can also disable the indexing option in Drill and compare an index-based plan to a full table scan plan.

Drill leverages indexes during the physical planning phase of the query. Drill estimates the cost of an index-based plan and a plan that includes a full table scan. See [Selection and Execution of Secondary Indexes](#) for information about how Drill selects a query plan. In cases where Drill does not select the index-based plan and instead selects a full table scan plan, you may want to remove the indexes to free up storage space and eliminate the overhead of the indexes.

The following example shows you how to determine if Drill selected an index-based plan for a query through the query profile in the Drill Web Console and the EXPLAIN PLAN FOR output.

## Example

The subsequent sections assume that an index exists on a table named "lineitem." The index, `I_single_c_5`, is a single field index created on the `L_QUANTITY` field. The index also covers the `L_SUPPKEY`, `L_DISCOUNT`, `L_SHIPDate`, and `L_SHIPMODE` fields. If a query contains fields covered by the index, the query is a covering query. If a query contains fields not covered by the index, the query is non-covering and requires a lookup back into the primary table to retrieve data.

The following list summarizes the assumptions:

- **Table name:** lineitem
- **Index name:** I\_single\_c\_5
- **Indexed field:** L\_QUANTITY
- **Included fields:** L\_SUPPKEY, L\_DISCOUNT, L\_SHIPDate, L\_SHIPMODE

## Query Profile

View the query plan on the **Profiles** tab in the Drill Web Console. See [Starting the Web Console](#). Select the query you want to evaluate and then select the **Physical Plan** tab. You can see the physical plan that Drill used to execute the query.

The following image shows the physical plan that Drill used to execute this simple equality query:

```
SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5;
```

The screenshot displays the Apache Drill interface. At the top, there are navigation tabs: Query, Profiles, Storage, Metrics, Threads, Logs, Options, and Documentation. The main content area is titled "Query and Planning" and has sub-tabs for Query, Physical Plan, Visualized Plan, and Edit Query. The Physical Plan tab is active, showing a tree view of the query execution plan. The plan consists of several stages: 00-00 Screen, 00-01 Project, 00-02 SelectionVectorRemover, 00-03 Limit, 00-04 Project, 00-05 Project, and 00-06 Scan. The Scan stage is highlighted in yellow. Below the plan, the "Query Profile" section shows the query status as "STATE: COMPLETED", the foreman as "sidelit", and a total of 1 fragment. The duration is 0.523 sec, with a breakdown: PLANNING: 0.502 sec, QUEUED: Not Available, and EXECUTION: 0.021 sec.

In the plan, you can see that Drill scanned the index, `l_single_c_5`, instead of the primary table. The query was completely covered by the index because the index contains all fields referenced in the query and the query filtered on the indexed field.

## EXPLAIN PLAN

Alternatively, you can issue the `EXPLAIN` command to see how Drill executes a query. To see the chosen physical execution plan for a query without running the query, issue the `EXPLAIN PLAN FOR` command. This command shows you if Drill plans to use the index when executing the query.

The following image shows the physical plan that Drill plans to use to execute this simple equality query:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+-----+-----+
| text | json |
+-----+-----+
| 00-00   Screen
00-01     Project(L_SHIPDate=[0])
00-02     SelectionVectorRemover
00-03     Limit(fetch=[10])
00-04     Limit(fetch=[10])
00-05     Project(L_SHIPDate=[1])
00-06     Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5}),
indexName=l_single_c_5, columns=[`L_QUANTITY`, `L_SHIPDate`]]])
```

In the plan, you can see that Drill plans to use the index, `l_single_c_5`, instead of performing a full table scan. The query is completely covered by the index because the index contains all fields referenced in the query and the query filters on the indexed field.

## Compare Plans

If you want to compare an index-based plan against a plan with a full table scan, disable the `planner.enable_index_planning` option in Drill, and run the `EXPLAIN PLAN FOR` command for the query. Running this command with the `planner.enable_index_planning` option disabled forces Drill to generate a plan that includes a full table scan. You can compare the full table scan plan against the index-based plan to compare the costs and resource consumption of each plan.

You can see in the following query, with the indexing feature turned on, Drill generated a plan using the index:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+-----+-----+
| text | json |
+-----+-----+
| 00-00   Screen
00-01     Project(L_SHIPDate=[0])
00-02     SelectionVectorRemover
00-03     Limit(fetch=[10])
00-04     Limit(fetch=[10])
00-05     Project(L_SHIPDate=[1])
00-06     Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5}),
indexName=l_single_c_5, columns=[`L_QUANTITY`, `L_SHIPDate`]]])
```

If you turn the option off, as shown:

```
ALTER SESSION SET planner.enable_index_planning = false
```

You can run the EXPLAIN PLAN FOR command again to see the plan with a full table scan included:

```
EXPLAIN PLAN FOR SELECT L_SHIPDate FROM lineitem WHERE L_QUANTITY = 5 LIMIT
10;
+-----+-----+
| text | json |
+-----+-----+
| 00-00 | Screen
00-01 | Project(L_SHIPDate=[0])
00-02 | SelectionVectorRemover
00-03 | Limit(fetch=[10])
00-04 | UnionExchange
01-01 | SelectionVectorRemover
01-02 | Limit(fetch=[10])
01-03 | Project(L_SHIPDate=[1])
01-04 | Scan(groupscan=[JsonTableGroupScan
[ScanSpec=JsonScanSpec [tableName=maprfs:///drill/testdata/tpch/sf1/maprdb/
json/lineitem, condition=(L_QUANTITY = {"$numberLong":5})],
columns=[`L_QUANTITY`, `L_SHIPDate`]])
|
```

**NOTE:** To see the cost of each plan, go to the Drill Web Console and view the query profile for each EXPLAIN PLAN FOR command that you issue through the command line.

### Drill Limitations

Provides information about Drill limitations and solutions where applicable.

### Max Drill Query Size Depends on ZooKeeper jute.maxbuffer Value

#### Issue

Drill cannot run a query that exceeds the ZooKeeper `jute.maxbuffer` value of 1 MB.

#### Solution

For the ZooKeeper `jute.maxbuffer` property, follow the recommendations in the ZooKeeper documentation.

**CAUTION:** The `jute.maxbuffer` property is marked as an unsafe option. Do not change it to a higher value to run larger queries. For additional details about why this property is unsafe, see the Apache ZooKeeper documentation: <https://zookeeper.apache.org/doc/r3.6.2/zookeeperAdmin.html>

The following error indicates that the query is too large. To resolve this error, rewrite the query to fit within the `jute.maxbuffer` limit:

```
Query execution error. Details:
EXECUTION_ERROR ERROR: Failed to
persist query info. Query length is
too big.
```

In Drill EEP version 8.1.0 and earlier and EEP version 9.1.1 and earlier, the following type of error may also indicate that the query is too large:

```
Query execution
error. Details: SYSTEM
ERROR: ConnectionLossException:
KeeperErrorCode =
ConnectionLoss for /drill/running/
1bb44a40-c715-7b38-c310-05de39dfb3e7
```

In Drill EEP version 8.1.1, this error could indicate that the `jute.maxbuffer` value set for the Drillbit does not correspond with the ZooKeeper `jute.maxbuffer` value.

To change the value of `jute.maxbuffer` in Drill, add the `-Djute.maxbuffer` Java property to `DRILL_JAVA_OPTS` in `<drill_home>/conf/drill-env.sh`, as shown in the following example:

```
export
DRILL_JAVA_OPTS="$DRILL_JAVA_OPTS -Djute.maxbuffer=900000
```

If you change the `jute.maxbuffer` value, you must update the system property on all servers (ZooKeeper nodes) and clients (Drillbit nodes) to have the same value. Failure to change the value on all servers and clients can result in further errors.

### Working with subqueries

- The SELECT list in a scalar subquery can only contain one item/column.
- Correlated subqueries should return exactly one row.
- The WHERE clause of a subquery should not refer to more than one column of the table in the outer query.

### Queries on JSON Files and Tables in HPE Ezmeral Data Fabric Return an OutOfMemoryException

An architectural limitation in Apache Drill can cause an overconsumption of memory when Drill queries files or tables with a certain JSON structure, resulting in an `OutOfMemoryException`.

Drill may return an `OutOfMemoryException` for queries that run against JSON files stored in HPE Ezmeral Data Fabric Database and HPE Ezmeral Data Fabric File Store that have many key-value pairs if the queries include the key-value pairs.

For example, the following JSON files could cause Drill to return an `OutOfMemoryException` when queries that include the key-value pairs run against the files:

#### JSON file with objects that have many key-value pairs

```
{
  "context" : {
    "1": "a",
    "2": "b",
    "3": "c",
    ... // many key-value pairs;
    not showing 9996 of them
    "10000": "d"
```

```

    }
  }
  {
    "context" : {
      "10001": "b"
      ... //many key-value pairs;
      not showing 19998 of them
      "30000": "z"
    }
  }
  {
    "context" : {
      "3": "c"
    }
  }
  {
    "context" : {
    }
  }
  {
    "context" : {
      "5": "e"
    }
  }
}

```

**JSON file with thousands of objects, each having a unique key**

```

{
  "context" : {
    "1": "a"
  }
}
{
  "context" : {
    "2": "b"
  }
}
{
  "context" : {
    "3": "c"
  }
}
{
  "context" : {
    "4": "d"
  }
}
{
  "context" : {
    "5": "e"
  }
}
}

```

In this scenario, if a JSON file contains thousands of objects with unique keys (in 30,000+ documents), the following query would cause an `OutOfMemoryException`:

```

SELECT context FROM
maprfs.`folderWithJSONDocuments`;

```

## Issue Cause

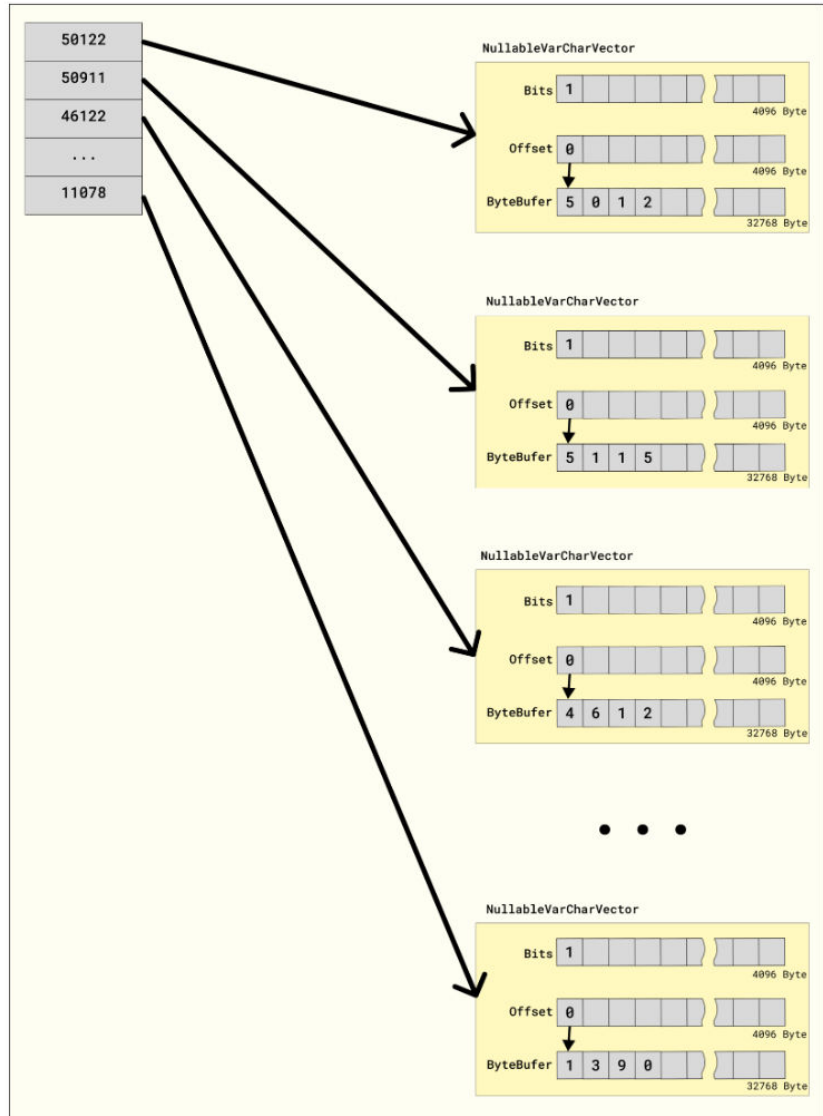

Drill was designed to run queries against massive amounts of data. To successfully run such queries, Drill has a columnar execution engine that works with vectors. Drill creates a separate vector for each unique key and then allocates memory to each vector. Each vector stores about 1,024 values, which varies slightly depending on the data type of the value.

In the following illustration, each key has a VARCHAR value and Drill creates a NullableVarCharVector for each unique key:

### JSON

```

{
  "context" : {
    "50122" : "5012",
    "50911" : "5115",
    "46122" : "4612",
    ...
    "11078" : "1390"
  }
}
    
```

Drill allocates 40960 bytes of direct memory to each NullableVarCharVector. You can see how Drill fills each vector with 7 bytes (2 bytes for a single CHAR string, like "a" and 5 bytes for internally used values).

In cases where Drill is querying thousands upon thousands of JSON files, this works well. However, in cases where Drill queries a single file, a memory issue occurs because each key-value pair in the JSON file may consume more than 1000x more memory than is required for the corresponding value. Each vector unnecessarily holds memory for several values, resulting in failed queries due to a memory shortage.

Refer to [Value Vectors](#) for more information about vectors in Drill.

### Issue Resolution

To resolve or prevent this issue, change the format of the key-value pairs in the JSON file from an object to an array of objects, as shown in the following example:

```

{
  "context" : [
    {
      "key": "1",
      "value": "a"
    },
    {
      "key": "2",
      "value": "b"
    },
    {
      "key": "3",
      "value": "c"
    },
    ...
    {
      "key": "100000",
      "value": "z"
    }
  ]
}
    
```

When a JSON file has an array of objects, Drill only creates two NullableVarCharVectors – one for the "key" and one for the "value". With this structure, only two vectors need to hold memory.

In the following illustration, you can see how Drill fills two vectors with many values versus filling thousands of vectors with only a few values:

```

JSON
{
  "context" : [
    {
      "key": "50122",
      "value": "5012",
    },
    {
      "key": "50911",
      "value": "5115",
    },
    {
      "key": "46122",
      "value": "4612",
    },
    ...
    {
      "key": "11078",
      "value": "1390"
    }
  ]
}
    
```

## Unequal JOIN Support

By default, unequal joins are disabled in Drill because Drill does not have optimized JOIN operators to process these types of queries. An unequal join contains a condition with an inequality comparison between columns. An unequal join uses operators, such as `<>`, `<`, `>`, `<=`, or `>=` to establish the relationship between the joined columns. For example:

```
SELECT *
FROM table1
JOIN table2
ON table1.column_name <= table2.column_name;
```

By default, if you run a query with an unequal join, the query fails and Drill returns the following error:

```
Error: UNSUPPORTED_OPERATION ERROR: This query cannot be planned possibly
due to either a cartesian join or an inequality join.
If a cartesian or inequality join is used intentionally, set the option
'planner.enable_nljoin_for_scalar_only' to false and try again.
```

Although Drill does not have optimized JOIN operators, Drill can process these types of queries in a non-efficient way using a nested loop join operator. To enable this, set the `planner.enable_nljoin_for_scalar_only` option to `false`. Drill can then execute `LEFT` and `INNER` joins; however, `RIGHT` joins will still fail with the error message shown.

Even when `planner.enable_nljoin_for_scalar_only` is disabled, Drill may still return an `UNSUPPORTED_OPERATION ERROR` for `LEFT` joins due to the join optimizations in Drill. If Drill detects that the right input is larger than the left, Drill optimizes the join such that the left and right inputs are flipped and the `LEFT` join type will be changed to `RIGHT`. If the query contains non-equi joins, after such optimizations, the query will fail because the nested loop join operator does not allow `RIGHT` joins.

Using the following query as an example:

```
SELECT *
FROM table1
LEFT JOIN table2
ON table1.column_name <= table2.column_name;
```

If `table1` is smaller than `table2` or even empty, Drill applies a join optimization on the query and the query fails with the following error:

```
Error: UNSUPPORTED_OPERATION ERROR: This query cannot be planned possibly
due to either a cartesian join or an inequality join.
If a cartesian or inequality join is used intentionally, set the option
'planner.enable_nljoin_for_scalar_only' to false and try again.
```

The same optimization can make a `RIGHT` join executable when the left input is smaller than the right. In this case, the left and right inputs will be flipped and the `RIGHT` join type will be changed to `LEFT`. The nested loop operator supports `LEFT` joins. This is how Drill executes a query with a `RIGHT` join and no errors.

To avoid non-equi join errors, disable the join optimization by setting the `planner.enable_join_optimization` option to `false`.

 **IMPORTANT:** Join optimizations improve query performance. If you disable the `planner.enable_join_optimization` option, it disables optimizations for all join types. If you need to disable this option for non-equi joins, only disable the `planner.enable_join_optimization` option at the session level using the `ALTER SESSION SET` command or through the Drill Web UI.

## Vulnerability Reports

Provides vulnerability information in relation to Drill.

### CVE-2022-42889

This vulnerability *does not* impact Drill. The `commons-text` in Drill is only used for the following `StringDistanceFunctions` that involve classes from a [similarity](#) package:

- `cosine_distance`
- `fuzzy_score`
- `hamming_distance`
- `jaccard_distance`
- `jaro_distance`
- `levenshtein_distance`
- `longest_common_substring_distance`

Drill *does not* use `StringSubstitutor`, which is what produces the vulnerability.

## Hadoop

Starting from release 6.2.0, Hadoop (YARN) is decoupled from the core platform and exists as an ecosystem component as part of EEP. This is an essential requirement to support multi-tenant computer clusters for the HPE Ezmeral Data Fabric. For more information about YARN, see [YARN](#) on page 4734.

## HBase

Apache HBase™ is the Hadoop database, a distributed, scalable, big data store. You can use Apache HBase when you need random, realtime read-write access to your Big Data. This section describes how to use HBase with the MapR Platform, but does not duplicate Apache documentation.

The goal of Apache HBase is to host very large tables – billions of rows with millions of columns – atop clusters of commodity hardware. Apache HBase is an open-source, distributed, versioned, column-oriented store modeled after Google's Bigtable: A Distributed Storage System for Structured Data by Chang et al. Just as Bigtable leverages the distributed data storage provided by the Google File System, Apache HBase provides Bigtable-like capabilities on top of Hadoop and Hadoop-compatible filesystems, such as the file system.

Installing Apache HBase on a MapR cluster involves storing all HBase components in a single volume mapped to directory `/hbase` in the cluster. Tables are stored in a flat namespace, not grouped logically with related files. Because all Apache HBase data resides in one volume, only one set of storage policies can be applied to the entire Apache HBase datastore. Mirrors and snapshots of the HBase volume do not provide functional replication of the datastore. Despite this limitation, mirrors can be used to back up HLogs and HFiles in order to provide a recovery point for Apache HBase data.

This section documents how to work with HBase on the MapR Converged Data Platform. You can refer also to documentation available from the [Apache HBase project](#).

**NOTE:** The HPE Ezmeral Data Fabric Database provides native storage for table data, compatible with the HBase API. For new applications, consider using HPE Ezmeral Data Fabric Database binary tables for increased performance, more versatile table operations, and easier cluster administration.

## Configuring HBase

### Configure MapR-SASL Security (Authentication and Encryption) for HBase

This section describes the manual method for configuring security in HBase.

Starting with EEP 6.3.0, HBase services are secured by default with MapR-SASL. After installing HBase, you configure it by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option. There are two methods to configure HBase to be secure by default:

- Automatic Method
- Manual Method

#### Automatic Method

If you installed HBase by using the MapR Installer, the MapR Installer configures HBase daemons during installation. Additional configuration is not required.

#### Manual Method

After a new manual installation, to generate a valid default ecosystem configuration, run:

```
$MAPR_HOME/server/configure.sh -R
```

Four HBase services require configuration:

- HBase Master
- HBase RegionServer
- HBase Thrift
- HBase REST

Each service can be configured for authentication and encryption, as shown later on this page:

#### HBase Master and RegionServer

The Master and RegionServer services require the same configuration for security.

##### Authentication

To enable MapR-SASL authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

##### Encryption

To enable MapR-SASL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rpc.protection</name>
  <value>privacy</value>
</property>
```

Possible values for the `hbase.rpc.protection` property are:

- authentication (auth)
- integrity (auth-int)

- `privacy` (`auth-conf`)

The best practice is to spell out the values (authentication/integrity/privacy). The abbreviated values (in parentheses) can work, but using them is not recommended. Encryption is enabled only for the highest level of security (`privacy`).

### HBase Thrift

It is possible to configure the HBase Thrift service to work over sockets or over the HTTP protocol. For authentication purposes, configuration is the same for both cases. For encryption, configuration is different for each case. Note that starting with the `EEP6.3.0` property, `hbase.thrift.security.authentication` is no longer used to configure HBase Thrift for authentication.

### Authentication

HBase Thrift relies on the same property used for Master and RegionServer. To enable authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

### Encryption for Thrift over Sockets

To enable encryption with MapR-SASL for Thrift over sockets, make sure that the `hbase.regionserver.thrift.http` property is set to `false` and the following property is present in the `hbase-site.xml` file:

```
<property>
  <name>hbase.thrift.security.qop</name>
  <value>auth-conf</value>
</property>
```

Possible values for `hbase.thrift.security.qop` are:

- `auth`
- `auth-int`
- `auth-conf`

Encryption is enabled only for the highest level of security (`auth-conf`).

### Encryption for Thrift over HTTP

To enable Thrift to work over the HTTP protocol, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
```

To enable Thrift over HTTP encryption through SSL, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.thrift.ssl.enabled</name>
```

```
<value>true</value>
</property>
```

## HBase REST

### Authentication

To enable HBase REST authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rest.authentication.type</name>

  <value>org.apache.hadoop.security.authentication.server.MultiMechsAuthenticati
  onHandler</value>
</property>
```

With the `MultiMechsAuthenticationHandler`, MapR-SASL, Kerberos, and PAM authentication headers are supported. A custom `AuthenticationHandler` could be implemented and specified with the full class name in this property.

### Encryption

To enable HBase REST SSL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.rest.ssl.enabled</name>
  <value>true</value>
</property>
```

## HBase Services Web UIs

Web UIs are available for each HBase service. The Web UIs run simultaneously with the service and within the same process. Security for these UIs must be configured too.

### Authentication

To enable HBase Web UI authentication, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.security.authentication</name>
  <value>maprsasl</value>
</property>
```

Authentication is implemented through the `MultiMechsAuthenticationHandler` and therefore supports MapR-SASL, Kerberos, and PAM authentication headers.

### Encryption

To enable HBase Web UI SSL encryption, include the following property in the `hbase-site.xml` file:

```
<property>
  <name>hbase.ssl.enabled</name>
  <value>true</value>
</property>
```

## Configure HBase to use Kerberos

HBase supports MapR-SASL and Kerberos security, and can run securely independently of the security status of your HPE Ezmeral Data Fabric cluster.

## Procedure

To configure HBase to use Kerberos, perform the following steps:

1. Install the `mapr-hbase-master` and `mapr-hbase-regionserver` packages on the cluster.
2. On all HBase nodes, perform the following steps:
  - a) Install the `krb5` packages and configure the Kerberos client as per the configuration for your environment.
  - b) Set up the HBase Kerberos principal `mapr/<fqdn>@<realm>`. Each node requires a unique keytab file and Kerberos identity.
  - c) Create an `hbase.keytab` file with the HBase Kerberos principal with the [same process](#) used to generate the CLDB keytab.
  - d) Copy the `hbase.keytab` file to the `/opt/mapr/conf` directory.
  - e) Use the `chown` command to change the keytab file's ownership to `mapr:mapr`.
  - f) Use the `chmod` command to set the file's permissions to `600`.
  - g) Update the `hbase-site.xml` file by adding the following section:

```
<property>
  <name>hbase.security.authentication</name>
  <value>kerberos</value>
</property>
<property>
  <name>hbase.security.authorization</name>
  <value>>true</value>
</property>
<property>
  <name>hbase.regionserver.kerberos.principal</name>
  <value>mapr/_HOST@<KERBEROS_REALM></value>
</property>
<property>
  <name>hbase.master.kerberos.principal</name>
  <value>mapr/_HOST@<KERBEROS_REALM></value>
</property>
```

- h) On a HPE Ezmeral Data Fabric cluster with security features enabled, replace the `${SIMPLE_LOGIN_OPTS}` value of the `MAPR_HBASE_SERVER_OPTS` property with `${KERBEROS_LOGIN_OPTS}` and the value of the `MAPR_HBASE_CLIENT_OPTS` property with `${HYBRID_LOGIN_OPTS}`. Also remove the `-Dzookeeper.sasl.client=false` option from the definition of `MAPR_HBASE_CLIENT_OPTS`.

These properties are located in the `/opt/mapr/conf/env.sh` file.

- i) On a HPE Ezmeral Data Fabric cluster with security features disabled, replace the `${SIMPLE_LOGIN_OPTS}` value of the `MAPR_HBASE_SERVER_OPTS` and `MAPR_HBASE_CLIENT_OPTS` properties in the `/opt/mapr/conf/env.sh` file with `${KERBEROS_LOGIN_OPTS}`.

- On all HBase regionserver nodes, update the `hbase-site.xml` file by adding the following section:

```
<property>
  <name>hbase.regionserver.keytab.file</name>
  <value>/opt/mapr/conf/hbase.keytab</value>
</property>
<property>
  <name>hbase.coprocessor.region.classes</name>
  <value>
org.apache.hadoop.hbase.security.token.TokenProvider,org.apache.hadoop.hbase.security.access.AccessController</value>
</property>
```

- On the HBase master node, update the `hbase-site.xml` file by adding the following section:

```
<property>
  <name>hbase.master.keytab.file</name>
  <value>/opt/mapr/conf/hbase.keytab</value>
</property>
<property>
  <name>hbase.coprocessor.master.classes</name>
  <value>org.apache.hadoop.hbase.security.access.AccessController</value>
</property>
```

- Restart the HBase master and regionserver nodes.

## Enable Impersonation for HBase

### About this task

HBase can be configured to offer impersonation, with or without Kerberos. This means that users can send commands to HBase through Hue without losing the fact that they will be run under their own credentials, instead of the hue user.

For instructions, see [Enable Impersonation for HBase Thrift1 Gateway](#).

### Configure HBase ACLs

HBase supports Access Control Lists (ACLs) to limit the privileges of users on the system. Before you can use ACLs, you need to perform the steps to enable ACLs.

HBase ACLs support the following privileges:

- Read
- Write
- Execute
- Create tables
- Administrator

The possible scopes are:

- Superuser
- Global
- Namespace

- Table
- ColumnFamily
- Cell

For information about each scope, see [Understanding Access Levels](#).

Once you enable the use of ACLs, you can grant and remove privileges from users by using the `grant` and `revoke` commands from the HBase shell. The following example grants user `jfoo` read privileges from column family `cf1` of table `mytable`:

```
hbase(main):001:0> grant 'jfoo' 'R' 'mytable','cf1'
```

This example removes user `kbar`'s administrative privileges on the cluster:

```
hbase(main):001:0> revoke 'kbar' 'A'
```

### Enable HBase Access Control

The following steps explain how to enable HBase ACLs.

#### Procedure

1. On the HBase Region Server, edit the `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` file, and add the following section:

```
<property>
  <name>hbase.coprocessor.region.classes</name>

  <value>org.apache.hadoop.hbase.security.token.TokenProvider,org.apache.ha
doop.hbase.security.access.AccessController</value>
</property>
<property>
  <name>hbase.superuser</name>
  <value><admin1>,<admin2>,@<group1>,...</value> <!-- group names are
prefixed with '@' -->
</property>
```

2. On the HBase Master, edit the `/opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml` file, and add the following section:

```
<property>
  <name>hbase.coprocessor.master.classes</name>
  <value>org.apache.hadoop.hbase.security.access.AccessController</
value>
</property>
<property>
  <name>hbase.superuser</name>
  <value><admin1>,<admin2>,@<group1>,...</value> <!-- group names are
prefixed with '@' -->
</property>
```

3. Restart HBase on every node.

### Set Up Compression with HBase

Using compression with HBase reduces the number of bytes transmitted over the network and stored on disk. These benefits often outweigh the performance cost of compressing the data on every write and uncompressing it on every read.

## GZip Compression

GZip compression is included with most Linux distributions and works natively with HBase. To use GZip compression, specify it in the per-column family compression flag while creating tables in HBase shell. For example:

```
create 'mytable', {NAME=>'colfam', COMPRESSION=>'gz' }
```

## LZ4 Compression

The LZ4 algorithm gives a slightly worse compression ratio than the LZO algorithm – which in turn is worse than algorithms like DEFLATE. However, compression speeds are similar to LZO and several times faster than DEFLATE, while decompression speeds can be significantly higher than LZO. Here is an example of configuring LZ4 compression:

```
create 'mytable1', {NAME=>'colfam', COMPRESSION=>'lz4' }
```

## Snappy Compression

The Snappy compression algorithm is optimized for speed over compression. Snappy compression is included in the core Data Fabric installation, and no additional configuration is required.

### Configure the Default Database for HBase Clients

For HBase version 1.1 and later, a default database configuration determines whether clients connect to HBase tables or HPE Ezmeral Data Fabric Database tables. You can change the default setting for all HBase clients, or you can set the database for a particular job. This setting is ignored for HBase 0.98.12 client connections.

*Set the Default Database using `configure.sh`*

### About this task

`configure.sh` automatically sets the default database for a node based on the presence of the following `mapr` packages:

- `mapr-hbase-master`
- `mapr-hbase-regionserver`

`configure.sh` also provides a parameter that you can use to set the default database. To explicitly set the default database to either `maprdb` or `hbase`, run `configure.sh` with the `-defaultdb` parameter. For example:

```
configure.sh -R -defaultdb maprdb
```

The following table describes the effect of various `configure.sh` commands on the default database setting:

**Table**

If ...	And you run <code>configure.sh</code> with the following <code>-defaultdb</code> parameter ...		
	No <code>-defaultdb</code> parameter specified	<code>-defaultdb hbase</code>	<code>-defaultdb maprdb</code>
<code>hbasemaster</code> or <code>hbaseregionserver</code> is installed on a node	The default database is set to <code>hbase</code> .	The default database is set to <code>hbase</code>	The default database is set to <code>hbase</code> , and the <code>maprdb</code> setting is ignored.

Table (Continued)

If ...	And you run <code>configure.sh</code> with the following <code>-defaultdb</code> parameter ...		
	No <code>-defaultdb</code> parameter specified	<code>-defaultdb hbase</code>	<code>-defaultdb maprdb</code>
<code>hbasemaster</code> and <code>hbaseregionserver</code> are NOT installed on a node	The default database is set to <code>maprdb</code> .	The default database is set to <code>hbase</code> . However, this configuration does not work because HBase is not running.	The default database is set to <code>maprdb</code> .

For more information about `configure.sh`, see [configure.sh](#) on page 2826.

*Set the Default Database using `hbase-site.xml`*

### About this task

You can configure the `mapr.hbase.default.db` property in the `hbase-site.xml` to override the default database that is set for the cluster:

### Procedure

1. In the `hbase-site.xml`, edit the default value of `mapr.hbase.default.db`, and set it to either `hbase` or `maprdb`.

For example:

```
<property>
  <name>mapr.hbase.default.db</name>
  <value>hbase</value>
</property>
```

2. Copy the property to the `hbase-site.xml` on each node that runs HBase, including any HBase client nodes.

*Set the Database Type in the Job Configuration*

### Procedure

To set the database type in the job configuration you can add the following code:

- To connect to HPE Ezmeral Data Fabric Database tables:

```
Configuration conf = HBaseConfiguration.create();
conf.set("mapr.hbase.default.db", "maprdb");
Connection connection = ConnectionFactory.createConnection(conf);
Table table = connection.getTable(<TABLE_NAME>);
```

- To connect to HBase tables:

```
Configuration conf = HBaseConfiguration.create();
conf.set("mapr.hbase.default.db", "hbase");
Connection connection = ConnectionFactory.createConnection(conf);
Table table = connection.getTable(<TABLE_NAME>);
```

### HBase Configuration Properties

This section describes and shows examples of the configuration properties used in the `hbase-site.xml` file.

## Basic Properties

### Hbase.rootdir

*Description:* Specifies where the HBase data is stored. If not specified, by default HBase uses the `/tmp/` local folder. It is possible to use the local file system or a remote file system instance.

*Example:*

```
<property>
  <name>hbase.rootdir</name>
  <value>maprfs:///hbase</value>
</property>
```

### HBase.cluster.distributed

*Description:* The mode the cluster will be in. Possible values are false for standalone mode and true for distributed mode. If false, startup runs all HBase and ZooKeeper daemons together in the one JVM.

**Default:** false.

*Example:*

```
<property>
  <name>hbase.cluster.distributed</
name>
  <value>true</value>
</property>
```

### Hbase.zookeeper.quorum

*Description:* Comma-separated list of servers in the ZooKeeper ensemble. For example, `host1.mydomain.com,host2.mydomain.com,host3.mydomain.com`. By default this property is set to `localhost` for local and pseudo-distributed modes of operation. For a fully-distributed setup, this property should be set to a full list of ZooKeeper ensemble servers. If `HBASE_MANAGES_ZK` is set in `hbase-env.sh`, this is the list of servers that HBase will start or stop ZooKeeper on as part of cluster start or stop. Client-side, we will take this list of ensemble members and put it together with the `hbase.zookeeper.property.clientPort` config. and pass it into the Zookeeper constructor as the `connectString` parameter. Port could be specified together with hosts. In this case, the `hbase.zookeeper.property.clientPort` configuration is useless.

*Example:*

```
<property>
  <name>hbase.zookeeper.quorum</
name>
  <value>node11.cluster.com:5181</
value>
</property>
```

### Dfs.support.append

*Description:* Specifies whether DFS allows appends to files.

**Hbase.fsutil.maprfs.impl***Example:*

```
<property>
  <name>dfs.support.append</name>
  <value>>true</value>
</property>
```

*Description:* Specifies the FSUtil class (the utility methods for interacting with the underlying file system) used in HBase.

*Example:*

```
<property>
  <name>hbase.fsutil.maprfs.impl</name>

  <value>org.apache.hadoop.hbase.util.FS
  MapRUtils</value>
</property>
```

**Hbase.regionserver.handler.count**

*Description:* Sets the count of RPC Listener instances spun up on RegionServers. The same property is used by the Master for a count of master handlers. Too many handlers can be counter-productive. Make it a multiple of the CPU count. If mostly read-only, handlers count close to CPU count does well. Start with twice the CPU count and tune from there.

**Default:** 30.

*Example:*

```
<property>

  <name>hbase.regionserver.handler.count
  </name>
  <value>30</value>
</property>
```

**Fs.mapr.threads**

*Description:* Controls concurrency in the HPE Ezmeral Data Fabric Database client.

*Example:*

```
<property>
  <name>fs.mapr.threads</name>
  <value>64</value>
</property>
```

**Mapr.hbase.default.db**

*Description:* Specifies whether to use HBase or the HPE Ezmeral Data Fabric Database client. Possible values are hbase and maprdb.

*Example:*

```
<property>
  <name>mapr.hbase.default.db</name>
  <value>hbase</value>
</property>
```

## Security Properties

To support authorization, four properties must be enabled:

- `hbase.security.authorization`
- `hbase.security.exec.permission.checks`
- `hbase.coprocessor.master.classes`
- `hbase.coprocessor.region.classes`

If any one of them is missing, authorization will not be fully supported.

### **Hbase.security.authorizaation**

*Description:* Specifies whether authorization is enabled or not.

*Example:*

```
<property>
<name>hbase.security.authorization</name>
  <value>true</value>
</property>
```

### **Hbase.security.exec.permission.checks**

*Description:* Without this option, all users continue to have access to execute endpoint coprocessors. This option is not enabled when you enable HBase Secure Authorization for backward compatibility.

*Example:*

```
<property>
<name>hbase.security.exec.permission.c
hecks</name>
  <value>true</value>
</property>
```

### **hbase.coprocessor.master.classes**

*Description:* A comma-separated list of coprocessors that are loaded by the master (MasterObserver coprocessors). The AccessController has to be active to support authorization.

*Example:*

```
<property>
<name>hbase.coprocessor.master.classes
</name>
<value>org.apache.hadoop.hbase.securit
y.access.
  AccessController</value>
</property>
```

### **Hbase.coprocessor.region.classes**

*Description:* A comma-separated list of RegionObserver and Endpoint coprocessors. TokenProvider and AccessController must be active to support authorization.

*Example:*

```
<property>
<name>hbase.coprocessor.region.classes
</name>

<value>org.apache.hadoop.hbase.security.token.TokenProvider.
org.apache.hadoop.hbase.security.access.AccessController</value>
</property>
```

**Authentication and Encryption Properties****hbase.security.authentication**

*Description:* Defines whether to use SASL mechanisms in HBase to authenticate RPC connections from clients to HBase Master and RegionServer. Also defines whether to support authentication for HBaseThrift. Specifying `maprsasl` enables authentication for HBaseThrift over http.

*Example:*

```
<property>
<name>hbase.security.authentication</name>
<value>maprsasl</value>
</property>
```

**hbase.security.token.authentication.method**

*Description:* Enables [SCRAM](#) as a token authentication method. For FIPS-enabled nodes, running `/opt/mapr/server/configure.sh` automatically adds this property to `hbase-site.xml`. In clusters with a mix of FIPS and non-FIPS nodes, you must manually add this property to non-FIPS nodes.

*Example:*

```
<property>
<name>hbase.security.token.authentication.method</name>
<value>SCRAM-SHA-256</value>
</property>
```

**hbase.rpc.protection**

*Description:* Enables or disables transport security encryption. To support encryption, the `auth-conf` (privacy) value must be specified. Possible values are:

- `auth` or `authentication`
- `auth-int` or `integrity`
- `auth-conf` or `privacy`

*Example:*

```
<property>
  <name>hbase.rpc.protection</name>
  <value>auth-conf</value>
</property>
```

**hbase.ssl.enabled**

*Description:* Enables or disables SSL encryption for HBase WebUIs.

*Example:*

```
<property>
  <name>hbase.ssl.enabled</name>
  <value>true</value>
</property>
```

**hbase.thrift.ssl.enabled**

*Description:* Enables or disables SSL encryption for HBaseThrift. Works only for HBaseThrift over http (the `hbase.regionserver.thrift.http` property must be set to true).

*Example:*

```
<property>
  <name>hbase.thrift.ssl.enabled</
name>
  <value>true</value>
</property>
```

**Hbase.thrift.security.qop**

*Description:* Enables or disables transport security encryption for HBaseThrift. Use the `auth-conf` value to support encryption. This property works only for HBaseThrift over sockets (the `hbase.regionserver.thrift.http` property must be set to false). Possible values are:

- auth
- auth-int
- auth-conf

*Example:*

```
<property>
  <name>hbase.thrift.security.qop</
name>
  <value>auth-conf</value>
</property>
```

**hbase.rest.authentication.type**

*Description:* Defines the AuthenticationHandler to use during user-to-HBaseRest authentication. The `MultiMechsAuthenticationHandler` supports PAM, MapR SASL, and Kerberos authentication. If this property is not specified, authentication for HBaseRest is disabled.

*Example:*

```
<property>
<name>hbase.rest.authentication.type</name>
<value>org.apache.hadoop.security.authentication.server.
    MultiMechsAuthenticationHandler</value>
</property>
```

**hbase.rest.ssl.enabled**

*Description:* Enables or disables SSL encryption (from client to server and vice versa) for the HBaseRest service.

*Example:*

```
<property>
  <name>hbase.rest.ssl.enabled</name>
  <value>true</value>
</property>
```

**Impersonation Properties****hbase.thrift.support.proxyuser**

*Description:* Enables or disables impersonation for HBaseThrift. Works only for thrift over http (the `hbase.regionserver.thrift.http` property must be set to true).

*Example:*

```
<property>
<name>hbase.thrift.support.proxyuser</name>
  <value>true</value>
</property>
```

**hbase.rest.support.proxyuser**

*Description:* Enables or disables impersonation for HBaseRest.

*Example:*

```
<property>
<name>hbase.rest.support.proxyuser</name>
  <value>true</value>
</property>
```

**hbase.regionserver.thrift.http**

*Description:* Defines whether to use HBaseThrift over http (if `true` is specified) or over sockets. Used to support impersonation for thrift over http.

*Example:*

```
<property>
<name>hbase.regionserver.thrift.http</
name>
  <value>true</value>
</property>
```

## Using HBase

This section includes the following topics about working with HBase:

### Getting Started in HBase

#### About this task

In this section, we'll create an HBase table on the cluster, enter some data, query the table, then clean up the data and exit.

HBase tables are organized by column, rather than by row. Furthermore, the columns are organized in groups called *column families*. When creating an HBase table, you must define the column families before inserting any data. Column families should not be changed often, nor should there be too many of them, so it is important to think carefully about what column families will be useful for your particular data. Each column family, however, can contain a very large number of columns. Columns are named using the format `family:qualifier`.

Unlike columns in a relational database, which reserve empty space for columns with no values, HBase columns simply don't exist for rows where they have no values. This not only saves space, but means that different rows need not have the same columns; you can use whatever columns you need for your data on a per-row basis.

#### Procedure

1. Start the HBase shell by typing the following command:

```
hbase shell
```

2. Create a table called `weblog` with one column family named `stats`:

```
create 'weblog', 'stats'
```

3. Verify the table creation by listing everything:

```
list
```

4. Add a test value to the `daily` column in the `stats` column family for row 1:

```
put 'weblog', 'row1', 'stats:daily', 'test-daily-value'
```

5. Add a test value to the weekly column in the stats column family for row 1:

```
put 'weblog', 'row1', 'stats:weekly', 'test-weekly-value'
```

6. Add a test value to the weekly column in the stats column family for row 2:

```
put 'weblog', 'row2', 'stats:weekly', 'test-weekly-value'
```

7. Type `scan 'weblog'` to display the contents of the table. Sample output:

```
ROW                COLUMN+CELL
 row1              column=stats:daily, timestamp=1321296699190,
 value=test-daily-value
 row1              column=stats:weekly, timestamp=1321296715892,
 value=test-weekly-value
 row2              column=stats:weekly, timestamp=1321296787444,
 value=test-weekly-value
 2 row(s) in 0.0440 seconds
```

8. Type `get 'weblog', 'row1'` to display the contents of row 1. Sample output:

```
COLUMN            CELL
 stats:daily      timestamp=1321296699190, value=test-daily-value
 stats:weekly     timestamp=1321296715892, value=test-weekly-value
 2 row(s) in 0.0330 seconds
```

9. Type `disable 'weblog'` to disable the table.

10. Type `drop 'weblog'` to drop the table and delete all data.

11. Type `exit` to exit the HBase shell.

## Running MapReduce Jobs with HBase

### About this task

To run MapReduce applications with data stored in HBase, use a command such as the following to export table data to the HPE Ezmeral Data Fabric file system:

```
$ hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/
hbase-server-1.1.13.0-mapr-1912.jar export t1 /user/mapr/t1
```

or

```
$ hbase org.apache.hadoop.hbase.mapreduce.Export t1 /user/mapr/t4
```

The result is the same because of the tools included in the `hbase-server.jar` file:

```
$ hadoop fs -ls /user/mapr/t1/
Found 2 items
-rwxr-xr-x  3 mapr mapr          0 2019-11-11 15:00 /user/mapr/t1/_SUCCESS
-rw-r--r--  3 mapr mapr       249 2019-11-11 15:00 /user/mapr/t1/
part-m-00000
$ hadoop fs -ls /user/mapr/t4/
Found 2 items
-rwxr-xr-x  3 mapr mapr          0 2019-11-11 15:09 /user/mapr/t4/_SUCCESS
-rw-r--r--  3 mapr mapr       249 2019-11-11 15:09 /user/mapr/t4/
```

```
part-m-00000
$
```

Following is an example of the full output:

```
$ hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/
hbase-server-1.1.13.0-mapr-1912.jar export t1 /user/mapr/t1

The following table shows the tools included in the hbase-server.jar:

Name <sup>1</sup>	Class <sup>2</sup>	Description
rowcounter	RowCounter	Count rows in HBase table
CellCounter	CellCounter	Count cells in HBase table
export	Export	Write table data to HPE Ezmeral Data Fabric file system
import	Import	Import data written by Export
importtsv	ImportTsv	Import data in TSV format
completebulkload	LoadIncrementalHFiles	Complete a bulk data load
copytable	CopyTable	Export a table from local cluster to peer cluster

Name <sup>1</sup>	Class <sup>2</sup>	Description
verifyrep	VerifyReplication	Compare the data from tables in two different clusters  <b>NOTE:</b> This function does not work for incrementColumnValues cells since the timestamp is changed after being appended to the log.
WALPlayer	WALPlayer	Replay WAL files
exportsnapshot	ExportSnapshot	Export the specific snapshot to a given file system

<sup>1</sup> Class is used for `hbase.org.apache.hadoop.hbase.mapreduce.<class>...`

<sup>2</sup> Name is used for `hadoop jar /opt/mapr/hbase/hbase-1.1.13/lib/hbase-server-1.1.13.0-mapr-1912.jar <name>...`

### Using the libhbase Library

libhbase is a JNI-based, thread-safe C library that implements a native HBase client. You can use libhbase to build applications that access HBase.

This page contains the following topics:

- Installing libhbase
- Upgrading libhbase
- Building applications with libhbase
- Configuring the application environment
- Running a libhbase performance test

For examples that show how to use the APIs, see the [sample source file](#).

### Installing libhbase

Install libhbase on the nodes from which you will build and run the application.

Complete the following steps to install libhbase from a repository:

1. Configure the repository to point to <http://package.ezmeral.hpe.com/releases/MEP/MEP-6.3.0/>.

**IMPORTANT:** To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Ezmeral Token-Authenticated Internet Repository](#) on page 93.

2. Based on your operating system, run one of the following commands to install the package:

- On Red Hat/Centos: `yum install mapr-libhbase`
- On SLES: `zypper install mapr-libhbase`
- On Ubuntu: `apt-get install mapr-libhbase`

Once the installation completes, the libhbase installation includes the following directories under `/opt/mapr/libhbase/libhbase-<version>`:

```
/
+---bin/
+---conf/
+---include/
|   +---hbase/
```

```

+---lib/
|   +---native/
+---src
    +---examples/
    |   +---async/
    +---test/
        +---native/
            +---common/

```

**NOTE:** The `include` folder contains the headers required to build applications. The `lib/native` directory contains shared libraries.

## Upgrading libhbase

To upgrade to a more recent version of libhbase:

1. Install the new version.
2. Re-configure the application environment to refer to the new libraries.

## Building Applications with libhbase

libhbase should be installed on each node that builds the application.

Note the following items when you build applications with libhbase:

- The headers required to build applications are located under `/opt/mapr/libhbase/libhbase-<version>/include`.
- libhbase shared library is located in the following directory: `/opt/mapr/libhbase/libhbase-<version>/lib/native`.
- Since libhbase uses JNI, you must also link your application against libjvm. In general, the libjvm library is located within the JDK/JRE installation directory.

For example, the following command builds the `hello_hbase` application with the `hello_hbase.c` source code:

```

gcc -o hello_hbase hello_hbase.c -I/opt/mapr/
libhbase/libhbase-0.98.7/include -L/opt/mapr/libhbase/libhbase-0.98.7/lib/
native -lhbase -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm

```

## Configuring the Application Environment

Complete the following steps to configure the node from which you run the application:

- Verify that libhbase is installed on the node.
- Verify that both the libhbase and libjvm shared libraries are in the application's library search path. The libhbase shared library is located under `/opt/mapr/libhbase/libhbase-<version>/lib/native`. In general, the libjvm library is located within the JDK/JRE installation directory.
- Specify any JARs required by the application with one of the following environment variables: `CLASSPATH` or `HBASE_LIB_DIR`.
- Specify custom JVM options, such as `-Xmx`, using the environment variable `LIBHBASE_OPTS`.

## Running a libhbase Performance Test

libhbase 0.98.7 includes a performance test that supports sequential/random gets and puts. In libhbase 0.98.9, the performance test utility also includes support for Zipfian, support for uniform random key generation, and it test for scans. You can run the test using this [shell script](#).

## HBase Client and HPE Ezmeral Data Fabric Database Binary Tables

HPE Ezmeral Data Fabric 6.0.x and 6.1 provide Apache HBase-compatible APIs and client interfaces but do not support HBase as an ecosystem component. HPE Ezmeral Data Fabric Database [binary tables](#) provide native storage for table data and include high performance and availability, versatile table operations, and streamlined cluster administration. The following APIs and tools are available for HPE Ezmeral Data Fabric Database binary tables:

### HBase Client

- After installing the HBase Client, you can use HBase Shell commands to manipulate HPE Ezmeral Data Fabric Database binary tables on a remote machine. See [Installing HBase on a Client Node](#) on page 237 and [HPE Ezmeral Data Fabric Database HBase Shell \(Binary Tables\)](#) on page 5540.
- HPE Ezmeral Data Fabric Database supports binary tables through the libMapRClient (a library of C APIs) and Apache HBase Java APIs. See [Developing Applications for Binary Tables](#) on page 3241.

### HBase REST Gateway

- The HBase REST Gateway allows users to manipulate HPE Ezmeral Data Fabric Database binary tables through the HBase REST API. See [Installing the HBase REST Gateway](#) on page 239.

### HBase Thrift Gateway

- The HBase Thrift Gateway allows users to manipulate HPE Ezmeral Data Fabric Database binary tables through the HBase Thrift API. See [Installing the HBase Thrift Gateway](#) on page 239.

## Using the HBase Thrift Gateway

HBase Thrift Gateway includes an API and a service that accepts Thrift requests to connect to HPE Ezmeral Data Fabric Database and HBase tables. The HBase Thrift Gateway is installed as a service that is managed by Warden. Installing `mapr-hbasethrift` adds the `warden.hbasethrift.conf` file to the `/opt/mapr/conf/conf.d` directory.

**NOTE:** MapR-SASL authentication, encryption, and impersonation for HBase Thrift Gateway are enabled by default on secure clusters.

## Starting the HBase Thrift Service

### About this task

To start the HBase thrift service, enter the following command with the name of the host where hbasethrift is running:

```
maprcli node services -name hbasethrift -action start -nodes <node_hostname>
```

## Configure Kerberos for HBase Thrift Gateway

### About this task

**Procedure**

1. Add the following to the `hbase-site.xml` file for every Thrift gateway:

```
<property>
  <name>hbase.thrift.keytab.file</name>
  <value>$KEYTAB</value>
</property>
<property>
  <name>hbase.thrift.kerberos.principal</name>
  <value>$USER/_HOST@HADOOP.LOCALDOMAIN</value>
  <!-- This may need to be HTTP/_HOST@REALM and _HOST may not work.
You may have to put the concrete full hostname. -->
</property>
<property>
  <name>hbase.thrift.security.qop</name>
  <value>auth-conf</value>
</property>
<!-- Add these if you need to configure a different DNS interface from
the default -->
<property>
  <name>hbase.thrift.dns.interface</name>
  <value>default</value>
</property>
<property>
  <name>hbase.thrift.dns.nameserver</name>
  <value>default</value>
</property>
```

Substitute the appropriate credential and keytab for `$USER` and `$KEYTAB` respectively.

2. If you are running HBase Thrift in HTTP mode, you must add additional properties to the `hbase-site.xml` to enable HTTP connections through Kerberos. This is required if you enabled the following property in the `hbase-site.xml`:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>true</value>
</property>
```

Add the following properties to enable HTTP connections through Kerberos:

```
<property>
  <name>hbase.thrift.spnego.principal</name>
  <value>HTTP/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
<property>
  <name>hbase.thrift.spnego.keytab.file</name>
  <value>$KEYTAB</value>
</property>
```

- To use HPE Ezmeral Data Fabric Database tables without the full path, add the following property to the `core-site.xml` file:

```
<property>
  <name>hbase.table.namespace.mappings</name>
  <value>*:</value>
</property>
```

Add this property **ONLY** if you are working with HPE Ezmeral Data Fabric Database tables. Working with HBase tables is not possible when this property is present. For more information, see [Considerations for Upgrading to HBase 1.1.13](#) on page 343. For more information about mapping tables, see [Mapping to HBase Table Namespaces](#) on page 457.

## Results

The Thrift gateway authenticates with HBase using the supplied credential. No authentication is performed by the Thrift gateway itself. All client access via the Thrift gateway uses the Thrift gateway's credential and has its privilege.

## Enable Impersonation for HBase Thrift Gateway

### About this task

To configure the Thrift gateway to authenticate to HBase on the client's behalf, and to access HBase using a proxy user:

### Procedure

- To allow proxy users, add the following to the `hbase-site.xml` file for every HBase node:

```
<property>
  <name>hadoop.proxyuser.$USER.groups</name>
  <value>$GROUPS</value>
</property>
<property>
  <name>hadoop.proxyuser.$USER.hosts</name>
  <value>$GROUPS</value>
</property>
```

- To enable the `doAs` feature, add the following to the `hbase-site.xml` file for every Thrift gateway:

```
<property>
  <name>hbase.regionserver.thrift.http</name>
  <value>>true</value>
</property>
<property>
  <name>hbase.thrift.support.proxyuser</name>
  <value>>true</value>
</property>
```

- Restart the Thrift gateway processes for the changes to take effect. If a node is running Thrift, the output of the `jps` command will list a `ThriftServer` process.
  - To restart Thrift on a node, use the following `maprcli` command:

```
maprcli node services -name hbasethrift -action restart -nodes
<node_hostname>
```

## Using the HBase REST Gateway

HBase REST Gateway includes an API and a service that accepts REST requests to connect to HPE Ezmeral Data Fabric Database and HBase tables. Starting in version 0.98.9, the HBase REST Gateway is installed as a service that is managed by Warden. When `mapr-hbase-rest` is installed, the `warden.hbase-rest.conf` file is added to the `/opt/mapr/conf/conf.d` directory.

**NOTE:** PAM authentication, encryption, and impersonation for HBase REST are enabled by default on secure clusters.

## Starting the HBase REST Service

### About this task

To start the HBase REST service, enter the following command with the name of the host where `hbaserest` is running:

```
maprcli node services -name hbaserest -action start -nodes <node_hostname>
```

## Configure Kerberos for HBase REST Gateway

### About this task

### Procedure

1. Add the following to the `hbase-site.xml` file for every REST Gateway:

```
<property>
  <name>hbase.rest.keytab.file</name>
  <value>$KEYTAB</value>
</property>
<property>
  <name>hbase.rest.kerberos.principal</name>
  <value>$USER/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
```

Substitute the appropriate credential and keytab for `$USER` and `$KEYTAB` respectively.

The REST Gateway will authenticate with HBase using the supplied credential.

2. To enable REST Gateway Kerberos authentication for client access, add the following to the `hbase-site.xml` file for every REST Gateway:

```
<property>
  <name>hbase.rest.authentication.type</name>
  <value>kerberos</value>
</property>
<property>
  <name>hbase.rest.authentication.kerberos.principal</name>
  <value>HTTP/_HOST@HADOOP.LOCALDOMAIN</value>
</property>
<property>
  <name>hbase.rest.authentication.kerberos.keytab</name>
  <value>${KEYTAB}</value>
</property>
<!-- Add these if you need to configure a different DNS interface from
the default -->
<property>
  <name>hbase.rest.dns.interface</name>
  <value>default</value>
</property>
<property>
  <name>hbase.rest.dns.nameserver</name>
  <value>default</value>
</property>
```

Substitute the keytab for HTTP for `KEYTAB`.

## Enable Impersonation for HBase REST Gateway

### About this task

To enable HBase REST Gateway impersonation, configure all HBase servers to allow proxy users, then configure every REST Gateway to enable impersonation.

### Procedure

- To enable REST Gateway impersonation, add the following to the `hbase-site.xml` file for every REST gateway:

```
<property>
  <name>hbase.rest.support.proxyuser</name>
  <value>true</value>
</property>
```

## HBase REST Gateway and HBase Thrift Gateway Secured By Default to Use SSL

Starting in EEP 6.0.0, HBase REST and HBase Thrift use SSL by default on secured clusters.

1. On a secure cluster, by default, HBase REST and HBase Thrift read the `ssl-client.xml` file and configure SSL using this file.

2. To enable HBase REST and Thrift encryption, use the following properties. Note that SSL for Thrift is enabled only when the `hbase.regionserver.thrift.http` property is `true`:

#### Enabling HBase REST encryption

```
<property>
  <name>hbase.rest.ssl.enabled</name>
  <value>true</value>
</property>
```

#### Enabling HBase Thrift encryption

```
<property>
  <name>hbase.thrift.ssl.enabled</name>
  <value>true</value>
</property>
```

## HCatalog

HCatalog is a table and storage management layer for Hadoop that enables users with different data processing tools — Pig, MapReduce — to more easily read and write data on the grid. HCatalog's table abstraction presents users with a relational view of data in the Hadoop distributed filesystem (HDFS) and ensures that users need not worry about where or in what format their data is stored — RCFile format, text files, SequenceFiles, or ORC files.

HCatalog supports reading and writing files in any format for which a SerDe (serializer-deserializer) can be written. By default, HCatalog supports RCFile, CSV, JSON, and SequenceFile, and ORC file formats. To use a custom format, you must provide the InputFormat, OutputFormat, and SerDe.

HCatalog is also automatically installed and upgraded along with Hive. For information about using HCatalog with Hive, see [Hive and WebHCat Integration](#) and [Hive and HCatalog Integration](#).

## Hive

Apache Hive™ is a data warehouse system for Hadoop that facilitates easy data summarization, ad-hoc queries, and the analysis of large datasets stored in Hadoop-compatible file systems, such as HPE Ezmeral Data Fabric. Hive provides a mechanism to project structure onto this data and query the data using a SQL-like language called HiveQL. At the same time this language also allows traditional map/reduce programmers to plug in their custom mappers and reducers when it is inconvenient or inefficient to express this logic in HiveQL.

You can refer also to documentation available from the [Apache Hive project](#).

Hive components include the following:

- Hive Metastore
- HiveServer2
- HCatalog
- WebHCat
- Hive CLI
- Beeline

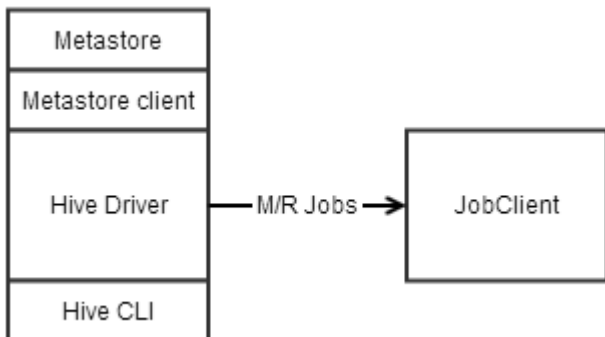

**NOTE:** If you installed Hive using the installer with the "Enable Security" check box selected, Hive is secured and no further configuration is required. However, if you installed Hive manually and wish to enable security for Hive, see [Hive Security Configuration Options](#) on page 4186 for information.

The following examples show how these components communicate with each other and when you might want to configure security features such as authentication and encryption:

**Case 1: Jobs Submitted by the Hive CLI, Embedded Metastore**

In this case, all the information needed by Hive is contained within a single process, and no security is needed beyond that already provided by the JobClient's communications.

**Case 2: Jobs Submitted by the Hive CLI, Remote Metastore**

In this case, Hive needs to access a metastore remote to Hive's process using a Thrift interface. This communication can be left secured with Kerberos, or secured with MapR-SASL.

**Case 3: Jobs Submitted by HiveServer2, Embedded Metastore**

In this case, JDBC or ODBC on a user's machine sends queries to HiveServer2, which submits the queries to the driver for parsing. The communication between JDBC and HiveServer2 can be secured with username and password with SSL, MapR-SASL, or with Kerberos. Either approach offers authentication and encryption. JDBC/ODBC can also be configured to use username and password without SSL, which offers authentication *only*.

To use SSL from a client machine the `ssl_truststore` file must be copied from the cluster to the client.

#### Case 4: Jobs Submitted by HiveServer2, Remote Metastore

In this case, JDBC or ODBC on a user's machine sends queries to HiveServer2, which submits the queries to the driver, which runs the query and returns the results. The metastore is remote. In this case, there are two communications links to secure: the Thrift interface between the metastore client and server, and the Thrift interface between the client JDBC/ODBC and HiveServer2. The security arrangements for these links are identical to Cases 2 and 3.

#### Getting Started with Hive

##### About this task

In this tutorial, you'll create a Hive table, load data from a tab-delimited text file, and run a couple of basic queries against the table. For details on setting up HiveServer2 and starting BeeLine, see [Using JDBC or Beeline to Connect to HiveServer2](#) on page 4282.

**NOTE:** If you are using HiveServer2, you will use the BeeLine CLI instead of the Hive shell, as shown below.

#### Take a look at the source data

##### About this task

First, take a look at the contents of the file using the terminal:

##### Procedure

1. Save the following data to a text file named `sample-table.txt`:

The `sample-table.txt` table columns are delimited by tabs:

```

1320352532    1001    http://www.mapr.com/doc    http://www.mapr.com
192.168.10.1
1320352533    1002    http://www.mapr.com    http://www.example.com
192.168.10.10
1320352546    1001    http://www.mapr.com    http://www.mapr.com/doc
192.168.10.1
  
```

If you are working on the Data Fabric Virtual Machine, we'll be loading the file from the Virtual Machine's local filesystem (not the cluster storage layer), so save the file in the Home directory (for example, `/home/mapr`).

2. Make sure you are in the Home directory where you saved `sample-table.txt` (type `cd ~` if you are not sure).
3. Type `cat sample-table.txt` to display the following output.

### Results

```
mapr@mapr-desktop:~$ cat sample-table.txt
1320352532    1001    http://www.mapr.com/doc    http://www.mapr.com
192.168.10.1
1320352533    1002    http://www.mapr.com    http://www.example.com
192.168.10.10
1320352546    1001    http://www.mapr.com    http://www.mapr.com/doc
192.168.10.1
```

Notice that the file consists of only three lines, each of which contains a row of data fields separated by the TAB character. The data in the file represents a web log.

### Create a table in Hive and load the source data:

#### Procedure

1. Type the following command to start the Hive shell, using tab-completion to expand the `<version>`:

```
/opt/mapr/hive/hive-<version>/bin/hive
```

2. At the `hive>` prompt, type the following command to create the table:

```
CREATE TABLE web_log(viewTime INT, userid BIGINT, url STRING, referrer
STRING, ip STRING) ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t';
```

3. Type the following command to load the data from `sample-table.txt` into the table:

```
LOAD DATA LOCAL INPATH '/home/mapr/sample-table.txt' INTO TABLE web_log;
```

### Run basic queries against the table

#### Procedure

- Try the simplest query, one that displays all the data in the table:

```
SELECT web_log.* FROM web_log;
```

This query would be inadvisable with a large table, but with the small sample table it returns very quickly.

- Try a simple `SELECT` to extract only data that matches a desired string:

```
SELECT web_log.* FROM web_log WHERE web_log.url LIKE '%doc';
```

This query launches a MapReduce application to filter the data.

### Configuring Hive

This section contains the following topics:

## Configure Hive Directories

You can configure the following Hive directories:

- Hive Scratch Directory
- Hive Warehouse Directory
- Hive Error Logs Directory

### Hive Scratch Directory

In Hive 1.0, HPE Ezmeral Data Fabric configures the Hive scratch directory to be `/user/<user.name>/tmp/hive/<user.name>`. In Hive 0.13, the default scratch directory is `/user/<user.name>/tmp/hive`. The hive user must have write access to the `/user` folder.

To modify this parameter, perform one of the following operations:

- Set this parameter in the `hive-site.xml`. Copy the `hive.exec.scratchdir` property elements from the `$HIVE_HOME/conf/hive-default.xml.template` file and paste them into an XML configuration element in the `$HIVE_HOME/conf/hive-site.xml` file. Then, modify the value elements for these directories in the `hive-site.xml` file.
- Set this parameter from the Hive shell. Example:

```
hive> set hive.exec.scratchdir=/myvolume/tmp
```

**NOTE:** You will see better performance when queries import data from a table that is in the same Data Fabric volume as Hive scratch directory.

### How Hive Handles Scratch Directories on HPE Ezmeral Data Fabric

When a query requires Hive to query existing tables and create data for new tables, Hive uses the following workflow:

1. Create the query scratch directory `hive_<timestamp>_<randomnumber>` under the Hive scratch directory.
2. Create the following directories as subdirectories of the scratch directory:
  - a. Final query output directory. This directory's name takes the form `-ext-<number>`.
  - b. An output directory for each MapReduce application. These directories' names take the form `-mr-<number>`.
3. Hive executes the tasks, including MapReduce applications and loading data to the query output directory.
4. Hive loads the data from output directory into a table. By default, the table's directory is in the `/user/hive/warehouse` directory. You can configure this location with the `hive.metastore.warehouse.dir` parameter in `hive-site.xml`, unless the table DDL specifies a custom location. Hive renames the output directory to the table directory in order to load the output data to the table.
5. The scratch directories are automatically deleted after the query completes successfully.

HPE Ezmeral Data Fabric uses [Administering Volumes](#) on page 1161, which are logical units that enable you to apply policies to a set of files, directories, and sub-volumes. When the output directory and the table directory are in different volumes, this workflow involves moving data across volumes. Moving data

across volumes is slower than moving data within a volume. Therefore, HPE Ezmeral Data Fabric sets `hive.optimize.insert.dest.volume` to `true` to automatically create a scratch directory in the same volume as the target table.

### Hive Warehouse Directory

Hive tables are stored in the Hive warehouse directory. By default, HPE Ezmeral Data Fabric configures the Hive warehouse directory to be `/user/hive/warehouse` under the root volume. This default is defined in the `$HIVE_HOME/conf/hive-default.xml.template` file.

To modify this parameter, perform one of the following operations:

- Set this parameter in the `hive-site.xml`. Copy the `hive.metastore.warehouse.dir` property elements from the `$HIVE_HOME/conf/hive-default.xml.template` file and paste them into an XML configuration element in the `$HIVE_HOME/conf/hive-site.xml` file. Then, modify the value elements for these directories in the `hive-site.xml` file.
- Set this parameter from the Hive shell. Example:

```
hive> set hive.metastore.warehouse.dir=/myvolume/mydirectory
```

**NOTE:** You will see better performance when queries move data between tables in the same volume.

### Hive Error Logs Directory

The log files are stored in `/opt/mapr/hive/hive-<version>/logs/<user>` by default.

To modify the log location:

1. Configure `hive.log.dir` in `$HIVE_HOME/conf/hive-log4j.properties` file. Example:

```
hive.log.dir=<other_location>
```

2. Set the sticky bit on the new directory. Example:

```
chmod 1777 <other_location>
```

### Configuring Hive Client on a Data Fabric Client Node

This topic describes how to configure the Hive client on a Data Fabric client node.  
*Configuring Hive Client for EEP 9.0.0 and Later*

#### About this task

To use the Hive client with secure clusters for EEP 9.0.0 and later, perform the following steps:

#### Procedure

1. Install the Data Fabric client. See [Installing the Data Fabric Client on Red Hat and Oracle Linux \(Non-FIPS\)](#) on page 397.
2. Copy `maprtrustcreds.jceks` from the `MAPR_HOME/conf` directory on the cluster to the `MAPR_HOME/conf` directory on the Data Fabric client.

### Configuring MSCK REPAIR TABLE

This section guides you through configuring `MSCK REPAIR TABLE` command to compare and update the partitions in Hive Metastore and file systems.

Use the `MSCK REPAIR TABLE` command to manually update (ADD, DROP, SYNC) the partitions on Hive metastore with respect to file systems like HDFS, Amazon S3, filesystem, and others.

For example: You specify the location of filesystem when you create a Hive table. When you add or delete the partitions to or from the filesystem, the partitions in filesystem and Hive metastore becomes inconsistent.

Run `MSCK REPAIR TABLE` command to compare the partitions in filesystem and the partitions in Hive metastore and update the partitions in Hive metastore.

```
MSCK [REPAIR] TABLE <table name> [ADD/DROP/SYNC PARTITIONS];
```

Configure the Hive Metastore with the following Hive property:

Property	Default	Description
hive.msck.repair.batch.max.retries	0	Maximum number of retries for the msck repair command when adding unknown partitions. If the value is greater than zero it will retry adding unknown partitions until the maximum number of attempts is reached or batch size is reduced to 0, whichever is earlier. In each retry attempt, it will reduce the batch size by a factor of 2 until it reaches zero. If the value is set to zero it will retry until the batch size becomes zero as described above.

### Configuring Database for Hive Metastore

The metadata for Hive tables and partitions are stored in the Hive Metastore. By default, the Hive Metastore stores all Hive metadata in an embedded Apache Derby database in the file system. The following sections describe how to configure other DBs for Hive Metastore.

 **CAUTION:** Do not use `datanucleus.schema.autoCreateAll` for populating underlying databases. For more details, see [prohibited usage of datanucleus.schema.autoCreateAll property](#).

#### *Use MySQL for the Hive Metastore*

The metadata for Hive tables and partitions are stored in the Hive Metastore. By default, the Hive Metastore stores all Hive metadata in an embedded Apache Derby database in the HPE Ezmeral Data Fabric file system. Derby only allows one connection at a time; if you want multiple concurrent Hive sessions, you can use MySQL for the Hive Metastore.

### Prerequisites

Review the following prerequisites before you begin:

- Verify that MySQL (version 5.6.17 or later) is installed on the machine that will host the Hive metastore, and also verify that you can connect to the MySQL server from the Hive machine. You can run the Hive metastore on any machine that is accessible from Hive. You can test this with the following command:

```
mysql -h <hostname> -u <user>
```

- The database administrator must create a database for the Hive metastore data, and the username specified in `javax.jdo.option.ConnectionUserName` must have permissions to access it. The database can be specified using the `ConnectionURL` parameter. The tables and schemas are created automatically when the metastore is first started.

**TIP:** In MapR 6.1.0 and earlier releases, the following steps can be used interchangeably for MariaDB.

### About this task

Complete the following steps to configure Hive to use MySQL for the Hive Metastore:

- !** **IMPORTANT:** For [MySQL 8](#), set the `javax.jdo.option.ConnectionDriverName` property to `com.mysql.cj.jdbc.Driver`. The `com.mysql.jdbc.Driver` is deprecated. The new driver class is `com.mysql.cj.jdbc.Driver`. However, the driver is automatically registered via the Service Provider Interface, so manual loading of the driver class is generally unnecessary.

### Procedure

1. Update the `hive-site.xml` in the Hive configuration directory (`/opt/mapr/hive/hive-<version>/conf`) with the following contents:

```
<configuration>

  <property>
    <name>javax.jdo.option.ConnectionURL</name>
    <value>jdbc:mysql://localhost:3306/hive?
createDatabaseIfNotExist=true</value>
    <description>JDBC connect string for a JDBC metastore</description>
  </property>

  <property>
    <name>javax.jdo.option.ConnectionDriverName</name>
    <value>com.mysql.jdbc.Driver</value>
    <description>Driver class name for a JDBC metastore</description>
  </property>

  <property>
    <name>javax.jdo.option.ConnectionUserName</name>
    <value>root</value>
    <description>username to use against metastore database</description>
  </property>

  <property>
    <name>javax.jdo.option.ConnectionPassword</name>
    <value><fill in with password></value>
    <description>password to use against metastore database</description>
  </property>

  <property>
    <name>hive.metastore.uris</name>
    <value>thrift://localhost:9083</value>
  </property>

</configuration>
```

2. Run the `schematool` command as an initialization step.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

3. To connect to an existing MySQL metastore, make sure the `ConnectionURL` parameter and the `Thrift URIs` parameters in `hive-site.xml` point to the metastore's host and port.

- To set a specific port for Thrift URIs, add the command `export METASTORE_PORT=<port>` into the file `hive-env.sh` (if `hive-env.sh` does not exist, create it in the Hive configuration directory). Example:

```
export METASTORE_PORT=9083
```

- Start the Hive Metastore service using one of the following commands:

If you want the Hive Metastore to be managed by Warden, the `maprcli`, and the Control System:

```
maprcli node services -name hivemeta -action start -nodes <space
delimited list of nodes>
```

If you want the Hive Metastore to be managed with standard hive commands:

```
/opt/mapr/hive/hive-<version>/bin/hive --service metastore --start
```

You can use also use `nohup hive --service metastore` to run the Metastore in the background.

**WARNING:** If you have not configured a MySQL Metastore, do not run the Hive shell from an NFS mount location. If you try to do this, Hive will fail. The same problem will occur if you use the `hive-site.xml` file to configure the Metastore on an NFS mount location. Avoid both of these configurations.

### *Configuring a Remote MySQL Database for the Hive Metastore*

#### **About this task**

After installing MySQL, perform the following steps to configure Hive Metastore on MySQL

#### **Procedure**

- Install the MySQL connector. To install:

- MySQL connector on a RHEL 6+ system**

On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file to the `/opt/mapr/hive/hive-<version>/lib/` directory.

```
$ sudo yum install
mysql-connector-java
$ ln -s /usr/share/
java/mysql-connector-java.jar /opt/
mapr/hive/hive-<version>/lib/
mysql-connector-java.jar
```

- MySQL connector on a SLES system**

On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file to the `/opt/mapr/hive/hive-<version>/lib/` directory.

```
$ sudo zypper install
mysql-connector-java
$ ln -s /usr/share/
java/mysql-connector-java.jar /opt/
mapr/hive/hive-<version>/lib/
mysql-connector-java.jar
```

- **MySQL connector on a Debian/Ubuntu system**

On the Hive Metastore server host, install `mysql-connector-java` and symbolically link the file into the `/opt/mapr/hive/hive-<version>/lib/` directory.

```
$ sudo apt-get install  
libmysql-java  
$ ln -s /usr/  
share/java/libmysql-java.jar /opt/  
mapr/hive/hive-<version>/lib/  
mysql-connector-java.jar
```

2. Create the database and an associated user. The following commands are for a Hive Metastore with hostname `metastorehost` to create a MySQL user with name `hive` and password `mypassword`:

```
$ mysql -u root -p  
  
mysql> CREATE DATABASE metastore;  
mysql> CREATE USER 'hive'@'metastorehost' IDENTIFIED BY 'mypassword';  
...  
mysql> REVOKE ALL PRIVILEGES, GRANT OPTION FROM 'hive'@'metastorehost';  
mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'hive'@'metastorehost';  
mysql> FLUSH PRIVILEGES;  
mysql> quit;
```

- Configure the Metastore service to communicate with the MySQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file. Suppose a MySQL database running on `myhost` and the user account `hive` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mysql://myhost/metastore</value>
  <description>the URL of the MySQL database</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.mysql.jdbc.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hive</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

**NOTE:** Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

- Run `schemaTool` to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

#### *Configuring a Remote PostgreSQL Database for the Hive Metastore*

Before you can run the Hive metastore with a remote PostgreSQL database, you must configure a JDBC driver to the remote PostgreSQL database, set up the initial database schema, and configure the PostgreSQL user account for the Hive user.

After installing PostgreSQL, perform the following steps to configure Hive Metastore on PostgreSQL.

#### **Installing and Configuring PostgreSQL for the Hive Metastore**

- Download the PostgreSQL JDBC driver.

Refer to the official [PostgreSQL JDBC Driver website](#) to download the JDBC driver and get information about the latest updates. Determine the appropriate database version and get the released drivers and JAR file.

- Run the following commands using `sudo`:

- a. Move the JAR into the Java share directory:

```
sudo mv <postgresql-jdbc.jar> /usr/share/java/postgresql-jdbc.jar
```

- b. Change the access mode of the JAR file to 644:

```
sudo chmod 644 /usr/share/java/postgresql-jdbc.jar
```

- c. Create symbolic link to the /usr/lib/hive/lib/ directory, for example:

```
sudo ln -s /usr/share/java/postgresql-jdbc.jar /opt/mapr/hive/  
hive-<version>/lib/postgresql-jdbc.jar
```

3. Create the Metastore database and user accounts:

```
$ sudo -u postgres psql  
  
postgres=# CREATE USER hiveuser WITH PASSWORD 'mypassword';  
postgres=# CREATE DATABASE metastore;
```

To verify the connection from the Metastore service host, run the following command:

```
psql -h myhost -U hiveuser -d metastore  
metastore=#
```

4. Configure the Metastore service to communicate with the PostgreSQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file. Suppose a PostgreSQL database running on host `myhost` under the user account `hive` with the password `mypassword`, set the following configuration properties in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:postgresql://myhost/metastore</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>org.postgresql.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

**NOTE:** Though you can use the same `hive-site.xml` properties on all the hosts (client, metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all of the hosts; the other properties are only needed on the Metastore host.

5. Run `schemaTool` to create the initial DB structure:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType postgres -initSchema
```

### *Configuring a Remote Oracle Database for the Hive Metastore*

#### **About this task**

After installing Oracle, perform the following steps to configure Hive Metastore on Oracle.

#### **Procedure**

1. Install the Oracle JDBC Driver.
  - a) Download the Oracle JDBC Driver (`ojdbc6.jar`) from the Oracle [website](#).
  - b) Move the `ojdbc6.jar` file to `/opt/mapr/hive/hive-<version>/lib/` directory

## 2. Create the Metastore database and user account.

Connect to your Oracle database as administrator, create the user that will use the Hive Metastore, and create the Metastore schema. For example:

```
$ sqlplus "sys as sysdba"
SQL> create user hiveuser identified by mypassword;
SQL> grant connect to hiveuser;
SQL> grant all privileges to hiveuser;
SQL>CREATE DATABASE metastore
```

## 3. Configure the Metastore service to communicate with the Oracle database by setting the necessary properties (shown below) in the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file.

Suppose an Oracle database running on `myhost` and the user account `hiveuser` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:oracle:thin:@//myhost/metastore</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>oracle.jdbc.OracleDriver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

**NOTE:** Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

## 4. Run `schemaTool` to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType oracle -initSchema
```

### Configuring an Oracle Schema

You must create schemas for Oracle databases manually.

#### About this task

Use `schematool` to view and create relational database management system (RDBMS) schemas.

See [Apache Hive documentation](#) for the detailed steps.

### *Configuring a Remote MS SQL SERVER Database for the Hive Metastore*

#### **About this task**

After installing MS SQL, perform the following steps to configure Hive Metastore on MS SQL.

#### **Procedure**

1. Create `hiveuser` and Metastore schema.

```
1>CREATE DATABASE metastore;
2>GO
1>CREATE LOGIN <hiveuser> with password='<mypassword>;
2>CREATE USER <hiveuser> for login <hiveuser>;
3>GRANT <PRIVILEGES> to <hiveuser>;
4>GO
```

2. Download JDBC Driver from [here](#), untar the file, and follow instructions in the `install.txt` file to install the driver.

3. Copy the JAR file to `/opt/mapr/hive/hive-version>/lib/` directory.

- For Java 7

```
cp ~/sqljdbc_6.0/enu/jre7/sqljdbc41.jar /opt/mapr/hive/
hive-<version>/lib/
```

- For Java 8

```
cp ~/sqljdbc_6.0/enu/jre8/sqljdbc42.jar /opt/mapr/hive/
hive-<version>/lib/
```

- Configure the Metastore service to communicate with the MS SQL database by setting the necessary properties (shown below) in the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file. Suppose an MS SQL database running on `myhost` and the user account `hiveuser` with the password `mypassword`, set the following properties (overwriting any existing values) in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:sqlserver://<SERVER_NAME>:1433;DatabaseName=metastore;</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.microsoft.sqlserver.jdbc.SQLServerDriver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>mypassword</value>
</property>

<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address (or fully-qualified domain name) and port of
the metastore host</description>
</property>
```

**NOTE:** Though you can set the same `hive-site.xml` properties on all the hosts (client, Metastore, HiveServer), `hive.metastore.uris` is the only property that must be configured on all the hosts; the other properties are only needed on the Metastore host.

- Run `schemaTool` to create the initial DB structure.

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mssql -initSchema
```

### *Configuring MariaDB for the Hive Metastore*

#### **Installing MariaDB**

To install MariaDB, use the MariaDB Repository Configuration Tool. See [MariaDB Downloads](#).

#### **Configuring Repositories**

The following steps describe how to configure a repository and install the latest available stable version of MariaDB for different operating systems.

- Configure a repository for MariaDB:

- **Red Hat / CentOS and SLES**

Copy and paste the following custom MariaDB repository entry into a file under `/etc/yum.repos.d/`. You can name the file `MariaDB.repo` or something similar:

```
# MariaDB 10.4 RedHat repository list
# http://downloads.mariadb.org/mariadb/repositories/
[mariadb]
name = MariaDB
baseurl = http://yum.mariadb.org/10.4/rhel7-amd64
gpgkey=https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
gpgcheck=1
```

- **Ubuntu**

You can also create a custom MariaDB `sources.list` file. To do so, after importing the signing key as outlined above, copy and paste the following into a file under `/etc/apt/sources.list.d/`. You can name the file `MariaDB.list` or something similar. Or you can add it to the bottom of your `/etc/apt/sources.list` file:

```
# MariaDB 10.4 repository list - created 2020-04-17 08:34 UTC
# http://downloads.mariadb.org/mariadb/repositories/
deb [arch=amd64,arm64,ppc64el] http://mirror.mephi.ru/mariadb/repo/
10.4/ubuntu bionic main
deb-src http://mirror.mephi.ru/mariadb/repo/10.4/ubuntu bionic main
```

## 2. After the `sources.list` file is in place, install MariaDB:

- **Red Hat / CentOS**

```
sudo yum clean all && sudo yum install mariadb-server mariadb-client
```

- **SLES**

```
sudo zypper update && sudo zypper install mariadb
```

- **Ubuntu**

```
sudo apt update && sudo apt install mariadb-server
```

## 3. Start the MariaDB server:

- **Red Hat / CentOS and Ubuntu**

```
sudo service mariadb start
```

- **SLES**

```
sudo systemctl start mariadb
```

#### 4. In the command line, run the `mysql_secure_installation` shell script:

```
sudo mysql_secure_installation
Enter current password for root (enter for none): press Enter
Set root password? Y
New password: Type new root password
Re-enter new password: Confirm the password
Remove anonymous users? Y
Disallow root login remotely? Y
Remove test database and access to it? Y
Reload privilege tables now? Y
```

### Configuring a JDBC Driver for MariaDB

Before you can run the Hive Metastore with a MariaDB database, you must:

- Configure a JDBC driver for the MariaDB database.
- Set up the initial database schema.
- Configure the MariaDB user account for the Hive user.

Use the following steps:

1. Install the MariaDB Connector/J manually with a `.jar` file. The MariaDB Connector/J can also be installed by manually installing a `.jar` file to a directory in your CLASSPATH. Download the MariaDB Connector/J `.jar` files from the following URL: <https://downloads.mariadb.com/Connectors/java/connector-java-2.5.4/>.
2. Copy the `.jar` files to the `/opt/mapr/hive/hive-<version>/lib/` directory:

```
cp mariadb-java-client-2.5.4-sources.jar /opt/mapr/hive/
hive-<version>/lib/
cp mariadb-java-client-2.5.4.jar /opt/mapr/hive/hive-<version>/lib/
cp mariadb-java-client-2.5.4-javadoc.jar /opt/mapr/hive/
hive-<version>/lib/
```

3. Restart Hive services:

```
maprcli node services -name hivemeta -action restart -nodes 'hostname -f'
maprcli node services -name hs2 -action restart -nodes 'hostname -f'
```

4. Create the Hive Metastore database and user accounts:

```
$ mysql -u root -p <password>

MariaDB [(none)]> CREATE USER hiveuser IDENTIFIED BY PASSWORD 'password';
MariaDB [(none)]> CREATE DATABASE metastore;
MariaDB [(none)]> REVOKE ALL PRIVILEGES, GRANT OPTION FROM
'hiveuser'@'metastorehost';
MariaDB [(none)]> GRANT ALL PRIVILEGES ON metastore.* TO
'hiveuser'@'metastorehost';
MariaDB [(none)]> FLUSH PRIVILEGES;
MariaDB [(none)]> quit;
```

### Configuring the Hive Metastore on MariaDB

Use these steps:

1. In the Hive configuration directory (`/opt/mapr/hive/hive-<version>/conf`), update the `hive-site.xml` file with the following properties. Beginning with EEP 7.0.0, you must use the MySQL driver with MariaDB:

```
<property>
  <description>the URL of the MariaDB database</description>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mysql://<hostname>:3306/metastore</value>
</property>
<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.mysql.jdbc.Driver</value>
</property>
<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value>hiveuser</value>
</property>
<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value><fill in with password></value>
</property>
<property>
  <description>IP address (or FQDN) and port of the metastore host</
description>
  <name>hive.metastore.uris</name>
  <value>thrift://<hostname>:9083</value>
</property>
```

2. Run the `schematool` command as an initialization step:

```
/opt/mapr/hive/hive-<version>/bin/schematool -dbType mysql -initSchema
```

### User Impersonation for Hive

User impersonation enables Hive to submit jobs as a particular user. Without impersonation, Hive submits queries and hadoop commands as the user that started HiveServer2 and Hive Metastore. On a Data Fabric cluster, this user is typically the `mapr` user or the user specified in the `MAPR_USER` [environment variable](#).

**NOTE:** Impersonation is enabled by default.

#### *Enable User Impersonation*

On non-secure clusters

**Procedure**

1. Set the following properties in the `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where HiveServer2 is installed:

```
<property>
  <name>hive.server2.enable.doAs</name>
  <value>true</value>
  <description>Set this property to enable impersonation in Hive Server
  2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description>Set this property to enable Hive Metastore service
  impersonation in non-secure mode. In non-secure mode, setting this
  property to true will cause the metastore to execute DFS operations
  using the client's reported user and group permissions. Note that this
  property must be set on both the client and server sides. If the client
  sets it to true and the server sets it to false, the client setting will
  be ignored.</description>
</property>
```

2. Set the following property `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where Hive Metastore is installed:

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description>Set this property to enable Hive Metastore service
  impersonation in non-secure mode. In non-secure mode, setting this
  property to true will cause the metastore to execute DFS operations
  using the client's reported user and group permissions. Note that this
  property must be set on both the client and server sides. If the client
  sets it to true and the server sets it to false, the client setting will
  be ignored.</description>
</property>
```

On secure (MAPR-SASL and Kerberos) clusters

**Procedure**

1. Set the following properties in the `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where HiveServer2 is installed:

```
<property>
  <name>hive.server2.enable.doAs</name>
  <value>true</value>
  <description>Set this property to enable impersonation in Hive Server
  2</description>
</property>
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>>false</value>
  <description>Set this property to enable Hive Metastore service
  impersonation in non-secure mode. In non-secure mode, setting this
  property to true will cause the metastore to execute DFS operations
  using the client's reported user and group permissions. Note that this
  property must be set on both the client and server sides. If the client
  sets it to true and the server sets it to false, the client setting will
  be ignored.</description>
</property>
```

2. Set the following property `/opt/mapr/hive/<version>/conf/hive-site.xml` file on the nodes where Hive Metastore is installed:

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>>false</value>
  <description>Set this property to enable Hive Metastore service
  impersonation in non-secure mode. In non-secure mode, setting this
  property to true will cause the metastore to execute DFS operations
  using the client's reported user and group permissions. Note that this
  property must be set on both the client and server sides. If the client
  sets it to true and the server sets it to false, the client setting will
  be ignored.</description>
</property>
```

**NOTE:** The `hive.metastore.execute.setugi` property is set to false automatically after `/opt/mapr/server/configure.sh -R` is running.

On both secure and non-secure clusters

**Procedure**

On nodes where the **Resource Manager** and the **Node Manager** are installed, set the following properties in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file:

```
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value>
  <description>Allow the superuser mapr to impersonate any member of any
  group</description>
</property>
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value>*</value>
  <description>The superuser can connect from any host to impersonate a
```

```
user</description>
</property>
```

## Results

-  **WARNING:** The impersonated user must have write permissions to `/user/hive/warehouse` and `/user/mapr-user/tmp/hive` directories.

*Verify that User Impersonation is Enabled*

### About this task

To verify that Hive queries do not run as the `mapr` user, connect to HiveServer2 as a user other than `mapr`. Then run queries and verify that queries were run as the user that connected to HiveServer2.

To verify that hadoop commands submitted by Hive do not run as the `mapr` user, start the shell or connect to HiveServer2 as a user other than `mapr`. Then create some tables, and verify that the tables in `/user/hive/warehouse` are created under the user that started the shell or the user connected to HiveServer2.

*Example: Hive Impersonation*

The following examples illustrate Hive impersonation:

### Example 1

1. Log in as a non-`mapr` user and generate a Data Fabric ticket:

```
$ su mapruser1
$ maprlogin password
```

2. Connect to HiveServer2:

```
$ hive --service beeline
Beeline version 2.3.3-mapr-SNAPSHOT by Apache Hive
beeline> !connect jdbc:hive2://node4.cluster.com:10000/
default;ssl=true;auth=maprsasl
Connecting to jdbc:hive2://node4.cluster.com:10000/
default;ssl=true;auth=maprsasl
Connected to: Apache Hive (version 2.3.3-mapr-SNAPSHOT)
Driver: Hive JDBC (version 2.3.3-mapr-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

3. Create a table, and upload data:

```
0: jdbc:hive2://node4.cluster.com:10000/defau> create table
impersonation_example_first (id int, username string);
0: jdbc:hive2://node4.cluster.com:10000/defau> insert into
impersonation_example_first values (1, 'mapruser1');
```

4. To check that impersonation works, use the following commands to check the `/warehouse` directory of the Data Fabric file system:

```
$ hadoop fs -ls /user/hive/warehouse
Found 1 items
drwxr-xr-x - mapruser1 mapruser1      1 2019-05-22 14:40
/user/hive/warehouse/impersonation_example_first

$ hadoop fs -ls /user/hive/warehouse/impersonation_example_first
Found 1 items
-rwxrwxrwx  3 mapruser1 mapruser1      12 2019-10-15 07:21
/user/hive/warehouse/impersonation_example_first/000000_0
```

## Example 2

1. Generate a Data Fabric ticket for a non-mapr user.
2. Connect through JDBC using the `hive.server2.proxy.user` option with a non-mapr user name as an argument:

```
$ hive --service beeline
beeline> !connect
jdbc:hive2://node4.cluster.com:10000/
default;auth=maprsasl;ssl=true;hive.server2.proxy.user=mapruser1
Connecting to
jdbc:hive2://node4.cluster.com:10000/
default;auth=maprsasl;ssl=true;hive.server2.proxy.user=mapruser1
Client: auth-conf,auth-int,auth.Using Server one
Connected to: Apache Hive (version 2.3.3-mapr-SNAPSHOT)
Driver: Hive JDBC (version 2.3.3-mapr-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

3. Create a table and upload data:

```
0: jdbc:hive2://node4.cluster.com:10000/default> create table
impersonation_example_second (id int);
0: jdbc:hive2://node4.cluster.com:10000/default> insert into table
impersonation_example_second values (1), (2), (3), (5);
```

4. Check the owner of the table and data:

```
$ hadoop fs -ls /user/hive/warehouse/impersonation_example_second
Found 1 items
drwxrwxrwx - mapruser1 mapruser1      1 2019-05-23 12:29
/user/hive/warehouse/impersonation_example_second

$ hadoop fs -ls /user/hive/warehouse/impersonation_example_second
Found 1 items
-rwxrwxrwx  3 mapruser1 mapruser1      8 2019-05-23 12:29
/user/hive/warehouse/impersonation_example_second/000000_0
```

## Hive Security

You can configure the following features for Hive security:

### Hive Security Configuration Options

This section describes changes made in Hive default configuration. It shows how to configure Hive after manual installation.

Unlike the previous releases, starting in EEP 4.0, Hive should be configured by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option after installing Hive. Hive demons will not start automatically if Hive is not configured correctly. The security configuration are described in the following sections:

1. Automatic
2. Manual
3. Custom

**NOTE:** Do not use ecosystem `$HIVE_HOME/bin/configure.sh` script for Hive configuration. Every configuration of Hive should be done via the `$MAPR_HOME/server/configure.sh` utility by running it with the `-R` option. The core `$MAPR_HOME/server/configure.sh` utility invokes the ecosystem `configure.sh` script automatically with appropriate security option.

#### Automatic

If you installed Hive using the Data Fabric Installer, the Data Fabric Installer configures Hive daemons during installation. Additional configuration is not required.

#### Manual

After a new manual installation, to generate a valid default ecosystem configuration, run:

```
$MAPR_HOME/server/configure.sh -R
```

Table

Node, Package	Hive	HiveServer2	Hive Metastore	WebHCat
Node 1	X	X		
Node 2	X		X	
Node 3	X			X

- After a manual installation, run the following command on Node 1, Node 2, and Node 3:

```
$MAPR_HOME/server/configure.sh -R
```

As a result:

- All Hive daemons are configured to support MapR-SASL. If the `hive.metastore.sasl.enabled` property is enabled in the `hive-site.xml` file, its value is set to `true`. If the property is not present, it is added in the `configuration` section as follows:

```
<property>
  <name>hive.metastore.sasl.enabled</name>
  <value>true</value>
</property>
```

- HiveServer2 is configured to support encryption between Hiveserver2 and Hive clients. If the `hive.server2.thrift.sasl.qop` property is available in the `hive-site.xml` file, its value is set to `auth-conf`. If the property is not present, it is added in the configuration section as follows:

```
<property>
  <name>hive.server2.thrift.sasl.qop</name>
  <value>auth-conf</value>
</property>
```

- The `configure.sh` script creates a backup folder for the current Hive configuration before it changes the configuration. All configuration properties including `*.conf`, `*.properties`, and `*.xml` are saved in the backup folder.

```
$HIVE_HOME/conf.YYYYMMDD_HHMMSS
```

- 644 Unix permissions are applied to all configuration files. Each run of `configure.sh` with the `-R` option overwrites permissions of the configuration files to 644.
- The Hive default ports listed below are verified as available. If a port is not available, the `configure.sh` script generates an error message during configuration.

Hive default ports are as follows:

Role	Default Port
Hive Metastore	9083
HiveServer2	10000
HiveWebHCat	50111

### Custom

For PAM, LDAP, and Kerberos custom configurations, run `configure.sh` with the `-R` option:

```
$MAPR_HOME/server/configure.sh -R
```

The `hive-site.xml` file is not changed. However, Warden files are copied and a `HIVE_HOME/conf` backup folder is created.

### Preventing a Non-Administrative User from Installing Hooks

For a fresh install of EEP 6.1, a non-administrative user is prevented from installing hooks by default. For a minor version update (for example, EEP 6.0.0 to EEP 6.1.0 or EEP 5.0.1 to EEP 5.0.2), you need to modify the Hive configuration to prevent a malicious user from using Hive hooks to install malware on your Data Fabric cluster.

#### About this task

In general, a hook is a mechanism for intercepting events, messages, or function calls during processing. Hive hooks are a mechanism to tie into the internal workings of Hive without the need of re-compiling Hive. Hive hooks, in this sense, provide the ability to extend and integrate external functionality with Hive.

Any user using beeline can install Java code as a Hive hook. On HPE Ezmeral Data Fabric, these hooks run as the `mapr` user, which could represent a security vulnerability. To prevent a malicious user from using Hive hooks to install malware on a Data Fabric cluster, the cluster admin should add the following properties to the default value of `hive.conf.restricted.list` in the `hive-site.xml` file, and then restart HiveServer 2 (HS2):

- `hive.exec.pre.hooks`

- `hive.exec.post.hooks`
- `hive.exec.failure.hooks`
- `hive.exec.query.redactor.hooks`

Adding the properties prevents a non-admin user from installing hooks into Hive.

### Procedure

1. Add all hook-related properties to the default value of `hive.conf.restricted.list` in the `hive-site.xml` file:

#### Hive 2.3

- `hive.exec.pre.hooks`
- `hive.exec.post.hooks`
- `hive.exec.failure.hooks`
- `hive.exec.query.redactor.hooks`
- `hive.semantic.analyzer.hook`
- `hive.query.lifetime.hooks`
- `hive.exec.driver.run.hooks`
- `hive.server2.session.hook`

#### Hive 2.1

- `hive.exec.pre.hooks`
- `hive.exec.post.hooks`
- `hive.exec.failure.hooks`
- `hive.exec.query.redactor.hooks`
- `hive.semantic.analyzer.hook`
- `hive.exec.driver.run.hooks`
- `hive.server2.session.hook`

2. Make sure `hive.conf.restricted.list` configuration parameter already has a default value which contains:

#### Hive 2.3

```
hive.security.authenticator.manager
hive.security.authorization.manager
Hive.security.metastore.authorization.manager
hive.security.metastore.authenticator.manager
Hive.users.in.admin.role,hive.server2.xsrf.filter.enabled
hive.security.authorization.enabled
hive.server2.authentication.ldap.basedn
hive.server2.authentication.ldap.url
hive.server2.authentication.ldap.Domain
```

```
hive.server2.authentication.ldap.groupDNPattern
hive.server2.authentication.ldap.groupFilter
hive.server2.authentication.ldap.use
rDNPattern
hive.server2.authentication.ldap.use
rFilter
hive.server2.authentication.ldap.groupMembershipKey
hive.server2.authentication.ldap.use
rMembershipKey
hive.server2.authentication.ldap.groupClassKey
hive.server2.authentication.ldap.customLDAPQuery
```

**Hive 2.1**

```
hive.security.authenticator.manager
hive.security.authorization.manager
hive.users.in.admin.role
hive.server2.xsrf.filter.enabled
```

3. Add the default values already present in `hive.conf.restricted.list` to the `hive-site.xml` file:

**Hive 2.3**

```
<property>
  <name>hive.conf.restricted.list</
name>
  <value>

hive.security.authenticator.manager,
hive.security.authorization.manager,
hive.security.metastore.authorization
n.manager,
hive.security.metastore.authenticato
r.manager,
hive.users.in.admin.role,hive.server
2.xsrf.filter.enabled,
hive.security.authorization.enabled,
hive.server2.authentication.ldap.bas
eDN,
hive.server2.authentication.ldap.url
,
hive.server2.authentication.ldap.Dom
ain,
hive.server2.authentication.ldap.gro
upDNPattern,
hive.server2.authentication.ldap.gro
```

```

upFilter,

hive.server2.authentication.ldap.use
rDNPattern,

hive.server2.authentication.ldap.use
rFilter,

hive.server2.authentication.ldap.gro
upMembershipKey,

hive.server2.authentication.ldap.use
rMembershipKey,

hive.server2.authentication.ldap.gro
upClassKey,

hive.server2.authentication.ldap.cus
tomLDAPQuery,
    hive.exec.pre.hooks,
    hive.exec.post.hooks,
    hive.exec.failure.hooks,
    hive.exec.query.redactor.hooks,
    hive.semantic.analyzer.hook,
    hive.query.lifetime.hooks,
    hive.exec.driver.run.hooks,
    hive.server2.session.hook,
    </value>
</property>

```

## Hive 2.1

```

<property>
  <name>hive.conf.restricted.list</
name>
  <value>

hive.security.authenticator.manager,

hive.security.authorization.manager,
    hive.users.in.admin.role,

hive.server2.xsrf.filter.enabled,
    hive.exec.pre.hooks,
    hive.exec.post.hooks,
    hive.exec.failure.hooks,
    hive.exec.query.redactor.hooks,
    hive.semantic.analyzer.hook,
    hive.exec.driver.run.hooks,
    hive.server2.session.hook,
    </value>
</property>

```

**NOTE:** Values of the `hive.conf.restricted.list` are split into separate lines for better readability. In the actual `hive-site.xml` file, no spaces or newlines exist between the commas.

### Configuring Security Headers for Web Servers

This section describes how to configure response headers for REST API servers used in Hive WebHCat and the HiveServer2 web UI.

## About the Headers File

The XML file with security headers is located at:

```
/opt/mapr/hive/hive-<version>/conf/headres.xml
```

The headres.xml file contains the following headers:

```
<?xml version="1.0" encoding="utf-8" ?>
<!DOCTYPE properties SYSTEM "http://java.sun.com/dtd/properties.dtd">
<properties>
  <entry key="X-Content-Type-Options">nosniff</entry>
  <entry key="X-XSS-Protection">1; mode=block</entry>
  <entry key="Strict-Transport-Security">max-age=31536000;
includeSubDomains</entry>
  <entry key="Content-Security-Policy">default-src https:</entry>
</properties>
```

This table describes each header:

Header	Description	Default Value
X-XSS-Protection	Stops pages from loading when reflected cross-site scripting (XSS) is detected. Supported by IE, Chrome, and Safari.	1: mode=block
X-Content-Type-Options	Indicates that the MIME types advertised in the Content-Type headers should not be changed and should be followed.	nosniff
Strict-Transport-Security	Tells all browsers that the website should only be accessed using HTTPS instead of using HTTP.	max-age=31536000;includeSubDomains
Content-Security-Policy	Allows web-site administrators to control resources the user agent is allowed to load for a given page. This helps guard against cross-site scripting attacks (XSS).	default-src https:

## Configuring Security Headers for WebHCat

To enable security headers for WebHCat, add the following to the webhcat-site.xml file, and replace <version> with your Hive version:

```
<property>
<name>templeton.jetty.response.headers.file</name>
<value>/opt/mapr/hive/hive-<version>/conf/headers.xml</value>
</property>
```

After configuring and restarting WebHCat, you should see security headers in the server response. For example:

```
< HTTP/1.1 200 OK
< Date: Thu, 03 Oct 2019 11:35:39 GMT
< Set-Cookie:
hadoop.auth="u=mapr&p=mapr&t=multiauth&e=1570138539451&s=CpX+tI7sScnnSUZpAlK
df+7hamM="; Path=/; Domain=.cluster.com; Expires=Thu, 03-Oct-2019 21:35:39
GMT; Secure; HttpOnly
< Content-Security-Policy: default-src https:
< X-XSS-Protection: 1; mode=block
< X-Content-Type-Options: nosniff
< Strict-Transport-Security: max-age=31536000
< Content-Type: application/json
```

```
< Transfer-Encoding: chunked
< Server: Jetty(9.4.19.v20190610)
```

### Configuring Security Headers for HiveServer2 Web UI

To enable security headers for the Hiveserver2 Web UI, add the following to the `hive-site.xml` file, replacing `<version>` with your Hive version:

```
<property>
  <name>hive.server2.webui.jetty.response.headers.file</name>
  <value>/opt/mapr/hive/hive-<version>/conf/headers.xml</value>
</property>
```

Then restart HiveServer2.

### Configuring Custom Headers

To configure custom headers for web servers, edit the `headers.xml` file, and add `Custom-header` as follows:

```
<entry key="Custom-header">custom-value</entry>
```

### Security Headers Auto-Configuration

If you install Hive on a secure cluster (MapR SASL or Kerberos) and run the following command after Hive installation, Hive automatically configures itself to enable security headers, and no additional action is needed:

```
/opt/mapr/server/configure.sh -R
```

#### *Hive Authentication*

The authentication method that you configure for the Hive Metastore, HiveServer2, and WebHcat determines how these Hive components access and connect to each other.

Clients of these components may require additional configuration and specific connection strings based on the selected authentication method.

To enable and use authentication for Hive, complete the following steps:

1. Determine which authentication methods are supported for each component and its clients.
2. Configure authentication for Hive components and their clients. See the following topics:
  - [Authentication for Hive Metastore](#)
  - [Authentication for HiveServer2](#)
  - [Authentication for WebHCat](#)
3. Determine how clients connect to each component. See [Connecting to Hive](#).

### Hive Metastore Authentication Support

The following table describes the different supported authentication methods for Hive Metastore and how it impacts the authentication options for its clients:

Data Fabric Cluster	Hive Metastore (Remote) Authentication	HiveServer 2 Authentication Options	WebHCat Authentication Options
Secure	NONE	<ul style="list-style-type: none"> <li>• NONE</li> <li>• KERBEROS</li> <li>• LDAP</li> <li>• PAM</li> <li>• CUSTOM</li> <li>• MAPRSASL</li> <li>• NOSASL</li> </ul>	PAM
Secure	KERBEROS	KERBEROS	KERBEROS with <a href="#">SPNEGO</a>
Secure	MAPRSASL (default)*	MAPRSASL (default)*	PAM
Not Secure	NONE	NONE	Simple authentication with <user.name> only

\*As of Hive 0.13-1504 and Hive 1.0-1504, Hive Metastore supports MapR-SASL and MapR-SASL is enabled by default when the Data Fabric cluster is secure.

### HiveServer2 Authentication Support

The following table describes the different supported authentication option for HiveServer2 based on the authentication method configured for Hive Metastore:

Data Fabric Cluster	Hive Metastore (Remote) Authentication	HiveServer 2 Authentication Options
Secure	NONE	NONE
Secure	NONE	KERBEROS
Secure	NONE	LDAP
Secure	NONE	PAM (default)*
Secure	NONE	CUSTOM
Secure	NONE	MAPRSASL*
Secure	KERBEROS	KERBEROS
Secure	MAPRSASL (default)*	MAPRSASL*
Not Secure	NONE	NONE

\*As of Hive 0.13-1510, Hive 1.0-1510, and Hive 1.2.1-1510, PAM and MapR-SASL are enabled by default when the cluster is secure. In Hive 0.13-1508 and Hive 1.0-1508, PAM is enabled by default when the cluster is secure. In Hive 0.13-1504 and Hive 1.0-1504, MapR-SASL is supported and enabled by default when the Data Fabric cluster is secure.

Clients of HiveServer2 authenticate with the same authentication method that is configured for HiveServer2. Clients of HiveServer 2 include ODBC, JDBC, and Beeline.

 **NOTE:** Connections to HiveServer2 using ODBC do not support MapR-SASL.

### WebHCat Authentication Support

The following table describes the different authentication options for WebHCat based on the authentication method configured for Hive Metastore :

Data Fabric Cluster	Hive Metastore (Remote) Authentication	WebHCat Authentication
Secure	KERBEROS	KERBEROS with <a href="#">SPNEGO</a>
Secure	KERBEROS	PAM
Secure	MAPRSASL (default)*	PAM
Not Secure	NONE	Simple authentication with user.name only

\*As of Hive 0.13-1504 and Hive 1.0-1504, Hive Metastore supports MapR-SASL and MapR-SASL is enabled by default when the Data Fabric cluster is secure.

Clients of WebHCat authenticate with the same authentication method that is configured for WebHCat. Web browsers are clients of WebHCat.

### Description of Security Values

The following table describes the different security values:

Authentication Options	Description
NONE	No authentication check
LDAP	LDAP/AD based authentication
KERBEROS	Kerberos/GSSAPI authentication
CUSTOM	Custom authentication provider (use with property <code>hive.server2.custom.authentication.class</code> )
PAM	Pluggable authentication module
NOSASL	Raw transport
MAPRSASL	MapR SASL security

### Authentication for Hive Metastore

You can configure authentication for in-bound client connections to the Hive Metastore when the metastore is remote, not embedded. Clients of Hive Metastore include the HiveCLI, HCatalog, HiveServer2, and WebHCat.

Hive Metastore supports the following authentication methods:

- MapR-SASL authentication
- Kerberos Authentication

### MapR-SASL Authentication

MapR-SASL is available starting with the 1504 release of Hive 0.13 and Hive 1.0 and it is the default authentication method when the cluster is secure.

## Kerberos Authentication

When the cluster is secure, you can configure Hive Metastore to use Kerberos authentication. You must also configure Hive Metastore clients to use Kerberos when authenticating with Hive Metastore.

### Configuring Hive Metastore Authentication

This section describes how to configure the `hive.metastore.authentication` property for secured and unsecured clusters. It describes cases when the property must be configured explicitly and when it can be omitted from `hive-site.xml`.

Hive Metastore supports two types of authentication: `MAPRSASL` and `KERBEROS`. At startup, Hive Metastore reads the system property `metastore.auth`. If `metastore.auth` is equal to null, then the authentication type is `NONE`. Otherwise, Hive Metastore takes the value of the system property `metastore.auth` and assigns it to the Hive Metastore configuration property `hive.metastore.authentication`.

You do not need to set up the `metastore.auth` system property manually. If a cluster is secured, Hive assigns the `MAPRSASL` value to the `metastore.auth` property. If a cluster is not secured, Hive assigns the `NONE` value to the `metastore.auth` property.

To enable Kerberos authentication, set the value of `hive.metastore.authentication` directly in `hive-site.xml`, as shown in the following table:

**Table**

Security	Value of <code>hive.metastore.authentication</code>	Notes
No security	<code>NONE</code>	The value is set automatically. You do not need to make an entry in <code>hive-site.xml</code> .
MapR SASL security	<code>MAPRSASL</code>	The value is set automatically. You do not need to make an entry in <code>hive-site.xml</code> .
Kerberos security	<code>KERBEROS</code>	You must make the following entry in <code>hive-site.xml</code> : <pre>&lt;property&gt; &lt;name&gt;hive.metastore.authentication&lt;/name&gt; &lt;value&gt;KERBEROS&lt;/value&gt; &lt;/property&gt;</pre>

### Configure Hive Metastore to use MapR-SASL

#### About this task

#### Procedure

Edit the `/opt/mapr/conf/env.sh` file and set the following properties:

```
MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"
MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab"
```

### Configuring Hive Metastore Clients to use MapR-SASL

#### About this task

The Hive metastore clients are configured to use MapR-SASL when authenticating with Hive Metastore.

 **NOTE:** Hive Metastore clients must provide a valid Data Fabric ticket to connect to the Hive Metastore. See [Connecting to Hive](#) on page 4282 for details.

### Procedure

1. Ensure that the cluster is secure.
2. Edit the `/opt/mapr/conf/env.sh` file and set the following property:

```
MAPR_HIVE_LOGIN_OPTS="-D hadoop.login=maprsasl"
```

Configure Hive Metastore to use Kerberos

### About this task

Enabling Hive Metastore to use Kerberos authentication requires a kerberos principal, kerberos keytab, and the following configurations.

Complete the following steps on each node where a Hive Metastore is installed:

### Procedure

1. Create a Kerberos server identity and add it to a keytab file. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file:

 **NOTE:** MapR clusters do not provide Kerberos infrastructure. The tips in this step assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

```
# kadmin
: addprinc -randkey username/<FQDN@REALM>
: ktadd -k /opt/mapr/conf/hive.keytab username/<FQDN@REALM>
```

The `hive.keytab` file must be owned and readable only by the `mapr` user.

2. Configure the following properties in the following file:

```
/opt/mapr/hive/hive-<version>/conf/hive-site.xml
```

Property	Value
<code>hive.metastore.kerberos.keytab.file</code>	The Keytab file that contains the HiveMetastore principal.
<code>hive.metastore.kerberos.principal</code>	<The HiveMetastore principal. For example, mapr/<FQDN@REALM>.>

```
<property>
  <name>hive.metastore.kerberos.keytab.file</name>
  <value>/opt/mapr/conf/metastore.keytab</value>
  <description>The path to the Kerberos Keytab file
  containing the metastore thrift server's service principal.</
description>
</property>
<property>
  <name>hive.metastore.kerberos.principal</name>
  <value>mapr/<FQDN@REALM></value>
```

```
<description>The service principal for the metastore thrift server.
The special string _HOST will be replaced automatically with the correct
hostname.</description>
</property>
```

3. Configure the following properties in `/opt/mapr/conf/env.sh` on each node where the Hive Metastore is installed:

- Set `MAPR_HIVE_LOGIN_OPTS` to

```
"-Dhadoop.login=hybrid"
```

- Set `MAPR_HIVE_SERVER_LOGIN_OPTS` to

```
"-Dhadoop.login=hybrid"
```

### Configure Hive Metastore Clients to use Kerberos

When the Hive Metastore is configured to use Kerberos authentication, you must also configure Hive Metastore Clients to use Kerberos when authenticating with Hive Metastore.

#### About this task

Complete the following steps on each node where a Hive Metastore client is installed:

#### Procedure

1. Configure `MAPR_HIVE_LOGIN_OPTS` to `"-Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.
2. Configure the following property in `hive-site.xml`:

Property	Value
<code>hive.metastore.kerberos.principal</code>	The HiveMetastore principal. For example, <code>mapr/&lt;FQDN@REALM&gt;</code> .

```
<property>
  <name>hive.metastore.kerberos.principal</name>
  <value>mapr/<FQDN@REALM></value>
  <description>The service principal for the metastore thrift server.
The special string _HOST will be replaced automatically with the correct
hostname.</description>
</property>
```

#### What to do next

See [Connecting to Hive](#) on page 4282 for details on how to connect to HiveMetastore once the server and client node are configured to use Kerberos.

**NOTE:** The `MAPR_HIVE_LOGIN_OPTS` and `MAPR_HIVE_SERVER_LOGIN_OPTS` were added in 1504 release of Hive 0.13 and Hive 1.0. If you have Hive 0.13 from a prior release, you do not need to configure these properties. Instead, set `MAPR_ECOSYSTEM_LOGIN_OPTS` and `MAPR_ECOSYSTEM_SERVER_LOGIN_OPTS` to `"-Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.

### Authentication for HiveServer2

You can configure authentication for in-bound client connection to HiveServer2. Clients of HiveServer 2 include beeline and odbc/jdbc client applications.

Credentials are submitted from the HiveServer2 clients to HiveServer2 as plain text. To secure the credential transmission, MapR supports SSL encryption for HiveServer2. For information about how to configure encryption, see [Hive Encryption](#).

HiveServer2 supports the following authentication methods:

#### Configure MapR-SASL Authentication for HiveServer 2

##### About this task

MapR-SASL is available starting with the 1504 release of Hive 0.13 and Hive 1.0. However, the configuration requirements for MapR-SASL differ based on the version of Hive that you have installed:

- As of Hive 0.13-1501, Hive 1.0-1510, and Hive 1.2-1510, MapR-SASL and PAM are enabled by default on a secure cluster; no configuration is required. Complete the steps below if you want HiveServer2 to only accept MapR-SASL authentication.
- In Hive 0.13-1508 and Hive 1.0-1508, MapR-SASL is not the default and must be configured.
- In Hive 0.13-1504 and Hive 1.0-1504, MapR-SASL is the default authentication method when the cluster is secure. No configuration is required.

##### Procedure

1. Configure the following property in hive-site.xml on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	MAPRSASL

```
<property> <name>hive.server2.authentication</name> <value>MAPRSASL</value></property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated list of nodes>
```

#### Configure HiveServer2 to use LDAP Authentication

##### Procedure

1. Configure the following properties in the hive-site.xml file on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	LDAP
hive.server2.authentication.ldap.url	The access URL for your LDAP server
hive.server2.authentication.ldap.baseDN	The base LDAP DN for your LDAP server. For example, ou=People,dc=mycompany,dc=com.

Property	Value
hive.server2.authentication.ldap.userDNPattern	User DN Pattern - A DN pattern that can be used to directly login users to the LDAP database. This pattern is used for creating a DN string for "direct" user authentication, where the pattern is relative to the base DN in ldapUrl.

```
<property>
  <name>hive.server2.authentication</name>
  <value>LDAP</value>
</property>
<property>
  <name>hive.server2.authentication.ldap.url</name>
  <value><LDAP URL></value>
</property>
<property>
  <name>hive.server2.authentication.ldap.baseDN</name>
  <value><LDAP Base DN></value>
</property>
```

For generic LDAP servers, you must use:

- a. hive.server2.authentication.ldap.baseDN
- b. hive.server2.authentication.ldap.userDNPattern

However, Active Directory (AD) does not require the above two options, they can be replaced by the following property:

- hive.server2.authentication.ldap.Domain

Property	Value
hive.server2.authentication.ldap.Domain	The active directory domain for your environment.

```
<property>
  <name>hive.server2.authentication.ldap.Domain</name>
  <value><AD Domain Name></value>
</property>
```

## 2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

Configure HiveServer2 to use PAM Authentication

### About this task

You can configure HiveServer2 to use Pluggable Access Modules (PAM). The configuration requirements for PAM differ based on the version of Hive that you have installed.

Hive Version	Default Configuration	Configuration Requirement
--------------	-----------------------	---------------------------

Hive 2.3	1904	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1901	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1808	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
Hive 2.1	1904	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1901	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1808	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.
	1803	MapR-SASL and PAM are enabled by default on a secure cluster.	No configuration is required.

Configure HiveServer2 to explicitly use PAM Authentication

### Procedure

1. In the `hive-site.xml` on each HiveServer2 node, set the `hive.server2.authentication` property to PAM:

```
<property>
  <name>hive.server2.authentication</name>
  <value>PAM</value>
</property>
```

2. Restart HiveServer2 to apply these changes:

```
maprcli node services -name hs2 -action restart -nodes <comma-separated
list of nodes>
```

Configure HiveServer 2 to use Custom Authentication

## Procedure

1. Create a custom Authenticator class derived from the following interface:

```
public interface PasswdAuthenticationProvider {
    /**
     * The Authenticate method is called by the HiveServer2 authentication
     layer
     * to authenticate users for their requests.
     * If a user is to be granted, return nothing/throw nothing.
     * When a user is to be disallowed, throw an appropriate {@link
     AuthenticationException}.
     *
     * For an example implementation, see {@link
     LdapAuthenticationProviderImpl}.
     *
     * @param user - The username received over the connection request
     * @param password - The password received over the connection request
     * @throws AuthenticationException - When a user is found to be
     * invalid by the implementation
     */
    void Authenticate(String user, String password) throws
    AuthenticationException;
}
```

The [SampleAuthenticator.java](#) on page 4201 code has an example implementation that has stored usernames and passwords.

2. Configure the following properties in the `hive-site.xml` file on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	CUSTOM
hive.server2.custom.authentication.class	The authentication class name. For example, <code>hive.server2.custom.authentication.class</code>

```
<property>
<name>hive.server2.authentication</name>
<value>CUSTOM</value>
</property>

<property>
<name>hive.server2.custom.authentication.class</name>
<value>hive.test.SampleAuthenticator</value>
</property>
```

3. Restart Hiveserver2 to apply the changes:

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

### SampleAuthenticator.java

```
package hive.test;

import java.util.Hashtable;
import javax.security.sasl.AuthenticationException;
import org.apache.hive.service.auth.PasswdAuthenticationProvider;
```

```

/*
javac -cp $HIVE_HOME/lib/hive-service-0.11-mapr.jar
SampleAuthenticator.java -d .
jar cf sampleauth.jar hive
cp sampleauth.jar $HIVE_HOME/lib/.
*/

public class SampleAuthenticator implements PasswdAuthenticationProvider {

    Hashtable<String, String> store = null;

    public SampleAuthenticator () {
        store = new Hashtable<String, String>();
        store.put("user1", "passwd1");
        store.put("user2", "passwd2");
    }

    @Override
    public void Authenticate(String user, String password)
        throws AuthenticationException {

        String storedPasswd = store.get(user);

        if (storedPasswd != null && storedPasswd.equals(password))
            return;

        throw new AuthenticationException("SampleAuthenticator: Error
validating user");
    }
}

```

## Configure HiveServer 2 to use Kerberos

### About this task

**NOTE:** You can configure HiveServer2 to use Kerberos authentication. Data Fabric clusters do not provide Kerberos infrastructure. The tips in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

Enabling HiveServer to use Kerberos authentication requires following steps on each node where HiveServer 2 is installed:

### Procedure

1. Create a Kerberos Identity and keytab. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file: The `hive.keytab` file must be owned and readable only by the `mapr` user.

```

# kadmin
: addprinc -randkey username/<FQDN@REALM>
: ktadd -k /opt/mapr/conf/hive.keytab username/<FQDN@REALM>

```

2. Configure the following properties in `hive-site.xml` on each node where `hiveserver2` is installed:

v

Property	Value
hive.server2.authentication	KERBEROS
hive.server2.authentication.kerberos.principal	<HiveServer2 Principle. For example, mapr/ FQDN@REALM>
hive.server2.authentication.kerberos.keytab	<The keytab file for the HiverServer2 principle. For example, /opt/mapr/conf/hive.keytab>

```
<property>
  <name>hive.server2.authentication</name>
  <value>KERBEROS</value>
  <description>authenticationtype</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.principal</name>
  <value>mapr/FQDN@REALM</value>
  <description>HiveServer2 principal. If _HOST is used as the FQDN
portion, it will be replaced with the actual hostname of the running
instance.</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.keytab</name>
  <value>/opt/mapr/conf/hive.keytab</value>
  <description>Keytab file for HiveServer2 principal</description>
</property>
```

3. Reconfigure the following options in `env.sh (/opt/mapr/conf/env.sh)` on each node where `hiveserver2` is installed:

**NOTE:** These configurations are listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the changes in the `/opt/mapr/conf/env_override.sh` file. For more information, see [About env\\_override.sh](#) on page 3082.

Existing Configuration	Required Configuration
<pre>MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab" MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"</pre>	<pre>MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=hybrid"  MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"</pre>

4. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated list of nodes>
```

### Configure HiveServer 2 Clients to use Kerberos

#### About this task

When HiveServer 2 is configured to use Kerberos authentication, you must also configure HiveServer2 clients to use Kerberos.

On each node where HiveServer2 clients (not including Beeline) are installed, reconfigure the following option in `env.sh` (`/opt/mapr/conf/env.sh`) file:

Existing Configuration	Required Configuration
<code>MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprasl"</code>	<code>MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"</code>

**NOTE:** This configuration is listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the change in the `/opt/mapr/conf/env_override.sh` file. For more information, see [About env\\_override.sh](#) on page 3082.

On each node where Beeline is installed, reconfigure the following option in `beeline.sh` (`$hive_home/bin/ext/beeline.sh`) file:

Existing Configuration	Required Configuration
<code>HADOOP_OPTS="\$HADOOP_OPTS\$ {MAPR_HIVE_LOGIN_OPTS}"</code>	<code>HADOOP_OPTS="\$HADOOP_OPTS\$ {KERBEROS_LOGIN_OPTS}"</code>

For more information, see [Connecting to Hive](#) on page 4282.

**NOTE:** The `MAPR_HIVE_LOGIN_OPTS` and `MAPR_HIVE_SERVER_LOGIN_OPTS` were added in 1504 release of Hive 0.13 and Hive 1.0. If you have Hive 0.13 from a prior release, you do not need to configure these properties. Instead, set `MAPR_ECOSYSTEM_LOGIN_OPTS` and `MAPR_ECOSYSTEM_SERVER_LOGIN_OPTS` to `"-Dhadoop.login=hybrid"` in `/opt/mapr/conf/env.sh`.

Configure HiveServer2 Web UI to use PAM Authentication

### About this task

You can configure HiveServer2 web UI to use Pluggable Access Modules (PAM) authentication. The following Hive properties are added to enable PAM authentication for the HiveServer2 web UI:

```
hive.server2.webui.use.pam
Default value: false
Description: If true, the HiveServer2 WebUI will be secured with PAM
```

```
hive.server2.webui.pam.authenticator
Default value: org.apache.hive.http.security.PamAuthenticator
Description: Class for PAM authentication
```

### Modifying the hive-site.xml file:

#### Procedure

Configure the following properties in the `hive-site.xml` file to enable authentication on each node where HiveServer2 is installed:

```
<!-- HS2 web UI PAM -->
<property>
  <name>hive.server2.webui.use.pam</name>
  <value>true</value>
</property>
```

```

<!-- HS2 web UI SSL -->
<property>
  <name>hive.server2.webui.use.ssl</name>
  <value>true</value>
</property>

<property>
  <name>hive.server2.webui.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
</property>

<property>
  <name>hive.server2.webui.keystore.password</name>
  <value><ssl-keystore-password></value>
</property>

```

**NOTE:** After running `/opt/mapr/server/configure.sh -R`, all properties needed for HiveServer2 Web UI to use PAM authentication is added automatically to `hive-site.xml` on the MapR-SASL secure cluster. Connections to HiveServer2 using ODBC do not support MapR-SASL.

## Authentication for WebHCat

You can configure authentication for in-bound client connections to WebHCat. Clients of WebHCat include web browsers. WebHCat is a client of Hive Metastore.

WebHCat supports the following authentication methods:

## Configure Kerberos Authentication for WebHCat

### About this task

When security features are enabled on your Data Fabric cluster and Kerberos is in use, communications between WebHCat and its clients can use Kerberos with [SPNEGO](#).

To enable WebHCat to use Kerberos, complete the following steps on the node where WebHCat is installed.

### Procedure

1. Create the principal `HTTP/<FQDN@REALM>` for WebHCat and add the principal to the keytab file. For example:

```

kadmin: addprinc -randkey HTTP/<FQDN@REALM>
kadmin: xst -k /opt/mapr/conf/HTTP.keytab HTTP/<FQDN>

```

2. Verify the following:

- The principal was added to the `/opt/mapr/conf/HTTP.keytab` file and that the file is only readable by the `mapr` user. For example: `chown mapr /opt/mapr/conf/HTTP.keytab`
- The node where the WebHCat server is running has an HTTP user with a valid `maprlogin` password.

3. Add the following section to the `/opt/mapr/hive/hive-<version>/hcatalog/etc/webhcat/webhcat-site.xml` file:

```
<property>
  <name>templeton.kerberos.secret</name>
  <value>secret value</value>
</property>
<property>
  <name>templeton.kerberos.principal</name>
  <value>HTTP/<FQDN@REALM></value>
</property>
<property>
  <name>templeton.kerberos.keytab</name>
  <value>/opt/mapr/conf/HTTP.keytab</value>
</property>
```

4. Add the following section to the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file:

```
<property>
  <name>hadoop.proxyuser.HTTP.groups</name>
  <value>*</value>
  <description>Allow the superuser mapr to impersonate any member of
any group</description>
</property>
<property>
  <name>hadoop.proxyuser.HTTP.hosts</name>
  <value>*</value>
  <description>The superuser can connect from any host to
impersonate a user</description>
</property>
```

5. Start WebHCat. See [Managing the WebHCat Server](#).
6. To test if the connection is working, generate a Kerberos ticket with the `kinit` utility and then run the following command:

```
curl --negotiate -i -u : 'http://<FQDN>:50111/templeton/v1/ddl/
database/'
```

#### Configure Simple Authentication for WebHCat

When the Data Fabric cluster is not secure, simple authentication is enabled for WebHCat. No configuration is required.

#### Configure PAM Authentication for WebHCat

When the Data Fabric cluster is secure, username and password authentication is enabled for WebHCat. No configuration is required.

#### *Configuring Hive for SCRAM Token Authentication*

This topic describes the manual and automatic options to configure Hive for SCRAM token authentication.

Starting from EEP 8.1.0, Hive supports SCRAM token and SCRAM-SHA-256 authentication in HPE Ezmeral Data Fabric.

#### Table

#	Property	Data Type	Default value	Description
---	----------	-----------	---------------	-------------

Table (Continued)

1	hive.delegation.token.authentication	String	DIGEST	Delegation token authentication method. Possible values are DIGEST, SCRAM
---	--------------------------------------	--------	--------	---

To connect to HiveServer2 on EEP 8.1.0 from Hive client on EEP 8.0.x, set `hive.delegation.token.authentication` property in HPE Ezmeral Data Fabric.

### Manually Configuring SCRAM Token Authentication

To configure SCRAM token and SCRAM-SHA-256 authentication, set the following property on `HIVE_HOME/conf/hive-site.xml` file:

```
<property>
  <name>hive.delegation.token.authentication</name>
  <value>SCRAM</value>
</property>
```

The default value for `hive.delegation.token.authentication` is DIGEST.

To use `hive.delegation.token.authentication` for Hive, configure Hadoop for SCRAM:

- Set the value of `hadoop.security.token.authentication.method` property to SCRAM-SHA-256 in `yarn-site.xml` file.
- Set `scram.password` property and ensure encrypted password file is available in file system.

To learn more, see Hadoop documentation.

### Auto Configuring SCRAM Token Authentication

Execute `MAPR_HOME/server/configure.sh -R` script on a newly installed MapR-SASL or KERBEROS secured cluster to automatically configure the following authentications:

1. For a FIPS enabled cluster, Hive configures `hive.delegation.token.authentication=SCRAM` authentication.
2. For a non-FIPS cluster if you configure Hadoop with `hadoop.security.token.authentication.method=SCRAM` authentication, Hive configures the SCRAM authentication.
3. For other clusters, Hive configures `hive.delegation.token.authentication=DIGEST` authentication.

For non-secure clusters, Hive configures `hive.delegation.token.authentication=DIGEST` authentication.

You can see `hive.delegation.token.authentication` property in `HIVE_HOME/conf/hive-site.xml` when you execute `configure.sh` command on newly installed cluster.

When you upgrade Hive, the upgrade does not update the value of the set `hive.delegation.token.authentication` property.

Manually set the value of `hive.delegation.token.authentication` property when you change the cluster settings from FIPS to non-FIPS or from non-FIPS to FIPS.

### Hive Encryption

When you configure encryption, the thrift messages sent between the Hive Metastore, HiveServer 2, and HiveServer2 clients are encrypted.

When you configure encryption, the thrift messages sent between the Hive Metastore, HiveServer 2, and HiveServer2 clients are encrypted.

Encryption is supported when HiveServer2 has no authentication or when it is configured to use MapR-SASL or Kerberos authentication.

This section contains the following topics:

## Configure Encryption with MapR-SASL or Kerberos Authentication

### About this task

Complete the following steps on each node where HiveServer2 is installed:

### Procedure

1. In `hive-site.xml` file, set the following property:

Property	Value
<code>hive.server2.thrift.sasl.qop</code>	<code>auth-conf</code>

**NOTE:** As of Hive 0.13-1504 and Hive 1.0-1504, `hive.server2.thrift.sasl.qop` is set to `auth-conf` by default on secure clusters.

```
<property>
  <name>hive.server2.thrift.sasl.qop</name>
  <value>auth-conf</value>
  <description>Sasl QOP value; one of 'auth', 'auth-int' and
  'auth-conf'</description>
</property>
```

2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

## Configure Encryption without Authentication

### About this task

Complete the following steps on each node where HiveServer2 is installed:

### Procedure

1. In `hive-site.xml` file, set the following properties:

Property	Value
<code>hive.server2.use.SSL</code>	<code>true</code>
<code>hive.server2.ssl.keystore</code>	<code>&lt;path to keystore file&gt;</code>
<code>hive.server2.ssl.keystore.password</code>	<code>&lt;password&gt;</code>

**WARNING:** If you specify the password in the `hive-site.xml` file, protect the file with the appropriate file permissions. HiveServer2 automatically prompts for the keystore password during startup when no password is stored in the `hive-site.xml` file.

```
<property>
  <name>hive.server2.use.ssl</name>
  <value>true</value>
  <description>enable/disable SSL communication</description>
</property>
<property>
  <name>hive.server2.ssl.keystore</name>
  <value><path-to-keystore-file></value>
  <description>path to keystore file</description>
</property>

<property>
  <name>hive.server2.ssl.keystore.password</name>
  <value><password></value>
  <description>keystore password</description>
</property>
```

## 2. Restart HiveServer2 to apply these changes.

```
maprcli node services -name hs2 -action restart -nodes <comma separated
list of nodes>
```

## Configure HiveServer2 Clients to use Encryption

Based on the encryption method, the requirements for clients to connect to HiveServer2 differ.

- When HiveServer2 uses encryption with MapR-SASL or Kerberos authentication, the client must specify the same sasl qop value that is set for HiveServer2 (auth-conf is the default, recommended option).
- When HiveServer2 uses SSL encryption without authentication, the client must specify a truststore. The `ssl_truststore` file must be copied from the cluster to the client. Specifying a truststore password is optional.

For details, see [Connecting to Hive](#) on page 4282.

## Configure the TLS (SSL) Protocol Version in Hive

Beginning with EEPs 6.3.1 and 7.0.0, the default protocol version for TLS (SSL) is `TLSv1.2`, but you can use the `hive.ssl.protocol.version` property to set a custom value for TLS (SSL).

### Setting the TLS (SSL) Protocol Version

To enable the direct configuration of the TLS (SSL) version, Hive provides the following property:

Property	Type	Default Value	Description
<code>hive.ssl.protocol.version</code>	String	<code>TLSv1.2</code>	SSL protocol versions for all Hive servers.

To set a custom value for the TLS (SSL) protocol version in Hive:

1. Add the following to the `hive-site.xml` file:

```
<property>
  <name>hive.ssl.protocol.version</name>
```

```
<value><custom_value></value>
</property>
```

In this example, <custom\_value> can be one of the following:

- SSLv2
- SSLv3
- SSLv2Hello
- TLSv1
- TLSv1.1
- TLSv1.2

For more information, see the following table:

#	Algorithm Name (TLS/SSL Version)	Description
1	Default	Use the default algorithm.
2	SSL	Supports some versions of SSL; may support other versions.
3	SSLv2	Supports SSL version 2 or later; may support other versions.
4	SSLv3	Supports SSL version 3; may support other versions.
5	TLS	Supports some versions of TLS; may support other versions.
6	TLSv1	Supports <a href="#">RFC 2246: TLS version 1.0</a> ; may support other versions.
7	TLSv1.1	Supports <a href="#">RFC 4346: TLS version 1.1</a> ; may support other versions.
8	TLSv1.2	Supports <a href="#">RFC 5246: TLS version 1.2</a> ; may support other versions.

2. Restart all Hive services.

### Special Considerations for Protocol Versions

Note these special considerations for the protocol versions:

- When `hive.ssl.protocol.version` is set to `TLSv1.2`, the protocol supports TLS 1.2. When `hive.ssl.protocol.version` is set to `TLSv1`, the protocol supports TLS versions up to TLS 1.0 (but not TLS 1.1 and 1.2). When `hive.ssl.protocol.version` is set to `TLSv1.1`, the protocol supports versions up to TLS 1.1 (but not TLS 1.2).
- `SSLv2Hello` is not a real encryption protocol. It merely enables clients to find out which encryption protocols are supported by the server to which they connect. As long as `SSLv2Hello` is used only by clients and servers to negotiate a safe protocol, such as `TLSv1.1` or `TLSv1.2`, it does not pose a security risk.

- Hive has a property called `hive.ssl.protocol.blacklist` with a default value of `SSLv2,SSLv3,SSLv2Hello,TLSv1,TLSv1.1`. If you want to enable `TLSv1.1`, for example, you must remove it from the blacklist above. For example:

```
<property>
<name>hive.ssl.protocol.blacklist</name>
<value>SSLv2,SSLv3,SSLv2Hello,TLSv1</value>
</property>

<property>
<name>hive.ssl.protocol.version</name>
<value>TLSv1.1</value>
</property>
```

- If you use the TLS (SSL) protocol version from the blacklist, you will get the following exception when connecting to Hiveserver2 via JDBC:

```
Unknown HS2 problem when communicating with Thrift server.
Error: Could not open client transport with JDBC
Uri: jdbc:hive2://<hostname>:10000/default;auth=maprsasl;ssl=true:
javax.net.ssl.SSLHandshakeException: Received fatal alert:
handshake_failure (state=08S01,code=0)
```

- Empty values are allowed for `hive.ssl.protocol.version`. Hive uses the default value in that case. The same is true for `hive.ssl.protocol.blacklist`.
- The `hive.ssl.protocol.version` property is out of scope for a secure-by-default configuration. This means that it will not appear in the `hive-site.xml` after you use the `Hive configure.sh` script. Nevertheless, the default value of `hive.ssl.protocol.version` is still `TLSv1.2`, and you do not need to set it explicitly.

### *Hive Password Encryption*

EEP 4.0 introduces default configuration for Hive Metastore password encryption using the Data Fabric Installer. The password is stored in the `hive-site.xml` file.

EEP 4.0 introduces default configuration for Hive Metastore password encryption using the Data Fabric Installer. The password is stored in the `hive-site.xml` file.

**NOTE:** For Hive-2.1 (EEP-5.0.0 and later) and Hive-2.3 (EEP-6.0.0 and later) installed using the Data Fabric Installer, `javax.jdo.option.ConnectionPassword` is automatically encrypted.

```
<property>
  <name>javax.jdo.option.ConnectionPassword<name>
  <value>{password}<value>
</property>
```

The `hadoop.security.credential.provider.path` configuration property replaces the `javax.jdo.option.ConnectionPassword` property in the `hive-site.xml` file that contains the path to the keystore file created by the Hadoop Credential Provider. Credential providers store and protect passwords out of clear text for the underlying database. By default, the Data Fabric Installer creates the keystore file in the Data Fabric file system. `/user/${MAPR_USER}/hivemetastore.jceks`.

**NOTE:** Starting from Hive-2.3 EEP 6.0.0, SSL keystore passwords, `hive.server2.webui.keystore.password`, `hive.server2.keystore.password`, and `templeton.keystore.password`, are automatically read from the `/opt/mapr/conf/ssl-client.xml` file without any additional steps from your side. But you can still encrypt them manually and store them in the `*jceks` files.

## Reset Data Fabric Installer Default Configuration

To remove changes made by the Data Fabric Installer and reset Hive to its default setting:

1. Open the `hive-site.xml` file.
2. Delete the `hadoop.security.credential.provider.path` property.
3. Add the `javax.jdo.option.ConnectionPassword` property.
4. Save and close the `hive-site.xml` file.

## Manual Password Encryption

**NOTE:** For any user to use Hive, the keystore file requires read permission (644). To limit keystore file access to a smaller number of Hive users, modify permissions as necessary.

**ATTENTION:** When you wish to run the `hadoop credential` command for provisioning a password or secret to a particular credential store provider, use the `-provider` command line option to explicitly indicate which provider store to use. If a path of multiple providers is given, the first non-transient provider will be used. Note that this provider may or may not be the one that you intended to use.

To encrypt a password manually:

1. Create the keystore file using the Hadoop Credential Provider as follows:

```
hadoop credential create javax.jdo.option.ConnectionPassword -provider
<path-to-keystore>
```

Where `<path-to-keystore>` is `jceks://<file-system-name>/<path-to-keystore>`.

For example, `jceks://maprfs/user/mapr/hivemetastore.jceks`

**NOTE:** On running the command, you are prompted to enter and re-enter the password to encrypt. Once you provide the password and confirm the password, the `javax.jdo.option.ConnectionPassword` is created and the `org.apache.hadoop.security.alias.JavaKeyStoreProvider` is updated.

2. Delete the `javax.jdo.option.ConnectionPassword` property in the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>{yourpassword}</value>
</property>
```

3. Add the `hadoop.security.credential.provider.path` property to the `/opt/mapr/hive/<hive-release-version>/conf/hive-site.xml` file:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>jceks://maprfs/user/mapr/hivemetastore.jceks</value>
  <description>specify password to use against metastore database here</
description>
</property>
```

- Restart the Hive services to update the configuration:

```
maprcli node services -name hivemeta -action restart -nodes `hostname -f`
maprcli node services -name hs2 -action restart -nodes `hostname -f`
maprcli node services -name hcat -action restart -nodes `hostname -f`
```

### Encrypt the Oozie Database Password

Follow the steps given below to encrypt the Oozie database password:

- Configure Oozie to use a MySQL database as described in [Configure a MySQL Data Store for Oozie](#).

- Optionally, export the Hadoop credential store password as a system variable:
 

```
$ export HADOOP_CREDSTORE_PASSWORD=password.
```

- Add `oozie.service.jpaservice.jdbc.password` to the `jceks` keystore:

```
$ hadoop credential create
oozie.service.jpaservice.jdbc.password -provider jceks://path/to/
oozie.jceks
Enter the password:
Enter the password again:
oozie.service.jpaservice.jdbc.password has been successfully created.
org.apache.hadoop.security.alias.JavaKeyStoreProvider has been updated.
```

- Verify that the MySQL password was added:

```
Keystore type: JCEKS
Keystore provider: SunJCE

Your keystore contains 1 entry

Alias name: oozie.service.jpaservice.jdbc.password
Creation date: Apr 11, 2018
Entry type: SecretKeyEntry
```

- Once the `jceks` file is created, add the `hadoop.security.credential.provider.path` property to the `oozie-site.xml` file with the path to the `jceks` file. The `jceks` path location can be `maprfs` or a local file (`local-fs`).

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>jceks://path/to/oozie.jceks</value>
</property>
```

- Update the password property to use `*****` instead of a word-readable password:

```
<property>
  <name>oozie.service.JPAService.jdbc.password</name>
  <value>*****</value>
</property>
```

### Hive Authorization

HPE Ezmeral Data Fabric has built-in platform authorization that protects all data regardless of the execution engine. This topic describes alternative authorization modes you can choose to implement.

For more information, refer to [Authorization in Data Fabric](#) on page 829.

In addition to the centralized authorization provided by the HPE Ezmeral Data Fabric, you can use several authorization modes for Hive. The use cases and trade-offs for these authorization modes are described in the sections below.

#### Understanding Hive Authorization Use Cases

Table Storage Layer and SQL Query Engine are the two primary use cases for client-based authorization protection, delivered as part of the open source project.

##### **Use Case 1: Table Storage Layer**

This is the use case for Hive [HCatalog API](#) users.

In this case, Hive provides a table abstraction and metadata for files on storage (typically Data Fabric file system). You have direct access to Data Fabric file system and the metastore server (which provides an API for metadata access).

Data Fabric file system access is authorized through the use of Data Fabric file system [permissions](#). You need to authorize metadata access using Hive configuration.

##### **Use Case 2: SQL Query Engine**

This is one of the most common use cases of Hive. This is the "Hive view" of SQL users and BI tools. This use case has the following two subcategories:

- Hive command line users - You have direct access to Data Fabric file system and the Hive metastore, which makes this use case similar to use case 1.
- ODBC/JDBC and other HiveServer2 API users (Beeline CLI is an example) - You have all data or metadata access through HiveServer2. You do not have direct access to Data Fabric file system or the metastore.

#### Understanding Hive Authorization Modes

Different modes of Hive authorization are available to satisfy different use cases.

##### **Secure by Default Configuration (Storage Based Authorization in the Metastore Server)**

Hive default security configuration is the storage based authorization in the Metastore server. Managed by `mapr-tickets` and `impersonation level`, Hive configurations control the data access and MapR filesystem permissions act as one source of truth for the table storage access. By enabling storage based authorization in the metastore server, you can use this single source for truth and have a consistent data and metadata authorization policy.

For use cases where the users have direct access to the data, Hive configurations do not control the data access. The MapR filesystem permissions act as the one source of truth for table storage access. To control metadata access on the metadata objects such as databases, tables, and partitions, MapR filesystem checks if you have permission to access the corresponding directories on the filesystem.

You can also protect access through HiveServer2 ([use case 2.2](#)) by ensuring that the queries run as the end user. The `hive.server2.enable.doAs` option should be `true` in the HiveServer2 configuration, this is a default value.

For more information, see [Hive Security Configuration Options](#) on page 4186.

##### **SQL Standards Based Authorization in HiveServer2**

Although storage based authorization provides access control at the level of databases, tables, and partitions, it can only control authorization at finer levels such as columns and views for MapR Database tables and not for files because the access control provided by the filesystem is at the level of directory and files. SQL standards authorization makes authorization possible for files BUT at the expense of not being able to enforce that access from any other tool.

For enabling SQL standards based authorization, refer to [SQL Standards-Based Hive Authorization](#) on page 4215.

### Legacy Hive Authorization

Old default authorization is the authorization mode that has been available in earlier versions of Hive. However, this mode does not have a complete access control model, leaving many security gaps unaddressed.

For example, the permissions needed to grant privileges for a user are not defined, and any user can grant themselves access to a table or database.

This model is similar to the SQL standards based authorization mode, in that it provides grant or revoke statement-based access control. However, the access control policy is different from SQL standards based authorization, and they are not compatible. Use of this mode is also supported for Hive command line users. However, for reasons mentioned under the discussion of SQL standards based authorization, it is not a secure mode of authorization for the Hive command line.

### Related Links

For information related to Hive authorization modes, see:

- [Storage Based Authorization in the Metastore Server](#)
- [HCatalog Authorization](#)
- [SQL Standard Based Hive Authorization](#)
- [Hive deprecated authorization mode / Legacy Mode](#)
- [Hive security design document](#)
- [Hive security document](#)

### SQL Standards-Based Hive Authorization

Using EEP 6.0.0 and later, you can configure SQL standards-based authorization to enable fine grained access control with SQL commands.

The SQL standards-based authorization mode can be used in conjunction with storage-based authorization on the Metastore server. Like the current default authorization in Hive, SQL standards-based authorization is also enforced at query compilation time. To provide security through this option, the client must be secured. You can do this by allowing users access only through HiveServer2, and by restricting the user code and non-SQL commands that can be run. The checks will happen against the user who submits the request, but the query will run as the Hive server user. The directories and files for input data would have read access for this Hive server user. For users who do not need to protect against malicious users, this could potentially be supported through the Hive command line as well.

1. Add the following properties to `hive-site.xml`:

```

<!-- SQL standard based authorization -->
<property>
  <name>hive.server2.enable.doAs</name>
  <value>>false</value>
</property>
<property>
  <name>hive.users.in.admin.role</name>
  <value>mapr</value>
</property>
<property>
  <name>hive.security.metastore.authorization.manager</name>

  <value>org.apache.hadoop.hive.ql.security.authorization.MetaStoreAuthzAPI
  AuthorizerEmbedOnly</value>
</property>
<property>
  <name>hive.security.authorization.manager</name>

  <value>org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQL
  StdConfOnlyAuthorizerFactory</value>
</property>

```

2. Create a `hiveserver2-site.xml` configuration file:

```
touch /opt/mapr/hive/hive-<version>/conf/hiveserver2-site.xml
```

Add the following properties to the `hiveserver2-site.xml` file:

```

<configuration>
<property>
  <name>hive.security.authorization.manager</name>

  <value>org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd.SQL
  StdHiveAuthorizerFactory</value>
</property>
<property>
  <name>hive.security.authorization.enabled</name>
  <value>>true</value>
</property>
<property>
  <name>hive.security.authenticator.manager</name>

  <value>org.apache.hadoop.hive.ql.security.SessionStateUserAuthenticator</
  value>
</property>
<property>
  <name>hive.metastore.uris</name>
  <value></value>
</property>
</configuration>

```

3. Change the owner of the `hiveserver2-site.xml` file to `mapr`, and restart Hive services:

```

chown mapr:mapr /opt/mapr/hive/hive-<version>/conf/hiveserver2-site.xml

maprcli node services -name hs2 -action restart -nodes `hostname -f`
maprcli node services -name hivemeta -action restart -nodes `hostname -f`

```

If you are a database administrator and want to run commands such as `create role` and `drop role` or access objects without being given explicit access, you must run the `set role` command.

### 1. Create a test role:

```
hive> set role admin;
OK
Time taken: 0.02 seconds

hive> create role example_role;
OK
Time taken: 0.099 seconds

hive> show roles;
OK
admin
public
role1
example_role
Time taken: 0.02 seconds, Fetched: 3 row(s)
```

### 2. Grant access:

```
hive> GRANT example_role to USER testuser;
OK
Time taken: 0.058 seconds

hive> GRANT SELECT on table eg_test to role example_role;
OK
Time taken: 0.146 seconds
```

### 3. Using the test role, check access:

```
sudo -u mapruser1 hive
```

If there is an access violation, correct it. The following is an example of an access violation error:

```
hive> insert into table eg_test values (4), (5), (6);
FAILED: RuntimeException Cannot create staging directory
'maprfs:///user/hive/warehouse/
eg_test/.hive-staging_hive_2018-06-08_10-24-11_566_5325052587659005252-1'
:
User mapruser1(user id 5001) has been denied access to
create .hive-staging_hive_2018-06-08_10-24-11_566_5325052587659005252-1
```

You can apply access restrictions to all actions except for READ access.

The following are examples of permitted access operations:

- **Select:**

```
hive> select count (*) from eg_test;
OK
3
Time taken: 2.491 seconds, Fetched: 1 row(s)
```

- Describe:

```
hive> describe extended eg_test;
OK
id                int

Detailed Table Information
Table(tableName:eg_test, dbName:default, owner:mapr,
createTime:1528453013, lastAccessTime:0, retention:0,
sd:StorageDescriptor(cols:[FieldSchema(name:id, type:int,
comment:null)]),
location:maprfs:/user/hive/warehouse/eg_test,
inputFormat:org.apache.hadoop.mapred.TextInputFormat,
outputFormat:org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat
,
compressed:false, numBuckets:-1, serdeInfo:SerDeInfo(name:null,
serializationLib:org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe,
parameters:{serialization.format=1}), bucketCols:[], sortCols:[],
parameters:{},
skewedInfo:SkewedInfo(skewedColNames:[], skewedColValues:[],
skewedColValueLocationMaps:{}),
storedAsSubDirectories:false), partitionKeys:[], parameters:
{totalSize=6, numRows=3, rawDataSize=3,

viewExpandedText:null, tableType:MANAGED_TABLE, rewriteEnabled:false)
Time taken: 0.12 seconds, Fetched: 3 row(s)
```

- Show columns:

```
hive> SHOW COLUMNS from eg_test;
OK
id
Time taken: 0.049 seconds, Fetched: 1 row(s)
```

**NOTE:** For more information about privileges required for Hive operations, see the [open source documentation](#).

### Configure Hive Metastore to use Storage-Based Authorization

Describes how to enable storage-based authorization (SBA) for the Hive Metastore server.

Storage-based authorization controls access to the data using HDFS permissions (HDFS ACL). To control access to metadata objects, such as databases, tables, and partitions, it checks if you have permission on the corresponding directories on the file system.

To enable storage-based authorization for the Hive Metastore server, set these properties in `hive-site.xml`:

Property	Value	Description
<code>hive.metastore.pre.event.listeners</code>	<code>org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEventListener*</code>	Turns on Metastore security. A <code>MetaStorePreEventListener</code> that performs authorization or authentication checks on the metastore side. Note that this can only perform authorization checks on defined metastore <code>PreEventContexts</code> , such as the adding, dropping, and altering of databases, tables, and partitions.

Property	Value	Description
hive.security.metastore.authorization.manager	org.apache.hadoop.hive.ql.security.authorization.StorageBasedAuthorizationProvider* Note: <ul style="list-style-type: none"> <li>The StorageBasedAuthorizationProvider setting first appeared on the Metastore side only in Hive 0.10.0. With Hive 0.12.0 and later, it can also run on the client side.</li> <li>Starting from EEP 6.1.0, hive.security.metastore.authorization.manager is set to the StorageBasedAuthorizationProvider value by default.</li> </ul>	StorageBasedAuthorizationProvider - Specifies use of an HDFS permission-based model (recommended) for the Metastore-side authorization provider. DefaultHiveMetastoreAuthorizationProvider - This default implements the standard Hive grant/revoke model.
hive.security.metastore.authenticator.manager	org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticator (default)	Authentication manager class name to be used in the metastore for authentication. The user-defined authenticator should implement the org.apache.hadoop.hive.ql.security.HiveAuthenticationProvider interface.
hive.security.metastore.authorization.auth.reads	true (default)	Default value (does not appear in hive-site.xml file). Set to true, Metastore authorization also performs a read authorization check (first supported in Hive 0.14.0).
hive.server2.enable.doAs	true (default)	Use for protected access through HiveServer2.

\* In secure clusters, the Data Fabric "secure-by-default" configuration implicitly configures these properties in the hive-site.xml file.

### SBA configuration example in hive-site.xml File

```
<property>
  <name>hive.security.metastore.authorization.manager</name>

  <value>org.apache.hadoop.hive.ql.security.authorization.StorageBasedAutho
  rizationProvider</value>
</property>

<property>
  <name>hive.security.metastore.authenticator.manager</name>

  <value>org.apache.hadoop.hive.ql.security.HadoopDefaultMetastoreAuthenticato
  r
  </value>
</property>

<property>
  <name>hive.security.metastore.authorization.auth.reads</name>
  <value>true</value>
</property>

<property>
```

```

    <name>hive.server2.enable.doAs</name>
    <value>true</value>
  </property>

  <property>
    <name>hive.metastore.pre.event.listeners</name>

    <value>org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEventListener</value>
  </property>

```

If you use storage-based authorization, you still need to use one of the following authorization models to protect actions within the HiveServer2:

- [Configuring Fallback Hive Authorizer](#) on page 4220
- [SQL Standards-Based Hive Authorization](#) on page 4215

#### *Fallback Hive Authorizer*

Fallback Hive Authorizer is used by Hive DDL (Data Definition Language) tasks for access control and for checking authorization from `Driver.doAuthorization()`.

It is designed to prevent [CVE-2018-11777](#).

In addition to the centralized authorization provided by HPE Ezmeral Data Fabric, you can use several authorization modes for Hive. The use cases and trade-offs for these authorization modes are described in the sections below.

#### Configuring Fallback Hive Authorizer

You can enable protection of actions within the HiveServer2 instance by using the Fallback Authorizer.

#### **About this task**

Use the Fallback Authorizer when you want to protect access for Hive clients (JDBC/ODBC, Beeline CLI, and other HiveServer2 API users).

To enable Fallback Authorization for Hive clients, set these properties in the `hive-site.xml` file:

Property	Value	Description
<code>hive.security.authorization.enabled</code>	<code>true*</code>	Enable or disable the Hive client authorization.
<code>hive.security.authorization.manager</code>	<code>org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.FallbackHiveAuthorizerFactory*</code>	Class name for the Hive client authorization manager.
<code>hive.users.in.admin.role</code>	<code>mapr*</code>	Comma-separated list of users who need to be added to the <code>admin</code> role. Note that a user who belongs to the <code>admin</code> role needs to run the <code>set role</code> command before getting the privileges of the <code>admin</code> role, as the <code>admin</code> role is not in <code>current roles</code> by default.

\* In secure clusters, the MapR "Secure-by-Default" configuration implicitly configures the Fallback Authorizer in the `hive-site.xml` file.

Fall Back Authorizer applies the following restrictions:

- Allows `set` only for selected allowlist parameters.
- Disallows `dfs` commands except for `admin`.

- Disallows local file location in SQL statements except for `admin`.
- Disallows `ADD JAR`, `COMPILE`, and `TRANSFORM` statements.

### Fallback Authorization Configuration Example in `hive-site.xml` File

```
<property>
  <name>hive.security.authorization.enabled</name>
  <value>true</value>
</property>

<property>
  <name>hive.security.authorization.manager</name>

<value>org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.Fall
backHiveAuthorizerFactory</value>
</property>

<property>
  <name>hive.users.in.admin.role</name>
  <value>mapr</value>
</property>
```

### Action Restrictions with Fallback Hive Authorizer

After enabling Fallback Hive Authorizer, you can perform action restriction operations.

#### Procedure

- Disallow local file location in SQL statements for all except the administrator.
- Allow `set` for selected white list parameters.
- Disallow `dfs` commands for all except the administrator.
- Disallow `ADD JAR` statements for all except the administrator.
- Disallow `COMPILE` statements for all except the administrator.
- Disallow `TRANSFORM` statements.

### Using a White List with Fallback Hive Authorizer

You can add an exception to Fallback Hive Authorizer restrictions using the `hive.security.authorization.sqlstd.confwhitelist.append` property.

#### About this task

The `hive.security.authorization.sqlstd.confwhitelist` property is list of comma-separated Java regexes that you can append to. Appending to this list instead of updating the original list means that you can append to the default set by SQL-standard authorization instead of replacing it entirely.

You can modify the configurations parameters that match these regexes when SQL-standard authorization is enabled.

To get the default value, use the `set <param>` command. The `hive.conf.restricted.list` checks are still enforced after the white-list check.

An example of a white-list configuration is as follows:

```
<property>
  <name>hive.security.authorization.sqlstd.confwhitelist.append</name>
```

```
<value>hive.reloadable.aux.jars.path</value>
</property>
```

### Procedure

- After adding this configuration to the `hive-site.xml` file, execute the following command:

```
set hive.reloadable.aux.jars.path=/path/to/jar
```

### Considerations for Hive on JDK 17

#### Considerations for Hive on JDK 17

When configured correctly, Hive works on JDK 17, but it is still possible to encounter an error such as:

```
Caused by: java.lang.reflect.InaccessibleObjectException: <detailed
description>: module java.base does not "opens <module name>" to unnamed
module
```

Here is an example of the error:

```
Caused by: java.lang.reflect.InaccessibleObjectException: Unable to make
field private final int java.time.LocalDate.year accessible: module
java.base does not "opens java.time" to unnamed module
```

To fix the issue, you must add the following fix:

```
--add-opens java.base/<module name>=ALL-UNNAMED
```

For example:

```
--add-opens java.base/java.time=ALL-UNNAMED
```

You must add the fix in two places:

- `HADOOP_OPTS` variable in the `hive-env.sh` conf file
- `mapreduce.map.java.opts`, `mapreduce.reduce.java.opts`,  
`yarn.app.mapreduce.am.command-opts` properties of the `hive-site.xml` conf file

Here is an example of making the fix:

1. Add the following entry to the `hive-env.sh` file:

```
export HADOOP_OPTS="-XX:+IgnoreUnrecognizedVMOptions --add-opens
java.base/java.time=ALL-UNNAMED"
```

## 2. Add the following properties to the `hive-site.xml` file:

```

<property>
  <name>mapreduce.map.java.opts</name>
  <value>-Xmx900m --add-opens
java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC --add-opens
java.base/java.net=ALL-UNNAMED --add-opens
java.base/java.nio=ALL-UNNAMED --add-opens java.base/
java.util=ALL-UNNAMED --add-opens java.base/
java.util.concurrent.atomic=ALL-UNNAMED --add-opens java.base/
java.util.regex=ALL-UNNAMED --add-opens java.base/java.time=ALL-UNNAMED</
value>
</property>
<property>
  <name>mapreduce.reduce.java.opts</name>
  <value>-Xmx2560m --add-opens
java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC --add-opens
java.base/java.net=ALL-UNNAMED --add-opens
java.base/java.nio=ALL-UNNAMED --add-opens java.base/
java.util=ALL-UNNAMED --add-opens java.base/
java.util.concurrent.atomic=ALL-UNNAMED --add-opens java.base/
java.util.regex=ALL-UNNAMED --add-opens java.base/java.time=ALL-UNNAMED</
value>
</property>
<property>
  <name>yarn.app.mapreduce.am.command-opts</name>
  <value>-Xmx2560m --add-opens
java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC --add-opens
java.base/java.net=ALL-UNNAMED --add-opens
java.base/java.nio=ALL-UNNAMED --add-opens java.base/
java.util=ALL-UNNAMED --add-opens java.base/
java.util.concurrent.atomic=ALL-UNNAMED --add-opens java.base/
java.util.regex=ALL-UNNAMED --add-opens java.base/java.time=ALL-UNNAMED</
value>
</property>

```

## Integrating Hive

### Hive and HPE Ezmeral Data Fabric Database Integration

You can create HPE Ezmeral Data Fabric Database binary tables from Hive that can be accessed by both Hive and HPE Ezmeral Data Fabric Database. You can run Hive queries on HPE Ezmeral Data Fabric Database binary tables, convert existing HPE Ezmeral Data Fabric Database binary tables into Hive-HPE Ezmeral Data Fabric Database tables, and run Hive queries on those tables as well.

#### *Install and Configure Hive*

### Procedure

1. Install and configure Hive if it is not already installed. See [Installing Hive](#) on page 240 for details.

- Execute the `jps` command and ensure that all relevant Hadoop, Data Fabric, and Zookeeper processes are running. Example:

```
$ jps
1549 jenkins.war
15051 QuorumPeerMain
30935 Jps
15551 CommandServer
15293 ResourceManager
15328 NodeManager
15131 WardenMain
```

- Open the `hive-site.xml` file with your favorite editor, or create a `hive-site.xml` file if it doesn't already exist:

```
$ cd $HIVE_HOME
$ vi conf/hive-site.xml
```

- Copy the following XML code and paste it into the `hive-site.xml` file.

**NOTE:** If you already have an existing `hive-site.xml` file with a configuration element block, just copy the `property` element block code below and paste it inside the configuration element block in the `hive-site.xml` file. Be sure to use the correct values for the paths to your auxiliary JARs and ZooKeeper IP numbers.

Example configuration:

```
configuration>

<property>
  <name>hive.aux.jars.path</name>
  <value>file:///opt/mapr/hive/hive-<version>/lib/
hive-hbase-handler-<version>-mapr.jar,
file:///opt/mapr/hbase/hbase-<version>/lib/
hbase-client-<version>-mapr.jar, file:///opt/mapr/hbase/
hbase-<version>/lib/hbase-server-<version>-mapr.jar,file:///opt/mapr/
mapr/zookeeper/zookeeper-<version>/zookeeper-<version>.jar</value>
  <description>A comma separated list (with no spaces)
of the jar files required for Hive-HBase integration</description>
</property>

<property>
  <name>hbase.zookeeper.quorum</name>
  <value>xx.xx.x.xxx,xx.xx.x.xxx,xx.xx.x.xxx</value>
  <description>A comma separated list (with no spaces) of
the IP addresses of all ZooKeeper servers in the cluster.</description>
</property>

<property>
  <name>hbase.zookeeper.property.clientPort</name>
  <value>5181</value>
  <description>The Zookeeper
client port. The MapR default clientPort is 5181.</description>
</property>

</configuration>
```

- Save and close the `hive-site.xml` file.

## Results

If you have successfully completed all of the steps in this section, you're ready to begin the tutorial in the next section.

### *Getting Started with Hive and HPE Ezmeral Data Fabric Database Binary Integration*

In this tutorial we will:

- Create a Hive table
- Populate the Hive table with data from a text file
- Query the Hive table
- Create a Hive-HPE Ezmeral Data Fabric Database table
- Introspect the Hive-HPE Ezmeral Data Fabric Database table from the HBase shell
- Populate the Hive-HPE Ezmeral Data Fabric Database table with data from the Hive table
- Query the Hive-HPE Ezmeral Data Fabric Database table from Hive
- Convert an existing HPE Ezmeral Data Fabric Database table into a Hive-MapR table

Be sure that you have successfully completed all of the steps in [Installing Hive](#) on page 240 and review the HPE Ezmeral Data Fabric Database topics before beginning this Getting Started tutorial.

This Getting Started tutorial is based on the Hive-HBase Integration section of the Apache Hive Wiki. However, please note that there are some significant differences.

### **Create a Hive table with two columns**

Change to your Hive installation directory if you're not already there and start Hive:

```
$ cd $HIVE_HOME
$ bin/hive
```

### **Execute the CREATE TABLE command to create the Hive pokes table**

```
hive> CREATE TABLE pokes (foo INT, bar STRING);
```

### **To see if the pokes table has been created successfully, execute the SHOW TABLES command**

```
hive> SHOW TABLES;
OK
pokes
Time taken: 0.74 seconds
```

The pokes table appears in the list of tables. **Populate the Hive pokes table with data:**

The kv1.txt file is provided in the \$HIVE\_HOME/examples/files directory. Execute the LOAD DATA LOCAL INPATH command to populate the Hive pokes table with data from the kv1.txt file.

```
hive> LOAD DATA LOCAL INPATH './examples/files/kv1.txt' OVERWRITE INTO
TABLE pokes;
```

A message appears confirming that the table was created successfully, and the Hive prompt reappears:

```
Copying data from file:
...
OK
```

```
Time taken: 0.278 seconds
hive>
```

### Execute a SELECT query on the Hive `pokes` table

```
hive> SELECT * FROM pokes WHERE foo = 98;
```

The SELECT statement executes, runs a MapReduce application, and prints the application output:

```
OK
98      val_98
98      val_98
Time taken: 18.059 seconds
```

The output of the SELECT command displays two identical rows because there are two identical rows in the Hive `pokes` table with a key of 98.

#### **WARNING:**

Hive tables can have multiple identical keys. As we will see shortly, HPE Ezmeral Data Fabric Database tables cannot have multiple identical keys, only unique keys.

### Create a Hive-HPE Ezmeral Data Fabric Database table

Enter these four lines of code at the Hive prompt:

```
hive> CREATE TABLE mapr_table_1(key int, value string)
> STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
> WITH SERDEPROPERTIES ("hbase.columns.mapping" = ":key,cfl:val")
> TBLPROPERTIES ("hbase.table.name" = "/user/mapr/xyz");
```

After a brief delay, a message appears confirming that the table was created successfully:

```
OK
Time taken: 5.195 seconds
```

Note: The TBLPROPERTIES command is not required, but those new to Hive-HPE Ezmeral Data Fabric Database integration may find it easier to understand what's going on if Hive and HPE Ezmeral Data Fabric Database use different names for the same table.

In this example, Hive will recognize this table as "mapr\_table\_1" and HPE Ezmeral Data Fabric Database will recognize this table as "xyz".

### Start the HBase shell

Keeping the Hive terminal session open, start a new terminal session for HBase, then start the HBase shell:

```
$ cd $HBASE_HOME
$ bin/hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
Version 0.90.4, rUnknown, Wed Nov  9 17:35:00 PST 2011

hbase(main):001:0>
```

### Execute the `list` command to see a list of HBase tables

```
hbase(main):001:0> list
TABLE
```

```
/user/mapr/xyz
1 row(s) in 0.8260 seconds
```

HBase recognizes the Hive-HPE Ezmeral Data Fabric Database table named `xyz` in directory `/user/mapr`. This is the same table known to Hive as `mapr_table_1`.

### Display the description of the `/user/mapr/xyz` table in the HBase shell

```
hbase(main):004:0> describe "/user/mapr/xyz"
DESCRIPTION                               ENABLED
{NAME => '/user/mapr/xyz', FAMILIES => [{NAME => 'cfl', DATA_B true
LOCK_ENCODING => 'NONE', BLOOMFILTER => 'NONE', REPLICATION_SCOPE => '0', VERSIONS => '3', MIN_VERSION
S => '0', TTL => '2147483647', KEEP_DELETED_CELLS => 'false', BLOCKSIZE => '65536', IN_MEMORY => 'false', ENCODE_ON_DISK => 'true', BLOCKCACHE => 'true'}
]}
1 row(s) in 0.0240 seconds
```

### From the Hive prompt, insert data from the Hive table `pokes` into the Hive-HPE Ezmeral Data Fabric Database table `mapr_table_1`

```
hive> INSERT OVERWRITE TABLE mapr_table_1 SELECT * FROM pokes WHERE foo=98;
...
2 Rows loaded to mapr_table_1
OK
Time taken: 13.384 seconds
```

### Query `mapr_table_1` to see the data we have inserted into the Hive-HPE Ezmeral Data Fabric Database table

```
hive> SELECT * FROM mapr_table_1;
OK
98      val_98
Time taken: 0.56 seconds
```

Even though we loaded two rows from the Hive `pokes` table that had the same key of 98, only one row was actually inserted into `mapr_table_1`. This is because `mapr_table_1` is a HPE Ezmeral Data Fabric Database table, and although Hive tables support duplicate keys, HPE Ezmeral Data Fabric Database tables only support unique keys. HPE Ezmeral Data Fabric Database tables arbitrarily retain only one key, and silently discard all of the data associated with duplicate keys.

### Convert a pre-existing HPE Ezmeral Data Fabric Database table to a Hive-HPE Ezmeral Data Fabric Database table

To convert a pre-existing HPE Ezmeral Data Fabric Database table to a Hive-HPE Ezmeral Data Fabric Database table, enter the following four commands at the Hive prompt.

Note that in this example the existing HPE Ezmeral Data Fabric Database table is `my_mapr_table` in directory `/user/mapr`.

```
hive> CREATE EXTERNAL TABLE mapr_table_2(key int, value string)
> STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
> WITH SERDEPROPERTIES ("hbase.columns.mapping" = "cfl:val")
> TBLPROPERTIES("hbase.table.name" = "/user/mapr/my_mapr_table");
```

Now we can run a Hive query against the pre-existing HPE Ezmeral Data Fabric Database table `/user/mapr/my_mapr_table` that Hive sees as `mapr_table_2`:

```
hive> SELECT * FROM mapr_table_2 WHERE key > 400 AND key < 410;
Total MapReduce jobs = 1
Launching Job 1 out of 1
Number of reduce tasks is set to 0 since there's no reduce operator
...
OK
401      val_401
402      val_402
403      val_403
404      val_404
406      val_406
407      val_407
409      val_409
Time taken: 9.452 seconds
```

### Optimizing HPE Ezmeral Data Fabric Database Tables Search by ID

Starting from the 1904 release (EEP 6.0.2, EEP 6.1.1, and EEP 6.2.0), search by ID is supported with Hive HPE Ezmeral Data Fabric Database JSON tables.

#### About this task

Property of Optimization

#### Prerequisites

The property name is `hive.mapr.db.json.fetch.by.id.task.conversion` and the value has a boolean type and by default is set to `true`, which means it is enabled.

#### Procedure

- To disable optimization, set `hive.mapr.db.json.fetch.by.id.task.conversion` to `false`.

Conditions for Optimization

#### Procedure

- This optimizer is designed for queries such as:

```
SELECT *
FROM <mapr_db_json_table>
WHERE _id = <constant_string_value>;
```

or:

```
SELECT *
FROM <mapr_db_json_table>
WHERE _id = <constant_string_value> AND (<condition_1>) AND
(<condition_2>) ... AND (<condition_N>);
```

or:

```
SELECT *
FROM <mapr_db_json_table>
WHERE <Constant false operator>
```

where `_id` is a key column of HPE Ezmeral Data Fabric Database JSON table. It provides usage of the `findById()` method of the HPE Ezmeral Data Fabric Database JSON table. The following functionality is not supported:

- joins
- group by
- distinct
- lateral view
- subquery
- create table as select (CTAS) or insert
- analyze
- single source

The predicate is not actually a part of the filter, so it is ignored by push down:

```
SELECT * FROM t WHERE (CASE WHEN _id = 'value_a' THEN 2 ELSE 4 END) > 3;
```

## Using Optimization

### Procedure

1. Consider the following HPE Ezmeral Data Fabric Database JSON table:

```
CREATE TABLE t(doc_id string, col1 string, col2 string)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/user/mapr/
db_json_table", "maprdb.column.id" = "doc_id");
```

2. Run the `EXPLAIN` command:

```
EXPLAIN SELECT col1 FROM t WHERE doc_id='id_004';
```

### 3. The following output is produced:

```
STAGE DEPENDENCIES:
  Stage-0 is a root stage

STAGE PLANS:
  Stage: Stage-0
  MapR DB JSON Fetch By Id Operator
  limit: -1
  Processor Tree:
  TableScan
  alias: t_small
  filterExpr: (doc_id = 'id_004') (type: boolean)
  Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
  stats: NONE
  Filter Operator
  predicate: (doc_id = 'id_004') (type: boolean)
  Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
  stats: NONE
  Select Operator
  expressions: coll (type: string)
  outputColumnNames: _col0
  Statistics: Num rows: 1 Data size: 0 Basic stats: PARTIAL Column
  stats: NONE
  ListSink
```

An important part of a query plan is that it shows if optimization is available for the query:

```
STAGE PLANS:
  Stage: Stage-0
  MapR DB JSON Fetch By Id Operator
```

## Connecting Using Hive HPE Ezmeral Data Fabric Database JSON Connector

This section describes the Hive connector for HPE Ezmeral Data Fabric Database JSON table.

### About this task

The Hive connector supports the creation of HPE Ezmeral Data Fabric Database based Hive tables. You can create a JSON table on HPE Ezmeral Data Fabric Database and load CSV data and/or JSON files to HPE Ezmeral Data Fabric Database using the connector. HPE Ezmeral Data Fabric Database based Hive tables can be:

- Queried just like file system based Hive tables.
- Combined with file system based Hive tables in joins and sub-queries.

**NOTE:** If you use Drill to query Hive tables based on MapR Database tables, you can [enable the native Drill reader](#), which can improve query performance.

The following table lists the Hive data type and the corresponding (supported) HPE Ezmeral Data Fabric Database OJAI type:

Hive Type	HPE Ezmeral Data Fabric Database OJAI Type
BOOLEAN	BOOLEAN
BINARY	BINARY
TINYINT	BYTE
DATE	DATE

Hive Type	HPE Ezmeral Data Fabric Database OJAI Type
DOUBLE	DOUBLE
FLOAT	FLOAT
INT	INT
BIGINT	LONG
SMALLINT	SHORT
STRING	STRING
TIMESTAMP	TIMESTAMP

The Hive connector for HPE Ezmeral Data Fabric Database JSON table also supports the use of the following complex data types:

- map
- array
- struct

**NOTE:** The HPE Ezmeral Data Fabric Database JSON tables do not support ACID transactions, bucketing, and alteration.

## Creating a HPE Ezmeral Data Fabric Database JSON Table and Hive Table Using Hive

### Procedure

- To create a table, run the command similar to the following:

**NOTE:** The required properties are shown in bold.

```
CREATE TABLE primitive_types (
  id string,
  bo boolean,
  d double,
  da date,
  f double,
  i int,
  s string,
  ts timestamp)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/tbl","maprdb.column.id" = "id");
```

Here:

- The `maprdb.table.name`, `maprdb.column.id` and `STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'` are mandatory properties.
- The value for `maprdb.column.id` column should be of type string or binary.

To create a Hive table that exists on HPE Ezmeral Data Fabric Database, specify `EXTERNAL` in the table DDL. If the table created is `EXTERNAL`, when the table is dropped, only its metadata is deleted; the underlying HPE Ezmeral Data Fabric Database data remains intact. On the other hand, if the table is not `EXTERNAL`, dropping the table deletes both the metadata associated with the table and the underlying HPE Ezmeral Data Fabric Database data.

For example, suppose a JSON table named `/apps/my_users` with the following values:

```
{ "_id": "001", "first_name": "John", "last_name": "Doe", "age": 34 }
{ "_id": "002", "first_name": "Jack", "last_name": "Smith", "age": 26 }
```

To create a Hive table over existing HPE Ezmeral Data Fabric Database JSON table:

```
CREATE EXTERNAL TABLE primitive_types (
  user_id string,
  first_name string,
  last_name string,
  age int)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/apps/my_users", "maprdb.column.id" =
"user_id");
```

Now, because table `primitive_types` points to HPE Ezmeral Data Fabric Database table, you can perform ETL query similar to file system based Hive tables:

```
SELECT COUNT(*) FROM test_external;
SELECT MAX(age) AS label FROM test_external;
...
```

## Loading CSV Data to HPE Ezmeral Data Fabric Database JSON Table

### Procedure

1. Create intermediate table.

For example:

```
CREATE TABLE stage(id STRING, name STRING, age INT) ROW FORMAT DELIMITED
FIELDS TERMINATED BY ',';
```

2. Load data to table.

For example:

```
LOAD DATA INPATH '/data' into table stage;
```

3. Create HPE Ezmeral Data Fabric Database table in Hive.

For example:

```
CREATE TABLE users(id STRING, name STRING, age INT)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/users", "maprdb.column.id" = "id");
```

4. Insert data through stage table.

For example:

```
INSERT INTO TABLE users select id, name, age from stage;
```

## Loading JSON Files to HPE Ezmeral Data Fabric Database JSON Table

## Procedure

### 1. Add SerDe JAR for JSON.

For example:

```
add jar /opt/mapr/hive/hive-<version>/hcatalog/share/hcatalog/
hive-hcatalog-core-<version>-mapr.jar
```

### 2. Create intermediate table.

For example:

```
CREATE EXTERNAL TABLE stage(id string, name string, age int)
ROW FORMAT SERDE 'org.apache.hive.hcatalog.data.JsonSerDe'
STORED AS TEXTFILE;
```

### 3. Load data in stage table.

For example:

```
LOAD DATA INPATH '/data' into table stage;
```

**NOTE:** If there is a key in the JSON file that starts with "\_" (for example, "\_id"), then treat the names as literals upon creating the schema and query using the same literal syntax. For example, specify ``_id`` string without any special serde properties. Then in the query, use `select `_id` from sometable;` Alternatively, you can use `'org.openx.data.jsonserde.JsonSerDe'` and add `WITH SERDEPROPERTIES ("mapping.id" = "_id")` to your table definition.

### 4. Create HPE Ezmeral Data Fabric Database table in Hive.

For example:

```
CREATE TABLE users(id STRING, name STRING, age INT)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/users", "maprdb.column.id" = "id");
```

### 5. Insert data through stage table.

For example:

```
INSERT INTO TABLE users select id, name, age from stage;
```

If there is a key in your JSON file that starts with "\_" (for example, "\_id"), treat the names as literals upon creating the schema and also query using the same literal syntax. In the above example, it would look like ``_id`` string without any special serde properties for it. Then, use again in query as shown below:

```
select `_id` from sometable;
```

Alternatively, use `org.openx.data.jsonserde.JsonSerDe` and add `WITH SERDEPROPERTIES ("mapping.id" = "_id")` to your table definition.

## Example

Refer to [Hive MapR Database JSON Connector Tutorial](#) for a connector example.

Understanding the UPDATE Statement

Starting with EEP 6.0.0 (Hive 2.3), EEP 5.0.1 (Hive 2.1), EEP 4.1.2, and EEP 3.0.4, the UPDATE statement is supported with Hive HPE Ezmeral Data Fabric Database JSON tables.

You can use the UPDATE statement to update primitive, complex, and complex nested data types in HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

### Updating Primitive Data Types

This section describes how to use the UPDATE statement to update primitive data types in HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

#### Procedure

1. Create a HPE Ezmeral Data Fabric Database JSON table and a Hive table:

```
CREATE TABLE simple_types_update (
>>>>>>> Incorporated edit comments
  doc_id string,
  bo boolean,
  d double,
  da date,
  f float,
  i int,
  s string,
  ts timestamp,
  ti tinyint,
  bi bigint,
  si smallint,
  bin binary)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/"
simple_types_update", "maprdb.column.id" = "doc_id");
```

2. Insert data into the table:

```
INSERT INTO TABLE simple_types_update VALUES ('1', true, 124.14,
'2017-11-29', 9192.12,
214566190, 'text', '2017-03-17 00:14:13', 125, 9223372036854775806,
23434, "binary string");
```

3. Run the UPDATE command on the table:

```
UPDATE simple_types_update
SET da = '2018-12-11',
bo = FALSE,
f = 91.777
WHERE doc_id = '1';
```

4. Verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables.

- Verifying Hive table data:

```
hive> SELECT * FROM simple_types_update;

1      false      124.14      2018-12-11      91.777      214566190      text
2017-03-17 00:14:13      125      9223372036854775806      23434      binary
string
```

- Verifying HPE Ezmeral Data Fabric Database JSON table data:

```
find '/simple_types_update'

{"_id":"1","bi":{"$numberLong":9223372036854775806},"bin":
{"$binary":"YmluYXJ5IHNOcmVudWZwAAAAAAAAA=="},
"bo":false,"d":124.14,"da":{"$dateDay":"2018-12-11"},
"f":{"$numberFloat":91.777},"i":{"$numberInt":214566190},
"s":"text","si":{"$numberShort":23434},"ti":{"$numberByte":125},"ts":
{"$date":"2017-03-17T00:14:13.000Z"}}
```

## Updating Complex Data Types

This section describes how to use the `UPDATE` statement to update complex data types in HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

### Procedure

1. Create a HPE Ezmeral Data Fabric Database JSON table and a Hive table:

```
CREATE TABLE complex_types_update (
  doc_id string,
  info MAP<STRING, INT>,
  pets ARRAY<STRING>,
  user_info STRUCT<name:STRING, surname:STRING, age:INT, gender:STRING>
  STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
  TBLPROPERTIES("maprdb.table.name" = "/
  complex_types_update","maprdb.column.id" = "doc_id");
```

2. Insert data into the table:

```
INSERT INTO TABLE complex_types_update SELECT '1', map('age', 28),
array('Cat', 'Cat', 'Cat'),
named_struct('name', 'Santa', 'surname', 'Claus', 'age', 1000, 'gender',
'MALE');
```

3. Run the `UPDATE` command on the table:

```
UPDATE complex_types_update SET
info = map('year', 32),
pets = array('Dog', 'Cat', 'Pig'),
user_info = named_struct('name', 'Vasco', 'surname', 'da Gama', 'age',
558, 'gender', 'MALE')
WHERE doc_id = '1';
```

4. Verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables.

- Verifying Hive table data:

```
hive> SELECT * FROM complex_types_update;

1      {"year":32}      ["Dog","Cat","Pig"]
{"name":"Vasco","surname":"da Gama","age":558,"gender":"MALE"}
```

- Verifying HPE Ezmeral Data Fabric Database JSON table data:

```
find '/complex_types_update'

{"_id":"1","info":{"year":{"$numberInt":32}},"pets":
["Dog","Cat","Pig"],"user_info":{"age":{"$numberInt":558},
"gender":"MALE","name":"Vasco","surname":"da Gama"}}
```

### Updating Complex Nested Data Types

This section describes how to use the UPDATE statement to update complex nested data types in HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

#### Procedure

1. Create a HPE Ezmeral Data Fabric Database JSON table and a Hive table using Hive:

```
CREATE TABLE complex_nested_data_type_update
(
    entry STRING,
    num INT,
    postal_addresses MAP <STRING,
    struct
<USER_ID:STRING,ADDRESS:STRING,ZIP:STRING,COUNTRY:STRING>>
)
stored BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
tblproperties
(
    "maprdb.table.name" = "/complex_nested_data_type_update",
    "maprdb.column.id" = "entry"
);
```

2. Insert data into the table:

```
INSERT INTO TABLE complex_nested_data_type_update
SELECT '001', '1',
MAP ( 'Bill',
Named_struct ('user_id', '1', 'address', '3205 Woodlake ct', 'zip',
'45040', 'country', 'USA'));
```

3. Run the UPDATE command on the table by updating the COUNTRY value in map(struct):

```
UPDATE complex_nested_data_type_update
SET postal_addresses = MAP ('Bill',
Named_struct ('user_id', '1', 'address', '3205 Woodlake ct', 'zip',
'45040', 'country', 'Hun'))
WHERE entry = '001';
```

4. Verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables.

- Verifying Hive table data:

```
hive> SELECT * FROM complex_nested_data_type_update;

001    1    {"Bill":{"user_id":"1","address":"3205 Woodlake
ct","zip":"45040","country":"Hun"}}
```

- Verifying HPE Ezmeral Data Fabric Database JSON table data:

```
find '/complex_nested_data_type_update'
{"_id":"001","num":{"$numberInt":1},"postal_addresses":{"Bill":
{"address":"3205 Woodlake
ct","country":"Hun","user_id":"1","zip":"45040"}}}
```

### UPDATE Statement Limitations

This section describes the features that the `UPDATE` statement does not support.

The `UPDATE` statement has the following known limitations:

- The `UPDATE` statement is fully supported only for primitive data types (see [Connecting to HPE Ezmeral Data Fabric Database](#)).
- The `UPDATE` statement is partly supported for complex data types; you can replace only the whole value of a complex type with new a value.
- You cannot update the `maprdb.column.id` value.

### Understanding the INSERT INTO Statement

This section describes how to use the `INSERT INTO` statement to insert or overwrite rows in nested HPE Ezmeral Data Fabric Database JSON tables, using the Hive connector.

- [Single-row insert](#) on page 4237
- [Multiple-row insert](#) on page 4239
- [Overwriting data](#) on page 4242

**NOTE:** The output shown in these examples is for illustration only; actual Hive CLI output varies, depending on your specific situation.

### Single-row insert

You can use the `INSERT INTO` statement to insert a single table row into a nested HPE Ezmeral Data Fabric Database table using one of two methods.

For example, imagine that you have the following Hive HPE Ezmeral Data Fabric Database JSON table, `nested_data_insert`:

```
CREATE TABLE nested_data_insert
(
  entry STRING,
  num INT,
  postal_addresses MAP <STRING,
  struct <USER_ID:STRING,ADDRESS:STRING, ZIP:STRING,COUNTRY:STRING>>
)
stored BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
tblproperties
(
  "maprdb.table.name" = "/nested_data_insert",
  "maprdb.column.id" = "entry"
);
```

- You can insert the new row into your table by using a dummy table:

```
WITH dummy_table AS
  (SELECT '001' AS KEY,
         '1' AS num,
         MAP ('Adam',
             Named_struct ('user_id', '1', 'address', '3205 Woodlake
ct', 'zip', '45040', 'country', 'Usa'),
             'Wilfred',
             Named_struct ('user_id', '2', 'address', '777 Brockton
Avenue', 'zip', '34000', 'country', 'Ita')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

- Alternatively, you can insert the new row into your table by using a SELECT statement:

```
INSERT INTO TABLE nested_data_insert
SELECT '002',
       '2',
       MAP ('Bill',
           Named_struct ('user_id', '1', 'address', '328 Virginia Ave',
'zip', '54956', 'country', 'Bol'),
           'Stiv',
           Named_struct ('user_id', '2', 'address', 'Schererville',
'zip', '46375', 'country', 'Efi'));
```

After you insert data, you should verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables:

- Verify the insertion into the Hive table by using the `SELECT * FROM` syntax.

```
SELECT * FROM nested_data_insert;
```

Sample output:

**Table**

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	1	Adam	1	3205 Woodlake ct	45040	Usa
		Wilfred	2	777 Brockton Avenue	34000	Ita
002	2	Bill	1	328 Virginia Ave	54956	Bol
		Stiv	2	Schererville	46375	Efi

- Verify the insertion into the HPE Ezmeral Data Fabric Database JSON table data using the `find` statement:

```
find '/nested_data_insert'

{
  "Adam": {
    "user_id": "1",
    "address": "3205 Woodlake ct",
    "zip": "45040",
    "country": "Usa"
  },
  "Wilfred": {
    "user_id": "2",
    "address": "777 Brockton Avenue",
    "zip": "34000",
    "country": "Ita"
  }
}

{
  "Bill": {
    "user_id": "1",
    "address": "328 Virginia Ave",
    "zip": "54956",
    "country": "Bol"
  },
  "Stiv": {
    "user_id": "2",
    "address": "Schererville",
    "zip": "46375",
    "country": "Efi"
  }
}
```

### Multiple-row insert

Now imagine that you want to insert three rows of data into `nested_data_insert`.

- You can insert the new rows into your table by using a dummy table:

```
WITH dummy_table AS
  (SELECT '003' AS KEY,
    '3' AS num,
    MAP ('Rony',
      Named_struct ('user_id', '1', 'address', '4333 Backer
str', 'zip', '12311', 'country', 'Hun')) AS postal_addresses
  UNION ALL SELECT '004' AS KEY,
    '4' AS num,
    MAP ('Ivan',
      Named_struct ('user_id', '1', 'address', '833
Bridle Avenue', 'zip', '95111', 'country', 'CA')) AS postal_addresses
  UNION ALL SELECT '005' AS KEY,
    '5' AS num,
    MAP ('Ivan',
      Named_struct ('user_id', '1', 'address', '664
Devon Ave', 'zip', '92021', 'country', 'Tog')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;
```

- Alternatively, you can insert the new rows into your table by using a `SELECT` statement:

```
INSERT INTO TABLE nested_data_insert
SELECT '006',
      '6',
      MAP ('Rony',
          Named_struct ('user_id', '1', 'address', '150 National City',
'zip', '91950', 'country', 'Hun'))
UNION ALL
SELECT '007',
      '7',
      MAP ('Tomason',
          Named_struct ('user_id', '1', 'address', '272 Ocean Circle' ,
'zip', '92801', 'country', 'CA'))
UNION ALL
SELECT '008',
      '8',
      MAP ('Davin',
          Named_struct ('user_id', '1', 'address', '81 Augusta Ave',
'zip', '93905', 'country', 'CA'));
```

After you insert data, you should verify that the data is inserted in both Hive and HPE Ezmeral Data Fabric Database JSON tables:

- Verify the insertion into the Hive table by using the `SELECT * FROM` syntax.

```
SELECT * FROM nested_data_insert WHERE entry > '002' ;
```

Sample output:

**Table**

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
003	3	Rony	1	4333 Backer str	12311	Hun
004	4	Ivan	1	833 Bridle Avenue	95111	CA
005	5	Ivan	1	664 Devon Ave.	92021	Tog
006	6	Rony	1	150 National City	91950	Hun
007	7	Tomason	1	272 Ocean Circle	92801	CA
008	8	Davin	1	81 Augusta Ave	93905	CA

- Verify the insertion into the HPE Ezmeral Data Fabric Database JSON table data using the `find` statement:

```
find '/nested_data_insert'

{
  "_id": "003",
  "num": {
    "$numberInt": 3
  },
  "postal_addresses": {
    "Rony": {
      "address": "4333 Backer str",
      "country": "Hun",
      "user_id": "1",
      "zip": "12311"
    }
  }
}

{
  "_id": "004",
  "num": {
    "$numberInt": 4
  },
  "postal_addresses": {
    "Ivan": {
      "address": "833 Bridle Avenue",
      "country": "CA",
      "user_id": "1",
      "zip": "95111"
    }
  }
}

{
  "_id": "005",
  "num": {
    "$numberInt": 5
  },
  "postal_addresses": {
    "Ivan": {
      "address": "664 Devon Ave",
      "country": "Tog",
      "user_id": "1",
      "zip": "92021"
    }
  }
}

{
  "_id": "006",
  "num": {
    "$numberInt": 6
  },
  "postal_addresses": {
    "Rony": {
      "address": "150 National City",
      "country": "Hun",
      "user_id": "1",
      "zip": "91950"
    }
  }
}

{
  "_id": "007",
```

```

    "num": {
      "$numberInt": 7
    },
    "postal_addresses": {
      "Tomason": {
        "address": "272 Ocean Circle",
        "country": "CA",
        "user_id": "1",
        "zip": "92801"
      }
    }
  }
}
{
  "_id": "008",
  "num": {
    "$numberInt": 8
  },
  "postal_addresses": {
    "Davin": {
      "address": "81 Augusta Ave",
      "country": "CA",
      "user_id": "1",
      "zip": "93905"
    }
  }
}
}

```

**Overwriting data**

Still using sample table `nested_data_insert`, you can use the `INSERT` statement on a dummy table to overwrite one or more complete rows.

For example, to overwrite the first row in `nested_data_insert (001)` with new values, use the following syntax:

```

WITH dummy_table AS
(SELECT '001' AS KEY,
 '1' AS num,
 MAP ('newAdam',
 Named_struct ('user_id', '1', 'address', 'newAdress', 'zip', 'newZip',
 'country', 'newCountry')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT *
FROM dummy_table;

```

After you overwrite data, you should verify that the data is changed in both Hive and HPE Ezmeral Data Fabric Database JSON tables:

- Verify the data into the Hive table by using the `SELECT * FROM` syntax.

```

hive> SELECT * FROM nested_data_insert WHERE entry = '001';

```

Sample output:

**Table**

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	1	newAdam	1	newAddress	newZip	newCountry

- Verify the data in the HPE Ezmeral Data Fabric Database JSON table data using the `findbyid` statement:

```
findbyid '/nested_data_insert' --id 001

{
  "_id": "001",
  "num": {
    "$numberInt": 1
  },
  "postal_addresses": {
    "newAdam": {
      "address": "newAddress",
      "country": "newCountry",
      "user_id": "1",
      "zip": "newZip"
    }
  }
}
```

For another example, imagine that you want to overwrite 003 and 004 rows in `nested_data_insert` with new values:

```
WITH dummy_table AS (
  SELECT '003' AS KEY,
  '3' AS num,
  MAP ('newName1',
  Named_struct ('user_id', '1', 'address', 'newAddress1', 'zip', 'newZip1',
  'country', 'newCountry1')) AS postal_addresses
  UNION ALL
  SELECT '004' AS KEY,
  '4' AS num,
  MAP ('newName2',
  Named_struct ('user_id', '1', 'address', 'newAddress2', 'zip', 'newZip2',
  'country', 'newCountry2')) AS postal_addresses)
INSERT INTO nested_data_insert
SELECT * FROM dummy_table;
```

After you overwrite the data, you should verify that the data is changed in both Hive and HPE Ezmeral Data Fabric Database JSON tables.

- Verify the data in the Hive table by using the `SELECT * FROM` syntax.

```
hive> SELECT * FROM nested_data_insert WHERE entry IN ('003', '004');
```

Sample output:

**Table**

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
003	3	newName1	1	newAddress1	newZip1	newCountry1
004	4	newName2	1	newAddress2	newZip2	newCountry2

Verify the data in the HPE Ezmeral Data Fabric Database JSON table data using the `findbyid` statement:

```
findbyid '/nested_data_insert' --id 003
{
```

```

    "_id": "003",
    "num": {
      "$numberInt": 3
    },
    "postal_addresses": {
      "newName1": {
        "address": "newAddress1",
        "country": "newCountry1",
        "user_id": "1",
        "zip": "newZip1"
      }
    }
  }
}
findbyid '/nested_data_insert' --id 004
{
  "_id": "004",
  "num": {
    "$numberInt": 4
  },
  "postal_addresses": {
    "newName2": {
      "address": "newAddress2",
      "country": "newCountry2",
      "user_id": "1",
      "zip": "newZip2"
    }
  }
}
}

```

**WARNING:** If you exclude columns both from the SELECT statement in your INSERT statement and from the table schema, the value of this column changes to NULL.

Finally, imagine that you want to overwrite the first row in `nested_data_insert` (001) with new values and overwrite the `num` column to NULL:

```

WITH dummy_table AS
(SELECT '001' AS KEY,
MAP ('newAdam',
Named_struct ('user_id', '1', 'address', 'newAddress', 'zip', 'newZip',
'country', 'newCountry')) AS postal_addresses)
INSERT INTO nested_data_insert (entry, postal_addresses)
SELECT * FROM dummy_table;

```

After you overwrite data, you should verify that the data is changed in both Hive and HPE Ezmeral Data Fabric Database JSON tables.

- Verify the data in the Hive table by using the `SELECT * FROM` syntax.

```
hive> SELECT * FROM nested_data_insert WHERE entry = '001';
```

Sample output:

**Table**

entry	num	postal_address				
			USER_ID	ADDRESS	ZIP	COUNTRY
001	NULL	newAdam	1	newAddress	newZip	newCountry

- Verify the data in the HPE Ezmeral Data Fabric Database JSON table (num row is not present):

```
findbyid '/nested_data_insert' --id 001

{
  "_id": "001",
  "postal_addresses": {
    "newAdam": {
      "address": "newAddress",
      "country": "newCountry",
      "user_id": "1",
      "zip": "newZip"
    }
  }
}
```

### Understanding the MERGE Statement

You can use the `MERGE` statement to perform record-level `INSERT` and `UPDATE` operations efficiently within Hive tables.

The `MERGE` statement can be a key tool for Data Fabriccluster data management. It is based on ANSI-standard SQL.

The following scenarios can help you understand how to use the `MERGE` statement:

- [Simple merge.maprdb.column.id is the join key](#) on page 4245
- [Simple merge.maprdb.column.id is not the join key](#) on page 4246
- [DELETE syntax in the MERGE statement](#) on page 4246
- [Multiple source rows match a given target row \(cardinality violation\)](#) on page 4247
- [Merge on mixed data types](#) on page 4248
- [Merge into external HPE Ezmeral Data Fabric Database JSON tables](#) on page 4249
- [Merge into partitioned HPE Ezmeral Data Fabric Database JSON tables](#) on page 4249
- [Merge into temporary HPE Ezmeral Data Fabric Database JSON tables](#) on page 4249

#### Simple merge.maprdb.column.id is the join key

Consider merging the following example source and target tables:

**Table**

id	first_name	last_name	age
001	Dorothi	Hogward	7777
002	Alex	Bowee	7777
088	Robert	Dowson	25

**Table**

id	first_name	last_name	age
001	John	Smith	45
002	Michael	Watson	27
003	Den	Brown	33

You can use the following SQL-standard MERGE statement:

```
MERGE into customer_db_json_target trg
USING customer_source src
ON src.id = trg.id
WHEN MATCHED THEN UPDATE SET age = src.age
WHEN NOT MATCHED THEN
INSERT VALUES (src.id, src.first_name, src.last_name, src.age);
```

The result is:

id	first_name	last_name	age
001	John	Smith	7777
002	Michael	Watson	7777
003	Den	Brown	33
088	Robert	Dowson	25

**NOTE:** The age column is updated and a new id column is inserted.

### Simple `merge.maprdb.column.id` is not the join key

Merging when `merge.maprdb.column` is not the join key is not recommended.

### DELETE syntax in the MERGE statement

This section describes how to use the DELETE syntax in the MERGE statement for HPE Ezmeral Data Fabric Database JSON tables. Included are examples of usage and limitations.

Consider two tables: `tgt` which is the target table of the MERGE statement, and `src`, which is the source table from which data will be taken. Both tables use `MapRDBJsonStorageHandler` to store data. The following table shows the initial contents of the `tgt` table:

**Table**

id	Value
1	AAA
2	BBB
3	CCC
4	DDD
5	EEE

The following table shows the initial contents of the `src` table:

**Table**

id	Value
1	AAA
222	BBB---
3	CCC
444	DDD---
5	EEE

The following merge statement contains a `WHEN MATCHED THEN DELETE` clause. It means that if the `id` from the `tgt` table equals the `id` from the `src` table, the row is removed from the `tgt` table. When the value of `id` does not match, a new row is inserted into the `tgt` table:

```
MERGE INTO tgt
USING src ON tgt.id=src.id
WHEN MATCHED THEN DELETE
WHEN NOT MATCHED THEN INSERT VALUES (src.id, src.value);
```

The following table shows the result of the merge:

**Table**

id	Value
2	BBB
222	BBB---
4	DDD
444	DDD---

Here we removed rows with `id` 1, 3, and 5 from the `tgt` table because they existed in the `src` table, and they matched values from the `tgt` table. We did not touch rows with `id` 2 and 4, because there were no such values in the `src` table. We inserted new rows with `id` values 222 and 444 because they existed in the `src` table and did not exist in the `tgt` table.

### Limitations

The preceding solution has three limitations:

1. Subqueries are not supported as a source when `DELETE` is used.
2. The source table should be a HPE Ezmeral Data Fabric Database JSON table when deletion is used in a `MERGE` operator.
3. The `DELETE` operator is not supported with additional conditions after `WHEN MATCHED`. Use either a single `UPDATE` or `DELETE`.

Limitation #3 means that queries like the following are not supported:

```
MERGE INTO tgt
USING src
ON tgt._id = src._id
WHEN MATCHED AND [boolean expression1] THEN DELETE
WHEN MATCHED AND [boolean expression2] THEN UPDATE
WHEN NOT MATCHED THEN INSERT
```

### Multiple source rows match a given target row (cardinality violation)

Consider merging the two tables `customer_db_json` and `customer_new`:

**Table**

id	first_name	last_name	age
001	John	Smith	45
002	Michael	Watson	27
003	Den	Brown	33

And:

Table

id	first_name	last_name	age
001	Dorothi	Hogward	77
001	Dorothi	Hogward	77
088	Robert	Dowson	25

To MERGE customer\_new and customer\_db\_json:

```
MERGE INTO customer_db_json trg
USING customer_new src ON src.id = trg.id
WHEN MATCHED THEN UPDATE
SET first_name = src.first_name,
last_name = src.last_name
WHEN NOT MATCHED THEN INSERT VALUES
(src.id, src.first_name, src.last_name, src.age);
```

This example causes an exception because of duplicate values in the id column in the customer\_new table:

```
Caused by: org.apache.hadoop.hive ql.metadata.HiveException: Error
evaluating cardinality_violation(_col0)
```

To avoid cardinality violation, set `hive.merge.cardinality.check=false`, but in this case the result is unpredictable because there is no rule that defines the order of duplicated data that will be inserted by using the MERGE statement.

### Merge on mixed data types

The merge operation also supports mixed data types, such as arrays, maps, and structures.

Consider two tables `mixed_types_source` and `mixed_types_target`:

Table

doc_id	user_info
1	{"name":"Brandon","surname":"Lee","age":31,"gender":"MALE"}
2	{"name":"Johnson","surname":"Fall","age":23,"gender":"MALE"}
3	{"name":"Mary","surname":"Dowson","age":11,"gender":"FEMALE"}
4	{"name":"Paul","surname":"Rodgers","age":41,"gender":"MALE"}

And:

Table

id	user_info
1	{"name":"Lexx","surname":"Comfuzer","age":31,"gender":"MALE"}

To merge `mixed_types_source` and `mixed_types_target`:

```
MERGE INTO mixed_types_target trg
USING mixed_types_source src
ON src.doc_id = old.doc_id
WHEN MATCHED THEN UPDATE
SET user_info = src.user_info
```

```
WHEN NOT MATCHED THEN INSERT VALUES
(src.doc_id, src.user_info);
```

The result is:

**Table**

id	first_name
1	{ "name": "Brandon", "surname": "Lee", "age": 31, "gender": "MALE" }
2	{ "name": "Johnson", "surname": "Fall", "age": 23, "gender": "MALE" }
3	{ "name": "Mary", "surname": "Dowson", "age": 11, "gender": "FEMALE" }
4	{ "name": "Paul", "surname": "Rodgers", "age": 41, "gender": "MALE" }

Note that you cannot update only a part of a complex structure field. For example, suppose you have a structure stored as one field in a Hive table:

```
{ "name": "Johnson", "surname": "Fall", "age": 23, "gender": "MALE" }
```

You cannot update only the `age` field in the structure. You can only replace all values of the structure with new ones. For details, see [Understanding the UPDATE Statement](#) on page 4233.

### Merge into external HPE Ezmeral Data Fabric Database JSON tables

The `MERGE` operator is also available for external HPE Ezmeral Data Fabric Database JSON tables. You can use the `MERGE` statement to insert and update values in external Data Fabric database JSON table targets.

### Merge into partitioned HPE Ezmeral Data Fabric Database JSON tables

Partitioned HPE Ezmeral Data Fabric Database JSON tables are not supported.

### Merge into temporary HPE Ezmeral Data Fabric Database JSON tables

The `MERGE` operator is also available for temporary HPE Ezmeral Data Fabric Database JSON tables. Use temporary tables as target tables for merge. No additional syntax is needed.

## Understanding the DELETE FROM Operation

In EEP 6.3.1 and later, you can use the `DELETE FROM` operation with HPE Ezmeral Data Fabric Database JSON tables.

### Delete All Data from a Table

To delete all data from a HPE Ezmeral Data Fabric DatabaseJSON table use the following operator:

```
DELETE FROM <table_name>;
```

**Example.** In this example we create a table, insert data, and delete all rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

**Table**

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query gives an empty set. Deletions are supported only for HPE Ezmeral Data Fabric Database JSON tables and transactional tables.

```
DELETE FROM customer;
SELECT doc_id, first_name, last_name FROM customer;
```

**Example.** In this example, we try to delete data from a non-transactional and non-Data Fabric Database JSON table:

```
DROP TABLE IF EXISTS simple_data;
CREATE TABLE simple_data (id INT);
INSERT INTO TABLE simple_data VALUES (1), (2), (3);
DELETE FROM simple_data;
```

The result is:

```
FAILED: SemanticException Operation is not supported. Table is nor ACID
neither MapRdbJSON
```

**Delete a Single Row from a Table**

To delete a single row from a HPE Ezmeral Data Fabric Database JSON table, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> = <value>;
```

Where:

<table\_name> is the HPE Ezmeral Data Fabric Database JSON table.

<id> is a key column of the Data Fabric Database JSON table. It corresponds to the `maprdb.column.id` property.

<value> is the value to be deleted.

**Example.** In this example, we create a table, insert data, and delete a single row:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

**Table**

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes a single row using the `WHERE` clause:

```
DELETE FROM customer WHERE doc_id = "002";
SELECT doc_id, first_name, last_name FROM customer;
```

**Table**

doc_id	first_name	last_name
001	Max	Born
003	Robby	Smart

**Note.** Deletions are supported only for key columns of HPE Ezmeral Data Fabric Database JSON tables.

**Example.** In this example, we try to use a column other than a key column of the Data Fabric Database JSON table in deletion.

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Column `first_name` is not the key column of the table.

```
DELETE FROM customer WHERE first_name = "Max";
```

The result is:

```
FAILED: SemanticException Deletion over column first_name is forbidden. Use
only key column of MapR Db Json table: doc_id
```

### Delete Several Rows from a Table

To delete several rows from a table, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> IN (<value1>, <value2>, ...);
```

Where:

<table\_name> is the HPE Ezmeral Data Fabric Database JSON table.

<id> is a key column of the MapR Database JSON table. It corresponds to the `maprdb.column.id` property.

<value1>, <value2>, are values to be deleted.

**Example.** In this example, we create a table, insert data, and delete several rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes several rows using the WHERE ... IN clause:

```
DELETE FROM customer WHERE doc_id IN ("001", "002");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
003	Robby	Smart

### Delete All Rows in a Table Except Listed Rows

To delete all rows from a table except a listed row, use the following syntax:

```
DELETE FROM <table_name> WHERE <id> NOT IN (<value1>, <value2>, ...);
```

Where:

<table\_name> is the HPE Ezmeral Data Fabric Database JSON table.

<id> is a key column of the MapR Database JSON table. It corresponds to the `maprdb.column.id` property.

<value1>, <value2>, are values to be preserved.

**Example.** In this example, we create a table, insert data, and delete all rows except the listed rows:

```
DROP TABLE IF EXISTS customer;
CREATE TABLE customer(doc_id STRING, first_name STRING, last_name STRING)
STORED BY 'org.apache.hadoop.hive.maprdb.json.MapRDBJsonStorageHandler'
TBLPROPERTIES("maprdb.table.name" = "/customer", "maprdb.column.id" =
"doc_id");
INSERT INTO TABLE customer VALUES ("001", "Max", "Born"), ("002", "Demmy",
"John"), ("003", "Robby", "Smart");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
001	Max	Born
002	Demmy	John
003	Robby	Smart

The following query deletes all rows except the listed rows:

```
DELETE FROM customer WHERE doc_id NOT IN ("003");
SELECT doc_id, first_name, last_name FROM customer;
```

Table

doc_id	first_name	last_name
003	Robby	Smart

### Limitations of the DELETE FROM Operation

The following are three limitations of the current implementation:

- The current implementation does not support arbitrary conditions in the WHERE clause of the DELETE statement even if a key column is used.

**Example.** In this example, DELETE FROM is used with an arbitrary condition:

```
DELETE FROM customer WHERE doc_id == "003" OR doc_id <> "005";
```

The result is:

```
FAILED:
  SemanticException This condition is not supported for MapR Db
  Json deletions. Supported
  WHERE clauses are: <id> = value, <id> IN (value1, value2, ...),
  <id> NOT IN (value1, value2,
  ...)
```

- The current implementation does not support subqueries in the WHERE clause.
- The current implementation does not support deletions in the MERGE statement.

### Hive and HBase Integration

You can create HBase tables from Hive that can be accessed by both Hive and HBase. This allows you to run Hive queries on HBase tables. You can also convert existing HBase tables into Hive-HBase tables and run Hive queries on those tables as well.

*Install and Configure Hive and HBase*

#### Procedure

1. Install and configure Hive if it is not already installed. See [Installing Hive](#) on page 240.
2. Install and configure HBase if it is not already installed. See [Installing HBase](#) on page 235.
3. Run the `jps` command, and ensure that all relevant Hadoop, HBase and Zookeeper processes are running:

```
$ jps
21985 HRegionServer
1549 jenkins.war
15051 QuorumPeerMain
30935 Jps
15551 CommandServer
15698 HMaster
15293 ResourceManager
15328 NodeManager
15131 WardenMain
```

### *Getting Started with Hive-HBase Integration*

In this tutorial you will:

- Create a Hive table
- Populate the Hive table with data from a text file
- Query the Hive table
- Create a Hive-HBase table
- Introspect the Hive-HBase table from HBase
- Populate the Hive-Hbase table with data from the Hive table
- Query the Hive-HBase table from Hive
- Convert an existing HBase table into a Hive-HBase table

Be sure that you have successfully completed all the steps in the Install and Configure Hive and HBase section before beginning this Getting Started tutorial. This Getting Started tutorial closely parallels the Hive-HBase Integration section of the Apache Hive Wiki, and thanks to Samuel Guo and other contributors to that effort.

#### **Create a Hive table with two columns:**

Change to your Hive installation directory if you're not already there and start Hive:

```
$ cd $HIVE_HOME
$ bin/hive
```

#### **Execute the CREATE TABLE command to create the Hive pokes table:**

```
hive> CREATE TABLE pokes (foo INT, bar STRING);
```

#### **To see if the pokes table has been created successfully, execute the SHOW TABLES command:**

```
hive> SHOW TABLES;
OK
pokes
Time taken: 0.74 seconds
```

The `pokes` table appears in the list of tables.

#### **Populate the Hive pokes table with data**

Execute the `LOAD DATA LOCAL INPATH` command to populate the Hive `pokes` table with data from the `kv1.txt` file.

The `kv1.txt` file is provided in the `$HIVE_HOME/examples` directory.

```
hive> LOAD DATA LOCAL INPATH './examples/files/kv1.txt' OVERWRITE INTO
TABLE pokes;
```

A message appears confirming that the table was created successfully, and the Hive prompt reappears:

```
Copying data from file:
...
OK
Time taken: 0.278 seconds
hive>
```

**Execute a SELECT query on the Hive pokes table:**

```
hive> SELECT * FROM pokes WHERE foo = 98;
```

The SELECT statement executes, runs a MapReduce application, and prints the job output:

```
OK
98      val_98
98      val_98
Time taken: 18.059 seconds
```

The output of the SELECT command displays two identical rows because there are two identical rows in the Hive `pokes` table with a key of 98. Note: This is a good illustration of the concept that Hive tables can have multiple identical keys. As we will see shortly, HBase tables cannot have multiple identical keys, only unique keys.

**To create a Hive-HBase table, enter these four lines of code at the Hive prompt:**

```
hive> CREATE TABLE hbase_table_1(key int, value string)
> STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
> WITH SERDEPROPERTIES ("hbase.columns.mapping" = ":key,cfl:val")
> TBLPROPERTIES ("hbase.table.name" = "xyz");
```

After a brief delay, a message appears confirming that the table was created successfully:

```
OK
Time taken: 5.195 seconds
```

Note: The TBLPROPERTIES command is not required, but those new to Hive-HBase integration may find it easier to understand what's going on if Hive and HBase use different names for the same table.

In this example, Hive will recognize this table as `"hbase_table_1"` and HBase will recognize this table as `"xyz"`.

**Start the HBase shell:**

Keeping the Hive terminal session open, start a new terminal session for HBase, then start the HBase shell:

```
$ cd $HBASE_HOME
$ bin/hbase shell
HBase Shell; enter 'help<RETURN>' for list of supported commands.
Type "exit<RETURN>" to leave the HBase Shell
Version 0.90.4, rUnknown, Wed Nov  9 17:35:00 PST 2011

hbase(main):001:0>
```

**Execute the list command to see a list of HBase tables:**

```
hbase(main):001:0> list
TABLE
xyz
1 row(s) in 0.8260 seconds
```

HBase recognizes the Hive-HBase table named `xyz`. This is the same table known to Hive as `hbase_table_1`.

**Display the description of the xyz table in the HBase shell:**

```
hbase(main):004:0> describe "xyz"
DESCRIPTION
```

```

    ENABLED
    {NAME => 'xyz', FAMILIES => [{NAME => 'cf1', BLOOMFILTER => 'NONE',
    REPLICATI true
    ON_SCOPE => '0', COMPRESSION => 'NONE', VERSIONS => '3', TTL =>
    '2147483647', BL
    OCKSIZE => '65536', IN_MEMORY => 'false', BLOCKCACHE => 'true'}}}
1 row(s) in 0.0190 seconds

```

### From the Hive prompt, insert data from the Hive table pokes into the Hive-HBase table hbase\_table\_1

```

hive> INSERT OVERWRITE TABLE hbase_table_1 SELECT * FROM pokes WHERE foo=98;
...
2 Rows loaded to hbase_table_1
OK
Time taken: 13.384 seconds

```

### Query hbase\_table\_1 to see the data we have inserted into the Hive-HBase table:

```

hive> SELECT * FROM hbase_table_1;
OK
98      val_98
Time taken: 0.56 seconds

```

Even though we loaded two rows from the Hive `pokes` table that had the same key of 98, only one row was actually inserted into `hbase_table_1`. This is because `hbase_table_1` is an HBASE table, and although Hive tables support duplicate keys, HBase tables only support unique keys. HBase tables arbitrarily retain only one key, and will silently discard all the data associated with duplicate keys.

### Convert a pre-existing HBase table to a Hive-HBase table

To convert a pre-existing HBase table to a Hive-HBase table, enter the following four commands at the Hive prompt.

Note that in this example the existing HBase table is `my_hbase_table`.

```

hive> CREATE EXTERNAL TABLE hbase_table_2(key int, value string)
> STORED BY 'org.apache.hadoop.hive.hbase.HBaseStorageHandler'
> WITH SERDEPROPERTIES ("hbase.columns.mapping" = "cf1:val")
> TBLPROPERTIES("hbase.table.name" = "my_hbase_table");

```

Now we can run a Hive query against the pre-existing HBase table `my_hbase_table` that Hive sees as `hbase_table_2`:

```

hive> SELECT * FROM hbase_table_2 WHERE key > 400 AND key < 410;
Total MapReduce jobs = 1
Launching Job 1 out of 1
Number of reduce tasks is set to 0 since there's no reduce operator
...
OK
401      val_401
402      val_402
403      val_403
404      val_404
406      val_406
407      val_407
409      val_409
Time taken: 9.452 seconds

```

## Hive and HPL/SQL Integration

**Note:** This feature is presented as a developer preview. Developer previews are not tested for production environments, and should be used with caution.

HPL/SQL includes a Hive UDF function that allows you to execute HPL/SQL scripts (user-defined functions written in HPL/SQL language) in Hive queries.

HPL/SQL uses the `hplsql_locals.sql` file to parse a prepared procedure that can be used in the Hive query. If you want to add and use multiple functions, you should add each function to the `hplsql_locals.sql` file.

For example, to call the `hello` function from a Hive query, you can add a `hello` function to the `hplsql_locals.sql` file:

```
CREATE FUNCTION hello(text STRING)
  RETURNS STRING
  BEGIN
    RETURN 'Hello, ' || text || '!';
  END;
```

There are two possible ways to run the HPL/SQL `hello` function:

### Running HPL/SQL from Hive CLI/Hive Beeline

The `hplsql_locals.sql` file must be located in the directory where the Hive CLI is started or in the `/opt/mapr/hive/hive-<version>/bin` directory if you are using Beeline. After adding the `hello` function to the `hplsql_locals.sql` file, register the HPL/SQL UDF in Hive as follows:

```
CREATE TEMPORARY FUNCTION hplsql AS 'org.apache.hive.hplsql.Udf';
```

To use the `hello` function written in HPL/SQL language in Hive, use a query such as the following:

```
SELECT hplsql('hello(:1)', name) FROM users;
```

### Running HPL/SQL from the HPL/SQL CLI

When you run HPL/SQL scripts using the HPL/SQL CLI, you can use user-defined functions the same way you use built-in functions:

```
hplsql -e "SELECT hello(name) FROM users;"
```

The HPL/SQL CLI automatically connects to HiveServer2 using the configuration from the `hplsql-site.xml` file, registers the Hive UDF, and modifies the function call in the SQL statements. But you must ensure that the `hplsql_locals.sql` file containing the user-defined functions is located in the `/opt/mapr/hive/hive-<version>/bin` directory, where HiveServer2 can parse it.

For more information, see [User-Defined Functions and Stored Procedures](#).

## Hive and HCatalog Integration

The [HCatalog](#) on page 4162 library provides applications with a table view of the file system layer in your cluster, expanding your application's options from read/write data streams to add table operations such as `get row` and `store row`. The HCatalog library stores the metadata required for its operations in the Hive Metastore.

The `hcat` utility can execute any of the data definition language (DDL) commands available in Hive that do not involve launching a MapReduce application. Internally, the `hcat` utility passes DDL commands to the `hive` program. Data stored in the Data Fabric file system is serialized and deserialized through

`InputStorageFormats` and `OutputStorageFormats` objects for records. Fields within a record are parsed with `SerDes`.

**WARNING:**

The `hive-json-serde-0.2.jar` JSON serializer/deserializer has not implemented a `serialize()` method and as a result does not function.

The WebHCat server provides a REST-like web API for HCatalog. For more information about using WebHCat, see [Hive and WebHCat Integration](#) on page 4260.

This section contains the following topics:

*Accessing HCatalog Tables from Hive*

**About this task**

To access tables created in HCatalog in Hive, use the following command to append paths to your `HADOOP_CLASSPATH` environment variable:

```
export HADOOP_CLASSPATH=${HADOOP_CLASSPATH}:$HCAT_HOME/share/hcatalog/
storage-handlers/hbase/lib/hbase-storage-handler-<version>.jar:$HCAT_HOME/
share/hcatalog/hcatalog-core-<version>-mapr.jar:$HCAT_HOME/share/hcatalog/
hcatalog-pig-adapter-<version>-mapr.jar:$HCAT_HOME/share/hcatalog/
hcatalog-server-extensions-<version>-mapr.jar
```

*Loading and Retrieving Data from Pig*

**About this task**

To use the HCatalog library `HCatLoader` and `HCatStorer` to load and retrieve data from Pig:

**Procedure**

1. Create a table with the `hcat` utility.

```
hcat -e "create table hcatpig(key int, value string)"
```

2. Verify that the table and table definition both exist.

```
hcat -e "describe formatted hcatpig"
```

3. Load data into the table from Pig: Copy the `$HIVE_HOME/examples/files/kv1.txt` file into the MapRFS file system, then start Pig and load the file with the following commands:

```
pig -useHCatalog -Dfs.default.name=maprfs://CLDB_Host:7222/
grunt> A = LOAD 'kv1.txt' using PigStorage('\u0001') AS(key:INT,
value:chararray);
grunt> STORE A INTO 'hcatpig' USING
org.apache.hive.hcatalog.pig.HCatStorer();
```

- Retrieve data from the `hcatpig` table with the following Pig commands: Another way to verify that the data is loaded into the `hcatpig` table is by looking at the contents of `maprfs://user/hive/warehouse/hcatpig/`. HCatalog tables are also accessible from the Hive CLI. All Hive queries work on HCatalog tables.

```
B = LOAD 'default.hcatpig' USING
org.apache.hive.hcatalog.pig.HCatLoader();
dump B; // this should display the records in kv1.txt
```

## Running MapReduce Applications

### About this task

This example uses a sample MapReduce program named `HCatalogMRTest.java`.

### Procedure

- From the command line, issue the following commands to define the environment:

```
export LIB_JARS=
$HCAT_HOME/share/hcatalog/hcatalog-core-<version>-mapr.jar,
$HIVE_HOME/lib/hive-metastore-<version>-mapr.jar,
$HIVE_HOME/lib/libthrift-<version>.jar,
$HIVE_HOME/lib/hive-exec-<version>-mapr.jar,
$HIVE_HOME/lib/libfb303-<version>.jar,
$HIVE_HOME/lib/jdo2-api-<version>-ec.jar,
$HIVE_HOME/lib/slf4j-api-<version>.jar

export HADOOP_CLASSPATH=
$HCAT_HOME/share/hcatalog/hcatalog-core-<version>-mapr.jar:
$HIVE_HOME/lib/hive-metastore-<version>-mapr.jar:
$HIVE_HOME/lib/libthrift-<version>.jar:
$HIVE_HOME/lib/hive-exec-<version>-mapr.jar:
$HIVE_HOME/lib/libfb303-<version>.jar:
$HIVE_HOME/lib/jdo2-api-<version>-ec.jar:
$HIVE_HOME/conf:
$HADOOP_HOME/conf:
$HIVE_HOME/lib/slf4j-api-<version>.jar
```

- Compile `HCatalogMRTest.java`:

```
javac -cp `hadoop classpath`:${HCAT_HOME}/share/hcatalog/
hcatalog-core-<version>-mapr.jar HCatalogMRTest.java -d .
```

- Create a JAR file:

```
jar -cf hcatmrtest.jar org
```

- Create an output table:

```
hcat -e "create table hcatpigoutput(key int, value int)"
```

5. Run the job: At the end of the job, the file `hcatpigoutput` should have entries in the form `key, count`.

```
hadoop --config $HADOOP_HOME/conf jar ./hcatmrtest.jar
org.myorg.HCatalogMRTest -libjars $LIB_JARS hcatpig hcatpigoutput
```

### *Running Non-MapReduce Applications*

#### **About this task**

This example uses a sample MapReduce program named `TestReaderWriter.java`.

#### **Procedure**

1. Add the following JAR files to your `$HADOOP_CLASSPATH` environment variable with the following command:

```
export HADOOP_CLASSPATH=$HADOOP_CLASSPATH:/opt/
mapr/hive/hive-<version>/lib/antlr-runtime-3.4.jar:/opt/mapr/hive/
hive-<version>/lib/hive-cli-<version>-mapr.jar
```

2. Compile the test program with the following command:

```
javac -cp `hadoop classpath`:${HCAT_HOME}/share/hcatalog/
hcatalog-core-<version>-mapr.jar TestReaderWriter.java -d <directory>
```

3. Create a JAR file with the following command:

```
jar -cf hcatrwtest.jar org
```

4. Run the job with the following command:

```
hadoop jar /root/<username>/hcatalog/hcatrwtest.jar
org.apache.hive.catalog.data.TestReaderWriter -libjars $LIB_JARS
```

#### **Results**

The last command should result in a table named `mytbl` that is populated with data.

#### **Hive and WebHCat Integration**

The WebHCat server provides a REST-like web API for HCatalog. Applications make HTTP requests to run Pig, Hive, and HCatalog DDL from within applications.

This topic contains the following sections:

#### *Configuring the WebHCat Server*

#### **About this task**

The properties to configure WebHCat are in the following file:

```
/opt/mapr/hive/hive-<version>/hcatalog/etc/webhcat/webhcat-site.xml
```

When you set up WebHCat, you can configure file system and Zookeeper as storage.

**Procedure**

1. To configure storage for WebHCat, add the MapRFS location property.

```
<property> <name>templeton.storage.class</name>
<value>org.apache.hive.hcatalog.templeton.tool.HDFSStorage</value> </
property> <property> <name>templeton.storage.root</name> <value>/user/
mapr/webhcat</value> <description>The path to the directory to use for
storage</description> </property>
```

2. To configure WebHCat for Pig:

- a) Compress the Pig installation, then move the compressed file to the MapRFS layer.

```
# cd /opt/mapr/pig
# tar -czvf /tmp/pig-<version>.tar.gz pig-<version>/
# hadoop fs -mkdir /user/mapr/webhcat
# hadoop fs -put /tmp/pig-<version>.tar.gz /user/mapr/webhcat/
```

- b) Set the value of the `templeton.pig.archive` property to the location of the compressed file.

```
<property> <name>templeton.pig.archive</name> <value>maprfs:///user/
mapr/webhcat/pig-<version>.tar.gz</value> </property>
```

- c) Set the value of the `templeton.pig.path` property to the path inside the compressed Pig file where the Pig binary is located.

```
<property>
  <name>templeton.pig.path</name>
  <value>pig-<version>.tar.gz/pig-<version>/bin/pig</value>
</property>
```

3. To configure WebHCat for Hive:

- a) Compress the Hive installation, then move the compressed file to the file system layer.

```
# cd /opt/mapr/hive
# tar -czvf /tmp/hive-<version>.tar.gz hive-<version>/
# hadoop fs -mkdir /user/mapr/webhcat
# hadoop fs -put /tmp/hive-<version>.tar.gz /user/mapr/webhcat
```

- b) Set the value of the `templeton.hive.archive` property to the location of the compressed file.

```
<property> <name>templeton.hive.archive</name> <value>maprfs:///user/
mapr/webhcat/hive-<version>.tar.gz</value> </property>
```

- c) Set the value of the `templeton.hive.path` property to the path inside the compressed Hive file where the Hive binary is located.

```
<property>
  <name>templeton.hive.path</name>
  <value>hive-<version>.tar.gz/hive-<version>/bin/hive</value>
</property>
```

4. To Configure WebHCat for streaming:

- a) Copy the Streaming JAR to the file system layer.

```
# hadoop fs -put
/opt/mapr/hadoop/hadoop-<version>/contrib/streaming/
hadoop-<version>-dev-streaming.jar /user/mapr/webhcat
```

- b) Set the `templeton.streaming.jar` property to the location of the streaming JAR.

```
<property> <name>templeton.streaming.jar</name> <value>maprfs:///user/
mapr/webhcat/hadoop-<version>-dev-streaming.jar</value> </property>
```

### Configure WebHCat Server to use SSL Encryption

#### About this task

You can configure WebHCat REST-API to use SSL (Secure Sockets Layer) encryption. The following WebHCat properties are added to enable SSL:

```
templeton.use.ssl
Default value: false
Description: Set this to true for using SSL encryption for WebHCat server

templeton.keystore.path
Default value: <empty string>
Description: SSL certificate keystore location for WebHCat server

templeton.keystore.password
Default value: <empty string>
Description: SSL certificate keystore password for WebHCat server

templeton.ssl.protocol.blacklist
Default value: SSLv2,SSLv3
Description: SSL Versions to disable for WebHCat server

templeton.host
Default value: 0.0.0.0
Description: The host address the WebHCat server will listen on
```

#### Modifying the `webhcat-site.xml` file:

#### Procedure

Configure the following properties in the `webhcat-site.xml` file to enable SSL encryption on each node where HWebHCat is installed:

```
<!-- WebHCat SSL -->
<property>
  <name>templeton.use.ssl</name>
  <value>true</value>
</property>

<property>
  <name>templeton.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
</property>

<property>
  <name>htempleton.keystore.password</name>
```

```
<value><ssl-keystore-password></value>
</property>
```

**NOTE:** After running `/opt/mapr/server/configure.sh -R`, all properties needed to enable SSL encryption for WebHCat are added automatically to `webhcat-site.xml` on the MapR-SASL secure cluster.

To check status of WebHCat server configured for SSL encryption, use following command:

```
curl -k 'https://<user>:<password>@<host>:50111/templeton/v1/status'
```

#### Requirements for Using Automatically Generated PEM Files

To use automatically generated PEM files for the WebHCat REST API on a MapR-SASL cluster, you need to have a cluster with a host name that consists at least of three parts: administrator user name and password, and WebHCat REST API host.

#### About this task

Check the status of the WebHCat REST API to make sure you have a cluster with a host name that consists of the administrator user name and password, and WebHCat REST API host service:

```
curl --cacert /opt/mapr/conf/ssl_truststore.pem -u
<cluster_admin_user>:<cluster_admin_password>
"https://<myhost.mapr.com>:50111/templeton/v1/status" -v
```

#### Results

The sample output for this example is as follows:

```
* TCP_NODELAY set
* Connected to c74v610.mapr.com (192.168.122.254) port 50111 (#0)
* Cipher selection: ALL:!EXPORT:!EXPORT40:!EXPORT56:!aNULL:!LOW:!
RC4:@STRENGTH
* successfully set certificate verify locations:
CAfile: /opt/mapr/conf/ssl_truststore.pem
CApath: none
* (303) (OUT), TLS Unknown, Certificate Status (22):
* (303) (OUT), TLS handshake, Client hello (1):
* (303) (IN), TLS handshake, Server hello (2):
* (303) (IN), TLS handshake, Certificate (11):
* (303) (IN), TLS handshake, Server key exchange (12):
* (303) (IN), TLS handshake, Server finished (14):
* (303) (OUT), TLS handshake, Client key exchange (16):
* (303) (OUT), TLS change cipher, Client hello (1):
* (303) (OUT), TLS handshake, Finished (20):
* (303) (IN), TLS change cipher, Client hello (1):
* (303) (IN), TLS handshake, Finished (20):
* SSL connection using unknown / ECDHE-RSA-AES256-GCM-SHA384
* Server certificate:
*  subject: CN=*.mapr.com
*  start date: May 10 15:18:03 2018 GMT
*  expire date: Apr 16 15:18:03 2118 GMT
*  common name: *.mapr.com (matched)
*  issuer: CN=*.mapr.com
*  SSL certificate verify ok.
* Server auth using Basic with user 'mapr'
> GET /templeton/v1/status HTTP/1.1
> Host: c74v610.mapr.com:50111
> Authorization: Basic bWFwcjptYXBy
> User-Agent: curl/7.59.0
```

```
> Accept: */*
>
< HTTP/1.1 200 OK

< Transfer-Encoding: chunked
< Server: Jetty(7.6.0.v20120127)
<
* Connection #0 to host c74v610.mapr.com left intact
{"version": "v1", "status": "ok"}
```

### Managing the WebHCat Server

#### About this task

As of Hive 0.13-1504 and Hive 1.0-1504, WebHCat is managed by Warden. Therefore, you can start and stop WebHCat using maprccli and the Control System.

#### Starting the WebHCat Server

#### About this task

Applies to versions prior to Hive 0.13-1504 and Hive 1.0-1504:

```
# ./webhcat_server.sh start
```

#### Starting WebHCat Using the maprccli

#### Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprccli node services command:

```
maprccli node services -name hcat -action start -nodes <space delimited
list of nodes>
```

#### Stopping WebHCat Using the maprccli

#### Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprccli node services command:

```
maprccli node services -name hcat -action stop -nodes <space delimited
list of nodes>
```

#### Starting or Stopping WebHCat Using the Control System

#### Procedure

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **WebHcat** to open the Nodes screen displaying all the nodes on which Hive Metastore is configured.

- On the Nodes screen, click the hostname of each node to display its Node Properties screen.
- On each Node Properties screen, use the **Stop/Start** button in the WebHcat row under Manage Node Services to start WebHcat.

### Checking the Error Logs

#### About this task

Go to the following folder:

```
/opt/mapr/hive/hive-<version>/logs/<user.name>/webhcat
```

**NOTE:** If you are running a Hive 0.13 version prior Hive 0.13-1504, go to the `/tmp/<user.name>/webhcat` folder to view the error logs.

### Verifying the Server's Status

#### About this task

In a web browser, navigate to:

```
http://hostname:50111/templeton/v1/status?user.name=root
```

A healthy server will return the string `{"status": "ok", "version": "v1"}`. You can change the port number from the default value of 50111 by editing the `webhcat-site.xml` file.

#### *Running Jobs on the WebHcat Server*

#### About this task

##### REST Calls in WebHcat

The base URI for REST calls in WebHcat is `http://<host>:<port>/templeton/v1/`. The following table lists elements appended to the base URI and DDL commands.

URI	Description
<b>Server Information</b>	
<code>/status</code>	Shows WebHcat server status.
<code>/version</code>	Shows WebHcat server version.
<b>DDL Commands</b>	
<code>/ddl/database</code>	List existing databases.
<code>/ddl/database/&lt;mydatabase&gt;</code>	Shows properties for the database named <i>mydatabase</i> .
<code>/ddl/database/&lt;mydatabase&gt;/table</code>	Shows tables in the database named <i>mydatabase</i> .
<code>/ddl/database/&lt;mydatabase&gt;/table/&lt;mytable&gt;</code>	Shows the table definition for the table named <i>mytable</i> in the database named <i>mydatabase</i> .
<code>/ddl/database/&lt;mydatabase&gt;/table/&lt;mytable&gt;/property</code>	Shows the table properties for the table named <i>mytable</i> in the database named <i>mydatabase</i> .

### Launching a MapReduce Job with WebHcat

**About this task**

WebHCat launches two jobs for each MapReduce job. The first job, `TempletonControllerJob`, has one map task. The map task launches the actual job from the REST API call. Check the status of both jobs and the output directory contents.

**Procedure**

1. Copy the MapReduce example job to the MapRFS layer:

```
hadoop fs -put /opt/mapr/hadoop/hadoop-<version>/
hadoop-<version>-dev-examples.jar /user/mapr/webhcat/examples.jar
```

2. Use the `curl` utility to launch the job:

```
curl -s -d jar=examples.jar -d class="terasort" -d
arg=teragen.test -d arg=whop3 'http://localhost:50111/templeton/v1/
mapreduce/jar?user.name=<username>'
```

### Launching a Streaming MapReduce Job with WebHCat

**Procedure**

1. Use the `curl` utility to launch the job:

```
curl -s -d arg=teragen.test -d output=mycounts -d mapper=/bin/cat -d
reducer="/usr/bin/wc -w" 'http://localhost:50111/templeton/v1/mapreduce/
streaming?user.name=<username>'
```

2. Check the job status for both WebHCat jobs at the jobtracker page in the Control System.

### Launching a Pig Job with WebHCat

**Procedure**

1. Copy a data file into MapRFS:

```
hadoop fs -put $HIVE_HOME/examples/files/kv1.txt /user/<user name>/
```

2. Create a `test.pig` file with the following contents:

```
A = LOAD 'kv1.txt' using PigStorage('\u0001') AS(key:INT,
value:chararray);
STORE A INTO 'pig.output';
```

3. Copy the `test.pig` file into MapR filesystem:

```
hadoop fs -put test.pig /user/<user name>/
```

4. Run the Pig REST API command:

```
curl -s -d file=test1.pig -d arg=-v 'http://localhost:50111/templeton/v1/
pig?user.name=<username>'
```

5. Monitor the contents of the `pig.output` directory.

6. Check the JobTracker page for two jobs: `TempletonControllerJob` and `PigLatin`.

## Launching a Hive Job with WebHCat

### Procedure

1. Create a table:

```
curl -s -d execute="create+external+table+ext3(t+TIMESTAMP)+location /
user/<user name>/ext3" 'http://localhost:50111/templeton/v1/hive?
user.name=<username>'
```

2. Load data into the table:

```
curl -s -d execute="insert+overwrite+table+ext3+select+*+from+datetable"
'http://localhost:50111/templeton/v1/hive?user.name=<username>'
```

3. List the tables:

```
curl -s -d execute="show+tables" -d statusdir='hive.output' 'http://
localhost:50111/templeton/v1/hive?user.name=<username>'
```

The list of tables is in `hive.output/stdout`.

## The Job Queue

### About this task

To show HCatalog jobs for a particular user, navigate to the following address:

```
http://<hostname>:<port>/templeton/v1/queue/?user.name=<username>
```

The default port for HCatalog is 50111.

### Hive and Tez Integration

You can use Tez, instead of MapReduce, for generic data processing tasks. Tez significantly increases the processing speed. Tez, working with Hive, provides lower latency for interactive queries and higher throughput for batch queries.

*Configuring Hive and Tez*

### About this task

To configure Hive on Tez, repeat the following steps on each node where you want to configure Hive on Tez. Tez mode for MR jobs is not compatible with all MR jobs, so do not set up the whole cluster to work on Tez.

There is a known issue related to the incomplete removal of previously installed Tez packages. The issue affects platforms on which Tez was installed but later removed using `sudo apt-get remove mapr-tez`. Because of Ubuntu-specific behavior and Tez source-code issues, the `remove` command removes Tez only partially in some installations. If this happens, an error is generated when you try to re-install Tez on Ubuntu, as described following in step 1. If you believe your installation might have this issue, you can prevent the error. Before performing the following steps, use the `purge` command to completely remove all previously installed Tez packages.

**Procedure**

1. Install Tez if it is already not installed. To install Tez, run the following command:

On CentOS / RedHat	<code>yum install mapr-tez</code>
On SLES	<code>zypper install mapr-tez</code>
On Ubuntu	<code>apt-get install mapr-tez</code>

**NOTE:** Repeat this step on each node where you want Hive on Tez to be configured.

2. Create the `/apps/tez` directory on Data Fabric file system.

To create, run the following commands:

```
hadoop fs -mkdir /apps
hadoop fs -mkdir /apps/tez
```

3. Upload the Tez libraries to the `/tez` directory on the Data Fabric file system.

To upload, run the following commands:

```
hadoop fs -put /opt/mapr/tez/tez-<version> /apps/tez
hadoop fs -chmod -R 755 /apps/tez
```

4. Verify the upload.

To verify, run the following command:

```
hadoop fs -ls /apps/tez/tez-<version>
```

5. Set the Tez environment variables. To set, open the `/opt/mapr/hive/hive-<version>/conf/hive-env.sh` file, add the following lines, and save the file:

```
export TEZ_CONF_DIR=/opt/mapr/tez/tez-<version>/conf
export TEZ_JARS=/opt/mapr/tez/tez-<version>/*:/opt/mapr/tez/
tez-<version>/lib/*
export HADOOP_CLASSPATH=$TEZ_CONF_DIR:$TEZ_JARS:$HADOOP_CLASSPATH
```

**NOTE:** Repeat this step on each node where you want Hive on Tez to be configured.

6. Configure Hive for Tez engine. To configure, open the `/opt/mapr/hive/hive-<version>/conf/hive-site.xml` file, add the following lines, and save the file.

```
<property>
  <name>hive.execution.engine</name>
  <value>tez</value>
</property>
```

Add the `hive.exec.pre.hooks`, `hive.exec.post.hooks`, and `hive.exec.failure.hooks` properties with value `org.apache.hadoop.hive.ql.hooks.ATSHook` to use the Hive queries page in the Tez UI.

**NOTE:** Starting from EEP 7.1.0, the following execution-hooks properties are managed by running `configure.sh` command with `-R` option.

```
<property>
  <name>hive.exec.pre.hooks</name>
  <value>org.apache.hadoop.hive.ql.hooks.ATSHook</value>
</property>

<property>
  <name>hive.exec.post.hooks</name>
  <value>org.apache.hadoop.hive.ql.hooks.ATSHook</value>
</property>

<property>
  <name>hive.exec.failure.hooks</name>
  <value>org.apache.hadoop.hive.ql.hooks.ATSHook</value>
</property>
```

**NOTE:** Repeat this step on each node where you want Hive on Tez to be configured.

7. Run `configure.sh` with the `-R` option.

```
/opt/mapr/server/configure.sh -R
```

**NOTE:** Starting in EEP 6.0.1 and later, Tez should be configured by running the `$MAPR_HOME/server/configure.sh` script with the `-R` option.

8. Configure Tez shuffle on a secured cluster:  
Refer to [Tez Shuffle](#) on page 4277 to configure SSL encryption on shuffle.

#### *Known Issues and Restrictions*

**Sqoop importing data into Hive fails when the entire cluster is configured to use Tez.**

This is because of Sqoop's incompatibility with Tez.

**Workaround:** Do not configure the entire cluster to use Tez.

**Percentage sampling is not supported in `org.apache.hadoop.hive.ql.io.HiveInputFormat`.**

Hive uses `org.apache.hadoop.hive.ql.io.HiveInputFormat` by default and so queries like `'SELECT * FROM tablename TABLESAMPLE(20 percent);'` will not work for Hive on Tez.

**Workaround:** Instead of `org.apache.hadoop.hive.ql.io.HiveInputFormat`, use

```
org.apache.hadoop.hive ql.io.CombineHive
InputFormat.
```

To change input format, do one of the following:

- Set `hive.tez.input.format` in hive shell. For example:

```
hive> set
hive.tez.input.format=org.apache.ha
doop.hive.ql.io.CombineHiveInputFor
mat;
```

- Add `org.apache.hadoop.hive.ql.io.CombineHiveInputFormat` to `hive-site.xml` file. For example:

```
<property>
  <name>hive.tez.input.format</
name>

  <value>org.apache.hadoop.hive.ql.io
.CombineHiveInputFormat</value>
</property>
```

**Hive on Tez does not work well with Sequence Files Schema changes**

TEZ-2741

**Limitations with common joins**

HIVE-11693: The `CommonMergeJoinOperator` only sets big table position when it has inputs for big table. If the input is empty, the method is not called.

**HiveServer2 on Tez doesn't support concurrent queries within one session**

HIVE-9223: When multiple queries are submitted in the same HS2 session concurrently, some queries fail with an error.

**Tez upgrade issues**

- No support for preserving configuration from EEP-5.0.0 and EEP-4.1.1 (ECO-1803) to EEP-6.0.0(1808) or EEP-5.0.1(1808) on Ubuntu.
- No support for preserving Tomcat configuration from previous EEPs to EEP-6.0.0 (1808).
- You should manually stop the Tomcat service and delete the tomcat folder as a precondition if you are updating or upgrading Tez from the following EEPs:  
EEP-4.0.0  
EEP-4.1.0

**Tez shuffle SSL encryption issue**

During a shuffle phase, the `javax.net.ssl.SSLException` error could occur on a multi-node cluster due to insufficient Tez shuffle SSL encryption configuration, see [Tez Shuffle](#) on page 4277 for a solution.

*SQL Limitations*

The following is a list of SQL limitations on Hive on Tez:

Issue	Summary
HIVE-11693	CommonMergeJoinOperator throws exception with Tez.

Issue	Summary
HIVE-9989	Hive on Tez group by with cast(NULL AS BIGINT) throws NPE.
HIVE-11270	Tez gives different responses when run on Physical tables and logical views.
HIVE-9223	HiveServer2 on Tez doesn't support concurrent queries within one session.
HIVE-13623	Hive on Tez produces wrong results when withClause and (outer) joins.
TEZ-2741	Hive on Tez does not work well with Sequence Files Schema changes.
HIVE-13926	Cannot limit reduce (not both Map and Reduce) memory in Tez engine.

### *Hive-on-Tez User Interface*

This section describes how to install, configure, manage, and start the Hive-on-Tez user interface.

 **WARNING:** The Hive-on-Tez user interface supports RM HA only starting from the 1803 release (EEP 4.1.1 and EEP-5.0.0).

### Installing the Hive-on-Tez User Interface

This topic describes installation of the Hive-on-Tez user interface by using the Data Fabric Installer or manual steps.

#### Installation Using the Data Fabric Installer

When you use the Data Fabric Installer to install Tez, the timeline server for the Hive-on-Tez user interface is installed automatically. If the **Enable MapR Secure Cluster** option is enabled in the Data Fabric Installer, the timeline server is installed to be secure.

The Tomcat server is installed into this folder:

```
/opt/mapr/tez/tez-<version>/tomcat/apache-tomcat-<version>
```

To start using the Hive-on-Tez user interface if the **Enable MapR Secure Cluster** option is enabled or if the cluster is Kerberized, you must log in to the timeline server user interface:

```
https://<hostname>:8190
```

#### Manual Installation

To install the Hive-on-Tez user interface manually:

1. Install and configure `mapr-tez` as described in [Configuring Hive and Tez](#) on page 4267.
2. Install the timeline server:

<b>On CentOS / Red Hat</b>	<code>yum install mapr-timelineserver</code>
<b>On SLES</b>	<code>zypper install mapr-timelineserver</code>
<b>On Ubuntu</b>	<code>apt-get install mapr-timelineserver</code>

**NOTE:** Install the timeline server on a single node. The Hive-on-Tez user interface does not support High Availability (HA).

## Configuring the Timeline Server to Use the Hive-on-Tez User Interface

This topic describes how to configure the timeline server to use the Hive-on-Tez user interface. This topic includes security configuration information.

### About this task

When the timeline server is installed using the MapR Installer, the installer secures the timeline server automatically. When you install the timeline server manually, use these steps.

**NOTE:** This procedure assumes that you have previously configured the cluster using the `configure.sh` script.

### Procedure

1. Run `configure.sh -R` (on all Hive nodes), replacing `<hostname>` with the name of your timeline server node:

```
sudo /opt/mapr/server/configure.sh -R -TL <hostname>
```

**NOTE:** Make sure the hostname matches the CN in `ssl_keystore` for secure clusters. If not, all hive and yarn jobs fail. The hostname can be obtained using the `$hostname -f` command.

Running `configure.sh -R` configures the timeline server properties in `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-site.xml` for enhanced security.

2. To use the timeline server with Kerberos, you need to make additional entries to the `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-site.xml` file. Replace the following variables with real values:

- MAPR\_PRINCIPAL
- PATH\_TO\_KEYTAB
- HTTP\_PRINCIPAL

```
<property>
  <name>yarn.timeline-service.principal</name>
  <value>MAPR_PRINCIPAL</value>
</property>
<property>
<name>yarn.timeline-service.keytab</name>
  <value>PATH_TO_KEYTAB</value>
</property>
<property>
  <name>yarn.timeline-service.http-authentication.kerberos.principal</
name>
  <value>HTTP_PRINCIPAL</value>
</property>
<property>
  <name>yarn.timeline-service.http-authentication.kerberos.keytab</name>
  <value>PATH_TO_KEYTAB</value>
</property>
```

3. Restart the resource manager:

```
maprcli node services -name resourcemanager -action restart -nodes
<hostname>
```

## Configuring the Tomcat Server

This topic describes how to configure and manage the Tomcat server for the Hive-on-Tez user interface.

### Extracting the Tomcat Server

You can only extract the Tomcat server after you manually install Tez. Tez has a built-in Tomcat Server archive with the latest version. You can find the archive at:

```
$TEZ_HOME/tomcat/tomcat.tar.gz
```

To extract the Tomcat server, use these commands in the command line:

```
cd $TEZ_HOME/tomcat/
sudo tar -zxvf tomcat.tar.gz -C $TEZ_HOME/tomcat
```

Change the permissions for the /tomcat directory to the user who will be running the Tomcat server:

```
sudo chown -R <$USER>:<$USER_GROUP> $TEZ_HOME/tomcat
```

### Configuring the Timeline Server Base URL and Resource Manager WEB URL

To set the `timelineBaseUrl` and `RMwebUrl`, update the Tez configuration file.

The file location is:

```
$TEZ_HOME/tomcat/apache-tomcat-<version>/webapps/tez-ui/config/configs.js
```

To configure the Timeline Server Base URL and Resource Manager WEB URL:

1. Replace `TIME_LINE_BASE_URL` with the real URL. For example:

- For a non-secure configuration:

```
'http://localhost:8188'
```

- For a secure configuration:

```
'https://localhost:8190'
```

2. Replace `RM_WEB_URL` with the real URL. For example:

- For a non-secure configuration:

```
'http://localhost:8088'
```

- For a secure configuration:

```
'https://localhost:8090'
```

- For a proxy server, specify the user-defined URL in the `yarn-site.xml` file, as shown:

```
<property>
  <name>yarn.web-proxy.address</name>
  <value><hostname>:<port></value>
</property>
```

Replace `RM_WEB_URL` with the value specified as the `yarn.web-proxy.address` property.

### Configuring SSL for the Tomcat Server on a Secure Cluster

To start the Tomcat server with the exposed SSL port, edit the following properties in the `$TEZ_HOME/tomcat/apache-tomcat-<version>/conf/server.xml` file, replacing `<ssl-keystore-password>` with the real SSL keystore password.

1. Find the default configuration of the exposed port:

```
<Connector port="9383"
  protocol="HTTP/1.1"
  connectionTimeout="20000"
  redirectPort="8443" />
```

2. Change the configuration for SSL:

```
<Connector port="9393"
  SSLEnabled="true"
  maxThreads="150"
  scheme="https"
  secure="true"
  clientAuth="false"
  sslProtocol="TLS"
  keystoreFile="/opt/mapr/conf/ssl_keystore"
  keystorePass="<ssl-keystore-password>" />
```

**NOTE:** If you used Installer version 1.15.0.0 to install the cluster, see [Hive-on-Tez User Interface Known Issues](#) on page 4276.

### Starting and Stopping the Tomcat Server

To start the Tomcat server, run this script:

```
$TEZ_HOME/tomcat/apache-tomcat-<version>/bin/startup.sh
```

To stop the Tomcat server, run this script:

```
$TEZ_HOME/tomcat/apache-tomcat-<version>/bin/shutdown.sh
```

**NOTE:** The `timelineBaseUrl` maps to the YARN Timeline Server, and the `RMWebUrl` maps to the YARN Resource Manager. For default port information, see [Ports Used by HPE Ezmeral Data Fabric Software](#) on page 3084.

### Configuring the Tez UI (Tomcat) to be Managed by Warden

This section describes how to use manual steps to configure and verify that the Tez UI (Apache Tomcat) is managed by Warden.

Using the Installer to install Tez configures the Tez UI to be managed by *Warden* by default.

## Prerequisites

Before continuing, ensure that the following prerequisites are met:

- Hive and Tez are installed on the node.
- You have completed all of the tasks described under [Hive-on-Tez User Interface](#) on page 4271.
- The Tez UI is up and running and functioning properly.

## Manually Configure the Tez UI Server

To manually configure the Tez UI server so that it can be managed by Warden and the Control System, copy and rename the `warden.tezui.conf.template` file in the Tez `conf` dir:

```
mv /opt/mapr/tez/tez-<version>/conf/warden.tezui.conf.template /opt/mapr/
conf/conf.d/warden.tezui.conf
```

## Verify that the Tez UI Is Managed by Warden

After configuration, to verify that the Tez UI is managed by Warden, you can try using the Tez UI directly, or use the command line to check the list of open files (specify port 9383 or 9393):

```
lsof -i:<port>
```

The following example shows that the Tomcat service is running:

```
lsof -i:9383
COMMAND  PID USER  FD   TYPE DEVICE SIZE/OFF NODE NAME
java     31580 mapr   56u  IPv6 271941      0t0  TCP *:9383 (LISTEN)
```

## Use maprcli Commands to Stop, Start, or Restart the Tez UI

The following `maprcli` commands help you manage the Tomcat server. Use these commands to confirm that you can manage the Tez UI through the `maprcli`. You can also use these commands to stop, start, or restart the Tomcat server after configuration changes.

To stop node services for the Tez UI:

```
/opt/mapr/bin/maprcli node services -name tezui -action stop -nodes
<tez_ui_node_name>
```

To start node services for the Tez UI:

```
/opt/mapr/bin/maprcli node services -name tezui -action start -nodes
<tez_ui_node_name>
```

To restart node services for the Tez UI:

```
/opt/mapr/bin/maprcli node services -name tezui -action restart -nodes
<tez_ui_node_name>
```

## Use the Control System Commands to Stop, Start, or Restart the Tez UI

In the Control System, the procedure is generally the same for stopping, starting, and restarting the Tez UI:

1. Log in to the Control System and click **Services** to display the list of services on the cluster.
2. Click one of the following icons for the Tez UI service:

- To stop the service, click .
- To start the service, click .
- To restart the service, click .

### Integrating the Hive-on-Tez User Interface with Tez

This topic describes how to integrate the Hive-on-Tez user interface with Tez.

1. Add the following entry to the `/opt/mapr/tez/tez-<version>/conf/tez-site.xml` file, replacing `<hostname>: <port>` with the real host name. You can use 9383 or 9393 for the port. 9383 is HTTP and 9393 is HTTPS Tomcat port for the Hive-on-Tez user interface.

```
<property>
  <description>Enable Tez to use the Timeline Server for History
  Logging</description>
  <name>tez.history.logging.service.class</name>

  <value>org.apache.tez.dag.history.logging.ats.ATSHistoryLoggingService</
  value>
</property>

<property>
  <description>URL for where the Tez UI is hosted</description>
  <name>tez.tez-ui.history-url.base</name>
  <value>http(s)://<hostname>:<port>/tez-ui/</value>
</property>
```

Repeat this step on each node where you want the Hive-on-Tez user interface to be configured.

### Connecting to the Hive-on-Tez User Interface

This topic describes how to connect to the Hive-on-Tez user interface.

To start using the Hive-on-Tez user interface on a MapR secure or Kerberized cluster, you must log in to the timeline server user interface and RM UI:

```
https://<hostname>:8190
```

```
https://<hostname>:8090
```

To connect to the Hive-on-Tez user interface on secure clusters, use a browser to navigate to:

```
https://<hostname>:9393/tez-ui/
```

where `<hostname>` is the host where the Tomcat server is running.

### Hive-on-Tez User Interface Known Issues

This topic describes known issues that you should be aware of while troubleshooting.

#### Installer Configuration Known Issues

If you used Installer version 1.15.0.0 to install the cluster, re-assign the following existing truststore SSL variables with the correct keystore SSL variables:

Existing variables (truststore)	Correct variables (keystore)
<code>keystoreFile="/opt/mapr/conf/ssl_truststore"</code>	<code>keystoreFile="/opt/mapr/conf/ssl_keystore"</code>
<code>keystorePass="&lt;ssl-truststore-password&gt;"/&gt;</code>	<code>keystorePass="&lt;ssl-keystore-password&gt;"/&gt;</code>

## Timeline Server Known Issues

**(Issue 29538)** After an incremental install or rolling upgrade to MapR 6.1, the timeline server does not start. To resolve this issue, add the following entry to `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/yarn-env.sh`:

```
export YARN_TIMELINESERVER_OPTS="$ {YARN_TIMELINESERVER_OPTS} $
{MAPR_LOGIN_OPTS} "
```

To grant administrative privileges to any user(s), modify `yarn-site.xml`, as shown:

```
<property>
  <name>yarn.admin.acl</name>
  <value><user_name></value>
</property>
```

After the `yarn.admin.acl` property takes effect, the user specified by `<user_name>` has administrative privileges and access to all jobs.

For example, User-A can access all the jobs owned by User-A, by default. If User-A needs access to jobs owned by other users, administrative privileges can be granted to User-A through the `yarn.admin.acl` property.

### Tez Shuffle

Tez uses `org.apache.hadoop.mapred.ShuffleHandler` provided by MapReduce version 2.0 (MRv2) as an auxiliary service, which you can choose to configure via the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/mapred-site.xml` file.

On a secured cluster, Tez shuffle, SSL encryption configuration is enabled in `/opt/mapr/tez/tez-<version>/conf/tez-site.xml` by default:

<code>tez.runtime.shuffle.ssl.enable</code>	<code>true</code>
<code>tez.runtime.shuffle.keep-alive.enabled</code>	<code>true</code>

Also, you must configure Tez shuffle for YARN by adding the following property to the `mapred-site.xml` file. Edit the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/mapred-site.xml` file:

<code>mapreduce.shuffle.ssl.enabled</code>	<code>true</code>
--	-------------------

### Queue Management with Hive-on-Tez

HiveServer2 provides built-in functionality to set-up and handle a pool of Tez sessions in default queues. Tez initiates a session and keeps it alive to run sequential queries. Queries can be submitted through HiveServer2 clients, such as Beeline and the Hive CLI. You can manage queues through properties in `hive-site.xml`.

Queue management is strongly connected to the type of YARN Scheduler used. By default, an HPE Ezmeral Data Fabric cluster uses Fair Scheduler and Hive-on-Tez to run queries in queues with a user name. If a query is submitted from the Hive CLI, the real user name is used. If a query is submitted from a HiveServer2 client, such as Beeline, the queue name depends on the HiveServer2 impersonation configuration property, `hive.server2.enable.doAs`, where the queue name could be the real user name or the user name of the Hiveserver2 process.

With Capacity Scheduler, Hive queries submitted from the CLI and Beeline are configured through the `capacity-scheduler.xml` file. Default queue names are chosen from the scheduler settings, but you can also use the `tez.queue.name=<queue_name>` property to run queries in a specific queue.

Application Masters (AM) are strongly bound to YARN. You cannot change the queue for an AM that is already started. If impersonation is enabled for HiveServer2, a new AM starts next to an existing AM for a default queue. Do not use or close a default queue at the end of a lifetime.

**NOTE:** HiveServer2 works with or without impersonation. Impersonation is set through the `hive.server2.enable.doAs` property.

### Run Queries in a Specific Queue

If you want all queries to run in a specific queue, you can configure a queue name through the `tez.queue.name` property. When you configure a queue name through the `tez.queue.name` property, Tez sets the queue name for all jobs submitted from the client to the configured `tez.queue.name`. You can set this property before each query through the Hive SET command, as shown:

```
set tez.queue.name=<queue_name>;
```

Or, you can set the property in the `hive-site.xml` file, as shown:

```
<property>
  <name>tez.queue.name</name>
  <value>my_queue</value>
</property>
```

**IMPORTANT:** If you set `tez.queue.name` in `hive-site.xml`, and you want the queue name to persist across all queries in the session, you must also set the `hive.server2.tez.unset.tez.queue.name` property in `hive-site.xml` to `false`, as shown:

```
<property>
  <name>tez.queue.name</name>
  <value>my_queue</value>
</property>
<property>
  <name>hive.server2.tez.unset.tez.queue.name</name>
  <value>false</value>
</property>
```

If `hive.server2.tez.unset.tez.queue.name` is set to `true`, Hive will not persist the `tez.queue.name` across queries and instead uses the default cluster queue names.

### Configuration Properties

HiveServer2 has several settings related to queue management. Specify the following properties in the `hive-site.xml` file:

Property	Description	Default Value
<code>tez.queue.name</code>	The queue name for all jobs submitted from a given client. Set through the Hive CLI via the SET command before running a query or through <code>hive-site.xml</code> . If you set the property through <code>hive-site.xml</code> , and you want the setting to persist across all queries that run, set <code>hive.server2.tez.unset.tez.queue.name</code> to <code>false</code> .	No default. Must be explicitly set.
<code>hive.server2.tez.initialize.default.sessions</code>	When set to <code>true</code> , enables you to use HiveServer2 without turning on Tez for HiveServer2. Useful when you want to run queries over Tez without the pool of sessions.	<code>false</code>

Property	Description	Default Value
hive.server2.tez.default.queues	A list of comma-separated values that correspond to YARN queues of the same name. When HiveServer2 is launched in Tez mode, this configuration must be set to enable multiple Tez sessions to run in parallel on the cluster.	empty string
hive.server2.tez.sessions.per.default.queue	A positive integer that determines the number of Tez sessions that should launch in each of the queues specified by <code>hive.server2.tez.default.queues</code> . Determines the parallelism on each queue. For example, if you specify two default queues and two sessions per default queue, four application masters start.	1
hive.server2.tez.session.lifetime	Defines the lifetime of the Tez sessions launched by HiveServer2 when default sessions are enabled. Set to 0 to disable session expiration.	162h
hive.server2.tez.unset.tez.queue.name	Controls whether the <code>tez.queue.name</code> persists across all queries in a session. Must be set to <code>false</code> for the <code>tez.queue.name</code> to persist. When set to <code>true</code> , the <code>tez.queue.name</code> only applies to the first query that runs; thereafter, the default cluster queue names are used.   <b>NOTE:</b> This functionality was introduced in EEP 7.01 and EEP 6.3.2. A patch for previous EEP versions is available. See <a href="#">Applying a Patch</a> .	true

## Managing Hive Services

This section includes the following topics:

### Starting Hive

You can start the Hive shell from `HIVE_HOME/bin/` with the `hive` command. Example:

```
/opt/mapr/hive/hive-<version>/bin/hive
```

When the Hive shell starts, it reads an initialization file called `.hiverc` which is located in the `HIVE_HOME/bin/` or `$HOME/` directories. You can edit this file to set custom parameters or commands that initialize the Hive command-line environment, one command per line.

When you run the Hive shell, you can specify a MySQL initialization script file using the `-i` option. Example:

```
/opt/mapr/hive/hive-<version>/bin/hive -i <filename>
```

### Setting the Execution Engine

Consider the following definitions:

Term	Definition
runtime	The execution time of the job.
session time	The time from the start of the Hive shell or Beeline until you exit.

You can change the execution engine during a session (session time), but not while executing a job in the session (runtime). If you specify the execution engine before starting the job, it overrides the

hive.execution.engine property in the hive-site.xml file. For example, to specify the execution engine:

```
hive> set hive.execution.engine=tez;
hive> *perform some query here*
```

If you open another Hive shell or Beeline session, you will not see the setting in the session from before, and you can set the needed properties for every session.

**!** **IMPORTANT:** Hewlett Packard Enterprise strongly recommends configuring Tez as an execution engine instead of an MR execution engine. MR execution engine is deprecated in Hive and is not suitable for use in production environments.

If you are currently using the MR execution engine for accessing Hive CLI and HS2, Hive generates the following warning message:

```
Hive-on-MR is deprecated in Hive 2 and may not be available in the future
versions. Consider using a different execution engine (i.e. spark, tez) or
using Hive 1.X releases.
```

To install and configure Tez as an execution engine for Hive, see [Configuring Hive and Tez](#).

### Managing Hive Metastore

The Hive Metastore is started automatically by the warden at installation time if the mapr-hivemetastore package is installed. It is sometimes necessary to start or stop the service (for example, after changing the configuration). You can start and stop Hive Metastore in two ways:

- Using the maprccli node services command - Using this command, you can start Hive Metastore on multiple nodes at one time.
- Using the MapR Control System

*To start Hive Metastore using the maprccli:*

#### Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprccli node services command:

```
/opt/mapr/bin/maprccli node services -name hivemeta -action start -nodes
<space delimited list of nodes>
```

*To stop Hive Metastore using the maprccli:*

#### Procedure

1. Make a list of nodes on which Hive Metastore is configured.
2. Issue the maprccli node services command:

```
maprccli node services -name hivemeta -action stop -nodes <space
delimited list of nodes>
```

*To start or stop Hive Metastore using the Control System:*

### Procedure

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **Hive Metastore** to open the Nodes screen displaying all the nodes on which Hive Metastore is configured.
3. On the Nodes screen, click the hostname of each node to display its Node Properties screen.
4. On each Node Properties screen, use the **Stop/Start** button in the Hive Metastore row under Manage Node Services to start Hive Metastore.

### Managing Hiveserver2

Hiveserver2 is started automatically at installation time by the warden if the `mapr-hiveserver2` package is installed. It is sometimes necessary to start or stop the service (for example, after changing the configuration). You can start and stop Hiveserver2 in two ways:

- Using the `maprcli node services` command - Using this command, you can start Hiveserver2 on multiple nodes at one time.
- Using the MapR Control System

*To start Hiveserver2 using the maprcli:*

### Procedure

1. Make a list of nodes on which Hiveserver2 is configured.
2. Issue the `maprcli node services` command:

```
maprcli node services -name hs2 -action start -nodes <space delimited
list of nodes>
```

*To stop Hiveserver2 using the maprcli:*

### Procedure

1. Make a list of nodes on which Hiveserver2 is configured.
2. Issue the `maprcli node services` command:

```
maprcli node services -name hs2 -action stop -nodes <space delimited
list of nodes>
```

*To start or stop Hiveserver2 using the Control System:*

### Procedure

1. In the Navigation pane, expand the Cluster Views pane and click **Dashboard**.
2. In the Services pane, click **Hiveserver2** to open the Nodes screen displaying all the nodes on which Hiveserver2 is configured.
3. On the Nodes screen, click the hostname of each node to display its Node Properties screen.

- On each Node Properties screen, use the **Stop/Start** button in the Hiveserver2 row under Manage Node Services to start Hiveserver2.

### Connecting to Hive

This section contains the following topics:

#### Connecting to Hive Metastore

The connection requirements Hive Metastore clients use to connect to Hive Metastore is based on the Hive Metastore authentication method:

Authentication Method	Connection Requirements
MapR-SASL	Client nodes require the following: <ul style="list-style-type: none"> <li>They are configured to use MapR-SASL when authenticating with Hive Metastore.</li> <li>A valid Data Fabric ticket.</li> </ul>
Kerberos	Client nodes require the following: <ul style="list-style-type: none"> <li>They are configured to use Kerberos when authenticating with Hive Metastore.</li> <li>A valid Kerberos ticket.</li> </ul>
No Authentication	If the cluster is not secure, client nodes do not require any Data Fabric tickets.

Connecting to HMS is provided by the thrift service. You can configure it in hive-site.xml with hive.metastore.uris property:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n<:9083</value>
  <description>IP address (or fully-qualified domain name) and port of the
  metastore host</description>
</property>
```

### Connecting to HiveServer2

The method that HiveServer2 clients use to connect to HiveServer2 is based on the HiveServer2 Authentication method and the type of client.

#### Using JDBC or Beeline to Connect to HiveServer2

The HiveServer2 authentication method and client type determine how the HiveServer2 clients connect to HiveServer2.

**TIP:** For details on how to install and use ODBC to connect to Hive, see [Using ODBC to Connect to HiveServer2](#) on page 4289. When connecting to Hive via ODBC, the client must have a valid Data Fabric or Kerberos ticket.

#### Using JDBC or Beeline to Connect to HiveServer2

The default port for HiveServer2 is 10000.

The following table lists HiveServer2 authentication mechanisms with the connection parameters required in the JDBC connection string. For a complete list of the JDBC connection string parameters, refer to the next section, Hive JDBC Connection String Parameters.

HiveServer2 Authentication	Connection Requirements
No Authentication	<p><b>Connection String:</b> jdbc:hive2://&lt;hs2_hostname&gt;:10000&lt;database&gt;; You must enter a valid user name.</p> <p><b>For encryption, JDBC requires a truststore and an optional truststore password.</b></p> <ul style="list-style-type: none"> <li>• <b>Connection String with Encryption:</b> jdbc:hive2://&lt;hs2_hostname&gt;:10000/&lt;database&gt;; You must enter a valid user name.ssl=true;sslTrustStore=&lt;path-to-truststore&gt;;sslTrustStorePassword=&lt;password&gt;</li> <li>• <b>Connection String with Encryption (truststore passed in JVM arguments):</b> jdbc:hive2://&lt;hs2_hostname&gt;:&lt;port&gt;/&lt;database&gt;;ssl=true</li> </ul> <p> <b>NOTE:</b> Prior to connecting to an application that uses JDBC, such as Beeline, you can run the following command to pass the truststore parameters as Java arguments:</p> <pre data-bbox="927 842 1455 1003">export HADOOP_OPTS="-Djavax.net.ssl.trustStore=&lt;path-to-trust-store-file&gt; -Djavax.net.ssl.trustStorePassword=&lt;password&gt;"</pre>
MapR-SASL (included as part of the secure by default configuration)	<p><b>Connection String:</b> jdbc:hive2://&lt;hs2_hostname&gt;:10000/&lt;database&gt;;auth=maprsasl;ssl=true;</p> <p>MapR-SASL encryption is enabled by default. For more information, see <a href="#">Configuring JDBC Connection String with SSL Encryption Enabled or Disabled</a>.</p> <p> <b>NOTE:</b> MapR-SASL is not supported for Hive in HTTP mode.</p> <p><b>Connection for Java Application:</b> Use the -D flag to append the JVM argument: -Dhadoop.login=maprsasl.</p>
PAM	<p><b>Connection String:</b> jdbc:hive2://&lt;hs2_hostname&gt;:10000/&lt;database&gt;;user=&lt;user&gt;;password=&lt;password&gt;</p>
PAM + SSL (included as part of the secure by default configuration)	<p><b>Connection String:</b> jdbc:hive2://&lt;hs2_hostname&gt;:10000/&lt;database&gt;;ssl=true;user=&lt;user&gt;;password=&lt;password&gt;. For more information, see <a href="#">Configuring JDBC Connection String with SSL Encryption Enabled or Disabled</a>.</p>

HiveServer2 Authentication	Connection Requirements
Kerberos	<p><b>Connection String:</b> jdbc:hive2://&lt;hostname&gt;:10000/default;principal=mapr/&lt;FQDN@REALM&gt;</p> <p><b>Connection for Java Application:</b> Use the <code>-D</code> flag to append the JVM argument: <code>-Dhadoop.login=hybrid</code></p> <p> <b>NOTE:</b> The client nodes must also have a Kerberos ticket and be configured to connect to HiveServer2 to use Kerberos.</p>
LDAP	<p><b>Connection String:</b> jdbc:hive2://&lt;hs2_hostname&gt;:10000/&lt;database&gt;;user=&lt;ldap_user&gt;;password=&lt;ldap_password&gt;</p>
ZooKeeper	<p><b>Connection String:</b> jdbc:hive2://&lt;hostname&gt;:&lt;port&gt;,&lt;hostname&gt;:&lt;port&gt;;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=hiveserver2</p> <p><b>Example:</b></p> <pre>hive --service beeline -u     'jdbc:hive2://     zookeeper1.com:5181,zookeeper2.com:5181,     zookeeper3.com:5181;serviceDiscoveryMod     e=zooKeeper;zooKeeperNamespace=hiveserve     r2' -n mapr -p</pre>

### Hive JDBC Connection String Parameters

The following example shows a common Hive JDBC connection string:

```
jdbc:hive2://zookeeper_quorum|hs2_host:port/[db]
[;principal=<hs2_principal>/<hs2_host>|_HOST@<KDC_REALM>]
[;transportMode=binary|http][;httpPath=<http_path>]
[;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=<zk_namespace>]
[;auth=maprsasl][;ssl=true|false][;sslKeyStore=<key_store_path>]
[;keyStorePassword=<key_store_password>][;sslTrustStore=<trust_store_path>]
[;trustStorePassword=<trust_store_password>][;twoWay=true|false]
```

The following table lists all the Hive JDBC connection string parameters with default values where applicable:

JDBC Parameter	Default	Comment
zookeeper_quorum		Zookeeper quorum. Used only if HA mode for HiveServer2 is enabled.
hs2_host		The hostname of the node with an active HS2 server running.
port	10000/10001	HiveServer2 port. Defaults to 10000 in binary mode. Defaults to 10001 in HTTP transport mode.
[db]	default	The database name to which you want to connect.

[;principal=<hs2_principal>/<hs2_host> _HOST@<KDC_REALM>]		Kerberos principal. Used with Kerberos security only.
[;transportMode=binary http]	binary	HS2 uses a TThreadPoolServer (from Thrift) for TCP (binary) mode, or a Jetty server for the HTTP mode.  HTTP mode is required when a proxy is needed between the client and server, for example, for load balancing or security reasons.
[;httpPath=<http_path>]	cliservice or /	The corresponding HTTP endpoint. The default value is cliservice or /. See conf hive.server2.thrift.http.path
[;serviceDiscoveryMode=zookeeper;zooKeeperNamespace=<zookeeper_namespace>]		<zookeeper_namespace> is the parent node in ZooKeeper used by HiveServer2 when supporting dynamic service discovery.
[;auth=maprsasl]		Used with MapR SASL security.
[;ssl=true false]	false	Used to enable SSL encryption.
[;sslKeyStore=<key_store_path>]	Default value is read from \$MAPR_HOME/conf/ssl-client.xml	This parameter only takes effect when ssl=true. Path is the path to the keystore.
[;keyStorePassword=<key_store_password>]	Default value is read from \$MAPR_HOME/conf/ssl-client.xml	This param will take effect only when ssl=true. Keystore password.
[;sslTrustStore=<trust_store_path>]	Default value is read from \$MAPR_HOME/conf/ssl-client.xml	This param will take effect only when ssl=true. Path is the path to the truststore.
[;trustStorePassword=<trust_store_password>]	Default value is read from \$MAPR_HOME/conf/ssl-client.xml	This parameter only takes effect when ssl=true. Password is the truststore password.
[;twoWay=true false]		<a href="#">HIVE-10447</a> enabled the JDBC driver to support 2-way SSL in HTTP mode. Currently, HiveServer2 does not support 2-way SSL. This feature is useful when there is an intermediate server, such as Knox, which requires the client to support 2-way SSL.

### Beeline Examples

This page shows examples for connecting to HiveServer2 using Beeline.

The following table is a guide for interpreting the examples on this page. In the examples, replace the variables (information in brackets) with your site-specific values. Be sure to remove the brackets when you insert your information:

Variable	Description
<hs2_hostname>	The name of the host where HiveServer2 is installed.
<database>	The database name to connect to.
<username>	The JDBC username.
<password>	The password for the JDBC user.
<FQDN@realm>	Fully qualified domain name & Kerberos realm.

### Using Beeline with no Encryption and no Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/<database>;
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>;: <username>
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

### Using Beeline with Encryption and no Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/
<database>;ssl=true;sslTrustStore=truststore.jks;sslTrustStorePassword=tsp
Connecting to jdbc:hive2://<hs2_hostname>:10000/
<database>;ssl=true;sslTrustStore=truststore.jks;sslTrustStorePassword=tsp
Enter username for jdbc:hive2://<hs2_hostname>:10000/
<database>;ssl=true;sslTrustStore=truststore.jks;sslTrustStorePassword=tsp:
<username>
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

### Connecting to HiveServer2 with MapR-SASL Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/
<database>;auth=maprsasl;ssl=true
Connecting to jdbc:hive2://<hs2_hostname>:10000/
<database>;auth=maprsasl;ssl=true
19/01/31 12:15:33 [main]: WARN maprsasl.MaprSaslClient: SASL
Server qopProperty: auth-confis different from Client:
auth-conf,auth-int,auth.Using Server one
Connected to: Apache Hive (version 2.3.3-mapr-1901)
Driver: Hive JDBC (version 2.3.3-mapr-1901)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>
```

Starting from EEP 6.0.0, with secure by default configuration, it is a default connection string for a secure cluster. For more information, see [Configuring JDBC Connection String with SSL Encryption Enabled or Disabled](#).

### Using Beeline with PAM Authentication

```
hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/<database>;
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;
```

```

Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>;: <username>
Enter password for jdbc:hive2://<hs2_hostname>:10000/<database>;:
<password>
Connected to: Apache Hive (version 2.3.3-mapr-1901)
Driver: Hive JDBC (version 2.3.3-mapr-1901)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>

```

## Connecting to HiveServer2 with ZooKeeper

```

hive --service beeline -u
'jdbc:hive2://
zookeeper1.com:5181,zookeeper2.com:5181,zookeeper3.com:5181;/serviceDiscover
yMode=zooKeeper;zooKeeperNamespace=hiveserver2' -n mapr -p

```

## Connecting to HiveServer2 with PAM Authentication and SSL Encryption

```

hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true;
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true;
Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>: <username>
Enter password for jdbc:hive2://<hs2_hostname>:10000/<database>: <password>
Connected to: Apache Hive (version 2.3.3-mapr)
Driver: Hive JDBC (version 2.3.3-mapr)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>

```

Starting from EEP 6.0.0, with secure-by-default configurations, the default connection string is for a secure cluster. For more information, see [Configuring JDBC Connection String with SSL Encryption Enabled or Disabled](#).

## Using Beeline with Kerberos

Beeline must pass the Kerberos principal for HiveServer2 in the JDBC connection string. The connection strings you pass to Beeline must use the principal name that you configured for HiveServer2.

The following example shows a sample Beeline authentication with Kerberos:

```

hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:10000/
<database>;principal=mapr<FQDN@REALM>
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;principal=mapr/
<FQDN@REALM>
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/def>
Connected to: Apache Hive (version 2.3.3-mapr)
Driver: Hive JDBC (version 2.3.3-mapr)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>

```

## Using Beeline with Encryption but no Authentication (truststore parameters passed as JVM arguments)

```

Hive --service beeline
Beeline version 2.3.3-mapr-1901 by Apache Hive
beeline> !connect jdbc:hive2://<hs2_hostname>:1000/<database>;ssl=true
Connecting to jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true

```

```

Enter username for jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true:
<username>
Enter password for jdbc:hive2://<hs2_hostname>:10000/<database>;ssl=true:
<password>
Connected to: Apache Hive (version 2.3.3-mapr)
Driver: Hive JDBC (version 2.3.3-mapr)
Transaction isolation: TRANSACTION_REPEATABLE_READ
0: jdbc:hive2://<hs2_hostname>:10000/<database>

```

### Generating a Kerberos Ticket

Use the `kinit` utility to generate the ticket and then use `klist` to verify that a ticket exists.

```

# kinit <username>/<FQDN@REALM>
# klist

Credentials cache: API:501:9
  Principal: username/<FQDN@REALM>
  Cache version: 0

Server: krbtgt/<FQDN@REALM>
Client: username/<FQDN@REALM>
Ticket etype: aes128-cts-hmac-sha1-96
Ticket length: 256
Auth time:   Jun 11 10:01:48 2014
End time:    Jun 12 18:01:34 2014
Renew till:  Jun 18 10:01:48 2014
Ticket flags: pre-authent, initial, renewable, forwardable
Addresses: addressless

```

### Configuring JDBC Connection String with SSL Encryption Enabled or Disabled

You can configure a JDBC connection string with SSL encryption enabled or disabled.

#### SSL encryption to HiveServer2 is enabled (`hive.server2.use.SSL=true`)

The following table describes the JDBC connection string when SSL encryption is enabled between the Hive client and HiveServer2.

Table

Authentication Type	JDBC Parameter	Example
PAM	<code>ssl=true</code>	<code>jdbc:hive2://&lt;hostname&gt;:10000/default;ssl=true &lt;login&gt;&lt;password&gt;</code>
MapR-SASL	<code>ssl=true</code>	<code>jdbc:hive2://&lt;hostname&gt;:10000/default;auth=maprsasl;ssl=true</code>
Kerberos	<code>ssl=true</code>	<code>jdbc:hive2://&lt;hostname&gt;:10000/default;principal=&lt;user/fqdn@EXAMPLE.COM&gt;;ssl=true</code>

#### SSL encryption to HiveServer2 is disabled (`hive.server2.use.SSL=false`)

The following table describes the JDBC connection string when SSL encryption is disabled between the Hive client and HiveServer2.

Table

Authentication Type	JDBC Parameter	Example
PAM	--	jdbc:hive2:// <hostname>:10000/default; <login> <password>
MapR-SASL	--	jdbc:hive2:// <hostname>:10000/ default;auth=maprsasl
Kerberos	--	jdbc:hive2:// <hostname>:10000/ default;principal=<user/ fqdn@EXAMPLE.COM

### Using ODBC to Connect to HiveServer2

This section contains details about setting up and using the ODBC Connector for Hive.

#### Before You Begin

The Data Fabric Hive ODBC Connector is an ODBC driver for Apache Hive 0.7.0 and later that complies with the ODBC 3.52 specification. You can download the Hive ODBC connector from [https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR\\_Hive/](https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR_Hive/). To access the repository, see [Using the HPE Ezmeral Token-Authenticated Internet Repository](#) on page 93.

After downloading the driver, refer to the documentation for [Hive ODBC Driver](#) to install and configure the driver. The [Hive ODBC Driver](#) supports the following Advanced Options:

- Enable Auto Reconnect
- Driver Config Take Precedence
- Fast SQL Prepare
- Get Tables With Query
- Invalid Session Auto Recover
- Show System Table
- Socket Timeout
- Default String Column Length
- Rows Fetched Per Block
- Use Native Query

To use the ODBC driver, configure a *Data Source Name* (DSN), a definition that specifies how to connect to Hive. DSNs are typically managed by the operating system and may be used by multiple applications. Some applications do not use DSNs. You will need to refer to your particular application's documentation to understand how it connects using ODBC.

The standard query language for ODBC is SQL. HiveQL, the standard query language for Hive, includes a subset of ANSI SQL-92. Applications that connect to Hive using ODBC may need queries altered if the queries use SQL features that are not present in Hive. Applications that use SQL will recognize HiveQL, but might not provide access to HiveQL-specific features such as multi-table insert.

Please refer to the [Hive Language Manual](#) for up-to-date information on HiveQL.

## The SQL Connector

The SQL Connector feature translates standard SQL-92 queries into equivalent HiveQL queries. The SQL Connector performs syntactical translations and structural transformations. For example:

- **Quoted Identifiers:** When quoting identifiers, HiveQL uses back quotes (`), while SQL uses double quotes ("). Even when a driver reports the back quote as the quote character, some applications still generate double-quoted identifiers.
- **Table Aliases:** HiveQL does not support the AS keyword between a table reference and its alias.
- The JOIN, INNER JOIN, and CROSS JOIN SQL syntaxes are translated to the HiveQL JOIN syntax.
- SQL TOP N queries are transformed to HiveQL LIMIT queries.

## Hive ODBC Connector on Linux

### System Requirements

- The 32-bit and 64-bit version of the following operating systems:
  - Red Hat® Enterprise Linux® (RHEL) 6 or 7
  - SUSE Linux Enterprise Server (SLES) 11 or 12
  - Debian 8 or 9
  - Ubuntu 14.04, 16.04, or 18.04
- 45 MB of available disk space.
- An installed ODBC driver manager:
  - iODBC 3.52.7 or above (OR)
  - unixODBC 2.2.12 or above

The HPE Ezmeral Data Fabric ODBC Driver with SQL Connector for Apache Hive requires a Hadoop cluster with the Hive service installed and running. The HPE Ezmeral Data Fabric ODBC Driver with SQL Connector for Apache Hive is suitable for use with all versions of Hive. Download the ODBC connector from the following location: [MapR\\_Hive](#).

 **IMPORTANT:** To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Ezmeral Token-Authenticated Internet Repository](#) on page 93.

The RPM files are applicable for:

- Red Hat® Enterprise Linux® (RHEL) 6 or 7
- SUSE Linux Enterprise Server (SLES) 11 or 12

The DEB files are applicable for:

- Debian 8 or 9
- Ubuntu 14.04, 16.04, or 18.04

The latest version of the Hive ODBC connector is at version 2.6.14.1014.

## Install the Hive ODBC Connector on Linux

## About this task

The Data Fabric ODBC Driver with SQL Connector for Apache Hive driver files are installed in the following directories:

- `/opt/mapr/hiveodbc/ErrorMessage` – Error messages files directory
- `/opt/mapr/hiveodbc/Setup` – Sample configuration files directory
- `/opt/mapr/hiveodbc/lib/32` – 32-bit shared libraries directory
- `/opt/mapr/hiveodbc/lib/64` – 64-bit shared libraries directory

To install the Data Fabric ODBC Driver with SQL Connector for Apache Hive:

## Procedure

1. Log in as the `root` user.
2. Use RPM to install the rpm package corresponding to your Linux distribution:
  - [32-bit](#)
  - [64-bit](#)

The Data Fabric ODBC Driver with SQL Connector for Apache Hive depends on the following resources:

- `cyrus-sasl-2.1.22-7` or later
- `cyrus-sasl-gssapi-2.1.22-7` or later
- `cyrus-sasl-plain-2.1.22-7` or later

If the package manager in your Linux distribution cannot resolve the dependencies automatically when installing the driver, download and manually install the packages required by the version of the driver that you want to install.

## Configure the Hive ODBC Connector Driver on Linux

The `LD_LIBRARY_PATH` environment variable must include the paths to the:

- Libraries for the installed ODBC driver manager
- Shared libraries for the Data Fabric ODBC Driver with SQL Connector for Apache Hive

**Important:** The Linux version of the driver bundles together functionality for both 32-bit and 64-bit environments. Do not include the paths to both 32- and 64-bit shared libraries in `LD_LIBRARY_PATH` at the same time. Include only the path to the shared libraries corresponding to the driver matching the bitness of the client application used. For example, if you are using a 64-bit client application and ODBC driver manager libraries are installed in `/usr/local/lib`, then set `LD_LIBRARY_PATH` as follows:

```
export LD_LIBRARY_PATH=/usr/local/lib:/opt/mapr/hiveodbc/lib/64
```

For more information about how to set environment variables permanently, refer to your Linux shell documentation.

## Configuring ODBC Connections for Linux

## Files

ODBC driver managers use configuration files to define and configure ODBC data sources and drivers. By default, the following configuration files residing in the user's home directory are used:

- `.odbc.ini` – The file used to define ODBC data sources (required)
- `.odbcinst.ini` – The file used to define ODBC drivers (optional)
- `.mapr.hiveodbc.ini` – The file used to configure the MapR ODBC Driver with SQL Connector for Apache Hive (required)

## Sample Files

The driver installation contains the following sample configuration files in the Setup directory:

- `odbc.ini`
- `odbcinst.ini`
- `mapr.hiveodbc.ini`

The names of the sample configuration files do not begin with a period (.) so that they will appear in directory listings by default. A filename beginning with a period (.) is hidden. For `odbc.ini` and `odbcinst.ini`, if the default location is used, then the filenames must begin with a period (.) . For `mapr.hiveodbc.ini`, the filename must begin with a period (.) and must reside in the user's home directory. If the configuration files do not already exist in the user's home directory, then the sample configuration files can be copied to that directory and renamed. If the configuration files already exist in the user's home directory, then the sample configuration files should be used as a guide for modifying the existing configuration files.

## Configuring the Environment

By default, the configuration files reside in the user's home directory. However, two environment variables, `ODBCINI` and `ODBCSYSINI`, can be used to specify different locations for the `odbc.ini` and `odbcinst.ini` configuration files. Set `ODBCINI` to point to your `odbc.ini` file. Set `ODBCSYSINI` to point to the directory containing the `odbcinst.ini` file. For example, if your `odbc.ini` file is located in `/etc` and your `odbcinst.ini` file is located in `/usr/local/odbc`, then set the environment variables as follows:

```
export ODBCINI=/etc/odbc.ini export ODBCSYSINI=/usr/local/odbc
```

```
export ODBCINI=/etc/odbc.ini export ODBCSYSINI=/usr/local/odbc
```

For version 2.1.8 and above, you must also set `MAPRHIVEINI` to point to the `mapr.hiveodbc.ini` file in the user's home directory:

```
export MAPRHIVEINI=/etc/.mapr.hiveodbc.ini
```

For version 2.1.5 and below, you set `MAPRINI` to point to the `mapr.hiveodbc.ini` file in the user's home directory:

```
export MAPRINI=<user_home>/mapr.hiveodbc.ini
```

## Configuring the `odbc.ini` File

ODBC Data Sources are defined in the `odbc.ini` configuration file. The file is divided into several sections:

- `[ODBC]` is optional and used to control global ODBC configuration, such as ODBC tracing.
- `[ODBC Data Sources]` is required, listing DSNs and associating DSNs with a driver.

- A section having the same name as the data source specified in the [ODBC Data Sources] section is required to configure the data source.

Here is an example `odbc.ini` configuration file for Linux:

```
[ODBC Data Sources]
Sample MapR Hive DSN 32=MapR Hive ODBC Driver 32-bit
[Sample MapR Hive DSN 32]
Driver=/opt/mapr/hiveodbc/lib/32/libmaprhiveodbc32.so
HOST=MyHiveServer
PORT=10000
```

### To create a data source:

1. Open the `.odbc.ini` configuration file in a text editor.
2. Add a new entry to the [ODBC Data Sources] section. Type the data source name (DSN) and the driver name.
3. To set configuration options, add a new section having a name matching the data source name (DSN) you specified in step 2. Specify configuration options as keyvalue pairs.
4. Save the `.odbc.ini` configuration file.

**NOTE:** You can set configuration options in your `odbc.ini` and `.mapr.hiveodbc.ini` files. Configuration options set in a `.mapr.hiveodbc.ini` file apply to all connections, whereas configuration options set in an `odbc.ini` file are specific to a connection. Configuration options set in `odbc.ini` take precedence over configuration options set in `.mapr.hiveodbc.ini`.

### Configuring the `odbcinst.ini` File

ODBC Drivers are defined in the `odbcinst.ini` configuration file. The configuration file is optional because drivers can be specified directly in the `odbc.ini` configuration file. The `odbcinst.ini` file is divided into the following sections:

- [ODBC Drivers] lists the names of all the installed ODBC drivers.
- section having the same name as the driver name specified in the [ODBC Drivers] section lists driver attributes and values.

Here is an example `odbcinst.ini` file for Linux:

```
[ODBC Drivers]
MapR Hive ODBC Driver 32-bit=Installed
MapR Hive ODBC Driver 64-bit=Installed
[MapR Hive ODBC Driver 32-bit]
Description=MapR Hive ODBC Driver (32-bit)
Driver=/opt/mapr/hiveodbc/lib/32/libmaprhiveodbc32.so
[MapR Hive ODBC Driver 64-bit]
Description=MapR Hive ODBC Driver (64-bit)
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
```

### To define a driver:

1. Open the `.odbcinst.ini` configuration file in a text editor.

2. Add a new entry to the [ODBC Drivers] section. Type the driver name, and then type **=Installed**

**NOTE:** Assign the driver name as the value of the Driver attribute in the data source definition instead of the driver shared library name.

3. In `.odbcinst.ini`, add a new section having a name matching the driver name you typed in step 2, and then add configuration options to the section based on the sample `odbcinst.ini` file provided with the MapR ODBC Driver with SQL Connector for Apache Hive in the Setup directory. Specify configuration options as keyvalue pairs.
4. Save the `.odbcinst.ini` configuration file.

#### Configuring the `mapr.hiveodbc.ini` File

Describes how to configure the Data Fabric ODBC Driver with SQL Connector for Apache Hive to work with your ODBC driver manager.

#### About this task

To configure the Data Fabric ODBC Driver with SQL Connector for Apache Hive to work with your ODBC driver manager:

#### Procedure

1. Open the `.mapr.hiveodbc.ini` configuration file in a text editor.

The following is an example of the `.mapr.hiveodbc.ini` file template:

```
[Driver]

ErrorMessagesPath=/opt/mapr/hiveodbc/ErrorMessage/
LogLevel=0
LogPath=
SwapFilePath=/tmp
```

2. Edit the `DriverManagerEncoding` setting. The value usually must be UTF-16 or UTF-32, depending on the ODBC driver manager you use. iODBC uses UTF-32 and unixODBC uses UTF-16. Consult your ODBC Driver Manager documentation for the correct setting to use.

3. Edit the `ODBCInstLib` setting. The value is the name of the `ODBCInst` shared library for the ODBC driver manager you use. The configuration file defaults to the shared library for `iODBC`. In Linux, the shared library name for `iODBC` is `libiodbcinst.so`.

**NOTE:** Consult your ODBC driver manager documentation for the correct library to specify. You can specify an absolute or relative filename for the library. If you intend to use the relative filename, then the path to the library must be included in the library path environment variable. In Linux, the library path environment variable is named `LD_LIBRARY_PATH`.

The following is an example of the `.mapr.hiveodbc.ini` file with filled `DriverManagerEncoding` and `ODBCInstLib` settings:

```
$ cat /etc/.mapr.hiveodbc.ini

[Driver]

ErrorMessagesPath=/opt/mapr/hiveodbc/ErrorMessage/
LogLevel=0
LogPath=
SwapFilePath=/tmp

#add for unixODBC
DriverManagerEncoding=UTF-16
ODBCInstLib=libodbcinst.so
```

4. Save the `.mapr.hiveodbc.ini` configuration file.

## Configuring Authentication

You can configure the following types of authentication:

- No authentication
- MapR-SASL
- User name
- User name and password
- Kerberos

When `hive.server2.authentication` is set to `KERBEROS`, then you must configure your connection to use Kerberos.

To find out the authentication setting your Hive Server 2 is set to use, review the following properties in the `hive-site.xml` file:

- `hive.server2.authentication`
- `hive.server2.enable.doAs`

### Using No Authentication

To use no authentication, set the `AuthMech` configuration key for the DSN to 0.

### Using MapR-SASL

To configure MapR-SASL SASL in `odbc.ini`, set the following option:

```
AuthMech=13
```

### Using User Name

To configure User Name authentication:

1. Set the AuthMech configuration key for the DSN to 2.
2. Set the UID key to the appropriate user name recognized by the Hive server.

### Using User Name and Password

To configure User Name and Password authentication:

1. Set the AuthMech configuration key for the DSN to 3.
2. Set the UID key to the appropriate user name recognized by the Hive server.
3. Set the PWD key to the password corresponding to the user name you provided in step 2.

### Using Kerberos

**To configure Kerberos authentication:**

1. Set the H2SAuthMech configuration key for the DSN to 1.
2. If your Kerberos setup does not define a default realm or if the realm of your Hive server is not the default, then set the appropriate realm using the HS2KrbRealm key.
3. Set the HS2HostFQDN key to the fully qualified domain name of the Hive Server 2 host.
4. Set the HS2KrbServiceName key to the service name of the Hive Server 2 host.

### Hive ODBC Connector on Windows

There are versions of the connector for 32-bit and 64-bit applications. The 64-bit version of the connector works only with 64-bit DSNs; the 32-bit connector works only with 32-bit DSNs. Because 64-bit Windows machines can run both 64-bit and 32-bit applications, install both versions of the connector in order to set up DSNs to work with both types of applications. If both the 32-bit connector and the 64-bit connector are installed, you must configure DSNs for each independently, in their separate Data Source Administrators.

### Install the Hive ODBC Connector on Windows

#### About this task

To use MapR Hive ODBC Connector on Windows requires:

- Windows® 7 Professional or Windows® 2008 R2. Both 32 and 64-bit editions are supported.
- The Microsoft Visual C++ 2010 Redistributable Package (runtimes required to run applications developed with Visual C++ on a computer that does not have Visual C++ 2010 installed.)
- A Hadoop cluster with the Hive service installed and running. You should find out from the cluster administrator the hostname or IP address for the Hive service and the port that the service is running on. (The default port for Hive is 10000.)

**Procedure**

1. Download and run the ODBC connector.

Download the ODBC connector from the following location: [MapR\\_Hive](#). Select either the 64-bit or 32-bit connector.

**IMPORTANT:** To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Ezmeral Token-Authenticated Internet Repository](#) on page 93.

2. Accept the license agreement.
3. Select an installation folder.
4. On the Information window, click **Next**.
5. On the Completing... window, click **Finish**.
6. Install a DSN corresponding to your Hive server.

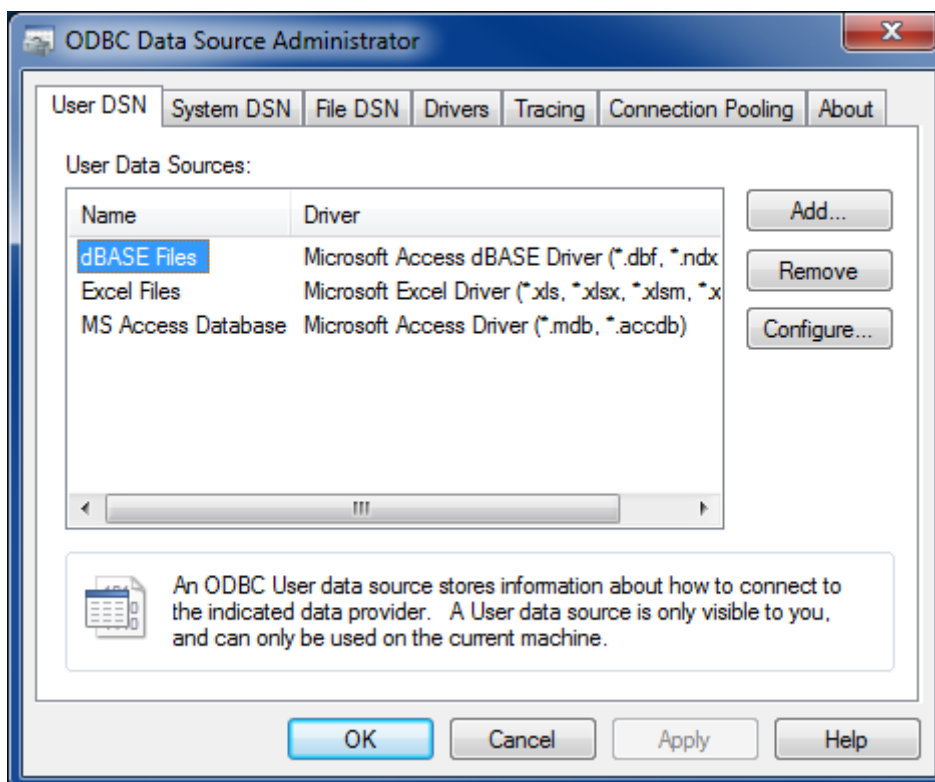

## Configure Hive ODBC Connections on Windows

**About this task**

To create a Data Source Name (DSN)

**Procedure**

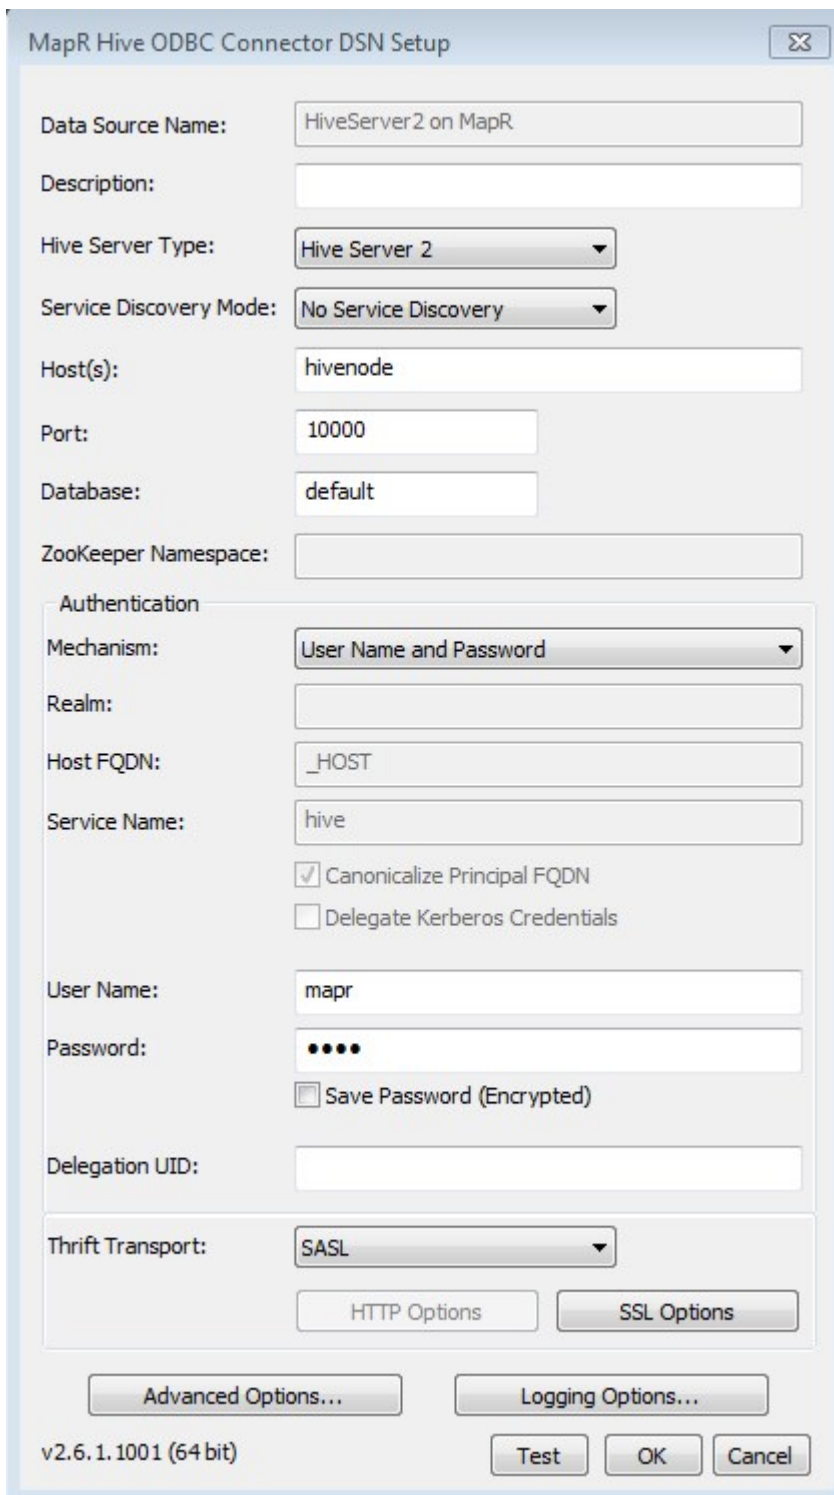

1. Open the Data Source Administrator from the Start menu. Example: **Start > MapR Hive ODBC Driver 2.0 > 64-Bit ODBC Driver Manager**
2. On the **User DSN** tab click **Add** to open the Create New Data Source dialog.

3. Select **MapR Hive ODBC Connector** and click **Finish** to open the Hive ODBC Driver DSN Setup window.

4. Enter the connection information for the Hive instance:

MapR Hive ODBC Connector DSN Setup

Data Source Name: HiveServer2 on MapR

Description:

Hive Server Type: Hive Server 2

Service Discovery Mode: No Service Discovery

Host(s): hivenode

Port: 10000

Database: default

ZooKeeper Namespace:

Authentication

Mechanism: User Name and Password

Realm:

Host FQDN: \_HOST

Service Name: hive

Canonicalize Principal FQDN

Delegate Kerberos Credentials

User Name: mapr

Password: ••••

Save Password (Encrypted)

Delegation UID:

Thrift Transport: SASL

HTTP Options SSL Options

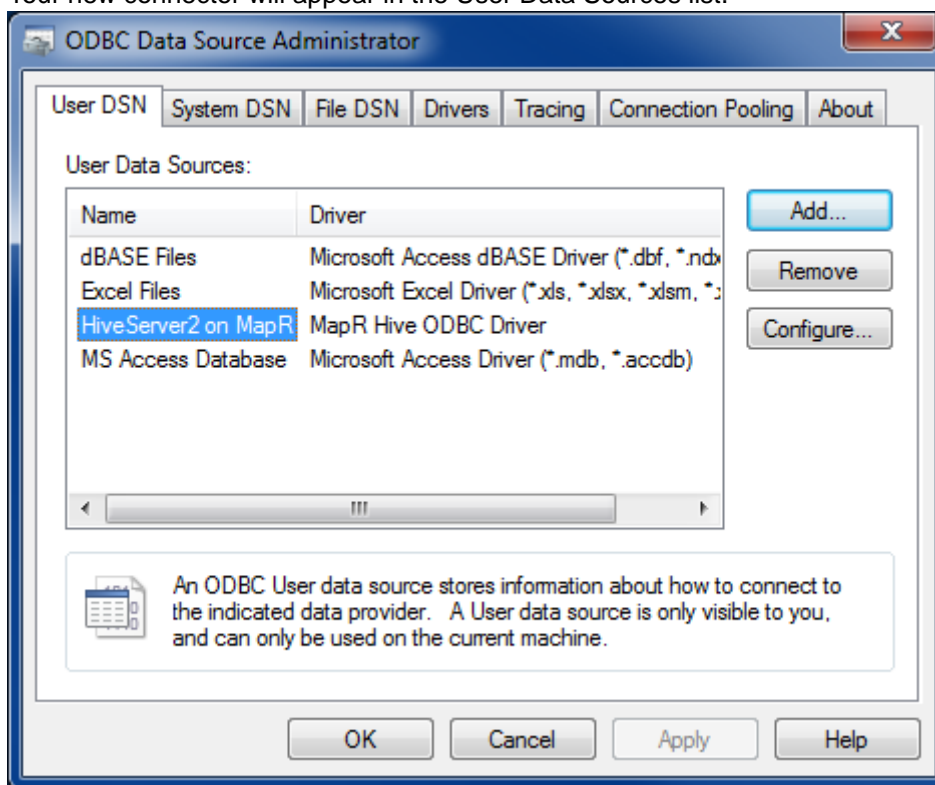

Advanced Options... Logging Options...

v2.6.1.1001 (64 bit) Test OK Cancel

- **Data Source Name** — Specify a name for the DSN.
- **Description** — Enter an optional description for the DSN.
- **Host** — Enter the hostname or IP of the server running HiveServer1 or HiveServer2.
- **Port** — Enter the listening port for the Hive service.

- **Database** — Leave as `default` to connect to the default Hive database, or enter a specific database name.
  - **Hive Server Type:** — Set to `HiveServer1` or `HiveServer2`.
  - **Authentication** — If you are using `HiveServer2`, set the following.
    - **Mechanism:** — Set to the authentication mechanism you're using. The MapR ODBC driver supports user name, user name and password, username and password over SSL authentication, and Kerberos.
    - **User Name:** — Set the user to run queries as.
    - **Password:** — The user's password, if your selected authentication mechanism requires one.
5. Optionally, click **Test** to test the connection.
  6. Click **OK**.

Your new connector will appear in the User Data Sources list.

### What to do next

For steps to apply custom configurations, see [Hive ODBC Driver](#).

Hive ODBC Connector on Mac OS X

### System Requirements

- Mac OS X version 10.6.8 or later
- 100 MB of available disk space
- iODBC 3.52.7 or above
- unixODBC 2.2.12 or above

The Data Fabric ODBC Driver with SQL Connector for Apache Hive requires a Hadoop cluster with the Hive service installed and running. The Data Fabric ODBC Driver with SQL Connector for Apache Hive is suitable for use with all versions of Hive. The driver supports both 32- and 64-bit client applications.

Download the MacOS Hive ODBC connector from [MapR\\_Hive](#).

**IMPORTANT:** To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Ezmeral Token-Authenticated Internet Repository](#) on page 93.

## Installation

The Data Fabric ODBC Driver with SQL Connector for Apache Hive driver files are installed in the following directories:

- `/opt/mapr/hiveodbc/ErrorMessage`s – Error messages files directory
- `/opt/mapr/hiveodbc/Setup` – Sample configuration files directory
- `/opt/mapr/hiveodbc/lib/universal` – Binaries directory

To install the Data Fabric ODBC Driver with SQL Connector for Apache Hive:

1. Double-click to mount the `MapRHiveODBC.dmg` disk image.
2. Double-click `MapRHiveODBC.pkg` to run the Installer.
3. Follow the instructions in the Installer to complete the installation process.
4. When the installation completes, click **Close**.

## Configuration

### Setting the `DYLD_LIBRARY_PATH` Environment Variable

The `DYLD_LIBRARY_PATH` environment variable must include the paths to:

- Installed ODBC driver manager libraries
- Installed Data Fabric ODBC Driver with SQL Connector for Apache Hive shared libraries

For example, if ODBC driver manager libraries are installed in `/usr/local/lib`, then set `DYLD_LIBRARY_PATH` as follows:

```
export DYLD_LIBRARY_PATH=/usr/local/lib/opt/mapr/hiveodbc/lib/universal
```

Refer to your Mac OS X shell documentation for details on how to set environment variables permanently.

### Configure Hive ODBC Connections on Mac OS X

See [Configuring ODBC Connections for Linux](#) for details on creating ODBC connections.

## Configuring Encryption for ODBC Connection

Explains how to configure SSL encryption between ODBC connection to Hiveserver2 on non-secure cluster.

### About this task

Hive uses cyrus-sasl-plain package for ODBC connection.

### Procedure

1. Generate `ssl_keystore/ssl_truststore` by running the following command:

```
sudo bash /opt/mapr/server/manageSSLKeys.sh create -ug mapr:mapr
```

**IMPORTANT:** Make a note of the `CN=HOST_NAME` parameter in the output.

2. Configure SSL for Hive as described in [Configure Encryption without Authentication](#) on page 4208.
3. Generate the `.pem` file. To generate:
  - a) Verify that `ssl_keystore` and `ssl_truststore` are present on the system.

```
cd /opt/mapr/conf
ll *ssl*store*
```

If `ssl_keystore` and `ssl_truststore` are not present, then generate them.

- b) Generate `.pem` file using `<ssl-keystore-password> password`.

```
keytool -importkeystore -srckeystore ssl_keystore -destkeystore
ssl_keystore.p12 -srcstoretype jks -deststoretype pkcs12
```

- c) Verify that the `ssl_keystore.p12` and `ssl_keystore.pem` files are created.

For example:

```
openssl pkcs12 -in ssl_keystore.p12 -out ssl_keystore.pem
openssl x509 -text -in ssl_keystore.pem
```

4. Configure SSL for ODBC driver by making the following changes in the `/etc/odbc.ini`, `/etc/odbcinst.ini`, and `/etc/mapr.hiveodbc.init` files. That is, in the:

- `/etc/odbc.ini` file:
  - a. Replace `<HOST_NAME>` with the host name.
  - b. Set the value for `TrustedCerts` to path to `ssl_keystore.pem` file.
  - c. Add the following to the file:

```
[ODBC Data Sources]
Sample MapR Hive DSN=Hive Hive ODBC Driver 64-bit
[Hive]
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
HOST=<HOST_NAME>
PORT=10000
SSL=1
CAIssuedCertNamesMismatch=1
TrustedCerts=/opt/mapr/conf/ssl_keystore.pem
AuthMech=4
```

- `/etc/odbcinst.ini` file, add the following:

```
[ODBC Drivers]
MapR Hive ODBC Driver=Installed
[MapR Hive ODBC Driver 64-bit]
Description=MapR Hive ODBC Driver (64-bit)
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
```

- `etc/mapr.hiveodbc.ini` file, add the following:

```
[Driver]
ErrorMessagesPath=/opt/mapr/hiveodbc/ErrorMessage/
LogLevel=0
LogPath=
SwapFilePath=/tmp
```

## Example

### Sample `/etc/odbc.ini` file

```
[ODBC Data Sources]
Sample MapR Hive DSN=Hive Hive ODBC Driver 64-bit
[Hive]
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
HOST=<HOST_NAME>
PORT=10000
SSL=1
CAIssuedCertNamesMismatch=1
TrustedCerts=/opt/mapr/conf/ssl_keystore.pem
AuthMech=4
```

**Sample /etc/odbcinst.ini file**

```
[ODBC Drivers]
Mapr Hive ODBC Driver=Installed
[Mapr Hive ODBC Driver 64-bit]
Description=Mapr Hive ODBC Driver (64-bit)
Driver=/opt/mapr/hiveodbc/lib/64/libmaprhiveodbc64.so
```

**Sample /etc/mapr.hiveodbc.ini file**

```
[Driver]
ErrorMessagesPath=/opt/mapr/hiveodbc/ErrorMessage/
LogLevel=0
LogPath=
SwapFilePath=/tmp
```

**Connecting to WebHCat**

The method that WebHCat clients use to connect to WebHCat is based on the WebHCat Authentication method:

WebHCat Authentication	Connection Requirements
Simple	<p>Clients pass the username as the <code>user.name</code> parameter in the REST call. No password is required. Example:</p> <pre>http://&lt;hostname&gt;:50111/ templeton/v1/ddl/database/default/table/ table01?user.name=juser</pre>
PAM	<p>Clients enter username and password authentication through a pop-up dialog box in the web browser session.</p>
Kerberos with SPNEGO	<p>Clients can use one of the following methods:</p> <ul style="list-style-type: none"> <li>curl example: <pre>curl --negotiate -i -u : 'http:// &lt;FQDN&gt;:50111/templeton/v1/ddl/ database/'</pre> </li> <li>Web browser with user name and password. For more information, see <a href="#">Configuring SPNEGO on Data Fabric</a> on page 1837</li> </ul> <p> <b>NOTE:</b> With either method you must also have a Kerberos ticket in the cache. See <a href="#">Example: Generating a Kerberos Ticket</a></p>

**Enabling High Availability for Hive**

This section describes how to enable High Availability for HiveServer2 and HiveMetastore.

**NOTE:** You can achieve High Availability(HA) through HA tools like HAProxy or F5. Based on the tools used, you need to configure reverse DNS lookups and implement other security features. However, the HPE Ezmeral Data Fabric does not support any HA tool.

**Related concepts**

[Enabling High Availability for Spark Thrift Server](#) on page 4643

**Enabling High Availability for HiveServer2**

**About this task**

Perform the following steps to enable High Availability for HiveServer2.

*Configuring Hive*

**Procedure**

1. Modify the `warden.hs2.conf` file as shown below on all the nodes where Hive is installed.

```
services=hs2:all
```

2. Add the following properties to the `hive-site.xml` file on all the nodes where HiveServer2 is installed.

Property	Value	Description
<code>hive.server2.support.dynam ic.service.discovery</code>	true (default is false)	Set to true to enable HiveServer2 dynamic service discovery for its clients.
<code>hive.server2.zookeeper.name space</code>	hiveserver2 (default value)	The parent node in ZooKeeper, which is used by HiveServer2 when supporting dynamic service discovery.
<code>hive.zookeeper.quorum</code>	<code>&lt;hostname&gt;:5181,&lt;hostname&gt;:5181,&lt;hostname&gt;:5181</code>	List of ZooKeeper servers to talk to. Used in connection string by JDBC/ODBC clients instead of URI of specific HiveServer2 instance.
<code>hive.zookeeper.client.port</code>	5181 (default value)	The port of the ZooKeeper servers to talk to. If the list of Zookeeper servers specified in <code>hive.zookeeper.quorum</code> does not contain port numbers and so, this value is used.
<code>hive.zookeeper.session.time out</code>	600000 (default value)	Zookeeper client's session timeout value. The client is disconnected, and as a result, all locks are released if a heartbeat is not sent within the timeout period.

3. Restart all the nodes where Hive service is installed after updating the configuration.

*Connecting with JDBC/ODBC Clients*

**Procedure**

- Connect to HiveServer2 with JDBC/ODBC clients using the following connection string:

```
jdbc:hive2://<zookeeper_ensemble>/;serviceDiscoveryMode=zooKeeper;  
zooKeeperNamespace=<hiveserver2_zookeeper_namespace>
```

Here:

<code>&lt;zookeeper_ensemble&gt;</code>	Specifies a comma-separated list of ZooKeeper servers that form the ensemble. For example: <code>&lt;zk_host1&gt;:&lt;zk_port1&gt;,&lt;zk_host2&gt;:&lt;zk_port2&gt;,&lt;zk_host3&gt;:&lt;zk_p</code>
<code>&lt;hiveserver2_zookeeper_namespace&gt;</code>	Specifies the namespace on Zookeeper under which HiveServer2 znodes are added. The namespace value is configured in <code>hive.server2.zookeeper.namespace</code>

## Deregistering HiveServer2 Instances from Zookeeper

### About this task

Remove a HiveServer2 instance from Zookeeper by running the following commands (in the ZooKeeper command line interface) to deregister the server.

### Procedure

1. Launch the ZooKeeper command line interface and get the HiveServer2 znode by running the following commands:

```
/opt/mapr/zookeeper/zookeeper-<version>/bin/zkCli.sh -server <ip:port of
zookeeper instance>
ls /<hive.server2.zookeeper.namespace>
```

2. Run the command to deregister HiveServer2. To deregister:

- A particular HiveServer2, run the following command:

```
delete /hiveserver2 serverUri=<hostname:port>;version=<hive
version>;sequence=<sequence number>
```

After you deregister the HiveServer2 from Zookeeper, it will not return the deregistered HiveServer2 for new client connections. However, active client sessions are not affected by deregistering the HiveServer2 from Zookeeper.

- All HiveServer2 instances of a particular version, run the following command:

```
hive --service hiveserver2 --deregister <version_number>
```

### Example HiveServer2 High Availability Setup

This section describes a High Availability set up for HiveServer2 on a sample HPE Ezmeral Data Fabric cluster. Suppose a three-node cluster with the following (optional) IP addresses and host names:

IP Address	Host Name
192.168.33.11	node1
192.168.33.12	node2
192.168.33.13	node3

Use the following string to connect to the HiveServer2:

```
jdbc:hive2://
node1:5181,node2:5181,node3:5181/;serviceDiscoveryMode=zooKeeper;zooKeeperNa
mespace=hiveserver2
```

To deregister HiveServer2:

1. Launch the ZooKeeper command-line interface using the following command:

```
/opt/mapr/zookeeper/zookeeper-3.5.6/bin/zkCli.sh -server
192.168.33.13:5181
```

2. Look at the ZooKeeper namespace using the following command:

```
ls /hiveserver2
```

Output:

```
[serverUri=node3:10000;version=2.1.1-mapr-1703;sequence=0000000004,
serverUri=node1:10000;version=2.1.1-mapr-1703;sequence=0000000006]
```

3. Deregister:

- HiveServer2 on node3:

```
delete
serverUri=node3:10000;version=2.1.1-mapr-1703;sequence=0000000004
```

- All HiveServer2 instances:

```
hive --service hiveserver2 --deregister 2.1.1-mapr-1703
```

## Enabling High Availability for Hive Metastore

### About this task

To enable High Availability for Hive Metastore.

### Procedure

1. Enable remote access to the underlying database from different nodes.
2. Add all Metastore instances to `hive.metastore.uris` on all the nodes, as a list of comma-separated values.

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<hostname1>:9083,thrift://<hostname2>:9083</value>
</property>
```

3. Restart Hive Metastore services on all nodes, where Hive Metastore services are installed.
4. Restart all HiveServer2 instances.

### Results

Enabling high availability for the Hive Metastore does not require changes to the `warden.hivemetastore.conf` file. Active-active mode is not supported for Hive Metastore. Hence, there is one active instance of the Hive Metastore service at any given point in time. The other instances of the Hive Metastore service are in standby state.

You can check the state of Hive Metastore service on the Control System.

### Example

Suppose that Hive Metastore is installed on three nodes, node1, node2, node3, while MySQLServer is installed on node3, as given below.

IP Address	Host Name
192.168.33.11	node1
192.168.33.12	node2
192.168.33.13	node3

1. Change the MySQL configuration:

```
nano /etc/my.cnf
```

2. Comment out the following properties:

```
#bind-address
#skip-networking
```

If these properties are not in `my.cnf`, you can skip editing `my.cnf`. Restart the MySQL server.

3. Enable remote access for the underlying database by granting permissions in the underlying database. Connect to MySQL server from `node3`, and provide access to `node1` and `node2`.

```
mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'root'@'192.168.33.11'
IDENTIFIED BY 'secret' WITH GRANT OPTION;
mysql> GRANT ALL PRIVILEGES ON metastore.* TO 'root'@'192.168.33.12'
IDENTIFIED BY 'secret' WITH GRANT OPTION;
mysql> flush privileges;
```

4. Optionally, verify the connectivity to the MySQL server running on `node3` from `node1` and `node2`. For example, run the following commands:

- On `node1`:

```
mysql -h node3 -uroot -psecret
```

- On `node2`:

```
mysql -h node3 -uroot -psecret
```

5. Add all Metastore instances to `hive.metastore.uris` on all nodes with the Hive instance:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://192.168.33.11:9083,thrift://
192.168.33.12:9083,thrift://192.168.33.13:9083 </value>
</property>
```

6. Restart Hive Metastore services on all nodes where Hive Metastore service is installed and then all `HiveServer2` instances.

```
maprcli node services -name hivemeta -action restart -nodes
<comma-separated list of Hive Metastore nodes>
```

## 7. Restart all HiveServer2 instances.

```
maprcli node services -name hs2 -action restart -nodes <comma-separated list of HiveServer2 nodes>
```

Check the status of Hive Metastore on the Control System. Following is a sample view of the Control System displaying the status of Hive Metastore.

All (23)

Service	Running Nodes	Standby Nodes	Failed Nodes	Stopped Nodes	
MEP					
Data Access Gateway	2	-	0	0

## Hive Features in HPE Ezmeral Data Fabric

Describes HPE Ezmeral Data Fabric-specific features in Hive.

### Removing Temporary Hive Files

Starting from EEP 8.1.0, EEP 7.1.2, and EEP 6.3.6, to remove the temporary Hive files created during the Hive session, set the value of `hive.scratchdir.lock` property to `true` on `hive-site.xml` file.

```
<property>
  <name>hive.scratchdir.lock</name>
  <value>>true</value>
</property>
```

For the previous EEP versions, manually remove the temporary Hive files that are not used by the active Hive sessions.

You have two different situations:

- If you have configured the HiveServer2 in a node, set `hive.scratchdir.lock` property on the `hive-site.xml` file to automatically remove the temporary Hive files.
- If you have not configured the HiveServer2 in a node, set the `hive.scratchdir.lock` property and run the following command to remove the temporary Hive files.

```
hive --service cleardanglingscratchdir
```

### Symbolic Link Support in Hive

Starting from EEP 7.1.0, all [hadoop fs](#) commands support operations on symlinks (symbolic links). Hive supports symlinks in EEP 8.0.0 onwards. You can create symlinks through the command line interface or file system API (MapRFileSystem.java).

Symlink creation via CLI has the following requirements:

- [NFS installed](#)
- [NFS mounted](#) (mount `hadoop fs` to the local file system)

### Creating Symlinks

The following examples demonstrate how to create symbolic links via CLI and MapRFileSystem API:

- Create a *relative* symlink via CLI:

```
ln -rs /mountPoint/path/to/file /
mountPoint/path/to/symlink
```

- Create an *absolute* symlink via CLI:

```
ln -s /mountPoint/path/to/file /
mountPoint/path/to/symlink
```

- Create a symlink via MapRFileSystem API:

```
MapRFileSystem maprFS
= MapRFileSystem.get(new
Configuration());
maprFS.createSymlink(pathToTarget,
pathToLink, createParentFlag);
```

### Using Symlinks for Hive Operations

Once a symlink is created, you can use the symlink for Hive operations, such as table location and data file, as demonstrated in the following steps:

1. Create a table directory:

```
mkdir /mapr/my.cluster.com/user/
hive/warehouse/ext_tbl_symlink
```

2. Create a symlink from a data source to a table location:

```
ln -s /mapr/my.cluster.com/user/
mapr/source_files/data.txt /mapr/
my.cluster.com/user/hive/warehouse/
ext_tbl_mh120/data_link.txt
```

3. Create an external Hive table in the `ext_tbl_symlink` directory (created in step 1):

```
CREATE EXTERNAL TABLE
file_link_table (...) ROW FORMAT
DELIMITED FIELDS TERMINATED BY ","
STORED AS TEXTFILE LOCATION '/user/
hive/warehouse/ext_tbl_symlink';
```

The Hive table has a symbolically linked text file as the data source. Data can be processed as if it is a regular data file.

### Configuring Symlinks Support

When you have many small files and you are using symlinks, the performance of Hive operations are slower.

To enable or disable the symlink support, configure the `hive.sym.link.support.enabled` property in `hive-site.xml` file.

```
<property>

<name>hive.sym.link.support.enabled</
name>
  <value>>false</value>
  <description>Enables or disables
symlink support in Hive. Enabling
this functionality leads to
verification of each files and
folders to be a symlink which results
in slower performance when there
are many small files to process.</
description>
</property>
```

The value of this property is set to `false` by default. To enable the symlink support, set the value to `true` and restart Hive services.

### Hive 3.1.3 API Changes

This topic describes the public API changes that occurred between Hive 2.3.9 EEP 8.1.0 and Hive 3.1.3 EEP 9.0.0.

For more information, see [Hive 3.1.3.0 - 2210 \(EEP 9.0.0\) Release Notes](#) on page 5966.

### JDBC Classes API Changes

This section contains changes made to classes related to the JDBC API in Hive.

**Class `org.apache.hive.jdbc.HiveConnection`** The following table lists the added methods for Hive.

Method	Description
<code>List&lt;JdbcConnectionParams&gt; getAllUrls(String zookeeperBasedHS2Url)</code>	Get all direct HiveServer2 URLs from a ZooKeeper based HiveServer2 URL .

**Class `org.apache.hive.jdbc.HiveStatement`** No changes.

**Class `org.apache.hive.jdbc.Utils`** The following table lists the added methods for Hive.

Method	Description
<code>public JdbcConnectionParams(JdbcConnectionParams params) {</code>	Constructor: based on connection parameters.

<pre>public static String getCanonicalHostNam e(String hostName)</pre>	<p>Method to get canonicalized hostname, given a hostname (possibly a CNAME).</p> <ul style="list-style-type: none"> <li>• Allows service-principals to use simplified CNAMEs.</li> <li>• @param hostName: The hostname to be canonicalized.</li> <li>• @return: Given a CNAME, the canonicalized hostname is returned. If not found, the original hostname is returned.</li> </ul>
<pre>static void configureConnParams FromZooKeeper(JdbcC onnectionParams connParams)</pre>	<p>To configure using ZooKeeper.</p>

**Security-related API Changes:**

None.

**NOTE:**

- All API functionality changes are compatible with previous versions.
- For migration from ACID (transactional) tables in Hive 2.x to ACID (transactional) tables in Hive 3.x. separate document.
- To learn about known issues related to Hive-3.1.3 database configuration, Data Fabric SASL connection from edge nodes,HPE Ezmeral Data Fabric Object Store data processing with Hive-3.1.3, see [Hive 3.1.3.0 - 2210 \(EEP 9.0.0\) Release Notes](#) on page 5966.

**Hive 2.3 API Changes**

This topic describes the public API changes that occurred between Hive 2.1 EEP 5.0.0 and Hive 2.3 EEP 6.0.0.

For more information, see [Hive Release Notes](#) on page 5951.

**JDBC classes API changes**

This section contains changes made to classes related to the JDBC API in Hive.

**Table**

Method	Description
<pre>List&lt;String&gt; parseInitFile(String initFile)</pre>	<p>Parses initial SQL file skipping comments that starts with # or --.</p>

Table

Method	Description
<code>void setInPlaceUpdateStream(InPlaceUpdate stream)</code>	Only used by the beeline client to set the stream on which in place progress updates are to be shown.

Table

Method	Description
<code>JdbcConnectionParams parseURL(String uri)</code>	<p>Parse JDBC connection URL The new format of the URL is:</p> <pre>jdbc:hive2://:,:/dbName;sess_var_list? hive_conf_list#hive_var_list</pre> <p>where the optional <code>sess</code>, <code>conf</code>, and <code>var</code> lists are semicolon separated = pairs. For utilizing dynamic service discovery with HiveServer2, multiple comma-separated host:port pairs can be specified as shown above. The JDBC driver resolves the list of URIs and picks a specific server instance to connect to. Currently, dynamic service discovery using ZooKeeper is supported, in which case the host:port pairs represent a ZooKeeper ensemble. As before, if the host/port is not specified, it the driver runs an embedded Hive:</p> <ul style="list-style-type: none"> <li><code>jdbc:hive2://ubuntu:11000/db2?hive.cli.conf.printhead=true;hive.exec.mode.local.auto.inputbytes.max=9999#stab=salesTable;icol=customerID</code></li> <li><code>jdbc:hive2://?hive.cli.conf.printhead=true;hive.exec.mode.local.auto.inputbytes.max=9999#stab=salesTable;icol=customerID</code></li> <li><code>jdbc:hive2://ubuntu:11000/db2;user=foo;password=bar</code></li> </ul> <p>Connect to <code>http://server:10001/hs2</code>, with specified basicAuth credentials and initial database:</p> <pre>jdbc:hive2://server:10001/ db;user=foo;password=bar? hive.server2.transport.mode= http;hive.server2.thrift.http.path=hs2</pre>

### Security-related API changes

The following properties are removed from the default `hive-site.xml` configuration on a secured cluster:

Table

Property	Value
<code>hive.server2.webui.keystore.path</code>	<code>/opt/mapr/conf/ssl_keystore.</code>
<code>hive.server2.webui.keystore.password</code>	Default keystore password.

The following property is added to the default `hive-site.xml` configuration on a secured cluster:

**Table**

Method	Description
hive.server2.use.SSL true	true

Since the HiveServer2 server is configured to use SSL encryption by default starting from Hive-2.3 EEP-6.0.0, add `ssl=true;` to a JDBC connection string when PAM or MAPR-SASL authentication is used.

For example:

Old JDBC connection string with PAM authentication:

```
beeline> !connect jdbc:hive2://<host>:10000/default;
```

New JDBC connection string with PAM authentication:

```
beeline> !connect jdbc:hive2://<host>:10000/default;ssl=true;
```

**NOTE:** All API functionality changes are compatible with previous versions.

**Hive 2.1 API**

This section contains the following:

**New Classes in Hive 2.1**

Hive 2.1 includes the following new classes:

Class	Description
org.apache.hadoop.hive.common. <a href="#">DiskRangeInfo</a>	Contains disk range information including disk ranges and total length.
org.apache.hadoop.hive.common. <a href="#">JvmPauseMonitor</a>	This is based on the JvmPauseMonitor from Hadoop.
org.apache.hadoop.hive.common. <a href="#">StringableMap</a>	A utility class that can convert a HashMap of Properties into a colon separated string, and can take the same format of string and convert it to a HashMap of Properties.
org.apache.hadoop.hive.common. <a href="#">ValidCompactorTxnList</a>	An implementation of org.apache.hadoop.hive.common.ValidTxnList for use by the compactor.
org.apache.hadoop.hive.common.io. <a href="#">.DiskRange</a>	The sections of a file.
org.apache.hadoop.hive.common.io. <a href="#">DiskRangeList</a>	Alternative for Java linked list iterator interface to support concurrent modifications of the same list by multiple iterators.
org.apache.hadoop.hive.common.jsonexplain.tez. <a href="#">Printer</a>	Creation of output string to show JSON plan.
org.apache.hadoop.hive.common.jsonexplain.tez. <a href="#">TezJsonParserUtils</a>	JsonParser for Tez that prints a JSONObject into outputStream.

Class	Description
org.apache.hadoop.hive.common.metrics. <a href="#">LegacyMetrics</a>	The Metrics Subsystem allows exposure of a number of named parameters/counters via JMX, is intended to be used as a static subsystem, and has a couple of primary ways in which it can be used: <ul style="list-style-type: none"> <li>Using the set and get methods to set and get named parameters.</li> <li>Using the incrementCounter method to increment and set named parameters in one go, rather than having to make a get and then a set.</li> <li>Using the startScope and endScope methods to start and end named "scopes" that record the number of times they have been instantiated and amount of time (in milliseconds) spent inside the scopes.</li> </ul>
org.apache.hadoop.hive.common.type. <a href="#">RandomTypeUtil</a>	Creates random data of different object types.
org.apache.hadoop.hive.conf. <a href="#">VariableSubstitution</a>	Substitution of environment variables.
org.apache.hadoop.hive.contrib.genericudf.example. <a href="#">GenericUDFAdd10</a>	Initializes the GenericUDF (once per instance), evaluates the GenericUDF with the arguments, and gets the string to display.
org.apache.hadoop.hive.io. <a href="#">HdfsUtils</a>	Utils to resolve file properties in MAPR filesystem.
org.apache.hadoop.hive.metastore. <a href="#">AcidEventListener</a>	It handles cleanup of dropped partition/table/database in ACID related metastore tables.
org.apache.hadoop.hive.metastore. <a href="#">FileMetadataHandler</a>	The base implementation of a file metadata handler for a specific file type.
org.apache.hadoop.hive.metastore. <a href="#">FileMetadataManager</a>	Handle storage functions of metadata.
org.apache.hadoop.hive.metastore. <a href="#">HMSMetricsListener</a>	Report metrics of metadata added and deleted by this Hive Metastore.
org.apache.hadoop.hive.metastore. <a href="#">Metastore</a>	Class to arrange work with Metastore.
org.apache.hadoop.hive.metastore. <a href="#">PartFilterExprUtil</a>	Utility functions for working with partition filter expressions.
org.apache.hadoop.hive.metastore.api. <a href="#">AbortTxnsRequest</a>	Class for handling transactions request.
org.apache.hadoop.hive.metastore.api. <a href="#">AddForeignKeyRequest</a>	Class for handling foreign key request.
org.apache.hadoop.hive.metastore.api. <a href="#">AddPrimaryKeyRequest</a>	Class for handling primary key request.
org.apache.hadoop.hive.metastore.api. <a href="#">CacheFileMetadataRequest</a>	Class for caching metadata requests.
org.apache.hadoop.hive.metastore.api. <a href="#">CacheFileMetadataResult</a>	Class for caching metadata results.
org.apache.hadoop.hive.metastore.api. <a href="#">ClearFileMetadataResult</a>	Class for clearing metadata results.
org.apache.hadoop.hive.metastore.api. <a href="#">DropConstraintRequest</a>	Class for dropping constraint requests.
org.apache.hadoop.hive.metastore.api. <a href="#">ForeignKeysRequest</a>	Class for handling foreign key requests.

Class	Description
org.apache.hadoop.hive.metastore.api. <a href="#">ForeignKeysResponse</a>	Class for getting response from all functions.
org.apache.hadoop.hive.metastore.api. <a href="#">GetAllFunctionsResponse</a>	Class for getting response from all functions.
org.apache.hadoop.hive.metastore.api. <a href="#">GetFileMetadataByExprRequest</a>	Class for getting metadata from expression response.
org.apache.hadoop.hive.metastore.api. <a href="#">GetFileMetadataByExprResult</a>	Class for getting metadata from expression result.
org.apache.hadoop.hive.metastore.api. <a href="#">MetadataPpdResult</a>	Class for describing metadata rpd result.
org.apache.hadoop.hive.metastore.api. <a href="#">PrimaryKeysRequest</a>	Class for describing primary key result.
org.apache.hadoop.hive.metastore.api. <a href="#">PrimaryKeysResponse</a>	Class for describing primary key response.
org.apache.hadoop.hive.metastore.api. <a href="#">PutFileMetadataRequest</a>	Class for output metadata request to file.
org.apache.hadoop.hive.metastore.api. <a href="#">PutFileMetadataResult</a>	Class for output metadata result to file.
org.apache.hadoop.hive.metastore.api. <a href="#">SQLForeignKey</a>	Class for describing SQL foreign key.
org.apache.hadoop.hive.metastore.api. <a href="#">SQLPrimaryKey</a>	Class for describing SQL primary key.
org.apache.hadoop.hive.metastore.api. <a href="#">TableMeta</a>	Class for describing table metadata.
org.apache.hadoop.hive.metastore.model. <a href="#">MConstraint</a>	Model of constraints stored in metastore.
org.apache.hadoop.hive.metastore.txn. <a href="#">TxnUtils</a>	Class for handling transactions.
org.apache.hadoop.hive.ql. <a href="#">CompilationOpContext</a>	Contains the operator sequence ID and a subset of compilation context that is passed to operators to get rid of some globals.
org.apache.hadoop.hive.ql. <a href="#">QueryDisplay</a>	Contains limited query information to save for WebUI. The class is synchronized, as WebUI may access information about a running query.
org.apache.hadoop.hive.ql. <a href="#">QueryState</a>	The class to store query level info such as queryId.
org.apache.hadoop.hive.ql.exec. <a href="#">AbstractMapOperator</a>	Abstract Map operator.
org.apache.hadoop.hive.ql.exec. <a href="#">GlobalWorkMapFactory</a>	Get job that has been executed on cluster as a map value.
org.apache.hadoop.hive.ql.exec. <a href="#">ObjectCacheWrapper</a>	Wrapping class for ObjectCache class.
org.apache.hadoop.hive.ql.exec. <a href="#">SerializationUtilities</a>	Utilities related to serialization and deserialization.
org.apache.hadoop.hive.ql.exec. <a href="#">UDFClassLoader</a>	UDFClassLoader is used to dynamically register udf (and related) jars. This was introduced to fix HIVE-11878. Each session will have its own instance of UDFClassLoader to support HiveServer2, which can contain multiple active sessions.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">CacheTran</a>	Class for making cache persistent.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">SmallTableCache</a>	Class for cache cleaning if new query is present.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">SparkDynamicPartitionPruner</a>	The spark version of DynamicPartitionPruner.

Class	Description
org.apache.hadoop.hive.ql.exec.spark.status.impl. <a href="#">SparkJobUtils</a>	Utilities for spark job.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">ColumnarSplitSizeEstimator</a>	Split size estimator for columnar file formats.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">HostAffinitySplitLocationProvider</a>	This maps a split (path + offset) to an index based on the number of locations provided.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">InPlaceUpdates</a>	Class responsible for inplace updates.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">KeyValuesFromKeyValue</a>	Provides a key/values (note the plural values) interface out of a KeyValueReader, needed by ReduceRecordSource when reading input from a key/value source.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">KeyValuesFromKeyValues</a>	Provides a key/values interface out of a KeyValuesReader for use by ReduceRecordSource.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">LlapObjectCache</a>	Llap implementation for the shared object cache.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">Utils</a>	Utilities for running tez jobs.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">IntervalDayTimeColumnVector</a>	This class represents a nullable interval day time column vector capable of handling a wide range of interval day time values.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">ListColumnVector</a>	The representation of a vectorized column of list objects.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">MapColumnVector</a>	The representation of a vectorized column of map objects.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">MultiValuedColumnVector</a>	The representation of a vectorized column of multi-valued objects, such as lists and maps.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">StructColumnVector</a>	The representation of a vectorized column of struct objects.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">TimestampColumnVector</a>	This class represents a nullable timestamp column vector capable of handling a wide range of timestamp values.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">UnionColumnVector</a>	The representation of a vectorized column of struct objects.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorSparkHashTableSinkOperator</a>	Vectorized version of SparkHashTableSinkOperator. It delegates all the work to super class Copied from VectorFileSinkOperator.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorSparkPartitionPruningSinkOperator</a>	Vectorized version for SparkPartitionPruningSinkOperator.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">BRoundWithNumDigitsDoubleToDouble</a>	Banking rounding implementation.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">CastDoubleToTimestamp</a>	Cast double type to timestamp type.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">CastLongToTimestamp</a>	Cast long type to timestamp type.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">CastMillisecondsLongToTimestamp</a>	Cast milliseconds long type to timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">CastStringGroupToString</a>	Cast string group type to string type.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">CastTimestampToBoolean</a>	Cast timestamp type to boolean.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.CastTimestampToDate	Cast timestamp type to decimal type.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastTimestampToDouble	Cast timestamp type to double type.
org.apache.hadoop.hive.ql.exec.vector.expressions.CastTimestampToLong	Cast timestamp type to long type.
org.apache.hadoop.hive.ql.exec.vector.expressions.DateColSubtractDateColumn	Subtract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions.DateColSubtractDateScalar	Subtract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions.DateScalarSubtractDateColumn	Subtract two variables of date type.
org.apache.hadoop.hive.ql.exec.vector.expressions.FilterStructColumnInList	Evaluates an IN filter on a batch for a vector of structs.
org.apache.hadoop.hive.ql.exec.vector.expressions.FilterTimestampColumnInList	Evaluates IN filter on a batch for a vector of timestamps.
org.apache.hadoop.hive.ql.exec.vector.expressions.FunctionBRoundWithNumDigitsDecimalToDecimal	Banking rounding for decimal digits.
org.apache.hadoop.hive.ql.exec.vector.expressions.FunctionDecimalToTimestamp	This is a superclass for unary decimal functions and expressions returning timestamps that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions.FunctionTimestampToDecimal	This is a superclass for unary timestamp functions and expressions returning decimals that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions.FunctionTimestampToLong	This is a superclass for unary timestamp functions and expressions returning long that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprDoubleColumnDoubleColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprIntervalDayTimeColumnColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprIntervalDayTimeColumnScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprIntervalDayTimeScalarColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprIntervalDayTimeScalarScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprLongColumnLongColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampColumnColumn	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampColumnColumnBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampColumnScalar	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampColumnScalarBase	Computes IF(expr1, expr2, expr3) for 3 input column expressions.

Class	Description
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarColumn</a>	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarColumnBase</a>	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarScalar</a>	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.IfExprTimestampScalarScalarBase</a>	Computes IF(expr1, expr2, expr3) for 3 input column expressions.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColEqualLongColumn</a>	If equal two columns as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColEqualLongScalar</a>	If equal long column and long scalar as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterEqualLongColumn</a>	If greater or equal two columns as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterEqualLongScalar</a>	If greater or equal long column and long scalar.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterLongColumn</a>	If greater two columns as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColGreaterLongScalar</a>	If greater long column and long scalar as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessEqualLongColumn</a>	If less equal two columns as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessEqualLongScalar</a>	If less equal long column and long scalar as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessLongColumn</a>	If less two columns as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColLessLongScalar</a>	If less long column and long scalar as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColNotEqualLongColumn</a>	If not equal two columns as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongColNotEqualLongScalar</a>	If not equal long column and long scalar as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarEqualLongColumn</a>	If equal long scalar and long column.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarGreaterEqualLongColumn</a>	If greater equal long scalar and long column as vector.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarGreaterLongColumn</a>	If greater long scalar and long column as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarLessEqualLongColumn</a>	If less equal long scalar and long column as vector.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarLessLongColumn</a>	If less long scalar and long column as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.LongScalarNotEqualLongColumn</a>	If not equal long scalar and long column as vectors.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.expressions.SelectStringColLikeStringScalar</a>	Select like statement for string column and string scalar.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">StructColumnInList</a>	Evaluates an IN boolean expression (not a filter) on a batch for a vector of structs.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">TimestampColumnInList</a>	Returns a boolean value indicating if a column is IN a list of constants.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">TimestampToStringUnaryUDF</a>	This is a superclass for unary long functions returning strings that operate directly on the input and set the output.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFDateTimestamp</a>	Vectorized version of TO_DATE(timestamp).
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFDayOfMonthDate</a>	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFDayOfMonthTimestamp</a>	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFHourDate</a>	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFHourTimestamp</a>	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFMinuteDate</a>	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFMinuteTimestamp</a>	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFMonthDate</a>	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFMonthTimestamp</a>	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFSecondDate</a>	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFSecondTimestamp</a>	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFTimestampFieldDate</a>	Abstract class to return various fields from a Timestamp or Date.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFTimestampFieldTimestamp</a>	Abstract class to return various fields from a Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFUnixTimeStampDate</a>	Returns Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFUnixTimeStampTimestamp</a>	Returns Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFWeekOfYearDate</a>	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFWeekOfYearTimestamp</a>	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFYearDate</a>	Expression to get year as a long.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFYearTimestamp</a>	Expression to get year as a long.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. <a href="#">VectorUDAFVgTimestamp</a>	Generated from template VectorUDAFVg.txt.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. <a href="#">VectorUDAFStdPopTimestamp</a>	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. <a href="#">VectorUDAFStdSampTimestamp</a>	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. <a href="#">VectorUDAFVarPopTimestamp</a>	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.exec.vector.expressions.aggregates. <a href="#">VectorUDAFVarSampTimestamp</a>	Vectorized implementation for VARIANCE aggregates.
org.apache.hadoop.hive.ql.hooks. <a href="#">LineageLogger</a>	Implementation of a post execute hook that logs lineage info to a log file.
org.apache.hadoop.hive.ql.hooks. <a href="#">PostExecOrcFileDump</a>	Post execution hook to print orc file dump for files that will be read by fetch task.
org.apache.hadoop.hive.ql.hooks. <a href="#">PostExecTezSummaryPrinter</a>	Post execution hook to print hive tez counters to console error stream.
org.apache.hadoop.hive.ql.io. <a href="#">HdfsUtils</a>	Utilities for hadoop fs.
org.apache.hadoop.hive.ql.io. <a href="#">IOContextMap</a>	Uses the global static map of IOContext-s inside IOContext, uses threadlocal for Spark, and creates inheritable threadlocal with attemptId (only set in LLAP), which will propagate to all the Tez threads.
org.apache.hadoop.hive.ql.io. <a href="#">NullScanFileSystem</a>	Filesystem that does not allow Hive to read files for nullscans.
org.apache.hadoop.hive.ql.io. <a href="#">ProxyLocalFileSystem</a>	This class is to workaround existing issues on LocalFileSystem.
org.apache.hadoop.hive.ql.io. <a href="#">SyntheticFileId</a>	Create synthetic ID for file.
org.apache.hadoop.hive.ql.io.orc. <a href="#">ExternalCache</a>	Metastore-based footer cache storing serialized footers.
org.apache.hadoop.hive.ql.io.orc. <a href="#">MetastoreExternalCachesByConf</a>	An implementation of external cache and factory based on metastore.
org.apache.hadoop.hive.ql.io.orc. <a href="#">OrcFileFormatProxy</a>	File format proxy for ORC.
org.apache.hadoop.hive.ql.io.orc. <a href="#">RecordReaderImpl</a>	Implementation of record reader.
org.apache.hadoop.hive.ql.io.parquet.read. <a href="#">ParquetFilterPredicateConverter</a>	Translate the search argument to the filter predicate parquet uses.
org.apache.hadoop.hive.ql.io.sarg. <a href="#">ConvertAstToSearchArg</a>	Converting asterisk and use it as a search argument.
org.apache.hadoop.hive.ql.io.sarg. <a href="#">SearchArgumentImpl</a>	The implementation of SearchArguments.
org.apache.hadoop.hive.ql.lib. <a href="#">PreOrderOnceWalker</a>	This class takes list of starting nodes and walks them in pre-order.
org.apache.hadoop.hive.ql.log. <a href="#">HiveEventCounter</a>	A log4J2 appender that simply counts logging events in four levels: fatal, error, warn, and info.
org.apache.hadoop.hive.ql.log. <a href="#">NoDeleteRollingFileAppender</a>	Instantiate a RollingFileAppender and open the file designated by filename. The opened filename will become the output destination for this appender.
org.apache.hadoop.hive.ql.log. <a href="#">NullAppender</a>	A NullAppender that never outputs a message to any device.

Class	Description
<a href="#">org.apache.hadoop.hive.ql.log.PidFilePatternConverter</a>	FilePattern converter that converts %pid pattern to @ information obtained at runtime.
<a href="#">org.apache.hadoop.hive.ql.metadata.ForeignKeyInfo</a>	ForeignKeyInfo is a metadata structure containing the foreign keys associated with a table.
<a href="#">org.apache.hadoop.hive.ql.metadata.PrimaryKeyInfo</a>	PrimaryKeyInfo is a metadata structure containing the primary key associated with a table.
<a href="#">org.apache.hadoop.hive.ql.metadata.TableIterable</a>	Gets Table objects for a table list.
<a href="#">org.apache.hadoop.hive.ql.optimizer.OperatorComparatorFactory</a>	Comparator for table operators.
<a href="#">org.apache.hadoop.hive.ql.optimizer.PartitionColumnsSelector</a>	Takes a Filter expression, and if its predicate contains an IN operator whose children are constant structs or structs containing constant fields, it will try to generate predicate with IN clauses containing only partition columns.
<a href="#">org.apache.hadoop.hive.ql.optimizer.PointLookupOptimizer</a>	Takes a Filter expression, and if its predicate contains an OR operator whose children are constant equality expressions, it will try to generate an IN clause (which is more efficient).
<a href="#">org.apache.hadoop.hive.ql.optimizer.RedundantDynamicPruningConditionsRemoval</a>	Takes a Filter operator on top of a TableScan and removes dynamic pruning conditions if static partition pruning has been triggered already.
<a href="#">org.apache.hadoop.hive.ql.optimizer.SparkRemoveDynamicPruningBySize</a>	Disables pruning if the number of keys for dynamic pruning is too large.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.HivePlannerContext</a>	Creating context for Hive Planner.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.HiveRelBuilder</a>	Builder for relational expressions in Hive.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.HiveRelFactories</a>	Factory class for creating relational operators for queries.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.HiveRegistryExecutorImpl</a>	Hive registry executor implementation.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.HiveRegistryUtil</a>	Utilities for hive registry executor.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveBetween</a>	Operand type-inference strategy where an unknown operand type is derived from the first operand with a known type, but the first operand is a boolean.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveIn</a>	Create in clause instance for hive queries.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveMultiJoin</a>	A HiveMultiJoin represents a succession of binary joins.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit</a>	Sorting limit in hive queries.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregateJoinTransposeRule</a>	Planner rule that pushes an <code>org.apache.calcite.rel.core.Aggregate</code> past a <code>org.apache.calcite.rel.core.Join</code> .
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregateProjectMergeRule</a>	Planner rule that recognizes a <code>HiveAggregate</code> on top of a <code>HiveProject</code> and if possible, aggregates through the project or removes the project.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveAggregatePullUpConstantsRule</a>	Rule for pull up constants aggregation.

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterAggregateTransposeRule	Transpose rule for filter aggregation.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterProjectTSTransposeRule	Transpose rule for filtering project TST.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveFilterSortTransposeRule	Transpose rule for filtering sort.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinProjectTransposeRule	Transpose rule for join project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HivePointLookupOptimizerRule	Takes a Filter expression, and if its predicate contains an OR operator whose children are constant equality expressions, tries to generate an IN clause (which is more efficient).
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveProjectFilterPullUpConstantsRule	Planner rule that infers constant expressions from Filter into a Project operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveProjectSortTransposeRule	Transpose rule for project sort.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveReduceExpressionsRule	Collection of planner rules that apply various simplifying transformations on RexNode trees.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveReduceExpressionsWithStatsRule	This rule simplifies the condition in Filter operators using the column statistics (if available).
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveRelColumnsAlignment	Infers the order in Aggregate columns and the order of conjuncts in a Join condition that might be more beneficial to avoid additional sort stages.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortJoinReduceRule	Planner rule that pushes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit past a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveJoin.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortLimitPullUpConstantsRule	Planner rule that pulls up constant keys through a SortLimit operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortMergeRule	This rule will merge two HiveSortLimit operators.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortProjectTransposeRule	Transpose rule for sort project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortRemoveRule	Planner rule that removes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveSortUnionReduceRule	Planner rule that pushes a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveSortLimit past a org.apache.hadoop.hive.ql.optimizer.calcite.reloperators.HiveUnion.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveUnionPullUpConstantsRule	Planner rule that pulls up constants through a Union operator.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdPredicates	Infers predicates for a project.
org.apache.hadoop.hive.ql.optimizer.physical.LlapDecider	LlapDecider takes care of tagging certain vertices in the execution graph as "llap", which in turn causes them to be submitted to an llap daemon instead of a regular yarn container.

Class	Description
org.apache.hadoop.hive.ql.optimizer.physical. <a href="#">MemoryDecider</a>	MemoryDecider is a simple physical optimizer that adjusts the memory layout of tez tasks.
org.apache.hadoop.hive.ql.optimizer.physical. <a href="#">SerializeFilter</a>	SerializeFilter is a simple physical optimizer that serializes all filter expressions in Tablescan Operators.
org.apache.hadoop.hive.ql.optimizer.spark. <a href="#">CombineEquivalentWorkResolver</a>	CombineEquivalentWorkResolver searches inside SparkWork, finds and combines equivalent works.
org.apache.hadoop.hive.ql.optimizer.spark. <a href="#">SparkPartitionPruningSinkDesc</a>	Description of spark partition pruning sink.
org.apache.hadoop.hive.ql.parse. <a href="#">AnalyzeCommandUtils</a>	Utilities for command analysis.
org.apache.hadoop.hive.ql.parse. <a href="#">ColumnStatsAutoGatherContext</a>	ColumnStatsAutoGatherContext is passed to the compiler when set hive.stats.autogather is true during the INSERT OVERWRITE command.
org.apache.hadoop.hive.ql.parse. <a href="#">MaskAndFilterInfo</a>	Information for masking and filtering.
org.apache.hadoop.hive.ql.parse. <a href="#">TableMask</a>	The main purpose for this class is for authorization.
org.apache.hadoop.hive.ql.parse.spark. <a href="#">SparkPartitionPruningSinkOperator</a>	This operator gets partition info from the upstream operators and writes them to HDFS.
org.apache.hadoop.hive.ql.parse.spark. <a href="#">SplitOpTreeForDPP</a>	This processor triggers on SparkPartitionPruningSinkOperator.
org.apache.hadoop.hive.ql.plan. <a href="#">AbortTxnsDesc</a>	Descriptor for aborting transactions.
org.apache.hadoop.hive.ql.plan. <a href="#">CacheMetadataDesc</a>	Description for metadata cache.
org.apache.hadoop.hive.ql.plan. <a href="#">ShowCreateDatabaseDesc</a>	Shows the name of the database.
org.apache.hadoop.hive.ql.plan. <a href="#">VectorPartitionConversion</a>	PartitionConversion.
org.apache.hadoop.hive.ql.plan. <a href="#">VectorPartitionDesc</a>	VectorMapDesc.
org.apache.hadoop.hive.ql.plan. <a href="#">VectorReduceSinkDesc</a>	VectorReduceSinkDesc.
org.apache.hadoop.hive.ql.plan. <a href="#">VectorReduceSinkInfo</a>	VectorGroupByAggregationInfo.
org.apache.hadoop.hive.ql.ppd. <a href="#">SimplePredicatePushDown</a>	Implementation of predicate push down.
org.apache.hadoop.hive.ql.security.authorization. <a href="#">DefaultHiveAuthorizationTranslator</a>	Default implementation of HiveAuthorizationTranslator.
org.apache.hadoop.hive.ql.security.authorization.plugin. <a href="#">AbstractHiveAuthorizer</a>	Abstract class that extends HiveAuthorizer.
org.apache.hadoop.hive.ql.session. <a href="#">ClearDanglingScratchDir</a>	A tool to remove dangling scratch directory.
org.apache.hadoop.hive.ql.stats. <a href="#">StatsCollectionContext</a>	Creating context for stats collection.
org.apache.hadoop.hive.ql.txn.compactor. <a href="#">HouseKeeperServiceBase</a>	Housekeeper for running services.
org.apache.hadoop.hive.ql.udf. <a href="#">UDFChr</a>	UDFChr converts an integer into its ASCII equivalent.
org.apache.hadoop.hive.ql.udf. <a href="#">UDFCrc32</a>	UDFCrc32.
org.apache.hadoop.hive.ql.udf. <a href="#">UDFMd5</a>	UDFMd5.
org.apache.hadoop.hive.ql.udf. <a href="#">UDFReplace</a>	UDFReplace replaces all substrings that are matched with a replacement substring.

Class	Description
org.apache.hadoop.hive.ql.udf.UDFSha1	UDFSha.
org.apache.hadoop.hive.ql.udf.UDFVersion	UDFVersion
org.apache.hadoop.hive.ql.udf.generic.BaseMaskUDF	User defined function for masking.
org.apache.hadoop.hive.ql.udf.generic.GenericUDAFSumEmptyIsZero	User defined aggregation function for summing empty as zeros.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFAesBase	Base for user defined functions.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFAesDecrypt	User defined function for decryption.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFAesEncrypt	User defined function for encryption.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFBRound	User defined function for banking rounding.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFBaseNWayCompare	Base class for comparison UDF's (Greatest and Least).
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMask	User defined function for masking.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskFirstN	User defined function for masking first n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskHash	User defined function that returns a hashed value based on str.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskLastN	User defined function for masking last n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskShowFirstN	User defined function for showing masked first n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFMaskShowLastN	User defined function for showing masked last n symbols.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFParamsUtils	Generic UDF params utility class.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFQuarter	GenericUDFQuarter.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFRegex	UDF to extract a specific group identified by a java regex.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFSha2	GenericUDFSha2.
org.apache.hadoop.hive.ql.udf.generic.GenericUDFSubstringIndex	GenericUDFSubstringIndex.
org.apache.hadoop.hive.ql.udf.generic.GenericUDTFGetSplits	GenericUDTFGetSplits.
org.apache.hadoop.hive.ql.util.DependencyResolver	Query dependency resolver.
org.apache.hadoop.hive.ql.util.ResourceDownloader	Resource downloader.
org.apache.hadoop.hive.ql.util.TimestampUtils	Utilities for Timestamps and the relevant conversions.
org.apache.hadoop.hive.serde2.DefaultFetchFormatter	Serializes row by user specified serde and calls toString() to make string type result.
org.apache.hadoop.hive.serde2.NoOpFetchFormatter	A No-op fetch formatter.

Class	Description
org.apache.hadoop.hive.serde2.binarysortable. <a href="#">BinarySortableSerDeWithEndPrefix</a>	Serializer desrializer for binary sortable.
org.apache.hadoop.hive.serde2.thrift. <a href="#">ColumnBuffer</a>	Column buffer.
org.apache.hadoop.hive.serde2.thrift. <a href="#">ThriftFormatter</a>	Thrift formatter.
org.apache.hadoop.hive.serde2.thrift. <a href="#">ThriftJDBCBinarySerDe</a>	Serializes the final output to thrift-able objects directly in the SerDe.
org.apache.hadoop.hive.thrift. <a href="#">HiveDelegationTokenManager</a>	Delegation token manager.
org.apache.hive.beeline. <a href="#">ClientCommandHookFactory</a>	Updates some client side information after executing some Hive commands.
org.apache.hive.beeline. <a href="#">ClientHook</a>	This is the client's hook and used for new Hive CLI.
org.apache.hive.common.util. <a href="#">DateParser</a>	Date parser class for Hive.
org.apache.hive.common.util. <a href="#">FixedSizedObjectPool</a>	Simple object pool of limited size.
org.apache.hive.common.util. <a href="#">HashCodeUtil</a>	Utilities for hash code.
org.apache.hive.common.util. <a href="#">IntervalDayTimeUtils</a>	DateUtils.
org.apache.hive.hcatalog.streaming. <a href="#">AbstractRecordWriter</a>	Class for defining record writer.
org.apache.hive.jdbc. <a href="#">HttpTokenAuthInterceptor</a>	The class is instantiated with the username and password, it is then used to add header with these credentials to HTTP requests
org.apache.hive.jdbc. <a href="#">XsrfHttpRequestInterceptor</a>	Http request interceptor for xsrf token.
org.apache.hive.service.cli.operation. <a href="#">GetCrossReferenceOperation</a>	GetCrossReferenceOperation.
org.apache.hive.service.cli.operation. <a href="#">GetPrimaryKeysOperation</a>	GetPrimaryKeysOperation.
org.apache.hive.service.cli.operation. <a href="#">SQLOperationDisplay</a>	Used to display some info in the HS2 WebUI.
org.apache.hive.service.cli.operation. <a href="#">SQLOperationDisplayCache</a>	Cache some SQLOperation information for WebUI
org.apache.hive.service.cli.thrift. <a href="#">RetryingThriftCLIServiceClient</a>	RetryingThriftCLIServiceClient.

### New Interfaces in Hive 2.1

Hive 2.1 includes the following new interfaces:

Interface	Description
org.apache.hadoop.hive.common. <a href="#">Pool</a>	Simple object pool to prevent GC on small objects passed between threads.
org.apache.hadoop.hive.common.io. <a href="#">Allocator</a>	An allocator provided externally to storage classes to allocate MemoryBuffer-s.
org.apache.hadoop.hive.common.io. <a href="#">DataCache</a>	An abstract data cache that IO formats can use to retrieve and cache data.
org.apache.hadoop.hive.conf. <a href="#">HiveVariableSource</a>	Getting hive variables.
org.apache.hadoop.hive.metastore. <a href="#">FileFormatProxy</a>	Same as PartitionExpressionProxy, but for file format specific methods for metadata cache.

org.apache.hadoop.hive.metastore. <a href="#">HouseKeeperService</a>	Runs arbitrary background logic inside the metastore service.
org.apache.hadoop.hive.metastore.txn. <a href="#">TxnStore</a>	A handler to answer transaction related calls that come into the metastore server.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">KeyValuesAdapter</a>	Key-values interface for the Reader used by ReduceRecordSource
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">IStructInExpr</a>	Interface used for both filter and non-filter versions of IN to simplify VectorizationContext code.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">ITimestampInExpr</a>	Interface used to process timestamp in expression.
org.apache.hadoop.hive.ql.io. <a href="#">ColumnarSplit</a>	Interface when implemented should return the estimated size of columnar projections that will be read from the split.
org.apache.hadoop.hive.ql.io. <a href="#">LLapAwareSplit</a>	Split that is aware that it could be executed in LLAP.
org.apache.hadoop.hive.ql.io. <a href="#">LLapWrappableInputFormatInterface</a>	Marker interface for LLAP; serves no other purpose.
org.apache.hadoop.hive.ql.io. <a href="#">SelfDescribingInputFormatInterface</a>	Marker interface to indicate a given input format is self-describing and can perform schema evolution itself.
org.apache.hadoop.hive.ql.io. <a href="#">StreamingOutputFormat</a>	Marker interface for streaming output formats.
org.apache.hadoop.hive.ql.security.authorization.plugin. <a href="#">HiveAuthorizationTranslator</a>	This interface has functions that provide the ability to customize the translation from Hive internal representations of Authorization objects to the public API objects This is an interface that is not meant for general use, it is targeted to some specific use cases of Apache Sentry (incubating).
org.apache.hadoop.hive.serde2. <a href="#">FetchFormatter</a>	<b>(For internal-use only)</b> Used in ListSinkOperator for formatting final output.

### Changed Classes in Hive 2.1

The following classes have changes in Hive 2.1:

Class	Description
org.apache.hadoop.hive.accumulo.mr. <a href="#">HiveAccumuloTableOutputFormat</a>	Output format for accumulo tables.
org.apache.hadoop.hive.cli. <a href="#">CliDriver</a>	CliDriver.
org.apache.hadoop.hive.cli. <a href="#">OptionsProcessor</a>	OptionsProcessor.
org.apache.hadoop.hive.common. <a href="#">CompressionUtils</a>	Contains methods used for the purposes of compression. This class should not be accessed from code run in Hadoop.
org.apache.hadoop.hive.common. <a href="#">FileUtils</a>	Collection of file manipulation utilities common across Hive.
org.apache.hadoop.hive.common. <a href="#">HiveStatsUtils</a>	HiveStatsUtils.
org.apache.hadoop.hive.common. <a href="#">JavaUtils</a>	Collection of Java class loading/reflection related utilities common across Hive.
org.apache.hadoop.hive.common. <a href="#">LogUtils</a>	Utilities common to logging operations.
org.apache.hadoop.hive.common. <a href="#">ObjectPair</a>	Creating pair out of templates.
org.apache.hadoop.hive.common. <a href="#">ServerUtils</a>	ServerUtils (specific to HiveServer version 1)

Class	Description
org.apache.hadoop.hive.common. <a href="#">StatsSetupConst</a>	Defines the constant strings used by the statistics implementation.
org.apache.hadoop.hive.common. <a href="#">ValidReadTxnList</a>	An implementation of org.apache.hadoop.hive.common.ValidTxnList for use by readers.
org.apache.hadoop.hive.common.cli. <a href="#">CommonCliOptions</a>	Reusable code for Hive Cli's.
org.apache.hadoop.hive.common.io. <a href="#">NonSyncByteArrayInputStream</a>	A thread-not-safe version of ByteArrayOutputStream, which removes all synchronized modifiers.
org.apache.hadoop.hive.common.type. <a href="#">HiveDecimal</a>	HiveDecimal.
org.apache.hadoop.hive.common.type. <a href="#">HiveIntervalDayTime</a>	Day-time interval type representing an offset in days/hours/minutes/seconds, with nanosecond precision.
org.apache.hadoop.hive.common.type. <a href="#">HiveVarchar</a>	HiveVarChar.
org.apache.hadoop.hive.conf. <a href="#">HiveConf</a>	Hive Configuration.
org.apache.hadoop.hive.conf. <a href="#">HiveConfUtil</a>	Hive Configuration utils
org.apache.hadoop.hive.contrib.serde2. <a href="#">MultiDelimitSerDe</a>	This SerDe allows user to use multiple characters as the field delimiter for a table.
org.apache.hadoop.hive.contrib.serde2. <a href="#">RegexSerDe</a>	RegexSerDe uses regular expression (regex) to serialize/deserialize.
org.apache.hadoop.hive.contrib.serde2. <a href="#">TypedBytesSerDe</a>	TypedBytesSerDe uses typed bytes to serialize/deserialize.
org.apache.hadoop.hive.contrib.serde2.s3. <a href="#">S3LogDeserializer</a>	S3LogDeserializer.
org.apache.hadoop.hive.hbase. <a href="#">AbstractHBaseKeyPredicateDecomposer</a>	Simple abstract class to help with creation of a DecomposedPredicate.
org.apache.hadoop.hive.hbase. <a href="#">CompositeHBaseKeyFactory</a>	Factory that creates composite keys.
org.apache.hadoop.hive.hbase. <a href="#">HBaseLazyObjectFactory</a>	Replaces original keyOI with OI which is create by HBaseKeyFactory provided by serde property for hbase.
org.apache.hadoop.hive.hbase. <a href="#">HBaseSerDe</a>	HBaseSerDe can be used to serialize object into an HBase table and deserialize objects from an HBase table.
org.apache.hadoop.hive.hbase. <a href="#">HBaseSerDeHelper</a>	Helper class for HBaseSerDe
org.apache.hadoop.hive.hbase. <a href="#">HiveHBaseTableInputFormat</a>	HiveHBaseTableInputFormat implements InputFormat for HBase storage handler tables, decorating an underlying HBase TableInputFormat with extra Hive logic such as column pruning and filter pushdown.
org.apache.hadoop.hive.hbase. <a href="#">HiveHBaseTableOutputFormat</a>	HiveHBaseTableOutputFormat implements HiveOutputFormat for HBase tables.
org.apache.hadoop.hive.hbase. <a href="#">LazyHBaseCellMap</a>	LazyHBaseCellMap refines LazyMap with HBase column mapping.
org.apache.hadoop.hive.hwi. <a href="#">HWIContextListener</a>	After getting a contextInitialized event, this component starts an instance of the HiveSessionManager.
org.apache.hadoop.hive.hwi. <a href="#">HWIServer</a>	This is the entry point for HWI.
org.apache.hadoop.hive.hwi. <a href="#">HWISessionItem</a>	HWISessionItem can be viewed as a wrapper for a Hive shell.

Class	Description
org.apache.hadoop.hive.hwi.HWISessionManager	HiveSessionManager is a Runnable started inside a web application context.
org.apache.hadoop.hive.metastore.Deadline	Monitors long running methods in a thread.
org.apache.hadoop.hive.metastore.HiveAlterHandler	Hive specific implementation of alter.
org.apache.hadoop.hive.metastore.HiveMetaStore	Removes application logic to a separate interface.
org.apache.hadoop.hive.metastore.HiveMetaStoreClient	Hive Metastore Client.
org.apache.hadoop.hive.metastore.HiveMetaStoreFsImpl	Class to handle methods for filesystem and data related to metastore.
org.apache.hadoop.hive.metastore.LockComponentBuilder	A builder for LockComponents.
org.apache.hadoop.hive.metastore.LockRequestBuilder	Builder class to make constructing LockRequest easier.
org.apache.hadoop.hive.metastore.MetaStoreSchemaInfo	Information about metastore schemas stored in database.
org.apache.hadoop.hive.metastore.MetaStoreUtils	Utilities to handle metastore data.
org.apache.hadoop.hive.metastore.ObjectStore	Interface between the application logic and the database store that contains the objects.
org.apache.hadoop.hive.metastore.PartitionDropOptions	Generalizes the switches for dropPartitions().
org.apache.hadoop.hive.metastore.RetryingHMSHandler	Handler for hive metastore.
org.apache.hadoop.hive.metastore.RetryingMetaStoreClient	RetryingMetaStoreClient.
org.apache.hadoop.hive.metastore.StatObjectConverter	Contains conversion logic that creates Thrift stat objects from JDO stat objects and plain arrays from DirectSQL.
org.apache.hadoop.hive.metastore.Warehouse	Represents a warehouse where data of Hive tables is stored.
org.apache.hadoop.hive.metastore.api.AbortTxnRequest	Aborting transaction request.
org.apache.hadoop.hive.metastore.api.AddDynamicPartitions	Adding dynamic partitions.
org.apache.hadoop.hive.metastore.api.AddPartitionsRequest	Adding partition request.
org.apache.hadoop.hive.metastore.api.AddPartitionsResult	Adding partition result.
org.apache.hadoop.hive.metastore.api.AggrStats	Aggregation statistics.
org.apache.hadoop.hive.metastore.api.BinaryColumnStatsData	Binary column statistics data.
org.apache.hadoop.hive.metastore.api.BooleanColumnStatsData	Boolean column statistics data.
org.apache.hadoop.hive.metastore.api.CheckLockRequest	Checking request on acquiring lock.
org.apache.hadoop.hive.metastore.api.ColumnStatistics	Column statistics class.
org.apache.hadoop.hive.metastore.api.ColumnStatisticsDesc	Column statistics description.
org.apache.hadoop.hive.metastore.api.ColumnStatisticsObject	Column statistics object.

Class	Description
org.apache.hadoop.hive.metastore.api. <a href="#">CommitTxnRequest</a>	Commit transaction request.
org.apache.hadoop.hive.metastore.api. <a href="#">CompactionRequest</a>	Compaction request.
org.apache.hadoop.hive.metastore.api. <a href="#">CurrentNotificationEventId</a>	Current notification event ID.
org.apache.hadoop.hive.metastore.api. <a href="#">Database</a>	Class that describes database.
org.apache.hadoop.hive.metastore.api. <a href="#">Date</a>	Date class.
org.apache.hadoop.hive.metastore.api. <a href="#">DateColumnStatsData</a>	Date column statistics data.
org.apache.hadoop.hive.metastore.api. <a href="#">Decimal</a>	Handling decimal type.
org.apache.hadoop.hive.metastore.api. <a href="#">DecimalColumnStatsData</a>	Decimal column statistics data.
org.apache.hadoop.hive.metastore.api. <a href="#">DoubleColumnStatsData</a>	Double column statistics data.
org.apache.hadoop.hive.metastore.api. <a href="#">DropPartitionsExpr</a>	Drop partitions expression.
org.apache.hadoop.hive.metastore.api. <a href="#">DropPartitionsRequest</a>	Drop partitions request.
org.apache.hadoop.hive.metastore.api. <a href="#">DropPartitionsResult</a>	Drop partitions result.
org.apache.hadoop.hive.metastore.api. <a href="#">EnvironmentContext</a>	Environment context structure.
org.apache.hadoop.hive.metastore.api. <a href="#">FieldSchema</a>	Field schema structure.
org.apache.hadoop.hive.metastore.api. <a href="#">FireEventRequest</a>	Fire event request.
org.apache.hadoop.hive.metastore.api. <a href="#">FireEventResponse</a>	Fire event response.
org.apache.hadoop.hive.metastore.api. <a href="#">Function</a>	Function structure.
org.apache.hadoop.hive.metastore.api. <a href="#">GetOpenTxnsInfoResponse</a>	Getter for open transactions information about response.
org.apache.hadoop.hive.metastore.api. <a href="#">GetOpenTxnsResponse</a>	Getter for open transactions response.
org.apache.hadoop.hive.metastore.api. <a href="#">GetPrincipalsInRoleRequest</a>	Getting request for principals in role.
org.apache.hadoop.hive.metastore.api. <a href="#">GetPrincipalsInRoleResponse</a>	Getting response for principals in role.
org.apache.hadoop.hive.metastore.api. <a href="#">GetRoleGrantsForPrincipalRequest</a>	Getting request for granting role for principal.
org.apache.hadoop.hive.metastore.api. <a href="#">GetRoleGrantsForPrincipalResponse</a>	Getting response for granting role for principal.
org.apache.hadoop.hive.metastore.api. <a href="#">GrantRevokePrivilegeRequest</a>	Request for revoking granted privilege.
org.apache.hadoop.hive.metastore.api. <a href="#">GrantRevokePrivilegeResponse</a>	Response for revoking granted privilege.

Class	Description
org.apache.hadoop.hive.metastore.api. <a href="#">GrantRevokeRoleRequest</a>	Request for revoking granted role.
org.apache.hadoop.hive.metastore.api. <a href="#">GrantRevokeRoleResponse</a>	Response for revoking granted role.
org.apache.hadoop.hive.metastore.api. <a href="#">HeartbeatRequest</a>	Request for heartbeat.
org.apache.hadoop.hive.metastore.api. <a href="#">HeartbeatTxnRangeRequest</a>	Request for transaction range request.
org.apache.hadoop.hive.metastore.api. <a href="#">HeartbeatTxnRangeResponse</a>	Response for transaction range response.
org.apache.hadoop.hive.metastore.api. <a href="#">HiveObjectPrivilege</a>	Description of privileges for hive object.
org.apache.hadoop.hive.metastore.api. <a href="#">HiveObjectRef</a>	Hive object reference.
org.apache.hadoop.hive.metastore.api. <a href="#">Index</a>	Description of index.
org.apache.hadoop.hive.metastore.api. <a href="#">InsertEventRequestData</a>	Class to handle data about insert event on request.
org.apache.hadoop.hive.metastore.api. <a href="#">LockComponent</a>	Description of lock component.
org.apache.hadoop.hive.metastore.api. <a href="#">LockRequest</a>	Description of lock request.
org.apache.hadoop.hive.metastore.api. <a href="#">LockResponse</a>	Description of lock response.
org.apache.hadoop.hive.metastore.api. <a href="#">LongColumnStatsData</a>	Description of long column statistics data.
org.apache.hadoop.hive.metastore.api. <a href="#">NotificationEvent</a>	Description of notification event.
org.apache.hadoop.hive.metastore.api. <a href="#">NotificationEventRequest</a>	Description of notification event on request.
org.apache.hadoop.hive.metastore.api. <a href="#">NotificationEventResponse</a>	Description of notification event on response.
org.apache.hadoop.hive.metastore.api. <a href="#">OpenTxnRequest</a>	Description of open transactions on request.
org.apache.hadoop.hive.metastore.api. <a href="#">OpenTxnsResponse</a>	Description of open transactions on response.
org.apache.hadoop.hive.metastore.api. <a href="#">Order</a>	Description of order.
org.apache.hadoop.hive.metastore.api. <a href="#">Partition</a>	Description of partition.
org.apache.hadoop.hive.metastore.api. <a href="#">PartitionListComposingSpec</a>	Description of partition list composing specification.
org.apache.hadoop.hive.metastore.api. <a href="#">PartitionSpec</a>	Description of partition specification.
org.apache.hadoop.hive.metastore.api. <a href="#">PartitionSpecWithSharedSD</a>	Description of partition specification with shared sd.
org.apache.hadoop.hive.metastore.api. <a href="#">PartitionWithoutSD</a>	Description of partition without sd.
org.apache.hadoop.hive.metastore.api. <a href="#">PartitionsByExprRequest</a>	Description of partitions by expression request.
org.apache.hadoop.hive.metastore.api. <a href="#">PartitionsByExprResult</a>	Description of partitions by expression result.
org.apache.hadoop.hive.metastore.api. <a href="#">PartitionsStatsRequest</a>	Description of partition statistics request.

Class	Description
org.apache.hadoop.hive.metastore.api.PartitionsStatsResult	Description of partitions statistics result.
org.apache.hadoop.hive.metastore.api.PrincipalPrivilegeSet	Description of setting principal privilege.
org.apache.hadoop.hive.metastore.api.PrivilegeBag	Description of privilege bag.
org.apache.hadoop.hive.metastore.api.PrivilegeGrantInfo	Description of granted privilege info.
org.apache.hadoop.hive.metastore.api.ResourceUri	Description of resource URI.
org.apache.hadoop.hive.metastore.api.Role	Description of role.
org.apache.hadoop.hive.metastore.api.RolePrincipalGrant	Description of granted principal role.
org.apache.hadoop.hive.metastore.api.Schema	Description of schema.
org.apache.hadoop.hive.metastore.api.SerDelInfo	Description of serializer deserializer information.
org.apache.hadoop.hive.metastore.api.SetPartitionsStatsRequest	Description of setting partition statistics on request.
org.apache.hadoop.hive.metastore.api.ShowCompactRequest	Show compaction on request.
org.apache.hadoop.hive.metastore.api.ShowCompactResponse	Show compaction on response.
org.apache.hadoop.hive.metastore.api.ShowCompactResponseElement	Show compaction response element.
org.apache.hadoop.hive.metastore.api.ShowLocksRequest	Show locks on request.
org.apache.hadoop.hive.metastore.api.ShowLocksResponse	Show locks on response.
org.apache.hadoop.hive.metastore.api.ShowLocksResponseElement	Show locks response element.
org.apache.hadoop.hive.metastore.api.SkewedInfo	Description for skewed information.
org.apache.hadoop.hive.metastore.api.StorageDescriptor	Description for storage descriptor.
org.apache.hadoop.hive.metastore.api.StringColumnStatisticsData	Description for string column statistics data.
org.apache.hadoop.hive.metastore.api.Table	Description for data.
org.apache.hadoop.hive.metastore.api.TableStatsRequest	Description for table statistics request.
org.apache.hadoop.hive.metastore.api.TableStatsResult	Description for table statistics result.
org.apache.hadoop.hive.metastore.api.AlreadyExistsException	Custom exception to handle already exists error.
org.apache.hadoop.hive.metastore.api.ConfigValSecurityException	Custom exception to handle configuration value security error.
org.apache.hadoop.hive.metastore.api.IndexAlreadyExistsException	Custom exception to handle index already exists error.
org.apache.hadoop.hive.metastore.api.InvalidInputException	Custom exception for invalid input error.
org.apache.hadoop.hive.metastore.api.InvalidObjectException	Custom exception for invalid object error.

Class	Description
org.apache.hadoop.hive.metastore.api.InvalidOperationException	Custom exception for invalid operation error.
org.apache.hadoop.hive.metastore.api.InvalidPartitionException	Custom exception for invalid partition error.
org.apache.hadoop.hive.metastore.api.MetaException	Custom exception for metastore related error.
org.apache.hadoop.hive.metastore.api.NoSuchLockException	Custom exception in case of invalid lock.
org.apache.hadoop.hive.metastore.api.NoSuchObjectException	Custom exception in case of invalid object.
org.apache.hadoop.hive.metastore.api.NoSuchTxnException	Custom exception in case of invalid transaction.
org.apache.hadoop.hive.metastore.api.TxnAbortedException	Custom exception in case of aborted transaction.
org.apache.hadoop.hive.metastore.api.TxnOpenException	Custom exception in case of not close transaction.
org.apache.hadoop.hive.metastore.api.UnknownDBException	Custom exception in case of unknown database.
org.apache.hadoop.hive.metastore.api.UnknownPartitionException	Custom exception in case of unknown partition.
org.apache.hadoop.hive.metastore.api.UnknownTableException	Custom partition in case of unknown table.
org.apache.hadoop.hive.metastore.events.EventCleanerTask	Cleaning tasks from event table.
org.apache.hadoop.hive.metastore.parser.ExpressionTree	Represents the filter as a binary tree.
org.apache.hadoop.hive.metastore.txn.CompactionInfo	Information on a possible or running compaction.
org.apache.hadoop.hive.metastore.txn.CompactionInfo	Utility methods for creating and destroying txn database/schema, plus methods for querying against metastore tables.
org.apache.hadoop.hive.ql.Context	Context for Semantic Analyzers.
org.apache.hadoop.hive.ql.Driver	Driver to process commands on cluster.
org.apache.hadoop.hive.ql.QueryPlan	QueryPlan can be serialized to disk to restart/resume the progress of it in the future, either within or outside of the current JVM.
org.apache.hadoop.hive.ql.QueryProperties	QueryProperties.
org.apache.hadoop.hive.ql.exec.AbstractFileMergeOperator	Fast file merge operator for ORC and RCfile.
org.apache.hadoop.hive.ql.exec.AbstractMapJoinOperator	Class to handle join input's join keys.
org.apache.hadoop.hive.ql.exec.AppMasterEventOperator	AppMasterEventOperator sends any rows it receives to the Tez AM.
org.apache.hadoop.hive.ql.exec.AutoProgressor	AutoProgressor periodically sends updates to the job tracker so that it doesn't consider this task attempt dead if there is a long period of inactivity.
org.apache.hadoop.hive.ql.exec.CollectOperator	Buffers rows emitted by other operators.
org.apache.hadoop.hive.ql.exec.ColumnStatsTask	ColumnStatsTask implementation.

Class	Description
org.apache.hadoop.hive.ql.exec. <a href="#">ColumnStatsUpdateTask</a>	ColumnStatsUpdateTask implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">CommonJoinOperator</a>	Join operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">CommonMergeJoinOperator</a>	Consolidate the join algorithms to either hash based joins (MapJoinOperator) or sort-merge based joins, this operator is being introduced.
org.apache.hadoop.hive.ql.exec. <a href="#">ConditionalTask</a>	Conditional Task implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">DDLTask</a>	DDLTask implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">DefaultBucketMatcher</a>	Finding right bucket.
org.apache.hadoop.hive.ql.exec. <a href="#">DemuxOperator</a>	DemuxOperator is an operator used by MapReduce Jobs optimized by CorrelationOptimizer.
org.apache.hadoop.hive.ql.exec. <a href="#">DummyStoreOperator</a>	For SortMerge joins, this is a dummy operator, which stores the row for the small table before it reaches the sort merge join operator.
org.apache.hadoop.hive.ql.exec. <a href="#">ExplainTask</a>	ExplainTask implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">FetchOperator</a>	FetchTask implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">FetchTask</a>	FetchTask implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">FileSinkOperator</a>	File Sink operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">FilterOperator</a>	Filter operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">ForwardOperator</a>	Forward Operator Just forwards.
org.apache.hadoop.hive.ql.exec. <a href="#">FunctionRegistry</a>	FunctionRegistry.
org.apache.hadoop.hive.ql.exec. <a href="#">FunctionTask</a>	FunctionTask.
org.apache.hadoop.hive.ql.exec. <a href="#">GroupByOperator</a>	GroupBy operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">HashTableDummyOperator</a>	Hash table operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">HashTableSinkOperator</a>	Hash table sink operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">JoinOperator</a>	Join operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">LateralViewForwardOperator</a>	LateralViewForwardOperator.
org.apache.hadoop.hive.ql.exec. <a href="#">LateralViewJoinOperator</a>	The lateral view join operator is used for FROM src LATERAL VIEW udtf()...
org.apache.hadoop.hive.ql.exec. <a href="#">LimitOperator</a>	Limit operator implementation Limits the number of rows to be passed on.
org.apache.hadoop.hive.ql.exec. <a href="#">ListSinkOperator</a>	For fetch task with operator tree, row read from FetchOperator is processed via operator tree and finally arrives to this operator.
org.apache.hadoop.hive.ql.exec. <a href="#">MapJoinOperator</a>	Map side Join operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">MapOperator</a>	Map operator.
org.apache.hadoop.hive.ql.exec. <a href="#">MapredContext</a>	Runtime context of MapredTask providing additional information to GenericUDF
org.apache.hadoop.hive.ql.exec. <a href="#">MoveTask</a>	MoveTask implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">MuxOperator</a>	MuxOperator is used in the Reduce side of MapReduce jobs optimized by Correlation Optimizer.

Class	Description
org.apache.hadoop.hive.ql.exec. <a href="#">ObjectCacheFactory</a>	ObjectCacheFactory returns the appropriate cache depending on settings in the hive conf.
org.apache.hadoop.hive.ql.exec. <a href="#">Operator</a>	Base operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">OperatorFactory</a>	OperatorFactory.
org.apache.hadoop.hive.ql.exec. <a href="#">OperatorUtils</a>	Utilities to handle operators.
org.apache.hadoop.hive.ql.exec. <a href="#">OrcFileMergeOperator</a>	Fast file merge operator for ORC files.
org.apache.hadoop.hive.ql.exec. <a href="#">PTFOperator</a>	Class to handle partitioned table functions operators.
org.apache.hadoop.hive.ql.exec. <a href="#">PTFPartition</a>	Represents a collection of rows that is acted upon by a TableFunction or a WindowFunction.
org.apache.hadoop.hive.ql.exec. <a href="#">PTFRollingPartition</a>	Represents a collection of rows that is acted upon by a TableFunction or a WindowFunction.
org.apache.hadoop.hive.ql.exec. <a href="#">PTFUtils</a>	Utilities to handle partitioned table functions.
org.apache.hadoop.hive.ql.exec. <a href="#">PartitionKeySampler</a>	Class to handle partition key sampler.
org.apache.hadoop.hive.ql.exec. <a href="#">RCFileMergeOperator</a>	Fast file merge operator for RC files.
org.apache.hadoop.hive.ql.exec. <a href="#">ReduceSinkOperator</a>	Reduce Sink Operator sends output to the reduce stage.
org.apache.hadoop.hive.ql.exec. <a href="#">Registry</a>	Function registry.
org.apache.hadoop.hive.ql.exec. <a href="#">SMBMapJoinOperator</a>	Sorted Merge Map Join Operator.
org.apache.hadoop.hive.ql.exec. <a href="#">ScriptOperator</a>	ScriptOperator.
org.apache.hadoop.hive.ql.exec. <a href="#">SelectOperator</a>	Select operator implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">SkewJoinHandler</a>	At runtime in Join, output big keys in one table into one corresponding directories, and all same keys in other tables into different dirs (one for each table).
org.apache.hadoop.hive.ql.exec. <a href="#">SparkHashTableSinkOperator</a>	Operator for spark hashtable sink.
org.apache.hadoop.hive.ql.exec. <a href="#">StatsNoJobTask</a>	StatsNoJobTask is used in cases where stats collection is the only task for the given query (no parent MR or Tez job).
org.apache.hadoop.hive.ql.exec. <a href="#">TableScanOperator</a>	Table Scan Operator If the data is coming from the map-reduce framework, just forward it.
org.apache.hadoop.hive.ql.exec. <a href="#">Task</a>	Task implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">TaskResult</a>	TaskResult implementation.
org.apache.hadoop.hive.ql.exec. <a href="#">TemporaryHashSinkOperator</a>	Operator temporary hash sink.
org.apache.hadoop.hive.ql.exec. <a href="#">TerminalOperator</a>	Terminal Operator Base Class.
org.apache.hadoop.hive.ql.exec. <a href="#">TezDummyStoreOperator</a>	A dummy store operator same as the dummy store operator but for tez.
org.apache.hadoop.hive.ql.exec. <a href="#">TopNHash</a>	Stores binary key/value in sorted manner to get top-n key/value TODO: rename to TopNHeap?
org.apache.hadoop.hive.ql.exec. <a href="#">UDTFOperator</a>	UDTFOperator.
org.apache.hadoop.hive.ql.exec. <a href="#">UnionOperator</a>	Union Operator Just forwards.
org.apache.hadoop.hive.ql.exec. <a href="#">Utilities</a>	Utilities.

Class	Description
org.apache.hadoop.hive.ql.exec.mr. <a href="#">ExecDriver</a>	ExecDriver is the central class in co-ordinating execution of any map-reduce task.
org.apache.hadoop.hive.ql.exec.mr. <a href="#">ExecMapper</a>	ExecMapper is the generic Map class for Hive.
org.apache.hadoop.hive.ql.exec.mr. <a href="#">ExecMapperContext</a>	ExecMapperContext is the generic Map context class for Hive.
org.apache.hadoop.hive.ql.exec.mr. <a href="#">HadoopJobExecHelper</a>	Handle information about hadoop job.
org.apache.hadoop.hive.ql.exec.mr. <a href="#">JobDebugger</a>	JobDebugger takes a RunningJob that has failed and grabs the top 4 failing tasks and outputs this information to the Hive CLI.
org.apache.hadoop.hive.ql.exec.mr. <a href="#">MapredLocalTask</a>	MapredLocalTask represents any local work (i.e.: client side work) that hive needs to execute.
org.apache.hadoop.hive.ql.exec.mr. <a href="#">Throttle</a>	Intelligence to make clients wait if the cluster is in a bad state.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">BytesBytesMultiHashMap</a>	HashMap that maps byte arrays to byte arrays with limited functionality necessary for MapJoin hash tables, with small memory overhead.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">HashMapWrapper</a>	Simple wrapper for persistent Hashmap implementing only the put/get/remove/clear interface.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">HybridHashTableContainer</a>	Hash table container that can have many partitions -- each partition has its own hashmap, as well as row container for small table and big table.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">KeyValueContainer</a>	An eager key/value container that puts every row directly to output stream.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">MapJoinBytesTableContainer</a>	Table container that serializes keys and values using LazyBinarySerDe into BytesBytesMultiHashMap, with very low memory overhead.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">MapJoinKey</a>	The base class for MapJoinKey.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">MapJoinTableContainerSerDe</a>	Serialization/deserialization of table container for join.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">ObjectContainer</a>	An eager object container that puts every row directly to output stream.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">RowContainer</a>	Simple persistent container for rows.
org.apache.hadoop.hive.ql.exec.persistence. <a href="#">UnwrapRowContainer</a>	Unwraps values from current key with valueIndex in mapjoin desc.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">GroupByShuffler</a>	Shuffle group by operator.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">HiveSparkClientFactory</a>	Factory class for spark client.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">LocalHiveSparkClient</a>	LocalSparkClient submit Spark job in local driver, it's responsible for build spark client environment and execute spark work.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">MapInput</a>	Input for mapper.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">MapTran</a>	Mapper tran.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">ReduceTran</a>	Reduce tran.

Class	Description
org.apache.hadoop.hive.ql.exec.spark. <a href="#">RemoteHiveSparkClient</a>	RemoteSparkClient is a wrapper of org.apache.hive.spark.client.SparkClient, which wrap a spark job request and send to an remote SparkContext.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">ShuffleTran</a>	Shuffle tran.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">SortByShuffler</a>	Sorting class for shuffler.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">SparkTask</a>	Description of spark task.
org.apache.hadoop.hive.ql.exec.spark. <a href="#">SparkUtilities</a>	Contains utilities methods used as part of Spark tasks.
org.apache.hadoop.hive.ql.exec.spark.session. <a href="#">SparkSessionImpl</a>	Implementation of spark session.
org.apache.hadoop.hive.ql.exec.spark.status.impl. <a href="#">JobMetricsListener</a>	Listener for job metrics.
org.apache.hadoop.hive.ql.exec.spark.status.impl. <a href="#">LocalSparkJobStatus</a>	Spark job local status.
org.apache.hadoop.hive.ql.exec.spark.status.impl. <a href="#">RemoteSparkJobStatus</a>	Used with remove spark client.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">DagUtils</a>	DagUtils.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">DynamicPartitionPruner</a>	DynamicPartitionPruner takes a list of assigned partitions at runtime (split generation) and prunes them using events generated during execution of the dag.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">HiveSplitGenerator</a>	Generates splits inside the AM on the cluster.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">MapRecordProcessor</a>	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">MapRecordSource</a>	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">MergeFileRecordProcessor</a>	Record processor for fast merging of files.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">RecordProcessor</a>	Process input from tez LogicalInput and write output It has different subclasses for map and reduce processing
org.apache.hadoop.hive.ql.exec.tez. <a href="#">ReduceRecordProcessor</a>	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">ReduceRecordSource</a>	Process input from tez LogicalInput and write output - for a map plan Just pump the records through the query plan.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">SplitGrouper</a>	SplitGrouper is used to combine splits based on head room and locality.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">TezJobMonitor</a>	TezJobMonitor keeps track of a tez job while it's being executed.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">TezProcessor</a>	Hive processor for Tez that forms the vertices in Tez and processes the data.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">TezSessionPoolManager</a>	This class is for managing multiple tez sessions particularly when HiveServer2 is being used to submit queries.
org.apache.hadoop.hive.ql.exec.tez. <a href="#">TezSessionState</a>	Holds session state related to Tez

Class	Description
org.apache.hadoop.hive.ql.exec.tez. <a href="#">TezTask</a>	TezTask handles the execution of TezWork.
org.apache.hadoop.hive.ql.exec.tez.tools. <a href="#">KeyValueInputMerger</a>	A KeyValuesReader implementation that returns a sorted stream of key-values by doing a sorted merge of the key-value in LogicalInputs.
org.apache.hadoop.hive.ql.exec.tez.tools. <a href="#">KeyValuesInputMerger</a>	A KeyValuesReader implementation that returns a sorted stream of key-values by doing a sorted merge of the key-value in LogicalInputs.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">BytesColumnVector</a>	This class supports string and binary data by value reference.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">ColumnVector</a>	ColumnVector contains the shared structure for the sub-types, including NULL information, and whether this vector repeats, i.e.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">DecimalColumnVector</a>	A vector of HiveDecimalWritable objects.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">DoubleColumnVector</a>	This class represents a nullable double precision floating point column vector.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">LongColumnVector</a>	This class represents a nullable int column vector.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">TimestampUtils</a>	Utilities for Timestamps and the relevant conversions.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorAppMasterEventOperator</a>	App Master Event operator implementation.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorAssignRow</a>	This class assigns specified columns of a row from a Writable row objects.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorColumnOrderedMap</a>	This class collects column information for mapping vector columns, including the hive type name.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorColumnInfo</a>	Class to keep information on a set of typed vector columns.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorCopyRow</a>	This class copies specified columns of a row from one VectorizedRowBatch to another.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorDeserializeRow</a>	This class deserializes a serialization format into a row of a VectorizedRowBatch.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorExtractRow</a>	This class extracts specified VectorizedRowBatch row columns into writables.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorFileSinkOperator</a>	File Sink operator implementation.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorFilterOperator</a>	Filter operator implementation.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorGroupByOperator</a>	Vectorized GROUP BY operator implementation.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorHashKeyWrapper</a>	A hash map key wrapper for vectorized processing.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorLimitOperator</a>	Limit operator implementation Limits the number of rows to be passed on.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorMapJoinBaseOperator</a>	The *NON-NATIVE* base vector map join operator class used by VectorMapJoinOperator and VectorMapJoinOuterFilteredOperator.

Class	Description
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorMapJoinOperator</a>	The vectorized version of the MapJoinOperator.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorMapJoinOuterFilteredOperator</a>	This is the *NON-NATIVE* vector map join operator for just LEFT OUTER JOIN and filtered.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorMapOperator</a>	The vectorized MapOperator.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorReduceSinkOperator</a>	The vectorized reduce sink operator.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorSMBJoinOperator</a>	VectorSMBJoinOperator.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorSelectOperator</a>	Select operator implementation.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorSerializeRow</a>	This class serializes columns from a row in a VectorizedRowBatch into a serialization format.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorizationContext</a>	Context class for vectorization execution.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorizedBatchUtil</a>	The vectorized MapOperator.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorizedRowBatch</a>	A VectorizedRowBatch is a set of rows, organized with each column as a vector.
org.apache.hadoop.hive.ql.exec.vector. <a href="#">VectorizedRowBatchCtx</a>	Context for Vectorized row batch.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">CastDecimalToTimestamp</a>	Type cast decimal to timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">CastTimestampToDecimal</a>	To be used to cast timestamp to decimal.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">ColAndCol</a>	Evaluate AND of 2 or more boolean columns and store the boolean result in the output boolean column.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">ColOrCol</a>	Evaluate OR of 2 or more boolean columns and store the boolean result in the output boolean column.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">ConstantVectorExpression</a>	Constant is represented as a vector with repeating values.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">DecimalUtil</a>	Utility functions for vector operations on decimal values.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">FilterExprOrExpr</a>	Represents an Or expression.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">FilterStringColumnInList</a>	Evaluate an IN filter on a batch for a vector of strings.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">FuncRoundWithNumDigitsDecimalToDecimal</a>	Function for rounding decimals.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">MathExpr</a>	Math expression evaluation helper functions.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">NullUtil</a>	Utility functions to handle null propagation.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">StringColumnInList</a>	Evaluate an IN boolean expression (not a filter) on a batch for a vector of strings.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">String Expr</a>	String expression evaluation helper functions.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFDateAddColCol</a>	Vectorized user defined function for adding columns.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFDateAddColScalar</a>	Vectorized user defined function for adding column and scalar.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFDateDiffColCol</a>	Vectorized user defined function for finding difference between two columns.
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFDateLong</a>	Vectorized version of TO_DATE(TIMESTAMP)/TO_DATE(DATE).
org.apache.hadoop.hive.ql.exec.vector.expressions. <a href="#">VectorUDFDateString</a>	Vectorized version of TO_DATE(STRING) As TO_DATE() now returns DATE type, this should be the same behavior as the DATE cast operator.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinCommonOperator</a>	Common operator class for native vectorized map join.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinGenerateResultOperator</a>	Contains methods for generating vectorized join results and forwarding batches.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinInnerBigOnlyGenerateResultOperator</a>	This class has methods for generating vectorized join results for the big table only variation of inner joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinInnerBigOnlyLongOperator</a>	Specialized class for doing a vectorized map join that is an inner join on a Single-Column Long and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinInnerBigOnlyMultiKeyOperator</a>	Specialized class for doing a vectorized map join that is an inner join on Multi-Key and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinInnerBigOnlyStringOperator</a>	Specialized class for doing a vectorized map join that is an inner join on a Single-Column String and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinInnerGenerateResultOperator</a>	Contains methods for generating vectorized join results for inner joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinInnerLongOperator</a>	Specialized class for doing a vectorized map join that is an inner join on a Single-Column Long and only big table columns appear in the join result so a hash multi-set is used.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinInnerMultiKeyOperator</a>	Specialized class for doing a vectorized map join that is an inner join on a Multi-Key using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinInnerStringOperator</a>	Specialized class for doing a vectorized map join that is an inner join on a Single-Column String using a hash map.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinLeftSemiGenerateResultOperator</a>	Contains methods for generating vectorized join results for left semi joins.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinLeftSemiLongOperator</a>	Specialized class for doing a vectorized map join that is an left semi join on a Single-Column Long using a hash set.
org.apache.hadoop.hive.ql.exec.vector.mapjoin. <a href="#">VectorMapJoinLeftSemiMultiKeyOperator</a>	Specialized class for doing a vectorized map join that is an left semi join on Multi-Key using hash set.

Class	Description
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinLeftSemiStringOperator</a>	Specialized class for doing a vectorized map join that is an left semi join on a Single-Column String using a hash set.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterGenerateResultOperator</a>	Contains methods for generating vectorized join results for outer joins.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterLongOperator</a>	Specialized class for doing a vectorized map join that is an outer join on a Single-Column Long using a hash map.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterMultiKeyOperator</a>	Specialized class for doing a vectorized map join that is an outer join on Multi-Key using a hash map.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinOuterStringOperator</a>	Specialized class for doing a vectorized map join that is an outer join on a Single-Column String using a hash map.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.VectorMapJoinRowBytesContainer</a>	An eager bytes container that puts row bytes to an output stream.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastBytesHashMap</a>	Bytes key hash map optimized for vector map join. This is the abstract base for the multi-key and string bytes key hash map implementations.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastBytesHashMultiSet</a>	Bytes key hash multi-set optimized for vector map join. This is the abstract base for the multi-key and string bytes key hash multi-set implementations.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastBytesHashUtil</a>	Utilities for bytes key hash multi-set optimized for vector map join.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastHashTable</a>	Vector map join fast hash table.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastKeyStore</a>	Vector map join fast key store.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashMap</a>	Vector map join fast long hash map.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashMultiSet</a>	Vector map join fast long hash multi set.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashSet</a>	A single LONG key hash set optimized for vector map join.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashTable</a>	A single long value map optimized for vector map join.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastLongHashUtil</a>	Utilities for vector map join of single long value.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastMultiKeyHashMap</a>	A multi-key value hash map optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastMultiKeyHashMultiSet</a>	A multi-key hash multi-set optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastMultiKeyHashSet</a>	A multi-key hash set optimized for vector map join. The key is stored as the provided bytes (uninterpreted).
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastStringCommon</a>	A single byte array value hash map optimized for vector map join.
<a href="#">org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastTableContainer</a>	HashTableLoader for Tez constructs the hashtable from records read from a broadcast edge.

Class	Description
org.apache.hadoop.hive.ql.exec.vector.mapjoin.hashtable. <a href="#">VectorMapJoinHashMapResult</a>	Abstract class for a hash map result. For reading the values, one-by-one.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.hashtable. <a href="#">VectorMapJoinHashTableResult</a>	Root abstract class for a hash table result.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.optimized. <a href="#">VectorMapJoinOptimizedCreateHashTable</a>	Create hash table for vector map join.
org.apache.hadoop.hive.ql.hooks. <a href="#">HookContext</a>	Hook Context keeps all the necessary information for all the hooks.
org.apache.hadoop.hive.ql.hooks. <a href="#">PostExecutePrinter</a>	Implementation of a post execute hook that simply prints out its parameters to standard output.
org.apache.hadoop.hive.ql.hooks. <a href="#">PreExecutePrinter</a>	Implementation of a pre execute hook that simply prints out its parameters to standard output.
org.apache.hadoop.hive.ql.index. <a href="#">HiveIndex</a>	Holds index related constants.
org.apache.hadoop.hive.ql.index. <a href="#">HiveIndexQueryContext</a>	Used to pass information between the IndexProcessor and the plugin IndexHandler during query processing
org.apache.hadoop.hive.ql.index. <a href="#">HiveIndexResult</a>	HiveIndexResult parses the input stream from an index query to generate a list of file splits to query.
org.apache.hadoop.hive.ql.index. <a href="#">HiveIndexedInputFormat</a>	Input format for doing queries that use indexes.
org.apache.hadoop.hive.ql.index. <a href="#">IndexPredicateAnalyzer</a>	IndexPredicateAnalyzer decomposes predicates, separating the parts which can be satisfied by an index from the parts which cannot.
org.apache.hadoop.hive.ql.index. <a href="#">IndexSearchCondition</a>	IndexSearchCondition represents an individual search condition found by IndexPredicateAnalyzer.
org.apache.hadoop.hive.ql.index. <a href="#">TableBasedIndexHandler</a>	Index handler for indexes that use tables to store indexes.
org.apache.hadoop.hive.ql.index.compact. <a href="#">HiveCompactIndexInputFormat</a>	Hive compact index input format.
org.apache.hadoop.hive.ql.io. <a href="#">AcidUtils</a>	Utilities that are shared by all of the ACID input and output formats.
org.apache.hadoop.hive.ql.io. <a href="#">BucketizedHiveInputFormat</a>	BucketizedHiveInputFormat serves the similar function as hiveInputFormat but its getSplits() always group splits from one input file into one wrapper split.
org.apache.hadoop.hive.ql.io. <a href="#">CombineHiveInputFormat</a>	CombineHiveInputFormat is a parameterized InputFormat which looks at the path name and determine the correct InputFormat for that path name from mapredPlan.pathToPartitionInfo().
org.apache.hadoop.hive.ql.io. <a href="#">HiveFileFormatUtils</a>	An util class for various Hive file format tasks.
org.apache.hadoop.hive.ql.io. <a href="#">HiveInputFormat</a>	HiveInputFormat is a parameterized InputFormat which looks at the path name and determine the correct InputFormat for that path name from mapredPlan.pathToPartitionInfo().
org.apache.hadoop.hive.ql.io. <a href="#">IOConstants</a>	Input output constants.
org.apache.hadoop.hive.ql.io. <a href="#">IOContext</a>	IOContext basically contains the position information of the current key/value.
org.apache.hadoop.hive.ql.io. <a href="#">NullRowsInputFormat</a>	NullRowsInputFormat outputs null rows, maximum 100.
org.apache.hadoop.hive.ql.io. <a href="#">OneNullRowInputFormat</a>	OneNullRowInputFormat outputs one null row.

Class	Description
org.apache.hadoop.hive ql.io.RCFileInputFormat	RCFileInputFormat.
org.apache.hadoop.hive ql.io.SequenceFileInputFormatChecker	SequenceFileInputFormatChecker.
org.apache.hadoop.hive ql.io.avro.AvroContainerOutputFormat	Write to an Avro file from a Hive process.
org.apache.hadoop.hive ql.io.merge.MergeFileMapper	Mapper for fast file merging of ORC and RC files.
org.apache.hadoop.hive ql.io.merge.MergeFileTask	Task for fast merging of ORC and RC files.
org.apache.hadoop.hive ql.io.orc.CompressionKind	An enumeration that lists the generic compression algorithms that can be applied to ORC files.
org.apache.hadoop.hive ql.io.orc.OrcFile	Contains factory methods to read or write ORC files.
org.apache.hadoop.hive ql.io.orc.OrcFileKeyWrapper	Key for OrcFileMergeMapper task.
org.apache.hadoop.hive ql.io.orc.OrcFileStripeMergeRecordReader	Record reader for orc file stripe merge.
org.apache.hadoop.hive ql.io.orc.OrcFileValueWrapper	Value for OrcFileMergeMapper.
org.apache.hadoop.hive ql.io.orc.OrcInputFormat	A MapReduce/Hive input format for ORC files.
org.apache.hadoop.hive ql.io.orc.OrcNewSplit	OrcFileSplit.
org.apache.hadoop.hive ql.io.orc.OrcRecordUpdater	A RecordUpdater where the files are stored as ORC.
org.apache.hadoop.hive ql.io.orc.OrcSerde	A serde class for ORC.
org.apache.hadoop.hive ql.io.orc.OrcSplit	OrcFileSplit.
org.apache.hadoop.hive ql.io.orc.ReaderImpl	Implementation of record reader.
org.apache.hadoop.hive ql.io.orc.VectorizedOrcInputFormat	A MapReduce/Hive input format for ORC files.
org.apache.hadoop.hive ql.io.orc.WriterImpl	An ORC file writer.
org.apache.hadoop.hive ql.io.parquet.LeafFilterFactory	Factory class for leaf filter.
org.apache.hadoop.hive ql.io.parquet.MapredParquetOutputFormat	A Parquet OutputFormat for Hive (with the deprecated package mapred)
org.apache.hadoop.hive ql.io.parquet.convert.DataWritableRecordConverter	A MapWritableReadSupport, encapsulates the tuples
org.apache.hadoop.hive ql.io.parquet.convert.ETypeConverter.BinaryConverter	ETypeConverter is an easy way to set the converter for the right type.
org.apache.hadoop.hive ql.io.parquet.convert.HiveCollectionConverter	Converter for collections.
org.apache.hadoop.hive ql.io.parquet.convert.HiveGroupConverter	Converter for groups.
org.apache.hadoop.hive ql.io.parquet.convert.HiveStructConverter	A MapWritableGroupConverter, real converter between hive and parquet types recursively for complex types.
org.apache.hadoop.hive ql.io.parquet.read.DataWritableReadSupport	A MapWritableReadSupport Manages the translation between Hive and Parquet
org.apache.hadoop.hive ql.io.parquet.read.ParquetRecordReaderWrapper	Wrapper for parquet record reader.
org.apache.hadoop.hive ql.io.parquet.serde.ParquetHiveSerDe	A ParquetHiveSerDe for Hive (with the deprecated package mapred)

Class	Description
org.apache.hadoop.hive.ql.io.parquet.write. <a href="#">DataWritableWriter</a>	DataWritableWriter sends a record to the Parquet API with the expected schema in order to be written to a file.
org.apache.hadoop.hive.ql.io.parquet.write. <a href="#">ParquetRecordWriterWrapper</a>	Wrapper for parquet record writer.
org.apache.hadoop.hive.ql.io.rcfile.stats. <a href="#">PartialScanMapper</a>	PartialScanMapper.
org.apache.hadoop.hive.ql.io.rcfile.stats. <a href="#">PartialScanTask</a>	PartialScanTask.
org.apache.hadoop.hive.ql.io.rcfile.stats. <a href="#">PartialScanWork</a>	Partial Scan Work.
org.apache.hadoop.hive.ql.io.rcfile.truncate. <a href="#">ColumnTruncateMapper</a>	A factory for creating SearchArguments, as well as modifying those created by this factory.
org.apache.hadoop.hive.ql.io.rcfile.truncate. <a href="#">ColumnTruncateTask</a>	Base class for operator graph walker this class takes list of starting ops and walks them one by one.
org.apache.hadoop.hive.ql.io.sarg. <a href="#">SearchArgumentFactory</a>	A factory for creating SearchArguments, as well as modifying those created by this factory.
org.apache.hadoop.hive.ql.lib. <a href="#">DefaultGraphWalker</a>	Base class for operator graph walker this class takes list of starting ops and walks them one by one.
org.apache.hadoop.hive.ql.lib. <a href="#">RuleExactMatch</a>	Implementation of the Rule interface for Nodes Used in Node dispatching to dispatch process/visitor functions for Nodes.
org.apache.hadoop.hive.ql.lockmgr. <a href="#">DbLockManager</a>	An implementation of HiveLockManager for use with org.apache.hadoop.hive.ql.lockmgr. <a href="#">DbTxnManager</a> .
org.apache.hadoop.hive.ql.lockmgr. <a href="#">DbTxnManager</a>	An implementation of HiveTxnManager that stores the transactions in the metastore database.
org.apache.hadoop.hive.ql.lockmgr. <a href="#">HiveLockObject</a>	The class is used to uniquely identify a HiveLockObject.
org.apache.hadoop.hive.ql.lockmgr. <a href="#">LockException</a>	Exception from lock manager.
org.apache.hadoop.hive.ql.lockmgr.zookeeper. <a href="#">ZooKeeperHiveLock</a>	The class is used to uniquely identify ZookeeperHiveLock.
org.apache.hadoop.hive.ql.lockmgr.zookeeper. <a href="#">ZooKeeperHiveLockManager</a>	Zookeeper lock manager.
org.apache.hadoop.hive.ql.log. <a href="#">PerfLogger</a>	PerfLogger.
org.apache.hadoop.hive.ql.metadata. <a href="#">Hive</a>	Contains functions that implement meta data/DDDL operations using calls to the metastore.
org.apache.hadoop.hive.ql.metadata. <a href="#">HiveException</a>	Generic exception class for Hive.
org.apache.hadoop.hive.ql.metadata. <a href="#">HiveMetaStoreChecker</a>	Verify that the information in the metastore matches what is on the filesystem.
org.apache.hadoop.hive.ql.metadata. <a href="#">HiveUtils</a>	General collection of helper functions.
org.apache.hadoop.hive.ql.metadata. <a href="#">Partition</a>	A Hive Table Partition: is a fundamental storage unit within a Table.
org.apache.hadoop.hive.ql.metadata. <a href="#">SessionHiveMetaStoreClient</a>	Client for hivemetastore during session.
org.apache.hadoop.hive.ql.metadata. <a href="#">Table</a>	A Hive Table: is a fundamental unit of data in Hive that shares a common schema/DDDL.
org.apache.hadoop.hive.ql.metadata. <a href="#">VirtualColumn</a>	Provides metadata that is not stored in table itself.
org.apache.hadoop.hive.ql.metadata.formatting. <a href="#">JsonMetadataFormatter</a>	Format table and index information for machine readability using json.

Class	Description
<a href="#">org.apache.hadoop.hive.ql.metadata.formatting.MetadataFormatUtils</a>	This class provides methods to format table and index information.
<a href="#">org.apache.hadoop.hive.ql.optimizer.BucketMapJoinOptimizer</a>	this transformation does bucket map join optimization.
<a href="#">org.apache.hadoop.hive.ql.optimizer.BucketingSortingReduceSinkOptimizer</a>	This transformation does optimization for enforcing bucketing and sorting.
<a href="#">org.apache.hadoop.hive.ql.optimizer.ColumnPruner</a>	Implementation of one of the rule-based optimization steps.
<a href="#">org.apache.hadoop.hive.ql.optimizer.ColumnPrunerProcCtx</a>	This class implements the processor context for Column Pruner.
<a href="#">org.apache.hadoop.hive.ql.optimizer.ColumnPrunerProcFactory</a>	Factory for generating the different node processors used by ColumnPruner.
<a href="#">org.apache.hadoop.hive.ql.optimizer.ConstantPropagate</a>	Implementation of one of the rule-based optimization steps.
<a href="#">org.apache.hadoop.hive.ql.optimizer.ConstantPropagateProcCtx</a>	Implements the processor context for Constant Propagate.
<a href="#">org.apache.hadoop.hive.ql.optimizer.ConstantPropagateProcFactory</a>	Factory for generating the different node processors used by ConstantPropagate.
<a href="#">org.apache.hadoop.hive.ql.optimizer.ConvertJoinMapJoin</a>	ConvertJoinMapJoin is an optimization that replaces a common join (aka shuffle join) with a map join (aka broadcast or fragment replicate join when possible).
<a href="#">org.apache.hadoop.hive.ql.optimizer.GenMRProcContext</a>	Processor Context for creating map reduce task.
<a href="#">org.apache.hadoop.hive.ql.optimizer.GenMapRedUtils</a>	General utility common functions for the Processor to convert operator into map-reduce tasks.
<a href="#">org.apache.hadoop.hive.ql.optimizer.GlobalLimitOptimizer</a>	This optimizer is used to reduce the input size for the query for queries which are specifying a limit.
<a href="#">org.apache.hadoop.hive.ql.optimizer.GroupByOptimizer</a>	This transformation does group by optimization.
<a href="#">org.apache.hadoop.hive.ql.optimizer.IdentityProjectRemover</a>	This optimization tries to remove SelectOperator from tree which don't do any processing except forwarding columns from its parent to its children.
<a href="#">org.apache.hadoop.hive.ql.optimizer.JoinReorder</a>	Implementation of rule-based join table reordering optimization.
<a href="#">org.apache.hadoop.hive.ql.optimizer.LimitPushdownOptimizer</a>	Make RS calculate top-K selection for limit clause.
<a href="#">org.apache.hadoop.hive.ql.optimizer.MapJoinProcessor</a>	Implementation of one of the rule-based map join optimization.
<a href="#">org.apache.hadoop.hive.ql.optimizer.NonBlockingOpDeDupProc</a>	Merges SEL-SEL or FIL-FIL into single operator
<a href="#">org.apache.hadoop.hive.ql.optimizer.ReduceSinkMapJoinProc</a>	This processor addresses the RS-MJ case that occurs in Tez on the small/hash table. The work that RS will be a part of must be connected to the MJ work via a broadcast edge.
<a href="#">org.apache.hadoop.hive.ql.optimizer.SamplePruner</a>	The transformation step that does sample pruning.
<a href="#">org.apache.hadoop.hive.ql.optimizer.SimpleFetchAggregation</a>	Execute final aggregation stage for simple fetch query on fetch task.

Class	Description
org.apache.hadoop.hive.ql.optimizer. <a href="#">SimpleFetchOptimizer</a>	Tries to convert simple fetch query to single fetch task, which fetches rows directly from location of table/partition.
org.apache.hadoop.hive.ql.optimizer. <a href="#">SkewJoinOptimizer</a>	SkewJoinOptimizer.
org.apache.hadoop.hive.ql.optimizer. <a href="#">SortedDynPartitionOptimizer</a>	When dynamic partitioning (with or without bucketing and sorting) is enabled, this optimization sorts the records on partition, bucket and sort columns respectively before inserting records into the destination table.
org.apache.hadoop.hive.ql.optimizer. <a href="#">SortedMergeBucketMapJoinOptimizer</a>	Replace a bucket map join with a sorted merge map join.
org.apache.hadoop.hive.ql.optimizer. <a href="#">StatsOptimizer</a>	There is a set of queries which can be answered entirely from statistics stored in metastore.
org.apache.hadoop.hive.ql.optimizer. <a href="#">Transform</a>	Optimizer interface.
org.apache.hadoop.hive.ql.optimizer.calcite. <a href="#">HiveCalciteUtil</a>	Generic utility functions needed for Calcite based Hive CBO.
org.apache.hadoop.hive.ql.optimizer.calcite. <a href="#">HiveRelOptUtil</a>	Splits different join conditions.
org.apache.hadoop.hive.ql.optimizer.calcite. <a href="#">RelOptHiveTable</a>	Class for handling all table metadata.
org.apache.hadoop.hive.ql.optimizer.calcite. <a href="#">TraitsUtil</a>	Traits utilities.
org.apache.hadoop.hive.ql.optimizer.calcite.cost. <a href="#">HiveRelMdCost</a>	HiveRelMdCost supplies the implementation of cost model.
org.apache.hadoop.hive.ql.optimizer.calcite.cost. <a href="#">HiveVolcanoPlanner</a>	Refinement of org.apache.calcite.plan.volcano.VolcanoPlanner for Hive.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. <a href="#">HiveAggregate</a>	Describing aggregate function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. <a href="#">HiveFilter</a>	Describing filter function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. <a href="#">HiveJoin</a>	Describing join function as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. <a href="#">HiveProject</a>	Creates a HiveProject.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. <a href="#">HiveSemiJoin</a>	Describing semi join operator as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. <a href="#">HiveTableScan</a>	Relational expression representing a scan of a HiveDB collection.
org.apache.hadoop.hive.ql.optimizer.calcite.reloperators. <a href="#">HiveUnion</a>	Describing union operator as relational operator.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. <a href="#">HiveFilterJoinRule</a>	Creates a PushFilterPastJoinRule with an explicit root operand.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. <a href="#">HiveJoinProjectTransposeRule</a>	Transpose rule for hive join project.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. <a href="#">HiveFilterSetOpTransposeRule</a>	Creates a HiveFilterSetOpTransposeRule.
org.apache.hadoop.hive.ql.optimizer.calcite.rules. <a href="#">HiveInsertExchange4JoinRule</a>	Not an optimization rule.

Class	Description
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinAddNotNullRule	Creates an HiveJoinAddNotNullRule.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinPushTransitivePredicatesRule	Planner rule that infers predicates from on a org.apache.calcite.rel.core.Join and creates org.apache.calcite.rel.core.Filters if those predicates can be pushed to its inputs.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveJoinToMultiJoinRule	Rule that merges a join with multijoin/join children if the equi compared the same set of input columns.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HivePreFilteringRule	Pull out deterministic expressions from non-deterministic and push down deterministic expressions as a separate filter.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveProjectMergeRule	ProjectMergeRule merges a org.apache.calcite.rel.core.Project into another org.apache.calcite.rel.core.Project, provided the projects aren't projecting identical sets of input references.
org.apache.hadoop.hive.ql.optimizer.calcite.rules.HiveRelFieldTrimmer	Hive relational expression field trimmer.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdCollation	Hive relational expression metadata collation.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdDistinctRowCount	Hive relational expression metadata.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdDistribution	Hive relational expression metadata distribuiton.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdMemory	Hive relational expression metadata memory
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdParallelism	Hive relational expression metadata parallelism.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdRowCount	Hive relational expression metadata row count.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdSelectivity	Hive relational expression metadata selectivity.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdSize	Hive relational expression metadata size.
org.apache.hadoop.hive.ql.optimizer.calcite.stats.HiveRelMdUniqueKeys	Hive relational expression metadata unique keys.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.ASTConverter	Abstract syntax tree converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.ExpressionNodeConverter	Expression node converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.HiveOpConverter	Hive operation converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.HiveOpConverterPostProc	Post processing hive operation converter.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.PlanModifierForASTConv	Modifying plan for converting abstract syntax tree.
org.apache.hadoop.hive.ql.optimizer.calcite.translator.PlanModifierForReturnPath	Modifying plan for operation tree.

Class	Description
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.translator.RexNodeConverter</a>	Row expression node converter.
<a href="#">org.apache.hadoop.hive.ql.optimizer.calcite.translator.SqlFunctionConverter</a>	Converting SQL function.
<a href="#">org.apache.hadoop.hive.ql.optimizer.correlation.CorrelationOptimizer</a>	Implementation of Correlation Optimizer.
<a href="#">org.apache.hadoop.hive.ql.optimizer.correlation.CorrelationUtilities</a>	Utilities for both CorrelationOptimizer and ReduceSinkDeDuplication.
<a href="#">org.apache.hadoop.hive.ql.optimizer.correlation.ReduceSinkDeDuplication</a>	If two reducer sink operators share the same partition/sort columns and order, they can be merged.
<a href="#">org.apache.hadoop.hive.ql.optimizer.index.RewriteGBUsingIndex</a>	RewriteGBUsingIndex is implemented as one of the Rule-based Optimizations.
<a href="#">org.apache.hadoop.hive.ql.optimizer.index.RewriteParseContextGenerator</a>	RewriteParseContextGenerator is a class that offers methods to generate operator tree for input queries.
<a href="#">org.apache.hadoop.hive.ql.optimizer.lineage.ExprProcFactory</a>	Expression processor factory for lineage.
<a href="#">org.apache.hadoop.hive.ql.optimizer.lineage.Generator</a>	Generates the lineage information for the columns and tables from the plan before it goes through other optimization phases.
<a href="#">org.apache.hadoop.hive.ql.optimizer.lineage.LineageCtx</a>	Contains the lineage context that is passed while walking the operator tree in Lineage.
<a href="#">org.apache.hadoop.hive.ql.optimizer.lineage.OpProcFactory</a>	Operator factory for the rule processors for lineage.
<a href="#">org.apache.hadoop.hive.ql.optimizer.listbucketingpruner.ListBucketingPruner</a>	The transformation step that does list bucketing pruning.
<a href="#">org.apache.hadoop.hive.ql.optimizer.metainfo.annotation.AnnotateWithOpTraits</a>	This class annotates each operator with its traits. The OpTraits class specifies the traits that are populated for each operator.
<a href="#">org.apache.hadoop.hive.ql.optimizer.pcr.PartitionConditionRemover</a>	The transformation step that does partition condition remover.
<a href="#">org.apache.hadoop.hive.ql.optimizer.pcr.PcrExprProcFactory</a>	Expression processor factory for partition condition removing.
<a href="#">org.apache.hadoop.hive.ql.optimizer.physical.CrossProductCheck</a>	Check each MapJoin and ShuffleJoin Operator to see they are performing a cross product.
<a href="#">org.apache.hadoop.hive.ql.optimizer.physical.Vectorizer</a>	Class to define vectorization.
<a href="#">org.apache.hadoop.hive.ql.optimizer.ppr.PartitionExpressionProxyForMetastore</a>	The basic implementation of PartitionExpressionProxy that uses ql package classes.
<a href="#">org.apache.hadoop.hive.ql.optimizer.ppr.PartitionPruner</a>	The transformation step that does partition pruning.
<a href="#">org.apache.hadoop.hive.ql.optimizer.spark.SparkReduceSinkMapJoinProc</a>	This processor addresses the RS-MJ case that occurs in spark on the small/hash table side of things. The work that RS will be a part of must be connected to the MJ work via be a broadcast edge.
<a href="#">org.apache.hadoop.hive.ql.optimizer.stats.annotation.AnnotateWithStatistics</a>	Create a list of top op nodes
<a href="#">org.apache.hadoop.hive.ql.optimizer.unionproc.UnionProcessor</a>	FileSinkProcessor is a simple rule to remember seen unions for later processing.
<a href="#">org.apache.hadoop.hive.ql.parse.ASTNode</a>	Definition of abstract syntax tree node.

Class	Description
org.apache.hadoop.hive.ql.parse.BaseSemanticAnalyzer	BaseSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.CalcitePlanner	Cost based optimizer planner.
org.apache.hadoop.hive.ql.parse.ColumnAccessAnalyzer	Analysis of column access.
org.apache.hadoop.hive.ql.parse.ColumnStatsSemanticAnalyzer	ColumnStatsSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.DDLSemanticAnalyzer	DDLSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.ExplainSQRewriteSemanticAnalyzer	ExplainSQRewriteSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.ExplainSemanticAnalyzer	ExplainSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.ExportSemanticAnalyzer	ExportSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.FunctionSemanticAnalyzer	FunctionSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.GenTezProcContext	GenTezProcContext.
org.apache.hadoop.hive.ql.parse.GenTezUtils	GenTezUtils is a collection of shared helper methods to produce TezWork.
org.apache.hadoop.hive.ql.parse.GlobalLimitCtx	context for pruning inputs.
org.apache.hadoop.hive.ql.parse.ImportSemanticAnalyzer	ImportSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.LoadSemanticAnalyzer	LoadSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.MacroSemanticAnalyzer	MacroSemanticAnalyzer.
org.apache.hadoop.hive.ql.parse.MapReduceCompiler	Compiling list of tasks.
org.apache.hadoop.hive.ql.parse.MetadataExportListener	Listens for drop events and, if set, exports the table's metadata as JSON to the trash of the user performing the drop
org.apache.hadoop.hive.ql.parse.ParseContext	Parse Context: The current parse context.
org.apache.hadoop.hive.ql.parse.ParseDriver	ParseDriver.
org.apache.hadoop.hive.ql.parse.ParseUtils	Library of utility functions used in the parse code.
org.apache.hadoop.hive.ql.parse.QB	Implementation of the query block.
org.apache.hadoop.hive.ql.parse.QBParseInfo	Implementation of the parse information related to a query block.
org.apache.hadoop.hive.ql.parse.RowResolver	Implementation of the Row Resolver.
org.apache.hadoop.hive.ql.parse.SemanticAnalyzer	Implementation of the semantic analyzer.
org.apache.hadoop.hive.ql.parse.SemanticAnalyzerFactory	SemanticAnalyzerFactory.
org.apache.hadoop.hive.ql.parse.SplitSample	Stores all the information specified in the TABLESAMPLE(...) clause.
org.apache.hadoop.hive.ql.parse.TaskCompiler	TaskCompiler is a the base class for classes that compile operator pipelines into tasks.
org.apache.hadoop.hive.ql.parse.TezCompiler	TezCompiler translates the operator plan into TezTasks.

Class	Description
org.apache.hadoop.hive.ql.parse.TypeCheckCtx	This class implements the context information that is used for typechecking phase in query compilation.
org.apache.hadoop.hive.ql.parse.TypeCheckProcFactory	The Factory for creating typecheck processors.
org.apache.hadoop.hive.ql.parse.UpdateDeleteSemanticAnalyzer	A subclass of the org.apache.hadoop.hive.ql.parse.SemanticAnalyzer that just handles update and delete statements.
org.apache.hadoop.hive.ql.parse.WindowingSpec	Windowing Specification.
org.apache.hadoop.hive.ql.parse.spark.GenSparkProcContext	GenSparkProcContext maintains information about the tasks and operators as we walk the operator tree to break them into SparkTasks.
org.apache.hadoop.hive.ql.parse.spark.GenSparkUtils	GenSparkUtils is a collection of shared helper methods to produce SparkWork Cloned from GenTezUtils.
org.apache.hadoop.hive.ql.parse.spark.GenSparkWorkWalker	Walks the operator tree in DFS fashion.
org.apache.hadoop.hive.ql.parse.spark.OptimizeSparkProcContext	OptimizeSparkProcContext.
org.apache.hadoop.hive.ql.plan.AbstractOperatorDesc	Operator description.
org.apache.hadoop.hive.ql.plan.AlterTableDesc	AlterTableDesc.
org.apache.hadoop.hive.ql.plan.AlterTableSimpleDesc	Contains information needed to modify a partition or a table
org.apache.hadoop.hive.ql.plan.BaseWork	BaseWork.
org.apache.hadoop.hive.ql.plan.ColumnStatsDesc	Contains the information needed to persist column level statistics
org.apache.hadoop.hive.ql.plan.ColumnStatsWork	ColumnStats Work.
org.apache.hadoop.hive.ql.plan.CommonMergeJoinDesc	Description of merge join operator.
org.apache.hadoop.hive.ql.plan.CreateTableDesc	CreateTableDesc.
org.apache.hadoop.hive.ql.plan.CreateViewDesc	CreateViewDesc.
org.apache.hadoop.hive.ql.plan.DDLWork	DDLWork.
org.apache.hadoop.hive.ql.plan.DropTableDesc	DropTableDesc.
org.apache.hadoop.hive.ql.plan.DynamicPartitionCtx	Dynamic partition context.
org.apache.hadoop.hive.ql.plan.DynamicPruningEventDesc	Dynamic pruning event description.
org.apache.hadoop.hive.ql.plan.ExplainWork	ExplainWork.
org.apache.hadoop.hive.ql.plan.ExprNodeDesc	ExprNodeDesc.
org.apache.hadoop.hive.ql.plan.ExprNodeDescUtils	Utilities for expression node description.
org.apache.hadoop.hive.ql.plan.FetchWork	FetchWork.
org.apache.hadoop.hive.ql.plan.FileSinkDesc	FileSinkDesc.
org.apache.hadoop.hive.ql.plan.FilterDesc	FilterDesc.
org.apache.hadoop.hive.ql.plan.GroupByDesc	GroupByDesc.
org.apache.hadoop.hive.ql.plan.HashTableSinkDesc	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan.JoinCondDesc	Join conditions Descriptor implementation.

Class	Description
org.apache.hadoop.hive.ql.plan. <a href="#">JoinDesc</a>	Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. <a href="#">LateralViewJoinDesc</a>	LateralViewJoinDesc.
org.apache.hadoop.hive.ql.plan. <a href="#">LimitDesc</a>	LimitDesc.
org.apache.hadoop.hive.ql.plan. <a href="#">LoadTableDesc</a>	LoadTableDesc.
org.apache.hadoop.hive.ql.plan. <a href="#">MapJoinDesc</a>	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. <a href="#">MapWork</a>	MapWork represents all the information used to run a map task on the cluster.
org.apache.hadoop.hive.ql.plan. <a href="#">MapredWork</a>	MapredWork.
org.apache.hadoop.hive.ql.plan. <a href="#">MergeJoinWork</a>	Creating merge join work.
org.apache.hadoop.hive.ql.plan. <a href="#">PartitionDesc</a>	PartitionDesc.
org.apache.hadoop.hive.ql.plan. <a href="#">PlanUtils</a>	PlanUtils.
org.apache.hadoop.hive.ql.plan. <a href="#">ReduceSinkDesc</a>	ReduceSinkDesc.
org.apache.hadoop.hive.ql.plan. <a href="#">ReduceWork</a>	ReduceWork represents all the information used to run a reduce task on the cluster.
org.apache.hadoop.hive.ql.plan. <a href="#">SelectDesc</a>	SelectDesc.
org.apache.hadoop.hive.ql.plan. <a href="#">SparkHashTableSinkDesc</a>	Map Join operator Descriptor implementation.
org.apache.hadoop.hive.ql.plan. <a href="#">Statistics</a>	Statistics.
org.apache.hadoop.hive.ql.plan. <a href="#">StatsWork</a>	ConditionalStats.
org.apache.hadoop.hive.ql.plan. <a href="#">TableScanDesc</a>	Table Scan Descriptor Currently, data is only read from a base source as part of map-reduce framework.
org.apache.hadoop.hive.ql.plan. <a href="#">TezWork</a>	TezWork.
org.apache.hadoop.hive.ql.plan. <a href="#">UnionWork</a>	Simple wrapper for union all cases.
org.apache.hadoop.hive.ql.plan. <a href="#">VectorGroupByDesc</a>	VectorGroupByDesc.
org.apache.hadoop.hive.ql.plan.ptf. <a href="#">BoundaryDef</a>	Map-reduce boundaries definition.
org.apache.hadoop.hive.ql.plan.ptf. <a href="#">CurrentRowDef</a>	Current row definition.
org.apache.hadoop.hive.ql.plan.ptf. <a href="#">OrderExpressionDef</a>	Order expression definition.
org.apache.hadoop.hive.ql.plan.ptf. <a href="#">RangeBoundaryDef</a>	Range boundary definition.
org.apache.hadoop.hive.ql.plan.ptf. <a href="#">ValueBoundaryDef</a>	Value boundary definition.
org.apache.hadoop.hive.ql.plan.ptf. <a href="#">WindowFrameDef</a>	Window frame definition.
org.apache.hadoop.hive.ql.ppd. <a href="#">ExprWalkerInfo</a>	Context for Expression Walker for determining predicate pushdown candidates It contains a ExprInfo object for each expression that is processed.
org.apache.hadoop.hive.ql.ppd. <a href="#">OpProcFactory</a>	Operator factory for predicate pushdown processing of operator graph Each operator determines the pushdown predicates by walking the expression tree.
org.apache.hadoop.hive.ql.ppd. <a href="#">PredicatePushDown</a>	Implements predicate pushdown.
org.apache.hadoop.hive.ql.ppd. <a href="#">PredicateTransitivePropagate</a>	Propagates filters to other aliases based on join condition
org.apache.hadoop.hive.ql.ppd. <a href="#">SyntheticJoinPredicate</a>	Creates synthetic predicates that represent "IN (keylist other table)"

Class	Description
org.apache.hadoop.hive.ql.processors. <a href="#">AddResourceProcessor</a>	AddResourceProcessor.
org.apache.hadoop.hive.ql.processors. <a href="#">CommandProcessorResponse</a>	Encapsulates the basic response info returned by classes the implement the CommandProcessor interface.
org.apache.hadoop.hive.ql.processors. <a href="#">CompileProcessor</a>	Processor allows users to build code inside a hive session, then use this code as a UDF, Serde, or even a more complex entity like an input format or hook.
org.apache.hadoop.hive.ql.processors. <a href="#">CryptoProcessor</a>	Processes HADOOP commands used for HDFS encryption.
org.apache.hadoop.hive.ql.processors. <a href="#">DeleteResourceProcessor</a>	DeleteResourceProcessor.
org.apache.hadoop.hive.ql.processors. <a href="#">DfsProcessor</a>	DfsProcessor.
org.apache.hadoop.hive.ql.processors. <a href="#">SetProcessor</a>	SetProcessor.
org.apache.hadoop.hive.ql.security.authorization. <a href="#">AuthorizationPreEventListener</a>	AuthorizationPreEventListener : A MetaStorePreEventListener that performs authorization/authentication checks on the metastore-side.
org.apache.hadoop.hive.ql.security.authorization. <a href="#">AuthorizationUtils</a>	Utility code shared by hive internal code and sql standard authorization plugin implementation
org.apache.hadoop.hive.ql.security.authorization. <a href="#">HiveAuthorizationProviderBase</a>	Class for authorization that returns userNames and groupNames.
org.apache.hadoop.hive.ql.security.authorization.plugin. <a href="#">AuthorizationMetaStoreFilterHook</a>	Metastore filter hook for filtering out the list of objects that the current authorization implementation does not allow user to see
org.apache.hadoop.hive.ql.security.authorization.plugin. <a href="#">HiveAuthorizerImpl</a>	Convenience implementation of HiveAuthorizer.
org.apache.hadoop.hive.ql.security.authorization.plugin. <a href="#">HiveAuthzContext</a>	Provides context information in authorization check call that can be used for auditing and/or authorization.
org.apache.hadoop.hive.ql.security.authorization.plugin. <a href="#">HivePrivilegeObject</a>	Represents the object on which privilege is being granted/revoked, and objects being used in queries.
org.apache.hadoop.hive.ql.security.authorization.plugin. <a href="#">HiveV1Authorizer</a>	Hive v1 authorization class.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. <a href="#">DummyHiveAuthorizationValidator</a>	A no-op HiveAuthorizationValidator for use from hive cli.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. <a href="#">SQLAuthorizationUtils</a>	Utilities for SQL based authorization.
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. <a href="#">SQLStdHiveAccessController</a>	Implements functionality of access control statements for sql standard based authorization
org.apache.hadoop.hive.ql.security.authorization.plugin.sqlstd. <a href="#">SQLStdHiveAuthorizationValidator</a>	Class to check if user has privileges to perform certain action according to SQL standart hive authorization.
org.apache.hadoop.hive.ql.session. <a href="#">LineageState</a>	LineageState.
org.apache.hadoop.hive.ql.session. <a href="#">OperationLog</a>	OperationLog wraps the actual operation log file, and provides interface for accessing, reading, writing, and removing the file.
org.apache.hadoop.hive.ql.session. <a href="#">SessionState</a>	SessionState encapsulates common data associated with a session.

Class	Description
org.apache.hadoop.hive.ql.stats. <a href="#">StatsFactory</a>	A factory of stats publisher and aggregator implementations of the StatsPublisher and StatsAggregator interfaces.
org.apache.hadoop.hive.ql.stats. <a href="#">StatsUtils</a>	Utilities of stats publisher and aggregator.
org.apache.hadoop.hive.ql.stats.fs. <a href="#">FSSStatsAggregator</a>	File system stats aggregator.
org.apache.hadoop.hive.ql.stats.fs. <a href="#">FSSStatsPublisher</a>	File system stats publisher.
org.apache.hadoop.hive.ql.txn.compactor. <a href="#">CompactorMR</a>	Performs compactions via an MR job.
org.apache.hadoop.hive.ql.txn.compactor. <a href="#">Worker</a>	Performs compactions.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFAverage</a>	GenericUDFAverage.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDAFStreamingEvaluator</a>	User defined aggregate function streaming evaluator.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDAFSum</a>	GenericUDAFSum.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDF</a>	A Generic User-defined function (GenericUDF) for the use with Hive.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFBasePad</a>	A Generic User-defined function (GenericUDF) for the use with Hive.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFBridge</a>	GenericUDFBridge encapsulates UDF to provide the same interface as GenericUDF.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFDateAdd</a>	UDFDateAdd.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFDateSub</a>	UDFDateSub.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFFromUtcTimestamp</a>	Generic user defined function to compute UTC timestamp.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFGreatest</a>	GenericUDF Class for SQL construct "greatest(v1, v2, ..
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFLeast</a>	GenericUDF Class for SQL construct "least(v1, v2, ..
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFLpad</a>	UDFLpad.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPAnd</a>	GenericUDF Class for computing and.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPEqual</a>	GenericUDF Class for operation EQUAL.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPEqualOrGreaterThan</a>	GenericUDF Class for operation EqualOrGreaterThan.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPEqualOrLessThan</a>	GenericUDF Class for operation EqualOrLessThan.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPGreaterThan</a>	GenericUDF Class for operation GreaterThan.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPLessThan</a>	GenericUDF Class for operation LessThan.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPNotEqual</a>	GenericUDF Class for operation Not EQUAL.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPNotNull</a>	GenericUDFOPNotNull.

Class	Description
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPNull</a>	GenericUDFOPNull.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFOPor</a>	GenericUDF Class for computing or.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFRound</a>	Rounding function permits rounding off integer digits in decimal numbers, which essentially downgrades the scale to negative territory.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFRpad</a>	UDFRpad.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFToUnixTimeStamp</a>	Deterministic version of UDFUnixTimeStamp.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">GenericUDFUtils</a>	Util functions for GenericUDF classes.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">NumDistinctValueEstimator</a>	Take the average of the index for all the bit vectors and get the estimated NDV (estimateNumDistinctValues).
org.apache.hadoop.hive.ql.udf.generic. <a href="#">NumericHistogram</a>	A generic, re-usable histogram class that supports partial aggregations.
org.apache.hadoop.hive.ql.udf.generic. <a href="#">RoundUtils</a>	Utility class for generic round UDF.
org.apache.hadoop.hive.ql.udf.ptf. <a href="#">WindowingTableFunction</a>	A window function performs a calculation across a set of table rows that are somehow related to the current row.
org.apache.hadoop.hive.ql.util. <a href="#">DateTimeMath</a>	Operations involving/returning year-month intervals.
org.apache.hadoop.hive.ql.util. <a href="#">DosToUnix</a>	Converting windows script to UNIX.
org.apache.hadoop.hive.ql.util. <a href="#">ZooKeeperHiveHelper</a>	Get the ensemble server addresses from the configuration. The format is: host1:port,host2:port
org.apache.hadoop.hive.serde2. <a href="#">AbstractSerDe</a>	Abstract class for implementing SerDe.
org.apache.hadoop.hive.serde2. <a href="#">ColumnProjectionUtils</a>	ColumnProjectionUtils.
org.apache.hadoop.hive.serde2. <a href="#">DelimitedJSONSerDe</a>	DelimitedJSONSerDe.
org.apache.hadoop.hive.serde2. <a href="#">MetadataTypedColumnsetSerDe</a>	MetadataTypedColumnsetSerDe.
org.apache.hadoop.hive.serde2. <a href="#">OpenCSVSerde</a>	OpenCSVSerde use opencsv to deserialize CSV format.
org.apache.hadoop.hive.serde2. <a href="#">RegexSerDe</a>	RegexSerDe uses regular expression (regex) to deserialize data.
org.apache.hadoop.hive.serde2. <a href="#">SerDeUtils</a>	SerDeUtils.
org.apache.hadoop.hive.serde2. <a href="#">WriteBuffers</a>	The structure storing arbitrary amount of data as a set of fixed-size byte buffers.
org.apache.hadoop.hive.serde2.avro. <a href="#">AvroLazyObjectInspector</a>	Lazy objectinspector for avro serialization
org.apache.hadoop.hive.serde2.avro. <a href="#">AvroSerDe</a>	Read or write Avro data from Hive.
org.apache.hadoop.hive.serde2.avro. <a href="#">AvroSerdeUtils</a>	Utilities useful only to the AvroSerde itself.
org.apache.hadoop.hive.serde2.binarysortable. <a href="#">BinarySortableSerDe</a>	BinarySortableSerDe can be used to write data in a way that the data can be compared byte-by-byte with the same order.
org.apache.hadoop.hive.serde2.binarysortable.fast. <a href="#">BinarySortableDeserializeRead</a>	Directly deserialize with the caller reading field-by-field the LazyBinary serialization format.
org.apache.hadoop.hive.serde2.binarysortable.fast. <a href="#">BinarySortableSerializeWrite</a>	Directly serialize, field-by-field, the BinarySortable format.

Class	Description
org.apache.hadoop.hive.serde2.io. <a href="#">DateWritable</a>	DateWritable Writable equivalent of java.sql.Date.
org.apache.hadoop.hive.serde2.io. <a href="#">HiveDecimalWritable</a>	Get a HiveDecimal instance from the writable and constraint it with maximum precision/scale.
org.apache.hadoop.hive.serde2.io. <a href="#">TimestampWritable</a>	TimestampWritable Writable equivalent of java.sql.Timestamp Timestamps are of the format YYYY-MM-DD HH:MM:SS.[fff...] We encode Unix timestamp in seconds in 4 bytes, using the MSB to signify whether the timestamp has a fractional portion.
org.apache.hadoop.hive.serde2.lazy. <a href="#">LazyBinary</a>	LazyBinary stores a binary object in a LazyObject.
org.apache.hadoop.hive.serde2.lazy. <a href="#">LazyHiveDecimal</a>	LazyHiveDecimal stores hive decimal object in LazyObject.
org.apache.hadoop.hive.serde2.lazy. <a href="#">LazyMap</a>	LazyMap stores a map of Primitive LazyObjects to LazyObjects.
org.apache.hadoop.hive.serde2.lazy. <a href="#">LazySerDeParameters</a>	SerDeParameters.
org.apache.hadoop.hive.serde2.lazy. <a href="#">LazySimpleSerDe</a>	LazySimpleSerDe can be used to read the same data format as MetadataTypedColumnsetSerDe and TCTLSeparatedProtocol.
org.apache.hadoop.hive.serde2.lazy. <a href="#">LazyUtils</a>	LazyUtils.
org.apache.hadoop.hive.serde2.lazy.fast. <a href="#">LazySimpleDeserializeRead</a>	Directly deserialize with the caller reading field-by-field the LazySimple (text) serialization format.
org.apache.hadoop.hive.serde2.lazy.fast. <a href="#">LazySimpleSerializeWrite</a>	Directly serialize, field-by-field, the LazyBinary format.
org.apache.hadoop.hive.serde2.lazy.objectinspector. <a href="#">LazyListObjectInspector</a>	LazyListObjectInspector works on array data that is stored in LazyArray.
org.apache.hadoop.hive.serde2.lazy.objectinspector. <a href="#">LazyMapObjectInspector</a>	LazyMapObjectInspector works on struct data that is stored in LazyStruct.
org.apache.hadoop.hive.serde2.lazy.objectinspector. <a href="#">LazyUnionObjectInspector</a>	LazyUnionObjectInspector works on union data that is stored in LazyUnion.
org.apache.hadoop.hive.serde2.lazybinary. <a href="#">LazyBinarySerDe</a>	The LazyBinarySerDe class combines the lazy property of LazySimpleSerDe class and the binary property of BinarySortable class.
org.apache.hadoop.hive.serde2.lazybinary.fast. <a href="#">LazyBinaryDeserializeRead</a>	Directly deserialize with the caller reading field-by-field the LazyBinary serialization format.
org.apache.hadoop.hive.serde2.lazybinary.fast. <a href="#">LazyBinarySerializeWrite</a>	Directly serialize, field-by-field, the LazyBinary format.
org.apache.hadoop.hive.serde2.objectinspector. <a href="#">ObjectInspectorFactory</a>	ObjectInspectorFactory is the primary way to create new ObjectInspector instances.
org.apache.hadoop.hive.serde2.objectinspector. <a href="#">ObjectInspectorUtils</a>	ObjectInspectorFactory is the primary way to create new ObjectInspector instances.
org.apache.hadoop.hive.serde2.objectinspector. <a href="#">ReflectionStructObjectInspector</a>	ReflectionStructObjectInspector works on struct data that is stored as a native Java object.
org.apache.hadoop.hive.serde2.objectinspector. <a href="#">SettableUnionObjectInspector</a>	SettableUnionObjectInspector.
org.apache.hadoop.hive.serde2.objectinspector. <a href="#">StandardStructObjectInspector</a>	ListStructObjectInspector works on struct data that is stored as a Java List or Java Array object.

Class	Description
org.apache.hadoop.hive.serde2.objectinspector. <a href="#">StandardUnionObjectInspector</a>	StandardUnionObjectInspector works on union data that is stored as UnionObject.
org.apache.hadoop.hive.serde2.objectinspector. <a href="#">ThriftUnionObjectInspector</a>	Always use the ObjectInspectorFactory to create new ObjectInspector objects, instead of directly creating an instance of this class.
org.apache.hadoop.hive.serde2.typeinfo. <a href="#">HiveDecimalUtils</a>	Utilities for decimal precision and scale.
org.apache.hadoop.hive.serde2.typeinfo. <a href="#">TypeInfoUtils</a>	TypeInfoUtils.
org.apache.hadoop.hive.shims. <a href="#">Hadoop23Shims</a>	Implementation of shims against Hadoop 0.23.0.
org.apache.hadoop.hive.shims. <a href="#">HadoopShimsSecure</a>	Base implementation for shims against secure Hadoop 0.20.3/0.23.
org.apache.hadoop.hive.shims. <a href="#">ShimLoader</a>	ShimLoader.
org.apache.hadoop.hive.shims. <a href="#">Utils</a>	Utilities for split location provider.
org.apache.hadoop.hive.thrift. <a href="#">DelegationTokenSecretManager</a>	A Hive specific delegation token secret manager.
org.apache.hadoop.hive.thrift. <a href="#">HadoopThriftAuthBridge</a>	Functions that bridge Thrift's SASL transports to Hadoop's SASL callback handlers and authentication classes.
org.apache.hadoop.hive.thrift. <a href="#">TokenStoreDelegationTokenSecretManager</a>	Extension of DelegationTokenSecretManager to support alternative to default in-memory token management for fail-over and clustering through plug-able token store (ZooKeeper etc.).
org.apache.hive.beeline. <a href="#">BeeLine</a>	A console SQL shell with command completion.
org.apache.hive.beeline. <a href="#">Commands</a>	Implementation of beeline commands.
org.apache.hive.common.util. <a href="#">BloomFilter</a>	BloomFilter is a probabilistic data structure for set membership check.
org.apache.hive.common.util. <a href="#">DateUtils</a>	DateUtils.
org.apache.hive.common.util. <a href="#">HiveStringUtils</a>	HiveStringUtils General string utils Originally copied from o.a.hadoop.util.StringUtils
org.apache.hive.common.util. <a href="#">HiveTestUtils</a>	Utilities for testing hive.
org.apache.hive.common.util. <a href="#">Murmur3</a>	Murmur3 is successor to Murmur2 fast non-cryptographic hash algorithms.
org.apache.hive.common.util. <a href="#">ShutdownHookManager</a>	The ShutdownHookManager enables running shutdownHook in a deterministic order, higher priority first.
org.apache.hive.common.util. <a href="#">StreamPrinter</a>	StreamPrinter.
org.apache.hive.hcatalog.cli. <a href="#">HCatCli</a>	HCatalog command line interface.
org.apache.hive.hcatalog.common. <a href="#">HCatConstants</a>	List of constants used by HCatalog.
org.apache.hive.hcatalog.streaming. <a href="#">ConnectionError</a>	Exception to catch connection errors.
org.apache.hive.hcatalog.streaming. <a href="#">DelimitedInputWriter</a>	Streaming Writer handles delimited input (eg.
org.apache.hive.hcatalog.streaming. <a href="#">HiveEndPoint</a>	Information about the hive end point (i.e.
org.apache.hive.hcatalog.streaming. <a href="#">InvalidTable</a>	Exception to catch invalid table.
org.apache.hive.hcatalog.streaming. <a href="#">StrictJsonWriter</a>	Streaming Writer handles utf8 encoded Json (Strict syntax).

Class	Description
org.apache.hive.hcatalog.templeton. <a href="#">AppConfig</a>	The configuration for Templeton.
org.apache.hive.hcatalog.templeton. <a href="#">Main</a>	The main executable that starts up and runs the Server.
org.apache.hive.jdbc <a href="#">.HiveConnection</a>	HiveConnection.
org.apache.hive.jdbc <a href="#">.HiveDatabaseMetaData</a>	HiveDatabaseMetaData.
org.apache.hive.jdbc <a href="#">.HivePreparedStatement</a>	HivePreparedStatement.
org.apache.hive.jdbc <a href="#">.HiveQueryResultSet</a>	HiveQueryResultSet.
org.apache.hive.jdbc <a href="#">.HiveStatement</a>	HiveStatement.
org.apache.hive.jdbc <a href="#">.JdbcColumn</a>	Column metadata.
org.apache.hive.jdbc <a href="#">.Utils</a>	Utilities for jdbc.
org.apache.hive.service. <a href="#">ServiceUtils</a>	Utilities to correctly process domain names etc.
org.apache.hive.service.auth. <a href="#">AuthenticationProviderFactory</a>	Helps select a PasswdAuthenticationProvider for a given {@code AuthMethod}.
org.apache.hive.service.auth. <a href="#">HiveAuthFactory</a>	Helps in some aspects of authentication.
org.apache.hive.service.auth. <a href="#">LdapAuthenticationProviderImpl</a>	Utilities to correctly process domain names etc.
org.apache.hive.service.auth. <a href="#">TSetupAddressProcessor</a>	Sets the ipAddress for operations executed via HiveServer2.
org.apache.hive.service.cli. <a href="#">CLIService</a>	CLIService.
org.apache.hive.service.cli. <a href="#">CLIServiceUtils</a>	CLIServiceUtils.
org.apache.hive.service.cli. <a href="#">ColumnBasedSet</a>	ColumnBasedSet.
org.apache.hive.service.cli. <a href="#">ColumnDescriptor</a>	ColumnDescriptor.
org.apache.hive.service.cli. <a href="#">ColumnValue</a>	Protocols before HIVE_CLI_SERVICE_PROTOCOL_V6 (used by RowBasedSet)
org.apache.hive.service.cli. <a href="#">EmbeddedCLIServiceClient</a>	Embedded CLI Service Client.
org.apache.hive.service.cli. <a href="#">FetchOrientation</a>	Fetch Orientation.
org.apache.hive.service.cli. <a href="#">GetInfoType</a>	Get Info type.
org.apache.hive.service.cli. <a href="#">GetInfoValue</a>	Get Info value.
org.apache.hive.service.cli. <a href="#">Handle</a>	Handle.
org.apache.hive.service.cli. <a href="#">HandleIdentifier</a>	Handle identifier.
org.apache.hive.service.cli. <a href="#">HiveSQLException</a>	Hive SQL exception.

Class	Description
org.apache.hive.service.cli. <a href="#">OperationHandle</a>	Handler for operation.
org.apache.hive.service.cli. <a href="#">OperationState</a>	Operation State.
org.apache.hive.service.cli. <a href="#">OperationStatus</a>	Operation Status.
org.apache.hive.service.cli. <a href="#">OperationType</a>	OperationType.
org.apache.hive.service.cli. <a href="#">RowBasedSet</a>	Row Based Set.
org.apache.hive.service.cli. <a href="#">RowSetFactory</a>	Row set factory class.
org.apache.hive.service.cli. <a href="#">SessionHandle</a>	Session Handle.
org.apache.hive.service.cli. <a href="#">TableSchema</a>	Table Schema.
org.apache.hive.service.cli. <a href="#">TypeDescriptor</a>	Type Descriptor.
org.apache.hive.service.cli. <a href="#">TypeQualifiers</a>	Holds type qualifier information for a primitive type, such as char/varchar length or decimal precision/scale.
org.apache.hive.service.cli.operation. <a href="#">ClassicTableTypeMapping</a>	Classic Table Type Mapping.
org.apache.hive.service.cli.operation. <a href="#">ExecuteStatementOperation</a>	Implementation of statement execution.
org.apache.hive.service.cli.operation. <a href="#">HiveCommandOperation</a>	Executes a HiveCommand.
org.apache.hive.service.cli.operation. <a href="#">HiveTableTypeMapping</a>	Hive Table Type Mapping.
org.apache.hive.service.cli.operation. <a href="#">LogDivertAppender</a>	Divert appender to redirect operation logs to separate files.
org.apache.hive.service.cli.operation. <a href="#">MetadataOperation</a>	Metadata Operation.
org.apache.hive.service.cli.operation. <a href="#">Operation</a>	Class to define operation.
org.apache.hive.service.cli.operation. <a href="#">OperationManager</a>	Operation Manager.
org.apache.hive.service.cli.operation. <a href="#">SQLOperation</a>	SQL Operation.
org.apache.hive.service.cli.session. <a href="#">HiveSessionImpl</a>	Hive Session.
org.apache.hive.service.cli.session. <a href="#">HiveSessionImplwithUGI</a>	Hive session implementation with UGI.
org.apache.hive.service.cli.session. <a href="#">SessionManager</a>	Session Manager.
org.apache.hive.service.cli.thrift. <a href="#">ThriftBinaryCLIService</a>	Initialize worker threads in hive CLI startup.
org.apache.hive.service.cli.thrift. <a href="#">ThriftCLIService</a>	Thrift CLI Service.
org.apache.hive.service.cli.thrift. <a href="#">ThriftCLIServiceClient</a>	Thrift CLI Service Client.
org.apache.hive.service.cli.thrift. <a href="#">ThriftHttpCLIService</a>	Service to handle requests over HTTP.
org.apache.hive.service.cli.thrift. <a href="#">ThriftHttpServlet</a>	Thrift Http servlet.
org.apache.hive.spark.client. <a href="#">MetricsCollection</a>	Provides metrics collected for a submitted job.
org.apache.hive.spark.client. <a href="#">SparkClientUtilities</a>	Utilities for spark client.
org.apache.hive.spark.client.rpc. <a href="#">Rpc</a>	Encapsulates the RPC functionality.
org.apache.hive.spark.client.rpc. <a href="#">RpcConfiguration</a>	Definitions of configuration keys and default values for the RPC layer.
org.apache.hive.spark.client.rpc. <a href="#">RpcServer</a>	An RPC server.

## Changed Interfaces in Hive 2.1

The following interfaces have changed in Hive 2.1:

Interface	Description
org.apache.hadoop.hive.common. <a href="#">ValidTxnList</a>	Models the list of transactions that should be included in a snapshot.
org.apache.hadoop.hive.metastore. <a href="#">AlterHandler</a>	Interface for Alter Table and Alter Partition code
org.apache.hadoop.hive.metastore. <a href="#">IMetaStoreClient</a>	Wrapper around hive metastore thrift api
org.apache.hadoop.hive.metastore. <a href="#">RawStore</a>	
org.apache.hadoop.hive.metastore. <a href="#">PartitionExpressionProxy</a>	The proxy interface that metastore uses for variety of QL operations (metastore can't depend on QL because QL depends on metastore; creating metastore-client module would be a proper way to solve this problem).
org.apache.hadoop.hive ql.exec.persistence. <a href="#">MapJoinTableContainer</a>	
org.apache.hadoop.hive ql.exec.spark. <a href="#">SparkShuffler</a>	
org.apache.hadoop.hive ql.exec.spark. <a href="#">SparkTran</a>	
org.apache.hadoop.hive ql.exec.spark.session. <a href="#">SparkSession</a>	
org.apache.hadoop.hive ql.exec.spark.status. <a href="#">SparkJobStatus</a>	SparkJobStatus identify what Hive want to know about the status of a Spark job.
org.apache.hadoop.hive ql.exec.vector.expressions. <a href="#">VectorExpressionWriter</a>	Interface used to create Writable objects from vector expression primitives.
org.apache.hadoop.hive ql.exec.vector.mapjoin.hashtable. <a href="#">VectorMapJoinHashTable</a>	
org.apache.hadoop.hive ql.io. <a href="#">InputFormatChecker</a>	Check for validity of the input files.
org.apache.hadoop.hive ql.io.orc. <a href="#">Reader</a>	The interface for reading ORC files.
org.apache.hadoop.hive ql.io.orc. <a href="#">RecordReader</a>	A row-by-row iterator for ORC files.
org.apache.hadoop.hive ql.io.orc. <a href="#">Writer</a>	The HIVE interface for writing ORC files.
org.apache.hadoop.hive ql.io.sarg. <a href="#">SearchArgument</a>	Primary interface for <a href="#">SearchArgument</a> , which are the subset of predicates that can be pushed down to the RecordReader.
org.apache.hadoop.hive ql.lockmgr. <a href="#">HiveTxnManager</a>	An interface that allows Hive to manage transactions.
org.apache.hadoop.hive ql.metadata.formatting. <a href="#">MetaDateFormatter</a>	Interface to format table and index information.
org.apache.hadoop.hive ql.plan. <a href="#">OperatorDesc</a>	
org.apache.hadoop.hive ql.security.authorization.plugin. <a href="#">HiveAuthorizationValidator</a>	Interface used to check if user has privileges to perform certain action.
org.apache.hadoop.hive ql.security.authorization.plugin. <a href="#">HiveAuthorizer</a>	Interface for hive authorization plugins.
org.apache.hadoop.hive ql.stats. <a href="#">StatsAggregator</a>	An interface for any possible implementation for gathering statistics.
org.apache.hadoop.hive ql.stats. <a href="#">StatsPublisher</a>	An interface for any possible implementation for publishing statics.

Interface	Description
org.apache.hadoop.hive.shims. <a href="#">HadoopShims</a>	In order to be compatible with multiple versions of Hadoop, all parts of the Hadoop interface that are not cross-version compatible are encapsulated in an implementation of this class.
org.apache.hive.hcatalog.streaming. <a href="#">StreamingConnection</a>	Represents a connection to a HiveEndPoint.
org.apache.hive.hcatalog.streaming. <a href="#">TransactionBatch</a>	Represents a set of Transactions returned by Hive.
org.apache.hive.service.cli. <a href="#">ICLIService</a>	
org.apache.hive.service.cli. <a href="#">RowSet</a>	
org.apache.hive.service.cli.operation. <a href="#">TableTypeMapping</a>	
org.apache.hive.service.cli.session. <a href="#">HiveSession</a>	
org.apache.hive.service.cli.session. <a href="#">HiveSessionBase</a>	Methods that don't need to be executed under a doAs context are here.
org.apache.hive.spark.client. <a href="#">JobContext</a>	Holds runtime information about the job execution context.
org.apache.hive.spark.client. <a href="#">SparkClient</a>	Defines the API for the Spark remote client.

### Removed API in Hive 2.1

The following classes and interfaces are not available with Hive 2.1:

### Removed Classes

Class	Description
org.apache.hadoop.hive.common.metrics.Metrics	Metrics Subsystem - allows exposure of a number of named parameters/counters via jmx, intended to be used as a static subsystem Has a couple of primary ways it can be used: (i) Using the set and get methods to set and get named parameters (ii) Using the incrementCounter method to increment and set named parameters in one go, rather than having to make a get and then a set.
org.apache.hadoop.hive.hbase.HBaseStatsAggregator	A class that implements the StatsAggregator interface through HBase.
org.apache.hadoop.hive.hbase.HBaseStatsPublisher	A class that implements the StatsPublisher interface through HBase.
org.apache.hadoop.hive.hbase.HBaseStatsSetupConstants	HBase constants statistics setup.
org.apache.hadoop.hive.hbase.HBaseStatsUtils	Utilities for hbase statistics.
org.apache.hadoop.hive.metastore.ProtectMode	Protection Mode.
org.apache.hadoop.hive.metastore.txn.CompactionTxnHandler	Extends the transaction handler with methods needed only by the compactor threads.
org.apache.hadoop.hive.metastore.txn.TxnHandler	A handler to answer transaction related calls that come into the metastore server.
org.apache.hadoop.hive.metastore.txn.ValidCompactorTxnList	And implmentation of org.apache.hadoop.hive.common.ValidTxnList for use by the compactor.
org.apache.hadoop.hive.ql.exec.DefaultFetchFormatter	Serializes row by user specified serde and call toString() to make string type result

Class	Description
org.apache.hadoop.hive.ql.exec.Heartbeater	Class to handle heartbeats for MR and Tez tasks.
org.apache.hadoop.hive.ql.exec.vector.RandomRowObjectSource	Generates object inspector and random row object[].
org.apache.hadoop.hive.ql.exec.vector.VectorAssignRowDynBatch	Assigns specified columns of a VectorizedRowBatch row from a Writable row Object[].
org.apache.hadoop.hive.ql.exec.vector.VectorAssignRowSameBatch	Assigns specified columns of a VectorizedRowBatch row from a Writable row Object[].
org.apache.hadoop.hive.ql.exec.vector.VectorSerializeRowNoNulls	Serializes columns from a row in a VectorizedRowBatch into a serialization format.
org.apache.hadoop.hive.ql.exec.vector.VectorizedColumnarSerDe	VectorizedColumnarSerDe is used by Vectorized query execution engine for columnar based storage supported by RCFile.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFDayOfMonthLong	Expression to get day of month.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFHourLong	Returns hour of day.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMinuteLong	Returns minute value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFMonthLong	Returns month value.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFSecondLong	Expression to get seconds.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFTimestampFieldLong	Abstract class to return various fields from a Timestamp or Date.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFUnixTimeStampLong	Return Unix Timestamp.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFWeekOfYearLong	Expression to get week of year.
org.apache.hadoop.hive.ql.exec.vector.expressions.VectorUDFYearLong	Expression to get year as a long.
org.apache.hadoop.hive.ql.exec.vector.mapjoin.fast.VectorMapJoinFastIntHashUtil	Utilities for mapr join in vectorization mode.
org.apache.hadoop.hive.ql.io.VectorizedRCFileInputFormat	A MapReduce/Hive Vectorized input format for RC files.
org.apache.hadoop.hive.ql.io.VectorizedRCFileRecordReader	RCFileRecordReader.
org.apache.hadoop.hive.ql.io.orc.FileDump	A tool for printing out the file structure of ORC files.
org.apache.hadoop.hive.ql.io.orc.InStream	Class to define input stream.
org.apache.hadoop.hive.ql.io.orc.Metadata	Metadata stored in underlying db.
org.apache.hadoop.hive.ql.io.orc.MetadataReader	Class to read and process metadata.
org.apache.hadoop.hive.ql.io.orc.OrcProto	Class to serialize data stored in orc.
org.apache.hadoop.hive.ql.io.orc.OrcUtils	Utilities to process orc files.
org.apache.hadoop.hive.ql.io.orc.RecordReaderFactory	Factory to create ORC tree readers.
org.apache.hadoop.hive.ql.io.orc.RecordReaderUtils	Stateless methods shared between RecordReaderImpl and EncodedReaderImpl.

Class	Description
org.apache.hadoop.hive.ql.io.orc.StripeStatistics	Information about index data stored in stripe.
org.apache.hadoop.hive.ql.io.orc.TreeReaderFactory	Factory for creating ORC tree readers.
org.apache.hadoop.hive.ql.log.PidDailyRollingFileAppender	Logging pids in file.
org.apache.hadoop.hive.ql.optimizer.calcite.HiveConfigContext	Hive configuration context.
org.apache.hadoop.hive.ql.optimizer.calcite.reoperators.HiveLimit	Define limit operator.
org.apache.hadoop.hive.ql.optimizer.calcite.reoperators.HiveSort	Define sort operator.
org.apache.hadoop.hive.ql.parse.VariableSubstitution	The Hive variable substitution mechanism was designed to avoid some of the code that was getting baked into the scripting language on top of Hive.
org.apache.hadoop.hive.ql.session.DependencyResolver	Creating list of dependency jars.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregator	Counter statistics aggregator.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregatorSpark	Counter statistics aggregator for Spark.
org.apache.hadoop.hive.ql.stats.CounterStatsAggregatorTez	This class aggregates stats via counters and does so for Tez Tasks.
org.apache.hadoop.hive.ql.stats.CounterStatsPublisher	Counter statistics publisher.
org.apache.hadoop.hive.ql.udf.UDFRegExp	UDFRegExp.
org.apache.hadoop.hive.shims.Hadoop20SShims	Implementation of shims against Hadoop 0.20 with Security.
org.apache.hadoop.hive.shims.HiveEventCounter	Hive event counter.
org.apache.hadoop.hive.shims.Jetty20SShims	In order to be compatible with multiple versions of Jetty, all parts of the Jetty interface that are not cross-version compatible are encapsulated in an implementation of this class.
org.apache.hadoop.mapred.WebHCatJTShim20S	This is in org.apache.hadoop.mapred package because it relies on JobSubmissionProtocol which is package private
org.apache.hive.benchmark.vectorization.VectorizationBenchmark	Measures the performance for vectorization.
org.apache.hive.jdbc.ZooKeeperHiveClientHelper	Resolve to a host:port by connecting to ZooKeeper and picking a host randomly.
org.apache.hive.service.cli.Column	Column.
org.apache.hive.service.cli.Type	Type.
org.apache.hive.service.cli.thrift.TArrayTypeEntry	Array type entry.
org.apache.hive.service.cli.thrift.TBinaryColumn	Binary column.
org.apache.hive.service.cli.thrift.TBoolColumn	Boolean column.
org.apache.hive.service.cli.thrift.TBoolValue	Boolean value.
org.apache.hive.service.cli.thrift.TByteColumn	Byte column.
org.apache.hive.service.cli.thrift.TByteValue	Byte value.

Class	Description
org.apache.hive.service.cli.thrift.TCLIService	Command line interface service.
org.apache.hive.service.cli.thrift.TCLIServiceConstants	Command line interface constants.
org.apache.hive.service.cli.thrift.TCancelDelegationTokenReq	Cancel delegation token request.
org.apache.hive.service.cli.thrift.TCancelDelegationTokenResp	Cancel delegation token response.
org.apache.hive.service.cli.thrift.TCancelOperationReq	Cancel operation request.
org.apache.hive.service.cli.thrift.TCancelOperationResp	Cancel operation response.
org.apache.hive.service.cli.thrift.TCloseOperationReq	Close operation request.
org.apache.hive.service.cli.thrift.TCloseOperationResp	Close operation response.
org.apache.hive.service.cli.thrift.TCloseSessionReq	Close session request.
org.apache.hive.service.cli.thrift.TCloseSessionResp	Close session response.
org.apache.hive.service.cli.thrift.TColumn	Column.
org.apache.hive.service.cli.thrift.TColumnDesc	Column description.
org.apache.hive.service.cli.thrift.TColumnValue	Column value.
org.apache.hive.service.cli.thrift.TDoubleColumn	Double column.
org.apache.hive.service.cli.thrift.TDoubleValue	Double value.
org.apache.hive.service.cli.thrift.TExecuteStatementReq	Execute statement request.
org.apache.hive.service.cli.thrift.TExecuteStatementResp	Execute statement response.
org.apache.hive.service.cli.thrift.TFetchOrientation	Fetch orientation.
org.apache.hive.service.cli.thrift.TFetchResultsReq	Fetch results request.
org.apache.hive.service.cli.thrift.TFetchResultsResp	Fetch results response.
org.apache.hive.service.cli.thrift.TGetCatalogsReq	Get catalogs request.

### Removed Interfaces

Interface	Description
org.apache.hadoop.hive.ql.exec. <i>FetchFormatter</i>	(For internal-use only) Used in ListSinkOperator for formatting final output
org.apache.hadoop.hive.ql.io.orc. <i>BinaryColumnStatistics</i>	Statistics for binary columns.
org.apache.hadoop.hive.ql.io.orc. <i>BooleanColumnStatistics</i>	Statistics for boolean columns.
org.apache.hadoop.hive.ql.io.orc. <i>ColumnStatistics</i>	Statistics that are available for all types of columns.
org.apache.hadoop.hive.ql.io.orc. <i>CompressionCodec</i>	Compress the in buffer to the out buffer.
org.apache.hadoop.hive.ql.io.orc. <i>CompressionCodec.Modifier</i>	Compress the in buffer to the out buffer.
org.apache.hadoop.hive.ql.io.orc. <i>ConversionTreeReaderFactory</i>	Factory for creating ORC tree readers.
org.apache.hadoop.hive.ql.io.orc. <i>DateColumnStatistics</i>	Statistics for DATE columns.

Interface	Description
<a href="#">org.apache.hadoop.hive.ql.io.orc.DecimalColumnStatistics</a>	Statistics for decimal columns.
<a href="#">org.apache.hadoop.hive.ql.io.orc.DirectDecompressionCodec</a>	Decompression codec.
<a href="#">org.apache.hadoop.hive.ql.io.orc.DoubleColumnStatistics</a>	Statistics for float and double columns.
<a href="#">org.apache.hadoop.hive.ql.io.orc.IntegerColumnStatistics</a>	Statistics for all of the integer columns, such as byte, short, int, and long.
<a href="#">org.apache.hadoop.hive.ql.io.orc.PositionProvider</a>	An interface used for seeking to a row index.
<a href="#">org.apache.hadoop.hive.ql.io.orc.StringColumnStatistics</a>	Statistics for string columns.
<a href="#">org.apache.hadoop.hive.ql.io.orc.StripeInformation</a>	Information about the stripes in an ORC file that is provided by the Reader.
<a href="#">org.apache.hadoop.hive.ql.io.orc.TimestampColumnStatistics</a>	Statistics for Timestamp columns.
<a href="#">org.apache.hadoop.hive.ql.stats.StatsCollectionTaskIndependent</a>	Marker interface to differentiate between stats publisher / aggregator which don't track stats per task, as oppose to others which do.

### Deprecated API in Hive 2.1

The following classes, interfaces, and fields have been deprecated in Hive 2.1.

#### Deprecated Classes

<a href="#">org.apache.hadoop.hive.ql.exec.ByteWritable</a>
<a href="#">org.apache.hadoop.hive.serde.Constants</a>
<a href="#">org.apache.hadoop.hive.ql.io.FlatFileInputFormat</a>
<a href="#">org.apache.hadoop.hive.ql.io.FlatFileInputFormat.FlatFileRecordReader</a>
<a href="#">org.apache.hadoop.hive.ql.io.IgnoreKeyTextOutputFormat</a> <i>use <a href="#">HiveIgnoreKeyTextOutputFormat</a> instead</i>
<a href="#">org.apache.hadoop.hive.serde2.lazy.LazySimpleSerDe.SerDeParameters</a>
<a href="#">org.apache.hadoop.hive.ql.exec.UDAF</a> <i>Either implement <a href="#">GenericUDAFResolver2</a> or extend <a href="#">AbstractGenericUDAFResolver</a> instead.</i>

#### Deprecated Interfaces

<a href="#">org.apache.hadoop.hive.serde2.Deserializer</a>
<a href="#">org.apache.hadoop.hive.ql.udf.generic.GenericUDAFEvaluator.AggregationBuffer</a> <i>use <a href="#">GenericUDAFEvaluator.AbstractAggregationBuffer</a> instead</i>
<a href="#">org.apache.hadoop.hive.ql.udf.generic.GenericUDAFResolver</a> <i>Use <a href="#">GenericUDAFResolver2</a> instead.</i>
<a href="#">org.apache.hadoop.hive.serde2.SerDe</a>
<a href="#">org.apache.hadoop.hive.serde2.Serializer</a>

**Deprecated Fields**

<a href="#">org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.AVRO_SERDE_SCHEMA</a>
<a href="#">org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_DOC</a>
<a href="#">org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_LITERAL</a>
<a href="#">org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_NAME</a>
<a href="#">org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_NAMESPACE</a>
<a href="#">org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_RETRIEVER</a>
<a href="#">org.apache.hadoop.hive.serde2.avro.AvroSerdeUtils.SCHEMA_URL</a>
<a href="#">org.apache.hive.hplsql.HplsqlParser.tokenNames</a> <i>Use <a href="#">HplsqlParser.VOCABULARY</a> instead.</i>
<a href="#">org.apache.hive.hplsql.HplsqlLexer.tokenNames</a> <i>Use <a href="#">HplsqlLexer.VOCABULARY</a> instead.</i>

**Deprecated Methods**

<a href="#">org.apache.hadoop.hive.metastore.IMetaStoreClient.addDynamicPartitions(long, String, String, List&lt;String&gt;)</a> <i>in Hive 1.3.0/2.1.0 - will be removed in 2 releases</i>
<a href="#">org.apache.hadoop.hive.metastore.HiveMetaStoreClient.addDynamicPartitions(long, String, String, List&lt;String&gt;)</a>
<a href="#">org.apache.hadoop.hive.serde2.ColumnProjectionUtils.appendReadColumnIDs(Configuration, List&lt;Integer&gt;)</a> <i>for backwards compatibility with &lt;= 0.12, use <a href="#">appendReadColumns</a></i>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.bucketCols(List&lt;String&gt;, int)</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.collectionItemsTerminatedBy(char)</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.comments(String)</a>
<a href="#">org.apache.hadoop.hive.metastore.IMetaStoreClient.compact(String, String, String, CompactionType)</a>
<a href="#">org.apache.hadoop.hive.metastore.HiveMetaStoreClient.compact(String, String, String, CompactionType)</a>
<a href="#">org.apache.hadoop.hive.ql.metadata.HiveStorageHandler.configureTableJobProperties(TableDesc, Map&lt;String, String&gt;)</a>
<a href="#">org.apache.orc.impl.InStream.create(String, ByteBuffer[], long[], long, CompressionCodec, int)</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.create(String, String, List&lt;HCatFieldSchema&gt;)</a>
<a href="#">org.apache.hive.hcatalog.api.HCatAddPartitionDesc.create(String, String, String, Map&lt;String, String&gt;)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.LazyFactory.createColumnarStructInspector(List&lt;String&gt;, List&lt;TypeInfo&gt;, byte[], Text, boolean, byte)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyObjectInspector(TypeInfo, byte[], int, Text, boolean, byte)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyObjectInspector(TypeInfo, byte[], int, Text, boolean, byte, boolean)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyObjectInspector(TypeInfo, byte[], int, Text, boolean, byte, boolean, ObjectInspectorFactory.ObjectInspectorOptions)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyObjectInspector(TypeInfo, byte[], int, Text, boolean, byte, ObjectInspectorFactory.ObjectInspectorOptions)</a>

<a href="#">org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyStructInspector(List&lt;String&gt;, List&lt;TypeInfo&gt;, byte[], Text, boolean, boolean, byte)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.LazyFactory.createLazyStructInspector(List&lt;String&gt;, List&lt;TypeInfo&gt;, byte[], Text, boolean, boolean, byte, boolean)</a>
<a href="#">org.apache.hadoop.hive.metastore.IMetaStoreClient.dropTable(String, boolean)</a> <i>As of release 0.6.0 replaced by <a href="#">IMetaStoreClient.dropTable(String, String, boolean, boolean)</a>. This method will be removed in release 0.7.0.</i>
<a href="#">org.apache.hadoop.hive.metastore.HiveMetaStoreClient.dropTable(String, boolean)</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.escapeChar(char)</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.fieldsTerminatedBy(char)</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.Builder.fileFormat(String)</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getBucketCols()</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getCols()</a>
<a href="#">org.apache.hadoop.hive.serde2.dynamic_type.SimpleCharStream.getColumn()</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getComments()</a>
<a href="#">org.apache.hadoop.hive ql.io.RCFile.Writer.getCompressionCodec()</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getDatabaseName()</a>
<a href="#">org.apache.hive.hcatalog.api.HCatAddPartitionDesc.getDatabaseName()</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getExternal()</a>
<a href="#">org.apache.hadoop.hive ql.exec.Utilities.getFileExtension(JobConf, boolean)</a> <i>Use <a href="#">Utilities.getFileExtension(JobConf, boolean, HiveOutputFormat)</a></i>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getFileFormat()</a>
<a href="#">org.apache.hive.hcatalog.common.HCatUtil.getHiveClient(HiveConf)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleListObjectInspector(ObjectInspector, byte, Text, boolean, byte)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleMapObjectInspector(ObjectInspector, ObjectInspector, byte, byte, Text, boolean, byte)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleStructObjectInspector(List&lt;String&gt;, List&lt;ObjectInspector&gt;, byte, Text, boolean, boolean, byte)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleStructObjectInspector(List&lt;String&gt;, List&lt;ObjectInspector&gt;, byte, Text, boolean, boolean, byte, ObjectInspectorFactory.ObjectInspectorOptions)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleStructObjectInspector(List&lt;String&gt;, List&lt;ObjectInspector&gt;, List&lt;String&gt;, byte, Text, boolean, boolean, byte)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazySimpleStructObjectInspector(List&lt;String&gt;, List&lt;ObjectInspector&gt;, List&lt;String&gt;, byte, Text, boolean, boolean, byte, ObjectInspectorFactory.ObjectInspectorOptions)</a>
<a href="#">org.apache.hadoop.hive.serde2.lazy.objectinspector.LazyObjectInspectorFactory.getLazyUnionObjectInspector(List&lt;ObjectInspector&gt;, byte, Text, boolean, byte)</a>
<a href="#">org.apache.hadoop.hive.serde2.dynamic_type.SimpleCharStream.getLine()</a>
<a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getLocation()</a>
<a href="#">org.apache.hive.hcatalog.api.HCatAddPartitionDesc.getLocation()</a>

<p><a href="#">org.apache.hive.hcatalog.data.schema.HCatFieldSchema.getMapKeyType()</a>  <i>as of 0.13, slated for removal with 0.15 use <a href="#">HCatFieldSchema.getMapKeyTypeInfo()</a> instead</i></p>
<p><a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getNumBuckets()</a></p>
<p><a href="#">org.apache.hadoop.hive ql.udf.generic.SimpleGenericUDAFParameterInfo.getParameters()</a></p>
<p><a href="#">org.apache.hadoop.hive ql.udf.generic.GenericUDAFParameterInfo.getParameters()</a></p>
<p><a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getPartitionCols()</a></p>
<p><a href="#">org.apache.hive.hcatalog.api.HCatAddPartitionDesc.getPartitionSpec()</a></p>
<p><a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getSerdeParams()</a></p>
<p><a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getSortCols()</a></p>
<p><a href="#">org.apache.hive.hcatalog.api.HCatCreateTableDesc.getStorageHandler()</a></p>
<p><a href="#">org.apache.hadoop.hive.metastore.IMetaStoreClient.getTable(String)</a>  <i>As of release 0.6.0 replaced by <a href="#">IMetaStoreClient.getTable(String, String)</a>. This method will be removed in release 0.7.0.</i></p>

## Troubleshooting Hive and Tez

This section includes Hive and Tez troubleshooting tips.

### HDFS Literal Deprecated

Starting in Hive-2.3, the `hdfs` literal is deprecated. Specifying a table location using the `hdfs` URI scheme will cause queries to fail because the Hive parser recognizes the `hdfs` literal in the `LOCATION` key word and triggers HDFS encryption, which is not supported.

If you use the `hdfs` literal with the `LOCATION` keyword in Hive queries:

```
CREATE TABLE IF NOT EXISTS i (id INT) LOCATION 'hdfs:///i';
```

The system logs the following warning:

```
LOG.warn("hdfs:// is deprecated filesystem and will be removed in future
releases. Use maprfs://
instead");
```

To avoid `hdfs` literal issues, update all instances of `hdfs` with `maprfs` in tables, partitions, and databases. Also update the `hive-site.xml` file to remove `hdfs` from the URI scheme list.

#### Update hive-site.xml

Remove `hdfs` from the `hive.exim.uri.scheme.whitelist` Hive configuration property in `hive-site.xml`, as shown:

```
<property>
<name>hive.exim.uri.scheme.whitelist</
name>
  <value>maprfs,...,..,s3</value>
</property>
```

#### Update Tables and Partitions

To replace the table and partition location with `maprfs`, run:

```
MariaDB [hive]> update SDS set
LOCATION = REPLACE(LOCATION, 'hdfs',
'maprfs') where LOCATION like
'%hdfs%';
```

#### Update Databases

To replace the database location with `maprfs`, run:

```
MariaDB [hive]> update
DBS set DB_LOCATION_URI =
REPLACE(DB_LOCATION_URI, 'hdfs',
'maprfs') where DB_LOCATION_URI like
'%hdfs%';
```

### Prohibited usage of `datanucleus.schema.autoCreateAll` property

The usage of the `datanucleus.schema.autoCreateAll` property is prohibited in all cases. Instead of using this property, you must run the `schematool` command. Refer to [HIVE-21302](#) for more information.

## WebHCat

Secure WebHCat operations depend on the Hive metastore having Kerberos enabled. If Kerberos is not enabled for the Hive metastore, null pointer exceptions similar to the following will appear:

```
2013-10-06 20:38:55,198 ERROR metastore.RetryingHMSHandler
(RetryingHMSHandler.java:invoke(134)) -
MetaException(message: java.lang.NullPointerException)
    at

java.util.concurrent.ThreadPoolExecutor$Worker.runTask(ThreadPoolExecutor.ja
va:895)
    at
java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:9
18)
```

If you are updating to the `mapr-hive-2.3.6-mapr-1912 (EEP-6.3.0)` package, you should manually replace the old `webhcat-default.xml` configuration file with the new one and restart the WebHCat service:

```
cp /opt/mapr/hive/hive-2.3/hcatalog/etc/webhcat.new/
webhcat-default.xml /opt/mapr/hive/hive-2.3/hcatalog/etc/webhcat/
```

## Hive in an Azure Cluster

When Hive services are installed on an Azure cluster, it is possible that the services will not start because Azure assigns too long (over 64 symbols) host names. Perform following steps to fix this issue:

**NOTE:** This issue is fixed on MapR core 6.0.1 starting from build 20180320175756.GA-1.x86\_64.

### 1. Edit the `/etc/hosts` file:

```
nano /etc/hosts
```

This is an example of a `/etc/hosts` file for an Azure cluster:

```
127.0.0.1    localhost localhost.localdomain localhost4
localhost4.localhostdomain4
::1         localhost localhost.localdomain localhost6
localhost6.localhostdomain6
172.24.8.4  anaikregtestc73522602-cluster-com-mapr-vm0.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm0
172.24.8.5  anaikregtestc73522602-cluster-com-mapr-vm1.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm1
172.24.8.6  anaikregtestc73522602-cluster-com-mapr-vm2.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm2
172.24.8.7  anaikregtestc73522602-cluster-com-mapr-vm3.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm3
172.24.8.8  anaikregtestc73522602-cluster-com-mapr-vm4.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm4
```

### 2. Add a short alias for each node:

**NOTE:** You can use any short alias. In this example, `vm0`, `vm1`, `vm2`, `vm3`, and `vm4` are used:

```
127.0.0.1    localhost localhost.localdomain localhost4
localhost4.localhostdomain4
::1         localhost localhost.localdomain localhost6
localhost6.localhostdomain6
172.24.8.4  anaikregtestc73522602-cluster-com-mapr-vm0.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm0 vm0
172.24.8.5  anaikregtestc73522602-cluster-com-mapr-vm1.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm1 vm1
172.24.8.6  anaikregtestc73522602-cluster-com-mapr-vm2.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm2 vm2
172.24.8.7  anaikregtestc73522602-cluster-com-mapr-vm3.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm3 vm3
172.24.8.8  anaikregtestc73522602-cluster-com-mapr-vm4.izqafobxqxbuzkv4ledlp3snic.dx.
internal.cloudapp.net anaikregtestc73522602-cluster-com-mapr-vm4 vm4
```

### 3. Perform step 1 and 2 for each node in the cluster.

#### Tez Upgrade Issues

- Preserving configuration on Ubuntu is not supported from EEP 4.1.1 and EEP 5.0.0 (1803) to EEP 6.0.0 (1808) or EEP 5.0.1 (1808).
- Preserving Tomcat configuration is not supported from any previous EEP to EEP 6.0.0 (1808).

- You must manually stop the Tomcat service and delete the Tomcat folder as a precondition if you are updating or upgrading Tez from the following EEPs:
  - EEP 4.0.0
  - EEP 4.1.0

### User Names, Group Names, and LDAP

LDAP configuration allows you to use group names and usernames with spaces, so it is possible to name groups with spaces in them, for example, `domain users`. The following structure is possible in the MapR FileSystem:

```
drwxr-xr-x  - afischer      domain users      0 2018-10-03 16:10 /
user/abc
drwxr-xr-x  - mapr        mapr              0 2018-10-05 16:51 /
user/def
drwxr-xr-x  - dschexnayder domain users      8 2018-10-10 13:30 /
user/xyz
drwxr-xr-x  - mapr        mapr              1 2018-10-09 14:23 /user/
hive
drwxr-xr-x  - mapr        mapr              11 2018-10-10 01:56 /user/
mapr
drwxr-xr-x  - mlitovsky   domain users      0 2018-10-06 11:08 /user/
hjbs
drwxr-xr-x  - pcurtis     domain users      5 2018-10-04 19:33 /user/
jknd
drwxr-xr-x  - mapr        mapr              3 2018-10-08 16:29 /user/
ewkd
drwxr-xr-x  - talvarez    domain users      0 2018-10-04 17:02 /
user/lkd
```

According to [HADOOP-12505](#), the Hadoop community does not allow spaces in group names, and because of that so does Hive. Each time you perform a query in Hive on a group name that has a space, you will see the following exception:

```
-chgrp: 'domain users' does not match expected pattern for group
```

The workaround is to not use spaces in group names or user names.

### HiveServer 2 takes time to start because of `get_all_databases`

Materialized view registry and cache is introduced in [HIVE-14496](#) for Hive 2.3.0.

The goal of the cache is to avoid parsing and creating logical plans for the materialized views at query runtime. When a query arrives, you need to consult this cache and extract the logical plans for the views (which are already parsed) from it. Materialized view registry class scans all databases and tables in each database during initialization and that may cause long time to start HiveServer2.

Property `hive.materializedview.enable.views.registry` is added to control the usage of materialized view registry:

**Property:** `hive.materializedview.enable.views.registry`

**Default value:** `true`

**Description:** In case of a large amount of databases and tables in Hive, usage of materialized view registry and cache force HiveServer2 to scan all of them in order to cache the query plan for a view. This leads to an extremely long time for HiveServer2 to start.

This property is used to disable view registry and cache for this case. To disable materialized view registry and cache, add the following to `hive-site.xml` and restart Hive services.

```
<property>
  <name>hive.materializedview.enable.views.registry</name>
  <value>>false</value>
</property>
```

### Database and Table Names Containing a Dot (.)

HIVE-16907 rejects queries with database and table names that contain a dot (.), and this behavior is backported to Hive 2.3.

Databases and tables that contain a dot (.) in the name are not supported now. For example:

```
{code}
insert into `tdb.t1` select * from t2;
{code}
Throws error:
{code}
FAILED: SemanticException
org.apache.hadoop.hive.ql.parse.SemanticException: Line 1:12 Table or
database name may not contain dot(.) character 'tdb.t1'
{code}
```

Avoid using unsupported characters in database and table names.

### Hive Logging

This section describes Hive logging for Hive 2.1 and later releases and includes information about log splitting.

#### Hive Logging (Hive 2.3 and Later)

For Hive 2.3 and later starting with EEP 6.3.0, this topic describes the folder structure of the Hive logs and includes details about the log-file contents and how log files are installed in multinode installations.

#### Hive Log Folder Structure

Table 1 shows the Hive log folder structure:

Table

Folder or File	Description
<code>\${HIVE_HOME}/log</code>	Root folder for all Hive logs
<pre>hive-\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.out hive-\${ADMIN_USER}-metastore-\${HOSTNAME}.out init_derby_db_\${TIMESTAMP}.log</pre>	Each service has a separate file for logging
<code>\${HIVE_HOME}/log/\${ADMIN_USER}</code>	Root folder for admin cluster logs
<pre>\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.log \${ADMIN_USER}-metastore-\${HOSTNAME}.log \${ADMIN_USER}-cli-\${HOSTNAME}.log</pre>	Cluster admin log files

**Table (Continued)**

Folder or File			Description
<code>\${HIVE_HOME}/log/\${ADMIN_USER}/webhcat/</code>			Root folder for webHcat logs
		<code>webhcat.log</code> <code>webhcat-console.log</code> <code>webhcat-console-error.log</code>	WebHcat log files
<code>\${HIVE_HOME}/log/\${OTHER_USER}</code>			Root folder for a user other than the admin user
		<code>\${OTHER_USER}-cli-\${HOSTNAME}.log</code>	CLI log for a user other than the admin user

In Table 1:

This element	Represents
<code>\${HIVE_HOME}</code>	The Hive home folder, which is usually <code>/opt/mapr/hive/hive</code> .
<code>\${ADMIN_USER}</code>	The admin user of a cluster that runs HiveServer2 and HiveMetastore daemons. Usually, this is the <code>mapr</code> user.
<code>\${HOSTNAME}</code>	The name of the host where the daemon runs.
<code>\${TIMESTAMP}</code>	The date and time of log creation.
<code>\${OTHER_USER}</code>	A user other than the admin user.
<code>\${OTHER_USER}-cli-\${HOSTNAME}.log</code>	The log file that is created when <code>\${OTHER_USER}</code> launches the Hive CLI.

### Content of Log Files

Table 2 shows the content of the log files:

**Table**

File Name	Description
<code>hive-\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.out</code>	Contains information about when the HiveServer2 daemon was started and the PID of the file.
<code>hive-\${ADMIN_USER}-metastore-\${HOSTNAME}.out</code>	Contains information about when the HiveMetastore daemon was started and the PID of the file.
<code>\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.log</code>	Contains information from the HiveServer2 daemons. This file also contains the job progress.
<code>\${ADMIN_USER}-metastore-\${HOSTNAME}.log</code>	Contains information from the HiveMetastore daemons.
<code>\${ADMIN_USER}-cli-\${HOSTNAME}.log</code>	Created when a user runs the Hive CLI over the <code>\${ADMIN_USER}</code> . This file contains the job progress.
<code>\${OTHER_USER}-cli-\${HOSTNAME}.log</code>	Created when a user runs the Hive CLI over the <code>\${OTHER_USER}</code> . This file also contains the job progress.
<code>init_derby_db_\${TIMESTAMP}.log</code>	Created if and only if Hive was configured for Apache Derby through cluster installation.

## Log Files in a Multinode Hive Installation

Table 3 shows a Hive multinode installation (that is, Hive packages installed on different nodes):

**Table**

	Hive Metastore	HiveServer2	HiveWebHCat
node1			
node2			
node3			

See Table 4 for the log configurations:

**Table**

File or Folder Name	node1	node2	node3
hive- <code>{ADMIN_USER}</code> -metastore- <code>{HOSTNAME}</code> .out			
<code>{ADMIN_USER}</code> -metastore- <code>{HOSTNAME}</code> .log			
hive- <code>{ADMIN_USER}</code> -hiveserver2- <code>{HOSTNAME}</code> .out			
<code>{ADMIN_USER}</code> -hiveserver2- <code>{HOSTNAME}</code> .log			
/webhcat/			
webhcat.log			
webhcat-console.log			
webhcat-console-error.log			
/ <code>{ADMIN_USER}</code> /			

### Related concepts

[Disabling Log Splitting of Hive Log Files](#) on page 4378

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

[Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID](#) on page 4378

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metastore log files by process ID.

### Hive Logging (Hive 2.1 and Later)

For certain Hive 2.1 and later releases, this topic describes the folder structure of the Hive logs and includes details about the log-file contents and how log files are installed in multinode installations.

The Hive log information in this topic applies to Hive 2.1 and later releases beginning with the 1803 release-date identifier. Included are the Hive releases in Ecosystem Packs (EEPs) 3.0.3, 3.0.4, 3.0.5, 4.1.1, 4.1.2, 4.1.3, 4.1.4, 5.0.x, 6.0.x, 6.1.1, and 6.2.0. For more information about release-date identifiers, see [Release History for EEPs](#) on page 5822.

### Default log folder structure

Hive logs have the following folder structure:

```

{HIVE_HOME}/log
{HIVE_HOME}/log/hive-{ADMIN_USER}-hiveserver2-{HOSTNAME}.out
{HIVE_HOME}/log/hive-{ADMIN_USER}-metastore-{HOSTNAME}.out
{HIVE_HOME}/log/init_derby_db_{TIMESTAMP}.log
{HIVE_HOME}/log/{ADMIN_USER}

```

```

${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log
${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-metastore-${HOSTNAME}.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat-console.log
${HIVE_HOME}/log/${ADMIN_USER}/webhcat/webhcat-console-error.log
${HIVE_HOME}/log/${OTHER_USER}
${HIVE_HOME}/log/${OTHER_USER}/${OTHER_USER}-hiveserver2-${HOSTNAME}.log

```

Here:

```

${HIVE_HOME} - Hive home folder. Usually this is /opt/mapr/hive/hive.
${ADMIN_USER} - Admin user of cluster that runs HiveServer2 and
HiveMetastore daemons. Usually this is mapr.
${HOSTNAME} - Name of the host where a daemon runs.
${TIMESTAMP} - Date and time of log creation.
${OTHER_USER} - Not an admin user.

```

### Content of log files

Files ``${HIVE_HOME}/log/hive-${ADMIN_USER}-hiveserver2-${HOSTNAME}.out`` and ``${HIVE_HOME}/log/hive-${ADMIN_USER}-metastore-${HOSTNAME}.out`` contain information about when HiveServer2 and HiveMetastore daemons are started, and what are their PIDs.

Files ``${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log`` and ``${HIVE_HOME}/log/${ADMIN_USER}/${ADMIN_USER}-hiveserver2-${HOSTNAME}.log`` contain information from HiveServer2 and HiveMetastore daemons. File ``${ADMIN_USER}-hiveserver2-${HOSTNAME}.log`` also contains job progress.

The ``${HIVE_HOME}/log/${OTHER_USER}/${OTHER_USER}-hiveserver2-${HOSTNAME}.log`` file is created when somebody runs Hive CLI over the ``${OTHER_USER}``. The ``${OTHER_USER}-hiveserver2-${HOSTNAME}.log`` file contains job progress.

The ``${HIVE_HOME}/log/init_derby_db-${TIMESTAMP}.log`` file is created if and only if Hive was configured for Derby Db through cluster installation.

### Log files on multi node Hive installation

Consider Hive multi node installation (that is Hive packages are installed on different nodes). See Table 1:

Table

	Hive Metastore	HiveServer2	HiveWebHCat
node1			
node2			
node3			

See Table 2 for log configurations.

Table

	node1	node2	node3
<code>`\${HIVE_HOME}/logs/hive-\${ADMIN_USER}-metastore- \${HOSTNAME}.out`</code>			
<code>`\${HIVE_HOME}/logs/\${ADMIN_USER}/\${ADMIN_USER}-metastore- \${HOSTNAME}.log`</code>			
<code>`\${HIVE_HOME}/logs/hive-\${ADMIN_USER}-hiveserver2- \${HOSTNAME}.out`</code>			

Table (Continued)

	node1	node2	node3
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/\${ADMIN_USER}-hiveserver2-\${HOSTNAME}.log</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/webhcat.log</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/webhcat-console.log</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}/webhcat/webhcat-console-error.log</code>			
<code>\${HIVE_HOME}/logs/\${ADMIN_USER}</code>			

**Related concepts**

[Disabling Log Splitting of Hive Log Files](#) on page 4378

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

[Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID](#) on page 4378

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metastore log files by process ID.

**Disabling Log Splitting of Hive Log Files**

By default, Hive log files are split into HiveServer2 and Metastore log files, but you can disable log splitting by editing the `hive-env.sh` file.

This information is valid for Hive-2.1+ starting from the EEP-1803 release.

**Disabling Log Splitting of Hive Log Files**

You can disable splitting the Hive log files into HiveServer2 and Metastore log files. To write all logs to the `hive.log` file, use these steps:

1. Edit the `hive-env.sh` file to set `SPLIT_HIVE_LOGS_INTO_FILES` property to `false`.

```
export SPLIT_HIVE_LOGS_INTO_FILES="false"
```

**NOTE:** To restore the default behavior from your previous Hive log configuration, set the `SPLIT_HIVE_LOGS_INTO_FILES` property to `true`, or comment out this property and restart Hive services.

2. Restart Hive services.

**Splitting Hive Logs into HiveServer2 and Metastore logs by Process ID**

Starting from the 1904 release, you can split Hive log files into HiveServer2 and Metastore log files by process ID.

To enable this feature, you must create a `hive-log4j2.properties` file, if one does not already exist, and then edit it:

1. If the `hive-log4j2.properties` file does not exist, create it from the template:

```
cp /opt/mapr/hive/hive-<version>/conf/
hive-log4j2.properties.template /opt/mapr/hive/hive-<version>/conf/
hive-log4j2.properties
```

2. Edit the `hive-log4j2.properties` file to replace Daily Rolling File Appender (DRFA) with the PID appender:

```
#property.hive.root.logger = DRFA
property.hive.root.logger = PID
#appenders = console, DRFA
appenders = console, PID
```

3. Restart Hive services.

The resultant Hive log structure is as follows:

The HiveServer2 log is located at:

```
${HIVE_HOME}/log/<ADMIN_USER>/
<ADMIN_USER>-hiveserver2-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where:

- `${HIVE_HOME}` is the home folder for Hive.
- `<ADMIN_USER>` is the administrator user of the cluster. Typically, `mapr`.
- `<HOSTNAME>` is the host where HiveServer2 log file is placed.
- `<PID>` is the process ID of HiveServer2.

The Metastore log is located at:

```
${HIVE_HOME}/log/<ADMIN_USER>/
<ADMIN_USER>-metastore-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where:

- `${HIVE_HOME}` is the home folder for Hive.
- `<ADMIN_USER>` is the administrator user of the cluster. Typically, `mapr`.
- `<HOSTNAME>` is the host where Hive Metastore log file is placed.
- `<PID>` is the process ID of Hive Metastore.

### Logging CLI session

After splitting logs for HiveServer2 and Hive Metastore, CLI log appears separately for each CLI session at `${HIVE_HOME}/logs/<USERNAME>`.

A log file is created for every launched CLI session:

```
${HIVE_HOME}/log/<USERNAME>/
<USERNAME>-hiveserver2-<HOSTNAME>.log.<PID>@<HOSTNAME>
```

Where `<PID>` is process identifier of the CLI session.

## Viewing Hive Audit Logs

Starting in EEP 7.1.0, you can view Hive audit logs for connected, disconnected, and total connected users.

To view audit logs, add the following property in the `hive-site.xml` file:

```
<property>
  <name>hive.enable.full.list.of.connected.users</name>
  <value>true</value>
</property>
```

By default, logs are updated every five seconds.

The following table describes the Hive Parameters used to manage the user audit logs:

Parameter	Default value	Description
<code>hive.enable.full.list.of.connected.users</code>	false	Enables the logging of the users currently connected to Hive when set to true. Use for debugging purposes only.
<code>hive.full.list.of.connected.users.update.interval</code>	5	Enables the log updates for currently connected Hive users in seconds. Must be used with the <code>hive.enable.full.list.of.connected.users</code> parameter. Use for debugging purposes only.

## How to View Audit Logs

Enable the `hive.enable.full.list.of.connected.users` property in `hive-site.xml` file. You can view audit logs for connected, disconnected, and total connected users in HiveServer2 logs located in `${HIVE_HOME}/logs/mapr/mapr-hiveserver2-<hostname>.log` directory.

The following examples show you how the audit logs look in different scenarios:

### Logs display for new user connection

Log entries for connected users provide the current session ID, username, IP address of the user, and the authentication type.

```
INFO [HiveServer2-Handler-Pool:
Thread-51] HiveSessionImpl.audit:
Connected:
sessionId=4c25b6d6-6e8e-4d56-83ba-52ea
271d0545 user=mapr ip=192.168.33.11
auth=MAPRSASL
```

### Logs display for disconnected user

Log entries for disconnected users provide the current session ID, username, IP address of the user, and the authentication type.

```
INFO [HiveServer2-Handler-Pool:
Thread-51] HiveSessionImpl.audit:
Disconnected:
sessionId=4c25b6d6-6e8e-4d56-83ba-52ea
271d0545 user=mapr ip=192.168.33.11
auth=MAPRSASL
```

### Logs display for total connected users

Log entries for total connected users start with a message `-Start of connected users list`, and provides the current session ID, username, IP address of the user, operation count, active time, idle time,

authentication type, and end with a message- End of the connected user's list.

```
INFO [pool-4-thread-1]
SessionManager.audit: Start of the
connected users list

INFO [pool-4-thread-1]
SessionManager.audit:
sessionId=c6261d49-1a71-4404-8cad-9cac
11a28151 user=mapr ip=192.168.33.11
operationCount=0 activeTime(s)=268
IdleTime(s)=268, auth=MAPRSASL

INFO [pool-4-thread-1]
SessionManager.audit:
sessionId=36b4d8d4-f201-43da-90eb-cb68
3d343b80 user=mapr ip=192.168.33.11
operationCount=0 activeTime(s)=198
IdleTime(s)=197, auth=MAPRSASL

INFO [pool-4-thread-1]
SessionManager.audit:
sessionId=32b50c8a-28ca-46a5-bbcd-963c
9b22af7f user=mapruser1
ip=192.168.33.11 operationCount=0
activeTime(s)=4 IdleTime(s)=4,
auth=PAM

INFO [pool-4-thread-1]
SessionManager.audit: End of the
connected user's list
```

## How to Audit a Hive Query

The audit log in HiveServer2 allows you to trace the activities of a Hive query. The log entries for a Hive query includes username, user's IP address, query ID, query type, and query string.

To audit a Hive query, run any Hive query and then see the HiveServer2 logs located in `${HIVE_HOME}/logs/mapr/mapr-hiveserver2-<hostname>.log` directory.

```
INFO [HiveServer2-Background-Pool: Thread-54]
Driver.audit: user=mapr ip=192.168.33.11
queryId=mapr_20210426155754_ace67f82-9a0c-4d0e-9ac5-c529b9798ec7 query
type=SHOWTABLES queryStr=show tables
```

## HttpFS

HttpFS provides a service that enables you to submit HTTP REST calls to distributed file systems. You can use HttpFS to perform read and write operations on the file system.

Beginning with release 7.1.0, HttpFS is a part of `mapr-hadoop`. For HttpFS to work correctly, you must install the following Hadoop packages:

- `mapr-hadoop-util`
- `mapr-hadoop-client`
- `mapr-hadoop-core`

For more information about the Hadoop packages, see [Installing Hadoop and YARN](#) on page 233.

This section includes the following topics:

### Authentication on Secure Clusters for HttpFS

In secure clusters, HttpFS can use any of the following authentication methods:

- HttpFS authentication, such as native security (MapR-SASL)
- Kerberos (for which additional configuration is required)
- Plain security using PAM, which is determined automatically

In a secure cluster, HttpFS runs a script to set the following properties by default. In a non-secure cluster, you must add the following properties manually to the `httpfs-site.xml` file:

```
httpfs.hadoop.authentication.type=multiauth
httpfs.authentication.type=multiauth
```

### Configuring HttpFS

You can configure the following features to perform distributed file system operations securely through HttpFS.

The following topics describe how to configure various security mechanisms for HttpFS.

#### Kerberos Authentication for HttpFS

Complete the following steps to enable Kerberos security on nodes that run the HttpFS service:

*Modify the `httpfs-site.xml` File*

#### About this task

A Kerberos-ready version of the `httpfs-site.xml` file called `httpfs-site.xml.kerberos` is provided in `/opt/mapr/hadoop/hadoop-3.3.x/etc/hadoop/httpfs-site.xml`. Edit this file and specify the Kerberos principal name for the nodes running HttpFS, restart the HttpFS server, and then test the set-up. Each step is explained here.

To set up the `httpfs-site.xml` file for each node running the HttpFS service, follow these steps:

#### Procedure

1. Assign a new name to the existing `httpfs-site.xml` file (to preserve the original version when the file gets overwritten in step 2):

```
cd /opt/mapr/hadoop/hadoop-3.3.x/etc/hadoop
cp httpfs-site.xml httpfs-site.xml.original
```

2. Edit the `httpfs-site.xml` file, and insert the principal name as shown, substituting your fully qualified domain name and realm for `<node_name>@<REALM>`:

```
<property>
<name>httpfs.authentication.type</name>
<value>kerberos</value>
</property>

<property>
<name>httpfs.hadoop.authentication.type</name>
<value>kerberos</value>
</property>

<property>
<name>httpfs.authentication.kerberos.principal</name>
<value>HTTP/<node_name>@<REALM></value>
</property>

<property>
<name>httpfs.authentication.kerberos.keytab</name>
<value>/opt/mapr/conf/mapr.keytab</value>
</property>

<property>
<name>httpfs.hadoop.authentication.kerberos.principal</name>
<value>mapr/<node_name>@<REALM></value>
</property>

<property>
<name>httpfs.hadoop.authentication.kerberos.keytab</name>
<value>/opt/mapr/conf/mapr.keytab</value>
</property>

<property>
<name>httpfs.authentication.kerberos.name.rules</name>
<value>DEFAULT</value>
</property>
```

3. Restart the HttpFS server so the changes will take effect:

```
maprcli node services -name httpfs -action restart -nodes <node_name>
```

4. Test that security is in place by entering the following command to create a file in the file system. The command will fail if security is not set up correctly:

```
curl --negotiate -u : -b ~/cookiejar.txt -c ~/cookiejar.txt -i -X PUT
"http://<node_name>:14000/webhdfs/v1/user/mapr/some_file?op=MKDIRS"
```

## PAM Authentication for HttpFS

### About this task

Complete the following steps to enable PAM authentication for HttpFS.

## Procedure

1. Add the `httpfs.hadoop.authentication.type` and `httpfs.authentication.type` properties to the `/opt/mapr/hadoop/hadoop-3.3.4/etc/hadoop/httpfs-site.xml` file, as shown:

```
<property>
  <name>httpfs.hadoop.authentication.type</name>
  <value>multiauth</value>
</property>

<property>
  <name>httpfs.authentication.type</name>
  <value>multiauth</value>
</property>
```

**NOTE:** On secure clusters, the `multiauth` authentication is enabled by default.

2. Restart the HttpFS service:

```
maprcli node services -name httpfs -action restart -nodes <space
delimited list of nodes>
```

3. After restarting the service, run cURL with the PUT operation, as shown in this example:

**NOTE:** If HttpFS is configured with plain authentication through PAM, the cURL request must contain a username and password.

```
curl -X PUT "https://mapr:mapr@<node_name>:14000/webhdfs/v1/tmp/example?
op=mkdirs"
```

## SSL Security for HttpFS

### About this task

On a secure cluster, HttpFS uses the secure-by-default configuration. Use the following topics to explicitly enable custom security on HttpFS.

You also need to enable SSL if [custom security](#) is enabled.

### Verifying SSL Security for HttpFS

You need to run `curl` commands to verify that HTTPS is enabled for HttpFS.

## Procedure

Run one of the following `curl` commands to check that HTTPS is enabled. These commands fetch the file `some_file.txt` from the file system under `/user/mapr` and attempt to open it securely over HTTPS.

- To check if HTTPS is enabled, run the following command

```
curl -u <user_name> -k
  "https://<node_name>:14000/webhdfs/v1/user/mapr/some_file.txt?op=open"
```

- If you configured Hue to use SSL encryption with certificate-based authentication for communication with HttpFS, run the following command

- ```
curl -u <user_name> -k
  --cert /opt/mapr/hue/hue-<version>/cert.pem
  --key /opt/mapr/hue/hue-<version>/hue_private_keystore.pem
  "https://<node_name>:14000/webhdfs/v1/user/mapr/some_file.txt?op=open"
```

### Enabling SSL Security for HttpFS

You can enable SSL security for HttpFS using an `ssl_keystore` and `ssl_truststore`. These are generated automatically for a secure cluster in `/opt/mapr/conf/`. When using SSL on nonsecure clusters, you must manually generate a keystore and truststore.

### About this task

To enable SSL security for HttpFS with credential provider, use the following steps:

### Procedure

1. Enable SSL in `etc/hadoop/httpfs-site.xml` configuration file:

```
<property>
  <name>httpfs.ssl.enabled</name>
  <value>true</value>
  <description>
    Whether SSL is enabled. Default is false, i.e. disabled.
  </description>
</property>
```

2. Use the credential provider to create secure SSL passwords:

```
hadoop credential create ssl.server.keystore.password -value 123 \
  -provider localjceks://file/home/mapr/httpfs.jceks
```

```
hadoop credential create ssl.server.keystore.keypassword -value 123 \
  -provider localjceks://file/home/mapr/httpfs_keypassword.jceks
```

3. Run the Java `keytool` command to create an SSL certificate for the HttpFS server:

```
keytool -genkey -alias jetty -keyalg RSA
```

You will be prompted to answer a series of questions to create a keystore file named `.keystore`.

- You must enter the same password for “keystore password” as the value of the property `ssl.server.keystore.password` set while creating secure SSL passwords.
- You must answer “What is your first and last name?” (i.e. “CN”) with the host name of the machine where the HttpFS Server will be running.

The `.keystore` file will be stored in the HttpFS user home directory.

4. Configure the `etc/hadoop/ssl-server.xml` file to set the SSL keystore location:

```
<property>
  <name>ssl.server.keystore.location</name>
  <value>/home/mapr/.keystore</value>
  <description>Keystore to be used. Must be specified.
</description>
</property>
```

- Configure the `/opt/mapr/hadoop/hadoop-3.3.4/etc/hadoop/httpfs-site.xml` file with the following property to set credential provider path and enable the credential provider:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>localjceks://file/home/lmccay/aws.jceks</value>
  <description>Path to interrogate for protected credentials.</
description>
</property>
```

- Restart the HttpFS server:

```
maprcli node services -action restart -name httpfs -nodes <node>
```

### User Impersonation for HttpFS

If you want HttpFS to impersonate a user from a set of hosts, or to impersonate a user that belongs to a set of groups, you can configure the proxy-user functionality. Configuring this functionality enables the proxy user to perform “doAs” operations. To configure proxy-user functionality, add configuration properties to the `httpfs-site.xml` and `core-site.xml` files.

Complete the following steps to configure user impersonation for HttpFS:

- Add the following configuration properties to the `httpfs-site.xml` file:
  - `httpfs.proxyuser.#USER#.hosts`
  - `httpfs.proxyuser.#USER#.groups`
- Replace `#USER#` with the user name of the proxy that can perform “doAs” operations. For the host property, you can add a list of host names as the value. For the group property, you can add a list of groups as the value. Alternatively, you can add a wildcard character (`*`) as the value for host and group properties. To add multiple users, copy the property and replace `#USER#` with the proxy user name.

#### Host Example

```
<property>
  <name>httpfs.proxyuser.mapr.hosts</name>
  <value>*</value>
</property>
```

#### Group Example

```
<property>
  <name>httpfs.proxyuser.mapr.groups</name>
  <value>*</value>
</property>
```

To use impersonation, issue a cURL command with the `doas=<impersonated_user's name>` parameter.

#### Example 1

Where `user.name` is `mapr` and `doas` (or the impersonated user's name) is **sampleusername**.

```
curl -i -X PUT -T one
"http://<node_name>:14000/webhdfs/v1/user/mapr/TEST/one
?op=CREATE&user.name=mapr&doas=sampleusername&data=true"
-H "Content-Type:application/octet-stream"
```

#### Example 2

For any user (and password) other than the `mapr` user (for example, `test_user1`), set the `hadoop.proxyuser.<user_name>.hosts</name>` property in the `/opt/mapr/hadoop/hadoop-3.3.x/etc/hadoop/httpfs-site.xml` file, as shown.

```
<property>
  <name>hadoop.proxyuser.<test_user1>.hosts</name>
  <value>*</value>
</property>
```

Run cURL.

Where `trueuser.name` is `test_user1` and `doas` (or the impersonated user's name) is `test_user2`.

```
curl -u fred -i -X PUT -T /etc/hosts --header "Content-Type:application/
octet-stream"
"http://<node_name>:14000/webhdfs/v1/<path_to_test_file>
?op=CREATE&doas=<test_user2>&data=true&user.name=<test_user1>"
```

### Network Timeout for HttpFS

The network timeout is the amount of idle time (in milliseconds) that can pass before the HttpFS network connection closes automatically. Depending on your installed EEP, you can use one of the following properties to control the network timeout:

EEP*	Timeout Property	Default Timeout (ms)	Config File
9.0.0 and later	<code>hadoop.http.idle_timeout.ms</code>	60000	<code>/opt/mapr/hadoop/hadoop-&lt;version&gt;/etc/hadoop/httpfs-site.xml</code>
7.0.0 through 8.1.0	<code>hadoop.http.max_idle_time.ms</code>	10000	<code>/opt/mapr/httpfs/httpfs-&lt;version&gt;/etc/hadoop/httpfs-site.xml</code>

\*For a guide to the supported EEPs, see [EEP Support and Lifecycle Status](#) on page 5760.

If your applications require the network connection to remain open longer than the default timeout, consider increasing the timeout value. To change the timeout value:

1. Add a timeout property to the `httpfs-site.xml` file. For the appropriate property and the location of the `httpfs-site.xml` file, see the nearby table.

For example, in a cluster installed with EEP 7.0.0, adding the following property to `/opt/mapr/httpfs/httpfs-<version>/etc/hadoop/httpfs-site.xml` sets a timeout value of 30 seconds:

```
<property>
<name>hadoop.http.max_idle_time.ms</name>
<value>30000</value>
</property>
```

2. Restart the HttpFS server so the changes take effect:

```
maprcli node services -name httpfs -action restart -nodes <node_name>
```

### Finishing HttpFS Configuration Changes

After making configuration changes for the `mapr-httpfs` package, run the `configure.sh` script on all nodes where the `mapr-httpfs` package was installed:

```
sudo bash /opt/mapr/server/configure.sh -R
```

## Troubleshooting HttpFS

### About this task

To debug authentication issues, follow these steps:

### Procedure

1. Edit the `log4j` properties file located at `/opt/mapr/hadoop/hadoop-3.3.x/etc/hadoop/httpfs-log4j.properties` and insert the following lines to activate debug capabilities:

```
log4j.logger.org.apache.hadoop.fs.http.server=DEBUG, httpfs
log4j.logger.org.apache.hadoop.lib=DEBUG, httpfs
log4j.logger.org.apache.hadoop.security.authentication.server=DEBUG,
httpfs
```

2. Search the logs located at `/opt/mapr/hadoop/hadoop-3.3.x/logs` for the words *ERROR* or *Exception*.

## Hue

Hue is the open source UI that interacts with Apache Hadoop and its ecosystem components, such as Hive, Pig, and Oozie. It is also a framework for creating interactive Web applications.

For information about Hue versions, see the [Ecosystem Support Matrix](#).

Hue is supported on the following browsers:

Windows	Linux	Mac
Chrome	Chrome	Chrome
Firefox 3.6+	Firefox 3.6+	Firefox 3.6+
Safari 5+		Safari 5+
Internet Explorer 8+		

### Hue Feature Support

The following table lists supported and unsupported Hue functionality:

Supported	Not Supported
<p>Query editors</p> <ul style="list-style-type: none"> <li>• Hive (for performing queries on Apache Hive)</li> <li>• Impala (for submitting interactive SQL and HiveQL queries)</li> <li>• DB Query (for viewing data in MySQL, PostgreSQL, Oracle and Sqlite)</li> <li>• Pig (for submitting Pig scripts)</li> <li>• Job Designer (for creating and submitting MapReduce/Streaming/Java jobs)</li> <li>• Spark (beta feature for submitting Spark jobs for hue-3.9.0/3.10.0)</li> <li>• Drill (for performing queries on Apache Drill through JDBC) in hue-3.12</li> </ul> <p>Data browsers</p> <ul style="list-style-type: none"> <li>• Metastore Tables (for managing databases, tables, and partitions of the Hive metastore)</li> <li>• HBase browser (for creating, editing, and searching tables)</li> <li>• Sqoop Transfer (for transferring bulk data between Hadoop and various types of structured datastores)</li> </ul> <p>Workflows</p> <ul style="list-style-type: none"> <li>• Oozie (for creating and running workflow and coordinator jobs)</li> </ul> <p>Hue 4.X supports ADLS browser for accessing files and directories in Azure Data Lake Store.</p> <p>S3 Browser (for accessing files and directories in Amazon S3)</p> <p>File Browser (for accessing files and directories in file system)</p> <ul style="list-style-type: none"> <li>• Job Browser (for accessing MapReduce applications)</li> <li>• User Admin (for adding, deleting, and managing Hue users and groups)</li> </ul>	<p>Hue integration with the following components is not supported:</p> <ul style="list-style-type: none"> <li>• Sentry 1.6, 1.7 on a secure cluster that uses data-fabric-SASL authentication.</li> </ul> <p> <b>NOTE:</b> Sentry 1.6, 1.7 on a secure cluster that uses Kerberos authentication is supported.</p> <ul style="list-style-type: none"> <li>• Solr Search</li> <li>• Zookeeper</li> </ul>

### Configure Hue

After you install Hue, perform the following configuration steps:

1. Complete the general configuration steps. This includes integrating Hue with ResourceManager and HttpFS.
2. Perform the steps to integrate each additional component that you want to use with Hue.
  - Hive
  - HPE Ezmeral Data Fabric Database
  - Impala

- Oozie
- Spark

You may also want to:

- Configure Security
- Configure DB Query
- Configure Hue Interface Authentication

**NOTE:** The `hue.ini` file is the main configuration file for running Hue on a cluster. This file is located at `/opt/mapr/hue/hue-<version>/desktop/conf/hue.ini`. When you update the value of a property in the `hue.ini`, remove any hashes (`##`) that appear directly before the property name. You must also restart Hue for these changes to take effect.

### Configure General Hue Settings

The following topics provide instructions for configuring general Hue settings:

*Enable User Impersonation for Hue*

#### About this task

To enable Hue to submit requests on behalf of any other user, complete the following steps:

#### Procedure

1. Verify or configure the following lines to the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml` file for all nodes running ResourceManager:

```
<property>
  <name>hadoop.proxyuser.<default_user>.hosts</name>
  <value>*</value>
</property>

<property>
  <name>hadoop.proxyuser.<default_user>.groups</name>
  <value>*</value>
</property>
```

2. To enable the Hue file browser to view files in the filesystem, add the following proxy user settings in the configuration block of the `httpfs-site.xml`:

```
<!-- Hue HttpFS proxy user setting -->
<configuration>
  <property>
    <name>httpfs.proxyuser.<default_user>.hosts</name>
    <value>*</value>
  </property>

  <property>
    <name>httpfs.proxyuser.<default_user>.groups</name>
    <value>*</value>
  </property>
</configuration>
```

3. Perform any additional Hue configurations and then restart Hue so that the changes will take effect. See [Starting the Hue Webserver](#).

In most cases, `mapr` is the `<default_user>`. The `<default_user>` you specify must also be the `default_user` that is configured in the `[desktop]` section of the `hue.ini`.

**NOTE:** Based on the ecosystem components that you want to use, additional configuration may be required.

*Disable an Application in the Hue Interface (optional)*

### About this task

If you want to disable an application (such as Impala), follow these steps:

### Procedure

1. In the `[desktop]` section of the `hue.ini` file, uncomment the `# app_blacklist=` statement and insert the name of the app you want to disable (`impala` in this example).

**NOTE:** Do not remove `search` from the `app_blacklist`. The Hue UI will not work if the search application is enabled.

```
# Comma-separated list of apps not to load at server startup.
# Note that rdbms is the name used for dbquery.
app_blacklist=spark,zookeeper,search,impala,sqoop,rdbms
```

**NOTE:** After removing an application from `app_blacklist`, you must update the Hue internal database to create the tables required for the application that was enabled:

```
sudo /opt/mapr/server/configure.sh -R
```

2. Once all changes are made, restart Hue so the changes will take effect.

**NOTE:** You can re-enable a blacklisted application at any time, and then restart Hue.

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

*Change the File Size Restriction for the File Browser (optional)*

### About this task

The Hue File Browser will not open files that are 1.0 GB or greater. Starting with Hue 4.2, file size limitation equals 1.0 GB with no way to modify it.

#### *Prevent Hue from Creating User Home Directories*

Describes how to disable the automatic creation of user home directories.

By default, Hue creates a directory in the filesystem for a user when the user logs in to the Hue service.

For example, if a `/user` volume is configured in the filesystem, Hue creates a `/user/<username>` directory in the volume each time a user logs in to the Hue service. If a quota is not placed on that `/user` volume, a user could potentially place an unlimited amount of data in the volume.

If you do not want Hue to create a home directory for each user that logs in to the Hue service, disable the `ensure_home_directory` option in the `[desktop]` `[[auth]]` section of the `hue.ini` file, as shown:

```
[desktop]
[[auth]]
ensure_home_directory=false
```

Restart the Hue service for the setting to take effect.

**NOTE:** This functionality is available by default starting in EEP 7.1.0. Previous versions of EEP can obtain this functionality through a patch. See [Applying a Patch](#) on page 465.

### Configure Hue Interface Authentication

You can configure the following user authentication methods for the Hue interface:

Authentication Method	Description
Hue User Administration	Use the Hue interface to create and manage user accounts for each Hue user.
LDAP	Import LDAP users into Hue and then use LDAP to authenticate users with their LDAP credentials. For more information, see <a href="#">Configure Hue with LDAP</a> .
PAM	Use multiple PAM modules to authenticate users. PAM authentication is configured by default. When you use this method, you cannot edit users in the Hue interface.

#### *Using a Non-Default Authentication Method*

#### About this task

The default authentication method is PAM.

To edit the authentication method used for the Hue interface, complete the following steps:

#### Procedure

1. Set the `backend` property equal to your selected authentication method. For example, to use Hue's user authentication, select `desktop.auth.backend.AllowFirstUserDjangoBackend`.
2. If you choose not to use PAM, comment the `pam_service` property.

#### Example

Example hue.ini configured to use PAM Authentication

```
[[auth]]
# Authentication backend. Common settings are:
# - django.contrib.auth.backends.ModelBackend (entirely Django backend)
# - desktop.auth.backend.AllowAllBackend (allows everyone)
# - desktop.auth.backend.AllowFirstUserDjangoBackend
# (Default. Relies on Django and user manager, after the first login)
# - desktop.auth.backend.LdapBackend
# - desktop.auth.backend.PamBackend - WARNING: existing users in Hue may be
unaccessible if they not exist in OS
# - desktop.auth.backend.SpnegoDjangoBackend
# - desktop.auth.backend.RemoteUserDjangoBackend
# - libsaml.backend.SAML2Backend
# - libopenid.backend.OpenIDBackend
# - liboauth.backend.OAuthBackend
# (Support Twitter, Facebook, Google+ and LinkedIn
backend=desktop.auth.backend.PamBackend

# The service to use when querying PAM.
pam_service=sudo sshd login
```

### Configure Hue with LDAP

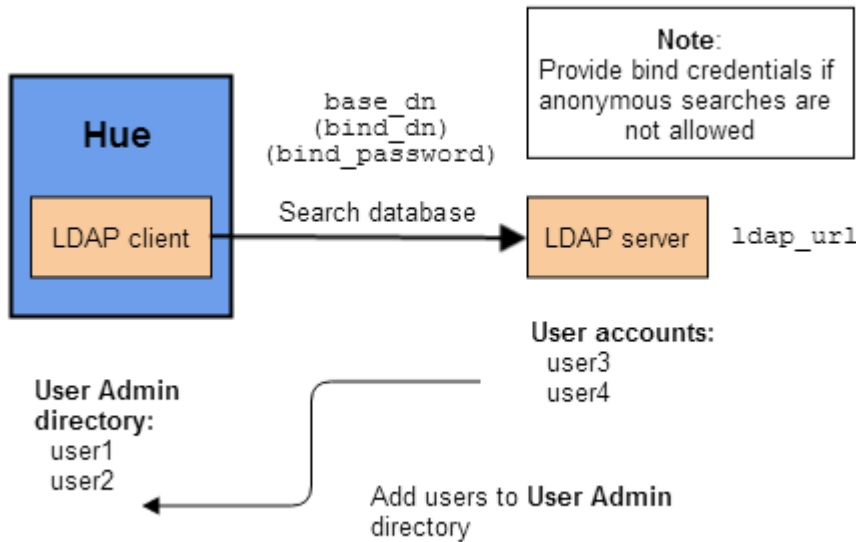

If you use LDAP to authenticate users, you can retrieve user account information from your LDAP database and import it directly into Hue's `User Admin` directory. This way, you do not have to use the Hue interface to create user accounts for each Hue user individually.

Once you import users, you can also use LDAP with Hue to authenticate users with their LDAP credentials. Each of these tasks is explained in the following sections:

#### Setting up Users from an LDAP Database

##### About this task

This diagram shows how the LDAP client embedded in Hue searches the LDAP server's database for user names, and then adds them to the `User Admin` directory for Hue.

The following table shows the parameters you need to set in the `ldap` section of the `hue.ini` file so you can import users.

**WARNING:** The `hue.ini` file is located at `/opt/mapr/hue/hue-<version>/desktop/conf/`.

Parameter	Description	Comments
<code>ldap_url</code>	The URL of your LDAP server.	
<code>base_dn</code>	Top of the search tree, which defines the search scope.	
<code>bind_dn</code>	Distinguished name (DN) of the user to bind as.	Can be omitted for anonymous searches.
<code>bind_password</code>	Password of the bind user.	Can be omitted for anonymous searches.
<code>user_filter</code>	Limits the scope of the search by applying a filter.	This parameter is optional.
<code>user_name_attr</code>	The attribute used for username in the LDAP schema.	Examples: <code>cn</code> (for common name) or <code>uid</code> (for user ID).

To set up Hue users by importing information from an LDAP database:

**Procedure**

1. Establish communication with the LDAP server by setting the `ldap_url` parameter in the `ldap` section of the `hue.ini` file. Uncomment the line and change the value from the default ( `ldap://localhost` ) to the URL for your LDAP server.

```
# URL of the LDAP server
##ldap_url=ldap://localhost
```

2. Provide the `base_dn` information to define the search scope. Uncomment the line where `base_dn` is defined and replace with your `base_dn`.

```
# The search base for finding users and groups
## base_dn="DC=mycompany,DC=com"
```

3. If your LDAP server does not support anonymous searches, you need to provide the `bind_dn` and `bind_password`. Uncomment the lines with these parameters and change the values to your `bind_dn` and your `bind_password`.

```
# Distinguished name of the user to bind as -- not necessary if the LDAP
server
# supports anonymous searches
## bind_dn="CN=ServiceAccount,DC=mycompany,DC=com"

# Password of the bind user -- not necessary if the LDAP server
supports
# anonymous searches
## bind_password=
```

4. If you want to narrow the scope of the directory search, specify a `user_filter` in the `users` section under the `ldap` section of the `hue.ini` file. This is optional.

```
[[[users]]]

# Base filter for searching for users
## user_filter="objectclass=*"
```

5. Set the `user_name_attr` parameter in the `users` section under the `ldap` section of the `hue.ini` file. If your LDAP directory schema does *not* use the attribute `sAMAccountName` for the username, uncomment the line and change the value of the `user_name_attr` to the attribute you use. For example, if the directory schema uses the `uid` attribute, change the value of the parameter as shown:

```
[[[users]]]

# The username attribute in the LDAP schema
## user_name_attr=sAMAccountName
```

```
user_name_attr=uid
```

6. Restart `httpfs` so `ldap` settings will take effect.
7. Restart Hue once all configuration changes have been made so the changes will take effect.

## Authenticating Hue Users with LDAP Credentials

This section explains how to edit the `ldap` section of the `hue.ini` file to enable Hue user authentication with LDAP credentials. These instructions assume you have completed the steps in [Setting up Users from an LDAP Database](#).

**WARNING:**

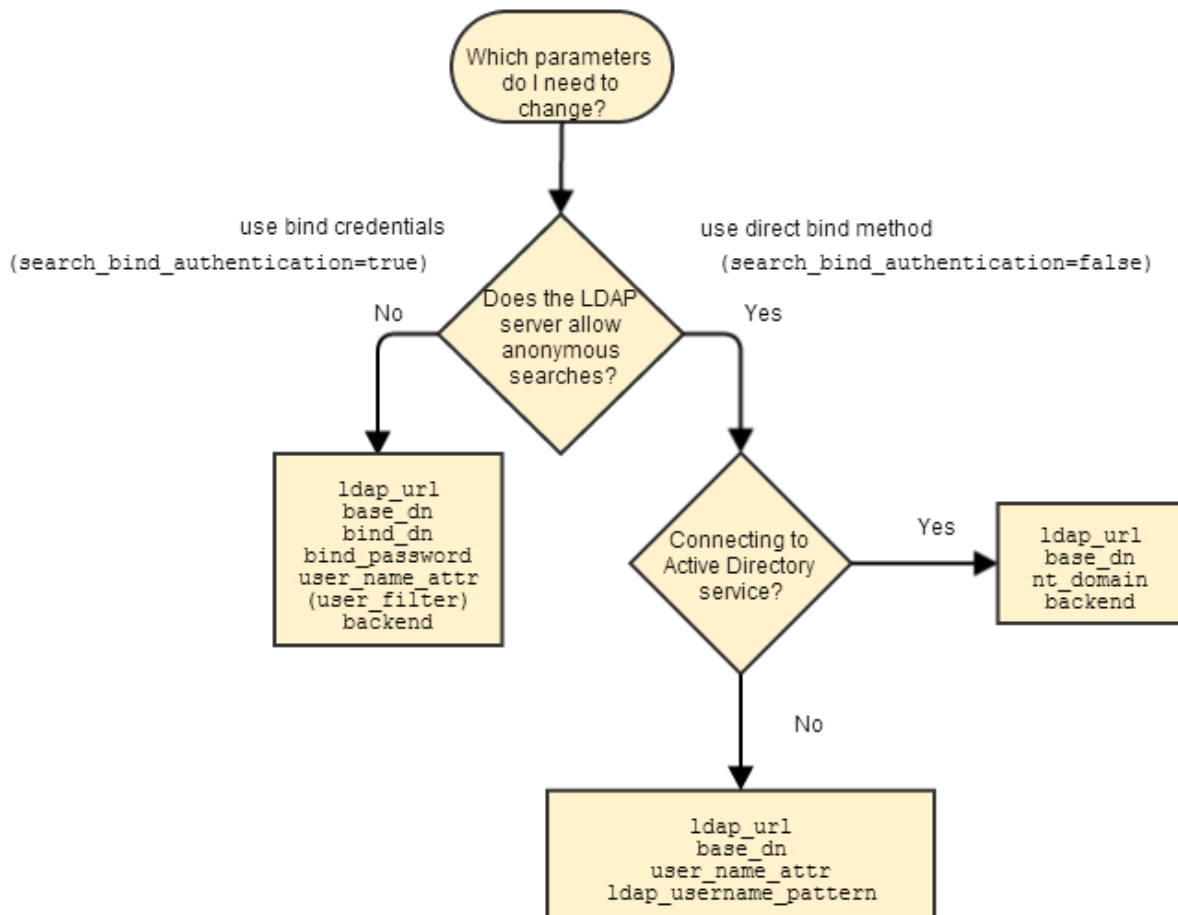

If you switch to authentication through LDAP credentials, the Hue User Admin users will lose superuser privileges unless you take one of the following actions:

- Import one or more superuser accounts from LDAP and assign them superuser permission.
- If you have already enabled the LDAP authentication back end, log into Hue using the LDAP back end, which will create an LDAP user. Next, disable the LDAP authentication back end and use User Admin to give the superuser permission to the new LDAP user.

Before you edit the parameters in the `hue.ini` file, determine whether your LDAP server allows anonymous searches.

- If anonymous searches *are* allowed, use the **direct bind** method.
- If anonymous searches *are not* allowed, use bind credentials (also known as **search and bind**).

The following flow chart shows which parameters you must specify for each of these authentication methods:

These are the parameters you need to set in the `ldap` section of the `hue.ini` file so you can authenticate Hue users with LDAP credentials:

Parameter	Description	Comments
search_bind_authentication	Determines which authentication method to use: search and bind, or direct bind.	<p>When set to <i>true</i>, Hue performs an LDAP search using <code>bind_dn</code> and <code>bind_password</code> as provided in <code>hue.ini</code>. The search can be further limited by the search filter <code>user_filter</code>.</p> <p>When set to <i>false</i>, Hue performs a direct bind to LDAP using the credentials provided from one of these sources:</p> <ul style="list-style-type: none"> <li>the UPN, formed by concatenating <code>&lt;shortname&gt;</code> (the user name provided on the Hue login page) and <code>nt_domain</code> (if <code>nt_domain</code> is specified)</li> <li>the <code>ldap_username_pattern</code> (if <code>nt_domain</code> is not specified)</li> </ul>
nt_domain	The NT domain to connect to. This parameter is <i>only</i> used with Active Directory.	Used with the <i>direct bind</i> method of authentication. If <code>nt_domain</code> is specified, then <code>ldap_username_pattern</code> is ignored.
ldap_username_pattern	Used to connect to directory services other than Active Directory.	Used with the <i>direct bind</i> method of authentication. Usually takes the form "cn=<username>,dc=example,dc=com"
backend	The backend to use for authenticating users.	Needs to be set to <code>desktop.auth.backend.LdapBackend</code> for Hue authentication.

### Using Bind Credentials (Search and Bind)

#### About this task

To use the search and bind method for LDAP authentication, edit these parameters in the `ldap` section of the `hue.ini` file:

#### Procedure

- Set `search_bind_authentication=true`.
- In the `Authentication backend` section, add the following line after the `##backend=` statement: Hue searches `base_dn` for an entry with `user_name_attr` that contains the user name provided on the Hue login page.

```
backend=desktop.auth.backend.LdapBackend
```

- Restart Hue once all configuration changes have been made so the changes will take effect.

### Using Direct Bind

**About this task**

To use the direct bind method for LDAP authentication, edit these parameters in the `ldap` section of the `hue.ini` file:

**Procedure**

1. Set `search_bind_authentication=false`.
2. If you are using the Active Directory directory service, uncomment the line with the `nt_domain` parameter. Change the value from `nt_domain=mycompany.com` to the NT domain you want to connect to.
3. If you are using any other directory service, uncomment the line with `ldap_username_pattern` and specify the format, such as the one shown here: Note that `<username>` will be replaced by the information provided on the Hue login page.

```
ldap_username_pattern="cn=<username>,dc=example,dc=com"
```

4. Restart Hue once all configuration changes have been made so the changes will take effect.

**Configure the Hue Database**

The Hue server stores user-account information, the job submission history, and Hive queries in one of the following supported databases:

- SQLite, the embedded Hue database (the default database)
- MySQL
- PostgreSQL
- Oracle
- MariaDB

**NOTE:** Using SQLite is not recommend.

*Configure Hue to Store Data in MySQL or MariaDB*

**About this task**

**Procedure**

1. Configure the database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Set the following properties with your database connection parameters:

```
[desktop]
...
[[database]]
engine=mysql
host=<host>
port=3306
user=<user>
password='<password>'
name=<database>
```

Example of configuration:

```
[desktop]
...
[[database]]
engine=mysql
host=node1
port=3306
user=hue
password=hue_password
name=hue
```

If the connection is secured through SSL/TLS, specify the CA, Cert, and Key paths, as shown in the following example:

```
[desktop]
[[database]]
...
options='{ "ssl": { "key": "/path/to/client-key.pem", "cert": "/path/to/client-cert.pem", "ca": "/path/to/ca.pem" } }'
```

You can find detailed documentation for other options in the Django [Connecting to the Database](#) documentation.

2. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

*Configure Hue to Store Data in PostgreSQL*

**About this task**

**Procedure**

1. Install the following packages:

<b>CentOS</b>	<code>yum install gcc python-devel postgresql-devel</code>
<b>SLES</b>	<code>zypper install gcc python-devel postgresql-devel</code>
<b>Ubuntu</b>	<code>apt-get install gcc python-dev postgresql-server-dev-all</code>

2. Ensure that the `pg_config` command is in your `PATH`. For example, on CentOS with PostgreSQL 9.4 development package from the [postgresql.org](https://www.postgresql.org) official repository, you need to add the directory with `pg_config` manually:

```
export PATH="/usr/pgsql-9.4/bin:$PATH"
```

3. Install the Python `psycopg2` package in Hue:

```
cd /opt/mapr/hue/hue-<version>
source ./bin/activate
pip install psycopg2
deactivate
```

4. Configure database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Set the following properties for your database connection parameters:

```
[desktop]
...
[[database]]
engine=postgresql_psycopg2
host=<host>
port=5432
user=<user>
password=<password>
name=<database>
schema=<schema>
```

**Example of Configuration**

```
[desktop]
...
[[database]]
engine=postgresql_psycopg2
host=node1
port=5432
user=hue
password=hue_password
name=hue
schema=public
```

5. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

## 6. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

### Configure Hue to Store Data in Oracle Database

#### About this task

**NOTE:** To configure Hue with Oracle 12, you need the [Oracle 11 Instant Client](#) Base and SDK.

#### Procedure

##### 1. Install the following packages:

<b>CentOS</b>	<code>yum install gcc python-devel</code>
<b>SLES</b>	<code>zypper install gcc python-devel</code>
<b>Ubuntu</b>	<code>apt-get install gcc python-dev</code>

##### 2. Ensure that the library required to install the Oracle module in Hue is available through the `LD_LIBRARY_PATH` environment variable. The module that provides support for Oracle in Hue requires the `libclntsh.so` library to be available through the `LD_LIBRARY_PATH` environment variable. Typically, the library is located under the `$ORACLE_HOME` or `$ORACLE_HOME/lib` directories. Also, the library might include a version in the filename (for example, `libclntsh.so.11.1`), but the Oracle module for Hue requires it to be named `libclntsh.so`.

###### a) Ensure that the `ORACLE_HOME` environment variable is set:

```
export ORACLE_HOME=<path_to_oracle_installation>
```

###### b) Use the `find` command to locate the library:

```
find "$ORACLE_HOME" -name "libclntsh.so*"
```

###### c) Go to the directory and ensure that the library is available and has the proper filename. If not, you can create a symbolic link:

```
ln -s libclntsh.so.11.* libclntsh.so
```

###### d) Add the following variables to the Hue environment configuration by creating a file in `/opt/mapr/hue/hue-<version>/bin/env.d/`. For example, create `/opt/mapr/hue/hue-<version>/bin/env.d/99custom` with the following content:

```
export ORACLE_HOME="<path_to_oracle_installation>"
export LD_LIBRARY_PATH="$ORACLE_HOME:$LD_LIBRARY_PATH"
```

or the following, depending on your Oracle configuration:

```
export ORACLE_HOME="<path_to_oracle_installation>"
export LD_LIBRARY_PATH="$ORACLE_HOME/lib:$LD_LIBRARY_PATH"
```

##### 3. Depending on the Oracle instant client version installed:

- a) Run the shell script:

```
$ sudo sh -c "echo /usr/lib/oracle/<version-number>/client64/lib
> /etc/ld.so.conf.d/oracle-instantclient.conf"
```

- b) Use the `ldconfig` command to create the linking:

```
$ sudo ldconfig
```

- c) Verify the dynamic linking:

```
$ sudo ldconfig -p | grep -i oracle
```

For example:

```
ldconfig -p | grep -i oracle
libcijdbc11.so (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libcijdbc11.so
libociei.so (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libociei.so
libocci.so.11.1 (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libocci.so.11.1
libnnz11.so (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libnnz11.so
libclntsh.so.11.1 (libc6,x86-64) => /opt/oracle/instantclient_11_2/
libclntsh.so.11.1
```

4. Install the Python `cx_Oracle` package in Hue:

```
cd /opt/mapr/hue/hue-<version>
source ./bin/activate
pip install cx_Oracle==5.3
deactivate
```

**NOTE:** Python `cx_Oracle` version 5.3 is supported.

5. Configure the database connection parameters in the `[desktop][[database]]` section of `hue.ini`. Note these considerations:

- Make sure that you have the appropriate permissions to use LOBs; for example, `SQL GRANT` on `SYS.DBMS_LOB`.
- `SID` refers to the Oracle system ID, which is used to uniquely identify the database.

```
[desktop]
...
[[database]]
engine=oracle
host=<host>
port=1521
user=<user>
password=<password>
name=<SID of the database>
```

- To achieve a multithreading environment, you can specify the `options={'threaded':true}` parameter in this section. For example:

```
[desktop]
...
[[database]]
engine=oracle
host=node1
port=1521
user=hue
password=hue_password
name=XE
options={'threaded':true}
```

By setting the `port=0` parameter, you can use the Oracle Service Name instead of specifying the SSID. For example:

```
[desktop]
...
[[database]]
engine=oracle
port=0
user=hue
password=hue_password
name=node1:1521/hue
```

## 6. Perform the initial data migration:

```
sudo /opt/mapr/server/configure.sh -R
```

## 7. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <node_with_hue>
```

## Configuring an Oracle Schema

You must create schemas for Oracle databases manually.

### About this task

Edit the `hue.ini` file to use an Oracle database:

For detailed steps, see `inspectdb` and `dumpdb` Hue commands, <http://gethue.com/hue-api-execute-some-builtin-commands/>.

### Configure Hue with Security

Based on the Hue version and the version of the other components that Hue communicates with, you can configure the following security features:

**NOTE:** You cannot enable both Kerberos and MapR-SASL on the same cluster.

#### *Configure Hue to use Kerberos*

After you set up a Kerberos principal and keytab file, you can configure Hue to use the Kerberos authentication protocol.

After you set up a Kerberos principal and keytab file, enable the Kerberos Ticket Renewal service, update `hue.ini` and `core-site.xml` with the required parameters, and restart the Warden and Hue services.

## Enabling the Kerberos Ticket Renewer Service

The Kerberos Ticket Renewer service (`kt_renewer`) renews tickets for the Hue service. Hue automatically starts the `kt_renewer` process on clusters that use Kerberos for authentication. Kerberos tickets have a default expiration time of 7 days. The `kt_renewer` service extracts the Kerberos ticket from the keytab file and renews the ticket before it expires.

You can access the `kt_renewer` process log files in the following locations:

- `${HUE_HOME}/logs/kt_renewer.out`
- `${HUE_HOME}/logs/kt_renewer.log`

To use the Kerberos Ticket Renewer service:

1. Enable the Kerberos Ticket Renewer Service:
  - In the `kdc.conf` file, add the `max_renewable_life` parameter.
  - In the `krb5.conf` file, add the `renew_lifetime` parameter.
2. Update the `hue.ini` file to include the Kerberos credentials cache path (`ccache_path`) and ticket renewal frequency (`keytab_reinit_frequency`), as shown in the following example:

```
[desktop]
    [[kerberos]]
        ...
        # Path to keep Kerberos credentials cached
        # ccache_path=/tmp/custom_hue_krb5_ccache
        # Frequency in seconds with which Hue will renew its
keytab
        # keytab_reinit_frequency=86400
        ...
```

## Modifying the hue.ini File

In the `kerberos` section of the `hue.ini` file, make the following changes:

1. Supply the path to Hue's Kerberos keytab file.
2. Supply the Kerberos principal name for Hue.
3. Supply the path to `kinit`.
4. In the `[[yarn_clusters]] [[default]]` section:
  - If you are using a certificate signed by the CA (Certificate Authority), set the `ssl_cert_ca_verify` value to `True`.
  - If you are using a self-signed certificate or no certificate, leave the value set to `False`.
5. **For Hue with secure Hive:** In the `beeswax` section, make sure that the `hive_conf_dir` property points to a directory containing a valid `hive-site.xml` file (either the original or a synced copy).
6. **Optional:** To enable SSL encryption, see [Enable SSL Encryption Between Hue and Hive](#).

7. Make sure that you specified a fully-qualified domain name (FQDN) for all services integrated with Hue that uses Kerberos:

**HttpFS:** Set the `webhdfs_url` property in the `[hadoop]` `[[hdfs_clusters]]` `[[[default]]]` section.

**HiveServer2:** Set the `hive_server_host` property in the `[beeswax]` section.

**Impala:** Set the `server_host` property in the `[impala]` section.

**Spark:** Set the `livy_server_url` property in the `[impala]` section.

**NOTE:** Support for Kerberos integration with Livy was introduced in Hue 4.X.

**HBase:** Set the `hbase_clusters` property in the `[hbase]` section.

**Drill:** Refer to section.

The changes are summarized in the following `hue.ini` files, which you can use as a template:

```
[desktop]
[[kerberos]]
# Path to Hue's Kerberos keytab file
hue_keytab=/opt/mapr/conf/mapr.keytab

# Kerberos principal name for Hue
# hue_principal=mapr/<hostname>@<realm>
# Substitute your hostname and realm in the example below
hue_principal=mapr/perfnodel81.perf.lab@dev-maprtech

# Path to keep Kerberos credentials cached
# ccache_path=/tmp/custom_hue_krb5_ccache
# Frequency in seconds with which Hue will renew its keytab
# keytab_reinit_frequency=86400

# Path to kinit
# Note that the actual path depends on which Linux OS you are using
kinit_path=/usr/bin/kinit

[beeswax]
# If Kerberos security is enabled, use fully-qualified domain name
# (FQDN)
hive_server_host=<FQDN of Hive Server>
# Hive configuration directory, where hive-site.xml is located.
hive_conf_dir=/opt/mapr/hive/hive-<version>/conf
# Change this if your Hive is secured
security_enabled=true
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI

[impala]
# Host of the Impala Server (one of the Impalad)
server_host=<FQDN of Impalad>
# Kerberos principal
impala_principal=mapr/perfnodel81.perf.lab@dev-maprtech

[hadoop]
...
[[hdfs_clusters]]
[[[default]]]
# Enter the filesystem uri
fs_defaultfs=maprfs:///

# Use WebHdfs/HttpFs as the communication mechanism.
```

```

# Domain should be the NameNode or HttpFs host.
# Default port is 14000 for HttpFs.
webhdfs_url=https://<FQDN of HttpFS>:14000/webhdfs/v1

# Change this if your HDFS cluster is secured
security_enabled=True

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI
...
[[yarn_clusters]]
[[[default]]]
# Enter the host on which you are running the ResourceManager
## resourcemanager_host=localhost

# The port where the ResourceManager IPC listens on
## resourcemanager_port=8032

# Whether to submit jobs to this cluster
submit_to=true

# Change this if your YARN cluster is secured
security_enabled=true

# URL of the ResourceManager API
## resourcemanager_api_url=https://localhost:8090

# URL of the ProxyServer API
## proxy_api_url=https://localhost:8090

# URL of the HistoryServer API
history_server_api_url=https://localhost:19890

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI

# In secure mode (HTTPS), if SSL certificates from Resource Manager's
# Rest Server have to be verified against certificate authority
ssl_cert_ca_verify=False

[spark]
# The Livy Server URL.
livy_server_url=https://<FQDN of Livy Server>:8998

# Whether Livy requires client to perform Kerberos authentication.
security_enabled=True

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
mechanism=GSSAPI

[liboozie]
# The URL where the Oozie service runs on. This is required in order for
# users to submit jobs.
oozie_url=https://<FQDN of Oozie>:<oozie_port_number>/oozie

# Requires FQDN in oozie_url if enabled
security_enabled=true
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI

[hbase]
# Comma-separated list of HBase Thrift servers for clusters in the format
of '(name|host:port)'.
# Use full hostname with security.

```

```
# If using Kerberos we assume GSSAPI SASL, not PLAIN.
hbase_clusters=(Cluster|<FQDN of Hbase Thrift Server>:9090)
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=GSSAPI
```

**NOTE:** You need to manually set `security_enabled` property to `true` and `mechanism` property to `GSSAPI` for a Kerberised environment. These options are automatically configured only on a `data-fabric-SASL` cluster.

### Modifying the `core-site.xml` File

In the `core-site.xml` file, provide the shortname for the Kerberos principal as shown. In addition, verify that you configured the proxyuser during configuration. See [Configure Hue](#) for details.

```
<!-- Hue security configuration -->
<property>
  <name>hue.kerberos.principal.shortname</name>
  <value>mapr</value>
</property>
<property>
  <name>hadoop.proxyuser.mapr.groups</name>
  <value>*</value> <!-- A group that all users of Hue belong to, or the
wildcard value "*" -->
</property>
<property>
  <name>hadoop.proxyuser.mapr.hosts</name>
  <value><hue_server_FQDN></value>
</property>
```

### Restarting Warden and Hue

After you make all the changes to the files listed above, restart Warden and Hue so the changes will take effect.

#### *Configure Hue to use MapR-SASL*

You can configure Hue to use MapR-SASL for its communications with various components on a secure cluster. Hue automatically detects and sets the security configuration of the cluster and its components. Therefore, in some cases, minimal configuration is required.

The following components are supported by Hue with MapR-SASL:

- HttpFS
- YARN and Spark History Server
- Hive
- Livy
- HBase Thrift
- Oozie
- Drill

**NOTE:** For secure by default clusters or for clusters where the `customSecurity` flag is not added, Hue automatically sets `security_enabled` to `true` and `mechanism` to `MAPR-SECURITY` for these components. In all other cases, `security_enabled` and `mechanisms` variables are set to `false` and `none` respectively, but these options can be configured manually for custom setups.

An example of a default configuration with automatically defined `security_enabled` and `mechanism` properties for HttpFS is as follows:

```
[hadoop]
[[hdfs_clusters]]
# HA support by using HttpFs
[[[default]]]
...
# Change this if your HDFS cluster is secured
security_enabled=${security_enabled}

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=${mechanism}
...
```

An example of a manual configuration of `security_enabled` and `mechanism` properties for HttpFS is as follows:

```
[hadoop]
[[hdfs_clusters]]
# HA support by using HttpFs
[[[default]]]
...
# Change this if your HDFS cluster is secured
security_enabled=true

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=MAPR-SECURITY
...
```

**NOTE:** After you configure the `hue.ini`, you must restart Hue. However, if you configure multiple sections of the same file, you can restart Hue one time after your updates are complete.

### *Configure LDAP Authentication Between Hue and Hive*

#### **About this task**

You can configure Hue to use LDAP Authentication when it communicates with HiveServer2. Before you configure Hue to use LDAP authentication with HiveServer2, verify that HiveServer2 is configured to use LDAP authentication. For more information, see [Configure HiveServer2 to use LDAP Authentication](#) on page 4198.

Complete the following steps to configure LDAP authentication between Hue and Hive:

#### **Procedure**

1. Configure Hue to connect to Hive with LDAP authentication:
  - a) Configure the `[beeswax]` section of the `hue.ini`: set `mechanism` option.

```
[beeswax]
...
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=LDAP
```

- b) Configure the `[beeswax]` section of the `hue.ini` (for Hive integration only):

```
[beeswax]
...
# Override the default desktop username and password of the hue user
used for authentications with other services.
# e.g. Used for LDAP/PAM pass-through authentication.
auth_username=sampleuser
auth_password=123456
...
```

Or configure the `[desktop]` section of the `hue.ini` to set the username and password for all services that require username/password authentication:

```
[desktop]
...
# Default LDAP/PAM/.. username and password of the hue user used
for authentications with other services.
# Inactive if password is empty.
# e.g. LDAP pass-through authentication for HiveServer2 or Impala.
Apps can override them individually.
auth_username=sampleuser
auth_password=123456
...
```

2. **Optional:** Configure Hue to authenticate users through LDAP. See [Configure Hue with LDAP](#).
3. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <space delimited
list of nodes>
```

### *Configure PAM Authentication Between Hue and Hive*

#### **About this task**

In Hue 3.10, you can configure Hue to use PAM authentication when it communicates with HiveServer2. Before you configure Hue to use PAM authentication with HiveServer2, verify that HiveServer2 is configured to use PAM authentication. See [Configure HiveServer2 to Use PAM Authentication](#) for more information.

Complete the following steps to configure PAM authentication between Hue and Hive:

**Procedure**

1. Configure the [beeswax] section of the hue.ini file. Set the mechanism option to none. Set the auth\_username and auth\_password options in the [desktop] or [beeswax] sections of hue.ini (where auth\_username and auth\_password are the user credentials for the user who authenticates the Hue service with HiveServer2).

The following example summarizes these changes:

```
[desktop]
...
# Default LDAP/PAM/.. username and password of the Hue user used
for authentication with other services.
# Inactive if password is empty.
# e.g. LDAP pass-through authentication for HiveServer2 or Impala.
Apps can override them individually.
auth_username=mapr
auth_password=<user_password>
...
[beeswax]
...
# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY
mechanism=none
```

2. Restart Hue:

```
maprcli node services -name hue -action restart -nodes <Hue node>
```

*Enable SSL Encryption Between Hue and Hive***About this task**

Hue automatically determines when SSL encryption is enabled in Hive by reading the hive-site.xml file.

**Procedure**

1. The following example shows how to correctly configure the directory path where the hive-site.xml file is located in the hive\_conf\_dir property in [beeswax] section of the hue.ini file:

```
[beeswax]
...
# Hive configuration directory, where hive-site.xml is located
hive_conf_dir=/opt/mapr/hive/hive-2.3/conf
```

- The following examples show how to enable or disable Hue verification of service certificates by configuring `ssl_cacerts` and `ssl_validate` properties in `[desktop]` section of the `hue.ini` file:

**Example for enabling certificate verification:**

```
[desktop]
...

# Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
ssl_cacerts=/opt/mapr/conf/ssl_truststore.pem

# Choose whether Hue should validate certificates received from the
server.
ssl_validate=true
```

**Example for disabling certificate verification:**

```
[desktop]
...

# Path to default Certificate Authority certificates. As an example: /
path/to/cacert.pem
# ssl_cacerts=

# Choose whether Hue should validate certificates received from the
server.
ssl_validate=false
```

- After you change these properties, restart Hue to apply your changes:

```
maprcli node services -name hue -action start -nodes <hostname>
```

### *Enable SSL Encryption Between Hue and HttpFS*

#### **About this task**

As of HttpFS 1.0-1504 and Hue 3.7-1505, you can enable SSL encryption and mutual-based authentication between Hue and HttpFS on a secure cluster that is version 4.0.2 or greater.

Complete the following steps to enable SSL encryption and mutual-based authentication between Hue and HttpFS on a secure cluster:

#### **Procedure**

- Configure HttpFS to use SSL or verify that HttpFS is configured to use SSL. For details, see [SSL Security for HttpFS](#).
- Set the `webhdfs_url` property in the `[hadoop] [[hdfs_clusters]] [[[default]]]` section of the `hue.ini` file to contain the correct URL for HttpFS with the HTTPS schema and domain of the HttpFS server:

```
[hadoop]
[[hdfs_clusters]]
[[[default]]]
# Use WebHdfs/HttpFs as the communication mechanism.
# Domain should be the NameNode or HttpFs host.
# Default port is 14000 for HttpFs.
webhdfs_url=https://node1.cluster.com:14000/webhdfs/v1
```

3. You can enable or disable Hue verification of service certificates by configuring `ssl_cacerts` and `ssl_validate` properties in the `[desktop]` section of the `hue.ini` file.

**Example for enabling certificate verification:**

```
[desktop]
...

# Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
ssl_cacerts=/opt/mapr/conf/ssl_truststore.pem

# Choose whether Hue should validate certificates received from the
server.
ssl_validate=true
```

**Example for disabling certificate verification:**

```
[desktop]
...

# Path to default Certificate Authority certificates. As example: /
path/to/cacert.pem
# ssl_cacerts=

# Choose whether Hue should validate certificates received from the
server.
ssl_validate=false
```

4. [OPTIONAL] Configure mutual authentication between Hue and HttpFS. Add the following configuration in the `hue.ini` file under the `[hadoop]` `[[hdfs_clusters]]` `[[[default]]]` section.

- `mutual_ssl_auth=True`
- `ssl_cert=/path/to/certificate.pem`
- `ssl_key=/path/to/private_key.pem`

Use absolute paths for `ssl_cert` and `ssl_key`. Hue does not support private keys with a passphrase in this step.

The changes are summarized in the following example in the `hue.ini` file, which you can use as a template:

```
[hadoop]
[[hdfs_clusters]]
# HA support by using HttpFs
[[[default]]]
# Use WebHdfs/HttpFs as the communication mechanism.
# Domain should be the NameNode or HttpFs host.
# Default port is 14000 for HttpFs.
webhdfs_url=https://node1.cluster.com:14000/webhdfs/v1
...
# SSL certificate based authentication
ssl_cert=/path/to/certificate.pem
ssl_key=/path/to/private_key.pem
```

## 5. Restart Hue.

```
maprcli node services -name hue -action start -nodes <ip_address>
```

## 6. To test that SSL encryption is enabled for HttpFS, run the following command:

```
curl -k --cert /path/to/certificate.pem --key /path/to/private_key.pem
"https://node1.cluster.com:14000/webhdfs/v1?
op=GETFILESTATUS&user.name=mapr"
```

### *Troubleshoot Hue Security Issues*

To troubleshoot Kerberos security issues, enable the debugger by changing the following setting in the `/opt/mapr/conf/env.sh` file:

```
# uncomment the following line to debug client kerberos issues
#MAPR_KERBEROS_DEBUG="-Dsun.security.krb5.debug=true -Dsun.security.spnego.d
ebug=true -Djavax.net.debug=all"
```

Under the Hue installation directory, check `logs/runcpserver.log` for errors. Some sample error messages are shown below.

### **Could not start SASL**

If you see this message, try using [renewable tickets](#):

```
TypeError: TTransportException('Could not start SASL: Error in
sasl_client_start (-1) SASL(-1): generic failure: GSSAPI Error: Unspecified
GSS failure. Minor code may provide more information (Ticket expired)',)
is not JSON serializable
```

Run the `kinit` command to generate a new ticket with a long running lifetime, then restart the Hue webserver.

### **Configuration Error**

If you see this message, it means that the ticket generated by the `kinit` command from `maprlogin` kerberos was not copied to `/tmp/hue_krb5_ccache`:

```
Caused by: javax.security.auth.login.LoginException: Configuration Error -
useTicketCache should be set to true to use the ticket cache /tmp/
hue_krb5_ccache
```

This can happen when you generate a new ticket after the original ticket expires and forget to copy it into the ticket cache. Run the following command to copy the ticket into the ticket cache:

```
kinit -k -t /opt/mapr/conf/mapr.keytab -c /tmp/hue_krb5_ccache mapr/
perfnodel81.perf.lab@dev-maprtech
```

### **Password incorrect while getting initial credentials**

This message (Password incorrect while getting initial credentials) appears when you create a keytab file, but try to authenticate with a password. The act of creating a keytab causes a new random key to be placed in the Kerberos database and into the keytab file (`/opt/mapr/conf/mapr.keytab`). That key does not have a password associated with it, so you can only authenticate using the keytab.

If you want to authenticate with a password, run the `cpw` command in `kadmin` instead of the `ktadd` command.

## Integrate Hue

This section contains the following topics with information for integrating Hue with other ecosystem components:

### Integrate Hue with HPE Ezmeral Data Fabric Database Binary Tables

You can use the Hue HBase application to access HPE Ezmeral Data Fabric Database binary tables.

**NOTE:** In order to use the Hue HBase application, you need to install the HBase Client and the HBase Thrift Gateway. For more information, see the [Installing Core and Ecosystem Components](#) on page 92.

#### Step 1: Setting up HPE Ezmeral Data Fabric Database Binary Table Mapping

To use the Hue HBase application to access HPE Ezmeral Data Fabric Database binary tables, you need to set the `hbase.table.namespace.mappings` property.

### Table Mapping Naming Conventions

A table mapping takes the form `name:map`, where `name` is the table name to redirect and `map` is the modification made to the name. The value in `name` can be a literal string or contain the `*` wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

### Example: Map Table Names to HPE Ezmeral Data Fabric Database

In the following example, the `hbase.table.namespace.mappings` property is set so that any flat table name, such as `mytable`, is treated as a HPE Ezmeral Data Fabric Database table in the directory `/tables_dir/mytable`.

```
<property>
  <name>hbase.table.namespace.mappings</name>
  <value>*:/tables_dir</value>
</property>
```

Once you finish enabling table mapping in the `core-site.xml` file, start (or restart) the HBase thrift server so the changes will take effect.

```
maprcli node services -name hbasethrift -action start -nodes node001
```

## Step 2: Configure Hue for HPE Ezmeral Data Fabric Database

### About this task

To configure Hue for HPE Ezmeral Data Fabric Database, edit the `hbase` section of the `hue.ini` file, which looks like this:

```
[hbase]
# Comma-separated list of HBase Thrift servers for
# clusters in the format of '(name|host:port)'.
## hbase_clusters=(Cluster|localhost:9090)

# Hard limit of rows or columns per row fetched before truncating.
## truncate_limit = 500
```

In this file, make the following changes:

### Procedure

1. Uncomment the `## hbase_clusters=(Cluster|localhost:9090)` statement and provide the list of HBase Thrift servers.

```
hbase_clusters=(<clustername1>|<hostname1>:9090),(<clustername2>|
<hostname2>:9090)[,...]
```

2. Uncomment the `truncate_limit` statement and change the value if necessary.

### Integrate Hue with Hive

Describes how to integrate Hue with Hive through settings in the `hue.ini` file.

### About this task

By default, Hue connects to a single instance of HiveServer2 through the `hive_server_host` parameter in `hue.ini`; however, if high availability (HA) is enabled for HiveServer2, Hue can leverage that. If one instance of HiveServer2 goes down, the client automatically connects to another instance of HiveServer2.

### Verify the Hive Version

Before you integrate Hue with HiveServer2 (HA or single instance), verify that the path specified in the `hive_conf_dir` property applies to the Hive version that you have installed. If needed, update the path to reflect the Hive version that you have installed.

```
# Hive configuration directory, where hive-site.xml is located
hive_conf_dir=/opt/mapr/hive/hive-<version>/conf
```

If Hue and Hive are installed on separate nodes, you must also copy the Hive `conf` directory to the Hue node.

### Integrating Hue with HiveServer2 High Availability

If you want Hue to leverage HiveServer2 HA, [enable high availability for HiveServer2](#), and update the `hue.ini` file to include the following properties and settings:

```
[beeswax]
#Whether to use service discovery for llap.
hive_discovery_llap = true
#Is llap (hive server interactive) running in HA.
hive_discovery_llap_ha = true
#Whether to use service discovery for HiveServer2.
hive_discovery_hs2 = true
```

```
[libzookeeper]
#ZooKeeper ensemble; comma-separated list of host/port.
ensemble=<host:port>:5181
```

Note that the `hive_server_host` and `hive_server_port` properties in `hue.ini` are not required if using HiveServer2 HA. Service discovery overrides the server and thrift port.

Perform any additional Hue configurations and then restart Hue for changes to take effect. See [Starting the Hue Webservice](#).

### Integrating Hue with a Single Instance of HiveServer2

Update the `beeswax` section of the `hue.ini` file to include the following properties and settings:

 **NOTE:** This is not required on a single node cluster.

```
[beeswax]

# Host where HiveServer2 is running.
# If Kerberos security is enabled, use fully-qualified domain name (FQDN).
hive_server_host=<FQDN of Hive Server>

# Port that HiveServer2 Thrift server runs on.
hive_server_port=10000
```

Perform any additional Hue configurations and then restart Hue for changes to take effect. See [Starting the Hue Webservice](#).

### Configuring Data and Metadata Directories

When Hue and Hive are used together, they are usually configured to share metadata and data directories. However, you can create separate directories for Hue and Hive.

The locations of the shared directories are specified by the following properties in the `hive-site.xml` file:

- `hive.metastore.uris` (the hostname and port of the Hive Metastore node)
- `hive.metastore.warehouse.dir` (the directory where the default database for the warehouse is located)

See [Configure Shared Hive Data and Metadata Directories for Hue](#) and [Configure Separate Hive Data and Metadata Directories for Hue](#) for more information.

*Configure Shared Hive Data and Metadata Directories for Hue*

### About this task

To configure shared Hive data and metadata directories for Hue:

## Procedure

1. Change the `hive.metastore.uris` property as shown:

```
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://localhost:9083</value>
  <description> URI where clients contact Hive metastore server </
description>
</property>
```

**NOTE:** The `hive.metastore.warehouse.dir` property can keep its default value and does not need to be changed.

2. Enable Hue impersonation by setting the following property to `true`.

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description> Set this property to enable Hive Metastore service
impersonation in unsecure mode.
  In unsecure mode, setting this property to true causes the metastore
to execute DFS operations
  using the client's reported user and group permissions. Note that
this property must be set on
  BOTH the client and server sides. </description>
</property>
```

3. Set the location of the `sharelib`.

```
<property>
  <name>oozie.service.WorkflowAppService.system.libpath</name>
  <value>/oozie/share/lib</value>
</property>
```

4. To enable the Hive Metastore service to share the embedded Derby database, add the following property blocks to the `hive-site.xml` file on the node running `hiveserver2` to point to the location of the Derby metastore:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:derby:;databaseName=/<local dir>/metastore_db;create=true</
value>
  <description>JDBC connect string for a JDBC metastore</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>org.apache.derby.jdbc.EmbeddedDriver</value>
  <description>Driver class name for a JDBC metastore</description>
</property>
```

5. To enable the Hive Metastore service to share a MySQL database, add the following property blocks to the `hive-site.xml` file:

```
<property>
  <name>javax.jdo.option.ConnectionURL</name>
  <value>jdbc:mysql://<ip_address>:3306/hive_11?
createDatabaseIfNotExist=true</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionDriverName</name>
  <value>com.mysql.jdbc.Driver</value>
</property>

<property>
  <name>javax.jdo.option.ConnectionUserName</name>
  <value><UserName></value>
  <description>Substitute the actual username</description>
</property>

<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value><Password></value>
  <description>Substitute the actual password</description>
</property>
```

### *Configure Separate Hive Data and Metadata Directories for Hue*

#### **About this task**

If you want to store Hue data and metadata in separate directories from Hive data and metadata, follow these steps:

#### **Procedure**

1. Copy `hive-site.xml` to a new location. (The original `hive-site.xml` file remains in the previous location for use by Hive.)
2. Edit `hue.ini` and change the `hive_conf_dir` property so it points to the new location for `hive-site.xml`.
3. Change the `hive.metastore.warehouse.dir` property in the new `hive-site.xml` file so it points to the directory where Hue data will be located.
4. Change the `hive.metastore.uris` property so it points to the directory for Hue's `metastore_db`.
5. Set the `hive.metastore.execute.setugi` property to `true`.

```
<property>
  <name>hive.metastore.execute.setugi</name>
  <value>true</value>
  <description> Set this property to enable Hive Metastore service
impersonation in non-secure mode.
  In non-secure mode, setting this property to true causes the
metastore to execute DFS operations
  using the client's reported user and group permissions. Note that
this property must be set on
  BOTH the client and server sides. </description>
</property>
```

## Integrate Hue with Spark (Experimental Only)

### About this task

You can configure Hue to use the Spark Notebook UI. This allows users to submit Spark jobs from Hue.

**NOTE:** Spark Notebook is a feature that utilizes the Spark REST Job Server (Livy). The `mapr-livy` package must be installed on a node where the `mapr-spark` package is installed or the Livy service will not start.

### Procedure

1. In the `[spark]` section of the `hue.ini`, set the `livy_server_host` parameter to the host where the Livy server is running.

```
[spark]
# IP or hostname of livy server.
livy_server_url=https://<host>:8998
```

**NOTE:** If the Livy server runs on the same node as the Hue UI, you are not required to set this property as the value defaults to the local host.

2. Restart Hue.

```
maprcli node services -name hue -action restart -nodes <hue node>
```

### Results

#### Additional Information

- If needed, you can use the Control System or `maprcli` to start, stop, or restart the Livy Server. For more information, see [Managing Services](#) on page 1129.

#### **NOTE: Troubleshooting Tip**

If you have more than one version of Python installed, you may see the following error when executing Python samples:

```
Py4JJavaError: An error occurred while calling
z:org.apache.spark.api.python.PythonRDD.collectAndServe...
```

#### **Workaround:**

Set the following environment variables in `/opt/mapr/spark/spark-<version>/conf/spark-env.sh`:

```
export PYSARK_PYTHON=/usr/bin/python2.7
export PYSARK_DRIVER_PYTHON=/usr/bin/python2.7
```

## Integrate Hue with Drill

Starting in EEP 6.0, Drill is officially supported with Hue. When you integrate Drill with Hue, users can run Drill queries from the Hue interface and visualize data.

Drill integrates with Hue through configuration options in the `/opt/mapr/hue/hue-<version>/conf/hue.ini` file. A user can authenticate to Hue through Plain, Kerberos, or data-fabric-SASL authentication. The user that authenticates to Hue is the user that runs the Drill queries from Hue.

When connecting to Drill, Hue performs outbound impersonation to Drill as the user that authenticated to Hue. Drill accepts the outbound impersonation from Hue as an inbound impersonation. Drill then performs outbound impersonation to the filesystem or MapR Database.

 **NOTE:** In a secure cluster, you can only access the Hue interface through HTTPS.

 **NOTE:** SSL encryption is currently not supported.

## Prerequisites

Note the following prerequisites before you integrate Hue with Drill:

- The cluster must have the latest versions of [Hue](#), [Drill](#), and [HTTPFS](#) installed. Hue uses HTTPFS to communicate with the file system. You can see the latest component versions in the [Component Versions for Released EEPs](#). If you install Hue and Drill on a secure cluster, Hue and Drill are installed with the default security configurations and outbound impersonation is enabled.

- ### Installer

When you install Hue and Drill using the Installer, HTTPFS is installed automatically, and Hue is automatically configured to integrate Drill without having to perform any manual configuration. The installer configures a Zookeeper connection to Drill in `hue.ini`, by default.

- ### Manual Installation

- Install HTTPFS and then configure Hue, as described in the following section, *Configuring Hue*
- In a secure cluster, Drill must have [user impersonation enabled](#).
  - Drill has an inbound impersonation policy option, `exec.impersonation.inbound_policies`, that allows the Hue process user (proxy user) to impersonate the Hue authenticated user as an outbound impersonation from Hue to Drill. This option is automatically configured when Drill and Hue are installed using the Installer with default security enabled, or when you run `configure.sh` on a secure cluster. If you do not run `configure.sh`, you must manually add this option to the impersonation configuration in the `/opt/mapr/drill/drill-<version>/conf/drill-override.conf` file, as shown:

```
impersonation.enabled: true,
  impersonation.max_chained_user_hops: 3,
  exec.impersonation.inbound_policies: "[{proxy_principals:{users:
[\"mapr\"}],target_principals:{users:[\"*\"]}}]\",
```

- If you plan to use Kerberos for authentication, you will need to include the Hue keytab file and Kerberos principal name for Hue in the `hue.ini` file. If needed, complete the steps listed in the [Creating a Kerberos Principal and Extracting the Kerberos Ticket from the keytab File](#) sections on the [Configure Hue to use Kerberos](#) on page 4402 page.

## Configuring Hue

If you manually installed Hue, Drill, and HTTPFS, you must modify the `hue.ini` file to include the configuration information needed for Hue to connect with Drill and HTTPFS. The `hue.ini` file contains sections where you configure Hue to integrate with various components, like Drill and HTTPFS. You can access the `hue.ini` file in the `/opt/mapr/hue/hue-<version>/desktop/conf` directory. Start/Restart the services after you update the `hue.ini` file.

 **NOTE:** If you installed Hue and Drill using the Installer, these options are populated automatically in the `hue.ini` file; no configuration is required. In a secure cluster, the authentication mechanism defaults to MAPR-SECURITY.

Complete the following steps to integrate Hue with Drill:

- Edit the Drill configuration in `hue.ini`.**

The `hue.ini` file contains a `[[[drill]]]` section under which you can see configuration options needed for Hue to connect with Drill. You must uncomment an option (remove the `#` character) in the `hue.ini` file for the option to take effect.

The following tables list and describe the Drill options with possible values and also provide examples:

Options	Descriptions	Examples
<code>connection_type=</code>	<p>Tells Hue how to connect to Drill. Enter one of the following values:</p> <ul style="list-style-type: none"> <li>• <code>direct</code></li> <li>• <code>zookeeper</code></li> </ul> <p>A <code>direct</code> connection is a connection in which Hue connects directly to a Drillbit. A <code>ZooKeeper</code> connection is a connection in which Hue communicates with ZooKeeper and ZooKeeper provides Hue with a Drillbit to connect with.</p>	<code>connection_type=zookeeper</code>
<code>drillbits=</code>	<p>Enter the node IP address of the Drillbit that Hue connects with. Only enter a node address if using the “<code>direct</code>” <code>connection_type</code>.</p>	<p><code>drillbits=10.10.100.2:31010</code></p> <p>To list multiple Drillbits, separate each IP address by a comma, as shown:</p> <p><code>drillbits=10.10.100.2:31010, 10.10.100.3:31010</code></p> <p> <b>NOTE:</b> Port 31010 is the user port between nodes in a Drill cluster. This port is needed for an external client to connect into the cluster nodes and for the Drill Web Console.</p>
<code>zk_quorum=</code>	<p>Enter the list of ZooKeeper node IP addresses in the ZooKeeper quorum. Only enter the IP addresses for the ZooKeeper quorum if using the “<code>zookeeper</code>” <code>connection_type</code>.</p>	<code>zk_quorum=10.10.100.3:5181, 10.10.100.4:5181, 10.10.100.5:5181</code>
<code>zk_cluster_id=</code>	<p>Enter the name of the Drill cluster that you want Hue to connect to.</p>	<code>zk_cluster_id=dev-drillbits</code>

<p>mechanism=</p>	<p>The type of authentication enabled. Enter one of the following values:</p> <ul style="list-style-type: none"> <li>• None</li> <li>• GSSAPI</li> <li>• Data Fabric-SECURITY</li> </ul> <p>Use None for Plain authentication. Use GSSAPI for Kerberos authentication. Use MAPR-SECURITY for maprsasl.</p> <p>If you set the mechanism to “none” and impersonation is enabled, you must set the username and password to the admin or proxy user that will impersonate Hue end users. You can set these with the user= and password= options.</p> <p>If you set the mechanism to GSSAPI, you must also include the ccache_path= option. For this option, enter the caching location for Kerberos credentials, for example: ccache_path=/tmp/hue_krb5_ccache</p> <p> <b>NOTE:</b> See <a href="#">Configure Hue to use Kerberos</a> on page 4402</p> <p>You can set the Drill Kerberos principal and/or Hue impersonation using the option named “options=.” See “options=” below.</p>	<p>mechanism=none</p>
<p>user=</p>	<p>If using Plain authentication, enter the username. If using another authentication mechanism, do not enter a value.</p> <p>Set the username to the admin or proxy user that will impersonate Hue end users.</p> <p>If impersonation is disabled, the you can set the user to any user. Hue will connect to Drill as the user specified.</p>	<p>user=mapr</p>
<p>password=</p>	<p>If using Plain authentication, enter the password. If using another authentication mechanism, do not enter a value.</p> <p>Set the password for the admin or proxy user that will impersonate Hue end users.</p> <p>If impersonation is disabled, set the password for the use specified.</p>	<p>password=mapr8</p>

password_script=	<p>Indicates which script to run for the database password when a password is required and the password= option is not set. Enter the location of the script.</p> <p>The following shell script is an example of a password script:</p> <pre>#!/bin/bash case \$1 in drill) echo "password_1";; some-output) echo "password_2";; *) echo "wrong argument" &gt;&amp;2 exit 1;; esac</pre>	password_script='/root/hue_password_script/password_script.sh drill'
options=	<p>Additional options related to impersonation and Kerberos authentication. This option takes the following values:</p> <ul style="list-style-type: none"> <li>• impersonation</li> <li>• principal</li> </ul> <p>Impersonation enables or disables outbound impersonation in Hue. Principal is the Drill service principal when Kerberos authentication is enabled.</p>	<pre>options='{ "impersonation": true, "principal": "mapr/localhost@REALM" }'</pre> <pre>options='{ "impersonation": true }'</pre> <pre>options='{ "impersonation": false }'</pre>

## 2. Add the HTTPFS URL in hue.ini.

The `hue.ini` file contains a `[[[default]]]` section in the `[hadoop]` block under which you can see HDFS configuration options. You must uncomment an option (remove the `#` character) in the `hue.ini` file for the option to take effect.

In the `[[[default]]]` section of the `[hadoop]` block, enter the IP address of the HTTPFS node as the value for the `webhdfs_url=` option, as shown:

```
# Use WebHdfs/HttpFs as the communication mechanism.
# Domain should be the NameNode or HttpFs host.
# Default port is 14000 for HttpFs.
webhdfs_url=https://<httpfs-node-ip-address>:14000/webhdfs/v1
```

## 3. Start the services.

Start/Restart Hue, Drill, and HTTPS to apply the updated configurations, as shown in the following examples:

```
maprcli node services -name hue -action start -nodes
<hue-node-ip-address>

maprcli node services -name drill-bits -action start -nodes
<list-of-drill-node-ip-addresses>

maprcli node services -name httpfs -action start -nodes
<httpfs-node-ip-address>
```

## Run Drill Queries in Hue

Once you have configured Hue and started the services, you can run Drill queries from Hue and visualize your data.

Complete the following steps to run Drill queries in Hue:

1. In your web browser, enter the Hue URL to navigate to the Hue web interface, as shown:

```
http://hue-node-ip-address:8888
```

2. If prompted, enter your user credentials. The Hue interface opens.
3. In the **Query** drop-down, select **Editor > Drill**. The left navigation panel displays the list of schemas available in Drill.
4. Select a schema, for example `dfs.default`, and then enter a query in the text field.
5. Click the blue play button to execute the query. Query results display.
6. Optionally, you can use the buttons to the left of the query results to visualize the data.

*Configure Hue to use Drill on a MapR-SASL-Secured Cluster*

You can configure Hue to use Drill on a MapR-SASL cluster.

### Procedure

1. Configure Hue to use Drill:
  - a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name="Drill"

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=MAPR-SECURITY

    # Available options:
    # "impersonation" to enable or disable outbound impersonation.
    # "principal" of Drill service. Used when Kerberos authentication
    is enabled.
    options='{ "impersonation": true, "principal": "mapr/
    <node>@REALM" }'
```

- Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

### *Configure Hue to use Drill on Kerberos-Secured Cluster*

You can configure Hue to use Drill on a Kerberos-secured cluster.

#### **Procedure**

- Configure Hue to use Drill:

- In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
[[databases]]
...
[[[drill]]]

# Name to show in the UI.
nice_name="Drill"

# Database backend to use.
engine=drill

# Connection type. This can be:
# 1. direct
# 2. zookeeper
connection_type=direct

# Drillbit address for direct connection.
drillbits=<node>:31010

# Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
mechanism=GSSAPI

# Available options:
# "impersonation" to enable or disable outbound impersonation.
# "principal" of Drill service. Used when Kerberos authentication
is enabled.
options='{ "impersonation": true, "principal": "mapr/
<node>@REALM" }'
```

- Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

### *Configure Hue to use Drill on PAM-Secured Cluster*

You can configure Hue to use Drill on a Pluggable Authentication Modules (PAM) secured cluster.

#### **Procedure**

- Configure Hue to use Drill:

- a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name="Drill"

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=none

    # Username to authenticate with when connecting to the database.
    # Used with plain authentication (mechanism set to "none").
    user=<user>

    # Password matching the username to authenticate with when
    # connecting to the database.
    # Used with plain authentication (mechanism set to "none").
    password=<password>
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

### *Configure Hue to use Drill on an Unsecured Cluster*

You can configure Hue to use Drill on an unsecure cluster.

#### **Procedure**

1. Configure Hue to use Drill:

- a) In the `hue.ini`, go to the Drill section, and set the parameters. For example:

```
[librdbms]
  [[databases]]
    ...
    [[[drill]]]

    # Name to show in the UI.
    nice_name="Drill"

    # Database backend to use.
    engine=drill

    # Connection type. This can be:
    # 1. direct
    # 2. zookeeper
    connection_type=direct

    # Drillbit address for direct connection.
    drillbits=<node>:31010

    # Security mechanism of authentication none/GSSAPI/MAPR-SECURITY.
    mechanism=none
```

2. Restart Hue to apply the updated configuration:

```
maprcli node services -name hue -action restart -nodes <node>
```

### *Configure Hue to Connect to Drill Using the Drill ODBC Driver*

Describes how to connect Hue to Drill using the Drill ODBC Driver.

Starting in EEP 7.0.0 (Hue 4.6.0.0 and Drill 1.16.1.0), you can install the Drill ODBC driver and then use the driver to connect Hue to Drill. Note that the Drill ODBC Driver is not available for Ubuntu.

For Hue, the ODBC Driver provides better performance than the JDBC Driver. The ODBC Driver is invoked directly from the Python VM of the Hue process whereas Hue must launch a separate Java Gateway process with the JDBC Driver to translate the Python instructions to JVM instructions, which degrades performance.

### Prerequisites

Before you connect Hue to Drill:

- [Install the Drill ODBC Driver on your system.](#)
- Install the `unixODBC` package on your system:

```
yum install unixODBC
```

- (Optional) Configure the ODBC DSN (Data Source Name) in the `~/.odbc.ini` file, as described in [Apache Drill Docs: Configuring ODBC on Linux](#).

### Configuring Hue to Connect to Drill

To configure Hue to connect to Drill through the Drill ODBC Driver, add the Drill ODBC interpreter entry in the `notebook` section of `hue.ini` using the `sqlalchemy` interface, as shown in the following example:

```
[notebook]
# ...
```

```
[[interpreters]]
# ...
[[[drillodbc]]]
name=Drill ODBC
interface=sqlalchemy
## Specify Drill ODBC connection parameters separated by "&".
## Ensure that Drill ODBC drivers and unixODBC installed.
options='{ "url": "drill+odbc:///?<ODBC connection parameters>" }'
```

The following example shows a Hue configuration with the ODBC DSN (Data Source Name) configured in `~/.odbc.ini`. Note that the `DelegationUID=${USER}` property enables outbound impersonation from Hue to Drill.

```
[notebook]
# ...
[[[interpreters]]]
# ...
[[[drillodbc]]]
name=Drill ODBC
interface=sqlalchemy
options='{ "url": "drill+odbc:///?DSN=MapR Drill 64-bit&DelegationUID=${USER}" }'
```

The following example shows a Hue configuration that uses a Drillbit connection with default security (MapRSASL) enabled:

```
[notebook]
# ...
[[[interpreters]]]
# ...
[[[drillodbc]]]
name=DrillODBC
interface=sqlalchemy
options='{ "url": "drill+odbc:///?Driver=/opt/mapr/drill/lib/64/
libdrillodbc_sb64.so&ConnectionType=Direct&HOST=node1.cluster.com&PORT=31010
&AuthenticationType=MapRSASL&DelegationUID=${USER}" }'
```

**NOTE:** If you do not use the DSN, you must manually specify the full path to the Drill ODBC Driver, for example:

```
Driver=/opt/mapr/drill/lib/64/libdrillodbc_sb64.so
```

### More information

<https://drill.apache.org/docs/odbc-configuration-reference/>

<https://drill.apache.org/docs/configuring-odbc-on-linux/>

[https://docs.datafabric.hpe.com/62/attachments/JDBC\\_ODBC\\_drivers/DrillODBCInstallandConfigurationGuide.pdf](https://docs.datafabric.hpe.com/62/attachments/JDBC_ODBC_drivers/DrillODBCInstallandConfigurationGuide.pdf)

### Integrate Hue With Spark

#### About this task

**IMPORTANT:** Hue integration with Spark is an experimental feature.

**Procedure**

1. In the [spark] section of the hue.ini file, set the livy\_server\_url parameters to the host and port where the Livy server is running:

```
[spark]
# The Livy Server URL.
livy_server_url=https://node10.cluster.com:8998
```

2. To configure Hue to use Spark modes, modify livy.conf (vim /opt/mapr/livy/livy-<version>/conf/livy.conf):

- a) If Spark jobs run on local mode, set the livy.spark.master property:

```
...
# What spark master Livy sessions should use.
livy.spark.master = local[*]
...
```

- b) If Spark jobs run on YARN mode, set the livy.spark.master and livy.spark.deployMode properties (client or cluster). For example:

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- c) If Spark jobs run on Standalone mode, set the livy.spark.master property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = spark://ubuntu500:7077
```

- d) If Spark jobs run on Mesos mode, set the livy.spark.master property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = mesos://<mesos-master-node-ip>:5050
```

**NOTE:** Integration of Spark on Mesos with Hue is not supported in cluster deployment mode.

3. If you want to be able to access Hive through Spark in Hue, configure Spark with Hive, and set livy.repl.enableHiveContext to true in livy.conf. For example:

```
...
# Whether to enable HiveContext in livy interpreter, if it is true
hive-site.xml will be detected
# on user request and then livy server classpath automatically.
livy.repl.enableHiveContext = true
...
```

- If you plan to use PySpark, you must set the PYTHONPATH environment variable in `livy-env.sh` (`/opt/mapr/livy/livy-<version>/conf/livy-env.sh`):

```
...
export PYTHONPATH=$SPARK_HOME/python/lib/py4j-<version>-
src.zip:$SPARK_HOME/python/:$PYTHONPATH
```

For example:

```
...
export PYTHONPATH=$SPARK_HOME/python/lib/py4j-0.10.7-
src.zip:$SPARK_HOME/python/:$PYTHONPATH
```

- Ensure that R is installed on the node if you plan to run SparkR. To install R to run SparkR jobs:

**On Ubuntu**

```
sudo apt-get install r-base
```

**On Red Hat / Rocky**

```
sudo yum install R
```

- Restart the Spark REST Job Server (Livy).

```
maprcli node services -name livy -action restart -nodes <livy node>
```

- Restart Hue:

```
maprcli node services -name hue -action restart -nodes <hue node>
```

### Integrate Hue with Relational Databases

There are two options for integrating Hue with relational databases:

- SQLAlchemy interpreter interface (*recommended*)
- RDBMS Hue application (*legacy*)

The Hue UI can be integrated to browse and query the following databases:

- MySQL/MariaDB (supported only with the SQLAlchemy interface)
- Oracle
- PostgreSQL
- SQLite

### Integrate with the SQLAlchemy Interpreter Interface

You can connect different databases by adding corresponding entries into the `[notebook]` `[[interpreters]]` section of the `hue.ini`.

In the new section, you need to specify `interface=sqlalchemy` and the SQLAlchemy connection string in the `url` field of the `options` parameter.

Later on this page you can find examples of connection configurations for different relational databases. Additional information about the SQLAlchemy connection options can be found in the following SQLAlchemy documentation:

[Engine Configuration — SQLAlchemy 1.3 Documentation](#)**Integrate with MySQL / MariaDB**

Here is an example of integrating the Hue UI with MySQL / MariaDB:

```
[notebook]
# ...
[[interpreters]]
# ...
[[mysql]]
name = MySQL
interface=sqlalchemy
## https://docs.sqlalchemy.org/en/latest/dialects/mysql.html
options='{ "url": "mysql+mysqlconnector://root:secret@database:3306/hue" }'
```

For information about SQLAlchemy MySQL/MariaDB connector options, see the following article:

[MySQL / MySQL-Connector — SQLAlchemy 1.3 Documentation](#)

**NOTE:** The default SQLAlchemy MySQL dialect is not available in Hue 4.11. Instead, you must use `mysql+mysqlconnector`.

**Integrate with Oracle**

Before integrating the Hue UI with an Oracle Database, you must install the `cx_Oracle` Python module in Hue. To do this, follow steps 1-4 in the [Configure Hue to Store Data in Oracle Database](#) documentation.

For more information about the SQLAlchemy Oracle connector options, see the following article:

[Oracle / cx\\_Oracle – SQLAlchemy 1.3 Documentation](#)

```
[notebook]
# ...
[[interpreters]]
# ...
[[oracle]]
name = Oracle
interface=sqlalchemy
options='{ "url": "oracle://hue:hue@host:1521/hue" }'
```

**Integrate with PostgreSQL**

Before integrating Hue UI with the PostgreSQL RDBMS, install the `psycopg2` Python module. To do this, follow steps 1-3 in the [Configure Hue to Store Data in PostgreSQL](#) documentation.

For more information about SQLAlchemy PostgreSQL connection options, see the following article:

[PostgreSQL / psycopg2 – SQLAlchemy 1.3 Documentation](#)

Here is an example of integrating the Hue UI with PostgreSQL:

```
[notebook]
# ...
[[interpreters]]
# ...
[[postgresql]]
name = PostgreSQL
interface=sqlalchemy
options='{ "url": "postgresql://hue:hue@host:5432/hue" }'
```

**Integrate with SQLite**

For information about SQLAlchemy SQLite connector options, see the following article:

[SQLite / Pysqlite — SQLAlchemy 1.3 Documentation](#)

Here's an example of integrating the Hue UI with SQLite:

```
[notebook]
# ...
[[interpreters]]
# ...
[[[sqlite]]]
  name = SQLite
  interface=sqlalchemy
  options='{ "url": "sqlite:///relative/path/to/database/file.db" }'
  # options='{ "url": "sqlite:///absolute/path/to/database/file.db" }'
```

**Integrate with the RDBMS Hue Application**

Beginning with Hue 4.11:

- The following method is obsolete.
- MySQL integration is not supported in the RDBMS Hue application.

To configure access to a relational database server through the Hue RDBMS application, you need to add your database configuration as an entry in the `[librdbms][[databases]]` section of `hue.ini`. You also need to add a corresponding entry to the `[notebook][[interpreters]]` section with the same section name and the interface parameter set to `rdbms`.

**Table**

Parameter	Used for SQLite?	Value
<code>nice_name</code>	Yes	The <code>nice_name</code> of the current configuration entry.
<code>engine</code>	No	The database back end to use. Available values are: <ul style="list-style-type: none"> <li>• <code>oracle</code></li> <li>• <code>postgresql</code></li> <li>• <code>sqlite</code></li> </ul>
<code>host</code>	No	The IP or hostname of the database server to connect to.
<code>port</code>	No	The ports that the database server is listening to. The default ports are: <ul style="list-style-type: none"> <li>• PostgreSQL:5432</li> <li>• Oracle Express Edition:1521</li> </ul>
<code>name</code>	Yes	The database name to connect to. Leave this property empty if you do not want to connect to a specific database on your database server. For SQLite, this is the path to the database file.
<code>user</code>	No	The user name to authenticate with when connecting to the database server.
<code>password</code>	No	The password for the user name that you will authenticate with when connecting to the database server.
<code>password_script</code>	No	As an alternative to specifying the <code>password</code> explicitly in the <code>hue.ini</code> , you can use the <code>password_script</code> parameter to specify the path to the executable file that will be invoked by Hue to read the password.
<code>options</code>	Yes	For additional options to send to the database server when connecting, see this page: <a href="https://docs.djangoproject.com/en/1.11/ref/databases/">https://docs.djangoproject.com/en/1.11/ref/databases/</a>

Following are examples for connecting to different relational databases.

### Integrate with Oracle

Before integrating Hue UI with an Oracle database, install the `cx_Oracle` Python module in Hue. To do this, follow steps 1-4 in the [Configure Hue to Store Data in Oracle Database](#) documentation.

Here is an example of integrating the Hue UI with Oracle:

```
[librdbms]
# ...
[[databases]]
# ...
[[[oracle]]]
nice_name="Oracle DB"
name=example_database
engine=oracle
host=example.host
port=1521
user=example_user
password=example_password

# ...
[notebook]
# ...
[[interpreters]]
# ...
[[[oracle]]]
    name = Oracle
    interface=rdbms
```

### Integrate with PostgreSQL

Before integrating Hue UI with the PostgreSQL RDBMS, install the `psycopg2` Python module. To do this, follow steps 1-3 in the [Configure Hue to Store Data in PostgreSQL](#) documentation.

Here is an example of integrating the Hue UI with PostgreSQL:

```
[librdbms]
# ...
[[databases]]
# ...
[[[postgresql]]]
nice_name="PostgreSQL DB"
name=mysqldb
engine=postgresql
host=example.host
port=5432
user=example_user
password=example_password

# ...
[notebook]
# ...
[[interpreters]]
# ...
[[[postgresql]]]
    name = PostgreSQL
    interface=rdbms
```

### Integrate with SQLite

Here is an example of integrating the Hue UI with SQLite:

```
[librdbms]
# ...
[[databases]]
# ...
[[[sqlite]]]
nice_name=SQLite
name=/path/to/sqlite.db
engine=sqlite

# ...
[notebook]
# ...
[[interpreters]]
# ...
[[[sqlite]]]
name = sqlite
interface=rdbms
```

### Use Hue

This section provides information about using Hue, but it does not duplicate the Hue documentation.

You can also refer to the [Hue documentation](#).

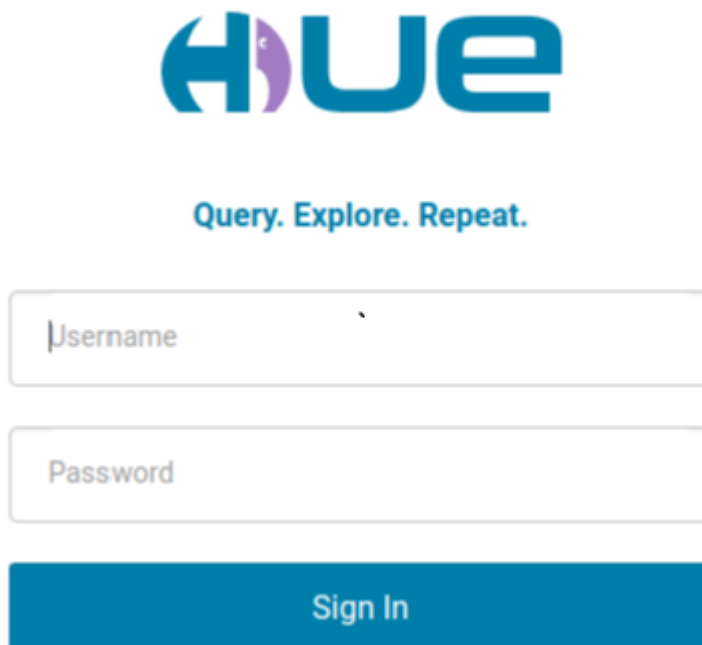

This section includes the following topics:

### Logging in to Hue 4.X

Once Hue is installed and the configuration files have been edited, direct your browser to the IP address where you installed Hue.

### Procedure

- Open the Hue homepage: `ip_address>:8888`  
The following screen appears:

The screenshot shows the Hue login interface. At the top is the Hue logo, which consists of a blue 'H' with a purple circle inside it, followed by the word 'UE' in blue. Below the logo is the tagline 'Query. Explore. Repeat.' in blue. Underneath the tagline are two white input fields with rounded corners. The first field is labeled 'Username' and the second is labeled 'Password'. At the bottom of the form is a solid blue button with the text 'Sign In' in white.

- Sign in with your username, enter the password `mapr` and click **Sign in**. You can find your username in the `/opt/mapr/conf/daemon.conf` file.

### Using Hue Welcome Tour

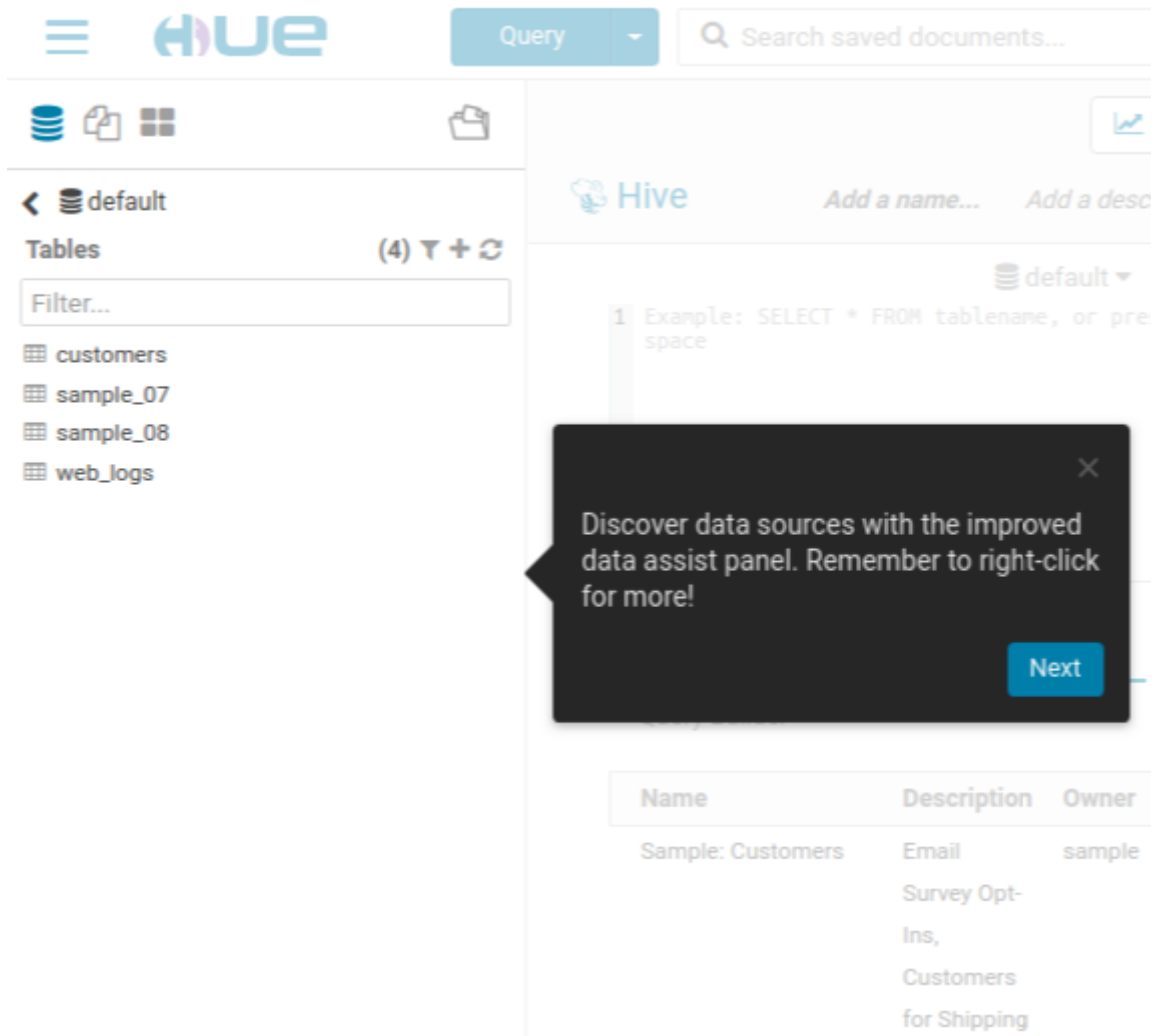

After your first login, you will be introduced to the new features in Hue 4 by the "Welcome Hue 4!" tour.

#### Procedure

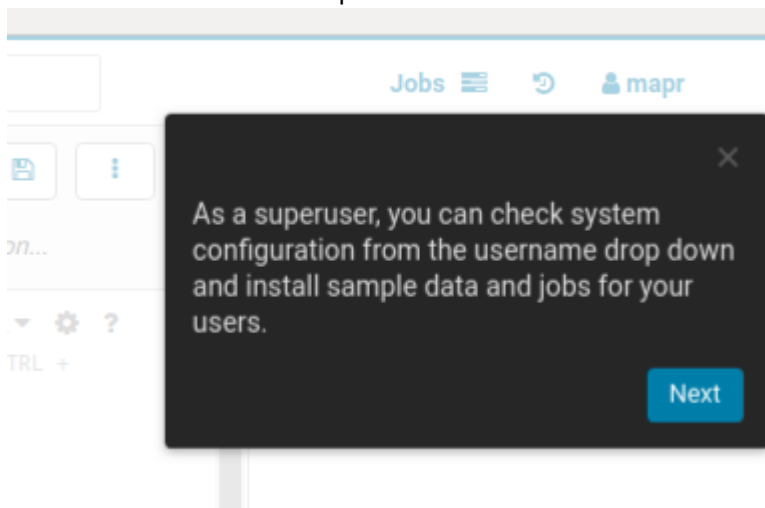

1. Start the welcome tour.  
The following screen appears:

2. You are first introduced to the navigation bar:

3. You are introduced to the superuser menu:

4. You are introduced to the left assist panel:

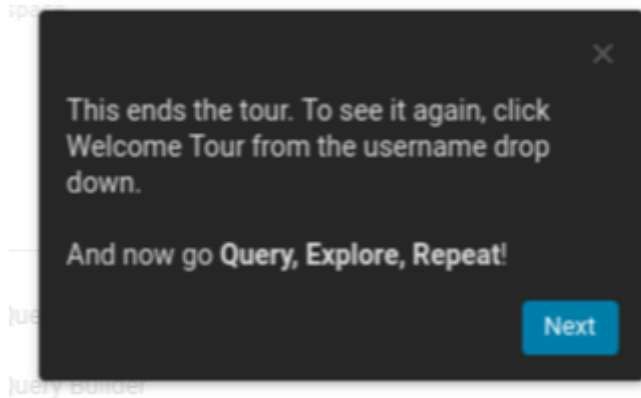

5. You are introduced to the main working zone:

6. You are introduced to the right assist panel:

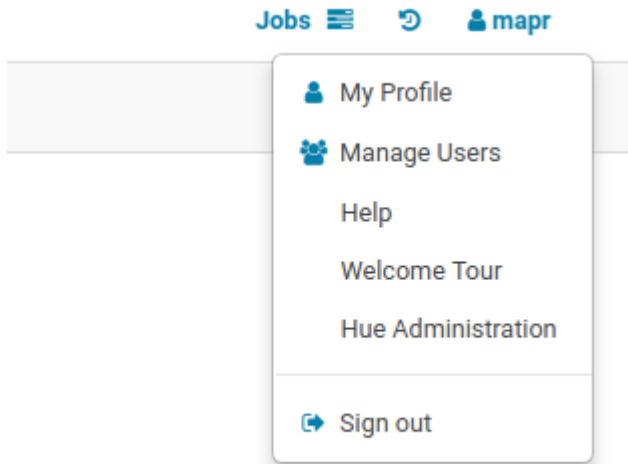

7. You then come to the end of the tour:

### Getting Started with the Quick Start Wizard (Hue 4.X)

With the Quick Start Wizard you can check configuration, install examples, and create users.

Click on **Hue Administration** in the user menu:

### Step 1: Check Configuration

## Quick Start Wizard - Hue™ 4.2.0 - Query. Explore. Repeat.

Step 1: Check Configuration

Step 2: Examples

Step 3: Users

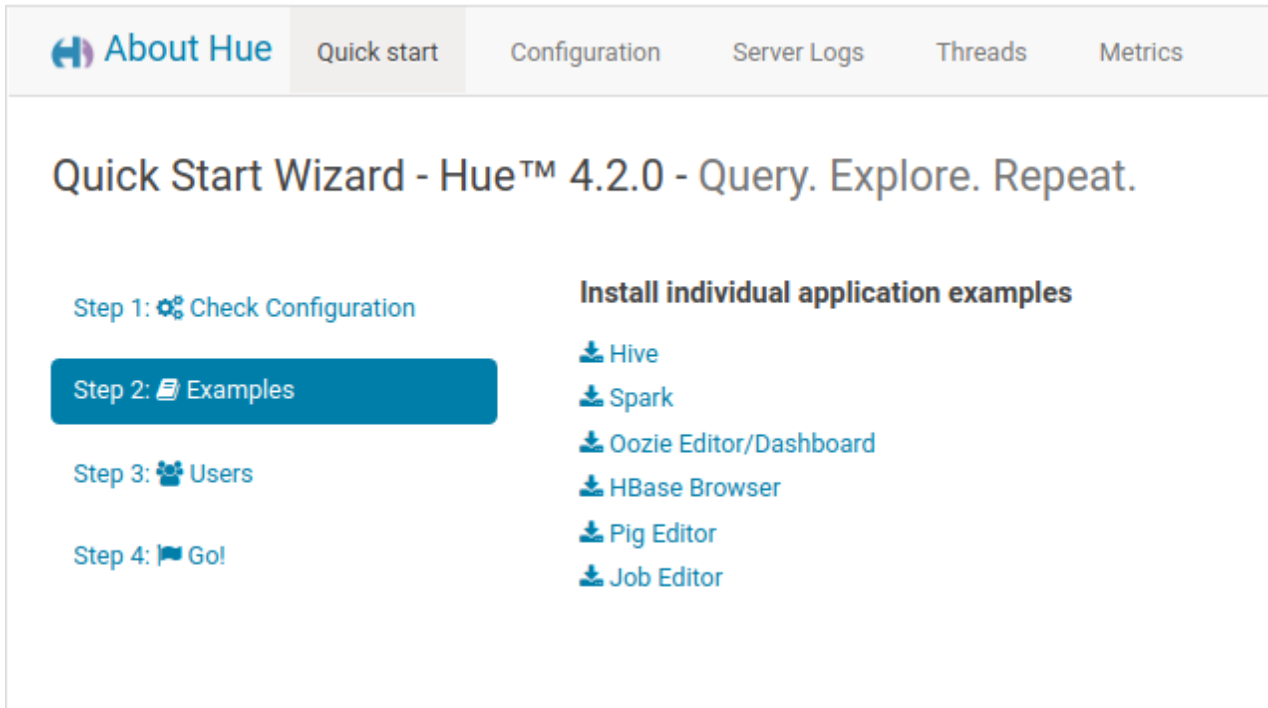

Step 4: Go!

### Checking current configuration

Configuration files located in `/opt/mapr/hue/hue-4.2.0/desktop/conf`

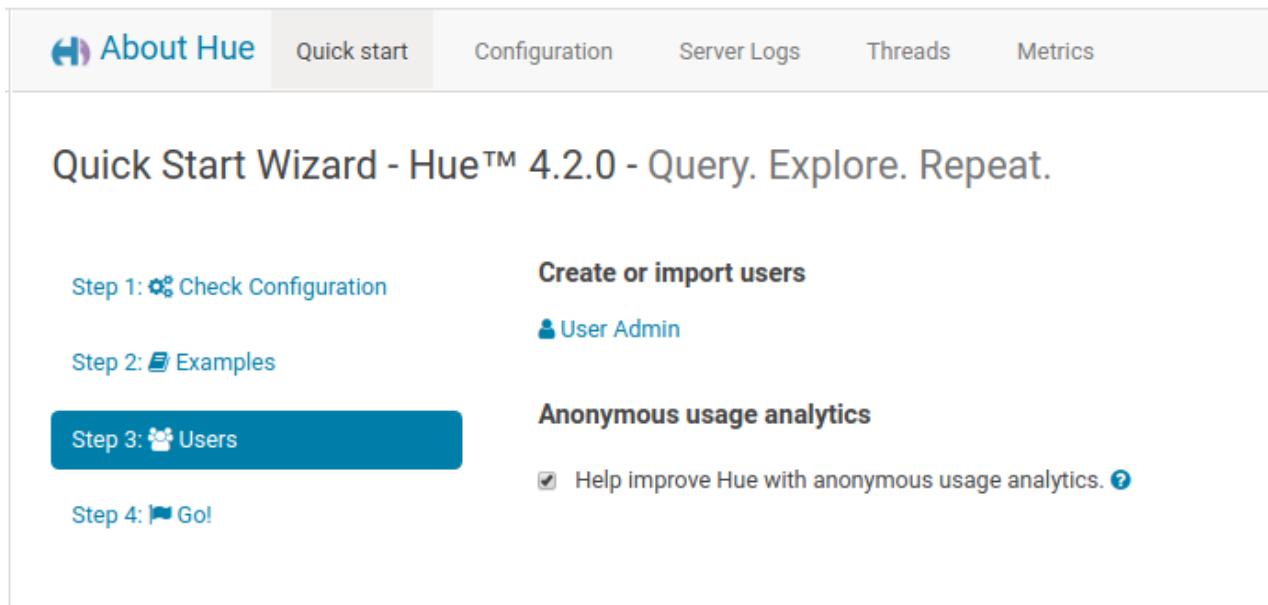

All OK. Configuration check passed.

## Step 2: Examples

The screenshot shows the Hue Quick Start Wizard interface. At the top, there is a navigation bar with the following items: "About Hue" (with a logo), "Quick start" (highlighted), "Configuration", "Server Logs", "Threads", and "Metrics". Below the navigation bar, the main heading reads "Quick Start Wizard - Hue™ 4.2.0 - Query. Explore. Repeat." On the left side, there is a vertical list of steps: "Step 1: Check Configuration" (with a gear icon), "Step 2: Examples" (with a document icon and highlighted in a blue box), "Step 3: Users" (with a group of people icon), and "Step 4: Go!" (with a flag icon). On the right side, under the heading "Install individual application examples", there is a list of application examples, each with a download icon: "Hive", "Spark", "Oozie Editor/Dashboard", "HBase Browser", "Pig Editor", and "Job Editor".

## Step 3: Users

The screenshot shows the Hue Quick Start Wizard interface. At the top, there is a navigation bar with the following items: "About Hue" (with a logo), "Quick start", "Configuration" (highlighted), "Server Logs", "Threads", and "Metrics". Below the navigation bar, the main heading reads "Quick Start Wizard - Hue™ 4.2.0 - Query. Explore. Repeat." On the left side, there is a vertical list of steps: "Step 1: Check Configuration" (with a gear icon), "Step 2: Examples" (with a document icon), "Step 3: Users" (with a group of people icon and highlighted in a blue box), and "Step 4: Go!" (with a flag icon). On the right side, under the heading "Create or import users", there is a list of user options: "User Admin" (with a person icon). Below this, under the heading "Anonymous usage analytics", there is a checkbox labeled "Help improve Hue with anonymous usage analytics." which is checked.

**NOTE:** By default, the Hue interface is configured to use PAM for authentication; so you cannot create or import users. For more information, see [Configure Hue Interface Authentication](#).

### User Administration in Hue 4.X

By default, the Hue interface is configured to use PAM for authentication; so you cannot use the Hue interface to create users or edit their passwords.

**NOTE:** For more information, see [Configure Hue Interface Authentication](#).

This section contains the following topics:

### Changing Your Password

Once you log in, you can change your Hue password.

#### About this task

To change your Hue password, perform the following steps:

#### Procedure

1. Click on your **Username** at the top right of the navigation menu bar and select **Edit Profile** from the drop-down menu. In this example, the username is **mapr**.

The *Hue Users* dialog box opens.

2. Enter your current password in the *Current password* field and enter your new password in the *New Password* field. Retype the password in the *Password confirmation* field.

User Admin **Users** Groups Permissions

## Hue Users - Edit user: mapr

Step 1: Credentials (required) Step 2: Names and Groups Step 3: Advanced

Username

Password

Password confirmation

Create home directory

Back Next Update user

3. Click **Update user**.

### *Adding Users*

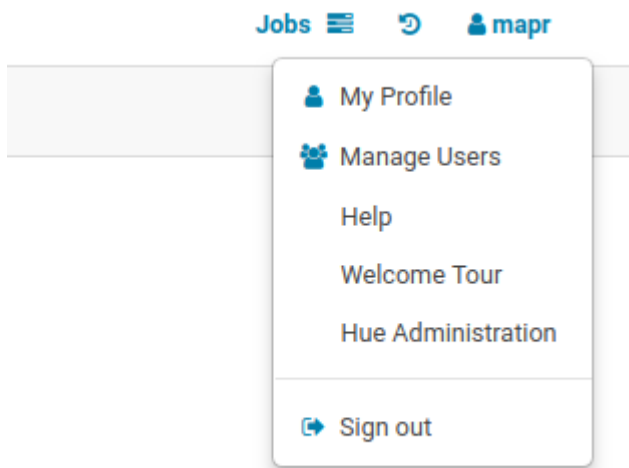

When you click on your username, all users are displayed.

### **About this task**

To create more users, follow these steps:

### **Procedure**

1. Click on your **Username** at the top right of the navigation menu bar and select **Manage Users** from the drop-down menu.

In this example, the username is **mapr**.

2. The *Hue Users - Create user* dialog box opens.

 A screenshot of the 'Hue Users - Create user' dialog box. The interface has a breadcrumb trail: 'User Admin' > 'Users' > 'Groups' > 'Permissions'. The main heading is 'Hue Users - Create user'. Below the heading, there are three steps: 'Step 1: Credentials (required)', 'Step 2: Profile and Groups', and 'Step 3: Advanced'. Step 1 is the active step. It contains three input fields: 'Username', 'New Password', and 'Password confirmation'. Below these fields is a checkbox labeled 'Create home directory' which is checked. At the bottom of the dialog, there are three buttons: 'Back', 'Next', and 'Add user'.

Click **Add user** to finish the process. If you want to assign superuser privileges to the user, click **Next** to proceed to the next screen.

3. Fill in the *Username*, *New Password*, and *Password confirmation* fields.
4. (Optional) Fill in the user's name and email address, and assign a group.

**User Admin** | Users | Groups | Permissions

## Hue Users - Create user

Step 1: Credentials (required) | Step 2: Profile and Groups | Step 3: Advanced

First name

Last name

Email address

Groups  Select all

**D**

5. (Optional) Assign superuser privileges to the user that you just added by checking the *Superuser status* box.

**User Admin** | Users | Groups | Permissions

## Hue Users - Create user

Step 1: Credentials (required) | Step 2: Profile and Groups | Step 3: Advanced

Active

Superuser status

6. Click **Add User**.

### Managing HPE Ezmeral Data Fabric Database Binary Tables in Hue 4.X

You can create and manage HPE Ezmeral Data Fabric Database binary tables in the HBase Browser of the Hue interface.

This section includes the following sections:

### Using the Hbase Browser

When you open the Hbase Browser, you can view all the directories and HPE Ezmeral Data Fabric Database binary tables available in the file system.

You can use the HBase Browser to create, edit, and search for HPE Ezmeral Data Fabric Database binary tables. However, you cannot enable, disable, or drop HPE Ezmeral Data Fabric Database binary tables.

**NOTE:** The browser also lists HPE Ezmeral Data Fabric Database JSON tables. However, their appearance is not different from that of HPE Ezmeral Data Fabric Database binary tables. You cannot edit JSON tables.

The screenshot shows the Hbase Browser interface. At the top, it says "Home - Cluster" with a "Switch Cluster" dropdown menu. Below this is a search bar labeled "Search for Table Name" and a "Drop" button. To the right is a "New Table" button. Below the search bar, there is a table with one row containing "new\_table1". Below the table, it says "No data available in table" and shows a directory tree with folders like user, oozie, tmp, opt, installer, apps, hbase, and var.

### Creating a HPE Ezmeral Data Fabric Database Binary Table

You can create a new HPE Ezmeral Data Fabric Database Binary Table.

#### Procedure

1. In the Hbase Browser, click **New Table**.
2. In the **Table Name** field, provide the full name of the table that you want to create. For example, `my_new_table`.

Create New Table
✕

Table Name:

Column Families:

✕ somefield
➕ Add a column property

➕ Add an additional column family

Cancel
Submit

3. In the *Column Families* field, you can add column families and column properties.
4. Click **Submit**. The table that you created appears in the Hbase Browser:

## Home - Cluster

Switch Cluster ▾

Search for Table Name

🗑️ Drop

➕ New Table

---

<input type="checkbox"/> Table Name
<input type="checkbox"/> new_table1
<input type="checkbox"/> my_new_table

No data available in table

📁 /

- 📁 user
- 📁 oozie
- 📁 tmp
- 📁 opt
- 📁 installer
- 📁 apps
- 📁 hbase
- 📁 var

## Starting the Hue Webserver

After you configure the `hue.ini`, you need to start the Hue Webserver and verify that it has started.

### Procedure

1. To start/restart the Hue Webserver, run the following command:

- If Hue is installed on a cluster node (the common use case and recommended practice), run the following command to start the Hue webserver:

```
maprcli node services -name hue -action start -nodes <ip_address>
```

- If Hue is installed on a cluster node (the common use case and recommended practice), run the following command to restart the Hue webserver:

```
maprcli node services -name hue -action restart -nodes <ip_address>
```

- If Hue is installed on an edge node (not recommended), run the following command to start the Hue webserver:

```
/opt/mapr/hue/hue-<version>/bin/hue-server start
```

2. To verify that the Hue webserver started, enter: `lsuf -i:8888`

The output from this command should look similar to this:

```
COMMAND      PID USER   FD    TYPE    DEVICE  SIZE/OFF  NODE  NAME
python2.6    27688 mapr    3u    IPv4    69955314      0t0   TCP  *:ddi-tcp-1
(LISTEN)
python2.6    27691 mapr    3u    IPv4    69955314      0t0   TCP  *:ddi-tcp-1
(LISTEN)
```

You can also check Hue webserver logs to verify that Hue webserver started. If the Hue webserver was installed on a *cluster* node or an *edge* node, the log is found here:

```
/opt/mapr/hue/hue-<version>/logs/runcpserver.log
```

## Livy

Apache Livy is primarily used to provide integration between Hue and Spark.

Beginning with EEP 4.0.0, Livy is included as its own package in EEP repositories. Before EEP 4.0.0, Livy was included as `mapr-hue-livy` and released only as a part of Hue. For more information about Livy, see [Apache Livy](#).

This documentation set covers the following topics for Livy:

- [Installing Livy](#) on page 255
- [Configure Livy](#) on page 4447
- [Pre-Upgrade Steps for Livy](#) on page 351
- [Upgrading Livy](#) on page 370
- [Post-Upgrade Steps for Livy](#) on page 386

### Livy Limitations

This page describes some limitations of the HPE Ezmeral Data Fabric implementation of Apache Livy.

Current limitations are as follows:

- The Livy programmatic Java/Scala/Python API is not supported.
- Livy artifacts are not published in the public Maven repository with other HPE Ezmeral Data Fabric artifacts.

### Configure Livy

This topic describes how to configure Livy.

For information about the required package names to configure the Livy server, see [Livy](#) on page 4446.

### Configure Livy with Security

On secure clusters, MapR-SASL authentication, encryption, and impersonation for Livy are enabled by default.

The Livy user interface is available on port 8998. To start the user interface, open a browser, and navigate to the following address:

```
https://<hostname>:8998
```

### Configure Livy on Kerberos

This topic describes how to configure Livy on Kerberos.

To configure Livy on Kerberos, add the following properties to the `livy.conf` file:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/_HOST@HADOOP.LOCALDOMAIN
livy.server.auth.kerberos.keytab = $KEYTAB
livy.server.launch.kerberos.principal = $USER/_HOST@HADOOP.LOCALDOMAIN
livy.server.launch.kerberos.keytab = $KEYTAB
```

For example:

```
livy.server.auth.type = kerberos
livy.server.auth.kerberos.principal = HTTP/node2.cluster@NODE1
livy.server.auth.kerberos.keytab = /opt/mapr/conf/mapr.keytab
livy.server.launch.kerberos.principal = mapr/node2.cluster@NODE1
livy.server.launch.kerberos.keytab = /opt/mapr/conf/mapr.keytab
```

### Livy UI on Kerberos

**NOTE:** You can login to the Livy UI on a Kerberos setup only using a web browser configured with SPNEGO.

The other option is to configure multiauth authentication on Kerberized configurations to allow you to login to Livy UI not only with SPNEGO/MapR-Negotiation mechanisms but also with PAM credentials.

### Configure Livy with Custom SSL Encryption

This topic describes how to configure Livy with custom SSL encryption.

### Procedure

1. By default, on a secure cluster, Livy reads the `ssl-server.xml` file and configures SSL from this file.

2. If you want to use custom SSL configuration, add the following properties to the `livy.conf` file:

```
## Use this keystore for the SSL certificate and key.
livy.keystore = <path-to-ssl_keystore>

# Specify the keystore password.
livy.keystore.password = <password>

# Specify the key password.
livy.key-password = <password>
```

### Configure Livy with Spark Modes

This topic describes how to configure Livy with different Spark modes.

Use these steps to configure Livy:

1. Modify the `livy.conf` file (`/opt/mapr/livy/livy-<version>/conf/livy.conf`):
  - a. If Spark jobs run in local mode, set the `livy.spark.master` property:

```
...
# What spark master Livy sessions should use.
livy.spark.master = local[*]
...
```

- b. If Spark jobs run in YARN mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
...
```

or

```
...
# What spark master Livy sessions should use.
livy.spark.master = yarn
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- c. If Spark jobs run in Standalone mode, set the `livy.spark.master` and `livy.spark.deployMode` properties (client or cluster). For example:

```
...
# What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = client
...
```

or

```
...
# What spark master Livy sessions should use.
livy.spark.master = spark://node:7077
# What spark deploy mode Livy sessions should use.
livy.spark.deployMode = cluster
...
```

- d. If Spark jobs run in Mesos mode, set the `livy.spark.master` property. For example:

```
# What spark master Livy sessions should use.
livy.spark.master = mesos://<mesos-master-node-ip>:5050
```

2. To you want to use impersonation with Livy, set `livy.impersonation.enabled` to `true` in `livy.conf`. For example:

```
# If livy should impersonate the requesting users when creating a new
session.
livy.impersonation.enabled = true
```

3. If you want to be able to access Hive through Spark for Livy, you should configure Spark with Hive, and set `livy.repl.enableHiveContext` to `true` in `livy.conf`. For example:

```
...
# Whether to enable HiveContext in livy interpreter, if it is true
hive-site.xml will be detected
# on user request and then livy server classpath automatically.
livy.repl.enableHiveContext = true
...
```

**NOTE:** If Hive is installed on a cluster and if Spark is configured on Hive, this property is set to `true` by default: `livy.repl.enableHiveContext = true`.

4. To apply the needed changes, restart the Livy service:

```
maprcli node services -name livy -action restart -nodes <livy node>
```

## HPE Ezmeral Data Fabric Streams Clients and Tools

Describes the supported HPE Ezmeral Data Fabric Streams tools and clients.

### HPE Ezmeral Data Fabric Streams Tools

Starting in EEP 8.0.0 and Core 6.2, Kafka 2.6.1.0 supports the following tools and components:

- Kafka Streams API 1.1
- KSQL 6.0.0.0
- Kafka REST 6.0.0.0
- Kafka Connect 10.0.0.0
- Kafka Schema Registry 6.0.0.0
- Spark Streaming

For a complete list of supported versions in each EEP, see [Component Versions for Released EEPs](#) on page 5783.

The following points describe the Kafka tools and provide links to additional information:

- [Kafka Streams](#) on page 4467: This tool is a programming library used for creating Java or Scala streaming applications.
- [KSQL](#) on page 4450: This tool is an open source streaming SQL engine that implements continuous, interactive queries.
- [Kafka Schema Registry](#): This tool provides a RESTful interface for storing and retrieving Avro schemas.
- [Kafka REST Proxy](#) on page 4478: This tool is used as a RESTful interface to HPE Ezmeral Data Fabric Streams.
- [Kafka Connect](#) on page 4518: This tool is used to stream data between HPE Ezmeral Data Fabric Streams and other storage systems.

### HPE Ezmeral Data Fabric Streams Clients

HPE Ezmeral Data Fabric Streams client applications can be developed for HPE Ezmeral Data Fabric Streams (as of MapR 5.2.1 with EEP 3.0). The HPE Ezmeral Data Fabric Streams clients are based on distributions of librdkafka that works with HPE Ezmeral Data Fabric Streams.

- HPE Ezmeral Data Fabric Streams C Client - Used to develop HPE Ezmeral Data Fabric Streams applications in C. See [HPE Ezmeral Data Fabric Streams C Applications](#) on page 3592
- HPE Ezmeral Data Fabric Streams Java Client - Used to develop HPE Ezmeral Data Fabric Streams applications in Java. See [HPE Ezmeral Data Fabric Streams Java Applications](#) on page 3550
- HPE Ezmeral Data Fabric Streams Python Client - Used to develop HPE Ezmeral Data Fabric Streams applications in Python. This client is available as of MapR 5.2.1 with EEP 3.0. See [HPE Ezmeral Data Fabric Streams Python Applications](#) on page 3795

**Table**

MapR release	EEP Release	Kafka librdkafka version
As of MapR 6.0.1	As of 5.0	0.11.3

### KSQL

KSQL is an open-source streaming SQL engine that implements continuous, interactive queries.

Use KSQL to query, read, write, and process data in real-time, at scale, through SQL commands. KSQL interacts directly with the [Kafka Streams API](#), eliminating the need for a Java application.

The KSQL data flow architecture is designed such that the user interacts with the KSQL server and the KSQL server interacts with the HPE Ezmeral Data Fabric Streams server.

## Use Cases

Common use cases include fraud detection, personalization, notifications, real-time analytics, and sensor data and IoT.

## Architecture

A set of KSQL processes run as a cluster, and the KSQL server process completes queries. You can dynamically add more processing capacity by starting more instances of the KSQL server. These instances are fault-tolerant: if one fails, the others continue the work. Queries are launched using the interactive KSQL command line client, which sends commands to the cluster over a REST API. The command line allows you to inspect the available streams and tables, issue new queries, check the status of and terminate running queries.

### KSQL Server

The KSQL server runs the engine that completes KSQL queries. This includes processing, reading, and writing data to and from the target Kafka cluster. KSQL servers form KSQL clusters and can run in containers, virtual machines, and bare-metal machines. You can add and remove servers in a KSQL cluster during live operations to elastically scale processing capacity. You can deploy different KSQL clusters to achieve workload isolation.

### KSQL CLI

You can interactively write KSQL queries through the KSQL command line interface (CLI). The KSQL CLI acts as a client to the KSQL server.

## KSQL Deployment Modes

You can deploy KSQL queries through Interactive or Non-Interactive mode.

### Interactive Mode

In Interactive mode, users interact with the KSQL server through a REST API, such as the KSQL CLI. Interactive mode is useful when users need to write and verify their queries interactively on a shared KSQL cluster. In interactive KSQL clusters, the authenticated KSQL user must have open access to create, read, write, delete topics, and use of any consumer group.

Starting in EEP 7.0.0 (Core 6.2.0 and KSQL 5.2.1.0), Interactive mode is recommended for production.

**Non-Interactive Mode (Headless Mode)**

Non-interactive mode supports locked-down or “headless” deployment scenarios where interactive use of the KSQL cluster is disabled, thereby preventing KSQL CLI access. In this mode, you can write queries to an SQL file, which allows for version control, and lock down access to KSQL servers to prevent users from interacting directly with the KSQL cluster.

**KSQL Security**

By default, KSQL is secured when installed on secured clusters (clusters secured by the data fabric ticket-based security). See [KSQL Security](#) on page 4452 for additional information.

**For More Information**

- [Apache Kafka KSQL](#)
- [Configuring Apache Kafka KSQL Server](#)
- [Apache Kafka Streams](#)

**KSQL Security**

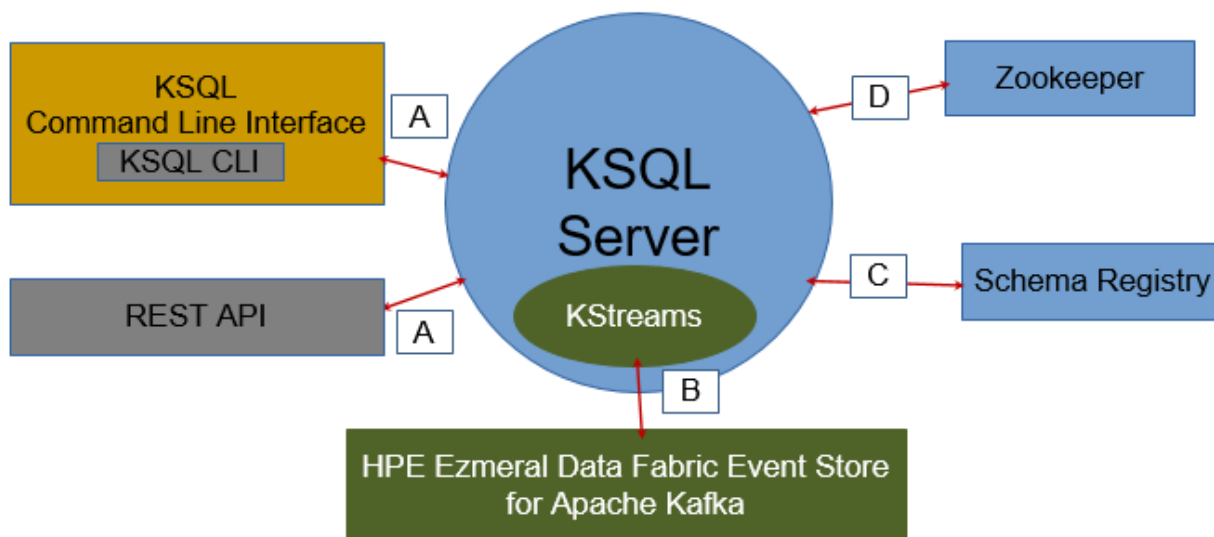

Discusses KSQL security topics.

**KSQL Security Overview**

By default, KSQL is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (MapR-SASL) enabled. Default security provides authentication, encryption, impersonation, and authorization. For encryption, SSL/TLS protocols are supported.

**KSQL Communication Paths**

The following image depicts the KSQL communication paths:

The following table lists the supported security mechanisms for the KSQL communication paths:

**NOTE:** Path B does not have a network connection and therefore does not need to be secured. However, impersonation works for this path through KSQL Server.

Security Features	Supported Mechanisms	Communication Paths Secured	
<b>Authentication</b>	MapR-SASL (ticket-based security)	<b>D</b> - KSQL Server and ZooKeeper	
		<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server	
		<b>C</b> - KSQL Server and Schema Registry	
	Basic (PAM)	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server	
		<b>C</b> -KSQL Server and Schema Registry	
	Cookie	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server	
		<b>C</b> - KSQL Server and Schema Registry	
<b>Encryption</b>	MapR-SASL (ticket-based security)	<b>D</b> - KSQL Server and ZooKeeper	
		<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server	
		<b>C</b> -KSQL Server and Schema Registry	
	SSL/TLS	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server	
		<b>C</b> - KSQL Server and Schema Registry	
	<b>Authorization</b>	Based on filesystem permissions	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL server
	<b>Impersonation</b>	User impersonation	<b>A</b> - KSQL client (KSQL CLI/REST API) and KSQL Server
<b>B</b> - KSQL Server to Streams for Apache Kafka			
<b>C</b> - KSQL Server and Schema Registry			
<b>Auditing</b>	Not supported	--	

### Impersonation

See [KSQL Impersonation](#) on page 4456.

### Authorization

See [KSQL Authorization](#) on page 4455.

### Authenticating to KSQL

To authenticate to the KSQL server from the KSQL CLI, include the `--auth` flag and indicate the authentication type for your KSQL environment, for example:

```
ksql --auth MAPRSASL http://<ip-address>:8084
//Note that 8084 is the default port for KSQL.
```

The default value for `--auth` is MAPRSAL. The `--auth` flag accepts the following values:

- `--auth BASIC` (For basic or PAM, the system prompts users for a username and password.)

- `--auth MAPRSASL` (For MapR-SASL, a mapr user ticket is used.)
- `--auth NONE` (For none, authentication is disabled.)

To connect the KSQL client to a KSQL server running in a remote cluster, include the `--cluster` option with the remote cluster name, as shown:

```
ksql --cluster my.mapr.cluster https://<ip-address>:8084
```

## KSQL COMMANDS

The KSQL COMMANDS internal topic is used to backup information about KSQL streams, KSQL tables, KSQL persistent queries, and so on. KSQL uses KSQL COMMANDS to restore the KSQL server state in case there is a fault or server restart.

Each KSQL Server cluster has a unique service ID which is provided through the `ksql.service.id` property. By default, the `ksql.service.id` is `_default`. To provide additional security, `ksql.service.id`-specific folders are created in the `ksql-internal-stream` stream.

**NOTE:** The `/apps` directory has only write access to `mapr` user. Therefore, the `/apps/ksql` directory cannot be modified or deleted by any user other than `mapr` user.

KSQL `ksql.service.id`-specific folders are created in the `/apps/ksql/` directory for every KSQL server cluster (represented by `ksql.service.id`).

## Default Stream

KSQL Server provides a default stream for topics when they are being processed. When KSQL Server is not impersonated (non-interactive or interactive+no-impersonation), the KSQL Server default stream is used.

## KSQL Cleanup

The KSQL cleanup feature is integrated to ensure that the underlying KSQL state (such as internal topics) are cleaned up correctly. See [Application Reset Tool](#) on page 4473 for more information.

## Deployment

The Warden service (`mapr-warden`) manages KSQL Servers in clusters.

**NOTE:** A service ID (`ksql.service.id`) is uniquely created for the KSQL implementation; this means that the user associated with the `service ID` cannot grant permissions to other users to use the same service ID.

## Cookie Authentication for KSQL

User credentials or challenge strings use cookies to sign requests. After cookies are received on the client side, user credentials or challenge strings are erased from memory. For KSQL, when cookies expire, you have to login again to get the new cookies. Default expiration time for cookies is one week.

## Specify a Custom KSQL Truststore Location on a Secure Cluster

By default, the KSQL CLI uses the truststore file located in `/opt/mapr/conf/ssl_truststore` on a secure cluster; however, you can specify a custom SSL truststore file location through properties set from the command line or in the `ksql-server.properties` file.

**Use the Default Truststore File**

To use the default truststore file while working in the KSQL CLI, run:

```
ksql https://node1.cluster.com:8084
```

**Specify a Custom KSQL Truststore from the Command Line**

Use the `--truststore` flag with the directory location where the SSL truststore file is located and the `--truststore-password` with the truststore password, as shown in the following example:

```
ksql https://
node1.cluster.com:8084 --truststore /o
pt/mapr/conf/
ssl_truststore2 --truststore-password
test123
```

**For More Information**

- [Apache Kafka KSQL](#)
- [Configuring Apache Kafka KSQL Server](#)

*KSQL Authorization*

Describes authorization for Kafka KSQL.

In secure clusters, authorization is enabled by default. In insecure clusters, authorization is disabled by default.

You can enable or disable authorization for KSQL in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file through the following option:

```
authorization.enable=[true|false]
```

**Permissions**

Permissions grant or deny access to users that run commands and maintain background processes that interact with KSQL internal data and structure information, such as persistent queries, tables, streams, and server configuration. *Read* permission grants users and groups access to `FETCH`, `SHOW`, and `DESCRIBE`. *Modify* permission grants users and groups access to `ADD`, `UPDATE`, and `REMOVE`.

Each user or group in a cluster can have no permissions, *read* permission, *modify* permission, or both *read* and *modify* permission to the KSQL service. By default all data-fabric cluster users have both *read* and *modify* permissions.

Internally, the authorization filter is based on *consumeperms* and *produceperms* for the KSQL Kafka store internal stream (`/apps/ksql/<service.id>/ksql-commands:ksql-authorization-auxiliary-topic`). *Consumeperms* correspond to the KSQL service *read* permissions. *Produceperms* correspond to the KSQL service *modify* permissions. These permissions can be changed by modifying the ACE of *produceperms* and *consumeperms* for `/apps/ksql/<service.id>/ksql-commands:ksql-authorization-auxiliary-topic`.

The following sections describe KSQL statements that require *read* and *modify* access.

**Statements that Require Read Access****DESCRIBE [EXTENDED] ...**

List the columns in a stream or table along with its attributes and information.

<b>DESCRIBE FUNCTION ...</b>	Provides a description of a function including an input parameters and the return type.
<b>EXPLAIN ...</b>	Show the execution plan for a SQL expression or, given the ID of a running query, show the execution plan plus additional runtime information and metrics.
<b>PRINT ...</b>	Print the contents of Kafka topics to the KSQL CLI.
<b>SELECT ...</b>	Selects rows from a KSQL stream or table.
<b>SHOW ...</b>	List functions, streams, tables, queries, properties.
<b>SHOW TOPICS &lt;MAPR_STREAM&gt;</b>	List topics.

### Statements that Require Modify Access

<b>CREATE STREAM TABLE ... WITH (...)</b>	Create a new stream or table with the specified columns and properties.
<b>CREATE STREAM TABLE ... [WITH (...)] AS SELECT ...</b>	Create a new stream or table and continuously write the result of the SELECT query into the stream.
<b>INSERT INTO ... SELECT ...</b>	Stream the result of the SELECT query into an existing stream and its underlying topic.
<b>INSERT INTO ... VALUES ...</b>	Produce a row into an existing stream or table and its underlying topic based on explicitly specified values.
<b>DROP STREAM TABLE [IF EXISTS] ...</b>	Drops an existing stream or table.
<b>DROP STREAM TABLE [IF EXISTS] ... DELETE TOPIC</b>	Drops an existing stream or table and deletes the underlying topic.
<b>TERMINATE ...</b>	Terminate a persistent query.

#### *KSQL Impersonation*

Describes impersonation for Kafka KSQL.

The HPE Ezmeral Data Fabric Event Store implementation performs impersonation on behalf of KSQL CLI users in KSQL Servers. Impersonation authorizes the impersonated user to perform permission-sensitive operations.

**Requirement:** For impersonation to work, KSQL authentication must be enabled; otherwise, the server will not start and the system will return an error. When authentication is enabled, all commands run as the authenticated user instead of the KSQL principal. The KSQL principal is the user that started KSQL server.

You can enable or disable impersonation for KSQL in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file through the following option:

```
impersonation.enable=[true|false]
```

#### **Related concepts**

[KSQL Authorization](#) on page 4455

Describes authorization for Kafka KSQL.

#### **KSQL Configuration**

Set KSQL configuration and security parameters in the `ksql-server.properties` file. The default port for KSQL is 8084.

#### **Configuring KSQL to Run in Non-Interactive (Headless) Mode**

To run KSQL in non-interactive mode, set the parameters shown and then start KSQL.

**NOTE:** Note that the `ksql.default.stream` parameter is optional, but recommended. This parameter sets the default stream to consume from and send the messages to. The default stream is used if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message is sent to `exampleStream:exampleTopic`.

Set the following properties in the `/opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties` file:

```
ksql.command.topic.suffix=commands
ksql.service.id=app2
listeners=http://localhost:8084
ksql.default.stream=/sample-stream
```

Start KSQL:

```
$ KSQL_INSTALL_DIR/bin/ksql-server-start /opt/mapr/ksql/ksql-<version>/etc/ksql/ksql-server.properties --queries-file some-queries-file.sql
```

### Configuring KSQL to Run in Interactive Mode

The following example shows the configuration parameters that you must set in the `ksql-server.properties` file to run KSQL in interactive (distributed) mode:

```
ksql.command.topic.suffix=commands
ksql.service.id=app2
listeners=http://192.168.121.73:8084
ksql.default.stream=/sample-stream
```

**NOTE:** You must set the `listeners` parameter to an actual IP address.

### For more information

- For installation information, see [Installing KSQL](#) on page 245.
- For Apache Kafka information, see the [Apache Kafka Streams API](#), [Apache Kafka Producer Clients](#), and the [Apache Kafka Consumer Clients](#).

### KSQL Configuration Parameters

Set the KSQL configuration parameters in the `/opt/mapr/ksql/ksql-<version>/config/ksql-server.properties` file. For more information about configuration parameters, see [KSQL Configuration Parameter Reference](#).

The following table describes some KSQL configuration parameters:

Parameter	Description
<code>ksql.default.stream</code>	The stream that is used when a topic is used without a stream name.
<code>ksql.schema.registry.enable</code>	Flag for enabling Avro format support with Schema Registry. Default value: false
<code>ksql.schema.registry.service.id</code>	Indicates the ID of the schema registry service. Default value: default_
<code>ksql.schema.registry.discovery.timeout</code>	The timeout (in milliseconds) for requests to Schema Registry URL storage. Default value: 60000
<code>ksql.schema.registry.discovery.retries</code>	The number of retries for Schema Registry URL discovery. Default value: 6

Parameter	Description
ksql.schema.registry.discovery.interval	The interval (in milliseconds) between retries for Schema Registry URL discovery. Default value: 15000

### KSQL Security Parameters

Describes KSQL security parameters.

Security parameters provide an authentication, encryption, and impersonation layer between the KSQL clients and the KSQL Server. In secure clusters, KSQL is secured by default.

**Requirement:** Before you configure KSQL security parameters, verify that an `ssl_keystore` and an `ssl_truststore` file have been created.

The following table describes KSQL security parameters:

Parameter	Description	Type	Default
ksql.schema.registry.maprsasl.auth	Enable MapR Sasl authentication for Avro format with Schema Registry.	boolean	false
authentication.cookie.expiration	Authentication cookie expiration time in seconds.	long	7200 (2 hours)
authorization.enable	Set 'true' or 'false' to enable or disable authorization for KSQL service. See <a href="#">KSQL Authorization</a> on page 4455.	boolean	false
authentication.enable	Whether or not to enable authentication.	boolean	false
impersonation.enable	Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user. See <a href="#">KSQL Impersonation</a> on page 4456.	boolean	false
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: <a href="http://localhost:8084">http://localhost:8084</a>	list	none
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none
ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	<ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .DES.</li> <li>• .MD5.</li> <li>• .RC4.</li> </ul>
ssl.client.auth	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store. <i>This option is not available in KSQL 6.0.</i>	boolean	false
ssl.client.authentication	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store. Possible values are NONE, REQUESTED, and REQUIRED. <i>This option is available in KSQL 6.0.</i>	string	none

Parameter	Description	Type	Default
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>SSLv3</li> <li>TLSv1.0</li> </ul>
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. <b>IMPORTANT:</b> Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=https</code> . Leave blank to use Jetty's default.	string	none
ssl.key.password	The password of the private key in the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.   <b>NOTE:</b> If the <code>ssl-client.xml</code> file is changed, restart KSQL.	string	empty
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	empty
ssl.keystore.location	Location of the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.   <b>NOTE:</b> If the <code>ssl-client.xml</code> file is changed, restart KSQL.	string	empty
ssl.keystore.password	The store password for the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.   <b>NOTE:</b> If the <code>ssl-client.xml</code> file is changed, restart KSQL.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the <code>SslContextFactory</code> .	string	TLS
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false

Parameter	Description	Type	Default
headers.file	The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.	string	empty

**Related reference**

[KSQL Security](#) on page 4452

Discusses KSQL security topics.

**KSQL Reference**

KSQL-specific commands are commands for setting your KSQL configuration, exiting the CLI, and so on.

Run the KSQL with --help to see the available options.

```
./bin/ksql --help
```

CLI commands include:

- help
- clear
- output
- output <format>
- history
- version
- exit

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

*KSQL Statements***General Syntax**

KSQL is started by issuing the `./bin/ksql` command and the KSQL statements are run in the KSQL command line once it starts.

KSQL statements must be terminated with a semicolon (;).

For multi-line statements:

- In the CLI, you use a back-slash (\) to indicate continuation of a statement on the next line.
- Do not use backslashes (\) for multi-line statements in .sql files.

**CREATE STREAM****CREATE STREAM WITH clause**

Creates a new stream with the specified columns and properties.

```
CREATE STREAM stream_name ( { column_name data_type } [, ...] )
  WITH ( property_name = expression [, ...] );
```

**CREATE STREAM WITH clause and AS SELECT**

Creates a new stream with the specified columns and properties along with the corresponding HPE Ezmeral Data Fabric Streams topic.

```
CREATE STREAM stream_name
  [WITH ( property_name = expression [, ...] )]
  AS SELECT select_expr [, ...]
  FROM from_item [, ...]
  [ WHERE condition ]
  [PARTITION BY column_name]
```

**CREATE TABLE****CREATE TABLE WITH clause**

Creates a new KSQL table with the specified columns and properties.

```
CREATE TABLE table_name ( { column_name data_type } [, ...] )
  WITH ( property_name = expression [, ...] );
```

**CREATE TABLE WITH clause and AS SELECT**

Creates a new stream with the specified columns and properties along with the corresponding HPE Ezmeral Data Fabric Streams topic and stream.

```
CREATE TABLE table_name
  [WITH ( property_name = expression [, ...] )]
  AS SELECT select_expr [, ...]
  FROM from_item [, ...]
  [ WINDOW window_expression ]
  [ WHERE condition ]
  [ GROUP BY grouping_expression ]
  [ HAVING having_expression ];
```

**DESCRIBE****DESCRIBE**

Lists the columns in a stream or table along with their data type and other attributes.

```
DESCRIBE (stream_name|table_name);
```

**DESCRIBE EXTENDED**

Displays DESCRIBE information with additional runtime statistics, HPE Ezmeral Data Fabric Streams topic details, and the set of queries that populate the table or stream.

```
DESCRIBE [EXTENDED] (stream_name|table_name);
```

**EXPLAIN****EXPLAIN**

Shows the execution plan for a SQL expression or, given the ID of a running query, shows the execution plan plus additional runtime information and metrics.

```
EXPLAIN (sql_expression|query_id);
```

## DROP STREAM

### DROP STREAM

Drops an existing stream

```
DROP STREAM stream_name;
```

## DROP TABLE

### DROP TABLE

Drops an existing table.

```
DROP TABLE table_name;
```

## PRINT

### PRINT

Prints topic contents to the KSQL CLI.

**NOTE:** SQL grammar defaults to uppercase formatting. To print topics containing lower-case characters, use quotations.

```
PRINT qualified_name (FROM BEGINNING)? ((INTERVAL | SAMPLE) number)?
```

### Print Example

```
ksql> print '/sample-stream:streams-pipe-input' FROM BEGINNING;
Format:STRING
3/16/18 1:04:39 AM EET , 1 , record1
3/16/18 1:04:39 AM EET , 5 , record5
3/16/18 1:04:39 AM EET , 6 , record6
3/19/18 4:22:51 PM EET , null , Hello
3/19/18 4:23:05 PM EET , null , Hello2
```

## SELECT

### SELECT

Selects rows from a KSQL stream or table. The result of this statement is not persisted in a topic and is only printed out in the console. To stop the continuous query in the CLI press Ctrl-C.

```
SELECT select_expr [, ...]
FROM from_item
[ LEFT JOIN join_table ON join_criteria ]
[ WINDOW window_expression ]
[ WHERE condition ]
[ GROUP BY grouping_expression ]
[ HAVING having_expression ]
EMIT CHANGES
[ LIMIT count ];
```

**SELECT CAST expression type**

Casts an expression's type to a new type.

```
CAST (expression AS data_type);
```

```
SELECT userid, CONCAT(CAST(COUNT(*) AS VARCHAR), '_HELLO')
FROM pageviews
WINDOW TUMBLING (SIZE 20 SECONDS)
GROUP BY userid
EMIT CHANGES;
```

**SELECT LIKE operator**

The LIKE operator is used for prefix or suffix matching. Currently KSQL supports %, which represents zero or more characters.

```
column_name LIKE pattern;
```

```
SELECT userid
FROM pageviews
WHERE userid LIKE '%4'
EMIT CHANGES;
```

**SHOW TOPICS****SHOW TOPICS**

Prints topic information for all topics for the default stream (specified by ksql.default.stream). If the default stream is not specified, then an exception is thrown.

```
SHOW TOPICS;
```

**SHOW TOPICS <stream\_name>**

Prints topic information for all topics from the specified stream. For example: /sample-stream

```
SHOW TOPICS '/sample-stream';
```

**SHOW STREAMS****SHOW STREAMS**

List the defined streams.

```
SHOW | LIST STREAMS;
```

**SHOW TABLES****SHOW TABLES**

List the defined TABLES.

```
SHOW | LIST TABLES;
```

**SHOW QUERIES**

**SHOW QUERIES**

List the running persistent queries.

```
SHOW | LIST QUERIES;
```

**SHOW PROPERTIES****SHOW PROPERTIES**

Lists the configuration setting that are currently in effect.

```
SHOW PROPERTIES;
```

**TERMINATE****TERMINATE**

Terminate a persistent query. Persistent queries run continuously until they are explicitly terminated

```
TERMINATE query_id;
```

*Scalar Functions*

The following are scalar functions for KSQL.

**Table**

Function	Example	Description
ABS	ABS(col1)	Absolute value of a value.
CEIL	CEIL(col1)	Ceiling of a value.
CONCAT	CONCAT(col1, '_hello')	Concatenate two strings.
EXTRACTJSONFIELD	EXTRACTJSONFIELD(message, '\$.log.cloud')	Given a string column in JSON format, extract the field that matches.
ARRAYCONTAINS	ARRAYCONTAINS(['1, 2, 3'], 3)	Given a JSON or AVRO array, checks if a search value is contained in it.
FLOOR	FLOOR(col1)	Floor of a value.
LCASE	LCASE(col1)	Convert a string to lowercase.
LEN	LEN(col1)	Length of a string.
RANDOM	RANDOM()	Returns a random DOUBLE value between 0 and 1.0
ROUND	ROUND(col1)	Round a value to the nearest BIGINT value.
STRINGTOTIMESTAMP	STRINGTOTIMESTAMP(col1, 'yyyy-MM-dd HH:mm:ss.SSS')	Converts a string value in the given format into the BIGINT value representing the timestamp.
SUBSTRING	SUBSTRING(col1, 2, 5)	Returns the substring with the start and end indices.
TIMESTAMP TO STRING	TIMESTAMP TO STRING(ROWTIME, 'yyyy-MM-dd HH:mm:ss.SSS')	Converts a BIGINT timestamp value into the string representation of the timestamp in the given format.
TRIM	TRIM(col1)	Trim the spaces from the beginning and the end of the string.

**Table (Continued)**

Function	Example	Description
CASE	CASE(col1)	Convert a string to uppercase.

*Aggregate Functions*

The following are aggregate functions for KSQL.

**Table**

Function	Example	Description
COUNT	COUNT(col1)	Counts the number of rows.
MAX	MAX(col1)	Returns the maximum value for a given column and window.
MIN	MIN(col1)	Returns the minimum value for a given column and window.
SUM	SUM(col1)	Sums the column values.
TOPK	TOPK(col1, K)	Returns the TopK values for the given column and window.
TOPKDISTINCT	TOPKDISTINCT(col1, K)	Returns the distinct TopK values for the given column and window.

**Pipe Code Sample**

Provides sample code for a Pipe example.

The following is a Pipe code sample that moves an inputTopic to an outputTopic:

```
ksql> CREATE STREAM stream3 (message varchar) WITH (kafka_topic='/
sample-stream:inputTopic', value_format='DELIMITED');

ksql> CREATE STREAM stream4 WITH (kafka_topic='/
sample-stream:streams-pipe-output1', value_format='DELIMITED') AS SELECT *
FROM stream3;
```

**KSQL Demo**

The following demo example creates a stream, performs a non-persistent query, and a persistent query.

**Setup**

Complete the following steps to prepare your environment for querying:

1. Create a default stream using /sample-stream:

```
maprcli stream create -path /sample-stream
-produceperm p -consumeperm p -topicperm p
```

2. Run the following script to generate test data that writes to an HPE Ezmeral Data Fabric Streams topic:

```
./bin/ksql-datagen quickstart=pageviews format=delimited
topic=/sample-stream:pageviews maxInterval=10000
```

**3. Run KSQL CLI and create a KSQL table:**

```
> ./bin/ksql http://<ksql-server>:8084
ksql> CREATE STREAM pageviews
      (viewtime BIGINT,
       userid VARCHAR,
       pageid VARCHAR)
      WITH (KAFKA_TOPIC='/sample-stream:pageviews',
           VALUE_FORMAT='DELIMITED');

ksql> CREATE TABLE PAGEVIEWS_TABLE
      WITH(KAFKA_TOPIC='/sample-stream:pageviews_table')
      AS
      SELECT userid,
             MAX(viewtime)
      FROM pageviews
      GROUP BY userid;
```

**4. Run the SHOW TABLES command to list your KSQL tables:**

```
ksql> SHOW TABLES;
```

**Run a Non-persistent Query**

For a non-persistent query in KSQL 6.0, run:

```
ksql> SELECT * FROM PAGEVIEWS_TABLE WHERE userid='User_1';
```

**Run a Persistent Query**

For a persistent query, do the following:

**1. Create the topic, /sample-stream:input-topic:**

```
maprcli stream topic create -path /sample-stream -topic input-topic
```

**2. Create a KSQL input stream:**

```
ksql> CREATE STREAM stream1 (message varchar) WITH
      (kafka_topic='/sample-stream:input-topic' ,
       value_format='DELIMITED');
```

**3. Create persistent query with filtering:**

```
ksql> CREATE STREAM stream2
      WITH (kafka_topic='/sample-stream:output-topic' ,
           value_format='DELIMITED')
      AS SELECT * FROM stream1 WHERE LEN(message) > 2;
```

**4. List your queries:**

```
ksql> SHOW QUERIES;
```

5. Run the provided sample code for the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
--broker-list fake.server.id:9092 --topic /sample-stream:input-topic
```

6. Run the provided sample code for the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
--bootstrap-server fake.server.id:9092
--topic /sample-stream:output-topic
```

7. Produce some data:

```
>Hi
>Hello
>No
>Yes
```

8. Get the next results:

```
Hello
Yes
```

### Auxiliary Scripts Location

The sample code for `kafka-console-producer.sh` and `kafka-console-consumer.sh` is packaged with MapR Kafka. Once MapR Kafka is installed, you can find them at:

```
/opt/mapr/kafka/kafka-<version>/bin/
```

### Kafka Streams

Kafka Streams is a programming library used for creating Java or Scala streaming applications and, specifically, building streaming applications that transform input topics into output topics.

Kafka Streams allows you to build moderately complex operational streaming applications faster by offloading common functions such as failure recovery, joins and enrichment, and aggregations and windowing.

Kafka Streams application is a distributed Java application that is launched with one or more Kafka Streams application instances. Kafka Streams applications can be built using the KStream library. A KStream application instance is required to be provided with an `application.id` property. The `application.id` property uniquely identifies the Kafka Streams distributed application.

**ATTENTION:** The Kafka Streams application must always be launched as the same user.

### Architecture

An application that uses the Kafka Streams API is a normal Java application. Package, deploy, and monitor it like you would do for any other Java application. There is no need to install separate processing clusters or similar special-purpose and expensive infrastructure.

**NOTE:** You can run one or more instances of your application. They run independently but will automatically discover each other and collaborate. In addition, you can elastically add and remove application instances during live operations. If one instance dies, another instance continues where that instance left off.

The following diagram shows an application that is running three (3) application instances.

#### For More Information

[Apache Kafka Streams](#)

#### Kafka Streams Configuration

Describes how to configure Kafka Streams.

#### Kafka Streams Configuration

To configure Kafka Streams, set the following parameters in the Java API StreamsConfig instance:

- (Optional) Set the HPE Ezmeral Data Fabric Streams `streams.default.stream` configuration parameter. See [Apache Kafka Streams: Configuring a Streams Application](#) for more information about all of the configuration parameters, required and optional.

The default stream is used to consume from and send the messages to, if the topic name does not include the stream name. For example, if a message is sent to `exampleTopic` and this parameter is set to `/exampleStream`, then the message will be sent to `/exampleStream:exampleTopic`.

**NOTE:** If the default stream option is not set and the topic name is specified without a stream name, an exception is thrown.

- Set the Apache Kafka Streams `application.id` configuration parameter. See [Apache Kafka Streams: Configuring a Streams Application](#) for more information about all of the configuration parameters, required and optional.

#### For more information

- For installation information, see [Installing Kafka Streams](#) on page 246.
- For Apache Kafka Streams information, see [Apache Kafka Streams: Configuring a Streams Application](#).

#### Supported Apache Kafka Streams APIs

Specifies the supported and not supported Apache Kafka Streams APIs.

## Supported APIs

MapR Kafka Streams uses the same APIs as Apache Kafka Streams. Behavior for HPE Ezmeral Data Fabric Streams is the same as for Apache Kafka Streams. See [Apache Kafka Streams documentation](#) .

## Not Supported APIs

The following `stream` methods in the `StreamsBuilder` class are not supported:

- `<K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern)`
- `<K,V> KStream<K,V> stream(java.util.regex.Pattern topicPattern, Consumed<K,V> consumed)`

Use the following `stream` method instead:

- `<K,V> KStream<K,V>stream(java.util.Collection<java.lang.String> topics)`

## Running a Kafka Streams Java App

Describes how to set up and run a Kafka Streams Java application.

### Setup

To set up your project, add the required dependencies to the `pom.xml` file, as shown in the example. Note that the versions you use may differ from the versions shown in the example. Version numbers typically change with new releases.

Maven artifacts are published to <https://repository.mapr.com/maven/>. You can also refer to [Maven Artifacts for the HPE Ezmeral Data Fabric](#) on page 4759 for dependency versions.

### Example pom.xml

The following example shows the dependencies you must add to `pom.xml`.

```

<repository>
  <id>mapr-releases</id>
  <url>https://repository.mapr.com/maven/</url>
</repository>
<dependency>
  <groupId>org.apache.kafka</groupId>
  <artifactId>kafka-clients</artifactId>
  <version>2.1.1.200-mapr-710</version>
</dependency>
<dependency>
  <groupId>org.apache.kafka</groupId>
  <artifactId>kafka-streams</artifactId>
  <version>2.1.1.200-mapr-710</version>
</dependency>
<dependency>
  <groupId>com.mapr.streams</groupId>
  <artifactId>mapr-streams</artifactId>
  <version>6.2.0.0-mapr</version>
</dependency>
<dependency>
  <groupId>org.rocksdb</groupId>
  <artifactId>rocksdbjni</artifactId>
  <version>5.7.3</version>
</dependency>
<dependency>

```

```
<groupId>commons-logging</groupId>
<artifactId>commons-logging</artifactId>
<version>1.1.1</version>
</dependency>
```

**IMPORTANT:** For Kafka 3.6.1, enter 5.18.4 as the `rocksdbjni` version, and use `kafka-eventstreams` instead of `mapr-streams`, as shown:

```
<dependency>
  <groupId>org.rocksdb</groupId>
  <artifactId>rocksdbjni</artifactId>
  <version>5.18.4</version>
</dependency>
<dependency>
  <groupId>org.apache.kafka</groupId>
  <artifactId>kafka-eventstreams</artifactId>
  <version>3.6.1-eep-930</version>
</dependency>
```

### Running a Kafka Streams App on a Cluster

To run a Kafka Streams Java application on a cluster:

1. Copy the `<Kafka Streams Java application>.jar` file to an arbitrary folder on your cluster.
2. Run the following shell command on your cluster:
  - For Kafka 2.1.1, run:

```
java -cp "$(mapr clientclasspath):<Kafka Streams Java
application>.jar" <Kafka Streams Application Main Class Name>
```

- For Kafka 3.6.1, run:

```
java cp "$(mapr clientclasspath):/opt/mapr/kafka/kafka<version>/libs/
kafka-eventstreams<version>.jar:<Kafka Streams Java application>.jar"
<Kafka Streams Application Main Class Name>
```

### Pipe Code Sample

Provides sample code for a Pipe example.

The following is a Pipe code sample that moves records from an `inputTopic` to an `outputTopic`:

```
...
final StreamBuilder builder = new StreamBuilder();
KStream<String,String> source = builder.stream(inputTopic);
source.to(outputTopic);
final Topology topology= builder.build();
final KafkaStreams streams=new KafkaStreams(topology, props);
...
streams.start();
...
```

### Kafka Streams Demo

Provides a Kafka Streams demo example that creates a stream and topics and runs the `WordCountDemo` class code. The sample code produces and consumes messages.

1. Create the a stream named /sample-stream:

```
maprcli stream create -path /sample-stream -produceperm p -consumeperm p -topicperm p
```

2. Create word-count-input and word-count-output topics:

```
maprcli stream topic create -path /sample-stream -topic word-count-input
maprcli stream topic create -path /sample-stream -topic word-count-output
```

3. Build the word count application and copy its JAR file to your cluster.
4. Run the WordCountDemo class.

- For Kafka 2.1.1 and earlier, run:

```
java -cp "$(mapr clientclasspath):<Word Count Application Name>.jar"
WordCountDemo
```

- For Kafka 2.6.1, run:

```
java -cp "$(mapr clientclasspath):/opt/mapr/kafka/kafka-<version>/libs/
kafka-eventstreams<version>.jar:<Word Count Application Name>.jar"
WordCountDemo
```

5. Run the console producer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-producer.sh
--broker-list fake.server.id:9092
--topic /sample-stream:word-count-input
```

6. Run the console consumer:

```
/opt/mapr/kafka/kafka-<version>/bin/kafka-console-consumer.sh
--bootstrap-server fake.server.id:9092
--topic /sample-stream:word-count-output
--property print.key=true
```

7. Produce some input with the console producer:

```
>word27 word28 word27 word29
```

8. Get the following output:

```
word28 1
word27 2
Word29 1
```

### WordCountDemo Class Code

```
import org.apache.kafka.common.serialization.Serdes.StringSerde;
import org.apache.kafka.common.serialization.Serdes;
import org.apache.kafka.common.utils.Bytes;
```

```

import org.apache.kafka.streams.KafkaStreams;
import org.apache.kafka.streams.StreamsBuilder;
import org.apache.kafka.streams.StreamsConfig;
import org.apache.kafka.streams.Topology;
import org.apache.kafka.streams.kstream.*;
import org.apache.kafka.streams.state.KeyValueStore;

import java.util.Arrays;
import java.util.Locale;
import java.util.Properties;
import java.util.concurrent.CountDownLatch;

public class WordCountDemo {

    public static final String INPUT_TOPIC = "/
sample-stream:word-count-input";
    public static final String OUTPUT_TOPIC = "word-count-output"; //
Default stream will be used

    public static final String DEFAULT_STREAM = "/sample-stream";

    public static final String APP_ID = "app-id";

    public static void main(String[] args) {
        Properties props = new Properties();
        props.put(StreamsConfig.APPLICATION_ID_CONFIG, APP_ID);
        props.put(StreamsConfig.DEFAULT_KEY_SERDE_CLASS_CONFIG,
StringSerde.class);
        props.put(StreamsConfig.DEFAULT_VALUE_SERDE_CLASS_CONFIG,
StringSerde.class);

        props.put(StreamsConfig.COMMIT_INTERVAL_MS_CONFIG, 500); // Put
attention to this property
        props.put(StreamsConfig.STREAMS_DEFAULT_STREAM_CONFIG,
DEFAULT_STREAM);

        final StreamsBuilder builder = new StreamsBuilder();

        KStream<String, String> wordCountStream = builder.<String,
String>stream(INPUT_TOPIC)
            .flatMapValues(value ->
Arrays.asList(value.toLowerCase(Locale.getDefault()).split("\\W+")))
            .groupBy((key, value) -> value)
            .count(Materialized.<String, Long, KeyValueStore<Bytes,
byte[]>>as("counts-store"))
            .mapValues(x -> x.toString())
            .toStream();

        wordCountStream.to(OUTPUT_TOPIC, Produced.with(Serdes.String(),
Serdes.String()));

        final Topology topology = builder.build();
        final KafkaStreams streams = new KafkaStreams(topology, props);
        final CountDownLatch latch = new CountDownLatch(1);

        // attach shutdown handler to catch control-c
        Runtime.getRuntime().addShutdownHook(new
Thread("streams-shutdown-hook") {
            @Override
            public void run() {
                streams.close();
            }
        });
    }
}

```

```

        latch.countDown();
    }
});

try {
    streams.start();
    latch.await();
} catch (Throwable e) {
    e.printStackTrace();
    System.exit(1);
}
System.exit(0);
}
}

```

 **NOTE:** The `kafka-console-producer.sh` and `kafka-console-consumer.sh` scripts are part of the **mapr-kafka** package.

### Application Reset Tool

This tool allows you to reset an application and force it to reprocess its data from scratch by using the application reset tool. This tool can be useful for development and testing, or when fixing bugs.

#### Description

The application reset tool (ART) handles the Kafka Streams user topics (input, output, and intermediate topics) and internal topics differently when resetting the application.

The application reset tool does the following for each topic type:

- Input topics: Reset to the beginning of the topic. This means that it sets the application's committed consumer offsets for all partitions to each partition's `earliest` offset (for consumer group `application.id`).
- Intermediate topics: Skip to the end of the topic, i.e., set the application's committed consumer offsets for all partitions to each partition's `logSize` (for consumer group `application.id`).
- Internal topics: Delete the internal topic (this automatically deletes any committed offsets).

The application reset tool does not do the following:

- Reset output topics of an application. If any output (or intermediate) topics are consumed by downstream applications, it is your responsibility to adjust those downstream applications as appropriate when you reset the upstream application.
- Reset the local environment of your application instances. It is your responsibility to delete the local state on any machine on which an application instance was run.

See [Confluent Application Reset Tool](#) for additional reference information.

### Running the Application Reset Tool

Invoke the application reset tool from the command line:

```
/opt/mapr/bin/kafka-streams-application-reset.sh
```

The tool accepts the following parameters:

 **NOTE:** Parameters can be combined as needed. For example, if you want to restart an application from an empty internal state, but not reprocess previous data, simply omit the `--input-topics` and `--intermediate-topics` parameters.

Option	Description
--application-id <String: id>	(Required) The Kafka Streams application ID (application.id).
--default-stream	The default stream that is used when the topic name is specified but the stream name is not.
--config-file <String: file name>	Property file containing configs to be passed to admin clients and embedded consumer.
--dry-run	Display the actions that would be performed without executing the reset commands.
--input-topics <String: list>	Comma-separated list of user input topics. For these topics, the tool will reset the offset to the earliest available offset.
--intermediate-topics <String: list>	Comma-separated list of intermediate user topics (topics used in the through() method). For these topics, the tool will skip to the end.

### Resetting your Local Environments

To reset the local environments of your application instances, you must delete your application's local state directory on any machines where the application instance was run. You must do this before restarting an application instance on the same machine. You can use either of these methods:

 **NOTE:** This is a complete application reset

The API method `KafkaStreams#cleanUp()` in your application code. Manually delete the corresponding local state directory (default location: `/tmp/kafka-streams/<application.id>`). For more information, see `state.dir` `StreamsConfig` class.

### Example

In this example you are developing and testing an application locally and you want to iteratively improve your application via run-reset-modify cycles.

```
package mapr.examples.streams;

import ...;

public class ResetDemo {

    public static void main(String[] args) throws Exception {
        // Kafka Streams configuration
        Properties streamsConfiguration = new Properties();
        streamsConfiguration.put(StreamsConfig.APPLICATION_ID_CONFIG,
"my-streams-app");
        // ...and so on...

        // Define the processing topology
        StreamsBuilder builder = new StreamsBuilder();
        builder.stream("my-input-topic")
            .selectKey(...)
            .through("rekeyed-topic")
            .countByKey("global-count")
            .to("my-output-topic");

        KStreams app = new KafkaStreams(builder.build(), streamsConfiguration);

        // Delete the application's local state.
        // Note: In real application you'd call `cleanUp()` only under
```

```
// certain conditions. See tip on `cleanUp()` below.
app.cleanUp();

app.start();

// Note: In real applications you would register a shutdown hook
// that would trigger the call to `app.close()` rather than
// using the sleep-then-close example we show here.
Thread.sleep(30 * 1000L);
app.close();
}
}
```

You can then perform run-reset-modify cycles as follows:

```
# Run your application
$ bin/kafka-run-class mapr.examples.streams.ResetDemo

# After stopping all application instances, reset the application
$ bin/kafka-streams-application-reset.sh --application-id my-streams-app \
   --input-topics my-input-topic \
   --intermediate-topics rekeyed-topic

# Now you can modify/recompile as needed and then re-run the application
again.
# You can also experiment, for example, with different input data without
# modifying the application.
```

### Kafka Streams Security

Discusses Kafka Streams security topics.

### Internal Topics

All Kafka Streams application's internal topics are grouped in the Kafka Streams application directory: **/apps/kafka-streams**.

- The **/apps** directory has only write access to **mapr user**. The **/apps/kafka-streams** directory is not modifiable/deletable by any user other than **mapr user**.
- All users can create sub-directories inside the **/apps/kafka-streams** directory. Only the following users have read/write/delete permission for sub-directories or files created in this directory.
  - **mapr user**
  - Current user of the sub-directory:
    - If security is enabled, the current user is the Data Fabric ticket identity. See [Managing Tickets](#) on page 1822 for more information.
    - If security is **not** enabled, the current Data Fabric identity.

### Kafka Streams Application Specific Folders

Some Kafka Streams applications need to create internal topics. These topics are created in the **/apps/kafka-streams/<application.id>** directory.

-  **IMPORTANT:** This directory is created at runtime by the Kafka Streams application and can only be modified by the current user or super users. This directory can only be deleted by the [Application Reset Tool](#) on page 4473 (ART) and, again, by only the current user or super users.

## Application Reset Tool and Cleanup APIs

The application reset tool allows to reset a Kafka Streams application's internal state, such that it can re-process its input data from scratch. Kafka Streams internal topics can be cleaned using application reset tool.

Only the current user of the Kafka Streams application or **mapr user** has permissions to clean up a Kafka Streams application using Application Reset Tool. The Application Reset Tool is integrated with the cleanup APIs so that the application's internal topics are prefixed with the same directory.

The application reset tool takes `application.id` as the input for cleaning up Kafka Streams application. As part of this process, all internal-topics are deleted for the application user under the **/apps/kafka-streams/<application.id>** directory, including the **/apps/kafka-streams/<application.id>** directory. See [Application Reset Tool](#) on page 4473 for more information.

### Changes in Kafka 2.6.1

Describes several differences to note when upgrading from Kafka 2.1.1 to 2.6.1.

#### Classpath change

- Kafka 2.6.1 uses classes from `kafka-eventstreams.jar` instead of `mapr-streams.jar` to access the cluster.
- If an application fails with a `ClassNotFoundException` or `NoClassDefFoundError` for classes in packages under `com.mapr.kafka.eventstreams.*`, verify that `kafka-eventstreams.jar` is in the Java classpath. You can find `kafka-eventstreams.jar` in the `/opt/mapr/lib/` directory, or you can download it from the Maven repository.

#### Scala changes

- Scala version 2.11 is no longer supported. Scala versions 2.12 and 2.13 are supported.
- Scala code leveraging the `NewTopic(String, int, short)` constructor with literal values must explicitly call `toShort` on the second literal.

#### RocksDBs change

- Kafka Streams version 2.6.1 requires RocksDB version 5.18.4.

#### Default consumer group id

- The default consumer group id has been changed from the empty string (" ") to `null`. Consumers that use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of the consumer configuration. For more information, see [KIP-289](#).

#### `client.dns.lookup`

The default value for the `client.dns.lookup` configuration has been changed from default to `use_all_dns_ips`. If a hostname resolves to multiple IP addresses, clients and brokers will now attempt to connect to each IP in sequence until the connection is successfully established. For more information, see [KIP-602](#).

**DSL**

- Use the DSL operator, `cogroup()`, to aggregate multiple streams together at once.
- Kafka Streams DSL switches its used store types. While this change is mainly transparent to users, there are some corner cases that may require code changes.

**KStream.toTable() API**

Use the `KStream.toTable()` API to translate an input event stream into a `KTable`.

**Serde type Void**

Use the Serde type, `Void`, to represent null keys or null values from an input topic.

**Sticky partitioning**

The `DefaultPartitioner` now uses a sticky partitioning strategy. This means that records for a specific topic with null keys and no assigned partition will be sent to the same partition until the batch is ready to be sent. When a new batch is created, a new partition is chosen. This decreases latency to produce, but it may result in uneven distribution of records across partitions in edge cases. Generally, users will not be impacted, but this difference may be noticeable in tests and other situations producing records for a very short amount of time.

**Rebalancing**

- We are introducing incremental cooperative rebalancing to the clients' group protocol, which allows consumers to keep all of their assigned partitions during a rebalance and in the end revoke only those which must be migrated to another consumer for the overall cluster balance. The `ConsumerCoordinator` will choose the latest `RebalanceProtocol` that is commonly supported by all of the consumer's supported assignors.
- We are introducing a new rebalancing protocol for Kafka Connect based on incremental cooperative rebalancing. The new protocol does not require stopping all the tasks during a rebalancing phase between Connect workers. Instead, only the tasks that need to be exchanged between workers are stopped and they are started in a follow-up rebalance. The new Connect protocol is enabled by default. For more details on how it works and how to enable the old behavior of eager rebalancing, checkout incremental cooperative rebalancing design.

**Deprecated APIs**

- Deprecated `UsePreviousTimeOnInvalidTimestamp` and replaced with `UsePartitionTimeOnInvalidTime Stamp`.
- Provided support to query stale stores (for high availability) and the stores belonging to a specific partition by deprecating `KafkaStreams.store(String, QueryableStoreType)` and replacing it with `KafkaStreams.store(StoreQueryParameters)`.

- The internal `PartitionAssignor` interface has been deprecated and replaced with a new `ConsumerPartitionAssignor` in the public API. Some methods/signatures are slightly different between the two interfaces. Users implementing a custom `PartitionAssignor` should migrate to the new interface as soon as possible.
- The blocking `KafkaConsumer#committed` methods have been extended to allow a list of partitions as input parameters rather than a single partition. It enables fewer request/response iterations between clients and brokers fetching for the committed offsets for the consumer group. The old overloaded functions are deprecated and we would recommend users making their code changes to leverage the new methods
- The default consumer group id has been changed from the empty string ( " ") to `null`. Consumers who use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of their consumer configuration.

### Kafka REST Proxy

The Kafka REST Proxy provides a RESTful interface to HPE Ezmeral Data Fabric Streams clusters to consume and produce messages and to perform administrative operations.

It allows you to:

- Consume messages from topics or concrete topic partitions.
- Produce messages to topics or partitions.
- View the state of the cluster.

Use cases include ingesting messages into a stream-processing framework and scripting administrative operations.

### Configuration

This section describes how to configure the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams.

You can set these configuration parameters in the `kafka-rest.properties` file. The Control System displays information about the Kafka REST Proxy for the HPE Ezmeral Data Fabric Streams service. By default, the service runs on port **8082**.

To install the Kafka REST Proxy, see [Installing HPE Ezmeral Data Fabric Streams Tools](#) on page 252.

To configure the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams, edit the following file:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

To view the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams log files, see the following location:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/logs/kafka-rest.log
```

**NOTE:** After installation, Warden automatically detects the configuration and starts the service. To configure the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams, stop the service, configure the parameters, and restart the service. To stop and restart services, see [maprcli node services](#). For example:

```
maprcli node services -name kafka-rest -action stop
```

```
https://<host>:8443/rest/node/services?  
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

### Configuration Parameters

This section provides the Kafka REST Proxy for HPE Ezmeral Data Fabric Streams parameters.

These parameters are configurable in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

**NOTE:** Starting in EEP 8.0.0, Schema Registry (version 6.0.0.0) supports Avro, JSON Schema, and Protobuf formats.

**Table**

Parameter	Description
<code>api.v2.enable</code>	Enables the REST Proxy v2 API when set to <code>true</code> . Default is <code>true</code> . This parameter is available starting in Kafka REST 6.0.0.0.
<code>api.v3.enable</code>	Enables the REST Proxy v3 API when set to <code>true</code> . Default is <code>false</code> . This parameter is available starting in Kafka REST 6.0.0.0.
<code>advertised.listeners</code>	List of advertised listeners used when generating absolute URLs in responses. Supports <code>http</code> and <code>https</code> protocols. Each listener must include the protocol, hostname, and port. For example: <code>http://myhost:8080</code> , <code>https://0.0.0.0:8081</code> . This parameter is available starting in Kafka REST 6.0.0.0.
<code>schema.registry.enable</code>	Enables Avro serialization and deserialization support with Schema Registry. Starting in Schema Registry 6.0.0.0, enables JSON Schema, and Protobuf serialization and deserialization as well as Avro.
<code>schema.registry.url</code>	The base URL for the schema registry for use by the Avro serializer. Starting in Schema Registry 6.0.0.0, also for use by the JSON Schema and Protobuf serializers, as well as Avro. This setting is ignored if <code>schema.registry.enable</code> is set to <code>false</code> . The default value is resolved from Zookeeper.
<code>schema.registry.service.id</code>	Indicates the ID of the schema registry service. Default: <code>default_</code>
<code>schema.registry.discovery.timeout</code>	The timeout in milliseconds for request to Schema Registry URL storage. Default: 60000
<code>schema.registry.discovery.retries</code>	The number of retries for Schema Registry URL discovery. Default: 6
<code>schema.registry.discovery.interval</code>	The interval in milliseconds between retries for Schema Registry URL discovery. Default: 15000
<code>streams.default.stream</code>	The default stream the consumer should poll messages from and the producer should send messages to. If the topic name does not specify the stream path, and the property has a valid value, then this topic name is found in the default stream.

Table (Continued)

Parameter	Description
id	Unique ID for this REST server instance. This is used in generating unique IDs for consumers that do not specify their ID. The ID is empty by default, which makes a single server setup easier to get up and running, but is not safe for multi-server deployments where automatic consumer IDs are used. Type: string. Default: empty
consumer.threads	The number of threads to run consumer requests on. Type: int. Default: 1
simpleconsumer.cache.max.records	Maximum number of records that can be stored in a single cache. Records with higher offsets replace records with lower ones. The value must be greater than 0. Type: int. Default: 1000.
simpleconsumer.max.caches.num	Maximum number topic-partition combinations for which records are cached. If this parameter is set to 0, then caching is disabled and extra records are thrown away. Cache improves performance if records are fetched sequentially thus increasing offsets.  A pool of caches are available to store extra fetch records by a KafkaConsumer for a particular TopicPartition. The cache increases performance when records are fetched from a particular topic partition in a sequential manner. For example, every next request will start with the following offset after the offset of the latest fetched record in the previous request. Type: int. Default: 0
simpleconsumer.max.poll.time	Specifies the maximum number of milliseconds that are spent for polling records by a simpleconsumer. The greater the value means greater latency but higher throughput. Type: int. Default: 1000
simpleconsumer.pool.size.max	Maximum number of SimpleConsumers that can be instantiated. If 0, then the pool size is not limited. Type: int. Default: 25
simpleconsumer.pool.timeout.ms	Amount of time to wait for an available SimpleConsumer from the pool before failing. Use 0 for no timeout. Type: int. Default: 1000
consumer.instance.timeout.ms	Amount of idle time (in milliseconds) before a consumer instance is automatically destroyed. Type: int. Default: 300000 (5 minutes)
consumer.iterator.backoff.ms	Amount of time (in milliseconds) to backoff when an iterator runs out of data. If a consumer has a dedicated worker thread, this is effectively the maximum error for the entire request timeout. This parameter should be small enough to closely target the timeout, but large enough to avoid busy waiting. Type: int. Default: 50
consumer.request.max.bytes	Maximum number of bytes in unencoded message keys and values returned by a single request. This can be used by administrators to limit the memory used by a single consumer and to control the memory usage required to decode responses on clients that cannot perform a streaming decode. Note that the actual payload will be larger due to overhead from base64 encoding the response data and from JSON encoding the entire response. Type: long. Default: 6710884
consumer.request.timeout.ms	The maximum total time (in milliseconds) to wait for messages for a request if the maximum number of messages has not yet been reached. Type: int. Default: 1
producer.threads	Number of threads to run producer requests on. Type: int. Default: 5
producer.streams.buffer.max.time.ms	Buffers messages in the producer for the maximum time specified time. A thread flushes all the messages that have been buffered beyond the time specified. Default: 1

Table (Continued)

Parameter	Description
producers.max.caches.num	Maximum number user names for which producers are cached. If 0, then caching is disabled and producer will be created for each request. Default: 20
request.logger.name	Name of the SLF4J logger to write the NCSA Common Log Format request log. Type: string. Default: io.confluent.rest-utils.requests.
response.mediatype.default	The default response media type that should be used if no specify types are requested in an Accept header. Type: string. Default: application/vnd.kafka.v1+json
response.mediatype.preferred	An ordered list of the server's preferred media types used for responses, from most preferred to least. Type: list. Default: application/vnd.kafka.v1+json, application/vnd.kafka+json, application/json
access.control.allow.methods	Sets the value to the Jetty Access-Control-Allow-Origin header for specified methods. Type: string. Default: empty
access.control.allow.origin	Sets the value for the Jetty Access-Control-Allow-Origin header. Type: string. Default: empty
host.name	The host name used to generate absolute URLs in responses. If empty, the default canonical hostname is used. Type: string. Default: empty
debug	Boolean indicating whether extra debugging information is generated in some error response entities. Type: Boolean. Default: false
shutdown.graceful.ms	Amount of time to wait after a shutdown request for outstanding requests to complete. Type: int. Default: 1000
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporterinterface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics. Type: list. Default: empty
metrics.jmx.prefix	Prefix to apply to metric names for the default JMX reporter. Type: string. Default: kafka.rest
metrics.num.samples	The number of samples maintained to compute metrics. Type: int. Default: 2
metrics.sample.window.ms	The metrics system maintains a configurable number of samples over a fixed window size. This configuration controls the size of the window. For example, used to maintain two samples each measured over a 30 second period. When a window expires, the oldest window is erased and overwritten. Type: long. Default: 30000

*Security Parameters*

Describes Kafka REST security parameters.

By default, Kafka REST is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (MapR-SASL) enabled. Default security provides authentication, encryption, and impersonation for Kafka REST.

Configure security for Kafka REST through the security parameters in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

**NOTE:** Ensure that both a `ssl_keystore` and a `ssl_truststore` file have been created.

Table

Parameter	Description	Type	Default
<code>authentication.cookie.expiration</code>	Authentication cookie expiration time in seconds.	long	7200 (2 hours)
<code>authentication.enable</code>	Whether or not to enable authentication.	boolean	false
<code>impersonation.enable</code>	Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user.	boolean	false
<code>listeners</code>	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: <code>http://localhost:8082</code>	list	none
<code>ssl.cipher.suites</code>	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none
<code>ssl.cipher.suites.exclude</code>	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	<ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .DES.</li> <li>• .MD5.</li> <li>• .RC4.</li> </ul>
<code>ssl.client.auth</code>	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store.	boolean	false
<code>ssl.disabled.protocols</code>	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>
<code>ssl.enabled.protocols</code>	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
<code>ssl.endpoint.identification.algorithm</code>	The endpoint identification algorithm to validate the server hostname using the server certificate. <b>IMPORTANT:</b> Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=https</code> . Leave blank to use Jetty's default.	string	none

Table (Continued)

Parameter	Description	Type	Default
ssl.key.password	<p>The password of the private key in the keystore file.</p> <p>This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.</p> <p> <b>NOTE:</b> If the <code>ssl-client.xml</code> file is changed, Kafka REST must be restarted.</p>	string	empty
ssl.keymanager.algorithm	<p>The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.</p>	string	empty
ssl.keystore.location	<p>Location of the keystore file.</p> <p>This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.</p> <p> <b>NOTE:</b> If the <code>ssl-client.xml</code> file is changed, Kafka REST must be restarted.</p>	string	empty
ssl.keystore.password	<p>The store password for the keystore file.</p> <p>This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file.</p> <p> <b>NOTE:</b> If the <code>ssl-client.xml</code> file is changed, Kafka REST must be restarted.</p>	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the <code>SslContextFactory</code> .	string	TLS-v1.2-
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty

Table (Continued)

Parameter	Description	Type	Default
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false
headers.file	The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.	string	empty

### SSL Security Configuration

Describes how to configure Kafka REST security.

### Secure by Default

As of release 6.0, the Data Fabric Installer performs the Kafka REST configuration for new installations. This means that:

- If Data Fabric core is installed as *secure*, then Kafka REST is also installed as *secure*.
- If Data Fabric core is installed as *insecure*, then Kafka REST is also installed as *insecure*.

### Manually Securing Kafka REST Only

 **CAUTION:** This configuration is *not* a typical configuration.

If you have an *insecure* Data Fabric cluster, and you want to *secure* Kafka REST, do the following:

1. Generate the server and client certificates.
2. Add any necessary property configurations to the `kafka-rest.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8082,https://0.0.0.0:8085
ssl.keystore.location=<ssl-keystore-path>
ssl.keystore.password=<ssl-keystore-password>
ssl.key.password=<ssl-keystore-password>
```

3. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

4. Run a curl command to ensure that HTTPS is enabled.

```
curl -X GET https://node1:8085/streams/%2Ftesting/topics --cacert
<certificate-path>
```

### Manually Unsecuring Kafka REST

 **WARNING:** This scenario is *NOT* recommended or supported.

If you have an *secure* Data Fabric cluster, and you want to *insecure* Kafka REST, do the following:

1. In the `kafka-rest.properties` configuration file, change **https://** to **http://** for the listeners and remove the **ssl.\*** properties. For example:

```
listeners=http://0.0.0.0:8082
```

2. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

### *User Impersonation*

Describes how to disable, enable, and use impersonation with Kafka REST.

User impersonation enables Kafka REST jobs to be submitted as a particular user. Without impersonation, Kafka REST submits jobs as the user that started Kafka REST server.

On an HPE Ezmeral Data Fabric cluster, the impersonated user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable. By default, impersonation is disabled for unsecured clusters and enabled for secure clusters.

### Enabling User Impersonation

To enable user impersonation, set the following properties in `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties`:

- `authentication.enable=true`
- `impersonation.enable=true`

### Disabling User Impersonation

In the `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties` file, disable PAM authentication and the `impersonation.enable` property.

1. To disable PAM authentication, set `authentication.enable=false`.
2. To disable user impersonation, set `impersonation.enable=false`.

### Example: Verify that a list of topics is owned by an impersonated user

This example demonstrates how to get a list of topics from a particular stream and then verifies that the list of topics is owned by a particular user. Depending on whether or not impersonation is enabled (the default), you may need to use a different `curl` command.

```
$ sudo maprcli stream info -json -path /stream
{
  "timestamp":1598950735841,
  "timeofday":"2020-09-01 08:58:55.841 GMT+0000 AM",
  "status":"OK",
  "total":1,
  "data":[
    {
      "path":"/stream",
      "physicalsize":57344,
      "logicalsize":32768,
      "numtopics":1,
      "defaultpartitions":1,
      "ttl":604800,
      "compression":"lz4",
```

```

        "autocreate":true,
        "produceperm":"u:root",
        "consumeperm":"u:root",
        "topicperm":"u:root",
        "copyperm":"u:root",
        "adminperm":"u:root",
        "kafkatopic":false,
        "ischangelog":false,
        "defaulttimestamptype":"CreateTime",
        "compact":false,
        "mincompactionlag":0,
        "deleteretention":86400000,
        "throttlefactor":0,
        "pidexpirysecs":604800
    }
]
}

```

If impersonation is enabled (the default), use the following query, where the query is submitted as the root user.

```

curl -u root -X GET https://`hostname`:8082/topics/
%2Fstream%3Atopic1 --cacert /opt/mapr/conf/ssl_truststore.pem
Enter host password for user 'root':
{"name":"/stream:topic1","configs":null,"partitions":
  [{"partition":0,"leader":0,"replicas":
    [{"broker":0,"leader":true,"in_sync":true},
     {"broker":0,"leader":false,"in_sync":true}]}]}

```

If impersonation is disabled, use the following query, where the query is submitted as the mapr user.

```

curl -X GET https://`hostname`:8082/topics/%2Fstream%3Atopic1 --cacert /opt/
mapr/conf/ssl_truststore.pem
{"error_code":40401,"message":"Topic not found."}

```

### Saving Kafka REST Configurations

Describes how Kafka REST configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka REST is stored in a folder with a timestamp.

- The configuration files are saved *and* overwritten by new configuration files when upgrading from:
  - 4.1.0 to 5.1.2
  - 5.1.2 to 6.0.0.0
- The configuration files are saved only (not overwritten) when upgrading from:
  - 5.1.2 to 5.1.2

### Example

The following example shows the list of configuration files that are saved when upgrading from mapr-kafka-rest 5.1.2 (EEP 7.0.0) to mapr-kafka-rest 5.1.2 (EEP 7.0.1):

```

ls /opt/mapr/kafka-rest/
kafka-rest-5.1.2  kafka-rest-5.1.2.0.202009100923  kafka-restversion

ls /opt/mapr/kafka-rest/kafka-rest-5.1.2.0.202009100923/config/
headers.xml  kafka-rest.properties  log4j.properties  warden.kafka-rest.conf

```

## Services Management

The Kafka REST Proxy for HPE Ezmeral Data Fabric Streams service can be started, restarted, and stopped via the `maprcli nodes services` command or using the REST API equivalent.

The following `maprcli nodes services` commands summarize the commands. For more information, see [node services](#) on page 2298.

### CLI commands

```
maprcli node services -name kafka-rest -action start -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action stop -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action restart -nodes <node_list>
```

### REST

```
https://<host>:8443/rest/node/services?
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

### HTTP Methods and URI Summary

This section provides HTTP method and URI summaries for multiple Kafka REST Proxy API versions for HPE Ezmeral Data Fabric Streams.

#### API v3: Kafka REST Proxy Summary

Availability of Kafka REST Proxy API v3 started in Kafka REST 6.0.0.0 on Core 6.2.0.

API v3 is disabled by default. To enable API v3, set the `api.v3.enable` parameter in the `kafka-rest.properties` file to `true`. See [Configuration Parameters](#) on page 4479.

**NOTE:** Kafka REST 6.0.0.0 supports [API v3](#) and [API v2](#) only. Kafka REST 6.0.0.0 does not support API v1.

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

HTTP Method	URI	Description
GET	<a href="#">GET /v3/clusters</a> on page 4505	Retrieves a list of metadata about clusters. Only retrieves the current HPE Ezmeral Data Fabric cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}</a> on page 4507	Retrieves metadata about a specific cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics</a> on page 4508	Retrieves a list of topic names on the specific cluster.
POST	<a href="#">POST /v3/clusters/{string: cluster_id}/topics</a> on page 4517	Creates a new topic on the specific cluster.
DELETE	<a href="#">DELETE /v3/clusters/{string: cluster_id}/topics/{string: topic_name}</a> on page 4518	Deletes a topic from the specific cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}</a> on page 4509	Retrieves metadata about a specific topic within a cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions</a> on page 4511	Retrieves a list of partitions for the topic within a cluster.

HTTP Method	URI	Description
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}</a> on page 4513	Retrieves metadata about a specific partition within a topic and a cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas</a> on page 4514	Retrieves a list of replicas within a partition, a topic and a cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas/{string: broker_id}</a> on page 4515	Retrieves metadata about a specific replica within a partition, a topic and a cluster.

### API v2: Kafka REST Proxy Summary

Availability of Kafka REST Proxy API v2 started in Kafka REST 4.0.0 on Core 6.0.x.

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

HTTP Method	URI	Description
GET	<a href="#">/topics</a>	Retrieves a list of topic names.
GET	<a href="#">/topics/{string: topic_name}</a>	Retrieves metadata about a specific topic.
POST	<a href="#">/topics/{string: topic_name}</a>	Produces messages to a topic.
GET	<a href="#">/topics/{string: topic_name}/partitions</a>	Retrieves a list of partitions for the topic.
GET	<a href="#">/topics/{string: topic_name}/partitions/{string: partition_id}</a>	Retrieves metadata about a specific partition within a topic.
GET	<a href="#">GET /topics/{string: topic_name}/partitions/{string: partition_id}/offsets</a> on page 4494	Returns a summary with beginning and end offsets for the given topic and specific partition. Supported as of Kafka Rest 6.0.0.0.
POST	<a href="#">/topics/{string: topic_name}/partitions/{string: partition_id}</a>	Produces messages into a partition of a topic.
POST	<a href="#">/consumers/{string: group_name}</a>	Creates a new consumer instance in the consumer group.
DELETE	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}</a>	Destroys the consumer instance.
POST	<a href="#">/consumers/{string: group_name}/instances/{string: consumer_instance_id}/offsets</a>	Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.
GET	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/offsets</a>	Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/subscription</a>	Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription.
GET	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/subscription</a>	Gets the current subscribed list of topics.
DELETE	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/subscription</a>	Unsubscribes from topics currently subscribed to.

HTTP Method	URI	Description
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/assignments</a>	Manually assigns a list of partitions to a consumer.
GET	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/assignments</a>	Retrieves the list of partitions manually assigned to this consumer.
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/positions</a>	Overrides the fetch offsets that the consumer will use for the next set of records to fetch.
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/positions/beginning</a>	Seek to the first offset for each of the given partitions.
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/positions/end</a>	Seek to the last offset for each of the given partitions.
GET	<a href="#">GET /consumers/{string: group_name}/instances/{string: instance_id}/records</a>	Fetches data for the topics or partitions specified using one of the subscribe/assign APIs.
GET	<a href="#">/streams/{string: stream_name}/topics</a>	Retrieves a list of topics in a given stream.

### API v1: Kafka REST Proxy Summary

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

**NOTE:** Kafka REST 6.0.0.0 does not support API v1. Kafka REST 6.0.0.0 supports API v1 and v2 only.

HTTP Method	URI	Description
GET	<a href="#">/topics</a>	Retrieves a list of topic names.
GET	<a href="#">/topics/{topic: string}</a>	Retrieves metadata about a specific topic.
POST	<a href="#">/topics/{topic: string}</a>	Produces a message into a topic.
GET	<a href="#">/topics/{topic: string}/partitions</a>	Retrieves a list of partitions for the topic.
GET	<a href="#">/topics/{topic: string}/partitions/{partition_id: string}</a>	Retrieves metadata about specific partition in a topic.
POST	<a href="#">/topics/{topic: string}/partitions/{partition_id: string}</a>	Produces messages to one partition of the topic.
GET	<a href="#">/topics/{topic: string}/partition/{partition_id: string}/messages?offset={int}&amp;count={int}</a>	Consumes messages from one partition of the topic.
GET	<a href="#">/stream/{stream: string}/topics</a>	Retrieves a list of topics in a given stream.
POST	<a href="#">/consumers/{group: string}</a>	Creates a new consumer instance in the consumer group.
POST	<a href="#">/consumers/{group: string}/instances/{instance: string}/offsets</a>	Commits offsets for the consumer. Returns a list of the partitions with the committed offsets.
DELETE	<a href="#">/consumers/{group: string}/instances/{instance: string}</a>	Destroys the consumer instance.
GET	<a href="#">/consumers/{group: string}/instances/{instance: string}/topics/{topic: string}</a>	Consumes messages from a topic.

### API v2 HTTP Methods and URIs

Availability of Kafka REST Proxy API v2 started in Kafka REST 4.0.0 on Core 6.0.x.

#### GET /topics

Retrieves a list of topic names.

#### Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4479

#### Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Returns a list of topic names in the default stream. Returns topic names that contain a stream path.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}

#### Syntax

```
http://<host>:8082/topics
```

#### Request Example

```
$ curl "Content-Type: application/vnd.kafka.v2+json" "http://localhost:8082/topics"
```

#### Response Example

```
[
  "streaming_data/stream:testtopic1",
  "streaming_data/stream:testtopic2"
]
```

#### GET /topics/{string: topic\_name}

Retrieves metadata about a specific topic.

#### Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4479

#### Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about a specific HPE Ezmeral Data Fabric Streams topic. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, topic1 is equivalent to <code>default_stream:topic1</code>
<code>streams.default.stream</code> is not defined	Gets metadata about a specific HPE Ezmeral Data Fabric Streams topic. A fully qualified topic name is passed that contains the stream path.

**NOTE:** The full name for the HPE Ezmeral Data Fabric Streams topic contains characters such as a forward slash (/) and a colon (:), therefore, it should be encoded. For example, /streaming\_data/stream:topic-1 is equivalent to %2Fstreaming\_data%2Fstream%3Atopic-1.

#### Table

Parameters	Description
topic_name (string)	Name of the topic to get metadata about.

#### Syntax

Syntax for a topic in a default stream where the default stream is configured:

```
http://<host>:8082/topics/<topic_string>
```

Syntax for a topic where the fully qualified topic name is specified:

```
http://<host>:8082/topics/%2F<streaming_data>%2F<stream>%3A<topic1>
```

#### Request Example

```
curl "http://localhost:8082/topics/test"
```

#### Response Example

```
{
  "name": "test",
  "configs": null,
  "partitions":
  [
    {
      "partition": 0,
      "leader": 0,
      "replicas":
      [
        {"broker": 0, "leader": true, "in_sync": true},
        {"broker": 0, "leader": false, "in_sync": true}
      ]
    }
  ]
}
```

POST /topics/{string: topic\_name}  
Produces messages to a topic.

#### Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4479

#### Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Produces messages into specific HPE Ezmeral Data Fabric Streams topics. If the topic name does not contain a stream path, then the default stream path is used.

Table (Continued)

Parameters Defined	Response
<b>streams.default.stream</b> is not defined	Produces messages into a HPE Ezmeral Data Fabric Streams topic. The topic name should contain a stream path and be encoded.

**NOTE:** If the topic does not exist, the following error results: [{"error\_code":40401, "message": "Topic not found."}]. New topics are not created by the POST operation.

Table

Parameters	Description
<b>topic_name</b> ( <i>string</i> )	Name of the topic to produce the messages to.

### Syntax

```
http://<host>:8082/topics/<topic_string>
```

### Request Example

This example produces a message using binary embedded data with the value, Kafka, to the topic, test.

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2" --data
'{"records":[{"value":"S2Fma2E="}]}' "http://localhost:8082/topics/test"
```

### Response Example

```
{
  "offsets":
  [
    {
      "partition":0,
      "offset": 1,
      "error_code":null,
      "error":null
    }
  ],
  "key_schema_id":null,
  "value_schema_id":null
}
```

GET /topics/{string: topic\_name}/partitions  
Retrieves a list of partitions for the topic.

### Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4479.

Table

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within a topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<b>streams.default.stream</b> is not defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within topic. The user could only pass fully qualified topic name that contains stream path.

**Table**

Parameters	Description
<b>topic_name</b> ( <i>string</i> )	Name of the topic.

**Syntax**

```
http://<host>:8082/topics/<topic_name>/partitions
```

**Request Example**

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
"http://localhost:8082/topics/testtopic1/partitions"
```

**Response Example**

```
[
  {
    "partition":0,
    "leader":0,
    "replicas":
      [
        {
          "broker":0,
          "leader":true,
          "in_sync":true
        }
      ]
  },
  {
    "partition":1,
    "leader":0,
    "replicas":
      [
        {
          "broker":0,
          "leader":true,
          "in_sync":true
        }
      ]
  }
]
```

GET /topics/{string: topic\_name}/partitions/{string: partition\_id}  
Retrieves metadata about a specific partition within a topic.

**Description**

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4479.

**Table**

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets metadata about a specific partition within a HPE Ezmeral Data Fabric Streams topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<b>streams.default.stream</b> is not defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within a topic. The user could only pass fully qualified topic names that contains stream path.

**Table**

Parameters	Description
<b>topic_name</b> ( <i>string</i> )	Name of the topic.
<b>partition_id</b> ( <i>int</i> )	ID of the partition to inspect.

**Syntax**

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

**Request Example**

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
http://localhost:8082/topics/%2Fstreaming_data%2Fstream%3Atesttopic1/
partitions/0
```

**Response Example**

```
{
  "partition":0,
  "leader":0,
  "replicas":
  [
    {
      "broker":0,
      "leader":true,
      "in_sync":true
    }
  ]
}
```

GET /topics/{string: topic\_name}/partitions/{string: partition\_id}/offsets

Returns a summary with beginning and end offsets for the given topic and specific partition.

**Description**

Information retrieved varies depending on the configuration. See the `streams.default.stream` in [Configuration Parameters](#) on page 4479.

**Table**

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets summary with beginning and end offsets for the specific partition of the HPE Ezmeral Data Fabric Streams topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<b>streams.default.stream</b> is not defined	Gets summary with beginning and end offsets for the specific HPE Ezmeral Data Fabric Streams partition within a topic. You can only pass the fully qualified topic names that contain the stream path.

**Table**

Parameter	Description
<b>topic_name</b> ( <i>string</i> )	Name of the topic.
<b>partition_id</b> ( <i>int</i> )	ID of the partition to inspect.

## Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>/offsets
```

## Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2" http://localhost:8082/topics/%2Fstreaming_data%2Fstream%3Atesttopic1/partitions/0/offsets
```

## Response Example

```
{
  "beginning_offset":0,
  "end_offset":0
}
```

POST /topics/{string: topic\_name}/partitions/{string: partition\_id}  
Produces messages into a partition of a topic.

## Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 4479.

### Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Produces messages into a partition of HPE Ezmeral Data Fabric Streams topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, messages are produced into topics in the default stream path.
<code>streams.default.stream</code> is not defined	Produces messages into a partition within HPE Ezmeral Data Fabric Streams topic. The user could only pass fully qualified topic name that contains stream path.

### Table

Parameters	Description
<code>topic_name</code> ( <i>string</i> )	Topic to produce the messages to.
<code>partition_id</code> ( <i>int</i> )	Partition to produce the messages to.

## Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2+json" --data '{"records":[{"key":"a2v5","value":"Y29uZmx1ZW50"}]}' "http://localhost:8082/topics/testtopic1/partitions/0"
```

## Response Example

```
{
  "offsets":
  [
    {
      "partition": 0,
      "offset": 1,
      "error_code": null, "error": null}
  ],
  "key_schema_id": null,
  "value_schema_id": null
}
```

POST /consumers/{string: group\_name}

Creates a new consumer instance in the consumer group.

## Description

### Table

Parameters	Description
<b>group_name</b> ( <i>string</i> )	The name of the consumer group to join.
<b>name</b> ( <i>string</i> )	Name for the consumer instance, which will be used in URLs for the consumer. This must be unique, at least within the proxy process handling the request. If omitted, falls back on the automatically generated ID. Using automatically generated names is recommended for most use cases.
<b>format</b> ( <i>string</i> )	The format of consumed messages, which is used to convert messages into a JSON-compatible form. Valid values: "binary", "avro", "json". If unspecified, defaults to "binary".
<b>auto.offset.reset</b> ( <i>string</i> )	Sets the <b>auto.offset.reset</b> setting for the consumer. Values: latest, earliest, none
<b>auto.commit.enable</b> ( <i>string</i> )	Sets the <b>auto.commit.enable</b> setting for the consumer.

**NOTE:** You cannot set the time-to-live (TTL) for consumer instances or consumer groups. However, consumers can be configured to be deleted after some idle time. The amount of idle time before a consumer instance is automatically destroyed is set by the `consumer.instance.timeout.ms` property in the **kafka-rest.properties** file. See [Configuration Parameters](#) on page 4479.

## Syntax

```
http://<host>:8082/consumers/<group_name>
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json"
--data '{"name": "user", "format": "binary", "auto.offset.reset":
"earliest"}'
http://localhost:8082/consumers/groupptest
```

## Response Example

The response JSON object is in the following form:

- **instance\_id** (*string*) – Unique ID for the consumer instance in this group. The `instance_id` is automatically generated if the `name` parameter is not specified.

- **base\_uri** (*string*) – Base URI used to construct URIs for subsequent requests against this consumer instance. This will be of the form `http://hostname:port/consumers/consumer_group/instances/instance_id`.

```
{
  "instance_id": "user",
  "base_uri": "http://localhost:8082/consumers/groupptest/instances/
user"
}
```

DELETE /consumers/{string: group\_name}/instances/{string: instance\_id}  
Destroys the consumer instance.

### Description

The request must be made to the specific REST proxy instance holding the consumer instance.

### Table

Parameters	Description
<b>group_name</b> ( <i>string</i> )	The name of the consumer group.
<b>instance</b> ( <i>string</i> )	The ID of the consumer instance

### Syntax

```
http://<host>:8082/topics/<group_name>/instances/<instance_string>
```

### Request Example

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/consumers/my_binary_consumer/instances/
rest-consumer-11561681-
8ba5-4b46-bed0-905ae1769bc6
```

### Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group\_name}/instances/{string: consumer\_instance\_id}/offsets  
Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.

### Parameters

### Table

Parameters	Description
<b>group_name</b> ( <i>string</i> )	The name of the consumer group.
<b>instance_id</b> ( <i>string</i> )	The ID of the consumer instance.
<b>offsets</b>	A list of offsets to commit for partitions.
<b>offsets[i].topic</b> ( <i>string</i> )	Name of the topic
<b>offsets[i].partition</b> ( <i>int</i> )	Partition ID
<b>offset</b>	The offset to commit.

## Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_instance_id>/offsets
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"offsets": [{"topic":
"/mystream:first", "partition": 0, "offset": 5}]}'
https://node2:8082/consumers/groupptest/instances/user/offsets
```

## Response Example

```
HTTP/1.1 200 OK
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/offsets

Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).

## Parameters

### Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.
<b>partitions</b>	A list of partitions to find the last committed offsets.
<b>partitions[i].topic</b> ( <i>string</i> )	Name of the topic.
<b>partitions[i].partition</b> ( <i>int</i> )	Partition ID

## Syntax

```
http://localhost:8082/consumers/<group_name>/instances/<consumer_name>/offsets
```

## Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.binary.v2+json" --data
'{"partitions": [{"topic": "/stream:topic", "partition": 0}]}'
https://node2:8082/consumers/groupptest/instances/user/offsets
```

## Response Example

The response JSON object is in the following form:

- offsets - A list of committed offsets.
- offsets[i].topic (string) – Name of the topic for which an offset was committed
- offsets[i].partition (int) – Partition ID for which an offset was committed
- offsets[i].offset (int) – Committed offset

- `offsets[i].metadata` (string) – Metadata for the committed offset

```
{ "offsets":
  [
    {
      "topic": "/stream:topic",
      "partition": 0,
      "offset": 21,
      "metadata": ""
    }
  ]
}
```

POST `/consumers/{string: group_name}/instances/{string: instance_id}/subscription`

Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription.

### Parameters

Table

Parameter	Description
<code>group_name</code> (string)	Name of the consumer group.
<code>instance</code> (string)	ID of the consumer instance.

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/subscription
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"topics":["/stream:first","/stream:second"]}'
https://localhost:8082/consumers/groupptest/instances/user/subscription
```

### Response Example

```
HTTP/1.1 204 No Content
```

GET `/consumers/{string: group_name}/instances/{string: instance_id}/subscription`

Gets the current subscribed list of topics.

### Parameters

Table

Parameter	Description
<code>group_name</code> (string)	Name of the consumer group.
<code>instance</code> (string)	ID of the consumer instance.

## Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

## Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/subscription
```

## Response Example

The response JSON object is in the following form:

- topics – A list of subscribed topics
- topics[i] (string) – Name of the topic

```
{
  "topics": [
    "/stream:first",
    "/stream:second"
  ]
}
```

**DELETE** /consumers/{string: group\_name}/instances/{string: instance\_id}/subscription  
Unsubscribes from topics currently subscribed to.

## Parameters

### Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.

## Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

## Request Example

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/subscription
```

## Response Example

```
HTTP/1.1 204 No Content
```

**POST** /consumers/{string: group\_name}/instances/{string: instance\_id}/assignments  
Manually assigns a list of partitions to a consumer.

## Parameters

### Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
assignments
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions":[{"topic":"first","partition":0}]}'
https://localhost:8082/consumers/groupptest/instances/user/assignments
```

### Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/assignments

Retrieves the list of partitions currently assigned to this consumer.

## Parameters

### Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
assignments
```

### Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/assignments
```

### Response Example

The response JSON object is in the following form:

- partitions – A list of partitions assigned to this consumer.
- partitions[i].topic (*string*) – Name of the topic.

- `partitions[i].partition (int)` – Partition ID

```
{
  "partitions": [
    {
      "topic": "test",
      "partition": 0
    },
    {
      "topic": "test",
      "partition": 1
    }
  ]
}
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/positions

Overrides the fetch offsets that the consumer will use for the next set of records to fetch.

### Parameters

#### Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.
<b>offsets</b>	A list of offsets
<b>offsets[i].topic</b> ( <i>string</i> )	Name of the topic
<b>offsets[i].partition</b> ( <i>int</i> )	Partition ID
<b>offsets[i].offset</b> ( <i>int</i> )	Seek to offset for the next set of records to fetch.

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"offsets": [{"topic": "/stream:first", "partition": 0, "offset": 3}]}'
https://localhost:8082/consumers/groupptest/instances/user/positions
```

### Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/positions/beginning

Seek to the first offset for each of the given partitions.

## Parameters

### Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.
<b>partitions</b>	A list of partitions.
<b>partitions[i].topic</b> ( <i>string</i> )	Name of the topic
<b>partitions[i].partition</b> ( <i>int</i> )	Partition ID

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions/beginning
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions": [{"topic": "/stream:first", "partition": 0}]}'
https://localhost:8082/consumers/groupptest/instances/user/positions/
beginning
```

### Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/positions/end  
Seek to the last offset for each of the given partitions.

## Parameters

### Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.
<b>partitions</b>	A list of partitions.
<b>partitions[i].topic</b> ( <i>string</i> )	Name of the topic
<b>partitions[i].partition</b> ( <i>int</i> )	Partition ID

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions/end
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions": [{"topic": "/stream:first", "partition": 0}]}'
https://localhost:8082/consumers/groupptest/instances/user/positions/end
```

### Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/records

Fetches data for the topics or partitions specified using one of the subscribe/assign APIs.

### Parameters

The format of the embedded data returned by this request is determined by the format specified in the initial consumer instance creation request and must match the format of the Accept header.

**NOTE:** This request *must* be made to the specific REST proxy instance holding the consumer instance.

### Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.
<b>timeout</b>	The number of milliseconds for the underlying client library poll(timeout) request to fetch the records. Default: 5000ms.
<b>max_bytes</b>	The maximum number of bytes of unencoded keys and values that should be included in the response. This provides approximate control over the size of responses and the amount of memory required to store the decoded response. The actual limit is the minimum of this setting and the server-side configuration consumer.request.max.bytes. Default: unlimited

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/records
```

### Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/groupptest/instances/user/records
```

### Response Example

```
[
  {

GET /streams/{string: stream\_name}/topics  
Retrieves a list of topics in a given stream.

### Description

Stream names contain characters such as backslashes (/) and colons (:), and, therefore, should be encoded.

### Table

Parameters	Description
<b>stream_name</b> ( <i>string</i> )	The name of the stream.

### Syntax

```
http://<host>:8082/streams/<stream_name>/topics
```

### Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/streams/%2Fstreaming_data%2Fstream/topics
```

### Response Example

```

[
  "/streaming_data/stream:testtopic1",
  "/streaming_data/stream:testtopic2"
]

```

### API v3 HTTP Methods and URIs

Availability of Kafka REST Proxy API v3 started in Kafka REST 6.0.0.0 on Core 6.2.0. API v3 is disabled by default. To enable API v3, set the `api.v3.enable` parameter in the `kafka-rest.properties` file to `true`. See [Configuration Parameters](#).

**NOTE:** Kafka REST 6.0.0.0 supports [API v3](#) and [API v2](#) only. Kafka REST 6.0.0.0 does not support API v1.

GET /v3/clusters  
Retrieves a list of metadata about the cluster.

### Description

Retrieves one cluster only. Always retrieves the current HPE Ezmeral Data Fabric cluster.

### Syntax

```
http://<host>:8082/v3/clusters
```

**Request Example**

```
curl -X GET -H "Content-Type: application/json" http://localhost:8082/v3/clusters
```

**Response Example**

```
{
  "kind": "KafkaClusterList",
  "metadata": {
    {
      "self": "http://node1.cluster.com:8082/v3/clusters",

```

GET /v3/clusters/{string: cluster\_id}/topics

Retrieves a list of topic names on the specific cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4479.

### Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Returns a list of topic names and metadata in the default stream. Returns topic names and metadata that contains a stream path.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

### Table

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.

### Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

### Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics"
```

### Response Example

        }
    }
    ]
}

```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}  
Retrieves metadata about a specific topic within a cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4479.

Table

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets metadata about a specific HPE Ezmeral Data Fabric Streams topic on this cluster. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, topic1 is equivalent to default_stream:topic1.
<b>streams.default.stream</b> is not defined	Gets metadata about a specific HPE Ezmeral Data Fabric Streams topic on this cluster. A fully qualified topic name is passed that contains the stream path.

**NOTE:** The full name for the HPE Ezmeral Data Fabric Streams topic contains characters such as a forward slash (/) and a colon (:). Therefore, the topic should be encoded. For example, /streaming\_data/stream:topic-1 is equivalent to %2Fstreaming\_data%2Fstream%3Atopic-1.

Table

Parameters	Description
<b>cluster_id</b> ( <i>string</i> )	Cluster's id.
<b>topic_name</b> ( <i>string</i> )	Name of the topic.

### Syntax

```
http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>
```

### Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2"
```

### Response Example

```

```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}/partitions/{string: partition\_id}  
Retrieves metadata about a specific partition within a topic and a cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4479.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about a specific partition within a HPE Ezmeral Data Fabric Streams topic on this cluster. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific HPE Ezmeral Data Fabric Streams partitions within a topic. The user could only pass fully qualified topic names that contains stream path.

Table

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.
<code>topic_name</code> ( <i>string</i> )	Name of the topic.
<code>partition_id</code> ( <i>int</i> )	ID of the partition to inspect.

### Syntax

```

http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>

```

## Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics/tp-2/partitions/1"
```

## Response Example

```
{
  "kind": "KafkaPartition",
  "metadata": {
    {
      "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1",
      "resource_name": "crn:///kafka=682798077049224619/topic=str:tp-2/partition=1"
    },
    "cluster_id": "682798077049224619",
    "topic_name": "/str:tp-2",
    "partition_id": 1,
    "leader": {
      {
        "related": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1/replicas/0"
      },
      "replicas": {
        {
          "related": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1/replicas"
        },
        "reassignment": {
          {
            "related": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1/reassignment"
          }
        }
      }
    }
  }
}
```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}/partitions/{string: partition\_id}/replicas  
Retrieves a list of replicas within a partition, a topic, and a cluster.

## Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4479.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about specific replicas of the HPE Ezmeral Data Fabric Streams partition within a topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific replicas of the HPE Ezmeral Data Fabric Streams partition within a topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
<b>cluster_id</b> ( <i>string</i> )	Cluster's id.
<b>topic_name</b> ( <i>string</i> )	Name of the topic.
<b>partition_id</b> ( <i>int</i> )	ID of the partition to inspect.

**Syntax**

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>/replicas
```

**Request Example**

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1/replicas"
```

**Response Example**

```
{
  "kind": "KafkaReplicaList",
  "metadata": {
    {
      "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/
topics/tp-2/partitions/1/replicas",
      "next": null
    },
    "data": [
      {
        {
          "kind": "KafkaReplica",
          "metadata": {
            {
              "self": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/str:tp-2/partitions/1/replicas/0",
              "resource_name": "crn:///kafka=682798077049224619/
topic=str:tp-2/partition=1/replica=0"
            },
            "cluster_id": "682798077049224619",
            "topic_name": "/str:tp-2",
            "partition_id": 1,
            "broker_id": 0,
            "is_leader": true,
            "is_in_sync": true,
            "broker": {
              {
                "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/brokers/0"
              }
            }
          }
        }
      ]
    }
  }
}
```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}/partitions/{string: partition\_id}/replicas/{string: broker\_id}

Retrieves metadata about a specific replica within a partition, a topic, and a cluster.

## Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4479.

**Table**

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about specific broker of the HPE Ezmeral Data Fabric Streams partition within a topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific broker of the HPE Ezmeral Data Fabric Streams partition within a topic. The user could only pass fully qualified topic name that contains stream path.

**Table**

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.
<code>topic_name</code> ( <i>string</i> )	Name of the topic.
<code>partition_id</code> ( <i>int</i> )	ID of the partition to inspect.
<code>broker_id</code> ( <i>int</i> )	ID of the broker to inspect.

## Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>/replicas/<broker_id>
```

## Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1/replicas/0"
```

## Response Example

```
{
  "kind": "KafkaReplica",
  "metadata": {
    {
      "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/
topics/str:tp-2/partitions/1/replicas/0",
      "resource_name": "crn:///kafka=682798077049224619/topic=str:tp-2/
partition=1/replica=0"
    },
    "cluster_id": "682798077049224619",
    "topic_name": "/str:tp-2",
    "partition_id": 1,
    "broker_id": 0,
    "is_leader": true,
    "is_in_sync": true,
    "broker": {
      {
        "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/brokers/0"
```

```
}
}
```

POST /v3/clusters/{string: cluster\_id}/topics  
Creates a new topic on the specific cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4479

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Creates a topic in the default stream and returns its metadata.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.

### Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

### Request Example

```
$ curl -X POST -H "Content-Type: application/json" --data '{"topic_name": "new-topic", "partitions_count": 4}' "http://localhost:8082/v3/clusters/682798077049224619/topics"
```

### Request Response

```
{
  "kind": "KafkaTopic",
  "metadata": {
    {
      "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/new-topic",
      "resource_name": "crn:///kafka=682798077049224619/topic=new-topic"
    },
    "cluster_id": "682798077049224619",
    "topic_name": "new-topic",
    "is_internal": false,
    "replication_factor": 0,
    "partitions": {
      {
        "related": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/new-topic/partitions"
      },
      "configs": {
        {
          "related": "http://node1.cluster.com:8082/v3/clusters/"
        }
      }
    }
  }
}
```

```

682798077049224619/topics/new-topic/configs"
  },
  "partition_reassignments": {
    "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/new-topic/partitions/-/reassignment"
  }
}

```

**DELETE** /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}  
 Deletes a topic from the specific cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 4479.

### Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Deletes topic from the default stream.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

### Table

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.
<code>topic_name</code> ( <i>string</i> )	Name of the topic.

### Syntax

```

http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>

```

### Request Example

```

$ curl -X DELETE -H "Content-Type: application/json" "http://
localhost:8082/v3/clusters/682798077049224619/topics/new-topic"

```

### Response Example

```

HTTP/1.1 204 No Content

```

### Kafka Connect

Kafka Connect is a utility for streaming data between HPE Ezmeral Data Fabric Streams and other storage systems.

Examples of other systems include:

- Relational databases
- Logs and metrics
- Hadoop and data warehouses

- NoSQL data stores

Kafka Connect makes it easy to integrate all your data via Kafka, making it available as realtime streams. For example, you can use Kafka Connect to:

- Stream changes from a relational database to make events available with low latency for stream processing applications.
- Import realtime logs and metrics into HPE Ezmeral Data Fabric Streams and process them to detect anomalies.
- Implement a process of loading data into HPE Ezmeral Data Fabric Streams from your primary data storage systems, performing filtering, transformations, and enrichment with a stream processing framework, and publish the data to the HPE Ezmeral Data Fabric File Store.

**NOTE:** Built-in security is not available.

### Architecture of Kafka Connect

Kafka Connect for HPE Ezmeral Data Fabric Streams has the following major models in its design: connector, worker, and data.

### Connector Model

A connector is defined by specifying a Connector class and configuration options to control what data is copied and how to format it.

- Each Connector instance is responsible for defining and updating a set of Tasks that actually copy the data.
- Kafka Connect manages the Tasks; the Connector is only responsible for generating the set of Tasks and indicating to the framework when they need to be updated.
- Source and Sink Connectors/Tasks are distinguished in the API to ensure the simplest possible API for both.

There are two types of tasks:

- **Source** - Source tasks ingest data from data storage systems and stream the data to HPE Ezmeral Data Fabric Streams.
- **Sink** - Sink tasks stream data from HPE Ezmeral Data Fabric Streams to other storage systems.

HPE Ezmeral Data Fabric supports the following connectors:

- JDBC Source Connector

The Kafka JDBC source connector is a type connector used to stream data from relational databases into HPE Ezmeral Data Fabric Streams topics. JDBC Source Connector for HPE Ezmeral Data Fabric Streams supports integration with Hive 2.1.

- JDBC Sink Connector

The Kafka JDBC sink connector is a type connector used to stream data from HPE Ezmeral Data Fabric Streams topics to relational databases that have a JDBC driver.

- HDFS Sink Connector

The Kafka HDFS sink connector is a type connector used to stream data from HPE Ezmeral Data Fabric Streams to file system. By default, the resulting data is produced to file system in Avro format. In addition, Parquet files can be written to file system.

## Worker Model

A Kafka Connect for HPE Ezmeral Data Fabric Streams cluster consists of a set of Worker processes that are containers that execute Connectors and Tasks. A worker is a JVM process with a REST API that is able to execute streaming tasks.

- Workers automatically coordinate with each other to distribute work and provide scalability and fault tolerance.
- The Workers distribute work among any available processes, but are not responsible for management of the processes;
- Any process management strategy can be used for Workers. For example, cluster management tools like YARN or Mesos, configuration management tools like Chef or Puppet, or direct management of process lifecycles.

## Data Model

Connectors copy streams of messages from a partitioned input stream to a partitioned output stream, where at least one of the input or output is *always* Kafka.

- Each of these streams is an ordered set messages where each message has an associated offset.
- The format and semantics of these offsets are defined by the Connector to support integration with a wide variety of systems; however, to achieve certain delivery semantics in the face of faults requires that offsets are unique within a stream and streams can seek to arbitrary offsets.
- Message contents are represented by Connectors in a serialization-agnostic format.
- Pluggable Converters are available for storing this data in a variety of serialization formats.
- Schemas are built-in, allowing important metadata about the format of messages to be propagated through complex data pipelines. However, schema-free data can also be use when a schema is simply unavailable.

## Connectors, Tasks, and Workers

Describes how Kafka Connect for HPE Ezmeral Data Fabric Streams works and how connectors, tasks, offsets, and workers are associated.

## Connectors

Connectors (or a **connector instance**) are logical jobs that are responsible for managing the copying of data between HPE Ezmeral Data Fabric Streams and another systems. Each connector instantiates a set of **tasks** that copies the data. By allowing the connector to break a single job into many tasks, support is built-in for parallelism and scalable data copying with very little configuration. **Connector plugins** are jars that add the classes that implement a connector.

## Offsets

As connectors run, Kafka Connect tracks **offsets** for each one so that connectors can resume from their previous position in the event of failures or graceful restarts for maintenance. They track the current position in the stream of data being copied and because each connector may need to track many offsets for different **partitions** of the stream. For example, when loading data from a database, the offset might be a transaction ID that identifies a position in the database change log.

Users generally do not need to worry about the format of offsets, especially since they differ from connector to connector. However, Kafka Connect does require persistent storage for offset data to ensure it can recover from faults. This storage for offset data is configurable. See [Standalone Worker Configuration Options](#) on page 4525 and [Distributed Worker Configuration Options](#) on page 4526.

## Workers

Connectors and tasks are logical units of work and must be scheduled to execute in a process. Kafka Connect calls these processes **workers**. With Kafka Connect for MapR streams, the worker processors run as a service. This service can be run in either standalone mode or distributed mode.

- In standalone mode, the cluster consists of a single worker that is supplied with tasks that are useful for testing and debugging purposes.
- In distributed mode, the cluster consisting from multiple workers with the same `group.id`, `offset.storage.topic`, and `config.storage.topic`. Connector tasks are submitted via the Kafka Connect REST API.

The following list the location of the standalone and distributed worker configuration files:

```
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

**NOTE:** Distributed mode is supported on MapR 5.2.1 and above

**NOTE:** Port 8083 is the default port.

**NOTE:** If you running multiple workers on the same node, the `rest.port` parameter must be different for each worker.

### *Configuring in Standalone Mode*

The section describes how to configure and execute workers in Kafka connect standalone mode.

Standalone mode is the simplest mode, where a single process is responsible for executing all connectors and tasks. Since it is a single process, it requires minimal configuration.

Configuring and running in standalone mode, involves configuring the standalone properties and connector parameters before executing the standalone shell command along with the properties files on the command line.

The following parameters must be provided in the **connect-standalone.properties** file.

- `offset.storage.file.filename` - Storage for connector offsets which are stored on the local filesystem in standalone mode. Using the same file leads to offset data being deleted or overwritten with different values.
- `rest.port` - Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this parameter must have different values for each instance.

**NOTE:** If you are running multiple standalone instances on the same host, these parameters must be different for each instances. Therefore, an additional properties file is created for the instance with different parameter values.

To run a worker in standalone mode:

1. Edit the **./config/connect-standalone.properties** file and add the name of the local file that will store the connector offsets.
2. Edit the **quickstart-sqlite.properties** file (JDBC connector configuration file).
3. Run the **./bin/connect-standalone.sh** command along with the properties files on the command line.

For example:

```
cd /opt/mapr/kafka/kafka-<version>
./bin/connect-standalone.sh
./config/connect-standalone.properties
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-sqlite.properties
```

The first parameter is always a configuration file for the worker. This configuration gives you control over settings such as which cluster to use and the serialization format. See [JDBC Connector](#) on page 4530 for more information. All additional parameters should be connector configuration files. Each file contains a single connector configuration.

### Configuring in Distributed Mode

This section describes how to configure and run workers in Kafka Connect distributed mode.

Distributed mode provides scalability and automatic fault tolerance for Kafka Connect. In distributed mode, multiple worker processes are started using the same group.id. These processes automatically coordinate to schedule execution of connectors and tasks across all available workers. If a worker is added, shuts down, or fails unexpectedly, the rest of the workers detect this and automatically coordinate to redistribute connectors and tasks across the updated set of available workers.

 **NOTE:** Distributed mode is available as of EEP 2.0.1.

The following diagrams illustrates a three-node Kafka Connect distributed mode cluster where:

- Connectors are monitoring the source or sink system for changes that require reconfiguring tasks.
- Tasks are automatically balanced across the active workers by copying a subset of a connector's data.
- The division of work between tasks is shown by the partitions that each task is assigned.

Interaction with a distributed-mode cluster is via the REST API (rather than on the command line). To create a connector, the workers are started and then REST request is made to create a connector. See [REST API](#) on page 4546.

 **NOTE:** Kafka Connect workers do not have a special “leader” process that you have to interact with to use the REST API. All nodes can respond to REST requests, including creating, listing, modifying, and destroying connectors.

To run the worker in distributed mode:

1. In the `connect-distributed.properties` file, define the topics that will store the connector state, task configuration state, and connector offset state.

In distributed mode, the workers need to be able to discover each other and have shared storage for connector configuration and offset data. In addition to the usual worker settings, ensure you have configured the following for the cluster:

- **group.id** - ID that uniquely identifies the cluster these workers belong to. Ensure this is unique for all groups that work with a cluster.
- **config.storage.topic** - Topic to store the connector and task configuration state in. Although this topic can be auto-created if your cluster has auto topic creation enabled, it is highly recommended that you create it before starting the cluster. This topic should **always** have a single partition and be highly replicated (3x or more).
- **offset.storage.topic** - Topic to store the connector offset state in. To support large HPE Ezmeral Data Fabric Streams clusters, this topic should have a large number of partitions (for example, 25 or 50 partitions and highly replicated (3x or more).
- **rest.port** - Port where the REST interface listens for HTTP requests. If you run more than one worker per host (for example, if you are testing distributed mode locally during development), this setting must have different values for each instance.

2. Set the group.id value for all of the workers in the cluster.

**NOTE:** All workers that belong to the same cluster must have the same group.id value.

3. Start the Kafka Connect service in distributed mode:

```
maprcli node services -name kafka-connect -action start -nodes
<node_list>
```

For more information, see [Managing Kafka Connect Services](#) on page 4540.

**NOTE:** >Distributed mode does not have any additional command line parameters. If other instances are already running, new workers either start a new group or join an existing one, and then wait for work to do. For information on managing the connectors running in the cluster, see [REST API](#) on page 4546.

## Connector Configuration

This section describes how and where connectors are configured.

Connector configurations are key-value mappings. For standalone mode, these parameters are defined in a properties file and passed to the Connect process on the command line. In distributed mode, they will be included in the JSON payload for the request that creates (or modifies) the connector. Most configurations are connector dependent, but there are a few settings common to all connectors:

- name - Unique name for the connector. Attempting to register again with the same name will fail.
- connector.class - The Java class for the connector
- tasks.max - The maximum number of tasks that should be created for this connector. The connector may create fewer tasks if it cannot achieve this level of parallelism.

Sink connectors also have one additional option to control their input:

- topics - A list of topics to use as input for this connector

For other options, consult the documentation for the JDBC and HDFS connectors. See [JDBC Connector](#) on page 4530 and [HDFS Connector](#) on page 4540.

## Worker Configuration

This section describes how and where to configure workers.

Whether you're running standalone or distributed mode, Kafka Connect workers are configured by passing a properties file containing any required or overridden options as the first parameter to the worker process.

#### *Common Worker Configuration Options*

You can set common worker configuration options for standalone or distributed mode in the `connect-<standalone/distributed>.properties` file. The options control basic functionality, including which cluster to communicate with and data format.

#### **Setting the Schema Registry URL for the Avro Converter**

Set the Schema Registry URL for the converter through the following properties:

- `key.converter.schema.registry.url=<URL:PORT>`
- `value.converter.schema.registry.url=<URL:PORT>`
- For Avro, use `io.confluent.connect.avro.AvroConverter`.
- For Protobuf, use `io.confluent.connect.protobuf.ProtobufConverter`.
- For JSON Schema, use `io.confluent.connect.json.JsonSchemaConverter`.

If you do not set these properties, the Schema Registry URL is taken from ZooKeeper.

The following table describes the common worker configuration parameters:

Parameter	Description
<b>plugin.path</b>	The comma-separated list of paths to directories that contain Kafka Connect plugins. <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: empty</li> </ul>
<b>key.converter</b>	Converter class for key Connect data. This controls the format of the data that will be written to HPE Ezmeral Data Fabric Streams for source connectors or read from MapR Streams for sink connectors. <ul style="list-style-type: none"> <li>• Type: class</li> <li>• Default: empty</li> </ul>
<b>value.converter</b>	Converter class for value Connect data. This controls the format of the data that will be written to HPE Ezmeral Data Fabric Streams for source connectors or read from MapR Streams for sink connectors. <ul style="list-style-type: none"> <li>• Type: class</li> <li>• Default: empty</li> </ul>
<b>internal.key.converter</b>	Converter class for internal key Connect data that implements the Converter interface. Used for converting data like offsets and configs. <ul style="list-style-type: none"> <li>• Type: class</li> <li>• Default:</li> </ul>
<b>internal.value.converter</b>	Converter class for offset value Connect data that implements the Converter interface. Used for converting data like offsets and configs. <ul style="list-style-type: none"> <li>• Type: class</li> <li>• Default:</li> </ul>

Parameter	Description
<b>offset.flush.interval.ms</b>	Interval (milliseconds) at which to try committing offsets for tasks. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 60000</li> </ul>
<b>offset.flush.timeout.ms</b>	Maximum number of milliseconds to wait for records to flush and partition offset data to be committed to offset storage before cancelling the process and restoring the offset data to be committed in a future attempt. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 5000</li> </ul>
<b>rest.advertised.host.name</b>	If set, this is the hostname that will be given out to other workers to connect to. <ul style="list-style-type: none"> <li>Type: string</li> </ul>
<b>rest.advertised.port</b>	If set, this is the port that will be given out to other workers to connect to. <ul style="list-style-type: none"> <li>Type: int</li> </ul>
<b>rest.host.name</b>	Hostname for the REST API. If this is set, it will only bind to this interface. <ul style="list-style-type: none"> <li>Type: string</li> </ul>
<b>rest.port</b>	Port for the REST API to listen on. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 8083</li> </ul>
<b>task.shutdown.graceful.timeout.ms</b>	Amount of time to wait (milliseconds) for tasks to shutdown gracefully. This is the total amount of time, not per task. All task have shutdown triggered, then they are waited on sequentially. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 5000</li> </ul>
<b>streams.consumer.streams.default.stream</b>	If set, topic names can be used in the Sink task configuration without the stream name. The defined default stream is used.
<b>streams.producer.producer.default.stream</b>	If set, topic names can be used in the Source task configuration without the stream name. The defined default stream is used.

#### *Standalone Worker Configuration Options*

This section describes worker parameters that are specific to standalone configurations.

The `offset.storage.file.filename` and `rest.port` parameter are specific to the standalone worker configuration. These parameters are sent in the `connect-standalone.properties` file.

#### Table

Parameter	Description
<b>rest.port</b>	Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this setting must have different values for each instance. Type: int. Default: 8083

Table (Continued)

Parameter	Description
<b>offset.storage.file.filename</b>	The file to store connector offsets in. By storing offsets on disk, a standalone process can be stopped and started on a single node and resume where it previously left off. Type: string. Default: empty

*Distributed Worker Configuration Options*

This topic describes the worker parameters that are specific to distributed configurations.

In addition to the common worker configuration options, the following are available in distributed mode. These parameters are set in the `connect-distributed.properties` file.

Table

Parameter	Description	Type	Default
<b>group.id</b>	A unique string that identifies the Connect cluster group that the worker belongs to.	string	""
<b>config.storage.topic</b>	The name of the HPE Ezmeral Data Fabric Streams topic to store connector and task configuration data in. This <i>must</i> be the same for all workers with the same group.id. For example: <code>/path/to/stream:topic-prefix-</code>	string	""
<b>status.storage.topic</b>	The name of the HPE Ezmeral Data Fabric Streams topic where connector and task configuration updates are stored. This <i>must</i> be the same for all workers with the same group.id.	string	""
<b>offset.storage.topic</b>	The HPE Ezmeral Data Fabric Streams topic to store offset data for connectors in. This <i>must</i> be the same for all workers with the same group.id. For example: <code>/path/to/stream:topic-prefix-</code>	string	""
<b>heartbeat.interval.ms</b>	The expected time between heartbeats to the group coordinator when using Kafka's group management facilities.  Heartbeats are used to ensure that the worker's session stays active and to facilitate rebalancing when new members join or leave the group. The value must be set lower than <code>session.timeout.ms</code> , but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	int	3000
<b>session.timeout.ms</b>	The timeout used to detect failures when using Kafka's group management facilities.	int	30000
<b>connections.max.idle.ms</b>	Close idle connections after the number of milliseconds specified by this config.	long	540000
<b>receive.buffer.bytes</b>	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	int	32768
<b>request.timeout.ms</b>	The configuration controls the maximum amount of time the client will wait for the response of a request.  If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	int	40000

Table (Continued)

Parameter	Description	Type	Default
<b>send.buffer.bytes</b>	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	int	131072
<b>worker.sync.timeout.ms</b>	When the worker is out of sync with other workers and needs to resynchronize configurations, wait up to this amount of time before giving up, leaving the group, and waiting a backoff period before rejoining.	int	3000
<b>worker.unsync.backoff.ms</b>	When the worker is out of sync with other workers and fails to catch up within worker.sync.timeout.ms, leave the Connect cluster for this long before rejoining.	int	300000
<b>client.id</b>	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just IP/port by allowing a logical application name to be included in server-side request logging.	string	""
<b>metadata.max.age.ms</b>	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	long	300000
<b>metric.reporters</b>	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	list	[]
<b>metrics.num.samples</b>	The number of samples maintained to compute metrics.	int	2
<b>metrics.sample.window.ms</b>	The number of samples maintained to compute metrics.	long	30000
<b>reconnect.backoff.ms</b>	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	long	50
<b>retry.backoff.ms</b>	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	long	100

### Security Configuration Options

Describes Kafka Connect security parameters.

Security mechanisms provide an authentication, encryption, and impersonation layer between the Kafka Connect REST API clients and the Kafka Connect REST Gateway. By default, Kafka Connect is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (MapR-SASL) enabled. Default security provides authentication, encryption, and impersonation for Kafka Connect.

Configure security for Kafka Connect through the security parameters in the `connect-distributed.properties` file.

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

**NOTE:** Ensure that both a `ssl_keystore` and a `ssl_truststore` file have been created.

Table

Parameter	Description	Type	Default
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. If a listener uses HTTPS, the appropriate SSL configuration parameters need to be set as well. Each listener must include the protocol, hostname, and port. For example: http://localhost:8082	list	none
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none
authentication.enable	Enable authentication. Data Fabric supports multiple authentication methods at same time: Basic and MapR-SASL.	boolean	false
authentication.cookie.expiration	The option is used to specify expiration time (in seconds) for authentication cookie.	long	7200 (2 hours)
impersonation.enable	Whether or not to enable impersonation, if disabled - all manipulation will be performed from the admin of cluster user.	boolean	false
headers.file	The option is used to specify XML file that contains security and custom headers. The headers will be added to a response by Jetty server.	string	none
hadoop.http.authentication.types	A list of hadoop authentication types for MultiMechsAuthenticationHandler	list	maprauth, basic
ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .*DES.*</li> <li>• .*MD5.*</li> <li>• .*RC4.*</li> </ul>
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if ssl_endpoint_identification_algorithm=http s. Leave blank to use Jetty's default.	string	none
ssl.key.password	The password of the private key in the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty

Table (Continued)

Parameter	Description	Type	Default
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.keystore.location	Location of the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keystore.password	The store password for the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLSv1.2
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS

### SSL Security Configuration

Describes how to configure Kafka Connect security on a HPE Ezmeral Data Fabric cluster.

### Secure by Default

As of Core 6.0, the Installer performs the Kafka Connect configuration for new installations. This means that:

- If core is installed as *secure*, then Kafka Connect is also installed as *secure*.
- If core is installed as *unsecure*, then Kafka Connect is also installed as *unsecure*.

### Manually Securing Kafka Connect Only

 **CAUTION:** This configuration is *not* a typical configuration.

If you have an *unsecure* HPE Ezmeral Data Fabric cluster, and you want to *secure* Kafka Connect, do the following:

1. Generate the server and client certificates.
2. Add any necessary property configurations to the `connect-distributed.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8083
ssl.keystore.location=<ssl-keystore-path>
ssl.keystore.password=<ssl-keystore-password>
ssl.key.password=<ssl-keystore-password>
```

### 3. Restart Kafka Connect.

```
maprcli node services -name kafka-connect -action restart -nodes <space
delimited list of nodes>
```

### 4. Run a curl command to ensure that HTTPS is enabled.

```
curl -X GET https://node1:8083/connectors --cacert <certificate-path>
```

#### *User Impersonation*

Describes how to disable, enable, and use impersonation with Kafka Connect.

User impersonation enables Kafka Connect jobs to be submitted as a particular user. Without impersonation, Kafka Connect submits jobs as the user that started the worker

On a HPE Ezmeral Data Fabric cluster, the impersonated user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable. By default, impersonation and PAM authentication in Kafka Connect are enabled on all types of security.

#### **Disabling User Impersonation**

To disable user impersonation, disable the PAM authentication and impersonation properties in the `opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties` file.

1. To disable PAM authentication, set `authentication.enable=false`.
2. To disable impersonation, set `impersonation.enable=false`.

#### **JDBC Connector**

The topics describes the JDBC connector, drivers, and configuration parameters.

The JDBC connector allows you to import data from any relational database into HPE Ezmeral Data Fabric Streams and export data from HPE Ezmeral Data Fabric Streams to any relational database with a JDBC driver. By using JDBC, this connector can support a wide variety of databases without requiring custom code for each one.

The JDBC connector provides flexibility regarding which databases you can import data from and how that data is imported. JDBC connector implements the data copying functionality on the generic JDBC APIs, and relies on JDBC drivers to handle the database-specific implementation of those APIs.

The supported relational databases include:

- MySQL
- Oracle
- PostgreSQL
- SQLite
- SQL Server
- Hive is supported for the JDBC Source Connector

#### *JDBC Driver*

Kafka Connect for HPE Ezmeral Data Fabric Streams provides a JDBC driver jar along with the connector configuration.

The JDBC driver (`kafka-connect-jdbc`) is set up by specifying the `CLASSPATH` variable. See [Installing HPE Ezmeral Data Fabric Streams Tools](#) on page 252.

The packaged connector is installed in the **share/java/kafka-connect-jdbc** directory, relative to the installation directory.

Alternatively, to add a new driver to the CLASSPATH,

1. Put the classpath of the connectors in the **kafka-connect-jdbc** directory:

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<connector version>/
share/java/kafka-connect-jdbc/
```

2. Create a symlink into the **share/java/kafka-connect-jdbc/** directory.

#### JDBC Configuration Options

Use the following parameters to configure the Kafka Connect for HPE Ezmeral Data Fabric Streams JDBC connector; they are modified in the `quickstart-sqlite.properties` file.

#### Configuration Modes

In *standalone* mode, JDBC connector configuration is specified in the **quickstart-sqlite.properties** file. Additional configurations such as the offset storage location and the port for the REST interface are specified in the **connect-standalone.properties** file. See [Configuring in Standalone Mode](#) on page 4521.

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-sqlite.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See [POST /connectors](#) on page 4547 and [PUT /connectors/{string:name}/config](#) on page 4550 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state, and connector offset state are specified in the **connect-distributed.properties** file. See [Configuring in Distributed Mode](#) on page 4522 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

#### JDBC Source Configuration Options

Table

Parameters	Description
<b>connection.url</b>	JDBC connection URL for the database to load. <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul>
<b>connection.user</b>	JDBC connection user. <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: NULL</li> </ul>
<b>connection.password</b>	JDBC connection password. <ul style="list-style-type: none"> <li>• Type: password</li> <li>• Default: NULL</li> </ul>

Table (Continued)

Parameters	Description
<b>connection.attempts</b>	Maximum number of attempts to retrieve a valid JDBC connection. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 3</li> </ul>
<b>connection.backoff.ms</b>	Backoff time in milliseconds between connection attempts. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 10000</li> </ul>
<b>table.whitelist</b>	List of tables to include in copying. If specified, table.blacklist may not be set. <ul style="list-style-type: none"> <li>Type: list</li> <li>Default: []</li> </ul>
<b>table.blacklist</b>	List of tables to exclude from copying. If specified, table.whitelist may not be set. <ul style="list-style-type: none"> <li>Type: list</li> <li>Default: []</li> </ul>
<b>numeric.precision.mapping</b>	Whether or not to attempt mapping <i>numeric</i> values by precision to integral types. <ul style="list-style-type: none"> <li>Type: boolean</li> <li>Default: false</li> </ul>
<b>schema.pattern</b>	Schema pattern to fetch table metadata from the database. <p>" " - Retrieves those without a schema.</p> <p>* - NULL (default) means that the schema name should not be used to narrow the search, all tables metadata would be fetched, regardless their schema.</p>

Table (Continued)

Parameters	Description
<b>mode</b>	<p>The mode for updating a table each time it is polled. Options include:</p> <ul style="list-style-type: none"> <li>• bulk - perform a bulk load of the entire table each time it is polled.</li> <li>• incrementing - use a strictly incrementing column on each table to detect only new rows. Note that this will not detect modifications or deletions of existing rows.</li> <li>• timestamp - use a timestamp (or timestamp-like) column to detect new and modified rows. This assumes the column is updated with each write, and that values are monotonically incrementing, but not necessarily unique.</li> <li>• timestamp+incrementing - use two columns, a timestamp column that detects new and modified rows and a strictly incrementing column which provides a globally unique ID for updates so each row can be assigned a unique stream offset.</li> </ul> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul> <p>Valid Values: [, bulk, timestamp, incrementing, timestamp+incrementing]</p> <p>The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an autoincrementing column. This column may not be nullable.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul> <p> <b>NOTE:</b> If you are using Hive JDBC with incrementing or timestamp mode, you should set the <code>validate.non.null</code> property to false because there are no "not null" columns in Hive.</p>
<b>timestamp.column.name</b>	<p>The name of the timestamp column to use to detect new or modified rows. This column may not be nullable.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul>
<b>validate.non.null</b>	<p>By default, the JDBC connector will validate that all incrementing and timestamp tables have NOT NULL set for the columns being used as their ID/timestamp. If the tables don't, JDBC connector will fail to start. Setting this to false will disable these checks.</p> <ul style="list-style-type: none"> <li>• Type: boolean</li> <li>• Default: true</li> </ul> <p> <b>NOTE:</b> If this parameter is false, specify exactly all columns that need to be imported to HPE Ezmeral Data Fabric Streams in the query parameter. For example instead of "query" : "select * from table", use "query" : "select col1, col2 from table"</p>

Table (Continued)

Parameters	Description
<b>incrementing.column.name</b>	<p>The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an auto-incrementing column. This column may not be nullable.</p> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>query</b>	<p>If specified, the query to perform to select new or updated rows. Use this setting to join tables, select subsets of columns in a table, or filter data. If used, this connector will only copy data using this query – whole-table copying will be disabled. Different query modes may still be used for incremental updates, but in order to properly construct the incremental query, it must be possible to append a WHERE clause to this query (i.e. no WHERE clauses may be used). If you use a WHERE clause, it must handle incremental queries itself.</p> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>poll.interval.ms</b>	<p>Frequency (milliseconds) to poll for new data in each table.</p> <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 5000</li> </ul>
<b>batch.max.rows</b>	<p>Maximum number of rows to include in a single batch when polling for new data. This setting can be used to limit the amount of data buffered internally in the connector.</p> <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 100</li> </ul>
<b>table.poll.interval.ms</b>	<p>Frequency (milliseconds) to poll for new or removed tables, which may result in updated task configurations to start polling for data in added tables or stop polling for data in removed tables.</p> <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 60000</li> </ul>
<b>topic.prefix</b>	<p>Prefix to prepend to table names to generate the name of the Kafka topic to publish data to, or in the case of a custom query, the full name of the topic to publish to. For example: <code>/path/to/stream:topic-prefix-</code>.</p> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>

Table (Continued)

Parameters	Description
<b>table.types</b>	<p>By default, the JDBC connector will only detect tables with type TABLE from the source Database. This config allows a command separated list of table types to extract. Options include:</p> <ul style="list-style-type: none"> <li>• TABLE</li> <li>• VIEW</li> <li>• SYSTEM TABLE</li> <li>• GLOBAL TEMPORARY</li> <li>• LOCAL TEMPORARY</li> <li>• ALIAS</li> <li>• SYNONYM</li> </ul> <p>Typically, TABLE or VIEW are used.</p> <ul style="list-style-type: none"> <li>• Type: list</li> <li>• Default: TABLE</li> </ul>
<b>timestamp.delay.interval.ms</b>	<p>How long to wait after a row with certain timestamp appears before it is included in the result. You may choose to add some delay to allow transactions with earlier timestamp to complete. The first execution fetches all available records (for example, starting at timestamp 0) until the current time minus the delay. Every following execution retrieves data from the last time data was fetched until the current time minus the delay.</p> <ul style="list-style-type: none"> <li>• Type: long</li> <li>• Default: 0</li> </ul>

### JDBC Sink Configuration Options

Table

Parameters	Description
<b>connection.url</b>	<p>JDBC connection URL.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul>
<b>connection.user</b>	<p>JDBC connection user.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: NULL</li> </ul>
<b>connection.password</b>	<p>JDBC connection password.</p> <ul style="list-style-type: none"> <li>• Type: password</li> <li>• Default: NULL</li> </ul>

Table (Continued)

Parameters	Description
<b>insert.mode</b>	<p>The insertion mode to use.</p> <ul style="list-style-type: none"> <li>• INSERT - Use standard SQL INSERT statements.</li> <li>• UPSERT - Use the appropriate upsert semantics for the target database if it is supported by the connector. For example: INSERT or IGNORE</li> <li>• UPDATE - Use the appropriate update semantics for the target database if it is supported by the connector. For example: UPDATE</li> <li>• Type: string</li> <li>• Default: INSERT</li> <li>• Valid Values: insert, upsert, update</li> </ul>
<b>batch.size</b>	<p>Specifies how many records to attempt to batch together for insertion into the destination table, when possible.</p> <ul style="list-style-type: none"> <li>• Type: int</li> <li>• Default: 3000</li> <li>• Valid Values: 0,...</li> </ul>
<b>table.name.format</b>	<p>A format string for the destination table name, which may contain <code>\${topic}</code> as a placeholder for the originating topic name. For example, <code>table_\${topic}</code> for the topic <code>orders</code> maps to the table name <code>table_orders</code>.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: <code>\${topic}</code></li> </ul>
<b>pk.mode</b>	<p>The primary key mode, also refer to <code>pk.fields</code> documentation for interplay. Supported modes are:</p> <ul style="list-style-type: none"> <li>• none - No keys utilized.</li> <li>• kafka - Kafka coordinates are used as the PK.</li> <li>• record_key - Field(s) from the record key are used, which may be a primitive or a struct.</li> <li>• record_value - Field(s) from the record value are used, which must be a struct.</li> <li>• Type: string</li> <li>• Default: none</li> <li>• Valid Values: none, kafka, record_key, record_value</li> </ul>

Table (Continued)

Parameters	Description
<b>pk.fields</b>	<p>List of comma-separated primary key field names. The runtime interpretation of this config depends on the pk.mode:</p> <ul style="list-style-type: none"> <li>• none - Ignored as no fields are used as primary key in this mode.</li> <li>• kafka - Must be a trio representing the Kafka coordinates. Defaults to __connect_topic,__connect_partition,__connect_offset if empty.</li> <li>• record_key - If empty, all fields from the key struct will be used, otherwise used to extract the desired fields - for primitive key only a single field name must be configured.</li> <li>• record_value - If empty, all fields from the value struct will be used, otherwise used to extract the desired fields.</li> <li>• Type: list</li> <li>• Default: ""</li> </ul>
<b>fields.whitelist</b>	<p>List of comma-separated record value field names. If empty, all fields from the record value are utilized, otherwise used to filter to the desired fields. Note: pk.fields is applied independently in the context of which field(s) form the primary key columns in the destination database, while this configuration is applicable for the other columns.</p> <ul style="list-style-type: none"> <li>• Type: list</li> <li>• Default: ""</li> </ul>
<b>auto.create</b>	<p>Whether to automatically create the destination table based on record schema if it is found to be missing by issuing CREATE.</p> <ul style="list-style-type: none"> <li>• Type: boolean</li> <li>• Default: false</li> </ul>
<b>auto.evolve</b>	<p>Whether to automatically add columns in the table schema when found to be missing relative to the record schema by issuing ALTER.</p> <ul style="list-style-type: none"> <li>• Type: boolean</li> <li>• Default: false</li> </ul>
<b>max.retries</b>	<p>The maximum number of times to retry on errors before failing the task.</p> <ul style="list-style-type: none"> <li>• Type: int</li> <li>• Default: 10</li> <li>• Valid Values: 0,..</li> </ul>
<b>retry.backoff.ms</b>	<p>The time in milliseconds to wait following an error before a retry attempt is made.</p> <ul style="list-style-type: none"> <li>• Type: int</li> <li>• Default: 3000</li> <li>• Valid Values: 0,..</li> </ul>

### Whitelists and Custom Query JDBC Examples

This section provides common usage scenarios using whitelists and custom queries.

#### Using Whitelists

Use a whitelist to limit changes to a subset of tables in a MySQL database, using id and modifiedcolumns that are standard on all whitelisted tables to detect rows that have been modified. This mode is the most robust because it can combine the unique, immutable row IDs with modification timestamps to guarantee modifications are not missed even if the process dies in the middle of an incremental update query.

The following is an example of a whitelist.

**NOTE:** Before running this example, you need to create the stream `/kafka-connect`

```

name=mysql-whitelist-timestamp-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector tasks.max=10
connection.url=jdbc:mysql://mysql.example.com:3306/my_database?
user=alice&password=secret
table.whitelist=users,products,transactions
mode=timestamp+incrementing
timestamp.column.name=modified
incrementing.column.name=id
topic.prefix=/kafka-connect:mysql-

```

#### Using Custom Queries

Use a custom query instead of loading tables to join data from multiple tables. As long as the query does not include its own filtering, you can still use the built-in modes for incremental queries (in this case, using a timestamp column).

**NOTE:** This limits you to a single output per connector and because there is no table name, the topic “prefix” is actually the full topic name in this case.

The following is an example of a custom query.

**NOTE:** Before running this example, you need to create the stream `/kafka-connect`

```

name=mysql-whitelist-timestamp-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector
tasks.max=10
connection.url=jdbc:postgresql://postgres.example.com/test_db?
user=bob&password=secret&ssl=true
query=SELECT users.id,
users.name,
transactions.timestamp,
transactions.user_id,
transactions.payment FROM users JOIN transactions ON (users.id =
transactions.user_id)
mode=timestamp
timestamp.column.name=timestamp
topic.prefix=/kafka-connect:mysql-joined-data

```

### Streaming Data JDBC Examples

This section provides common usage scenarios of streaming data between different databases to or from HPE Ezmeral Data Fabric Streams.

## Streaming Data from HPE Ezmeral Data Fabric Streams to a MySQL Database

The following is example code for streaming data from HPE Ezmeral Data Fabric Streams stream topics to a MySQL database.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "mysql-sink-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSinkConnector",
"connection.url": "jdbc:mysql://hostname:3306/mysql_db?
user=<user>&password=<password>",
"auto.create": "true",
"topics": "/kafka-connect:topic1",
"tasks.max": "2",
"insert.mode": "insert"
}}
```

## Streaming Data from a MySQL Database to HPE Ezmeral Data Fabric Streams

The following is example code for streaming data from a MySQL database to HPE Ezmeral Data Fabric Streams stream topics.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "mysql-source-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSourceConnector",
"connection.url": "jdbc:mysql://hostname:3306/newdb?
user=<user>&password=<password>"
"mode": "incrementing",
"incrementing.column.name": "id",
"topic.prefix": "/kafka-connect:mysql-",
"tasks.max": "1"
}}
```

## Streaming Data from a Hive Database to HPE Ezmeral Data Fabric Streams

The following is example code for streaming data from a Hive database to HPE Ezmeral Data Fabric Streams stream topics.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "hive-source-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSourceConnector",
"connection.url": "jdbc:hive2://hostname:10000/
database_name;user=<user>;password=<pa
ssword>",
"mode": "bulk",
"topic.prefix": "/kafka-connect:hive-",
"tasks.max": "1"
}}
```

 **NOTE:** For a secure HPE Ezmeral Data Fabric cluster, use `next.connection.url jdbc:hive2://hostname:10000/database_name;auth=maprsasl`

### Managing Kafka Connect Services

Lists the commands you use to start, stop, or restart Kafka Connect Services

Use the `maprcli node services` command with the `-action` parameter as follows:

```
maprcli node services -name kafka-connect -action start -nodes <node_list>
```

```
maprcli node services -name kafka-connect -action stop -nodes <node_list>
```

```
maprcli node services -name kafka-connect -action restart -nodes
<node_list>
```

For more information see [node services](#) on page 2298

### HDFS Connector

These topics describe the Kafka Connect for HPE Ezmeral Data Fabric Streams HDFS connector, driver, and configuration parameters.

The HDFS connector allows you to export data from HPE Ezmeral Data Fabric Streams topics to file system or HDFS files in a variety of formats. In addition, Hive integration is available, which can be use to make data immediately available for querying with HiveQL.

#### *HDFS Configuration Options*

Use the following parameters to configure the Kafka Connect for HPE Ezmeral Data Fabric Streams HDFS connector.

 **NOTE:** For the HDFS connector, both Avro and Parquet files can be written.

In *standalone* mode, specify the HDFS connector configuration in the **quickstart-hdfs.properties** file. You can also configure the offset storage location and the port for the REST interface, which are specified in the **connect-standalone.properties** file. See [Configuring in Standalone Mode](#) on page 4521.

```
/opt/mapr/kafka-connect-hdfs/kafka-connect-hdfs-<version>/etc/
kafka-connect-hdfs/quickstart-hdfs.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See [POST /connectors](#) on page 4547 and [PUT /connectors/\(string:name\)/config](#) on page 4550 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state, and connector offset state are specified in the **connect-distributed.properties** file. See [Configuring in Distributed Mode](#) on page 4522 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

**Table**

Parameter	Description
<b><i>flush.size</i></b>	Number of records written to the file system before invoking file commits. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: ""</li> </ul>

Table (Continued)

Parameter	Description
<b><i>hdfs.url</i></b>	The file system connection URL. This configuration has the format of <code>maprfs://hostname:port</code> and specifies the data fabric file system to export data to. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>connect.hdfs.keytab</i></b>	The path to the keytab file for the HDFS connector principal. This keytab file should only be readable by the connector user. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>connect.hdfs.principal</i></b>	The principal used when the file system is using Kerberos for authentication. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>format.class</i></b>	The format class used when writing data to the file system. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "io.confluent.connect.hdfs.avro.AvroFormat"</li> </ul> <p> <b>NOTE:</b> If you want to write to a Parquet set, use "io.confluent.connect.hdfs.parquet.ParquetFormat"</p>
<b><i>hadoop.conf.dir</i></b>	The Hadoop configuration directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>hadoop.home</i></b>	The Hadoop home directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>hdfs.authentication.kerberos</i></b>	Specifies whether the file system uses Kerberos for authentication. <ul style="list-style-type: none"> <li>Type: boolean</li> <li>Default: false</li> </ul>
<b><i>hdfs.namenode.principal</i></b>	The Kerberos principal for CLDB. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>hive.conf.dir</i></b>	The Hive configuration directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>

Table (Continued)

Parameter	Description
<b>hive.database</b>	The database used when the connector creates tables in Hive. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "default"</li> </ul>
<b>hive.home</b>	The Hive home directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>hive.integration</b>	Specifies whether Hive is integrated when running the connector. <ul style="list-style-type: none"> <li>Type: boolean</li> <li>Default: false</li> </ul>
<b>hive.metastore.uris</b>	The Hive metastore URIs. Can be an IP address or fully-qualified domain name and port of the metastore host. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>logs.dir</b>	Top-level file system directory to store the write ahead logs. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "logs"</li> </ul>
<b>partitioner.class</b>	The partitioner used when writing data to the file system. You can use DefaultPartitioner, which preserves the Kafka partitions; FieldPartitioner, which partitions the data to different directories according to the value of the partitioning field specified in partition.field.name; TimeBasedPartitioner, which partitions data according to the time ingested to the file system. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "io.confluent.connect.hdfs.partitionner.DefaultPartitioner"</li> </ul>
<b>rotate.interval.ms</b>	The time interval (milliseconds) before invoking file commits. This configuration ensures that file commits are invoked every configured interval. This configuration is useful when data ingestion rate is low and the connector didn't write enough messages to commit files. The default value -1 means that this feature is disabled. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: -1</li> </ul>
<b>schema.compatibility</b>	The schema compatibility rule used when the connector is observing schema changes. The supported configurations are NONE, BACKWARD, FORWARD and FULL. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "NONE"</li> </ul>

Table (Continued)

Parameter	Description
<b>topics</b>	A list of topics to use as input for the HDFS connector. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>topics.dir</b>	Top-level file system directory to store the data ingested from Kafka. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "topics"</li> </ul>
<b>locale</b>	The locale used when partitioning with TimeBasedPartitioner. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>partition.duration.ms</b>	The duration of a partition (milliseconds) used by TimeBasedPartitioner. The default value -1 means that TimeBasedPartitioner is not being used. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: -1</li> </ul>
<b>partition.field.name</b>	The name of the partitioning field when FieldPartitioner is used. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>path.format</b>	This configuration is used to set the format of the data directories when partitioning with TimeBasedPartitioner. The format set in this configuration converts the Unix timestamp to proper directories strings. For example, if you set <code>path.format='year'=YYYY/'month'=MM/'day'=dd/'hour'=HH/</code> , the data directories will have the format <code>/year=2015/month=12/day=07/hour=15</code> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>shutdown.timeout.ms</b>	Clean shutdown timeout. This makes sure that asynchronous Hive metastore updates are completed during connector shutdown. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 3000</li> </ul>
<b>timezone</b>	The timezone to use when partitioning with TimeBasedPartitioner. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>filename.offset.zero.pad.width</b>	Sets the width to the zero-pad offsets in the file system file names. If the offsets are too short it provides fixed width filenames that can be ordered by simple lexicographic sorting. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 10</li> </ul>

Table (Continued)

Parameter	Description
<b><i>kerberos.ticket.renew.period.ms</i></b>	The period in milliseconds to renew the Kerberos ticket. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 3600000 (milliseconds)</li> </ul>
<b><i>retry.backoff.ms</i></b>	Used to notify Kafka Connect to retry delivering a message batch or performing recovery in case of transient exceptions. The retry backoff is in milliseconds. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 5000 (milliseconds)</li> </ul>
<b><i>schema.cache.size</i></b>	The sized of the schema cache used in the Avro converter. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 1000</li> </ul>
<b><i>storage.class</i></b>	The underlying storage layer. The default is MapR-FS. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "io.confluent.connect.hdfs.storage.HdfsStorage"</li> </ul>

#### *HDFS Examples*

These examples provides sample code for streaming data to and from the file system.

#### **Streaming Data from HPE Ezmeral Data Fabric Streams to the File System**

This example provides sample code for streaming data from HPE Ezmeral Data Fabric Streams to the file system.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json

{
  "name": "maprfs-sink-connector",
  "config": {
    "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "1",
    "topics": "/kafka-connect:topic1",
    "hdfs.url": "maprfs://",
    "flush.size": "5",
    "rotate.interval.ms": "1000"
  }
}
```

#### **Streaming Data from HPE Ezmeral Data Fabric Streams to the File System in Parquet**

This example provides sample code for streaming data from HPE Ezmeral Data Fabric Streams to the file system in Parquet.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
```

```

Accept: application/json

{
  "name": "hdfs-connector-parquet",
  "config": {
    "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "/kafka-connect:topic2",
    "hdfs.url": "maprfs:///",
    "format.class": "io.confluent.connect.hdfs.parquet.ParquetFormat",
    "flush.size": "3"
  }
}

```

### Hive Integration

This topic describes how to integrate a Hive database with Kafka Connect for HPE Ezmeral Data Fabric Streams.

Kafka Connect for HPE Ezmeral Data Fabric Streams supports Hive integration. If a Hive database is enabled, an external Hive table is created and that can be queried via Hive shell.

**NOTE:** As of Kafka Connect 4.0.0 for HPE Ezmeral Data Fabric Streams Hive 2.1 is supported.

The Hive table name is constructed using a topic name in the following manner:

- In the HPE Ezmeral Data Fabric Streams topic, `/stream_path:topic-name`, the first forward slash (/) is removed, all other slashes are translated to underscores ( \_ ), and the colon (:) is translated to an underscore ( \_ ).
- All non-alphanumeric and non-underscore characters are removed from the string representing the Hive table name.

### Renaming Topics for Hive usage

The following example shows a topic named `/test-12:test1` is renamed for Hive usage.

```

$ hadoop fs -ls -R /topics
drwxr-xr-x  - mapr mapr          1 2016-10-05 19:46 /topics/+tmp
drwxr-xr-x  - mapr mapr          1 2016-10-05 19:46 /topics/+tmp/
test12_test1
drwxr-xr-x  - mapr mapr          0 2016-10-05 19:50 /topics/+tmp/
test12_test1/partition=1
drwxr-xr-x  - mapr mapr          1 2016-10-05 19:46 /topics/
test12_test1
drwxr-xr-x  - mapr mapr          2 2016-10-05 19:50 /topics/
test12_test1/partition=1
-rwxr-xr-x  3 mapr mapr          241 2016-10-05 19:47 /topics/
test12_test1/partition=1/test12_test1+1+0000000078+0000000080.avro
-rwxr-xr-x  3 mapr mapr          241 2016-10-05 19:50 /topics/
test12_test1/partition=1/test12_test1+1+0000000081+0000000083.avro

```

The following query and results shows the topic data in the Hive table.

```

> select * from test12_test1;
OK
16/10/05 20:06:59 INFO mapred.FileInputFormat: Total input paths to
process : 2
18  data10  1
18  data10  1
18  data10  1
18  data10  1

```

```

18 data10 1
18 data10 1
Time taken: 0.128 seconds, Fetched: 6 row(s)
>

```

### Streaming Data from HPE Ezmeral Data Fabric Streams to the Hive database

This example provides sample code for streaming data from HPE Ezmeral Data Fabric Streams to the Hive database.

```

POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json

{
  "name": "hdfs-connector-hive",
  "config": {
    "hive.integration": "true",
    "hive.database": "db3",
    "hive.conf.dir": "/opt/mapr/hive/hive-1.2/conf",
    "hive.metastore.uris": "thrift://localhost:9083",
    "schema.compatibility": "BACKWARD",
    "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "1",
    "topics": "/kafka-connect:topic3",
    "hdfs.url": "maprfs:///",
    "flush.size": "1"
  }
}

```

### REST API

The Kafka Connect REST API for HPE Ezmeral Data Fabric Streams manages connectors.

In standalone mode, a connector request is submitted on the command line. This mode is useful for getting status information, adding and removing connectors without stopping the process, and testing and debugging.

In distributed mode, the REST API is the primary interface to the cluster. Requests can be made to any cluster member where the REST API automatically forwards requests.

### Content Types

The REST API supports application/json as both the request and response entity content type. For example:

```

Accept: application/json
Content-Type: application/json

```

### Status & Errors

The REST API returns standards-compliant HTTP statuses.

**NOTE:** By default, the Kafka Connect REST API for HPE Ezmeral Data Fabric Streams service is run on port 8083.

### Table

HTTP	URI	Description
GET	/connectors	Gets a list of active connectors.

Table (Continued)

HTTP	URI	Description
POST	/connectors	Creates a new connector, returning the current connector information is successful.
GET	/connectors/(string:name)	Gets information about the connector.
GET	/connectors/(string:name)/config	Gets the configuration for the connector.
PUT	/connectors/(string:name)/config	Creates a new connector using the given configuration or updates the configuration for an existing connector.
GET	/connectors/(string:name)/tasks	Gets a list of tasks current running for the connector.
DELETE	/connectors/(string:name)/	Deletes a connector, halting all tasks and deleting its configuration.
GET	/connector-plugins	Lists the connector plugins available on this worker,
POST	/connectors/(string:name)/restart	Restarts a connector and its tasks.
GET	/connectors/(string:name)/tasks/ (int:taskId)/status	Gets the status for a task.
POST	/connectors/(string:name)/tasks/ (int:number of tasks)/restart	Restarts an individual task.
PUT	/connectors/(string:name)/pause	Pauses the connector and its tasks, which stops message processing until the connector is resumed.
PUT	/connectors/(string:name)/resume	Resumes a paused connector or do nothing if the connector is not paused.
GET	/connectors/(string:name)/status	Get current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks.

*GET /connectors*

Gets a list of active connectors.

### Syntax

```
http://<host>:8083/connectors
```

### Request Example

```
GET /connectors HTTP/1.1 Host: connect.example.com Accept: application/json
```

### Response Example

The response JSON object is in the following form:

- **connectors** (*array*) – List of connector names.

```
HTTP/1.1 200 OK Content-Type: application/json [ "my-jdbc-source",  
"my-hdfs-sink" ]
```

*POST /connectors*

Creates a new connector, returning the current connector information if successful.

## Description

The POST request along with the parameters is used to create connectors in distributed mode.

The following table provides the parameters needed to create a new connector.

Table

Parameters	Description
<b>name</b> ( <i>string</i> )	Name of the created connector
<b>config</b> ( <i>map</i> )	Configuration parameters for the connector. See <a href="#">HDFS Connector</a> on page 4540 and <a href="#">JDBC Connector</a> on page 4530 for configuration options.
<b>tasks</b> ( <i>array</i> )	List of active tasks generated by the connector.
<b>tasks[i].connector</b> ( <i>string</i> )	Name of the connector that the task belongs to.
<b>tasks[i].task</b> ( <i>int</i> )	Task ID within the connector.

## Syntax

```
http://<host>:8083/connectors/?
name=<connector_name>&config=<config_parameters>
```

## Request Example

```
POST /connectors HTTP/1.1 Host: connect.example.com Content-Type:
application/json Accept: application/json
{
  "name": "hdfs-sink-connector",
  "config": {
    "connector.class":
"io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "1",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"
  }
}
```

## Response Example

The response JSON object is in the following form:

- **name** (*string*) – Name of the connector to create.
- **config** (*map*) – Configuration parameters for the connector. All values should be strings.
- **tasks** (*array*) – List of active tasks generated by the connector.

```
HTTP/1.1 201 Created Content-Type: application/json
{
  "name": "hdfs-sink-connector",
  "config":
  {
    "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "test-topic",
```

```

    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"
  },
  "tasks": [
    { "connector": "hdfs-sink-connector", "task": 1 },
    { "connector": "hdfs-sink-connector", "task": 2 },
    { "connector": "hdfs-sink-connector", "task": 3 }
  ]
}

```

*GET /connector/(string:name)*

Gets information about a specific connector.

## Description

### Table

Parameters	Description
<b>name</b> ( <i>string</i> )	Name of the created connector.
<b>config</b> ( <i>map</i> )	Configuration parameters for the connector.
<b>tasks</b> ( <i>array</i> )	List of active tasks generated by the connector.
<b>tasks[i].connector</b> ( <i>string</i> )	Name of the connector the task belongs to.
<b>tasks[i].task</b> ( <i>int</i> )	Task ID within the connector.

## Syntax

```
http://<host>:8083/connectors/<name>
```

## Request Example

```
GET /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
Accept: application/json
```

## Response Example

```

HTTP/1.1 200 OK Content-Type: application/json
{
  "name": "hdfs-sink-connector",
  "config": {
    "connector.class":
    "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"    },
  "tasks": [
    { "connector": "hdfs-sink-connector", "task": 1 },
    { "connector": "hdfs-sink-connector", "task": 2 },
    { "connector": "hdfs-sink-connector", "task": 3 }
  ]
}

```

*GET /connectors/{string:name}/config*  
Gets the configuration for the connector.

### Description

#### Table

Parameters	Description
<b>config</b> ( <i>map</i> )	Configuration parameters for the connector.

### Syntax

```
http://<host>:8083/connectors/<string_name>/config
```

### Request Example

```
GET /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
```

### Response Example

```
HTTP/1.1 200 OK Content-Type: application/json
{
  "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
  "tasks.max": "10",
  "topics": "test-topic",
  "hdfs.url": "hdfs://fakehost:9000",
  "hadoop.conf.dir": "/opt/hadoop/conf",
  "hadoop.home": "/opt/hadoop",
  "flush.size": "100",
  "rotate.interval.ms": "1000"
}
```

*PUT /connectors/{string:name}/config*

Creates a new connector using the given configuration or updates the configuration for an existing connector. Returns information about the connector after the change has been made.

### Description

The PUT request along with the parameters is used to create connectors in distributed mode.

#### Table

Parameters	Description
<b>name</b> ( <i>string</i> )	Name of the created connector.
<b>config</b> ( <i>map</i> )	Configuration parameters for the connector. See <a href="#">HDFS Connector</a> on page 4540 and <a href="#">JDBC Connector</a> on page 4530 for configuration options.
<b>tasks</b> ( <i>array</i> )	List of active tasks generated by the connector.
<b>tasks[i].connector</b> ( <i>string</i> )	Name of the connector that the task belongs to.
<b>tasks[i].task</b> ( <i>int</i> )	Task ID within the connector.

### Syntax

```
http://<host>:8083/connectors/<string_name>/config
```

## Request Example

```
PUT /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
{
  "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
  "tasks.max": "10",
  "topics": "test-topic",
  "hdfs.url": "hdfs://fakehost:9000",
  "hadoop.conf.dir": "/opt/hadoop/conf",
  "hadoop.home": "/opt/hadoop",
  "flush.size": "100",
  "rotate.interval.ms": "1000"
}
```

## Response Example

The response JSON object is in the following form:

- config (map) – Configuration parameters for the connector. All values should be strings.

**NOTE:** In this example, the return status indicates that the connector was created. In the case of a configuration update, the status would be 200 OK.

```
HTTP/1.1 201 Created Content-Type: application/json
{
  "name": "hdfs-sink-connector",
  "config":
  {
    "connector.class":
    "io.confluent.connect.hdfs.HdfsSinkConnector",
    "tasks.max": "10",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"
  },
  "tasks": [
    { "connector": "hdfs-sink-connector", "task": 1 },
    { "connector": "hdfs-sink-connector", "task": 2 },
    { "connector": "hdfs-sink-connector", "task": 3 }
  ]
}
```

**GET /connectors/(string:name)/tasks**

Gets a list of tasks currently running for the connector.

## Description

Table

Parameters	Description
<b>tasks</b> (array)	List of active task configurations created by the connector.
<b>tasks[i].id</b> (string)	ID of the task.
<b>tasks[i].id.connector</b> (string)	Name of the connector that the task belongs to.
<b>tasks[i].id.task</b> (int)	Task ID within the connector.
<b>tasks[i].config</b> (map)	Configuration parameters for the task.

## Syntax

```
http://<host>:8083/connectors/<connector_name>/tasks
```

## Request Example

```
GET /connectors/hdfs-sink-connector/tasks HTTP/1.1 Host: connect.example.com
```

## Response Example

```
HTTP/1.1 200 OK
[
  {
    "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"
  },
  {
    "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
    "topics": "test-topic",
    "hdfs.url": "hdfs://fakehost:9000",
    "hadoop.conf.dir": "/opt/hadoop/conf",
    "hadoop.home": "/opt/hadoop",
    "flush.size": "100",
    "rotate.interval.ms": "1000"
  }
]
```

### *DELETE /connectors/(string:name)/*

Deletes a connector by halting all tasks and deleting its configuration.

## Syntax

```
http://<host>:8083/connectors/<connector_name>/
```

## Request Example

```
DELETE /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
```

## Response Example

```
HTTP/1.1 204 No Content
```

### *GET /connector-plugins*

Lists the connector plugins available on this worker.

## Syntax

```
http://<host>:8083/connector-plugins>
```

**Request Example**

```
GET /connector-plugins/ HTTP/1.1
Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 200 OK

[
  {
    "class": "io.confluent.connect.hdfs.HdfsSinkConnector"
  },
  {
    "class": "io.confluent.connect.jdbc.JdbcSourceConnector"
  }
]
```

**POST /connectors/(string:name)/restart**  
Restarts a connector and its tasks.

**Syntax**

```
http://<host>:8083/connectors/<string_name>/restart
```

**Request Example**

```
POST /connectors/hdfs-sink-connector/restart HTTP/1.1
Host: connect.example.com
```

**Response Example**

Return 409 (Conflict) if rebalance is in process.

```
HTTP/1.1 200 OK
```

**GET /connectors/(string:name)/tasks/(int:taskId)/status**  
Gets the status for a task.

**Syntax**

```
http://<host>:8083/connectors/<string_name>/tasks/<task ID>/status
```

**Request Example**

```
GET /connectors/hdfs-sink-connector/tasks/1/status HTTP/1.1
Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 200 OK

{"state": "RUNNING", "id": 1, "worker_id": "192.168.86.101:8083"}
```

*POST /connectors/(string:name)/tasks/(int:number of tasks)/restart*

Restarts an individual task.

### Syntax

```
http://<host>:8083/connectors/<string_name>/tasks/<number of tasks>/restart
```

### Request Example

```
GET /connectors/hdfs-sink-connector/tasks/1/restart HTTP/1.1
Host: connect.example.com
```

### Response Example

```
HTTP/1.1 200 OK
```

*PUT /connectors/(string:name)/pause*

Pauses the connector and its tasks, which stops message processing until the connector is resumed.

### Syntax

```
http://<host>:8083/connectors/<string_name>/pause
```

**NOTE:** This call is asynchronous and the tasks will not transition to PAUSED state at the same time.

### Request Example

```
PUT /connectors/hdfs-sink-connector/pause HTTP/1.1
Host: connect.example.com
```

### Response Example

```
HTTP/1.1 202 Accepted
```

*PUT /connectors/(string:name)/resume*

Resumes a paused connector or do nothing if the connector is not paused.

### Syntax

```
http://<host>:8083/connectors/<string_name>/resume
```

**NOTE:** This call is asynchronous and the tasks will not transition to RUNNING state at the same time.

### Request Example

```
PUT /connectors/hdfs-sink-connector/resume HTTP/1.1
Host: connect.example.com
```

### Response Example

```
HTTP/1.1 202 Accepted
```

**GET /connectors/{string:name}/status**

Gets current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks.

**Syntax**

```
http://<host>:8083/connectors/<string_name>/status
```

**Request Example**

```
GET /connectors/hdfs-sink-connector/status HTTP/1.1
Host: connect.example.com
```

**Response Example**

The response JSON object includes the following:

- name (string) – Name of the connector
- connector (map) – Map containing connector status
- tasks[i] (map) – Map containing the task status

```
HTTP/1.1 200 OK

{
  "name": "hdfs-sink-connector",
  "connector": {
    "state": "RUNNING",
    "worker_id": "localhost:8083"
  },
  "tasks":
  [
    {
      "id": 0,
      "state": "RUNNING",
      "worker_id": "localhost:8083"
    },
    {
      "id": 1,
      "state": "FAILED",
      "worker_id": "localhost:8083",
      "trace":
      "org.apache.kafka.common.errors.RecordTooLargeException\n"
    }
  ]
}
```

**Saving Kafka Connect Configurations**

Describes how Kafka Connect configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka Connect is stored in a folder with a timestamp.

- Files are saved *and* overwritten by new configuration files:
  - when upgrading from 4.1.0 to 5.1.2.
  - when upgrading from 5.1.2 to 10.0.0.

- Files are saved only (*not* overwritten):
  - when upgrading from 5.1.2 to 5.1.2.

### Example

The following example shows the list of configuration files that are saved when upgrading from `mapr-kafka-connect 5.1.2 (EEP 7.0.0)` to `mapr-kafka-connect 5.1.2 (EEP 7.0.1)`:

```
ls /opt/mapr/kafka/
kafka-2.1.1  kafka-2.1.1.0.202009090438  kafkaversion

ls /opt/mapr/kafka/kafka-2.1.1.0.202009090438/config/
connect-console-sink.properties  connect-distributed.properties
connect-file-source.properties  connect-standalone.properties
connect-console-source.properties  connect-file-sink.properties
connect-log4j.properties
```

### Kafka Schema Registry

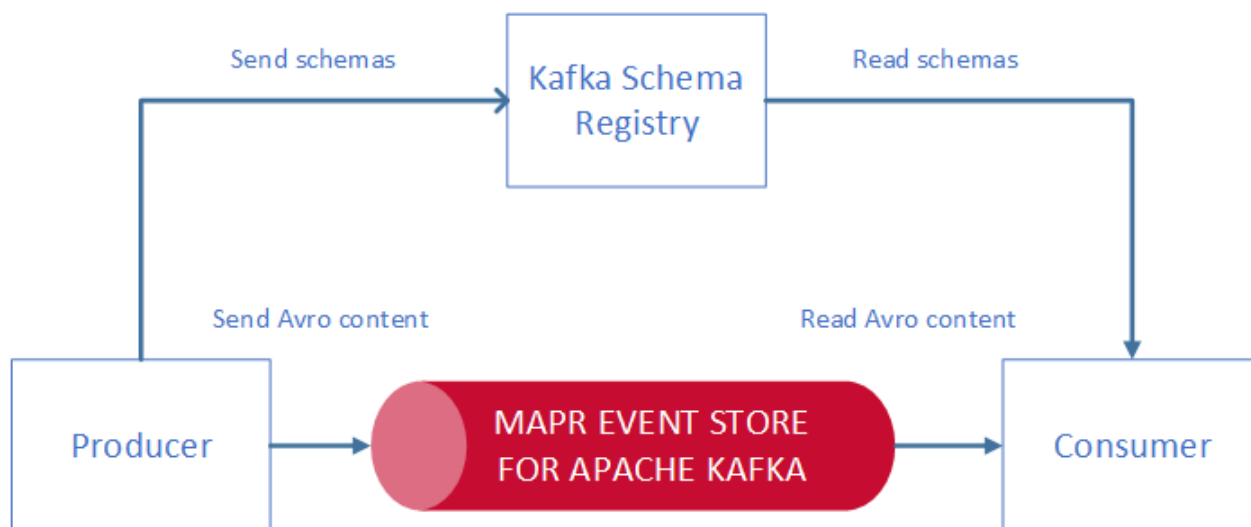

Kafka Schema Registry provides a RESTful interface for storing and retrieving schemas.

Schema Registry can store and retrieve Avro schemas.

Starting in version 6.0.0, Schema Registry can store and retrieve Avro, JSON Schema, and Protobuf schemas.

When you implement Kafka Schema Registry for your data schemas, they can self-evolve for compatibility with downstream consumers.

Kafka Schema Registry acts as a standalone serving layer for metadata, interacting with both the producer and consumer. It stores schemas for keys and values of records.

Kafka Schema Registry enables you to perform the following tasks:

- Store a versioned history of all schemas.
- Provide multiple compatibility settings.
- Support schema evolution according to the configured compatibility settings and the expanded support for the schema format.
- Provide serializers that interface with Kafka clients and manage schema storage and retrieval for Kafka messages that are sent in one of the supported schema formats.

- Develop your own custom formats to use with this interface.

You can also perform these tasks:

- List schemas by subject and also list all versions of a subject (schema).
- Retrieve a schema by version or ID.
- Retrieve the latest version of a schema.
- Verify that a schema is compatible with a certain version.

## Architecture

Kafka Schema Registry is designed to be distributed with a single master architecture. ZooKeeper coordinates the master election, based on the configuration. Kafka-coordinated master election is not currently supported.

HPE Ezmeral Data Fabric Streams is designed to be the durable backend for schema registry, providing a write-ahead change log for the state of schema registry and the schemas it contains.

## Interoperability

Kafka Schema Registry can interface with the following components:

- Kafka Client (producer, consumer APIs)
- KStreams
- KSQL
- Kafka Connect
- Kafka REST

## Performance and Scalability Impact

You can improve performance by decreasing the size of the message payload. Without Kafka Schema Registry, the message payload contains the user data and the schema metadata. With the Kafka Schema Registry, the message payload contains the user data and only the schema ID that is unique for each schema.

For scalability, you can launch Kafka Schema Registry on several nodes.

## For More Information

- [Installing Kafka Schema Registry](#)
- [Confluent Schema Registry documentation](#)

## Building and Deploying Kafka Schema Registry

To build and deploy Kafka Schema Registry with Maven, you must first install development versions of Kafka `common` and `rest-utils` utilities.

You can run Kafka Schema Registry instances on several cluster nodes. One node is the primary node and the other ones are secondary nodes.

Kafka Schema Registry requires ZooKeeper and HPE Ezmeral Data Fabric Streams.

The REST interface to schema registry includes a built-in Jetty server. The wrapper scripts `bin/schema-registry-start` and `bin/schema-registry-stop` are the recommended methods for starting and stopping the service.

In Apache Kafka, a schema is produced when:

- A message is produced and there is no equivalent schema in the schema registry
- A schema is created for key or value portion of the message

The associated schema subject is a “topic-key”:

- Each schema is associated with a version
- Every schema gets a globally unique ID

The consumer gets the messages’ schema using the schema ID:

```
$ curl -X GET http://localhost:8087/schemas/ids/1
{"schema": "\"string\""}

```

You can also query a schema for a given topic using the associated schema subject. For example, for `topic1` (for either key or value), `schema`, `all`, `latest`, or `specific` schema versions can be queried using the following REST commands:

```
$ curl -X GET http://localhost:8087/subjects/topic1-value/versions
[1]
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
{"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
{"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}

```

For a complete list of supported APIs, see [Confluent Schema Registry API Reference](#).

### Kafka Schema Registry Limitations

Describes the limitations related to the Kafka Schema Registry.

- **No Replication Support**

Replication for Kafka Schema Registry is not supported.

- **Manually Configure Kafka REST, KSQL, and Kafka Connect to work with Schema Registry**

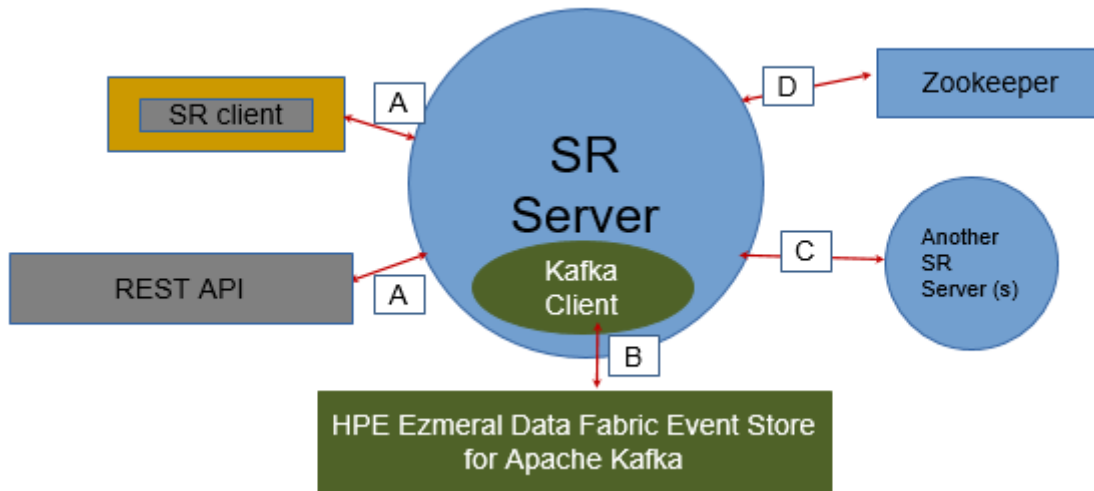

You must manually modify the Kafka REST, KSQL, and Kafka Connect configuration files if you want them to work with the Schema Registry.

### Kafka Schema Registry Security

Describes security mechanisms for Kafka Schema Registry.

### Schema Registry Communication Paths

The following image depicts the Schema Registry communication paths:

The following table lists the supported security mechanisms for the Schema Registry communication paths:

**NOTE:** Path B does not have a network connection and therefore does not need to be secured. However, impersonation works seamlessly for this path through Schema Registry Server.

Security Features	Supported Mechanisms	Communication Paths Secured	
<b>Authentication</b>	MapR-SASL (ticket-based security)	D – Schema Registry Server and ZooKeeper	
		A - Schema Registry Client and Schema Registry Server	
		C – Schema Registry Server and Schema Registry Server	
	Basic (PAM)	A - Schema Registry Client and Schema Registry Server	
		C – Schema Registry Server and Schema Registry Server	
		Cookie	A - Schema Registry Client and Schema Registry Server
<b>Encryption</b>	MapR-SASL (ticket-based security)	D - Schema Registry Server and ZooKeeper	
		A - Schema Registry Client and Schema Registry Server	
		C - Schema Registry Server and Schema Registry Server	
	SSL/TLS	A - Schema Registry Client and Schema Registry Server	
		C - Schema Registry Server and Schema Registry Server	
		<b>Authorization</b>	Based on filesystem permissions.
<b>Impersonation</b>	User impersonation		A - Schema Registry Client and Schema Registry Server
			B – Schema Registry Server to Streams for Apache Kafka
		C - Schema Registry Server and Schema Registry Server	
<b>Auditing</b>	Not supported	--	

### Kafka Schema Registry Configuration

Describes how to configure the Kafka Schema Registry for HPE Ezmeral Data Fabric Event Store.

Set the Schema Registry configuration parameters in the `/opt/mapr/schema-registry/schema-registry-<version>/etc/schema-registry/schema-registry.properties` file.

**schema.registry.service.id**

This parameter indicates the ID of the schema registry service. The default setting for this parameter is `default_`.

See [Schema Registry Configuration Options](#) for additional Schema Registry parameters.

By default, the Schema Registry service runs on port 8087.

*Security Parameters*

Describes Schema Registry security parameters.

Security mechanisms provide an authentication, encryption, and impersonation layer between the Schema Registry REST API clients and the Schema Registry Server. In secure clusters, Schema Registry is secured by default.

**Requirement:** Before you configure Schema Registry security parameters, verify that an `ssl_keystore` and an `ssl_truststore` file have been created.

The following table lists the Schema Registry security parameters:

Parameter	Description	Type	Default
authorization.enable	Set 'true' or 'false' to enable or disable authorization for Schema Registry service. See <a href="#">Schema Registry Authorization</a> on page 4562.	boolean	false
authentication.cookie.expiration	Authentication cookie expiration time in seconds.	long	7200 (2 hours)
authentication.enable	Whether or not to enable authentication.	boolean	false
impersonation.enable	Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user. See <a href="#">Schema Registry Impersonation</a> on page 4563.	boolean	false
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: <code>http://localhost:8087</code>	list	none
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none

ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	<ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .DES.</li> <li>• .MD5.</li> <li>• .RC4.</li> </ul>
ssl.client.auth	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store.	boolean	false
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. <b>IMPORTANT:</b> Jetty requires that the key's CN, stored in the keystore, must match the FQDN if <code>ssl_endpoint_identification_algorithm=https</code> . Leave blank to use Jetty's default.	string	none
ssl.key.password	The password of the private key in the keystore file. This parameter should be taken from the <code>/opt/mapr/conf/ssl-client.xml</code> file. If this parameter is not set, the property value is obtained from the <code>ssl-client.xml</code> file. <b>Note:</b> If the <code>ssl-client.xml</code> file is changed, Schema Registry must be restarted.	string	empty
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	empty

ssl.keystore.location	Location of the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. <b>Note:</b> If the ssl-client.xml file is changed, Schema Registry must be restarted.	string	empty
ssl.keystore.password	The store password for the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. <b>Note:</b> If the ssl-client.xml file is changed, Schema Registry must be restarted.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLS
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false
headers.file	The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.	string	empty

#### *Schema Registry Authorization*

Describes authorization for Kafka Schema Registry.

In secure clusters, authorization is enabled by default.

You can enable or disable authorization for the Schema Registry in the `<schema-registry-dir>/etc/schema-registry/schema-registry.properties` file through the following option:

```
authorization.enable=[true|false]
```

## Permissions

Permissions grant access to internal data in the Schema Registry, such as schemas, subjects, and server configurations. *Read* permission grants access to view data. *Modify* permission grants access to add, update, and remove data.

The following sections describe operations that require *read* and *modify* access.

**NOTE:** To avoid any unexpected behaviours when using Schema Registry with KSQL, Kafka Rest, Kafka Connect, or custom Java applications, both *read* and *modify* permissions are required.

## REST API Operations that Require Read Access

<b>GET</b> /schemas/ids/{int: id}	Get the schema string identified by the input ID.
<b>GET</b> /subjects/	Get a list of versions registered under the specified subject.
<b>GET</b> /subjects/(string: subject)/versions/(versionId: version)	Get a specific version of the schema registered under this subject.
<b>GET</b> /subjects/(string: subject)/versions/(versionId: version)/schema	Get the avro schema for the specified version of this subject.
<b>GET</b> /config	Get global compatibility level.
<b>GET</b> /config/(string: subject)	Get compatibility level for a subject.
<b>POST</b> /subjects/(string: subject)	Check if a schema has already been registered under the specified subject. If so, this returns the schema string along with its globally unique identifier, its version under this subject and the subject name.
<b>POST</b> /compatibility/subjects/(string: subject)/versions/(versionId: version)	Test input schema against a particular version of a subject's schema for compatibility.

## REST API Operations that Require Modify Access

<b>DELETE</b> /subjects/(string: subject)	Deletes the specified subject and its associated compatibility level if registered.
<b>POST</b> /subjects/(string: subject)/versions	Register a new schema under the specified subject.
<b>DELETE</b> /subjects/(string: subject)/versions/(versionId: version)	Deletes a specific version of the schema registered under this subject.
<b>PUT</b> /config	Update global compatibility level.
<b>PUT</b> /config/(string: subject)	Update compatibility level for the specified subject.

### Schema Registry Impersonation

Describes impersonation for Kafka Schema Registry.

Impersonation authorizes the impersonated user to perform permission-sensitive operations on the Schema Registry. In secure clusters, impersonation is enabled by default.

**Requirement:** For impersonation to work, Schema Registry authentication must be enabled; otherwise, the server will not start and the system will return an error. When authentication is enabled, all commands run as the authenticated user instead of the Schema Registry principal. The Schema Registry principal is the user that started the Schema Registry server.

You can enable or disable impersonation for the Schema Registry in the `<schema-registry-client>/etc/schema-registry/schema-registry.properties` file through the following option:

```
impersonation.enable=[true|false]
```

### Related concepts

[Schema Registry Authorization](#) on page 4562

Describes authorization for Kafka Schema Registry.

### Kafka Schema Registry Use Cases

Describes typical use cases to register and query a schema and serialize and deserialize data.

#### Use Case 1: Registering and Querying a Schema for a Kafka Topic

While Kafka topics do not have a schema, having an external store that tracks this metadata for a given Kafka topic helps answer the following questions:

- What are the different events in any given Kafka topic?
- What can I put into a given Kafka topic?
- Do all Kafka events have a similar type of schema?
- How do I parse and use the data in a given Kafka topic?

#### Sample workflow code:

The following sample commands register and query a schema in a Kafka topic:

```
# Register a new version of a schema under the subject "Kafka-key"
$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
  --data '{"schema": "{\"type\": \"string\"}'}' \
  http://localhost:8087/subjects/Kafka-key/versions
  {"id":1}

# Register a new version of a schema under the subject "Kafka-value"
$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
  --data '{"schema": "{\"type\": \"string\"}'}' \
  http://localhost:8087/subjects/Kafka-value/versions
  {"id":1}

# List all subjects
$ curl -X GET http://localhost:8087/subjects
  ["Kafka-value", "Kafka-key"]

# List all schema versions registered under the subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions
  [1]

# Fetch a schema by globally unique id 1
$ curl -X GET http://localhost:8087/schemas/ids/1
  {"schema": "\"string\""}

# Fetch version 1 of the schema registered under subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
```

```

{"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}
# Fetch the most recently registered schema under subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
{"subject": "Kafka-value", "version": 1, "id": 1, "schema": "\"string\""}

```

### Use Case 2: Serializing and Deserializing Data in a Kafka Topic

Schema Registry 5.1.2 works with the Avro format only. Schema Registry 6.0.0 works with the Avro format and also JSON Schema and Protobuf formats.

In addition to storing the schema metadata for a topic, Kafka Schema Registry also provides mechanisms for reading and writing data to a Kafka topic in supported formats.

You can plug the appropriate Serializer into the KafkaProducer to send messages to Kafka. A Serializer is available for each of the supported formats.

For Avro, use the `KafkaAvroSerializer`.

For JSON Schema, use the `KafkaJsonSchemaSerializer`.

For Protobuf, use the `KafkaProtobufSerializer`.

Currently, primitive types of `null`, `Boolean`, `Integer`, `Long`, `Float`, `Double`, `String`, `byte[]`, and the complex `IndexedRecord` type are supported.

Sending data of other types to `KafkaAvroSerializer` causes a `SerializationException` to occur. Typically, `IndexedRecord` is used for the value of the Kafka message. If used, the key of the Kafka message is often of one of the primitive types.

For example, when sending a message to a topic `t`, the schema for the key and the value is automatically registered in the Kafka Schema Registry under the subject `t-key` and `t-value`, respectively, if the compatibility test passes. The only exception is when the null type is never registered in the Kafka Schema Registry.

For consuming messages from a Kafka topic, the deserializer can be plugged analogically to the serializer.

### Use Case 3: Supporting KSQL Streams or Tables in Supported formats

KSQL requires that you use the Kafka Schema Registry to create KSQL Streams or Tables in supported formats.

Schema Registry supports Avro format. Specify `VALUE_FORMAT='AVRO'` to work with topics that contain messages in Avro format.

Starting in version 6.0.0, Schema Registry supports JSON Schema and Protobuf in addition to Avro. For JSON Schema and Protobuf, specify either `VALUE_FORMAT='JSON_SR'` or `VALUE_FORMAT='PROTOBUF'` to work with topics that contain messages in JSON Schema or Protobuf format.

#### Sample workflow code:

The following commands create and register a schema using an Avro console producer:

```

# Create a stream

$ maprcli stream create -path /sample-stream -produceperm p -consumeperm
p -topicperm p

# Use Avro console producer to create and register a schema

/sample-stream:pageviews-avro-topic

```

```
CREATE STREAM pageviews WITH (KAFKA_TOPIC='pageviews-avro-topic',
VALUE_FORMAT='AVRO');

CREATE TABLE users WITH (KAFKA_TOPIC='users-avro-topic',
VALUE_FORMAT='AVRO',
KEY='userid');
```

## Managing Kafka Schema Registry

Describes how to manage the internal stream for Kafka Schema Registry.

### Schema Registry Internal Stream

By default, the `schema-registry-internal-stream` topic stores the schemas.

The `schema-registry-internal-stream` topic is located in `/apps/schema-registry/schema-registry-internal-stream`. The `kafkastore.stream` property in the `SR_CONF_DIR/schema-registry.properties` file sets the internal stream topic.

By default, the `kafkastore.stream` property is set to `/apps/schema-registry/schema-registry-internal-stream`.

The internal stream is automatically created if it does not already exist. If the internal stream already exists and has the same permissions as the default, the system returns a warning. If `kafkastore.stream` is set to a value other than the default, the system returns an error if the stream does not exist. You must explicitly set permissions on the stream you designate as the Schema Registry internal stream.

You can use Warden and `/opt/mapr/server/configure.sh` to manage and configure Kafka Schema Registry. Any time you change Schema Registry configurations, run `configure.sh` for changes to take effect.

### Secure Cluster Default Permissions on the Internal Stream

By default, the internal stream is readable by all the users and writable only by the cluster administrator. For secure clusters, the default permissions are:

- `-produceperm u:$CLUSTER_ADMIN`
- `-consumeperm p`
- `-topicperm u:$CLUSTER_ADMIN`

The cluster admin is typically `mapr` or the value set for `MAPR_USER`.

### Log Compaction for the Schema Registry Internal Stream

Log compaction is the process of purging messages previously published to a topic partition while retaining the latest version. Log compaction for the Schema Registry internal stream is enabled by default.

 **IMPORTANT:** Log compaction requires a gateway on the same cluster as the Schema Registry internal stream. Also, TTL should be disabled because it can interfere with log compaction.

### Installing a Gateway

Run the command appropriate for your system:

- RedHat/CentOS

```
yum install mapr-gateway
```

- Ubuntu

```
apt-get install mapr-gateway
```

- SLES

```
zypper install mapr-gateway
```

### Related concepts

[Log Compaction](#) on page 772

Log compaction purges previous, older messages that were published to a topic-partition and retains the latest version of the record.

### More information

[Preparing Clusters for Log Compaction](#) on page 1507

Describes how to prepare your environment so you can use log compaction.

### Enabling High Availability for Kafka Schema Registry

You can enable high availability by installing multiple instances of schema registry on the same cluster.

### About this task

One node in the cluster acts as the primary instance. Only the primary instance can publish writes to the underlying Kafka log. The primary node can also manage read requests.

All other secondary nodes manage only read requests. These nodes serve registration requests indirectly by forwarding them to the current primary node and returning any response supplied by the primary node.

### Procedure

1. Install schema registry on several nodes. For installation instructions, see [Installing Kafka Schema Registry](#).
2. Configure high availability for the ensemble of ZooKeeper nodes. You can find the steps for this in the [open source documentation](#), section Clustered (Multi-Server) Setup.
3. Modify the schema registry configuration file on each node to specify the `kafkastore.connection.url` property with the ZooKeeper nodes that form the HA ensemble.
4. Run the `configure.sh -R` command on each schema registry node.

### Schema Registry Demos

Provides demonstrations for using Kafka Schema Registry to store and retrieve schemas.

The following topics demonstrate how to use Kafka Schema Registry to store and retrieve schemas in the supported formats:

*Kafka Schema Registry Demo for Avro*

Implements a Kafka Schema Registry demo example that stores and retrieves Avro schemas.

### Maven Dependencies

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```
<repositories>
  <repository>
    <id>confluent</id>
    <url>http://packages.confluent.io/maven/</url>
  </repository>
```

```

<repository>
  <id>mapr-maven</id>
  <url>https://repository.mapr.com/maven/</url>
  <releases><enabled>true</enabled></releases>
  <snapshots><enabled>true</enabled></snapshots>
</repository>
</repositories>

```

The following dependencies are needed for Avro and Kafka:

```

<dependency>
  <groupId>org.apache.avro</groupId>
  <artifactId>avro</artifactId>
  <version>1.9.2</version>
</dependency>
<dependency>
  <groupId>io.confluent</groupId>
  <artifactId>kafka-avro-serializer</artifactId>
  <version>5.1.2.0-mapr-700</version>
</dependency>

```

### Creating a Java class that corresponds to the Avro schema

Add the following plugins to the `pom.xml` file:

- Plugin to build code:

```

<plugin>
  <groupId>org.apache.avro</groupId>
  <artifactId>avro-maven-plugin</artifactId>
  <version>1.8.2</version>
  <executions>
    <execution>
      <phase>generate-sources</phase>
      <goals>
        <goal>schema</goal>
        <goal>protocol</goal>
        <goal>idl-protocol</goal>
      </goals>
      <configuration>
        <sourceDirectory>${project.basedir}/src/main/resources/avro/</
sourceDirectory>
        <stringType>String</stringType>
        <createSetters>false</createSetters>
        <enableDecimalLogicalType>true</enableDecimalLogicalType>
        <fieldVisibility>private</fieldVisibility>
      </configuration>
    </execution>
  </executions>
</plugin>

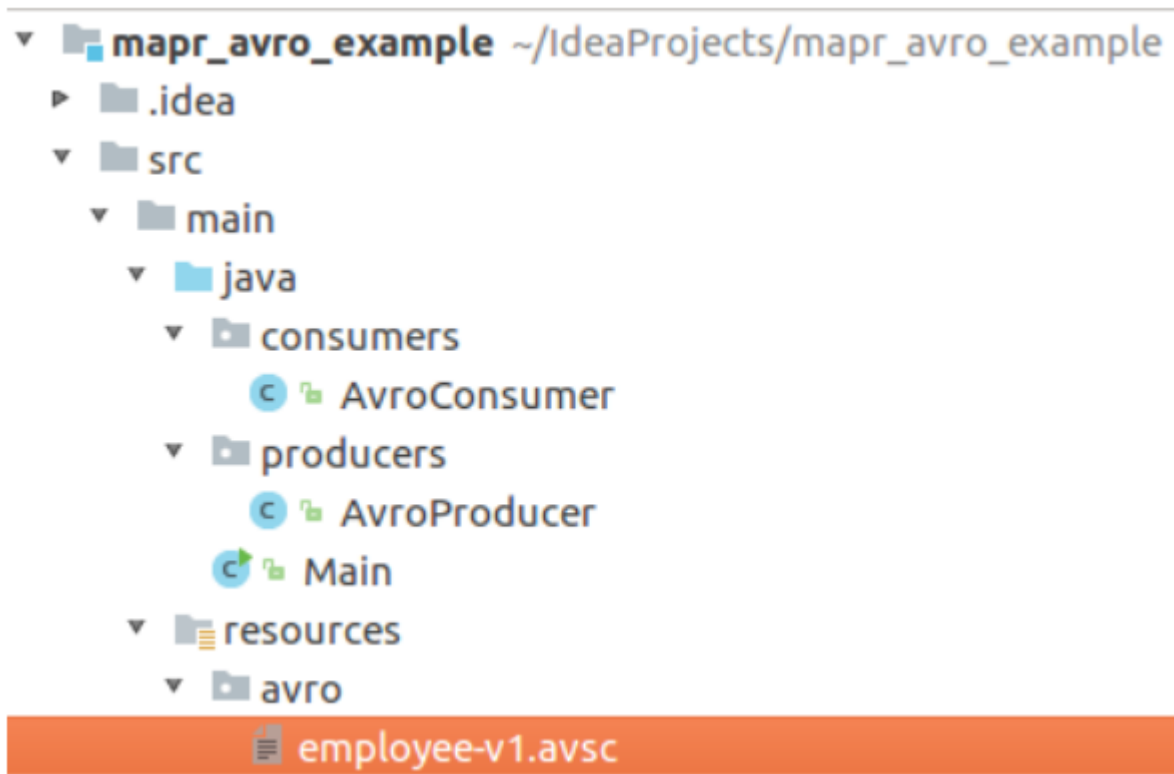

```

- Plugin to force the discovery of the generated classes:

```
<plugin>
  <groupId>org.codehaus.mojo</groupId>
  <artifactId>build-helper-maven-plugin</artifactId>
  <version>3.0.0</version>
  <executions>
    <execution>
      <id>add-source</id>
      <phase>generate-sources</phase>
      <goals>
        <goal>add-source</goal>
      </goals>
      <configuration>
        <sources>
          <source>target/generated-sources/avro</source>
        </sources>
      </configuration>
    </execution>
  </executions>
</plugin>
```

- Create a file with filename extension `.avsc` in the `src/main/resources` directory.

An example of an Avro schema is as follows:

```
{
  "namespace": "com.example",
  "type": "record",
  "name": "Employee",
  "doc": "Represents an Employee at a company",
  "fields": [
    { "name": "firstName", "type": "string", "doc": "The persons given name" },
  ],
}
```

```

        {"name": "lastName", "type": "string"},
        {"name": "age", "type": "int", "default": -1},
        {"name": "emails", "default": [], "type": {"type": "array", "items":
"string"}},
        {"name": "phoneNumber", "type": "string"}
    ]
}

```

The `Employee.class` Java class is auto-generated in the `target/classes/com/example` directory after executing the following commands:

```

$ mvn clean
$ mvn package

```

You can use this class in your program after performing these steps.

### Creating an Avro Producer

1. Import the following properties for the Kafka Producer:

```

import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroSerializer;
import io.confluent.kafka.serializers.KafkaAvroSerializerConfig;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.ArrayList;
import java.util.List;
import java.util.Properties;

```

2. Configure the following properties for Event Data Streams:

```

Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
    IntegerSerializer.class.getName());

// Configure the KafkaAvroSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
    KafkaAvroSerializer.class.getName());

//Schema registry location.
properties.setProperty(KafkaAvroSerializerConfig.SCHEMA_REGISTRY_URL_CONF
IG,
    "http://localhost:8087");

KafkaProducer<Integer, Employee> producer =
    new KafkaProducer<>(properties);

```

3. The following code sends  $n$  different objects of class `Employee.java` to the topic `avro_example` in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
Employee employee;

for (int i = 0; i < n; i++) {

    List<String> emails = new ArrayList<>();
    for (int j = 0; j < i; j++) {
        emails.add("john" + j + ".doe" + i + "@mail.com");
    }

    employee = Employee.newBuilder()
        .setFirstName("John" + i)
        .setLastName("Doe")
        .setAge(i + 5)
        .setEmails(emails)
        .setPhoneNumber("+1-202-555-" + i + i + i + i)
        .build();

    ProducerRecord<Integer, Employee> record =
        new ProducerRecord(topic, i, employee);

    producer.send(record, (recordMetadata, e) -> {
        if (e == null) {
            System.out.println("Success! ");
            System.out.println(recordMetadata.toString());
        } else {
            e.printStackTrace();
        }
    });
}

producer.flush();
producer.close();
```

### Creating an Avro Consumer

1. Import the following properties for the Kafka Consumer:

```
import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroDeserializer;
import io.confluent.kafka.serializers.KafkaAvroDeserializerConfig;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.util.Collections;
import java.util.Properties;
```

2. The properties to configure are similar to the Kafka producer, only Deserializers must be used instead of Serializers. Add one more property called `KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG`:

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
    IntegerDeserializer.class.getName());

//Use Kafka Avro Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
    KafkaAvroDeserializer.class.getName());

//Use Specific Record or else you get Avro GenericRecord.
properties.put(KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG,
    "true");

//Schema registry location.
properties.put(KafkaAvroDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
    "http://localhost:8087");

KafkaConsumer<Integer, Employee> consumer =
    new KafkaConsumer<>(properties);
```

3. The following code reads objects of the `Employee.java` class from the `avro_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
consumer.subscribe(Collections.singletonList(topic));

try {
    while (true) {
        ConsumerRecords<Integer, Employee> records =
            consumer.poll(Duration.ofMillis(100));
        records.forEach(record -> {

            Employee employeeRecord = record.value();

            System.out.printf("%s %d %d %s \n", record.topic(),
                record.partition(), record.offset(), employeeRecord);
        });
    }
} finally {
    consumer.close();
}
```

### *Kafka Schema Registry Demo for JSON Schema*

Implements a Kafka Schema Registry demo example that stores and retrieves schemas in JSON Schema format.

### **Maven Dependencies**

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```
<repositories>
  <repository>
    <id>confluent</id>
    <url>http://packages.confluent.io/maven/</url>
  </repository>
  <repository>
    <id>mapr-maven</id>
```

```

    <url>https://repository.mapr.com/maven/</url>
    <releases><enabled>true</enabled></releases>
    <snapshots><enabled>true</enabled></snapshots>
  </repository>
</repositories>

```

The following dependencies are needed for JSON Schema and MapR Kafka:

```

<dependency>
  <groupId>com.fasterxml.jackson.core</groupId>
  <artifactId>jackson-annotations</artifactId>
  <version>2.10.5</version>
</dependency>

<dependency>
  <groupId>io.confluent</groupId>
  <artifactId>kafka-json-schema-serializer</artifactId>
  <version>6.0.0.0-eep-800</version>
</dependency>

```

### Create a Java class that corresponds to JSON Schema

Create a Java class that includes Jackson annotations, for example:

```

import com.fasterxml.jackson.annotation.JsonProperty;

public class User {
    @JsonProperty
    public String firstName;
    @JsonProperty
    public String lastName;
    @JsonProperty
    public short age;
    public User() {}
    public User(String firstName, String lastName, short age) {
        this.firstName = firstName;
        this.lastName = lastName;
        this.age = age;
    }
    public String toString() {
        return String.format("first name: " + firstName
            + "; last name: " + lastName + "; age: " + age);
    }
}

```

### Create a JSON Schema Producer

1. Import the following properties for the Kafka Producer:

```

import io.confluent.kafka.serializers.json.KafkaJsonSchemaSerializer;
import
io.confluent.kafka.serializers.json.KafkaJsonSchemaSerializerConfig;
import io.demo.example.User;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.Properties;

```

## 2. Configure the following properties for the Event Data Streams:

```
Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
    IntegerSerializer.class.getName());

// Configure the KafkaJsonSchemaSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
    KafkaJsonSchemaSerializer.class.getName());

// Schema registry location.
properties.setProperty(KafkaJsonSchemaSerializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
    "http://localhost:8087");

KafkaProducer<Integer, User> producer =
    new KafkaProducer<>(properties);
```

## 3. Use the following code to send n different objects of class User.java to the topic json-schema\_example in the /sample-stream stream:

```
String topic = "/sample-stream:json-schema_example";

for (int i = 0; i < n; i++) {
    User user = new User("John" + i, "Doe", (short) (i + 30));

    ProducerRecord<Integer, User> record =
        new ProducerRecord(topic, i, user);

    producer.send(record, (recordMetadata, e) -> {
        if (e == null) {
            System.out.println("Success!");
            System.out.println(recordMetadata.toString());
        } else {
            e.printStackTrace();
        }
    });
}

producer.flush();
producer.close();
```

## Create a JSON Schema Consumer

### 1. Import the following properties for the Kafka Consumer:

```
import io.confluent.kafka.serializers.json.KafkaJsonSchemaDeserializer;
import
io.confluent.kafka.serializers.json.KafkaJsonSchemaDeserializerConfig;
import io.demo.example.User;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;
```

2. Add the `KafkaJsonSchemaDeserializerConfig.JSON_VALUE_TYPE` property to the properties of the Kafka Consumer to deserialize the output to the needed class.

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
    IntegerDeserializer.class.getName());

//Use Kafka JSON Schema Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
    KafkaJsonSchemaDeserializer.class.getName());

//A class that the message value should be deserialized to.
properties.put(KafkaJsonSchemaDeserializerConfig.JSON_VALUE_TYPE,
    User.class.getName());

//Schema registry location.
properties.put(KafkaJsonSchemaDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
    "http://localhost:8087");

KafkaConsumer<Integer, User> consumer =
    new KafkaConsumer<>(properties);
```

3. Use the following code to read objects of the `User.java` class from the `json-schema_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:json-schema_example";
consumer.subscribe(Collections.singletonList(topic));

try {
    while (true) {
        ConsumerRecords<Integer, User> records =
            consumer.poll(Duration.ofMillis(100));

        records.forEach(record -> {

            User userRecord = record.value();

            System.out.printf("%s %d %d %s \n", record.topic(),
                record.partition(), record.offset(),
                userRecord);
        });
    }
} finally {
    consumer.close();
}
```

### *Kafka Schema Registry Demo for Protobuf*

Implements a Kafka Schema Registry demo example that stores and retrieves Protobuf schemas.

### **Maven Dependencies**

Add the following repositories to the POM file to resolve Confluent and MapR dependencies:

```
<repositories>
  <repository>
    <id>confluent</id>
    <url>http://packages.confluent.io/maven/</url>
  </repository>
```

```

<repository>
  <id>mapr-maven</id>
  <url>https://repository.mapr.com/maven/</url>
  <releases><enabled>true</enabled></releases>
  <snapshots><enabled>true</enabled></snapshots>
</repository>
</repositories>

```

The following dependencies are needed for Protobuf and MapR Kafka:

```

<dependency>
  <groupId>com.google.protobuf</groupId>
  <artifactId>protobuf-java</artifactId>
  <version>3.17.3</version>
</dependency>

<dependency>
  <groupId>io.confluent</groupId>
  <artifactId>kafka-protobuf-serializer</artifactId>
  <version>6.0.0.0-eep-800</version>
</dependency>

```

### Create a Java class that corresponds to the Protobuf schema

Add the following plugin to the pom.xml file:

```

<plugin>
  <groupId>com.github.os72</groupId>
  <artifactId>protoc-jar-maven-plugin</artifactId>
  <version>3.11.4</version>
  <executions>
    <execution>
      <phase>generate-sources</phase>
      <goals>
        <goal>run</goal>
      </goals>
      <configuration>
        <inputDirectories>
          <include>src/main/resources/</include>
        </inputDirectories>
        <outputTargets>
          <outputTarget>
            <type>java</type>
            <addSources>none</addSources>
            <outputDirectory>src/main/java/</outputDirectory>
          </outputTarget>
        </outputTargets>
      </configuration>
    </execution>
  </executions>
</plugin>

```

Create a file with the .proto extension in the src/main/resources/proto directory. For example, person.proto. An example of a Protobuf schema is as follows:

```

syntax = "proto3";
package io.demo.example;
option java_outer_classname = "PersonImpl";

message Person {
  int32 id = 1;

```

```

string firstName = 2;
string lastName = 3;
string email = 4;
}

```

The `PersonImpl.class` Java class is auto-generated in the `src/main/java/io/demo/example` directory after running the following commands:

```

$ mvn clean
$ mvn package

```

You can use this class in your program to manage the class `Person.class`.

### Create a Protobuf Producer

To create a Protobuf producer:

1. Import the following properties for the Kafka Producer:

```

import io.confluent.kafka.serializers.protobuf.KafkaProtobufSerializer;
import
io.confluent.kafka.serializers.protobuf.KafkaProtobufSerializerConfig;
import io.demo.example.PersonImpl.Person;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.Properties;

```

2. Configure the following properties for the Event Data Streams:

```

Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
    IntegerSerializer.class.getName());

// Configure the KafkaProtobufSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
    KafkaProtobufSerializer.class.getName());

// Schema registry location.
properties.setProperty(KafkaProtobufSerializerConfig.SCHEMA_REGISTRY_URL_
CONFIG,
    "http://localhost:8087");

KafkaProducer<Integer, Person> producer =
    new KafkaProducer<>(properties);

```

- Use the following code to send  $n$  different objects of class `Person.java` to the topic `proto_example` in the `/sample-stream` stream:

```
String topic = "/sample-stream:proto_example";
Person person;

for (int i = 0; i < n; i++) {
    Person person = Person.newBuilder()
        .setId(i)
        .setFirstName("John")
        .setLastName("Doe")
        .setEmail("john" + i + ".doe@mail.com")
        .build();

    ProducerRecord<Integer, Person> record =
        new ProducerRecord(topic, i, person);

    producer.send(record, (recordMetadata, e) -> {
        if (e == null) {
            System.out.println("Success! ");
            System.out.println(recordMetadata.toString());
        } else {
            e.printStackTrace();
        }
    });
}

producer.flush();
producer.close();
```

### Create a Protobuf Consumer

To create a Protobuf consumer:

- Import the following properties for the Kafka Consumer:

```
import io.confluent.kafka.serializers.protobuf.KafkaProtobufDeserializer;
import
io.confluent.kafka.serializers.protobuf.KafkaProtobufDeserializerConfig;
import io.demo.example.PersonImpl.Person;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;
```

2. Add the `KafkaProtobufDeserializerConfig.SPECIFIC_PROTOBUF_VALUE_TYPE` property to the properties of the Kafka Consumer to deserialize the output to the needed class.

```

Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
    IntegerDeserializer.class.getName());

//Use Kafka Protobuf Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
    KafkaProtobufDeserializer.class.getName());

//A class generated by Protocol buffers that the message value should be
deserialized to.
properties.put(KafkaProtobufDeserializerConfig.SPECIFIC_PROTOBUF_VALUE_TY
PE,
    Person.class.getName());

//Schema registry location.
properties.put(KafkaProtobufDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG
,
    "http://localhost:8087");

KafkaConsumer<Integer, Person> consumer =
    new KafkaConsumer<>(properties);

```

3. Use the following code to read objects of the `Person.java` class from the `proto_example` topic in the `/sample-stream` stream:

```

String topic = "/sample-stream:proto_example";
consumer.subscribe(Collections.singletonList(topic));

try {
    while (true) {
        ConsumerRecords<Integer, Person> records =
            consumer.poll(Duration.ofMillis(100));

        records.forEach(record -> {

            Person personRecord = record.value();

            System.out.printf("%s %d %d %s \n", record.topic(),
                record.partition(), record.offset(),
                personRecord);
        });
    }
} finally {
    consumer.close();
}

```

### Structured Streaming in Spark

Starting in EEP 5.0.0, structured streaming is supported in Spark.

### Related Links

Spark streaming is integrated with HPE Ezmeral Data Fabric Streams for Apache Kafka.

- [Data Fabric Event Store For Apache Kafka Clients and Tools](#)

## Prerequisites for Using Structured Streaming in Spark

To deploy a structured streaming application in Spark, you must create a Data Fabric Streams topic and install a Kafka client on all nodes in your cluster.

### *Creating a Data Fabric Streams Topic*

#### Procedure

- Create a Data Fabric Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

### *Installing a Kafka Client*

#### Procedure

- Install a kafka-client on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

## Using Structured Streaming to Create a Word Count Application

The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.

### *Using Apache Kafka*

#### Example

##### Scala

```

val spark = SparkSession
    .builder
    .appName("StructuredKafkaWordCount")
    .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers", bootstrapServers)
    .option(subscribeType, topics)
    .load()
    .selectExpr("CAST(value AS STRING)")
    .as[String]
//Generate a running word count
val wordCounts =
lines.flatMap(_.split(" ")).groupBy("value").count()
//Run the query that prints the
running counts to the console
val query = wordCounts.writeStream
    .outputMode("complete")
    .format("console")
    .option("checkpointLocation", checkpointLocation)
    .start()

query.awaitTermination()

```

**Java**

```

SparkSession spark = SparkSession
    .builder()
    .appName("JavaStructured
KafkaWordCount")
    .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
    .readStream()
    .format("kafka")
    .option("kafka.bootstrap
.servers", bootstrapServers)
    .option(subscribeType,
topics)
    .load()
    .selectExpr("CAST(value
AS STRING)")
    .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
    .outputMode("complete")
    .format("console")
    .start();

query.awaitTermination();

```

**Python**

```

spark = SparkSession\
    .builder\
    .appName("StructuredKafkaWor
dCount")\
    .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
    .readStream\
    .format("kafka")\
    .option("kafka.bootstrap.ser
vers", bootstrapServers)\
    .option(subscribeType,
topics)\
    .load()\
    .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row

```

```
explode(
    split(lines.value, ' ')
    ).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that prints the
running counts to the console
query = wordCounts\
    .writeStream\
    .outputMode('complete')\
    .format('console')\
    .start()

query.awaitTermination()
```

### Using Data Fabric Event Store for Apache Kafka

#### Example

For Data Fabric Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```
var topic: String = "/user/mapr/stream:reviews"
val dfl = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
    "maprdemo:9092").option("subscribe", topic).option("group.id",
    "testgroup").option("startingOffsets",
    "earliest").option("failOnDataLoss",
    false).option("maxOffsetsPerTrigger", 1000).load()
```

### Writing a Structured Spark Stream to HPE Ezmeral Data Fabric Database JSON Table

The example in this section writes a structured stream in Spark to HPE Ezmeral Data Fabric Database JSON table.

#### Example

To write a structured Spark stream to HPE Ezmeral Data Fabric Database JSON table, use `MapRDBSourceConfig.Format` for Java and Scala and `com.mapr.db.spark.streaming` for Python to format the `tablePath`, `idFieldPath`, `createTable`, `bulkMode`, and `sampleSize` parameters.

#### Scala

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig
import org.apache.spark.sql.streaming.
{DataStreamReader, DataStreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._

df.select($"value" as "_id")
    .writeStream
    .format(MapRDBSourceConfig.Format)
    .option(MapRDBSourceConfig.TablePath
Option, "/table/path")
```

```

        .option(MapRDBSourceConfig.IdFieldPa
thOption, "value")
        .option(MapRDBSourceConfig.CreateTab
leOption, true)
        .option(MapRDBSourceConfig.BulkModeO
ption, true)
        .option(MapRDBSourceConfig.SampleSiz
eOption, 1000)
        .outputMode("append")
    }

```

## Java

```

import
com.mapr.db.spark.streaming.MapRDBSour
ceConfig;
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.SparkSession;
import
org.apache.spark.sql.streaming.DataStr
eamReader;
import
org.apache.spark.sql.streaming.DataStr
eamWriter;
import
org.apache.spark.sql.streaming.Streami
ngQueryException;

DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
    return df.selectExpr("CAST(value
AS STRING) as _id")
        .writeStream()
        .format(MapRDBSourceConfig
.Format())
        .option(MapRDBSourceConfig
.TablePathOption(), "/table/path")
        .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
        .option(MapRDBSourceConfig
.CreateTableOption(), true)
        .option(MapRDBSourceConfig
.BulkModeOption(), true)
        .option(MapRDBSourceConfig
.SampleSizeOption(), 1000)
        .outputMode("append");
}

```

## Python

```

from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
    return df.selectExpr("CAST(value AS
STRING) as _id") \
        .writeStream \
        .format("com.mapr.db.spark.
streaming") \
        .option("checkpointLocation
", checkpoint_dir) \
        .option("tablePath",

```

```

table_path) \
    .option("idFieldPath",
"value") \
    .option("createTable",
True) \
    .option("bulkMode", True) \
    .option("sampleSize", 1000)

```

### Writing a Spark Stream Word Count Application to HPE Ezmeral Data Fabric Database

The example in this section writes a Spark stream word count application to HPE Ezmeral Data Fabric Database.

#### Example

##### Scala

```

val spark = SparkSession
    .builder
    .appName("StructuredKafkaWordCou
nt")
    .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers
", bootstrapServers)
    .option(subscribeType, topics)
    .load()
    .selectExpr("CAST(value AS
STRING)")
    .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
    .format(MapRDBSourceConfig.Forma
t)
    .option(MapRDBSourceConfig.Table
PathOption, resultTable)
    .option(MapRDBSourceConfig.Creat
eTableOption, true)
    .option(MapRDBSourceConfig.IdFie
ldPathOption, "value")
    .outputMode("complete")
    .start()

query.awaitTermination()

```

##### Java

```

SparkSession spark = SparkSession
    .builder()
    .appName("JavaStructuredKaf
kaWordCount")
    .getOrCreate();

```

```

//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
    .readStream()
    .format("kafka")
    .option("kafka.bootstrap.s
ervers", bootstrapServers)
    .option(subscribeType,
topics)
    .load()
    .selectExpr("CAST(value
AS STRING)")
    .as(Encoders.STRING());

//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
    .format(MapRDBSourceConfig
.Format())
    .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
    .option(MapRDBSourceConfig
.CreateTableOption(), true)
    .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
    .outputMode("complete");
    .start();

query.awaitTermination();

```

## Python

```

spark = SparkSession\
    .builder\
    .appName("StructuredKafkaWo
rdCount")\
    .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
    .readStream\
    .format("kafka")\
    .option("kafka.bootstrap.ser
vers", bootstrapServers)\
    .option(subscribeType,
topics)\
    .load()\
    .selectExpr("CAST(value AS
STRING)")

#Split the lines into words

```

```

words = lines.select(
#Explode turns each item in an array
into a separate row
explode(
    split(lines.value, ' ')
    ).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB
query = wordCounts\
    .writeStream\
    .format("com.mapr.db.spa
rk.streaming") \
    .option("tablePath",
table_path) \
    .option("createTable",
True) \
    .option("idFieldPath",
"value") \
    .outputMode('complete')\
    .start()

query.awaitTermination()

```

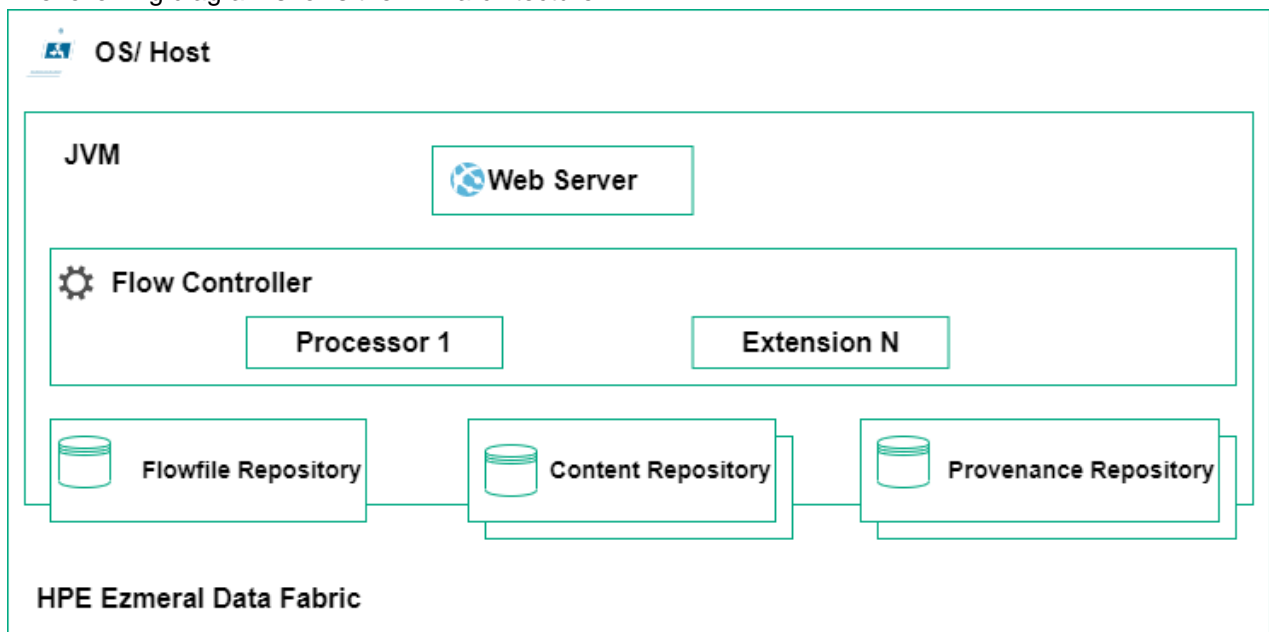

## NiFi

This topic provides an overview of Apache NiFi on HPE Ezmeral Data Fabric.

Starting from EEP 9.0.0, HPE Ezmeral Data Fabric supports Apache NiFi.

Apache NiFi is a dataflow system based on the concepts of flow-based programming which supports powerful and scalable directed graphs of data routing, transformation, and system mediation logic. NiFi has a web-based user interface for the design, control, feedback, and monitoring of dataflows.

The following diagram shows the NiFi architecture:

To transfer data in and out of HPE Ezmeral Data Fabric, NiFi supports the following sources and sinks.

- SQL Databases (MySQL, Postgres, etc.)
- NoSQL Databases (MongoDB, Redis, etc.)
- File storage (S3 compatible, SMB, FTP)
- Cloud services (GCP, Azure, AWS)
- HTTP requests
- Other

To install NiFi, see [Installing NiFi](#) on page 255 and to view the NiFi release notes, see [NiFi Release Notes](#) on page 6105.

To learn more about NiFi, see [Apache NiFi documentation](#).

### Accessing NiFi UI

This topic describes how to access NiFi the UI.

NiFi automatically starts after successful configuration.

Cluster Type	NiFi UI Endpoints
Secured	https://HOST_FQDN:12443/nifi
Unsecured	http://HOST_FQDN:12080/nifi

To log in to the NiFi UI on a secured cluster, you must have a username and password. By default, credentials are randomly generated and are located in the [NiFi Logs](#) on page 4587. For example:

```
cat /opt/mapr/nifi/nifi-<version>/logs/nifi-app.log | grep Generated
```

By default, a single-user login strategy is used on secured clusters. To change credentials, run:

```
/opt/mapr/nifi/nifi-<version>/bin/nifi.sh set-single-user-credentials  
"USERNAME" "PASSWORD"
```

After changing credentials, you must restart the NiFi services:

```
maprcli node services -name nifi -action restart -nodes <nodes list>
```

If you change ports, you must launch the reconfiguration script to update the Warden configurations with the proper values. To learn more, see [Sensitive Values Encryption](#).

### NiFi Logs

This topic describes how to view the logs for NiFi on HPE Ezmeral Data Fabric.

You can locate the logs for NiFi at `/opt/mapr/nifi/nifi-<version>/logs/` folder.

### Configuring NiFi

This topic describes where to locate configuration files for NiFi and how to configure NiFi for cluster mode.

The configuration files for NiFi are located at `/opt/mapr/nifi/nifi-<version>/conf` directory. Configuration is not necessary to start using NiFi.

Configuration Files	Description
nifi.properties	NiFi server side configuration
bootstrap.conf	NiFi launcher configuration

Configuration Files	Description
logback.xml	Logging settings
authorizers.xml	Authorization configuration
login-identity-providers.xml	Authentication configuration
state-management.xml	NiFi cluster-storing state configuration

NiFi automatically starts after successful configuration.

To learn more about NiFi configurations, see [Administration Guide](#).

### Configuring NiFi for Cluster Mode

To ensure that NiFi works on cluster mode, specify `Connect String` for `zk-provider` in `state-management.xml` file.

For example:

```
node4.cluster.com:5181
```

For example: On secured cluster, make the following changes in `nifi.properties` file.

- `nifi.web.https.host=node5.cluster.com` (set to FQDN on each node)
- `nifi.sensitive.props.key=abcd123456789` (set same on each node)
- `nifi.cluster.protocol.is.secure=true` (is necessary if clusters work with `https`)
- `nifi.cluster.is.node=true`
- `nifi.cluster.skip.hostname.verify=true` (is necessary if certificate is wildcard without `subjectAltNames`)
- `nifi.cluster.node.address=node5.cluster.com` (set to FQDN on each node)
- `nifi.zookeeper.connect.string=node4.cluster.com:5181` (set similar to `state-management.xml`)

### Starting, Stopping, and Restarting NiFi Services

This topic describes how to start, stop, and restart NiFi services on HPE Ezmeral Data Fabric.

#### About this task

The Warden daemon starts the NiFi server automatically at installation time.

You can start and stop NiFi from the command line or from the Control System. You can use the `maprccli node services` command to start NiFi on multiple nodes at one time.

#### Starting, Stopping, and Restarting NiFi Services Using Command Line

##### About this task

Perform the following steps to start or stop or restart NiFi from the command line:

##### Procedure

1. Make a list of nodes on which NiFi is configured.

2. Run the `maprcli node services` command with either `start`, `restart`, or `stop`, and specify the nodes on which NiFi is configured, separated by spaces.

```
maprcli node services -name nifi -action start|stop|restart -nodes
<nodes list>
```

## Starting, Stopping, and Restarting NiFi Services Using Scripts

### About this task

You can manually start or stop or restart or check the status by using the script located at `opt/mapr/nifi/nifi-<version>/bin/nifi.sh`.

For example:

```
/opt/mapr/nifi/nifi-1.16.3/bin/nifi.sh start|stop|restart|status
```

### NiFi Security

This topic describes how the Login Identity Provider provides authentication options for username and password for NiFi.

NiFi supports different authorization providers. The user authentication through username and password is performed by Login Identity Provider. Login Identity Provider provides three options to authenticate username and password:

1. Single User
2. Lightweight Directory Access Protocol/ Active Directory (LDAP/ AD)
3. Kerberos

To learn more, see [User Authentication](#).

By default, you can log in using Single User option on secured clusters.

MapR-SASL does not support UI login and impersonation.

### Kerberos

To authenticate username and password by using Kerberos on cluster, perform the following:

1. Add the following properties in `opt/mapr/nifi/nifi-<version>/conf/nifi.properties` file.

```
nifi.security.user.authorizer=managed-authorizer
nifi.security.user.login.identity.provider=kerberos-provider
nifi.kerberos.krb5.file=/etc/krb5.conf
```

2. Add the following providers in `/opt/mapr/nifi/nifi-<version>/conf/login-identity-providers.xml` file.

```
<provider>
  <identifier>kerberos-provider</identifier>
  <class>org.apache.nifi.kerberos.KerberosProvider</class>
  <property name="Default Realm">YOUR_REALM</property>
  <property name="Authentication Expiration">12 hours</property>
</provider>
```

3. Add the following authorizers in `/opt/mapr/nifi/nifi-<version>/conf/authorizers.xml` file.

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<authorizers>
  <userGroupProvider>
    <identifier>file-user-group-provider</identifier>
    <class>org.apache.nifi.authorization.FileUserGroupProvider</
class>
    <property name="Users File">./conf/users.xml</property>
    <property name="Legacy Authorized Users File"></property>
    <property name="Initial User Identity 1">YOUR_USER@REALM
(example: root/admin@NODE1)</property>
  </userGroupProvider>
  <accessPolicyProvider>
    <identifier>file-access-policy-provider</identifier>
    <class>org.apache.nifi.authorization.FileAccessPolicyProvider</
class>
    <property name="User Group Provider">file-user-group-provider</
property>
    <property name="Authorizations File">./conf/authorizations.xml</
property>
    <property name="Initial Admin Identity"> YOUR_USER@REALM
(example: root/admin@NODE1) </property>
    <property name="Legacy Authorized Users File"></property>
    <property name="Node Identity 1"></property>
  </accessPolicyProvider>
  <authorizer>
    <identifier>managed-authorizer</identifier>
    <class>org.apache.nifi.authorization.StandardManagedAuthorizer</
class>
    <property name="Access Policy
Provider">file-access-policy-provider</property>
  </authorizer>
</authorizers>
```

You can now log in with `YOUR_USER` and set proper policies for other users .

## LDAP/AD

To authenticate username and password by using LDAP/AD on cluster, perform the following:

1. Add the following properties in `opt/mapr/nifi/nifi-<version>/conf/nifi.properties` file.

```
nifi.security.user.login.identity.provider=ldap-provider
nifi.security.user.authorizer=managed-authorizer
```

2. Add the following providers in `/opt/mapr/nifi/nifi-<version>/conf/login-identity-providers.xml` file.

```

<provider>
  <identifier>ldap-provider</identifier>
  <class>org.apache.nifi.ldap.LdapProvider</class>
  <property name="Authentication Strategy">SIMPLE</property>
  <property name="Manager DN">MANAGER_DN (example:
cn=admin,dc=mapr,dc=local)</property>
  <property name="Manager Password">PASSWORD</property>
  <property name="TLS - Keystore"></property>
  <property name="TLS - Keystore Password"></property>
  <property name="TLS - Keystore Type"></property>
  <property name="TLS - Truststore"></property>
  <property name="TLS - Truststore Password"></property>
  <property name="TLS - Truststore Type"></property>
  <property name="TLS - Client Auth"></property>
  <property name="TLS - Protocol"></property>
  <property name="TLS - Shutdown Gracefully"></property>
  <property name="Referral Strategy">FOLLOW</property>
  <property name="Connect Timeout">10 secs</property>
  <property name="Read Timeout">10 secs</property>
  <property name="Url">LDAP_URL (example: ldap://127.0.0.1:389)</
property>
  <property name="User Search Base">dc=mapr,dc=local</property>
  <property name="User Search Filter">(cn={0})</property>
  <property name="Identity Strategy">USE_DN</property>
  <property name="Authentication Expiration">12 hours</property>
</provider>

```

3. Add the following authorizers in `/opt/mapr/nifi/nifi-<version>/conf/authorizers.xml` file.

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<authorizers>
  <userGroupProvider>
    <identifier>file-user-group-provider</identifier>
    <class>org.apache.nifi.authorization.FileUserGroupProvider</
class>
    <property name="Users File">./conf/users.xml</property>
    <property name="Legacy Authorized Users File"></property>
    <property name="Initial User Identity 1">ADMIN_USER (example:
cn=admin,dc=mapr,dc=local)</property>
  </userGroupProvider>
  <accessPolicyProvider>
    <identifier>file-access-policy-provider</identifier>
    <class>org.apache.nifi.authorization.FileAccessPolicyProvider</
class>
    <property name="User Group Provider">file-user-group-provider</
property>
    <property name="Authorizations File">./conf/authorizations.xml</
property>
    <property name="Initial Admin Identity">ADMIN_USER (example:
cn=admin,dc=mapr,dc=local) </property>
    <property name="Legacy Authorized Users File"></property>
    <property name="Node Identity 1"></property>
  </accessPolicyProvider>
  <authorizer>
    <identifier>managed-authorizer</identifier>
    <class>org.apache.nifi.authorization.StandardManagedAuthorizer</
class>
    <property name="Access Policy
Provider">file-access-policy-provider</property>
  </authorizer>
</authorizers>
```

You can now log in with ADMIN\_USER and add new users, groups and policies to NiFi. .

### Integrating NiFi with EEP Components

This topic describes how to configure NiFi to work with other EEP components in HPE Ezmeral Data Fabric. The information in this topic relates specifically to the EEP components and HPE distribution for Apache NiFi.

### HDFS

NiFi works with HDFS by using default HDFS processors.

If Hadoop configuration resources property is not set, Nifi automatically detects them in runtime.

### HBase and HPE Ezmeral Data Fabric Database Binary

Install and configure HBase on your cluster. See [Installing HBase](#) on page 235.

NiFi works with HBase by using default HBase processors. However, you must create `EEP_HbaseMaprDbClientService` service which automatically detects the configuration.

**NOTE:** Both HBase and HPE Ezmeral Data Fabric Database Binary uses the same implementation of NiFi.

## Hive

Install and configure Hive on your cluster. See [Installing Hive](#) on page 240.

To work with `SelectHive3_EEP_QL` and `UpdateHive3_EEP_Table` processors, configure `Hive3_EEP_ConnectionPool` with the following configuration details:

- Database Connection URL

- 

- On secured cluster:

```
jdbc:hive2:// <host>:10000/default;auth=maprsasl;ssl=true;
```

- See [Using JDBC or Beeline to Connect to HiveServer2](#) on page 4282.

- Database User

- Password

`PutHive3_EEP_Streaming` automatically detects Hive configuration.

**NOTE:** When you change the Hive version, you must manually configure Hive on pre-configured processors.

## Kafka

Kafka processors on the cluster node does not require any additional component installations.

**NOTE:** HPE Ezmeral Data Fabric does not support Kafka Transactions.

## HPE Ezmeral Data Fabric Object Store

Install, configure and generate `AccessKey` and `SecretKey` for HPE Ezmeral Data Fabric Object Store.

To work with S3 processors, you must specify the following:

- Access Key ID
- Secret Access Key
- Endpoint Override URL ([https://FQDN\\_HOST:9000](https://FQDN_HOST:9000))

## Installing Custom Processors for NiFi

This topic describes how to install custom processors for NiFi.

You can extend the capability of NiFi by installing custom processors, or processors that were not bundled with the NiFi package.

You can use one of the following methods to install custom processors:

- [Autoloading Custom Processors](#) on page 4593. This method does not require a restart to NiFi.
- [Installing Custom Processors](#) on page 4595. This method requires a restart to NiFi.

## Autoloading Custom Processors

Autoloading allows you to install custom processors without restarting NiFi.

See the instructions for [Autoloading Custom Processors](#) in the official Apache NiFi documentation.

To check the autoloading process of your custom processors, view `/opt/mapr/nifi/nifi-*/logs/nifi-app.log` and check the NAR Auto-Loader messages.

For example:

```
$ cat /opt/mapr/nifi/nifi-*/logs/nifi-app* | grep "NAR Auto-Loader"
2023-05-08 13:03:51,724 INFO [main] org.apache.nifi.nar.NarAutoLoader

## Installing Custom Processors

This is the original method for installing custom processors, which requires a restart to NiFi.

See the instructions for [Installing Custom Processors](#) in the official Apache NiFi documentation.

## OTel

This topic provides an overview of OpenTelemetry on HPE Ezmeral Data Fabric.

Starting from EEP 9.2.0, HPE Ezmeral Data Fabric supports OpenTelemetry (OTel).

OTel is an observability framework that allows you to instrument, generate, collect, and export telemetry data.

To install OTel, see [Installing OTel](#) on page 256 and to view the OTel release notes, see [OTel Release Notes](#) on page 6108.

To learn more about OTel, see [the official OpenTelemetry documentation](#).

### Adding an OTel Endpoint

This topic describes how to add an OTel endpoint using either the HPE Ezmeral Data Fabric UI or the command line.

#### Adding an OTel Endpoint with the HPE Ezmeral Data Fabric UI

To add an OTel endpoint with the HPE Ezmeral Data Fabric UI:

1. Log on to the Data Fabric UI.
2. Click the **Fabric administration** tab.
3. On the **OTEL endpoints** card, click **Add endpoint**. The **Add OTEL endpoint** side drawer opens.
4. Enter the **Name**.
5. Enter the **URL** of your OTel endpoint.
6. If your OTel endpoint contains a port, enter the port number.
7. To enable your OTel endpoint to return logs and/or metrics data, select **Logs** and/or **Metrics**.
8. Click **Select file** to select a key file to upload. Alternatively, drag and drop the key file to the **Upload files** area.
9. Click **Select file** to select a client certificate file to upload. Alternatively, drag and drop the client certificate file to the **Upload files** area.
10. Click **Add**.

#### Adding an OTel Endpoint with the Command Line

Use the following command to add an OTel endpoint:

```
maprcli otelendpoint add -name secureendpoint -url <endpoint-url> -port
<endpoint-port> -certfile <cert-path> -keyfile <key-path> -customopts
'{"exportlogs": "<true-or-false>", "exportmetrics": "<true-or-false>"}
```

To generate logs and/or metrics for your cluster, set `exportlogs` and/or `exportmetrics` as `true`. To disable generation of logs and/or metrics, set `exportlogs` and/or `exportmetrics` as `false`.

### OTel Logs and Metrics

This topic describes how to view the logs for OpenTelemetry (OTel) on HPE Ezmeral Data Fabric.

## Viewing Logs and Metrics in the HPE Ezmeral Data Fabric UI

To view the logs and metrics generated by OTel:

1. Log on to the Data Fabric UI.
2. Click the **Fabric administration** tab.
3. On the **Clusters** screen, locate the cluster for which you want to view logs and metrics.
4. Open the **Actions** menu, and select **Logs and metrics**.
5. You can now view logs and metrics for the cluster on the **Logs** and **Metrics** tabs.

## Starting, Stopping, and Restarting OTel Services

This topic describes how to start, stop, and restart OTel services on HPE Ezmeral Data Fabric.

### Starting and Stopping OTel Services Using the HPE Ezmeral Data Fabric UI

To start or stop the generation of logs and/or metrics by OTel:

1. Log on to the Data Fabric UI.
2. Click the **Fabric administration** tab.
3. On the **OTEL endpoints** card, click the ellipsis under **Actions** for the OTel endpoint.
4. Click **Edit**. The **Edit OTel endpoint** side drawer opens.
5. To enable logs and/or metrics, select the **Logs** and/or **Metrics** check boxes. To disable logs and/or metrics, deselect the **Logs** and/or **Metrics** check boxes.
6. Click **Save**.

### Restarting OTel Services Using the Command Line

To restart OTel services, run the following command:

```
maprcli node services -name ezotelcol -nodes <hostname> -action restart
```

## Ranger

This section describes the HPE Ezmeral Data Fabric implementation of Apache Ranger™ and provides all relevant details needed to use Ranger. The documentation in this section does not duplicate the documentation on the [Apache Ranger](#) site.

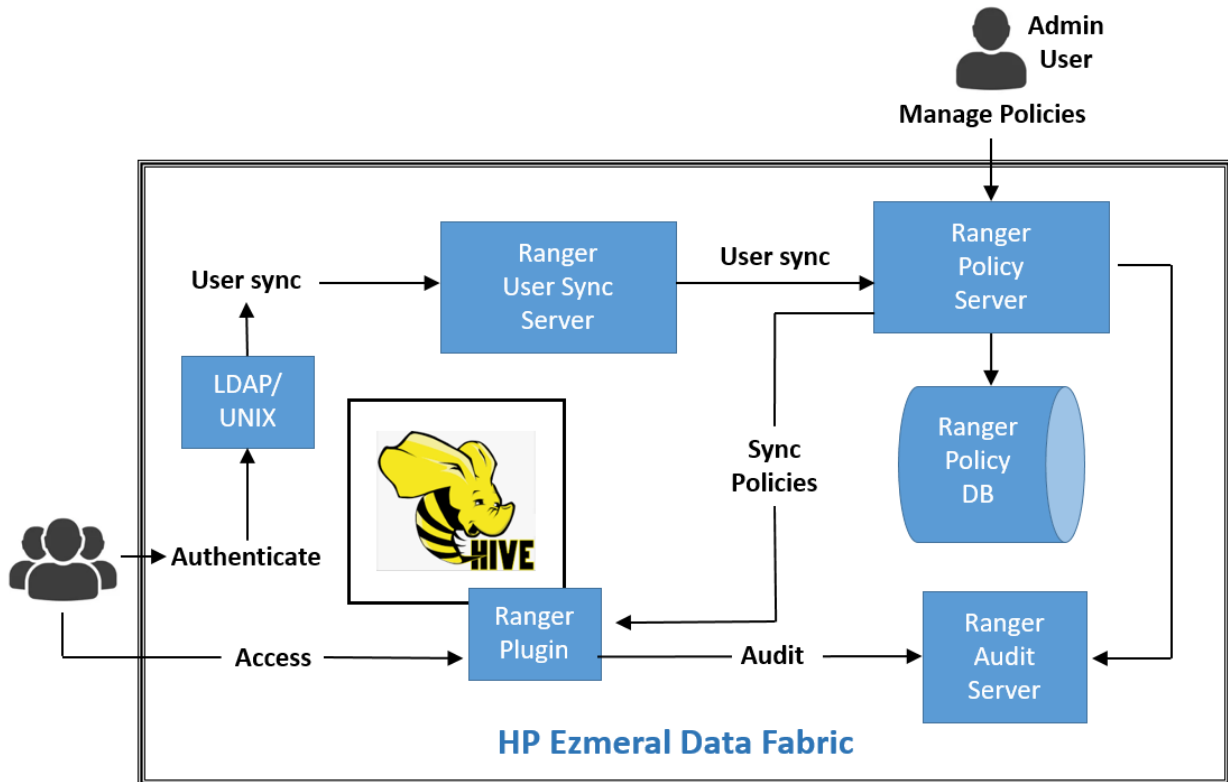

Apache Ranger is a framework to enable, monitor and manage data security across the Hadoop platform in the HPE Ezmeral Data Fabric. Apache Ranger provides centralized security administration and fine-grain access control for user access within Apache Hadoop, Apache Hive, Apache HBase, and other Apache components.

In the Data Fabric, Ranger enables:

- Centralized security administration to manage security-related tasks for HiveServer2 and Hive Metastore from a central user interface or using REST APIs.

- Fine-grained authorization for specific operations that are managed through a central administration tool.
- A standardized authorization method that is currently supported for HiveServer2 and Hive Metastore.

The following diagram shows the Ranger architecture as implemented within Data Fabric.

To install Ranger, see [Installing Ranger](#) on page 256 and [Installing Ranger Using the Installer](#) on page 5648. To view the Ranger release notes, see [Ranger Release Notes](#) on page 6122.

### Getting Started with Ranger

Describes how to start using Apache Ranger with the HPE Ezmeral Data Fabric.

Using the following steps to install, configure, and integrate Ranger with HiveServer2 and create a policy that you can test:

1. Install Ranger as described in [Installing Ranger](#) on page 256 or [Installing Ranger Using the Installer](#) on page 5648.
2. Configure the Ranger Admin and Usersync services as described in [Configuring Ranger](#) on page 4599.
3. Configure and enable the Hive plug-in, and create the Hive service in Ranger, as described in [Integrating HiveServer2 with Ranger](#) on page 4609.
4. Open the Ranger Admin UI using the secure address:
  - Secure address: `https://<FQDN>:6182`
5. In the Admin UI, navigate to the Hive service, remove all policies, and create a new policy such as the following. This policy provides `mapruser1` with SELECT and CREATE permissions on any database,

any table, and any column:

Policy Name \*   Enabled  Normal

Policy Label

database \*   Include

table \*   Include

column \*   Include

Description

Audit Logging  Yes

---

Select Role	Select Group	Select User	Permissions	Delegate Admin	
<input type="text"/>	<input type="text" value="Select Groups"/>	<input type="text" value="x:mapuser1"/>	<input checked="" type="checkbox"/> select <input checked="" type="checkbox"/> Create <input type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>

6. Click **Save** to save the new policy.

7. Check the logs to ensure that the policy refreshed successfully. After you create or update a policy, the Ranger-enabled HiveServer2 or Hive Metastore download the policy changes from the Admin service. To check the HiveServer2 log, navigate to `/opt/mapr/hive/hive-3.1.3/logs/mapr/mapr-hiveserver2-node1.cluster.com.log`. You should see something like this:

```
2022-09-26T10:59:33,936 INFO [main] util.RangerRolesProvider:
RangerRolesProvider(serviceName=hivedev): found updated version.
lastKnownRoleVersion=-1; newVersion=1
2022-09-26T10:59:34,229 INFO [main] util.PolicyRefresher:
PolicyRefresher(serviceName=hivedev): found updated version.
lastKnownVersion=-1; newVersion=18
2022-09-26T10:59:34,244 INFO [main] policyengine.PolicyEngine: Policy
engine will not perform in place update while processing policy-deltas.
2022-09-26T10:59:34,271 INFO [main]
policyengine.RangerPolicyRepository: This policy engine contains 1
policy evaluators
```

8. As the `mapuser1`, go to Beeline, and connect to HiveServer2:

```
$ hive --service beeline
Beeline version 3.1.3.0-eeep-900-SNAPSHOT by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:10000/
default;auth=maprsasl;ssl=false
Connecting to jdbc:hive2://node1.cluster.com:10000/
default;auth=maprsasl;ssl=false
22/09/26 11:18:24 [main]: WARN maprsasl.MaprSaslClient: SASL
Server qopProperty: auth-confis different from Client:
auth-conf,auth-int,auth.Using Server one
Connected to: Apache Hive (version 3.1.3.0-eeep-900-SNAPSHOT)
Driver: Hive JDBC (version 3.1.3.0-eeep-900-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

9. Try to run SELECT, CREATE, and DROP commands. SELECT and CREATE should succeed, but DROP should fail:

```
0: jdbc:hive2://node1.cluster.com:10000/defau> SELECT * FROM web_log;
...
INFO : OK
0: jdbc:hive2://node1.cluster.com:10000/defau> CREATE TABLE test(t int);
...
INFO : OK
0: jdbc:hive2://node1.cluster.com:10000/defau> DROP TABLE test;
Error: Error while compiling statement: FAILED:
HiveAccessControlException Permission denied: user [mapruser1] does not
have [DROP] privilege on [default/test] (state=42000,code=40000)
```

### For More Information

To learn about Ranger policies, users, groups, reports, and auditing, see the [Ranger User Guide](#).

For a list of Ranger features, see [Apache Ranger Features](#).

For information about REST API commands, see the Ranger REST API [Resources](#) page.

### Configuring Ranger

Describes how to set up Ranger services and run the configuration script.

Use these steps:

1. Set up Ranger services:
  - a. In the `install.properties` file in the Ranger Admin home directory (`/opt/mapr/ranger/ranger-<version>/ranger-admin/install.properties`), modify the properties using one of the following options:
    - If you have skipped [Step 1.](#) and [2.](#) in [Installing Ranger](#) on page 256 procedure, modify the following properties:

```
db_root_user=root
db_root_password=<root_db_password>

db_name=<created_db_name>
db_user=<created_db_user>
db_password=<created_db>

rangerAdmin_password=<min_8_char_with_numeric_and_min_one_capital>
rangerTagsync_password=<min_8_char_with_numeric_and_min_one_capital>

rangerUsersync_password=<min_8_char_with_numeric_and_min_one_capital
>
keyadmin_password=<min_8_char_with_numeric_and_min_one_capital>
```

- If you have performed [Step 1.](#) and [2.](#) in [Installing Ranger](#) on page 256 procedure, modify the following properties:

```
db_name=<created_db_name>
db_user=<created_db_user>
db_password=<created_db>

rangerAdmin_password=<min_8_char_with_numeric_and_min_one_capital>
rangerTagsync_password=<min_8_char_with_numeric_and_min_one_capital>

rangerUsersync_password=<min_8_char_with_numeric_and_min_one_capital>
>
keyadmin_password=<min_8_char_with_numeric_and_min_one_capital>
```

Later you will use the `keyadmin_password` to log on to the Ranger web UI.

- Run the setup script:

```
sudo /opt/mapr/ranger/ranger-<version>/ranger-admin/setup.sh
```

The `/ranger-admin/setup.sh` script copies some basic ugsync-related properties to the `ugsync.install.properties` and then runs the `ugsync` script. However, to custom configure `ugsync`, you must edit `/opt/mapr/ranger/ranger-2.3.0/ranger-usersync/install.properties` and then run `sudo /opt/mapr/ranger/ranger-2.3.0/ranger-usersync/setup.sh`.

- Run the configuration script as `root`. Running `configure.sh` restarts the Ranger Admin and Ranger UserSync services:

```
/opt/mapr/server/configure.sh -R
```

### Starting, Stopping, and Restarting Ranger Services

Describes how to start, stop, and restart Ranger services on the HPE Ezmeral Data Fabric.

The Warden daemon starts the Ranger daemon automatically at installation time. You can start, stop, or restart Ranger services from the Control System or from the command line (CLI).

The `mapr-ranger` package provides two services:

Service	Function
<code>ranger-admin</code>	Creates and synchronizes Ranger policies and applies them to the plug-in.
<code>ranger-usersync</code>	Gathers user information from Linux or Active Directory/Lightweight Directory Access Protocol (AD/LDAP) servers.

### Starting, Stopping, and Restarting Ranger Using the Control System

See:

- [Starting the Services on the Cluster Using the Control System](#) on page 1133
- [Stopping a Service on the Cluster Using the Control System](#) on page 1134
- [Restarting the Services on the Cluster Using the Control System](#) on page 1135

## Starting, Stopping, and Restarting Ranger Using the CLI

Using the `maprcli node services` command, you can start Ranger services on multiple nodes at the same time.

Use the following steps to start or stop or restart Ranger services from the `maprcli` command line:

1. Make a list of the nodes on which Ranger is configured.
2. Run the `maprcli node services` command with either `start`, `restart`, or `stop`, and specify the nodes on which Ranger is configured separated by spaces:

```
maprcli node services -name <ranger_service_name> -action start|stop|
restart -nodes <node_list>
```

## Configuring Security for Ranger

Describes how to configure security for Ranger.

### Configuring Encryption

Optionally, you can configure parameters that are used to encrypt passwords for Ranger internal use cases:

```
#Encryption
password_encryption_key=
password_salt=f77aLYLo
password_iteration_count=1000
password_encryption_algorithm=PBEWithHmacSHA512AndAES_128
```

Note that the `password_encryption_key` is empty by default. If you do not explicitly set the `password_encryption_key`, Ranger generates a key automatically. If reconfiguration using `setup.sh` is needed later, Ranger uses the generated key, and no user interaction is needed.

### Configuring SSL over DB

The following settings are SSL over DB related:

```
#SSL config
db_ssl_enabled=false
db_ssl_required=false
db_ssl_verifyServerCertificate=false
#db_ssl_auth_type=1-way|2-way, where 1-way represents standard one way ssl
authentication and 2-way represents mutual ssl authentication
db_ssl_auth_type=2-way
javax_net_ssl_keyStore=
javax_net_ssl_keyStorePassword=
javax_net_ssl_trustStore=
javax_net_ssl_trustStorePassword=
javax_net_ssl_trustStore_type=jks
javax_net_ssl_keyStore_type=jks

mysql_enabled_tls_protocols=TLSv1.2
```

### Configuring SSL Security

In a secure cluster, Ranger configures SSL security by using the EEP-specific key store by default. In a secure cluster, the Ranger Admin UI runs on `https://<hostname>:6182`.

To override the default SSL configuration, you can use either of the following options:

- Public CA Certificates

- Self-Signed Certificate

Only one step is different in these configuration options. If you use a self-signed certificate, you need to create the certificate, as directed in step 2.

### SSL Configuration for Services

1. If Ranger is configured and running, stop the Ranger service on each node:

```
maprcli node services -name ranger-admin -action stop -nodes `hostname`
maprcli node services -name ranger-usersync -action stop -nodes
`hostname`
```

2. If using the self-signed option, create the self-signed certificates. For example, to create the Admin keystore:

```
keytool -genkey -keyalg RSA -alias rangeradmin -keystore
ranger-admin-keystore.jks -storepass xasecure -validity 360 -keysize 2048
chmod 400 ranger-admin-keystore.jks
```

To create the Usersync trust store:

```
keytool -export -keystore ranger-admin-keystore.jks -alias
rangeradmin -file ranger-admin-trust.cer
chown mapr:mapr ranger-admin-trust.cer
keytool -import -file ranger-admin-trust.cer -alias
rangeradmintrust -keystore mytruststore.jks -storepass changeit
chown mapr:mapr mytruststore.jks
```

3. Modify the Ranger Admin `install.properties` file as follows:

```
polycmgr_external_url=https://FQDN:6182
polycmgr_http_enabled=false
polycmgr_https_keystore_file=/path/to/ranger-admin-keystore.jks
polycmgr_https_keystore_keyalias=rangeradmin
polycmgr_https_keystore_password=xasecure
```

4. Modify the Ranger Usersync `install.properties` file as follows:

```
# SSL Authentication
AUTH_SSL_ENABLED=true
AUTH_SSL_KEYSTORE_FILE=/etc/ranger/usersync/conf/cert/unixauthservice.jks
AUTH_SSL_KEYSTORE_PASSWORD=UnIx529p
AUTH_SSL_TRUSTSTORE_FILE=/path/to/mytruststore.jks
AUTH_SSL_TRUSTSTORE_PASSWORD=changeit
```

5. Run the Ranger Admin `setup.sh` script to configure the new options:

```
sudo /opt/mapr/ranger/ranger-<version>/ranger-admin/setup.sh
```

6. Restart the services if Ranger is already configured; otherwise, you must run `configure.sh` once the full configuration is completed:

```
maprcli node services -name ranger-admin -action start -nodes `hostname`
maprcli node services -name ranger-usersync -action start -nodes
`hostname`
```

## SSL Configuration for Plug-ins

1. Add the certificates that you specified for the services into the `install.properties` file of the corresponding plug-in as follows:

```
SSL_KEYSTORE_FILE_PATH=/path/to/ranger-admin-keystore.jks
SSL_KEYSTORE_PASSWORD=xasecure
SSL_TRUSTSTORE_FILE_PATH=/path/to/mytruststore.jks
SSL_TRUSTSTORE_PASSWORD=changeit
```

2. Run the script for the plug-in:

```
enable-<component>-plugin.sh
```

## Configuring the Security Type

In releases 7.2.0 and later, you can use a *security type* property to specify the authentication between Ranger and the HPE Ezmeral Data Fabric. This property determines the authentication protocol used by the Ranger Admin service. You can set the security type in the `install.properties` file or in the `ranger-admin-site.xml` file.

If you set the security type in this file . . .	Use this property name
<code>install.properties</code>	<code>security_type</code>
<code>site.xml</code>	<code>ranger.security.type</code>

Possible values for the property are:

Value	Description
<code>none</code>	The Ranger Admin runs in non-secure mode, and no authentication is required for API calls.
<code>maprsasl</code>	The Ranger Admin uses MapR-SASL authentication.
<code>kerberos</code>	The Ranger Admin uses Kerberos authentication.

If a value is not specified, Ranger uses the value found in `mapr-clusters.conf`.

## Configuring LDAP/AD for Ranger

Describes how to configure Ranger security so that the Ranger Admin service authenticates users through LDAP authentication, and the Ranger UserSync service sources users and groups from LDAP storage.

LDAP configuration consists of:

- Preparing the LDAP server
- Configuring the UserSync service
- Configuring the Admin service to enable LDAP

## Preparing the LDAP Server

The following information about preparing the LDAP server is provided as an example. Your installation could require different procedures and steps. The following example was created with OpenLDAP running on a dedicated node installed with Ubuntu 18.04. To prepare the LDAP server, you must install the server, configure it, and provide some test data:

1. Install the OpenLDAP server:

```
sudo apt update && sudo apt install -y slapd ldap-utils
sudo dpkg-reconfigure slapd
```

2. The terminal UI asks for some configuration information. Press **Enter** in all cases except when prompted for the admin password. When you are prompted to confirm the admin password, type `mapr`.

3. Verify that the service is running and responding:

```
$ ldapsearch -x -D 'cn=admin,dc=cluster,dc=com' -w mapr -b
'dc=cluster,dc=com' -LLL -H ldap://node2:389
dn: dc=cluster,dc=com
objectClass: top
objectClass: dcObject
objectClass: organization
o: cluster.com
dc: cluster

dn: cn=admin,dc=cluster,dc=com
objectClass: simpleSecurityObject
objectClass: organizationalRole
cn: admin
description: LDAP administrator
userPassword:: e1NTSEF9bXVTRkNncXFEMlhIY0MlQkFizjc2TXVld0VYK2FjcXk=
```

## 4. Provide some test data. For example:

```

$ cat test_data.ldif
dn: ou=People,dc=cluster,dc=com
objectClass: organizationalUnit
ou: People

dn: ou=Groups,dc=cluster,dc=com
objectClass: organizationalUnit
ou: Groups

dn: cn=ldapuser1,ou=People,dc=cluster,dc=com
cn: ldapuser1
objectClass: person
sn: ldapuser1

dn: cn=ldapuser2,ou=People,dc=cluster,dc=com
cn: ldapuser2
objectClass: person
sn: ldapuser2

dn: cn=ldapuser3,ou=People,dc=cluster,dc=com
cn: ldapuser3
objectClass: person
sn: ldapuser3

dn: cn=ldapuser4,ou=People,dc=cluster,dc=com
cn: ldapuser4
objectClass: person
sn: ldapuser4

dn: cn=ldapgroupA,ou=Groups,dc=cluster,dc=com
objectClass: groupOfNames
member: cn=ldapuser1,ou=People,dc=cluster,dc=com
member: cn=ldapuser2,ou=People,dc=cluster,dc=com
cn: ldapgroupA

dn: cn=ldapgroupB,ou=Groups,dc=cluster,dc=com
objectClass: groupOfNames
member: cn=ldapuser3,ou=People,dc=cluster,dc=com
member: cn=ldapuser4,ou=People,dc=cluster,dc=com
cn: ldapgroupB

$ ldapadd -x -D 'cn=admin,dc=cluster,dc=com' -w mapr -H ldap://
node2:389 -f test_data.ldif
adding new entry "ou=People,dc=cluster,dc=com"

adding new entry "ou=Groups,dc=cluster,dc=com"

adding new entry "cn=ldapuser1,ou=People,dc=cluster,dc=com"
adding new entry "cn=ldapuser2,ou=People,dc=cluster,dc=com"
adding new entry "cn=ldapuser3,ou=People,dc=cluster,dc=com"
adding new entry "cn=ldapuser4,ou=People,dc=cluster,dc=com"
adding new entry "cn=ldapgroupA,ou=Groups,dc=cluster,dc=com"
adding new entry "cn=ldapgroupB,ou=Groups,dc=cluster,dc=com"

```

**5. Specify user passwords, and verify LDAP authentication:**

```
$ for i in $(seq 4) ; do ldappasswd -D 'cn=admin,dc=cluster,dc=com' -w  
mapr -x "cn=ldapuser${i},ou=People,dc=cluster,dc=com" -s "pass${i}" -H  
ldap://node2:389 ; done  
$ for i in $(seq 4) ; do ldapwhoami -x -D "cn=ldapuser${  
{i},ou=People,dc=cluster,dc=com" -w "pass${i}" -H ldap://node2:389 ; done  
dn:cn=ldapuser1,ou=People,dc=cluster,dc=com  
dn:cn=ldapuser2,ou=People,dc=cluster,dc=com  
dn:cn=ldapuser3,ou=People,dc=cluster,dc=com  
dn:cn=ldapuser4,ou=People,dc=cluster,dc=com
```

6. Run `ldapsearch` again to check if everything is okay. The result should look like this:

```
$ ldapsearch -x -D 'cn=admin,dc=cluster,dc=com' -w mapr -b
'dc=cluster,dc=com' -LLL -H ldap://node2:389
dn: dc=cluster,dc=com
objectClass: top
objectClass: dcObject
objectClass: organization
o: cluster.com
dc: cluster

dn: cn=admin,dc=cluster,dc=com
objectClass: simpleSecurityObject
objectClass: organizationalRole
cn: admin
description: LDAP administrator
userPassword:: e1NTSEF9bXVTRkNncXFEM1hIY0M1QkFiZjc2TXV1d0VYK2FjcXk=

dn: ou=People,dc=cluster,dc=com
objectClass: organizationalUnit
ou: People

dn: ou=Groups,dc=cluster,dc=com
objectClass: organizationalUnit
ou: Groups

dn: cn=ldapuser1,ou=People,dc=cluster,dc=com
cn:: bGRhcHVzZXIxIA==
objectClass: person
sn: ldapuser1
userPassword:: e1NTSEF9eUVKaU1SYU5ub3AxeWxjVXk5aDVuNGJuYldmMVdHSDk=

dn: cn=ldapuser2,ou=People,dc=cluster,dc=com
cn:: bGRhcHVzZXIyIA==
objectClass: person
sn: ldapuser2
userPassword:: e1NTSEF9NmtLSHFxeUVwTTBtNHVBQjU3TGZueGduN3VaSXovWlc=

dn: cn=ldapuser3,ou=People,dc=cluster,dc=com
cn:: bGRhcHVzZXIzIA==
objectClass: person
sn: ldapuser3
userPassword:: e1NTSEF9UWVyeVZFVW9EMWpGdUpBZng4NVBQNmVKTzVsbjhWWEM=

dn: cn=ldapuser4,ou=People,dc=cluster,dc=com
cn:: bGRhcHVzZXI0IA==
objectClass: person
sn: ldapuser4
userPassword:: e1NTSEF9cy9xdm82RGh3Z2RjamZRbGZSZmdMTW03QjRCajJtdmM=

dn: cn=ldapgroupA,ou=Groups,dc=cluster,dc=com
objectClass: groupOfNames
member: cn=ldapuser1,ou=People,dc=cluster,dc=com
member: cn=ldapuser2,ou=People,dc=cluster,dc=com
cn: ldapgroupA

dn: cn=ldapgroupB,ou=Groups,dc=cluster,dc=com
objectClass: groupOfNames
member: cn=ldapuser3,ou=People,dc=cluster,dc=com
member: cn=ldapuser4,ou=People,dc=cluster,dc=com
cn: ldapgroupB
```

## Configuring the UserSync Service

The UserSync service can source users and groups from the LDAP server and push them to the Ranger Admin service. To configure this functionality:

1. Specify the following properties in the UserSync `install.properties` file:

```
SYNC_SOURCE = ldap
SYNC_LDAP_URL = ldap://node2:389
SYNC_LDAP_BIND_DN = cn=admin,dc=cluster,dc=com
SYNC_LDAP_BIND_PASSWORD = mapr
SYNC_LDAP_SEARCH_BASE = dc=cluster,dc=com
SYNC_GROUP_SEARCH_ENABLED=true
SYNC_GROUP_USER_MAP_SYNC_ENABLED=true
```

2. Run the UserSync `setup.sh` script, and restart `ranger-usersync`. You should see the following users in the admin users tab:

<input type="checkbox"/>	ldapuser4	User	External	LDAPIAD	ldapgroupb	Visible	
<input type="checkbox"/>	ldapuser2	User	External	LDAPIAD	ldapgroupa	Visible	
<input type="checkbox"/>	ldapuser3	User	External	LDAPIAD	ldapgroupb	Visible	
<input type="checkbox"/>	ldapuser1	User	External	LDAPIAD	ldapgroupa	Visible	

You should see the following groups in the groups tab:

<input type="checkbox"/>	ldapgroupa	External	LDAPIAD	Visible		
<input type="checkbox"/>	ldapgroupb	External	LDAPIAD	Visible		

## Configuring the Admin Service

The Admin service authenticates users when logging into the web UI through LDAP authentication. To configure this functionality:

1. Specify the following properties in the Admin `install.properties` file:

```
authentication_method=LDAP
xa_ldap_url=ldap://node2:389
xa_ldap_userDNpattern=cn={0},ou=People,dc=cluster,dc=com
xa_ldap_groupSearchBase=dc=cluster,dc=com
xa_ldap_base_dn=dc=cluster,dc=com
xa_ldap_bind_dn=cn=admin,dc=cluster,dc=com
xa_ldap_bind_password=mapr
```

2. Run the Admin service `setup.sh` script, and restart the service. After restarting the service, you should be able to log in to the web UI by using `ldapuser1` and password `pass1`:

### Integrating HiveServer2 with Ranger

Describes how to integrate HiveServer2 with Ranger.

Use these steps:

1. Ensure that the `mapr-ranger-hive-plugin` is installed, as described in [Installing Ranger](#) on page 256. If HiveServer2 is installed in HA mode, you must ensure that the `mapr-ranger-hive-plugin` is installed on both nodes for which HA is enabled.
2. Open the Ranger Admin UI using the secure address:
  - Secure address: `https://<FQDN>:6182`
3. In the **Service Manager** screen, create a Hive (Hadoop SQL) service by providing the following properties:

Properties Type	Property	Specify ...
Main Properties	Service Name	Any name for the service
	Username	<code>&lt;cluster-admin&gt;</code>
	Password	<code>&lt;cluster-admin-password&gt;</code>
	Jdbc.driverClass Name	<code>org.apache.hive.jdbc.HiveDriver</code>
	Jdbc.url	<code>jdbc:hive2://FQDN:10000/;ssl=true</code>
	<code>policy.download.auth.users</code>	Cluster admin or component's main user

4. Test the connection between Ranger and Hive:

5. Modify the following properties in the `install.properties` in the Ranger Hive plug-in home directory (`/opt/mapr/ranger/ranger-<version>/ranger-hive-plugin/install.properties`):

**IMPORTANT:** The `REPOSITORY_NAME` must be the same as the Service Name you specified in step 3, or the plug-in will not work.

```
POLICY_MGR_URL=http(s)://FQDN:<ranger-admin-port>
REPOSITORY_NAME=hivedev
COMPONENT_INSTALL_DIR_NAME=/opt/mapr/hive/hive-3.1.3
```

6. Enable the plug-in:

```
sudo /opt/mapr/ranger/ranger-<version>/ranger-hive-plugin/
enable-hive-plugin.sh
```

7. Restart Hive services:

```
maprcli node services -name hs2 -action restart -nodes `hostname`
maprcli node services -name hivemeta -action restart -nodes `hostname`
maprcli node services -name hcat -action restart -nodes `hostname`
```

8. To verify that the plug-in is active, navigate to **Audit > Plugin Status**:

Service Name	Service Type	Application	Host Name	Plugin IP	Cluster Name	Last Update	Download	Active	Last Update	Download
hivedev	Hadoop SQL	hiveServer2	node5.cluster.com	192.168.33.15	cyber.mapr.cluster	09/13/2022 11:01:26 AM an hour ago	09/13/2022 11:01:32 AM an hour ago	09/13/2022 11:01:33 AM an hour ago	--	--

## Integrating Hive Metastore with Ranger

Describes how to integrate Hive Metastore with Ranger.

Hive Metastore interacts directly with external clients such as Spark and Drill. Therefore, filtering and masking functionalities are not applicable for external clients.

Hive Metastore stores and manages metadata about Hive resources such as databases, tables, and columns. It is responsible for queries such as the following (not a complete list):

- CREATE
- SHOW
- DESCRIBE
- ALTER
- DROP
- SELECT

Integrating Ranger with Hive Metastore protects the preceding queries but does not protect queries that work with real, physical data, such as the following (not a complete list):

- UPDATE
- INSERT
- DELETE
- TRUNCATE

After you have successfully enabled the Ranger Hive plug-in and configured policies, use the following steps to enable Ranger authorization in the Hive Metastore:

1. In the `hive-site.xml` file, set the `hive.security.authorization.manager` property to `org.apache.ranger.authorization.hive.authorizer.RangerHiveAuthorizerFactory`:

```
<property>

<name>hive.security.authorization.manager</name>
<value>org.apache.ranger.authorization.hive.authorizer.RangerHiveAuthoriz
erFactory</value>

</property>
```

2. In the `hive-site.xml` file, add the `HiveMetaStoreAuthorizer` class to `hive.metastore.pre.event.listeners`:

```
<property>

<name>hive.metastore.pre.event.listeners</name>
<value>org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreE
ventListener,org.apache.hadoop.hive.ql.security.authorization.plugin.meta
store.HiveMetaStoreAuthorizer</value>

</property>
```

3. Restart the Hive Metastore. Restarting causes Ranger privilege checks to be performed on each request to the Hive Metastore:

```
maprcli node services -nodes <nodes> -name hivemeta -action restart
```

4. To disable Hive Metastore authentication with Ranger, return the following properties to their default values:

```
<property>

<name>hive.security.authorization.manager</name>
<value>
org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.Fallback
HiveAuthorizerFactory</value>

</property>
<property>

<name>hive.metastore.pre.event.listeners</name>
<value>org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreE
ventListener</value>

</property>
```

### Integrating Yarn with Ranger

Describes how to integrate Yarn with Ranger.

Use these steps:

1. Ensure that the Ranger Admin is configured, as described in [Installing Ranger](#) on page 256 and [Configuring Ranger](#) on page 4599.
2. Open the Ranger Admin UI using either the secure or non-secure address:
  - Secure address: `https://<FQDN>:6182`
  - Non-secure address: `http://<FQDN>:6080`
3. In the **Service Manager** screen, create a Yarn service by providing the following properties:

Properties Type	Property	Specify . . .
Main Properties	Service Name	Any name for the service
	Username	<cluster-admin>
	Password	<cluster-admin-password>
	YARN REST URL	<yarn-url-address>
	In <b>Add New Configurations</b> , add the property: policy.download.auth.users	Cluster admin or component's main user

Service Name \*

Display Name

Description

Active Status  Enabled  Disabled

Select Tag Service

Username \*

Password \*

YARN REST URL \*

Authentication Type

Common Name for Certificate

Add New Configurations

Name	Value
<input type="text" value="policy.download.auth.users"/>	<input type="text" value="mapr"/> <span style="color: red; font-weight: bold;">✕</span>

4. To test the connection between Ranger and Yarn, click **Test Connection**.

- Modify the following properties in the `install.properties` in the Ranger Yarn plug-in home directory (`RANGER_HOME/ranger-yarn-plugin/install.properties`):

```
# POLICY_MGR_URL=http(s)://policymanager.xasecure.net:6182 (or 6080)
POLICY_MGR_URL=http://FQDN:6182

# This is the repository name created within policy manager in item #1
REPOSITORY_NAME=yarndev

# Hadoop installation directory
COMPONENT_INSTALL_DIR_NAME=/opt/mapr/hadoop/hadoop-<version>
```

- Enable the plug-in:

```
sudo RANGER_HOME/ranger-yarn-plugin/enable-yarn-plugin.sh
```

- Restart Yarn services:

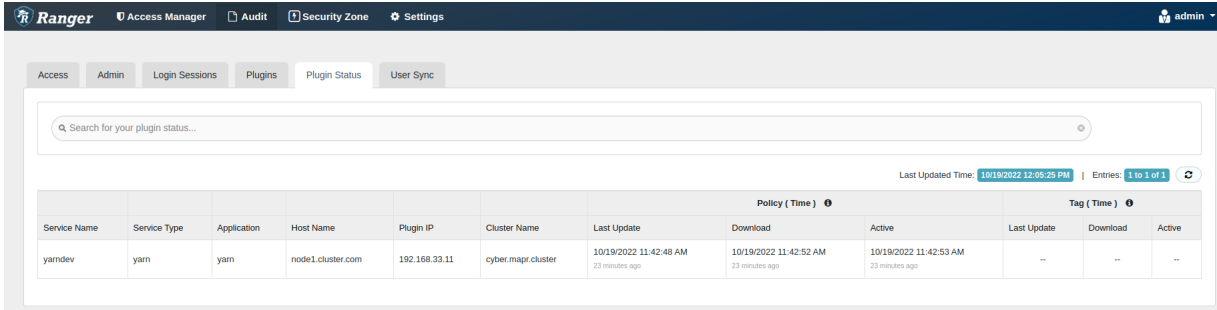

```
/opt/mapr/bin/maprcli node services -name resourcemanager -action
restart -nodes `hostname`
/opt/mapr/bin/maprcli node services -name nodemanager -action
restart -nodes `hostname`
```

Ranger adds the following property to `yarn-site.xml`:

```
<property>
  <name>yarn.authorization-provider</name>

  <value>org.apache.ranger.authorization.yarn.authorizer.RangerYarnAuthoriz
er</value>
</property>
```

- To verify that the plug-in is active, navigate to **Audit > Plugin Status**:

## Ranger Security and Data Fabric Security

Describes how Ranger security supplements the security features provided by the HPE Ezmeral Data Fabric.

### Ranger Manages Security for Ecosystem Components

Security for the HPE Ezmeral Data Fabric ensures that platform services can communicate securely and that users can successfully leverage those services. The HPE Ezmeral Data Fabric supports all four pillars of security (authentication, authorization, auditing, and encryption) without external security tools. The pillars are supported through a combination of technologies, including MapR-SASL, PAM, and tickets.

Ranger security provides an easy-to-use, optional security framework that is implemented on top of the existing platform security. Ranger allows you to manage security for HPE Ezmeral ecosystem components. Ranger is available for users who are migrating from other platforms and who want a familiar security interface on the HPE Ezmeral Data Fabric.

### Ranger Limitations

Ranger does not integrate with data-fabric platform security. You must manage Ranger security separately from Data Fabric security. To manage Ranger security, see [Getting Started with Ranger](#) on page 4597. To manage Data Fabric security, see [Security](#) on page 822.

You can use Ranger to manage security for ecosystem components if a Ranger plug-in is available to support the component. In EEP 9.0.0, Ranger provides security for Hive operations, as only the Hive plug-in is currently available. Other plug-ins are being developed to expand Ranger's capabilities on the Data Fabric platform.

While Data Fabric security can be extended to support a [secure trust relationship](#) between two or more clusters, using Ranger across multiple Data Fabric clusters is currently not supported.

### Data Fabric Security Invoked Before Ranger Security

Ranger is another component in the HPE Ezmeral Data Fabric ecosystem. Like the other ecosystem components, Ranger leverages platform security. Ranger services use Data Fabric security to communicate with each other. For example, Ranger clients (plug-ins) authenticate themselves to the Ranger Admin service using MapR-SASL tickets.

Using the Hive plug-in, Ranger can manage which users execute certain types of Hive Metastore queries. Both Hive and Ranger use MapR-SASL for service communications. Hive uses MapR-SASL for authentication, and also uses Ranger for authorization.

Data Fabric security is invoked before Ranger security. If a Ranger-authorized user attempts to perform an operation that the user is not authorized to perform on the platform, platform security disallows the operation. And the Ranger plug-in cannot enforce any rule governing the operation. For example, Ranger

is invoked only after Hive is started properly and accessed by a user who performs a query. Data Fabric security manages all of those operations.

### More information

[Security](#) on page 822

Provides an overview of the Data Fabric security features.

## Apache Spark

Apache Spark is an open-source processing engine that you can use to process Hadoop data. The following diagram shows the components involved in running Spark jobs. See [Spark Cluster Mode Overview](#) for additional component details.

HPE Ezmeral Data Fabric supports the following types of cluster managers:

- Spark's standalone cluster manager
- YARN

The configuration and operational steps for Spark differ based on the Spark mode you choose to install. The steps to integrate Spark with other components are the same when using either Standalone or YARN cluster mode, except where otherwise noted.

This section provides documentation about configuring and using Spark with HPE Ezmeral Data Fabric, but it does not duplicate the [Apache Spark](#) documentation.

You can also refer to additional documentation available on the [Apache Spark Product Page](#).

### Getting Started with Spark Interactive Shell

After you have a basic understanding of Apache Spark and have it installed and running on your cluster, you can use it to load datasets, apply schemas, and query data from the Spark interactive shell.

### Reading Data from file system

#### 1. Copy sample data into file system:

- For this example, the dataset constitutes a CSV file of a list of auctions.
- Download the file from GitHub: <https://github.com/mapr-demos/getting-started-spark-on-mapr/tree/master/data>.

- Copy the file into your cluster, in the `/apps/` directory, using the `cp/scp` or `hadoop put` command:

```
scp ./data/auctiondata.csv mapr@[mapr-cluster-node]:/mapr/[cluster-name]/
apps/
or
$ hadoop fs -put ./data/auctiondata.csv /apps
```

- This dataset is from eBay online auctions. The dataset contains the following fields:

```
auctionid - Unique identifier of an auction.
bid - Proxy bid placed by a bidder.
bidtime - Time (in days) that the bid was placed from the start of the
auction.
bidder - eBay username of the bidder.
bidderrate - eBay feedback rating of the bidder.
openbid - Opening bid set by the seller.
price - Closing price that the item sold for (equivalent to the second
highest bid + an increment).
item - Type of item.
```

The table below shows the fields with some sample data:

auctionid	bid	bidtime	bidder	bidderrate	openbid	price	item	daystolive
821303470 5	95	2.927373	jake7870	0	95	117.5	xbox	3

## 2. Start the Spark interactive shell:

- `$$SPARK_HOME` represents the home of your Spark installation in MapR, for example: `/opt/mapr/spark/spark-2.2.1/`.

```
$ $$SPARK_HOME/bin/spark-shell --master local[2]
```

## 3. Once the Spark shell is ready, load the dataset:

```
scala> val auctionData = spark.read.textFile("/apps/auctiondata.csv")
```

## 4. Display the first entry:

```
scala> auctionData.first()
```

## 5. Count the number of entries:

```
scala> auctionData.count()
```

## 6. Use other Spark actions:

```
// Displays first 20 lines
scala> auctionData.show()

// Displays first 3 lines - change value to see more/less
scala> auctionData.take(3)
```

7. Transform the dataset into a new one that contains only `xbox` lines, and count them:

```
scala> val auctionWithXbox = auctionData.filter(line =>
line.contains("xbox"))
scala> auctionWithXbox.count()
```

- This could also be done in a single line by chaining transformations and actions:

```
scala> auctionData.filter(line => line.contains("xbox")).count()
```

8. Use Spark Dataframes:

```
scala> val auctionDataFrame =
spark.read.format("csv").option("inferSchema",
true).load("/apps/
auctiondata.csv").toDF("auctionid", "bid", "bidtime", "bidder", "bidderrate",
"openbid", "price", "item", "daystolive")
```

9. Use a filter transformation on the Dataframe:

```
scala> auctionDataFrame.filter($"price" < 30).show()
```

**Figure 35: Schematic representation of performing transformations and actions on a dataset**

### Writing Data from file system

Using the same dataset, save all `xbox` items as a file in file system:

- You can use the `filter($"item" === "xbox")` filter and `write.json` or other options to save the result of the action to file system.

```
scala> auctionDataFrame.filter($"item" === "xbox").write.json("/apps/
results/json/xbox")
```

This command creates the `/apps/results/json/xbox` directory in which you will see the JSON file(s) created. You can use the same command to create Parquet or any other file format:

```
scala> auctionDataFrame.filter($"item" === "xbox").write.parquet("/apps/
results/parquet/xbox")
```

## Writing Data to HPE Ezmeral Data Fabric Database JSON

The first step when you are working with HPE Ezmeral Data Fabric Database JSON is to define a document `_id` that uniquely identifies the document.

Add a new `_id` field in the csv file and generate UUIDs to add to this field.

To load the Dataframe into the MapR-DB JSON:

```
dataframe.saveToMapRDB("tableName", createTable = true, bulkInsert = false,
idFieldPath = "_id")
```

The following commands will create a table and insert the data into: `/apps/auction_json_table`.

```
scala> import spark.implicits._
scala> import java.util.UUID
scala> import org.apache.spark.sql.SparkSession
scala> import org.apache.spark.sql.types._
scala> import org.apache.spark.sql.SaveMode
scala> import com.mapr.db.spark.sql._ // import the MapR-DB OJAI Connector
scala> val generateUUID = udf(() => UUID.randomUUID().toString) // create
UDF to generate UUID
scala> // showing that you can create your own schema
val customSchema =
  StructType(
    Array(
      StructField("actionid", StringType, true),
      StructField("bid", DoubleType, true),
      StructField("bidtime", DoubleType, true),
      StructField("bidder", StringType, true),
      StructField("bidderrate", IntegerType, true),
      StructField("openbid", DoubleType, true),
      StructField("price", DoubleType, true),
      StructField("item", StringType, true),
      StructField("daystolive", IntegerType, true)
    )
  )
```

You can now query the table using the HPE Ezmeral Data Fabric Database shell. Open a terminal on your cluster and run the following command:

```
$ mapr dbshell
maprdb mapr:> find /apps/auction_json_table --limit 10
```

## Reading Data from HPE Ezmeral Data Fabric Database JSON

Now that you have the data in HPE Ezmeral Data Fabric Database JSON, you can create and query a Spark Dataframe using the following commands:

```
scala> import com.mapr.db.spark.sql._
scala> import org.apache.spark.sql.Session
scala> val dataFromMapR = spark.loadFromMapRDB("/apps/auction_json_table")
scala> dataFromMapR.printSchema
scala> dataFromMapR.count

scala> dataFromMapR.filter($"price" < 30).show() // use a filter
```

### Related Links

- [Spark configure.sh](#) on page 4635
- [HPE Ezmeral Spark blog](#)

### Apache Spark Feature Support

HPE Ezmeral Data Fabric supports most Apache Spark features. However, there are some exceptions.

#### GPU Aware Scheduling Support on Spark

Starting from EEP 9.0.0, you can use RAPIDS Accelerator for Apache Spark by Nvidia to accelerate the processing for Spark by using the GPUs.

To use RAPIDS Accelerator on HPE Ezmeral Data Fabric:

1. Follow the setup instructions in the official RAPIDS documentation: [Getting Started](#) (link opens an external site in a new browser tab or window).
2. Set the Apache Spark version with the following option:

```
spark.rapids.shims-provider.override
```

The value for this option must be the name of a corresponding shim. You can find a list of available shims [here](#).

For example, to use the RAPIDS plugin with Spark version 3.3.2.100-ee9-912, you can set the version to 332 as follows:

```
spark.rapids.shims-provider.override=com.nvidia.spark.rapids.shims.spark332.SparkShimServiceProvider
```

For examples, limitations, and a full list of configuration details for RAPIDS, see [RAPIDS](#).

#### Delta Lake Support on Spark

Starting from EEP 8.x.x, Apache Spark 3 provides Delta Lake support on HPE Ezmeral Data Fabric.

Delta Lake is an open-source storage layer that supports ACID (Atomicity, Consistency, Isolation, and Durability) transactions to provide reliability, consistency, and scalability to Apache Spark applications. Delta Lake runs on the top of the existing

storage and is compatible with Apache Spark APIs. For more details, see [Delta Lake documentation](#).

You can use any Apache Spark APIs to read and write data with Delta Lake. Delta Lake stores the data in Parquet format as versioned Parquet files. Delta Lake has a well-defined open protocol called [Delta Transaction Protocol](#) that provides ACID transactions to Apache Spark applications.

To enable the Delta Lake:

1. Download the Delta Lake library from [Maven repository](#).
2. Add the Delta Lake library and set the following configuration options. For example:

```
/opt/mapr/spark/spark-3.1.2/bin/
spark-shell --jars ~/
delta-core_2.1.2-1.0.0.jar
--conf "spark.sql.extensions"=
io.delta.sql.DeltaSparkSessionExten
sion
--conf
"spark.sql.catalog.spark_catalog"=
org.apache.spark.sql.delta.catalog.
DeltaCatalog
```

Delta Lake stores the commits of every successful transaction (Spark job) as a DeltaLog or a Delta Lake transaction log.

For example: You can view these commit logs on MinIO Browser by navigating to `<table_name>/_delta_Log/`.

Commits in the transaction log:

```
/<table_name>/_delta_log/
00000000000000000000000000000000.json
/<table_name>/_delta_log/
00000000000000000000000000000001.json
/<table_name>/_delta_log/
00000000000000000000000000000003.json
```

Delta lake uses optimistic concurrency control to provide ACID transactions between writes operation. See [Concurrency Control](#).

To accelerate the data lake operations, use optimizations provided by Delta Lake. Z-Ordering method is used to combine related information in the same files. Delta Lake automatically maintains minimum and maximum values for each column in delta table and stores these values as part of the metadata. The co-location of related information is used by Delta Lake in data skipping algorithm which optimizes performance by reducing the amount of data to be read by Apache Spark. To learn more, see [Optimizations](#).

See [Setup Apache Spark with Delta Lake](#) and [Advanced Dependency Management](#) to start using Delta Lake.

**Spark SQL and Apache Derby Support on Spark**

If you are using Spark SQL with Derby database without Hive or Hive Metastore installation, you will see the following exception:

```
java.lang.RuntimeException: Unable to
instantiate
org.apache.hadoop.hive.ql.metadata.Ses
sionHiveMetaStoreClient
```

Add the `hive-service-2.3.*.jar` and `log4j2` jars to `/opt/mapr/spark/spark-3.x.x/jars` location to use Spark SQL with Derby Database without Hive or Hive Metastore installation.

The `log4j2` jars are located at `/opt/mapr/lib/log4j2/log4j-*.jar` location.

Spark 3.1.2 and Spark 3.2.0 does not support `log4j1.2` logging on HPE Ezmeral Data Fabric.

**Spark Thrift JDBC/ODBC Server Support**

Running the Spark Thrift JDBC/ODBC Server on a secure cluster is supported only on Spark 2.1.0 or later.

You can run the Spark Thrift JDBC/ODBC Server to enable connections to Hive 1.2.1 using Beeline; however, you can connect only to Hive versions supported by your Spark version.

**Spark SQL and Hive Support for Spark 2.1.0**

Spark 2.1.0 is able to connect to Hive 2.1 Metastore; however, only features of Hive 1.2 are supported.

**Spark SQL and Hive Support for Spark 2.0.1**

Spark SQL is supported, but it is not fully compatible with Hive. For details, see the [Apache Spark documentation](#).

The following Hive functions are not supported in Spark SQL:

- Tables with buckets
- UNION type
- Unique join
- Column statistics collecting
- Output formats: File format (for CLI), Hadoop Archive
- Block-level bitmap indexes and virtual columns
- Automatic determination of the number of reducers for JOIN and GROUP BY
- Metadata-only query
- Skew data flag
- STREAMTABLE hint in JOIN
- Merging of multiple small files for query results

**Spark SQL and Hive Support for Spark 1.6.1**

Spark SQL is supported, but it is not fully compatible with Hive. For details, see the [Apache Spark documentation](#). The following Spark SQL operations support the following Hive table formats:

	Hive 1.2 Table Format				
Spark SQL Operations	AVRO	ORC	Parquet	RC	default
create	Yes	Yes	Yes	Yes	Yes
drop	Yes	Yes	Yes	Yes	Yes
insert into	Yes	Yes	Yes	Yes	Yes
insert overwrite	Yes	Yes	Yes	Yes	Yes
select	Yes	Yes	Yes	Yes	Yes
load data	Yes	Yes	Yes	Yes	Yes

### Iceberg Support

Describes support for Iceberg in HPE Ezmeral Data Fabric 7.6.x.

### Apache Iceberg

Apache Iceberg is an open-source table format that helps to simplify the data processing of huge data sets on a file system or object store. Iceberg brings the simplicity of SQL tables to huge data sets.

Iceberg has the following capabilities:

- Iceberg tables are fast, safe, scalable, and can easily integrate with analytics engines like Spark, PrestoDB, Hive, and so on.
- Iceberg supports Atomicity, Consistency, Isolation, and Durability (ACID) transactions.
- You can use analytics engines like Spark, PrestoDB, Hive, and Impala to safely perform ACID transactions on the same table at the same time.
- Iceberg supports schema evolution, hidden partitioning, partition layout evolution, and time travel, which minimize unpleasant surprises.

For details, see the [Apache Iceberg](#) documentation.

### Data Fabric and Iceberg

Starting from Data Fabric 7.6.x, you can perform the following operations in the HPE Ezmeral Data Fabric Object Store:

- Create a schema for Avro, ORC, or Parquet data types, and modify the schema if needed.
- Create Iceberg tables using a specific schema and perform ACID transactions.
- Create a snapshot of a table to check time travel.
- Grant access permissions for an Iceberg table to different users.
- Perform data migration of data files into an Iceberg table, as well as migrate the metadata.
- Query an Iceberg table through Apache Spark.

- Create an Iceberg table in an external S3 bucket and query it through the HPE Ezmeral Data Fabric Object Store.

With these features, you can build a reliable and scalable Data-Lakehouse architecture.

### Getting Started with Iceberg

Summarizes what you need to know to begin using Iceberg with HPE Ezmeral Data Fabric release 7.6.x.

### Version Support

HPE Ezmeral Data Fabric 7.6.x has been tested with:

- [Iceberg 1.4.2](#)
- [mapr-spark-3.3.3.0](#)
- [iceberg-spark-runtime-3.3\\_2.12-1.4.2.jar](#)

Other data-processing engines, such as open-source Spark, PrestoDB, Flink, and data-processing technologies, such as Snowflake, have not been tested.

### Catalog Support

Catalogs manage the metadata for datasets and tables in Iceberg. You must specify the catalog when interacting with Iceberg tables through Spark. The following built-in catalogs have been tested for use with Data Fabric 7.6.x:

- HiveCatalog
- HadoopCatalog

### Spark Setup for Iceberg

Setting up Spark to use Iceberg is a two-step process:

1. Add the `org.apache.iceberg:iceberg-spark-runtime-<spark.version>_<scala.version>:<iceberg.version>` jar file to your application classpath. Add the runtime to the `jars` folder in your `spark` directory. Add it directly to the application classpath by using the `--package` or `--jars` option.
2. Configure a catalog. For information about using catalogs with Iceberg, see [Catalogs](#).

For examples, see the [Spark and Iceberg Quickstart](#).

### Configuring Your Spark Application

Consider adding the following parameters to your Spark application:

```
spark.sql.catalog.<catalog_name>.type=hive
spark.sql.catalog.<catalog_name>.warehouse=<path_to_your_warehouse>
spark.sql.catalog.<catalog_name>=org.apache.iceberg.spark.SparkSessionCatalog
spark.sql.legacy.pathOptionBehavior.enabled=true
```

### Spark Standalone

This section includes topics about configuring and using Spark in Standalone mode.

To integrate Spark with other ecosystem components, see [Integrating Spark](#).

For additional documentation, see the [Apache Spark](#) website.

## Installing Spark Standalone

This topic describes how to use package managers to download and install Spark Standalone from the EEP repository.

### Prerequisites

To set up the EEP repository, see [Step 11: Install Ecosystem Components Manually](#) on page 225.

### About this task

Spark is distributed as four separate packages:

Package	Description
mapr-spark	Install this package on any node where you want to install Spark. This package is dependent on the <code>mapr-client</code> , <code>mapr-hadoop-client</code> , <code>mapr-hadoop-util</code> , and <code>mapr-librdkafka</code> packages.
mapr-spark-master	Install this package on Spark master nodes. Spark master nodes must be able to communicate with Spark worker nodes over SSH without using passwords. This package is dependent on the <code>mapr-spark</code> and the <code>mapr-core</code> packages.
mapr-spark-historyserver	Install this optional package on Spark History Server nodes. This package is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.
mapr-spark-thriftserver	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.

Run the following commands as `root` or using `sudo`.

### Procedure

1. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory.

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

**NOTE:** Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically.

2. Install Spark using the appropriate commands for your operating system:

#### On CentOS 8.x / Red Hat 8.x

```
dnf install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On Ubuntu

```
apt-get install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On SLES

```
zypper install
mapr-spark mapr-spark-master
```

```
mapr-spark-historyserver
mapr-spark-thriftserver
```

**NOTE:** The `mapr-spark-historyserver`, `mapr-spark-master`, and `mapr-spark-thriftserver` packages are optional.

Spark is installed into the `/opt/mapr/spark` directory.

### 3. For Spark 2.x:

Copy the `/opt/mapr/spark/spark-<version>/conf/slaves.template` into `/opt/mapr/spark/spark-<version>/conf/slaves`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

For Spark 3.x:

Copy the `/opt/mapr/spark/spark-<version>/conf/workers.template` into `/opt/mapr/spark/spark-<version>/conf/workers`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

Put one worker node hostname on each line.

For example:

```
localhost
worker-node-1
worker-node-2
```

### 4. Set up [passwordless ssh](#) for the `mapr` user such that the Spark master node has access to all secondary nodes defined in the `conf/slaves` file for Spark 2.x and `conf/workers` file for Spark 3.x.

### 5. As the `mapr` user, start the worker nodes by running the following command in the master node. Since the Master daemon is managed by the Warden daemon, do not use the `start-all.sh` or `stop-all.sh` command.

For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
```

For Spark 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-workers.sh
```

### 6. If you want to integrate Spark with HPE Ezmeral Data Fabric Streams, install the Streams Client on each Spark node:

- On Ubuntu:

```
apt-get install mapr-kafka
```

- On RedHat/CentOS:

```
yum install mapr-kafka
```

### 7. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the HPE Ezmeral Data Fabric Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).

- After installing Spark Standalone but before running your Spark jobs, follow the steps outlined at [Configuring Spark Standalone](#) on page 4627.

### Configuring Spark Standalone

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run `configure.sh -R` as the final step in the configuration process.

#### *Configure High Availability for SparkMaster*

You configure high availability for the Spark Primary instance so that the instance does not become the single point of failure.

By using ZooKeeper to provide leader election and some state storage, you can launch multiple primary nodes in your cluster that are connected to the same ZooKeeper instance. Zookeeper elects one primary node to be the “leader,” and the others remain in standby mode. If the leader goes down, Zookeeper elects another primary node, recovers the old primary node's state, and resumes scheduling.

- Set `SPARK_DAEMON_JAVA_OPTS` in `spark-env.sh` with the appropriate ZooKeeper information for the cluster.

```
export SPARK_DAEMON_JAVA_OPTS="-Dspark.deploy.recoveryMode=ZOOKEEPER
-Dspark.deploy.zookeeper.url=<zookeeper1:5181,zookeeper2:5181,...>
-Djava.security.auth.login.config=/opt/mapr/conf/
mapr.login.conf -Dzookeeper.sasl.client=false
```

- Restart the Spark Primary instance and Spark History Server services:

- For Spark 2.0.1 and later:

```
maprcli node services -nodes <node-ip> -name spark-master -action
restart
```

- For Spark 1.6.1:

```
maprcli node services -nodes <node-ip> -name spark-master -action
restart
maprcli node services -nodes <node-ip> -name
spark-historyserver -action restart
```

- On the primary node, restart the Spark Secondary instances as the `mapr` user.

For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-slaves.sh
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
```

For Spark 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-workers.sh
/opt/mapr/spark/spark-<version>/sbin/start-workers.sh
```

#### *Configure Scratch Directory for Spark Standalone*

By default, Spark uses the `/tmp` directory as scratch space. Map output files and RDDs are stored in the scratch directory. To use a different directory, or a comma-separated list of multiple directories, set

SPARK\_LOCAL\_DIRS to the path to the new directory by adding the following line to the `$SPARK_HOME/conf/spark-env.sh` file:

```
export SPARK_LOCAL_DIRS=$SPARK_HOME/<path to scratch directory>
```

Make this change before starting the Spark services.

### Community Edition (Without NFS Support)

Reserve space on your local disk to use as the scratch directory for Spark.

### Enterprise Edition and Enterprise Database Edition (With NFS Support)

Create a local volume on each node with the `maprcli volume create` command, or from the Control System. Mount that local volume with NFS to a directory. Set that directory as the scratch directory for Spark.

**NOTE:** Due to <https://issues.apache.org/jira/browse/SPARK-6313>, make sure to set `spark.files.useFetchCache=false` in your `spark-defaults.conf` file.

### Using Spark Standalone

For a simple test of your Spark installation, run the following command:

- On Spark 2.0.1 or later:

```
/opt/mapr/spark/spark-<version>/bin/run-example --master spark://<Spark Master node hostname>:7077 SparkPi 10
```

- On Spark 1.6.1:

```
MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/spark-<version>/bin/run-example org.apache.spark.examples.SparkPi 10
```

For more information about running Spark applications, see the [Apache Spark Documentation](#).

*Run the Spark Shell in Standalone Mode*

### Procedure

- To run the Spark shell, use the following command:

- On Spark 2.0.1 and later:

```
/opt/mapr/spark/spark-<version>/bin/spark-shell --master spark://<Spark Master node hostname>:7077
```

- On Spark 1.6.1:

```
MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/spark-<version>/bin/spark-shell
```

### Security with Spark Standalone

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the Data Fabric installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure

clusters. See [Spark configure.sh](#) on page 4635 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

## Spark on YARN

This section contains topics about installing, configuring and using Spark on YARN.

 **IMPORTANT:** Spark 2.0.1 (and later) YARN mode is supported only on clusters in MRv2 (YARN) mode. It is not supported on clusters in MRv1 (classic) mode.

To integrate Spark with other ecosystem components, see [Integrating Spark](#) on page 4710

For additional documentation, see the [Apache Spark](#) documentation.

## Installing Spark on YARN

Describes how to use package managers to download and install Spark on YARN from the EEP repository.

### Prerequisites

To set up the EEP repository, see [Step 11: Install Ecosystem Components Manually](#) on page 225.

### About this task

Spark is distributed as three separate packages:

Package	Description
<code>mapr-spark</code>	Install this package on any node where you want to install Spark. This package is dependent on the following packages: <ul style="list-style-type: none"> <li><code>mapr-client</code></li> <li><code>mapr-hadoop-client</code></li> <li><code>mapr-hadoop-util</code></li> <li><code>mapr-librdkafka</code></li> </ul>
<code>mapr-spark-historyserver</code>	Install this optional package on Spark History Server nodes. This package is dependent on the following packages: <ul style="list-style-type: none"> <li><code>mapr-spark</code></li> <li><code>mapr-core</code></li> </ul>
<code>mapr-spark-thriftserver</code>	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. This package is dependent on the following packages: <ul style="list-style-type: none"> <li><code>mapr-spark</code></li> <li><code>mapr-core</code></li> </ul>

To install Spark on YARN (Hadoop 2), execute the following commands as `root` or using `sudo`:

### Procedure

1. Verify that JDK 11 or later is installed on the node where you want to install Spark.

2. Create the `/apps/spark` directory on the cluster file system, and set the correct permissions on the directory:

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

**NOTE:** Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically when using the Installer. However, you must manually create this directory when performing a manual installation.

3. Install the packages:

#### On Ubuntu

```
apt-get install
mapr-spark mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On Red Hat / Rocky

```
dnf install mapr-spark
mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On SLES

```
zypper install
mapr-spark mapr-spark-historyserver
mapr-spark-thriftserver
```

**NOTE:** The `mapr-spark-historyserver` and `mapr-spark-thriftserver` packages are optional.

4. If you want to integrate Spark with HPE Ezmeral Data Fabric Streams, install the Streams Client on each Spark node:

- **On Ubuntu:**

```
apt-get install mapr-kafka
```

- **On Red Hat / Rocky:**

```
yum install mapr-kafka
```

5. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the Data Fabric Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).

For repository-specific information, see [Maven Artifacts for the HPE Ezmeral Data Fabric](#) on page 4759

6. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

7. After installing Spark on YARN but before running your Spark jobs, follow the steps outlined in [Configuring Spark on YARN](#) on page 4630.

## Configuring Spark on YARN

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run `configure.sh -R` as the final step in the configuration process.

### *Configure Data Fabric Client Node to Run Spark Applications*

When Spark runs on YARN, Data Fabric client nodes require the `hadoop-yarn-server-web-proxy` JAR file to run Spark applications. On Windows, the client node also requires an update to the `SPARK_DIST_CLASSPATH`. A Data Fabric client node (a node with the `mapr-client` package, but without `mapr-core` packages) is also known as an edge node.

The `mapr-client` package does not include the JAR file required to run Spark applications. Therefore, you must copy the following JAR file from a Data Fabric cluster node to the same location on the Data Fabric client node where you want to run the Spark application:

```
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/
hadoop-yarn-server-web-proxy-<version>.jar
```

For example, here is a JAR file path for Hadoop 3.3.5:

```
/opt/mapr/hadoop/hadoop-3.3.5/share/hadoop/yarn/
hadoop-yarn-server-web-proxy-3.3.5.100-ee-920.jar
```

### *Configure Spark JAR Location*

#### **About this task**

By default, Spark on YARN uses Spark JAR files that are installed locally. The Spark JAR files can also be added to a world-readable location on file system. When you add the JAR files to a world-readable location, YARN can cache them on nodes to avoid distributing them each time an application runs. Complete the following steps to add the Spark JAR files to a world-readable location on file system:

#### **Procedure**

1. Create a zip archive containing all the JARs from the `SPARK_HOME/jars` directory. For example:

```
cd /opt/mapr/spark/spark-<version>/jars/
zip /opt/mapr/spark/spark-<version>/spark-jars.zip ./*
```

2. Copy the zip file from the local filesystem to a world-readable location on file system. You can upload it to the home of the current user:

```
hadoop fs -put /opt/mapr/spark/spark-<version>/spark-jars.zip
```

For example:

```
hadoop fs -put /opt/mapr/spark/spark-3.2.0/spark-jars.zip /user/mapr/
```

3. Set the `spark.yarn.archive` property in the `spark-defaults.conf` file located in `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` to point to the world-readable location where you added the zip file. Apply this setting on the node where you will be submitting your Spark jobs.

```
spark.yarn.archive maprfs:///<path to zip>
```

For example:

```
spark.yarn.archive maprfs:///user/mapr/spark-jars.zip
```

### *Configure Spark with the NodeManager Local Directory Set to file system*

#### **About this task**

This procedure configures Spark to use the mounted NFS directory instead of the `/tmp` directory on the local file system. Note that spill to disk should be configured to spill to the file system node local storage only if local disks are unavailable or space is limited on those disks.

#### **Procedure**

1. Install the `mapr-loopbacknfs` and `nfs-utils` packages if they are not already installed. For reference, see [Installing the mapr-loopbacknfs Package](#) on page 424 and [Setting Up Data Fabric NFS](#).
2. Start the `mapr-loopbacknfs` service by following the steps at [Managing the mapr-loopbacknfs Service](#) on page 1603.
3. To configure Spark Shuffle on NFS, complete these steps **on all nodes**:
  - a) Create a local volume for Spark Shuffle:

```
sudo -u mapr maprcli volume
create -name mapr.${hostname -f}.local.spark -path /var/mapr/local/${
hostname -f}/spark -replication 1 -localvolumehost ${hostname -f}
```

- b) Point the NodeManager local directory to the Spark Shuffle volume mounted through NFS by setting the following property in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml` file on the NodeManager nodes:

```
<property>
  <name>yarn.nodemanager.local-dirs</name>
  <value>/mapr/my.cluster.com/var/mapr/local/${mapr.host}/spark</
value>
</property>
```

- c) (Optional) Configure how many times the NodeManager can attempt to delete application-related directories from a volume when Spark is configured to use the mounted NFS directory instead of the `/tmp` directory on the local file system. Increasing the value (default is 2) of this property can prevent application cache data from accumulating in the volume. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See [Applying a Patch](#).

```
<property>
  <name>yarn.nodemanager.max-retry-file-delete</name>
  <value>2</value>
</property>
```

- d) Restart the NodeManager service and the Resource Manager service on the main node to pick up the `yarn-site.xml` changes:

```
maprcli node services -name nodemanager -action restart -nodes <node
1> <node 2> <node 3>
maprcli node services -name resourcemanager -action restart -nodes
<node 1> <node 2> <node 3>
```

### Using Spark on YARN

This section includes information about using Spark on YARN in a data-fabric cluster.

For a simple test of your Spark installation, run the following command as the `mapr` user:

- On Spark 2.0.1 or later:

```
/opt/mapr/spark/spark-<version>/bin/run-example --master
yarn --deploy-mode client SparkPi 10
```

- On Spark 1.6.1:

```
MASTER=yarn-client /opt/mapr/spark/spark-<version>/bin/run-example
org.apache.spark.examples.SparkPi 10
```

**NOTE:** These commands will fail if it is run as the root user.

For more information about running Spark applications, see the [Apache Spark documentation](#).

#### *Deployment Modes*

Spark is preconfigured for YARN and does not require any additional configuration to run.

Two deployment modes can be used to launch Spark applications on YARN:

- In `cluster` mode, jobs are managed by the YARN cluster. The Spark driver runs inside an Application Master (AM) process that is managed by YARN. This means that the client can go away after initiating the application.
- In `client` mode, the Spark driver runs in the client process, and the Application Master is used only to request resources from YARN.

MapR recommends using `cluster` deployment mode instead of `client` mode. If the Spark client that runs the job exits after submitting the job, there is no impact on job completion.

**Note:** In `cluster` deployment mode, the local directories used by the Spark executors and the Spark driver are the local directories that are configured for YARN (`yarn.nodemanager.local-dirs`).

**NOTE:** `SPARK_LOCAL_DIRS` is ignored when you run Spark on YARN.

#### *Run Spark from the Spark Shell*

#### **About this task**

In `yarn-client` mode, complete the following steps to run Spark from the Spark shell:

#### **Procedure**

1. Navigate to the Spark-on-YARN installation directory, and insert your Spark version into the command.

```
cd /opt/mapr/spark/spark-<version>/
```

2. Issue the following command to run Spark from the Spark shell:

- On Spark 2.0.1 and later:

```
./bin/spark-shell --master yarn --deploy-mode client
```

- On Spark 1.6.1:

```
MASTER=yarn-client ./bin/spark-shell
```

**NOTE:** You must use `yarn-client` mode to run Spark from the Spark shell. The `yarn-cluster` mode is not supported.

## Security with Spark on YARN

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the Data Fabric installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure clusters. See [Spark configure.sh](#) on page 4635 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

*Configure SSL Encryption for Spark on YARN*

### Prerequisites

Starting in EEP 8.0.0, if you are Non-Admin user starting a Spark Application, you must generate the KeyStore and KeyStore password and set it in Spark configuration files. For details, see [Security - Spark 3.1.2 Documentation](#). Otherwise, KeyStore and default KeyStore password generates automatically.

Starting in EEP 6.0.0, you can remove `spark.ssl.keyStorePassword`, `spark.ssl.trustStorePassword`, and `spark.ssl.keyPassword` from the `spark-defaults.conf` file for additional security. These passwords are stored in the `/opt/mapr/conf/ssl-client.xml` file and Spark can access passwords from this file itself.

**NOTE:** If passwords are present in both `/opt/mapr/conf/ssl-client.xml` and `/opt/mapr/spark/spark-2.3.1/conf/spark-defaults.conf` files, then the password from the `spark-defaults.conf` file is used.

### About this task

Complete the following step to manually configure encryption for the Spark HTTP file and broadcast servers:

### Procedure

In the `spark-defaults.conf` file on each spark node, configure the following properties. Starting in EEP 6.0.0, the configured algorithms mentioned in the following code are no longer available for your web service to pick up. You must remove the `spark.ssl.enabledAlgorithms TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA` line to let parties negotiate the matching ciphers.

- For Spark 2.0.1 and later:

```
spark.ssl.fs.enabled true
spark.ssl.keyPassword <ssl-keystore-password>
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.keyStorePassword <ssl-keystore-password>
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.protocol TLSv1.2
spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA
```

**NOTE:** Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#), as the final step in the configuration process, enables these settings.

- For Spark 1.6.1:

```
spark.ssl.akka.enabled true
spark.ssl.fs.enabled true
spark.ssl.keyPassword <ssl-keystore-password>
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.keyStorePassword <ssl-keystore-password>
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.protocol TLSv1.2
spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA
```

Spark UI SSL is not needed when running Spark on YARN because encryption is provided by the YARN protocol. **For versions prior to EEP 4.1.0**, to enable users logged in with a normal user account (not mapr or root) to run spark jobs on the cluster, disable Spark SSL for Spark-on-YARN jobs. To disable Spark SSL, add `spark.ssl.ui.enabled false` to the `spark-defaults.conf` file on each spark node. The `spark-defaults.conf` file is in the following location: `/opt/mapr/spark/spark-<version>/conf/`. Make sure SSL is enabled for the Spark history server.

When you manually configure encryption for Spark, set the same protocol and algorithms for each node. Otherwise, the connection between those components might fail.

### Spark `configure.sh`

Starting in the EEP 4.0 release, run `configure.sh -R` to complete your Spark configuration when manually installing Spark or upgrading to a new version.

The command is the following:

```
/opt/mapr/server/configure.sh -R
```

**NOTE:** You do not need to run this script for new installs, if you are using the Installer in EEP 4.0 or later.

In the case of [Spark Standalone](#) on page 4624 and [Spark on YARN](#) on page 4629, this is the last step in the configuration process.

All security configuration properties are specified within the following comment block in the `SPARK_HOME/conf/spark-defaults.conf` file:

```
#SECURITY BLOCK
...
#END OF THE SECURITY CONFIGURATION BLOCK
```

Do not remove these comments from the file, as well as any other comments within the block inserted by `configure.sh`. The script uses these comments to locate security properties.

To set ports to special values, use the `spark.driver.port` and `spark.blockManager.port` properties.

Starting in EEP 6.0.0, Spark services such as the History Server, Thrift Server, or Primary are restarted by `configure.sh` only for changes to the following Spark configuration files: `spark-defaults.conf`, `spark-env.sh`, `hive-site.xml`, or `log4j.properties`. If these files are unchanged, `configure.sh` does not restart any of the Spark services.

An update to Spark causes the `conf` directory from the previous the Spark version to be saved to the `spark-<old-version>.<old-timestamp>` directory. If your Spark version did not change during the update, then configurations from the `spark-<old-version>.<old-timestamp>` directory is automatically copied to the `spark-<version>` directory by the `configure.sh` script.

If you use `.customSecure`, at the first run, the `configure.sh` script copies the `hive-site.xml` file from Hive. For subsequent times, the `hive-site.xml` file is not copied from Hive and you would need to manually modify the `$SPARK_HOME/conf/hive-site.xml` file.

### Related concepts

[Customizing Security in HPE Ezmeral Data Fabric](#) on page 1933

Describes the `.customSecure` file and how HPE Ezmeral Data Fabric 6.x handles custom security settings.

### Spark SQL Thrift Server

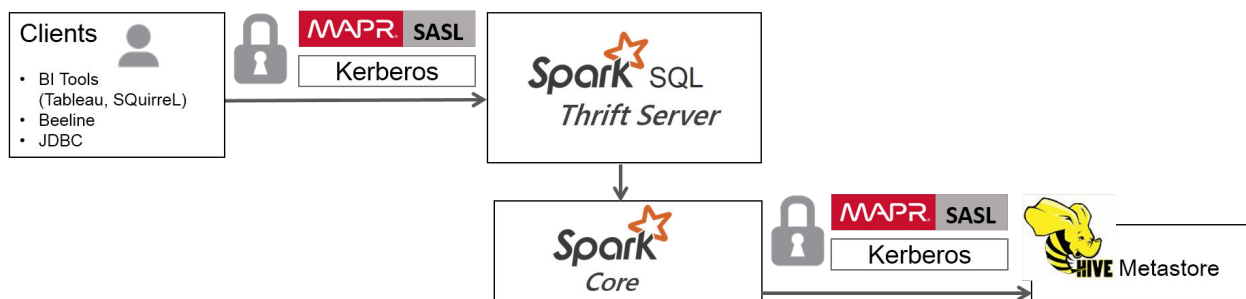

Spark SQL Thrift (Spark Thrift) was developed from Apache Hive HiveServer2 and operates like HiveServer2 Thrift server.

Spark Thrift is supported on secure clusters. You can run the Spark Thrift server and connect to Hive versions supported by Spark 2.1.0 and later with Business Intelligence (BI) tools or the Beeline command-line tool.

Starting in the EEP 4.0 release, the Spark Thrift server is available as a separate package. To install this package, see [Installing Spark Standalone](#) on page 259 or [Installing Spark on YARN](#) on page 261, depending on the type of cluster manager you are installing.

In EEP 3.0, MapR introduces additional security mechanisms for Spark with the Spark Thrift server. MapR-SASL and Kerberos are supported:

- For JDBC connections into Spark Thrift server
- Between Spark and Hive metastore

To enable these security mechanisms for the Spark Thrift server, starting in the EEP 4.0 release, for secure clusters, running `configure.sh -R` configures MapR-SASL security. The script modifies or creates a `SPARK_HOME/conf/hive-site.xml` file as follows:

- If Hive is installed in your cluster, the script copies `HIVE_HOME/conf/hive-site.xml` to `SPARK_HOME/conf` and modifies the file.
- If Hive is not installed and you are using MapR-SASL security, the script creates a new `SPARK_HOME/conf/hive-site.xml` file.
- Each time the script runs, if there is a pre-existing `SPARK_HOME/conf/hive-site.xml` file, the script saves a copy of the file in `SPARK_HOME/conf/hive-site.xml.old` before modifying it.

You can configure security manually by following the steps outlined in sub-topics listed on this page.

To launch the Spark Thrift server, perform the procedures required to configure [Apache Spark](#) on page 4616 to use [Hive](#) on page 4163.

#### **IMPORTANT:**

- Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 10000.
- Starting in the EEP 5.0.4 and EEP 6.3.0 releases, if you start and stop the Spark Thrift server by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 2304.

#### **Default Behavior**

The default behavior of the Spark Thrift server is as follows:

1. After installation, the Spark Thrift server is started in the local master mode.
2. If the Spark master package is installed, then Spark Thrift server is started in the standalone master mode.
3. If the `spark.master` property is set in the `spark-defaults.conf` file, then Spark Thrift server uses the master set by this property.

#### **Known Limitations**

- MapR-SASL support is implemented for Spark 2.1.0 and later versions of Spark. For Spark version information, see [Component Versions for Released EEPs](#) on page 5783.
- The ODBC drivers do not support MAPR-SASL.
- Username and password authentication through PAM is not supported in EEP 3.0.
- Spark Thrift server supports only features and commands in Hive 1.2.
- Although Spark 2.1.0 can connect to Hive 2.1 Metastore, only Hive 1.2 features and commands are supported by Spark 2.1.0.

#### **Related Links**

For information related to Spark Thrift server, see:

MapR	Apache
<ul style="list-style-type: none"> <li>• <a href="#">Hive Release Notes</a> on page 5951</li> <li>• <a href="#">Hive and Tez</a></li> <li>• <a href="#">Integrate Spark SQL with Hive</a></li> <li>• <a href="#">Hive</a></li> <li>• <a href="#">Authentication for HiveServer2</a></li> <li>• <a href="#">Spark Feature Support</a></li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Apache Spark 2.1.0 Security</a></li> <li>• <a href="#">Apache Thrift</a></li> <li>• <a href="#">Setting Up HiveServer2</a></li> </ul>

### Spark Thrift Server Clients

With Spark Thrift server, you can use JDBC and ODBC connection interfaces that enable a variety of external tools to access Spark and run SQL queries.

- The ODBC interface is used by BI tools (often produced by HPE Ezmeral Data Fabric partners such as [Tableau](#) or [Microstrategy](#)).
- The JDBC interface is used by clients such as Squirrel SQL or the Beeline simple SQL shell.

Data Fabric Hive JDBC clients that connect to HiveServer2 can also connect to Spark Thrift server without additional configuration. For details about clients, see [HiveServer2 Clients](#) and [Connecting to HiveServer2](#).

**!** **IMPORTANT:** Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number is 10000. Beginning with EEP 6.3.0, the connection port number is 2304 for both start/stop methods (using Warden and using `thriftserver.sh` scripts).

### MapR-SASL JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for MapR-SASL environments is:

```
jdbc:hive2://<hostname>:2304/default;auth=maprsasl;ssl=true
```

Otherwise, the port you use depends on the EEP version:

<b>EEP 4.0 through 6.2.x</b>	<code>jdbc:hive2://&lt;hostname&gt;:10000/default;auth=maprsasl;ssl=true</code>
<b>EEP 6.3.0 and later</b>	<code>jdbc:hive2://&lt;hostname&gt;:2304/default;auth=maprsasl;ssl=true</code>

### Kerberos JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for clusters secured with Kerberos is:

```
jdbc:hive2://<hostname>:2304/default;principal=mapr/<FQDN@REALM>;ssl=true
```

Otherwise, the port you use depends on the EEP version:

<b>EEP 4.0 through 6.2.x</b>	<code>jdbc:hive2://&lt;hostname&gt;:10000/default;principal=mapr/&lt;FQDN@REALM&gt;;ssl=true</code>
<b>EEP 6.3.0 and later</b>	<code>jdbc:hive2://&lt;hostname&gt;:2304/default;principal=mapr/&lt;FQDN@REALM&gt;;ssl=true</code>

### Starting the Thrift Server on a Custom Port

To start the Spark Thrift Server on a custom port, use the `hive.server2.thrift.port` option. For example, you can specify the following in the `/opt/mapr/spark/spark-2.4.4/conf/hive-site.xml` file:

```
<property>
<name>hive.server2.thrift.port</name>
<value>34512</value>
</property>
```

For more information, see the [Apache HiveServer2](#) documentation.

### Using Authentication with Spark Thrift Server

Spark Thrift server supports both MapR-SASL and Kerberos authentication. The authentication method that you configure for the Spark Thrift server determines how the connection is secured. Clients might require additional configuration and specific connection strings based on the authentication type.

To enable authentication, see:

- [Configuring Spark Thrift Server with MapR-SASL](#) on page 4639
- [Configuring Spark Thrift Server with Kerberos](#) on page 4640

To configure PAM for Spark Thriftserver, run `configure.sh` on the secure cluster.

For information about Hive integration, see:

- [Integrate Spark SQL with Hive](#)
- [Setting Up HiveServer2](#)
- [Hive](#)
- [Spark Feature Support](#)

### Configuring Spark Thrift Server with MapR-SASL

Describes how to enable and start the Spark Thrift server on all nodes.

You can configure Spark Thrift server to use MapR-SASL for its communications with various components on a secure data-fabric cluster. Minimal configuration is required.

**NOTE:** Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done through the 6.0 Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

To manually enable MapR-SASL authentication on a non-secure cluster or in versions earlier than EEP 4.0:

1. Verify that the `hive.server2.authentication` property in `hive-site.xml` is set to the value, `MAPRSASL`.

```
<property>
  <name>hive.server2.authentication</name>
  <value>MAPRSASL</value>
</property>
```

2. Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/`.

**IMPORTANT:** The data-fabric administrative user (generally, the account named `mapr`) should start the Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

### Bringing up the Spark Thrift server on every node

When you start and stop Warden after enabling Spark or after running [configure.sh](#) on page 2826 or after installing a patch, Spark starts only on one (1) node and not on all nodes. This happens because by default, the Warden configuration file for Spark has the value `1` instead of `all`. For example:

```
# grep services /opt/mapr/conf/conf.d/warden.spark-thriftserver.conf
services=spark-thriftserver:1:cldb
```

To fix this issue permanently:

1. Modify `/opt/mapr/spark/spark-2.4.0/warden/warden.spark-thriftserver.conf` and change `1` to `all`:

```
# grep services /opt/mapr/spark/spark-2.4.0/warden/
warden.spark-thriftserver.conf
      services=spark-thriftserver:all:cldb
```

2. Run `/opt/mapr/server/configure.sh -R`.

The change is then propagated to the `/opt/mapr/conf/conf.d/warden.spark-thriftserver.conf` file.

### Configuring Spark Thrift Server with Kerberos

You can configure Spark Thrift server to use Kerberos for its communications with various components on a secure Data Fabric cluster if necessary.

**NOTE:** Data Fabric clusters do not provide Kerberos infrastructure. The information in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

To enable Kerberos authentication:

1. Create a Kerberos identity and keytab. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file.
  - The `hive.keytab` file must be owned and readable only by the `mapr` user.

- FQDN@REALM is case-sensitive.

```
# kadmin
: addprinc -randkey mapr/<FQDN@REALM>
: ktadd -k /opt/mapr/conf/hive.keytab mapr/<FQDN@REALM>
```

2. Configure the following properties in `hive-site.xml` on each node where HiveServer2 is installed:

Property	Value
hive.server2.authentication	KERBEROS
hive.server2.authentication.kerberos.principal	mapr/FQDN@REALM (where mapr/FQDN@REALM is the principal that you want to use for the Spark Thrift server)
hive.server2.authentication.kerberos.keytab	/opt/mapr/conf/mapr.keytab (where /opt/mapr/conf/mapr.keytab is path to the keytab that must be used)

```
<property>
  <name>hive.server2.authentication</name>
  <value>KERBEROS</value>
  <description>authenticationtype</description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.principal</name>
  <value>mapr/FQDN@REALM</value>
  <description>Spark Thrift server principal. If _HOST is used as
the FQDN portion,
  it will be replaced with the actual hostname of the running
instance.
  </description>
</property>
<property>
  <name>hive.server2.authentication.kerberos.keytab</name>
  <value>/opt/mapr/conf/mapr.keytab</value>
  <description>Keytab file for Spark Thrift server principal</
description>
</property>
```

3. Reconfigure the following options in `env.sh` (`/opt/mapr/conf/env.sh`) on each node where HiveServer2 is installed:

**NOTE:** These configurations are listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the changes in the `/opt/mapr/conf/env_override.sh` file. For more information, see [About env\\_override.sh](#) on page 3082.

Existing Configuration	Required Configuration
MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab"	MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=hybrid"
MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"	MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"

- Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/`.

**IMPORTANT:** The MapR administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

- [Setting Up HiveServer2](#)
- [Hive](#)

## Configuring Spark Thrift Server Encryption

Spark Thrift server encryption is supported when authentication is enabled. You can configure encryption with MapR-SASL or with SSL/TLS.

### Configuring Encryption with MapR-SASL or Kerberos

Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done using Data Fabric Installer, the Installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

To manually configure encryption with MapR-SASL or Kerberos authentication on a non-secure cluster or in versions earlier than EEP 4.0, complete the following steps:

- Set the `hive.server2.thrift.sasl.qop` property in `hive-site.xml` to the value `auth-conf`. The SASL Quality of Protection (QOP), or `sasl.qop`, setting and the authentication with confidentiality (`auth-conf`) value support authentication:

```
<property>
  <name>hive.server2.thrift.sasl.qop</name>
  <value>auth-conf</value>
</property>
```

- Restart Spark Thrift server to apply the change:

**IMPORTANT:** The cluster administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files are owned by this user, and impersonation support (where applicable) functions correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

### Configuring Encryption with SSL/TLS

To enable encryption with SSL/TLS:

1. Add the following properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

```
spark.ssl.enabled true
spark.ssl.fs.enabled true
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.protocol TLSv1.2
spark.ssl.keyStorePassword      mapr123
spark.ssl.trustStorePassword    mapr123
```

After the properties are added, event logs will indicate that the job is encrypted.

2. To connect using Beeline with encryption, add the following properties to the `/opt/mapr/spark/spark-<version>/conf/hive-site.xml` file:

```
<property>
  <name>hive.server2.use.SSL</name>
  <value>true</value>
  <description>enable/disable SSL </description>
</property>

<property>
  <name>hive.server2.keystore.path</name>
  <value>/opt/mapr/conf/ssl_keystore</value>
  <description>path to keystore file</description>
</property>

<property>
  <name>hive.server2.keystore.password</name>
  <value>mapr123</value>
  <description>keystore password</description>
</property>
```

3. To start the Spark Thriftserver, use the following command:

```
/opt/mapr/spark/spark-<version>/sbin/start-thriftserver.sh --hiveconf
hive.server2.thrift.port=2304 --master yarn --deploy-mode client
```

The following example shows a connection string using Beeline (PAM+SSL):

```
./bin/beeline
Beeline version 1.2.0-mapr-1808-spark by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connecting to jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connected to: Spark SQL (version 2.1.0-mapr-mep-3.x-1808)
Driver: Hive JDBC (version 1.2.0-mapr-1808-spark)
Transaction isolation: TRANSACTION_REPEATABLE_READ
1: jdbc:hive2://node1.cluster.com:2304/default>
```

### Enabling High Availability for Spark Thrift Server

With EEPs 5.0.4 or 6.3.0 and later, you can enable high availability for the Spark Thrift Server. Note the following characteristics of high availability for the Spark Thrift Server:

- Unlike a HiveServer2 high-availability (HA) configuration, all Spark Thrift Servers are in an active state. ZooKeeper keeps track of the Thrift Servers. ZooKeeper chooses one of them to work and makes a record of the choice. If one of the Thrift Servers goes down, ZooKeeper looks for another Thrift Server, makes a record, and works with it.
- After configuration, you can use Beeline to connect to the Spark Thrift Server on each node. The Control System displays one thrift server as active with the others on standby, but you can connect to any of them.
- If a Spark Thrift Server stops or fails, ZooKeeper removes the record for the failed Spark Thrift Server, and the client connects to the next one in the ZooKeeper list.
- At its core, the running Spark Thrift Server is a job that you can start in YARN mode. This makes it possible to configure queues for the Spark Thrift Server in a multi-tenant cluster if high availability is enabled. You can do this by using the `./sbin/start-thriftserver` script and applying the special properties that YARN provides for managing queues.
- You don't need to configure load balancing. Spark handles load-balancing automatically through the use of parallelized requests and efficient resource management.

To enable high availability, use the following steps:

1. Install Spark Thrift Server on all the cluster nodes where it is needed:

**On Ubuntu**

```
apt-get install  
mapr-spark-thriftserver
```

**On Red Hat / CentOS**

```
yum install mapr-spark-thriftserver
```

**On SLES**

```
zypper install  
mapr-spark-thriftserver
```

2. Add the following properties to the `/opt/mapr/spark/spark-<spark_version>/conf/hive-site.xml` file on all the nodes where the Spark Thrift Server is installed

```
<property>
<name>hive.zookeeper.quorum</name>
<value><zk_host1_>,<zk_host_2>,...,<zk_host_n></value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value><zk_port></value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value><zk_namespace></value>
</property>
```

For example:

```
<property>
<name>hive.zookeeper.quorum</name>
<value>node1.cluster.com,node2.cluster.com,node3.cluster.com</value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value>5181</value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value>ts2-ts2</value>
</property>
```

**NOTE:** The values that you provide for the `hive.server2.zookeeper.namespace` property should be different for the `hive-site.xml` in the Spark and Hive directories.

- Restart the Spark Thrift Server to apply the changes following the script in the `.sbin` directory at `/opt/mapr/spark/spark-<spark_version>/` or by running a `maprcli` command on all configured nodes:

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

or

```
maprcli node services -nodes <host_1>,<host_2>,<host_n> -name
spark-thriftserver -action restart
```

- Launch the Zookeeper command line interface, and check the Spark Thriftserver znode by running the following commands:

```
/opt/mapr/zookeeper/zookeeper-<version>/bin/zkCli.sh -server <ip:port of
zookeeper instance>
ls /<hive.server2.zookeeper.namespace>
```

For example:

```
/opt/mapr/zookeeper/zookeeper-3.4.11/bin/zkCli.sh -server
node1.cluster.com:5181
ls /ts2-ts2
[serverUri=node1.cluster.com:2304;version=;sequence=0000000000]
```

- Using Beeline, you can connect to the Spark Thrift Server by using the following string:

```
beeline> !connect jdbc:hive2://<hostname -f>:5181/
default;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=<hive.server2.z
ookeeper.namespace>;
```

For example:

```
./bin/beeline
Warning: Unable to determine $DRILL_HOME
Beeline version 1.2.0-mapr-spark-MEP-6.0.0-1912 by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts
2;auth=maprsasl;
Connecting to jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts

```

**NOTE:** High availability for the Spark Thrift Server can be used in conjunction with HiveServer2 high availability. For more information about HiveServer2 high availability, see [Enabling High Availability for Hive](#) on page 4305.

### Spark History Server SSL

Describes how to enable SSL for Spark History Server.

**NOTE:** For secure clusters, Spark History Server UI authentication is enabled by default. If passwords are present in both `/opt/mapr/conf/ssl-client.xml` and `/opt/mapr/spark/spark-<spark_version>/conf/spark-defaults.conf` files, the password from the `spark-defaults.conf` file is used

Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

### HPE Ezmeral Data Fabric Database Connectors for Apache Spark

This section describes the HPE Ezmeral Data Fabric Database connectors that you can use with Apache Spark.

[Apache Spark](#) is a software framework that is used to process data in memory in a distributed manner. Spark is replacing MapReduce in many use cases. The HPE Ezmeral Data Fabric Database Connectors for Spark enable users to write applications that access HPE Ezmeral Data Fabric Database JSON and Binary tables.

#### Understanding the HPE Ezmeral Data Fabric Database OJAI Connector for Spark

Using the HPE Ezmeral Data Fabric Database OJAI connector for Spark enables you build real-time and batch pipelines between your data and HPE Ezmeral Data Fabric Database JSON. Before getting started, it is important that you understand Spark terminology and workflow, system requirements and support, and OJAI connector and API features.

The HPE Ezmeral Data Fabric Database OJAI connector includes a set of APIs that enable you to write applications that consume HPE Ezmeral Data Fabric Database JSON tables and use them in Spark. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark is a companion to the [HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark](#) on page 4698, which provides the equivalent functionality for HPE Ezmeral Data Fabric Database Binary tables.

#### HPE Ezmeral Data Fabric Database OJAI Connector with Spark Workflow

You can use the HPE Ezmeral Data Fabric Database OJAI Connector to extract data from HPE Ezmeral Data Fabric Database or file system and transform that data using either Spark or Spark SQL, and then load it into HPE Ezmeral Data Fabric Database JSON:

## HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark Features

Principal features of the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark include the following:

- Support for Scala and, beginning with EEP 4.1, Java and Python APIs

This matrix shows the programming languages and features supported:

	Scala	Java	Python
RDD	Yes	Yes	No
DataFrame	Yes	Yes	Yes
Dataset	Yes	Yes	No
DStream	Yes	No	No

- APIs that enable you to load data from a HPE Ezmeral Data Fabric Database JSON table to an Apache Spark RDD, DataFrame, or Dataset
- Projection and filter pushdown for better performance
- Custom partitioner for RDDs that enables you to partition data for better performance
- APIs that save an Apache Spark RDD, DataFrame, or DStream to a HPE Ezmeral Data Fabric Database JSON table using either normal or bulk insert
- Support for Scala and Java bean classes
- Support for data locality
- Support for secondary indexes starting from EEP 7.0.0 and EEP 6.3.1.

The following features are not supported:

- HPE Ezmeral Data Fabric Database Binary tables  
Only HPE Ezmeral Data Fabric Database JSON tables are supported; access to HPE Ezmeral Data Fabric Database binary tables is provided through the HPE Ezmeral Data Fabric Database Binary Connector.
- Secondary indexes are not supported for previous EEP 7.0.0 and EEP 6.3.1 versions.

## Supported Product Versions and System Requirements

To use the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, you must have the following minimum software versions:

- MapR: 5.2.1 or later
- EEP 3.0 or later
- Spark 2.1.0 or later
- Scala 2.11 or later
- Java 8 or later

Support for DataFrames and Datasets is available starting in the EEP 4.0 release.

## OJAI API

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark uses the [OJAI API](#) internally to access HPE Ezmeral Data Fabric Database JSON tables.

### More information

[Spark Programming Guide](#)

[Spark SQL, DataFrames and Datasets Guide](#)

[Spark Streaming Programming Guide](#)

### *Configuring the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark*

Before using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, you must edit the `pom.xml` file for your project.

Add the Spark core dependency into the `pom.xml` file:

**NOTE:** If all dependent JAR files are already present on the node, consider setting the `scope` parameter to `provided`. For example:

```
<scope>provided</scope>
```

Setting the scope this way reduces the size of the JAR file.

```
<dependency>
  <groupId>org.apache.spark</groupId>
  <artifactId>spark-core_<scala_version></artifactId>
  <version><spark_artifact_version></version>
</dependency>
```

Add the Spark Maven dependency to the `pom.xml` file:

```
<dependency>
  <groupId>com.mapr.db</groupId>
  <artifactId>maprdb-spark</artifactId>
  <version><spark_artifact_version></version>
</dependency>
```

For example, see the dependencies for Spark 2.4.4.0 (EEP 6.3.0 release):

```
<dependency>
  <groupId>org.apache.spark</groupId>
  <artifactId>spark-core_2.11</artifactId>
  <version>2.4.4.0-mapr-630</version>
</dependency>
<dependency>
  <groupId>com.mapr.db</groupId>
  <artifactId>maprdb-spark</artifactId>
  <version>2.4.4.0-mapr-630</version>
</dependency>
```

To enable Maven to download dependencies, add the following repository information to the `pom.xml` file:

```
<repository>
  <id>mapr-releases</id>
  <url>https://repository.mapr.com/maven/</url>
  <snapshots>
    <enabled>false</enabled>
  </snapshots>
  <releases>
    <enabled>true</enabled>
```

```
</releases>
</repository>
```

## Related concepts

[Maven Artifacts for the HPE Ezmeral Data Fabric](#) on page 4759

Maven artifacts can be used for dependency management when developing applications based on the the HPE Ezmeral Data Fabric.

### *Loading Data from HPE Ezmeral Data Fabric Database Using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark*

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark supports loading data as an Apache Spark RDD. Starting in the EEP 4.0 release, the connector introduces support for Apache Spark DataFrames and Datasets. DataFrames and Datasets perform better than RDDs. Whether you load your HPE Ezmeral Data Fabric Database data as a DataFrame or Dataset depends on the APIs you prefer to use. It is also possible to convert an RDD to a DataFrame.

### Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark RDD

You can use the following API to load JSON-format data from a HPE Ezmeral Data Fabric Database table into an Apache Spark RDD of a JSON document:

#### Scala

For loading as an RDD, apply the following method on a `SparkContext` object:

```
def loadFromMapRDB[T](table: String):
  RDD[T]
```

#### Java

For loading as an RDD, apply the following method on a `MapRDBJavaSparkContext` object:

```
mapRDBSparkContext.loadFromMapRDB(tabl
eName: String, clazz: Class)
```

**NOTE:** The only required parameter to the methods is `tableName`. All the others are optional.

The following example creates a `userprofilesRDD` by calling `loadFromMapRDB` from `SparkContext` (Scala) or `MapRDBSparkContext` (Java) and supplying the table (`"/tmp/user_profiles"`):

#### Scala

```
import com.mapr.db.spark._

val userprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles")
```

#### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
```

The following example creates a `userInfo` RDD by calling `loadFromMapRDB` from `SparkContext` (Scala) or `MapRDBSparkContext` (Java) and supplying the table (`"/tmp/UserInfo"`):

**Scala**

```
import com.mapr.db.spark._

val userInfo =
  sc.loadFromMapRDB("/tmp/UserInfo")
```

**Java**

```
import
  com.mapr.db.spark.api.java.MapRDBJavaS
  parkContext;

MapRDBJavaRDD<OJAI Document> userInfo
  =
  mapRDBSparkContext.loadFromMapRDB("/tm
  p/UserInfo")
```

In the previous example, the `userInfo` data contains the following information:

- Address (map type)
- Date of birth (date type)
- First name (string type)
- Interests (string type)
- Last name (string type)

The following prints the fields and shows the output for a sample user:

**Scala**

```
userInfo.foreach(println(_))
```

**Java**

```
userInfo.foreach(System.out::println)
;
```

```
{
  "address":
    { "Pin":95035,"city":"milpitas","street":"350 holger way"},
  "dob": "1947-11-29",
  "first_name": "David",
  "interests": ["football", "books", "movies"],
  "last_name": "Jones"
}
```

The following example shows a join operation performed on two different JSON documents using `address.city` as the join key:

**Scala**

```
import com.mapr.db.spark._

val maprd1 = sc.loadFromMapRDB("/tmp/
  user_profiles")

val maprd2 = sc.loadFromMapRDB("/tmp/
  user_income")
```

```
val collection = maprd1.map(a =>
(a.`address.city`[String],a))
.cogroup(maprd2.map(a=>(a.`address.cit
y`[String],a)))
.map(a =>
(a._1,a._2._1.size,a._2._2.size)).coll
ect
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import scala.Tuple2;
import scala.Tuple3;
import java.util.Collection;

MapRDBJavaRDD<OJAIDocument> maprd1 =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
MapRDBJavaRDD<OJAIDocument> maprd2 =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_income");

List collection =
maprd1.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a))
.cogroup(maprd2.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a)))
.map(a -> new Tuple3<>(a._1,
((Collection<?>)a._2._1).size(),
((Collection<?>)a._2._2).size()))
.collect();
```

The resulting RDD, `collection`, contains the count of the users in the `user_profiles` and `user_income` HPE Ezmeral Data Fabric Database tables.

The following example adds a new field into all the JSON documents:

**Scala**

```
import com.mapr.db.spark._

val maprd = sc.loadFromMapRDB("/tmp/
user_profiles")
val documents = maprd.map(a =>
{ a.`address.country` = "USA";
a}).collect
documents.saveToMapRDB("/tmp/
cleaned_user_profiles")
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAIDocument> maprd =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
List<OJAIDocument> documents =
```

```
maprd.map(a ->
{a.set("address.country", "USA");
return a;})

.collect();
mapRDBSparkContext.saveToMapRDB(docume
nts, "/tmp/cleaned_user_profiles");
```

### Improving Performance by Using Projection Pushdown and Filter Pushdown

To improve performance, you can supply a WHERE clause and projection fields to the `loadFromMapRDB` API. In the following example, a condition is supplied to the `loadFromMapRDB` function and only certain fields are specified in the SELECT clause:

#### Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")

.where([condit
ion])

.select("addre
ss",

"first_name",

"_id",

"last_name")
```

#### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")

.where([condition])

.select("address",

"first_name",

"_id",

"last_name");
```

The data is loaded based on the condition. The condition is pushed down to the server, and the server returns data based on the filtering. Only the fields specified in the SELECT clause are projected.

In the following example, the WHERE clause is used as a filter condition:

**Scala**

```
import com.mapr.db.spark._

val userprofilesRDD =
  sc.loadFromMapRDB("/tmp/
  user_profiles")
                                .where(field("sa
  lary") >= 100)
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
  .where(MapRDB.newCondition().is("salar
y",
QueryCondition.Op.GREATER_OR_EQUAL,
100));
```

The `userprofilesRDD` includes only those documents with a salary field greater than 100.

By specifying an `_id` field, you can find and retrieve a row for a given key:

**Scala**

```
import com.mapr.db.spark._

val userprofilesRDD =
  sc.loadFromMapRDB("/tmp/
  user_profiles")
                                .where(field("_i
  d") === "k2")
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
  .where(MapRDB.newCon
  dition().is("_id",
  QueryCondition.Op.EQUAL, "k2"));
```

**WHERE Clause Semantics**

The `loadFromMapRDB` API supports a WHERE clause to push down the filter to the JSON document API, ensuring that only relevant documents are propagated to the RDD.

You can use two options to provide the filter condition:

- Scala domain-specific language (DSL)
- `QueryCondition` (from OJAI API)

Following is an example of using `loadFromMapRDB` and supplying a condition by using Scala DSL:

#### Scala

```
Condition isDoe = field("last_name")
=== "Doe"
val userprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles").where(isDoe)
```

For more information about using Scala DSL, see [Scala DSL for Specifying Filter Conditions](#) on page 4657.

Following is an example of passing the condition using the `QueryCondition` API:

#### Scala

```
val maprd =
sc.loadFromMapRDB(tableName)
    .where(MapRDB.newConditio
n()
        .is("_id",
QueryCondition.Op.EQUAL, "k2")
        .build())
```

#### Java

```
MapRDBJavaRDD rdd =
mapRDBJavaSparkContext.loadFromMapRDB(
tableName)
    .where(MapRDB.newConditio
n().is("_id",
QueryCondition.Op.EQUAL,
"k2").build());
```

For more information about `QueryCondition`, see [Querying with Conditions](#) on page 3426.

**NOTE:** For additional information, see [Java Examples](#) in the source code.

### Creating an Apache Spark RDD of a Class

When loading data as an Apache Spark RDD, if you have a custom class in your application, you can present the data as objects of your class.

#### Scala

You must define the custom class using Jackson semantics for Scala modules. The following example defines a custom `User` class:

```
case class User (@JsonProperty("_id")
id:String,

@JsonProperty("first_name")
firstName:String,

@JsonProperty("last_name") lastName:
String,
                @JsonProperty("dob") dob:
ODate,
```

```
@JsonProperty("interests") interests:
List[String])
```

In the following example, by supplying `User` as a type parameter to the function while loading the HPE Ezmeral Data Fabric Database table, you can create an RDD of the `User` class:

```
val userprofilesRDD =
sc.loadFromMapRDB[User]("/tmp/
user_profiles")
      .where("conditio
n")
```

When specifying a bean class, the `SELECT` clause is unnecessary and is ignored.

You must define a custom bean class as follows:

```
public static class Person implements
Serializable {
    private String _id;
    private String firstName;
    private String lastName;
    private Date dob;
    private Seq<String>
interests;
    public String get_id()
{ return _id; }
    public void set_id(String
_id) { this._id = _id; }
    public String
getFirstName() { return firstName; }
    public void
setFirstName(String firstName)
{ this.firstName = firstName; }
    public String
getLastName() { return lastName; }
    public void
setLastName(String lastName)
{ this.lastName = lastName; }
    public Date getDob()
{ return dob; }
    public void setDob(Date
dob) { this.dob = dob; }
    public Seq<String>
getInterests() { return interests; }
    public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
}
```

In the following example, by supplying the `User` bean class as a type parameter while loading the HPE Ezmeral Data Fabric Database table, you can create a `MapRDBJavaRDD` of the `User` class:

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
```

## Java

```
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkContext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tmp/user_profiles",
User.class).where(<condition>);
```

### Scala DSL for Specifying Filter Conditions

When loading data from HPE Ezmeral Data Fabric Database as an Apache Spark RDD, you can use Scala DSL to specify filter conditions. This section shows examples of these filter conditions.

In the following examples, a class named `field` is introduced to represent a field in a condition. The field condition takes an argument as a String. The following table shows conditions written using Scala DSL:

Condition	Example
equality	<pre>val idOnlyPredicate = field("_id") === "k2"</pre>
greaterThan	<pre>val simplePredicateWithComparisonOperator = field("a.c.d") &gt; 10</pre>
notexists	<pre>val simpleNotExistsPredicate = field("a.c.e") notexists</pre>
IN	<pre>val inPredicate = field("a.c.d") in Seq(ODate.parse("2011-05-21"), ODate.parse("2013-02-22"))</pre>
typeof	<pre>val simpleTypeOfPredicate = field("a.c.d") typeof "INT"</pre>
complex condition with and	<pre>val inPredicateWithMapAndArray = (field("a.c.d") in Seq(5,10)) and (field("a.c.e") notin Seq("aaa","bbb"))</pre>
another complex condition	<pre>val compositePredicateWithAndOnly = ((field("a.b") notexists ) and (field("p.q") typeof "DATE")) and (field("a.c.d") &gt; 20L)</pre>
between	<pre>val predicateWithBetweenOp = field("a.c.d") between (ODate.parse("2015-01-15"), ODate.parse("2015-05-15"))</pre>
predicate with equality check on Sequence of elements (representing array)	<pre>val eqPredicateWithList = field("a.b") === Seq(12345L, "xyz")</pre>

Condition	Example
predicate with equality check on a map	<pre>val eqWithMapPredicate = field("a") === Map("k" -&gt; "kite",                                              "m" -&gt; "map")</pre>

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark supports these predicates:

- >
- >=
- <
- <=
- ===
- !=
- between
- exists
- notin
- in
- notexists
- typeof
- nottypeof
- like
- notlike
- matches
- notmatches
- sizeof

Here are examples for these operators:

- `field("a") > 10`
- `field("a") >= 10`
- `field("a") < 10`
- `field("a") <= 10`
- `field("a") === 10`
- `field("a") === Seq("aa", 10)`
- `field("a") === Map("aa" -> 10)`

- `field("a") != 10`
- `field("a") != Seq("aa", 10)`
- `field("a") != Map("aa" -> 10)`
- `field("a") between (10,20)`
- `field("a") exists`
- `field("a") notin Seq(10,20)`
- `field("a") in Seq(10, 20)`
- `field("a") notexists`
- `field("a") typeof "INT"`
- `field("a") nottypeof "INT"`
- `field("a") like "%s"`
- `field("a") notlike "%s"`
- `field("a") matches "*s"`
- `field("a") notmatches "*s"`

For `typeof`, these are the right-hand side values:

- `"INT"`
- `"INTEGER"`
- `"LONG"`
- `"BOOLEAN"`
- `"STRING"`
- `"SHORT"`
- `"BYTE"`
- `"NULL"`
- `"FLOAT"`
- `"DOUBLE"`
- `"DECIMAL"`
- `"DATE"`
- `"TIME"`
- `"TIMESTAMP"`
- `"INTERVAL"`

- "BINARY"
- "MAP"
- "ARRAY"

The `sizeof` operator can have the following operations:

- `sizeof(field("a")) === 10`
- `sizeof(field("a")) < 10`
- `sizeof(field("a")) > 10`
- `sizeof(field("a")) >= 10`
- `sizeof(field("a")) <= 10`
- `sizeof(field("a")) != 10`

### Java DSL for Specifying Filter Conditions

When loading data from HPE Ezmeral Data Fabric Database as an Apache Spark RDD, you can use Java DSL to specify filter conditions. This section shows examples of these filter conditions.

Condition	Example
equality	<pre>QueryCondition equality = MapRDB.newCondition().is("_id", QueryCondition.Op.EQUAL, "k2").build();</pre>
greaterThan	<pre>QueryCondition greatherThan = QueryCondition simpleWithComparisonOperator = MapRDB.newCondition().is("a.b.c", QueryCondition.Op.GREATER, 10).build();</pre>
notexists	<pre>QueryCondition notexists = MapRDB.newCondition().notExists("a.c.e").build();</pre>
IN	<pre>List&lt;ODate&gt; odateList = new ArrayList&lt;&gt;(); odateList.add(ODate.parse("2011-05-21")); odateList.add(ODate.parse("2013-02-22")); QueryCondition in = MapRDB.newCondition().in("a", odateList).build();</pre>
typeof	<pre>QueryCondition typeof = MapRDB.newCondition().typeof("a.c.d", Value.Type.INT).build();</pre>
complex condition with and	<pre>QueryCondition complexConditionWithAnd = MapRDB.newCondition() .and() .condition(MapRDB.newCondition().in("a", Arrays.asList(5, 10))) .condition(MapRDB.newCondition().notIn("b", Arrays.asList("aaa", "bbb"))) .close().build();</pre>

Condition	Example
another complex condition	<pre> QueryCondition anotherComplexCondition = MapRDB.newCondition()     .and()     .condition(MapRDB.newCondition().notExists("a.b"))     .condition(MapRDB.newCondition().typeOf("p.q", Value.Type.DATE))     .condition(MapRDB.newCondition().is("a.c.d", QueryCondition.Op.GREATER, 20L))     .close().build(); </pre>

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark supports these predicates:

- is (LESS, LESS\_OR\_EQUAL, EQUAL, NOT\_EQUAL, GREATER\_OR\_EQUAL, GREATER)
- equals
- and
- exists
- in
- like
- matches
- notEquals
- notExists
- notIn
- notLike
- notMatches
- notTypeOf
- or
- sizeOf
- typeOf

Here are examples for these operators:

- `MapRDB.newCondition().is("a", QueryCondition.Op.GREATER, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.GREATER_OR_EQUAL, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.LESS, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.LESS_OR_EQUAL, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.EQUAL, 10);`
- `MapRDB.newCondition().is("a", QueryCondition.Op.NOT_EQUAL, 10);`
- `MapRDB.newCondition().exists("a");`

- `MapRDB.newCondition().notIn("a", Arrays.asList(10, 20));`
- `MapRDB.newCondition().in("a", Arrays.asList(10, 20));`
- `MapRDB.newCondition().notExists("a");`
- `MapRDB.newCondition().typeof("a", Value.Type.INT);`
- `MapRDB.newCondition().notTypeOf("a", Value.Type.INT);`
- `MapRDB.newCondition().like("a", "%s");`
- `MapRDB.newCondition().notLike("a", "%s");`
- `MapRDB.newCondition().matches("a", "*s");`
- `MapRDB.newCondition().notMatches("a", "*s");`

For `typeof`, these are the right-hand side values:

- "INT"
- "INTEGER"
- "LONG"
- "BOOLEAN"
- "STRING"
- "SHORT"
- "BYTE"
- "NULL"
- "FLOAT"
- "DOUBLE"
- "DECIMAL"
- "DATE"
- "TIME"
- "TIMESTAMP"
- "INTERVAL"
- "BINARY"
- "MAP"
- "ARRAY"

The `sizeof` operator can have the following operations:

- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.EQUAL, 10);`

- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.LESS, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.GREATER, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.LESS_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.GREATER_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeof("a", QueryCondition.Op.NOT_EQUAL, 10);`

Using the Custom Partitioner with the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark  
In any distributed computing system, partitioning data is crucial to achieve the best performance. Apache Spark provides a mechanism to register a custom partitioner for partitioning the pipeline. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark includes a custom partitioner you can use to optimally partition data in an RDD.

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark's custom partitioner takes the following classes as keys:

- `String`
- `ByteBuffer` (as serializable `ByteBuffer`)

You can register this custom partitioner with either the `partitionBy` function or the `repartitionAndSortWithinPartitions` function.

The connector supports two versions of the custom partitioner. One version takes a HPE Ezmeral Data Fabric Database JSON table as an input. The partition information of the table is used to partition the data, so the `saveToMapRDB` call can use a `bulkInsert` to store the data. The `bulkInsert` option requires that you have the data already sorted on the `_id` key.

The other version of the custom partitioner takes an array of splits as an input.

### Specifying tablename for the Partitioner

If you already have a table that has been created and partitioned based on a set of keys, you can specify that the RDD be partitioned in the same way (using the same set of keys). In the following example, `/srctable` is provided as a reference partitioner for `/dsttable`:

#### Scala

```
sc.loadFromMapRDB("/srctable")
    .keyBy(doc =>
doc._id[String])
    .repartitionAndSortWithinP
artitions(MapRDBSpark.newPartitioner[S
tring]("/dsttable"))
    .saveToMapRDB("/
dsttable", createTable = false,
bulkInsert = true)
```

### Specifying a String Seq as an Array of Splits

In the following example, the first line creates an array of splits as `id1, id2 ... id9`. The rest of the example splits the RDD based on the array of splits:

#### Scala

```
val dstSplits: Array[String] = (1 to
9 by 3).map("id" + _).toArray
val partitionRDD =
sc.loadFromMapRDB("/srctable")
```

```

        .keyBy(doc =>
doc._id[String])
        .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[String](dstSplits))
        .saveToMapRDB("/dsttable", createTable = true,
bulkInsert = true)

```

### Specifying a ByteBuffer Seq as an Array of Splits

Suppose you have an array of byte buffers to use as the array of splits for the partitioner. You must convert the byte buffers to serializable byte buffers first:

#### Scala

```

// Converting bytebuffer to
serializable bytebuffer
val dstSplits =
arrayOfByteBuffer.map(x =>
MapRDBSpark.serializableBinaryValue(x)
)
sc.loadFromMapRDB("/srctable")
  //KeyBy serializable bytebuffer
  .keyBy(doc =>
doc.getBinarySerializable(binaryField)
)
  .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner(dstSplits))
  .saveToMapRDB("/dsttable",
createTable = true, bulkInsert = true)

```

### Specifying tablename for the Partitioner with ByteBuffer as Id Fields

Suppose you have a table with keys that are binary or `ByteBuffer`, and you have an RDD with some rows and some values. You can repartition the RDD based on the partitions of the table. The following example reads the document from `/srctable`, but you could provide any table. In the second line, the example specifies a `keyBy` call on an ID that is binary serializable. In the last line, `/dsttable` is the RDD that has a key of serializable `ByteBuffers`:

#### Scala

```

sc.loadFromMapRDB("/srctable")
  .keyBy(doc =>
doc.getIdBinarySerializable())
  .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[ByteBuffer]
("/dsttable"))

```

**NOTE:** You must provide the key type of the `PairedRDD` on which the partitioning is specified. If the IDs are serializable bytebuffers, specify `ByteBuffer`. Otherwise, specify `String`.

After the data is partitioned with the custom partitioner, all the downstream transformations should be non-partition-changing transformations. Here is the code for passing on partitioner for an RDD:

#### Scala

```

user_profiles.repartitionAndSortWithinPartitions
(
  MapRDBSpark.newPartitioner[String]
  (<table-name>))

```

Or you can use the `partitionBy` function on the RDD:

#### Scala

```
user_profiles.partitionBy(MapRDBSpark.  
newPartitioner[String](<table-name>))
```

The key of the data for this partitioner should be of the same type as that of the key of the table name. This partitioner yields a single partition if the table supplied to it is not pre-split. The number of partitions is calculated based on the table's existing tablet information.

For a table created with the `bulkInsert` option set to `true`, one of the following applies:

- If the table is pre-split, then the resulting partitions can be  $> 1$ .
- If the table is no-split, then the resulting partitions will be 1 if no partition information is available from the RDD lineage.

### Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark DataFrame

To load data from a HPE Ezmeral Data Fabric Database JSON table into an Apache Spark DataFrame, invoke the following API:

#### Scala

For loading as a DataFrame, apply the following method on a `SparkSession` object:

```
def loadFromMapRDB[T](tableName: String,  
                      schema: StructType):  
  DataFrame  
  
import com.mapr.db.spark.sql._  
  
val df  
= sparkSession.loadFromMapRDB[T]  
("/tmp/user_profiles"): DataFrame
```

#### Java

For loading as a DataFrame (Datasets of Row), apply the following method on a `MapRDBJavaSession` object:

```
def loadFromMapRDB(tableName: String,  
                  schema: StructType, sampleSize:  
                  Double): DataFrame  
  
import  
com.mapr.db.spark.sql.api.java.MapRDBJ  
avaSession;  
import  
org.apache.spark.sql.SparkSession;  
  
MapRDBJavaSession maprSession = new  
MapRDBJavaSession(spark);  
maprSession.loadFromMapRDB("/tmp/  
user_profiles");
```

**NOTE:** Java supports only DataSets of Row (`Dataset<Row>`).

**Python**

For loading as a DataFrame, apply the following method on a `SparkSession` object:

```
loadFromMapRDB(table_name, schema,
sample_size)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")
```

**NOTE:** PySpark supports only DataFrames (Dataset<Row>).

**NOTE:** The only required parameter to the methods is `tableName`. All the others are optional.

This creates a DataFrame object corresponding to the HPE Ezmeral Data Fabric Database table specified by the `tableName` parameter.

Both DataFrames and HPE Ezmeral Data Fabric Database tables work with structured data. DataFrames need a fixed schema, whereas HPE Ezmeral Data Fabric Database allows for a flexible schema. When loading data into a DataFrame, you can map your data to a schema by specifying the schema parameter in the `loadFromMapRDB` call. You can also provide an application class as the type `[T]` parameter in the call. These two approaches are the preferred methods for loading data into DataFrames.

For data exploration use cases, you might not know the schema of your HPE Ezmeral Data Fabric Database table. For those situations, the HPE Ezmeral Data Fabric Database OJAI connector for Apache Spark can infer the schema by sampling data from the table.

Whenever possible, the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark [pushes projections and filters](#) for better performance. This allows HPE Ezmeral Data Fabric Database to project and filter data before returning it to your client application.

The following subtopics describe these techniques.

### Optimizing HPE Ezmeral Data Fabric Database Lookups in Spark Jobs

The `lookupFromMapRDB()` API utilizes the primary and secondary indexes on a HPE Ezmeral Data Fabric Database table to optimize table lookups and outputs the results to an Apache Spark DataFrame.

**IMPORTANT:** The `lookupFromMapRDB()` API functionality requires a patch. The patch works with EEP 6.2.0 (Core 6.1.0, Spark 2.4.0.0) and EEP 6.3.0 (Core 6.1.0, Spark 2.4.4.0). To install patches, see [Applying a Patch](#)

The `loadfromMapRDB()` API in [MapR Database Connectors for Apache Spark](#) is optimized to load massive amounts of data from HPE Ezmeral Data Fabric Database tables with high throughput. In cases where a Spark job needs to lookup a small number of documents based on the equality (or short range) condition on a primary or secondary key, the `lookupFromMapRDB()` API should be used.

Invoke the `lookupFromMapRDB()` API when the filter conditions in short range and equality queries reference primary and secondary keys. If the filter condition references any non-primary keys (fields other than the `_id` field), a secondary index must exist on the secondary keys. Indexes on the filtering keys is essential to achieving reasonable performance of lookup queries in HPE Ezmeral Data Fabric Database tables.

The `lookupFromMapRDB()` API uses the secondary keys in indexes to lookup values in the primary table. For example, if a query contains the filter conditions `mydate = '2012-03-26'` and `myid = '120026015'`, a [secondary index](#) (of type composite) created on the `mydate` and `myid` fields must exist for the query to quickly output results.

Examples on the following tabs demonstrate how to invoke the `lookupFromMapRDB()` API to perform a lookup in a HPE Ezmeral Data Fabric Database table and output the results to an Apache Spark DataFrame:

#### Scala

```
import com.mapr.db.spark.sql._
import spark.implicits._
val df = spark.lookupFromMapRDB("/tbl")
df.filter("mydate" === "2012-03-26"
&& $"myid" === 120026015).show
```

#### Java

```
SparkSession sparkSession =
SparkSession.builder().getOrCreate();
MapRDBJavaSession mapRDBJavaSession =
new MapRDBJavaSession(sparkSession);
Dataset<Row> df2 =
mapRDBJavaSession.lookupFromMapRDB("/tbl");
df2.filter("mydate = '2012-03-26' and
myid = '120026015']").show();
```

#### Python

```
from pyspark.sql import SparkSession
df = spark.lookupFromMapRDB("/tbl")
df.filter("mydate = '2012-03-26' and
myid = '120026015']").show()
```

### Loading Data into a DataFrame Using an Explicit Schema

If you know the schema of your data, you can specify an explicit schema when loading a DataFrame.

The following example loads data into a user profile table using an explicit schema:

#### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val addressSchema =
StructType(StructField("Pin",
IntegerType) ::

StructField("city", StringType) ::

StructField("street", StringType) ::
Nil)

val personSchema =
StructType(StructField("_id",
StringType) ::

StructField("first_name",
StringType) ::

StructField("last_name",
StringType) ::

StructField("address",
addressSchema) ::

StructField("interests",
```

**Java**

```
ArrayType(StringType)) :: Nil)

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles", personSchema)
```

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.Session;

StructField[] addressSchema = {
    new
StructField("Pin", IntegerType, true,
Metadata.empty()),
    new
StructField("city", StringType, true,
Metadata.empty()),
    new
StructField("street", StringType,
true, Metadata.empty())
};
StructField[] schemaFields = {
    new StructField("_id", StringType,
true, Metadata.empty()),
    new StructField("first_name",
StringType, true, Metadata.empty()),
    new StructField("address", new
StructType(addressSchema), true,
Metadata.empty()),
    new StructField("interests", new
ArrayType(StringType, true), true,
Metadata.empty())
};
StructType personSchema = new
StructType(schemaFields);
MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles", personSchema);
```

**Python**

```
from pyspark.sql import SparkSession

addressSchema = [StructField("Pin",
IntegerType(), True),
                 StructField("city",
StringType(), True),
                 StructField("street", StringType(),
True)]
schemaFields = [StructField("_id",
StringType(), True),
                StructField("first_name",
StringType(), True),
                StructField("last_name",
StringType(), True),
```

```
StructField("address",
StructType(addressSchema), True),

StructField("interests",
ArrayType(StringType()), True)]
personSchema =
StructType(schemaFields)

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles", personSchema)
```

To create the DataFrame object named `df`, pass the schema as a parameter to the load call. Invoke the `loadFromMapRDB` method on a `SparkSession` object.

The resulting schema of the object is the following:

```
df.printSchema()
-----
root
|-- _id: String (nullable = true)
|-- first_name: String (nullable = true)
|-- last_name: String (nullable = true)
|-- address: Struct (nullable = true)
|   |-- Pin: integer (nullable = true)
|   |-- city: string (nullable = true)
|   |-- street: string (nullable = true)
|-- interests: array (nullable = true)
|   |-- element: string (containsNull = true)
```

When specifying `StructField` in a schema, optionally specify whether the field is nullable. In the example above, all fields are nullable.

Depending on the nullability of the field in the schema and the existence of fields in the HPE Ezmeral Data Fabric Database table, the load returns an `InvalidSchema` exception in the following cases:

- The schema contains a non-nullable field and the load attempts to put a NULL value into the field.
- The schema contains a non-nullable field and the field does not exist in the HPE Ezmeral Data Fabric Database table.
- The HPE Ezmeral Data Fabric Database table has fields that do not exist in the specified schema.

### Loading Data into a DataFrame Using a Type Parameter

If the structure of your data maps to a class in your application, you can specify a type parameter when loading into a DataFrame.

Specify the application class as the type parameter in the load call. The load infers the schema from the class.

The following example creates a DataFrame with a `Person` schema by passing the `Person` class as the type parameter in the load call:

#### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)
```

```

        case class Person(_id:
String,
        First_name: String,
        last_name: String,
        Address: Address,
        Interests: Seq[String])

val df
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles")

```

**Java**

```

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

public static class Address
implements Serializable {
    private Integer pin;
    private String street;
    private String city;

    public Integer getPin() { return
pin; }
    public void setPin(Integer pin)
{ this.pin = pin; }
    public String getStreet()
{ return street; }
    public void setStreet(String
street) { this.street = street; }
    public String getCity() { return
city; }
    public void setCity(String city)
{ this.city = city; }
}

public static class Person implements
Serializable {
    private String _id;
    private String firstName;
    private String lastName;
    private Date dob;
    private Seq<String> interests;

    public String get_id() { return
_id; }
    public void set_id(String _id)
{ this._id = _id; }
    public String getFirstName()
{ return firstName; }
    public void setFirstName(String
firstName) { this.firstName =
firstName; }
    public String getLastName()
{ return lastName; }
    public void setLastName(String
lastName) { this.lastName =
lastName; }
    public Date getDob() { return
dob; }
}

```

```

        public void setDob(Date dob)
        { this.dob = dob; }
        public Seq<String>
        getInterests() { return interests; }
        public void
        setInterests(Seq<String> interests)
        { this.interests = interests; }
    }
    MapRDBJavaSession maprSession = new
    MapRDBJavaSession(sparkSession);
    Dataset<Row> df =
    maprSession.loadFromMapRDB(tableName,
    Person.class);

```

You must invoke the `loadFromMapRDB` method on a `SparkSession` or `MapRDBJavaSession` object.

All fields in an application bean class are nullable by default. The only circumstance in which the load returns an `InvalidSchema` exception is if the HPE Ezmeral Data Fabric Database table contains fields not included in the bean class.

The resulting schema of the object is as follows:

```

df.printSchema()
-----
root
 |-- _id: String (nullable = true)
 |-- first_name: String (nullable = true)
 |-- last_name: String (nullable = true)
 |-- address: Struct (nullable = true)
 |   |-- Pin: integer (nullable = true)
 |   |-- street: string (nullable = true)
 |   |-- city: string (nullable = true)
 |-- interests: array (nullable = true)
 |   |-- element: string (containsNull = true)

```

### Loading Data into a DataFrame Using Schema Inference

If you do not know the schema of the data, you can use schema inference to load data into a `DataFrame`. This section describes how to use schema inference and restrictions that apply

When you do not specify a schema or a type when loading data, schema inference triggers automatically. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark internally samples documents from the HPE Ezmeral Data Fabric Database JSON table and determines a schema based on that data sample. By default, the sample size is 1000 documents. Alternatively, you can specify a sample size parameter. The parameter is optional in the `loadFromMapRDB` call and is named `sampleSize`. The following example specifies using a sample size of 100 documents:

#### Scala

```

import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df =
sparkSession.loadFromMapRDB(tableName,
sampleSize : 100)

```

#### Java

```

import
com.mapr.db.spark.sql.api.java.MapRDBJavaSession;
import
org.apache.spark.sql.SparkSession;

```

```
MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> df =
maprSession.loadFromMapRDB(tableName,
100);
```

### Python

```
from pyspark.sql import SparkSession

df = spark.loadFromMapRDB(table_name,
100)
```

**IMPORTANT:** Because schema inference relies on data sampling, it is non-deterministic. It is not well suited for production use where you need predictable results. Inferring schema results in reading sample rows from the table, hence execution time varies with number of rows in the source table.

### Sampling Using Reader Functions

An alternative to sampling data using the `loadFromMapRDB` call is to use reader functions.

To use the `DataFrame` reader function (for Scala only), call the following methods:

```
val df = sparkSession.read.maprdb(tableName)
```

To use the reader function with basic Spark, call the `read` function on a `SQLContext` object as follows:

### Scala

```
import org.apache.spark.sql.SQLContext

val df =
sqlContext.read.format("com.mapr.db.sp
ark.sql")
                .option("tableName",
<table-name>)
                .option("sampleSize",
100).load()
```

### Java

```
import
org.apache.spark.sql.SQLContext;

Dataset<Row> df = sqlContext.read()
                    .format("com.mapr.db
.spark.sql")
                    .option("tableName",
<table-name>).load();
```

### Python

```
from pyspark.sql import SQLContext

df = sql_context.read\
        .format("com.mapr.db.spark.sql.De
faultSource")\
        .option("tableName",
<table-name>).load()
```

## Type Conflict Resolution When Sampling

When sampling data during schema inference, you might encounter conflicting value types within a field. The connector uses the following rules to resolve type conflicts:

- If the two conflicting types are each one of the following, the resolved type is the wider of the two types:
  - `ByteType`
  - `ShortType`
  - `IntegerType`
  - `LongType`
  - `FloatType`
  - `DoubleType`

The type list above is arranged in increasing order of width. For example, if one document contains a field of type `ByteType` and the other contains a field of type `FloatType`, the resultant type is `FloatType`.

- If one of the types is `DecimalType`, then the resultant type is `DecimalType`, if and only if `DecimalType` is the wider of the two types.
- If the two types are `StructType`, each with different fields, then the resultant type is a new `StructType` that contains all the fields in each `StructType`.
- If the two types are `ArrayType`, each with different element types, then the resultant type is a new `ArrayType` where the type of the elements in the array is resolved using the aforementioned rules.
- If none of the above rules can be used for resolving type conflicts, then during data conversion, the load reports a `ConflictType` exception.

Suppose `Name` contains `String` values in some rows and a map with `first_name` and `last_name` as nested fields in other rows. During schema inference, the conflict resolution logic encounters two different types for the same field, `StringType` and `MapType`. It will note the conflict and return a `ConflictType` exception later when converting the data during the load.

By default, conflict exceptions occur during data conversion. To change this so that the exception is returned during the conflict resolution stage, set the `FailOnConflict` option to `true` :

### Scala

```
val df =
  spark.read.maprdb(<tableName>,
    Map("sampleSize" -> 100,
      "FailOnConflict" -> true))
```

## Invalid Schemas

When using schema inference, missing and extra fields are resolved in the following ways:

- If a field in the inferred schema is missing in the HPE Ezmeral Data Fabric Database JSON document, the field is set to null.
- If there are fields in a HPE Ezmeral Data Fabric Database JSON document that are not in the inferred schema, the load returns an `InvalidSchema` exception.

Type Mapping Between HPE Ezmeral Data Fabric Database JSON and DataFrames

This table maps data types between HPE Ezmeral Data Fabric Database JSON OJAI and Apache Spark DataFrame.

**NOTE:** Not all DataFrame data types are supported by HPE Ezmeral Data Fabric Database, for a list of supported data types, see [JSON Documents](#) on page 635.

OJAI Data Type	DataFrame Data Type
Boolean	BooleanType
String	StringType
Byte	ByteType
Short	ShortType
Int	IntegerType
Long	LongType
Float	FloatType
Double	DoubleType
Decimal	DecimalType
Date	DateType
Time	TimestampType
TimeStamp	TimeStampType
Interval	CalendarIntervalType
Binary	BinaryType
Map	StructType
Array	ArrayType

**NOTE:** The OJAI `Time` data type is converted to a Spark `TimestampType` with the date set to the epoch date. Spark SQL does not support a `TIME` type.

### Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark Dataset

You can use one of three ways to load data from HPE Ezmeral Data Fabric Database into an Apache Spark Dataset:

- Load the data into a Dataset.
- Load the data into a DataFrame, and then convert it to a Dataset.
- Load the data into a Dataset using a custom encoder.

#### Load into a Dataset

##### Scala

For loading as a Dataset, apply the following method on a `SparkSession` object:

```
def loadFromMapRDB[T](table: String,
  schema : StructType).as [T]: Dataset

import com.mapr.db.spark.sql._

val ds
```

```
= sparkSession.loadFromMapRDB[T]
("/tmp/user_profiles").as [T]: Dataset
```

## Java

For loading as a Dataset, apply the following method on a MapRDBJavaSession object:

```
def loadFromMapRDB[T <:
java.lang.Object](tableName: String,
schema: StructType, sampleSize:
Double, clazz: Class[T]): Dataset[T]

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);

Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
```

**NOTE:** The only required parameter to the methods is tableName. All the others are optional.

## Load into DataFrame and Convert to Dataset

To load the data as a DataFrame, see [Loading Data from HPE Ezmeral Data Fabric Database as an Apache Spark DataFrame](#) on page 4665. To convert the DataFrame to a Dataset, use the `as[<type>]` method. The `<type>` can be any of the basic types in Scala.

The following code example creates a `Dataset[Person]` using the `as[<type>]` method:

## Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)

case class Person (_id:String,
first_name:String,
last_name: String, dob:
java.sql.Date,
Interests: Seq[String,
address: Address)

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
```

## Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

public static class Address
implements Serializable {
private Integer pin;
private String street;
```

```

        private String city;

        public Integer getPin() { return
pin; }
        public void setPin(Integer pin)
{ this.pin = pin; }
        public String getStreet()
{ return street; }
        public void setStreet(String
street) { this.street = street; }
        public String getCity() { return
city; }
        public void setCity(String city)
{ this.city = city; }
}

public static class Person implements
Serializable {
    private String _id;
    private String firstName;
    private String lastName;
    private Date dob;
    private Seq<String> interests;
    public String get_id()
{ return _id; }
    public void
set_id(String _id) { this._id = _id; }
    public String
getFirstName() { return firstName; }
    public void
setFirstName(String firstName)
{ this.firstName = firstName; }
    public String
getLastName() { return lastName; }
    public void
setLastName(String lastName)
{ this.lastName = lastName; }
    public Date getDob()
{ return dob; }
    public void setDob(Date
dob) { this.dob = dob; }
    public Seq<String>
getInterests() { return interests; }
    public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
}

Dataset<Person> ds =
maprSession.loadFromMapRDB(tableName,
Person.class);

```

### Load into Dataset Using Custom Encoder

You can create a custom encoder for Java bean classes by calling the `Encoders.bean` method. `Encoders.bean` only support Java classes. To create a Dataset of the Scala class, the previous code can be used. The following example shows how to load into a Dataset by creating a custom encoder for a Java class named `beanClass`:

#### Scala

```

import
org.apache.spark.sql.SparkSession

```

```
import com.mapr.db.spark.sql._

val ds =
  sparkSession.loadFromMapRDB("/tmp/
  user_profiles")
    .as(Encoders.bean(beanClass))
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

maprSession.loadFromMapRDB("/tmp/
user_profiles").as(Encoders.bean(beanC
lass));
```

**Filter Pushdown**

After you have loaded data into a Dataset, you can apply filter pushdowns. The following example filters on `first_name`:

**Scala**

```
ds.filter($"first_name" === "David")
```

**Java**

```
ds.filter(col("first_name").equalTo("D
avid")).show();
```

See [Projection and Filter Pushdown with Apache Spark DataFrames and Datasets](#) on page 4677 for other examples.

**Projection and Filter Pushdown with Apache Spark DataFrames and Datasets**

Projection and filter pushdown improve query performance. When you apply the `select` and `filter` methods on DataFrames and Datasets, the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark pushes these elements to HPE Ezmeral Data Fabric Database where possible.

**Projection Pushdown**

Projection pushdown minimizes data transfer between HPE Ezmeral Data Fabric Database and the Apache Spark engine by omitting unnecessary fields from table scans. It is especially beneficial when a table contains many columns.

When you invoke the following `select` method on a DataFrame, the connector pushes the projection:

**Scala**

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles")
df.select("_id", "first_name",
"last_name")
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
```

```
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.select("_id", "first_name",
"last_name");
```

**Python**

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.select("_id", "first_name",
"last_name")
```

The equivalent example using Datasets is as follows:

**Scala**

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
ds.select("_id", "first_name",
"last_name")
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles", Person.class);
ds.select("_id", "first_name",
"last_name");
```

**Filter Pushdown**

Filter pushdown improves performance by reducing the amount of data passed between HPE Ezmeral Data Fabric Database and the Apache Spark engine when filtering data.

Consider the following example:

**Scala**

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB("/tmp/
```

**Java**

```
user_profiles")
df.filter("first_name = 'Bill'")
```

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
```

```
MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.filter("first_name = 'Bill'")
```

**Python**

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.filter("first_name = 'Bill'")
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark pushes the filter `firstName = 'Bill'` down to HPE Ezmeral Data Fabric Database.

The equivalent example using Datasets is as follows:

**Scala**

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
ds.filter($"first_name" === "Bill")
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

Dataset ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles").as(Encoders.bean(Perso
n.getClass()));
ds.filter(col("first_name").equalTo("B
ill"));
```

The following DataFrame filters those rows in which `first_name` is either "David" or "Peter":

**Scala**

```
df.filter($"first_name" === "David"
|| $"first_name" === "Peter")
```

**Java**

```
df.filter(col("first_name").equalTo("D
avid").or(col("first_name").equalTo("P
eter")))
```

**Python**

```
df.filter((col("first_name") ==
"David") | (col("first_name") ==
"Peter"))
```

The following DataFrame retrieves only the rows in which the first\_name is "David" and the last\_name is "Jones":

**Scala**

```
df.filter($"first_name" === "David"
&& $"last_name" === "Jones")
```

**Java**

```
df.filter(col("first_name").equalTo("D
avid").and(col("last_name").equalTo("J
ones")))
```

**Python**

```
df.filter((col("first_name") ==
"David") & (col("last_name") ==
"Jones"))
```

The following uses a not condition to return rows where the first\_name is not "David" and the last\_name is not "Peter":

**Scala**

```
df.filter(not($"first_name" ===
"David" || $"last_name" === "Peter"))
```

**Java**

```
df.filter(not(col("first_name").equalT
o("David").or(col("last_name").equalT
o("Peter"))))
```

**Python**

```
df.filter(~((col("first_name") ==
"David") | (col("last_name") ==
"Peter")))
```

The HPE Ezmeral Data Fabric Database OJAI Connector pushes down all of the filters shown in the earlier examples. It can push down the following types of filters, provided that the field is not an `Array` or `Map`:

- Equal To (=)
- Not Equal To (!=)
- Less Than (<)
- Less Than or Equal To (<=)
- Greater Than (>)
- Greater Than or Equal To (>=)
- In Predicate (IN)
- Like predicate (LIKE)
- AND, OR

- NOT

## Restrictions

Pushdowns with DataFrames and Datasets are not supported in the following scenarios:

- Filters on complex types, including arrays, maps, and structs

For example, a filter on a field in a map, as shown in the following example, is not pushed down:

### Scala

```
df.filter($"address.city" ===
  "Milpitas")
```

### Java

```
df.filter(col("address.city").equalTo(
  "Milpitas"));
```

### Python

```
df.filter(col("address.city") ==
  "Milpitas")
```

- Filters with functions `sizeof`, `typeof`, and `matches`

Spark SQL does not support these functions.

- Projections on complex types, including arrays, maps, and structs

For example, if you select an element of an array, as shown in the following example, it is not pushed down:

### Scala

```
ds.select($"hobbies" (0))
```

### Java

```
df.select(col("hobbies").getItem(0));
```

### Python

```
df.select(col("hobbies").getItem(0))
```

These limitations do not apply to pushdowns on RDDs. An alternative is to apply the [pushdown using an RDD](#), and then [convert the RDD to a DataFrame](#).

**NOTE:** HPE Ezmeral Data Fabric Database 6.0 introduces support for [Secondary Indexes](#) on page 674, but the HPE Ezmeral Data Fabric Database OJAI Connector for Spark does not currently leverage them.

## Converting an Apache Spark RDD to an Apache Spark DataFrame

When APIs are only available on an Apache Spark RDD but not an Apache Spark DataFrame, you can operate on the RDD and then convert it to a DataFrame.

You can convert an RDD to a DataFrame in one of two ways:

- Use the helper function, `rdd.toDF`.
- Convert the RDD to a DataFrame using the `createDataFrame` call on a `SparkSession` object.

## Using the toDF Helper Function

The `toDF` method is available through `MapRDBTableScanRDD`. The following example loads an RDD that filters on `first_name` equal to "Peter" and projects the `_id` and `first_name` fields, and then converts the RDD to a `DataFrame`:

### Scala

```
import com.mapr.db.spark.sql._

val df =
  sc.loadFromMapRDB(<table-name>)
    .where(field("first_name")
      === "Peter")
    .select("_id",
      "first_name").toDF()
```

## Using SparkSession.createDataFrame

With this approach, you can convert an `RDD[Row]` to a `DataFrame` by calling `createDataFrame` on a `SparkSession` object. The API for the call is as follows:

### Scala

```
def createDataFrame(RDD, schema:
  StructType)
```

You might need to first convert an `RDD[OJAIDocument]` to an `RDD[Row]`. The following example shows how to do this:

### Scala

```
val df = sparkSession.createDataFrame(
  rdd.map(doc
=>MapRDBSpark.docToRow(doc, schema)),
  schema)
```

`rdd` is of type `RDD[OJAIDocument]`. The `docToRow` call converts `rdd` to an `RDD[Row]` that is then passed to `createDataFrame`.

### Working with Complex JSON Document Types

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides APIs to process JSON documents loaded from HPE Ezmeral Data Fabric Database.

Suppose you want to calculate the number of users located in each city:

### Scala

```
import com.mapr.db.spark.sql._

val customerprofilesRDD =
  sc.loadFromMapRDB("/tmp/
  user_profiles")
val numberOfCustaccCities =
  customerprofilesRDD.map(a =>
  (a.`address.city`[String],a))
  .groupByKey
  y()
  .map(a =>
  (a._1, a._2.size))
```

### Java

```
import
  com.mapr.db.spark.api.java.MapRDBJavaS
```

```

parkContext;
import scala.Tuple2;
import java.util.Collection;

MapRDBJavaRDD<OJAI Document>
customerprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tmp/
user_profiles");
JavaRDD numberOfCustaccCities =
customerprofilesRDD.mapToPair
(a -> new
Tuple2<>(a.getString("address.city"),
a)).groupByKey()
.map(a -> new Tuple2<>(a._1,
((Collection<?>)a._2).size()));

```

If you have not provided an explicit cast, then the object is returned as `AnyRef`. To access methods specific to a class, such as `String` or `Integer`, you can cast it to a specific type later in the process.

Now suppose you want to collect all the addresses (address is of type `Map`) of all customers:

#### Scala

```

import com.mapr.db.spark.sql._

val customerprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles")
val customersAddress =
customerprofilesRDD.map(a =>
a.address).collect

```

#### Java

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAI Document>
customerprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
List<String> customersAddress =
customerprofilesRDD.map(a ->
a.getString("address")).collect();

```

`customersAddress` contains all of the addresses, but is returned as an `AnyRef` object.

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark introduces three new classes to wrap complex JSON types:

Class	Type
<code>DBMapValue</code>	<code>Map[String, AnyRef]</code>
<code>DBArrayValue</code>	<code>Array[AnyRef]</code>
<code>DBBinaryValue</code>	<code>ByteBuffer</code>

These classes are not exposed; however, you can access the underlying elements of `DBArrayValue` and `DBMapValue` by using the same functions as in `Seq` and `Map`. `DBArrayValue` works like a sequence, while `DBMapValue` works like a map.

`DBBinaryValue` is a class wrapper around `ByteBuffer`. `ByteBuffer` is not serializable, so you will get serialization errors if you use the `ByteBuffer` in Spark code. You must ensure that byte buffers are converted to `DBBinaryValue` or serialized byte buffers. The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides an API to convert `ByteBuffers` to serializable byte buffers.

### Accessing Values in a Map

`DBMapValue` is a type of `Map[String, AnyRef]`. Any functions that you can use to access values in the `Map`, you can also use to access values in `DBMapValue`. In the following example, `customeraddress` contains the address of the customers who reside in San Jose. `customeraddress` is an `Array[DBMapValue]`:

#### Scala

```
val customerAddress = maprd.map(a =>
  a.address[Map[String, AnyRef]])
    .filter(a => a != null &&
  a.get("city").contains("San Jose"))
    .collect
```

This example can also be written in Scala using a functional approach as follows:

#### Scala

```
val customerAddress = maprd.map(a
=> (a.address[Map[String, AnyRef]],
a).join(my_documents)
    .filter(a =>
Option(a).map(a =>
  a.get("city").contains("San
Jose")).getOrElse(false)))
    .collect
```

**NOTE:** You can push the condition specified in the filter condition to the HPE Ezmeral Data Fabric Database table scan by using the `where` clause.

### Accessing the Array JSON Object

This example uses a sequence to access the Array JSON object:

#### Scala

```
val custInterests = maprd.map(a =>
  a.interests[Seq[AnyRef]])
    .filter(a => a !=
  null && a(0) == "sports")
    .collect
```

### ByteBuffer Serialization

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following API to enable serialization of the `ByteBuffer`:

#### Scala

```
MapRDBSpark.serializableBinaryValue(
  teBuffer)
```

The following example shows an array of byte buffers or binary values that are converted to serialized byte buffers by using `MapRDBSpark.serializableBinaryValue`:

**Scala**

```
val dstSplits =
  arrayOfByteBuffer.map(x =>
    MapRDBSpark.serializableBinaryValue(x)
  )
```

***Saving Data to a HPE Ezmeral Data Fabric Database JSON Table***

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides an API to save an Apache Spark RDD to a HPE Ezmeral Data Fabric Database JSON table. Starting in the EEP 4.0 release, the connector introduces support for saving Apache Spark DataFrames and DStreams to HPE Ezmeral Data Fabric Database JSON tables.

Saving an Apache Spark RDD to a HPE Ezmeral Data Fabric Database JSON Table

**Saving an RDD[OJAIDocument] to HPE Ezmeral Data Fabric Database**

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following API to save an RDD[OJAIDocument] to a HPE Ezmeral Data Fabric Database table:

**Scala**

For saving an RDD, apply the following method on the RDD:

```
def saveToMapRDB(tablename: String,
  createTable: Boolean =
  false, bulkInsert: Boolean =
  false, idFieldPath: String =
  DocumentConstants.ID_KEY) : Unit
```

**Java**

For saving an RDD, apply one of the following methods on a MapRDBJavaSparkContext object:

```
def saveToMapRDB[D](javaRDD:
  JavaRDD[D], tableName: String,
  createTable: Boolean, bulkInsert:
  Boolean, idField: String): Unit

def saveRowRDDToMapRDB(javaRDD:
  JavaRDD[Row], tableName: String,
  createTable: Boolean, bulkInsert:
  Boolean, idField: String): Unit

def saveToMapRDB[K, V <: AnyRef]
  (javaPairRDD: JavaPairRDD[K, V],
  keyClazz: Class[K], valueClazz:
  Class[V], tableName: String,
  createTable: Boolean, bulkInsert:
  Boolean): Unit
```

**NOTE:** The only required parameter to the methods is `tableName`. All the others are optional.

In the following example, `address` and `first_name` data is loaded from the `"/tmp/user_profiles"` table, stored as an RDD (`userprofilesRDD`), and then saved to the `"/tmp/user_firstname_and_address"` table:

**Scala**

```
import com.mapr.db.spark._

val userprofilesRDD =
  sc.loadFromMapRDB("/tmp/
  user_profiles")
```

```

        .where("condition")
    )
        .select("address",
            "first_name")

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address")

```

## Java

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
        .where("condition")
        .select("address",
            "first_name");
mapRDBSparkContext.saveToMapRDB(userpr
ofilesRDD, "/tmp/
user_firstname_and_address", true,
false, "_id");

```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark also provides the following API to insert an RDD[OJAIDocument] to a HPE Ezmeral Data Fabric Database table:

**NOTE:** The `insertToMapRDB` API is available starting in the EEP 4.1.0 release.

## Scala

```

import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
userprofilesRDD.insertToMapRDB(tablena
me, createTable = true, bulkInsert =
false, idFieldPath = "_id")

```

## Java

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD<OJAIDocument>
userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");

```

```
mapRDBSparkContext.insertRowRDDToMapRDB(userprofilesRDD, tablename);
```

 **NOTE:** The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

This API supports the following parameters:

### Scala

Parameter	Default	Description
<code>tableName</code>	Not applicable	The name of the HPE Ezmeral Data Fabric Database table in which you are saving the document.
<code>createTable</code>	<code>false</code>	Creates the table before saving the documents. Note that if the table already exists and <code>createTable</code> is set to true, the API throws an exception.
<code>idFieldPath</code>	<code>_id</code>	Specifies the key to be used for the document.
<code>bulkInsert</code>	<code>false</code>	Loads a group of rows simultaneously. <code>bulkInsert</code> is similar to a bulk load in MapReduce.

### Java

Parameter	Default	Description
RDD (JavaRDD or JavaPairRDD)	Not applicable	Specifies the RDD which you are saving to the HPE Ezmeral Data Fabric Database table.
<code>tableName</code>	Not applicable	Specifies the name of the HPE Ezmeral Data Fabric Database table in which you are saving the document.
<code>createTable</code>	<code>false</code>	Creates the table before saving the document. Note that if the table already exists and <code>createTable</code> is set to true, the API throws an exception.
<code>idFieldPath</code>	<code>_id</code>	Specifies the key to be used for the document.
<code>bulkInsert</code>	<code>false</code>	Loads a group of rows simultaneously. <code>bulkInsert</code> is similar to a bulk load in MapReduce.
<code>keyClazz</code> (Only for JavaPairRDD)	Not applicable	Specifies the class type which is the key in the JavaPairRDD which you are saving into the HPE Ezmeral Data Fabric Database table.
<code>valueClazz</code> (Only for JavaPairRDD)	Not applicable	Specifies the class type which is the value in the JavaPairRDD which you are saving into the HPE Ezmeral Data Fabric Database table.

In Java, `saveToMapRDB` method works with `JavaRDD` and `JavaPairRDD`. For saving `JavaRDD[Row]`, use the `saveRowRDDToMapRDB` method.

The following example specifies a key by using the `idFieldPath` parameter and the `bulkInsert` value to save the RDD:

#### Scala

```
import com.mapr.db.spark._

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address",

idFieldPath = "user_id",

bulkInsert = false)
```

#### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
mapRDBSparkContext.saveToMapRDB(userpr
ofilesRDD, "/tmp/
user_firstname_and_address", false,
false, "user_id");
```

The following example saves an RDD of `Person` objects into the newly created `/tmp/Userinfo` table:

#### Scala

```
import com.mapr.db.spark._

val sparkConf =
new SparkConf().setAppName("json
app").setMaster("local[*]")
val sc = new SparkContext(sparkConf)
val people =
sc.parallelize(getUsers())
people.saveToMapRDB("/tmp/UserInfo",
createTable= true)
```

#### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

SparkConf sparkConf = new
SparkConf().setAppName("json
app").setMaster("local[*]");
SparkContext sc = new
SparkContext(sparkConf);
JavaRDD rdd =
sc.parallelize(getUsers());
mapRDBSparkContext.saveToMapRDB(rdd,
"/tmp/UserInfo", true);
```

The following example shows the `getUsers` function that allocates the `Person` objects:

**Scala**

```

def getUsers(): Array[Person] = {
  val users: Array[Person] =

    Array(
      Person("DavUSCalif", "David",
        "Jones",
          ODate.parse("1947-11-29"),
          Seq("football", "books",
            "movies"),
          Map("city" -> "milpitas",
            "street" -> "350 holger way",
            "Pin" -> 95035)),
      Person("PetUSUtah", "Peter",
        "pan",
          ODate.parse("1974-1-29"),
          Seq("boxing", "music",
            "movies"),
          Map("city" -> "salt lake",
            "street" -> "351 lake way", "Pin" ->
            89898)),
      Person("JamUSAriz", "James",
        "junior",
          ODate.parse("1968-10-2"),
          Seq("tennis", "painting",
            "music"),
          Map("city" -> "phoenix",
            "street" -> "358 pond way", "Pin" ->
            67765)),
      Person("JimUSCalif", "Jimmy",
        "gill",
          ODate.parse("1976-1-9"),
          Seq("cricket",
            "sketching"),
          Map("city" -> "san jose",
            "street" -> "305 city way", "Pin" ->
            95652)),
      Person("IndUSCalif",
        "Indiana", "Jones",
          ODate.parse("1987-5-4"),
          Seq("squash", "comics",
            "movies"),
          Map("city" -> "sunnyvale",
            "street" -> "35 town way", "Pin" ->
            95985)))

    users
  }

```

**Saving a JSON Document to HPE Ezmeral Data Fabric Database**

To save a JSON document using the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, you must first convert the JSON document into an OJAI document and then save the RDD, as shown in the following example:

**Scala**

```
import com.mapr.db.spark._

val documents = sc.parallelize((1 to
  10)
  .map(i => s"""{"_id":
    "$i", "test": "$i}"""))
val maprd = documents.map(a =>
  MapRDBSpark.newDocument(a))
maprd.saveToMapRDB("/tmp/testData")
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
org.apache.spark.api.java.JavaSparkCon
text;

JavaRDD<String> documents =
JavaSparkContext.fromSparkContext(sc)
  .parallelize(Arrays.asList
    (1, 2, 3, 4, 5, 6, 7, 8, 9, 10))
  .map(i -> { return
    "{\"id\": \"\" + i + \"\", \"test\":
    \"\" + i + \"\"}"; });
JavaRDD<OJAI Document> maprd =
documents.map(MapRDBSpark::newDocument
);
mapRDBSparkContext.saveToMapRDB(maprd,
"/tmp/testData");
```

An `_id` field is required to save JSON data into a table, so an `_id` field must be present. If you need only to convert the JSON data to an OJAI document (without saving to HPE Ezmeral Data Fabric Database), the `_id` field is not required. If the HPE Ezmeral Data Fabric Database table already contains a record with the same `_id` value, HPE Ezmeral Data Fabric Database replaces the record. Otherwise, it inserts a new record.

Just as you can load a JSON document into a Scala bean class (see [Creating an RDD of a Class](#)), you can save the RDD of Scala class objects in a HPE Ezmeral Data Fabric Database JSON table. `saveToMapRDB` can save any bean object as a JSON document by converting it to a JSON document.

**Table Splits and saveToMapRDB**

If the `createTable` parameter is set to `true`, `saveToMapRDB` can use the partition information from the RDD's lineage to create the splits for a new table:

**Scala**

```
sc.loadFromMapRDB("/tmp/
user_profiles").saveToMapRDB("/
userProfiles",

createTable = true)
```

Suppose `/tmp/user_profiles` has a table with five splits. `saveToMapRDB` uses this information to create the `/userProfiles` table with the same number and range of splits. You can also supply this information by using `MapRDBSpark.newPartitioner`:

**Scala**

```
sc.loadFromMapRDB("/tmp/
user_profiles").keyBy(doc =>
doc.get("_id"))
  .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[String]
  ("/profiles"))
  .saveToMapRDB("/userProfiles",
createTable = true)
```

For more information about partitioning, see [Using the Custom Partitioner with the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark](#) on page 4663.

**Saving an Apache Spark DataFrame to a HPE Ezmeral Data Fabric Database JSON Table**

To save an Apache Spark DataFrame to a HPE Ezmeral Data Fabric Database, invoke the `saveToMapRDB` method on the `DataFrame` object (Scala). This returns a `DataFrameWriter` object, from which you can invoke the `saveToMapRDB` method. For Java and Python, invoke the `saveToMapRDB` method on the `MapRDBJavaSession` object or `SparkSession` object, respectively.

If a row with the same ID already exists, the `saveToMapRDB` method updates or overwrites that row. If you want an exception to be thrown in this case, you can use the `insertToMapRDB` method.

**Scala**

```
import com.mapr.db.spark.sql._

df.write.saveToMapRDB("/tmp/userInfo")
```

For EEP 4.1.0 and later, you can directly invoke the `saveToMapRDB` method on the `DataFrame` object:

```
def saveToMapRDB(tableName: String,
idFieldPath : String = "_id",
createTable: Boolean = false,
bulkInsert: Boolean = false): Unit

import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df = spark.loadFromMapRDB("/tmp/
user_profiles")
df.saveToMapRDB(tableName,
createTable = true)
```

**Java**

For saving a `DataFrame (Dataset<Row>)`, apply the following method on a `MapRDBJavaSession` object:

```
def saveToMapRDB[T](df: DataFrame[T],
tableName: String, idFieldPath:
String, createTable: Boolean,
bulkInsert: Boolean): Unit

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
```

```
user_profiles");

maprSession.saveToMapRDB(ds, "/tmp/
userInfo");
```

**Python**

For saving a DataFrame, apply the following method on a Dataframe:

```
def saveToMapRDB(dataframe,
table_name, id_field_path =
default_id_field, create_table =
False, bulk_insert = False)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")

sparkSession.saveToMapRDB(df,
table_name, create_table=True)
```

**Inserting an Apache Spark DataFrame into a HPE Ezmeral Data Fabric Database JSON Table**

Starting in the EEP 4.1.0 release, you can use the `insertToMapRDB` API to insert an Apache Spark DataFrame into a Data Fabric Database JSON table in Python. The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

PySpark supports only `DataFrame(Dataset<Row>)`:

**Python**

```
sparkSession.insertToMapRDB(df,
tableName, idFieldPath, bulkInsert)
```

**Using Alternate Write Modes for HPE Ezmeral Data Fabric Database OJAI Connector**

You can use alternate write modes supported by Data Fabric Database OJAI Connector for Apache Spark to save an Apache Spark DataFrame to a Data Fabric Database JSON table.

Normally, the Apache Spark `DataFrameWriter` class supports the following write modes:

- Append
- Overwrite
- ErrorIfExists
- Ignore

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark returns an `OperationNotSupported` exception if you attempt to use one of these modes. The following example returns the error:

**Scala**

```
import org.apache.spark.sql.SaveMode
import com.mapr.db.spark.sql._

df.write.mode(SaveMode.Append).saveToM
apRDB("/tmp/userInfo")
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following alternative modes:

<b>Insert</b>	Inserts the data into the HPE Ezmeral Data Fabric Database table. Throws a <code>DBException</code> if a row with same <code>_id</code> value already exists in the table.
<b>Overwrite</b>	Overwrites the data in the table with the current <code>DataFrame</code> data. This operation drops the table and creates a new table with the data.
<b>ErrorIfExists</b>	Returns an exception ( <code>TableExistsException</code> ) if the table already exists. Otherwise, creates the table and inserts the data.
<b>Ignore</b>	Ignores the data in the table if the table already exists. Otherwise, creates the table and inserts the data.
<b>InsertOrReplace</b>	Replaces the row with the row in the <code>DataFrame</code> , if a row with the same <code>_id</code> already exists in the table. Otherwise, inserts the new row.

You cannot specify these modes using the Apache Spark `SaveMode` method. Doing so results in the same `OperationNotSupported` exception noted earlier. To use these modes, you must call the `option` method on a `DataFrameWriter` object. The following example sets the `Insert` mode:

#### Scala

```
df.write.option("Operation",
  "Insert").saveToMapRDB("/tmp/
  usersInfo")
```

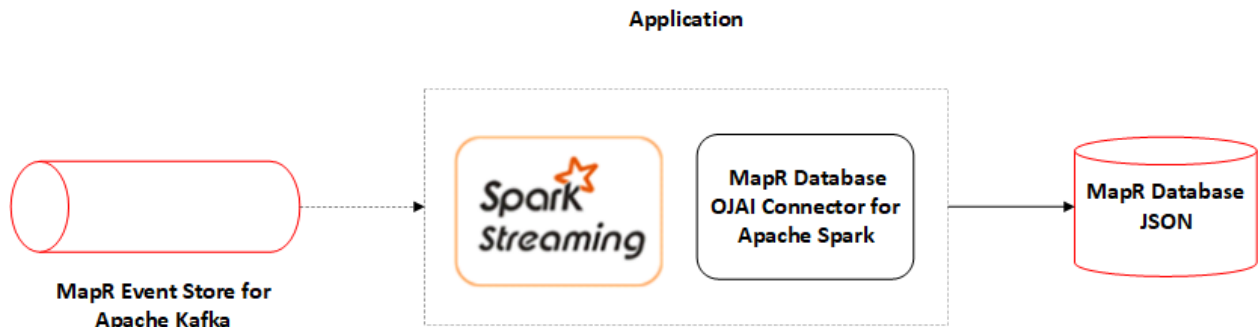

**NOTE:** The `UPDATE` mode for HPE Ezmeral Data Fabric Database OJAI Connector is not supported and it results in an `OperationNotSupported` exception.

### Saving an Apache Spark DStream to a HPE Ezmeral Data Fabric Database JSON Table

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark enables you to use HPE Ezmeral Data Fabric Database as a sink for Apache Spark DStreams.

**NOTE:** Saving of Apache Spark DStream to HPE Ezmeral Data Fabric Database JSON table is currently only supported in Scala.

The following API saves a `DStream[OJAIDocument]` object to a HPE Ezmeral Data Fabric Database table:

#### Scala

```
def saveToMapRDB(tablename: String,
  createTable: Boolean,
  bulkInsert: Boolean,
  idFieldPath: String): Unit
```

The parameters are as follows:

Parameter	Default	Description
tableName	Not applicable	The name of the HPE Ezmeral Data Fabric Database table to which you are saving the DStream.
createTable	false	Creates the table before saving the DStream. Note that if the table already exists and createTable is set to true, the API throws an exception.
idFieldPath	_id	Specifies the key to be used for the DStream.
bulkInsert	false	Loads a group of streams simultaneously. bulkInsert is similar to a bulk load in MapReduce.

 **NOTE:** The only required parameter for this function is tableName. All the others are optional.

The following example creates a DStream object, converts it to a DStream[OJAI Document] object, and then stores it in HPE Ezmeral Data Fabric Database:

#### Scala

```
val clicksStream: DStream[String] =
  createKafkaStream(...)
clicksStream.map(MapRDBSpark.newDocument()).saveToMapRDB("/clicks",
  createTable=true)
```

 **NOTE:** You must use the map(MapRDBSpark.newDocument()) API to convert the DStream object to a DStream[OJAI Document] object.

If clicksStream is a DStream of Strings, it can be saved to HPE Ezmeral Data Fabric Database using the saveToMapRDB API:

#### Scala

```
clicksStream.map(MapRDBSpark.newDocument(_)).saveToMapRDB("/clicks",
  createTable = true);
```

 **NOTE:** To use the saveToMapRDB API, you need to transform the DStream object to a DStream[OJAI Document] by using the Apache Spark Map API.

### Saving an Apache Spark Dataset to a HPE Ezmeral Data Fabric Database JSON Table

Starting in the EEP 4.1.0 release, the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark provides the following API to save a Dataset to a HPE Ezmeral Data Fabric Database table:

#### Scala

For saving a Dataset, apply the following method on a Spark object:

```
def saveToMapRDB(tableName: String,
  idFieldPath : String = "_id",
  createTable: Boolean =
  false, bulkInsert:Boolean = false):
  Unit

import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds = spark.loadFromMapRDB("/tmp/
user_profiles")
```

**Java**

```
ds.saveToMapRDB(tableName,
createTable = true)
```

For saving a Dataset, apply the following method on a MapRDBJavaSession object:

```
def saveToMapRDB[T](ds: Dataset[T],
tableName: String, idFieldPath:
String,
createTable: Boolean,
bulkInsert: Boolean): Unit

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
maprSession.saveToMapRDB(ds, true);
```

The HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark also provides the following API to insert a Dataset into a HPE Ezmeral Data Fabric Database table:

**Scala**

```
import com.mapr.db.spark._

ds.insertToMapRDB(tableName,
idFieldPath, bulkInsert)
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

maprSession.insertToMapRDB(ds,
tableName, idFieldPath, bulkInsert)
```

**NOTE:** The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

### Word Count Example Using HPE Ezmeral Data Fabric Database OJAI Connector

            Word(wordWithId(0),
wordWithId.drop(1).mkString(" "))
        }).toSeq
}

private case class Word(_id:
String, words: String)
}

```

*Using Serialization with the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark*

In the context of the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark, serialization refers to the methods that read and write objects into bytes. This section describes how to configure your application to use a more efficient serializer.

The Apache Spark cluster framework requires serialization to exchange objects between driver and cluster executors. This type of serialization has nothing to do with the way HPE Ezmeral Data Fabric Database serializes the objects onto the disk.

Because classes used in Spark transformations or actions must be serializable, classes created for the HPE Ezmeral Data Fabric Database OJAI Connector for Apache Spark are serializable.

Spark uses Java serialization by default, but it can alternatively use Kyro Serialization. A new Kyro registrar is introduced so you can avoid using the default Java serialization. Kyro serialization provides better performance than Java serialization.

The following example shows how to set the new Kyro registrar in `sparkconf`:

**Scala**

```
new sparkconf()
  .set("spark.serializer",
    "org.apache.spark.serializer.KryoSeriali
    zer")
  .set("spark.kryo.registrator",
    "com.mapr.db.spark.OJAIKryoRegistrato
    r")
```

A JSON document can use both complex and primitive value types. Java can serialize the primitive types, but for complex types (such as `Map`, `Array`, and `Binary`), you must use wrappers to achieve serialization. See [Working with Complex JSON Document Types](#) on page 4682 for details about these wrappers.

Time-related data types, such as `ODate`, `OInterval`, `OTime`, and `OTimeStamp`, use Java serialization by default. For efficiency, new serializers and comparators have been created for these data types.

Here are the new serializers and the type which each serializer applies:

Serializer	Type
<code>ODateSerializer</code>	<code>ODate</code> type
<code>OTimeSerializer</code>	<code>OTime</code>
<code>OTimeStampSerializer</code>	<code>OTimeStamp</code>
<code>OIntervalSerializer</code>	<code>OInterval</code>
<code>DBBinaryValueSerializer</code>	<code>ByteBuffer</code>

**HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark**

This section describes the three main interaction points between Spark and HBase APIs and provides examples for each interaction point.

The interaction points are:

Basic Spark	You can have an HBase Connection at any point in your Spark DAG.
Spark Streaming	You can have an HBase Connection at any point in your Spark Streaming application.
Spark Structured Streaming	Using Spark structured streaming to write data to a HPE Ezmeral Data Fabric Database binary table is currently not supported.
Spark Bulk Load	This option is currently not supported for HPE Ezmeral Data Fabric Database.
SparkSQL/DataFrames	You can write SparkSQL that draws on tables that are represented in HBase.

The following pages provide examples of each of these interaction points.

*Configuring the HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark*

### About this task

Use these steps to configure the HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark:

### Procedure

1. Verify that the `mapr-hbase` package is installed. For more information, refer to the [HBase release notes](#).
2. Copy the `HBASE_HOME/conf/hbase-site.xml` file to `SPARK_HOME/conf/`.
3. Specify the `hbase-site.xml` file in the `SPARK_HOME/conf/spark-defaults.conf`:

```
spark.yarn.dist.files    SPARK_HOME/conf/hbase-site.xml
```

### *HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark Integration with Basic Spark*

This page describes integration between Apache Spark and HBase APIs.

This section describes Spark integration with HBase APIs at the lowest and simplest levels. All other interaction points are built upon the concepts described here.

At the root of all integration with Spark and HBase APIs is the `HBaseContext`. The `HBaseContext` takes in HBase configurations and pushes them to the Spark executors. This allows you to have an `HBase Connection` per Spark executor in a static location.

### HBaseContext Usage Example

This example shows how `HBaseContext` can be used to do a `foreachPartition` on an RDD in Scala:

```
val sc = new SparkContext("local", "test")
val config = new HbaseConfiguration()
...
val hbaseContext = new HBaseContext(sc, config)

rdd.hbaseForeachPartition(hbaseContext, (it, conn) => {
  val bufferedMutator = conn.getBufferedMutator(TableName.valueOf("/apps/
my_table"))
  it.foreach((putRecord) => {
    val put = new Put(putRecord._1)
    putRecord._2.foreach((putValue) =>
      put.addColumn(putValue._1,
        putValue._2, putValue._3))
    bufferedMutator.mutate(put)
  })
  bufferedMutator.flush()
  bufferedMutator.close()
})
```

Here is the same example implemented in Java:

```
JavaSparkContext jsc = new JavaSparkContext(sparkConf);

try {
  List<byte[]> list = new ArrayList<>();
  list.add(Bytes.toBytes("1"));
  ...
  list.add(Bytes.toBytes("5"));

  JavaRDD<byte[]> rdd = jsc.parallelize(list);
  Configuration conf = HBaseConfiguration.create();
```

```

JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);

hbaseContext.foreachPartition(
    rdd,
    new VoidFunction<Tuple2<Iterator<byte[]>, Connection>>() {
        public void call(Tuple2<Iterator<byte[]>, Connection> t) throws
Exception {
            Table table = t._2().getTable(TableName.valueOf(tableName));
            BufferedMutator mutator =
t._2().getBufferedMutator(TableName.valueOf(tableName));
            while (t._1().hasNext()) {
                byte[] b = t._1().next();
                Result r = table.get(new Get(b));
                if (r.getExists()) {
                    mutator.mutate(new Put(b));
                }
            }

            mutator.flush();
            mutator.close();
            table.close();
        }
    });
} finally {
    jsc.stop();
}

```

All functionality between Spark and HBase Client is supported both in Scala and in Java, with the exception of SparkSQL, which supports any language that is supported by Spark. This section focuses on Scala examples.

The example here shows how to do a `foreachPartition` with a connection. A number of other Spark base functions are supported out of the box:

bulkPut	Enables massively parallel sending of puts to HBase.
bulkDelete	Enables massively parallel sending of deletes to HBase.
bulkGet	Enables massively parallel sending of gets to HBase to create a new RDD.
mapPartition	Enables the Spark Map function with a Connection object to allow full access to HBase.
hBaseRDD	Simplifies a distributed scan to create an RDD.

You can see examples of these commands in the [source code of the HBase-Spark Module](#).

*HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark Integration with Spark Streaming*

[Spark Streaming](#) is a micro-batching, stream-processing framework built on top of Spark. HBase APIs and Spark Streaming make great companions. When used alongside Spark Streaming, HBase APIs can serve as:

- A place to grab reference data or profile data on the fly.
- A place to store counts or aggregates in a way that supports the Spark Streaming promise of only once processing.

The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark integration points with Spark Streaming are similar to its normal Spark integration points. You can use the following commands straight off a Spark Streaming DStream:

bulkPut	Enables massively parallel sending of puts to HBase APIs.
---------	-----------------------------------------------------------

bulkDelete	Enables massively parallel sending of deletes to HBase APIs.
bulkGet	Enables massively parallel sending of gets to HBase APIs to create a new RDD.
mapPartition	Enables the Spark Map function with a Connection object to allow full access to HBase APIs.
hBaseRDD	Simplifies a distributed scan to create an RDD.

### bulkPut Example with DStreams

The following example shows a bulkPut with DStreams. It is similar to the RDD bulk put.

**NOTE:** To invoke the `hbaseBulkPut` method, make sure you import the `HBaseDStreamFunctions` class.

```
import org.apache.hadoop.hbase.spark.HBaseDStreamFunctions._

val sc = new SparkContext("local", "test")
val config = new HBaseConfiguration()

val hbaseContext = new HBaseContext(sc, config)
val ssc = new StreamingContext(sc, Milliseconds(200))

val rdd1 = ...
val rdd2 = ...
val queue = mutable.Queue[
  RDD[(Array[Byte],
  Array[(Array[Byte],
  Array[Byte],
  Array[Byte])])]]()

queue += rdd1
queue += rdd2

val dStream = ssc.queueStream(queue)

dStream.hbaseBulkPut(
  hbaseContext,
  TableName.valueOf(tableName),
  (putRecord) => {
    val put = new Put(putRecord._1)
    putRecord._2.foreach((putValue) =>
      put.addColumn(putValue._1, putValue._2, putValue._3))
    put
  })
```

The `hbaseBulkPut` function has three inputs:

- The `hbaseContext` that carries the configuration broadcast information link to the HBase Connections in the executors.
- The table name of the table you are putting data into.
- A function that will convert a record in the DStream into an HBase `Put` object.

The code snippet above has been extracted from <https://github.com/mapr/hbase/blob/1.1.8-mapr-1703/hbase-spark/src/test/scala/org/apache/hadoop/hbase/spark/HBaseDStreamFunctionsSuite.scala>.

### Bulk Loading Data into HBase with Spark

There are two options for bulk loading data into HBase with Spark:

 **NOTE:** The bulk load operation is currently not supported for HPE Ezmeral Data Fabric Database.

#### Basic bulk load functionality

The basic bulk load functionality works for cases where your rows have millions of columns and cases where your columns are not consolidated.

#### Thin-record bulk load option

The thin-record bulk load option with Spark is designed for tables that have fewer than 10,000 columns per row. The advantage of this option is higher throughput and less overall load on the Spark shuffle operation.

Both implementations work more or less like the MapReduce bulk load process. A partitioner partitions the RowKeys based on region splits, and the RowKeys are sent to the reducers in order, so that HFiles can be written directly from the reduce phase.

In Spark terms, the bulk load is implemented around a `SparkrepartitionAndSortWithinPartitions` followed by a `Spark foreachPartition`. Here is an example of using the basic bulk load functionality:

#### Bulk Loading Example

 **NOTE:** Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark._
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.util.Bytes._
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.SparkSession
import org.apache.hadoop.hbase.client.{HBaseAdmin, HConnectionManager}
val tableName = "table1"
val stagingFolder = "/home/mapr"
val columnFamily1 = "cf1"
@transient val conf = HBaseConfiguration.create()
val hbaseContext = new HBaseContext(sc, conf)
conf.set(TableInputFormat.INPUT_TABLE, tableName)
conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
conf.setInt("hbase.zookeeper.property.clientPort", 5181)
val rdd = sc.parallelize(Array(
  (toBytes("1"), (toBytes(columnFamily1), toBytes("a"),
toBytes("foo1"))),
  (toBytes("3"), (toBytes(columnFamily1), toBytes("b"),
toBytes("foo2.b"))))
))
rdd.hbaseBulkLoad(hbaseContext,
  TableName.valueOf(tableName),
  t => {
    val rowKey = t._1
    val family: Array[Byte] = t._2._1
    val qualifier = t._2._2
    val value: Array[Byte] = t._2._3
    val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
    Seq((keyFamilyQualifier, value)).iterator
  },
  stagingFolder)
val connection = HConnectionManager.createConnection(conf)
val table = connection.getTable(TableName.valueOf(tableName))
```

```
val load = new LoadIncrementalHFiles(conf)
load.doBulkLoad(
  new Path(stagingFolder),
  connection.getAdmin,
  table,
  connection.getRegionLocator(TableName.valueOf(tableName)))
```

### Required Parameters for Bulk Loading with Spark

The `hbaseBulkLoad` function takes three required parameters:

- The name of the table you intend to bulk load to.
- A function that converts a record in the RDD to a tuple key-value pair, with the tuple key being a `KeyFamilyQualifier` object and the value being the cell value. The `KeyFamilyQualifier` object holds the RowKey, Column Family, and Column Qualifier. The shuffle partitions on the RowKey but sorts by all three values.
- The temporary path for the HFile to be written out to. Following the Spark bulk load command, use the `HBase LoadIncrementalHFiles` object to load the newly created HFiles into HBase.

### Additional Parameters for Bulk Loading with Spark

You can set the following attributes with additional parameter options on `hbaseBulkLoad`:

- Max file size of the HFiles
- A flag to exclude HFiles from compactions
- Column Family settings for compression, bloomType, blockSize, and dataBlockEncoding

The following example shows the use of additional parameters:

**NOTE:** Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{FamilyHFileWriteOptions,
HBaseContext, KeyFamilyQualifier}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, HConstants, TableName}
import org.apache.spark.sql.SparkSession

val tableName = "table2"
val stagingFolder = "/home/mapr"
val columnFamily1 = "cf1"
val sc = spark.sparkContext
@transient val conf = HBaseConfiguration.create()
conf.set(TableInputFormat.INPUT_TABLE, tableName)
conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
conf.setInt("hbase.zookeeper.property.clientPort", 5181)
val hbaseContext = new HBaseContext(sc, conf)
val rdd = sc.parallelize(Array(
  (Bytes.toBytes("1"),
  (Bytes.toBytes(columnFamily1),
  Bytes.toBytes("a"), Bytes.toBytes("fool"))),
  (Bytes.toBytes("3"),
  (Bytes.toBytes(columnFamily1),
```

```

        Bytes.toBytes("b"),
        Bytes.toBytes("foo2.b")))))
val familyHBaseWriterOptions =
  new java.util.HashMap[Array[Byte], FamilyHFileWriteOptions]
val flOptions = new FamilyHFileWriteOptions("GZ", "ROW", 128, "PREFIX")
familyHBaseWriterOptions.put(Bytes.toBytes(columnFamily1), flOptions)
rdd.hbaseBulkLoad(hbaseContext,
  TableName.valueOf(tableName),
  t => {
    val rowKey = t._1
    val family:Array[Byte] = t._2._1
    val qualifier = t._2._2
    val value = t._2._3
    val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
    Seq((keyFamilyQualifier, value)).iterator
  },
  stagingFolder,
  familyHBaseWriterOptions,
  compactionExclude = false,
  HConstants.DEFAULT_MAX_FILE_SIZE)
val connection = HConnectionManager.createConnection(conf)
val table = connection.getTable(TableName.valueOf(tableName))
val load = new LoadIncrementalHFiles(conf)
load.doBulkLoad(new Path(stagingFolder),
  connection.getAdmin, table,
connection.getRegionLocator(TableName.valueOf(tableName)))

```

### Thin-Record Bulk Load Example

The following example shows how to call the thin-record bulk load implementation:

**NOTE:** Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```

import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{HBaseContext, _}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.SparkSession
val tableName = "table3"
val stagingFolder = "/home/mapr"
val columnFamily1 = "cf1"
@transient val conf = HBaseConfiguration.create()
val hbaseContext = new HBaseContext(sc, conf)
conf.set(TableInputFormat.INPUT_TABLE, tableName)
conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
conf.setInt("hbase.zookeeper.property.clientPort", 5181)
val rdd = sc.parallelize(Array(
  ("1", List(Bytes.toBytes(columnFamily1), Bytes.toBytes("a")),
Bytes.toBytes("fool")),
  ("3", List(Bytes.toBytes(columnFamily1), Bytes.toBytes("b"),
Bytes.toBytes("foo2.b")))))
rdd.hbaseBulkLoadThinRows(hbaseContext,
  TableName.valueOf(tableName),
  t => {
    val rowKey = t._1
    val familyQualifiersValues = new FamiliesQualifiersValues

```

```

    val q = t._2
    val family:Array[Byte] = q.head
    val qualifier = q(1)
    val value:Array[Byte] = q(2)
    println(s"family: $family")
    println(s"qualifier: $qualifier")
    println(s"value: $value")
    familyQualifiersValues +=(family, qualifier, value)
    (new ByteArrayWrapper(Bytes.toBytes(rowKey)),
familyQualifiersValues)}, stagingFolder, new java.util.HashMap[Array[Byte],
FamilyHFileWriteOptions], compactionExclude = false, 20)
    val connection = HConnectionManager.createConnection(conf)
    val table = connection.getTable(TableName.valueOf(tableName))
    val load = new LoadIncrementalHFiles(conf)
    load.doBulkLoad(
        new Path(stagingFolder),
        connection.getAdmin,
        table,
        connection.getRegionLocator(TableName.valueOf(tableName)))

```

The big difference in using bulk load for thin rows is that the function returns a tuple with the first value being the RowKey and the second value being an object of FamiliesQualifiersValues. FamiliesQualifiersValues contains all the values for this row for all column families.

### SparkSQL and DataFrames

The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark leverages [DataSource API \(SPARK-3247\)](#) introduced in Spark-1.2.0. The connector bridges the gap between simple HBase KV store and complex relational SQL queries and enables users to perform complex data analytical work on top of HPE Ezmeral Data Fabric Database binary tables using Spark. HBase Dataframe is a standard Spark Dataframe, and is able to interact with any other data sources, such as Hive, Orc, Parquet, JSON, and others. The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark applies critical techniques such as partition pruning, column pruning, predicate pushdown and data locality.

To use the HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark, you need to define the Catalog for the schema mapping between HPE Ezmeral Data Fabric Database binary tables and Spark tables, prepare the data and populate the HPE Ezmeral Data Fabric Database binary table, then load the HBase DataFrame. After that, users can do integrated query and access records in a HPE Ezmeral Data Fabric Database binary table with SQL query. The following examples illustrate the basic procedure.

### Define Catalog Example

The catalog defines a mapping between HPE Ezmeral Data Fabric Database binary tables and Spark tables. There are two critical parts of this catalog. One is the rowkey definition. The other is the mapping between the table column in Spark and the column family and column qualifier in HPE Ezmeral Data Fabric Database binary table. The following example defines a schema for a HPE Ezmeral Data Fabric Database binary table with name as my\_table, row key as key and a number of columns (col1 - col8). Note that the rowkey also has to be defined in details as a column (col10), which has a specific cf (rowkey).

```

def catalog = s"""{
  "table": {"namespace": "default", "name": "/path_to/my_table"},
  "rowkey": "key",
  "columns": {
    "col10": {"cf": "rowkey", "col": "key", "type": "string"},
    "col1": {"cf": "cf1", "col": "col1", "type": "boolean"},
    "col2": {"cf": "cf2", "col": "col2", "type": "double"},
    "col3": {"cf": "cf3", "col": "col3", "type": "float"},
    "col4": {"cf": "cf4", "col": "col4", "type": "int"},
    "col5": {"cf": "cf5", "col": "col5", "type": "bigint"},
    "col6": {"cf": "cf6", "col": "col6", "type": "smallint"},
    "col7": {"cf": "cf7", "col": "col7", "type": "string"},

```

```
    | "col8": {"cf": "cf8", "col": "col8", "type": "tinyint"}
    |}
  |}"".stripMargin
```

### Save the DataFrame Example

Data prepared by the user is a local Scala collection that has 256 HBaseRecord objects. The `sc.parallelize(data)` function distributes data to form an RDD. `toDF` returns a DataFrame. `writefunction` returns a DataFrameWriter used to write the DataFrame to external storage systems (e.g. HPE Ezmeral Data Fabric Database here). Given a DataFrame with a specified schema catalog, the `save` function creates a HPE Ezmeral Data Fabric Database binary table with five (5) regions and saves the DataFrame inside.

```
case class HBaseRecord(
  col0: String,
  col1: Boolean,
  col2: Double,
  col3: Float,
  col4: Int,
  col5: Long,
  col6: Short,
  col7: String,
  col8: Byte)

object HBaseRecord
{
  def apply(i: Int, t: String): HBaseRecord = {
    val s = s""row${"%03d".format(i)}""
    HBaseRecord(s,
      i % 2 == 0,
      i.toDouble,
      i.toFloat,
      i,
      i.toLong,
      i.toShort,
      s"String$i: $t",
      i.toByte)
  }
}

val data = (0 to 255).map { i => HBaseRecord(i, "extra")}

sc.parallelize(data).toDF.write.options(Map(
  HBaseTableCatalog.tableCatalog -> catalog,
  HBaseTableCatalog.newTable -> "5")
).format("org.apache.hadoop.hbase.spark")
.save()
```

### Load the DataFrame Example

In the `withCatalog` function, `sqlContext` is a variable of `SQLContext`, which is the entry point for working with structured data (rows and columns) in Spark. `read` returns a `DataFrameReader` that can be used to read data in a DataFrame. The `option` function adds input options for the underlying data source to the `DataFrameReader`. The `format` function specifies the input data source format for the `DataFrameReader`. The `load()` function loads input as a DataFrame. The data frame `df` returned by the

`withCatalog` function can be used to access the HPE Ezmeral Data Fabric Database binary table, as shown in the Language Integrated Query and SQL Query examples.

```
def withCatalog(cat: String): DataFrame = {
  sqlContext
  .read
  .options(Map(HBaseTableCatalog.tableCatalog->cat))
  .format("org.apache.hadoop.hbase.spark")
  .load()
}
val df = withCatalog(catalog)
```

### Language Integrated Query Example

`DataFrame` can do various operations, such as `join`, `sort`, `select`, `filter`, `orderBy`, and so on. In the following example, `df.filter` filters rows using the given SQL expression. `select` selects a set of columns: `col0`, `col1` and `col4`.

```
val s = df.filter(("col0" <= "row050" && "col0" > "row040") ||
  "col0" === "row005" ||
  "col0" <= "row005")
  .select("col0", "col1", "col4")
s.show
```

### SQL Query Example

`registerTempTable` registers `df` `DataFrame` as a temporary table using the table name `table1`. The lifetime of this temporary table is tied to the `SQLContext` that was used to create `df`. `sqlContext.sqlfunction` allows the user to execute SQL queries.

```
df.registerTempTable("table1")
sqlContext.sql("select count(col1) from table1").show
```

### Query with Different Timestamps

In `HBaseSparkConf`, you can set four parameters related to timestamp:

- `TIMESTAMP`
- `MIN_TIMESTAMP`
- `MAX_TIMESTAMP`
- `MAX_VERSIONS`

With `MIN_TIMESTAMP` and `MAX_TIMESTAMP`, you can query records with different timestamps or time ranges. In the meantime, use a concrete value instead of `tsSpecified` and `oldMs` in the following examples. The first example shows how to load `df` `DataFrame` with different timestamps. `tsSpecified` is specified by the user. `HBaseTableCatalog` defines the HBase and Relation relation schema. `writeCatalog` defines the catalog for the schema mapping.

```
val df = sqlContext.read
  .options(Map(
    HBaseTableCatalog.tableCatalog -> writeCatalog,
    HBaseSparkConf.TIMESTAMP -> tsSpecified.toString)
  ).format("org.apache.hadoop.hbase.spark")
  .load()
```

The following example shows how to load `df` DataFrame with different time ranges. `oldMs` is specified by the user.

```
val df = sqlContext.read
  .options(Map(
    HBaseTableCatalog.tableCatalog -> writeCatalog,
    HBaseSparkConf.MIN_TIMESTAMP -> "0",
    HBaseSparkConf.MAX_TIMESTAMP -> oldMs.toString)
  ).format("org.apache.hadoop.hbase.spark")
  .load()
After loading df DataFrame, users can query data.
df.registerTempTable("table")
sqlContext.sql("select count(col1) from table").show
```

### Native Avro Support

The HPE Ezmeral Data Fabric Database Binary Connector for Apache Spark supports different data formats such as Avro, JSON, and others. The following use case shows how Spark supports Avro. You can persist the Avro record into HPE Ezmeral Data Fabric Database binary tables directly. Internally, the Avro schema is converted to a native Spark Catalyst data type automatically. Note that both key-value parts in a HPE Ezmeral Data Fabric Database binary table can be defined in Avro format.

1. Define the `catalog` for schema mapping. `catalog` is a schema for a HPE Ezmeral Data Fabric Database binary table named `Avrotable`, a row key as `key`, and one column `col1`. The rowkey also has to be defined in details as a column (`col0`), which has a specific `cf` (rowkey).

```
def catalog = s"""{
  "table": {"namespace": "default", "name": "/path_to/
  avro_table"},
  "rowkey": "key",
  "columns": {
    "col0": {"cf": "rowkey", "col": "key",
    "type": "string"},
    "col1": {"cf": "cf1", "col": "col1", "type": "binary"}
  }
}""" .stripMargin
```

2. Prepare the data. `schemaString` is defined first. Then it is parsed to get `avroSchema`. `avroSchema` is used to generate `AvroHBaseRecord`. data prepared by users is a local Scala collection that has 256 `AvroHBaseRecord` objects.

```
object AvroHBaseRecord {
  val schemaString =
    s"""{"namespace": "example.avro",
        "type": "record",      "name": "User",
        "fields": [
          {"name": "name", "type": "string"},
          {"name": "favorite_number", "type": ["int", "null"]},
          {"name": "favorite_color", "type": ["string", "null"]},
          {"name": "favorite_array", "type": {"type": "array",
"items": "string"}},
          {"name": "favorite_map", "type": {"type": "map",
"values": "int"}}
        ]}""".stripMargin

  val avroSchema: Schema = {
    val p = new Schema.Parser
    p.parse(schemaString)
  }

  def apply(i: Int): AvroHBaseRecord = {
    val user = new GenericData.Record(avroSchema);
    user.put("name", s"name${"%03d".format(i)}")
    user.put("favorite_number", i)
    user.put("favorite_color", s"color${"%03d".format(i)}")
    val favoriteArray = new GenericData.Array[String](
      2,
      avroSchema.getField("favorite_array").schema())
    favoriteArray.add(s"number${i}")
    favoriteArray.add(s"number${i+1}")
    user.put("favorite_array", favoriteArray)
    import collection.JavaConverters._
    val favoriteMap = Map[String, Int](("key1" -> i), ("key2" ->
(i+1))).asJava
    user.put("favorite_map", favoriteMap)
    val avroByte = AvroSedes.serialize(user, avroSchema)
    AvroHBaseRecord(s"name${"%03d".format(i)}", avroByte)
  }
}

val data = (0 to 255).map { i =>
  AvroHBaseRecord(i)
}
```

3. Save the DataFrame. Given a data frame with the specified schema catalog, the following example creates a HPE Ezmeral Data Fabric Database binary table with five (5) regions and saves the data frame inside.

```
sc.parallelize(data).toDF.write.options(
  Map(
    HBaseTableCatalog.tableCatalog -> catalog,
    HBaseTableCatalog.newTable -> "5")
).format("org.apache.spark.sql.execution.datasources.hbase")
.save()
```

4. Load the DataFrame. In the `withCatalog` function, `read` returns a `DataFrameReader` that can be used to read data in as a `DataFrame`. The `option` function adds input options for the underlying data source to the `DataFrameReader`. There are two options: one is to set `avroSchema` as `AvroHBaseRecord.schemaString`. The other option is to set `HBaseTableCatalog.tableCatalog` as `avroCatalog`. The `load()` function loads input in as a `DataFrame`. The data frame `df` returned by the `withCatalog` function can be used to access the HPE Ezmeral Data Fabric Database binary table.

```
def avroCatalog = s"""{
  | "table": {"namespace": "default", "name": "avrotable"},
  | "rowkey": "key",
  | "columns": {
  |   | "col0": {"cf": "rowkey", "col": "key", "type": "string"},
  |   | "col1": {"cf": "cf1", "col": "col1", "avro": "avroSchema"}
  | }
  |}""" .stripMargin

def withCatalog(cat: String): DataFrame = {
  sqlContext
    .read
    .options(Map(
      "avroSchema" -> AvroHBaseRecord.schemaString,
      HBaseTableCatalog.tableCatalog -> avroCatalog
    ))
    .format("org.apache.spark.sql.execution.datasources.hbase")
    .load()
}

val df = withCatalog(catalog)
```

5. Query data using SQL. After loading `df` `DataFrame`, you can query data. `registerTempTable` registers `df` `DataFrame` as a temporary table using the table name `avrotable`. The `sqlContext.sql` function allows you to execute SQL queries.

```
df.registerTempTable("avrotable")
val c = sqlContext.sql("select count(1) from avrotable")
```

### Integrating Spark

This section includes the following topics about configuring Spark to work with other ecosystem components.

#### Integrate Spark-SQL (Spark 2.3.1 and later) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 2.3.0 or later users.

#### Prerequisites

**NOTE:** For Spark 2.2.1 and 2.3.1 versions, use the 4.0.0 avro version of `com.databricks:spark-avro_2.11`.

#### About this task

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

#### Procedure

1. Download the Avro 1.7.7 JAR file to the Spark `jars` (`opt/mapr/spark/spark-<version>/jars`) directory.

You can download the file from the maven repository: <http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7>

2. Add the following properties in `spark-defaults.conf`:

```
spark.driver.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
spark.executor.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
```

### Integrate Spark-SQL (Spark 1.6.1) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 1.6.1 or earlier users.

#### About this task

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

#### Procedure

1. Download the Avro 1.7.7 JAR file to the Spark lib (`opt/mapr/spark/spark-<version>/lib`) directory.

You can download the file from the maven repository: <http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7>

2. Use one of the following methods to add the Avro 1.7.7 JAR to the classpath:

- Prepend the Avro 1.7.7 JAR file to the `spark.executor.extraClassPath` and `spark.driver.extraClassPath` in the `spark-defaults.conf` (`/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf`) file:

```
spark.executor.extraClassPath /opt/mapr/spark/
spark-<spark_version>/lib/avro-1.7.7.jar:<rest_of_path>
spark.driver.extraClassPath /opt/mapr/spark/spark-<spark_version>/lib/
avro-1.7.7.jar:<rest_of_path>
```

- Specify the Avro 1.7.7 JAR files with command line arguments on the spark shell:

```
/opt/mapr/spark/spark-<version>/bin/spark-shell \
--packages com.databricks:spark-avro_2.10:2.0.1 \
--driver-class-path /opt/mapr/spark/spark-<version>/lib/avro-1.7.7.jar \
--conf spark.executor.extraClassPath=/opt/mapr/spark/
spark-<version>/lib/avro-1.7.7.jar --master <master-url>
```

### Integrate Spark with HBase

Integrate Spark with HBase or HPE Ezmeral Data Fabric Database when you want to run Spark jobs on HBase or HPE Ezmeral Data Fabric Database tables.

#### About this task

If you installed Spark with the MapR Installer, these steps are not required.

**Procedure**

1. Configure the HBase version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

```
hbase_versions=<version>
```

The HBase version depends on the current EEP and MapR version that you are running.

2. If you want to create HBase tables with Spark, add the following property to `hbase-site.xml`:

```
<property>
hbase.table.sanity.checks</name>
<value>false</value>
</property>
```

3. On each Spark node, copy the `hbase-site.xml` to the `{SPARK_HOME}/conf/` directory.

**TIP:** Starting in the EEP 7.0.0 release, you do not have to complete step 3. Running `configure.sh` copies the `hbase-site.xml` file to the Spark directory automatically.

4. Specify the `hbase-site.xml` file in the `SPARK_HOME/conf/spark-defaults.conf` file:

```
spark.yarn.dist.files SPARK_HOME/conf/hbase-site.xml
```

5. To verify the integration, complete the following steps:

- a) Create an HBase or HPE Ezmeral Data Fabric Database table:

```
create '<table_name>' , '<column_family>'
```

- b) Run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
/opt/mapr/spark/spark-<spark_version>/bin/spark-submit --master
<master> [--deploy-mode <deploy-mode>] --class
org.apache.hadoop.hbase.spark.example.rdd.HBaseBulkPutExample /opt/
mapr/hbase/hbase-<hbase_version>/lib/
hbase-spark-<hbase_version>-mapr.jar <table_name> <column_family>
```

The master URL for the cluster is either `spark://<host>:7077`, `yarn`, or `local` (without `deploy-mode`). The `deploy-mode` is either `client` or `cluster`.

- c) Check the data in the HBase or MapR-DB table:

```
hbase(main):001:0> scan '<table_name>'
```

**Integrate Spark-SQL (Spark 2.0.1 and later) with Hive**

You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 2.0.1 or later users.

**About this task**

For information about Spark-SQL and Hive support, see [Spark Feature Support](#).

**NOTE:** If you installed Spark with the MapR Installer, the following steps are not required.

## Procedure

1. Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration. Do not create a symbolic link instead of copying the file. You may need to edit the file with settings that are specific to the Spark Thrift server.
2. Add 644 permission to the `hive-site.xml` using the following command:

```
sudo chmod 644 /opt/mapr/spark/spark-<sparkVersion>/conf/hive-site.xml
```

3. If Hive is configured on Tez (not on MR), you must remove the Tez property from the Spark conf directory `hive-site.xml`. Delete this entry:

```
<property>
  <name>hive.execution.engine</name>
  <value>tez</value>
</property>
```

4. If Hive is configured on PAM, set "`hive.metastore.sasl.enabled = true`" in the `hive-site.xml` located in the Spark conf directory.
5. Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

Property	Configuration Requirements
<code>spark.yarn.dist.files</code>	For Spark on YARN, specify the location of the <code>hive-site.xml</code> file:  <pre>/opt/mapr/spark/spark-&lt;spark-version&gt;/conf/hive-site.xml</pre>
<code>spark.sql.hive.metastore.version</code>	Specify the Hive version that you are using.   <b>NOTE:</b> If you are using Hive Metastore 2.1, set the version to 1.2.1.

6. Depending on whether you plan to run with impersonation, perform one of the following:
  - Configure user impersonation. See [Hive User Impersonation](#) for the steps to configure impersonation in the Spark Thrift server.
  - Set `hive.server2.enable.doAs` to `false` in the `hive-site.xml` file.
7. To verify the integration, run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
<spark-home>/bin/run-example --master <master> [--deploy-mode <deploy-mode>] sql.hive.SparkHiveExample
```

The master URL for the cluster is either `spark://<host>:7077` or `yarn`. The `deploy-mode` is either `client` or `cluster`.

## What to do next

**NOTE:** The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

**NOTE:** If you plan to access Hive tables that store data in HPE Ezmeral Data Fabric Database, you need to copy the Hive HBase handler jar into the Spark jars directory. For example:

```
cp /opt/mapr/hive/hive-2.1/lib/hive-hbase-handler-2.1.1-mapr-1707.jar /opt/mapr/spark/spark-2.1.0/jars/
```

## Integrate Spark-SQL (Spark 1.6.1) with Hive

You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 1.6.1 or earlier users.

### About this task

For information about Spark-SQL and Hive support, see [Spark Feature Support](#).

**NOTE:** If you installed Spark with the MapR Installer, the following steps are not required.

### Procedure

1. Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration.
2. Configure the Hive version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

```
hive_versions=<version>
```

3. Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

Property	Configuration Requirements
<code>spark.yarn.dist.files</code>	<p>Option 1: For Spark on YARN, specify the location of the <code>hive-site.xml</code> and the datanucleus JARs:</p> <pre>/opt/mapr/hive/hive-&lt;hive-version&gt;/conf/hive-site.xml,/opt/mapr/hive/&lt;version&gt;/lib/datanucleus-api-jdo-&lt;version&gt;.jar,/opt/mapr/hive/&lt;version&gt;/lib/datanucleus-core-&lt;version&gt;.jar,/opt/mapr/hive/hive-1.2/lib/datanucleus-rdbms-&lt;version&gt;.jar</pre> <p>Option 2: For Spark on YARN, store <code>hive-site.xml</code> and datanucleus JARs on file system, and use the following syntax:</p> <pre>maprfs:///&lt;path to hive-site.xml&gt;,maprfs:///&lt;path to datanucleus jar files&gt;</pre>
<code>spark.sql.hive.metastore.version</code>	Specify the Hive version that you are using. For example, for Hive 1.2.x, set the value to 1.2.0.
<code>spark.sql.hive.metastore.jars</code>	<p>Specify the classpath to JARs for Hive, Hive dependencies, and Hadoop. These files must be available on the node from which you submit Spark jobs:</p> <pre>/opt/mapr/hadoop/hadoop-&lt;hadoop-version&gt;/etc/hadoop:/opt/mapr/hadoop/hadoop-&lt;hadoop-version&gt;/share/hadoop/common/lib/*:&lt;rest of hadoop classpath&gt;:/opt/mapr/hive/hive-&lt;version&gt;/lib/accumulo-core-&lt;version&gt;.jar:/opt/mapr/hive/hive-&lt;version&gt;/lib/hive-contrib-&lt;version&gt;.jar:&lt;rest of hive classpath&gt;</pre> <p>For example, when you run with Hive 1.2, you can set the following classpath:</p> <pre>/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/lib/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/*:/opt/mapr/hadoop/.hadoop-2.7.0/share/hadoop/mapreduce/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/yarn/*:/opt/mapr/hive/hive-1.2/lib/accumulo-core-1.6.0.jar:/opt/mapr/hive/hive-1.2/lib/hive-contrib-1.2.0-mapr-1607.jar:/opt/mapr/hive/hive-1.2/lib/*</pre> <p>For more information, see the <a href="#">Apache Spark documentation</a>.</p>

4. To verify the integration, run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
MASTER=<master-url> <spark-home>/bin/run-example sql.hive.HiveFromSpark
```

The master URL for the cluster is either `spark://<host>:7077`, `yarn-client`, or `yarn-cluster`.

## What to do next

**NOTE:** The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

### Integrate Spark with HPE Ezmeral Data Fabric Streams

Integrate Spark with MapR Streams to enable Spark to query HPE Ezmeral Data Fabric Streams for new messages at a given interval, process any new messages that are available, and also publish messages into HPE Ezmeral Data Fabric Streams.

You can use Spark to access HPE Ezmeral Data Fabric Streams through Spark's receiver-less, direct approach.

For more information, see the [Apache Spark documentation](#).

**NOTE:** Before you integrate Spark with HPE Ezmeral Data Fabric Streams, verify that the Streams Client is installed on all Spark nodes. For more information, see the [Installing Core and Ecosystem Components](#) on page 92.

### Configure Spark 2.2.1 and later to Consume HPE Ezmeral Data Fabric Streams Messages

Using the Kafka 0.9 API, you can configure a Spark application to query HPE Ezmeral Data Fabric Streams for new messages at a given interval. This information is for Spark 2.2.1 and later users.

## About this task

### Procedure

1. Install the [Data Fabric core Kafka package](#), if you have not already done so.
2. Copy the Kafka client jar into the Spark jars directory as shown below:

```
cp /opt/mapr/lib/kafka-clients-<version>.jar SPARK_HOME/jars
```

3. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-0-9_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

**NOTE:** If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the MapR Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<spark_version>/jars/`).

4. Consider the following when you write the Spark application:
  - a) Verify that it meets the following requirements:
    - Imports and use classes from `org.apache.spark.streaming.kafka09`. The following code snippet imports three classes.

```
import org.apache.spark.streaming.kafka09.{ConsumerStrategies,
KafkaUtils, LocationStrategies}
```

- Defines key and value deserializers in the kafkaParams map.

```
val kafkaParams = Map[String, String](
  ConsumerConfig.GROUP_ID_CONFIG -> groupId,
  ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG ->
    "org.apache.kafka.common.serialization.StringDeserializer",
  ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG ->
    "org.apache.kafka.common.serialization.StringDeserializer",
  ConsumerConfig.AUTO_OFFSET_RESET_CONFIG -> offsetReset)
```

- Does not configure a broker address or Zookeeper as these are not required for HPE Ezmeral Data Fabric Streams.
- b) Optionally, define a value for `spark.streaming.kafka.consumer.poll.ms` in the Spark configuration.

**NOTE:** You can configure the poll timeout using Spark option `spark.streaming.kafka.consumer.poll.ms`. If you do not configure `spark.streaming.kafka.consumer.poll.ms`, the `spark.network.timeout` property is used. If `spark.network.timeout` is empty, the default is 120 seconds.

```
val sparkConf = new SparkConf()
  .setAppName("v09DirectKafkaWordCount")
  .set("spark.streaming.kafka.consumer.poll.ms", pollTimeout)
```

Example:

<https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/V09DirectKafkaWordCount.scala> is a sample consumer program.

The `KafkaUtils.createDirectStream` method creates an input stream to read HPE Ezmeral Data Fabric Streams messages. The `ConsumerStrategies.Subscribe` method creates the consumer strategy that will limit the set of topics the stream subscribes to. This is derived from the `topics` parameter passed into the program. Using `LocationStrategies.PreferConsistent` will distribute partitions evenly across available executors.

```
val consumerStrategy = ConsumerStrategies.Subscribe[String, String]
  (topicsSet, kafkaParams)
val messages = KafkaUtils.createDirectStream[String, String](
  ssc, LocationStrategies.PreferConsistent, consumerStrategy)
```

### Configure Spark to Produce HPE Ezmeral Data Fabric Streams Messages

Using the Kafka 0.9 API, you can configure a Spark application to produce Data Fabric Streams messages.

#### Procedure

1. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

**NOTE:** If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the HPE Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<spark_version>/jars/`).

- When you write the Spark program, import and use classes from `org.apache.spark.streaming.kafka.producer._` and `org.apache.spark.streaming.dstream`.

The import of `org.apache.spark.streaming.stream.DStream` adds the following method from `DStream`:

```
sendToKafka(topic: String, conf: ProducerConf)
```

In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the `topics` parameter.

```
val producerConf = new ProducerConf(bootstrapServers =
  kafkaBrokers.split(",").toList)
  .withKeySerializer("org.apache.kafka.common.serialization.ByteArraySerializer")
  .withValueSerializer("org.apache.kafka.common.serialization.StringSerializer")

val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
  defaultRDD)

dStream.foreachRDD(_.sendToKafka(topics, producerConf))
dStream.count().print()
```

The `org.apache.kafka.common.serialization.ByteArraySerializer` and `org.apache.kafka.common.serialization.StringSerializer` properties are used by default, and in case you do not want to use another serializer, `withKeySerializer` and `withValueSerializer` methods are not necessary.

### Example

Source code for a sample producer program can be found at <https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala>

### Integrate Spark with R

You integrate Spark with R when you want to run R programs as Spark jobs.

### About this task

#### Procedure

- On each node that will submit Spark jobs, install R 3.2.2 or greater:

- On Ubuntu:

```
apt-get install r-base-dev
```

- On CentOS/RedHat:

```
yum install R
```

For more information about installing R, see the [R documentation](#).

- To verify the integration, run the following commands as the `mapr` user or as a user that `mapr` impersonates:

## a) Start Spark R:

- On Spark 2.0.1, 2.1.0, and later:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master>
[--deploy-mode <deploy-mode>]
```

- On Spark 1.6.1:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master-url>
```

## b) Run the following command to create a DataFrame using sample data:

On Spark 1.6.1:

```
people <- read.df(sqlContext, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

On Spark 2.0.1, 2.1.0, and later:

```
people <- read.df(spark, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

## c) Run the following command to display the data from the DataFrame that you just created:

```
head(people)
```

## Integrate Spark with Kafka

From EEP-5.0.0, Spark can be integrated with Kafka-1.0. You can configure a Spark application to produce Kafka messages.

### About this task

**NOTE:** Starting from EEP-8.0.0, HPE Ezmeral Data Fabric does not support `spark-streaming-kafka-producer`. To learn about Kafka integration on Apache Spark 3.1.2 and later in HPE Ezmeral Data Fabric, see [Structured Streaming + Kafka Integration Guide \(Kafka broker version 0.10.0 or higher\)](#).

**NOTE:** Starting from HPE Ezmeral Data Fabric 7.8.0, the configuration option `use.brokers` is available. This option is a boolean flag that specifies the type of server you are using to load the Apache Kafka client. By default, this value is set to `false`. Set this value to `true` if you are using Apache Kafka brokers as a server to load the Apache Kafka client.

For more information, see [Configuration Parameters](#) on page 3569.

### Procedure

1. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

2. When you write the Spark program, import and use classes from:

```
org.apache.spark.streaming.kafka.producer._
org.apache.spark.streaming.dstream.
```

The import of `org.apache.spark.streaming.stream.DStream` adds the following method from `DStream`:

```
sendToKafka(topic: String, conf: ProducerConf)
```

3. In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the `topics` parameter:

```
val producerConf = new ProducerConf(
  bootstrapServers = kafkaBrokers.split(",").toList)

val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
  defaultRDD)

dStream.foreachRDD(_.sendToKafka(topics, producerConf))
dStream.count().print()
```

### Example

Source code for a sample producer program can be found at <https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala>

### Spark JDBC and ODBC Drivers

Data Fabric provides JDBC and ODBC drivers so you can write SQL queries that access the Apache Spark data-processing engine. This section describes how to download the drivers, and install and configure them.

You can download the Spark JDBC driver from [https://package.ezmeral.hpe.com/tools/MapR-JDBC/MapR\\_Spark/](https://package.ezmeral.hpe.com/tools/MapR-JDBC/MapR_Spark/) and the Spark ODBC driver from [https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR\\_Spark/](https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR_Spark/).

 **IMPORTANT:** To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Ezmeral Token-Authenticated Internet Repository](#) on page 93.

After downloading the driver, refer to the documentation at [Spark JDBC Driver](#) to install and configure the JDBC driver and [Spark ODBC Driver](#) for the ODBC driver. A copy of the documentation also is available in each download package. The following table describes the driver versions available for various EEP releases:

	EEP version	Driver version	Driver link	Documentation link
JDBC version	EEP 6.0.0+	2.6.3	<a href="#">Spark JDBC Driver for version 2.6.3</a>	<a href="#">Spark JDBC Documentation for version 2.6.3</a>
	EEP 3.0.1+	1.1.8	<a href="#">Spark JDBC Driver for version 1.1.8</a>	<a href="#">Spark JDBC Documentation for version 1.1.8</a>

	EEP version	Driver version	Driver link	Documentation link
ODBC version	EEP 6.0.0+	2.6.1	<a href="#">Spark ODBC Driver for version 2.6.1</a>	<a href="#">Spark ODBC Documentation for version 2.6.1</a>
	EEP 2.0.2+	1.2.5	<a href="#">Spark ODBC Driver for version 1.2.5</a>	<a href="#">Spark ODBC Documentation for version 1.2.5</a>

**NOTE:** When connecting to the Spark Thrift Server using `beeline` and the JDBC driver, you might encounter the following error:

```
"Unsupported transaction isolation level: 4"
```

To avoid this error, pass the `isolation` parameter to `beeline` as follows:

```
bin/beeline --isolation=default
```

## Spark API Changes

This topic describes the public API changes that occurred for specific Spark versions.

### Spark 2.3.1 API Changes

EEP 6.0.0 supports Spark version 2.3.1.

For more information about Spark 2.3.1, see the [Spark Release Notes](#) on page 6132.

For a complete list of all new and changed APIs, refer to the [open source documentation](#).

### Spark 2.1.0 API Changes

This topic describes the public API changes that occurred between Apache Spark 2.0.1 and Spark 2.1.0.

For more information about Spark 2.1.0, see the [Spark Release Notes](#) and the [Spark 2.1.0 API Documentation](#).

## New API

- The `DataType` API is now mostly stable. Please see `InterfaceStability` annotations for the classes you need.
- Add the `from_json` and `to_json` functions to SQL.
- `StructType` now accepts Python Dictionaries.
- New ML algorithms have been added for Spark R.
- `SparkContext.addFile` is now supported for SparkR.
- SparkR now supports multinomial logistics regression.
- MLlib supports MLR in DataFrames, LSH.
- MLlib model loading is now backward-compatible with Spark 1.6.

## Changed API

- Parquet-MR is bumped to 1.8.1.
- `spark.sql.warehouse.dir` now needs to be set before `SparkSession` creation and is shared between multiple `SparkSessions`.

- Values generated by non-deterministic functions will not change after coalesce or union.
- The default `Locale` for `DateFormat/NumberFormat` is now `Locale.US`.
- Function `SIZE` returns -1 when its input parameter is null.

### Spark 2.0.1-1703 API Changes

This release does not introduce any changes to public Spark API apart from Structured Streaming, which is not supported by the MapR platform.

### Spark 2.0.1-1611 API Changes

This topic describes the public API changes that occurred between Apache Spark 1.6.1 and Spark 2.0.1.

### Removed Methods

The following items have been removed from [Apache Spark 2.0.1](#):

- Bagel (the Spark implementation of Google Pregel)
- Most of the deprecated methods from Spark 1.x, including:

Category	Subcategory	Instead of this removed API...	Use...
GraphX		<code>mapReduceTriplets</code>	<code>aggregateMessages</code>
		<code>runSVDPlusPlus</code>	<code>run</code>
		<code>GraphKryoRegistrator</code>	
SQL	<code>DataType</code>	<code>DataType.fromCaseClassString</code>	<code>DataType.fromJson</code>
	<code>DecimalType</code>	<code>DecimalType()</code>	<code>DecimalType(precision, scale)</code> precision explicitly
		<code>DecimalType(Option[PrecisionInfo])</code>	<code>DecimalType(precision scale)</code>
		<code>PrecisionInfo</code>	<code>DecimalType(precision, scale)</code>
		<code>precisionInfo</code>	precision and scale
		<code>Unlimited</code>	(No longer supported)
	<code>Column</code>	<code>Column.in()</code>	<code>isin()</code>
	<code>DataFrame</code>	<code>toSchemaRDD</code>	<code>toDF</code>
		<code>createJDBCTable</code>	<code>write.jdbc()</code>
		<code>saveAsParquetFile</code>	<code>write.parquet()</code>
		<code>saveAsTable</code>	<code>write.saveAsTable()</code>
		<code>save</code>	<code>write.save()</code>
		<code>insertInto</code>	<code>write.mode(SaveMode.Append).s</code>
	<code>DataframeReader</code>	<code>DataFrameReader.load(path)</code>	<code>option("path", path).load()</code>
	<code>Functions</code>	<code>cumeDist</code>	<code>cume_dist</code>
		<code>denseRank</code>	<code>dense_rank</code>
		<code>percentRank</code>	<code>percent_rank</code>
		<code>rowNumber</code>	<code>row_number</code>
		<code>inputFileName</code>	<code>input_file_name</code>
		<code>isNaN</code>	<code>isnan</code>

Category	Subcategory	Instead of this removed API...	Use...
		sparkPartitionId	spark_partition_id
		callUDF	udf
Core	SparkContext	Constructors no longer take preferredNodeLocationData param	
		tachyonFolderName	externalBlockStoreFolderName
		initLocalProperties, clearFiles, clearJars	(No longer needed)
		runJob method no longer takes allowLocal param	
		defaultMinSplits	defaultMinPartitions
		[Double, Int, Long, Float]AccumulatorParam	implicit objects from AccumulatorParam
		rddTo[Pair, Async, Sequence, Ordered]RDDFunctions	implicit functions from RDD
		[double, numeric]RDDToDoubleRDDFunctions	implicit functions from RDD
		intToIntWritable, longToLongWritable, floatToFloatWritable, doubleToDoubleWritable, boolToBoolWritable, bytesToBytesWritable, stringToText	implicit functions from WriteableFactories
		[int, long, double, float, boolean, bytes, string, writable]WritableConverter	implicit functions from WritableConverters
	TaskContext	runningLocally	isRunningLocally
		addOnCompleteCallback	addTaskCompletionListener
		attemptId	attemptNumber
	JavaRDDLike	splits	partitions
		toArray	collect
	JavaSparkContext	defaultMinSplits	defaultMinPartitions
		clearJars, clearFiles	(No longer needed)
	PairRDDFunctions	PairRDDFunctions.reduceByKeyToDriver	reduceByKeyLocally
	RDD	mapPartitionsWithContext	TaskContext.get
		mapPartitionsWithSplit	mapPartitionsWithIndex
		mapWith	mapPartitionsWithIndex
		flatMapWith	mapPartitionsWithIndex and flatMap
		foreachWith	mapPartitionsWithIndex and foreach
		filterWith	mapPartitionsWithIndex and filter
		toArray	collect
	TaskInfo	TaskInfo.attempt	TaskInfo.attemptNumber
	Guava Optional	Guava Optional	org.apache.spark.api.java.Optional

Category	Subcategory	Instead of this removed API...	Use...
	Vector	Vector, VectorSuite	
Configuration options and params		--name	
		--driver-memory	spark.driver.memory
		--driver-cores	spark.driver.cores
		--executor-memory	spark.executor.memory
		--executor-cores	spark.executor.cores
		--queue	spark.yarn.queue
		--files	spark.yarn.dist.files
		--archives	spark.yarn.dist.archives
		--addJars	spark.yarn.dist.jars
		--py-files	spark.submit.pyFiles

Note also the following deprecated configuration options and parameters:

- Methods from Python `DataFrame` that returned RDD have been moved to `dataframe.rdd`. For example, `df.map` is now `df.rdd.map`.
- Some streaming connectors (Twitter, Akka, MQTT, and ZeroMQ) have been removed.
- `org.apache.spark.shuffle.hash.HashShuffleManager` no longer exists. `SortShuffleManager` is the default since Spark 1.2.
- `DataFrame` is no longer a class. It is a subtype of `DataSet`.

## Behavior Changes

Spark 2.0.1 implements the following behavior changes:

- Spark 2.0.1 uses Scala 2.11 instead of 2.10.
- Floating literals in SQL are now parsed as decimal type instead of double type.
- The Kryo version is now 3.0.
- Jersey version is now 2.
- Java RDD `flatMap` and `mapPartitions` functions now require functions that return Java iterator instead of `Iterable`.
- Java RDD `countByKey` and `countApproxDistinctByKey` now return `Map[K => Long]` instead of `Map[K => Object]`.
- When writing Parquet files, the summary files are no longer written (set `parquet.enable.summary-metadata` to `true` to re-enable).
- Lots were changed in MLLib. Follow the [Apache Spark Migration Guide](#).
- `SparkContext.emptyRDD` now returns RDD instead of `EmptyRDD`.
- Spark Standalone Master no longer serves the jobs history.

- [org.apache.spark.api.java.JavaPairRDD](#) methods were changed:
  - `countByKey` and `countApproxDistinctByKey` now return `java.lang.Long` instead of `scala.Long`.
  - `sampleByKey` and `sampleByKeyExact` now return `java.lang.Double` instead of `scala.Double`.
- The Old Application History format that created folders for each application has been removed.
- `org.apache.spark.Logging` is now private. You can use `slf4j` directly instead.

### Other Deprecated Items

- Java 7 is now deprecated.
- Python 2.6 is now deprecated.
- `TaskContext.isRunningLocally` now is always false, as there is no more local execution of `yarn-client` and `yarn-cluster` as masters. Use `--master yarn` and `--deploy-mode client/cluster`.
- Instead of `HiveContext`, use `SparkSession.builder.enableHiveSupport`.
- Instead of `SQLContext`, use `SparkSession.builder`.
- Some methods related to `Accumulators`, `ShuffleWriteMetrics`, `SparkLoop`, `DataSet`, and `SQLContext` are now deprecated. You will see warnings in your application logs if you use them.

### Structured Streaming in Spark

Starting in EEP 5.0.0, structured streaming is supported in Spark.

### Related Links

Spark streaming is integrated with HPE Ezmeral Data Fabric Streams for Apache Kafka.

- [Data Fabric Event Store For Apache Kafka Clients and Tools](#)

### Prerequisites for Using Structured Streaming in Spark

To deploy a structured streaming application in Spark, you must create a Data Fabric Streams topic and install a Kafka client on all nodes in your cluster.

*Creating a Data Fabric Streams Topic*

### Procedure

- Create a Data Fabric Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

*Installing a Kafka Client*

### Procedure

- Install a `kafka-client` on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

### Using Structured Streaming to Create a Word Count Application

The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.

*Using Apache Kafka***Example****Scala**

```

val spark = SparkSession
    .builder
    .appName("StructuredKafkaWordCount")
    .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers", bootstrapServers)
    .option(subscribeType, topics)
    .load()
    .selectExpr("CAST(value AS
STRING)")
    .as[String]
//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()
//Run the query that prints the
running counts to the console
val query = wordCounts.writeStream
    .outputMode("complete")
    .format("console")
    .option("checkpointLocation",
checkpointLocation)
    .start()

query.awaitTermination()

```

**Java**

```

SparkSession spark = SparkSession
    .builder()
    .appName("JavaStructured
KafkaWordCount")
    .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
    .readStream()
    .format("kafka")
    .option("kafka.bootstrap
.servers", bootstrapServers)
    .option(subscribeType,
topics)
    .load()
    .selectExpr("CAST(value
AS STRING)")
    .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("

```

**Python**

```

    )).iterator(),
    Encoders.STRING()).groupBy("value").count();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
                .outputMode("complete")
                .format("console")
                .start();

query.awaitTermination();

```

```

spark = SparkSession\
        .builder\
        .appName("StructuredKafkaWordCount")\
        .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
        .readStream\
        .format("kafka")\
        .option("kafka.bootstrap.servers", bootstrapServers)\
        .option(subscribeType,
topics)\
        .load()\
        .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row
explode(
    split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that prints the
running counts to the console
query = wordCounts\
        .writeStream\
        .outputMode('complete')\
        .format('console')\
        .start()

query.awaitTermination()

```

### Using Data Fabric Event Store for Apache Kafka

#### Example

For Data Fabric Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```
var topic: String = "/user/mapr/stream:reviews"
val dfl = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
  "maprdemo:9092").option("subscribe", topic).option("group.id",
  "testgroup").option("startingOffsets",
  "earliest").option("failOnDataLoss",
  false).option("maxOffsetsPerTrigger", 1000).load()
```

#### Writing a Structured Spark Stream to HPE Ezmeral Data Fabric Database JSON Table

The example in this section writes a structured stream in Spark to HPE Ezmeral Data Fabric Database JSON table.

#### Example

To write a structured Spark stream to HPE Ezmeral Data Fabric Database JSON table, use `MapRDBSourceConfig.Format` for Java and Scala and `com.mapr.db.spark.streaming` for Python to format the `tablePath`, `idFieldPath`, `createTable`, `bulkMode`, and `sampleSize` parameters.

##### Scala

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig
import org.apache.spark.sql.streaming.
{DataStreamReader, DataStreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._

df.select($"value" as "_id")
  .writeStream
  .format(MapRDBSourceConfig.Format)
  .option(MapRDBSourceConfig.TablePath
Option, "/table/path")
  .option(MapRDBSourceConfig.IdFieldPa
thOption, "value")
  .option(MapRDBSourceConfig.CreateTab
leOption, true)
  .option(MapRDBSourceConfig.BulkModeO
ption, true)
  .option(MapRDBSourceConfig.SampleSiz
eOption, 1000)
  .outputMode("append")
}
```

##### Java

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig;
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.SparkSession;
import
```

```

org.apache.spark.sql.streaming.DataStreamReader;
import
org.apache.spark.sql.streaming.DataStreamWriter;
import
org.apache.spark.sql.streaming.StreamingQueryException;

DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
    return df.selectExpr("CAST(value
AS STRING) as _id")
        .writeStream()
        .format(MapRDBSourceConfig
.Format())
        .option(MapRDBSourceConfig
.TablePathOption(), "/table/path")
        .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
        .option(MapRDBSourceConfig
.CreateTableOption(), true)
        .option(MapRDBSourceConfig
.BulkModeOption(), true)
        .option(MapRDBSourceConfig
.SampleSizeOption(), 1000)
        .outputMode("append");
}

```

## Python

```

from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
    return df.selectExpr("CAST(value AS
STRING) as _id") \
        .writeStream \
        .format("com.mapr.db.spark.
streaming") \
        .option("checkpointLocation
", checkpoint_dir) \
        .option("tablePath",
table_path) \
        .option("idFieldPath",
"value") \
        .option("createTable",
True) \
        .option("bulkMode", True) \
        .option("sampleSize", 1000)

```

## Writing a Spark Stream Word Count Application to HPE Ezmeral Data Fabric Database

The example in this section writes a Spark stream word count application to HPE Ezmeral Data Fabric Database.

### Example

#### Scala

```

val spark = SparkSession
    .builder
    .appName("StructuredKafkaWordCou
nt")
    .getOrCreate()

```

```

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers", bootstrapServers)
    .option(subscribeType, topics)
    .load()
    .selectExpr("CAST(value AS
STRING)")
    .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
    .format(MapRDBSourceConfig.Format)
    .option(MapRDBSourceConfig.Table
PathOption, resultTable)
    .option(MapRDBSourceConfig.Creat
eTableOption, true)
    .option(MapRDBSourceConfig.IdFie
ldPathOption, "value")
    .outputMode("complete")
    .start()

query.awaitTermination()

```

**Java**

```

SparkSession spark = SparkSession
    .builder()
    .appName("JavaStructuredKaf
kaWordCount")
    .getOrCreate();

//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
    .readStream()
    .format("kafka")
    .option("kafka.bootstrap.s
ervers", bootstrapServers)
    .option(subscribeType,
topics)
    .load()
    .selectExpr("CAST(value
AS STRING)")
    .as(Encoders.STRING());

//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("

```

```

    ).iterator(),
    Encoders.STRING()).groupBy("value").count();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
            .format(MapRDBSourceConfig
.Format())
            .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
            .option(MapRDBSourceConfig
.CreateTableOption(), true)
            .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
            .outputMode("complete");
            .start();

query.awaitTermination();

```

## Python

```

spark = SparkSession\
        .builder\
        .appName("StructuredKafkaWo
rdCount")\
        .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
        .readStream\
        .format("kafka")\
        .option("kafka.bootstrap.ser
vers", bootstrapServers)\
        .option(subscribeType,
topics)\
        .load()\
        .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#Explode turns each item in an array
into a separate row
explode(
        split(lines.value, ' ')
        ).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB
query = wordCounts\
        .writeStream\
        .format("com.mapr.db.spa
rk.streaming") \
        .option("tablePath",
table_path) \

```

```

True) \
"value") \
        .option("createTable",
        .option("idFieldPath",
        .outputMode('complete')\
        .start()

query.awaitTermination()

```

### PAM Authentication for Spark

Spark supports PAM authentication on secure Data Fabric clusters.

In EEP-5.0.0, PAM authentication and encryption is enabled by default for all Spark Web UIs. After running `configure.sh`, if the cluster is secure and Spark is installed, Spark will be configured using PAM.

**NOTE:** Spark PAM is available in Spark-2.2.1 from EEP-5.0 and in Spark-2.1.0 from EEP-4.1.1.

See [Configuring PAM](#) on page 1843 for information on how PAM works with Data Fabric.

### Read or Write LZO Compressed Data for Spark

This topic provides details for reading or writing LZO compressed data for Spark.

#### Procedure

1. Install the LZO library:

```
sudo yum install lzo-devel lzo
```

2. Clone `hadoop-lzo` and build it:

```
[mapr@node1 ~]$ git clone https://github.com/twitter/hadoop-lzo
[mapr@node1 ~]$ cd hadoop-lzo
[mapr@node1 hadoop-lzo]$ mvn package
```

3. Copy the jar file to hadoop classpath:

```
[mapr@node1 hadoop-lzo]$ sudo
cp target/hadoop-lzo-0.4.21-SNAPSHOT.jar /opt/mapr/hadoop/hadoop-2.7.0/
share/hadoop/yarn/lib/
```

#### 4. Add two LZO compression codes to `core-site.xml`:

```
property: io.compression.codecs
codecs:
com.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec/
```

It will look like this:

```
<property>
  <name>io.compression.codecs</name>

  <value>org.apache.hadoop.io.compress.DefaultCodec,org.apache.hadoop.io.co
mpress.GzipCodec,org.apache.hadoop.io.compress.BZip2Codec,org.apache.hado
op.io.compress.DeflateCodec,org.apache.hadoop.io.compress.SnappyCodec,com
.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec</
value>
</property>

<property>
  <name>io.compression.codec.lzo.class</name>
  <value>com.hadoop.compression.lzo.LzoCodec</value>
</property>
```

#### 5. Run Spark and read LZO compressed data:

```
[mapr@node1 spark]$ ./bin/spark-shell --master yarn
spark.read.csv("/user/mapr/LzoCompressedCsv").show
```

#### 6. Write LZO compressed data with Spark:

```
scala>
df.write.option("codec", "com.hadoop.compression.lzo.LzopCodec").csv("csv1
")

[mapr@node1 spark]$ hadoop fs -ls /user/mapr/csv1
Found 2 items
-rwxr-xr-x  3 mapr mapr          0 2017-12-15 12:42 /user/mapr/csv1/_
_SUCCESS
-rwxr-xr-x  3 mapr mapr  493366 2017-12-15 12:42 /user/mapr/csv1/pa
rt-00000-256a95a9-eb9c-4048-b7ce-c95dfbef54d7.csv.lzo
```

#### Ports Used by Spark

To run a Spark job from a client node, ephemeral ports should be opened in the cluster for the client from which you are running the Spark job.

If you do not want to open all the ephemeral ports, you can use the configuration parameter to specify the range of ports.

To set ports to special values, use the `spark.driver.port`, `spark.blockManager.port`, and `spark.port.maxRetries` properties. The `spark.port.maxRetries` property is 16 by default.

For example, if you need to open port 200 for `spark.blockManager.port` from 40000, set `spark.blockManager.port = 40000` and `spark.port.maxRetries = 200`.

For a list of Web UIs ports dynamically used when starting spark contexts, see the [open source documentation](#).

The default port numbers that need to be opened on the firewall behind the client and MapR cluster nodes for Spark jobs to operate in YARN client, YARN cluster, and standalone modes are as follows:

Service	Port Number
Spark Standalone Master (RPC)	7077
Spark Standalone Master (Web UI)	8580, 8980*
Spark Standalone Worker	8581, 8981*
Spark Thrift Server	2304
Spark History Server	18080,18480*
Spark External Shuffle Service (if yarn shuffle service is enabled)	7337
CLDB	7222
ZooKeeper	5181
Nodes running ResourceManager	8032
MapR Filesystem Server	5660, 5692

\* refers to ports for secure clusters

### ACL Configuration for Spark

Starting in the EEP 6.0 release, the ACL configuration for Spark is disabled by default.

If you are authorized by PAM, you will have access to all Spark UIs. For the Spark History Server, you can only see the logs of your own Spark jobs if PAM is enabled (regardless of ACL being enabled).

Starting in Spark-2.4.4.0, MapR Spark ACLs behave like Apache Spark ACLs. With this change, all users can log in to the Spark History Server UI and see the full list of applications. Only an application owner or the users specified in `spark.ui.view.acls` or `history.ui.admin.acls` can see application details. Users specified in `history.ui.admin.acls` can see the details for all applications.

By default on a secure cluster:

```
spark.acls.enable false
spark.admin.acls mapr
spark.admin.acls.groups mapr
spark.ui.view.acls mapruser1
```

Other Example:

```
spark.acls.enable true - ACL is enabled and restricted access to Spark
master and thriftserver UIs for other users.
spark.admin.acls mapr - Administrator or "sudoer" of ACL access.
spark.admin.acls.groups mapr - Group of administrators.
spark.ui.view.acls mapruser1 - user who can be logged in to Spark master
and thriftserver UIs.
```

## YARN

YARN is a resource-management and scheduling framework that distributes resource-management and job-management duties. YARN assigns the resource-management and job-management duties as follows:

- **ResourceManager:** manages cluster resources and tracks resource usage and node health.
- **ApplicationMaster:** a framework-specific process that negotiates resources for a single application (a single job or a directed acyclic graph of jobs), which runs in the first *container* allocated for the application.

- A YARN component called the HistoryServer archives job metrics and metadata. Status on completed applications is available via REST APIs.

The ResourceManager allocates resources among all the applications running the cluster. The ResourceManager includes a pluggable scheduler, which is responsible for allocating resources according to the resource requirements of the running applications. Current MapReduce schedulers, including the Capacity Scheduler and the Fair Scheduler, can be plugged into the YARN scheduler directly.

Label-based scheduling provides job placement control on a multi-tenant Hadoop cluster. Administrators can control exactly which nodes are chosen to run jobs submitted by different users and groups. An administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When users run jobs, they can place them on specified nodes on a per-job basis (using a job label) or on a per-queue level (using a queue label).

The ResourceManager caches the mapping file, and checks every two minutes (the default monitoring period) for updates. If the file has been modified, the ResourceManager updates the labels for all active ApplicationMasters immediately.

Each application runs an ApplicationMaster to negotiate resources from the ResourceManager. The ApplicationMaster works with the NodeManagers to execute and monitor tasks. The duties of the ApplicationMaster are divided as follows:

- NodeManager: One instance runs on each node, to manage that node's resources.
- Container: An abstraction representing a unit of resources on a node.

The NodeManager provides containers to an application. The ResourceManager and the NodeManager provide the system for distributed management of applications and resources.

### **ResourceManager**

Describes the role of the ResourceManager.

The ResourceManager is mainly concerned with arbitrating available resources in the cluster among competing applications, with the goal of maximum cluster utilization. The ResourceManager includes a pluggable scheduler called the YarnScheduler, which allows different policies for managing constraints such as capacity, fairness, and service level agreements.

The ResourceManager manages resources as follows:

- Each NodeManager takes instructions from the ResourceManager, reporting and handling containers on a single node
- Each ApplicationMaster requests resources from the ResourceManager, then works with containers provided by NodeManagers

The ResourceManager communicates with application clients via an interface called the ClientService. A client can submit or terminate an application and gain information about the scheduling queue or cluster statistics through the ClientService.

Administrative requests are served by a separate interface called the AdminService, through which operators can get updated information about cluster operation.

Behind the scenes, the ResourceTrackerService receives node heartbeats from the NodeManager to track new or decommissioned nodes. The NMLivelinessMonitor and NodesListManager keep an updated status of which nodes are healthy so that the scheduler and the ResourceTrackerService can allocate work appropriately.

A component called the ApplicationMasterService manages ApplicationMasters on all nodes, keeping the scheduler informed. A component called the AMLivelinessMonitor keeps a list of ApplicationMasters and their last heartbeat times, in order to let the ResourceManager know what applications are healthy on the cluster. Any ApplicationMaster that does not heartbeat within a certain interval is marked as dead and re-scheduled to run on a new container.

At the core of the ResourceManager is an interface called the ApplicationsManager, which maintains a list of applications that have been submitted, are running, or are completed. The ApplicationsManager accepts job submissions, negotiates the first container for an application (in which the ApplicationMaster will run) and restarts the ApplicationMaster if it fails.

The ResourceManager and NodeManagers communicate via heartbeats.

Configure the ResourceManager for high availability so that the failure of the ResourceManager service is a not single point of failure for the cluster. High availability of the ResourceManager is configured by default when you run `configure.sh` without specifying the `-RM` parameter.

### **ApplicationMaster**

Describes the role of the ApplicationMaster.

The ApplicationMaster is an instance of a framework-specific library that negotiates resources from the ResourceManager and works with the NodeManager to execute and monitor the granted resources (bundled as containers) for a given application. An application can be a process or set of processes, a service, or a description of work.

The ApplicationMaster is run in a container like any other application. The ApplicationsManager, part of the ResourceManager, negotiates for the container in which an application's ApplicationMaster runs when the application is scheduled by the YarnScheduler.

While an application is running, the ApplicationMaster manages the following:

- Application life cycle
- Dynamic adjustments to resource consumption
- Execution flow
- Faults
- Providing status and metrics

The ApplicationMaster is designed to support a specific framework, and can be written in any language since its communication with the NodeManagers and the ResourceManager is accomplished using extensible communication protocols. The ApplicationMaster can be customized to extend the framework or run any other code. For this reason, the ApplicationMaster is not considered trustworthy, and is not run as a trusted service.

An ApplicationMaster typically requests resources on multiple nodes to complete a job by sending the ResourceManager requests that include locality preferences and attributes of the containers. When the ResourceManager is able to allocate a resource to the ApplicationMaster, it generates a lease that the ApplicationMaster pulls on a subsequent heartbeat. A security token associated with the lease guarantees its authenticity when the ApplicationManager presents the lease to the NodeManager to gain access to the container.

The Application Master heartbeats to the ResourceManager to communicate its changing resource needs, and to let the ResourceManager know it is still alive. In response, the ResourceManager can return a lease on additional containers on other nodes, or cancel the lease on some containers. The ApplicationMaster can then adjust its execution strategy to fit the increase or decrease in available resources. When cluster resources become scarce, the ResourceManager can also request that the ApplicationMaster relinquish some resources. The ApplicationMaster can move work to other running containers in order to give up resources gracefully.

### **Containers**

A YARN container is a result of a successful resource allocation, meaning that the ResourceManager has granted an application a lease to use a specific set of resources in certain amounts on a specific node.

The ApplicationMaster presents the lease to the NodeManager on the node where the container has been allocated, thereby gaining access to the resources.

To launch the container, the ApplicationMaster must provide a container launch context (CLC) that includes the following information:

- Environment variables
- Dependencies (local resources such as data files or shared objects needed prior to launch)
- Security tokens
- The command necessary to create the process the application plans to launch

The CLC makes it possible for the ApplicationMaster to use containers to run a variety of different kinds of work, from simple shell scripts to applications to virtual machines.

### MapReduce Version 2

Provides an overview of how MapReduce works.

YARN dynamically allocates resources for applications as they execute. The MapReduce version 1 (MRv1) has been rewritten to run as an application on top of YARN; this new version is called MapReduce version 2.0 (MRv2).

Figure 2. A comparison between MapReduce 1.0 and MapReduce 2.0

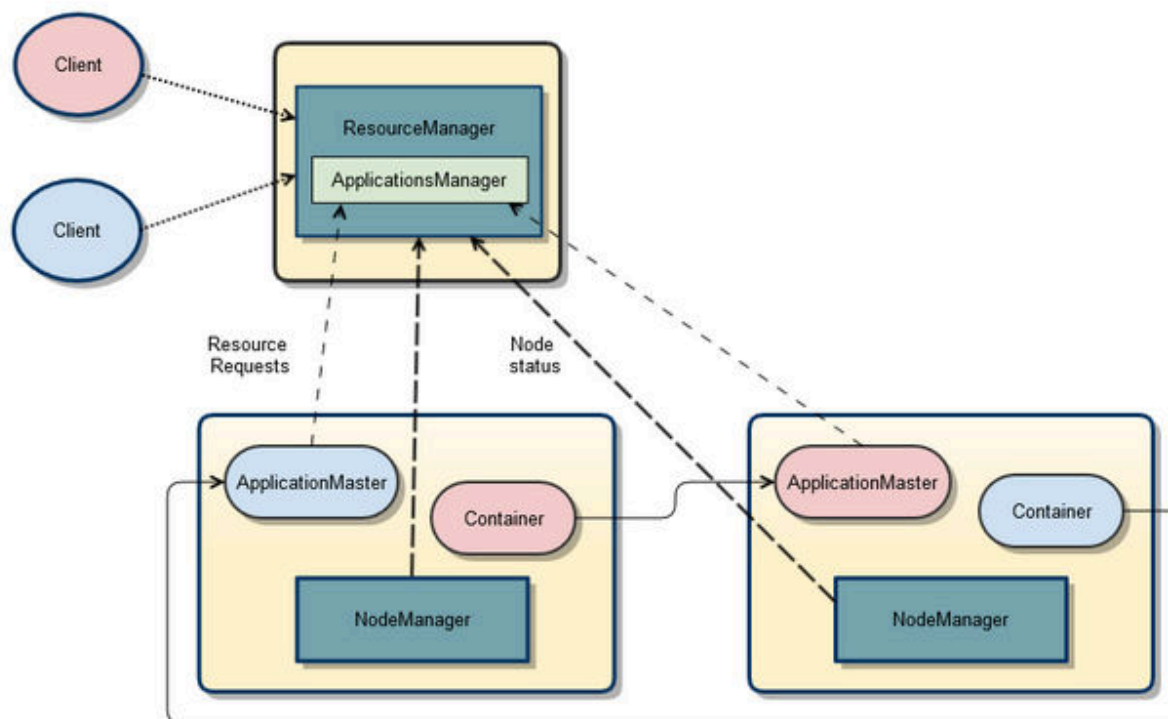

The main advancement in YARN architecture is the separation of resource management and job management, which were both handled by the same process (the JobTracker) in Hadoop 1.x. Cluster resources and job scheduling are managed by the ResourceManager, while resource negotiation and job monitoring are managed by an ApplicationMaster for each application running on the cluster. In MapReduce, each node advertises a relatively fixed number of map slots and reduce slots. This can lead to resource under-utilization, for example, when there is a heavy reduce load and map slots are available, because the map slots cannot accept reduce tasks (and vice versa).

YARN generalizes resource management for use by new engines and frameworks, allowing resources to be allocated and reallocated for different concurrent applications sharing a cluster. Existing MapReduce applications can run on YARN without any changes. At the same time, because MapReduce is now merely another application on YARN, MapReduce is free to evolve independently of the resource management infrastructure.

### How Applications Work in YARN

Describes the data flow during application execution in YARN.

The following diagram and steps describe how data flows during application execution in YARN.

The following steps summarize execution of the application:

1. A client submits an application to the YARN Resource Manager, including the information required for the Container Life Cycle (CLC).
2. The ApplicationsManager (in the Resource Manager) negotiates a container and bootstraps the ApplicationMaster instance for the application.
3. The ApplicationMaster registers with the Resource Manager and requests containers.
4. The ApplicationMaster communicates with NodeManagers to launch the containers it has been granted, specifying the CLC for each container.
5. The ApplicationMaster manages application execution. During execution, the application provides progress and status information to the ApplicationMaster. The client can monitor the application's status by querying the Resource Manager or by communicating directly with the ApplicationMaster.
6. The ApplicationMaster reports completion of the application to the Resource Manager.
7. The ApplicationMaster deregisters with the Resource Manager, which then cleans up the ApplicationMaster container.

### Direct Shuffle on YARN

Explains the shuffle phase of a MapReduce application.

### Overview of Direct Shuffle

During the shuffle phase of a MapReduce application, HPE Ezmeral Data Fabric writes to a file system volume limited by its topology to the local node instead of writing intermediate data to local disks controlled by the operating system. This improves performance and reduces demand on local disk space while making the output available cluster-wide.

Direct Shuffle is the default shuffle mechanism for HPE Ezmeral Data Fabric. However, you can modify the `yarn-site.xml` and `mapred-site.xml` configuration files to enable Apache Shuffle for MapReduce applications. See [Apache Shuffle on YARN](#).

The `LocalVolumeAuxiliaryService` runs in the `NodeManager` process. The `LocalVolumeAuxiliaryService` manages the local volume on each node and cleans up shuffle data after a MapReduce application has finished executing.

1. The MRAppMaster service initializes the application by calling `initializeApplication()` on the `LocalVolumeAuxiliaryService`.
2. The MRAppMaster service requests task containers from the `ResourceManager`. The `ResourceManager` sends the MRAppMaster information that MRAppMaster uses to request containers from the `NodeManager`.
3. The `NodeManager` on each node launches containers using information about the node's local volume from the `LocalVolumeAuxiliaryService`.
4. Data from map tasks is saved in MRAppMaster for later use in TaskCompletion events, which are requested by reduce tasks.
5. As map tasks complete, map outputs and map-side spills are written to the local volumes on the map task nodes, generating Task Completion events.

6. ReduceTasks fetch Task Completion events from the Application Manager. The task Completion events include information on the location of map output data, enabling reduce tasks to copy data from MapOutput locations.
7. Reduce tasks read the map output information.
8. Spills and interim merges are written to local volumes on the reduce task nodes.
9. MRAppMaster calls `stopApplication()` on the `LocalVolumeAuxiliaryService` to clean up data on the local volume.

### Configuration for Direct Shuffle

The default YARN parameters for Direct Shuffle are as follows:

```
<property>
  <name>yarn.nodemanager.aux-services</name>
  <value>mapreduce_shuffle,mapr_direct_shuffle</value>
  <description>shuffle service that needs to be set for Map Reduce to
run</description>
</property>
<property>
  <name>yarn.nodemanager.aux-services.mapr_direct_shuffle.class</name>
  <value>org.apache.hadoop.mapred.LocalVolumeAuxService</value>
</property>
```

The default mapred parameters for Direct Shuffle are as follows:

```
<property>
  <name>mapreduce.job.shuffle.provider.services</name>
  <value>mapr_direct_shuffle</value>
</property>
<property>
  <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
  <value>org.apache.hadoop.mapreduce.task.reduce.DirectShuffle</value>
</property>
<property>
  <name>mapreduce.job.map.output.collector.class</name>
  <value>org.apache.hadoop.mapred.MapRFsOutputBuffer</value>
</property>
<property>
  <name>mapred.ifile.outputstream</name>
  <value>org.apache.hadoop.mapred.MapRIFileOutputStream</value>
</property>
<property>
  <name>mapred.ifile.inputstream</name>
  <value>org.apache.hadoop.mapred.MapRIFileInputStream</value>
</property>
<property>
  <name>mapred.local.mapoutput</name>
  <value>>false</value>
</property>
<property>
  <name>mapreduce.task.local.output.class</name>
  <value>org.apache.hadoop.mapred.MapRFsOutputFile</value>
</property>
```

### Apache Shuffle on YARN

You can disable Direct Shuffle and enable Apache Shuffle by modifying the configuration options in the `yarn-site.xml` and `mapred-site.xml` files. This page describes how to configure Apache Shuffle for MapReduce applications.

The shuffling phase in Hadoop is the process of transferring mappers intermediate output to the reducers. Direct shuffle increases the load on file system disks. You can enable the Apache Shuffle to reduce the load on file system disks.

### Configuration for Apache Shuffle

Add the following property to `yarn-site.xml` file:

```
<property>
  <name>yarn.nodemanager.aux-services</name>
  <value>mapreduce_shuffle</value>
</property>
```

Add the following properties to `mapred-site.xml` file:

```
<property>
  <name>mapreduce.job.shuffle.provider.services</name>
  <value>mapreduce_shuffle</value>
</property>
<property>
  <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
  <value>org.apache.hadoop.mapreduce.task.reduce.Shuffle</value>
</property>
<property>
  <name>mapreduce.job.map.output.collector.class</name>
  <value>org.apache.hadoop.mapred.MapTask$MapOutputBuffer</value>
</property>
<property>
  <name>mapred.ifile.outputstream</name>
  <value>org.apache.hadoop.mapred.FileOutputStream</value>
</property>
<property>
  <name>mapred.ifile.inputstream</name>
  <value>org.apache.hadoop.mapred.FileInputStream</value>
</property>
<property>
  <name>mapred.local.mapoutput</name>
  <value>>true</value>
</property>
<property>
  <name>mapreduce.task.local.output.class</name>
  <value>org.apache.hadoop.mapred.YarnOutputFiles</value>
</property>
```

### Logging Options on YARN

Describes the logging options that are available on YARN.

For YARN applications, there are various logging options to choose from based on the data-fabric version and the types of applications that you run. In 4.0.2 and later versions, you have the following logging options:

- For MapReduce version 2 (MRv2) applications, the default logging option is to log files on the local filesystem. However, central logging and YARN log aggregation are also available.
- For non-MapReduce applications, the default logging option is to log files on the local filesystem. However, YARN log aggregation is also available.

#### Centralized Logging for MRv2

Centralized logging provides an application-centric view of all the log files generated by NodeManager nodes throughout the cluster. It enables users to gain

a complete picture of application execution by having all the logs available in a single directory, without having to navigate from node to node.

The MapReduce program generates three types of log output:

- Standard output stream: captured in the `stdout` file
- Standard error stream: captured in the `stderr` file
- Log4j logs: captured in the `syslog` file

Centralized logs are available cluster-wide as they are written to the following local volume on the data-fabric filesystem: /

```
var/mapr/local/<NodeManager node>/
logs/yarn/userlogs
```

Since the log files are stored in a local volume directory that is associated with each NodeManager node, you run the `maprcli job linklogs` command to create symbolic links for all the logs in a single directory. You can then use tools such as `grep` and `awk` to analyze them from an NFS mount point. You can also view the entire set of logs for a particular application using the HistoryServer UI.

The YARN log aggregation option aggregates logs from the local filesystem and moves log files for completed applications from the local filesystem to the data-fabric filesystem. This allows users to view the entire set of logs for a particular application using the HistoryServer UI or by running the `yarn logs` command.

## YARN Log Aggregation

### Support for ADLS

Starting with MapR 6.1, you can use Azure Data Lake Store (ADLS) as a data source or destination for all applications.

#### Prerequisites for Using ADLS

Setting up Azure Data Lake Store (ADLS) on the Azure portal enables you to access ADLS from any application.

- Create an account on the [Azure portal](#).
- Create an Azure Data Lake Store ([get started with Azure Data Lake Storage](#)).

#### Authenticating ADLS Account

To access data stored in Azure Data Lake Store (ADLS), you must first authenticate your ADLS account using your ADLS credentials.

#### Procedure

1. Obtain the following properties from your Azure application:

- `dfs.adls.oauth2.access.token.provider.type`  
ClientCredential, Refresh Tokens, or Client Keys to obtain the authentication type.

- `dfs.adls.oauth2.client.id`

Create an Azure Active Directory application and get your application ID and authentication key.

- `dfs.adls.oauth2.refresh.url`

Navigate to Azure Active Directory and click on `Endpoints`. Use the `OAUTH 2.0 TOKEN ENDPOINT` value.

- `dfs.adls.oauth2.credential`

Obtain the access token key value from `App Registrations` in your Azure account.

2. Add the properties obtained in step 1 to the `core-site.xml` file:

```
<!--ADL-->
<property>
  <name>dfs.adls.oauth2.access.token.provider.type</name>
  <value>ClientCredential</value>
</property>

<property>
  <name>dfs.adls.oauth2.client.id</name>
  <value>f377fab9-c0a3-4531-alc9-77345105</value>
</property>

<property>
  <name>dfs.adls.oauth2.refresh.url</name>
  <value>https://login.microsoftonline.com/25735fb/oauth2/token</
value>
</property>

<property>
  <name>dfs.adls.oauth2.credential</name>
  <value>WTkn4xS0ISsqyzo4R6bu/OW2oPyGNMzWRw/d2z2CGiw=</value>
</property>
```

**NOTE:** The `core-site.xml` file can be overwritten using the command line. You can also specify these properties at runtime. The syntax for overwriting ADLS properties at runtime using the command line is as follows:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
-Ddfs.adls.oauth2.access.token.provider.type=ClientCredential
-Ddfs.adls.oauth2.client.id=f377fab9-c0a3-4531-alc9-77345105
-Ddfs.adls.oauth2.refresh.url=https://login.microsoftonline.com/
25735fb/oauth2/token
-Ddfs.adls.oauth2.credential=WTkn4xS0ISsqyzo4R6bu/OW2oPyGNMzWRw/
d2z2CGiw= adl://testhue.azuredatalakestore.net/some_folder/testfile
adl://testhue.azuredatalakestore.net/some_folder/wordcountout
```

To provide your ADLS credentials securely, see [Securely Providing ADLS Credentials](#) on page 4744.

3. Provide your application with file access.
4. For secure clusters, MapR-SASL (Simple Authentication and Security Layer), and Kerberos, import the required CA certificate.
  - [Open source documentation](#)
  - [Azure documentation](#)
  - [Azure documentation on authorization and access control](#)

### Securely Providing ADLS Credentials

You can provide your ADLS credentials securely by hiding the open, readable configuration on the command line using the Hadoop credential provider.

#### Procedure

1. Generate a `jceks` file for ADLS authorization:

```
hadoop credential create dfs.adls.oauth2.client.id -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client ID
hadoop credential create dfs.adls.oauth2.credential -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client secret
hadoop credential create dfs.adls.oauth2.refresh.url -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value refresh URL
```

2. Run the `DistCp` example using the `jceks` file:

```
hadoop distcp
[-D hadoop.security.credential.provider.path=localjceks://hdfs/user/
USER_NAME/adlskeyfile.jceks]
hdfs://<NameNode Hostname>:9001/user/foo/007020615
adl://<Account Name>.azuredatalakestore.net/testDir/
```

3. Configure the `core-site.xml` file to use the `jceks` file:

```
<property>
  <name>hadoop.security.credential.provider.path</name>
  <value>localjceks://hdfs/user/USER_NAME/adlskeyfile.jceks</value>
  <description>Path to interrogate for protected credentials.</
description>
</property>
```

### Using ADLS for Data Input or Output

You can use Azure Data Lake Store (ADLS) as a source or destination for your application data.

#### Prerequisites

For general information about the features of ADLS, refer to the [Azure Data Lake Store documentation](#).

For information about configuring ADLS as storage for a Hadoop cluster, refer to the official [Apache documentation](#).

The Azure Data Lake Storage access path syntax is:

```
adl://<Account Name>.azuredatalakestore.net/
```

You can use ADLS the same way as you use file system, substituting an `adl` scheme instead of `maprfs`, `hdfs`, `webhdfs`, and so on.

**Procedure****1. Create a directory and read data:**

```
[mapr@node4 ~]$ hadoop fs -mkdir adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/

Found 1 items
drwxr-xr-x - 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:09
adl://<username>.azuredatalakestore.net/testdir
```

**2. Put data into ADLS from your local file system:**

```
[mapr@node4 ~]$ hadoop fs -put testfile adl://
<username>.azuredatalakestore.net/testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
testdir

Found 1 itemsrw-rr- 1 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:10
adl://<username>.azuredatalakestore.net/testdir/testfile
```

**3. Delete data from ADLS:**

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

**4. Run YARN jobs with your input and output stored in ADLS:**

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
adl://<username>.azuredatalakestore.net/testdir/testfile adl://
<username>.azuredatalakestore.net/wordcountout
```

**Deleting Data from ADLS**

You can delete your data from Azure Data Lake Store (ADLS).

**Procedure**

- To delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

**Configuring ATS 1.0 or 1.5 for Hadoop 3.3**

Describes how to configure the YARN Application Timeline Server (ATS) 1.0 and 1.5 for Hadoop 3.3.

EEP 9.0.0 introduced Hadoop 3.3, which uses ATsv2 by default. Hive 3 and the Tez UI currently do not support ATsv2, but you can configure ATsv1 for use with Hadoop 3, and doing so enables the Tez UI. Use the following steps:

1. Check to ensure that the `mapr-timelineserver` package didn't install, and remove it if it did.
2. On all nodes, add the following configuration to the `yarn-site.xml` file:

```
<property>
  <name>yarn.timeline-service.enabled</name>
  <value>>true</value>
</property>
<property>
  <name>yarn.timeline-service.hostname</name>
  <value><hostname></value>
</property>
<property>
  <name>yarn.resourcemanager.system-metrics-publisher.enabled</name>
  <value>>true</value>
</property>
<property>
  <name>yarn.timeline-service.http-cross-origin.enabled</name>
  <value>>true</value>
</property>
  <property>
    <name>yarn.timeline-service.version</name>
    <value>1.0f</value>
    <description>Timeline server version. Should be 1.0f or 1.5f</
description>
  </property>
```

3. For ATS 1.5, add these additional properties:

```
<property>
  <name>yarn.timeline-service.entity-group-fs-store.summary-store</
name>

<value>org.apache.hadoop.yarn.server.timeline.RollingLevelDBTimelineStore
</value>
</property>
<property>
  <name>yarn.timeline-service.store-class</name>

<value>org.apache.hadoop.yarn.server.timeline.EntityGroupFSTimelineStore<
/value>
</property>
<property>
  <name>yarn.timeline-service.entity-group-fs-store.active-dir</name>
  <value>/apps/ats/active/</value>
</property>
<property>
  <name>yarn.timeline-service.entity-group-fs-store.done-dir</name>
  <value>/apps/ats/done/</value>
</property>
<property>
  <name>yarn.timeline-service.leveldb-timeline-store.path</name>
  <value>/opt/mapr/hadoop/hadoop-3.3.4/ats/leveldb/</value>
</property>
<property>

<name>yarn.timeline-service.entity-group-fs-store.group-id-plugin-classes
</name>

<value>org.apache.tez.dag.history.logging.ats.TimelineCachePluginImpl</
value>
</property>
```

4. For ATS 1.5, create the following directories in the Hadoop file system:

Directory	Permission	uid and guid Owner
yarn.timeline-service.entity-group-fs-store.active-dir	1777	Cluster admin
yarn.timeline-service.entity-group-fs-store.done-dir	0700	Cluster admin

Use these commands:

```
hadoop fs -mkdir -p /apps/ats/active/
hadoop fs -mkdir -p /apps/ats/done/
hadoop fs -chmod 1777 /apps/ats/active/
hadoop fs -chmod 0700 /apps/ats/done/
```

5. For ATS 1.5, create the following directory in the local file system:

```
mkdir -p /opt/mapr/hadoop/hadoop-3.3.4/ats/leveldb/
```

**6. Change the owner manually:**

```
sudo chown -R mapr:root /opt/mapr/hadoop/hadoop-3.3.4/ats
```

**7. For ATS 1.5, copy the following libraries from Tez:**

```
cp /opt/mapr/tez/tez-<version>/
tez-yarn-timeline-cache-plugin-<artifact_name>.jar /opt/mapr/hadoop/
hadoop-<hadoop_version>/share/hadoop/yarn/lib/
cp /opt/mapr/tez/tez-<version>/tez-api-<artifact_name>.jar /opt/mapr/
hadoop/hadoop-<hadoop_version>/share/hadoop/yarn/lib/
cp /opt/mapr/tez/tez-<version>/tez-common-<artifact_name>.jar /opt/mapr/
hadoop/hadoop-<hadoop_version>/share/hadoop/yarn/lib/
```

**8. If the cluster is secure, add the security property to yarn-site.xml:**

```
<property>
  <name>yarn.timeline-service.http-authentication.type</name>

  <value>org.apache.hadoop.security.token.delegation.web.MaprDelegationTokenAuthenticationHandler</value>
</property>
```

**9. On all nodes, restart all YARN services (RM, NM, and JHS):**

```
maprcli node services -nodes 'hostname -f' -name resourcemanager -action
restart
maprcli node services -nodes 'hostname -f' -name nodemanager -action
restart
maprcli node services -nodes 'hostname -f' -name historyserver -action
restart
```

**10. Install ATS manually by using the appropriate command for your distribution:**

```
yum install mapr-timelineserverv1 (RHEL, Rocky, or Oracle Linux)
apt install mapr-timelineserverv1 (Ubuntu)
zypper install mapr-timelineserverv1 (SLES)
```

**11. Run configure.sh to configure and automatically start ATS:**

```
configure.sh -R -TL <hostname>
```

**12. To start, stop, or restart ATS manually, use the following commands as needed:****To start ATS:**

```
maprcli node
services -nodes 'hostname -f' -name
timelineserverv1 -action start
```

**To stop ATS:**

```
maprcli node
services -nodes 'hostname -f' -name
timelineserverv1 -action stop
```

**To restart ATS:**

```
maprcli node
services -nodes 'hostname -f' -name
timelineserverv1 -action restart
```

**Configuring ATS 2.0 for Hadoop 3.3**

Describes how to install and configure the YARN Application Timeline Server (ATS) 2.0 for Hadoop 3.3.

Use these steps:

1. Install the following packages:

Package	See for more information
mapr-timelineserver	<a href="#">Installing Hadoop and YARN</a> on page 233
mapr-hbase	<a href="#">Install HBase on a Cluster Node</a> on page 236
mapr-hbase-master	
mapr-hbase-regionserver	

2. Run the `configure.sh` script:

```
/opt/mapr/server/configure.sh -R -TL <FQDN>
```

3. Add the property for `hbase-site.xml` to the `yarn-site.xml`:

- Example for local path:

```
<property>
  <name>yarn.timeline-service.hbase.configuration.file</name>
  <value>file:/opt/mapr/hbase/hbase-1.4.14/conf/hbase-site.xml</
value>
</property>
```

- Example for Data Fabric file system path:

```
<property>
  <name>yarn.timeline-service.hbase.configuration.file</name>
  <value>maprfs:/tmp/hbase-site.xml</value>
</property>
```

4. Create the timeline service schema:

```
echo "export HBASE_CLASSPATH="/opt/mapr/hadoop/hadoop-3.3.4/share/hadoop/
yarn/timelineservice/*" >> /opt/mapr/hbase/hbase-1.4.14/conf/
hbase-env.sh
/opt/mapr/hbase/hbase-1.4.14/bin/hbase
org.apache.hadoop.yarn.server.timelineservice.storage.TimelineSchemaCreat
or -create
```

**5. Restart all YARN services: RM, NM, JHS, and ATS:**

```
maprcli node services -nodes 'hostname -f' -name resourcemanager -action
restart
maprcli node services -nodes 'hostname -f' -name timelineserver -action
restart
maprcli node services -nodes 'hostname -f' -name historyserver -action
restart
maprcli node services -nodes 'hostname -f' -name nodemanager -action
restart
```

**6. To access the Timeline Server 2.0 web UI, navigate to the following URL:**

```
https://<TIMELINEHOSTNAME>:8090/ui2/#/cluster-overview
```

## Zeppelin

Apache Zeppelin is an open source, Web-based data-science notebook. You can use it with Data Fabric components to conduct data discovery, ETL, machine learning, and data visualization.

You can run the package-based Zeppelin product only on a Data Fabric node (and not on an edge node). Out of the box, Zeppelin is integrated with open-source data-processing engines such as Apache Spark, Apache Drill, and Apache Hive, as well as with native Data Fabric engines (file system, HPE Ezmeral Data Fabric Database, and HPE Ezmeral Data Fabric Streams). Using the notebook simply requires connecting to Zeppelin through your browser.

Zeppelin provides the following benefits for your data-engineering and data-science use cases:

- An interactive development environment for writing, testing, and sharing data processing code snippets
- Support for a variety of interpreters for integrating with different backend components
- Support for extensible visualization libraries

For release-specific information, see [Zeppelin Release Notes \(Package-Based\)](#) on page 6170.

For installation information, see [Installing Zeppelin](#) on page 263.

For additional information about Zeppelin, refer to the [open source documentation](#).

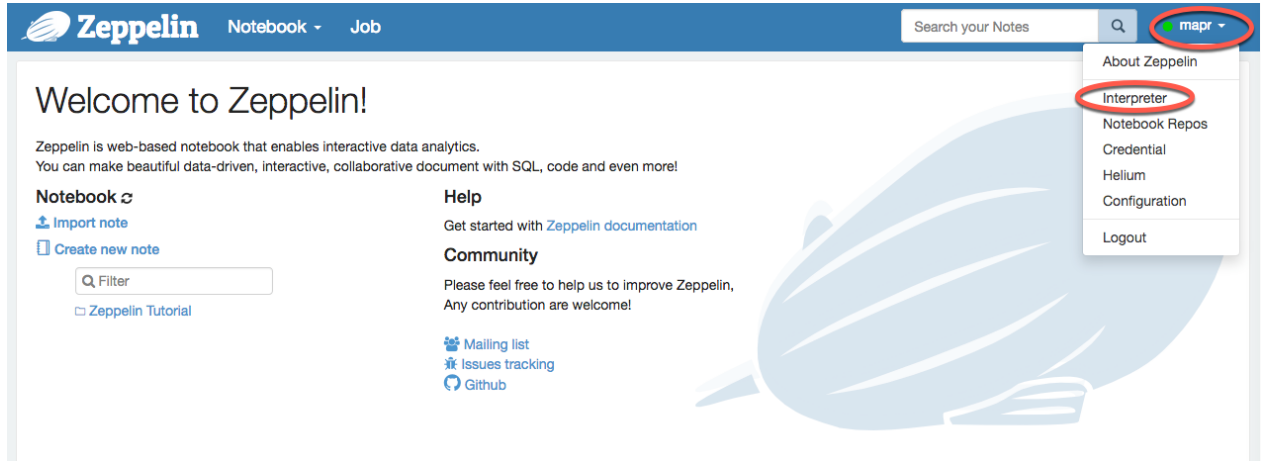

### Configuring Zeppelin Interpreters

Out-of-box, the interpreters in Apache Zeppelin on the HPE Ezmeral Data Fabric are preconfigured to run against different backend engines. You may need to perform manual steps to configure the Livy, Spark, and JDBC interpreters. You can configure the idle timeout threshold for interpreters.

To configure an interpreter:

1. Log in as the cluster administrator (typically `mapr`).

2. In the top right-hand menu, click **Interpreter**:

3. Search for the required interpreter.
4. Edit the required fields. For example, to configure the `%livy` interpreter, you need to edit the `zeppelin.livy.url` property. For a secure cluster, change `http` to `https`, and set the `hostname` instead of using the default `localhost`. Note that nonsecure clusters are not supported by releases 7.0.0 and later.
5. Click **Save**.

### Cloning the Zeppelin Interpreter

Describes how to change interpreter settings for different notebooks.

You can create a new notebook with custom settings by cloning the existing default interpreter. Use these steps:

1. Log in as the cluster administrator (typically `mapr`).
2. In the top right-hand menu, click **Interpreter**:

3. Click **Create**.
4. Enter the interpreter name, and select the interpreter group for which you want to clone the interpreter.
5. Set permissions for this new interpreter if required.  
Enter comma-separated users and groups in the fields. An empty field (\*) implies that anyone can run this interpreter.
6. Click **Save** to save your changes. The interpreter is relaunched automatically.

### Zeppelin Multiuser and Multi-Instance Support

Describes support for multiple users and multiple instances of the Zeppelin package-based product.

To work with different users in Zeppelin you must log in to the Zeppelin user interface (UI) as a required user. The user that you use for login purposes must already be created on the cluster and have a folder within the data-fabric file system with the correct permissions (for example: `/user/<user_name>`).

To work in different Zeppelin instances with a separate user, you need to install the Zeppelin package on a separate cluster node (one Zeppelin instance per node) and log in as a required user.

### Configuring Impersonation in Zeppelin

Impersonation for Apache Zeppelin is enabled and configured through the user interface for each interpreter. The following provides details for performing these configuration functions.

Set the interpreter for which impersonation is to be enabled to be instantiated by selecting or checking the following from the user interface:

- **Per User**
- **Isolated**
- **User Impersonate**

**spark** %spark, %sql, %pyspark, %ipyspark, %r, %ir, %shiny, %kotlin ●

#### Option

The interpreter will be instantiated  in  process ⓘ +

- User Impersonate
- Connect to existing process
- Set permission

Excluding Spark and JDBC-based interpreters such as Hive and Drill, impersonation operates in the background using one of the following methods:

- Passwordless sudo (default one)
- SSH-keys

### Passwordless sudo

For passwordless sudo use cases, interpreter processes for each user are started using `sudo` from the user that runs the notebook.

**NOTE:** This operation excludes Spark and JDBC-based interpreters, such as JDBC, Hive, and Drill.

The settings for the user that runs Zeppelin Server (the cluster admin) are configured to use sudo without a password. Typically, this configuration is done by adding the following line to the sudo configuration:

```
mapr ALL=(ALL) NOPASSWD: ALL
```

**WARNING:** Use caution when performing sudo configurations. Passwordless sudo configurations can weaken security on your cluster.

Note that on a secure cluster, the interpreter process is launched from the user that runs the notebook. As such, that user needs to specify a user ticket.

### SSH-key-based Impersonation

With SSH-key-based impersonation, the Zeppelin server user logs into the user shell with SSH (as opposed to executing commands with sudo). This method is more secure than using passwordless sudo configurations and can involve more configuration steps.

To enable SSH-key based impersonation:

1. Create a directory for the Zeppelin SSH key:

```
mkdir -p /opt/mapr/zeppelin/zeppelin-0.9.0/conf/sshkeys
```

2. Generate the keys (without passphrase):

```
ssh-keygen -f /opt/mapr/zeppelin/zeppelin-0.9.0/conf/sshkeys/zeppelin_key
```

3. Copy the keys to target users with the `ssh-copy-id` (using `localhost` as the host):

```
ssh-copy-id -i /opt/mapr/zeppelin/zeppelin-0.9.0/conf/sshkeys/zeppelin_key.pub <user>@localhost
```

For example:

```
ssh-copy-id -i /opt/mapr/zeppelin/zeppelin-0.9.0/conf/sshkeys/zeppelin_key.pub mapruser1@localhost
```

4. Configure Zeppelin to use those keys for impersonation by setting `ZEPPELIN_IMPERSONATE_CMD` to the following value in `conf/zeppelin-env.sh`:

```
export ZEPPELIN_IMPERSONATE_CMD='ssh -i ${ZEPPELIN_HOME}/conf/sshkeys/zeppelin_key ${ZEPPELIN_IMPERSONATE_USER}@localhost '
```

- Restart the Zeppelin server for these configurations to take effect:

```
maprcli node services -action restart -nodes $(hostname) -name zeppelin
```

- Optionally, enable impersonation for interpreters of your choice in the Zeppelin user interface by setting the interpreter to be instantiated. To do so, select **Per User** and **Isolated** process, and then check **User Impersonate** as shown below:

**spark** %spark, %sql, %pyspark, %ipyspark, %r, %ir, %shiny, %kotlin ●

**Option**

The interpreter will be instantiated  in  process ⓘ +

User Impersonate

Connect to existing process

Set permission

### Configuring Impersonation for the Spark Interpreter

Describes how to configure impersonation for the Spark Interpreter

The Spark interpreter uses the `--proxy-user` argument of the `spark-submit` utility to perform impersonation operations, as opposed to launching interpreter processes with `sudo`. As such, the Spark interpreter does not require the `NOPASSWD` permission or an existing `maprticket` for the target user.

To enable impersonation with the Spark interpreter you must configure the interpreter in the user interface to be instantiated **Per User** in **Isolated** process and check **User Impersonate**.

### Configuring Impersonation for JDBC Interpreters

For databases that use the JDBC interface and support inbound impersonation, you can configure impersonation to work without using `sudo`.

To do so, configure interpreter in the user interface to be instantiated **Per User** in **Isolated** process, check **User Impersonate**, and then configure the `default.proxy.user.property` property in the interpreter settings to contain the corresponding property name to be used to set the user to impersonate in the JDBC connection string.

See this table for a guide to the property you must set:

For	Set this property
Hive	<code>default.proxy.user.property=hive.server2.proxy.user</code>
Drill	<code>default.proxy.user.property=impersonation_target</code>

### Enabling Kerberos Security for Zeppelin

Describes how to set the principal and keytab properties for the Zeppelin server and configure interpreters to enable Kerberos for your Zeppelin installation.

#### Setting the Principal and Keytab Properties

Use these steps:

- Set the principal and keytab of the Zeppelin server. To do this, you must edit the following properties in the `zeppelin-site.xml`:
  - `zeppelin.server.kerberos.principal`
  - `zeppelin.server.kerberos.keytab`

For example:

```
<property>
  <name>zeppelin.server.kerberos.principal</name>
  <value>mapr/node1.cluster.com@NODE1</value>
  <description>principal for accessing kerberized hdfs</description>
</property>

<property>
  <name>zeppelin.server.kerberos.keytab</name>
  <value>/opt/mapr/conf/mapr.keytab</value>
  <description>keytab for accessing kerberized hdfs</description>
</property>
```

2. Restart the Zeppelin server:

```
maprcli node services -action restart -nodes $(hostname) -name zeppelin
```

3. Configure your interpreters to work in the Kerberized environment, as described in the following sections. Note that the Spark, HBase, and HPE Ezmeral Data Fabric Database Shell interpreters do not require additional configuration to work properly in a Kerberized environment.

### Configure the Livy Interpreter

To make the Livy interpreter work with the Livy server that is configured to use Kerberos-based authentication, add the `zeppelin.livy.principal` and `zeppelin.livy.keytab` options with corresponding values to the Livy interpreter configuration:

**livy** %livy, %sql, %pyspark, %sparkr, %shared ●

**Option**

The interpreter will be instantiated Per User ▾ in isolated ▾ process ⓘ +

User Impersonate

Connect to existing process

Set permission

**Properties**

Name	Value
zeppelin.livy.url	<input type="text" value="https://node1.cluster.com:8998"/>
zeppelin.livy.isMaprSecured	<input type="checkbox"/>
zeppelin.livy.principal	<input type="text" value="mapr/node1.cluster.com@NODE1"/>
zeppelin.livy.keytab	<input type="text" value="/opt/mapr/conf/mapr.keytab"/>

## Configure the Hive Interpreter

To configure the Hive interpreter to work with the Kerberos-enabled HiveServer2, set the the value of the `principal` option in the JDBC connection URL, and set `zeppelin.jdbc.auth.type`, `zeppelin.jdbc.principal` and `zeppelin.jdbc.keytab.location` properties in the Hive interpreter configuration:

**hive** %hive ●

**Option**

The interpreter will be instantiated Per User ▾ in isolated ▾ process ⓘ +

User Impersonate

Connect to existing process

Set permission

**Properties**

Name	Value
default.url	jdbc:hive2://node1.cluster.com:10000/default;ssl=true;principal=mapr/node1.cluster.com@NODE1
zeppelin.jdbc.auth.type	KERBEROS
zeppelin.jdbc.keytab.location	/opt/mapr/conf/mapr.keytab
zeppelin.jdbc.principal	mapr/node1.cluster.com@NODE1

## Configure the Drill Interpreter

To configure the Drill interpreter to work with Kerberos-enabled Drillbits, set the value of the `auth`, `user` and `keytab` options in the JDBC connection URL:

**drill** %drill ●

**Option**

The interpreter will be instantiated Per User ▾ in isolated ▾ process ⓘ +

User Impersonate

Connect to existing process

Set permission

**Properties**

Name	Value
default.url	jdbc:drill:drillbit=node1.cluster.com:31010;auth=kerberos;user=mapr/node1.cluster.com@NODE1;keytab=/opt/mapr/conf/mapr.keytab

## Using Zeppelin to Access Different Backend Engines

Contains links to examples for how to use Apache Zeppelin interpreters to access different backend engines. This includes running Apache Drill queries, Apache Hive queries, and Apache Spark jobs, as well as accessing database and streaming solutions.

## Links to Docker-Container-Based Zeppelin Information

The following pages were created for the Docker-container-based Zeppelin product but are also relevant for the package-based Zeppelin product:

- [Running Shell Commands in Zeppelin \(Docker Container\)](#)
- [Running Drill Queries in Zeppelin \(Docker Container\)](#)
- [Running Hive Queries in Zeppelin \(Docker Container\)](#)
- [Running Spark Jobs in Zeppelin \(Docker Container\)](#)
- [Running Database Shell Commands in Zeppelin \(Docker Container\)](#)
- [Accessing the Database in Zeppelin \(Docker Container\) Using the Database Binary Connector](#)
- [Accessing the Database in Zeppelin \(Docker Container\) Using the the Database OJAI Connector](#)
- [Accessing the Event Store For Apache Kafka in Zeppelin \(Docker Container\) Using the Livy Interpreter](#)
- [Accessing the Event Store For Apache Kafka in Zeppelin \(Docker Container\) Using the Spark Interpreter](#)

## Configuring Conda Python for Zeppelin

Describes how to configure Conda Python for Zeppelin.

The following steps assume that the miniconda distribution of Conda Python is already installed. For more information see the [Conda documentation](#).

Use these steps:

1. Create a Conda zip archive containing Python and all the libraries that you need.

### Python 2

The following example creates a custom Conda environment with Python 2 and three packages (matplotlib, numpy, and pandas):

```
mkdir custom_pyspark_env
conda create -p ./
custom_pyspark_env python=2 numpy
pandas matplotlib
cd custom_pyspark_env
zip -r custom_pyspark_env.zip ./
```

### Python 3

The following example creates a custom Conda environment with Python 3 and three packages (matplotlib, numpy, and pandas):

```
mkdir custom_pyspark3_env
conda create -p ./
custom_pyspark3_env python=3 numpy
pandas matplotlib
cd custom_pyspark3_env
zip -r custom_pyspark3_env.zip ./
```

**IMPORTANT:** Do not create an archive named `pyspark.zip`. This name is reserved for PySpark internals.

2. Upload the archive to the data-fabric file system. For example, if the archive name is `custom_pyspark_env.zip`, and you want to put the archive in a directory that all users can read:

```
hadoop fs -mkdir /apps/zeppelin
hadoop fs -put custom_pyspark_env.zip /apps/zeppelin
```

3. Add the full path (including `maprfs://` schema) to the archive into `spark.yarn.dist.archive`, and configure the Spark / Livy interpreter to use Python from this distribution.

Note that all archives listed in the property will be extracted into a working directory of YARN application.

4. For the Spark interpreter, set the `PYSPARK_PYTHON` and `PYSPARK_DRIVER_PYTHON` environment variables (it can be done by configuring Spark interpreter):

**spark** %spark, %sql, %pyspark, %ipyspark, %r, %ir, %shiny, %kotlin ●

**Option**

The interpreter will be instantiated Globally in shared process ⓘ

Connect to existing process

Set permission

**Properties**

Name	Value	Description
spark.yarn.dist.archives	<input type="text" value="maprfs:///apps/zeppelin/custom_pyspark_env.zip"/>	Sets additional archives for spark
PYSPARK_PYTHON	<input type="text" value="/custom_pyspark_env.zip/bin/python"/>	Python binary executable to use for PySpark in both driver and workers (default is python2.7 if available, otherwise python). Property `spark.pyspark.python` take precedence if it is set
PYSPARK_DRIVER_PYTHON	<input type="text" value="/custom_pyspark_env.zip/bin/python"/>	Python binary executable to use for PySpark in driver only (default is `PYSPARK_PYTHON`). Property `spark.pyspark.driver.python` take precedence if it is set

5. For the Livy interpreter, set the `livy.spark.yarn.appMasterEnv.PYSPARK_PYTHON` property:

**livy** %livy, %sql, %pyspark, %sparkr, %shared ●

**Option**

The interpreter will be instantiated Globally in shared process ⓘ

Connect to existing process

Set permission

**Properties**

Name	Value	Description
livy.spark.yarn.dist.archives	<input type="text" value="maprfs:///apps/zeppelin/custom_pyspark_env.zip"/>	Sets additional archives for spark
livy.spark.yarn.appMasterEnv.PYSPARK_PYTHON	<input type="text" value="/custom_pyspark_env.zip/bin/python"/>	Sets default python interpreter for PySpark

## Maven and the HPE Ezmeral Data Fabric

This section discusses topics associated with Maven and the HPE Ezmeral Data Fabric.

## Maven Artifacts for the HPE Ezmeral Data Fabric

Maven artifacts can be used for dependency management when developing applications based on the the HPE Ezmeral Data Fabric.

You can access the data-fabric Maven repository by browsing [Nexus](#) or as follows:

```
<repositories>
  <repository>
    <id>mapr-releases</id>
    <url>https://repository.mapr.com/maven/</url>
    <snapshots><enabled>false</enabled></snapshots>
    <releases><enabled>true</enabled></releases>
  </repository>
</repositories>
```

**Table**

Group Id	Artifact Id	Version	Maven Coordinat
com.mapr.util	baseutils	7.8.0.0-mapr	<pre>&lt;dependency&gt;   &lt;groupId&gt;com.mapr.util&lt;/groupId&gt;   &lt;artifactId&gt;baseutils&lt;/artifactId&gt;   &lt;version&gt;7.8.0.0-mapr&lt;/version&gt; &lt;/dependency&gt;</pre>
