"meetingnotes" --disable s3/mybucket
```

mc ilm rm

Deletes object lifecycle rules created on a bucket.

Run `mc ilm rm` to delete an object lifecycle rule or all object lifecycle rules created on a bucket.**Syntax**

```
mc ilm rm [FLAGS] TARGET
```

FLAGS:

```
--id value    id of the lifecycle rule
--force       force flag is to be used when deleting all lifecycle
configuration rules for the bucket
--all         delete all lifecycle configuration rules of the bucket, force
```

```

flag enforced
--json      enable JSON lines formatted output
--debug     enable debug output
--insecure  disable SSL certificate verification
--help, -h  show help

```

Parameters

Parameter	Description
--id	The rule ID of the object lifecycle rule to be deleted. id is case-sensitive.
--force	Use this option to forcibly delete all object lifecycle rules for a bucket.
--all	Use this option to delete all object lifecycle rules.
--json	Use the option to display output in JSON format.
--debug	Use the option to enable debug mode for output.
--insecure	Use the option to disable SSL certificate verification while running the command.
--help	Use this option to display the command help.

Example

1. Remove the object lifecycle rule having the ID 'newrule' for the bucket 'mybucket' on the alias 'myminio'.

```
mc ilm rm --id "newrule" myminio/mybucket
```

2. Remove all the object lifecycle rules for mybucket on alias 'myminio'.

```
mc ilm rm --all --force myminio/mybucket
```

mc ilm import

Imports lifecycle configuration in JSON format from standard input (STDIN).

Run `mc ilm import` to import all object lifecycle rules in JSON format from the standard input (STDIN).

You can import object lifecycle rules from a JSON file into Data Fabric from an exported JSON file.

See [mc ilm export](#) on page 3184 to export object lifecycle rules from Data Fabric into a JSON file.

Syntax

```
mc ilm import TARGET
```

Parameters

Parameter	Description
--help	Use this option to display the command help.

Example

1. Import the object lifecycle rules present in 'lifecycle.json' for the bucket 'mybucket' on the alias 'myminio'.

```
mc ilm export myminio/mybucket < lifecycle.json
```

2. Import the object lifecycle rules for the bucket 'mybucket' on the alias 'myminio' from STDIN. You must enter the JSON contents on STDIN.

```
mc ilm import myminio/mybucket
```

mc ilm export

Exports lifecycle configuration in JSON format to the standard output (STDOUT).

Run `mc ilm export` to export all object lifecycle rules in JSON format to STDOUT.

You can redirect the output to a JSON file for backup purpose. The JSON file can be imported back into Data Fabric at a later time, as and when required. Use the [mc ilm import](#) on page 3183 command to import object lifecycle rules into Data Fabric from the JSON file containing the exported object lifecycle rules.

Syntax

```
mc ilm export TARGET
```

Parameters

Parameter	Description
--help	Use this option to display the command help.

Example

Export lifecycle configuration for 'mybucket' to 'lifecycle.json'.

```
mc ilm export myminio/mybucket > lifecycle.json
```

Print lifecycle configuration for 'mybucket' to STDOUT

```
mc ilm export play/mybucket
```

mc ilm ls

Lists the object lifecycle rules.

Syntax

Run `mc ilm list` to list all object lifecycle rules.

```
mc ilm ls [FLAGS] TARGET
```

FLAGS:

```
--expiry display only expiration fields
--json enable JSON lines formatted output
--debug enable debug output
--insecure disable SSL certificate verification
--help, -h show help
```

Parameters

Parameter	Description
--expiry	Use the option to display expiration fields only.
--json	Use the option to display output in JSON format.
--debug	Use the option to enable debug mode for output.
--insecure	Use the option to disable SSL certificate verification while running the command.
--help	Use this option to display the command help.

Example

DESCRIPTION:

List lifecycle configuration rules set on a bucket.

EXAMPLES:

1. List the lifecycle management rules (all fields) for mybucket on alias 'myminio'.

```
mc ilm ls myminio/mybucket
```

2. List the lifecycle management rules (expiration date/days fields) for mybucket on alias 'myminio'.

```
mc ilm ls --expiry myminio/mybucket
```

3. List the lifecycle management rules in JSON format for mybucket on alias 'myminio'.

```
mc ilm ls --json myminio/mybucket
```

Utilities

Contains information about various scripts and utilities, that help setup, maintain, and monitor clusters.

The following scripts and utilities help you configure clusters, setup cross cluster security, setup storage pools, monitor CLDB activity, perform consistency checks and repair errors on volumes and snapshots, and maintain clusters with ease.

Script or Utility	Description
Cluster Configuration	
configure.sh on page 3186	Describes the syntax and parameters of the <code>configure.sh</code> script that you run for a number of tasks, including setting up Data Fabric client nodes, and configuring services for a node.
configure-crosscluster.sh on page 3201	Sets up cross-cluster security between two clusters.
disksetup on page 3230	Formats specified disks for use by Data Fabric storage, and adds those disks to the disktab file.
mrconfig on page 3291	Lets you create, remove, and manage storage pools, disk groups, and disks; and provides information about containers.
fcdebug on page 3237	Dynamically sets the loglevel to debug a library.
Auditing and Monitoring	

Script or Utility	Description
cldbguts on page 3218	Monitors CLDB activity. This utility prints information about the CLDB service that is running on the node from which you run the utility.
ectool on page 3233	Dumps or checks the validity of the stripelets in the backend volume that is associated with the volume configured for warm tiering.
expandaudit on page 3234	Expands IDs captured in the audit logs to their corresponding names.
fsck on page 3239	Detects and fixes inconsistencies in the filesystem.
gfsck on page 3241	Performs consistency checks and appropriate repairs on a volume, or a volume snapshot.
mapr-support-collect.sh on page 3275	Collects information about a cluster's recent activity, to help sHPE support diagnose problems.
mapr-support-dump.sh on page 3280	Collects node and cluster-level information for the node on which you invoke the script.
mrdirectorystats on page 3339	Prints the space usage for each directory, for a container.
mrfscmd on page 3342	Returns the path to the file specified by ID (fid).
stubfuse on page 3342	Determines the read and write performance of a FUSE mount point.
Authentication	
maprlogin on page 3283	Authenticates logins to secure Data Fabric clusters.

configure.sh

Describes the syntax and parameters of the `configure.sh` script that you run for a number of tasks including setting up HPE Data Fabric client nodes, and configuring services for a node.

NOTE: The `configure.sh` script must always be run as root.

You run `configure.sh` to [set up a HPE Data Fabric cluster node](#), or to [set up a HPE Data Fabric client node for communication with one or more clusters](#). You can also run `configure.sh` to update the configuration of a node. For example, you can use `configure.sh` to [change the services running on a node](#), or specify the [user that runs HPE Data Fabric services](#).

ATTENTION: On a Windows client, the `configure.sh` script is named `configure.bat`. The script requires the `-c` parameter and does not accept the `-Z` parameter, but otherwise works similarly as on a Linux client.

Steps Performed by configure.sh

`configure.sh` performs the following steps, each time you run it:

- **Updates `/opt/mapr/conf/mapr-clusters.conf` with the cluster name.** It creates or modifies a line in `/opt/mapr/conf/mapr-clusters.conf` containing a cluster name followed by a list of CLDB nodes. New entries are added to `mapr-clusters.conf` when the cluster name passed to the `-N` parameter is different from the existing cluster name in that file.
- **Checks that the node has at least 4GB of RAM, and that the `/tmp` and `/opt` partitions each have at least 1 GB of free space.** If these conditions are not met, the script asks for confirmation before continuing.

- **Disables standard NFS daemons.** If the node has the `mapr-nfs` role, the script disables the standard Linux NFS daemon, since both NFS processes cannot run on the same node.
- **Updates additional *.conf and *.xml files related to the cluster and the services running on the node.** For example, `yarn-site.xml`, `warden.conf`, and `cldb.conf` may be updated based on input to `configure.sh`.
- **On cluster nodes, it creates a group named *shadow*, adds the HPE Data Fabric user to this group, and then enables members of the *shadow* group to view the */etc/shadow* file.** Read access to the `/etc/shadow` file enables HPE Data Fabric users to authenticate with the HPE Data Fabric cluster.
- **Starts newly installed services.** Automatically starts new services, if Warden is running at the time you run `configure.sh`.
- **All changes to configuration options or system files are logged to */opt/mapr/logs/configure.log*.** You can use the `-L` parameter to specify a different log file name.

When you include disk-setup options (`-D` or `-F`) on nodes with the `mapr-fileserver` role, the script performs the following additional steps:

- **Runs disksetup to create the disktab file.** `configure.sh` takes the values that you specify in the `-disk-opts` option, and passes the value to `disksetup`. For example, if you include `-disk-opts FW5` when you run `configure.sh`, `configure.sh` runs `disksteup -F -W5`. If `disksetup` fails, `configure.sh` exits with an error.
- **Starts Zookeeper and Warden.** When the `configure.sh` script starts services, the message `starting <servicename>` is echoed to the standard output to enable the user to see which services are starting. When Warden starts, the Warden and ZooKeeper services are added to the `inittab` file as the first available `inittab` IDs, enabling these services to restart automatically on failure.

You can specify the `-no-autostart` option to prevent the script from starting Zookeeper or Warden when you run `configure.sh` with the `-F` or `-D` options.

Syntax

```
/opt/mapr/server/configure.sh
-C <cldb_list>
-Z <zookeeper_list>
-EZ <ext_zookeeper_list>
[<parameters>]
```

```
/opt/mapr/server/configure.sh
-C <cldb_list>
[ -M <cldb_mh_list ...> ]
-Z <zookeeper_list>
[<parameters>]
```

```
/opt/mapr/server/configure.sh
-C
[ -R ]
[<parameters>]
```

```
/opt/mapr/server/configure.sh
-R
[ -c ]
[<parameters>]
```

Options**-C**

Use the -C option for CLDB servers that only have a single IP address. This option takes a comma-separated list of the CLDB nodes that this machine uses to connect to the HPE Data Fabric cluster. The list is in the following format:

```
hostname[:port_no]
[,hostname[:port_no] ...]
```

-c

Specifies client setup. The -C option is required, while the -Z option is optional. See [set up a HPE Data Fabric client node for communication with one or more clusters](#).

-EZ

The -EZ option is optional when configuring the cluster, and is not applicable when configuring a client. This option takes a comma-separated list of the external IP addresses of the ZooKeeper nodes in the cluster. The list is in the following format:

```
hostname[:port_no]
[,hostname[:port_no] ...]
```

-M

Use the -M option only for multihomed CLDB servers that have more than one IP address. This option takes a comma-separated list of the multihomed CLDB nodes that this machine uses to connect to the HPE Data Fabric cluster. The list is in the following format:

```
hostname[:port_no][,
[hostname[:port_no] ...]]
```

-R

After initial node configuration, specifies that `configure.sh` should use the previously configured ZooKeeper and CLDB nodes. The -C and -Z parameters are not required when you specify -R. When -R is specified, the CLDB credentials are read from `mapr-clusters.conf`, while the ZooKeeper credentials are read from `warden.conf`. Use the -R option when you make changes to the services configured on a node without changing the CLDB and ZooKeeper nodes. Specify the `--noRecalcMem` parameter to skip recalculating memory settings when refreshing roles.

NOTE: This parameter impacts the JMX parameters in `/opt/mapr/conf/env_override.sh` in the following ways:

- When you set `MAPR_JMXLOCALBINDING` to `true`, running `/opt/mapr/server/configure.sh -R` sets `MAPR_JMXAUTH` to `false`, since JMX is only accessible from the local machine and does not require authentication.
- When you set `MAPR_JMXLOCALBINDING` to `false` but set `MAPR_JMXLOCALHOST` to `true`, running `/opt/mapr/server/configure.sh -R` sets `MAPR_JMXAUTH` to `true` and `MAPR_JMXSSL` to `false`, since JMX is only accessible from the local network and does not require secure authentication.
- When you set `MAPR_JMXLOCALBINDING` to `false` but set `MAPR_JMXREMOTEHOST` to `true`, running `/opt/mapr/server/configure.sh -R` sets `MAPR_JMXAUTH` to `true` and `MAPR_JMXSSL` to `true`, since JMX is now accessible remotely and requires secure authentication.

-Z

The `-Z` option is required unless you specify the `-c` (lowercase), or the `-R` option. The `-Z` option takes a comma-separated list of the ZooKeeper nodes in the cluster. The list is in the following format:

```
hostname[:port_no]
[,hostname[:port_no]...]
```

Parameters

-certdomain

Specifies a DNS domain for generated SSL wildcard certificates. This domain overrides the default DNS domain.

--create-user | -a

Creates a local user to run HPE Data Fabric services, using the user specified either with the `-u` parameter, or from the environment variable `$MAPR_USER`.

-D

Specifies a comma-delimited [list of disks](#) to use with the HPE Data Fabric filesystem. With the `-D` option, you cannot specify partitions. By default, the `configure.sh` script automatically starts cluster services, after the configuration finishes successfully. If you do not want cluster services to be restarted, include the `-no-autostart` option along with the `-D` option.

-d

The host and port of the MySQL database to use for storing HPE Data Fabric Metrics data.

-dare

Enables on-disk encryption at the cluster-level. When run on the first CLDB node with the `-genkeys` option, the utility generates the data-at-rest encryption master key file at `/opt/mapr/conf/dare.master.key`.

-defaultdb

Sets the default database (HBase or HPE Data Fabric Database) to which the HBase clients connect. If you do not explicitly configure this option, it defaults to hbase (HBase) when you have mapr-hbase-regionserver or mapr-hbase-master installed on the node. Otherwise, it defaults to maprdb (HPE Data Fabric Database). You can also change the database setting using hbase-site.xml or the HBase client connection. For more information, see [Configure the Default Database for HBase Clients](#) on page 4915.

-disk-opts

Denotes [disksetup](#) formatting options. Do not include spaces or commas between the disksetup options. For example, you can specify -disk-opts FW5 to format the disks (F), and configure five disks per storage pool (W5).

-disableSsl

Disables SSL for ZooKeeper nodes on **secure clusters**.

The new ZooKeeper (ZK version 3.8.3) supports SSL encryption for server-to-server communication. When you install a new clean 6.2 secure cluster, SSL between ZooKeeper servers is enabled automatically.

However when you perform a rolling upgrade, few nodes are upgraded to Data Fabric 6.2 (with the new ZooKeeper server), while other nodes still run the old Data Fabric 6.1, where the ZooKeeper is at version 3.4.11 and is incapable of using SSL.

You must disable SSL using this option, to get this hybrid cluster to work. You must enable SSL for ZooKeeper only AFTER you upgrade all nodes to Data Fabric 6.2.

You can use this option even when refreshing roles. For example: `configure.sh -R -disableSsl`.

Running configure.sh without this option enables SSL. To turn on SSL:

1. Shutdown the cluster.
2. On every ZooKeeper node, run `configure.sh -R` (without this `disableSsl` parameter).
3. Start the cluster.

The `sslQuorum` parameter in [zoo.cfg](#) on page 3390 controls whether or not the ZooKeeper nodes can use SSL for communication.

To verify that ZooKeeper nodes are communicating over SSL, check the ZooKeeper log for messages such as *SSL handshake complete with ...* and/or *Accepted TLS connection from....*

-dp

Specifies the password for logging into the MySQL database used for storing HPE Data Fabric Metrics data.

-ds

Specifies the name of the database schema to use for the MySQL database used for storing HPE Data Fabric Metrics data. The default schema name is *metrics*.

-du

Specifies the username for logging into the MySQL database used for storing HPE Data Fabric Metrics data.

-EP

Specifies an option that is passed directly to an ecosystem `configure.sh` script. These commands follow the form `-EP<ecosystem component name> <option>`. In general, `-EP` options are not documented, and should be used only if the documentation specifically instructs you to use them.

In HPE Data Fabric 6.0 and later, some ecosystem components have their own `configure.sh` scripts. The server `configure.sh` script or a user, can pass options directly to the ecosystem component by using the `-EP` syntax. For example, in the following command:

```
/opt/mapr/server/
configure.sh -R -EPkibana
'-kibanaPort 5610'
```

`-EPkibana '-kibanaPort 5610'` changes the default port for Kibana to 5610.

As ecosystem components are updated more frequently than HPE Data Fabric Core (which contains the server `configure.sh` script), implementing some `configure.sh` functions through an ecosystem `configure.sh` script can accelerate the introduction of new features.

-ES

Specifies a comma-separated list of host names or IP addresses that identify the Elasticsearch nodes. The Elasticsearch nodes can either be part of the current HPE Data Fabric cluster, or part of a different HPE Data Fabric cluster. Do not use this option when you configure a node for the first time. Use this option along with the `-R` parameter.

The list is in the following format:

```
hostname/IPAddress[:port_no]
[,hostname/IPAddress[:port_no]...]
```

NOTE: The default Elasticsearch port is 9200. If you want to use a different port, specify the port number when you list the Elasticsearch nodes.

-ESDB

Specifies a non-default location for writing index data on Elasticsearch nodes. To configure an index location, you only need to include this parameter on Elasticsearch nodes.

Elasticsearch requires a lot of disk space. Therefore, a separate filesystem for the index is recommended. It is not recommended to store index data under the `/` or the `/var` file system.

For more information, see [Log Aggregation and Storage](#) on page 2029.

-F

Specifies a path to a text file that [lists the disks and partitions to use with the HPE Data Fabric filesystem](#). By default, the `configure.sh` script automatically

-f

starts cluster services after the configuration finishes successfully. If you do not want cluster services to be restarted, include the `-no-autostart` option along with the `-F` option.

-forceSecurityDefaults

Specifies that the node should be configured without performing the system prerequisite check.

Instructs `configure.sh` to undo any custom security settings for a cluster, and reconfigure security to the default HPE Data Fabric value `-secure`. You must specify the `-secure` option. Using the `-forceSecurityDefaults` option removes the `/opt/mapr/conf/.customSecure` file. Use the following syntax:

```
/opt/mapr/server/
configure.sh -forceSecurityDefaults
[ -secure ] -C <CLDB_node> -Z
<ZK_node>
```

For more information, see [Customizing Security in HPE Data Fabric](#) on page 2211.

IMPORTANT: It is possible that the `-forceSecurityDefaults` operation might not undo all custom security settings since `configure.sh` cannot know all of the custom settings that were implemented. Therefore, you might have to edit some configuration files and settings to restore the cluster to full functionality.

-G

The group ID to use when creating `$MAPR_USER` with the `-create-user` or `-a` option; corresponds to the `-g` or `-gid` option of the `useradd` command in Linux.

-g

The group name under which HPE Data Fabric services run.

-genkeys

Generates needed keys and certificates for the initial CLDB node in a secure cluster. If specified with the `-dare` option, the `-genkeys` option generates a master key at `/opt/mapr/conf/dare.master.key` on the first CLDB node. Without the master key, you cannot start the cluster, nor can you access the data.

-H

Specifies the HTTPS port number for connecting to the CLDB node. The default port is 7443.

-HS

Specifies the IP or hostname of the node in the cluster that performs the HistoryServer role. This parameter is required only when a node in the cluster performs the HistoryServer role. In HPE Data Fabric 5.1 and later, this parameter is expanded to support the Mesos DNS-style name with format for Job History. The format is `<myriad-fwk-name>.mesos`. For example, if the `-MF` parameter is `myriadA`, the name is: `jobhistory.myriadA.mesos`. Myriad is not supported in HPE Data Fabric 6.2.0 and later.

--isvm

Specifies the virtual machine setup. Required when `configure.sh` is run on a cluster node, that is on a virtual machine. This option configures the script to use less memory.

-J	Specifies the JMX port for the CLDB. Default: 7220
-JMXEnable	Globally enables JMX support for services on the node. JMX is enabled by default.
-JMXDisable	Globally disables JMX support for services on the node.
-JMXLocalBindingEnable	Enables local binding for JMX connections.
-JMXLocalBindingDisable	Disables local binding for JMX connections.
-JMXLocalHostEnable	Enables the local-host TCP port for JMX. This setting is mutually exclusive with <code>JMXRemoteHostEnable</code> .
-JMXLocalHostDisable	Disables the local-host TCP port for JMX.
-JMXRemoteHostEnable	Enables the remote TCP port for JMX. This setting is mutually exclusive with <code>JMXLocalHostEnable</code> .
-JMXRemoteHostDisable	Disables the remote TCP port for JMX.
-K -kerberosEnable	Indicates that Kerberos security has been enabled . Kerberos security is disabled by default.
-keycloak	<p>Installs the Keycloak identity and access management (IAM) solution. Installing Keycloak is optional. Keycloak provides single-sign-on (SSO) support for the Data Fabric. Using the <code>-keycloak</code> parameter installs a preconfigured version of Keycloak on all nodes in the cluster. However, the Keycloak server is started on only one node.</p> <p>Keycloak is preconfigured with a single user (the <code>admin</code> user) and the following roles:</p> <ul style="list-style-type: none"> • Fabric manager • Infrastructure Administrator • Developer user <p>You can add new users or integrate your LDAP directory with Keycloak. See Adding New Users to Keycloak on page 1294 and Integrating Your LDAP Directory with Keycloak on page 1301.</p> <p>Keycloak installation creates a single client, the <code>edf-client</code>, which is the dedicated client for the Data Fabric. In Keycloak, a <i>client</i> is an application or service that can request authentication for a user. Keycloak installation also gives you access to the Keycloak admin portal. For more information, see Accessing the Keycloak Administration Console on page 1290.</p>
-L	Specifies a log file. If not specified, <code>configure.sh</code> logs errors to <code>/opt/mapr/logs/configure.log</code> .
-label	<p><i>Default Value:</i> default</p> <p><i>Possible Values:</i> Any registered label</p> <p><i>Description:</i> The label to use for the storage pool. See Using Storage Labels on page 1575 for more information on labels.</p> <p>The label should contain only the following characters:</p> <pre>A-Z a-z 0-9 _ - .</pre>

ATTENTION: This option is meant to be run ONLY on CLDB nodes. However, if you intend to use this option on data nodes, ensure that you first [register the label](#) on the data node before using this option.

- - logHTTPFS	Specifies the hostname to enable centralized logging using <code>fluentd</code> .
- MCL	Specifies the top-level directory where all the staging data as well as shuffle data is written for a specific Myriad framework. Used when multiple clusters are implementing Myriad. Myriad is not supported in HPE Data Fabric 6.2.0 and later.
- MP	Specifies the name of the Myriad framework that is displayed in the Mesos UI. Myriad is not supported in HPE Data Fabric 6.2.0 and later.
- MHA	Enables Myriad high availability. Myriad is not supported in HPE Data Fabric 6.2.0 and later.
- M7	Deprecated as of HPE Data Fabric 4.0.1.
-maprpam	When specified, the <code>configure.sh</code> script installs the HPE Data Fabric version of Pluggable Authentication Modules (PAM). This option is ignored if <code>-S</code> is not set.
- N	<p>Specifies the cluster name. If you do not specify a name, <code>configure.sh</code> applies a default name (<code>my.cluster.com</code>) to the cluster. Whenever you run <code>configure.sh</code>, be aware of the existing cluster name or names in <code>mapr-clusters.conf</code> and specify the <code>-N</code> parameter accordingly. If you specify a name that does not exist, a new line is created in <code>mapr-clusters.conf</code> and is treated as a configuration for a separate cluster.</p> <p>Subsequent runs of <code>configure.sh</code> without the <code>-N</code> parameter operate on this default cluster. If you specify a name when you first run <code>configure.sh</code>, you can modify the CLDB and ZooKeeper settings corresponding to the named cluster by specifying the same name and running <code>configure.sh</code> again. Whenever you need to re-run <code>configure.sh</code> on a given cluster (to add or rename nodes, for example), be sure to specify the same cluster name that you used when you ran <code>configure.sh</code> for the first time.</p>
-no-autostart	Specifies that the script should not start Zookeeper or Warden when you run <code>configure.sh</code> .
-no-auto-permission-update	Pass this option to prevent HPE Data Fabric from silently altering permissions in <code>/etc/shadow</code> .
-nocerts	When specified, the <code>configure.sh</code> script does not generate SSL certificates even when the <code>-genkeys</code> option is specified.
-noDB	Specifies that HPE Data Fabric Database is not in use.
- -noRecalcMem	Skips recalculating memory settings when refreshing roles. Can be used only with the <code>-R</code> option.
- OT	Specifies a comma-separated list of host names or IP addresses that identify the OpenTSDB nodes. The OpenTSDB nodes can be part of the current HPE Data Fabric cluster or part of a different

HPE Data Fabric cluster. Do not use this option when you configure a node for the first time. Use this option along with the `-R` parameter. The Warden service must be running when you use `configure.sh -R -OT`.

Use the following format to list the hostnames:

```
hostname/IP address[:port_no]
[,hostname/IP address[:port_no]...]
```

NOTE: The default OpenTSDB port is 4242. If you want to use a different port, specify the port number when you list the OpenTSDB nodes.

-on-prompt-cont

Specify:

- y to automatically respond Yes to all prompts.
- n to automatically respond No to all prompts.

-P

Specifies the Kerberos instance that is used to form a CLDB Kerberos principal in the form of `mapr/<instance-name>@<realm-name>`. Enclose this value in quotes ("). This value is ignored if Kerberos security is not enabled.

-QS

Use the `-QS` option to configure the OJAI Distributed Query Service. See [Configure the OJAI Distributed Query Service](#) on page 293.

-removePasswordsInXML

Can be used during an upgrade as part of the `configure.sh -R` command to remove the clear-text passwords stored in the Hadoop configuration files (`ssl-client.xml` and `ssl-server.xml`). During an upgrade, the passwords are retained for backward compatibility with some ecosystem services. To make the cluster more secure, you can use `-removePasswordsInXML` to remove the passwords from the `.xml` files on a node. See [Removing Clear-Text Passwords After Upgrade](#) on page 2087.

-RM

In HPE Data Fabric 5.1, this parameter is expanded to support the Mesos DNS-style hostname for Myriad configuration. The Mesos-style hostname is `<application name>.marathon.mesos`. When starting ResourceManager from Marathon, the `.<application name> rm`, for example, is `rm.marathon.mesos`.

In HPE Data Fabric 4.0.2, this parameter is not required unless you want to configure manual or automatic failover; zero configuration failover is enabled by default. In HPE Data Fabric 4.0.1, this parameter specifies the nodes in the cluster with the ResourceManager role.

List the nodes in the following format:
`hostname[,hostname]...`

For more information, see [ResourceManager High Availability](#) on page 2251. Myriad is not supported in HPE Data Fabric 6.2.0 and later.

-S | -secure

Specifies that this cluster is a secure cluster, and configures security on the platform and on all ecosystem components that support security. Default: secure.

-storepasswd <keypass>:<trustpass>

Generates credential stores, like the `-genkeys` parameter, but uses the given key or trust store passwords (or files containing passwords) to create the certificates. After configuring the primary (`-genkeys`) server, you can use this parameter to configure additional servers. See [Enabling Security on a Configured Cluster](#) on page 2048. The `-storepasswd` parameter does not create the CLDB, DARE, or master keys, which must be copied from the primary CLDB node.

The `-storepasswd` parameter is not needed for homogenous clusters (where all nodes are FIPS enabled or all nodes are non-FIPS-enabled). In homogenous clusters, the credential files can be copied and do not need to be regenerated. However, in operations on a non-homogenous cluster – for example, when adding a FIPS-enabled node to a non-FIPS cluster – you must use the `-storepasswd` parameter. There is no other way for the FIPS-enabled node to obtain the credential files.

Note that for client operations (for example, when adding a FIPS client to a non-FIPS cluster), the `<keypass>` value is not needed, and the command can be issued as `configure.sh -c -storepasswd :MyTrustPassword`. For more information, see [Configuring a FIPS Client for a Secure Non-FIPS Server](#) on page 381.

-syschk

Configures the system checks to be enabled or disabled. Value: Y/N.

-TL

Specifies the single node on which the timeline server is installed for the Hive-on-Tez user interface. When you install Tez manually, you must also install the timeline server and run `configure.sh -TL <timeline_server_node>` on all nodes to indicate where the timeline server resides.

-U

The user ID to use when creating \$MAPR_USER with either the `--create-user` or `-a` option; corresponds to the `-u` or `--uid` option of the `useradd` command in Linux.

-u

The user name under which HPE Data Fabric services run.

-v

In addition to logging information, also prints to stdout.

HSM Parameters - For more information, see [Setting-up KMIP—for Existing Data Fabric Installation](#) on page 971

-hsm

Performs HSM configuration. This will always run the [mrhsm init](#) on page 987 command to initialize the HSM if not already initialized. The `-hsm label` option is required if the `-hsm` option is specified for the first time.

When used with the `-genkeys` option, `-hsm` invokes the [mrhsm enable](#) on page 977 command to generate

the CLDB and also the DARE keys if the `-dare` option is specified.

Otherwise, `-hsm` configures the settings specified by the `-hsmip`, `-hsmport`, `-hsmcacert`, `-hsmclientcert`, `-hsmclientkey` and `-hsmkmipversion` options, but does not enable the HSM feature or generate any keys.

`-hsmip <ip-address>`

The comma-separated list of host names or IP addresses of the external HSM. This parameter is required only when no IP addresses have been configured, or when you need to modify the IP addresses of the external HSM.

`-hsmport <port>`

The KMIP port of the external HSM.

This parameter is optional. If omitted, this defaults to the standard KMIP port of 5696.

`-hsmcacert </path/to/cert>`

The full path name of the file containing the HSM CA certificate downloaded from the HSM.

This parameter is required only when no CA certificate has been configured, or when we need to modify the CA certificate.

`-hsmclientcert </path/to/cert>`

The full path name of the file containing the KMIP-enabled client certificate.

This parameter is required only when no client certificate has been configured, or when you need to modify the client certificate.

`-hsmclientkey </path/to/key>`

The full path name of the file containing the KMIP-enabled client key.

This parameter is required only when no client key has been configured, or when you need to modify the client key.

`-hsmlabel <label>`

The KMIP token label. This is an ASCII string which is used to describe the KMIP token and can range from 1 to 32 characters, e.g. Utimaco ESKM.

This parameter is only needed when initializing the KMIP token for the first time. It is ignored for subsequent invocations.

`-hsmsopin <so-pin>`

PIN for the Security Officer (SO). This should be between 4 to 255 characters inclusive. The SO PIN is set in the KMIP token during the initial invocation.

In subsequent invocations, the SO PIN entered into this utility must match the configured SO PIN. If this argument is not specified, you will be prompted to enter it. For more information about the SO PIN, see [About the SO PIN](#) on page 999.

`-hsmkmipversion <version>`

The KMIP version number to use for all communication with the external KMIP-enabled key store. Supported values are 1.0, 1.1, 1.2, 1.3 and 1.4. The default value is 1.1.

At the end of the `configure.sh` script, the HSM should be up and running, when you use the HSM parameters. Use the [mrhsm info](#) on page 981 command to check the HSM status.

Protection of Java key stores is NOT supported in the HSM for HPE Data Fabric 6.2. In later releases, `configure.sh` will generate PKCS#12 key stores instead of JCEKS key stores.

NOTE: The `--ipv6-support` and the `-6` parameter to enable IPv6 on a fabric in HPE Data Fabric v7.6 has been deprecated. Use the [cluster feature enable](#) on page 2316 command to enable IPv6.

Examples

1. **Add a node (not CLDB or ZooKeeper) to a cluster that is running the CLDB and ZooKeeper on three nodes:**

On the new node, run the following command:

```
/opt/mapr/server/configure.sh -C nodeA,nodeB,nodeC -Z nodeA,nodeB,nodeC
```

2. **Configure a client to work with cluster `my.cluster.com`, which has one CLDB at nodeA:**

On a Linux client, run the following command:

```
/opt/mapr/server/configure.sh -N my.cluster.com -c -C nodeA
```

On a Windows 7 client, run the following command:

```
C:\opt\mapr\server\configure.bat -N my.cluster.com -c -C nodeA
```

3. **Add a second cluster to the configuration:**

On a node in the second cluster `your.cluster.com`, run the following command:

```
/opt/mapr/server/configure.sh -C nodeZ -N your.cluster.com -Z  
<zkNodeA,zkNodeB,zkNodeC>
```

4. **Add CLDB servers with multiple IP addresses to a cluster:**

In this example, the cluster `my.cluster.com` has CLDB servers at nodeA, nodeB, nodeC, and nodeD. The CLDB servers nodeB and nodeD have two NICs each at `eth0` and `eth1`.

On a node in the cluster `my.cluster.com`, run the following command:

```
/opt/mapr/server/configure.sh -N my.cluster.com -C  
nodeAeth0,nodeCeth0 -M \  
nodeBeth0,nodeBeth1 -M nodeDeth0,nodeDeth1 -Z zknodeA
```

5. Start a cluster in secure mode using configure.sh

In this example, the cluster `my.cluster.com` has two CLDB servers at `nodeA` and `nodeB`. The ZooKeeper node for this cluster is at `nodeC`. To start the cluster in secure mode, run the following command on `nodeA`:

```
/opt/mapr/server/configure.sh -N my.cluster.com -C nodeA,nodeB -Z
nodeC -secure \
        -genkeys -F <disklist file>
```

This command creates the `ssl_truststore`, `ssl_keystore`, and `maprserverticket` files. Copy these files from `nodeA`'s `/opt/mapr/conf` directory to `nodeB`'s `/opt/mapr/conf` directory.

On `nodeB`, change the permissions on the `ssl_keystore` and `maprserverticket` files to 600 (the `mapr` user) by using the following command:

```
chmod 600 ssl_keystore maprserverticket
```

On the `ssl_truststore` file, change the permissions to 644 (world readable):

```
chmod 644 ssl_truststore
```

On `nodeB`, run the following command:

```
/opt/mapr/server/configure.sh -N mycluster.com -C nodeA,nodeB -Z
nodeC -secure -F \
        <disklist file>
```

6. Configure HSM:

A sample session transcript using the `/opt/mapr/server/configure.sh` script with DARE enabled is as follows. The portions in **bold** relate to the common HSM features, while the portions in *italics* relate to the DARE-specific features:

```
# /opt/mapr/server/configure.sh -secure -genkeys -N
test96.cluster.com -C perfnode96.lab:7222 -Z perfnode96.lab:5181 -F
disks.txt -dare -hsm -hsmip 10.10.30.129 -hsmlabel "SafeNet
KeySecure" -hsmopin 12345678 -hsmclientcert /root/safenet-keysecure/
client.pem -hsmcacert /root/safenet-keysecure/CA.pem -hsmclientkey /root/
safenet-keysecure/key.pem
create /opt/mapr/conf/conf.old

```

Troubleshooting configure.sh

When you run `configure.sh` with the `-OT` option for the first time, you might encounter an error message such as **directory /opt/mapr/conf/proxy is not owned by root**. You must ignore this transient error

message. If you repeatedly see this error during client operations, then re-run `configure.sh` with the `-R` option.

configure-crosscluster.sh

Use the `configure-crosscluster.sh` utility to set up cross-cluster security between two clusters.

You can use the [configure-crosscluster.sh](#) on page 3201 utility to set up cross-cluster security between two clusters. When you run this utility with the `create` subcommand, it establishes security between the local cluster and a remote cluster. After the setup, communication between the two clusters is bi-directional. You can run this utility on any node in the source cluster to grant secure access to users and servers (for replication, or mirroring) on the destination cluster.

The utility prompts for the passwords for both the local and remote clusters. All hosts on a cluster must have the same password. Alternatively, you can use `ssh` public key authentication between the current node and the other nodes in the local and remote clusters.

Prerequisites

Before running this utility, you must:

- Enable wire-level security for both the local and remote clusters.
Set `secure=true` in your cluster entry for `/opt/mapr/conf/mapr-clusters.conf`, for both the local and remote clusters.
- Ensure that the local and remote cluster are either all non-FIPS-enabled nodes or all FIPS-enabled nodes. See [FIPS Support](#) on page 3205 later on this page.
- Install the `pssh` (Parallel SSH) package from EPEL.
- Install the `expect` package.

If you plan to use a user other than the `mapr` administrative user for mirroring or gateway/streams replication, that user must already exist on both the local and remote clusters.

Permissions

In release 7.0.0 and later, the `configure-crosscluster.sh` script returns an error if it is run by a user other than the cluster owner (as configured in `${MAPR_HOME}/conf/daemon.conf`). For example, an error is generated if you run the script as the root superuser:

```
# /opt/mapr/server/configure-crosscluster.sh create all \
  -remoteip my_ip_addr.mycorp.net \
  -localtruststorepassword QHj9NmFyZ_j9_BUnyooEWa898a_xNvQY \
  -remotetruststorepassword 0KHy3gbF05XTYOTjLQPGXCibtGDpI_Di
User is root. This script must be run as the cluster owner mapr
```

Syntax

```
/opt/mapr/server/configure-crosscluster.sh create <cross-cluster-type>
[ -localcrossclusteruser <user> ]
[ -localhosts <path_to_file> ]
[ -localport <port_number> ]
[ -localtruststorepassword <password> ]
[ -remotetruststorepassword <password> ]
[ -localuser <user> ]
[ -recover <id> ]
[ -remotecrossclusteruser <user> ]
[ -remotehosts <port_number> ]
-remoteip <ip_address>
[ -remoteport <port_number> ]
[ -remoteuser <user> ]
```

Required Parameters

In release 7.0.0 and later, the trust store passwords are no longer in plain text, and the `configure-crosscluster.sh` script cannot automatically retrieve them. Therefore, you must provide the passwords:

localtruststorepassword	Password for the local trust store. Beginning with release 7.0.0, this parameter is required if the <code>ssl-server.xml</code> file does not contain the plain-text password.
remotetruststorepassword	Password for the remote trust store. Beginning with release 7.0.0, this parameter is required.

Type Parameters

The `<cross-cluster-type>` parameter specifies the type of entity for which cross-cluster access must be established. The value can be one of the following:

user	Used for direct data access for the given user. When you run the utility with the <code>user</code> parameter, it performs the following tasks on both the clusters: <ol style="list-style-type: none"> 1. Updates the <code>/opt/mapr/conf/mapr-clusters.conf</code> file to include the first entry from the <code>/opt/mapr/conf/mapr-clusters.conf</code> file on the other cluster.
-------------	---

- Imports the certificate of the other cluster in the `/opt/mapr/conf/ssl_truststore` file, and copies the updated `/opt/mapr/conf/ssl_truststore` file to all the other nodes on the cluster.

server

Used for Data Fabric server access such as mirroring and replication. When you run the utility with the `server` parameter, it performs the following tasks on both the clusters:

- Generates a cross-cluster ticket on this cluster for the other cluster, and copies the ticket to the CLDB node on the other cluster.
- Merges the ticket with the `/opt/mapr/conf/maprserverticket` file on the node on the other cluster, and copies the updated `/opt/mapr/conf/maprserverticket` file to all the other CLDB nodes on the other cluster.

all

Used for both user and server access. When you run the utility with the `all` parameter, it performs the following actions on both the clusters:

- Updates the `/opt/mapr/conf/mapr-clusters.conf` file to include the first entry from the `/opt/mapr/conf/mapr-clusters.conf` file on the other cluster.
- Imports the certificate of the other cluster in the `/opt/mapr/conf/ssl_truststore` file, and copies the updated `/opt/mapr/conf/ssl_truststore` file to all the other nodes on the cluster.
- Generates a cross-cluster ticket for the other cluster, copies the ticket to the CLDB node on the other cluster, merges the ticket with the `/opt/mapr/conf/maprserverticket` file on the node in the other cluster, and copies the updated `/opt/mapr/conf/maprserverticket` file to all other CLDB nodes on the other cluster.

Options

The `configure-crosscluster.sh` on page 3201 utility supports the following options:

localcrossclusteruser

Default value: local user

This option applies only to the `server` parameter. Specifies the name of the local cross-cluster user if different from the local user, for mirroring and replication of tables, and streams.

localhosts

Default value: No Default Value

Contains the full or relative path to the file containing the list of IP addresses or host names of the hosts to update in the local cluster. Specify one host per line in the file, excluding the current host. If you specify this option, the utility updates the configuration, both on the host on which you are running the utility, and on the

other nodes specified in the file. If you do not specify this option, the utility copies both the:

- Updated server security configuration in the `/opt/mapr/conf/maprserverticket` file to only the CLDB nodes in the local cluster.
- Updated user security configuration in the `/opt/mapr/conf/mapr-clusters.conf` file, and the `/opt/mapr/conf/ssl_truststore` file, to all the nodes in the local cluster.

localport

Default value: 22

Indicates the port to use to connect (using ssh or scp) to local cluster hosts.

localuser

Default value: mapr

Specifies the name of the user for the local cluster.

recover

Default value: No Default Value

Defines the option to recover from the failure to copy files to nodes in the local or remote cluster, due to failed cluster nodes. Use the special ID keyword latest to run with the contents of the most recent run. See [Troubleshooting and Recovery](#) on page 3209 for more information.

remotecrossclusteruser

Default value: remote user

This option applies only to the server parameter. Specifies the name of the remote cross-cluster user, if different from the remote user.

remotehosts

Default value: No Default Value

Contains the full or relative path to the file containing the list of IP addresses or host names of the hosts to update in the remote cluster. Specify one host per line in the file. If you do not specify this option, the utility copies both the:

- Updated server security configuration in the `/opt/mapr/conf/maprserverticket` file to only the CLDB nodes in the remote cluster.
- Updated user security configuration in the `/opt/mapr/conf/mapr-clusters.conf` file, and the `/opt/mapr/conf/ssl_truststore` file, to all the nodes in the remote cluster.

For example, if you have a file `myhosts.txt` in the current directory with the following contents:

```
10.10.20.100
10.10.20.101
10.10.20.102
```

then, specify `-remotehosts myhosts.txt` for this parameter.

ATTENTION: All hosts specified in this file must be directly reachable from the local hosts from which you run the [configure-crosscluster.sh](#) on page 3201 utility.

remoteip	<i>Default value:</i> No Default Value This option is mandatory. Specifies the host name or IP address of a host in the remote cluster.
remoteport	<i>Default value:</i> 22 Indicates the port to use to connect (using ssh or scp) to remote cluster hosts.
remoteuser	<i>Default value:</i> local user Designates the name of the user for the remote cluster.

FIPS Support

In release 7.0.0 and later, the `configure-crosscluster.sh` script supports FIPS clusters subject to the following limitations:

- Both the local and remote cluster must have nodes with the same FIPS setting. This means that one of the following statements is true:
 - All nodes in the local and remote cluster are secure non-FIPS nodes.
 - All nodes in the local and remote cluster are FIPS-enabled nodes.
- `configure-crosscluster.sh` with the basic options does not support mixed configurations consisting of combinations of FIPS and non-FIPS nodes. However, mixed configurations can be supported using manual steps. See [Configuring Cross-Cluster Security for a Mixed \(FIPS and Non-FIPS\) Configuration](#) on page 2232.

Verification

To verify that cross-cluster security is correctly set up, perform one of the following actions:

- If you ran the utility using the cross-cluster type `user` or `all`, and the utility completed successfully, you should be able to run remote commands from the local node after obtaining a user ticket using the [mapr login](#) on page 3283 utility. See [Configuring Secure Clusters for Running Commands Remotely](#) on page 2223 for more information.
- If you ran the utility using the cross-cluster type `server` or `all`, and the utility completed successfully, you should be able to perform various service operations from the local to the remote cluster and vice versa, mirroring volumes, and replicating tables and streams. See [Configuring Secure Clusters for Cross-Cluster Mirroring and Replication](#) on page 2226 for more information.

Sample Session

To configure cross-cluster security, run the utility on a CLDB host with wire-level security enabled, :

```
# /opt/mapr/server/configure-crosscluster.sh create all -remoteip
10.10.30.96
Remote IP is 10.10.30.96
WARNING: Strict host key checking will be disabled for this script.
Local user unset, defaulting to mapr
Remote user unset, defaulting to local user mapr
Enter password for mapr user (mapr) for local cluster:
Enter password for mapr user (mapr) for remote cluster:
Local cross-cluster user unset, defaulting to local user mapr
Remote cross-cluster user unset, defaulting to remote user mapr
Verifying connectivity to 10.10.30.96 and presence of mapr-clusters.conf
MapR credentials of user 'mapr' for cluster 'myCluster.cluster.com' are
written to '/tmp/maprticket_0'
Local host is running the CLDB
```

```

chyelin101.cluster.com secure=true qa-cnode101.lab:7222

written to '/tmp/mapr-xcs/29668/local_crosscluster_ticket'
SUCCESS
This script has logged in to both the local and remote clusters. Please log
out of
the clusters if needed.

```

Cleanup

After running the utility, you must perform two cleanup actions:

1. Log out of the local and remote clusters if needed, using the `maprlogin logout` command.
2. Delete the `/tmp/mapr-xcs` directory, if it is present, after verifying that the cross-cluster setup is correct.

If you run this utility without the `-recover` option, the utility creates temporary files in the `/tmp/mapr-xcs` directory under the current process ID. These directories contain sensitive information such as server tickets that are protected by Unix permissions. The utility preserves these tickets, so that you can perform troubleshooting and recovery actions, as needed. You must delete this directory after verifying that the cross-cluster setup is correct:

```
$ /bin/rm -rf /tmp/mapr-xcs
```

Post-Configuration Tasks

After you run this utility, cross-cluster security should be successfully set up between the local and the remote cluster. If you specified either the user or all cross-cluster type when running the utility, to perform any operations on the remote cluster from the local node, login to the remote cluster to obtain a user ticket using the `maprlogin` on page 3283 command.

```
$ maprlogin password -cluster <remote-cluster-name>
```

NOTE: You must obtain a new ticket when your current ticket expires.

Examples of Using the Cross-Cluster Utility

For examples on how to run the `configure-crosscluster.sh` on page 3201 utility, see [Configure-crosscluster.sh Examples](#) on page 3206.

More information

[Configure-crosscluster.sh Examples](#) on page 3206

Demonstrates how to use the `configure-crosscluster.sh` utility.

[Troubleshooting and Recovery](#) on page 3209

Configure-crosscluster.sh Examples

Demonstrates how to use the `configure-crosscluster.sh` utility.

This section contains some examples to show how to run the `configure-crosscluster.sh` utility.

These examples are valid only for installations in which:

- Both the local and remote clusters consist of all FIPS-enabled nodes.
- Both the local and remote clusters consist of all non-FIPS-enabled nodes.

The examples are not valid for installations in which a local or remote cluster has a mix of FIPS and non-FIPS-enabled nodes. To configure cross-cluster security where local and/or remote clusters consist of a combination of FIPS and secure non-FIPS nodes, see [Configuring Cross-Cluster Security for a Mixed \(FIPS and Non-FIPS\) Configuration](#) on page 2232.

Example 1

Release 7.0.0 and later require specifying passwords for the local and remote trust stores:

```
$ /opt/mapr/server/configure-crosscluster.sh create all \
  -localtruststorepassword kfSLfzJSIkv_DH7EK \
  -remotetruststorepassword m83SymAwcRXD1MndJFXXpha1008HD0eC \
  -remoteip 10.163.166.251
```

Example 2

Suppose both the local and remote cluster administrator usernames are `mapr`, and both the local and remote cross-cluster users for mirroring and gateway/streams replication are also `mapr`, specify only the `-remoteip` argument for a fresh run:

```
$ /opt/mapr/server/configure-crosscluster.sh create server \
  -localtruststorepassword kfSLfzJSIkv_DH7EK \
  -remotetruststorepassword m83SymAwcRXD1MndJFXXpha1008HD0eC \
  -remoteip 10.10.1.1
```

Example 3

Assume that the local cluster administrator username defaults to `mapr`, and the remote cluster administrator username defaults to the local cluster administrator username. Specify different user names for the local and remote cluster administrator using the `-localuser` and `-remoteuser` arguments. For example, if the local cluster administrator username is `admin` and the remote cluster administrator username is `mapr`:

```
$ /opt/mapr/server/configure-crosscluster.sh create server \
  -localtruststorepassword kfSLfzJSIkv_DH7EK \
  -remotetruststorepassword m83SymAwcRXD1MndJFXXpha1008HD0eC \
  -remoteip 10.10.1.1 \
  -localuser admin \
  -remoteuser mapr
```

Example 4

Assume that the local cross-cluster user defaults to the local cluster administrative user, and the remote cross-cluster user defaults to the remote cluster administrative user. To use a different cross-cluster user for mirroring or gateway/streams replication, specify the `-localcrossclusteruser` and/or `-remotecrossclusteruser` parameters. For example, if the local cross-cluster username is `crosscluster`, run the utility as follows:

```
$ /opt/mapr/server/configure-crosscluster.sh create server \
  -localtruststorepassword kfSLfzJSIkv_DH7EK \
```

```
-remotetruststorepassword m83SymAwcRXD1MndJFXXpha1008HD0eC \
-remoteip 10.10.1.1 \
-localcrossclusteruser crosscluster
```

Example 5

By default, the utility performs ssh and scp operations between the node where the utility is running and the other nodes in the local and remote clusters, using the default SSH port 22. To use a non-default SSH port, either for the local or remote clusters, specify the port number using the `-localport` or the `-remoteport` option. For example, if the SSH port for the local cluster is 10022, run the utility as follows. The remote SSH port is the default value of 22 if the `-remoteport` argument is not specified:

```
$ /opt/mapr/server/configure-crosscluster.sh create server \
  -localtruststorepassword kfSLfzJSIkv_DH7EK \
  -remotetruststorepassword m83SymAwcRXD1MndJFXXpha1008HD0eC \
  -remoteip 10.10.1.1 \
  -localport 10022
```

Example 6

By default, the utility runs the `maprc li node list` command on both the local and remote nodes to determine the list of hosts in the local and remote clusters, and updates the configuration for all the nodes in the local and remote clusters. To update the configuration only for a subset of nodes in either the local or remote cluster, such as when you want to update only the CLDB nodes, specify the path to the file containing the list of hosts, one per line, using the `-localhosts` and `-remotehosts` options respectively. For example, to update the configuration for only the local nodes specified in the file `/tmp/local` and the remote nodes specified in the file `/tmp/remote`, run:

```
$ /opt/mapr/server/configure-crosscluster.sh create server \
  -localtruststorepassword kfSLfzJSIkv_DH7EK \
  -remotetruststorepassword m83SymAwcRXD1MndJFXXpha1008HD0eC \
  -remoteip 10.10.1.1 \
  -localhosts /tmp/local \
  -remotehosts /tmp/remote
```

Example 7

To configure cross-cluster functionality for a user without setting up server cross-cluster functionality, specify `user` as the parameter. This parameter allows users to run commands such as `maprc li node list` using the `-cluster` parameter, and the remote cluster name:

```
$ /opt/mapr/server/configure-crosscluster.sh create user \
  -localtruststorepassword kfSLfzJSIkv_DH7EK \
  -remotetruststorepassword m83SymAwcRXD1MndJFXXpha1008HD0eC \
  -remoteip 10.10.1.1
```

Example 8

To configure both user and server cross-cluster functionality, specify `all` as the parameter, instead of `user` or `server`:

```
$ /opt/mapr/server/configure-crosscluster.sh create all \
  -localtruststorepassword kfSLfzJSIkv_DH7EK \
  -remotetruststorepassword m83SymAwcRXD1MndJFXXpha1008HD0eC \
  -remoteip 10.10.1.1
```

Example 9

To copy the configuration files from the most recently failed run, use the `-recover` option. To update the configuration for a specified list of local or remote hosts, use the `-recover` option together with the `-localhosts` and `-remotehosts` options.

```
$ /opt/mapr/server/configure-crosscluster.sh create server \
  -localtruststorepassword kfSLfzJSIkv_DH7EK \
  -remotetruststorepassword m83SymAwcRXD1MndJFXXpha1008HD0eC \
  -remoteip 10.10.1.103 \
  -localuser admin \
  -remoteuser mapr \
  -recover latest \
  -localhosts local \
  -remotehosts remote
```

See [Sample Failure, Troubleshooting, and Recovery Session](#) on page 3213 for more information.

Troubleshooting and Recovery

Typically, the utility succeeds and if the utility fails partially or completely, try the troubleshooting and recovery steps described here.

Completely Failed Runs

A completely failed run indicates that the utility did not set up cross-cluster communication between any of the local or remote nodes. Typical reasons for complete failure include:

- The prerequisites for running this utility were not met.

Refer to [Prerequisites](#) on page 3201 for running this utility.

- The utility was not run as `mapr` or administrative user.

The user running the utility must be able to run commands like `mapr login password`, `mapr login generateticket`, and `mapr cli node list`.

- The `-localuser` option was not specified when there was a non-default username (like `admin`) for the `mapr` user on the local node.
- The `-remoteuser` option was not specified when there was a non-default username (like `admin`) for the `mapr` user on the remote node.

- The username specified in the `-localcrosscluster` option does not exist in the local cluster.

This utility requires that the username specified in the `-localcrossclusteruser` option to exist before running the utility.

- The username specified in the `-remotecrosscluster` option does not exist in the remote cluster.

This utility requires that the username specified in the `-remotecrossclusteruser` option to exist before running the utility.

- The wrong password was specified for the local mapr user for the local cluster.

This utility uses commands like ssh and scp to access other nodes in the local cluster. So, if the public key authentication between the local node and the other nodes in the local cluster is not setup, you must have set a password for the mapr administrative user specified in the -localuser argument.

- The wrong password was specified for the remote mapr user for the remote cluster.

This utility uses commands like ssh and scp to access other nodes in the local cluster. So, if the public key authentication between the local node and the node specified in the -remoteip option is not setup, there must be a password for the mapr administrative user specified in the -remoteuser option.

For completely failed runs, examine the log file in /opt/mapr/logs/crosscluster.log and the output of the latest run in /tmp/mapr-xcs directory. The crosscluster.log looks something like the following:

```
Script started at Fri Sep 29 15:56:33
PDT 2017
Entering recovery mode. Using
cross-cluster directory /tmp/mapr-xcs/
13194
Verifying that pssh is present ... ok

LogLevel=quiet -p 22 mapr@10.10.1.103
ls /
opt/mapr/conf/mapr-clusters.conf
Logging in to local cluster
...
```

Partially Failed Runs

The utility may also report partial success. The utility does not fail due to inability to copy the updated files to the nodes in the local or remote clusters, so the most likely cause of partial failure is improperly configured or failed cluster nodes.

For partially failed runs, examine the contents of the latest run in `/tmp/mapr-xcs` directory in addition to the contents of the `/opt/mapr/logs/crosscluster.log` file.

In the following example, the latest run of the utility is in `/tmp/mapr-xcs/13194`, since this directory has the most recent modification date:

```
[admin@node95 ~]# ls -lt /tmp/mapr-xcs
total 8
drwx----- 14 mapr mapr 4096 Sep 29
15:49 13194
drwx----- 30 mapr mapr 4096 Sep 29
14:44 23802
```

The following is the sample content in `/tmp/mapr-xcs/13194`:

```
[admin@node95 mapr-xcs]# ls -l 13194
total 52
-rw-r--r-- 1 mapr mapr 59 Sep 29
15:49 local_clusterentry

15:56 STATUS

```

Troubleshooting

1. Look at `/tmp/mapr-xcs/<latest>/STATUS`. A non-zero value indicates an overall error.
2. If you encounter a non-zero overall status, look at the `STATUS` files in each of the subdirectories.
3. For the subdirectories reporting a non-zero status, look at the contents of the files in that subdirectory.
4. If there is an error in updating the local cluster hosts, and you did not use the `-localhosts` option when running the script, also look at `/tmp/mapr-xcs/<latest>/localclusterhosts.txt` file.

The `/tmp/mapr-xcs/<latest>/localclusterhosts.txt` file contains the list of IP addresses of the local cluster hosts, which is the first IP address of each node if there are multiple IP addresses, obtained from the following command:

```
maprcli node list -cluster <local-cluster-name> -columns hostname
```

Verify the contents of the file to ensure that the list of local cluster hosts is correct. The original output of the above command is in `/tmp/mapr-xcs/<latest>/localclusterhosts_full.txt`, and you should also check the output to ensure that the list is correct. Otherwise, fix the errors and re-run the script with the `-localhosts` option.

5. If there is an error in updating the remote cluster hosts, and you did not use the `-remotehosts` option when running the script, you should also look at `/tmp/mapr-xcs/<latest>/remotecclusterhosts.txt` file.

The `/tmp/mapr-xcs/<latest>/remotecclusterhosts.txt` file contains the list of IP addresses of remote cluster hosts, which is the first IP address of each node if there are multiple IP addresses, obtained from the following command:

```
ssh <remoteuser>@<remote-ip> maprcli node list -cluster
<remote-cluster-name> -columns hostname
```

Verify the contents of the file to ensure that the list of remote cluster hosts is correct. The original output of the above command is in `/tmp/mapr-xcs/<latest>/remotecclusterhosts_full.txt`, and you should also check the output to ensure that the list is correct. Otherwise, fix the errors and re-run the script with the `-remotehosts` option.

6. If you have an error copying to some or all of the local or remote cluster hosts, try doing an ssh to the local or remote cluster host (respectively) to ensure that it is accessible using the supplied username and password. If this fails, the copy operation in the script will also fail, since it relies on either public key authentication or username/password authentication to access the nodes. Specify the correct username and/or password and then re-run the script.

Sample Failure, Troubleshooting, and Recovery Session

Suppose the utility is run where one of the nodes in the local cluster (10.10.30.96) has a password that is different from other local cluster nodes, causing the ssh and scp commands to this node to fail.

1. Run the utility on the local node (10.10.30.95).

The highlighted text below are the warning messages. The utility continues to run, despite the warnings, to update the cross-cluster configuration on as many nodes as possible:

```
[admin@node95 cross-cluster]$ /opt/mapr/server/configure-crosscluster.sh
create server -remoteip 10.10.1.103 -localuser admin -remoteuser mapr
Remote IP is 10.10.1.103
WARNING: Strict host key checking will be disabled for this script.
Enter password for mapr user (admin) for local cluster:
Enter password for mapr user (mapr) for remote cluster:
Local cross-cluster user unset, defaulting to local user admin
Remote cross-cluster user unset, defaulting to remote user mapr
Verifying connectivity to 10.10.1.103 and presence of mapr-clusters.conf
MapR credentials of user 'admin' for cluster 'node95.cluster.com' are
written to '/tmp/maprticket_0'
node95.cluster.com secure=true node95.perf.lab:7222
WARNING: Copying local /opt/mapr/conf/mapr-clusters.conf to all hosts in
local cluster complete, but the operation failed for at least one node
in the cluster.
For details, look at the output directory /tmp/mapr-xcs/14043/
lpscp_clusterhosts_odir or error directory /tmp/mapr-xcs/14043/
lpscp_clusterhosts_edir.
Configuring cross-cluster communication for server-side operations
Generating cross-cluster ticket for user mapr on remote node
WARNING: Changing permissions of local maprserverticket complete, but
the operation failed for at least one node in the cluster.
For details, look at the output directory /tmp/mapr-xcs/14043/
lpssh_server_odir or error directory /tmp/mapr-xcs/14043/
lpssh_server_edir
WARNING: Cannot change permissions for local MapR server ticket for at
least 1 node
WARNING: Copy local maprserverticket to all hosts in local cluster
complete, but the operation failed for at least one node in the cluster.
For details, look at the output directory /tmp/mapr-xcs/14043/
lpscp_server_odir or error directory /tmp/mapr-xcs/14043/
lpscp_server_edir.
WARNING: Cannot copy local MapR server ticket for at least 1 node
Generating cross-cluster ticket for mirroring for user admin
MapR credentials of user 'admin' for cluster 'node95.cluster.com' are
written to '/tmp/mapr-xcs/14043/local_crosscluster_ticket'
An error has been encountered in configuring cross-cluster communication.
For more information, refer to the log file at /opt/mapr/logs/
crosscluster.log.
If the error is caused by non-functioning local and remote cluster
nodes, more information on the precise errors can be found in /tmp/
mapr-xcs/14043. The list of local cluster hosts is in /tmp/mapr-xcs/
14043/localclusterhosts.txt, and the list of remote cluster hosts is
in /tmp/mapr-xcs/14043/remotecusterhosts.txt.
In such cases, you can normally fix the error by editing the list of
local and/or remote cluster hosts file and then re-run the script using
the -r option, specifying the local or remote hosts file in
the -localhosts or -remotehosts option respectively.
This script has logged in to both the local and remote clusters. Please
log out of the clusters if needed.
```

2. Look at the specified directory, /tmp/mapr-xcs/14043, because the utility resulted in an error.

The overall status is 1 (indicating an error) as shown in bold below:

```
$ cat /tmp/mapr-xcs/14043/STATUS
1
```

3. Look at the STATUS files in each of the subdirectories to determine the content reporting error.

Content has non-zero status as shown in bold below:

```
[admin@node95 14043]$ find /tmp/mapr-xcs/14043 -print | grep STATUS |
xargs more
:~::~:
./rpscp_clusterhosts_edir/STATUS
:~::~:
0
:~::~:
./lpscp_clusterhosts_edir/STATUS
:~::~:
1          ↪FAIL
:~::~:
./lpssh_server_edir/STATUS
:~::~:
1          ↪FAIL
:~::~:
./lpscp_server_edir/STATUS
:~::~:
1          ↪FAIL
:~::~:
./rpssh_server_edir/STATUS
:~::~:
0
:~::~:
./rpscp_server_edir/STATUS
:~::~:
0
:~::~:
./STATUS
:~::~:
1          ↪Overall status is FAIL
```

4. Look at each of the files in the subdirectories reporting a non-zero status, for example, lpscp_clusterhosts_edir.

The error “lost connection” for 10.10.30.96 indicates that the local node 10.10.30.95 could not run the scp command to that node:

```
[admin@node95 14043]$ more lpscp_clusterhosts_edir/*
:~::~:
lpscp_clusterhosts_edir/10.10.30.95
:~::~:
lpscp_clusterhosts_edir/10.10.30.96
:~::~:
lost connection
:~::~:
lpscp_clusterhosts_edir/STATUS
:~::~:
1
```

5. Try to ssh to that node (10.10.30.96), using the same local password used for running the utility.

The ssh (and therefore also scp) command fails:

```
[admin@node95 14043]$ ssh admin@10.10.30.96 ls
Password:
Password:
Password:
admin@10.10.30.96's password:
Permission denied, please try again.
admin@10.10.30.96's password:
Received disconnect from 10.10.30.96: 2: Too many authentication
failures for admin
```

6. Run the utility again.

The utility detects that the previous run did not complete successfully and prompts you to run the utility with the recovery option. It also detects the directories that contain the detailed error information as shown below:

```
[admin@node95 cross-cluster]$ /opt/mapr/server/configure-crosscluster.sh
create server -remoteip 10.10.1.103 -localuser admin -remoteuser mapr
Remote IP is 10.10.1.103
WARNING: Strict host key checking will be disabled for this script.
The previous run of this script with ID 14043 did not complete
successfully. Examine the error directories in /tmp/mapr-xcs/14043
for details of the error:
/tmp/mapr-xcs/14043/lpscp_clusterhosts_edir
/tmp/mapr-xcs/14043/lpscp_server_edir
/tmp/mapr-xcs/14043/lpssh_server_edir
If the failure is down to partially failed nodes, you should exit now,
and re-run this script in recovery mode using the -recover option to
copy the configured tickets and files to the remaining nodes, instead of
continuing and generating new tickets.
Exit now? Enter y to exit, or n to continue: y

Exiting. Re-run this script with the -recover option.
```

7. Fix the error (in this example, by setting/changing the password for 10.10.30.96), and run the utility again with the `-recover` option to update the configuration for the previously failed operation for the local cluster node.

To copy the configuration again to all the nodes in the local and remote clusters, run the utility without the `-localhosts` and `-remotehosts` option. To rerun the utility to update the configuration for the failed nodes only, specify the IP addresses of the failed nodes only.

NOTE: Specify at least one node in the `-localhosts` and `-remotehosts` option. You can use hostnames instead of IP addresses, as long as you ensure that DNS is working properly between the local node you are running the utility on, and the nodes you specify in the `-localhosts` and `-remotehosts` options.

The output of the recovery session is shown below. Note that the utility returned a SUCCESS result:

```
[admin@node95 cross-cluster]$ cat local
10.10.30.96
[admin@node95 cross-cluster]$ cat remote
10.10.1.101
[admin@node95 cross-cluster]$ /opt/mapr/server/configure-crosscluster.sh
create server -remoteip 10.10.1.103 -localuser admin -remoteuser
mapr -recover latest -localhosts local -remotehosts remote
Remote IP is 10.10.1.103
WARNING: Strict host key checking will be disabled for this script.

This script has logged in to both the local and remote clusters. Please
log out of the clusters if needed.
```

Multiple Runs of the Utility

When running the utility with the `all` or `user` argument, you may see the following error if you run the utility multiple times:

```
keytool error: java.lang.Exception: Certificate not imported, alias
<remote.cluster.com> already exists
ERROR: Unable to import remote cluster certificate from /tmp/mapr-xcs/17056/
remote_mapcert into local SSL trust store
Please delete the certificate with the same alias remote.cluster.com from
the truststore first
```

Certificates with the same alias should be imported to the trust store only once. If you are able to run commands like `maprcli volume mount` on the remote cluster from the local cluster, you can ignore this error. If you really want to re-import the remote cluster certificate into the trust store, contact HPE support.

Also, note that when you run the utility multiple times, there are at least 2 entries with the same alias in `/opt/mapr/conf/maprserverticket` file. The utility generates a new cross-cluster ticket (useful for volume mirroring and table and streams replication) every time it is run, and does not delete any tickets in `/opt/mapr/conf/maprserverticket` file. Service tickets have a long lifetime, so this can be ignored if you are able to successfully perform volume mirroring, and table and streams replication operations. However, if you want to clean up the tickets, you can do the following:

1. Delete all the tickets with the remote cluster alias in the `/opt/mapr/conf/maprserverticket` file on the local node.
2. Delete all the tickets with the local cluster alias in the `/opt/mapr/conf/maprserverticket` file on the remote node referenced in the `-remoteip` parameter.
3. Re-run the utility with the `server` argument to set up the service tickets again.

cldbguys

Monitors the activity of the Container Location Database (CLDB). This utility prints information about the CLDB service that is running on the node from which you run the utility.

Monitoring the progress of the [container location database \(CLDB\)](#) may be useful when troubleshooting cluster issues.

The `cldbguys` utility prints information about active container reports, full container reports, registration requests, HPE Data Fabric file system heartbeats, NFS server heartbeats, and containers. You can run `cldbguys` from any [container location database \(CLDB\)](#) node; however, running this command from the [container location database \(CLDB\)](#) master node provides the most relevant information.

NOTE: After you run `cldbguys`, it continues to print the output until you kill the process. To prevent `cldbguys` from printing indefinitely, specify the `-n` parameter that denotes the number of times `cldbguys` should print the output.

Syntax:

```
/opt/mapr/bin/cldbguys [[acr | rpc | heartbeat | containers | alarms |
table | all] [-n iterations-count]
```

Output Fields:

NOTE: When you run `cldbguys` without any parameters, only the `fcr`, `clrpc`, `regn`, `mfs hb`, `nfs hb`, `assigns`, `roles`, `progress`, and the `con-chain` fields are displayed.

acr

Represents active container requests (ACR).

This column includes the following information:

- `nr`: Number of ACRs completed in the previous second. The first entry displays the total number of ACRs completed since the start of the CLDB service on the node.

- **pt**: Processing time (in milliseconds) for the ACRs completed in the previous second. The first entry displays the total time (in milliseconds) spent processing the ACRs since the start of the CLDB service on the node.
- **to**: Number of ACRs that took longer than expected in the previous second. The first entry displays the total number of ACRs that took longer than expected since the start of the CLDB service on the node.
- **d**: Number of duplicate ACRs received in the previous second. The first entry displays the total number of duplicate ACRs since the start of the CLDB service on the node.
- **dp**: Number of duplicate ACRs that required additional work in the previous second. The first entry displays the total number of duplicate ACRs that required additional work since the start of the CLDB service on the node.

fcr

Represents full container report (FCR).

This column includes the following information:

- **nr**: Number of FCRs completed in the previous second. The first entry displays the total number of FCRs completed since the start of the CLDB service on the node.
- **pt**: Processing time (in milliseconds) for the FCRs completed in the previous second. The first entry displays the total time (in milliseconds) spent processing the FCRs since the start of the CLDB service on the node.
- **to**: Number of FCRs that took longer than expected in the previous second. The first entry displays the total number of FCRs that took longer than expected since the start of the CLDB service on the node.

regn

Represents registration requests.

This column includes the following information:

- **nr**: Number of registration requests completed in the previous second. The first entry displays the total number of registration requests completed since the start of the CLDB service on the node.
- **pt**: Processing time (in milliseconds) for the registration requests completed in the previous second. The first entry displays the total time (in milliseconds) spent processing the registration requests since the start of the CLDB service on the node.

- **t o:** Number of registration requests that took longer than expected in the previous second. The first entry displays the total number of registration requests that took longer than expected since the start of the CLDB service on the node.
- **d:** Number of duplicate registration requests received in the previous second. The first entry displays the total number of duplicate registration requests since the start of the CLDB service on the node.
- **dp:** Number of duplicate registration requests that required additional work in the previous second. The first entry displays the total number of duplicate registration requests that required additional work since the start of the CLDB service on the node.

mfs hb

Information about HPE Data Fabric file system heartbeats.

This column includes the following information:

- **nr:** Number of HPE Data Fabric file system heartbeats completed in the previous second. The first entry displays total number of HPE Data Fabric file system heartbeats completed since the start of the CLDB service on the node.
- **pt:** Processing time (in microseconds) for the HPE Data Fabric file system heartbeats completed in the previous second. The first entry displays total time (in microseconds) spent processing HPE Data Fabric file system heartbeats since the start of the CLDB service on the node.
- **t o:** Number of HPE Data Fabric file system heartbeats that took longer than expected in the previous second. The first entry displays total number of HPE Data Fabric file system heartbeats that took longer than expected since the start of the CLDB service on the node.
- **bmc:** Number of times the Become Master Command (bmc) has been sent to this MFS.
- **otc:** Number of times the other commands (apart from bmc) has been sent to this MFS.

nfs hb

Information about NFS server heartbeats.

This column includes the following information:

- **nr:** Number of NFS server heartbeats completed in the previous second. The first entry displays total number of NFS server heartbeats completed since the start of the CLDB service on the node.

- **pt**: Processing time (in microseconds) for the NFS server heartbeats completed in the previous second. The first entry displays the total time (in microseconds) spent processing HPE Data Fabric file system heartbeats since the start of the CLDB service on the node.

assigns

This column includes the following information:

- **nr**: Number of container assign requests in the previous second. The first entry displays the total number of container assign requests since the start of the CLDB service on the node.
- **nc**: Number of containers created as part of the above container assign requests in the previous second. The first entry displays the total number of containers created since the start of the CLDB service on the node.
- **nrt**: Number of container assign requests for tablets in the previous second. The first entry displays the total number of container assign requests for tablets since the start of the CLDB service on the node.
- **nct**: Number of containers created as part of the above container assign requests for tablets in the previous second. The first entry displays the total number of container created in tablets since the start of the CLDB service on the node.
- **pt**: Time taken by container assignment RPC in milliseconds
- **tpt**: Time taken by container assignment tablet RPC in milliseconds
- **cas**: Number of storage pools scanned for container assignment requests

roles

Represents the roles of the various replica containers.

This column includes the following information:

- **bm**: Number of replica containers that are in the process of becoming master
- **ms**: Number of replica containers that the CLDB thinks have valid masters
- **wr**: Number of replica containers that are waiting for CLDB to assign a role to them
- **rs**: Number of replica containers that are re-syncing
- **vr**: Number of non-master replica containers that have finished resynchronization

- uu: Number of replica containers that are unused. For example, the number of replica containers that are on nodes or storage pools which have been offline or unavailable for more than an hour.

ATTENTION: It may take some time for the CLDB to be aware of role changes.

progress

This column includes the following information:

- m%: Percentage of containers that have valid masters
- uc: Number of unique containers
- v%: Percentage of replica containers that are valid (that is, have completed resynchronization)
- tr: Total number of replica containers

con-chain

This column includes the following information:

- ms: Number of unique containers that have a master
- 1r: Number of unique containers that have 2 valid copies of the data
- 2r: Number of unique containers that have 3 valid copies of the data

location

This column includes the following information:

- lu: Number of container location lookups
- up: Number of container location updates
- dl: Number of container location deletes
- sc: Number of container location scans

size

This column includes the following information:

- lu: Number of container size lookups
- up: Number of container size updates
- dl: Number of container size deletes
- sc: Number of container size scans

sptable

This column includes the following information:

- lu: Number of lookups on the SP-Container-Vol table
- up: Number of updates on the SP-Container-Vol table

- dl: Number of deletes on the SP-Container-Vol table
- sc: Number of scans on the SP-Container-Vol table

nodes

This column includes the following information:

- nn: Number of nodes in the cluster
- of: Number of offline nodes
- nsp: Number of storage pools
- of: Number of offline storage pools

Example Output:

```
/opt/mapr/bin/cldbguys all -n 3

[Retrieving Tiering Statistics Using guts](#) on page 1526

Explains how to use the guts utility to retrieve tiering statistics.

[guts](#) on page 3257

guts is a tool to measure/analyse performance. In the default mode, it prints one line every second, and counts the number of operations or bytes-processed in one second intervals. guts is an internal utility, and is subject to change without notice.

cldbguys acr

The acr option displays active container requests (ACR).

Syntax

```
/opt/mapr/bin/cldbguys acr
```

Output Fields

Field	Description
nr	Number of ACRs completed in the previous 1 second. The first entry displays the total number of ACRs completed since the start of the CLDB service on the node.
pt	Processing time (in milliseconds) for the ACRs completed in the previous 1 second. The first entry displays the total time (in milliseconds) spent processing the ACRs since the start of the CLDB service on the node.
to	Number of ACRs that took longer than expected in the previous 1 second. The first entry displays the total number of ACRs that took longer than expected since start of the CLDB service on the node.
d	Number of duplicate ACRs received in the previous 1 second. The first entry displays the total number of duplicate ACRs since start of the CLDB service on the node.
dp	Number of duplicate ACRs that required additional work in the previous 1 second. The first entry displays the total number of duplicate ACRs that required additional work since start of the CLDB service on the node.

Example Output

```
# /opt/mapr/bin/cldbguts acr
2017-09-01 15:15:25,034
      acr
nr      pt      to      d      dp

      0      0      0      0      0
```

cldbguts containers

The containers option displays information on the containers.

Syntax

```
/opt/mapr/bin/cldbguts containers
```

Output Fields

assigns

This column includes the following information:

Field	Description
nr	Number of ContainerAssign requests in the previous 1 second. The first entry displays the total number of ContainerAssign requests since the start of the CLDB service on the node.

Field	Description
nc	Number of containers created as part of the above ContainerAssign requests in the previous 1 second. The first entry displays the total number of containers created since the start of the CLDB service on the node.
nrt	Number of ContainerAssign requests for tablets in the previous 1 second. The first entry displays total number of ContainerAssign requests for tablets since the start of the CLDB service on the node.
nct	Number of containers created as part of the above ContainerAssign requests for tablets in previous 1 second. The first entry displays the total number of container created in tablets since the start of the CLDB service on the node.

roles

Represents the roles of the various replica containers. This column includes the following information:

Field	Description
bm	Number of replica containers that are in the process of becoming master
ms	Number of replica containers that the CLDB thinks have valid masters
wr	Number of replica containers that are waiting for CLDB to assign a role to them
rs	Number of replica containers that are re-syncing
vr	Number of non-master replica containers that have finished resynchronization

Field	Description
uu	Number of replica containers that are unused. For example, the number of replica containers that are on nodes or storage pools which have been offline or unavailable for more than an hour.

ATTENTION: It may take some time for the CLDB to be aware of any role changes.

progress

This column includes the following information:

Field	Description
m%	Percentage of containers that have valid masters
uc	Number of unique containers
v%	Percentage of master + replica containers that are valid container copies
tr	Total number of replica containers

con-chain

This column includes the following information:

Field	Description
ms	Number of unique containers that have a master
1r	Number of unique containers that have 2 valid copies of the data
2r	Number of unique containers that have 3 valid copies of the data

Example Output

```
# /opt/mapr/bin/cldbguts containers
2019-10-03 03:05:15,846

```

cldbgs heartbeat

The heartbeat option displays information on the heartbeat sent by the file system and NFS.

Syntax

```
/opt/mapr/bin/cldbgs heartbeat
```

Output Fields

mfs hb

Information about Data Fabric file system heartbeats. This column includes the following information:

Field	Description
nr	Number of Data Fabric file system heartbeats completed in the previous 1 second. The first entry displays the total number of Data Fabric file system heartbeats completed since the start of the CLDB service on the node.
pt	Processing time (in microseconds) for the Data Fabric file system heartbeats completed in the previous 1 second. The first entry displays total time (in microseconds) spent processing Data Fabric file system heartbeats since the start of the CLDB service on the node.
to	Number of Data Fabric file system heartbeats that took longer than expected in the previous 1 second. The first entry displays total number of Data Fabric file system heartbeats that took longer than expected since the start of the CLDB service on the node.
bmc	Number of Become Master commands (such as resync, reconnect, etc.) sent by CLDB since the start of CLDB.

nfs hb

Information about NFS server heartbeats. This column includes the following information:

Field	Description
nr	Number of NFS server heartbeats completed in the previous 1 second. The first entry displays total number of NFS server heartbeats completed since the start of the CLDB service on the node.
pt	Processing time (in microseconds) for the NFS server heartbeats completed in the previous 1 second. The first entry displays the total time (in microseconds) spent processing Data Fabric file system heartbeats since the start of the CLDB service on the node.

Example Output

```
# /opt/mapr/bin/cldbguts heartbeat
2019-10-03 03:14:56,811
      mfs hb      nfs hb
nr  pt  to  bmc  otc  nr  pt
 0   0   0   0   0    0   0

 0   0   0   0   0    0   0
```

cldbguts rpc

The rpc option returns a count of the RPCs that CLDB is processing from clients.

Syntax

```
/opt/mapr/bin/cldbguts rpc
```

Output Fields

clrpc

Represents a count of the client RPCs per second. This count includes:

1. ClusterInfoProc
2. ContainerLookupProc
3. ContainerRootLookupProc

This column includes the following information:

Field	Description
nr	Number of Client RPC's completed in the previous 1 second. The first entry displays total number of client RPCs completed since the start of the CLDB service on the node.
pt	Processing time (in milliseconds) for the Client RPCs completed in the previous 1 second. The first entry displays total time (in milliseconds) spent processing the client RPCs since the start of the CLDB service on the node.
to	Number of Client RPCs that took longer than expected in the previous 1 second. The first entry displays the total number of client RPCs that took longer than expected since the start of the CLDB service on the node.

fcr

Represents full container report (FCR). This column includes the following information:

Field	Description
nr	Number of FCRs completed in the previous 1 second. The first entry displays total number of FCRs completed since the start of the CLDB service on the node.
pt	Processing time (in milliseconds) for the FCRs completed in the previous 1 second. The first entry displays total time (in milliseconds) spent processing the FCRs since the start of the CLDB service on the node.

Field	Description
to	Number of FCRs that took longer than expected in the previous 1 second. The first entry displays the total number of FCRs that took longer than expected since the start of the CLDB service on the node.

regn

Represents registration requests. This column includes the following information:

Field	Description
nr	Number of registration requests completed in the previous 1 second. The first entry displays total number of registration requests completed since the start of the CLDB service on the node.
pt	Processing time (in milliseconds) for the registration requests completed in the previous 1 second. The first entry displays the total time (in milliseconds) spent processing the registration requests since the start of the CLDB service on the node.
to	Number of registration requests that took longer than expected in the previous 1 second. The first entry displays total number of registration requests that took longer than expected since the start of the CLDB service on the node.

Example Output

```
# /opt/mapr/bin/cldbguts rpc
2019-10-03 03:17:48,863
      fcr      clrpc
nr  pt  to      nr  pt  to      nr  pt  to
 0   0   0    16116  74239  0      0   0   0
 0   0   0      0     0   0      0   0   0
 0   0   0      0     0   0      0   0   0
```

disksetup

Describes the `disksetup` command that formats disks for use by HPE Data Fabric storage.

Description

NOTE: The disksetup command must be run as root.

The disksetup command formats specified disks for use by HPE Data Fabric storage, and adds those disks to the [disktab](#) file.

You do not need to set up Redundant Array of Independent Disks (RAID) on disks used by the file system. HPE Data Fabric uses disksetup to set up storage pools. In most cases, you should let HPE Data Fabric calculate storage pools using the default [stripe width](#) of two or three disks. If you anticipate a high volume of random-access I/O, you can use the -W option to specify larger storage pools of up to 8 disks each.

See [Setting Up Disks for Data Fabric](#) for more information about when and how to use disksetup.

IMPORTANT: On RHEL 8.1, run the following command to symlink /usr/bin/python to /usr/bin/python3. The disksetup command fails if /usr/bin/python is not found.

```
sudo alternatives --set python /usr/bin/python3
```

Syntax

```
/opt/mapr/server/disksetup
[-F]
[-G]
[-X]
[-M]
[-W <stripe_width>]
<disk list file>
```

Options

Option	Description
-F	Forces formatting of all specified disks. Disks that are already formatted for HPE Data Fabric are not reformatted by disksetup unless you specify this option. The -F option fails when a filesystem has an entry in the disktab file, is mounted, or is in use. Call <code>maprcli disk remove</code> to remove a disk entry from the disktab file.
-G	Generates the disktab file contents from input disk list, but does not format disks. Use this option if the disktab file is completely lost, and you need to regenerate it based on an input list of disks assigned to MapR-FS. This option reads the GUID from the provided disks, and generates the disktab output to stdout. You can redirect the output to a file.
-X	Fixes disktab contents from /proc/partitions, but does not format disks. Use this option if there is a change in the names of the disk devices referenced by disktab, but the disks themselves are still usable. For example, if /dev/sdb has been renamed to /dev/sdf but the device itself has the same GUID, only the disktab contents need to be updated to point to /dev/sdf.
-M	Uses the maximum available number of disks per storage pool.

Option	Description
-W	Specifies the number of disks per storage pool.

Examples

Setting up disks specified in the file /tmp/disks.txt:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

Reformatting all disks

To reformat all disks, remove the disktab file and issue the disksetup -F command to format the disk:

```
/opt/mapr/server/disksetup -F
```

To reformat a particular disk from the disktab, use the maprccli [disk remove](#) on page 2429 and maprccli [disk add](#) on page 2418 commands. For more information, see [Setting Up Disks for HPE Data Fabric](#) on page 1407.

Specifying disks

To specify the disks to be formatted for use by the HPE Data Fabric cluster, create a text file /tmp/disks.txt listing the disks and partitions for use by HPE Data Fabric on the node. Each line lists either a single disk, or all applicable partitions on a single disk. When listing multiple partitions on a line, separate each partition by spaces. For example:

```
/dev/sdb
/dev/sdc1 /dev/sdc2 /dev/sdc4
/dev/sdd
```

Later, when you run disksetup to format the disks, specify the disks.txt file. For example:

```
/opt/mapr/server/disksetup -F /tmp/disks.txt
```

IMPORTANT:

The disksetup command removes all data from the specified disks. Ensure that you specify the disks correctly, and that you have backed up any data that you wish to keep.

If you are re-using a node that was used previously in another cluster, be sure to format the disks to remove any traces of data from the old cluster.

WARNING: Run [disksetup](#) on page 3230 only after you run the [configure.sh](#) on page 3186 .

Test Purposes Only: Using a Flat File for Storage

When setting up a small cluster for evaluation purposes, if a particular node does not have physical disks or partitions available to dedicate to the cluster, you can use a flat file on an existing disk partition as the node's storage. Create at least a 16GB file, and include a path to the file in the disk list file for the [disksetup](#) on page 3230 script.

The following example creates a 20 GB flat file (bs=1G specifies 1 gigabyte blocks, multiplied by count=20) at /root/storagefile:

```
dd if=/dev/zero of=/root/storagefile bs=1G count=20
```

Next, add the following entry to the disk list file `/tmp/disks.txt` to be used by `disksetup`:

```
/root/storagefile
```

ectool

Dumps or checks the validity of the stripelets in the backend volume that is associated with the volume configured for warm tiering.

You can use the `/opt/mapr/server/tools/ectool` utility to dump or check the validity of the stripelets in the backend volume that is associated with the volume configured for warm tiering.

Syntax

```
/opt/mapr/server/tools/ectool <cmd> <params>
```

Commands

Command	Description
<code>dumpStripelet</code>	Dumps the content of a stripelet to the given file.
<code>listStripes</code>	Lists all the stripes in a given container.
<code>validateStripe</code>	Validates if the given parity stripelet is valid and matches with other stripelets of the stripe.
<code>validateCG</code>	Iterates over all the stripes of the Container Group and checks the validity using the rebuild operation.
<code>getFid</code>	Returns the fid for a Virtual Cluster Descriptor (VCD) ID.

Parameters

Parameter	Description
<code>cid</code>	The ID of the container.
<code>fid</code>	The ID of the file.
<code>file</code>	The path to the file.
<code>volid</code>	The ID of the (backend) volume, referred to as <code>ecstorevolume</code> in the CLI output, associated with the tier. The ID can be retrieved using the volume info on page 2969 command. For example: <pre>/opt/mapr/bin/maprcli volume info -name a4 -json grep ecstorevolume "ecstorevolume":"mapr.internal.ec.a4.87379483", /opt/mapr/bin/maprcli volume info -name mapr.internal.ec.a4.87379483 -json grep volumeid "volumeid":105118862,</pre>
<code>vcddid</code>	The ID of the Virtual Cluster Descriptor (VCD).

Usage

```
/opt/mapr/server/tools/ectool dumpStripelet volid fid file
/opt/mapr/server/tools/ectool listStripes volid cid
```

```
/opt/mapr/server/tools/ectool validateStripe valid fid
/opt/mapr/server/tools/ectool validateCG valid cid
/opt/mapr/server/tools/ectool getFid cid vcid
```

Examples

Dump the stripelet content to the file /tmp/t for the file specified by ID 2271.160.131606 in the volume specified by ID 116581327:

```
# /opt/mapr/server/tools/ectool dump 116581327 2271.160.131606 /tmp/t
Stripelet Read done!
```

List all the stripes in the container specified by ID 2271 for the volume specified by ID 116581327:

```
# /opt/mapr/server/tools/ectool list 116581327 2271
Inum:160 Uniq:131606 Size:4194304
Inum:161 Uniq:131608 Size:4194304
Inum:162 Uniq:131610 Size:4194304
```

Validates if the given stripelet matches with other stripelets of the stripe for the file specified by ID 2271.160.131606 in the volume specified by ID 116581327

```
# /opt/mapr/server/tools/ectool validateStripe 116581327 2271.160.131606
Valid Stripe
```

For the container specified by ID 2271, validate if all stripelets match with other stripelets of the corresponding stripe:

```
# /opt/mapr/server/tools/ectool validateCG 116581327 2271
Inum:160 Valid Stripe
Inum:161 Valid Stripe
Inum:162 Valid Stripe
```

expandaudit

Describes how to use the `expandaudit` utility to expand IDs captured in the audit logs to their corresponding names.

As you perform operations on the directories, files, and tables that you are auditing, the audit logs capture records of those operations. Those records identify the affected directories, files, and tables by means of file IDs, the volumes on which the operations took place by means of volume identifiers, and the users who performed the operations by means of user IDs. These IDs are used instead of names in the audit records because fetching the actual names of these objects and users in real-time is costly in terms of performance.

You can use the `expandaudit` utility to create copies of your logs files in which the IDs are resolved into names and inserted into the audit records.

This utility acts on audit logs that exist in the current Data Fabric cluster at the time that the utility is run.

Restrictions

This utility operates on audit logs for file system operations and HPE Data Fabric Database operations, which are logged in a local Data Fabric volume on each node where the operations are performed. These operations are logged in `FSAudit` and `DBAudit` log files.

File identifiers are converted to names only when either of the following conditions is met:

- The file exists at the time that `expandaudit` is run.

- The file has been deleted but the deletion of the file was logged and the log files being processed by `expandaudit` include the record of the file deletion.

If a volume is deleted, `expandaudit` does not convert identifiers for files that were in the volume unless the creation of the volume and files were logged.

If the creation of a file is audited and the file is later renamed, the file ID is converted to the current name.

Permissions

Although the permissions on the tool are 755, the tool generates output only when run by root or the user `mapr`.

Syntax

```
/opt/mapr/bin/expandaudit
expandaudit

[-volumename volume name]
[-volumeid volume ids. Either volume name or id must be specified]
-o output directory
[-i input directory]
[-d Specify for deleted volumes only]
[-cluster cluster name]
[-t number of threads used for parallel expansion across cluster
nod
    es. default 10]
For deleted volumes, user specified volume name will be used during
expansion
```

Parameters

Parameter	Description
<code>cluster</code>	The name of the cluster on which to run the command.
<code>d</code>	Required for deleted volumes as it indicates that the volume is deleted. If you specify this parameter, you must specify a volume ID to be used during expansion. The deleted volume is tracked by the specified volume ID. You can optionally specify a volume name. This specified volume name is used for the expanded output.

Parameter	Description
o	<p>The directory in the Data Fabric file system in which to create the copies of the audit logs. The directory must already exist.</p> <p>The directory structure is:</p> <pre><output directory>/<volume id>/<node>/<day>/<expanded audit log files></pre> <p>The file names are the same as the names of the input files, though you might see the following extensions:</p> <ul style="list-style-type: none"> .part: If present, this extension is on the log file with the most recent date. The input log file that corresponds to this output file might still have been receiving new audit records at the time that the <code>expandaudit</code> utility was run. If the utility is run again with the same output directory, the utility will update the .part file by including the most recent records and converting the identifiers in those records. .pending: This extension indicates files that contain one or more identifiers that the utility could not convert. <p> NOTE: Sometimes, you might see a combination of these two types of files, <code>part.pending</code>, which indicates that there is a problem converting identifiers in the most recent audit file.</p>
i	The input directory for location of cluster audit logs. The default value is <code>/var/mapr/local/</code> .
t	The number of threads to use for parallel expansion across cluster nodes. The default value is 10.
volumename	The name of the volume being audited. You must specify either the <code>volumename</code> or the <code>volumeid</code> parameter.
volumeid	The ID of the volume being audited. You must specify either the <code>volumename</code> or the <code>volumeid</code> parameter.

Sample Expansion of a Record for File System Operations

Original record

```
{
  "timestamp":
  {
    "$date": "2015-06-06T13:02:23.746Z"
  },
  "operation": "GETATTR",
  "uid": "1",
  "ipAddress":
  "10.10.104.53",
  "srcFid": "2049.652.263696",
  "volumeId": 68048396,
  "status": 0
}
```

Record processed by the `expandaudit` utility

```
{
  "timestamp":
  {
    "$date": "2015-06-06T13:02:23.746Z"
  },
  "operation": "GETATTR",
  "user":
  "userA",
  "uid": "1",
  "ipAddress": "10.10.104.53",
  "srcPath": "/customers/US_Western_Region.json",
  "srcFid": "2049.3296.268968",
  "volumeName": "data_analysis",
  "volumeId": 68048396,
  "status": 0
}
```

ATTENTION: Here, uid expands to user, srcFid expands to srcPath, and volumeID expands to volumeName. The original fields are also preserved in the output.

Sample Expansion of a Record for HPE Data Fabric Database Table Operations

Original record

```
{ "timestamp":
  { "$date": "2015-06-06T13:08:54.474Z" }, "operation": "DB_PUT", "uid": "1", "ipAddress":
  "10.10.104.51", "volumeId": 68048396, "columnFamily": "fam63", "columnQualifier":
  "col_96", "tableFid":
  "2049.56.262518", "status": 0 }
```

Record processed by the expandaudit utility

```
{ "timestamp": { "$date=2015-06-06T13:08:54.474Z" }, "operation": "DB_PUT", "user":
  "userA", "uid":
  "1", "ipAddress": "10.10.104.51", "volumeName": "mapr.cluster.root", "volumeId": "
  68048396",
  "columnFamily": "fam63", "columnQualifier": "col_96", "tablePath": "/
  mytable", "tableFid": "2049.56.262518",
  "status": "0" }
```

ATTENTION: Here, uid expands to user, volumeID expands to volumeName, and tableFid expands to tablePath. The original fields are also preserved in the output.

fcdebug

Dynamically sets the log level to debug a library.

You can modify the `core-site.xml` file to set the log level of all modules using the `fs.mapr.trace` property. However, you must restart FUSE for the change to take effect. As an alternative, you can use the `fcdebug` utility to debug a specific library (at runtime) without restarting FUSE.

NOTE: You may have to run this command once per library (to debug).

Syntax

```
/opt/mapr/server/tools/fcdebug [-i] [-p <process ID>] [-s <shm ID>] [-m
<module>] [-l <level>] [-o <slowOpsTraceThreshold>]
```

Parameters

Parameter	Description
-i	Lists the current debug level of all modules.
-l	Specifies the log level. Value can be one of the following: FATAL, ERROR, WARN, INFO, DEBUG.  NOTE: If you do not specify the log level, the default level is applied for the module.

Parameter	Description
-m	Specifies the module for which the log level is to be set. You can retrieve the list of modules with the <code>fcdebug -i -p <process ID></code> or the <code>fcdebug -i -s <shmid></code> command.  NOTE: If you do not specify the module, the log level is set on all modules.
-o	For RPCs, we use the -o parameter to rate limit error messages. Default value: 0 milliseconds (no error messages are printed) Value of x milliseconds indicates that error messages are printed every x milliseconds. There is no limit to the maximum value.
-p	Specifies the process ID of either the file client, or the FUSE-based POSIX client.
-s	Specifies the shared memory ID (shmid) of either the file client, or the FUSE-based POSIX client.

 **ATTENTION:** Specify either the process ID (-p) or the shmid (-s) option. If you specify both the options, only the shmid (-s) option is used.

Examples

The following command retrieves the list of modules:

Note: Use either the -p or the -s option.

```
/opt/mapr/server/tools/fcdebug -i -p 196614 (OR)
/opt/mapr/server/tools/fcdebug -i -s 335020032
```

 **NOTE:** You can run this command after dynamically setting the log level to verify the setting.

The following command dynamically sets the log level to DEBUG on the given module:

Note: Use either the -p or the -s option.

```
/opt/mapr/server/tools/fcdebug -p 196614 -m FuseOps -l DEBUG (OR)
/opt/mapr/server/tools/fcdebug -s 335020032 -m FuseOps -l DEBUG
```

 **NOTE:** It may take up to 30 seconds for the changes to take effect.

The following command sets the log level to DEBUG on all the modules:

Note: Use either the -p or the -s option.

```
/opt/mapr/server/tools/fcdebug -p 196614 -l DEBUG (OR)
/opt/mapr/server/tools/fcdebug -s 335020032 -l DEBUG
```

The following command resets the log level to the default value on all the modules:

Note: Use either the -p or the -s option.

```
/opt/mapr/server/tools/fcdebug -p 196614 (OR)
/opt/mapr/server/tools/fcdebug -s 335020032
```

fsck

Detects and fixes inconsistencies in the file system.

Use the file system check (fsck) utility to detect and fix inconsistencies in the file system.

Every storage pool has its own log to journal updates to the storage pool. The system performs all operations to a storage pool transactionally by journaling all operations to the log, before applying them to storage pool metadata. If file system is not shutdown cleanly, some metadata blocks may not persist. However, on the next load of the storage pool, log recovery takes care of these metadata blocks by replaying the records in the log. The fsck utility also replays the log before it checks the metadata consistency in a storage pool. The fsck utility walks the storage pool in question to verify all Data Fabric file system metadata (and data correctness if specified on the command line), and reports all potentially lost or corrupt containers, directories, tables, files, filelets, and blocks in the storage pool. The fsck utility:

- Checks whether all files and directories are reachable and all directory entries are valid.
- Checks whether BTrees are consistent for various inode types (such as files and directories).
- Walks the container file and visits every inode in the container to check that no block is owned by two inodes. Also, verifies the consistency of bitmaps of inodes and blocks.
- Checks consistency of snapshots.
- Visits every allocated block in the storage pool and recovers any blocks that are part of corrupted inodes.
- Checks consistency of HPE Data Fabric Database metadata.
- Checks consistency of tabletmap, tablets, buckets, and spill files.

The fsck utility can be used on an offline storage pool after a node failure, after a disk failure, or after a Data Fabric file system process crash, or simply to verify the consistency of data for suspected software bugs.

Typical process flow:

- Take the affected storage pools offline with the [mrconfig sp offline](#) on page 3333 command.
- Execute the fsck command on the storage pools (or disks) as specified in the following discussion.
- Bring the storage pools back online with the [mrconfig sp online](#) on page 3334 command.
- Execute the [gfsck](#) on page 3241 command on the cluster, volumes, or snapshots that were affected.

You can run the fsck command in two modes:

- Verification mode - fsck only reports errors; it does not attempt to fix or modify any data on disk. You can run fsck in verification mode on an offline storage pool at any time, and it will report errors if there is inconsistency. If it does not report any errors, you can bring up the storage pool online without any risk of data loss. To run the fsck utility in verification mode, use any parameter *except* the -r parameter.
- Repair mode - fsck attempts to repair a bad storage pool. When you run the fsck utility in repair mode on a storage pool, some volumes might need a global fsck ([gfsck](#) on page 3241) after bringing the storage pool online. There is potential for loss of data in this case. To run the fsck utility in repair mode, use the -r parameter.

Using the `/opt/mapr/server/fsck` utility with the `-r` option produces different results depending on the scenario. The `fsck` utility does not interpret the scenario nor does it have a safe mode.

- If a disk is offline because of an imbalanced b-tree, using `fsck -r` may result in data loss from bad containers, and data loss if additional replicas are unavailable.
- If a disk is offline because of an I/O error, using `fsck -r` produces indeterminate results. A disk that is returning I/O errors is questionable in terms of data content and reliability. For example, an operation that completed on the disk but was never returned, may have partial data remaining on the disk. Using `fsck -r` retains any partial data.
- If a disk is offline because of slow I/O, using `fsck -r` does not produce data loss.

The most conservative usage of `fsck` is to first run `fsck` without the `-r` option (verification mode) and check the output. If the output returns errors, then run `fsck` with the `-r` option.

Syntax

```
/opt/mapr/server/fsck [{<device-paths>}] or [-n <sp name>]
-l <log filename> ; default /opt/mapr/logs/fsck.log.<ts>.<pid>
-p <mfs port> ; default 5660
-N to disable status bar
-P to purge deleted containers in repair
-h for help
-j to skip log replay
-m <memory in MB> to set cache size for blocks
-d to check data blocks crc
-b to check db consistency
-C to specify the container-id when using -d
-I to specify inode-number when using -d and -C
-r to repair ; USE WITH CAUTION AS IT CAN LEAD TO LOSS OF DATA
```

Parameters

Parameter	Description
-b	Checks database consistency.
-C	Optional with the <code>-d</code> option. Specifies the read-write container ID on which CRC (cyclic redundancy check) must be performed. If this option is not specified with the <code>-d</code> option, the CRC is performed on all the containers on the storage pool.
-d	Performs a CRC on data blocks. By default, <code>fsck</code> will not validate the CRC of user data pages. Enabling this check causes the check to take a while to complete.
<device-paths>	<p>Paths to the disks that make up the storage pool.</p> <p> NOTE: Before running <code>fsck</code>, use the mrconfig disk remove on page 3305 command to remove all the disks from file system. For example:</p> <pre>/opt/mapr/server/mrconfig disk remove /dev/sdb /opt/mapr/server/fsck /dev/sdb</pre>
-h	Help

Parameter	Description
-l	Optional with the -C option. Specifies the inode number on which CRC (cyclic redundancy check) must be performed on the container specified by the -C option. If this option is not specified with the -C option, the CRC is performed on all the inodes.
-j	Skips log replay. Should be set only when log recovery fails. Log recovery can fail if the damaged blocks of a disk belong to the log, or if log recovery finds some CRC errors in the metadata blocks. *Using this parameter will typically lead to larger data loss. *
-l	The log filename. Default: /opt/mapr/logs/fsck.log.<ts>.<pid>
-m	Sets the cache size for blocks (MB).
-n	Storage pool name. This option works only if all the disks are in disktab. Otherwise, you must individually specify all the disks that make up the storage pool, using the <device-paths> parameter.
-N	Disables the status bar.
-p	The file system port. Default: 5660
-P	Purges deleted containers in repair.
-r	Runs in repair mode. USE WITH CAUTION AS THIS CAN LEAD TO LOSS OF DATA.

gfsck

Describes how you can use the gfsck command, under the supervision of HPE Data Fabric Support or Engineering, to perform consistency checks and appropriate repairs on a volume, or a volume snapshot.

You can use the gfsck command when the local fsck either repairs or loses some containers at the highest epoch. The gfsck command checks the consistency of the file system.

For an overview of using the GFSCK command, see [Using Global File System Checking](#) on page 1579.

Permissions Required

Although you need to be the *root* user to run this command, checking tiering-enabled volumes requires you to be the *mapr* user.

Syntax

```
/opt/mapr/bin/gfsck
[-h] [--help]
[-c] [--clear]
[-d] [--debug]
[-b] [--dbcheck]
[-r] [--repair]
[-y] [--assume-yes]
[-Gquick] [--check-tiermetadata-only]
[-Gfull] [--check-tiermetadata-full]
[-Dquick] [--check-tierdata-presence]
[-Dfull] [--check-tierdata-crc]
[-D] [--crc]
```

```

[-J] [--skip-tier-log-replay]
[-S3ObjectPresence] [--s3-object-presence]
[cluster=cluster-name (default=default)]
[rwvolume=volume-name (default=null)]
[snapshot=snapshot-name (default=null)]
[snapshotid=snapshot-id (default=0)]
[s3bucket=s3bucket-name (default=null)]
[fid=fid (default=null)]
[cid=cid (default=0)]
[startCid=cid (default=0)]
[rIdx=<repl index>] (replication index, only enables with [-D] [--crc])
[fidThreads=<check crc thread count for fid>] (default:16, max:128)
[cidThreads=<check crc thread count for cid>] (default:16, max:128)
[scanthreads=inode scanner threads count (default:10, max:1000)]
[print-repair-actions=path-to-repair-action-file]
[repair-from-repair-actions=path-to-repair-action-file-for-repair]
[-UseAuxMemory] [--use-aux-memory]
[DelEmptyContainers=<volume-name>]
[-downTimeMin=<time in minutes for allowed downtime>]
[--checkObjMapConsistency]
[print-reconstructed-objects=path-to-reconstructed-objects-file]

```

Parameters

-h --help	<p><i>Description:</i> Prints usage text</p> <p><i>User who must use this option:</i> Either root or mapr.</p>
-c --clear	<p><i>Description:</i> Clears flags that are in progress on volume containers to unblock operations if gfsck finishes abruptly.</p> <p>Users often mistake that the -c option can be used to clear the needsGfsck flag on the volume. However, the -c option does not affect the needsGfsck flag.</p> <p><i>User who must use this option:</i> Either root or mapr.</p>
-d --debug	<p><i>Description:</i> Provides information for debugging.</p> <p><i>User who must use this option:</i> Either root or mapr.</p>
-b --dbcheck	<p><i>Description:</i> Checks that every key in a tablet is within that tablet's startKey and endKey range. This option is I/O intensive, so use this option only if you suspect database inconsistency.</p> <p><i>User who must use this option:</i> root</p> <p>When used with S3 volumes, this option validates that <i>versionIds</i> of objects in a given partition are less than <i>maxVersionId</i> stored in Partition Map Entry.</p> <p><i>User who must use this option:</i> mapr.</p>
-r --repair	<p><i>Description:</i> Indicates and repairs the inconsistencies detected by -GQuick, -GFull, -DQuick, and -DFull. Repair is not supported for snapshots and mirrors.</p> <p><i>User who must use this option:</i> root</p>
-y --assume-yes	<p><i>Description:</i> If specified, assumes that containers without valid copies (as reported by CLDB) are deleted automatically. If not specified, gfsck pauses for user input: yes to delete, no to exit gfsck, or ctrl-C to quit.</p> <p><i>User who must use this option:</i> Either root or mapr.</p>

-D --crc	<p><i>Description:</i> Provides validation of the CRC of the data present in the volume. The data can either be local or offloaded.</p> <p>You can use this option at the volume, container, snapshot, and the filelet levels. <code>gfsck</code> reports corruption found at each level.</p> <p><i>User who must use this option:</i> <code>root</code></p>
-S3 --only-object-store	<p><i>Description:</i> Check objects in each bucket of a given Object Store volume and Object Store mirror volume for metadata inconsistencies.</p> <p><i>User who must use this option:</i> <code>mapr</code>.</p>
cluster	<p><i>Description:</i> Specifies the name of the cluster (default: default cluster)</p> <p><i>User who must use this option:</i> Either <code>root</code> or <code>mapr</code>.</p>
rwvolume	<p><i>Description:</i> Specifies the name of the volume (default: default cluster)</p> <p><i>User who must use this option:</i> Either <code>root</code> or <code>mapr</code>.</p>
fid	<p><i>Description:</i> Checks data CRC for the master copy of the specified <code>fid</code>. To check any other copy, use the <code>rIdx</code> option. You must use fid only with the <code>--crc</code> option.</p> <p><i>User who must use this option:</i> <code>mapr</code></p>
cid	<p><i>Description:</i> Checks data CRC for the master copy of the specified container ID. To check any other copy, use the <code>rIdx</code> option. The default value of 0 denotes that all containers are checked. You must use cid only with the <code>--crc</code> option.</p> <p><i>User who must use this option:</i> <code>mapr</code></p>
startCid	<p><i>Description:</i> <code>startCid</code> is only applicable with the option <code>--crc rwvolume=<volumename></code>.</p> <p>Use this option to start verification from the specific container instead of starting from the first container of that volume. If not provided, the <code>--crc</code> option checks the data CRC of all the containers.</p> <p>For example, assume that one particular volume has containers such as 205...2055...2900.. 3000 5000.. 9999.</p> <p>You can use the <code>startCid</code> option to start verification from container 3000, and all containers prior to 3000 will be skipped.</p> <p><i>User who must use this option:</i> <code>mapr</code></p>
rIdx	<p><i>Description:</i> Specifies the index (either <code>fid</code> or <code>cid</code>) of the copy of the data to check for errors.</p> <p>Use only with <code>-D</code> or <code>--crc</code> and either <code>fid</code> or <code>cid</code>.</p> <p>For example, <code>-D fid:2510.32.131204 rIdx=0</code> only checks the data for copy 1 of the specified <code>fid</code>.</p> <p><i>User who must use this option:</i> <code>mapr</code></p>
fidThreads	<p><i>Description:</i> Specifies the number of threads for scanning fids (default:16, max:128). You must use fidThreads only with the <code>--crc</code> option.</p>

cidThreads	<p><i>User who must use this option:</i> mapr</p> <p><i>Description:</i> Specifies the number of threads for scanning container IDs (default:16, max:128). You must use cidThreads only with the --crc option.</p> <p><i>User who must use this option:</i> mapr</p>
scanthreads	<p><i>Description:</i> Specifies the number of threads for scanning inodes (default:10, max:1000)</p> <p><i>User who must use this option:</i> Either root or mapr.</p>
print-repair-actions	<p><i>Description:</i> Prints all the repair actions identified on specific object store volume for which you have run the gfsck utility. The path-to-repair-action-file file name that is printed on console as part of the gfsck output must be provided as the input for the print-repair-actions parameter.</p> <p><i>User who must use this option:</i> mapr</p>
repair-from-repair-actions	<p><i>Description:</i> Repairs all repair actions identified on specific object store volume for which you have run the gfsck utility. The path-to-repair-action-file file name that is printed on console as part of the gfsck output must be provided as input for the repair-from-repair-actions parameter.</p> <p><i>User who must use this option:</i> mapr</p>
print-reconstructed-objects	<p><i>Description:</i> Used to print details of all repaired objects for specific object store volume. The path-to-reconstructed-objects-file file name that is printed on console as part of the gfsck object reconstruction must be provided as input for the print-reconstructed-objects parameter.</p> <p><i>User who must use this option:</i> mapr</p>
DelEmptyContainers	<p><i>Description:</i> Deletes empty containers from the specified volume.</p> <p><i>User who must use this option:</i> mapr</p>
downTimeMin	<p><i>Description:</i> Specifies the allowed volume downtime, in minutes, for the specified volume.</p> <p><i>User who must use this option:</i> mapr</p>
snapshot	<p><i>Description:</i> Specifies the name of the snapshot (default: null)</p> <p><i>User who must use this option:</i> Either root or mapr.</p>
snapshotid	<p><i>Description:</i> Specifies the snapshot ID (default: 0)</p> <p><i>User who must use this option:</i> Either root or mapr.</p>
UseAuxMemory	<p><i>Description:</i> Specifies if auxiliary memory is to be used for running the gfsck command. Use the option when you are running the gfsck command on buckets with a sizable number of large objects.</p> <p>Using the option helps with avoiding errors related to memory overflow, which might be encountered while running the gfsck command on buckets holding a huge number of large objects (millions or billions of large objects).</p> <p><i>User who must use this option:</i> mapr.</p>

Tier Options

-Gquick|--check-tiermetadata-only

Description: Checks if the entries in the meta data tables maintained internally for objects and tiers (the mapping between the Virtual Cluster Descriptor (VCD) map and object map) , are consistent, and reports an error if not.

User who must use this option: mapr

-Gfull|--check-tiermetadata-full

Description: Checks if the entries in the meta data tables maintained internally for objects and containers (the mapping between the VCD map and object map, along with the mapping between the VCD map and the MFS meta data), are consistent and reports an error if not.

User who must use this option: mapr

-Dquick|--check-tierdata-presence

Description: Specified with either -Gquick or -Gfull. Checks and reports if the object in the meta data tables exists in the tier or not.

User who must use this option: mapr

-Dfull|--check-tierdata-crc

Description: Specified with either -Gquick or -Gfull. Validates the data CRC for the object in the meta data tables.

User who must use this option: mapr

-J|--skip-tier-log-replay

Description: Skips replaying transactions from internal dot files if a tier operation ends abruptly. Data Fabric recommends that you use this option when running the GFSC utility on tiered volumes.

User who must use this option: Either root or mapr.

Examples

1. Debug Mode

In debug mode, run the `gfsck` command on the read/write volume named `mapr.cluster.root`:

```
/opt/mapr/bin/gfsck rwvolume=mapr.cluster.root -d
```

Sample output is as follows:

```
Starting GlobalFsk:
clear-mode           = false
debug-mode           = true
dbcheck-mode         = false
repair-mode          = false
assume-yes-mode      = false
cluster              = my.cluster.com
rw-volume-name       = mapr.cluster.root
snapshot-name        = null
snapshot-id          = 0
user-id              = 0
group-id             = 0

get volume properties ...
  rwVolumeName = mapr.cluster.root (volumeId = 205374230,
rootContainerId = 2049, isMirror = false)

put volume mapr.cluster.root in global-fsck mode ...

2. Verifying CRC of Filelet

```

# /opt/mapr/bin/gfsck -D fid=2085.32.131412 --debug
verifying data crc
  mode      =      fid
  fid       =      2085.32.131412
  debug-mode =      true
  repair-mode =     false
  cluster    =     default
  replication index =     -1
  user-id    =      0
  group-id   =      0

crc validate result for fid : 2085.32.131412
  total local cluster/vcfs verified : 51
  total local cluster/vcfs corrupted : 0
  total local cluster/vcfs skipped: 0
  total purged cluster/vcfs verified : 0
  total purged cluster/vcfs corrupted : 0
  total purged cluster/vcfs skipped: 0

```

3. Verifying CRC at a Container Level

For CRC checks at the container level, the output is not displayed on the terminal. Instead it is written to the `/opt/mapr/log/gfsck.log` file. Sample output is as follows:

```
/opt/mapr/bin/gfsck -D rwvolume=rocky
verifying data crc
mode = volume
rwVolumeName = rocky
fid thread count = 16
cid thread count = 16
debug-mode = false
repair-mode = false
cluster = default
replication index = -1
user-id = 0
group-id = 0
total containers : 6
total container skipped : 0
data crc verification completed with no errors
```

4. Check an HPE Data Fabric Object Store volume without corruption

Step 1: Extract the volume ID of a given bucket:

```
/opt/mapr/server/mrconfig s3 bucketinfo kbuck1
bucketdirfid 2503.43.131380
oltFid 2503.44.131382
odtFid 2503.48.131390
f2oFid 2503.51.131396
volid 96531604
creationTime 1642581709849
accountName default
```

Step 2: Obtain the volume name using the volume ID.

```
/opt/mapr/bin/maprcli volume list -columns volumename,volumeid | grep
96531604
mapr.s3bucketVol.000000003 96531604
```

Step 3: Run gfsck on the volume.

```
su mapr -c "/opt/mapr/bin/gfsck -S3
rwvolume=mapr.s3bucketVol.000000003 -d"
Starting GlobalFsk:
clear-mode = false
debug-mode = true
dbcheck-mode = false
repair-mode = false
assume-yes-mode = false
verify-only-object-store = true
cluster = ec-cluster
rw-volume-name = mapr.s3bucketVol.000000003
snapshot-name = null
snapshot-id = 0
cid = 0
fid = null
user-id = 5000
group-id = 5000

file-fidmap-filelet union --

  s3 bucket verification report --
    S3Bucket:256001024.43.131380 => Allok
    S3Bucket:256001024.43.131380 Stats =>
numObjectsScanned:5, numObjectsVerified:4, numObjectsNeedsRepair:0,
numObjectsStatusUnknown:0, numTinyObjects:1, numSmallObjects:1,
numFSObjects:2, numUnreachableSmallObjects:0
    total unreachable jumbo/large objects:0

```

The fields in the bucket verification report are as follows:

- numTinyObjects: Number of tiny objects per bucket in the volume.
- numSmallObjects: Number of small objects per bucket in the volume.
- numFSObjects: Number of large/jumbo objects per bucket in the volume.
- numObjectsNeedsRepair: Number of objects that need to be repaired.
- numUnreachableSmallObjects: Number of small objects that have an entry in ODT with no corresponding entry in OLT table.

5. Check an HPE Data Fabric Object Store volume with corruption**Step 1:** Extract the volume ID of a given bucket:

```
/opt/mapr/server/mrconfig s3 bucketinfo kbuck2
bucketdirfid 2503.43.131380
oltFid 2503.44.131382
odtFid 2503.48.131390
f2oFid 2503.51.131396
valid 96531653
creationTime 1642581709849
accountName default
```

Step 2: Obtain the volume name using the volume ID.

```
/opt/mapr/bin/maprcli volume list -columns volumenname,volumeid | grep
96531653
    mapr.s3bucketVol.000000006    96531653
```

Step 3: Run gfsck on the volume.

```
su mapr -c "/opt/mapr/bin/gfsck -S3
rwvolume=mapr.s3bucketVol.000000006 -d"
Starting GlobalFsck:

[Using Global File System Checking](#) on page 1579

Describes how to use the gfsck command to check and repair file system errors.

guts

guts is a tool to measure/analyse performance. In the default mode, it prints one line every second, and counts the number of operations or bytes-processed in one second intervals. guts is an internal utility, and is subject to change without notice.

guts provides information on entities such as:

CPU	Indicates whether the CPU is idle or busy
RPCs	Number of RPCs, RPCs-in, RPCs-out, bytes-in, and bytes-out

MFS	Number of local-writes, local-reads, and other operations (such as lookup, create and remove)
Log	Number of log writes, log flushes, and log force-flushes
IO	Number of disk-operations/second (read/write), and the disk-io/second in MB (read/write)

Syntax

```

/opt/mapr/bin/guts
  guts
  -help
  instance:<id>  time:unix time:all time:none (add timestamp to output)
  key:5660 (is server port)
  shmid:<shared memory id> (client's shared memory id, check ipcs)
  threadcpu:core threadcpu:all
  cpu:none  cpu:all
  net:sum  net:msum  net:ksum  net:all  net:none
  disk:none disk:ops disk:mb disk:all

```

Interpreting Output

The prefix *c* identifies client metrics. The suffix *P* refers to the number of pending RPCs. The suffix *C* denotes the number of completed RPCs.

The pending metrics are a snapshot of pending RPCs when the output is printed. The completed metrics are the increase that happened in the last print interval.

Parameters and Output

CPU

`cpu:all` — Percentage of idle time of each CPU on the system in the last second.

IO

The metrics are `ior` and `iow`, which are displayed by default.

- `ior` — The first number reports the number of I/O reads for a machine in the last second. The second number reports the amount of I/O reads in MB in the last second.
- `iow` — The first number reports the number of I/O writes for a machine in the last second. The second number reports the amount of I/O writes in MB in the last second.

Disk

- `disk:ops` — Number of I/O requests (read+write) for each disk in the last second.
- `disk:mb` — Amount of I/O in MB (read+write) for each disk in the last second.
- `disk:all` — The preceding two numbers for each disk in the last second. The first number is from `disk:ops`, the second number is from `disk:mb`.

File System

`fs:rw` — Reports MFS file system activities. Reported metrics are:

- `read` — The first number reports the number of remote reads in the last second. The second number reports the amount of data read in MB in the last second.
- `write` — The first number reports the number of remote writes in the last second. The second number reports the amount of data written in MB in the last second.
- `lread / lwrite` — are similar to the `read` and `write` metrics, but are applicable for local reads/writes.

In addition, `guts` displays the following *file system* metrics:

- `crP` — Total pending *read* RPCs in the last second.
- `crC` — Total completed *read* RPCs in the last second.

- `cwP` — Total pending *write* RPCs in the last second.
- `cwC` — Total completed *write* RPCs in the last second.
- `ccP` — Total pending *create* RPCs in the last second.
- `ccC` — Total completed *create* RPCs in the last second.
- `cuP` — Total pending *unlink* RPCs in the last second.
- `cuC` — Total completed *unlink* RPCs in the last second.

RPC

Reports the following metrics:

- `rpc:none` — Does not display any RPC related metrics.
- `rpc:op` — *rpc* metric
- `rpc:all` — *rpc*, *im*, and *om* metrics.
- `rpc` — Number of RPC calls received in the last second.
- `im` — Amount of RPC calls received in MB in the last second.
- `om` — Amount of RPC calls sent in MB in the last second.

Cache

`cache:small` — Metrics on *inode* and *dentry* cache, which are displayed by default. The metrics reported are:

- `icache` (inode cache) — The first number reports the number of inode cache lookups in the last second. The second number reports the number of inode cache lookup misses in the last second.
- `dcache` (dentry cache) — The first and second numbers report dcache lookups and lookup misses in the last second, respectively.

MOSS (Multithreaded Object Store Server)

Reports the following metrics:

- `moss:none` — Does not display any MOSS-related metrics.
- `moss:basic` — Displays only MOSS metrics related to the number of gets and puts.
- `moss:all` — Displays all MOSS-related metrics.

Metrics returned are:

- s3bc — Number of buckets created in the last second.
- s3bcd — Number of buckets deleted in the last second.
- s3bi — Number of bucket infos in the last second.
- s3bl — Number of buckets lists in the last second.
- tp — Number of tiny puts in the last second.
- sp — Number of small puts in the last second.
- lp — Number of large puts in the last second.
- jp — Number of jumbo puts in the last second.
- tg — Number of tiny gets in the last second.
- sg — Number of small gets in the last second.
- lg — Number of large gets in the last second.
- jg — Number of jumbo gets in the last second.
- oi — Number of object infos in the last second.
- ols — Number of object lists in the last second.
- otg — Number of object tags that are modified in the last second.
- oput — Number of total object puts (sum of tiny, small, large, and jumbo) in the last second.
- opm — Total size of data puts in MB in the last second.
- oget — Number of total object gets (the sum of tiny, small, large, and jumbo) in the last second.
- ogm — Total size of data gets in MB in the last second.

Network

- net : sum — Total network traffic in bytes received and transmitted from all network interfaces for a machine.
- net : msum — Total network traffic in megabytes.
- net : ksum — Total network traffic in kilobytes.
- net : all — Not yet implemented.
- net : none — Does not display any network related metrics.

Metrics returned are:

- **nI** — Total amount of network traffic *received* in bytes in the last second. This is a summation of network traffic from all network interfaces for a machine.
- **nO** — Total amount of network traffic *sent* in bytes in the last second. This is a summation of network traffic from all network interfaces in a machine.

Database

db: get — Metrics related to **get**s. The output columns are as follows:

- **rOP** — Number of RPCs completed for type **OP** in the last second.
- **rOPR** — Number of rows processed from all RPCs of type **OP** in the last second.
- **tOPR** — Number of rows processed from all RPCs in the last second.
- **cOP** — Number of in-progress RPCs for the **OP** (not differential).

Cleaner Metrics

guts displays the following *cleaner* metrics:

- **di** — Number of inodes dirtied by update operations in the last second.
- **ic** — Number of inodes cleaned by the drainer in the last second.
- **dd** — Number of data blocks dirtied by update operations in the last second.
- **dc** — Number of data blocks cleaned by the drainer in the last second.

Operational Metrics

guts displays the following *operational* metrics:

- **rput** — Number of *put* RPCs completed in the last second.
- **rputR** — Sum of *put* rows completed in the last second, from all *put* rpcs.
- **tputR** — Sum of *put* rows completed in the last second, from **all** rpcs (*put*, *increment*, *checkAndPut*, *Append ..*)
- **cput** — Number of *put* RPCs in progress currently. This is not a differential, but displays the number of outstanding *put* RPCs at that particular instant.
- **rget** — Number of *get* RPCs completed in the last second.
- **rgetR** — Sum of *get* rows completed in the last second, from all *get* RPCs.

- **tgetR** — Sum of *get* rows completed in the last second, from **all** rpcs (*get*, *increment*, *checkAndPut*, *Append* ..)
- **cget** — Number of *get* RPCs in progress currently. This is not a differential, but displays the number of outstanding *get* RPCs at that particular instant.
- **rsc** — Number of scan RPCs completed in the last second.
- **rscR** — Sum of scan rows returned in the last second, from **all** scan RPCs.
- **csc** — Number of scan RPCs currently in progress. This is not a differential, but shows the number of outstanding scan RPCs at that particular instant.
- **rinc** — Number of increment RPCs completed in the last second.
- **cinc** — Number of increment RPCs currently in progress. This is not a differential, but shows the number of outstanding increment RPCs at that particular instant.
- **rchk** — Number of *checkAndPut*/*checkAndDelete* RPCs completed in the last second.
- **rapp** — Number of append RPCs completed in the last second.
- **rtlk** — Number of tablet lookup RPCs completed in the last second.
- **ctlk** — Number of tablet lookup RPCs currently in progress. This is not a differential, but shows the number of outstanding lookup RPCs at that particular instant.
- **rbulkb** — Number of bulk-import-bucket RPCs completed in the last second.
- **rbulks** — Number of bulk-import-segment RPCs completed in the last second.

Put Metrics

guts displays the following *put* metrics:

- **rput** — Number of *put* RPCs completed in the last second.
- **rputR** — Sum of *put* rows completed in the last second, from **all** *put* rpcs.
- **tputR** — Sum of *put* rows completed in the last second, from **all** rpcs (*put*, *increment*, *checkAndPut*, *Append* ..)
- **cput** — Number of *put* RPCs in progress currently. This value is not a differential, but displays the number of outstanding *put* RPCs at that particular instant.

- `rsf` — Reserved free memory in MemIndex in MB. If this value falls very low, *put* RPCs can get throttled. This value is not a differential.
- `bucketWR`:
 - `Column1` : Number of bucket writes (calls to MFS) in the last second.
 - `Column2` : Amount of bucket writes in MB in the last second.
- `fl` — Number of bucket flushes fired in the last second.
- `ffl` — Number of force-flushes of buckets in the last second. If the bucket was flushed before it reached its optimal size, then the flush is counted as a force-flush.
- `sfl` — Number of segments touched by the bucket-flushes in the last second.
- `mcom` — Number of segments mini-packed in the last second.
- `fcom` — Number of segments packed fully in the last second.
- `ccom` — Number of segment packs running currently. This value is not a differential.
- `scr` — Number of segment creates in the last second.
- `spcr` — Number of spill creates in the last second.

Get Metrics

`guts` displays the following *get* metrics:

- `rget` — Number of *get* RPCs completed in the last second.
- `rgetR` — Sum of *get* rows completed in the last second, from all *get* RPCs.
- `tgetR` — Sum of *get* rows completed in the last second, from **all** rpcs (*get*, *increment*, *checkAndPut*, *Append ..*)
- `cget` — Number of *get* RPCs currently in progress. This is not a differential, but displays the number of outstanding *get* RPCs at that particular instant.
- `vcM` — Size of the value-cache in MB. This value is not differential.
- `cL` — Number of value-cache lookups in the last second.
- `vcH` — Number of value-cache hits in the last second.

- **bget** — Number of bucket *gets* in the last second. Will be 0 if there are no active buckets.
- **sg** — Number of segment *gets* in the last second. Will normally be equal to **tgetR** minus the number of value-cache hits.
- **spg** — Number of spill *gets* in the last second. This value is calculated as $\text{sigma}(\text{segments} * \text{spill-per-segment}) - \text{bloomFilterSkips}$
- **bskp** — Number of spill *gets* that were avoided/saved by the bloom filter in the last second.

Scan Metrics

guts displays the following *scan* metrics:

- **rsc** — Number of scan RPCs completed in the last second.
- **rscR** — Sum of scan rows returned in the last second, from **all** scan RPCs.
- **csc** — Number of scan RPCs currently in progress. This is not a differential, but shows the number of outstanding scan RPCs at that particular instant.
- **bsc** — Number of buckets scanned in the last second.
- **ssc** — Number of segments scanned in the last second.
- **spsc** — Number of spills scanned in the last second.
- **spscR** — Number of rows scanned from spills in the last second.
- **ldbr** — Number of *ldb* blocks read in the last second.
- **blkr** — Number of data blocks read in the last second (over *spills*, *buckets* ..)
- **raSg** — Number of segments for which read-ahead was done in the last second.
- **raSp** — Number of spills for which read-ahead was done in the last second.
- **nAdv** — Number of *advise* calls made to MFS for scan read-ahead in the last second.
- **raBl** — Sum of blocks in the *advise* calls made to MFS for scan read-ahead in the last second.

Cumulative Metrics

guts displays the following *cumulative* metrics:

- **cmP** — Total pending RPCs from the client in the last second.

- **cmC** — Total completed RPCs from the client in the last second.

DB Metrics

`gut s` displays the following *database* metrics:

- **cgP** — Total pending *get* RPCs.
- **cgC** — Total completed *get* RPCs.
- **cpP** — Total pending *put* RPCs.
- **cpC** — Total completed *put* RPCs.
- **csP** — Total pending *scan* RPCs.
- **csC** — Total completed *scan* RPCs.
- **ciP** — Total pending *increment* RPCs.
- **ciC** — Total completed *increment* RPCs.
- **caP** — Total pending *append* RPCs.
- **caC** — Total completed *append* RPCs.
- **cgR** — Total client *get* rows.
- **cpR** — Total client *put* rows.
- **csR** — Total client *scan* rows.
- **ciR** — Total client *increment* rows.
- **caR** — Total client *append* rows.

Example Usage

The following example demonstrates viewing client metrics. Perform the following steps:

1. Find the process ID of the client program.
2. Find all the shared memory segments (*shmem*) for this program:

```
ipcs -mp | grep <pid>
998080521  root      30030      21850
998113290  root      30030      30030
^^^^^^^^^^
shmem ID
```

Here, there are two shared memory segments — one between the client and MFS, and the other between the client and `gut s`.

3. Identify the correct *shmem* segment for guts:

```
ipcs | grep 998113290
0x00000000 998113290 root      666      2288      1      dest
ipcs | grep 998080521
0x00000000 998080521 root      660      20971520  1      dest
                        ^^^^^^^^^^
                        size
```

The *shmem* with size 20M is between client and MFS. Here, we select *shmem* with ID 998113290.

4. Run guts:

```
/opt/mapr/bin/guts client:all shmid:998113290
Printing only client statistics
cmP  cmC  cgP  cgC  cpP  cpC  csP  csC  ciP  ciC
caP  caC  crP  crC  cwP  cwC  ccP  ccC  cuP  cuC
0    0    0    0    0    0    0    0    0    0
0    0    0    0    0    0    0    0    0    0
0    0    0    0    0    0    0    0    0    0
```

Pass the *shmem* ID and one of the client options. Client options are one of:

- none — Used when printing MFS/dbserver statistics
- db — Prints client statistics for DB operations
- fs — Prints client statistics for file system operations
- all — Prints all client statistics

CLDB Guts

The `cldbguts` utility prints information about active container reports, full container reports, registration requests, MapR-FS heartbeats, NFS server heartbeats, and containers. For more information, see [cldbguts](#) on page 3218.

NFS Guts

`guts` displays the following *NFS* metrics:

- req — Number of requests received from all the NFS clients to this NFS server in the last second.
- dpC — Number of dropped calls from NFS client due to running out of ONC handles (probably cluster is responding slow OR [NFS client is bombarding the NFS server](#)).
- inReadReq — Number of incoming read requests from NFS clients.
- outReadResp — Number of outgoing read request responses to NFS Clients.
- inReadDataReq — Size/Length of incoming read requests (buffer size) from NFS Clients.
- outReadDataResp — Size/Length of outgoing read request response (buffer size) to NFS Clients.
- inWriteReq — Number of incoming write requests from NFS clients.
- outWriteResp — Number of outgoing read request responses to NFS clients.

- `inWriteDataReq` — Size/Length of incoming write request (buffer size) from NFS clients.
- `outWriteDataResp` — Size/Length of outgoing write request response (buffer size) to NFS Clients.

Running Guts

Start guts on the node for which you need to collect metrics.

```
/opt/mapr/bin/guts
00 01 02 03 04 05 06 07  rpc  lpc  write  lwrite  bwrite
read  lread  icache  dcache  di  ic  dd  dc  ior
iow  rput  rputR  cput  tputR  rget  rgetR  cget  tgetR  rsc  rscR  csc
86 90 84 84 87 93 81 84  5  6  0  0  1  0  0  0  0
0  3  0  8  0  163  1  337  22  13  16  1  0  73
4  0  0  0  1  0  0  0  0  0  0  0  0
62 77 70 82 93 61 50 84  12  20  0  0  3  0  0  0  0
0  10  0  27  0  41  0  6  0  3  0  0  0  0
0  0  0  0  0  3  0  0  0  0  0  0  0
63 78 59 56 84 64 32 86  4  5  0  0  5  0  0  0  0
0  0  0  5  0  27  0  8  0  22  0  0  0  0
0  3  1506  0  1506  0  0  0  0  0  0  0  0
83 76 77 82 68 69 82 67  1  0  0  0  0  0  0  0
0  0  0  0  0  0  0  0  0  0  0  0  0  0
0  0  0  0  0  0  0  0  0  0  0  0  0  0
94 49 91 56 75 48 57 92  1  0  0  0  0  0  0  0
0  0  0  0  0  0  0  0  0  0  0  0  0  0
0  0  0  0  0  0  0  0  0  0  0  0  0  0
97 96 99 89 93 94 82 95  2  0  0  0  1  0  0  0  0
0  0  0  1  0  8  0  2  0  1  0  0  0  0
0  0  0  0  0  0  0  0  0  0  0  0  0  0
99 99 96 97 99 98 99 82  19  6  0  0  1  0  0  0  0
0  3  0  186  0  18  0  0  0  0  0  0  0  0
0  0  0  0  0  1  0  0  0  0  0  0  0  0
```

To stop collecting metrics, press ^C.

Related reference

[cldbguts](#) on page 3218

Monitors the activity of the Container Location Database (CLDB). This utility prints information about the CLDB service that is running on the node from which you run the utility.

[Retrieving Tiering Statistics Using guts](#) on page 1526

Explains how to use the guts utility to retrieve tiering statistics.

manageSSLKeys.sh

Use the `manageSSLKeys.sh` utility to create and manage SSL certificates.

Syntax

```
# /opt/mapr/server/manageSSLKeys.sh
manageSSLKeys.sh is a tool to create and manage the SSL certificates.
it is run once on the first node from configure.sh
Usage: manageSSLKeys and one of
    create [-d DNSDOMAIN] [-N clustername] [-k keypass] [-t
trustpass] -ug <maprUserGroup>
    creates the SSL key and trust stores needed for HTTPS traffic
    -d specifies DNS domain used in wildcard certificate. Default
    is detected from Local OS
    -N clustername
    -k password for key store or file containing the key store
password
```

```

-t password for trust store or file containing the trust
store password
-ug MapR user/group, e.g., mapr:mapr
createcreds [-k keypass] -t trustpass -ug <maprUserGroup>
creates the key and trust store credential files maprkeycreds
and maprtrustcreds. This
is normally used in mixed FIPS and non-FIPS configurations in
addition to the convert utility.
-k key store password. If not specified, the key credential
file will not be created
-t trust store password for creating the trust credential
file. This is required
-ug MapR user/group, e.g., mapr:mapr. This is required
secureconfig [-N clustername] [-ug <maprUserGroup>] [-clientonly
true|false] [-k keypass] [-t trustpass]
Completes the secure configuration process. For internal use
only
-N clustername
-ug MapR user/group, e.g., mapr:mapr
-clientonly <true or false>
-keypass Key store password. If specified, this overrides the
key store password in the XML files
-trustpass Trust store password. If specified, this overrides
the trust store password in the XML files
merge <in trust store> <out trust store> <inPassword> <outPassword>
merges the certificates from the in trust store into the
existing out trust store
All arguments are required
copytruststore <outputFile> <password for local trust store>
[password for output (if different from local)]
copywithconfiguredpassword (deprecated in 7.0, use changepassword
instead) <srcStore> <destStore> <srcPassword>
createrandompassword (deprecated in 7.0, use changepassword instead)
[oldPassword (needed to override default password)]
changepassword [-k <oldKeyPassword>] [-kp <newKeyPassword>] [-t
<oldTrustPassword>] [-tp <newTrustPassword>]
change key password or trust password or both
-k password for key store or file containing the key store
password
-kp new password for key store, can only be used with -k
option. If -k is used without -kp,
a new random password will be generated for key store
-t password for trust store or file containing the trust
store password
-tp new password for trust store, can only be used with -t
option. If -t is used without -tp,
a new random password will be generated for trust store
(For a client node - must use both -t old -tp new and
no -k )
createusercert -u <user> -ug <maprUserGroup> [ -p <truststorepw> ]
[ -k <keystorepw> ] [ -a <alias> ] [ -s <sanInfo> ] [ -ips <comma seperated
IPs> ] [ -w ]
add a cert for specified user to the existing ssl_user[key|
trust]stores.
-a alias name for certificate
-p password for trust store or file containing trust store
password
-k password for key store or file containing key store
password
-s SAN info to add to certificate - like 'DNS.1 = *.mydomain'
-u user name to create certificate for
-ug MapR user/group, e.g., mapr:mapr
-ips comma seperated IPs, in case the node is having NATed
external IPs which is common in cloud deployment

```

```

-w overwrite the alias name, else fails if exist. Used in
regenerating the cert with external IPs
createusercerts [-p password] [-N <clustername> ] [-d
DNSDOMAIN ] -ug <maprUserGroup>
-N <clustername>
-d specifies DNS domain used in wildcard certificate. Default
is detected from Local OS
-p password for trust store or file containing trust store
password
-ug MapR user/group, e.g., mapr:mapr
convert [-N <clustername> ] [-k] [-n] -p <passwd> [-srcType JKS|
bcfks|pkcs12] [-dstType JKS|bcfks|pkcs12] <in key/trust store> <out key/
trust store>
converts an existing key/trust store from one store type to
another. If
the destination store type is pkcs12, this creates a new PEM
type key/trust store
if srcType and dstType are not specified, it is assumed that
you are
converting from JKS to PEM via pkcs12
-N <clustername>
-a denotes the certificate alias you want to convert
-k denotes you are converting a keystore
-n do not create a PEM type key/trust store
-p <passwd> store password. This is required
-srcType JKS|bcfks|pkcs12 denotes the source format of the
store
-dstType JKS|bcfks|pkcs12 denotes the destination format of
the store

```

Operations

manageSSLKeys.sh performs the following operations:

create

Description: Creates the SSL key and trust stores needed for HTTPS traffic.

Format: create [-d DNSDOMAIN] [-N clustername] [-k keypass] [-t trustpass] -ug <maprUserGroup>

Parameters:

- d: (*Optional*) DNS domain used for the wildcard certificate. The default domain is detected from the Local OS.
- N: (*Optional*) Name of the cluster.
- k: (*Optional*) Password for key store or file containing the key store password.
- t: (*Optional*) Password for trust store or file containing the trust store password.
- ug: (*Required*) User:Group to use for the key. For example: mapr:mapr.

createcreds

Description: Creates the key and trust store credential files maprkeycreds and maprtrustcreds. This command is usually used in mixed FIPS and non-FIPS configurations in addition to the convert utility.

Format: createcreds [-k keypass] -t trustpass -ug <maprUserGroup>

secureconfig*Parameters:*

- -k: (*Optional*) Key store password. If not specified, the key credential file is not created.
- -t: (*Required*) Trust store password for creating the trust store credential file.
- -ug: (*Required*) Cluster administrator user and group (for example, mapr :mapr).

Description: Completes the secure configuration process. **For internal use only.**

Format: secureconfig [-N clustername] [-ug <maprUserGroup>] [-clientonly true|false] [-k keypass] [-t trustpass]

Parameters:

- -N: (*Optional*) Cluster name.. The default is the cluster on which this command is run.
- -ug: (*Optional*) Cluster administrator user and group (for example, mapr :mapr). The default is mapr :mapr.
- -clientonly: (*Optional*) true or false. This flag ensures that the script does not fail on the client only nodes where the keystores are not present. The default is false.
- -keypass: (*Optional*) Key store password. If specified, this value overrides the key store password in the XML files.
- -trustpass: (*Optional*) Trust store password. If specified, this value overrides the trust store password in the XML files.

merge

Description: Merges the SSL certificates from the *in* trust store into the existing *out* trust store.

Format: merge <in trust store> <out trust store> <inPassword> <outPassword>

Parameters:

- in trust store: (*Required*) Source trust store from which to obtain the SSL certificates.
- out trust store: (*Required*) Destination trust store to merge the SSL certificates.
- inPassword: (*Required*) Password for the source trust store.
- outPassword: (*Required*) Password to set for the destination trust store.

copytruststore

Description: Makes a copy of the existing trust store on the node on which you run this command.

Format: copytruststore <outputFile> <password for local trust store> [password for output (if different from local)]

copywithconfiguredpassword*Parameters:*

- **outputFile:** *(Required)* The file in which to store the copy of the trust store.
- **password for local trust store:** *(Required)* The password of the trust store being copied.
- **password for output:** *(Optional)* The password to set for the output file. By default, this is the same as the password for the local trust store.

ATTENTION: This command is deprecated in version 7.0. Use `changepassword` instead.

Description: Copies the source trust store to the destination trust store and secures the destination with the existing source trust store password..

Format: `copywithconfiguredpassword <srcStore> <destStore> <srcPassword>`

Parameters:

- **srcStore:** *(Required)* Source trust store to copy.
- **destStore:** *(Required)* Destination trust store.
- **srcPassword:** *(Required)* The password for the source trust store.

createrandompassword

ATTENTION: This command is deprecated in version 7.0. Use `changepassword` instead.

Description: Creates a random trust store password.

Format: `createrandompassword [oldPassword (needed to override default password)]`

Parameters:

- **oldPassword:** *(Optional)* The password to overwrite the default one (mapr123).

changepassword

Description: Changes either the key password, the trust password, or both.

Format: `changepassword [-k <oldKeyPassword>] [-kp <newKeyPassword>] [-t <oldTrustPassword>] [-tp <newTrustPassword>]`

Parameters:

- **-k:** *(Optional)* Password for the key store or file containing the key store password.
- **-kp:** *(Optional)* New password for the key store (can only be used with the -k option). If -k is used without -kp, a new random password is generated for the key store.
- **-t:** *(Optional)* Password for the trust store or a file containing the trust store password.

- **-tp:** (*Optional*) New password for the trust store (can only be used with the **-t** option). If **-t** is used without **-tp**, a new random password is generated for the trust store.

For a client node, you must use both **-t** (old) and **-tp** (new) and not **-k**. For more information about using `changepassword`, see [Changing Key and Trust Store Passwords](#) on page 2094.

createusercert

Description: Adds a certificate for the specified user to the existing SSL user key or trust store.

Format: `createusercert -u <user> -ug <maprUserGroup> [ -p <truststorepw> ] [ -k <keystorepw> ] [ -a <alias> ] [ -s <sanInfo> ] [ -ips <comma seperated IPs> ] [ -w ]`

Parameters:

- **-u:** (*Required*) User name for which to create the certificate.
- **-ug:** (*Required*) Cluster administrator user and group (for example, `mapr:mapr`).
- **-p:** (*Optional*) Password for the trust store or a file containing the trust store password. If you omit this parameter, the command creates the trust store without password protection.
- **-k:** (*Optional*) Password for the key store or a file containing the key store password. If you omit this parameter, the command creates the key store without password protection.
- **-a:** (*Optional*) Alias name for the certificate.
- **-s:** (*Optional*) SAN information to add to the certificate (for example: `DNS.1=*mydomain`).
- **-ips:** (*Optional*) Comma seperated NATed external IPs, if any.
- **-w:** (*Optional*) Overwrite the alias name, else fails if it exists. Used in regenerating the certificate with external IPs.

createusercerts

Description: Creates SSL user certificates.

Format: `createusercerts [-p password] [-N <clustername> ] [-d DNSDOMAIN ] -ug <maprUserGroup>`

Parameters:

- **p:** (*Optional*) Password to use for the SSL user certificate.
- **N:** (*Optional*) Name of the cluster. The default is the cluster on which this command is run.
- **d:** (*Optional*) DNS domain used for the wildcard certificate. The default domain is detected from the Local OS.

convert

- *ug: (Required) User:Group* to use for the certificate. For example: *mapr:mapr*.

Description: Converts an existing key/trust store into a new PEM type key/trust store. If you do not specify the type of the source and the destination key/trust store, it is assumed that you are converting from JKS to PEM (via pkcs12).

Format: `convert [-N <clustername> ] [-k] [-n] -p <passwd> [-srcType JKS|bcfks|pkcs12] [-dstType JKS|bcfks|pkcs12] <in key/trust store> <out key/trust store>`

Parameters:

- *N: (Optional)* Cluster name. The default is the cluster on which this command is run.
- *k: (Optional)* Indicates that a keystore is being converted.
- *n: (Optional)* Do not create a PEM type key/trust store.
- *p: (Required)* Password of the existing key/trust store.
- *srcType: (Optional)* Format of the source key/trust store - one of JKS or bcfks or pkcs12. The default keystore for a non-FIPS cluster is JKS, while the default for a FIPS cluster is bcfks.
- *dstType: (Optional)* Format of the destination key/trust store - either JKS or bcfks or pkcs12. The default keystore for a non-FIPS cluster is JKS, while the default for a FIPS cluster is bcfks.
- *in key/trust store: (Required)* The existing key/trust store to convert.
- *out key/trust store: (Required)* The name to use for the converted key/trust store.

Examples

The following links demonstrate using the `manageSSLKeys.sh` utility.

- Change password: [Changing Key and Trust Store Passwords](#) on page 2094
- Copy trust store: [Enabling Security on a Configured Cluster](#) on page 2048
- Create user cert: [Step 1: Restart and Check Cluster Services](#) on page 484
- Regenerate trust store password: [Enabling Security on a Configured Cluster](#) on page 2048
- Merge trust store: [Configuring Secure Clusters for Running Commands Remotely](#) on page 2223
- Generate trust store and key store files: [Step 1: Restart and Check Cluster Services](#) on page 484 and [Configuring Encryption for ODBC Connection](#) on page 5077
- Convert type of keystore file: [Upgrading the Data Access Gateway](#) on page 530

mapr-support-collect.sh

Collects information about a cluster's recent activity, to help Data Fabric Support diagnose problems.

The "mini-dump" option limits the size of the support output. When the `-m` or `--mini-dump` option is specified along with a size, `mapr-support-collect.sh` collects only a head and tail, each limited to the specified size, from any log file that is larger than twice the specified size. The total size of the output is therefore limited to approximately $2 * \text{size} * \text{number of logs}$. The size can be specified in bytes, or using the following suffixes:

- `b` - bytes
- `k` - kilobytes (1024 bytes)
- `m` - megabytes (1024 kilobytes)

Syntax

```
/opt/mapr/support/tools/mapr-support-collect.sh
-h, --hosts HOST_FILE
    hosts file, each line has entries [user@]host[:port]
-H, --host HOST_ENTRY
    additional host entry of the form [user@]host[:port], multiple
can be specified
-Q, --no-cldb
    do not query CLDB for list of nodes
-n, --name NAME
    name of output file
-d, --output-dir DIR_PATH
    absolute path of output directory
-l, --no-logs
    do not include log files
--no-hadoop-logs
    do not include hadoop log files
--hbase-logs
    include hbase log files
--sqoop-logs
    include sqoop log files
--eco-logs
    include all ecosystem log files
--oozie-logs
    include oozie log files
--spark-logs
    include spark log files
--pig-logs
    include pig log files
--impala-logs
    include impala log files
--hue-logs
    include hue log files
--hive-logs
    include hive log files
--flume-logs
    include flume log files
--drill-logs
    include drill log files
--no-kibana-logs
    do not include kibana log files
--no-grafana-logs
    do not include grafana log files
--no-elasticsearch-logs
    do not include elasticsearch log files
--no-opentsdb-logs
```

```

    do not include opensdb log files
--no-collectd-logs
    do not include collectd log files
--no-fluentd-logs
    do not include fluentd log files
--no-vol-info
    do not collect volume information
-L, --libraries
    include libraries
-s, --no-statistics
    do not include statistics
-c, --no-conf
    do not include configurations
-i, --no-sysinfo
    do not include system information
-x, --exclude-cluster
    do not collect cluster diagnostics
-u, --user USER
    username for ssh connections
-K, --strict-hostkey
    check for strict host key in ssh connection
-p, --par PAR
    maximum number of nodes from which support dumps will be gathered
concurrently (default: 10)
-t, --dump-timeout DUMPTIMEOUT
    timeout for execution of mapr-support-dump command on a node
(default: 3600 seconds, 0 = no limit)
-T, --scp-timeout SCTIMEOUT
    timeout for copy of support dump output from a remote node to
local filesystem (default: no limit)
-y, --yes
    do not require acknowledgement of the number of nodes that will
be affected
-O, --online
    Leverage MapR APIs to gather support dumps. When not specified,
SSH and SCP will be used.
-S, --scp-port SCPPORT
    the local port to which remote nodes will establish an SCP session
--collect-cores
    Collect cores of running mfs processes from all nodes (off by
default)
--move-cores
    Move mfs and nfs cores from coresDir from all nodes (off by
default)
--use-hostname
    Use hostname to ssh instead of IP addresses (off by default)
--cldb CLDBNODE
    Use this option when the CLDB Service is down to point to a CLDB
node
--port PORT
    port number used by FileServer (default: 5660)
--nfsport NFS_MGMT_PORT
    port number used by NFS Server (default: 9998)
-m, --mini-dump SIZE
    Collects only first and last number of bytes of each log file if
file is greater than 2*SIZE.
    SIZE may have a multiplier suffix: b 512, k 1024, m 1024*1024
-A, --logs-age DAYS
    Use this option to collect logs newer than specified DAYS
(default: 7, nolimit: 0)
-f, --filter FILTER_STRING
    Use this option to filter nodes for which support dump should be
collected

```

-?, --help
display usage

Parameters

Parameter	Description
-h or --hosts	A file containing a list of hosts. Each line contains one host entry, in the format [user@]host[:port].
-H or --host	One or more hosts in the format [user@]host[:port].
-Q or --no-cldb	If specified, the command does not query the CLDB for list of nodes.
-n or --name	Specifies the name of the output file. If not specified, the default is a date-named file in the format YYYY-MM-DD-hh-mm-ss.tar.
-d or --output-dir	The absolute path to the output directory. The default path is /opt/mapr/support/collect/.
-l or --no-logs	If specified, the command output does not include any log files.
--no-hadoop-logs	If specified, the command output does not include Hadoop log files.
--hbase-logs	If specified, the command output includes HBase log files.
--sqoop-logs	If specified, the command output includes Sqoop log files.
--eco-logs	If specified, the command output includes the log files for all MapR ecosystem components.
--oozie-logs	If specified, the command output includes Oozie log files.
--spark-logs	If specified, the command output includes Spark log files.
--pig-logs	If specified, the command output includes Apache Pig log files.
--impala-logs	If specified, the command output includes Apache Impala log files.
--hue-logs	If specified, the command output includes Apache Hue log files.
--hive-logs	If specified, the command output includes Apache Hive log files.
--flume-logs	If specified, the command output includes Apache Flume log files.
--drill-logs	If specified, the command output includes Apache Drill log files.
--no-kibana-logs	If specified, the command output does not include Kibana log files.
--no-grafana-logs	If specified, the command output does not include Grafana log files.

Parameter	Description
--no-elasticsearch-logs	If specified, the command output does not include Elasticsearch log files.
--no-opentsdb-logs	If specified, the command output does not include OpenTSDB log files.
--no-collectd-logs	If specified, the command output does not include Collectd log files.
--no-fluentd-logs	If specified, the command output does not include Fluentd log files.
--no-vol-info	If specified, the command output does not include any volume information.
-L or --no-libraries	If specified, the command output does not include libraries.
-c or --no-conf	If specified, the command output does not include configurations.
-i or --no-sysinfo	If specified, the command output does not include system information.
-x or --exclude-cluster	<p>If specified, the command does not collect cluster diagnostics.</p> <p>Even if cluster diagnostics are excluded, the script still collects local logs and local system diagnostic information.</p>
-u or --user	The username for ssh connections.
-K or --strict-hostkey	If specified, checks for strict host key in the SSH connection. When specified, ssh never automatically adds host keys to the ~/.ssh/known_hosts file, and refuses to connect to a host whose host key has changed. This provides maximum protection against trojan horse attacks, but can be troublesome when the /etc/ssh/ssh_known_hosts file is poorly maintained or connections to new hosts are frequently made. This option forces the user to manually add all new hosts.
-p or --par	The maximum number of nodes from which support dumps are gathered concurrently (default: 10).
-t or --dump-timeout	The timeout in seconds for execution of the <code>mapr-support-dump</code> command on a node (default: 3600 seconds or 0 = no limit).
-T or --scp-timeout	The timeout in seconds for copy of support dump output from a remote node to the local filesystem (default: no limit).
-y or --yes	If specified, the command does not require acknowledgement of the number of nodes that are affected.
-O or --online	Specifies a space-separated list of nodes from which to gather support output, and uses the MapR APIs instead of ssh for transmitting the support data.

Parameter	Description
-S or --scp-port	The local port to which remote nodes establish a SCP session. The default port is 22.
--collect-cores	If specified, the command collects cores of running MFS processes from all nodes (default: off).
--move-cores	If specified, the command moves MFS and NFS cores from /opt/cores to /opt/mapr/logs/cores/ on all nodes (default: off).
--use-hostname	If specified, uses hostnames instead of IP address for SSH (default: off).
--cldb <cldbnode>	Use this option when the CLDB Service is down to point to a CLDB node.
--port	The port number used by FileServer (default: 5660).
--nfsport	The port number used by NFS Server (default: 9998).
-m or --mini-dump <size>	For any log file greater than 2 * <size>, collects only a head and tail each of the specified size. The <size> may have a suffix specifying units: <ul style="list-style-type: none"> • b - blocks (512 bytes) • k - kilobytes (1024 bytes) • m - megabytes (1024 kilobytes)
-A or --logs-ag	Use this option to collect logs newer than specified days (default: 7, nolimit: 0)
-f or --filter <filter string>	Use this option to specify a filter string. Support information is only collected for nodes with names that match the filter string.
-? or --help	Displays usage help text

Examples

Collect support information and dump it to the file /opt/mapr/support/collect/mysupport-output.tar:

```
/opt/mapr/support/tools/mapr-support-collect.sh -n mysupport-output
2019-09-16 21:37:28.884 INFO Creating nodes file
2019-09-16 21:37:28.907 INFO Querying CLDB for nodes in the cluster
2019-09-16 21:37:31.883 INFO Created nodes file
Diagnostics will be collected from 1 nodes. Press enter to continue:
2019-09-16 21:37:35.650 INFO Collecting cluster information
2019-09-16 21:38:35.282 INFO Collecting dump on <ip>
Password:
2019-09-16 21:41:12.917 INFO Copying dump from <ip>
Password:
2019-09-16 21:44:25.137 INFO Making a tarball of all the dumps
```

```
-----
----- Finished collecting diagnostics
information -----
-----
```

Successfully collected support information on cluster from CLDB.

```
Total no. of nodes from which dump collection was attempted: 1
Nodes from which support information gathering succeeded:      1
Number of nodes from which dump collection failed:            0
Number of nodes from which dump file could not be copied:      0
```

The tar ball of the dumps is available at: /opt/mapr/support/collect/mysupport-output.tar

mapr-support-dump.sh

Collects node and cluster-level information for the node on which you invoke the script.

The information collected is used to help HPE Support diagnose problems. Use [mapr-support-collect.sh](#) on page 3275 to collect diagnostic information from all nodes in the cluster.

The "mini-dump" option limits the size of the support output. When you specify the `-m` or `--mini-dump` option along with a size, `mapr-support-dump.sh` collects only a head and tail, each limited to the specified size, from any log file that is larger than twice the specified size. The total size of the output is therefore limited to approximately $2 * \text{size} * \text{number of logs}$. You can specify the size using the following suffixes:

- `b` - bytes
- `k` - kilobytes (1024 bytes)
- `m` - megabytes (1024 kilobytes)

Syntax

```
/opt/mapr/support/tools/mapr-support-dump.sh
[ -n | --name <name> ]
[ -l | --no-logs ]
[ --no-hadoop-logs ]
[ --hbase-logs ]
[ --sqoop-logs ]
[ --eco-logs ]
[ --oozie-logs ]
[ --spark-logs ]
[ --pig-logs ]
[ --impala-logs ]
[ --hue-logs ]
[ --hive-logs ]
[ --flume-logs ]
[ --drill-logs ]
[ -L | --libraries ]
[ -d | --output-dir <path> ]
[ -s | --no-statistics ]
[ -c | --no-conf ]
[ -i | --no-sysinfo ]
[ -o | --exclude-cluster ]
[ -O | --online ]
[ -z | --only-cluster ]
[ --collect-cores ]
[ --move-cores ]
[ --port <port> ]
[ --nfsport <port> ]
[ -m | --mini-dump <size> ]
[ -A | --logs-age <days> ]
[ -? | --help ]
```

Parameters

Parameter	Description
-n or --name	Specifies the name of the output file. If not specified, the default is a date-named file in the format YYYY-MM-DD-hh-mm-ss.tar
-l or --no-logs	Does not include log files.
--no-hadoop-logs	Does not include Hadoop log files
--hbase-logs	Includes Hbase log files.
--sqoop-logs	Includes Sqoop log files
--eco-logs	Includes all ecosystem log files.
--oozie-logs	Includes Oozie log files.
--spark-logs	Includes Spark log files.
--pig-logs	Includes Pig log files.
--impala-logs	Includes Impala log files.
--hue-logs	Includes Hue log files.
--hive-logs	Includes Hive log files.
--flume-logs	Includes Flume log files.
--drill-logs	Includes Drill log files.
-L or --libraries	Includes libraries.
-d or --output-dir	The absolute path to the output directory. If not specified, the default is /opt/mapr/support/collect/
-s or --no-statistics	Does not include statistics.
-c or --no-conf	Does not include configurations.
-i or --no-sysinfo	Does not include system information.
-o or --exclude-cluster	Does not collect cluster diagnostics.
-O or --online	Saves the support dump output file to the /var/mapr/cluster/support directory in maprfs. When not specified, the output file is stored at /opt/mapr/support/dump on the local machine filesystem. Specifies a space-separated list of nodes from which to gather support output, and uses the warden instead of ssh for transmitting the support data.
-z or --only-cluster	Collects diagnostic information at the cluster level only.
--collect-cores	Collects cores of running mfs processes from all nodes (off by default)
--move-cores	Moves mfs and nfs cores from /opt/cores from all nodes (off by default)
--port	The port number used by the FileServer. Default: 5660

Parameter	Description
--nfs-port	The port used by the NFS server. Default: 9998
-m, --mini-dump <size>	For any log file greater than 2 * <size>, collects only a head and tail each of the specified size. The <size> may have a suffix specifying units: <ul style="list-style-type: none"> • b - blocks (512 bytes) • k - kilobytes (1024 bytes) • m - megabytes (1024 kilobytes)
-A or --logs-age <days>	Collects logs newer than the specified number of days. The default value for this parameter is 7. Specify a value of 0 to have the <code>mapr-support-dump.sh</code> script collect logs of any age.
-? or --help	Displays usage help text

Output

The example produces a tar file at `/opt/mapr/support/dump/mysupport-output.tar`. To extract the tar file, use `tar -xf mysupport-output.tar`. The directory structure is as follows:

```
$ ls
mysupport-output    mysupport-output.tar

$ ls mysupport-output
MapRBuildVersion    hostid              mfsstate_commands
cluster             hostname            roles
cluster_summary.txt linux-release        support_dump.log
conf                logs                system_info
conf_file_metadata  mapr-clusters.conf
```

- **mfsstate_commands** - Contains all information collected about the state of the filesystem are stored the the `mfsstate_commands` directory.
- **cluster** - Contains information associated with `maprccli_commands`, `resourcemanager`, and `volume_dumps`.
- **system_info** - Contains all information related to the system state and configuration.
- **support_dump.log** - Contains console output of the individual commands launched by the support dump script.
- Commonly required files - `cluster_summary.txt`, `conf_file_metadata`, `hostid`, `hostname`, `linux-release`, `MapRBuildVersion`, `mapr-clusters.conf`, and `support_dump.log` are place in the dump root for easier access.

Example

Collect support information and dump it to the file `/opt/mapr/support/collect/mysupport-output.tar`:

```
/opt/mapr/support/tools/mapr-support-dump.sh -n mysupport-output
```

Example Output

```
/opt/mapr/support/tools/mapr-support-dump.sh -n mysupport-output
2015-06-25 11:51:38.397 INFO Starting Support dump collection. For
diagnostics, refer to supportdump.log inside the dump
2015-06-25 11:51:38.402 INFO Collecting system information

2015-06-25 11:53:19.183 INFO Collecting detailed cluster information
2015-06-25 11:54:03.219 INFO Dump collection is succesful. Tar file: /opt/
mapr/support/dump/mysupport-output.tar
```

maprlogin

Authenticates logins to secure HPE Data Fabric clusters.

The `/opt/mapr/bin/maprlogin` command line tool enables users to log into secure MapR clusters. Users authenticate themselves to the cluster with a [maprticket](#) that can be generated in the following ways:

- Run `maprlogin password` to authenticate with username and password.
- Run `maprlogin generateticket` to request a service, tenant, or cross-cluster ticket for use by an external application or user account (based on the current user's ticket).
- Run `maprlogin kerberos` after generating a Kerberos ticket with the `kinit` command.

NOTE: Tickets contain keys, and are used to authenticate users and MapR servers. Every user who wants to access a cluster must have a MapR user ticket (`maprticket_<uid>`) and every node in the cluster must have a MapR server ticket (`maprserverticket`).

For more details about different ways to generate tickets, see [Tickets](#).

Syntax

```
/opt/mapr/bin/maprlogin <argument> <option>
```

Arguments

Argument	Description
authtest	<p>Simulates runtime behavior during authentication. The following is the syntax for running the <code>maprlogin</code> command with this argument:</p> <pre>/opt/mapr/bin/maprlogin authtest [-cluster mapr cluster name]</pre> <p>For more information, see Options on page 3285.</p>

Argument	Description
end logout	<p>Logs out of the cluster. The following is the syntax for running the mapr login command with this argument:</p> <pre>/opt/mapr/bin/maprlogin end logout [-cluster mapr cluster name]</pre> <p>For more information, see Options on page 3285.</p>
generateticket	<p>Generates a ticket for another user or application. The user who runs the mapr login command with this option must already have a user ticket and must have fc (full control) ACL authorization on the cluster. See acl set.</p> <p>The following is the syntax for running the mapr login command with this argument:</p> <pre>/opt/mapr/bin/maprlogin generateticket -type service crosscluster servicewithimpersonation tenant -user <UNIX user name> [-cluster <cluster name>] -out <ticket location> [-duration <[Days:]Hours:Minutes OR -duration Seconds>] [-renewal <[Days:]Hours:Minutes OR -duration Seconds>] [-impersonateduids <uids to impersonate>] [-impersonatedgids <gids to impersonate>]</pre> <p>For more information, see Options on page 3285.</p>
kerberos	<p>Indicates the presence of a Kerberos ticket. The following is the syntax for running the mapr login command with this argument:</p> <pre>/opt/mapr/bin/maprlogin kerberos [-cluster <cluster name>] [-duration <ticket duration>]</pre> <p>For more information, see Options on page 3285.</p>
password	<p>The user's UNIX password. The following is the syntax for running the mapr login command with this argument:</p> <pre>/opt/mapr/bin/maprlogin password [-cluster <cluster name>] [-user <user name>] [-duration <ticket duration>] [-out <ticket location>]</pre> <p>For more information, see Options on page 3285.</p>
print	<p>Prints ticket of any type and contains information including the cluster name, the user ID, the date when the ticket was created, the ticket expiration date, and whether user can impersonate other users, and whether the ticket is for a tenant.</p> <p>In the service tickets, the value for CanImpersonate is true if impersonation is enabled for user and false if impersonation is disabled for the user. In the regular cluster ticket for the user, the value of CanImpersonate is always false. In the tenant ticket, the value for CanImpersonate is always true.</p> <p>The following is the syntax for running the mapr login command with this argument:</p> <pre>/opt/mapr/bin/maprlogin print [-ticketfile <location of ticket file>]</pre> <p>For more information, see Options on page 3285.</p>

Argument	Description
renew	<p>Renews the ticket, given a duration that does not cause the ticket to exceed its maximum lifetime. The original <code>-renewal</code> value for the ticket determines its maximum lifetime. The following is the syntax for running the <code>mapr login</code> command with this argument:</p> <pre> /opt/mapr/bin/maprlogin renew [-cluster <cluster name>] [-duration <ticket renew duration>] [-ticketfile <input ticket file>] [-out <ticket location>] </pre> <p>For more information, see Options on page 3285.</p>

Options

Option	Description	Default
-cluster	Name of the cluster to log into.	First cluster name in the <code>/opt/mapr/conf/mapr-clusters.conf</code> file.
-duration	<p>Length of time before the ticket expires, specified in one of the following formats:</p> <pre> -duration [Days:]Hours:Minutes - duration Seconds </pre> <p>Password-generated tickets are bounded by the CLDB duration and renewal properties that are set for the cluster:</p> <ul style="list-style-type: none"> <code>cldb.security.user.ticket.duration.seconds</code> (default=1209600) is used if duration is not specified while generating the ticket. <code>cldb.security.user.ticket.max.duration.seconds</code> (default=2592000) is the maximum duration allowed for a ticket. <p>For password-generated tickets, if <code>-duration</code> is not set with the <code>mapr login</code> command, the CLDB duration property is used by default.</p> <p>See config.</p> <p> NOTE: The service, <code>servicewithimpersonation</code>, tenant, and <code>crosscluster</code> tickets may have a very long lifetime; their duration is not bounded by these properties. For service and <code>crosscluster</code> tickets, the default value is LIFETIME.</p>	<ul style="list-style-type: none"> 1209600 seconds (14 days) for user tickets LIFETIME for service and cross-cluster tickets

Option	Description	Default
-impersonatedgids	<p>The comma-separated list of GIDs to impersonate. This can only be specified when generating a servicewithimpersonation ticket. If this is specified, the ticket owner can only impersonate the specified groups or users belonging to the specified groups.</p> <p>If impersonatedgids and impersonareduids are not specified, the ticket holder can impersonate all users on the cluster except the root user or the mapr user.</p>	No default
-impersonateduids	<p>The comma-separated list of UIDs to impersonate. This can only be specified when generating a servicewithimpersonation ticket. If this is specified, the ticket owner can only impersonate the specified users.</p> <p>If impersonatedgids and impersonareduids are not specified, the ticket holder can impersonate all users on the cluster except the root user or the mapr user.</p>	No default
-out	<p>A safe directory location where the ticket will be stored. Can be used with generateticket, password, and renew commands.</p> <p>You must specify a location when generating service and tenant tickets. (This requirement ensures that other tickets are not overwritten.)</p>	<p>/tmp/maprticket_<uid></p> <p>(default applies to non-service tickets only)</p>
-renewal	<p>Total lifetime of the ticket, specified in one of the following formats:</p> <ul style="list-style-type: none"> -renewal [Days:]Hours:Minutes -renewal Seconds <p>If -renewal is not set with the mapr login command, the CLDB renewal property is set by default (cldb.security.user.ticket.renew.duration.seconds). You can also set the cldb.security.user.ticket.renew.max.duration.seconds property, which is the maximum duration (7776000, by default) allowed for a ticket renewal.</p> <p> NOTE: Service, tenant, and crosscluster tickets are not bounded by these properties.</p> <p>For example, assume that the mapr login command passes the following options for a service ticket:</p> <p>-duration 30:0:0 -renewal 90:0:0</p> <p>The ticket will expire after 30 days unless it is renewed. If a mapr login renew command is submitted for the ticket before the initial 30 days pass, the ticket's lifetime may be extended up to a total maximum lifetime of 90 days. Tickets do not renew automatically; administrators must renew them with the mapr login renew command, specifying a valid renewal period, and they must do this before the duration period ends. The renewal period must be less than or equal to the remaining amount of time allowed on the ticket.</p> <p>Using the same example, if you renew a ticket on the 29th day of its life, you can renew it for up to 61 days. You can renew a ticket incrementally, for some number of days at a time, as long as you do not exceed the original renewal value.</p>	2592000 seconds (30 days)

Option	Description	Default
-ticketfile	Optional with print and renew commands. Specifies the path to ticket file, if different from default. If this is not specified, the command looks for the ticketfile (maprticket_<uid>) in the default location, which is /tmp on Linux and %TEMP% on Windows systems or in the location specified by the environment variable, \$MAPR_TICKETFILE_LOCATION.	<ul style="list-style-type: none"> Linux: /tmp Windows: %TEMP%
-type	Required ticket type for the generateticket command; value must be service, servicewithimpersonation, tenant, or crosscluster: <ul style="list-style-type: none"> service is used to generate service tickets for regular cluster operations. servicewithimpersonation is used to generate tickets for regular cluster operations, including allowing user to impersonate other users. tenant is used to generate tickets for tenant users that is valid for specific IPs. See Generating a Tenant Ticket that is Valid for Specific IPs Ticket for more information. crosscluster is used to generate tickets for inter-cluster operations, such as remote mirroring. The crosscluster option only works with the mapr user. 	No default; -type must be set in the maprlogin generateticket command.
-user	Required with the generateticket command. The UNIX user name of the user on the MapR cluster. For crosscluster tickets, the user must be mapr.	No default

maprlogin Command Examples

Describes common scenarios associated with maprlogin usage.

Generating and Displaying User Ticket

Generate a user ticket:

```
$ maprlogin password
[Password for user 'juser' at cluster 'my.cluster.com': ]
MapR credentials of user 'juser' for cluster 'my.cluster.com'
are written to '/tmp/maprticket_1000'
```

Display the ticket for the current user. Sample output is shown below.

```
$ maprlogin print
Opening keyfile /tmp/maprticket_1000
my.cluster.com: user = juser,
created = 'Mon Sep 17 08:30:26 PDT 2018', expires = 'Mon Oct 01 08:30:26
PDT 2018',
RenewalTill = 'Wed Oct 17 08:30:26 PDT 2018', uid = 20001, gids = 54261,
CanImpersonate = false
```

Generating and Displaying mapr User Ticket

Generate a ticket for the mapr user:

```
# su mapr
$ maprlogin password
[Password for user 'mapr' at cluster 'test.cluster.com': ]
MapR credentials of user 'mapr' for cluster 'test.cluster.com'
are written to '/tmp/maprticket_5000'
```

Display the ticket for the current user. Sample output is as follows.

```
$ maprlogin print
Opening keyfile /tmp/maprticket_5000
test.cluster.com: user = mapr, created = 'Mon Sep 17 09:18:19 PDT 2018',
expires = 'Mon Oct 01 09:18:19 PDT 2018', RenewalTill = 'Wed Oct 17
09:18:19 PDT 2018',
uid = 5000, gids = 5000, 0, 5001, CanImpersonate = true
```

Generating and Displaying Service Ticket

Generate a service ticket, *longlived_ticket*, in /tmp for *maprUser1*:

```
$ maprlogin generateticket -type service -out /tmp/longlived_ticket
-duration 30:0:0 -renewal 90:0:0 -user maprUser1
MapR credentials of user 'maprUser1' for cluster 'JSKCluster129_secure'
are written to '/tmp/longlived_ticket'
```

Display the service ticket in a specified location:

```
$ maprlogin print -ticketfile /tmp/ticketwithduration
Opening keyfile /tmp/ticketwithduration
JSKCluster129_secure: user = maprUser1,
created = 'Tue Jun 14 11:12:01 PDT 2017', expires = 'Thu Jul 14 11:12:01
PDT 2017',
RenewalTill = 'Mon Sep 12 11:12:01 PDT 2017',
uid = 0, gids = 0, CanImpersonate = false
```

Generating and Printing Service with Impersonation Ticket

Generate a service with impersonation ticket (in /var/tmp) for *maprUser1*:

```
$ maprlogin generateticket -type servicewithimpersonation -user maprUser1
-out /var/tmp/impersonationTicketMapRuser1
```

After generating the ticket, ensure that maprUser1 has read permissions on the ticket. If you move the ticketfile to a different location, set the \$MAPR_TICKETFILE_LOCATION environment variable.

Display the service with impersonation ticket in the specified location:

```
$ maprlogin print -ticketfile /var/tmp/impersonationTicketMapRuser1
Opening keyfile /var/tmp/impersonationTicketMapRuser1
JSKCluster129_secure: user = maprUser1,
created = 'Mon Apr 18 13:46:38 PDT 2017', expires = 'Mon May 02 13:46:38
PDT 2017',
RenewalTill = 'Wed May 18 13:46:38 PDT 2017',
uid = 501, gids = 502, CanImpersonate = true
```

To allow a user to impersonate only specific users and/or groups, use the `impersonateduids` and/or `impersonatedgids` options with the `maprlogin` command. For example:

```
$ maprlogin generateticket -type servicewithimpersonation -user
mapruser1 -out /var/tmp/impersonation_ticket -duration
30:0:0 -impersonateduids 1002,1003 -impersonatedgids 1005,1006 -renewal
90:0:0
```

The command generates a service with impersonation ticket. The ticket holder can impersonate users whose UIDs are 1002 and 1003, and users in the groups with GIDs 1005 and 1006. The ticket expires after 30 days and is stored in `/var/tmp/impersonation_ticket`. The ticket may be renewed at any time within 30 days and can be extended up to a maximum of 90 days. The ticket must be renewed explicitly before its expiration date; it does not renew automatically when it expires.

Generating a Tenant Ticket that is Valid for Specific IPs

Generate a tenant ticket (in `/tmp`) for user `test` that is valid for specific IPs:

```
$ maprlogin generateticket -type tenant -out /tmp/ticketip -ips
10.9.0.1,10.9.0.2 -user test
MapR credentials of user 'test' for cluster 'my.cluster.com' are written to
'/tmp/ticketip'
```

NOTE: The `-ips` argument is only valid for the tenant ticket type.

Display the generated tenant ticket:

```
$ maprlogin print -ticketfile /tmp/ticketip
Opening keyfile /tmp/ticketip
my.cluster.com: user = test, created = 'Tue Aug 25 00:34:14 PDT 2020',
expires = 'Tue Aug 25 00:34:14
PDT 12020', RenewalTill = 'Tue Aug 25 00:34:14 PDT 12020', uid = 5001, gids
= 7001,
CanImpersonate = true, isExternal = true, ips = 10.9.0.1,10.9.0.2,,
IsTenant = true
```

Generating and Displaying Cross-Cluster Ticket

Generate a cross-cluster ticket (in `/tmp`) for `maprUser1`:

```
$ maprlogin generateticket -type crosscluster -out /tmp/
crossclusterTicket -user maprUser1
MapR credentials of user 'maprUser1' for cluster 'JSKCluster128_secure'
are written to '/tmp/crossclusterTicket'
```

Display the contents of a cross-cluster ticket in the specified location:

```
$ maprlogin print -ticketfile /tmp/crossclusterTicket
Opening keyfile /tmp/crossclusterTicket
ClusterSecure: user = root,
created = 'Fri May 27 14:29:40 PDT 2017', expires = 'Fri May 27 14:29:40
PDT 12017',
RenewalTill = 'Fri May 27 14:29:40 PDT 12017',
uid = 0, gids = 0, CanImpersonate = false
```

Running an Authentication Test

authtest: This troubleshooting option simulates the behavior of the runtime during authentication, going through the [authentication flow](#).

Options: [-cluster] Specifies the name of the cluster.

Ending a Session Before the Ticket Expires

end or logout: Destroys tickets and logs out.

Options: [-cluster] Specifies the name of the cluster. By default, deletes all tickets for all clusters.

Renewing a Ticket Before It Expires

renew: Renews an existing ticket for a specified time period.

Options:

- [-cluster] - Specifies the name of the cluster.
- [-duration] - Specifies the ticket duration.

The duration you specify must be valid for the ticket in question, given the original -renewal value for the ticket and the life of the ticket when the renew command is run:

- You cannot renew a ticket that has already expired.
- You can renew the same ticket multiple times.
- The renewal period (or periods) cannot exceed the available time left for the ticket.

For example, assume that a ticket is created with a duration of 10 days and a renewal of 30 days:

```
maprlogin password -duration 10:0:0 -renewal 30:0:0
```

- On the 11th day, the ticket expires and cannot be renewed at all.
- On the 9th day, you can renew the ticket for any number of days up to a maximum of 21.
- On the 23rd day, you can renew the ticket for any number of days up to a maximum of 7.

Example: Renew a ticket and display the renewed ticket in the specified location:

```
$ maprlogin renew -out /tmp/RenewedsecureClusterTicket
-ticketfile /tmp/secureClusterTicket -duration 1:0:0

$ maprlogin print -ticketfile /tmp/RenewedsecureClusterTicket
Opening keyfile /tmp/RenewedsecureClusterTicket
JSKcluster129_secure: user = root,
created = 'Tue Jun 07 11:53:29 PDT 2017',
expires = 'Wed Jun 08 11:56:56 PDT 2017',
RenewalTill = 'Thu Jul 07 11:53:29 PDT 2017',
uid = 0, gids = 0, CanImpersonate = false
```

Troubleshooting maprlogin Failures

While the root causes of most failure cases with maprlogin can be quickly diagnosed, the following cases can prove challenging:

- When security is enabled for a cluster, the cluster's CLDB listens for connections on port 7443. If security for the cluster is disabled, the maprlogin utility is unable to reach the CLDB.

- The utility's connection uses HTTPS, which requires the file [conf/ssl_truststore](#) to exist on the client. If the file is not present, a secure connection cannot be negotiated.

Detailed error logs for `mapr login` connection attempts are kept at `logs/mapr login-<USERID>-nnnn.log`.

mrconfig

The `mrconfig` commands let you create, remove, and manage storage pools, disk groups, and disks; and provide information about containers.

WARNING: The `mrconfig` commands provide direct control and low-level access to the HPE Data Fabric file system. If you are not careful, or do not know what you are doing, you can irrevocably destroy valuable data. The `mrconfig` command must be run under the supervision of HPE support.

mrconfig cntr

Discusses the `mrconfig cntr` commands that allow you to manage containers and container replicas.

mrconfig cntr disablethrottle

Permits disabling throttling for resync of a container.

CAUTION: This `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig cntr disablethrottle` command allows you to disable throttling for resync of a container (specified by ID). Run this command on the node that is the source for the resync.

NOTE: By default, throttling is disabled if resync is not complete after 30 minutes, or when there is only one replica container.

Syntax

```
/opt/mapr/server/mrconfig cntr disablethrottle <cid>
```

Parameters

Parameter	Description
cid	The ID of the container.

Example

Command

```
/opt/mapr/server/mrconfig cntr disablethrottle 2049
```

Output

```
-----
|From Instance 5660::|
-----
Changing throttling on container 2049 throttle flag disable
```

mrconfig cntr resetthrottle

Permits resetting the throttle setting for resync of a container.

CAUTION: This `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig cntr resetthrottle` command allows you to reset the throttle setting for resync of a container (specified by ID).

NOTE: Run this command only after the resync operation (on the specified container) is complete.

Syntax

```
/opt/mapr/server/mrconfig ctr resetthrottle <cid>
```

Parameters

Parameter	Description
cid	The ID of the container.

Example

Command

```
# /opt/mapr/server/mrconfig ctr resetthrottle 2049
```

Output

```
-----
|From Instance 5660::|
-----
Changing throttling on container 2049 throttle flag reset
```

mrconfig ctr resyncprogress

Retrieves the status of a resync operation for containers or volumes.

CAUTION: This `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig ctr resyncprogress` command allows you to get the status of a resync operation for containers or volumes (specified by IDs).

Syntax

```
/opt/mapr/server/mrconfig ctr resyncprogress --cids|--volids <id,...>
```

Parameters

Parameter	Description
--cids	The comma-separated list of container IDs.
--volids	The comma-separated list of volume IDs.

Example

Command

```
# /opt/mapr/server/mrconfig ctr resyncprogress --cids 2104
```

Output

```
-----
|From Instance 5660::|
-----
List of Source Container Ids: 2104
List of Volume Ids:
```

Resync Progress Info

```
-----
Cid: 2104, Snapshot Cid: 4069905785, Vol Id: 233969254, Location: Source,
Peer Addr: 10.20.30.40:5660
ResyncType: Container Resync, Status: Resync In Progress, Total Inodes:
4095, Resync Complete: 4095
```

mrconfig dbinfo

Each instance of the file server on a node is responsible for processing and tracking activities that result from running database commands. The `mrconfig dbinfo` command displays information about the activities, including information related to containers, tablets, storage pools, tags, and threads processing operations on tables.

See [mrconfig](#) for instructions about running `mrconfig` commands.

mrconfig dbinfo arena

The `mrconfig dbinfo arena` command displays all the database related arenas (contiguous piece of memory), including the arena count and byte allocated.

See [mrconfig](#) for instructions about running `mrconfig` commands.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

Syntax

```
/opt/mapr/server/mrconfig dbinfo arena
```

Example

Display arena information.

```
/opt/mapr/server/mrconfig dbinfo arena

mrconfig dbinfo autoseup

The `mrconfig dbinfo autoseup` command displays information about replica autoseup for database tables.

See [mrconfig](#) for instructions about running `mrconfig` commands.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

Syntax

```
/opt/mapr/server/mrconfig dbinfo autoseup
```

Example

Display replica autoseup information for database tables.

```

/opt/mapr/server/mrconfig dbinfo autoseup
-----
Time: 2020-08-18 14:49:10,4851 Instance 5660

copyProgressPct 100
backoff 0 reschedAt 0 inQuickDelayList 0 inLateDelayList 0 error 0
extendedError

```

mrconfig dbinfo cidmapcache

The `mrconfig dbinfo cidmapcache` command displays the number of entries in the container ID cache and the number of successful and unsuccessful lookups performed by each instance of the file server on the cache.

See [mrconfig](#) for instructions about running `mrconfig` commands.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

Syntax

```
/opt/mapr/server/mrconfig dbinfo cidmapcache
```

Example

Display container ID information.

```

/opt/mapr/server/mrconfig dbinfo cidmapcache

mrconfig dbinfo copyregiontrackers

The `mrconfig dbinfo copyregiontrackers` command displays information about copy region progress for tables upon a replica autoseup.

See [mrconfig](#) for instructions about running `mrconfig` commands.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

Syntax

```
/opt/mapr/server/mrconfig dbinfo copyregiontrackers
```

Example

Display the copy region progress for tables upon replica autoseup.

```

/opt/mapr/server/mrconfig dbinfo copyregiontrackers
-----
Time: 2020-08-18 14:50:32,0558 Instance 5660

mrconfig dbinfo copyregionworkers

The `mrconfig dbinfo copyregionworkers` command displays information about the worker threads for parallel copy regions.

See [mrconfig](#) for instructions about running `mrconfig` commands.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

Syntax

```
/opt/mapr/server/mrconfig dbinfo copyregionworkers
```

Example

Display the

```

mrconfig dbinfo mem

The `mrconfig dbinfo mem` command displays memory information related to storage pools and buckets.

See [mrconfig](#) for instructions about running `mrconfig` commands.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

Syntax

```

/opt/mapr/server/mrconfig dbinfo mem

```

Example

Display memory information.

```

/opt/mapr/server/mrconfig dbinfo mem
-----
Time: 2020-08-17 10:39:14,2774 Instance 5660
-----

numActiveBuckets 0
totalActiveBucketsSz 0

```

mrconfig dbinfo replbuckets

The `mrconfig dbinfo replbuckets` command displays the replication progress information for the data in each bucket for each replica of a table.

See [mrconfig](#) for instructions about running mrconfig commands.

 **CAUTION:** The mrconfig command must be run under the supervision of HPE support.

Syntax

```
/opt/mapr/server/mrconfig dbinfo replbuckets
```

Example

Display replication progress.

```
/opt/mapr/server/mrconfig dbinfo replbuckets
-----
Time: 2020-08-18 15:01:00,5833 Instance 5660

```

mrconfig dbinfo repltable

The mrconfig dbinfo repltable command displays information about all the replicas setup on a table.

See [mrconfig](#) for instructions about running mrconfig commands.

 **CAUTION:** The mrconfig command must be run under the supervision of HPE support.

Syntax

```
/opt/mapr/server/mrconfig dbinfo [-v] repltable <tableFid>
```

Parameters

Parameter	Description
-V	Sets the verbose option.
tableFid	The file identifier for the table.

Example

Display the information about all the replicas setup on a table.

```
/opt/mapr/server/mrconfig dbinfo repltable 2049.557.263820
-----
Time: 2020-08-18 15:05:43,2650 Instance 5660

```

mrconfig dbinfo tablets

The `mrconfig dbinfo tablets` command displays information about tablets (table regions).

See [mrconfig](#) for instructions about running `mrconfig` commands.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

Syntax

```
/opt/mapr/server/mrconfig dbinfo tablets
```

Example

Display information about tablets.

```
/opt/mapr/server/mrconfig dbinfo tablets

-----

```

mrconfig dbinfo tabletsplits

The `mrconfig dbinfo tabletsplits` command displays information about the tablets (table regions) being split.

See [mrconfig](#) for instructions about running `mrconfig` commands.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

Syntax

```
/opt/mapr/server/mrconfig dbinfo tabletsplits
```

Example

Display information about the tablets currently being split.

```

/opt/mapr/server/mrconfig dbinfo tabletsplits
-----
Time: 2020-08-18 15:09:34,9493 Instance 5660

stabilizeState PAUSE_PARTITION_SPLITS

```

mrconfig dbinfo threads

The `mrconfig dbinfo threads` command displays information about the throttling queue for each thread processing BatchGet operations, such as the number of free and maximum slots. The command also displays the work areas (WA) for the RPCs being processed by the file server.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

You can configure the number of operations that run in parallel in `mfs.conf` through the `mfs.db.max.concurrent.internal.ops` option. See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```

/opt/mapr/server/mrconfig dbinfo threads

```

Example

Display the throttling queue information for BatchGet operations and work areas (WA) for the RPCs currently being processed by the file server.

```

/opt/mapr/server/mrconfig dbinfo threads

```

mrconfig dg

This section discusses the `mrconfig dg` commands that allow you to configure disk groups.

mrconfig dg create

Facilitates creation of disk groups.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig dg create` commands let you create disk groups (after you initialize disks with the `mrconfig disk init` command and add them to the node with the `mrconfig disk load` command).

You can create a disk group with one of two formats:

- Use the `mrconfig dg create raid0` command to create a striped disk group with a **RAID 0** format.
- Use the `mrconfig dg create concat` command to create a **concatenated** disk group (one disk after another).

After you create disk groups you will be ready to [create storage pools](#) on the disk groups.

See [mrconfig](#) for instructions about running `mrconfig` commands.

mrconfig dg create concat

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig dg create concat` command creates a concatenated disk group. When a disk group is created Data Fabric assigns one of the disks as the device path of the disk group. After you create a disk group you will be ready to [create a storage pool](#) on the disk group.

See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig dg create concat <path>
```

Parameters

Parameter	Description
path	The device path of each of the disks to add to the disk group; example <code>/dev/sdc /dev/sdd /dev/sde</code>

Examples

Create a concatenated disk group on a local node

```
/opt/mapr/server/mrconfig dg create concat /dev/sdc /dev/sdd /dev/sde
```

mrconfig dg create raid0

Creates a disk group striped for RAID 0.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig dg create raid0` command creates a disk group striped for RAID 0. When you create a disk group, Data Fabric assigns one of the disks as the device path of the disk group. After you create a disk group, you are ready to [create a storage pool](#) on the disk group.

See [mrconfig](#) for instructions about running mrconfig commands.

Syntax

```
/opt/mapr/server/mrconfig dg create raid0 [-d <stripeDepth>] <path>
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660
-d	The stripe depth in 8K blocs; default 128 (1 MB)
path	The device path of each of the disks to add to the disk group; example /dev/sdc /dev/sdd /dev/sde

Examples

Create a disk group striped for RAID 0 with a stripe depth of 24 on a local node

```
/opt/mapr/server/mrconfig dg create raid0 -d 24 /dev/sdc /dev/sdd /dev/sde
```

mrconfig dg help

The mrconfig dg help command displays online help for disk group commands.

CAUTION: The mrconfig command must be run under the supervision of HPE support.

See [mrconfig](#) for instructions about running mrconfig commands.

Syntax

```
/opt/mapr/server/mrconfig dg help
```

Examples

Display online help for mrconfig dg commands on a local node

```
/opt/mapr/server/mrconfig dg help
```

mrconfig dg list

The mrconfig dg list command lists the disk groups on all the file system disks on a node.

CAUTION: The mrconfig command must be run under the supervision of HPE support.

See [mrconfig](#) for instructions about running mrconfig commands.

Syntax

```
/opt/mapr/server/mrconfig dg list
```

Examples

List the disk groups on all the file system disks on localhost

```
/opt/mapr/server/mrconfig disk list
```

mrconfig disk

This section discusses the `mrconfig disk` commands.

mrconfig disk help

The `mrconfig disk help` command displays the help text for `mrconfig disk` commands.

See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig disk help
```

Example

Display the help text for `mrconfig disk` commands on a local node

```
/opt/mapr/server/mrconfig disk help
```

mrconfig disk init

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig disk init` command initializes a disk and formats it for the Data Fabric file system.

NOTE:

Warning: Initializing a Disk Causes Data Loss

Initializing a disk destroys the data on the disk, so be sure that all data on a disk is backed up and replicated before initializing the disk.

After executing the `mrconfig disk init` command, add the disk to the node with the [mrconfig disk load](#) command.

See [mrconfig](#) for instructions about running `mrconfig` commands. **Tip:**

To initialize, format, and load one or more disks in one step using:

- The Control System, see [Adding Disks to file system](#) on page 1409.
- The CLI, see [disk add](#) on page 2418 command.

Syntax

```
/opt/mapr/server/mrconfig disk init <path>
[-F]
<path>
```

Parameters

Parameter	Description
-F	Forces formatting of the disk for file system, regardless of prior formatting or existing data.

Parameter	Description
path	The device path of the disk; example /dev/sdc

Examples

Initialize a disk for file system on a local node

```
/opt/mapr/server/mrconfig disk init /dev/sdc
```

Initialize and format a disk for file system on a local node

```
/opt/mapr/server/mrconfig disk init -F /dev/sdc
```

Initialize and format a disk for file system on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx disk init -F /dev/sdc
```

mrconfig disk list

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig disk list` command lists all of the disks on a node that have a Data Fabric file system.

It also shows information about the disk groups and storage pools on the node including whether or not the storage pools are online.

See [mrconfig](#) for instructions about running `mrconfig` commands.

Tip:

To list system disks and other available disks on a node in addition to file system disks using:

- The Control System, see [Viewing the List of Disks](#) on page 1406.
- The CLI, see [disk list](#) on page 2422 command.

Syntax

```
/opt/mapr/server/mrconfig disk list [<path>]
```

Parameters

Parameter	Description
path	The path of the disk; if not included shows information about all disks on the node, if included only shows information about the specified disk; example: /dev/sdc

Examples

List information about all file system disks on a local node

```
/opt/mapr/server/mrconfig disk list
```

List information about file system disk /dev/sdc on a local node

```
/opt/mapr/server/mrconfig disk list /dev/sdc
```

mrconfig disk load

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

After initializing a disk with the `mrconfig disk init` command, load the disk into memory with the `mrconfig disk load` command.

See `mrconfig` for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig disk load <path>
<path>
```

Parameters

Parameter	Description
path	The device path of the disk; example <code>/dev/sdc</code>

Examples

Load a disk on a local node

```
/opt/mapr/server/mrconfig disk load /dev/sdc
```

mrconfig disk remove

The `mrconfig disk remove` command removes a disk from file system. A disk cannot be removed unless its storage pool is offline.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

**WARNING: Removing a Disk Causes Data Loss**

Removing a disk destroys the data on the disk, so be sure that all data on a disk is backed up and replicated before removing a disk.

The `mrconfig disk remove` command is typically used when replacing a failed disk on a node.

Syntax

```
/opt/mapr/server/mrconfig disk remove [<path>]
```

Parameters

Parameter	Description
path	The device path of the disk; example <code>/dev/sdc</code>

Examples

Remove a disk from a local node

```
/opt/mapr/server/mrconfig disk remove /dev/sdc
```

Removing Disks Using mrconfig

About this task**CAUTION:** The `mrconfig` command must be run under the supervision of HPE support.

Suppose one of three disks in a storage pool has failed, and the storage pool has gone offline.

To remove a disk with `mrconfig disk remove`:**Procedure**

1. Ensure that the data on the surviving disks is backed up/replicated.
2. Remove the failed disk from the node's disktab with the `mrconfig disk remove` command.
3. Physically remove the failed disk.
4. Physically attach the replacement disk.
5. Run the `mrconfig disk init` command on the replacement disk and on the other two disks that were in the disk group.
6. Run the `mrconfig disk load` command on each of the three disks.
7. Use the `mrconfig dg create` command to create a new disk group with the three disks.
8. Use the `mrconfig sp make` command to create a storage pool on the new disk group.

mrconfig infoThe `mrconfig info` commands provide information about memory, threads, volumes, containers and other information about the Data Fabric file system.See [mrconfig](#) for instructions about running `mrconfig` commands.*mrconfig info containerchain*The `mrconfig info containerchain` command displays the containerchain for a given container.
Example:

```
$ /opt/mapr/server/mrconfig info containerchain 2050
Container 2050 prev 256000049 next 0.
Container 256000049 prev 0 next 2050.
```

See [mrconfig](#) for instructions on running `mrconfig` commands.**Syntax**

```
mrconfig [-h <host>] [-p <port>] info containerchain <cid>
        <cid>
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660

Parameter	Description
cid	The container identifier

Tip:

Use the `mrconfig info dumpcontainers` command to find the container identifiers on a node.

Examples

Find the containerchain for a container with a cid of 2049 on a local node

```
/opt/mapr/server/mrconfig info containerchain 2049
```

Find the containerchain for a container with a cid of 2049 on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info containerchain 2049
```

`mrconfig info containerlist`

The `mrconfig info containerlist` command lists read/write container IDs for a specified volume.
Example:

```
$ /opt/mapr/server/mrconfig info containerlist volume1
Volume containers
2050
```

See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info containerlist
<volName>
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660
volName	The name of the volume

Tips:

You can see the names of volumes using:

- The **Volumes** view in the in the Control System.
- The `maprccli volume list` command.

Examples

Display information about the containers in a volume named marketing on a local node

```
/opt/mapr/server/mrconfig info containerlist marketing
```

Display information about the containers on a volume named marketing on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info containerlist marketing
```

mrconfig info containers
The `mrconfig info containers` command displays information about containers.

Example:

```
$ /opt/mapr/server/mrconfig info containers rw
RW containers: 1 2049 2050
$ /opt/mapr/server/mrconfig info containers resync
$ /opt/mapr/server/mrconfig info containers snapshot
Snapshot containers: 256000049
```

See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info containers
<container-type> [path]

    <container-type>
    [path]
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660
container-type	When specified, lists only containers of the specified type. Possible values: <ul style="list-style-type: none">rwresyncsnapshot
path	The path to a service pool (obtained with mrconfig sp list). When specified, lists only containers on the specified service pool.

Examples

Display a list of read/write containers on a local node

```
/opt/mapr/server/mrconfig info containers rw
```

Display a list of read/write containers on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info containers rw
```

mrconfig info dumpcontainers

The `mrconfig info dumpcontainers` command displays information about containers including container identifiers, volume identifiers, storage pools, total and free inodes per container.

Example:

```
$ /opt/mapr/server/mrconfig info dumpcontainers

dare:0 istiered:0 numtotalblocks:0 numpurgedblocks:0 numoffloadedblocks:0
maxUniq:131356 isResyncSnapshot:0 snapId:0 port:5660
```

See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info dumpcontainers
```

Input Parameters

Parameter	Description
-h	host IP address; default 127 . 0 . 0 . 1
-p	The file system port; default 5660

Output Fields

Field	Description
cid	Container ID
volid	Volume ID of the volume to which this container belongs.
sp	Storage pool to which this container belongs. For example: SP2:/dev/sde Here, SP2 is the name of the storage pool. /dev/sde is the disk on which the container resides.
spid	Storage pool ID
prev	Pointer to the previous snapshot cid or rw cid (for a clone container), in a snapshot chain.
next	Pointer to the next snapshot cid or rw cid (for a clone container), in a snapshot chain.
issnap	Indicates whether container is a snapshot or not, in a snapshot chain. <ul style="list-style-type: none"> 0 - rw container (Not a snapshot container) 1 - Snapshot
isclone	Indicates whether this container is a clone container created as part of the resync operation. <ul style="list-style-type: none"> 0 - Not a clone 1 - Is a clone
deleteinprog	Indicates whether this container is marked for deletion. <ul style="list-style-type: none"> 0 - Not marked for deletion 1 - Marked for deletion
fixedbyfsck	Indicates whether fsck was run on this container to fix any data or metadata errors. <ul style="list-style-type: none"> 0 - fsck was not run on the container 1 - fsck was run on the container

Field	Description
stale	Indicates whether the current cid is a stale cid or not. Container is marked as stale when it is yet to be processed for cleanup. <ul style="list-style-type: none"> 0 - Not stale 1 - Stale
querycldb	Indicates whether the container is awaiting its role from CLDB at the time of bringing up a cluster. <ul style="list-style-type: none"> 0 - Not waiting as CLDB has already defined the role for the container 1 - Waiting for CLDB to specify the role for the container
resyncinprog	Indicates if the container is resyncing from another container in the container chain. <ul style="list-style-type: none"> 0 - Resyncing in progress 1 - No resyncing
shared	Indicates whether the container is hosting any shared data. The value is the number of shared data blocks (each of size 8K).
owned	Indicates the number of data blocks (each of size 8K) that the container owns.
logical	Indicates the number of logical data blocks (each of size 8K) that are present in the container.
snapusage	Indicates the number of container blocks (each of size 8K) that are used for storing snapshot data.
snapusageupdated	Internal field.
ismirror	Indicates if this container is of a mirror volume or not. 0 - Is not of a mirror volume 1- Is of a mirror volume
isrwmirrorcapable	Indicates if the container belongs to a mirror volume, and if the volume can be converted to a rw volume, in case the primary volume goes down. <ul style="list-style-type: none"> 0 - Volume cannot be converted 1 - Volume can be converted
role	Role of the container, in the container chain. <ul style="list-style-type: none"> 0 - Master 1 - Not the master
totalInodes	Indicates the total number of inodes that can be created on the container.

Field	Description
freelnodes	Indicated the number of inodes that are still available to be used.
dare	Indicates whether the container belongs to a volume that is dare-enabled or not. <ul style="list-style-type: none"> 0 - Volume is not dare-enabled 1 - Volume is dare-enabled
istiered	Indicates whether the container belongs to a tiered (either cold-tiered or EC enabled) volume. <ul style="list-style-type: none"> 0 - Container belongs to a tiered volume 1 - Container does not belong to a tiered volume
numtotalblocks	Applicable only for tiered volumes, this parameter indicates the total number of data blocks present in the container.
numpurgedblocks	Applicable only for tiered volumes, this parameter indicates the number of data blocks that are offloaded and not locally present. This value decreases in case of recalls.
numoffloadedblocks	Applicable only for tiered volumes, this parameter indicates the number of data blocks that are off-loaded to the tier.
maxUniq	Internal field.
isResyncSnapshot	Indicates whether the container belongs to the resync snapshot. <ul style="list-style-type: none"> 0 - Container does not belong to the resync snapshot 1 - Container belongs to the resync snapshot
snapId	Indicates the snapshot ID to which this container belongs, if the ID is a snap cid.
port	Indicates the MFS port number used by the container.

Examples

Display information about containers on a local node

```
/opt/mapr/server/mrconfig info dumpcontainers
```

Display information about containers on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info dumpcontainers
```

mrconfig info fsstate

The `mrconfig info fsstate` command displays information about the status of the Data Fabric file system, for example whether or not storage pools are loaded. See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info fsstate
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660

Examples

Display information about the state of the Data Fabric file system on a local node

```
/opt/mapr/server/mrconfig info fsstate
```

Display information about the state of the Data Fabric file system on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info fsstate
```

mrconfig info fsthreads

The `mrconfig info fsthreads` command displays information about threads running on file system disks on a node. See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info fsthreads
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660

Examples

Display information about MapR filesystem threads on a local node

```
/opt/mapr/server/mrconfig info fsthreads
```

Display information about MapR filesystem threads on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info fsthreads
```

mrconfig info mastgateway

The `mrconfig info mastgateway` command must be run on a CLDB node. The command displays the status of the MAST Gateways, the total number of volumes assigned to them, and the number of active, inflight, and pending volumes.

See [mrconfig](#) on page 3291 for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig info mastgateway [<gwid>]
```

Parameters

Parameter	Description
gwid	The ID of the MAST Gateway for which to display information.

Examples

Display information about MAST Gateways on the cluster:

```
# /opt/mapr/server/mrconfig -h 10.20.30.400 info mastgateway
Num MastGateways: 2

Gateway : atsq8c46.qa.lab ( 6322920922584906487 )
Active : Yes
Active Vn : 101, Inflight Vn : 101
Num Active Vols : 4
Num Inflight Vols, Adds : 0, Removes : 0
Num Pending Vols, Adds : 0, Removes : 0

Active Vols :
153675213
97789611
23539482
45553484

Gateway : atsq8c48.qa.lab ( 8723754106996643487 )
Active : Yes
Active Vn : 100, Inflight Vn : 100
Num Active Vols : 0
Num Inflight Vols, Adds : 0, Removes : 0
Num Pending Vols, Adds : 0, Removes : 0
No vols assigned to gateway.
```

mrconfig info nfsthreads

The `mrconfig info nfsthreads` command displays information about in-progress NFS operations.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info nfsthreads
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The NFS port; default 2049

Output

The output shows the NFS operations currently running (in progress) including the IP address of the client and the type of operation. For example:

```
# /opt/mapr/server/mrconfig info nfsthreads
NFS Threads in progress = 15

Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
Client IP:127.0.0.1:0, Op Type: NFSPROC3_WRITE
```

Examples

Display information about the NFS processes currently running:

```
/opt/mapr/server/mrconfig info nfsthreads
```

Display information about NFS operations in-progress on a remote node with an IP address of xx.xx.xx.xx:

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info nfsthreads
```

mrconfig info orphanagecount

The `mrconfig info orphanagecount` command displays orphan entries for a given container (specified by ID).

Syntax

```
/opt/mapr/server/mrconfig info orphanagecount <cid>
```

Parameters

Parameter	Description
cid	The ID of the container.

Examples

Display the number of orphan entries for container 2067:

```
~# /opt/mapr/server/mrconfig info orphanagecount 2067
-----
Time: 2017-03-31 18:00:49,1085 Instance 5660
-----
orphanagecount cid 2067 count 812
```

mrconfig info orphanlist

The `mrconfig info orphanlist` command displays information about a container's orphans. See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info orphanlist <cid>  
    <cid>
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660
cid	The container identifier

Tip:

Use the `mrconfig info dumpcontainers` command to find the container identifiers on a node.

Examples

Display information about the orphans of a container with an identifier of 2049 on a local node

```
/opt/mapr/server/mrconfig info orphanlist 2049
```

Display information about the orphans of a container with an identifier of 2049 on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info orphanlist 2049
```

mrconfig info replication

The `mrconfig info replication` command displays information about container replication. See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info replication
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660

Examples

Display information about container replication on a local node

```
/opt/mapr/server/mrconfig info replication
```

Display information about container replication on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info replication
```

mrconfig info slabs

The `mrconfig info slabs` command displays a report about memory usage.

This report is sometimes used for troubleshooting by HPE customer support and is typically not used by customers.

See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info slabs
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660

Examples

Display information about memory usage on a local node

```
/opt/mapr/server/mrconfig info slabs
```

Display information about memory usage on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info slabs
```

mrconfig info threads

The `mrconfig info threads` command displays information about threads running on file system. See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info threads
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660

Examples

Display information about Data Fabric filesystem threads on a local node

```
/opt/mapr/server/mrconfig info threads
```

Display information about Data Fabric filesystem threads on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info threads
```

mrconfig info volume snapshot

The `mrconfig info volume snapshot` command displays information about volume snapshots.

Snapshot and this command require an upgrade to a HPE Data Fabric Enterprise Edition license if you don't already have it. See [mrconfig](#) for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig [-h <host>] [-p <port>] info volume snapshot
<volName> <snapName>

    <volName>
    <snapName>
```

Parameters

Parameter	Description
-h	host IP address; default 127.0.0.1
-p	The file system port; default 5660
volName	The name of the volume
snapName	The name of the snapshot

Tips:

To find volume and snapshot names:

- Navigate to the **Volume** view and the **Snapshot** view respectively in the Data Fabric Control System, or
- Execute the `maprcli volume snapshot list` command, which creates a report that displays volume names and snapshot names.

Examples

Display information about snapshot "snap-2012-01-01" of volume "myVolume" on a local node

```
/opt/mapr/server/mrconfig info volume snapshot myVolume snap-2012-01-01
```

Display information about snapshot "snap-2012-01-01" of volume "myVolume" on a remote node with an IP address of xx.xx.xx.xx

```
/opt/mapr/server/mrconfig -h xx.xx.xx.xx info volume snapshot myVolume
snap-2012-01-01
```

mrconfig info volume mastgateway

The `mrconfig info volume mastgateway` command displays the volume assignment information. This command must be run on a CLDB node.

See [mrconfig](#) on page 3291 for instructions about running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig info volume mastgateway [<volName>]
```

Parameters

Parameter	Description
volName	The name of the volume for which to retrieve the volume assignment information.

Examples

Display the volume assignment information:

```
# ./mrconfig -h 10.20.30.400 info volume mastgateway
Num volumes : 4

Volume : vol2 ( 153675213 )
State: ASSIGNED
Curr: atsq8c46.qa.lab ( 6322920922584906487 ), Active: Yes
Prop: **No Gw** ( -1 ), Active: No
Assign Suspended : No

Volume : vol1 ( 45553484 )
State: ASSIGNED
Curr: atsq8c46.qa.lab ( 6322920922584906487 ), Active: Yes
Prop: **No Gw** ( -1 ), Active: No
Assign Suspended : No

Volume : vol4 ( 97789611 )
State: ASSIGNED
Curr: atsq8c46.qa.lab ( 6322920922584906487 ), Active: Yes
Prop: **No Gw** ( -1 ), Active: No
Assign Suspended : No

Volume : vol3 ( 23539482 )
State: ASSIGNED
Curr: atsq8c46.qa.lab ( 6322920922584906487 ), Active: Yes
Prop: **No Gw** ( -1 ), Active: No
Assign Suspended : No
```

mrconfig mastgateway

This section describes the `mrconfig mastgateway` commands that allow you to test PUT, GET, and DELETE operations on the corresponding tier.

mastgateway ecgstats

Returns the list of containers under rebuild from CGManager.

Syntax

WARNING: The `mrconfig` command must be run under the supervision of HPE support.

```
mrconfig mastgateway ecgstats <cgid>
```

Parameters

Parameter	Description
cgid	The Container Gateway ID from which the containers under rebuild must be retrieved.

Output

For a given EC scheme k+m, where k is number of data stripelets and m is number of parity stripelets, the output fields are as follows:

ContainerGroupId	Container Gateway (CG) ID from which the containers under rebuild are retrieved.
numStripes	Total number of valid (v), invalid (i), and pre-allocated (pa) stripes minus the number of deleted (d) stripes. Calculated as: (v+i+pa) - d.
numValidStripes	Stripe that have at least k number of full stripelets.
numStripesToRecover	Stripes that have unelected stripelet(s), or number of full or partial stripelets less than k.
numStripesInRebuild	Stripes that are being rebuilt.
numDegradedStripes[0]	Stripes that can have no more failures.
numDegradedStripes[1]	Stripes that can suffer at most m-1 failures.
numMaxStripes	Maximum number of stripes in the CG. This value is calculated from the container size and the stripe size.
numActivePreallocStripes	Number of actual pre-allocated stripes.
numActiveAllocStripes	Number of allocated stripes in the CG. This value is taken from the pre-allocated list.
numActiveDeleteStripes	Number of valid stripes for which stripelets have been deleted by an operation such as compaction, for example.
numPreallocStripes	Maximum number of stripes that can be pre-allocated. Default Value: 32
activeBitmap	Number of containers that are up in the CG.
pendingUpBitmap	Number of containers that are in the process of being brought up in the CG.
containersInRebuild	Number of containers that are being rebuilt.

Example

```
# /opt/mapr/server/mrconfig mastgateway ecgstats 2351

MASTGateway service is alive on 127.0.0.1:8660
ContainerGroupId : 2351
numStripes : 189
numValidStripes : 173
numStripesToRecover : 0
numStripesInRebuild : 64
numDegradedStripes[0]: 0
numDegradedStripes[1]: 120
numMaxStripes : 8192
```

```

numActivePreallocStripes : 0
numActiveAllocStripes : 0
numActiveDeleteStripes : 0
numPreallocStripes : 32
activeBitmap : 1f
pendingUpBitmap : 0
containersInRebuild : 2353

```

Related reference

[dump ecginfo](#) on page 2450

Indicates whether rebuild is in progress for a container from CLDB.

mastgateway infomem

Returns memory information on the MAST Gateway node.

Syntax

CAUTION: The mrconfig command must be run under the supervision of HPE support.

```
mrconfig mastgateway infomem
```

Parameters

None

Output

Name	The name of the memory pool in the gateway. Each pool has a number of memory objects (not S3 objects) that are used by the MAST Gateway as needed.
Max Free	The maximum number of objects from this pool that can be free.
Active	The number of memory objects from this pool that are allocated and used by the MAST Gateway.
Avail	The number of memory objects that are free, and can be reused when needed.
Obj Size	The size of the object.
Num Objs	The number of objects on the tier.
TierType	The type of tier. Value can be: <ul style="list-style-type: none"> • Cold • Ec

Example

```

# /opt/mapr/server/mrconfig mastgateway infomem
MASTGw mem info on 127.0.0.1:8660
  Name           Max Free  Active    Avail    Obj Size
  WriteFragBufsS3      128      0        0      8388616
  FullReadFragBufs     64      0        0      8388616
  FragReadFragBufs    1024      0        0     1048576

  Name           Num Objs    Obj Size    TierType
ColdTiering, Recall Frag      0      8388608      Cold

```

ColdTiering, Recall Full	0	8388608	Cold
ColdTiering, Offload	0	8388608	Cold
EraseCoding, Recall Frag	0	25165824	Ec
EraseCoding, Recall Full	0	25165824	Ec
EraseCoding, Offload	0	25165824	Ec

mastgateway infothreads
Returns information on the threads processing the offload or recall operation.

Syntax

 **CAUTION:** The mrconfig command must be run under the supervision of HPE support.

```
mrconfig mastgateway infothreads
```

Parameters

None

Output

The command returns the following if it is run during an ongoing offload or recall operation.

threadId	The ID of the thread processing the operation.
volId	The ID of the volume being offloaded.
cid	The ID of the container associated with the volume.
cgid	The gateway ID of the container associated with the volume.
op	The operation being processed. Value can be: <ul style="list-style-type: none">• VolumeOffload• VolumeRecall

Example

Retrieve information on the threads processing the offload:

```
~# /opt/mapr/server/mrconfig -p 8660 mastgateway infothreads
InfoThreads on 127.0.0.1:8660
threadId: 0
volId: 23315726
cid: 2128
cgid: 2078
op: VolumeOffload

threadId: 1
volId: 23315726
cid: 2130
cgid: 2054
op: VolumeOffload

threadId: 10
volId: 23315726
cid: 2127
cgid: 2096
op: VolumeOffload
```

```
threadId: 11
volId: 23315726
cid: 2129
cgid: 2082
op: VolumeOffload
```

```
threadId: 12
volId: 23315726
cid: 2131
cgid: 2091
op: VolumeOffload
```

mastgateway refreshvolassignment

Triggers CLDB to re-assign specified volume to the least utilized MAST Gateway to rebalance tiering operations.

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

This can be used when new MAST Gateways are added or when MAST Gateways are removed from the cluster.

NOTE: You must run this command once for each volume to reassign. Run this command for all volumes if MAST Gateway is either newly added to the cluster or permanently removed from the cluster.

Syntax

```
mrconfig mastgateway refreshvolassignment <volname>
```

Parameters

Parameter	Description
volname	The name of the volume to reassign.

Result

If the volume is successfully re-assigned, a success message (similar to the one shown in the [Examples](#) on page 3323 below) is printed on the console where the command was triggered.

In case of an error, the volume might or might not be assigned to the newly added MAST Gateway. However, the volume would either continue to be assigned to the same MAST Gateway or would be assigned to a different gateway. You can re-run the command in case of a failure.

Examples

Refresh the assignment of the containers associated with volume named vold23:

```
# /opt/mapr/server/mrconfig mastgateway refreshvolassignment vold23
volume assignment refreshed successfully.
```

mastgateway resumevolume

Resume tiering activities and allow reads and writes on the volume data.

Syntax**CAUTION:** The `mrconfig` command must be run under the supervision of HPE support.

```
mrconfig mastgateway resumevolume <volname> [forceresume] [forcereset]
```

Parameters

Parameter	Description
volname	The name of the volume.
forceresume	This parameter is internal-only.
forcereset	This parameter is internal-only.

Examples

```
# /opt/mapr/server/mrconfig mastgateway resumevolume voltSECNEW9_3
2018-08-06 02:47:14,8585 ERROR Global mrconfig.cc:2120 ResumeVolume succeed
for volume : voltSECNEW9_3
```

mastgateway suspendvolume

Revoke and suspend a volume assigned to a MAST Gateway.

**CAUTION:** The `mrconfig` command must be run under the supervision of HPE support.

When the command is run:

1. The volume assignment to the MAST Gateway is revoked.
2. All tiering activities and client reads and overwrites on the volume are suspended.
3. The volume is reassigned to another MAST Gateway.

You must manually run the [mastgateway resumevolume](#) on page 3323 command to resume tiering activities, including reads and overwrites, on the volume data.

Syntax

```
/opt/mapr/server/mrconfig mastgateway suspendvolume <volname>
[ignoreflusherr deletcpfiles]
```

Parameters

Parameter	Description
volname	The name of the volume to reassign.
ignoreflusherr	This parameter is internal-only.
deletcpfiles	This parameter is internal-only.

Examples

Revoke volume assignment to MAST Gateway and suspend tiering activities on the volume:

```
# /opt/mapr/server/mrconfig mastgateway suspendvolume voltSECNEW9_3
2018-08-06 02:38:15,9360 INFO Global mrconfig.cc:2085 SuspendVolume :
success for volume voltSECNEW9_3
```

mastgateway tierget

Test retrieving an object from the storage tier.

Syntax

CAUTION: The mrconfig command must be run under the supervision of HPE support.

```
mrconfig mastgateway tierget
    <tierName>
    <objectID>
    <isSecure>
    [ <objectSize> ]
```

Parameters

Parameter	Description
isSecure	Specifies whether to use HTTPS or HTTP protocol. Value can be one of the following: <ul style="list-style-type: none"> true - for HTTPS protocol false - for HTTP protocol
objectID	The ID of the object to get from the storage tier. The ID must be the same ID (in string format) specified when offloading the object (using tierput command).
objectSize	The size of the object to get from the storage tier. The default value is 64KB.
tierName	The name of the storage tier. If necessary, run the tier list on page 2873 command to retrieve the names of the tiers.

Example

Retrieve the object named sampleamazonobj of size 20971520 on the tier named amazonTier:

```
# /opt/mapr/server/mrconfig mastgateway tierget amazonTier sampleamazonobj
true 20971520
time take for the operation: 8.748000 seconds
tierget successful
```

mastgateway tierdelete

Test deleting an object on the storage tier.

Syntax**CAUTION:** The `mrconfig` command must be run under the supervision of HPE support.

```
mrconfig mastgateway tierdelete
    <tierName>
    <objectID>
    <isSecure>
```

Parameters

Parameter	Description
isSecure	Specifies whether to use HTTPS or HTTP protocol. Value can be one of the following: <ul style="list-style-type: none"> <code>true</code> - for HTTPS protocol <code>false</code> - for HTTP protocol
objectID	The ID of the object to get from the storage tier. The ID must be the same ID (in string format) specified when offloading the object (using <code>tierput</code> command).
tierName	The name of the storage tier. If necessary, run the tier list on page 2873 command to retrieve the names of the tiers.

Example**Delete the object named `sampleamazonobj` of size 20971520 KB in the tier named `amazonTier`:**

```
# /opt/mapr/server/mrconfig mastgateway tierdelete amazonTier
sampleamazonobj true 20971520
time take for the operation: 0.339000 seconds
tierdelete successful
```

mastgateway tierput

Test offloading an object to the storage tier.

Syntax**CAUTION:** The `mrconfig` command must be run under the supervision of HPE support.

```
mrconfig mastgateway tierput
    <tierName>
    <objectID>
    <isSecure>
    [ <objectSize> ]
```

Parameters

Parameter	Description
isSecure	Specifies whether to use HTTPS or HTTP protocol. Value can be one of the following: <ul style="list-style-type: none"> • true - for HTTPS protocol • false - for HTTP protocol
objectID	The ID of the object to put on the storage tier. Value must be a string.
objectSize	The size of the object to put on the storage tier. The default value is 64KB.
tierName	The name of the storage tier. If necessary, run the tier list on page 2873 command to retrieve the names of the tiers.

Example

Test offload of an object, whose ID is sampleamazonobj and size is 20971520, to the tier named amazonTier:

```
# /opt/mapr/server/mrconfig mastgateway tierput amazonTier sampleamazonobj
true 20971520
time take for the operation: 4.291000 seconds
tierput successful
```

mrconfig rdma

Dumps RDMA server and connection information.

For an introduction to RDMA, see [Remote Direct Memory Access](#) on page 896.

mrconfig rdma dumpServerInfo

Displays information about the enabled RDMA servers, if any.

Syntax

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

```
mrconfig -p <RDMA port> rdma dumpServerInfo
```

Parameters

p	The optional RDMA port for which the information needs to be fetched. For example: <ul style="list-style-type: none"> • <code>mrconfig -p 5660 rdma dumpServerInfo</code> - for the first instance of the file system • <code>mrconfig -p 5661 rdma dumpServerInfo</code> - for the second instance of the file system. • <code>mrconfig -p 9998 rdma dumpServerInfo</code> - for the management RPC port of the NFS server Omitting this parameter fetches server information for the first instance of the file system.
---	--

Example

```
mrconfig rdma dumpServerInfo
  rdma server: port 5660 , epoch 1, sessionid 16, isserver True
  rdma memory: start 0x55df46d62000 size 58656284672
  id 0 ip 10.163.160.69:5660
```

[mrconfig rdma listEndPoints](#) on page 3328

Displays RDMA connection information.

mrconfig rdma listEndPoints
Displays RDMA connection information.

Syntax

 **CAUTION:** The mrconfig command must be run under the supervision of HPE support.

```
mrconfig -p <RDMA port> rdma listEndPoints
```

Parameters

p	<p>The optional RDMA port for which the connection information needs to be fetched. For example:</p> <ul style="list-style-type: none">• mrconfig -p 5660 rdma listEndPoints -for the first instance of the file system• mrconfig -p 5661 rdma listEndPoints -for the second instance of the file system• mrconfig -p 9998 rdma listEndPoints -for the management RPC port of the NFS server <p>Omitting this parameter fetches connection information for the first instance of the file system.</p>
---	---

Example

```
mrconfig rdma listEndPoints
  binding 0x55a003056400 conn 0x55a003056470 endpoint 0x55a00320a000

mrconfig sp

The `mrconfig sp` commands create and control storage pools.

WARNING: The `mrconfig` command must be run under the supervision of HPE support.

Storage pools are created on [disk groups](#), so disk groups must be [created](#) before storage pools can be created.

file system reads and writes data (and metadata) to and from logical storage units called volumes. Volumes store data in containers in storage pools.

Initially storage pools don't have any containers, the containers are automatically created for a volume as needed. When a container is created it is assigned a container identifier (cid).

Storage pools aren't associated with any particular volume – storage pools may hold containers for multiple volumes. Large files may be distributed across multiple containers, and therefore across multiple storage pools. Data replication happens at the container level.

Data cannot be written directly to containers, a volume is required.

You can create volumes in one of two ways:

- Click the **Create Volume** button in the **Data > Volumes** page in the MapR Control System, or
- Execute the `maprccli volume create` command.

See [mrconfig](#) for instructions about running `mrconfig` commands.

mrconfig sp help

The `mrconfig sp help` command displays the online help for storage pool commands.

See [mrconfig](#) for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp help
```

Examples

Display the online help for storage pools on a local node

```
/opt/mapr/server/mrconfig sp help
```

mrconfig sp list

Displays information about configured storage pools.

The `mrconfig sp list` command displays information about storage pools including the name, size, free space and path of each [storage pool](#), whether or not each [storage pool](#) is online or offline, and the total number of [storage pools](#). See [mrconfig](#) for instructions on running `mrconfig` commands.

Syntax

```
/opt/mapr/server/mrconfig sp list [-v] [sp path]
```

Parameters

Parameter	Description
path	The device path of the storage pool . If you do not specify the path, information about all storage pools is displayed. If you specify the path, only information about the specified storage pool is displayed; example /dev/sdc
-v	Print storage pool and cluster GUID information including whether or not the storage pool is enabled for data-at-rest encryption (DARE), and service pool log (journal) size.

Examples

Display information about all [storage pools](#) on a local node:

```
/opt/mapr/server/mrconfig sp list
```

Display information about a [storage pool](#) with a path /dev/sdc on a local node:

```
/opt/mapr/server/mrconfig sp list /dev/sdc
```

Display [storage pool](#) information including whether or not the [storage pool](#) is DARE-enabled:

```
# /opt/mapr/server/mrconfig sp list -v
ListSPs resp: status 0:2
No. of SPs (2), totalsize 3518339 MB, totalfree 691937 MB

SP 0: name SP1, Online, size 1761217 MB, free 377127 MB, path /dev/
sdb, log 200 MB, port 5660, guid 9dd586829e179476005b0ce23f0dae3c,
clusterUuid -7600986066553737256-4524271553806028052, disks /dev/sdb /dev/
sdd, dare 1
SP 1: name SP2, Online, size 1757121 MB, free 314809 MB, path /dev/
sde, log 200 MB, port 5660, guid daa5916af8909118005b0ce2430d6d54,
clusterUuid -7600986066553737256-4524271553806028052, disks /dev/sde /dev/
sdf, dare 1
```

Display [storage pool](#) information including the labels associated with the [storage pool](#):

```
# /opt/mapr/server/mrconfig sp list -v
ListSPs resp: status 0:1
No. of SPs (1), totalsize 294465 MB, totalfree 293940 MB
SP 0: name SP1, Online, size 294465 MB, free 293940 MB, path /dev/
sdb, log 200 MB, port 5660, guid 7d71f3739cd771cd005f910d2803b865,
clusterUuid -6879590211771954706-6360117451062264043,

disks /dev/sdb /dev/sdc /dev/sdd, dare 1, label default:0
```

mrconfig sp load

The `mrconfig sp load` command loads all of the disks associated with a storage pool.

See [mrconfig](#) for instructions on running `mrconfig` commands.

Syntax**CAUTION:** The `mrconfig` command must be run under the supervision of HPE support.

```
mrconfig sp load <sp name>
```

Parameters

Parameter	Description
sp name	The name of the storage pool; example SP2

Tips:

- Use the `mrconfig sp list` command to see storage pool names (examples SP1, SP2) and the device paths of the storage pools (example `/dev/sdc`).
- Use the `mrconfig disk list` command to see storage pool names (examples SP1, SP2), the device paths of the storage pools (example `/dev/sdc`), and the disks associated with each storage pool (examples `/dev/sdc`, `/dev/sdd`, `/dev/sde`).

Examples

Load the disks associated with the storage pool named SP2 on the local node

```
/opt/mapr/server/mrconfig sp load SP2
```

```
mrconfig sp make
```

**CAUTION:** The `mrconfig` command must be run under the supervision of HPE support.The `mrconfig sp make` command creates a storage pool on a concat disk group.**WARNING: Creating a Storage Pool Causes Data Loss**

Creating a storage pool on a disk group destroys the data on the disks in the disk group, so be sure that all data on the disks in the disk group is backed up and replicated before creating a storage pool.

See `mrconfig` for instructions on running `mrconfig` commands.**Syntax**

```
mrconfig sp make <dg path>
[ -P <yes/no> ]
[ -l <LogSize> ]
[ -s <deviceSize> ]
[ -L <Lable> ]
[ -F ]
[ -I <cid> ]
<dg path>
```

Parameters

Parameter	Description
-P	Primary partition or not; yes/no

Parameter	Description
-l	Log size in number of blocks; Note that this is a lowercase letter "l" (ell), not the number "1".
-s	Disk size in GB
-L	Label for this storage pool
-F	Force the overwrite of any existing storage pool
-i	Initialize the storage pool with one container with the specified container identifier, one directory, and one file. Note that this is an uppercase letter "I" (eye), not the letter "l" (ell) or the number "1".
dg path	The device path of the disk group; example /dev/sdc

Examples

Create a storage pool on a disk group with a path of /dev/sdc on a local node

```
/opt/mapr/server/mrconfig sp make /dev/sdc
```

Creating a Storage Pool Using mrconfig

About this task

CAUTION: The mrconfig command must be run under the supervision of HPE support.

To create a storage pool using mrconfig:

Procedure

1. Assume the disks /dev/sdb, /dev/sdc, and /dev/sdd are available; initialize them with mrconfig disk init:

```
/opt/mapr/server/mrconfig disk init /dev/sdb
/opt/mapr/server/mrconfig disk init /dev/sdc
/opt/mapr/server/mrconfig disk init /dev/sdd
```

2. Create a disk group with mrconfig dg create:

```
/opt/mapr/server/mrconfig dg create raid0 -d
128 /dev/sdb /dev/sdc /dev/sdd
```

3. Create a concatenated disk group with mrconfig dg create concat by specifying the primary drive.

```
/opt/mapr/server/mrconfig dg create concat /dev/sdb
```

4. At this point, you can use mrconfig dg list to see the layout of the disk group, and which disk is the primary disk. The primary disk can be used in other commands to refer to the disk group as a whole. Example:

```
/opt/mapr/server/mrconfig dg list
```

- From the disk group, create a storage pool with `mrconfig sp make`:

```
/opt/mapr/server/mrconfig sp make /dev/sdb
```

mrconfig sp offline

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig sp offline` command takes a loaded storage pool offline. When a storage pool is offline it remains loaded into memory but it is not available to Data Fabric file system for reads and writes.

The main use of the `mrconfig sp offline` command is to take a storage pool offline so the `fsck` (file system check) command can be run on one or more disks or storage pools if there are lost or corrupt containers, directories, tables, files, filelets, or blocks.

After running `fsck` the storage pool is brought back online with the `mrconfig sp online` command, and then typically the `gfsck` (global file system check) command would be run on the affected cluster, volumes, or snapshots.

See [mrconfig](#) for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp offline <sp path>
```

Parameters

Parameter	Description
sp path	The device path of the storage pool; example <code>/dev/sdc</code>

Examples

Offline a loaded storage pool with a path of `/dev/sdc` on localhost

```
/opt/mapr/server/mrconfig sp offline /dev/sdc
```

`mrconfig sp offline all`

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig sp offline all` command takes all of a node's loaded storage pools offline. When a storage pool is offline it remains loaded into memory, but it is not available to Data Fabric file system for reads and writes.

The main use of the `mrconfig sp offline all` command is to take all storage pools on a node offline so the `fsck` (file system check) command can be run on disks or storage pools if there are lost or corrupt containers, directories, tables, files, filelets, or blocks.

After running `fsck` the storage pools are brought back online with the `mrconfig sp online` command, and then typically the `gfsck` (global file system check) command would be run on the affected cluster, volumes, or snapshots.

See [mrconfig](#) for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp offline all
```

Examples

Offline all storage pools on a local node

```
/opt/mapr/server/mrconfig sp offline all
```

mrconfig sp online

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig sp online` command makes an offline storage pool online.

When a storage pool is taken offline with the `mrconfig sp offline` command, the storage pool is not available for reads and writes. Typically this is done so the `fsck` (filesystem check) command can be run to check for or repair filesystem inconsistencies.

After the storage pool is put back online with the `mrconfig sp online` command, the storage pool is once again available for reads and writes, and the `gfsck` (global filesystem check) command can be run on the affected cluster, volumes or snapshots.

See [mrconfig](#) for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp online <sp path>
```

Parameters

Parameter	Description
sp path	The device path of the storage pool; example <code>/dev/sdc</code>

Examples

Online a storage pool with a path of `/dev/sdc` on a local node

```
/opt/mapr/server/mrconfig sp online /dev/sdc
```

mrconfig sp refresh

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig sp refresh` command reloads the `disktab` file and adds any new disks to file system.

See [mrconfig](#) for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp refresh
```

Examples

Refresh the storage pools on the local node

```
/opt/mapr/server/mrconfig sp refresh
```

mrconfig sp rename

Use the `mrconfig sp rename` command to rename a storage pool on the node where you run the command.

See [mrconfig](#) for instructions on running `mrconfig` commands.

RESTRICTION:

You cannot use the `mrconfig sp rename` command to move a storage disk from one storage pool to another storage pool.

Syntax

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

```
mrconfig sp rename [-n <SPname>] <path>
```

Parameters

Parameter	Description
SPname	The new name for the storage pool. This is an optional parameter. If SPname is not specified, Data Fabric auto-assigns a new name to the storage pool.
path	The storage disk device path for the storage pool. This is a mandatory parameter.

ATTENTION: Use the `mrconfig sp rename` command to rename a storage pool on the node where you run the command. Before you run the command, ensure that the `mf's` service and the `warden` service are running on the node that hosts the storage pool.

The storage pool must be offline to be able to rename the storage pool. To take the storage pool offline, run the [mrconfig sp offline](#) on page 3333 command to take the storage pool offline.

Commands to use in conjunction with `mrconfig sp rename`

- Use the [mrconfig sp list](#) command to see storage pool names (examples SP1, SP2) and the storage disk device paths of the storage pools (example `/dev/sdc`).
- Use the [mrconfig disk list](#) command to see storage pool names (examples SP1, SP2), the storage disk device paths of the storage pools (example `/dev/sdc`), and the disks associated with each storage pool (examples `/dev/sdc`, `/dev/sdd`, `/dev/sde`).

Examples

Rename the storage pool on the local node that is associated with the storage disk `/dev/sdc` to SP2.

```
/opt/mapr/server/mrconfig sp rename -n SP2 /dev/sdc
```

Auto-assign a new name to the storage pool on the local node that is associated with the storage disk /dev/sdb.

```
/opt/mapr/server/mrconfig sp rename /dev/sdb
```

mrconfig sp shutdown

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig sp shutdown` command offlines all storage pools and stops the Data Fabric file system on their disks.

See [mrconfig](#) for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp shutdown
```

Examples

Offline all storage pools on the local node and stop Data Fabric file system on their disks

```
/opt/mapr/server/mrconfig sp shutdown
```

mrconfig sp unload

CAUTION: The `mrconfig` command must be run under the supervision of HPE support.

The `mrconfig sp unload` command unloads all of the disks associated with a storage pool.

See [mrconfig](#) for instructions on running `mrconfig` commands.

Syntax

```
mrconfig sp unload <sp name>
```

Parameters

Parameter	Description
sp name	The name of the storage pool; example SP2

Tips:

- Use the `mrconfig sp list` command to see storage pool names (examples SP1, SP2) and the device paths of the storage pools (example /dev/sdc).
- Use the `mrconfig disk list` command to see storage pool names (examples SP1, SP2), the device paths of the storage pools (example /dev/sdc), and the disks associated with each storage pool (examples /dev/sdc, /dev/sdd).

Examples

Unload the disks associated with the storage pool named SP2 on a local node

```
/opt/mapr/server/mrconfig sp unload SP2
```

mrconfig s3

The `mrconfig s3` commands display bucket statistics.

The [HPE Data Fabric Object Store](#) on page 609 uses buckets as the containers to store objects (be it text, movie or music files, for example).

The `mrconfig s3` commands display bucket statistics such as the account to which the bucket belongs, the time when the bucket was created, the internal ID of the bucket, the number of objects in the bucket, the size of the objects, the number of objects with compliance and legalhold enabled, and more.

See [mrconfig](#) for instructions about running `mrconfig` commands.

mrconfig s3 bucketinfo

Displays information about the bucket.

Syntax

```
mrconfig s3 bucketinfo <bucket name>
```

Parameters

Parameter	Description
bucket name	The name of the bucket; example finbucket

Example

View information for a bucket finbucket:

```
/opt/mapr/server/mrconfig s3 bucketinfo finbucket
bucketdirfid 2085.66.131352
oltFid 2085.67.131354
odtFid 2085.71.131362
f2oFid 2085.74.131368
valid 123999978
creationTime 1637640659057
accountName default
```

mrconfig s3 bucketstats

Displays comprehensive statistics about the objects inside the bucket.

Syntax

```
mrconfig s3 bucketstats <bucket name>
```

Parameters

Parameter	Description
bucket name	The name of the bucket; example finbucket

Example

View statistics for objects in a bucket finbucket:

```
/opt/mapr/server/mrconfig s3 bucketstats finbucket
oltfid 2085.67.131354
```

```

SizeHisto size >= 1099511627776 num 0

```

mrconfig s3 refreshstats

Refreshes statistics about the objects inside the bucket.

NOTE: You have to run this command as the `mapr` user whenever bucket stats are not correctly displayed, and then check the stats again.

Syntax

```
mrconfig s3 refreshstats <bucket name>
```

Parameters

Parameter	Description
bucket name	The name of the bucket; example <code>finbucket</code>

Example

Refresh statistics for objects in a bucket `finbucket`:

```

/opt/mapr/server/mrconfig s3 refreshstats finbucket
oltfid 2085.67.131354
statsVN 10
numInProgress 2

SizeHisto 68719476736 <= size < 1099511627776 num 0
SizeHisto size >= 1099511627776 num 0

```

mrdirectorystats

Prints the space usage for each directory, for a container.

The `mrdirectorystats` utility, when run for a container, prints the space usage information for all directories, starting from the root of the container. This utility is considerably faster than running `ls -R` command on the root of the container and is useful, for example, in identifying directories which need to be moved out to a different volume while trying to reduce the size of the current namespace container.

Syntax

```

/opt/mapr/server/mrdirectorystats
-c <container_id>
[ -p ]
[ -h ]

```

Parameters

Parameter	Description
c	The ID of the container.
h	Prints help for running the command.
p	Prints only parent file ID (PFid) and other information about the file IDs (fids) in the container.

Output

When you specify the `-c` option, the utility prints the following information per directory to the console:

DirFid	The directory inode number.
files	The number of regular files under the directory.
subdir	The number of sub-directories inside the directory.
others	The number of other types of files (except directories and regular files), such as device, symlinks, kvstores, tables, etc., inside the directory.
tfiles	The total number of regular files stored in the entire directory tree.
tsubdir	The total number of sub-directories stored in the entire directory tree.
tothers	The total number of other type of files stored in the entire directory tree.

cntrBlocks	The space occupied in block size (8k) by the direct blocks of the total regular files (tfiles) in the directory tree, for the current container.
fileletBlocks	A rough estimation of the sum of all the data blocks of all the filelets of regular files spread across different data containers.

NOTE: The utility also shows volume links if any volume exists in the container.

The utility prints the following if -p is specified with -c:

Inode	The inode of the file.
PFid	The parent file ID.
Type	The type of entity in the container. Value can be one of the following: <ul style="list-style-type: none"> Directory — indicates the entity is a directory. VolLink — indicates entity is a volume link. KvStore — indicates entity is KvStore.
SubType	The sub-type of the entity in the container. Value can be one of the following: <ul style="list-style-type: none"> Directory — indicates entity is directory. VolLink — indicates entity is a volume link. Table — indicates entity is a table. Entity can be table only if type is KvStore. Tabletmap — indicates entity is a tabletmap. Entity can be tabletmap only if type is KvStore. Schema — indicates entity is a schema. Entity can be schema only if type is KvStore.

Example

Retrieve the disk space usage information for a container by running the utility with the -c option:

```
# ./mrdirectorystats -c 2245
DirFid      files      subdir    others    tfiles     tsubdir    tothers
cntrBlocks  fileletBlocks
2245.16.2    5          3         3         6          4          3
0           65536
2245.39.131308 1          0         0         1          0          0
0           0
2245.40.131310 0          1         0         0          1          0
0           0
2245.41.131312 0          0         0         0          0          0
0           0
2245.45.131320 0          0         0         0          0          0
0           0
symlinks 2 fidmaps 1 tables 1 schemas 1 tabletmaps 1
```

Retrieve information about the file IDs in the container by running the utility with the -c and -p option:

```
# ./mrdirectorystats -p -c 2049
Inode :32      PFid: 2049.16.2      Type: VolLink      SubType: VolLink
Inode :33      PFid: 2049.16.2      Type: VolLink      SubType: VolLink
Inode :34      PFid: 2049.16.2      Type: Directory    SubType: Directory
Inode :35      PFid: 2049.34.131372  Type: VolLink      SubType: VolLink
Inode :36      PFid: 2049.16.2      Type: VolLink      SubType: VolLink
Inode :37      PFid: 2049.16.2      Type: VolLink      SubType: VolLink
Inode :38      PFid: 2049.16.2      Type: VolLink      SubType: VolLink
Inode :39      PFid: 2049.16.2      Type: KvStore      SubType: Table
Inode :40      PFid: 2049.16.2      Type: VolLink      SubType: VolLink
Inode :41      PFid: 2049.39.262468  Type: KvStore      SubType: Tabletmap
Inode :42      PFid: 2049.39.262468  Type: KvStore      SubType: Schema
```

mr diagnostics

Gathers node metrics.

The mr diagnostics utility [collects metrics on the node](#) on which it is run. Metrics include IO statistics, network throughput, CPU performance, memory consumption, swap space usage, disk usage, disk latency, and MFS throughput for the node.

Syntax

```
/opt/mapr/server/mrdiagnostics start (or) stop (or) restart
```

Parameters

Parameter	Description
start	Starts the utility
stop	Stops the utility
restart	Restarts the utility

Output

The mr diagnostics utility logs the collected metrics as a set of log files in the /opt/mapr/logs/stats/ directory. A sample collection is as follows:

```
ls /opt/mapr/logs/stats/
guts.m2-mapreng-vm167212.out      sar.dev.m2-mapreng-vm167212.out
gutsmfs.m2-mapreng-vm167212.out
sar.error.dev.m2-mapreng-vm167212.out
iostat.m2-mapreng-vm167212.out
topmfsparent.m2-mapreng-vm167212.out
mpstat.m2-mapreng-vm167212.out
topmfsthreads.m2-mapreng-vm167212.out
mrconfig_dbinfo.m2-mapreng-vm167212.out
top.processes.m2-mapreng-vm167212.out
mrconfig_info.m2-mapreng-vm167212.out  top.threads.m2-mapreng-vm167212.out
netstat.pan.m2-mapreng-vm167212.out    vmstat.m2-mapreng-vm167212.out
psOutput.m2-mapreng-vm167212.out
```

Configuration Parameters

The /opt/mapr/conf/mrdiagnostics.conf file contains the configuration for the mr diagnostics utility. The parameters are as follows:

stats.log.path	Path in which the output files (*.out) files are placed. The default path is /opt/mapr/logs/stats.
stats.log.interval	Frequency at which the metrics are collected. The value is in seconds. The default value is 1 second.
stats.log.size	The size at which the output files are rotated. The value is in KB. The default value is 1000000 KB (1 GB). If the total size of all the output files inside the /opt/mapr/logs/stats folder exceeds this value, the output files are compressed to a single tar file and stored in the /opt/mapr/logs folder.

mrfscmd

Returns the path to the file specified by ID (fid).

Before running the utility, ensure that the LD_LIBRARY_PATH environment variable is set for the path to the libjvm.so file. If necessary, run the following command to set the LD_LIBRARY_PATH:

```
export LD_LIBRARY_PATH=/usr/lib/jvm/java/jre/lib/amd64/server/
```

Syntax

```
/opt/mapr/server/mrfscmd fid path -fid <file-ID>
```

Parameters

Parameter	Description
fid	The ID of the file.

Output

On success, returns path to the file specified by ID (fid).
On failure, returns error.

Examples

The following examples show file path (on success) and errors returned by the utility.

```
# ./mrfscmd fid path -fid 2115.33.131412
/var/mapr/file1

# ./mrfscmd fid path -fid 2071.33.1313445
Error: Getting Path for Fid 2071.33.1313445 Failed - Stale file handle (116).

# ./mrfscmd fid path -fid 2071.33.
Error: Invalid Fid 2071.33.
```

stufuse

Simulates a FUSE mount point to determine its read and write performance.

Simulates a FUSE mount point and creates a large test file named hello. Use the dd command to print the maximum read and write performance of this mount point. The values give you a fair idea of the performance to expect from a Data Fabric POSIX FUSE client. For more information, see [HPE Data Fabric FUSE-Based POSIX Client](#) on page 1874

NOTE: Use an empty directory for the test, as the contents of this directory are emptied during the test. The files that are created during the test are not present after the test.

ATTENTION: Export the path to `libfuse.so` before running this command. Run:

```
export LD_LIBRARY_PATH="/opt/mapr/lib"
```

Syntax

```
/opt/mapr/bin/stubfuse <mountpoint> [<options>] [-h|--help]
```

Parameters

Parameter	Description
-h --help	Prints syntax and all supported options.
mountpoint	The simulated FUSE mount point. This parameter is required.
options	The options that can be specified with the command. Use -h or --help to retrieve the list of supported options.

Example

Retrieve the read and write performance for the mount point, `/tmp/egmnt`:

- For a write test: `dd if=/dev/zero of=/tmp/egmnt/hello count=100k bs=128k oflag=direct`

NOTE: The name of the output file has to be `hello`. Else, the command will fail.

- For a read test: `dd if=/tmp/egmnt/hello of=/dev/null count=100k bs=128k`

NOTE: The name of the input file has to be `hello`. Else, the command will fail.

The output will look similar to the following results:

```
100+0 records in
100+0 records out
5120 bytes (5.1 kB) copied, 0.000233249 s, 22.0 MB/s
```

update_insights.sh

Utility to manage Insight service related Iceberg tables.

The `update_insights.sh` file is a utility to manage the Insight service-related Iceberg Tables. These Iceberg tables are designed to store the audit records generated by Data Fabric in a more structured manner.

The `update_insights.sh` utility is available as a part of `mapr-insight` package.

The insight-related Iceberg tables are stored on Data Fabric. The tables use the Iceberg Catalog as Hive via the [Hive Metastore](#) service, which must be configured with RDBMS for production or could use the default Derby DB for trial purposes.

Insight related Iceberg tables are placed in the default namespace of Hive Metastore.

Prerequisites

- To be able to manage Insight related Iceberg tables, you must have the Hive Meta store service running on cluster (installable via `mapr-hivemetastore` package. The package is downloadable from the site that hosts the HPE Data Fabric packages).

NOTE: The `update_insights.sh` utility connects to Hive metastore using the thrift protocol(`thrift://localhost:9083`).

- Auditing must be enabled on the cluster or fabric and audit logs must be available before running the `update_insights.sh` utility.

Steps to configure Data Fabric before running the `update_insights.sh` utility

1. Install a basic Data Fabric cluster with `mapr-insight` package.
2. Once the cluster is up and running, install the `mapr-hivemetastore` package from EEP and configure `mapr-hivemetastore` onto the cluster/fabric.
3. Run `update_insights.sh` with it's options to manage the insight related Iceberg Tables

TIP: If you wish to add the MFS audit logs to Iceberg tables, Run the `expandaudit` utility on MFS audit records before updating Iceberg on the audit logs (There can be different FIDs that belong to the same file. Running `expandaudit` ensures that the filename is the same for different audit log entries that refer to different fids of a given file. The `expandaudit` utility makes the audit log contents more user-friendly by replacing ids with names).

Audit Log location

The `update_insights.sh` utility requires the audit log file location.

The following table lists the audit logs along with their respective locations.

Audit Log File	Location
MFS audit log	<code>/var/mapr/local/<hostname>/audit/5660/FS-Audit*</code> NOTE: The above statement denotes the absolute file path for file names beginning with FS-Audit
S3 audit log	<code>/var/mapr/local/mapr.s3.audit/<hostname></code>
CLDB audit log	<code>/opt/mapr/logs/cldbaudit.log</code>
Authentication audit log	<code>/opt/mapr/logs/authaudit.log</code>

Syntax

To view the usage help for `update_insights.sh`, change directory to `/opt/mapr/server/tools` and run the script with the `--help` argument.

```
cd /opt/mapr/server/tools
$ ./update_insights.sh
```

Following is the usage help.

```
usage: update_insights:
-a, --action <arg> {add|drop|print|count}
```

```

-b,--brief Brief snapshot listing.
-d,--delete-files Delete files when expiring snapshot
-da,--delete-added-files Whene expiring snapshot, delete files that were
added when snapshot was created
-e,--endline <arg> End line number to add from audit log file to insights,
default is EOF
-es,--expire-snap <arg> Expire snapshot with given snap-id
-et,--expire-ts <arg> Expire snapshots older than given ms timestamp
-f,--auditfile <arg> Path to Audit log file
-fpc,--fidPathDBCheck <arg> retrieve give fidPath entry
-fps,--fidPathDBScan dump the fidPathDB
-l,--list-snaps List snapshots
-lo,--list-orphans List orphan metadata files (does not handle data files)
-n,--table-name <arg> Use the given table, rather than the default for the
component
-ps,--print-schema Print schema
-s,--startline <arg> Start line number to add from audit log file to
insights, default is 1. Line numbers start at 1.
-t,--type <arg> {mfs|auth|cldb|s3server} component
-tm,--trial-mode Choose tables for trial mode.
-tn,--tail-n <arg> Number of records to be displayed from the last.
-v,--verbose Verbose snapshot listing.

```

TIP: If values for startline and endline are not specified while running `update_insights.sh`, the specified operation such as add, print is performed on the entire content of the audit log in question.

Option	Description
action	Denotes the action to perform on the audit log. Action can have the value add, drop, print count. Use the value add to add the specified audit file to Iceberg. A new file is added as a new snapshot to Iceberg. Use the value drop to drop or remove the Iceberg table. Use the value print to print the Iceberg table contents. Use the value count to count the number of rows in the Iceberg table. Must be used with the mandatory type option.
brief	Used, along with list-snaps option, to obtain brief list of Iceberg snapshots for the specified type of Iceberg table. Must be used with the mandatory type option.
delete-files	Used to delete data files associated with Iceberg snapshot, when the snapshot is expired. Used along with expire-snap or expire-ts option.
delete-added-files	Used to delete data files added in an Iceberg snapshot, when the snapshot is expired. Used along with expire-snap or expire-ts option.
endline	Used along with the action option of add (end line number to add audit log to specified type of Iceberg table) or print (end record number to have console output of records present in the specified type of Iceberg table). The default value is EOF. Must be used with the mandatory type option.
expire-snap	Used to expire Iceberg snapshot for the specified type of Iceberg table. Takes snapshot ID as parameter. Must be used with the mandatory type option.
expire-ts	Used to expire Iceberg snapshots that are older than the specified timestamp for the specified type of Iceberg table. The timestamp is Epoch Time in milliseconds. Specify a timestamp as an argument for this option. Must be used with the mandatory type option.

Option	Description
auditfile	The absolute path of the audit file to copy to Iceberg. For the add action, the auditfile is a required field. For the drop and print actions, the value is not required. Must be used with the mandatory type option.  IMPORTANT: If the audit file to add is on a local volume, you must mount the file system before running the utility, and then, provide the absolute path.
list-snaps	Used to list all snapshots for the specified type of Iceberg table. Must be used with the mandatory type option.
list-orphans	Used to parameter to list all orphan Iceberg metadata files that do not point to a Iceberg data file or snapshot, for the specified type of Iceberg table. Must be used with the mandatory type option.
table-name	Used to specify a custom Iceberg table name, else the type name will be used for Iceberg table. Must be used with the mandatory type option.
startline	used along with the action option of add (start line number to add audit log to specified type of Iceberg table) or print (start record number to have console output of records present in the specified type of Iceberg table). The default value is 1. Must be used with the mandatory type option.
type	type is a mandatory field which needs to used along with other options. The type of audit log file to add to, drop from or print to Iceberg tables. Type can accept the value, mfs, auth, cldb or s3server. Use the value, mfs for mfs audit log, auth for authentication log, cldb for cldb log and s3server for s3 server log. Operation on only a single audit log/component can be performed at a given time. Must be used with the mandatory type option.
tail-n	Used to display the last n records present in the Iceberg table. Must be used with the mandatory type option and action option. Must not be used with startline or endline options.
verbose	Used to get more detailed output when used along with options like list-snaps and list-orphan metadata files for the specified type of Iceberg table. verbose cannot be used in combination with brief option. Must be used with the mandatory type option.

Examples

Add cldb audit log to the Iceberg table.

```
#/opt/mapr/server/tools/update_insights.sh -t cldb -a add -f /opt/mapr/logs/
cldbaudit.log.json
WARNING: An illegal reflective access operation has occurred
WARNING: Illegal reflective access by com.mapr.fs.ShimLoader (file:/opt/

See [Configuring Data Fabric to Track User Behavior](#) on page 2040 for more information about user behavior tracking configuration in Data Fabric.

Configuration Files

This section contains reference information about various configuration files.

Configuration File Permissions

Files located in /opt/mapr/hadoop-2.x.x/etc/hadoop are owned by the root user account. To edit these files, you must be logged in as root user.

Automatic Rolloff of Old Configuration Files

Whenever you run configure.sh, the current warden.conf, mapr-clusters.conf, hibernate.cfg.xml, and db.conf configuration files are saved with the current timestamp appended to the name. They are saved to the following directory:

```
/opt/mapr/conf/conf.old
```

These configuration files are saved for backup purposes.

cldb.conf

Contains the configuration for CLDB nodes.

The file /opt/mapr/conf/cldb.conf specifies the configuration parameters for the CLDB nodes and the cluster topology.

cldb.containers.cache.entries

Default Value: 1000000

Description: The maximum number of read/write containers available in the CLDB cache.

cldb.default.topologyfileservers

Default Value: /data

Description: The default topology for newly-created volumes.

cldb.detect.dup.hostid.enabled

Default Value: false

Description: When true, CLDB disables all nodes with duplicate hostid, including new nodes that try to register with duplicate hostid and the existing node. Alarm NODE_ALARM_DUPLICATE_HOSTID is raised. This case requires administrator intervention to correct the hostid confusion. If duplicate hostid occurs on nodes running CLDB, the cluster may fail to start. Therefore, the alarm is not raised, but the cldb.log file in /opt/mapr/logs/ contains an error message.

cldb.enable.memory.tracker

Default Value: false

Description: Utility that monitors CLDB for memory usage and deadlocks. If true, memory allocations in CLDB are tracked. If memory usage of CLDB goes above certain limits, the utility generates core and shuts down the CLDB. Memory limit is configured as:

```
Xmx+non heap memory
constant(default:3072MB)
```

You can change the non-heap memory usage by setting `cldb.memory.max.nonheap.mb` to any custom value.

If CLDB memory usage goes beyond 130% of this limit, the utility dumps and shuts down CLDB. The default value is `false`.

`cldb.memory.mirror.factor`

Default Value: 70

Description: The parameter represents the percentage of CLDB memory that has been allocated for mirroring. The value for this parameter can be set using the [config save](#) on page 2394 command. Check out the example in the `config save` command for details on setting the value of the `cldb.memory.mirror.factor` parameter. For example, if you wish to allocate 50% of the total CLDB memory for the mirroring operation, specify the value of the `cldb.memory.mirror.factor` parameter as 50, while using the [config save](#) on page 2394 command to set the value.

`cldb.ignore.posix.only.hb.alarm`

Default Value: 1

Description: By default, this parameter is set to 1 to consider all nodes except edge nodes (nodes that have only POSIX clients and loopback NFS installed) for the [No Heartbeat alarm](#).

Set this parameter to 0 to include both edge as well as cluster nodes for the [No Heartbeat alarm](#).

NOTE: The edge nodes that went down before changing this parameter are not visible in alarms. However, edge nodes that go down after changing this parameter to 0 will be visible in alarms.

See the `-nfsnodes` option of the [node list](#) on page 2570 command to view edge nodes.

`cldb.ignore.stale.zk`

Default Value: `false`

Description: When this setting is `true`, the CLDB ignores the ZooKeeper's information regarding the most recent copy of CLDB data. Change this setting to `true` when the ZooKeeper information is stale. Restart the CLDB with this setting. After the CLDB starts, change the setting back to `false` then restart the CLDB again.

Only change this setting on CLDB nodes that are known to have the most recent copy of the CLDB data. Shut down all CLDB processes before changing this variable.

`cldb.jmxremote.port`

Default Value: 7220

Description: The CLDB JMX remote port

`cldb.max.security.policies`

Default Value: 10000

Description: Defines the maximum number of configured security policies. To prevent users from arbitrarily creating numerous security policies and draining CLDB performance, the maximum number of security policies is limited to 10000 by default.

`cldb.min.fileservers`

Default Value: 1

cldb.numthreads	<p><i>Description:</i> Number of file servers that must register with the CLDB before the root volume is created.</p> <p><i>Default Value:</i> 10</p> <p><i>Description:</i> The number of threads reserved for use by the CLDB.</p>
cldb.pbs.global.master	<p><i>Default Value:</i> 0</p> <p><i>Description:</i> Indicates the global primary cluster for the global namespace. Only the global primary security policy cluster can create/modify security policies. All other secondary security policy clusters can only view or import security policies.</p>
cldb.port	<p><i>Default Value:</i> 7222</p> <p><i>Description:</i> The port on which the CLDB listens.</p>
cldb.security.blacklist.cleanup.duration.seconds	<p><i>Default Value:</i> 36000</p> <p><i>Description:</i> Ticket blacklist cleanup interval.</p>
cldb.security.resolve.user	<p><i>Default Value:</i> 0</p> <p><i>Description:</i> Resolve UID:GID on client OS or on CLDB.</p>
cldb.security.user.ticket.duration.seconds	<p><i>Default Value:</i> 1209600</p> <p><i>Description:</i> Default ticket duration</p>
cldb.security.user.ticket.max.duration.seconds	<p><i>Default Value:</i> 2592000</p> <p><i>Description:</i> Maximum ticket duration</p>
cldb.security.user.ticket.renew.duration.seconds	<p><i>Default Value:</i> 2592000</p> <p><i>Description:</i> Default ticket renew duration</p>
cldb.security.user.ticket.renew.max.duration.seconds	<p><i>Default Value:</i> 7776000</p> <p><i>Description:</i> Maximum ticket renew duration</p>
cldb.snap.cntr.count.alarm.threshold	<p><i>Default Value:</i> 100000000</p> <p><i>Description:</i> The threshold (in minutes) for raising the CLUSTER_ALARM_TOO_MANY_SNAPSHOT_CONTAINER alarm.</p>
cldb.snap.cntr.count.disable.threshold	<p><i>Default Value:</i> 128000000</p> <p><i>Description:</i> The maximum number of snapshots to allow before disabling snapshot creation.</p>
cldb.snap.cntr.count.monitor.interval.minutes	<p><i>Default Value:</i> 60</p> <p><i>Description:</i> The interval of time (in minutes) to elapse between checking the number of snapshots on the cluster.</p>
cldb.sso.temp.ticket.expiry.time	<p><i>Default Value:</i> 20</p> <p><i>Description:</i> The number of minutes for which the temporary ticket is valid. In installations where single-sign on is configured, the CLDB issues the temporary ticket, as described in Configuring SSO on page 1289.</p>
cldb.v2.features.enabled	<p><i>Default Value:</i> 1</p> <p><i>Description:</i> Enables new features added in Data Fabric version 2.0. Used only during the upgrade process from v1.x to 2.x to control when new features become active. Once enabled, cannot be disabled.</p>

cldb.v3.features.enabled	<p><i>Default Value:</i> 1</p> <p><i>Description:</i> Enables new features added in Data Fabric version 3.0. Used only during the upgrade process from a pre-3.0 version to control when new features become active. Once enabled, cannot be disabled.</p>
cldb.web.port	<p><i>Default Value:</i> 7221</p> <p><i>Description:</i> The port that the CLDB uses for the webserver.</p>
cldb.zookeeper.servers	<p><i>Default Value:</i> Not Applicable</p> <p><i>Description:</i> The nodes that are running ZooKeeper, in the format \<host : port\>.</p>
hadoop.version	<p><i>Default Value:</i> Not Applicable</p> <p><i>Description:</i> The version of Hadoop supported by the cluster.</p>
net.topology.script.file.name	<p><i>Default Value:</i> Not Applicable</p> <p><i>Description:</i> The path to a script that associates IP addresses with physical topology paths. The script takes the IP address of a single node as input and returns the physical topology that should be associated with the specified node. This association is used only at the time a node is initially added to the cluster. To change topology for nodes already in the cluster, use the <code>mapcli node move</code> command.</p>
net.topology.table.file.name	<p><i>Default Value:</i> Not Applicable</p> <p><i>Description:</i> The path to a text file that associates IP addresses with physical topology paths. Each line of the text file is of format <hostname/ip> <rack>, with the IP address or hostname of one node, followed by the topology to associate with the node. This association is used only at the time a node is initially added to the cluster. To change topology for nodes already in the cluster, use the <code>mapcli node move</code> command.</p>
num.volmirror.threads	<p><i>Default Value:</i> 1</p> <p><i>Description:</i> The number of (volume mirror) threads to create to process mirroring requests. The specified number of threads will be created to process requests in parallel; the remaining requests will be in the queue till they are picked up by volume mirror thread.</p>

Example cldb.conf file

```
#
# CLDB Config file.
# Properties defined in this file are loaded during startup
# and are valid for only CLDB which loaded the config.
# These parameters are not persisted anywhere else.
#
# Wait until minimum number of fileserver register with
# CLDB before creating Root Volume
cldb.min.fileserver=1
# CLDB listening port
cldb.port=7222
# Number of worker threads
cldb.numthreads=10
# CLDB webport
cldb.web.port=7221
```

```

# CLDB https port
cldb.web.https.port=7443
# Disable duplicate hostid detection
cldb.detect.dup.hostid.enabled=false
# Deprecated: This param is no longer supported. To configure
# the container cache, use the param cldb.containers.cache.percent
# Number of RW containers in cache
#cldb.containers.cache.entries=1000000
#
# Percentage (integer) of Xmx setting to be used for container cache
#cldb.containers.cache.percent=20
#
#Frequency of the heartbeat interval

# Topology script to be used to determine
# Rack topology of node
# Script should take an IP address as input and print rack path
# on STDOUT. eg
# $>/home/mapr/topo.pl 10.10.10.10
# $>/mapr-rack1
# $>/home/mapr/topo.pl 10.10.10.20
# $>/mapr-rack2
#net.topology.script.file.name=/home/mapr/topo.pl
#
# Topology mapping file used to determine
# Rack topology of node
# File is of a 2 column format (space separated)
# 1st column is an IP address or hostname
# 2nd column is the rack path
# Line starting with '#' is a comment
# Example file contents
# 10.10.10.10 /mapr-rack1
# 10.10.10.20 /mapr-rack2
# host.foo.com /mapr-rack3
#net.topology.table.file.name=/home/mapr/topo.txt
#
# ZooKeeper address
cldb.zookeeper.servers=10.10.82.22:5181
# Hadoop metrics jar version
hadoop.version=2.7.0
# CLDB JMX remote port
cldb.jmxremote.port=7220
num.volmirror.threads=1
# Set this to set the default topology for all volumes and nodes
# The default for all volumes is /data by default
# UNCOMMENT the below to change the default topology.
# For e.g., set cldb.default.topology=/mydata to create volumes
# in /mydata topology and to place all nodes in /mydata topology
# by default
#cldb.default.topology=/mydata
enable.replicas.invariant.check=false

```

Related concepts

[Security Certificate Expiry Alarm](#) on page 3408

Describes the NODE_ALARM_CERTIFICATE_NEAR_EXPIRATION alarm.

core-site.xml

Describes the core-site.xml file that contains the configuration that overrides the default core parameters.

The /opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/core-site.xml file contains configuration that override the [default core parameters](#).

NOTE: /opt/mapr/hadoop/hadoop-0.20.2/conf/core-site.xml is a symlink to /opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml.

To override a default value, specify the new value within the <configuration> tags, using the following format:

```
<property>
  <name> </name>
  <value> </value>
  <description> </description>
</property>
```

[Default core Parameters](#) describes the possible entries to place in the <name> and <value> tags. The <description> tag is optional but recommended for maintainability.

WARNING: You can examine the current configuration information for this node by using the [hadoop conf -dump](#) command from a command line.

Default core-site.xml file

```
<?xml version="1.0"?>
<?xml-stylesheet type="text/xsl" href="configuration.xsl"?>

<!-- Put site-specific property overrides in this file. -->

<configuration>

</configuration>
```

Core Parameters

See [Default core Parameters](#).

daemon.conf

The file /opt/mapr/conf/daemon.conf specifies the user and group under which MapR services run, and whether all Data Fabric services run as the specified user/group, or only ZooKeeper and FileServer. The configuration parameters operate as follows:

- If mapr.daemon.user and mapr.daemon.group are set, the ZooKeeper and FileServer run as the specified user/group. Otherwise, they run as root.
- If mapr.daemon.runuser.warden=1, all services started by the warden run as the specified user. Otherwise, they run as root.

Sample daemon.conf file

```
mapr.daemon.user=mapr
mapr.daemon.group=mapr
mapr.daemon.runuser.warden=1
```

db.conf

The file /opt/mapr/conf/db.conf specifies configuration parameters for the Metrics database.

WARNING: Any time you make changes to the db.conf file, you must restart the hoststats service and Warden for those changes to take effect.

Field	Default	Description
db.url	localhost:3306	The URL and port for the MySQL server that stores Metrics data. This machine does not need to be a node in the cluster.
db.user	root	The MySQL user name.
db.passwd	mapr	The MySQL password. If the password contains the & character, it is replaced with the & string in the hibernate.cfg.xml file (following XML parsing standards).
db.schema	metrics	The name of the MySQL schema.
db.mode	mysql	Reserved for future use.
db.driverclass	com.mysql.jdbc.Driver	Reserved for future use.
db.joblastaccessed.limit.hours	48	<p>Task and task attempt data for a job are purged for jobs that have not been accessed in a number of hours equal to this parameter's value.</p> <p> NOTE: Note that there is an error in this parameter's name. Instead of <code>db.joblastaccessed.limit.hours</code>, spelled as the English word <i>accessed</i>, the parameter is written <code>db.joblastaccessed.limit.hours</code>.</p>
db.partition.finest.count.days	3	Integer number of days for which the finest data granularity is kept. Finest granularity is a ten-second resolution.
db.partition.fine.count.days	15	Integer number of days for which fine data granularity is kept. Fine granularity is a five-minute average of the finest resolution.
db.partition.coarse.count.years	100	Integer number of years for which the coarse data granularity is kept. Coarse granularity is a 24-hour average of the fine resolution.
metric.file.rotate	365	Integer number of days for which metrics files are kept in the local volume for each node.
metric.file.cleanupthreshold	512	Specifies a size in GB. When the total size of the metrics files exceeds the value of this parameter, all data over 30 days old is cleaned up.

Example db.conf file

```
db.url=localhost:3306
db.user=root
db.passwd=mapr
db.schema=metrics
db.mode=mysql
db.driverclass=com.mysql.jdbc.Driver
db.joblastaccessed.limit.hours=48
db.partition.finest.count.days=3
db.partition.fine.count.days=15
db.partition.coarse.count.years=100
### How many files with raw node metrics data to keep
metric.file.rotate=365
```

.dfs_attributes

Each directory in Data Fabric storage contains a hidden file called `.dfs_attributes` that controls compression and chunk size. To change these attributes, change the corresponding values in the file.

Example:

```
# lines beginning with # are treated as comments
Compression=lz4
ChunkSize=268435456
```

Valid values:

- Compression: lz4, lz4, zlib, or false
- Chunk size (in bytes): a multiple of 65535 (64 K) or zero (no chunks). Example: 131072

You can also set compression and chunksize using the [hadoop mfs](#) command.

disktab

Describes the use of the disktab file.

On each node, the file `/opt/mapr/conf/disktab` lists all of the physical drives and partitions that have been added to the file system. The `disktab` file is created by the [disksetup](#) command, and automatically updated when disks are added or removed (either using the Control System, or with the [disk add](#) and [disk remove](#) commands).

Sample disktab file

```
# MapR Disks Mon Nov 28 11:46:16 2011

```

exports

Access control for hosts

On each node, the file `/opt/mapr/conf/exports` lists the clusters and mount points available to mount with NFS.

Specify access control for hosts with a space-separated list of hosts, appending (rw) for read-write or (ro) for read-only access after each host. To specify a default access for all hosts not otherwise specified, add (rw) or (ro) after a space at the end of a line. The `exports` file follows the same semantics as a standard UNIX exports table. The following export options are supported:

Export option	Definition
ro	Provides read-only access.
rw	Provides read-write access.
root_squash	Squashes root privileges for remote users. For example, you can use: <pre>/mapr (rw,root_squash)</pre> This entry prevents the <code>/mapr</code> directory from being written to by the root user on remote hosts.
no_root_squash	Turns off root squashing for remote users.
all_squash	Squashes every remote user, including root.
anonuid, anongid	Specifies user and group IDs to use with remote users from a particular host.

Restricting clusters to specific hosts

To restrict access to a specific export path to particular hosts, use the following format:

```
<Path> <space-separated list of hosts and access rights>
```

For example, the line `/mapr/cluster1 host01(rw) host02(ro)` restricts read-write access to the cluster in `/mapr/cluster1` to host `host01`, and restricts read-only access to host `host02`. No other hosts have access.

NOTE: After making changes to this file, you do not have to restart the NFS server. You can run a `maprcli` command to refresh the exports definition without a restart. See [nfsmgmt](#) refresh exports.

Sample exports file

```
# Sample Exports file

# for /mapr exports
# <Path> <exports_control>

#access_control -> order is specific to default
```

```
# list the hosts before specifying a default for all
# host01(ro) host02(ro) host03(ro) (rw)
# enforces ro for a.b.c.d & 1.2.3.4 and everybody else is rw

# special path to export clusters in mapr-clusters.conf. To disable
exporting,
# comment it out. to restrict access use the exports_control
#
/mapr (rw)

#to export only certain clusters, comment out the /mapr & uncomment.
# Note: this will cause /mapr to be unexported
#/mapr/clustername (rw)

#to export /mapr only to certain hosts (using exports_control)
#/mapr a.b.c.d(rw) e.f.g.h(ro)

# export /mapr/cluster1 rw to a.b.c.d & ro to e.f.g.h (denied for others)
#/mapr/cluster1 a.b.c.d(rw) e.f.g.h(ro)

# export /mapr/cluster2 only to e.f.g.h (denied for others)
#/mapr/cluster2 e.f.g.h(rw)

# export /mapr/cluster3 rw to e.f.g.h & ro to others
#/mapr/cluster2 e.f.g.h(rw) (ro)
```

gateway.conf

Describes configuration parameters for the Data Fabric gateway.

The `/opt/mapr/conf/gateway.conf` file specifies configuration parameters for the gateway that supports table and stream replication.

WARNING: Changing the default settings in the `gateway.conf` file is not recommended and is not likely to improve performance. If you still need to make changes to the `gateway.conf` file, you must restart the gateway after doing so. See [Configuring Gateways for Table and Stream Replication](#) on page 1789.

Field	Default	Description
gateway.port	7660	The gateway listening port.
gateway.receive.numthreads	128	The number of worker threads to receive replication stream requests.
gateway.flush.numthreads	128	The number of flush threads to send put requests to replicas.
gateway.put.mem.mb	128	The maximum size limit (in MB) of the putbuffer memory.
gateway.logfile.size.mb	1024	The maximum size limit (in MB) of the Data Fabric gateway log file. When the size limit is reached, the logs get rolled over.
gateway.es.request.maxsize.kb	128	The maximum size limit (in KB) of replication requests distributed by Data Fabric source clusters. <i>This property is no longer supported.</i>

Field	Default	Description
gateway.es.cluster.maxClients	1	Max number of clients for the HPE Data Fabric Streams. <i>This property is no longer supported.</i>

Example gateway.conf file

```
#
# Gateway Config file.
# Properties defined in this file are loaded during startup
# and are valid for only Gateway which loaded the config.
# These parameters are not persisted anywhere else.
#
# Gateway listening port
#gateway.port=7660
# Number of worker threads to receive replication stream requests
#gateway.receive.numthreads=128
# Number of flush threads to send put requests to replicas
#gateway.flush.numthreads=128
#
# Max limit on putbuffer memory in MB
#gateway.put.mem.mb=128
#
# Max limit on log file size
#gateway.logfile.size.mb=1024
#
#
# Gateway ES properties
#gateway.es.request.maxsize.kb=128
#gateway.es.cluster.maxClients=1
```

Related concepts

[Administering Data Fabric Gateways](#) on page 1787

A HPE Data Fabric gateway mediates one-way communication between a source HPE Data Fabric cluster and a destination cluster. You can replicate HPE Data Fabric Database tables (binary and JSON) and HPE Data Fabric Streams streams. HPE Data Fabric gateways also apply updates from JSON tables to their secondary indexes and propagate Change Data Capture (CDC) logs.

[Configuring Gateways for Table and Stream Replication](#) on page 1789

Configuring gateways involves installing the `mapr-gateway` package on nodes on a Data Fabric destination cluster and then configuring the Data Fabric source cluster to communicate with the destination cluster. The Data Fabric source cluster is configured by specifying the destination cluster's CLDB node and gateway nodes.

[Gateways for Replicating HPE Data Fabric Database Tables](#) on page 831

In HPE Data Fabric Database table replication, HPE Data Fabric Database replicates updates to tables (binary and JSON) on source Data Fabric clusters to replicas of those tables on destination Data Fabric clusters. Gateways are services that receive these updates and apply them to the replicas. These gateways also propagate updates from JSON tables to their secondary indexes.

Related tasks

[Specifying the Location of Gateways](#) on page 1345

Describes how to set the location of the HPE Data Fabric gateways using either the Control System or the CLI.

Related reference

[cluster gateway delete](#) on page 2324

Deletes the list of Data Fabric gateways from a source Data Fabric cluster.

[cluster gateway get](#) on page 2326

Lists the Data Fabric gateways that a source Data Fabric cluster is using.

[cluster gateway list](#) on page 2328

Lists all the gateways that a source Data Fabric cluster is using.

[cluster gateway local](#) on page 2330

Lists the gateways configured on the Data Fabric cluster on which this command is run.

[cluster gateway resolve](#) on page 2333

Lists the gateways configured on a Data Fabric cluster that are running at the time that the command is issued.

[cluster gateway set](#) on page 2335

Specifies the locations of the Data Fabric gateways that a source Data Fabric cluster can use for table replication to a destination Data Fabric cluster or for indexing table data in an Elasticsearch cluster.

More information

[Managing Gateways](#) on page 1791

Describes the commands for listing gateways, checking status of gateways, managing gateways if they fail, and troubleshooting gateways.

mapr.login.conf

The HPE Data Fabric uses the Java Authentication and Authorization Service (JAAS) to control security features. The `/opt/mapr/conf/mapr.login.conf` file specifies configuration parameters for JAAS. Contact HPE support before changing any parameters in this file other than the ones listed in this document.

The MAPR_SERVER_KERBEROS Stanza

The CLDB uses this stanza to verify users that are authenticating with Kerberos. This stanza requires the `com.sun.security.auth.module.Krb5LoginModule` module.

Attribute	Default Value	Description
keyTab	<code>"/opt/mapr/conf/mapr.keytab"</code>	File path to the keytab file.
principal	<code>"mapr/my.cluster.com"</code>	The Kerberos principal to use.

The MAPR_WEBSERVER_KERBEROS Stanza

Web UIs on the cluster use this stanza to evaluate SPNEGO requests. This stanza requires the `com.sun.security.auth.module.Krb5LoginModule` module.

Attribute	Default Value	Description
keyTab	<code>"/opt/mapr/conf/mapr.keytab"</code>	File path to the keytab file.
principal	<code>"HTTP/yourhost"</code>	The principal <i>must</i> be HTTP. This principal is used to negotiate authentication for Web services over SPNEGO. You can set the value for <i>yourhost</i> manually, but be aware that you must set the principal in the <code>mapr.keytab</code> file to match this value.

The jpamLogin Stanza

The Data Fabric cluster uses this stanza to verify user ID and password authentication to all the servers on the cluster. You can modify this stanza to alter the PAM configuration used by the cluster. The `net.sf.jpam.jaas.JpamLoginModule` module is sufficient for this stanza. There are three provided default services. The order of the `serviceName` in the stanza (at cluster startup) determines which PAM

configuration file to use. If a failure occurs with a configuration, Data Fabric ignores the error and proceeds with the next entry.

Attribute	Provided Default Values	Description
serviceName	<ul style="list-style-type: none"> • sudo • sshd • mapr-admin 	<p>The PAM configurations to use for validating passwords, shown in their order of use.</p> <p>The configuration files are typically in <code>/etc/pam.d</code>.</p>

Other Stanzas

The `Server`, `Client`, `Server_simple`, `Client_simple`, and `hadoop_maprsasl` stanzas control important aspects of your cluster's stability. Consult with HPE support before modifying these stanzas.

mapr-clusters.conf

Provides information and instructions for configuring clusters to create the global namespace.

You can define one or more clusters in the `/opt/mapr/conf/mapr-clusters.conf` file on a node or client. To define a cluster, you specify the CLDB nodes in the cluster. Defining a cluster creates the global namespace. Note that the `mapr-clusters.conf` file on each node or client must have the same cluster configuration and naming convention to create the global namespace.

The following section describes the configuration format of the `mapr-clusters.conf` file:

Format:

```
<cluster-name1> secure=false <CLDB> <CLDB> ... <CLDB>
[ clustername2 <CLDB> <CLDB> <CLDB> ]
[ ... ]
```

The `<CLDB>` string format can contain multiple space-separated instances of the following:

- `host;ip:port` - Host, IP, and port (uses DNS to resolve hostnames, or provided IP if DNS is down)
- `host:port` - Hostname and IP (uses DNS to resolve host, specifies port)
- `ip:port` - IP and port (avoids using DNS to resolve hosts, specifies port)
- `host` - Hostname only (default, uses DNS to resolve host, uses default port)
- `ip` - IP only (avoids using DNS to resolve hosts, uses default port)

You can edit `mapr-clusters.conf` manually to add more clusters. For example:

```
<cluster-name3> <CLDB> <CLDB> <CLDB>
```

Security enabled, with and without Kerberos

With security enabled, without Kerberos, the format for the `mapr-clusters.conf` file is:

```
<clustername1> secure=true <CLDB> <CLDB> ... <CLDB>
[ <clustername2> <CLDB> <CLDB> ... <CLDB> ]
[ ... ]
```

With Kerberos enabled, the format for the `mapr-clusters.conf` file is:

```
<clustername1> secure=true kerberosEnable=true <CLDB> <CLDB> ... <CLDB>
    [ <clustername2> <CLDB> <CLDB> ... <CLDB> ]
    [ ... ]
```

NOTE: Before renaming a cluster using the `mapr-clusters.conf` file, stop the warden on all the nodes.

Adding multihomed CLDB entries to `mapr-clusters.conf` with `configure.sh`

In this example, the cluster `my.cluster.com` has CLDB servers at `nodeA`, `nodeB`, `nodeC`, and `nodeD`. The CLDB servers `nodeB` and `nodeD` have two NICs each at `eth0` and `eth1`. The entries in `mapr-clusters.conf` are separated by spaces for each server's entry. Within a server's entry, individual interfaces are separated by semicolons (;).

The command

```
configure.sh -N my.cluster.com -C nodeAeth0,nodeCeth0 -M
nodeBeth0,nodeBeth1 -M nodeDeth0,nodeDeth1 -Z zknodeA
```

generates the following entry in `mapr-clusters.conf`:

```
my.cluster.com nodeAeth0 nodeBeth0;nodeBeth1 nodeCeth0 nodeDeth0;nodeDeth1
```

Cluster Limits

There is no limit for the number of clusters for HDFS and NFSv3. However, the maximum number of clusters for FUSE is 16.

mapred-site.xml

Lists the parameters for MapReduce configuration.

MapReduce is a type of application that can run on the Hadoop 2.x framework. MapReduce configuration options are stored in the `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/mapred-site.xml` file and are editable by the root user. This file contains configuration information that overrides the default values for MapReduce parameters. Overrides of the default values for core configuration properties are stored in the [HPE Data Fabric Parameters](#) on page 3422 file.

To override a default value for a property, specify the new value within the `<configuration>` tags, using the following format:

```
<property>
  <name> </name>
  <value> </value>
  <description> </description>
</property>
```

Configurations for MapReduce Applications

The configuration comprises the following parameters:

mapreduce.framework.name

Value: yarn

Description: Execution framework set to Hadoop YARN.

mapreduce.input.fileinputformat.split.maxblocknum

Value: 0

Description: Number of blocks that can be added to one split. A value of 0 means that a single split is generated per node.

mapreduce.map.memory.mb	<i>Value:</i> 1024 <i>Description:</i> Larger resource limit for maps.
mapreduce.map.java.opts	<i>Value:</i> -Xmx900m --add-opens java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC <i>Description:</i> Larger heap-size for child jvms of maps.
mapreduce.reduce.memory.mb	<i>Value:</i> 3072 <i>Description:</i> Larger resource limit for reduces.
mapreduce.reduce.java.opts	<i>Value:</i> -Xmx2560m --add-opens java.base/java.lang=ALL-UNNAMED -XX:+UseParallelGC <i>Description:</i> Larger heap-size for child jvms of reduces.
mapreduce.task.io.sort.mb	<i>Value:</i> 512 <i>Description:</i> Higher memory limit while sorting data for efficiency.
mapreduce.task.io.sort.factor	<i>Value:</i> 100 <i>Description:</i> More streams merged at once while sorting files.
mapreduce.reduce.shuffle.parallelcopies	<i>Value:</i> 50 <i>Description:</i> Higher number of parallel copies run by reduces to fetch outputs from very large number of maps.

Configurations for MapReduce JobHistory Server

The configuration comprises the following parameters:

mapr.localspill.expiration.date	<i>Value:</i> days <i>Description:</i> Property to determine spill files expiration date in days. Default value is 30 days.
mapreduce.jobhistory.address	<i>Value:</i> MapReduce JobHistory Server <i>host:port</i> <i>Description:</i> Default port is 10020.
mapreduce.jobhistory.webapp.address	<i>Value:</i> MapReduce JobHistory Server Web UI <i>host:port</i> <i>Description:</i> Default port is 19888.
mapreduce.jobhistory.intermediate-done-dir	<i>Value:</i> /mr-history/tmp <i>Description:</i> Directory where history files are written by MapReduce applications.
mapreduce.jobhistory.intermediate-done-scan-timeout	<i>Value:</i> milliseconds <i>Description:</i> Timeout in milliseconds for rescanning the done_intermediate user directory to reduce JobHistory Server loading. Information about a job is received with a delay equal to the timeout. Adjust the setting based on the cluster load. Start with 5000 ms and increase timeout as needed.
mapreduce.jobhistory.done-dir	<i>Value:</i> /mr-history/done <i>Description:</i> Directory where history files are managed by the MapReduce JobHistory Server.

mapreduce.jobhistory.webapp.https.address	<i>Value:</i> Secure MapReduce JobHistory Server Web UI host:port (HTTPS) <i>Description:</i> Default port is 19890.
--	--

Sample Hadoop 2.x mapred-site.xml File

The following mapred-site.xml file defines values for two job history parameters.

```
<configuration>
  <property>
    <name>mapreduce.jobhistory.address</name>
    <value>__HS_IP__:10020</value>
  </property>
  <property>
    <name>mapreduce.jobhistory.webapp.address</name>
    <value>__HS_IP__:19888</value>
  </property>
</configuration>
```

Configuration for Apache Shuffle

You can disable Direct Shuffle and enable Apache Shuffle for MapReduce applications through the following settings:

mapreduce.job.shuffle.provider.services	<i>Value:</i> mapreduce_shuffle
mapreduce.job.reduce.shuffle.consumer.plugin.class	<i>Value:</i> org.apache.hadoop.mapreduce.task.reduce.Shuffle
mapreduce.job.map.output.collector.class	<i>Value:</i> org.apache.hadoop.mapred.MapTask\$MapOutputBuffer
mapred.ifile.outputstream	<i>Value:</i> org.apache.hadoop.mapred.FileOutputStream
mapred.ifile.inputstream	<i>Value:</i> org.apache.hadoop.mapred.FileInputStream
mapred.local.mapoutput	<i>Value:</i> true
mapreduce.task.local.output.class	<i>Value:</i> org.apache.hadoop.mapred.YarnOutputFiles

mfs.conf

Lists the parameters of the MFS configuration file.

The configuration file /opt/mapr/conf/mfs.conf specifies the following parameters about the file system server on each node.

WARNING: You must restart the File Server after making changes to this file.

Parameters

mfs.server.ip	<i>Default Value:</i> Not applicable <i>Description:</i> IP address of the File Server. For example, 192.168.10.10.
mfs.server.port	<i>Default Value:</i> 5660

mfs.cache.lru.sizes

Description: Port used for communication with the server.

Default Value:

- For version 4.0.1:
inode:6:log:6:meta:10:dir:40:small:15
- For version 4.0.2 and later versions:
inode:3:meta:6:small:27:dir:15:db:20:valc:3

Description: LRU cache configuration. See the section, **Notes on LRU Cache Configuration** for more information.

mfs.on.virtual.machine

Default Value: false

Description: Specifies whether the file system is running on a virtual machine.

mfs.io.disk.timeout

Default Value: 60 seconds

Description: Timeout, in seconds, after which a disk is considered failed and taken offline. You can increase the timeout to tolerate slow disks.

mfs.max.disks

Default Value: 48

Description: Maximum number of disks supported on a single node.

mfs.max.logfile.size.in.mb

Default Value: 1000 MB

Description: The maximum amount of disk space that the MFS logs can consume before the oldest log file is deleted; based on the following calculation:

$\text{maxSizePerLogFile} = \text{maxLogSize} / \text{MAX_NUM_OF_LOG_FILES}$

where

- maxLogSize = total amount of space that MFS log files can consume
- $\text{MAX_NUM_OF_LOG_FILES}$ = total number of MFS log files

mfs.max.resync.count

Default Value: 16

Description: The number of parallel resync operations.

mfs.subnets.whitelist

Default Value: Not Applicable

Description: A list of subnets (up to 256 characters) that are allowed to make requests to the File Server service and access data on the cluster.

mfs.disk.iothrottle.count

Default Value: 100

Description: The maximum number of outstanding requests on disk.

NOTE: You can disable throttling by setting a high value. This option is disabled if you set the value for `mfs.disk.is.ssd` to 1.

mfs.disk.resynciothrottle.factor

Default Value: 20

Description: Controls the amount of time to wait before submitting a request to disk. Increasing this value reduces the wait time, and decreasing this value

	increases the wait time. For example, setting the value to 40, halves the wait time, while setting the value to 10, doubles the wait time.
mfs.network.resynciothrottle.factor	<p><i>Default Value:</i> 20</p> <p>Description: Controls the amount of time to wait before sending a resync operation over the network. Increasing this value reduces the wait time, and decreasing this value increases the wait time. For example, setting the value to 40, halves the wait time, while setting the value to 10, doubles the wait time.</p>
mfs.ssd.trim.enabled	<p><i>Default Value:</i> 0</p> <p>Description: Set this parameter to 1 to enable TRIM operations for SSD devices.</p> <p> NOTE: Enable TRIM only if it is recommended by the SSD vendor.</p>
mfs.disk.is.ssd	<p><i>Default Value:</i> 0</p> <p>Description: Specifies whether (1) or not (0) the drives are SSD. If the value is 0, the drives are assumed to be rotations. If the value is 1, the noop scheduler on the SSD is automatically enabled, and I/O throttling is disabled.</p>
mfs.mem.debug.enabled	<p><i>Default Value:</i> 0</p> <p>Description: Specifies whether file server should (1) or should not (0) track all memory allocations. The default value is 0. If value is 1, you can determine the root cause for high memory allocation, or determine the component consuming the most memory.</p>
mfs.numrpcthreads	<p><i>Default Value:</i> 2</p> <p>Description: Specifies the number of RPC threads per MFS instance. The valid range of values is from 1 to 4.</p>
mfs.db.max.concurrent.internal.ops	<p><i>Default Value:</i> 73728 (72 * 1024)</p> <p><i>Max Value:</i> 131072 (128 * 1024)</p> <p><i>Min Value:</i> 36864 (36 * 1024)</p> <p>Description: Regulates how many BatchGet operations can run in parallel when secondary indexes are present on the table. PUT operations on tables with secondary indexes convert to BatchGet operations on the tables. PUT operations that convert to a high volume of BatchGets can degrade performance. BatchGet operations are spread equally across three threads (73728/3). Run mrconfig dbinfo threads to evaluate the throttling queue for each thread.</p>
mfs.num.compress.threads	<p><i>Default Value:</i> 1</p> <p>Description: Reserved for internal use.</p>
mfs.max.aio.events	<p><i>Default Value:</i> 5000</p> <p>Description: Reserved for internal use.</p>
mfs.disable.periodic.flush	<p><i>Default Value:</i> 0</p> <p>Description: Reserved for internal use.</p>
mfs.ignore.container.delete	<p><i>Default Value:</i> 0</p> <p>Description: Reserved for internal use.</p>

mfs.ignore.readdir.pattern	<i>Default Value:</i> 0 <i>Description:</i> Reserved for internal use.
mfs.disable.IO.affinity	<i>Default Value:</i> 0 <i>Description:</i> Reserved for internal use.
mfs.deserialize.length	<i>Default Value:</i> 8192 <i>Description:</i> Reserved for internal use.
mfs.enable.nat	<i>Default Value:</i> 0 <i>Description:</i> Reserved for internal use.
mfs.bulk.writes.enabled	<i>Default Value:</i> 0 <i>Description:</i> Reserved for internal use.

Example

```
mfs.server.ip=192.168.10.10
mfs.server.port=5660
mfs.cache.lru.sizes=inode:3:meta:6:small:27:dir:15:db:20:valc:3
mfs.on.virtual.machine=0
mfs.io.disk.timeout=60
mfs.max.disks=48
```

Notes on LRU Cache Configuration

The cache values are expressed as percentages, which vary based on the expected size of the data that the node is required to cache. The goal is to achieve a state in which most of the required data comes directly from the cache. You may need to tune the cache percentages based on your cluster configuration and the workload on specific nodes. Non-default allocations tend to work better for nodes that run only CLDB and nodes that do not have CLDB but do have a heavy HPE Data Fabric Database workload. Note the following recommendations.

- For CLDB-only nodes, increase the size of the cache for Dir LRU to 40%: change `dir:15` to `dir:40`. A CLDB-only node is a file server node that hosts only the CLDB volume `mapr.cldb.internal` (no user volume data is hosted on the node). Dir LRU is used to host B-tree pages.
- For non-CLDB nodes with no HPE Data Fabric Database workload, optimize the cache to host as many file pages as possible. Change the value of the parameter to: `inode:3:meta:6:small:27:dir:6`

The remainder of the cache is used to cache file data pages.

Note: You need to restart MFS for the change in `mfs.conf` to take effect.

nfsserver.conf

Lists the parameters for the Data Fabric NFS server.

The file `/opt/mapr/conf/nfsserver.conf` controls parameters related to Data Fabric services and the warden. Most of the parameters are not intended to be edited directly by users. The following list shows the parameters of interest:

Compression	<i>Default Value:</i> true <i>Description:</i> Indicates whether compression is on (true) or off (false).
ChunkSize	<i>Default Value:</i> 67108864 bytes (64 MB) <i>Description:</i> Size of each chunk.
CompThreads	<i>Default Value:</i> 2

	<p><i>Description:</i> Number of threads for compression or decompression.</p>
DrCacheSize	<p><i>Default Value:</i> 20480</p> <p><i>Description:</i> Duplicate request cache size.</p>
DrCacheTimeout	<p><i>Default Value:</i> 62 seconds</p> <p><i>Description:</i> Duplicate request cache timeout in seconds.</p>
DRCacheTimeOutOpt	<p><i>Default Value:</i> 0.5</p> <p><i>Description:</i> If the operations take more than $\text{DrCacheTimeout} * \text{DRCacheTimeOutOpt}$, the operations are not cached. For example, by default, if the operation takes more than 31 seconds — $(62 * .5) = 31$ seconds — the operation is not cached. A value of 0 disables the cache.</p>
HighMemLimitMB	<p><i>Default Value:</i> disabled (Parameter is commented out in the file)</p> <p><i>Description:</i> The maximum amount of memory (in MB) that the NFS server process can use. If the NFS server process uses more memory than this value, then the server is automatically shutdown, and a Core file is generated for debugging.</p> <p>For example: <code>HighMemLimitMB=10000</code> indicates that the NFS server is shutdown if it consumes more than 10GB of memory.</p> <p>This parameter is effective only if you enable the <code>MemDebugEnabled</code> parameter.</p>
LogLevel	<p><i>Default Value:</i> INFO</p> <p><i>Description:</i> Sets the level of log messages displayed in the output. Levels include:</p> <ul style="list-style-type: none"> • DEBUG • INFO • WARN • ERROR • CRITICAL • OFF
MaxLogFileSize	<p><i>Default Value:</i> 1024 MB</p> <p><i>Description:</i> The maximum amount of disk space that the NFS server logs can consume before the oldest log file is deleted, based on the following calculation:</p> <div style="background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> $\text{maxSizePerLogFile} = \text{maxLogFileSize} / \text{MAX_NUM_OF_LOG_FILES}$ </div> <p>where:</p>

- `maxLogFileSize` is the total amount of space that NFS server log files may consume
- `MAX_NUM_OF_LOG_FILES` is the total number of NFS server log files

Logrotate support for both the `.log` and the `.err` files honor this setting.

ATTENTION: `MaxLogFileSize` is not a combined size of `.log` and `.err` files. The `.log` and `.err` files can individually grow up to this size.

MemDebugEnabled

Default Value: `false` (Parameter is commented out in the file)

Description: Set this parameter to `true` to enable memory tracking for the NFS server. This parameter works along with the `HighMemLimitMB` parameter.

MinLenForDeserialization

Default Value: 8192

Description: Deserialize (if value is > 0) or do not deserialize (if value = 0) the response in the compression thread. If value is greater than 0, MapR deserializes requests with length $\geq$ value in the compression thread. If value is 0, requests of length $<$ value are deserialized in the RPC thread itself..

RamfsMntDir

Default Value: `/ramfs/mapr`

Description: Mount point for the `ramfs` file for mmap.

RamfsSize

Default Value: `0.25`

Description: Size of the ramfile to use (percent of total physical memory). A value of 0 disables the use of ramfs.

WindowsAceSupport

Default Value: `false`

Description: Allow (`true`) or deny (`false`) access to a Windows client when ACEs are set. If `true`, the mode bits are set to 777, the Windows client is granted access, and the operation is allowed based on the permissions enforced using mode bits and/or ACEs. If value is `false`, the mode bits are set to 000 and the Windows client is denied access. For more information, see [Mounting NFS on a Windows Client](#) on page 1823.

TIP: Use separate NFS servers for Windows clients and non-Windows clients.

warden.conf

Lists the configuration parameters for Warden.

The file `/opt/mapr/conf/warden.conf` controls parameters related to Data Fabric services and the Warden. Most of the parameters are not intended to be edited directly by users. The following list describes the parameters of interest:

NOTE: When defining heapsize values for services, keep in mind that `service.heapsize.percent` is bound by `service.heapsize.min`, if defined, and `service.heapsize.max`.

centralconfig.enabled	<p><i>Sample Value:</i> true</p> <p><i>Description:</i> Specifies whether to enable central configuration.</p>
cldb.port	<p><i>Sample Value:</i> 7222</p> <p><i>Description:</i> The port to use for communicating with the CLDB.</p>
enable.overcommit	<p><i>Sample Value:</i> true</p> <p><i>Description:</i> Set this value to <code>true</code> to allow services to start up, even if their memory demands exceed the memory provided by the node.</p>
hoststats.port	<p><i>Sample Value:</i> 5660</p> <p><i>Description:</i> The port to use for communicating with the HostStats service.</p>
hs.port	<p><i>Sample Value:</i> 1111</p> <p><i>Description:</i> Hoststats listening port for Metrics RPC activity.</p>
hs.rpcon	<p><i>Sample Value:</i> true</p> <p><i>Description:</i> Indicates whether or not to configure Job Management.</p>
hs.host	<p><i>Sample Value:</i> localhost</p> <p><i>Description:</i> Hoststats hostname for RPC activity.</p>
isDB	<p><i>Sample Value:</i> true</p> <p><i>Description:</i> Specifies if HPE Data Fabric Database is in use. When this value is <code>false</code>, the <code>service.command.mfs.heapsize.percent</code> is set to 20. Do not manually edit this value. For more information, see Allocating Memory for Nodes on page 1387..</p>
kvstore.port	<p><i>Sample Value:</i> 5660</p> <p><i>Description:</i> The port for communicating with the Key/Value Store.</p>
log.retention.exceptions	<p><i>Sample Value:</i> <code>mfs.log - *</code></p> <p><i>Description:</i> Retains the following log files instead of removing them during the log file cleanup that occurs every ten days: <code>cldb.log</code>, <code>hoststats.log</code>, <code>configure.log</code> and <code>mfs.log - *</code>.</p> <p>You can modify the list. This parameter accepts partial file names and asterisks. Log files listed as exceptions are retained indefinitely.</p> <p>To disable all exceptions, comment out this parameter, that is, <code>#log.retention.exceptions</code>. When this parameter is null, that is, <code>log.retention.exceptions=</code>, no files are picked for log cleanup.</p>

log.retention.time	<p><i>Sample Value:</i> 864000000</p> <p><i>Description:</i> All .log and .out files in the cluster are kept for a time period defined in milliseconds by the value of the log.retention.time parameter. The default value is ten days. Restart the Warden after changing this value.</p>
mapr.home.dir	<p><i>Sample Value:</i> /opt/mapr</p> <p><i>Description:</i> Data Fabric installation directory.</p>
mfs.port	<p><i>Sample Value:</i> 7222</p> <p><i>Description:</i> The port to use for communicating with the Fileserver.</p>
pollcentralconfig.interval.seconds	<p><i>Sample Value:</i> 300</p> <p><i>Description:</i> The frequency (in seconds) to check for central configuration updates.</p>
rpc.drop	<p><i>Sample Value:</i> false</p> <p><i>Description:</i> Drop outstanding metrics when the queue to send to hoststats is too large.</p>
service.command.cldb.heapsize.max	<p><i>Sample Value:</i> 4000</p> <p><i>Description:</i> The maximum heap space, specified in MB, that the CLDB can use.</p>
service.command.cldb.heapsize.min	<p><i>Sample Value:</i> 256</p> <p><i>Description:</i> The minimum heap space, specified in MB, that the CLDB can use.</p>
service.command.cldb.heapsize.percent	<p><i>Sample Value:</i> 8</p> <p><i>Description:</i> The percentage of heap space reserved for CLDB.</p>
service.command.cldb.retryinterval.time.sec	<p><i>Sample Value:</i> 600</p> <p><i>Description:</i> Specifies an interval in seconds. The warden attempts to restart a failed CLDB service when this interval expires.</p> <div>  <p>NOTE: The warden restarts the CLDB service only if the service has been stopped unintentionally - for example, the service crashed. Warden does not restart a CLDB service that has been stopped intentionally using the <code>maprccli node services</code> command.</p> </div>
service.command.mfs.heapsize.maxpercent	<p><i>Sample Value:</i> 85</p> <p><i>Description:</i> The maximum percentage of heap space that can be allocated to the file system. Restart the Warden after modifying this setting.</p>
service.command.mfs.heapsize.min	<p><i>Sample Value:</i> 512</p> <p><i>Description:</i> The minimum heap space, specified in MB, that can be allocated to the file system. Restart the Warden after modifying this setting.</p>
service.command.mfs.heapsize.percent	<p><i>Sample Value:</i> 35</p>

	<p><i>Description:</i> The percentage of heap space reserved for the file system. If the value for <code>isDB</code> is <code>true</code>, you cannot set this property to a value lower than 35. If you set this parameter to a value lower than 35, the value reverts to 35 when the Warden restarts, to ensure that when the HPE Data Fabric Database is enabled, corresponding cache allocation occurs. If you want to lower the heap size allocated to the file system, you must change <code>service.command.mfs.heapsize.maxpercent</code> instead. Restart the Warden after modifying this setting.</p>
service.command.nfs.heapsize.max	<p><i>Sample Value:</i> 1000</p> <p><i>Description:</i> The maximum heap space, specified in MB, that the NFS can use.</p>
service.command.nfs.heapsize.min	<p><i>Sample Value:</i> 64</p> <p><i>Description:</i> The minimum heap space, specified in MB, that the NFS can use.</p>
service.command.nfs.heapsize.percent	<p><i>Sample Value:</i> 3</p> <p><i>Description:</i> The percentage of heap space reserved for the NFS.</p>
service.command.os.heapsize.max	<p><i>Sample Value:</i> 750</p> <p><i>Description:</i> The maximum heap space, specified in MB, that can be used by the operating system.</p>
service.command.os.heapsize.min	<p><i>Sample Value:</i> 256</p> <p><i>Description:</i> The minimum heap space, specified in MB, for use by the operating system.</p>
service.command.os.heapsize.percent	<p><i>Sample Value:</i> 3</p> <p><i>Description:</i> The percentage of heap space reserved for the operating system.</p>
service.command.webserver.heapsize.min	<p><i>Sample Value:</i> 512</p> <p><i>Description:</i> The minimum heap space, specified in MB, for use by the Control System.</p>
service.command.webserver.heapsize.percent	<p><i>Sample Value:</i> 3</p> <p><i>Description:</i> The percentage of heap space reserved for the Control System.</p>
service.nice.value	<p><i>Sample Value:</i> -10</p> <p><i>Description:</i> The <code>nice</code> priority under which all services run.</p>
services.memoryallocation.alarm.threshold	<p><i>Sample Value:</i> 95</p> <p><i>Description:</i> The maximum amount of system memory that services running on the node can use before triggering the <code>NODE_ALARM_MEMORY_ALLOCATION_EXCEEDED</code> alarm.</p>
services.resetretries.time.sec	<p><i>Sample Value:</i> 3600</p> <p><i>Description:</i> Specifies a time interval in seconds. The <code>services.retries</code> parameter sets the number</p>

of times that the warden attempts to restart failing services within this interval.

services.retries

Sample Value: 3

Description: The number of times the Warden tries to restart a service that fails.

services.retryinterval.time.sec

Sample Value: 1800

Description: The number of seconds after which the warden attempts several times to start a failed service. The number of attempts after each interval is specified by the parameter `services.retries`.

warden.enable.jmxremote

Sample Value: false

Description: Set to `true` to enable the Warden JMX server.

zookeeper.servers

Sample Value: 10.250.1.61:5181 10.10.1.230:5181

Description: Space separated list of Zookeeper servers.

For information on configuration files for additional services, see [warden.<servicename>.conf](#).

warden.<servicename>.conf

Describes the service configuration files that Warden supports.

The `warden.conf` configuration file is associated with the standard services that are provided by HPE Data Fabric. Warden supports service monitoring for additional services.

Each of these supported services requires a configuration file, `warden.<servicename>.conf`, which is included with the package for that service. When you install any of these service packages, its corresponding configuration file is stored in `/opt/mapr/conf/conf.d`. The configuration files and their packages are as follows:

collectd

Configuration File: `warden.collectd.conf`

Description: Installed with the `mapr-collectd` package. This package is supported only for internal HPE Data Fabric Monitoring uses cases.

drill

Configuration File: `warden.drill-bits.conf`

Description: Installed with the `mapr-drill` package.

elasticsearch

Configuration File: `warden.elasticsearch.conf`

Description: Installed with the `mapr-elasticsearch` package. This package is supported only for internal HPE Data Fabric Monitoring uses cases.

fluentd

Configuration File: `warden.fluentd.conf`

Description: Installed with the `mapr-fluentd` package. This package is supported only for internal HPE Data Fabric Monitoring uses cases.

gateway

Configuration File: `warden.gateway.conf`

Description: Installed with the `mapr-gateway` package.

grafana

Configuration File: `warden.grafana.conf`

	<p><i>Description:</i> Installed with the <code>mapr-grafana</code> package. This package is supported only for internal HPE Data Fabric Monitoring uses cases.</p>
hue	<p><i>Configuration File:</i> <code>warden.hue.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-hue</code> package.</p>
httpfs	<p><i>Configuration File:</i> <code>warden.httpfs.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-httpfs</code> package.</p>
hbase thrift server	<p><i>Configuration File:</i> <code>warden.hbasethrift.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-hbasethrift</code> package.</p>
hbase rest gateway	<p><i>Configuration File:</i> <code>warden.hbase-rest.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-hbase-rest</code> package.</p>
historyserver	<p><i>Configuration File:</i> <code>warden.historyserver.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-historyserver</code> package.</p>
hive metastore	<p><i>Configuration File:</i> <code>warden.hivemeta.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-hivemetadadata</code> package.</p>
hiveserver2	<p><i>Configuration File:</i> <code>warden.hs2.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-hiveserver2</code> package.</p>
kibana	<p><i>Configuration File:</i> <code>warden.kibana.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-kibana</code> package. This package is supported only for internal HPE Data Fabric Monitoring uses cases.</p>
nodemanager	<p><i>Configuration File:</i> <code>warden.nodemanager.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-nodemanager</code> package.</p>
opentsdb	<p><i>Configuration File:</i> <code>warden.opentsdb.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-opentsdb</code> package. This package is supported only for internal HPE Data Fabric Monitoring uses cases.</p>
resourcemanager	<p><i>Configuration File:</i> <code>warden.resourcemanager.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-resourcemanager</code> package.</p>
sentry	<p><i>Configuration File:</i> <code>warden.sentry.conf</code></p> <p><i>Description:</i> Installed with the <code>mapr-sentry</code> package. However, Sentry is not automatically monitored by the Warden. When Sentry is configured to use the database storage model, you can manually copy the <code>/opt/mapr/sentry/sentry-<version>/conf.d/warden.sentry.conf</code> file to the <code>/opt/</code></p>

mapr/conf/conf.d directory to add Sentry to the list of services that the Warden monitors.

spark master

Configuration File: warden.spark-master.conf

Description: Installed with the spark-master package.

Configuring Service Properties

You can configure the following properties in the warden.<servicename>.conf file:

services

Description: Service name and number of nodes this service should run on, along with service dependencies. Format is serviceName:N[depServiceName]. Values for N = 1 or all

service.alarm.label

Description: Specifies the alarm name for this service. This is the alarm name that appears in the CLI when you do not request a terse output. Once tWarden starts the service, you cannot edit this value.

service.alarm.tersename

Description: Specifies the abbreviated alarm name for this service. This is the alarm name that appears in the Control System. Once Warden starts the service, you cannot edit this value.

service.command.monitor

Description: Monitor string (if the service monitor command does not provide sufficient monitoring).

service.command.monitorcommand

Description: Specifies a command that checks whether the service is running.

service.command.start

Description: Service start command.

service.command.stop

Description: Service stop command.

service.command.type

Description: Indicates whether the script runs in background (and exits) or inline (script does not exit). Type is either BACKGROUND or INLINE.

service.depends.local

Description: Indicates whether the service depends on a service instance locally, or on the master. Values = 1 (local) or 0 (master).

service.displayname

Description: The name of the service to display.

service.env

Description: Specifies environment variables to be use by the service. By default, it may include MAPR_MAPREDUCE_MODE=default. You can include a comma-separated list of environment variables. For example, service.env=MAPR_MAPREDUCE_MODE=default, ABC=1, XYZ=2.

service.heapsize.max

Description: Maximum heapsize in MB.

service.heapsize.min

Description: Minimum heapsize in MB.

service.heapsize.percent

Description: Specifies heapsize percent.

service.logs.location

Description: Location of the service log files.

service.port	<i>Description:</i> Port where the service is running (for example, the hue webserver runs on port 8888).
service.process.type	<i>Description:</i> Specifies the type of process. For example, <code>service.process.type=JAVA</code> indicates that the process is a Java process.
service.uri	<i>Description:</i> To include a link to a user interface associated with this service in the Control System, enter a Uniform Resource Identifier (URI) in this property, and specify the port in the <code>service.ui.port</code> property. For example, enter <code>/service1</code> for this property and then enter 8080 in the <code>service.ui.port</code> property to provide the following UI link for this service in the MCS: <code>http://<hostname>:8080/service1</code>
service.uri.port	<i>Description:</i> If you want to include a link to the user interface associated with this service in the Control System, enter the port in this property and also specify the URI in the <code>service.uri</code> property.

Memory Management for Services

The following memory parameters are used to reserve memory for the service:

- The `service.<servicename>.heapsize.percent` parameter controls the percentage of system memory allocated to the named service.
- The `service.<servicename>.heapsize.max` parameter defines the maximum heapsize used when invoking the service.
- The `service.<servicename>.heapsize.min` parameter defines the minimum heapsize used when invoking the service.

For example, the `service.command.gateway.heapsize.percent`, `service.command.gateway.heapsize.max`, and `service.command.gateway.heapsize.min` parameters in the `warden.gateway.conf` file control the amount of memory that Warden allocates to the gateway service before allocating memory to other services.

The actual heap size used when invoking a service is a combination of the three parameters according to the formula $\max(\text{heapsize.min}, \min(\text{heapsize.max}, \text{total-memory} * \text{heapsize.percent} / 100))$.

warden.hs2.conf Example

The hiveserver2 configuration file, `warden.hs2.conf`, looks like this:

```
services=hs2:1
service.displayname=HiveServer2
service.command.start=/opt/mapr/hive/hive-0.13/bin/hive --start --service hiveserver2
service.command.stop=/opt/mapr/hive/hive-0.13/bin/hive --stop --service hiveserver2
service.command.type=BACKGROUND
service.command.monitorcommand=/opt/mapr/hive/hive-0.13/bin/hive --status --service hiveserver2
service.port=9083
service.ui.port=9083
service.uri=about
```

```
service.logs.location=/tmp/mapr
service.process.type=JAVA
```

When hiveserver2 is installed, the warden.hs2.conf file is placed in the directory /opt/mapr/conf/conf.d. If Warden is running, it detects the file and starts the service. If Warden is not running, the file is picked up when Warden starts. Warden monitors the service and displays the status on the Control System UI.

yarn-site.xml

Describes the YARN configuration options.

YARN configuration options are stored in the /opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/yarn-site.xml file and are editable by the root user. This file contains configuration information that overrides the default values for YARN parameters. Overrides of the default values for core configuration properties are stored in the Default YARN parameters file.

To override a default value for a property, specify the new value within the <configuration> tags, using the following format:

```
<property>
  <name> </name>
  <value> </value>
  <description> </description>
</property>
```

The following configuration lists describe the possible entries that you can place between the <name> tags and between the <value> tags. The <description> tag is optional but recommended for maintainability.

Configuration for ResourceManager

Comprises the following parameters:

yarn.resourcemanager.hostname	The hostname of the ResourceManager. The configure.sh command automatically sets this value to the IP address that you provide with the -RM option. <i>Default value:</i> {IP Address}
yarn.resourcemanager.scheduler.address	The hostname and port of the Scheduler Interface. <i>Example value:</i> \$ {yarn.resourcemanager.hostname}:8030
yarn.resourcemanager.resource-tracker.address	The hostname and port of the Resource Manager. <i>Example value:</i> \$ {yarn.resourcemanager.hostname}:8025
yarn.resourcemanager.address	The address of the Applications Manager interface that is contained in the Resource Manager. <i>Example value:</i> \$ {yarn.resourcemanager.address}:8041

Configuration for NodeManager

Comprises the following parameters:

yarn.nodemanager.container-localizer.log.level	<i>Default Value:</i> INFO
---	----------------------------

	<p><i>Description:</i> You can change the log level for the container localizer by setting the configuring options in this property. Different configuring options available are INFO, DEBUG, and WARN. By default logs will be available in the Application Master logs location but based on your cluster configuration, they will be available in the application's localized log directory. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See Applying a Patch on page 431.</p>
yarn.nodemanager.max-retry-file-delete	<p><i>Default Value:</i> 2</p> <p><i>Description:</i> Defines how many times the NodeManager can attempt to delete application-related directories from a volume when Spark is configured to use the mounted NFS directory instead of the /tmp directory on the local filesystem. Increasing the value for this property can prevent application cache data from accumulating in the volume. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See Applying a Patch on page 431.</p>
yarn.nodemanager.kill-container-child-process	<p><i>Default Value:</i> false</p> <p><i>Description:</i> Enables NodeManager to automatically run the <code>kill -9</code> command to end processes that hang after YARN stops containers. Set to <code>true</code> to enable this behavior. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See Applying a Patch on page 431.</p>
yarn.nodemanager.container-executor.class	<p><i>Default Value:</i> org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor</p> <p><i>Description:</i> Identifies how containers are executed. Set to LinuxContainerExecutor by default, so that jobs can run as the user that submits the job.</p> <p> NOTE: If a system user (a user with <code>userID<500</code>) wants to submit a job, you must add the user in the <code>container-executor.cfg</code> file. The user <code>mapr</code> is already configured as an allowed system user.</p>
yarn.nodemanager.aux-services	<p><i>Default Value:</i> mapreduce_shuffle, mapr_direct_shuffle</p> <p><i>Description:</i> Selects a shuffle service that needs to be set for MapReduce to run.</p>
yarn.nodemanager.aux-services.mapreduce_shuffle.class	<p><i>Default Value:</i> org.apache.hadoop.mapred.ShuffleHandler</p> <p><i>Description:</i> This property, in conjunction with other properties, sets <i>direct shuffle</i> as the default shuffle for MapReduce.</p>
yarn.nodemanager.aux-services.mapr_direct_shuffle.class	<p><i>Default Value:</i> com.mapr.hadoop.mapred.LocalVolumeAuxService</p> <p><i>Description:</i> This property, in conjunction with other properties, sets <i>direct shuffle</i> as the default shuffle for MapReduce.</p>

Configuration for Timeline Server Security with MapR-SASL

Comprises the following parameter:

yarn.timeline-service.http-authentication.type	<i>Default Value:</i> <code>com.mapr.security.maprauth.MaprDelegationTokenAuthenticationHandler</code> <i>Description:</i> The authentication used for the timeline server HTTP endpoint.
---	---

Configuration for Timeline Server Security with Kerberos

Comprises the following parameter:

yarn.timeline-service.http-authentication.type	<i>Default Value:</i> <code>com.mapr.security.maprauth.MaprDelegationTokenAuthenticationHandler</code> <i>Description:</i> The authentication used for the timeline server HTTP endpoint.
yarn.timeline-service.http-authentication.kerberos.principal	<i>Default Value:</i> <code>principal(HTTP/nodex@NODEX)</code> <i>Description:</i> The Kerberos service principal for the timeline server HTTP endpoint.
yarn.timeline-service.http-authentication.kerberos.keytab	<i>Default Value:</i> <code>path to keytab(/opt/mapr/conf/mapr.keytab)</code> <i>Description:</i> The Kerberos keytab for the timeline server HTTP endpoint.
yarn.timeline-service.principal	<i>Default Value:</i> <code>mapr/nodex@NODEX</code> <i>Description:</i> The Kerberos principal for the timeline reader. NodeManager principal is used for the timeline collector as it runs as an auxiliary service inside NodeManager.
yarn.timeline-service.keytab	<i>Default Value:</i> <code>path to keytab(/opt/mapr/conf/mapr.keytab)</code> <i>Description:</i> The Kerberos keytab for the timeline reader. NodeManager keytab is used for the timeline collector as it runs as an auxiliary service inside NodeManager.

Configuration for MapReduce

Comprises the following parameter:

mapreduce.job.shuffle.provider.services	<i>Default Value:</i> <code>mapr_direct_shuffle</code> <i>Description:</i> This is the default shuffle handler for MapReduce. Contains a value from the <code>yarn.nodemanager.aux-services</code> property.
--	---

Configuration for Container Logs

Comprises the following parameters:

yarn.nodemanager.log-dirs	<i>Default Value:</i> <code>/opt/mapr/hadoop/hadoop-<version>/logs/userlogs/<applicationID>/<containerID>/<filename>.log</code> <i>Description:</i> The location to store container logs on the node. An application's log
----------------------------------	---

directory is `${yarn.nodemanager.log-dirs}/application_${appid}`. Individual containers' log directories are named `container_${contid}`. Each container directory will contain the files `stderr`, `stdin`, and `syslog` generated by that container.

NOTE: You can find the application ID associated with your job in the Control System.

yarn.log-aggregation-enable

Default Value: false

Description: Indicates whether the logs are aggregated.

yarn.nodemanager.log.retain-seconds

Default Value: 10800 (3 hours)

Description: Specifies the duration for which user logs are maintained, when log aggregation is disabled.

yarn.log-aggregation.retain-seconds

Default Value: -1

Description: Specifies the number of seconds to retain logs, when log aggregation is enabled. The default value of -1, disables the deletion of logs.

yarn.log-aggregation.retain-check-interval-seconds

Default Value: -1

Description: The interval between aggregated log retention checks. If set to 0 or a negative value, then the value is computed as one-tenth of the aggregated log retention time.

NOTE: Setting this to a low value may cause unnecessary log retention checks.

yarn.nodemanager.remote-app-log-dir

Default Value: /tmp/logs

Description: The location on the filesystem where the logs are aggregated.

yarn.nodemanager.remote-app-log-dir-suffix

Default Value: logs

Description: The suffix for the directory that stores the aggregated logs for each user.

Configuration for Apache Shuffle

You can disable Direct Shuffle and enable Apache Shuffle for MapReduce applications through the following setting:

yarn.nodemanager.aux-services

Value: mapreduce_shuffle

Configuration for aggregated logs

hadoop.users.acl.mapping

Indicates whether the user is permitted to access application logs generated by other users. Allows access to applications that are either in a running state or have completed execution, provided that log aggregation is enabled. Requires restart of the ResourceManager, NodeManager and components, along with either cleanup of existing aggregated logs or modification of the `hadoop.users.acl.force.init` property.

Value:

u:<user_name>,g:<group_name>=u:<app_user_name>,g:<app_group_name>;...

Example value:

u:userA=u:appUserA,u:appUserB;u:userB,g:groupB=u:appUserA,g:appGroupC

Description: Grant userA read access to the logs or running applications owned by appUserA and appUserB. Grant log read access to userB and all members of groupB for running applications owned by appUserA and members of appGroupC. If a user ACL is defined multiple times, only the most recent definition is applied.

hadoop.users.acl.force.init

Default value: false

Description: Specifies whether to force overwriting of ACEs for existing aggregated log files during log aggregation. When this property is set to false, the user must manually delete all existing aggregated logs after any change to the `hadoop.users.acl.mapping` property. When set to true, YARN will automatically update all ACEs after the Resource manager and Node manager are restarted. However, enabling this option may increase the startup time of the Resource manager.

To reset all permissions to their default settings:

1. Remove the `hadoop.users.acl.mapping` property from the configuration file.
2. Set the following properties to true:
 - `hadoop.users.acl.force.init`
 - `yarn.log-aggregation-enable`
3. Restart the following services to apply the changes:
 - ResourceManager
 - NodeManager

zoo.cfg

Lists the ZooKeeper configuration file.

Example zoo.cfg File

The file `/opt/mapr/zookeeper/zookeeper-$version/conf/zoo.cfg` specifies ZooKeeper configuration parameters.

```
# The number of milliseconds of each tick
tickTime=2000
# The number of ticks that the initial
# synchronization phase can take
initLimit=20
# The number of ticks that can pass between
# sending a request and getting an acknowledgement
syncLimit=10
# the directory where the snapshot is stored.
dataDir=/opt/mapr/zkdata
```

```

# the port at which the clients will connect
clientPort=5181
# max number of client connections
maxClientCnxns=1000
#autopurge interval - 24 hours
autopurge.purgeInterval=24
#superuser to allow zk nodes delete
superUser=mapr
#readuser to allow read zk info for authenticated clients
readUser=anyone
# cldb key location
mapr.cldbkeyfile.location=/opt/mapr/conf/cldb.key
#security provider name
authMech=MAPR-SECURITY
# security auth provider
authProvider.1=org.apache.zookeeper.server.auth.SASLAuthenticationProvider
# use maprserverticket not userticket for auth
mapr.usemaprserverticket=true
#
# Added for 3.4.11-mapr
#
# ZK-to-ZK server authentication using MAPR-SASL
# Set quorum.auth.enableSasl=false for insecure cluster, =true for secure
cluster
quorum.auth.enableSasl=true
quorum.auth.learnerRequireSasl=true
quorum.auth.serverRequireSasl=true
quorum.auth.learner.loginContext=QuorumLearner
quorum.auth.server.loginContext=QuorumServer
quorum.cnxn.threads.size=20
#
# Added for 3.5.6-mapr
#
# ZK server-to-server SSL encryption
#
sslQuorum=true
serverCnxnFactory=org.apache.zookeeper.server.NettyServerCnxnFactory
ssl.quorum.keyStore.location=/opt/mapr/conf/ssl_keystore.p12
ssl.quorum.keyStore.password=<randomly generated password>
ssl.quorum.trustStore.location=/opt/mapr/conf/ssl_truststore.p12
ssl.quorum.trustStore.password=<randomly generated password>
ssl.quorum.protocol=TLS
ssl.quorum.enabledProtocols=TLSv1.2
# MapR uses the cluster name in the certificates, no host names
ssl.quorum.hostnameVerification=false
#
# The Jetty Admin Server allows ZK access via a URL
# Like http://localhost:8080/commands/stat
# Default port 8080 may cause conflicts; thus server disabled by default
# admin.serverPort=8080
admin.enableServer=false
#
# For upgrade from an existing 3.4.11 or older that had no snapshots
snapshot.trust.empty=true
#

```

WARNING: maxClientCnxns limits the number of concurrent ZooKeeper connections that a single client machine may make. This value does not set a limit for the whole cluster. The default is 100. If you plan to run more than 100 jobs from a single node, increase this value.

ATTENTION: By default, only **authenticated** users (users with a valid ticket) are allowed to execute ZooKeeper related commands. To allow **all** users to execute ZooKeeper related commands, add the entry `sessionRequireClientSASLAuth=false` to this file and restart ZooKeeper.

Enable Encrypted Quorum Communication

Perform the following steps to enable encrypted quorum communication between ZooKeeper nodes:

1. Copy all *.p12 certificates from the master CLDB node to all the ZooKeeper nodes.
2. Set the user and group of all the *.p12 certificates to `mapr` on all the ZooKeeper nodes.
3. Set `sslQuorum=true` in the `zoo.cfg` file.
4. Restart ZooKeeper and Warden:

```
service mapr-zookeeper restart
service mapr-warden restart
```

Related tasks

[Enabling Security on a Configured Cluster](#) on page 2048

Describes how to enable security for the cluster, platform, ecosystem components, and network-based connections.

zookeeper-env.sh

Use this file to load or unload JMX parameters for ZooKeeper.

By default, in all Data Fabric versions, the ZooKeeper JMX parameters are not loaded.

To load ZooKeeper JMX parameters, set the `JMXDISABLE` parameter to `false` in the `zookeeper-env.sh` file within the `/opt/mapr/zookeeper/zookeeper-$version/conf` directory.

```
JMXDISABLE=false
```

Restart the ZooKeeper process: `service mapr-zookeeper restart`.

To unload ZooKeeper JMX parameters, set:

```
JMXDISABLE=true
```

in `zookeeper-env.sh`. Restart the ZooKeeper process: `service mapr-zookeeper restart`.

Alarms Reference

The pages in this section provide details about all of the types of alarms.

User/Group Alarms

User/group alarms indicate problems with user or group quotas. The following tables describe the Data Fabric user/group alarms.

- Entity Advisory Quota Alarm
- Entity Quota Alarm

Entity Advisory Quota Alarm

UI Column

User Advisory Quota Alarm

Logged As	AE_ALARM_AEADVISORY_QUOTA_EXCEEDED
Meaning	A user or group has exceeded its advisory quota. See Setting Quota Defaults for Users and Groups on page 1344 for more information about user/group quotas.
Resolution	No immediate action is required. To avoid exceeding the hard quota, clear space on volumes created by the user or group, or stop further data writes to those volumes.
Configuration	Configurable when setting/modifying entity properties. See Configuring the Alarm Threshold Using the CLI on page 1349 for more information.

Entity Quota Alarm

UI Column	User Quota Alarm
Logged As	AE_ALARM_AEQUOTA_EXCEEDED
Meaning	A user or group has exceeded its quota. Further writes by the user or group will fail. See Setting Quota Defaults for Users and Groups on page 1344 and Set or Modify Quotas for Users and/or Groups on page 1539 for more information about user/group quotas.
Resolution	Free some space on the volumes created by the user or group, or increase the user or group quota.
Configuration	Configurable when setting/modifying entity properties. See Configuring the Alarm Threshold Using the CLI on page 1349 for more information.

Cluster Alarms

Cluster alarms indicate problems that affect the cluster as a whole. The following sections describe the Data Fabric cluster alarms.

CLDB Low Memory Alarm

UI Column	Cluster freespace above CLDB heapsize
Logged As	CLUSTER_ALARM_CLDB_HEAPSIZE
Meaning	The CLDB process needs more memory to cache containers.
Resolution	<p>The CLDB heap size is no longer sufficient for the CLDB to cache containers. The solution is to increase the CLDB memory settings on all CLDB nodes, using the same value for the minimum and maximum heap sizes. The text the alarm code provides will include the minimum amount of memory required to be sufficient; however, to accommodate future growth, you should set these values to a somewhat higher number. For example, if the alarm indicates that the CLDB needs 4000 MB, you should set the minimum and maximum heap sizes to a larger value such as 4400 MB.</p> <p>The CLDB memory settings are controlled by the following parameters in the <code>warden.conf</code> file located in <code>\$MAPR_HOME/conf/::</code></p>

```
service.command.cldb.heapsize.max=<max
heap size>
service.command.cldb.heapsize.min=<min
heap size>
```

Restart the Warden service on each CLDB node after you edit the `warden.conf` file.

License Near Expiration

UI Column

License Near Expiration Alarm

Logged As

CLUSTER_ALARM_LICENSE_NEAR_EXPIRATION

Meaning

The Enterprise Edition license associated with the cluster is within 30 days of expiration.

Resolution

Renew the Enterprise Edition license.

Configuration

Configurable at cluster level. See [Configuring the Alarm Threshold Using the CLI](#) on page 1349 for more information.

License Expired

UI Column

License Expiration Alarm

Logged As

CLUSTER_ALARM_LICENSE_EXPIRED

Meaning

The Enterprise Edition license associated with the cluster has expired. Enterprise Edition features have been disabled.

Resolution

Renew the Enterprise Edition license.

Cluster Almost Full

UI Column

Cluster Almost Full

Logged As

CLUSTER_ALARM_CLUSTER_ALMOST_FULL

Meaning

The cluster storage is almost full. The percentage of storage used before this alarm is triggered is 90% by default, and is controlled by the configuration parameter `cldb.cluster.almost.full.percentage`.

Resolution

Reduce the amount of data stored in the cluster. If the cluster storage is less than 90% full, check the `cldb.cluster.almost.full.percentage` parameter via the `config load` command, and adjust it if necessary via the `config save` command.

Configuration

Configurable at cluster level. See [Configuring the Alarm Threshold Using the CLI](#) on page 1349 for more information.

Cluster Full

UI Column

Cluster Full

Logged As

CLUSTER_ALARM_CLUSTER_FULL

Meaning

The cluster storage is full. MapReduce operations have been halted.

Resolution

Free up some space on the cluster.

Maximum Licensed Nodes Exceeded alarm

UI Column	Licensed Nodes Exceeded Alarm
Logged As	CLUSTER_ALARM_LICENSE_MAXNODES_EXCEEDED
Meaning	The cluster has exceeded the number of nodes specified in the license.
Resolution	Remove some nodes, or upgrade the license to accommodate the added nodes.

New Cluster Features Disabled

UI Column	New Cluster Features Disabled
Logged As	CLUSTER_ALARM_NEW_FEATURES_DISABLED
Meaning	Features added in version 2.0 or 3.0 are not enabled on the cluster.
Resolution	Enable the latest features for the Data Fabric version that you are currently running.

Upgrade in Progress

UI Column	Software Installation & Upgrades
Logged As	CLUSTER_ALARM_UPGRADE_IN_PROGRESS
Meaning	A rolling upgrade of the cluster is in progress.
Resolution	No action is required. Performance may be affected during the upgrade, but the cluster should still function normally. After the upgrade is complete, the alarm is cleared.

VIP Assignment Failure

UI Column	VIP Assignment Alarm
Logged As	CLUSTER_ALARM_UNASSIGNED_VIRTUAL_IPS
Meaning	Core software was unable to assign a VIP to any NFS servers.
Resolution	Check the VIP configuration, and make sure at least one of the NFS servers in the VIP pool are up and running. See Setting Up VIPs for NFS . This alarm can also indicate that a VIP's hostname exceeds the maximum allowed length of 16. Check the log file <code>/opt/mapr/logs/nfsmon.log</code> for additional information.

DARE Enabled

UI Column	DARE Enabled Alarm
Logged As	CLUSTER_ALARM_DARE_COPY_MASTER_KEY
Meaning	Data-at-rest encryption (DARE) is enabled on the cluster.
Resolution	When DARE is enabled on the cluster, a data-at-rest encryption master key file is generated and stored in the <code>/opt/mapr/conf/tokens</code> folder on the

CLDB node. Before dismissing the alarm, make a backup of the /opt/mapr/conf/tokens folder. For an upgraded cluster, you must also back up the dare.master.key stored in /opt/mapr/conf/. Loss of the master key file or the /opt/mapr/conf/tokens folder can be catastrophic and irreversible and might result in loss of data.

DARE Incompatible

UI Column

DARE Incompatible Alarm

Logged As

CLUSTER_ALARM_DARE_INCOMPATIBLE

Meaning

Not all nodes on the cluster are enabled for data-at-rest encryption (DARE).

Resolution

When DARE is enabled on certain nodes in the cluster, there may still be some nodes that are not (yet) enabled for DARE. Enable DARE on all the nodes before dismissing the alarm.

Too Many Snapshots

UI Column

Too Many Snapshots

Logged As

CLUSTER_ALARM_TOO_MANY_SNAPSHOT_CONTAINERS

Meaning

There are too many snapshots on this cluster.

Resolution

Delete snapshots from the cluster before dismissing the alarm.

Service Endpoints changed

UI Column

Either of the following:

- API Server endpoints changed for <cluster-name>
- API Server endpoints changed for <cluster-name>. Added cluster <cluster-name>.
- API endpoints changed. Updated from Cluster Group primary.
- API Server endpoints changed by updating ClusterGroup Primary.
- API Server endpoints changed. Removed cluster <cluster-name>
- API Server endpoints changed by resetTable.

Logged As

CLUSTER_ALARM_CLUSTERGROUP_ENDPOINTS_UPDATED

Meaning

This alarm is an information alarm. The alarm indicates a change in API server endpoint(s), that is, IP address(es).

NOTE: The API server endpoints/IP addresses may be required by Data Fabric for high availability.

API server endpoints would change if one of the following occurs:

- A new cluster is added to the cluster group/global namespace
- An existing cluster is removed from the cluster group/global namespace
- The primary cluster for the cluster group/global namespace changes
- An API server is added to or removed from any of the member clusters of the cluster group

Resolution

Download the updated API server endpoints from the UI by following the instructions given on [Viewing the Fabric Endpoint](#) or by using the `clustergroup get cgtable` on page 2351 command. Dismiss the alarm manually on the UI to turn the alarm off.

Insights running in trial mode

UI Column

Insights running in trial mode

Logged As

CLUSTER_ALARM_INSIGHTS_TRIAL_MODE

Meaning

The insights feature that is enabled on the cluster is running in trial mode with Hive Metastore using the Derby RDBMS to store insights table metadata.

Resolution

Associate the Hive metastore with a production grade RDBMS such as PostgreSQL or MySQL. The alarm will be cleared once this is done.

Node Alarms

Node alarms indicate problems in individual nodes. The following tables describe the MapR node alarms.

CLDB Service Alarm

UI Column

CLDB Alarm

Logged As

NODE_ALARM_SERVICE_CLDB_DOWN

Meaning

The CLDB service on the node has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check whether the CLDB service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in [warden.conf](#) on page 3378. If the warden successfully restarts the CLDB service, the alarm is cleared. If the warden is unable to restart the CLDB service, see [more troubleshooting information](#).

Core Present Alarm

UI Column

Core Present

Logged As

NODE_ALARM_CORE_PRESENT

Meaning	A service on the node has crashed and created a core dump file. When all core files are removed, the alarm is cleared.
Resolution	See troubleshooting information .
Debug Logging Active	
UI Column	Excess Logs Alarm
Logged As	NODE_ALARM_DEBUG_LOGGING
Meaning	Debug logging is enabled on the node.
Resolution	Debug logging generates enormous amounts of data, and can fill up disk space. If debug logging is not absolutely necessary, turn it off: use the setloglevel on page 2699 command. If it is absolutely necessary, make sure that the logs in /opt/mapr/logs are not in danger of filling the entire disk.
Degraded Mode	
UI Column	Degraded Mode
Logged As	NODE_ALARM_DEGRADED_MODE
Meaning	<p>The node has entered degraded mode due to database or MFS performance issues.</p> <p>Every 15 minutes, MFS checks the node. The alarm is raised if any of the following conditions are met in that 15-minute interval:</p> <ul style="list-style-type: none"> Any operation in the DB memory work area is stuck for more than 6 minutes. More than 100 DHLs are seen in the 15-minute interval for any DB or MFS operations. More than 100 large DB scans with low selectivity in the 15-minute interval. <p> NOTE: The following settings are not tunable:</p> <ul style="list-style-type: none"> The 15-minute evaluation interval The threshold of 100 DHLs in a 15-minute period The threshold of 100 large low-selectivity DB scans in a 15-minute period The 6-minute DB operation timer The alarm duration; after the alarm is raised, it will remain raised for one hour.
Resolution	Investigate the workload and health of the node to identify and reduce the conditions that cause degraded mode:

- Check for DB operations that are stuck or running unusually long in the DB memory work area, and terminate or tune those operations if possible.
- Review recent DB and MFS activity for a high number of DHLs, and address any underlying hardware, network, or configuration issues that might be causing frequent failures or retries.
- Identify workloads that trigger large, low-selectivity DB scans (for example, full-table scans with broad filters), and optimize those queries or jobs to reduce scan volume and improve selectivity.
- Ensure the node has sufficient CPU, memory, and disk resources, and that there are no underlying hardware or I/O problems contributing to stalls or excessive scans.

The alarm remains raised for 1 hour, so if the alarm persists for longer than 1 hour after you have addressed these issues, collect relevant logs (MFS, DB, and node metrics) and contact your support representative for further analysis.

Disk Failure

UI Column

Disk Failure Alarm

Logged As

NODE_ALARM_DISK_FAILURE

Meaning

A disk has failed on the node.

Resolution

Check the disk health log (/opt/mapr/logs/faileddisk.log) to determine which disk failed and view any SMART data provided by the disk. See [Managing Disks](#) on page 1406.

Duplicate Host ID

UI Column

Duplicate Host Id

Logged As

NODE_ALARM_DUPLICATE_HOSTID

Meaning

Two or more nodes in the cluster have the same host ID.

Resolution

Multiple nodes with the same host ID are prevented from joining the cluster, in order to prevent addressing problems that can lead to data loss. To correct the problem and clear the alarm, make sure all host IDs are unique and use the `mapcli node allow-into-cluster` command to un-ban the affected host IDs.

FileServer Service Alarm

UI Column

FileServer Alarm

Logged As

NODE_ALARM_SERVICE_FILESERVER_DOWN

Meaning

The FileServer service on the node has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check whether the FileServer service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in [warden.conf](#) on page 3378 file. If the warden successfully restarts the FileServer service, the alarm is cleared. If the warden is unable to restart the FileServer service, see [more troubleshooting information](#).

Gateway Service Alarm**Label for Alarm on MCS UI**

Gateway Service Down

Text for Alarm on Log File

NODE_ALARM_SERVICE_GATEWAY_DOWN

Meaning

The gateway service has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check whether the gateway service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in [warden.conf](#) on page 3378. If the warden successfully restarts the gateway service, the alarm is cleared. If the warden is unable to restart the gateway service, see [more troubleshooting information](#).

Beeswax Service Alarm**Label for Alarm on MCS UI**

NODE_ALARM_SERVICE_BEESWAX_DOWN

Text for Alarm on Log File

NODE_ALARM_SERVICE_BEESWAX_DOWN

Meaning

The Beeswax service has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check if the Beeswax service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in [warden.conf](#) on page 3378. If the warden successfully restarts the Beeswax service, the alarm is cleared. If the warden is unable to restart the Beeswax service, see [more troubleshooting information](#).

S3 Server Alarm**Label for Alarm on MCS UI**

S3 Server Down

Text for Alarm on Log File

NODE_ALARM_SERVICE_S3SERVER_DOWN

Meaning

The S3 server has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check whether the S3 server is running. The warden will try three times to restart the S3 server automatically. After an interval (30 minutes by default) the warden will again try three times to restart the S3 server. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3378. If the warden successfully restarts the S3 server, the alarm is cleared. If the warden is unable to restart the S3 server, see [more troubleshooting information](#).

Heartbeat Processing Slow**UI Column**

Heartbeat Processing Slow Alarm

Logged As

NODE_ALARM_HB_PROCESSING_SLOW

Meaning

The time that has elapsed since the CLDB processed the previous heartbeat from the file system node has exceeded 5 seconds.

Resolution

When the CLDB is processing a heartbeat from a node, it will compare the current time to the time at which the previous heartbeat from that node was processed. If the elapsed time exceeds 5 seconds then this alarm is raised. If this alarm occurs frequently, investigate what might be causing the relevant node or nodes to be busy, or whether the CLDB nodes have enough resources to handle their load.

HBMaster Service Alarm**UI Column**

HBase Master Alarm

Logged As

NODE_ALARM_SERVICE_HBMASTER_DOWN

Meaning

The HBMaster service on the node has stopped running.

Resolution

To check whether the HBMaster service is running, go to the [node information page](#) or the **Services** page in the Control System. Warden will try three times to restart the service automatically. After an interval (30 minutes by default), Warden will again try three times to restart the service. The interval can be configured using the `services.retryinterval.time.sec` parameter in the `warden.conf` file. If Warden successfully restarts the HBMaster service, the alarm is cleared. If Warden is unable to restart the HBMaster service, it might be necessary to contact technical support.

HBRegion Service Alarm**UI Column**

Hbase RegionServer Alarm

Logged As

NODE_ALARM_SERVICE_HBREGION_DOWN

Meaning

The HBRegion service on the node has stopped running.

Resolution	To check whether the HBRegion service is running, go to the node information page or the Services page in the Control System. Warden will try three times to restart the service automatically. After an interval (30 minutes by default), Warden will again try three times to restart the service. The interval can be configured using the <code>services.retryinterval.time.sec</code> parameter in the <code>warden.conf</code> file. If Warden successfully restarts the HBRegion service, the alarm is cleared. If Warden is unable to restart the HBRegion service, it might be necessary to contact technical support.
High MAST Gateway Memory Alarm	
UI Column	High Memory Usage
Logged As	NODE_ALARM_HIGH_MASTGATEWAY_MEMORY
Meaning	Memory consumption of MAST Gateway exceeds the memory allocated for MAST Gateway.
Resolution	Tune the percentage of node memory allocated for MAST Gateway in the <code>/opt/mapr/conf/conf.d/warden.mastgateway.conf</code> file. See Configuring MAST Gateway for more information. If core is generated for this error, contact HPE support.
HistoryServer Alarm	
UI Column	HistoryServer Alarm
Logged As	NODE_ALARM_SERVICE_HISTORYSERVER_DOWN
Meaning	The HistoryServer on the node has stopped running.
Resolution	Go to the node information page or the Services page in the Control System to check whether HistoryServer is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter <code>services.retryinterval.time.sec</code> in the <code>warden.conf</code> on page 3378 file. If warden successfully restarts the HistoryServer, the alarm is cleared. If Warden is unable to restart the HistoryServer, see more troubleshooting information .
HiveMeta Alarm	
UI Column	HiveMeta Alarm
Logged As	NODE_ALARM_SERVICE_HIVEMETA_DOWN
Meaning	The HiveMeta service on the node has stopped running.
Resolution	Go to the node information page or the Services page in the Control System to check whether Hive Metastore is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This

30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the [warden.conf](#) on page 3378 file.

If Warden successfully restarts the Hive Metastore service, the alarm is cleared. If Warden is unable to restart the Hive Metastore service, see [more troubleshooting information](#).

HiveServer 2 Alarm

UI Column

HiveServer 2 Alarm

Logged As

NODE_ALARM_SERVICE_HS2_DOWN

Meaning

The HiveServer 2 service on the node has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check whether HiveServer 2 is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the [warden.conf](#) on page 3378 file.

If Warden successfully restarts the HiveServer 2 service, the alarm is cleared. If Warden is unable to restart the HiveServer 2 service, see [more troubleshooting information](#).

Hoststats Alarm

UI Column

HostStats

Logged As

NODE_ALARM_SERVICE_HOSTSTATS_DOWN

Meaning

The Hoststats service on the node has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check whether the Hoststats service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in [warden.conf](#) on page 3378 file. If the warden successfully restarts the service, the alarm is cleared. If the warden is unable to restart the service, review [more troubleshooting information](#).

Incorrect Topology Alarm

UI Column

CLDB Alarm

Logged As

NODE_ALARM_INCORRECT_TOPOLOGY_ALARM

Meaning

The `mapr.cldb.internal` volume's topology (normally `/cldb`) must include all CLDB nodes. This alarm signifies that one or more CLDB nodes are outside the CLDB volume's topology.

Resolution

There are two ways to resolve this alarm:

- Move any stray CLDB nodes into the topology in which `mapr.cldb.internal` resides. See [Setting Up Volume Topology](#) on page 1492 for more information.
- Change the volume topology of `mapr.cldb.internal` to include the stray CLDB nodes. See [Administering Volumes](#) on page 1429 for more information.

Installation Directory Full Alarm**UI Column**

Installation Directory Full

Logged As

NODE_ALARM_OPT_MAPR_FULL

Meaning

The partition `/opt/mapr` on the node is running out of space (95% full).

Resolution

Free up some space in `/opt/mapr` on the node.

Instance Mismatch Alarm**UI Column**

Instance Mismatch Alarm

Logged As

NODE_ALARM_NUM_INSTANCES_MISMATCH

Meaning

The number of file system instances is not as configured.

Resolution

Restart warden on the node by running the following command:

```
service mapr-warden restart
```

High FileServer Memory Alarm**UI Column**

High FileServer Memory Alarm

Logged As

NODE_ALARM_HIGH_MFS_MEMORY

Meaning

Memory consumed by **fileserver** service on the node is in excess of the allotted amount.

Resolution

Log on as root to the node for which the alarm is raised, and restart the Warden: `service mapr-warden restart`

Configuration

Configurable at cluster level. See [Configuring the Alarm Threshold Using the CLI](#) on page 1349 for more information.

MapR User Mismatch**UI Column**

MapR User Mismatch Alarm

Logged As

NODE_ALARM_MAPRUSER_MISMATCH

Meaning	The cluster nodes are not all set up to run MapR services as the same user (for example, some nodes are running MapR as root while others are running as <code>mapr_user</code>).
Resolution	For the nodes on which the User Mismatch alarm is raised, follow the steps in Changing the User for Data Fabric Services from the Command-Line on page 1403.
Memory Allocation Alarm	
UI Column	Memory Allocation Alarm
Logged As	NODE_ALARM_MEMORY_ALLOCATION_EXCEEDED
Meaning	The percentage of system memory required to run services on the node exceeds the set threshold and could potentially overload the node. If you installed a service on the node that causes the sum of memory used by the services on the node to exceed the threshold set, the system raises the alarm.
Resolution	<p>To clear the alarm, you can add more memory to the node, stop a service from running on the node, or remove a service from the node. You can run the <code>service list</code> command to see the memory allocated to each service on the node. See service list for more information.</p> <p>The <code>services.memoryallocation.alarm.threshold</code> property in <code>warden.conf</code> defines the maximum amount of system memory that services running on the node can use before triggering the alarm. The default setting for this property is 95 percent:</p> <pre>services.memoryallocation.alarm.threshold=95</pre> <p>The percentage of system memory that services can use on the node should not exceed 95. Restart the Warden service on the node after you edit the <code>warden.conf</code> file.</p>
Memory Usage Alarm	
UI Column	Memory Usage Alarm
Logged As	NODE_ALARM_MEMORY_SWAPPING
Meaning	The HostStats service raises this alarm for swap space when the delta of swap in memory and the delta of swap out memory exceeds the threshold set over a specific time period.
Resolution	To clear the alarm, you can increase the physical memory or reduce the load running on the node. You can run the <code>service list</code> command to see the memory allocated to each service on the node. See service list for more information.

The memory swapping alarm is controlled by the following properties in `/opt/mapr/conf/hoststats.conf`:

- `alarm.swapping.threshold`
- `alarm.swapping.counter`

The memory threshold for swap in and swap out is defined by the `alarm.swapping.threshold` property, which is set to 100MB by default. The duration over which HostStats checks the delta of the memory is defined by the `alarm.swapping.counter`, which is set to 100 seconds by default.

High NFS4 Memory Alarm

UI Column

High NFS4 Process Memory Consumption

Logged As

NODE_ALARM_HIGH_NFS4_MEMORY

Meaning

Memory consumed by **NFS4** service on the node is in excess of the allotted amount.

Resolution

Log on as root to the node for which the alarm is raised, and restart the NFS4 service or Warden:
`service mapr-warden restart`

Configuration

Configurable at cluster level. See [Configuring the Alarm Threshold Using the CLI](#) on page 1349 for more information.

NFS Gateway Alarm

UI Column

NFS Service Down

Logged As

NODE_ALARM_SERVICE_NFS_DOWN

Meaning

The NFS service on the node has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check whether the NFS service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in [warden.conf](#) on page 3378 file. If the warden successfully restarts the NFS service, the alarm is cleared. If the warden is unable to restart the NFS service, see [more troubleshooting information](#).

NFSv4 Service Alarm

NOTE: NFSv4 refers to NFS version 4.1.

UI Column

NFSv4 Service Down

Logged As

NODE_ALARM_SERVICE_NFS4_DOWN

Meaning

The NFSv4 service on the node has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check whether the NFS service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the parameter `services.retryinterval.time.sec` in `warden.conf` on page 3378 file. If the warden successfully restarts the NFS service, the alarm is cleared. If the warden is unable to restart the NFS service, refer to [NFSv4 Troubleshooting](#) on page 1856 to restart the service.

NodeManager Alarm

Explains how to resolve the issue with the Node Manager service stopping on the node.

UI Column

NodeManager Alarm

Logged As

NODE_ALARM_SERVICE_NODEMANAGER_DOWN

Meaning

The NodeManager service on the node has stopped running.

Resolution

Go to the [node information page](#) or the **Services** page in the Control System to check whether NodeManager is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter `services.retryinterval.time.sec` in the `warden.conf` on page 3378 file.

If warden successfully restarts the NodeManager, the alarm is cleared. If warden is unable to restart the NodeManager, see [more troubleshooting information](#).

No Disk Attached Alarm**UI Column**

No Disk Attached Alarm

Logged As

NODE_ALARM_NO_DISK_ATTACHED

Meaning

There are one or more file system instances on a node with no SP assigned to them.

Resolution

To clear the alarm, assign at least one SP per file system.

No Heartbeat Alarm

Describes the NODE_ALARM_NO_HEARTBEAT alarm.

UI Column

No Heartbeat Alarm

Logged As

NODE_ALARM_NO_HEARTBEAT

Meaning

Node is not undergoing maintenance, and no heartbeat detected for over 5 minutes.

Resolution

Check the status of the node manually.

Configuration

Configurable at cluster level. See [Configuring the Alarm Threshold Using the CLI](#) on page 1349 for more information.

This alarm is raised when a node is down for more than 5 minutes. By default, this alarm is not raised if an edge node is down. To raise an alarm for edge nodes as well, set the [CLDB parameter](#) `cldb.ignore.posix.only.hb.alarm` to 0 using the command:

```
/opt/mapr/bin/maprcli config save -values
'{"cldb.ignore.posix.only.hb.alarm": "0"}'
```

Security Certificate Expiry Alarm

Describes the `NODE_ALARM_CERTIFICATE_NEAR_EXPIRATION` alarm.

UI Column	SSL Certificate Expiry
Logged As	NODE_ALARM_CERTIFICATE_NEAR_EXPIRATION
Meaning	SSL certificates are expiring within the number of days denoted by the CLDB setting <code>cldb.ssl.cert.expiring.alarm.days</code> . See cldb.conf on page 3358 for more information.
Resolution	Renew the SSL certificates. See Importing a Certificate Authority Signed (CA Signed) SSL Certificate Into a MapR Cluster for more information.
Configuration	None.
Specification	<p>This alarm is raised when any of the first ten security certificates in <code>/opt/mapr/conf/ssl_keystore</code> or in <code>/opt/mapr/conf/ssl_truststore</code> are set to expire within the number of days denoted by the CLDB setting <code>cldb.ssl.cert.expiring.alarm.days</code>. Once the alarm is raised, the administrator needs to find out the certificates that are expiring, and renew them.</p> <p>To find out the certificates that are expiring, use the <code>/opt/mapr/server/getSSLExpiryCerts.py</code> Python script. For example:</p>

```
python /opt/mapr/server/
getSSLExpiryCerts.py -print
    Below certificates
    expiring in the next 120 days
    Truststore:
        Alias: 100day valid
    until: Mon Jul 13 04:04:15 PDT 2020
        Alias: 65day valid
    until: Mon Jun 08 03:45:44 PDT 2020
        Alias: 70day valid
    until: Sat Jun 13 03:46:00 PDT 2020
        Alias: 80day valid
    until: Tue Jun 23 03:46:14 PDT 2020
        Alias: 90day valid
    until: Fri Jul 03 04:03:57 PDT 2020
    Keystore:
        Alias: 3daymay17 valid
    until: Thu May 21 04:20:26 PDT 2020
```

Related reference

[cldb.conf](#) on page 3358

Contains the configuration for CLDB nodes.

Node Too Many Containers

UI Column	Too Many Containers Alarm
Logged As	NODE_ALARM_TOO_MANY_CONTAINERS
Meaning	Number of containers on this node reached the maximum limit.
Resolution	<p>Delete unused volumes or Snapshots. You can reset the maximum with:</p> <pre>maprcli config save -values {"pernode.numcntrs.alarm.thr": "<number>" }</pre>
Configuration	<p>Configurable at cluster level.</p> <p>This alarm is also raised when total number of containers (including snap containers) exceed 10 times the value of <code>pernode.numcntrs.alarm.thr</code>.</p> <p>See Configuring the Alarm Threshold Using the CLI on page 1349 for more information.</p>

PAM Misconfigured Alarm

UI Column	Pam Misconfigured Alarm
Logged As	NODE_ALARM_PAM_MISCONFIGURED
Meaning	The PAM authentication on the node is configured incorrectly.
Resolution	See PAM Configuration .

ResourceManager Alarm

UI Column	ResourceManager Alarm
Logged As	NODE_ALARM_SERVICE_RESOURCEMANAGER_DOWN
Meaning	The ResourceManager service on the node has stopped running.
Resolution	<p>Go to the node information page or the Services page in the Control System to check whether ResourceManager is running. Warden will try three times to restart the service automatically ever 30 minutes (by default). This 30 minute interval can be reconfigured using the parameter <code>services.retryinterval.time.sec</code> in the warden.conf on page 3378 file.</p> <p>If warden successfully restarts the ResourceManager, the alarm is cleared. If warden is unable to restart the ResourceManager, see more troubleshooting information.</p>

Root Partition Full Alarm

UI Column	Root Partition Full
Logged As	NODE_ALARM_ROOT_PARTITION_FULL

Meaning	The root partition (/) on the node is running out of space (99% full).
Resolution	Free up some space in the root partition of the node.

Tiny Buckets Flush Alarm

UI Column	Lot of Tiny Buckets Flushed
Logged As	NODE_ALARM_TINY_BUCKET_FLUSH
Meaning	Indicates lot of small buckets ($\leq 8\text{mb}$) are getting flushed in DB resulting in performance degradation. You may see put operation performance going down during this phase and will need to take corrective actions to fix it. This will not bring down the cluster and data is still accessible.
Resolution	Increase memory for file system as number of active tablets is very high.

Time Skew Alarm

UI Column	Time Skew Alarm
Logged As	NODE_ALARM_TIME_SKEW
Meaning	The clock on the node is out of sync with the master CLDB by more than 20 seconds.
Resolution	Use NTP to synchronize the time on all the nodes in the cluster.

Version Alarm

UI Column	Version Alarm
Logged As	NODE_ALARM_VERSION_MISMATCH
Meaning	One or more services on the node are running an unexpected version or there is a mismatch in the file system patch versions on the nodes.
Resolution	Stop the node, Restore the correct version of any services you have modified, and re-start the node. See Administering Nodes on page 1363.

WebServer Service Alarm

UI Column	Webserver Alarm
Logged As	NODE_ALARM_SERVICE_WEBSERVER_DOWN
Meaning	The WebServer service on the node has stopped running.
Resolution	Go to the node information page or the Services page in the Control System to check whether the WebServer service is running. The warden will try three times to restart the service automatically. After an interval (30 minutes by default) the warden will again try three times to restart the service. The interval can be configured using the

parameter `services.retryinterval.time.sec` in [warden.conf](#) on page 3378. If the warden successfully restarts the WebServer service, the alarm is cleared. If the warden is unable to restart the WebServer service, see [more troubleshooting information](#).

Table-Replication Alarms

You can view table-replication alarms using the Control System and the CLI. See [Viewing Active Table Replication Alarms](#) on page 1957 for more information.

Table Replication Errors

Explains the alarm that is raised when there are table replication errors.

Logged As	VOLUME_ALARM_TABLE_REPL_ERROR
Meaning	This alarm displays the paths and names of the source tables for which the alarms were issued. Up to ten (10) source tables, that have encountered an error, are displayed.

Diagnostics

To identify the cause of the alarm, run the [maprcli table replica list](#) command. This command displays an errors field with additional information about the error.

```
maprcli table replica list -path <table path>
```

The errors field provides the following information:

- Code - table replication error code:
- Host - host that the error occurred on
- Msg - error message information

For additional information about possible causes of the error, see the following log files (located in the **/opt/mapr/logs** directory):

- mfs.log-5 - for the nameserver node of the source table
- mfs.log-5 - for the nameserver node of the destination table
- gateway.log

Error Conditions

Possible Error Conditions	Description
A missing table or column family on the destination cluster	If a column family no longer exists in the replica, pause replication with the <code>maprcli table replica pause</code> command, recreate the column family with the <code>maprcli table cf create</code> command, run the CopyTable utility to copy data from the source table into the column family, and then resume replication with the <code>maprcli table replica resume</code> command.

Possible Error Conditions	Description
A mismatch in column family names for the table on the destination cluster	If the column family still exists in the replica but the name of the column family was changed, run the <code>maprcli table cf edit</code> command with the parameter <code>-newcfname</code> set to the correct name. Replication will resume automatically.
Unreachable gateways on the destination cluster	This error occurs only if none of the gateways on the cluster are reachable.
Autosetup with directcopy has failed while copying data from the source to the replica	<p>This error could be raised under the following conditions:</p> <ul style="list-style-type: none"> If this error occurs due to a connection failure, this alarm should get resolved once the connection is restored. If this error occurs due to other error conditions such as missing tables, mis-matched column families, or an unreachable gateway, the error condition may not get resolved on its own and may need administration action. For example, if a PUT operation fails on destination cluster due to an Out-Of-Space condition, the administrator will need to add more storage before the PUT retry succeeds.

Table Replication Lag High

Logged As

VOLUME_ALARM_TABLE_REPL_LAG_HIGH

Meaning

These alarms display the paths and names of the source tables for which the replication lag is high. High lag times might be caused by these conditions:

- High load on the source or replica
- Low network bandwidth between the source and replicas
- Miscellaneous error conditions that prevent replication from proceeding
- Replication explicitly paused on the source cluster

Configuration

Configurable at the volume level. See [volume create](#) on page 2929 for more information.

Table Replication Asynchronous

Logged As

VOLUME_ALARM_TABLE_REPL_ASYNC

Meaning

These alarms display the pathnames of the source tables that are involved.

If HPE Data Fabric Database is replicating synchronously and it judges the latency of the replication stream to be too high, it will switch to asynchronous replication temporarily.

After a new gateway is created, an existing gateway is restarted, or after latency is sufficiently reduced, HPE Data Fabric Database switches the mode of replication back to synchronous.

You can also check whether a source table is being replicated synchronously or asynchronously by

running the command [table replica list](#) on page 2853 .

Elasticsearch Formatting Alarm

Logged As

NODE_ALARM_SERVICE_ELASTICSEARCH_EXCP

Meaning

The put of primary table cannot be converted/formatted for pushing to ElasticSearch. If the primary table has ElasticSearch as one of its replicas, that may miss updates on some rows as they could not be converted to a supported format for ElasticSearch.

Resolution

Check for rows that could not be formatted for pushing to ElasticSearch in file system logs and insert row with data that can be pushed to ElasticSearch.

Secondary Index Alarms

Secondary index alarms indicate issues that HPE Data Fabric Database might encounter while updating secondary indexes. It is important that you understand what the alarms indicate, and how to resolve the issue causing them.

Secondary Index Update Lag High

Logged As

VOLUME_ALARM_TABLE_INDEX_LAG_HIGH

Meaning

This alarm displays the paths and names of the source tables for which replication lag is high. High lag times might be caused by these conditions:

- High load on the source or replica
- Low network bandwidth between the source and replicas
- Miscellaneous error conditions that prevent replication from proceeding
- Replication explicitly paused on the source cluster

Resolution

If you have configured the threshold for this alarm too low, you can increase the threshold. You configure this lag at the volume level by specifying the `dbindexlagsecalarmthresh` parameter. See [volume modify](#) on page 3018 for more information.

Secondary Index Update Error

Logged As

VOLUME_ALARM_TABLE_INDEX_ERROR

Meaning

This alarm occurs if the JSON table regions cannot connect to any of the internal gateways used to update fields in a secondary index. This might be caused by these conditions:

- The replication gateway failed.
- You have configured too few replication gateway instances.

Resolution	If the gateway failed, restart it. Otherwise, add more gateways. See Managing Gateways on page 1791 for further information.
-------------------	--

Secondary Index Encoding Error

Logged As	VOLUME_ALARM_TABLE_INDEX_ENCODING_ERROR
------------------	---

Meaning	<p>This alarm occurs when any of the following encoding errors occur during index updates:</p> <ul style="list-style-type: none"> The indexed rowkey size is too big (> 32 Kb). The indexed field contains a CAST function, and a failure occurs evaluating the CAST function.
----------------	---

Resolution	<p>You must either correct your underlying data or redefine the index to avoid missing rows. See Troubleshooting Secondary Index Encoding Errors on page 1731 for details about how to identify these errors and possible corrective actions.</p> <p>You also must manually clear this alarm, even if you drop the index or the table.</p>
-------------------	--

Volume Alarms

Volume alarms indicate problems in individual volumes. The following sections describe the Data Fabric volume alarms.

Compaction Failed

UI Column	Volume Compaction Failed
Logged As	VOLUME_ALARM_COMPACTON_FAILURE
Meaning	Data could not be purged as the compactor did not complete the run.
Resolution	Wait for the compactor to run again or manually trigger the compactor using the volume compact on page 2924 command.

Compaction Skipped Large Container Volume Alarm

Compaction is skipped due to large container with garbage below the garbage threshold in the container.

Label for Alarm on MCS UI	Compaction Skipped Large Container
Text for Alarm on Log File	VOLUME_ALARM_COMPACTON_SKIPPED_LARGE_CONTAINER
Meaning	<p>Compaction has been skipped for the container because container size is large, but the amount of garbage to be reclaimed from the container is not large enough. When the amount of garbage to reclaim is less than the value specified for <code>mastgateway.ctc.opt.largenuminodes.threshmb</code> (default is 2GB), compaction is skipped. Refer to Data Compaction and Recall Criteria on page 591 for details on data compaction and recall criteria.</p>

Compaction is skipped for some large containers having garbage beyond configured threshold. This happens when the value of the configuration variable, `mastgateway.ctc.opt.largenuminodes.skipqualifiedctrs.enabled`, is set to 1.

NOTE: Refer to [config](#) on page 2378 for the detailed description of the configuration variables.

Resolution

Use one of the following ways as suitable.

- Increase the garbage threshold high enough so that when compaction runs, the actual amount of garbage goes below this higher threshold. The variable, `mastgateway.ctc.opt.largenuminodes.thresholdmb`, represents the garbage threshold.
- Run compaction manually with a lower overhead threshold. This causes compactor to free up more space. However, this option causes compaction to run longer. Default overhead threshold is 30%. Refer to [Running the Compactor Using the CLI and REST API](#) on page 1524 for details on running compaction manually.

The alarm goes away when compaction frees up enough space in the container. The alarm continues to display if the garbage in the container after compaction is above the garbage threshold.

Data Unavailable

UI Column

Logged As

Meaning

Data Alarm

VOLUME_ALARM_DATA_UNAVAILABLE

This is a potentially very serious alarm that may indicate data loss. Some of the data on the volume cannot be located. This alarm indicates that enough nodes have failed to bring the replication factor of part or all of the volume to zero. For example, if the volume is stored on a single node and has a replication factor of one, the Data Unavailable alarm will be raised if that volume fails or is taken out of service unexpectedly. If a volume is replicated properly (and therefore is stored on multiple nodes) then the Data Unavailable alarm can indicate that a significant number of nodes is down.

Resolution

Investigate any nodes that have failed or are out of service.

- You can see which nodes have failed by looking at the [Node Health](#) pane in the **Overview** page in the Control System.
- Check the cluster(s) for any snapshots or mirrors that can be used to re-create the volume.

For additional troubleshooting information, see [how to handle this alarm](#).

Data Under-Replicated

Describe the alarm that is triggered when a volume is under replicated.

UI Column	Replication Alarm
Logged As	VOLUME_ALARM_DATA_UNDER_REPLICATED
Meaning	The volume replication factor is lower than the desired replication factor set for the volume. This can be caused by failing disks or nodes, or the cluster may be running out of storage space.
Resolution	Investigate any nodes that are failing. You can see which nodes have failed by looking at the Node Health pane in the Overview page on the Control System. Determine whether it is necessary to add disks or nodes to the cluster. This alarm is generally raised when the nodes that store the volumes or replicas have not sent a heartbeat for five minutes. To prevent re-replication during normal maintenance procedures, Data Fabric waits a specified interval (by default, one hour) before considering the node dead and re-replicating its data. You can control this interval by setting the <code>cldb.fs.mark.rereplicate.sec</code> parameter using the <code>config save</code> command. For additional troubleshooting information, see how to handle this alarm .

Warm-Tier Data Node Down

Provides the resolution for the Warm-Tier Data Node Down alarm.

UI Column	Warm-Tier Data Node Down
Logged As	VOLUME_ALARM_DEGRADED_EC_STRIPES
Meaning	One of the nodes or SPs, on which either the data or parity fragments associated with the tiering enabled volume resides, is offline or down.
Resolution	Data Fabric tolerates failure of nodes equal to the number of parity fragments. However, to ensure the availability of data, add nodes to the topology or cluster.

Data Under-Encoded

UI Column	Volume Data Under-Encoded
Logged As	VOLUME_ALARM_CRITICALLY_DEGRADED_EC_STRIPES
Meaning	The number of nodes that are down is equal to the number of parity fragments.
Resolution	Data Fabric tolerates failure of nodes equal to the number of parity fragments. However, to ensure the availability of data, add nodes to the topology or cluster.

Data Below-Parity

UI Column	Volume Data Below-Parity
Logged As	VOLUME_ALARM_EC_DATA_UNAVAILABLE

Meaning	The number of SPs or nodes that are offline or down exceed the number of parity fragments set for the tiering-enabled volume. Data Fabric only tolerates failure of nodes equal to the number of parity fragments set for the tiering-enabled volume.
Resolution	Add more nodes to the topology or cluster.
Offload/Recall Failed	
UI Column	Volume Offload/Recall Failed
Logged As	VOLUME_ALARM_OFFLOAD_RECALL_FAILURE
Meaning	The volume data could not be offloaded or could not be recalled.
Resolution	Check the log file for more information on the error. For some errors, CLDB tries to offload the data again after a brief wait. For more information, see Retrying Failed Operation on page 1521.
Inodes Limit Exceeded	
UI Column	Inodes Exceeded Alarm
Logged As	VOLUME_ALARM_INODES_EXCEEDED
Meaning	The volume contains too many files or the size of the namespace container size has exceeded the configured limit.
Resolution	<p>This alarm indicates that not enough volumes are set up to handle the number of files stored in the cluster or the size of the name container exceeds the limit. Typically, each user or project should have a separate volume. To resolve the name container issue, investigate the cause for the alarm. After careful consideration, create one or more volumes and move data into the new volumes.</p> <p>See How to handle the VOLUME_ALARM_INODES_EXCEEDED alarm for more information on resolving this alarm.</p>
Configuration	Configurable at cluster and volume level. See Configuring the Alarm Threshold Using the CLI on page 1349 for more information.
Large Row	
UI Label	Large Row
Logged As	VOLUME_ALARM_TABLE_LARGE_ROW_WARNING
Meaning	A row in a table within the specified volume has reached 75% of the maximum supported row size of 2 GB. The alarm provides the rowkey and the name of the table. If the rowsize exceeds 2 GB, subsequent HPE Data Fabric Database operations on the corresponding table region will fail with an I/O error.

Resolution

Ensure that client applications that access the table are managing row data correctly, so that no row exceeds 2 GB. The method of resolving the alarm depends on the way in which client applications were managing row data.

For example, if client applications allowed too many versions of cell data, delete excess versions. If client applications neglected to remove old columns or column families, remove those manually.

Mirror Failure**UI Column**

Mirror Alarm

Logged As

VOLUME_ALARM_MIRROR_FAILURE

Meaning

A mirror operation failed.

Resolution

Make sure the CLDB is running on both the source cluster and the destination cluster. Look at the CLDB log (/opt/mapr/logs/cldb.log) and the filesystem log (/opt/mapr/logs/mfs.log) on both clusters for more information. If the attempted mirror operation was between two clusters, make sure that both clusters are reachable over the network. Make sure the source volume is available and reachable from the cluster that is performing the mirror operation. For more troubleshooting information, see [how to handle this alarm](#).

No Nodes in Topology**UI Column**

No Nodes in Vol Topo

Logged As

VOLUME_ALARM_NO_NODES_IN_TOPOLOGY

Meaning

The path specified in the volume's topology no longer corresponds to a physical topology that contains any nodes, either due to node failures or changes to node topology settings. While this alarm is raised, MapR places data for the volume on nodes outside the volume's topology to prevent write failures.

Resolution

Add nodes to the specified volume topology, either by moving existing nodes or adding nodes to the cluster. See [Understanding Topology](#) on page 563.

Snapshot Failure**UI Column**

Snapshot Alarm

Logged As

VOLUME_ALARM_SNAPSHOT_FAILURE

Meaning

A snapshot operation failed.

Resolution

Make sure the CLDB is running. Look at the CLDB log (/opt/mapr/logs/cldb.log) and the Data Fabric file system log (/opt/mapr/logs/mfs.log) on both clusters for more information. If the attempted snapshot was a scheduled snapshot that was running in the background, try a manual snapshot. For more

troubleshooting information, see [how to handle this alarm](#).

Snapshot Restore Failure

Describes the alarm that is triggered when the Snapshot Restore operation fails repeatedly.

UI Column	Snapshot Restore Failure Alarm
Logged As	VOLUME_ALARM_SNAPRESTORE_MAXRETRIES_EXCEEDED
Meaning	The snapshot restore operation failed and is retried for more than five (5) times for a single container.
Resolution	View MFS and CLDB logs to determine the cause of failure. Ensure that the master containers for all nodes are up and running.

Related concepts

[Restoring a Volume From a Snapshot](#) on page 593

Provides a synopsis of restoring a volume from a snapshot. Describes the implications, and the prerequisites.

Topology Almost Full

UI Column	Vol Topo Almost Full
Logged As	VOLUME_ALARM_TOPOLOGY_ALMOST_FULL
Meaning	The nodes in the specified topology are running out of storage space.
Resolution	Move volumes to another topology, enlarge the specified topology by adding more nodes, or add disks to the nodes in the specified topology.
Configuration	Configurable at cluster level. See Configuring the Alarm Threshold Using the CLI on page 1349 for more information.

Label Almost Full

The alarm that is triggered when Storage Pools/Nodes with the specified label are running out of space.

UI Column	Vol Label Almost Full
Logged As	VOLUME_ALARM_LABEL_ALMOST_FULL
Meaning	The free storage space on Storage Pools/Nodes with the specified label is lesser than the threshold value. This can disrupt creation/replication of containers with the specified label.
Resolution	Move volumes to another topology with sufficient free storage space on nodes with the specified label, enlarge the current topology by adding more nodes with the specified label, or add disks with the specified label to the nodes in the current topology.
Configuration	Configurable at cluster level. See Configuring the VOLUME_ALARM_LABEL_ALMOST_FULL alarm for more information.

Topology Full Alarm

UI Column	Vol Topo Full
Logged As	VOLUME_ALARM_TOPOLOGY_FULL
Meaning	The nodes in the specified topology have out of storage space.
Resolution	Move volumes to another topology, enlarge the specified topology by adding more nodes, or add disks to the nodes in the specified topology.

Label Full Alarm

The alarm that is triggered when Storage Pools/Nodes with the specified label are completely out of space.

UI Column	Vol Label Full
Logged As	VOLUME_ALARM_LABEL_FULL
Meaning	There is no more free storage space on Storage Pools/Nodes with the specified label. This will definitely disrupt creation/replication of containers with the specified label.
Resolution	Move volumes to another topology with sufficient free storage space on nodes with the specified label, enlarge the current topology by adding more nodes with the specified label, or add disks with the specified label to the nodes in the current topology.

NOTE: There is a [Label Almost Full](#) on page 3419 alarm that is raised when the available storage space goes below the configured threshold.

Volume Advisory Quota Alarm

UI Column	Vol Advisory Quota Alarm
Logged As	VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED
Meaning	A volume has exceeded its advisory quota.
Resolution	No immediate action is required. To avoid exceeding the hard quota, clear space on the volume or stop further data writes.
Configuration	Configurable in volume properties. See Configuring the Alarm Threshold Using the CLI on page 1349 for more information.

Volume Become Master Stuck

UI Column	VOLUME BECOME MASTER STUCK
Logged As	VOLUME_ALARM_BECOME_MASTER_STUCK
Meaning	This means that there are some containers (associated with the volume) that don't have Master role. The alarm description displays the containers on which Master role is not assigned.
Resolution	Run dump containerinfo on page 2438 command to determine the node on which role is not

assigned and restart that node. If you see the alarm after the node is restarted, contact HPE support.

Volume CGs Violating Reliability Alarm

UI Column

Vol CGs Violating Reliability Alarm

Logged As

VOLUME_ALARM_CGS_VIOLATING_RACK_RELIABILITY

Meaning

A volume has violated rack reliability constraints. This alarm is raised after more parity containers of a CG are allocated and located in a rack of the volume ectopology. This might occur when nodes in the backend EC volume are moved across racks of ectopology.

Resolution

CGs are properly moved to another rack. The software triggers internal actions that move CG containers across racks to ensure that they conform to honorrackreliability requirements. After required containers are moved, the software clears the alarm.

Configuration

Configurable in volume properties. See the honorrackreliability ec rack reliability parameter in [Volume Modify](#) or [volume create](#) on page 2929 for more information.

Volume with Non-Local Containers

UI Column

Local Volume containers non-local

Logged As

VOLUME_ALARM_DATA_CONTAINERS_NONLOCAL

Meaning

This is a local volume and its containers should all reside on the same node. Some containers were created on another node, which may cause performance issues in MapReduce applications.

Resolution

Recreate the local volume or review information on [how to handle this alarm](#).

Volume Quota Alarm

UI Column

Vol Quota Alarm

Logged As

VOLUME_ALARM_QUOTA_EXCEEDED

Meaning

A volume has exceeded its quota. Further writes to the volume will fail.

Resolution

Free some space on the volume or increase the volume hard quota.

Configuration

Configurable in volume properties. See [Configuring the Alarm Threshold Using the CLI](#) on page 1349 for more information.

HPE Data Fabric Environment

This section provides information associated with the Data Fabric environment.

HPE Data Fabric Parameters

Describes Data Fabric parameters and their default values.

The following table lists user-configurable parameters and their default values. These default values reflect those in the default configuration files, plus any overrides shipped out-of-the-box in `core-site.xml`, `mapred-site.xml` or other configuration files. You can override these values by editing or adding them in `mapred-site.xml` or `core-site.xml` using the `-D` option to the `hadoop jar` command whenever you submit a job or set values explicitly in your code.

Parameter	Default
<code>fs.mapr.bailout.on.library.mismatch</code>	true
<code>fs.mapr.bind.retries</code>	false
<code>fs.mapr.working.dir</code>	
<code>fs.maprfs.impl</code>	
<code>fs.mapr.threads</code>	64
<code>fs.ramfs.impl</code>	
<code>fs.s3.block.size</code>	33554432
<code>fs.s3.blockSize</code>	33554432
<code>fs.s3.buffer.dir</code>	
<code>fs.s3.impl</code>	
<code>fs.s3.maxRetries</code>	4
<code>fs.s3.sleepTimeSeconds</code>	10
<code>fs.s3n.block.size</code>	33554432
<code>fs.s3n.blockSize</code>	33554432
<code>fs.s3n.impl</code>	
<code>fs.trash.interval</code>	0
<code>hadoop.logfile.count</code>	10
<code>hadoop.logfile.size</code>	10000000
<code>hadoop.native.lib</code>	TRUE
<code>hadoop.proxyuser.root.groups</code>	root
<code>hadoop.proxyuser.root.hosts</code>	
<code>hadoop.rpc.socket.factory.class.default</code>	
<code>hadoop.security.authentication</code>	simple
<code>hadoop.security.authorization</code>	FALSE
<code>hadoop.security.group.mapping</code>

Default HPE Data Fabric Configurations

Lists sources from which default Data Fabric configuration parameters are derived.

The default values for configuration parameters can come from various sources:

- marpred-default.xml
- core-default.xml
- yarn-default.xml
- Data Fabric code
- Hadoop code

The topics in this section include the default values for each parameter and the source of the default.

NOTE: For each parameter, an entry in the <name>-site.xml file overrides the default.

Default Core Parameters

Property	Description
dfs.bytes-per-checksum	Default value: 512 Default source: code
dfs.ha.fencing.ssh.connect-timeout	Default value: 30000 Default source: core-default.xml
dfs.namenode.checkpoint.dir	Default value: \${hadoop.tmp.dir}/dfs/secondary Default source: code
dfs.namenode.checkpoint.edits.dir	Default value: \${fs.checkpoint.dir} Default source: code
dfs.namenode.checkpoint.period	Default value: 3600 Default source: code
file.blocksize	Default value: 67108864 Default source: core-default.xml
file.bytes-per-checksum	Default value: 512 Default source: core-default.xml
file.client-write-packet-size	Default value: 65536 Default source: core-default.xml

file.replication	Default value: 1 Default source: core-default.xml
file.stream-buffer-size	Default value: 4096 Default source: core-default.xml
fs.AbstractFileSystem.file.impl	Default value: org.apache.hadoop.fs.local.LocalFs Default source: core-default.xml
fs.AbstractFileSystem.ftp.impl	Default value: org.apache.hadoop.fs.ftp.FtpFs Default source: core-default.xml
fs.AbstractFileSystem.har.impl	Default value: org.apache.hadoop.fs.HarFs Default source: core-default.xml
fs.AbstractFileSystem.hdfs.impl	Default value: com.mapr.fs.MFS Default source: code
fs.AbstractFileSystem.maprfs.impl	Default value: com.mapr.fs.MFS Default source: code
fs.AbstractFileSystem.viewfs.impl	Default value: org.apache.hadoop.fs.viewfs.ViewFs Default source: core-default.xml
fs.automatic.close	Default value: TRUE Default source: core-default.xml
fs.checkpoint.size	Default value: 67108864 Default source: code
fs.client.resolve.remote.symlinks	Default value: TRUE Default source: core-default.xml
fs.defaultFS	Default value: maprfs:/// Default source: code
fs.df.interval	Default value: 60000 Default source: core-default.xml
fs.du.interval	Default value: 600000 Default source: core-default.xml
fs.file.impl	Default value: org.apache.hadoop.fs.LocalFileSystem Default source: code
fs.ftp.host	Default value: 0.0.0.0 Default source: core-default.xml
fs.ftp.host.port	Default value: 21 Default source: core-default.xml

fs.ftp.impl	Default value: org.apache.hadoop.fs.ftp.FTPFileSystem Default source: code
fs.har.impl	Default value: org.apache.hadoop.fs.HarFileSystem Default source: code
fs.har.impl.disable.cache	Default value: TRUE Default source: core-default.xml
fs.hdfs.impl	Default value: com.mapr.fs.MapRFileSystem Default source: code
fs.hftp.impl	Default value: org.apache.hadoop.hdfs.HftpFileSystem Default source: code
fs.hsftp.impl	Default value: org.apache.hadoop.hdfs.HsftpFileSystem Default source: code
fs.kfs.impl	Default value: org.apache.hadoop.fs.kfs.KosmosFileSystem Default source: code
fs.mapr.flush.unaligned	Default value: false Default source: code
fs.mapr.rathreads	Default value: 0 Default source: code
fs.mapr.working.dir	Default value: /user/\$USERNAME/ Default source: code
fs.mapr.write.idleflush.timeout	Default value: 3 seconds Default source: code
fs.maprfs.impl	Default value: com.mapr.fs.MapRFileSystem Default source: code
fs.permissions.umask-mode	Default value: 22 Default source: core-default.xml
fs.ramfs.impl	Default value: org.apache.hadoop.fs.InMemoryFileSystem Default source: code
fs.s3.block.size	Default value: 33554432 Default source: code
fs.s3.blockSize	Default value: 33554432 Default source: code

fs.s3.buffer.dir	Default value: \${hadoop.tmp.dir}/s3 Default source: core-default.xml
fs.s3.impl	Default value: org.apache.hadoop.fs.s3native.NativeS3FileSystem Default source: code
fs.s3.maxRetries	Default value: 4 Default source: core-default.xml
fs.s3.sleepTimeSeconds	Default value: 10 Default source: core-default.xml
fs.s3a.attempts.maximum	Default value: 10 Default source: core-default.xml
fs.s3a.buffer.dir	Default value: \${hadoop.tmp.dir}/s3a Default source: core-default.xml
fs.s3a.connection.establish.timeout	Default value: 5000 Default source: core-default.xml
fs.s3a.connection.maximum	Default value: 15 Default source: core-default.xml
fs.s3a.connection.ssl.enabled	Default value: TRUE Default source: core-default.xml
fs.s3a.connection.timeout	Default value: 50000 Default source: core-default.xml
fs.s3a.fast.buffer.size	Default value: 1048576 Default source: core-default.xml
fs.s3a.fast.upload	Default value: FALSE Default source: core-default.xml
fs.s3a.impl	Default value: org.apache.hadoop.fs.s3a.S3AFileSystem Default source: core-default.xml
fs.s3a.max.total.tasks	Default value: 1000 Default source: core-default.xml
fs.s3a.multipart.purge	Default value: FALSE Default source: core-default.xml
fs.s3a.multipart.purge.age	Default value: 86400 Default source: core-default.xml
fs.s3a.multipart.size	Default value: 104857600 Default source: core-default.xml

fs.s3a.multipart.threshold	Default value: 2147483647 Default source: core-default.xml
fs.s3a.paging.maximum	Default value: 5000 Default source: core-default.xml
fs.s3a.threads.core	Default value: 15 Default source: core-default.xml
fs.s3a.threads.keepalivetime	Default value: 60 Default source: core-default.xml
fs.s3a.threads.max	Default value: 256 Default source: core-default.xml
fs.s3n.block.size	Default value: 33554432 Default source: code
fs.s3n.blockSize	Default value: 33554432 Default source: code
fs.s3n.impl	Default value: org.apache.hadoop.fs.s3native.NativeS3FileSystem Default source: code
fs.s3n.multipart.copy.block.size	Default value: 5368709120 Default source: core-default.xml
fs.s3n.multipart.uploads.block.size	Default value: 67108864 Default source: core-default.xml
fs.s3n.multipart.uploads.enabled	Default value: FALSE Default source: core-default.xml
fs.swift.impl	Default value: org.apache.hadoop.fs.swift.snative.SwiftNativeFileSystem Default source: core-default.xml
fs.webhdfs.impl	Default value: org.apache.hadoop.hdfs.web.WebHdfsFileSystem Default source: code
ftp.blocksize	Default value: 67108864 Default source: core-default.xml
ftp.bytes-per-checksum	Default value: 512 Default source: core-default.xml
ftp.client-write-packet-size	Default value: 65536 Default source: core-default.xml
ftp.replication	Default value: 3 Default source: core-default.xml

ftp.stream-buffer-size	Default value: 4096 Default source: core-default.xml
ha.failover-controller.cli-check.rpc-timeout.ms	Default value: 20000 Default source: core-default.xml

Default YARN Parameters

Parameter	Description
mapreduce.job.hdfs-servers	Default value: \${fs.defaultFS} Default source: yarn-default.xml
yarn.acl.enable	Indicates whether ACLs are enabled. Default value: FALSE Default source: yarn-default.xml

yarn.admin.acl	<p>ACL of who can be admin of the YARN cluster.</p> <p>Default value: *</p> <p>Default source: yarn-default.xml</p>
yarn.am.liveness-monitor.expiry-interval-ms	<p>The expiry interval for application master reporting.</p> <p>Default value: 600000</p> <p>Default source: yarn-default.xml</p>
yarn.app.mapreduce.job.update-status-max-retries	<p>The number of job status update retries.</p> <p>Default value: 0 (retried only 1 time)</p> <p>For a value N, the update is retried 1+N times.</p>
yarn.app.mapreduce.job.update-status-retry-interval	<p>The interval in milliseconds for job status update retries.</p> <p>Default value: 2000 (2000 millisecond or 2 seconds delay is observed before each retry attempt)</p>
yarn.client.application-client-protocol.poll-interval-ms	<p>The interval that the yarn client library uses to poll the completion status of the asynchronous API of application client protocol.</p> <p>Default value: 200</p> <p>Default source: yarn-default.xml</p>
yarn.client.failover-proxy-provider	<p>When HA is enabled, the class to be used by Clients, AMs and NMs to failover to the Active RM. It should extend <code>org.apache.hadoop.yarn.client.RMFailoverProxyProvider</code>.</p> <p>Default value: <code>org.apache.hadoop.yarn.client.ConfiguredRMFailoverProxyProvider</code></p> <p>Default source: yarn-default.xml</p> <p>When you configure failover <code>configure.sh</code> may change the default value by adding a value for this parameter in <code>yarn-site.xml</code>. For more information, see ResourceManager Configuration Properties.</p>
yarn.client.failover-retries	<p>When HA is enabled, the number of retries per attempt to connect to a ResourceManager. In other words, it is the <code>ipc.client.connect.max.retries</code> to be used during failover attempts.</p> <p>Default value: 0</p> <p>Default source: yarn-default.xml</p>
yarn.client.failover-retries-on-socket-timeouts	<p>When HA is enabled, the number of retries per attempt to connect to a ResourceManager on socket timeouts. In other words, it is the <code>ipc.client.connect.max.retries.on.timeouts</code> to be used during failover attempts.</p> <p>Default value: 0</p> <p>Default source: yarn-default.xml</p>

yarn.client.max-nodemangers-proxies	<p>Maximum number of proxy connections for node manager. It should always be more than 1. NMClient and MRAppMaster will use this to cache connection with node manager. There will be at max one connection per node manager. Ex. configuring it to a value of 5 will make sure that client will at max have 5 connections cached with 5 different node managers. These connections will be timed out if idle for more than system wide idle timeout period. The token if used for authentication then it will be used only at connection creation time. If new token is received then earlier connection should be closed in order to use newer token. This and (yarn.client.nodemanager-client-async.thread-pool-max-size) are related and should be sync (no need for them to be equal).</p> <p>Default value: 0</p> <p>Default source: yarn-default.xml</p>
yarn.client.nodemanager-client-async.thread-pool-max-size	<p>Max number of threads in NMClientAsync to process container management events.</p> <p>Default value: 500</p> <p>Default source: yarn-default.xml</p>
yarn.client.nodemanager-connect.max-wait-ms	<p>Default value: 900000</p> <p>Default source: yarn-default.xml</p>
yarn.client.nodemanager-connect.retry-interval-ms	<p>Default value: 10000</p> <p>Default source: yarn-default.xml</p>
yarn.dfs-logging.dir-glob	<p>Default value: maprfs:///var/mapr/local/*/logs/yarn/userlogs</p> <p>Default source: Code</p>
yarn.dfs-logging.handler-class	<p>Default value: com.mapr.hadoop.yarn.util.MapRFSLoggingHandler</p> <p>Default source: Code</p>
yarn.external.token.manager	<p>Default value: com.mapr.hadoop.yarn.security.MapRTicketManager</p> <p>Default source: Code</p>
yarn.http.policy	<p>Configures the HTTP endpoint for YARN Daemons. The following values are supported: -HTTP_ONLY : Service is provided only on http -HTTPS_ONLY : Service is provided only on https</p> <p>Default value: HTTP_ONLY</p> <p>Default source: yarn-default.xml</p>
yarn.ipc.rpc.class	<p>RPC class implementation.</p> <p>Default value: org.apache.hadoop.yarn.ipc.HadoopYarnProtoRPC</p> <p>Default source: yarn-default.xml</p>

yarn.log-aggregation.retain-check-interval-seconds	<p>How long to wait between aggregated log retention checks. If set to 0 or a negative value, then the value is computed as one-tenth of the aggregated log retention time.</p> <p>Default value: -1</p> <p>Default source: yarn-default.xml</p> <p>See YARN Log Aggregation.</p>
yarn.log-aggregation.retain-seconds	<p>How long to keep aggregation logs before deleting them. -1 disables.</p> <p>Default value: 2592000</p> <p>Default source: code</p> <p>See YARN Log Aggregation.</p>
yarn.log-aggregation-enable	<p>Whether to enable log aggregation.</p> <p>Default value: FALSE</p> <p>Default source: yarn-default.xml</p> <p>See YARN Log Aggregation.</p>
yarn.mapr.ticket.expiration	<p>Default value: 604800000</p> <p>Default source: code</p>
yarn.nm.liveness-monitor.expiry-interval-ms	<p>How long to wait until a NodeManager is considered dead.</p> <p>Default value: 600000</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.container-localizer.log.level	<p>Configuring container localizer logs</p> <p>Default value: INFO</p> <p>Default source: code</p>
yarn.nodemanager.address	<p>The address of the container manager in the NM.</p> <p>Default value: \${yarn.nodemanager.hostname}:0</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.admin-env	<p>Environment variables that should be forwarded from the NodeManager's environment to the container's environment.</p> <p>Default value: MALLOC_ARENA_MAX=\$MALLOC_ARENA_MAX</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.aux-services	<p>The valid service name should only contain a-zA-Z0-9_ and can not start with numbers.</p> <p>Default value: mapreduce_shuffle, mapr_direct_shuffle</p> <p>Default source: code</p>
yarn.nodemanager.aux-services.mapr_direct_shuffle.class	<p>Default value: com.mapr.hadoop.mapred.LocalVolumeAuxService</p> <p>Default source: code</p>

yarn.nodemanager.aux-services.mapreduce_shuffle.class	Default value: org.apache.hadoop.mapred.ShuffleHandler Default source: yarn-default.xml
yarn.nodemanager.check-interval-localizing-container.ms	The frequency at which the ApplicationMaster checks the running time of the localizing container. Specified in milliseconds. Default value: -1 Default source: YarnConfiguration
yarn.nodemanager.container-executor.class	Identifies who will execute (launch) the containers. Default value: org.apache.hadoop.yarn.server.nodemanager.LinuxContainerExecutor Default source: code
yarn.nodemanager.container-manager.thread-count	Number of threads the container manager uses. Default value: 20 Default source: yarn-default.xml
yarn.nodemanager.container-monitor.interval-ms	How often to monitor containers. Default value: 3000 Default source: yarn-default.xml
yarn.nodemanager.container-monitor.procs-tree.smaps-based-rss.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.nodemanager.delete.debug-delay-sec	Number of seconds after an application finishes before the NodeManager's DeletionService will delete the application's localized file directory and log directory. To diagnose Yarn application problems, set this property's value large enough (for example, to 600 = 10 minutes) to permit examination of these directories. After changing the property's value, you must restart the NodeManager in order for it to have an effect. The roots of Yarn applications' work directories are configurable with the yarn.nodemanager.local-dirs property (see below), and the roots of the Yarn applications' log directories is configurable with the yarn.nodemanager.log-dirs property (see also below). Default value: 0 Default source: yarn-default.xml
yarn.nodemanager.delete.thread-count	Number of threads used in cleanup. Default value: 4 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.interval-ms	Frequency of running disk health checker code. Default value: 1200000 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.max-disk-utilization-per-disk-percentage	Default value: 90 Default source: yarn-default.xml

yarn.nodemanager.disk-health-checker.min-free-space-per-disk-mb	Default value: 0 Default source: yarn-default.xml
yarn.nodemanager.disk-health-checker.min-healthy-disks	The minimum fraction of number of disks to be healthy for the nodemanager to launch new containers. This correspond to both yarn-nodemanager.local-dirs and yarn.nodemanager.log-dirs. i.e. If there are less number of healthy local-dirs (or log-dirs) available, then new containers will not be launched on this node. Default value: 0.25 Default source: yarn-default.xml
yarn.nodemanager.docker-container-executor.exec-name	Default value: /usr/bin/docker Default source: yarn-default.xml
yarn.nodemanager.env-whitelist	Environment variables that containers may override rather than use NodeManager's default. Default value: JAVA_HOME,HADOOP_COMMON_HOME,HADOOP_HDFS_HOME,HADOOP_CONF_DIR,HADOOP_YARN_HOME Default source: yarn-default.xml
yarn.nodemanager.external.token.localizer	Default value: com.mapr.hadoop.yarn.nodemanager.MapRTicketLocalizer Default source: code
yarn.nodemanager.health-checker.interval-ms	Frequency of running node health script. Default value: 600000 Default source: yarn-default.xml
yarn.nodemanager.health-checker.script.timeout-ms	Script time out period. Default value: 1200000 Default source: yarn-default.xml
yarn.nodemanager.hostname	The hostname of the NM. Default value: 0.0.0.0 Default source: yarn-default.xml
yarn.nodemanager.keytab	Keytab for NM. Default value: /etc/krb5.keytab Default source: yarn-default.xml

yarn.nodemanager.linux-container-executor.cgroups.hierarchy	<p>The cgroups hierarchy under which to place YARN processes (cannot contain commas). If yarn.nodemanager.linux-container-executor.cgroups.mount is false (that is, if cgroups have been pre-configured), then this cgroups hierarchy must already exist and be writable by the NodeManager user, otherwise the NodeManager may fail. Only used when the LCE resources handler is set to the CgroupsLCEResourcesHandler.</p> <p>Default value: /hadoop-yarn</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.linux-container-executor.cgroups.mount	<p>Whether the LCE should attempt to mount cgroups if not found. Only used when the LCE resources handler is set to the CgroupsLCEResourcesHandler.</p> <p>Default value: false</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.linux-container-executor.cgroups.strict-resource-usage	<p>Default value: FALSE</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.linux-container-executor.nonsecure-mode.limit-users	<p>Default value: TRUE</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.linux-container-executor.nonsecure-mode.local-user	<p>Default value: nobody</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.linux-container-executor.nonsecure-mode.user-pattern	<p>The allowed pattern for UNIX user names enforced by Linux-container-executor when used in nonsecure mode (use case for this is using cgroups). The default value is taken from /usr/sbin/adduser.</p> <p>Default value: ^[_.A-Za-z0-9][-@_\.A-Za-z0-9]{0,255}?[\$]?\$</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.linux-container-executor.resources-handler.class	<p>The class which should help the LCE handle resources.</p> <p>Default value: org.apache.hadoop.yarn.server.nodemanager.util.DefaultLCEResourcesHandler</p> <p>Default source: yarn-default.xml</p>

yarn.nodemanager.local-cache.max-files-per-directory	<p>It limits the maximum number of files which will be localized in a single local directory. If the limit is reached then sub-directories will be created and new files will be localized in them. If it is set to a value less than or equal to 36 [which are sub-directories (0-9 and then a-z)] then NodeManager will fail to start. For example; [for public cache] if this is configured with a value of 40 (4 files + 36 sub-directories) and the local-dir is /tmp/local-dir1, then it will allow 4 files to be created directly inside /tmp/local-dir1/filecache. For files that are localized further, it will create a sub-directory "0" inside /tmp/local-dir1/filecache and will localize files inside it until it becomes full. If a file is removed from a sub-directory that is marked full, then that sub-directory will be used back again to localize files.</p> <p>Default value: 8192</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.local-dirs	<p>List of directories to store localized files in. An application's localized file directory will be found in: \${yarn.nodemanager.local-dirs}/usercache/\${user}/appcache/application_\${appid}. Individual containers' work directories, called container_\${contid}, will be subdirectories of this.</p> <p>Default value: \${hadoop.tmp.dir}/nm-local-dir</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.localizer.address	<p>Address where the localizer IPC is.</p> <p>Default value: \${yarn.nodemanager.hostname}:8040</p>
yarn.nodemanager.localizer.cache.cleanup.interval-ms	<p>Interval in between cache cleanups.</p> <p>Default value: 60000</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.localizer.cache.target-size-mb	<p>Target size of localizer cache in MB, per local directory.</p> <p>Default value: 10240</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.localizer.client.thread-count	<p>Number of threads to handle localization requests.</p> <p>Default value: 5</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.localizer.fetch.thread-count	<p>Number of threads to use for localization fetching.</p> <p>Default value: 4</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.log.retain-seconds	<p>Time in seconds to retain user logs. Only applicable if log aggregation is disabled.</p> <p>Default value: 10800</p> <p>Default source: yarn-default.xml</p>

yarn.nodemanager.log-aggregation.compression-type	<p>T-file compression types used to compress aggregated logs.</p> <p>Default value: none</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.log-aggregation.roll-monitoring-interval-seconds	<p>Default value: -1</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.log-dirs	<p>Where to store container logs. An application's localized log directory will be found in <code>\${yarn.nodemanager.log-dirs}/application_\${appid}</code>. Individual containers' log directories will be below this, in directories named <code>container_\${scontid}</code>. Each container directory will contain the files <code>stderr</code>, <code>stdin</code>, and <code>syslog</code> generated by that container.</p> <p>Default value: <code>\${yarn.log.dir}/userlogs</code></p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.pmem-check-enabled	<p>Whether physical memory limits will be enforced for containers.</p> <p>Default value: true</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.process-kill-wait.ms	<p>Max time to wait for a process to come up when trying to cleanup a container.</p> <p>Default value: 2000</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.recovery.enabled	<p>Default value: TRUE</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.remote-app-log-dir	<p>Where to aggregate logs to.</p> <p>Default value: <code>/tmp/logs</code></p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.remote-app-log-dir-suffix	<p>The remote log dir will be created at <code>{yarn.nodemanager.remote-app-log-dir}/\${user}/{thisParam}</code></p> <p>Default value: logs</p> <p>Default source: yarn-default.xml</p>
yarn.nodemanager.resource.cpu-vcores	<p>Number of CPU cores that can be allocated for containers.</p> <p>Default value: <code>\${nodemanager.resource.cpu-vcores}</code></p> <p>Default source: code</p>
yarn.nodemanager.resource.io-spindles	<p>Default value: <code>\${nodemanager.resource.io-spindles}</code></p> <p>Default source: code</p>

yarn.nodemanager.resource.memory-mb	Amount of physical memory, in MB, that can be allocated for containers. Default value: \${nodemanager.resource.memory-mb} Default source: code
yarn.nodemanager.resource.percentage-physical-cpu-limit	Default value: 100 Default source: yarn-default.xml
yarn.nodemanager.resourcemanager.minimum.version	The minimum allowed version of a resourcemanager that a nodemanager will connect to. The valid values are NONE (no version checking), EqualToNM (the resourcemanager's version is equal to or greater than the NM version), or a Version String. Default value: NONE Default source: yarn-default.xml
yarn.nodemanager.sleep-delay-before-sigkill.ms	Number of ms to wait between sending a SIGTERM and SIGKILL to a container. Default value: 250 Default source: yarn-default.xml
yarn.nodemanager.vmem-check-enabled	Whether virtual memory limits will be enforced for containers. Default value: false Default source: yarn-default.xml
yarn.nodemanager.vmem-pmem-ratio	Ratio between virtual memory to physical memory when setting memory limits for containers. Container allocations are expressed in terms of physical memory, and virtual memory usage is allowed to exceed this allocation by this ratio. Default value: 2.1 Default source: yarn-default.xml
yarn.nodemanager.webapp.address	NM Webapp address. Default value: \${yarn.nodemanager.hostname}:8042 Default source: yarn-default.xml
yarn.nodemanager.windows-container.cpu-limit.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.nodemanager.windows-container.memory-limit.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.resourcemanager.address	The address of the applications manager interface in the ResourceManager. Default value: \${yarn.resourcemanager.hostname}:8032 Default source: yarn-default.xml When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 2261.

yarn.resourcemanager.admin.address	<p>The address of the ResourceManager admin interface.</p> <p>Default value: \${yarn.resourcemanager.hostname}:8033</p> <p>Default source: yarn-default.xml</p> <p>When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 2261.</p>
yarn.resourcemanager.admin.client.thread-count	<p>Number of threads used to handle the ResourceManager admin interface.</p> <p>Default value: 1</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.am.max-attempts	<p>The maximum number of application attempts. This is a global setting for all ApplicationMasters. Each ApplicationMaster can specify its individual maximum number of application attempts via the API, but the individual number cannot be more than the global upper bound. If it is, the ResourceManager will override it. The default number is set to 2, to allow at least one retry for the ApplicationMaster.</p> <p>Default value: 2</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.application-tokens.master-key-rolling-interval-secs	<p>Interval for the roll over for the master key used to generate application tokens.</p> <p>Default value: 86400</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.aux-services	<p>Default value: RMVolumeManager</p> <p>Default source: code</p>
yarn.resourcemanager.aux-services.HSVolumeManager.class	<p>Default value: com.mapr.hadoop.yarn.resourcemanager.RMVolumeManager</p> <p>Default source: code</p>
yarn.resourcemanager.aux-services.RMVolumeManager.class	<p>Default value: com.mapr.hadoop.yarn.resourcemanager.RMVolumeManager</p> <p>Default source: code</p>
yarn.resourcemanager.client.thread-count	<p>The number of threads used to handle applications manager requests.</p> <p>Default value: 50</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.configuration.provider-class	<p>Default value: org.apache.hadoop.yarn.LocalConfigurationProvider</p> <p>Default source: yarn-default.xml</p>

yarn.resourcemanager.connect.max-wait.ms	Maximum time to wait to establish connection to the ResourceManager. Default value: 900000 Default source: yarn-default.xml
yarn.resourcemanager.connect.retry-interval.ms	How often to retry connecting to the ResourceManager. Default value: 30000 Default source: yarn-default.xml
yarn.resourcemanager.container.liveness-monitor.interval-ms	How often to check that containers are still alive. Default value: 600000 Default source: yarn-default.xml
yarn.resourcemanager.container-tokens.master-key-rolling-interval-secs	Interval for the roll over for the master key used to generate container tokens. It is expected to be much greater than yarn.nm.liveness-monitor.expiry-interval-ms and yarn.rm.container-allocation.expiry-interval-ms. Otherwise the behavior is undefined. Default value: 86400 Default source: yarn-default.xml
yarn.resourcemanager.delayed.delegation-token.removal-interval-ms	Interval at which the delayed token removal thread runs. Default value: 30000 Default source: yarn-default.xml
yarn.resourcemanager.dir	Default value: /var/mapr/cluster/yarn/rm Default source: code
yarn.resourcemanager.fs.state-store.num-retries	Default value: 0 Default source: yarn-default.xml
yarn.resourcemanager.fs.state-store.retry-interval-ms	Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.fs.state-store.retry-policy-spec	hdfs client retry policy specification. hdfs client retry is always enabled. Specified in pairs of sleep-time and number-of-retries and (t0, n0), (t1, n1), ..., the first n0 retries sleep t0 milliseconds on average, the following n1 retries sleep t1 milliseconds on average, and so on. Default value: 2000, 500 Default source: yarn-default.xml
yarn.resourcemanager.fs.state-store.uri	URI pointing to the location of the FileSystem path where RM state will be stored. This must be supplied when using org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore as the value for yarn.resourcemanager.store.class Default value: /var/mapr/cluster/yarn/rm/system Default source: code

yarn.resourcemanager.ha.automatic-failover.embedded	<p>Enable embedded automatic failover. The embedded elector relies on the RM state store to handle fencing, and is primarily intended to be used in conjunction with ZKRMStateStore.</p> <p>Default value: TRUE</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.ha.automatic-failover.enabled	<p>Enable automatic failover.</p> <p>Default value: TRUE</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.ha.automatic-failover.zk-base-path	<p>The base znode path to use for storing leader information, when using ZooKeeper based leader election.</p> <p>Default value: /yarn-leader-election</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.ha.custom-ha-rmaddressfinder	<p>Default value: org.apache.hadoop.yarn.client.MapRZKBasedRMAddressFinder</p> <p>Default source: code</p>
yarn.resourcemanager.ha.enabled	<p>Enable RM high-availability. If enabled:</p> <ol style="list-style-type: none"> 1. The RM starts in the Standby mode by default and transitions to the Active mode after it is prompted to do so. 2. The nodes in the RM ensemble are listed in yarn.resourcemanager.ha.rm-ids. 3. The id of each RM comes from yarn.resourcemanager.ha.id, 4. The actual physical addresses come from the configs of the pattern: {rpc-config}.{id}. <p>Default value: false</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.hostname	<p>The hostname of the ResourceManager.</p> <p>Default value: 0.0.0.0</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.keytab	<p>The keytab for the ResourceManager.</p> <p>Default value: /etc/krb5.keytab</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.leveldb-state-store.path	<p>Default value: \${hadoop.tmp.dir}/yarn/system/rmstore</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.max-completed-applications	<p>The maximum number of completed applications RM keeps.</p> <p>Default value: 10000</p> <p>Default source: yarn-default.xml</p>

yarn.resourcemanager.nodemanager.minimum.version	<p>The minimum allowed version of a connecting nodemanager. The valid values are NONE (no version checking), EqualToRM (the nodemanager's version is equal to or greater than the RM version), or a Version String.</p> <p>Default value: NONE</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.nodemanager.heartbeat-interval-ms	<p>The heart-beat interval in milliseconds for every NodeManager in the cluster.</p> <p>Default value: 1000</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.principal	<p>The Kerberos principal for the ResourceManager.</p> <p>Default value:mapr</p> <p>Default source: code</p>
yarn.resourcemanager.proxy-user-privileges.enabled	<p>Default value: FALSE</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.recovery.enabled	<p>Enable RM to recover state after starting. If true, then yarn.resourcemanager.store.class must be specified.</p> <p>Default value: false</p> <p>When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 2261.</p>
yarn.resourcemanager.resource-tracker.address	<p>Default value: \${yarn.resourcemanager.hostname}:8031</p> <p>Default source: yarn-default.xml</p> <p>When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 2261.</p>
yarn.resourcemanager.resource-tracker.client.thread-count	<p>Number of threads to handle resource tracker calls.</p> <p>Default value: 50</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.scheduler.address	<p>The address of the scheduler interface.</p> <p>Default value: \${yarn.resourcemanager.hostname}:8030</p> <p>Default source: yarn-default.xml</p> <p>When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 2261.</p>

yarn.resourcemanager.scheduler.class	<p>The class to use as the resource scheduler.</p> <p>Default value: org.apache.hadoop.yarn.server.resourcemanager.scheduler.fair.FairScheduler</p> <p>Default source: code</p>
yarn.resourcemanager.scheduler.client.thread-count	<p>Number of threads to handle scheduler interface.</p> <p>Default value: 50</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.scheduler.monitor.enable	<p>Enable a set of periodic monitors (specified in yarn.resourcemanager.scheduler.monitor.policies) that affect the scheduler.</p> <p>Default value: false</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.scheduler.monitor.policies	<p>The list of SchedulingEditPolicy classes that interact with the scheduler. A particular module may be incompatible with the scheduler, other policies, or a configuration of either.</p> <p>Default value: org.apache.hadoop.yarn.server.resourcemanager.monitor.capacity.ProportionalCapacityPreemptionPolicy</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.staging	<p>Default value: /var/mapr/cluster/yarn/rm/staging</p> <p>Default source: code</p>
yarn.resourcemanager.state-store.max-completed-applications	<p>The maximum number of completed applications RM state store keeps, less than or equals to \$ {yarn.resourcemanager.max-completed-applications}. By default, it equals to \$ {yarn.resourcemanager.max-completed-applications}. This ensures that the applications kept in the state store are consistent with the applications remembered in RM memory. Any values larger than \$ {yarn.resourcemanager.max-completed-applications} will be reset to \$ {yarn.resourcemanager.max-completed-applications}. Note that this value impacts the RM recovery performance. Typically, a smaller value indicates better performance on RM recovery.</p> <p>Default value: \$ {yarn.resourcemanager.max-completed-applications}</p> <p>Default source: yarn-default.xml</p>

yarn.resourcemanager.store.class	<p>The class to use as the persistent store. If org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore is used, the store is implicitly fenced; meaning a single ResourceManager is able to use the store at any point in time. More details on this implicit fencing, along with setting up appropriate ACLs is discussed under yarn.resourcemanager.zk-state-store.root-node.acl.</p> <p>Default value: org.apache.hadoop.yarn.server.resourcemanager.recovery.FileSystemRMStateStore</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.system	<p>Default value: /var/mapr/cluster/yarn/rm/system</p> <p>Default source: code</p>
yarn.resourcemanager.system-metrics-publisher.dispatcher.pool-size	<p>Default value: 10</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.system-metrics-publisher.enabled	<p>Default value: FALSE</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.webapp.address	<p>The http address of the ResourceManager web application.</p> <p>Default value: \${yarn.resourcemanager.hostname}:8088</p> <p>Default source: yarn-default.xml</p> <p>When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 2261.</p>
yarn.resourcemanager.webapp.delegation-token-auth-filter.enabled	<p>Default value: TRUE</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.webapp.https.address	<p>The https address of the ResourceManager web application.</p> <p>Default value: \${yarn.resourcemanager.hostname}:8090</p> <p>Default source: yarn-default.xml</p> <p>When you configure failover configure.sh may change the default value by adding a value for this parameter in yarn-site.xml. For more information, see ResourceManager Configuration Properties on page 2261.</p>
yarn.resourcemanager.work-preserving-recovery.enabled	<p>Default value: TRUE</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.work-preserving-recovery.scheduling-wait-ms	<p>Default value: 10000</p> <p>Default source: yarn-default.xml</p>
yarn.resourcemanager.zk-acl	<p>ACL's to be used for ZooKeeper znodes.</p> <p>Default value: world:anyone:rwcd</p> <p>Default source: yarn-default.xml</p>

yarn.resourcemanager.zk-num-retries	Number of times RM tries to connect to ZooKeeper. Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.zk-retry-interval-ms	Retry interval in milliseconds when connecting to ZooKeeper. Default value: 1000 Default source: yarn-default.xml
yarn.resourcemanager.zk-state-store.parent-path	Full path of the ZooKeeper znode where RM state will be stored. This must be supplied when using <code>org.apache.hadoop.yarn.server.resourcemanager.recovery.ZKRMStateStore</code> as the value for <code>yarn.resourcemanager.store.class</code> Default value: /rmstore Default source: yarn-default.xml
yarn.resourcemanager.zk-timeout-ms	ZooKeeper session timeout in milliseconds. Session expiration is managed by the ZooKeeper cluster itself, not by the client. This value is used by the cluster to determine when the client's session expires. Expirations happens when the cluster does not hear from the client within the specified session timeout period (i.e. no heartbeat). Default value: 10000 Default source: yarn-default.xml
yarn.scheduler.maximum-allocation-mb	The maximum allocation for every container request at the RM, in MBs. Memory requests higher than this won't take effect, and will get capped to this value. Default value: 8192 Default source: yarn-default.xml
yarn.scheduler.maximum-allocation-vcores	The maximum allocation for every container request at the RM, in terms of virtual CPU cores. Requests higher than this won't take effect, and will get capped to this value. Default value: 4 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-mb	The minimum allocation for every container request at the RM, in MBs. Memory requests lower than this won't take effect, and the specified value will get allocated at minimum. Default value: 1024 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-vcores	The minimum allocation for every container request at the RM, in terms of virtual CPU cores. Requests lower than this won't take effect, and the specified value will get allocated the minimum. Default value: 1 Default source: yarn-default.xml

yarn.resourcemanager.zk-timeout-ms	Default value: 10000 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-mb	Default value: 1024 Default source: yarn-default.xml
yarn.scheduler.minimum-allocation-vcores	Default value: 1 Default source: yarn-default.xml
yarn.sharedcache.admin.address	Default value: 0.0.0.0:8047 Default source: yarn-default.xml
yarn.sharedcache.admin.thread-count	Default value: 1 Default source: yarn-default.xml
yarn.sharedcache.app-checker.class	Default value: org.apache.hadoop.yarn.server.sharedcachemanager.RemoteAppChecker Default source: yarn-default.xml
yarn.sharedcache.checksum.algo.impl	Default value: org.apache.hadoop.yarn.sharedcache.ChecksumSHA256Impl Default source: yarn-default.xml
yarn.sharedcache.cleaner.initial-delay-mins	Default value: 10 Default source: yarn-default.xml
yarn.sharedcache.cleaner.period-mins	Default value: 1440 Default source: yarn-default.xml
yarn.sharedcache.cleaner.resource-sleep-ms	Default value: 0 Default source: yarn-default.xml
yarn.sharedcache.client-server.address	Default value: 0.0.0.0:8045 Default source: yarn-default.xml
yarn.sharedcache.client-server.thread-count	Default value: 50 Default source: yarn-default.xml
yarn.sharedcache.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.sharedcache.nested-level	Default value: 3 Default source: yarn-default.xml
yarn.sharedcache.nm.uploader.replication.factor	Default value: 10 Default source: yarn-default.xml
yarn.sharedcache.nm.uploader.thread-count	Default value: 20 Default source: yarn-default.xml

yarn.sharedcache.root-dir	Default value: /sharedcache Default source: yarn-default.xml
yarn.sharedcache.store.class	Default value: org.apache.hadoop.yarn.server.sharedcachemanager.store.InMemorySCMStore Default source: yarn-default.xml
yarn.sharedcache.store.in-memory.check-period-mins	Default value: 720 Default source: yarn-default.xml
yarn.sharedcache.store.in-memory.initial-delay-mins	Default value: 10 Default source: yarn-default.xml
yarn.sharedcache.store.in-memory.staleness-period-mins	Default value: 10080 Default source: yarn-default.xml
yarn.sharedcache.uploader.server.address	Default value: 0.0.0.0:8046 Default source: yarn-default.xml
yarn.sharedcache.uploader.server.thread-count	Default value: 50 Default source: yarn-default.xml
yarn.sharedcache.webapp.address	Default value: 0.0.0.0:8788 Default source: yarn-default.xml
yarn.timeline-service.address	Default value: \${yarn.timeline-service.hostname}:10200 Default source: yarn-default.xml
yarn.timeline-service.client.max-retries	Default value: 30 Default source: yarn-default.xml
yarn.timeline-service.client.best-effort	Default value: FALSE Default source: yarn-default.xml To enable an application to run successfully after it is retried, set this to TRUE
yarn.timeline-service.client.retry-interval-ms	Default value: 1000 Default source: yarn-default.xml
yarn.timeline-service.client.socket-timeout-ms	Timeout for timeline client socket connection. Defaults to 60000 milliseconds (1 minute). Default source: yarn-default.xml
yarn.timeline-service.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.timeline-service.generic-application-history.aux-services	Default value: HSVolumeManager Default source: code
yarn.timeline-service.handler-thread-count	Default value: 10 Default source: yarn-default.xml

yarn.timeline-service.hostname	Default value: 0.0.0.0 Default source: yarn-default.xml
yarn.timeline-service.http-authentication.simple.anonymous.allowed	Default value: TRUE Default source: yarn-default.xml
yarn.timeline-service.http-authentication.type	Default value: simple Default source: yarn-default.xml
yarn.timeline-service.keytab	Default value: /etc/krb5.keytab Default source: yarn-default.xml
yarn.timeline-service.leveldb-state-store.path	Default value: \${hadoop.tmp.dir}/yarn/timeline Default source: yarn-default.xml
yarn.timeline-service.leveldb-timeline-store.path	Default value: \${hadoop.tmp.dir}/yarn/timeline Default source: yarn-default.xml
yarn.timeline-service.leveldb-timeline-store.read-cache-size	Default value: 104857600 Default source: yarn-default.xml
yarn.timeline-service.leveldb-timeline-store.start-time-read-cache-size	Default value: 10000 Default source: yarn-default.xml
yarn.timeline-service.leveldb-timeline-store.start-time-write-cache-size	Default value: 10000 Default source: yarn-default.xml
yarn.timeline-service.leveldb-timeline-store.ttl-interval-ms	Default value: 300000 Default source: yarn-default.xml
yarn.timeline-service.recovery.enabled	Default value: FALSE Default source: yarn-default.xml
yarn.timeline-service.state-store-class	Default value: org.apache.hadoop.yarn.server.timeline.recovery.LeveldbTimelineStateStore Default source: yarn-default.xml
yarn.timeline-service.store-class	Default value: org.apache.hadoop.yarn.server.timeline.LeveldbTimelineStore Default source: yarn-default.xml
yarn.timeline-service.ttl-enable	Default value: TRUE Default source: yarn-default.xml
yarn.timeline-service.ttl-ms	Default value: 604800000 Default source: yarn-default.xml
yarn.timeline-service.webapp.address	Default value: \${yarn.timeline-service.hostname}:8188 Default source: yarn-default.xml

yarn.timeline-service.webapp.https.address	Default value: \${yarn.timeline-service.hostname}:8190 Default source: yarn-default.xml
yarn.timeline-service.webapp.all-ifaces	Redirects all opening container logs from timeline server to 0.0.0.0. Default value: TRUE Default source: code
yarn.use-central-logging-for-mapreduce-only	Default value: FALSE Default source: code

Default mapred Parameters

Property	Description
io.sort.record.percent	Default value: 0.17 Default source: code
map.sort.class	Default value: org.apache.hadoop.util.QuickSort Default source: mapred-default.xml
mapr.localoutput.dir	Default value: output Default source: code
mapr.localspill.dir	Default value: spill Default source: code
mapr.map.keyprefix.ints	Default value: 1 Default source: code
mapr.mapred.localvolume.root.dir.name	Default value: nodeManager Default source: code
mapreduce.am.max-attempts	Default value: 2 Default source: mapred-default.xml
mapreduce.app-submission.cross-platform	Default value: FALSE Default source: mapred-default.xml
mapreduce.client.completion.pollinterval	Default value: 5000 Default source: mapred-default.xml
mapreduce.client.output.filter	Default value: FAILED Default source: mapred-default.xml
mapreduce.client.progressmonitor.pollinterval	Default value: 1000 Default source: mapred-default.xml
mapreduce.client.submit.file.replication	Default value: 10 Default source: mapred-default.xml
mapreduce.cluster.acls.enabled	Default value: FALSE Default source: mapred-default.xml

mapreduce.cluster.local.dir	Default value: \${hadoop.tmp.dir}/mapred/local Default source: mapred-default.xml
mapreduce.cluster.temp.dir	Default value: \${hadoop.tmp.dir}/mapred/temp Default source: mapred-default.xml
mapreduce.fileoutputcommitter.algorithm.version	Default value: 1 Default source: mapred-default.xml
mapreduce.framework.name	Default value: yarn Default source: code
mapreduce.ifile.readahead	Default value: TRUE Default source: mapred-default.xml
mapreduce.ifile.readahead.bytes	Default value: 4194304 Default source: mapred-default.xml
mapreduce.input.fileinputformat.list-status.num-threads	Default value: 1 Default source: mapred-default.xml
mapreduce.input.fileinputformat.split.minsize	Default value: 0 Default source: mapred-default.xml
mapreduce.input.lineinputformat.linespermap	Default value: 1 Default source: mapred-default.xml
mapreduce.job.acl-modify-job	Default value: Default source: mapred-default.xml
mapreduce.job.acl-view-job	Default value: Default source: mapred-default.xml
mapreduce.job.classloader	Default value: FALSE Default source: mapred-default.xml
mapreduce.job.committer.setup.cleanup.needed	Default value: TRUE Default source: mapred-default.xml
mapreduce.job.complete.cancel.delegation.tokens	Default value: TRUE Default source: mapred-default.xml
mapreduce.job.counters.max	Default value: 120 Default source: mapred-default.xml
mapreduce.job.emit-timeline-data	Default value: FALSE Default source: mapred-default.xml
mapreduce.job.end-notification.max.attempts	Default value: 5 Default source: mapred-default.xml

mapreduce.job.end-notification.max.retry.interval	Default value: 5000 Default source: mapred-default.xml
mapreduce.job.end-notification.retry.attempts	Default value: 0 Default source: mapred-default.xml
mapreduce.job.end-notification.retry.interval	Default value: 1000 Default source: mapred-default.xml

Environment Variables

Describes the environment variables specific to the HPE Data Fabric.

For core release 6.0 and later, environment variables should be set in `/opt/mapr/conf/env_override.sh`. Editing `/opt/mapr/conf/env.sh` is no longer recommended. For more information, see [About env_override.sh](#) on page 3467.

Variable	Example Values	Description
CLDB_EXTERNAL_RPC_PORT	5000	If clients outside the cluster cannot reach CLDB on the default port, use the CLDB_EXTERNAL_RPC_PORT environment variable to specify the port on which CLDB can be reached.
JAVA_HOME	/usr/lib/jvm/java-7-sun	The directory where the correct version of Java is installed.
MAPR_ECOSYSTEM_LOGIN_OPTS	*hybrid*	Specifies the JAAS configuration to use with installed open source components.
MAPR_EXTERNAL	10.10.123.25, 10.10.123.30	If your cluster nodes have multiple NICs, use the MAPR_EXTERNAL environment variable to grant external clients access to a cluster node on specific IP addresses. The value of the MAPR_EXTERNAL environment variable on a node is a comma-separated list of up to four IP addresses with no spaces.
MAPR_HOME	/opt/mapr (default)	The directory in which the core software is installed.  CAUTION: Specifying a MAPR_HOME directory other than /opt/mapr is not supported and can cause installation errors.
MAPR_JWT_TOKEN_LOCATION	/tmp/jwt	If SSO is configured, you can use this environment variable to set the location of the JWT token. Doing so removes the need to provide a ticket when issuing <code>maprc li</code> commands. It also removes the need to provide an AccessKey and SecretKey when issuing MinIO (<code>mc</code>) commands for the Object Store.
MAPR_SUBNETS	10.10.123.0/24, 10.10.124.0/24	MAPR_SUBNETS is used for Data Fabric RPC to RPC communication. The MFS, CLDB, NFS, and LOOPBACKNFS modules use this environment variable. The NFS and LOOPBACKNFS modules use this environment variable when registering with CLDB. If you do not want Data Fabric to use all NICs on each node, use this environment variable to restrict Data Fabric traffic to specific NICs. Set MAPR_SUBNETS to a comma-separated list of up to four subnets in CIDR notation with no spaces. If you do not set MAPR_SUBNETS, Data Fabric uses all NICs present on the node. If MAPR_SUBNETS is set, make sure that the node can reach all nodes in the cluster (servers and clients) using the specified subnets.

Variable	Example Values	Description
MAPR_USER	mapr (default)	Used with configure.sh on page 3186 to specify the user under which Data Fabric runs its services. If not explicitly set, it defaults to the user mapr. After configure.sh is run, the value is stored in daemon.conf on page 3363 .

About env_override.sh

Describes the purpose of the `env_override.sh` file.

The `env_override.sh` file allows you to create to store custom settings for environment variables. By default, `/opt/mapr/conf/env.sh` contains environment variables for a HPE Data Fabric cluster, but upgrading to a new Data Fabric release causes the `env.sh` file to be replaced. (A backup is stored as `/opt/mapr/conf/env.sh<timestamp>`.) After `env.sh` is replaced, any custom settings are removed.

For Data Fabric 6.0 and later, keep any custom settings in `/opt/mapr/conf/env_override.sh`. It is no longer necessary to modify `env.sh`.

Upgrading a cluster does not remove or modify `env_override.sh`. `/opt/mapr/conf/env.sh` reads the `env_override.sh` file at the end of its execution. If the same parameter is listed in both `env.sh` and `env_override.sh`, the value specified in `env_override.sh` is used. If `env_override.sh` is not present, the values in `env.sh` are used.

You create `env_override.sh` from a blank file and insert `export` statements into the file. For example:

Sample env_override.sh File

```
export CLDB_EXTERNAL_RPC_PORT=5000
export JAVA_HOME=/usr/lib/jvm/java-11-openjdk-11.0.8.10-0.el8_2.x86_64
export MAPR_HOME=/opt/mapr
export MAPR_EXTERNAL=10.10.123.25,10.10.123.30
export MAPR_SUBNETS=10.10.123.0/24,10.10.124.0/24
export MAPR_USER=mapr
export MAPR_ECOSYSTEM_LOGIN_OPTS=*hybrid*
```

Controlling Access to JMX Metrics

Environment variables and `configure.sh` options introduced in release 6.2.0 let you control how metrics are collected and who can access the metrics from JMX-enabled services.

JMX is a technology for monitoring system services. In the HPE Data Fabric, you can use environment variables or `configure.sh` options to enable or disable access to JMX metrics. The JMX-enabled services are:

- CLDB
- Drill
- Hive
- NodeManager
- Oozie
- ResourceManager
- Spark

Understanding the MAPR_JMX Variables

The following table describes the environment variables. For release 6.2.0, JMX is enabled by default, and local binding is enabled by default:

Environment Variable	Default Value		Description
	Secure Cluster	Non-Secure Cluster	
MAPR_JMXAUTH*	true	false	Enables or disables authentication for JMX metrics for a node. JMXAUTH is only used in conjunction with MAPR_JMXLOCALHOST or MAPR_JMXREMOTEHOST. JMXAUTH is ignored if MAPR_JMXRLOCALBINDING is set to true.
MAPR_JMXDISABLE*	false	false	If set to true, disables JMX for the entire node. In this scenario, Collectd does not receive JMX metrics.
MAPR_JMXLOCALBINDING*	true	true	If set to true, disables TCP/IP listening on the the local JMX port. There is no TCP/IP listener at all after you turn on local binding. In this scenario, you can only get JMX metrics from the node itself by configuring a process that attaches to the Java process, such as a debugger tool. You can connect only to processes that you own.
MAPR_JMXLOCALHOST	false	false	Enables the JMX server in the Java processes to listen on the local host and on the JMX port number. The local host is a TCP/IP listener that listens on the local host only. It does not let you connect remotely.
MAPR_JMXREMOTEHOST	false	false	Enables the JMX server to listen on the JMX port and allows users from outside the cluster to connect to that port. You can turn on REMOTEHOST if you want to have a cluster with both LOCALBINDING and REMOTEHOST. Turning on REMOTEHOST allows you to use JConsole, Virtual VM, or any of these other tools to log in and look at what the Java processes is doing. If MAPR_JMXREMOTEHOST is set to true, the system always uses SSL and authentication.
MAPR_JMXSSL*	false	false	Enables or disables SSL for JMX metrics for a node. This variable is ignored if MAPR_JMXREMOTEHOST is set to true.

*For internal use only. Manually changing the the value of this environment variable is not recommended.

Changing the MAPR_JMX Environment Variables

Suppose you want to change the value of MAPR_JMXREMOTEHOST to true. Doing so allows you to use a tool, such as JConsole, to log in remotely and monitor the Java processes. To change the MAPR_JMXREMOTEHOST setting:

1. Export the new value of MAPR_JMXREMOTEHOST in /opt/mapr/conf/env_override.sh:

```
export MAPR_JMXREMOTEHOST=true
```

2. Run `/opt/mapr/server/configure.sh -R`, and restart all services. For example:
 - a. Stop Warden by using the `systemctl stop mapr-warden` command.
 - b. Stop ZooKeeper by using the `systemctl stop mapr-zookeeper` command.
 - c. Restart ZooKeeper by using the `systemctl start mapr-zookeeper` command.
 - d. Restart Warden by using the `systemctl start mapr-warden` command.

Using the JMX Options for `configure.sh`

The following `configure.sh` options are supported for managing JMX on individual nodes:

Option	Description
-JMXEnable	Enables JMX support for every service on the node where JMX is configured to be enabled. JMX is enabled by default.
-JMXDisable	Globally disables JMX support for all JMX-enabled services on the node.
-JMXLocalBindingEnable	Enables local binding for JMX connections. Local binding is enabled by default.
-JMXLocalBindingDisable	Disables local binding for JMX connections.
-JMXLocalHostEnable	Enables the local-host TCP port for JMX. This setting is mutually exclusive with <code>JMXRemoteHostEnable</code> .
-JMXLocalHostDisable	Disables the local-host TCP port for JMX.
-JMXRemoteHostEnable	Enables the remote TCP port for JMX. This setting is mutually exclusive with <code>JMXLocalHostEnable</code> .
-JMXRemoteHostDisable	Disables the remote TCP port for JMX.

To use -JMX options, run `configure.sh -R` with the -JMX option on the desired node. For example:

```
/opt/mapr/server/configure.sh -R -JMXRemoteHostEnable
```

Ports Used by HPE Data Fabric Software

Lists the ports used by Data Fabric services.

Avoiding Port Conflicts

To avoid trouble with port conflicts on your Data Fabric clusters, try these tips:

- Remap the ports for the HBaseMaster and HBaseRegionServer services to ports below 32768.
- Set the ephemeral port range to stop at 50029 by changing the value in the file `/proc/sys/net/ipv4/ip_local_port_range`. Note that this setting changes the available number of ephemeral ports from the default of 28233 ports to 17233.

Ports Needed for POSIX Clients and File System to Communicate With Each Other

POSIX clients communicate with the CLDB and server components of the Data Fabric filesystem. You need to open the relevant ports for TCP connectivity from POSIX clients to the Data Fabric file-system cluster nodes. Open the CLDB, file-system server, and file-system server instances ports, as detailed in the following section.

Services and Ports Quick Reference

The following list defines the ports used by a Data Fabric cluster, along with the default port numbers. All the ports used by Data Fabric software are **TCP** ports.

Airflow Webserver	<p><i>Source IP:</i> Nodes/clients accessing Airflow webserver</p> <p><i>Destination IP:</i> Nodes running Airflow webserver</p> <p><i>Ports:</i> 8780</p> <p><i>Purpose:</i> Used by Airflow webserver clients to access the Airflow webserver</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Airflow Scheduler	<p><i>Source IP:</i> Airflow webserver</p> <p><i>Destination IP:</i> Nodes running Airflow scheduler</p> <p><i>Ports:</i> 8793</p> <p><i>Purpose:</i> Used by Airflow webserver to access the Airflow scheduler</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
API Server (apiserver)	<p><i>Source IP:</i> Cluster nodes running apiserver</p> <p><i>Destination IP:</i> Cluster nodes running apiserver</p> <p><i>Ports:</i></p> <ul style="list-style-type: none"> • 5701 • 5702 <p><i>Purpose:</i> Clustering support</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
CLDB	<p><i>Source IP:</i> Nodes running any Data Fabric services, clients interacting with the file system</p> <p><i>Destination IP:</i> Cluster nodes running CLDB services</p> <p><i>Ports:</i> 7222</p> <p>A client reads CLDB IP and port number from the <code>/opt/mapr/conf/mapr-clusters.conf</code> file. The client initially tries to communicate with CLDB on port 7222. Once it establishes the connection, it fetches the additional CLDB IPs and ports from the connected CLDB.</p> <p>By default, CLDB listens on ports 7222 and 7223. For performance reasons, additional ports may be opened, depending on the configuration parameter <code>cldb.num.rpc.threads</code> in the <code>/opt/mapr/conf/cldb.conf</code> file. For example, setting <code>cldb.num.rpc.threads=3</code>, opens up ports 7222, 7223 and 7224.</p>

NOTE: The `cldb.num.rpc.threads` parameter is hard-coded with a default value of 3. To change this value, add this parameter with the new value to the `/opt/mapr/conf/cldb.conf` file.

NOTE: If you upgrade from Core 5.2.x or Core 6 to Core 6.1 and above, the value of `cldb.num.rpc.threads` is not changed. The default remains as 3, which means three ports are open for each CLDB node.

The client tries connecting to the CLDBs till timeout occurs in the case of soft mount, while the client indefinitely retries in the case of hard mount. If a client cannot connect to a CLDB port, the CLDB is marked unreachable. For example, assume a CLDB with IP 10.10.10.10 and 3 ports 7222, 7223 and 7224. If a client fails to connect to the CLDB say on port 7223, the CLDB 10.10.10.10 is marked unreachable, and the client will not try the two other ports for the next few minutes. It tries to connect with the next CLDB entry in the list.

For load balancing at CLDB, a client will always pick a random port among the available CLDB ports.

Purpose: file system API calls

Parameter and File where Port is Configured:

- `/opt/mapr/conf/cldb.conf`
- `/opt/mapr/conf/warden.conf`
- `/opt/mapr/conf/mapr-clusters.conf`

CLDB JMX Monitor Port

Source IP: Nodes running CLDB services

Destination IP: CLDB JMX monitor port

Ports: 7220

Purpose: The port on which Collectd gathers CLDB metrics through JMX.

Parameter and File where Port is Configured: Not Applicable

CLDB web port

Source IP: Nodes/clients connecting to the CLDB GUI

Destination IP: Cluster nodes running CLDB services

Ports: 7221

Purpose: CLDB GUI for a cluster with security disabled. For a secure cluster, the port is 7443 as defined by the `mapr login` utility.

Parameter and File where Port is Configured: `/opt/mapr/conf/cldb.conf`

maprlogin utility

Source IP: Connections using the `maprlogin` utility

Destination IP: Cluster nodes running CLDB services

Ports: 7443

Purpose: When security is enabled for a cluster, the CLDB listens for connections on port 7443. If security is disabled, the `mapr login` utility is unable to reach the CLDB.

Data Access Gateway

Parameter and File where Port is Configured: Not Applicable

Source IP: Clients using the HPE Data Fabric Database JSON REST API with HTTPS

Destination IP: Not Applicable

Ports: 8243

Purpose: The port used to connect to the Data Access Gateway using HTTPS

Parameter and File where Port is Configured: `rest.https.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`

Data Access Gateway

Source IP: Node.js OJAI client

Destination IP: Cluster nodes running the Data Access Gateway service

Ports: 5678

Purpose: The port used to connect the OJAI client to the Data Access Gateway

Parameter and File where Port is Configured: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`

Data Access Gateway

Source IP: Python OJAI client

Destination IP: Cluster nodes running the Data Access Gateway service

Ports: 5678

Purpose: The port used to connect the OJAI client to the Data Access Gateway

Parameter and File where Port is Configured: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`

Data Access Gateway

Source IP: Go OJAI client

Destination IP: Cluster nodes running the Data Access Gateway service

Ports: 5678

Purpose: The port used to connect the OJAI client to the Data Access Gateway

Parameter and File where Port is Configured: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`

Data Access Gateway

Source IP: C# OJAI client

Destination IP: Cluster nodes running the Data Access Gateway service

Ports: 5678

Purpose: The port used to connect the OJAI client to the Data Access Gateway

Parameter and File where Port is Configured: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`

Data Access Gateway

Source IP: Java OJAI thin client

Destination IP: Cluster nodes running the Data Access Gateway service

Ports: 5678

Apache Kafka Wire Protocol Service

Purpose: The port used to connect the OJAI client to the Data Access Gateway

Parameter and File where Port is

Configured: `grpc.service.port` in `/opt/mapr/data-access-gateway/conf/properties.cfg`

Source IP: Apache Kafka Client

Destination IP: Cluster nodes running the Data Access Gateway service

Ports: 9092

Purpose: The port used by Apache Kafka Wire Protocol Service to connect the Kafka client to the Data Access Gateway service.

Parameter and File where Port is Configured:

`port` in `/opt/mapr/data-access-gateway/conf/kafka-server.conf`

Drill JMX Port

Source IP: Nodes running the Drillbit service

Destination IP: Drill JMX Port

Ports: 6090

Purpose: The port on which Collectd gathers Drill metrics via JMX.

Parameter and File where Port is Configured: Not Applicable

Drill Web UI

Source IP: Nodes running the Drillbit service

Destination IP: Nodes running the Drillbit service

Ports: 8047

Purpose: TCP port needed for the Drill Web UI and clients using REST API and nodes running the Drillbit service.

Parameter and File where Port is Configured:

`drill.exec.http.port` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`

Drill (User Port)

Source IP: Nodes running the Drillbit service and clients using JDBC/ODBC

Destination IP: Nodes running the Drillbit service

Ports: 31010

Purpose: TCP user port address. Used between nodes in a Drill cluster. Needed for an external client, such as Tableau, to connect into the cluster nodes. Also needed for the Drill Web UI. You can also use this port to connect directly to a Drillbit.

Parameter and File where Port is

Configured: `drill.exec.rpc.user.server.port` in `/opt/mapr/drill/drill-<version>/conf/drill-override.conf`

Drill (Control Port)

Source IP: Nodes running the Drillbit service

Destination IP: Nodes running the Drillbit service

Ports: 31011

Purpose: TCP port that controls the port address. Used between nodes in a Drill cluster. Needed for multi-node installation of Drill.

Parameter and File where Port is

Configured: `drill.exec.rpc.bit.server.port`

Drill (Data Port)

in /opt/mapr/drill/drill-<version>/conf/
drill-override.conf

Source IP: Nodes running the Drillbit service

Destination IP: Nodes running the Drillbit service

Ports: 31012

Purpose: TCP data port address. Used between nodes in a Drill cluster. Needed for multi-node installation of Drill.

Parameter and File where Port is Configured:
drill.exec.rpc.bit.server.port + 1
in /opt/mapr/drill/drill-<version>/conf/
drill-override.conf

Drill (ZooKeeper Port)

Source IP: Clients using JDBC/ODBC and nodes running ZooKeeper services

Destination IP: Nodes running the Drillbit service

Ports: 5181

Purpose: ZooKeeper port used to connect to Drill through the JDBC driver.

Parameter and File where Port is Configured: See the ZooKeeper entry in this list.

Elasticsearch (Components Communication Port)

Source IP: Non-Elasticsearch components, such as a web browser, curl, and Kibana, that connect to Elasticsearch.

Destination IP: Nodes running Elasticsearch for monitoring use cases

Ports: 9200

Purpose: Non-Elasticsearch components use this port when communicating with Elasticsearch.

Parameter and File where Port is Configured: You can configure a different port for monitoring use cases when you run the [configure.sh](#) on page 3186 script with the -ES parameter.

Elasticsearch (Daemons Communication Port)

Source IP: Nodes running Elasticsearch

Destination IP: Nodes running Elasticsearch for monitoring use cases

Ports: 9300

Purpose: Elasticsearch uses this port for communications between Elasticsearch daemons.

Parameter and File where Port is Configured: Not Applicable

Gateway

Source IP: Nodes sending operations to replicate

Destination IP: Nodes running the gateway service

Ports: 7660

Purpose: The port used by gateway services to listen for incoming replication operations.

Parameter and File where Port is Configured: Not Applicable

Grafana

Source IP: Web Browsers

Destination IP: Nodes running Grafana for monitoring

Ports: 3000

HBase Master	<p><i>Purpose:</i> Web browsers use this port when connecting to Grafana.</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p> <p><i>Source IP:</i> HBase Clients</p> <p><i>Destination IP:</i> Nodes running HBase Master services</p> <p><i>Ports:</i> 16000</p> <p><i>Purpose:</i> HBase API and HBase shell use this port to connect to HBase Master</p> <p><i>Parameter and File where Port is Configured:</i> /opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml</p>
HBase Master Web UI	<p><i>Source IP:</i> HBase Master Web UI clients</p> <p><i>Destination IP:</i> Nodes running HBase Master services</p> <p><i>Ports:</i> 16010</p> <p><i>Purpose:</i> Information Web UI of HBase Master</p> <p><i>Parameter and File where Port is Configured:</i> /opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml</p>
HBase Thrift Server	<p><i>Source IP:</i> HBase Thrift Server clients</p> <p><i>Destination IP:</i> Nodes running HBase Thrift Server</p> <p><i>Ports:</i> 9090</p> <p> NOTE: On RHEL, if the web console is on port 9090, set the <code>hbase.regionserver.thrift.port</code> property in <code>hbase-site.xml</code> to configure the HBase Thrift server port. Then restart the HBase services to avoid any port conflicts.</p> <p><i>Purpose:</i> The HBase client uses this port to connect to HBase, using the Thrift protocol</p> <p><i>Parameter and File where Port is Configured:</i> /opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml</p>
HBase Thrift Web UI	<p><i>Source IP:</i> HBase Thrift Web UI clients</p> <p><i>Destination IP:</i> Nodes running HBase Thrift</p> <p><i>Ports:</i> 9095</p> <p><i>Purpose:</i> Information Web UI of HBase Thrift</p> <p><i>Parameter and File where Port is Configured:</i> /opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml</p>
HBase REST Server	<p><i>Source IP:</i> HBase REST Server clients</p> <p><i>Destination IP:</i> Nodes running HBase REST Server</p> <p><i>Ports:</i> 8080</p> <p><i>Purpose:</i> The HBase client uses this port to connect to HBase using the HTTP protocol</p> <p><i>Parameter and File where Port is Configured:</i> /opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml</p>
HBase REST Web UI	<p><i>Source IP:</i> HBase REST Web UI clients</p> <p><i>Destination IP:</i> Nodes running HBase REST</p>

HBase Regionserver*Ports:* 8086*Purpose:* Information Web UI of HBase REST*Parameter and File where**Port is Configured:* /opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml*Source IP:* HBase Clients*Destination IP:* Nodes running HBase Regionserver services*Ports:* 16020*Purpose:* HBase API and HBase shell use this port to connect to HBase RegionServer*Parameter and File where**Port is Configured:* /opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml**HBase Regionserver UI***Source IP:* HBase Regionserver Web UI clients*Destination IP:* Nodes running HBase Regionserver*Ports:* 16030*Purpose:* Information Web UI of HBase Regionserver*Parameter and File where**Port is Configured:* /opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml**HistoryServer RPC***Source IP:* Not Applicable*Destination IP:* Nodes running MapReduce JobHistory Server*Ports:* 10020*Purpose:* Not Applicable*Parameter and File where Port is Configured:* Not Applicable**HistoryServer Web UI and REST APIs***Source IP:* Clients that access Job History Server UI in a non-secure cluster*Destination IP:* Secure nodes running MapReduce JobHistory Server in a non-secure cluster*Ports:* 19888*Purpose:* Non-secure HistoryServer Web UI and REST APIs*Parameter and File where Port is Configured:* See [mapred-site.xml](#) on page 3371**HistoryServer Web UI and REST APIs***Source IP:* Clients that access Job History Server UI in a secure cluster*Destination IP:* Secure nodes running MapReduce JobHistory Server in a secure cluster*Ports:* 19890*Purpose:* Secure HistoryServer Web UI and REST APIs*Parameter and File where Port is Configured:* See [mapred-site.xml](#) on page 3371**Hive Metastore***Source IP:* Nodes/clients performing Hive queries/operations*Destination IP:* Nodes running the Hive metastore services

	<p><i>Ports:</i> 9083</p> <p><i>Purpose:</i> Used by Hive clients to query/access the Hive metastore</p> <p><i>Parameter and File where Port is Configured:</i> /opt/mapr/hive/hive-<version>/conf/hive-site.xml</p>
Hiveserver2	<p><i>Source IP:</i> Nodes or clients performing hive queries using JDBC/ODBC</p> <p><i>Destination IP:</i> Nodes running Hiveserver2</p> <p><i>Ports:</i> 10000</p> <p><i>Purpose:</i> Port through which clients perform hive queries</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Hiveserver2 Web UI	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Nodes running Hiveserver2 Web UI</p> <p><i>Ports:</i> 10002</p> <p><i>Purpose:</i> Provides access to Hive configuration settings, local logs, metrics, and information about active sessions and queries.</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Hoststats	<p>See <code>hoststats.port</code> and <code>hs.port</code> in the Warden configuration file.</p>
Httpfs	<p><i>Source IP:</i> Nodes/clients accessing httpfs services</p> <p><i>Destination IP:</i> Nodes running httpfs services</p> <p><i>Ports:</i> 14000</p> <p><i>Purpose:</i> Used by httpfs file clients to access the httpfs server</p> <p><i>Parameter and File where Port is Configured:</i></p> <ul style="list-style-type: none"> • /opt/mapr/hadoop/hadoop-<version>/etc/hadoop/httpfs-env.sh
Hue Webserver	<p><i>Source IP:</i> Nodes/clients accessing Hue web services</p> <p><i>Destination IP:</i> Nodes running Hue web services</p> <p><i>Ports:</i> 8888</p> <p><i>Purpose:</i> Used by Hue webserver clients to access the Hue webserver</p> <p><i>Parameter and File where Port is Configured:</i> /opt/mapr/hue/hue*/desktop/conf/hue.ini</p>
KSQL	<p><i>Source IP:</i> All cluster nodes</p> <p><i>Destination IP:</i> Nodes running KSQL</p> <p><i>Ports:</i> 8084</p> <p><i>Purpose:</i> KSQL</p> <p><i>Parameter and File where Port is Configured:</i> \$KSQL_INSTALL_DIR/etc/ksql/ksqlserver.properties</p>
Kafka Connect	<p><i>Source IP:</i> All cluster nodes</p>

Kafka REST

Destination IP: Nodes running Kafka Connect
Ports: 8083
Purpose: Kafka Connect REST API calls
Parameter and File where Port is Configured: /opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties

Kafka Schema Registry

Source IP: All cluster nodes
Destination IP: Nodes running Kafka REST
Ports: 8082
Purpose: Kafka Connect REST API calls
Parameter and File where Port is Configured: /opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties

Kibana

Source IP: All cluster nodes
Destination IP: Nodes running Kafka Schema Registry
Ports: 8087
Purpose: Kafka Schema Registry API calls
Parameter and File where Port is Configured: /opt/mapr/schema-registry/schema-registry-<version>/config/schema-registry.properties

MAST Gateway

Source IP: Web browsers
Destination IP: Nodes running Kibana for monitoring use cases
Ports: 5601
Purpose: Web browsers use this port when connecting to Grafana.
Parameter and File where Port is Configured: Not Applicable

file system server

Source IP: Nodes running MAST Gateway service
Destination IP: Nodes running MAST Gateway service
Ports: 8660
Purpose: Data Fabric clients use this port to connect to the MAST Gateway
Parameter and File where Port is Configured: /opt/mapr/conf/mastgateway.conf

file system server

Source IP: Nodes running any Data Fabric services, clients interacting with the file system
Destination IP: Nodes running FileServer services
Ports: 5660, 5692, 5724, and 5756
Purpose: The filesystem is a random read-write distributed filesystem that allows applications to concurrently read and write directly to disk. Clients use these ports to access the file-system server.
Parameter and File where Port is Configured: Not Applicable
Source IP: Nodes running the gateway service
Destination IP: Nodes running the file system
Ports: 6660

	<p><i>Purpose:</i> The port on which gateway nodes send replicated operations to nodes in destination clusters.</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
file system server instances	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Not Applicable</p> <p><i>Ports:</i> See Working with Multiple Instances of the File System on page 1356</p> <p><i>Purpose:</i> Multiple file system instances</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Object Store	<p><i>Source IP:</i> Nodes accessing MOSS</p> <p><i>Destination IP:</i> Nodes running MOSS</p> <p><i>Ports:</i> 9000</p> <p><i>Purpose:</i> Port for MOSS</p> <p><i>Parameter and File where Port is Configured:</i> The <code>moss.port</code> option in <code>/opt/mapr/conf/moss.conf</code>.</p> <p> CAUTION: The default port for S3 Gateway is also 9000. If you run S3 Gateway and Object Store, change one of the ports to avoid conflicts.</p>
S3 Gateway	<p><i>Source IP:</i> Nodes accessing the S3 Gateway server</p> <p><i>Destination IP:</i> Nodes running the S3 Gateway server</p> <p><i>Ports:</i> 9000</p> <p><i>Purpose:</i> Port for the S3 Gateway server</p> <p><i>Parameter and File where Port is Configured:</i> The <code>ports</code> option in <code>/opt/mapr/objectstore-client/objectstore-client-<version>/conf/minio.json</code></p>
NFS	<p><i>Source IP:</i> Nodes/clients accessing the filesystem via the NFS protocol</p> <p><i>Destination IP:</i> Nodes running Data Fabric NFS Services</p> <p><i>Ports:</i> 2049</p> <p> NOTE: NFSv4 refers to NFS version 4.1.</p> <p><i>Purpose:</i> NFSv3 or NFSv4 access to the file system</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
NFS	<p><i>Source IP:</i> Nodes running NFS services</p> <p><i>Destination IP:</i> Nodes running NFS services</p> <p><i>Ports:</i> 9997, 9998</p> <p><i>Purpose:</i> NFS VIP Management</p> <p><i>Parameter and File where Port is Configured:</i> <code>/opt/mapr/conf/nfsserver.conf</code></p>
NiFi (nonsecure UI over HTTP)	<p><i>Source IP:</i> Nodes or clients accessing the NiFi (UI/API) service</p> <p><i>Destination IP:</i> Nodes running the NiFi service</p> <p><i>Ports:</i> 8080</p>

	<p><i>Purpose:</i> Used by NiFi users to access the NiFi REST API or UI</p> <p><i>Parameter and File where Port is Configured:</i> <code>nifi.web.http.port</code> in <code>/opt/mapr/nifi/nifi-*/conf/nifi.properties</code></p>
NiFi (secured UI over HTTPS)	<p><i>Source IP:</i> Nodes or clients accessing the NiFi (UI/API) service</p> <p><i>Destination IP:</i> Nodes running the NiFi service</p> <p><i>Ports:</i> 12443</p> <p><i>Purpose:</i> Used by NiFi users to access the NiFi REST API or UI</p> <p><i>Parameter and File where Port is Configured:</i> <code>nifi.web.https.port</code> in <code>/opt/mapr/nifi/nifi-*/conf/nifi.properties</code></p>
NiFi (socket port for Site-to-Site communication)	<p><i>Source IP:</i> Nodes running the NiFi service</p> <p><i>Destination IP:</i> Nodes running the NiFi service</p> <p><i>Ports:</i> 12448</p> <p><i>Purpose:</i> The remote input socket port for Site-to-Site communication between two NiFi instances</p> <p><i>Parameter and File where Port is Configured:</i> <code>nifi.remote.input.socket.port</code> in <code>/opt/mapr/nifi/nifi-*/conf/nifi.properties</code></p>
NiFi (to receive communications from NiFi Bootstrap)	<p><i>Source IP:</i> Nodes running the NiFi service</p> <p><i>Destination IP:</i> Nodes running the NiFi service</p> <p><i>Ports:</i> 12445</p> <p><i>Purpose:</i> Used by NiFi to receive communications from NiFi Bootstrap</p> <p><i>Parameter and File where Port is Configured:</i> <code>nifi.listener.bootstrap.port</code> in <code>/opt/mapr/nifi/nifi-*/conf/nifi.properties</code></p>
NiFi (to receive communications from NiFi)	<p><i>Source IP:</i> Nodes running the NiFi service</p> <p><i>Destination IP:</i> Nodes running the NiFi service</p> <p><i>Ports:</i> 12444</p> <p><i>Purpose:</i> Used by NiFi Bootstrap to receive communications from NiFi</p> <p><i>Parameter and File where Port is Configured:</i> <code>nifi.bootstrap.listen.port</code> in <code>/opt/mapr/nifi/nifi-*/conf/bootstrap.conf</code></p>
NodeManager JMX Port	<p><i>Source IP:</i> Nodes running NodeManager</p> <p><i>Destination IP:</i> NodeManager JMX Port</p> <p><i>Ports:</i> 8027</p> <p><i>Purpose:</i> The port on which Collectd gathers metrics from NodeManager nodes via JMX.</p> <p><i>Parameter and File where Port is Configured:</i>Not Applicable</p>
NodeManager	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Nodes running NodeManager</p> <p><i>Ports:</i> 8099</p> <p><i>Purpose:</i> The node manager manages the health of each node in the cluster.</p>

NodeManager Localizer RPC

Parameter and File where Port is Configured: `yarn.nodemanager.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`

Source IP: Not Applicable

Destination IP: Nodes running NodeManager

Ports: 8040

Purpose: The port that node manager uses to localize resources for a node. With localization, remote resources are downloaded to the local filesystem for access.

Parameter and File where Port is Configured: `yarn.nodemanager.localizer.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`

NodeManager Web UI and REST APIs

Source IP: External Web browsers and REST clients accessing NodeManager services in a non-secure cluster

Destination IP: Nodes running NodeManager services in a non-secure cluster

Ports: 8042

Purpose: NodeManager HTTP port

Parameter and File where Port is Configured: `yarn.nodemanager.webapp.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`

NodeManager Web UI and REST APIs

Source IP: External Web browsers and REST clients accessing NodeManager services in a secure cluster

Destination IP: Nodes running NodeManager services in a secure cluster

Ports: 8044

Purpose: NodeManager HTTPS port

Parameter and File where Port is Configured: `yarn.nodemanager.webapp.https.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`

OpenTSDB

Source IP: OpenTSDB clients, such as `Collectd`.

Destination IP: Nodes running OpenTSDB for monitoring use cases.

Ports: 4242

Purpose: `Collectd` uses this port to write metrics to OpenTSDB.

Parameter and File where Port is Configured: You can configure a different port for monitoring use cases when you run [configure.sh](#) on page 3186 script with the `-OT` parameter.

Port Mapper

Source IP: Nodes running Data Fabric NFS Services

Destination IP: Nodes/clients accessing the filesystem using the NFS protocol

Ports: 111

Purpose: RPC Portmap services used to connect to the file system using NFSv3

Ranger (nonsecure Admin UI for http)

Parameter and File where Port is Configured: Not Applicable

Source IP: Nodes or clients accessing the Ranger Admin (UI/API) service

Destination IP: Nodes running the Ranger Admin service

Ports: 6080

Purpose: Used by Ranger Admin clients to access the Ranger Admin service

Parameter and File where Port is Configured: `ranger.service.http.port` in `/opt/mapr/ranger/ranger-2.3.0/ranger-admin/conf/ranger-admin-site.xml`

Ranger (secure Admin UI for https)

Source IP: Nodes or clients accessing the Ranger Admin (UI/API) service

Destination IP: Nodes running the Ranger Admin service

Ports: 6182

Purpose: Used by Ranger Admin clients to access the Ranger Admin service

Parameter and File where Port is Configured: `ranger.service.https.port` in `/opt/mapr/ranger/ranger-2.3.0/ranger-admin/conf/ranger-admin-site.xml`

Ranger Usersync

Source IP: Nodes or clients accessing the Ranger Usersync service

Destination IP: Nodes running the Ranger Usersync service

Ports: 5151

Purpose: Used by the Ranger Admin to access the Ranger Usersync service

Parameter and File where Port is Configured: `ranger.usersync.port` in `/opt/mapr/ranger/ranger-2.3.0/ranger-usersync/conf/ranger-ugsync-site.xml`

ResourceManager JMX Port

Source IP: Nodes running ResourceManager

Destination IP: ResourceManager JMX port

Ports: 8025

Purpose: The port on which Collectd gathers metrics from the ResourceManager using JMX.

Parameter and File where Port is Configured: Not Applicable

ResourceManager Admin RPC

Source IP: Applications that access the ResourceManager

Destination IP: Nodes running ResourceManager

Ports: 8033

Purpose: The port that applications use to access the ResourceManager RPC

Parameter and File where Port is Configured: `yarn.resourcemanager.admin.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`

ResourceManager Client RPC*Source IP:* Clients that submit YARN applications*Destination IP:* Nodes running ResourceManager*Ports:* 8032*Purpose:* The port that clients use to access the YARN applications*Parameter and File where Port is**Configured:* `yarn.resourcemanager.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`**ResourceManager Resource Tracker RPC (for NodeManagers)***Source IP:* Applications that access the ResourceManager*Destination IP:* Nodes running ResourceManager*Ports:* 8031*Purpose:* The port that applications use to access the Resource Manager Tracker RPC*Parameter and File where Port is Configured:*`yarn.resourcemanager.resource-tracker.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`**ResourceManager Scheduler RPC (for ApplicationMasters)***Source IP:* Applications that access the ResourceManager*Destination IP:* Nodes running ResourceManager*Ports:* 8030*Purpose:* The port on which the applications in the cluster talk to the ResourceManager.*Parameter and File where Port is Configured:*`yarn.resourcemanager.scheduler.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`**ResourceManager Web UI (HTTP)***Source IP:* Clients that access ResourceManager UI in a non-secure cluster*Destination IP:* Nodes running ResourceManager master in a non-secure cluster*Ports:* 8088*Purpose:* ResourceManager Web UI*Parameter and File where Port is Configured:*`yarn.resourcemanager.webapp.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`**ResourceManager Web UI (HTTPS)***Source IP:* Clients that access ResourceManager UI in a secure cluster*Destination IP:* Nodes running ResourceManager master in a secure cluster*Ports:* 8090*Purpose:* ResourceManager Web UI*Parameter and File where Port is Configured:*`yarn.resourcemanager.webapp.address` in `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml`**Shuffle HTTP***Source IP:* Not Applicable*Destination IP:* Shuffle HTTP

	<p><i>Ports:</i> 13562</p> <p><i>Purpose:</i> The port that MapReduce Shuffle uses. Transferring the map outputs to reducer inputs in sorted form is the shuffle operation.</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Spark Standalone Master (RPC)	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Not Applicable</p> <p><i>Ports:</i> 7077</p> <p><i>Purpose:</i> The port on which to submit jobs in a Spark standalone cluster.</p> <p><i>Parameter and File where Port is Configured:</i> SPARK_MASTER_PORT in SPARK_HOME/conf/spark-env.sh</p>
Spark Standalone Master (Web UI)	<p><i>Source IP:</i> Nodes/clients accessing Spark services in a non-secure cluster</p> <p><i>Destination IP:</i> Nodes running Spark services in a non-secure cluster</p> <p><i>Ports:</i> 8580</p> <p><i>Purpose:</i> The port on which browsers connect to Spark master in a non-secure Spark standalone cluster.</p> <p><i>Parameter and File where Port is Configured:</i> SPARK_MASTER_WEBUI_PORT in SPARK_HOME/conf/spark-env.sh</p>
Spark Standalone Master (Web UI)	<p><i>Source IP:</i> Nodes/clients accessing Spark services in a secure cluster</p> <p><i>Destination IP:</i> Nodes running Spark services in a secure cluster</p> <p><i>Ports:</i> 8980</p> <p><i>Purpose:</i> The port on which browsers connect to a Spark master in a secure Spark standalone cluster.</p> <p><i>Parameter and File where Port is Configured:</i> SPARK_MASTER_WEBUI_PORT in SPARK_HOME/conf/spark-env.sh</p>
Spark Standalone Worker	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Not Applicable</p> <p><i>Ports:</i> 8081</p> <p><i>Purpose:</i> The port on which browsers connect to Spark workers in a Spark standalone cluster.</p> <p><i>Parameter and File where Port is Configured:</i> SPARK_WORKER_WEBUI_PORT in SPARK_HOME/conf/spark-env.sh</p>
Spark Thrift Server (if start and stop server using Spark scripts)	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Not Applicable</p> <p><i>Ports:</i> 10000</p> <p><i>Purpose:</i> The port on which JDBC clients connect to Spark Thrift server.</p> <p><i>Parameter and File where Port is Configured:</i> hive.server2.thrift.port in SPARK_HOME/conf/hive-site.xml</p>

Spark Thrift Server (if start and stop server through Warden, starting in EEP 4.0)*Source IP:* Not Applicable*Destination IP:* Not Applicable*Ports:* 2304*Purpose:* The port on which JDBC clients connect to Spark Thrift server.*Parameter and File where Port is Configured:*
hive.server2.thrift.port in SPARK_HOME/
conf/hive-site.xml**Spark History Server***Source IP:* Clients that access Spark Job History in a non-secure cluster*Destination IP:* Nodes running Spark History Server in a non-secure cluster*Ports:* 18080*Purpose:* The port on which browsers connect to a non-secure Spark history server.*Parameter and File where Port is Configured:*
spark.history.ui.port in SPARK_HOME/conf/
spark-default.conf"**Spark History Server***Source IP:* Clients that access Spark Job History in a secure cluster*Destination IP:* Nodes running Spark History Server in a secure cluster*Ports:* 18480*Purpose:* The port on which browsers connect to a secure Spark history server.*Parameter and File where Port is Configured:*
spark.ssl.historyServer.port
in SPARK_HOME/conf/spark-defaults.conf
(starting from Spark-2.2.1)**Spark External Shuffle Service***Source IP:* Not Applicable*Destination IP:* Not Applicable*Ports:* 7337*Purpose:* The port on which Spark jobs connect to External Shuffle server.*Parameter and File where Port is Configured:*
spark.shuffle.service.port in SPARK_HOME/
conf/spark-default.conf**Tez Shuffle***Source IP:* Not Applicable*Destination IP:* Not Applicable*Ports:* 13563*Purpose:* Port to communicate with the Tez Shuffler. A Tez specific shuffle handler allows data to be shuffled in a way that takes advantage of the new features in Tez*Parameter and File where Port is Configured:* Not Applicable**Timeline Server***Source IP:* Not Applicable*Destination IP:* Not Applicable*Ports:* 10200*Purpose:* Hadoop IPC port used for internal communication in Hadoop

	<p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Timeline Server Web Interface (HTTP)	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Not Applicable</p> <p><i>Ports:</i> 8188</p> <p><i>Purpose:</i> Non-secure web access for the Timeline Server. The Timeline Server allows storage and retrieval of an application's current and historic information in a generic fashion.</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Timeline Server Web Interface (HTTPS)	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Not Applicable</p> <p><i>Ports:</i> 8190</p> <p><i>Purpose:</i> Secure web access for the Timeline Server</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Tomcat Port (Hive-on-Tez UI)	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Not Applicable</p> <p><i>Ports:</i> 9383</p> <p><i>Purpose:</i> The non-secure port to access the Tez UI. Hive-on-Tez speeds up execution of Hive queries.</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Tomcat SSL Port (Hive-on-Tez UI)	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Not Applicable</p> <p><i>Ports:</i> 9393</p> <p><i>Purpose:</i> The secure port to access the Tez UI.</p> <p><i>Parameter and File where Port is Configured:</i> Not Applicable</p>
Web UI	<p><i>Source IP:</i> External web browser accessing either a non-secure or a secure cluster</p> <p><i>Destination IP:</i> Nodes running the Control System Web UI in a non-secure or a secure cluster</p> <p><i>Ports:</i> 8443</p> <p><i>Purpose:</i> Control System Web UI</p> <p><i>Parameter and File where Port is Configured:</i> /opt/mapr/apiserver/conf/properties.cfg</p>
Zeppelin	<p><i>Source IP:</i> Not Applicable</p> <p><i>Destination IP:</i> Not Applicable</p> <p><i>Ports:</i> 9995</p> <p><i>Purpose:</i> The port to connect to the Zeppelin Docker container</p> <p><i>Parameter and File where Port is Configured:</i> Configurable by setting ZEPPELIN_SSL_PORT when running the Zeppelin Docker image</p>
ZooKeeper	<p><i>Source IP:</i> Nodes running ZooKeeper services, clients executing ZooKeeper API calls</p> <p><i>Destination IP:</i> Nodes running ZooKeeper services</p>

Ports: 5181
Purpose: ZooKeeper API calls
Parameter and File where Port is Configured:

- /opt/mapr/zookeeper/zookeeper-<version>/conf/zoo.cfg
- /opt/mapr/conf/warden.conf, /opt/mapr/conf/cldb.conf
- /opt/mapr/hbase/hbase-<version>/conf/hbase-site.xml
- /opt/mapr/hive/hive-<version>/conf/hive-site.xml

ZooKeeper follower-to-leader Communication

Source IP: Nodes running ZooKeeper services
Destination IP: Nodes running ZooKeeper services
Ports: 2888
Purpose: ZooKeeper Server > Server Communication
Parameter and File where Port is Configured: /opt/mapr/zookeeper/zookeeper-<version>/conf/zoo.cfg

ZooKeeper Leader Election

Source IP: Nodes running ZooKeeper services
Destination IP: Nodes running ZooKeeper services
Ports: 3888
Purpose: ZooKeeper Server > Server Communication
Parameter and File where Port is Configured: /opt/mapr/zookeeper/zookeeper-<version>/conf/zoo.cfg

Log Files

Lists the log files for each HPE Data Fabric component.
The table below provides information on the log files for the components.

 **NOTE:** NFSv4 refers to NFS version 4.1.

Component	Type of Log	Log File	Configuration File	Rotation	Maximum File Size	# of Backups	Expiration Period
CLDB	Main	/opt/mapr/logs/cldb.log	/opt/mapr/conf/log4j.cldb.properties	By Size	100MB	9	-
	Disk Balancer	/opt/mapr/logs/cldbdiskbalancer.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Role Balancer	/opt/mapr/logs/cldbrolebalancer.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Time Skew	/opt/mapr/logs/timeskew.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Data Fabric filesystem Summary	/opt/mapr/logs/cldbfssummary.log	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	10 days
	Audit	/opt/mapr/logs/cldbaudit.log.json	/opt/mapr/conf/log4j.cldb.properties	Daily	-	-	-
	Guts	/opt/mapr/logs/cldbguts.log	/opt/mapr/conf/log4j.properties	-	-	-	10 days
	Proxy	/opt/mapr/logs/cldbproxy.log	/opt/mapr/conf/log4j.properties	-	-	-	10 days

Component	Type of Log	Log File	Configuration File	Rotation	Maximum File Size	# of Backups	Expiration Period
WebServer	Main	/opt/mapr/apiserver/logs/apiserver.log	/opt/mapr/apiserver/conf/properties.cfg	Every Startup	-	10	10 days
			/opt/mapr/conf/log4j.mcs.properties	Daily	-	-	
	Authentication Audit	/opt/mapr/logs/authaudit.log.json	/opt/mapr/apiserver/conf/log4j2.xml	Daily	-	-	-
	PAM	/opt/mapr/logs/pam.log	/opt/mapr/conf/log4j.properties	Daily	-	-	10 days

Increasing Log Retention

To increase log retention for specific component, you can modify the configuration file and reset the value of the properties.

Increasing Log Retention for file system

In the `/opt/mapr/conf/mfs.conf` file, increase the value for the `mfs.max.logfile.size.in.mb` property. The value for this property is computed using the following formula:

```
maxSizePerLogFile = maxLogSize / MAX_NUM_OF_LOG_FILES
```

Here:

- `maxLogSize` specifies the total amount of space that file system log files can consume.
- `MAX_NUM_OF_LOG_FILES` specifies the total number of file system log files (5 hard coded).

For example, for a value of 10 GB, there will be 5 log files (`mfs.log-3` to `mfs.log-3.4`) of 2GB each.

Increasing Log Retention for CLDB

NOTE: This setting does not impact audit logging.

In the `/opt/mapr/conf/log4j2.cldb.xml` file, modify the `SizeBasedTriggeringPolicy` and `DefaultRolloverStrategy` properties.

- Modify the size attribute for `SizeBasedTriggeringPolicy` that specifies the size of each `cldb.log` before rolling over to write to a new log file. For example,
`<SizeBasedTriggeringPolicy size="1024MB"/>`
- Modify the max attribute for `DefaultRolloverStrategy` that specifies the number of `cldb.log*` files to be retained before the oldest one is deleted. For example,
`<DefaultRolloverStrategy max="20" fileIndex="min"/>`

With the aforementioned values for `SizeBasedTriggeringPolicy` and `DefaultRolloverStrategy`, the CLDB log files can grow to 20GB (1024*20), before they are purged.

IMPORTANT: You must restart CLDB on all nodes for the change in the values of CLDB log retention properties to take effect. Restart the passive CLDB nodes first, followed by restarting of the active CLDB node, so that the active CLDB node fails over to a passive CLDB node with the new values for CLDB log retention properties. Run the following command to restart a CLDB node.

```
maprcli node services -cldb restart -nodes $(hostname)
```

Increasing Log Retention for Hadoop Services

You can increase log retention for ResourceManager, NodeManager, HistoryServer, and TimelineServer by modifying the following properties in the `/opt/mapr/hadoop/hadoop-<Version>/etc/hadoop/log4j.properties` file:

- `hadoop.log.maxfilesize` — specifies the size of each `<service-name>-<hostname>.log` before rolling over.
- `hadoop.log.maxbackupindex` — specifies the number of `<service-name>-<hostname>.log*` before the oldest one is deleted.

For example, suppose the following configuration:

- `hadoop.log.maxfilesize = 1024Mb`
- `hadoop.log.maxbackupindex = 10`

There will be 10 GB of total service-specific logs (1GB per file) before the oldest file is purged.

Setting the Tracing Level

To check all the modules and their current logging levels, run the following command:

```
maprcli trace info
```

To set the tracing level for a module, run the `maprcli trace setlevel` command. For example:

```
maprcli trace setlevel -module FuseMonitor -level DEBUG
```

Configuring Profiling for Operations

To check the amount of time it took to complete each operation (from the time of submission), enable profiling for client RPC and file system operations. To enable profiling for:

- Client RPC, run the following command:

```
fcdebug -s <shmid> -m ClntProfileRpc -1 DEBUG
```

TIP: For more information, see [fcdebug](#).

Enabling profiling for the client RPC will allow you to determine, for each RPC, the amount of time it took to receive a response after submitting the request.

- file system operations, run the following command:

```
maprcli trace setlevel -module FSProfile -level debug
```

TIP: For more information, see [maprcli](#).

Enabling profiling for file system operations will allow you to determine the amount of time it took file system to process each operation.

By default, profiling is disabled for both client RPC and file system operations. Once enabled, the log for:

- Client RPC should look similar to the following:

```
2016-06-16 10:58:04,6404 DEBUG ClntProfileRpc
fs/client/fileclient/cc/client.cc:3483 Thread: 32188 Profile: CltRpcDone:
server 10.10.100.196:5692 took 1 msec error 0 FID 2125.34.262486 Getattr

2016-06-16 11:13:55,7480 DEBUG ClntProfileRpc
fs/client/fileclient/cc/client.cc:3202 Thread: 32161 Profile: CltRpcDone:
server 10.10.100.196:5692 took 1 msec error 0 FID 2125.16.2 PathWalkPlus
path
abc
```

- file system should look similar to the following:

```
2016-06-19 15:51:05,0231 DEBUG FSProfile unlink.cc:2456 OP unlink:
localTm 34
elapsedTm 34 client 10.10.100.196 err 0 PFID: 1.32.131398 name
unreachableFSIdTable itype Regular

2016-06-19 15:51:11,0249 DEBUG FSProfile writev3.cc:1296 OP Write:
localTm 13
elapsedTm 13 client 10.10.100.196 err 0 FID: 2121.532.2364014 off 29234

2016-06-19 15:51:08,1184 DEBUG FSProfile readdir.cc:505 OP ReadDir:
elapsedTm
28 client 10.10.100.196 err 0 FID: 2121.16.2 Isplus true
```

For example, to check the time it took for a read RPC, run the following command:

```
# cat /opt/mapr/logs/ffs.log* | grep -nrui "ClntRpcDone" | grep -nrui "read"
| less
1009:1014:2016-06-16 11:21:51,8203 DEBUG ClntProfileRpc
fs/client/fileclient/cc/client.cc:4900 Thread: 32151 Profile: CltRpcDone:
server10.10.100.196:5660 took 0 msec for Proc Read error 0 FID
2182.32.131232
off 7143424 len 131072 name 2125.34.262486
```

Archiving CLDB Logs

The CLDB logs can be archived by setting the value for the configuration parameter, `cldb.logarchiver.enabled`, using the `maprccli config save` command. The value can be:

- 0 — disable
- 1 — enable

To:

- Enable archiving, run the following command:

```
maprccli config save -values '{"cldb.logarchiver.enabled":"1"}'
```

- Disable archiving, run the following command:

```
maprccli config save -values '{"cldb.logarchiver.enabled":"0"}'
```

The default value for this parameter is 2, which indicates that the CLDB log archiving is disabled; but on clusters with 50 or more file system nodes, the CLDB log archiving will be automatically enabled unless the value is explicitly set to 0.

If/when archiving is enabled:

- All static CLDB log files, except the active `cldb.log` file, are periodically scanned and archived in `/var/mapr/cldblog/<hostname>` directory.
- The filename for the archived log file is autogenerated based on the date and timestamp on the first log line in the file chosen for archival.

For example, suppose a log file with the following first line:

```
2017-04-06 12:42:16,020 INFO CLDB [main]: Loading properties file : /opt/
mapr/conf/cldb.conf
```

The archived log filename in `/var/mapr/cldblog/<hostname>` directory will be:
`2017-04-06_12.42.16.020`

Enabling Runtime Logging

To enable logging at runtime for the file client (`libfsalmapr.so` library), run the `fcdebug` utility:

```
/opt/mapr/server/tools/fcdebug -s <shmid> -m <module> [-l <level>]
/opt/mapr/server/tools/fcdebug -i -s <shmid>
```

Before running this command, make a note of the following:

- If necessary, run `maprccli trace info` to retrieve the list of modules.
 The default value for module is all.
- Level should be one of FATAL, ERROR, WARN, INFO, DEBUG.
 If level is not specified, default level is applied for the module.
- The `-i` lists the current debug level of all modules.
- The `shmid` is available in the `fsal.log-*` files when `LibMapRClient` is loaded.

For example, the first line in the log file is something similar to the following:

```
2017-02-13 11:56:32,6809 ERROR FuseAPI fs/client/fileclient/cc/
fuse_api.cc:1371
Thread: 428 Shmid to be used by fcdebug 512720897
```

This `shmid` can be used with `fcdebug`.

NOTE: Run `fcdebug` once for every library (every library has a separate shared memory). The `shmid`s can be found in the respective `fsal` log files.

Viewing Audit Logs

The following sections describe audit logs for execution of any `maprccli` command, REST API call, or action in Control System, and audit logs for cluster administration, file system, table, and stream operations.

Viewing Log Entries for Audited maprccli Command Runs

Describes where audit records of operations performed using the CLI are stored and how to view them.

The running of any `maprccli` command on the cluster is logged in the local filesystem on the node on which the `maprccli` command is run. The log file is `/opt/mapr/mapr-cli-audit-log/audit.log.json`. Auditing of CLI operations is always enabled, whether or not auditing is enabled for cluster-level operations with the `maprccli audit cluster` command.

A typical log entry provides a timestamp for the `maprccli` command that has run, the UID of the user that has run the command, the IP address from which the user has run the command, the command itself, and the status that the command returns. Status codes are 0 for success and 1 for failure. The error messages field provides the reasons for failures.

Below are some typical log entries:

```
{
  "timestamp": {
    "$date": "2015-06-15T11:45:56.434Z",
    "uid": 2147483632,
    "ipAddress": "10.10.20.12",
    "command": "volume info",
    "arguments": {
      "name": "mapr.opt",
      "status": 1,
      "errors": ["Volume lookup of mapr.opt failed, No such volume"]
    }
  },
  "timestamp": {
    "$date": "2015-06-15T11:49:34.434Z",
    "uid": 2147483632,
    "ipAddress": "10.10.20.12",
    "command": "alarm add",
    "arguments": {
      "baseService": "1",
      "alarm": "NODE_ALARM_SERVICE_GATEWAY_DOWN",
      "service": "gateway",
      "displayName": "Gateway ServiceDown",
      "serviceName": "GatewayService",
      "terse": "nagwsd"
    },
    "status": 1,
    "errors": [
      "Terse name of nagwsd already exists in the system.",
      "Alarm NODE_ALARM_SERVICE_GATEWAY_DOWN already exists in the system."
    ]
  },
  "timestamp": {
    "$date": "2015-06-15T11:49:52.598Z",
    "uid": 2147483632,
    "ipAddress": "10.10.20.12",
    "command": "volume create",
    "arguments": {
      "name": "mapr.hbase",
      "path": "/hbase",
      "replicationtype": "low_latency"
    },
    "status": 1,
    "errors": ["Volume Name mapr.hbase, Already In Use"]
  }
}
```

Viewing Audit Logs for Cluster Administration

Describes where audit records of cluster administration operations are stored and how to view them.

Entries for audit logs are initially held in memory until 128 operations have been logged or 10 seconds have elapsed, whichever happens first. At that point, the new log entries are flushed to disk.

Audit logs are in JSON format, so they can be queried by Drill or processed by other third-party tools or your own scripts.

Audit logs are readable only by the `mapr` and `root` users on the cluster where the logs are located. These users can also copy and delete audit logs.

The status field in every log entry shows the status of the attempted operation. The status codes are taken from the Linux `errno.h` file. For a list of these codes, see [Status Codes That Can Appear in Audit Logs](#).

Audit logs use Coordinated Universal Time (UTC) in the records of audited operations.

The cleanup of old audit log files is handled by Warden either when they are older than 10 days (the default retention time) or when they are older than the number of days set for the `log.retention.time` parameter in the `/opt/mapr/conf/warden.conf` file. To prevent Warden from removing the log files, by default, `cldbaudit*` and `authaudit*` are listed under the `log.retention.exceptions` parameter in the `warden.conf` file.

To enable Warden to automatically cleanup log files, remove `cldbaudit*` and `authaudit*` from the `log.retention.exceptions` parameter in the `warden.conf` file and, if you want a shorter cleanup

time, set the value for `log.retention.time` parameter in the `warden.conf` file. The value for `log.retention.time` must be specified in milliseconds.

To disable all exceptions, comment out the `log.retention.exceptions` parameter, that is, `#log.retention.exceptions`. When this parameter is null, that is, `log.retention.exceptions=`, no files are picked for log cleanup.

Viewing Audit Logs for File System, Table, and Stream Operations

Describes where file system, HPE Data Fabric Database, and HPE Data Fabric Streams audit logs are stored and how to view them.

Operations on the HPE Data Fabric file, database, and event data are captured and recorded in the audit logs. The operations take place within volumes and have effects at the level of the file system.

These audit logs are stored in a system volume created specifically to store them. This volume is created automatically during cluster installations and upgrades. Operations are logged on the nodes on which the operations are executed, which could differ from the nodes where operations are initiated. Logs are stored in the file system at `/var/mapr/local/<node_name>/audit/`. By default, only root and the cluster administrator (typically `mapr`) can read the log files. To allow other users to read the logs, set ACEs on the directory granting readfile (`rf`), readdir (`rd`), and lookupdir (`ld`) permissions to the users. For example:

```
~# hadoop dfs -setace -R -aces "rf:u:root|u:mapr|u:m7user1,rd:u:root|u:mapr|u:m7user1,ld:u:root|u:mapr|u:m7user1" /var/mapr/local/sample.qa.lab/audit/
```

NOTE: For more information, see [Enabling Volume, Directory, and File Authorizations with ACEs](#) on page 2130.

Audit logs for operations on directories and files

Operations on directories and files, as well as the deletion of HPE Data Fabric Database tables, are logged in files that have this naming convention: `FSAudit.log.json-dd-mm-yyyy-<001-999>`

To see what information is recorded in typical log entries, see [Example Log Entries for Audited File System Operations](#).

Audit logs for operations on HPE Data Fabric Database tables and HPE Data Fabric Streams

All operations on HPE Data Fabric Database tables and HPE Data Fabric Streams are logged in files that have this naming convention: `DBAudit.log.json-dd-mm-yyyy-<001-999>`

Operations that result from `maprcli` commands, REST calls, or activity in MCS are also logged in `/opt/mapr/mapr-cli-audit-log/audit.log.json` on the local file system of the nodes where the operations are processed.

To see what information is recorded in typical log entries, see [Example Log Entries for Audited Operations on HPE Data Fabric Database Binary and JSON Tables](#) on page 3512.

NOTE: Due to how the creation of tables is processed internally, sometimes the creation of tables is logged in `FSAudit.log.json`, rather than in `DBAudit.log.json`.

Common Features of Audit Logs for File System, Table, and Stream Operations

Entries for audit logs are initially held in memory until 128 operations have been logged or 10 seconds have elapsed, whichever happens first. At that point, the new log entries are flushed to disk, depending on the [coalesce](#) interval.

The coalesce interval represents the interval of time during which READ, WRITE, or GETATTR operations on one file from one client IP address and UID/GID are logged only once for a particular operation, if auditing is enabled.

For example, suppose that a client application reads a single file three times in 6 minutes, so that there is one read at 0 minutes, another at 3 minutes, and a final read at 6 minutes. If the coalesce interval is at least 6 minutes, then only the first read operation is logged. However, if the interval is between 4 minutes, then only the first and third read operations are logged. If the interval is 2 minutes, all three read operations are logged.

Now however, if the client was also writing to the file, irrespective of the coalesce interval for the read operation in the example stated previously, the write operation is logged, as it is a different operation from reading.

The default value is 60 minutes. Setting this field to a larger number helps prevent audit logs from growing quickly. To change the coalesce interval, see [volume audit](#) on page 2919.

Audit logs are in JSON format, so they can be queried by Drill or processed by other third-party tools or your own scripts.

Audit logs are readable only by the `mapr` and `root` users on the cluster where the logs are located. These users can also copy and delete audit logs.

The status field in every log entry shows the status of the attempted operation. The status codes are taken from the Linux `errno.h` file. For a list of these codes, see [Status Codes That Can Appear in Audit Logs](#).

Audit logs use Coordinated Universal Time (UTC) in the records of audited operations.

When operations are performed on directories, files, or tables that are being audited, the full names for those objects, as well as the current volume and the name of the user performing the operation, are not immediately available to the auditing feature. What are immediately available are IDs for those objects and users. Converting IDs to names at run-time would be costly for performance. Therefore, audit logs contain file identifiers (FIDs) for directories, files, and tables; volume identifiers for volume; and user identifiers (UIDs) for users.

You can resolve identifiers into names by using the [expandaudit](#) utility. This utility creates a copy of the log files for a specified volume, and in that copy are the names of the file system objects, users, and volumes that are in the audit log records. You can then query or process the copy.

A sample of the logs is as follows:

```
{
  "timestamp":
  {
    "$date": "2021-07-14T13:05:01.506Z",
    "resource": "test-audit-logs",
    "operation": "volumeMirrorPermCheck",
    "username": "root",
    "uid": 0,
    "clientip": "10.163.167.214",
    "status": 0
  }
},
{
  "timestamp":
  {
    "$date": "2021-07-14T08:44:01.553Z",
    "resource": "255",
    "operation": "volumeLookup",
    "username": "root",
    "uid": 0,
    "clientip": "10.163.167.214",
    "status": 2
  }
}
```

NOTE: There will be an entry in the audit log for each IP address on a node. For example, suppose there is a node with multiple IP addresses. The audit log on this node may show multiple entries of the same operation, each associated with a different IP address.

NOTE: The number of bytes read or written is not recorded.

Example Log Entries for Audited File System Operations

When auditing of file system operations is enabled at the cluster level, volume level, and file system level, each operation on a directory or file is logged on the node on which the operation was initiated.

Typical log entries provide a timestamp of the operation, the type of operation, the UID of the user who ran the command, the IP address from which the user ran the command, identifiers of the affected resources, the volume identifier, and the status of the operation. Status codes come from the Linux `errno.h` file. For a list of these codes, see [Status Codes That Can Appear in Audit Logs](#).

NOTE: Due to the way that the creation of tables is processed internally, sometimes the creation of tables is logged in `FSAudit.log.json`, rather than in `DBAudit.log.json`.

Below are some typical log entries:

```
{
  "timestamp":
  {
    "$date": "2015-06-06T10:44:22.800Z",
    "operation": "MKDIR",
    "uid": 0,
    "ipAddress":
    "10.10.104.51",
    "parentFid": "2049.51.131248",
    "childFid": "2049.56.131258",
    "childName":
    "ycsbTmp_1433587462796",
    "volumeId": 68048396,
    "status": 0
  }
  {
    "timestamp":
    {
      "$date": "2015-06-06T10:44:22.823Z",
      "operation": "LOOKUP",
      "uid": 0,
      "ipAddress":
      "10.10.105.51",
      "srcFid": "2049.56.131258",
      "srcName": "range0",
      "volumeId": 68048396,
      "status": 2
    }
    {
      "timestamp":
      {
        "$date": "2015-06-06T10:44:22.824Z",
        "operation": "CREATE",
        "uid": 0,
        "ipAddress":
        "10.10.104.51",
        "parentFid": "2049.56.131258",
        "childFid": "2049.57.131260",
        "childName": "range0",
        "volumeId": 68048396,
        "status": 0
      }
      {
        "timestamp":
        {
          "$date": "2015-06-06T10:44:22.838Z",
          "operation": "WRITE",
          "uid": 0,
          "ipAddress":
          "10.10.105.51",
          "srcFid": "2049.57.131260",
          "volumeId": 68048396,
          "status": 0
        }
        {
          "timestamp":
          {
            "$date": "2015-06-06T10:44:48.628Z",
            "operation": "READ",
            "uid": 0,
            "ipAddress":
            "10.10.105.51",
            "srcFid": "2049.63.131272",
            "volumeId": 68048396,
            "status": 0
          }
        }
      }
    }
  }
}
```

To convert the user IDs to usernames, file identifiers to pathnames, and volume IDs to volume names, run the [expandaudit](#) on page 3234 utility. For example, here are the same audit records after they were processed by this utility:

```
{
  "timestamp": "{ $date=2015-06-06T10:44:22.800Z }",
  "operation": "MKDIR",
  "user": "root",
  "uid": "0",
  "ipAddress":
  "10.10.104.51",
  "parentPath": "/ycsb1433587356934",
  "childPath": "/ycsb1433587356934/ycsbTmp_1433587462796",
  "childName": "ycsbTmp_1433587462796",
  "VolumeName": "mapr.cluster.root",
  "volumeId": "68048396",
  "status": "0"
  {
    "timestamp": "{ $date=2015-06-06T10:44:22.823Z }",
    "operation": "LOOKUP",
    "user": "root",
    "uid": "0",
    "ipAddress":
    "10.10.105.51",
    "srcPath": "/ycsb1433587356934/ycsbTmp_1433587462796",
    "srcName": "range0",
    "VolumeName": "mapr.cluster.root",
    "volumeId": "68048396",
    "status": "2"
  }
  {
    "timestamp": "{ $date=2015-06-06T10:44:22.824Z }",
    "operation": "CREATE",
    "user": "root",
    "uid": "0",
    "ipAddress":
    "10.10.104.51",
    "parentPath": "/ycsb1433587356934/ycsbTmp_1433587462796",
    "childPath": "/ycsb1433587356934/ycsbTmp_1433587462796/range0",
    "childName": "range0",
    "VolumeName": "mapr.cluster.root",
    "volumeId": "68048396",
    "status": "0"
  }
  {
    "timestamp": "{ $date=2015-06-06T10:44:22.838Z }",
    "operation": "WRITE",
    "user": "root",
    "uid": "0",
    "ipAddress":
    "10.10.105.51",
    "srcPath": "/ycsb1433587356934/ycsbTmp_1433587462796/range0",
    "VolumeName": "mapr.cluster.root",
    "volumeId": "68048396",
    "status": "0"
  }
  {
    "timestamp": "{ $date=2015-06-06T10:44:48.628Z }",
    "operation": "READ",
    "user": "root",
    "uid": "0",
    "ipAddress":
    "10.10.105.51",
    "srcPath": "/ycsb1433587356934/ycsbTmp_1433587462796/range6",
    "VolumeName": "mapr.cluster.root",
    "volumeId": "68048396",
    "status": "0"
  }
}
```

Example Log Entries for Audited Operations on HPE Data Fabric Database Binary and JSON Tables

When auditing of table operations is enabled at the cluster level, volume level, and file system level, each operation on a table is logged on the node where the operation was executed, which could differ from the node where the operation was initiated.

Typical log entries provide a timestamp of the operation, the type of operation, the UID of the user who ran the command, the IP address from which the user ran the command, identifiers of the affected resources, and the status of the operation. Fields such as “ColumnFamily” and “Column” for some operations are also included when applicable. Row keys are not included. Status codes come from the Linux `errno.h` file. For a list of these codes, see [Status Codes That Can Appear in Audit Logs](#).

NOTE: Due to the way that the creation of tables is processed internally, sometimes the creation of tables is logged in `FSAudit.log.json`, rather than in `DBAudit.log.json`.

NOTE: Audit logs do not display the indices of array elements when there are put or update operations on arrays that are in documents within JSON tables.

Below are some typical log entries:

```
{
  "timestamp": {
    "$date": "2015-06-06T11:31:02.621Z"
  },
  "operation": "DB_GET",
  "uid": 0,
  "ipAddress": "10.10.105.51",
  "volumeId": 48210891,
  "tableFid": "2751.77.131402",
  "status": 0
}
{
  "timestamp": {
    "$date": "2015-06-06T11:31:02.623Z"
  },
  "operation": "DB_SCAN",
  "uid": 0,
  "ipAddress": "10.10.104.51",
  "volumeId": 48210891,
  "tableFid": "2751.77.131402",
  "status": 0
}
{
  "timestamp": {
    "$date": "2015-06-06T11:31:02.624Z"
  },
  "operation": "DB_PUT",
  "uid": 0,
  "ipAddress": "10.10.104.51",
  "volumeId": 48210891,
  "columnFamily": "cf0",
  "columnQualifier": "c0",
  "tableFid": "2751.77.131402",
  "status": 0
}
```

To convert the user IDs to usernames, file identifiers to pathnames, and volume IDs to volume names, run the [expandaudit](#) utility. For example, here are the same audit records after they were processed by this utility:

```
{
  "timestamp": {
    "$date": "2015-06-06T11:31:02.621Z"
  },
  "operation": "DB_GET",
  "uid": 0,
  "ipAddress": "10.10.105.51",
  "VolumeName": "mapr.cluster.root",
  "volumeId": 48210891,
  "tablePath": "/ycsb1433588330006/ycsbTable0",
  "status": 0
}
{
  "timestamp": {
    "$date": "2015-06-06T11:03:16.721Z"
  },
  "operation": "DB_SCAN",
  "user": "root",
  "uid": 0,
  "ipAddress": "10.10.105.51",
  "VolumeName": "mapr.cluster.root",
  "volumeId": 48210891,
  "tablePath": "/ycsb1433588330006/ycsbTable0",
  "status": "0"
}
{
  "timestamp": {
    "$date": "2015-06-06T11:31:02.624Z"
  },
  "operation": "DB_PUT",
  "uid": 0,
  "ipAddress": "10.10.104.51",
  "VolumeName": "mapr.cluster.root",
  "volumeId": 48210891,
  "columnFamily": "cf0",
  "columnQualifier": "c0",
  "tablePath": "/ycsb1433588330006/ycsbTable0",
  "status": 0
}
```

Managing Audit Logs for File System and Table Operations

There are three parameters that you can use to manage audit logs for file system and table operations:

- `-maxSize`
- `-retention`
- `-coalesce`

You can set the first two parameters with the `maprcli audit data` command. You can set the third parameter with the `maprcli volume audit` command.

Effects of the `-maxSize` parameter

When you enable auditing with the `audit data` on page 2311 `maprcli audit data` command, you can use the `-maxSize` parameter to specify the size at which an alarm is raised concerning the size of the audit volume. The alarm is displayed on the dashboard in the Control System and in the output of the `alarm list` on page 2298 `maprcli alarm list` command. This alarm simply means that the threshold size has been reached. Audited operations are still logged to the audit volume in question.

There are three actions that you can take:

- If you decide that you want to be notified when the audit volume reaches a smaller or larger size, you can change the threshold by running the `maprcli audit data` command and changing the value of the `-maxSize` parameter.
- If you want to try preventing audit log files from growing as quickly as they are, you can change the number of identical operations that are logged within a number of minutes. Run the `maprcli audit data` command and increase the value of the `-coalesce` parameter. This parameter is described subsequently.
- If you are concerned about longer-term space requirements for storing audit log files, you can change the number of days to keep old log files before they are deleted. Run the `maprcli audit data` command and decrease the value of the `-retention` parameter. This parameter is also described below.

Effects of the `-retention` parameter

When you enable auditing with the `maprcli audit data` command, you can use the `-retention` parameter to specify how many days to keep old log files.

Audit logs are rotated every night at midnight UTC time. The saved audit logs are kept until the retention period expires.

For example, suppose the retention period is 30 days. The node 192.168.10.15 in the volume `/myVolume` contains 30 days of saved log files for file-system operations and the current date is March 30, 2016. The directory `/var/mapr/local/102.168.10.15/audit/` contains these log files:

`FSAudit.log.json-30-03-2016-001`

`FSAudit.log.json-29-03-2016-001`

`FSAudit.log.json-28-03-2016-001`

...

`FSAudit.log.json-01-03-2016-001`

NOTE: If MFS is restarted on the same day, audit logs gets rotated, and new files with convention -002, -003, and so on are created with each restart.

If there is no more disk space for new entries in audit logs, audit logging stops.

If the size of the audit log volume exceeds its quota, an alarm is raised, though logging continues. The alarm is `VOLUME_ALARM_ADVISORY_QUOTA_EXCEEDED`. You can view alarms in [the Control System](#) or by running the command `maprcli alarm list`. The default quota is 32 GB.

Effects of the `-coalesce` parameter

The `coalesce` on page 8499 parameter represents the interval of time during which READ, WRITE, or GETATTR operations on one file from one client IP address and UID/GID are logged only once for a particular operation, if auditing is enabled.

For example, suppose that a client application reads a single file three times in 6 minutes, so that there is one read at 0 minutes, another at 3 minutes, and a final read at 6 minutes. If the coalesce interval is at least 6 minutes, then only the first read operation is logged. However, if the interval is between 4 minutes, then only the first and third read operations are logged. If the interval is 2 minutes, all three read operations are logged.

Now however, if the client was also writing to the file, irrespective of the coalesce interval for the read operation in the example stated previously, the write operation is logged, as it is a different operation from reading.

The default value is 60 minutes. Setting this field to a larger number helps prevent audit logs from growing quickly.

Status Codes That Can Appear in Audit Logs

In the status field in entries in audit logs, numeric codes other than 0 for success can appear. For the list of possible codes, their keyword equivalents, and descriptions, refer to the standard Linux `errno-base.h` and `errno.h` files. The `authaudit.log.json` file contains HTTP status codes. See [HTTP Status Codes](#) for more information.

Viewing Application Logs

You can use logs to view the status and analyze the execution of applications in a cluster.

To view the status or to access logs for running applications, you can use the user interface associated with the YARN framework.

- For MapReduce version 2 or non-MapReduce applications, access the ResourceManager user interface from the Control System to view the status and logs for a particular application.

For completed applications, the distributed nature of YARN frameworks can make analyzing the execution of applications difficult because tasks and containers are scattered throughout the cluster. Without centralized or aggregated logging, you must manually access all the log files for a completed application by merging the log details for a particular application across multiple nodes in the cluster. With centralized or aggregated logging, you can access all the logs for a completed application in a centralized location. However, the steps to access logs for completed applications differ based on the configured logging option.

Logging Options

In a HPE Data Fabric cluster, the logging option that you configure defines how the logs are stored and accessed:

- **Centralized logging.** The logs are written to local volumes on the file system.
- **YARN log aggregation.** The logs are written to the local file system, and then the container logs from each node are aggregated and stored on the file system.
- **Local logging.** The log files for each job or application are written to the local file system. This method is the default behavior for MapReduce version 2 (MRv2) applications and non-MapReduce applications.
 - For MRv2 or other applications that run on YARN, the logs are written to the following directory on the local file system: `/opt/mapr/hadoop/hadoop-2.x.x/logs/user logs/`

The logging options that you can choose from are determined by the type of jobs or applications that you run:

Type of Job or Application	Available Logging Options
MRv2	<ul style="list-style-type: none"> Centralized logging YARN log aggregation Local logging (default)
YARN applications (non-MapReduce)	<ul style="list-style-type: none"> YARN log aggregation Local logging (default)

If you enable centralized logging for MRv2, the MapReduce applications uses centralized logging, while the other YARN applications in the cluster use local logging.

NOTE: Select a logging option that stores the logs on the file system for the following reasons:

- Prevent job or application failures due to a lack of space on the local file system for logs.
- Prevent the loss or inaccessibility of logs due to node failure. Logs stored in a local volume are two-way replicated.

YARN Log Aggregation

The YARN Log Aggregation option aggregates and moves log files for completed applications from the local file system to the HPE Data Fabric . This allows users to view the entire set of logs for a particular application using the HistoryServer UI or by running the `yarn logs` command.

By default, YARN container logs are not aggregated on the Data Fabric . Instead, the logs are retained for 3 hours on the local file system before they are deleted. To enable YARN log aggregation or to edit the configuration of YARN log aggregation, you must edit the `yarn-site.xml` file in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/`

Enabling YARN Log Aggregation

To enable YARN log aggregation, add or edit the following properties in `yarn-site.xml`:

- Set the value of the `yarn.log-aggregation-enable` to `true`.
- Configure the `yarn.log.server.url` property to contain the URL of the YARN HistoryServer, which should look like the following:

secure cluster	<code>https://<historyserver-host>:19890/jobhistory/logs</code>
----------------	---

- Optional: Set the `yarn.nodemanager.remote-app-log-dir` value to a location in the HPE Data Fabric file system. By default, the location is `maprfs:///tmp/logs`.
- Optional: Set the `yarn.nodemanager.remote-app-log-dir-suffix` value to the name of the folder that should contain the logs for each user. By default, the folder name is `logs`.

Aggregated logs are owned by the user who runs the job. For example, if user **admin** runs a job, the logs are stored to `maprfs:///tmp/logs/admin`. If user **analyst** runs a job, the logs are stored to `maprfs:///tmp/logs/analyst`. If these two users do not share the same UNIX group, they will be unable to see each other's logs.

NOTE: If centralized logging and YARN log aggregation are enabled, the logs for MapReduce version 2 applications are managed by Centralized Logging while the logs for non-MapReduce applications are managed by YARN log aggregation.

Enabling YARN Local-Node Log Aggregation

The steps in this procedure configure log aggregation for NodeManager processes, enabling you to store the logs on nodes (node-local volumes) where the YARN containers are launched.

To enable YARN local-node log aggregation, add or edit the following properties in the `yarn-site.xml` file:

1. Set the `yarn.node-local-log-aggregation.enable` value to `true`.

NOTE: The default setting for YARN Log Aggregation (`yarn.log-aggregation-enable`) should be removed or set to `false` in the `yarn-site.xml` file.

2. Optional: Set the `yarn.node-local-log-aggregation.metadata-path` value to a location in the system. By default the location is `maprfs:///NM_REMOTE_APP_LOG_DIR/<user>/logsMeta`. `NM_REMOTE_APP_LOG_DIR` should match the `yarn.nodemanager.remote-app-log-dir` property.

NOTE: The location should not be an absolute path (the location begins from `/`). In the file system (`maprfs`), the default setting for `NM_REMOTE_APP_LOG_DIR` is `/tmp/logs`.

3. Optional: Set the `node-local-log-aggregation.metadata-filename` value to the name of the metafile that should contain the information about containers for each node. By default, the file name is `containers.seq`. If you use default paths, the file is stored at `/tmp/logs/${user}/logsMeta/<appId>/<nodeName>/containers.seq`.
4. Restart NodeManager and HistoryServer services.

Aggregated logs are owned by the user who runs the job.

Different users cannot see each other's logs. For example, if the HPE Data Fabric user **admin** runs a job, the logs are stored in `maprfs:///var/mapr/local/<nodeName>/mapred/nodeManager/logs/admin/<appId>`. If a user **analyst** runs a job, the logs are stored in `maprfs:///var/mapr/local/<nodeName>/mapred/nodeManager/logs/analyst/<appId>`.

Viewing Logs for Completed Applications

With YARN log aggregation, you can use yarn commands or the HistoryServer UI to access logs for completed applications.

View Application Logs from the Command Line

About this task

Get the application ID and then view log files for the application.

Get the Application ID

To get the application ID for an application that is in a "running" state, you can run the following command:

```
yarn application -list
```

However, if you run `yarn application -list` after a job completes, the command will not return any information.

To get the application ID for an application in any state (submitted, accepted, or running), run the following command:

```
yarn application -list -appStates ALL
```

The `yarn application -list` command returns information similar to the following, including the application ID:

```
20/10/19 14:57:51 INFO
client.MapRZKBasedRMFailoverProxyProvi
der: Updated RM address to
node1.cluster.com/192.168.33.11:8032
Total number of applications
(application-types: [] and states:
[SUBMITTED, ACCEPTED, RUNNING]):1
Application-Id Application-Name
Application-Type User Queue State
Final-State Progress Tracking-URL
application_1603118361219_0002
QuasiMonteCarlo MAPREDUCE mapr
root.mapr ACCEPTED UNDEFINED 0% N/A
```

View Application Logs

Run the following command to view log files for an application:

```
yarn logs -applicationId
<application-ID>

//Example: yarn logs -applicationId
application_1603118361219_0002
```

Using UI to View Logs for Completed Applications

Explains how to view HistoryServer logs using the graphical interface.

About this task

You can view the logs for completed applications through the Control System and by directly accessing the HistoryServer UI.

Using the Control System to View the HistoryServer Logs for Completed Applications

Procedure

1. Log on to the Control System and click **Services** to display the list of services.

NOTE: The **Services** menu is not available on the Kubernetes version of the Control System.

2. Click the **History Server** link in the list of services to display the **JobHistory** page in a new tab.
3. Click the job ID link for the job you want to view the logs for.
4. Click the logs link in the **Logs** column of the **Application Master** section.

Using the HistoryServer UI to View Logs for Completed Applications

Procedure

1. Open a browser and go to the following URL to open the JobHistory page:

Non-secure cluster

```
http://<IP address of HistoryServer
node>:19888
```

Secure cluster

```
https://<IP address of
HistoryServer node>:19890
```

2. Click the job ID link for the job for which you want to view the logs.
3. Click the logs link in the **Logs** column of the **Application Master** section.

Editing the Retention Settings of Aggregated Logs

About this task

By default, aggregate logs are stored on the HPE Data Fabric file system for 30 days. The retention time for aggregated logs also applies to centralized logs.

To edit the retention settings, add or edit the following properties in the *yarn-site.xml* file:

Procedure

1. Set the value of `yarn.log-aggregation.retain-seconds` to the duration that the logs are maintained. If you set a negative value for `yarn.log-aggregation.retain-seconds`, logs are not deleted.

NOTE: The duration specified by `yarn.log-aggregation.retain-seconds` starts from the time that the application starts running. Therefore, if you configure the duration, be sure to consider how long you want the log to remain in addition to the amount of time that the application will take to run. For example, if you expect most applications to take 20 seconds to run, do not set the value of this property to 20 seconds because the log might be deleted as soon as the applications completes.

2. Optionally, set the `yarn.log-aggregation.retain-check-interval-seconds` to specify how often the log retention check should be run. By default, it is one-tenth of the log retention time.

Results

For more details about the properties that impact the YARN container logs and the aggregation option, see [yarn-site.xml](#).

Centralized Logging

Describes the centralized logging feature of HPE Data Fabric.

Data Fabric's Centralized Logging feature provides a job-centric or application-centric view of all log files generated by a MapReduce program. With centralized logging, the log files are written to local volumes in the Data Fabric filesystem. You can run the `maprc li job link logs` command for running or completed jobs to create a centralized log directory populated with symbolic links to all log files pertaining to the specified jobs or to the application.

Managing Centralized Logs for MapReduce Version 2 Applications

To manage centralized logs for MapReduce Version 2 applications, enable centralized logging, configure log retention, and view application logs.

Enabling Centralized Logging for MapReduce Version 2

Describes how to enable central logging for MapReduce version 2 applications.

About this task

As of MapR version 4.0.2, you can use centralized logging for MapReduce version 2 applications. However, this feature is disabled by default. In MapR version 4.0.1, centralized logging is not supported for MapReduce version 2 applications.

Procedure

- Configure the `yarn.use-central-logging-for-mapreduce-only` property in the `yarn-site.xml` file to enable or disable centralized logging.
The `yarn-site.xml` file is located in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop/`.
- To disable centralized logging, remove the property `yarn.use-central-logging-for-mapreduce-only` from the `yarn-site.xml` file, or set the value of `yarn.use-central-logging-for-mapreduce-only` to `false` in the `yarn-site.xml` file.
- To enable centralized logging, set the value of `yarn.use-central-logging-for-mapreduce-only` to `true` in the `yarn-site.xml` file. If you enable centralized logging while applications are running, restart all ResourceManagers. In a production cluster, restart ResourceManagers one at a time to prevent interruption to the running applications. The applications running during this process may not have centralized logging enabled.

Configuring Log Retention Time for MapReduce Version 2 Applications

Lists the parameter that controls the log retention time for MapReduce applications.

Procedure

- Set the value of `yarn.log-aggregation.retain-seconds` to the number of seconds you want to retain the logs once the application starts in the `yarn-site.xml` file.

The value defaults to 30 days. The value that you set for this property also applies to the retention of aggregated YARN logs.

The `yarn-site.xml` file is in the following directory: `/opt/mapr/hadoop/hadoop-2.x.x/etc/hadoop`.

Viewing Logs for Completed MapReduce Version 2 Applications

With centralized logging, you can use `maprcli` or the HistoryServer user interface to access completed logs.

Using the Command Line to View Logs for Completed Applications

Describes how to view logs from the CLI.

Procedure

1. Use the `maprcli job linklogs` command to create centralized logs for completed applications. For example, you can run the following `maprcli job linklogs` command to create centralized logs for `application_1434605941718_0001`:
`maprcli job linklogs -jobid application_1434605941718_0001 -todir /logsdire`
The centralized log directory contains symbolic links that are organized by hostname and containerID.

2. To determine where the logs are located, run the following command on the directory that contains the symlinks to the log files for a specific container:

```
hadoop mfs -ls <toDir>/<applicationID>/hosts/<hostName>/<containerID>
```

For example, if you specified `logsdDir` as the directory, you might issue a command similar to the following example. The system then displays the location of the log files:

```
hadoop mfs -ls /logsdDir/application_1434605941718_0001/hosts/
qa-node178.qa.lab/container_e02_1434605941718_0001_01_000003

Found 1 items
lrwxrwxrwx U U U 3 root root 138 2015-06-18 05:50 0
/logsdDir/application_1434605941718_0001/hosts/qa-node178.qa.lab/
container_e02_1434605941718_0001_01_000003
->
../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/userlogs/
application_1434605941718_0001/container_e02_1434605941718_0001_01_000003
p 2068.40.262432 qa-node178.qa.lab:5660 qa-node175.qa.lab:5660
```

The link location appears after the arrow.

3. To determine the types of log files that are available for this container and the path to each available log file, run the following command:

```
hadoop fs -ls <link location>
```

For example:

```
hadoop fs -ls ../../../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/
userlogs/application_1434605941718_0001/
container_e02_1434605941718_0001_01_000003

-rw-r----- 2 root root 2337 2015-06-18 05:48
../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/userlogs/
application_1434605941718_0001/
container_e02_1434605941718_0001_01_000003/syslog
```

In this example, the path to the `syslog` is the only one that is displayed in the output. However, the `stdout` or `stderr` may also be available depending on what is generated by the application.

4. Run one of the following options to view the contents of a log file:
 - a) To view the end of the log file, run `hadoop fs -tail <path to log file>`.

```
hadoop fs -tail ../../../../../../var/mapr/local/qa-node178.qa.lab/logs/
yarn/userlogs/application_1434605941718_0001/
container_e02_1434605941718_0001_01_000003/syslog
```

- b) To view the entire log file, run `hadoop fs- cat <path to log file>`.

```
hadoop fs- cat ../../../../../../var/mapr/local/qa-node178.qa.lab/logs/yarn/
userlogs/application_1434605941718_0001/
container_e02_1434605941718_0001_01_000003/syslog
```

Using the HistoryServer UI to View Logs for Completed Applications
Describes how to view logs using the HistoryServer interface.

About this task

You can view the logs in the HistoryServer interface.

View Logs in the HistoryServer Interface Launched Using the Control System

Procedure

1. Log on to the Control System and click **Services** to display the list of services installed on the cluster.
2. Click the HistoryServer link in the list of services to open the **Job History** page in a new tab.
3. Click the Job ID link for the job for which you want to view the logs.
4. Click the logs link in the **Logs** column of the **Application Master** section.

View Logs Using the HistoryServer Interface

Procedure

1. Go the URL similar to the following example, to open the Job History page:

```
<IP address of HistoryServer node>:19888
```

2. Click the Job ID link for the job for which you want to view the logs.
3. Click the logs link in the **Logs** column of the **Application Master** section.

Viewing the Service Log

Explains how to view service logs using Kibana.

About this task

If Kibana is installed on the node, you can view the service log in the Kibana UI from the Control System. To view the log in the Kibana UI from the Control System:

Procedure

1. Log in to the Control System and do one of the following:
 - Click **Services** to display the list of services installed on the cluster.
 - Go to the **Summary** tab in the [service information page](#) for the service.
2. Click  in the **Log Viewer** column to view the log for the associated service in the Kibana UI. See [Kibana User Guide](#) for more information.

Cluster Maintenance Schedule

Lists a sample maintenance schedule for the cluster.

A maintenance schedule shows which tasks a cluster administrator should perform daily, weekly, monthly, and quarterly, along with the initial setup tasks. This sample schedule is offered as a template that you can customize to suit your needs.

Initial Setup	Daily	Weekly	Monthly	Quarterly
Perform hardware checks	Check alarms	Check logs (cluster and job logs)	Clean up logs	Audit storage use
Check Prerequisites	Onboard new users	Check for zombie jobs	Reevaluate node and volume topology	Perform security audit

Initial Setup	Daily	Weekly	Monthly	Quarterly
Verify Installation	Offboard users	Perform simple performance test	Check performance (jobs, I/O)	Upgrade core, Hive, HCatalog
High Availability planning	Check cluster health	Verify snapshots	Verify mirrors	
Set up VIPs for NFS for the HPE Data Fabric	Perform hardware maintenance (disks)	Remove old snapshots	Clean up data	
Benchmark and tuning		Failbacks to restore service layout	file system balancing	
Set up node and volume topologies				
Capacity planning			Upgrade ecosystem components (other than Hive and HCatalog, which are done quarterly)	
Set up user permissions (ACLs, directory permissions, users, home directories)				
Set up quotas				
Set up compression				
Configure cluster queues for MapReduce jobs				
Set up schedules (fair scheduler, capacity scheduler, job placement)				
Set up snapshots and mirrors				
Configure NICs				
Set up monitoring tools				
Set up security				
Create a disaster recovery plan				

Language Support for HPE Data Fabric Database Tables

This section lists the human languages that HPE Data Fabric tables can store, retrieve, and process.

Data Fabric tables can store, retrieve, and process data in the following languages:

A

Abaza Abkhazian Achinese Acoli Adangme Adyghe Afar Afrikaans Aghem Ainu Akan Akkadian Akoose Albanian Aleut Amharic Amo Ancient Egyptian Ancient Greek Angika Arabic Aragonese Aramaic Arapaho Arawak Armenian Aromanian Assamese Assyrian Neo-Aramaic Asturian Asu Atikamekw Atsam Avaric Avestan Awadhi Aymara Azerbaijani

Troubleshooting Cluster Administration

Lists the common errors and their solutions.

The following list identifies how to address several cluster administration issues:

The URL reported by YARN for tracking job details does not load.

This URL uses the output of the `hostname -f` command, which must be the fully qualified domain name (FQDN) for the node. On Ubuntu, make sure that the `/etc/hostname` file is configured with the node's FQDN. On CentOS/Redhat, make sure that the `/etc/sysconfig/network` file is configured with the node's FQDN, then restart the node.

The ResourceManager does not start.

If the ResourceManager does not come up, check the following:

- Check that you supplied the correct ResourceManager hostname or IP address in the `-RM` parameter when running [configure.sh](#) on each node at installation time. If you are not sure, you can re-run [configure.sh](#) to correct the problem.
- Do not specify a ResourceManager port with the hostname or IP address in the `-RM` parameter; there is no `<port>` option.
- Make sure that you specified the same ResourceManager hostname or IP address on all nodes when running [configure.sh](#).
- For more information about what might be causing a problem, check the ResourceManager logs: `/opt/mapr/hadoop/hadoop-<version>/logs`

The NodeManager does not start.

If the NodeManager does not come up, check the following:

- Make sure that the fileserver role is installed on the node by looking in the `/opt/mapr/roles` directory.
- Make sure that the fileserver service is running, using either the [service list](#) command or the Control System.
- For more information about what might be causing a problem, check the NodeManager logs: `/opt/mapr/hadoop/hadoop-2.3.0/logs`

Job history is not available.

If job history is not recorded, check the following:

- Make sure that the HistoryServer role is installed on the desired node by looking in the `/opt/mapr/roles` directory. Note that only one node in the cluster can have the HistoryServer role.

- Make sure the HistoryServer is running on the desired node, using either the [service list](#) command or the Control System.
- Check that you supplied the correct HistoryServer hostname or IP address in the -HS parameter when running [configure.sh](#) on each node at installation time. If you are not sure, you can re-run [configure.sh](#) to correct the problem.

Submitted applications do not show up in the ResourceManager.

If you submit an application and it does not appear in the ResourceManager, check the following:

- Make sure the application is running in YARN and not as a local application (check for *app_local* or *job_local* in the application output).
- Check the class path on which the application was invoked, and make sure that */opt/mapr/hadoop/hadoop-<version>/etc/hadoop* includes the class paths.
- Make sure that you are running the correct version of Hadoop. Example:

```
ls -l /usr/bin/hadooplrwxrwxrwx 1
root root 40
Mar 4 11:38 /usr/bin/
hadoop -> /opt/mapr/hadoop/
hadoop-2.3.0/bin/hadoop
```

The application throws a ClassNotFoundException exception at job submission time.

If you submit an application and it throws the ClassNotFoundException exception, check the following:

- Check that the application jar is correctly packaged with the required class.
- Make sure that you are running the correct version of Hadoop. Example:

```
ls -l /usr/bin/hadooplrwxrwxrwx 1
root root 40
Mar 4 11:38 /usr/bin/
hadoop -> /opt/mapr/hadoop/
hadoop-2.3.0/bin/hadoop
```

I want to move the HistoryServer and ResourceManager to different nodes.

If you have installed the HistoryServer and the ResourceManager on the same node (when you initially ran [configure.sh](#) you did not specify the -HS parameter, or you specified the same IP address or hostname for both the -RM and -HS parameters), you can use [configure.sh](#) to move one or both services to different nodes. Make sure to specify both the -HS parameter and the -RM parameter, because if you only specify the -RM parameter the HistoryServer will move to the ResourceManager node.

Timing issue prevents services from starting on a secure cluster.

If your cluster has security features enabled, you may encounter a timing issue that results in services failing to start during initial configuration with the -F option. (This issue does not arise if you are bringing up a cluster that has already been installed and configured.)

When you run the [configure.sh](#) script with the `-F` option, the ZooKeeper and Warden services start up on the primary node first, then as other nodes are installed, services are automatically started on those nodes. However, because of this timing issue, Warden may fail to communicate with ZooKeeper, and the cluster may fail to come up.

If you encounter this problem, do not use the `-F` option. Instead, stop all ZooKeeper and Warden services on all nodes, then start the ZooKeeper services on all of the ZooKeeper nodes (that is, the nodes where the ZooKeeper packages are installed). Finally, start the Warden services on all nodes.

How to find a node's serverid.

Some `maprccli` commands take an argument `serverid`, which is an unique identifier for each node in a cluster. This id is also sometimes referred to as the *node id*.

To find the `serverid`, use the [maprccli node list](#) command, which lists information about all nodes in a cluster. The `id` field is the value to use for `serverid`.

For example:

```
maprccli node list -columns hostname,id
id                               hostname
ip
4800813424089433352  node-28.lab
10.10.20.28
6881304915421260685  node-29.lab
10.10.20.29
4760082258256890484  node-31.lab
10.10.20.31
8350853798092330580  node-32.lab
10.10.20.32
2618757635770228881  node-33.lab
10.10.20.33
```

You can also get this listing as a JSON object by using the `-json` option. For example:

```
maprccli node list -columns
id,hostname -json
{
  "timestamp":1358537735777,
  "status":"OK",
  "total":5,
  "data":[
    {
      "id":"4800813424089433352",
      "ip":"10.10.20.28",
      "hostname":"node-28.lab"
    },
    {
      "id":"6881304915421260685",
      "ip":"10.10.20.29",
```

```

"hostname": "node-29.lab"
    },
    {
      "id": "4760082258256890484",
      "ip": "10.10.20.31",
      "hostname": "node-31.lab"
    },
    {
      "id": "8350853798092330580",
      "ip": "10.10.20.32",
      "hostname": "node-32.lab"
    },
    {
      "id": "2618757635770228881",
      "ip": "10.10.20.33",
      "hostname": "node-33.lab"
    }
  ]
}

```

Error 'mv Failed to rename maprfs...' when moving files across volumes.

Prior to version 2.1, you cannot move files across volume boundaries in the HPE Data Fabric Platform. You can move files within a volume using the `hadoop fs -mv` command, but attempting to move files to a different volume results in an error of the form "mv: Failed to rename maprfs://<source path> to <destination path>".

As a workaround, you can copy the file(s) from source volume to destination volume, and then remove the source files.

The example below shows the failure occurring. In this example directories /a and /b are mount-points for two distinct volumes.

```

hadoop fs -ls /
  Found 2 items
  drwxrwxrwx   - root root
0 2011-12-02 15:14 /a
  drwxrwxrwx   - root root
0 2011-12-02 15:09 /b

hadoop fs -put testfile /a
hadoop fs -ls /a
  Found 1 items
  -rwxrwxrwx   3 root root
2048000 2011-12-02 15:18 /a/testfile

root@node1:~# hadoop fs -mv /a/
testfile /b
mv: Failed to rename maprfs://
10.10.80.71:7222/a/testfile to /b

```

The following example shows the work-around, moving a file /a/testfile to directory /b, and then removing the source file.

```
hadoop fs -cp /a/testfile /b/testfile
hadoop fs -ls /b
    Found 1 items
    -rwxrwxrwx    3 root root
    2048000 2011-12-02 15:19 /b/testfile

hadoop fs -rmr /a/testfile
    Deleted maprfs://
    10.10.80.71:7222/a/testfile

hadoop fs -ls /a
```

This workaround is only necessary if /a and /b correspond to different volumes.

**'ERROR
com.mapr.baseutils.cldbutils.CLDBRpcCommonUtils' in
cldb.log, caused by mixed-case cluster name in
mapr-clusters.conf.**

HPE Data Fabric cluster names are case sensitive. However, some versions of MapR v1.2.x have a bug in which the cluster names specified in /opt/mapr/conf/mapr-clusters.conf are not treated as case sensitive. If you have a cluster with a mixed-case name, after upgrading from v1.2 to v2.0+, you may experience CLDB errors (in particular for mirror volumes) which generate messages like the following in cldb.log:

```
2012-07-31 04:43:50,716 ERROR
com.mapr.baseutils.cldbutils.CLDBRpcCommonUtils
[VolumeMirrorThread]: Unable to reach
cluster with name: qacluster1.2.9. No
entry found in file /conf/
mapr-clusters.conf for cluster
qacluster1.2.9.
Failing the CLDB RPC with status 133
```

(The path given in this message is relative to /opt/mapr/, which might be misleading.)

As a work-around after upgrading, to continue working with mirror volumes created in v1.2, duplicate any lines with upper-case letters in mapr-clusters.conf, converting all letters to lower case.

Mirror volumes created in v2.0+ do not exhibit this behavior.

Managed Control System does not display on Internet Explorer.

The Managed Control System supports Internet Explorer version 9 and above. In IE9, **Compatibility View** under the **Tools** menu must be turned off, or else the user interface will not display correctly.

Unable to kill a job using the Metrics UI.

The following error displays when the root user tries to kill a job using the Metrics UI: Failed to get Job information for job_x, Error: mapr is not allowed to impersonate root

To resolve this issue, add the following properties to [core-site.xml](#) in directory `/opt/mapr/hadoop/hadoop-0.20.2/etc/`:

```
<property>
<name>hadoop.proxyuser.mapr.groups</name>
<value>*</value>
<description>Allow the superuser mapr to impersonate any member of any group</description>
</property>

<property>
<name>hadoop.proxyuser.mapr.hosts</name>
<value>*</value>
<description>The superuser can connect from any host to impersonate a user</description>
</property>
```

YARN logs are deleted before the application completes.

The duration that YARN container logs are maintained starts from the time that the application starts running.

When YARN container logs are not aggregated, the YARN container logs are retained for 3 hours on each node. To update the duration, edit the value of `yarn.nodemanager.log.retain-seconds` in the [yarn-site.xml](#) file.

When YARN container log aggregation is enabled, by default, the aggregated logs are not deleted. However, this setting can be overridden in [yarn-site.xml](#) file. To update the duration, edit the value of `log-aggregation.retain-seconds` in the [yarn-site.xml](#) file.

You must consider how long you want the log to remain past the amount of time that the application will take to run. For example, if you expect most applications to take 20 seconds to run, do not set the value of this property to 20 seconds because the log may be deleted before the applications completes.

YARN applications fail because /tmp subdirectories have been deleted.

Some RHEL and CentOS platforms include the `tmpwatch` service by default. This service cleans up the `/tmp` directory on a regular basis. However, this operation causes the deletion of directories that are needed for applications to run (for example, `nm-local-dir` for YARN). The running NodeManager process does not re-create these missing directories, causing applications to fail.

Jobs fail when the timeline server is down

The timeline server for the Hive-on-Tez user interface does not support high availability. Jobs fail when the resource manager cannot connect to the timeline server. However, you can change the `yarn.timeline-service.client.best-effort` property to `TRUE` in the [yarn-site.xml](#) file to allow applications to run successfully even when the timeline server is down.

Best Practices for Backing Up HPE Data Fabric Information

Lists the best practices and performance considerations to follow when backing up HPE Data Fabric information.

To back up configuration information and data from your HPE Data Fabric cluster, you must install the appropriate Linux backup client from your backup software provider on your servers in your HPE Data Fabric cluster. Your backup client user must have the proper filesystem, and volume permissions. For details on how to configure HPE Data Fabric volume permissions see [Creating Volume-level ACLs](#) on page 2125 and [Managing Access Controls](#) on page 2123.

Backup Configuration Data

By default, all installation files on the cluster, for each server in the cluster, are stored in a single directory on each server in the HPE Data Fabric cluster. To ensure that you backup all the configuration files, HPE Data Fabric supported applications, as well as log files, back up the `/opt/mapr` directory for all servers in the cluster.

Note that the `/opt/mapr` location includes all log files. Log files can add a significant amount of data to your backup environment, so evaluate if they are needed for your business continuity requirements. To backup just the configuration files for the cluster, backup the `/opt/mapr/conf` directory from all servers in the cluster.

Backup Volume Data

HPE Data Fabric's recommended way to backup and restore data, is to enable and configure snapshots and volume mirroring for your data, to another HPE Data Fabric cluster. This step ensures that your business continuity and disaster recovery needs are met.

See the following links for setting up Snapshots, Mirroring, Table and Streams replications.

- Snapshots: [Managing Snapshots](#) on page 1531
- Mirrors: [Mirror Volumes](#) on page 565
- Data Fabric DB Table Replication: [Managing Table Replication](#) on page 1692
- Data Fabric Streams Replication: [Stream Replication](#) on page 866

If you do not have a secondary cluster to mirror your data, back up your volumes by specifying the following path in your Linux backup agent: `/mapr/cluster_name/` - For example: `/mapr/my.cluster.com/`.

Performance Considerations When Backing Large Data Sets

You could run into bandwidth and performance limitations when you specify only one path to your HPE Data Fabric cluster, where your data in your volumes is stored on only one Linux host agent. The bottleneck can occur due to the size of that data you are backing up (large file sizes), or due to the number of files you have in your directory structure (millions of files in one directory).

To mitigate performance issues, break up the volumes across multiple Linux backup agents, with specific mount paths. For example:

```
HPE Ezmeral Data Fabric Linux Host 1 (hostname1):
    /mapr/my.cluster.com/volume1
    /mapr/my.cluster.com/volume2
    /mapr/my.cluster.com/volume3
```

```
HPE Ezmeral Data Fabric Linux Host 2 (hostname2):
    /mapr/my.cluster.com/volume4
```

```
/mapr/my.cluster.com/volume5
/mapr/my.cluster.com/volume6
```

HPE Ezmeral Data Fabric Linux Host 3 (hostname3):

```
/mapr/my.cluster.com/volume7
/mapr/my.cluster.com/volume8
/mapr/my.cluster.com/volume9
```

Preserve Metadata About the Volumes

To preserve metadata such as permissions and [ACE](#) rules, run a pre-script process as the mapr user, in your backup agent. For example in your pre-script configuration for your host agent for your cluster, you would run:

```
maprcli volume dump create
    -name volume1 -dumpfile volume1_fulldump1 -e statefile1
```

Some backup software may need "stderr" or "stdout" codes to run pre or post processing scripts within their product. In that case, you may need to write a bash script to dump the file to a location of your choice, and ensure that your backup agent is configured to backup that directory. Consult your backup software provider's documentation. For information on creating volume dumps, see [Create and Maintain Volume Dump File](#) on page 2964.

IPv6 Support in Data Fabric

Describes the IPv6 support feature for Data Fabric.

 **IMPORTANT:** HPE Ezmeral Ecosystem Pack (EEP) components do not support IPv6.

Data Fabric can be installed on hosts with IPv6 addresses. In other words, external endpoints for Data Fabric can have IPv6 addresses. Data Fabric can communicate with clients over IPv6 addressing. Inter-cluster traffic and intra-cluster traffic over IPv6 connections is supported with IPv4 compatibility.

Data Fabric deployment over IPv6 addresses is possible when both the hardware hosting Data Fabric and the Data Fabric software are able to detect and support IPv6 addresses.

The underlying hardware that hosts Data Fabric must have a network interface card (NIC) that supports IPv6 addressing.

An application that wishes to communicate with Data Fabric over IPv6 can do so, when Data Fabric is installed on IPv6-compatible hardware and IPv6 support is enabled on Data Fabric.

 **NOTE:** When you have a network interface card (NIC) that supports both IPv4 and IPv6 addressing, each IP address must be identifiable by a distinct hostname. In other words, a single hostname must NOT map to both the IPv4 and IPv6 addresses.

The following table describes the terminology related to IPv6 client/server nodes.

Term	Description
IPv6-aware	The term denotes readiness of the underlying hardware. It indicates that the NIC associated with a node that hosts Data Fabric is IPv6 compatible, and can communicate with other nodes with IPv6 and IPv4 addresses.
IPv6-unaware	The term denotes readiness of the underlying hardware. It indicates that the NIC associated with a node that hosts Data Fabric is incompatible to handle IPv6 traffic, and can handle IPv4 traffic only.
IPv6-enabled	The term denotes that IPv6 is enabled on Data Fabric software. The Data Fabric node on which IPv6 is enabled is able to communicate with IPv6 addresses. The node is able to communicate with IPv4 addresses.

Term	Description
IPv6-only	The term denotes that IPv6 is enabled on Data Fabric software. The Data Fabric node on which IPv6 is enabled is able to communicate exclusively with IPv6 addresses only. Communication with IPv4 addresses is not supported on this node.

The following matrix explains in detail the communication between a client node and a Data Fabric node for various IP address type combinations.

Type of application (Type of client node)	IPv6-unaware server (IPv4 -only server node)	IPv6-unaware server (IPv6-enabled server node)	IPv6-aware server (IPv6-only server node)	IPv6-aware server (IPv6-enabled server node)
IPv6-unaware client (IPv4-only node)	client-server communication takes place over IPv4	client-server communication takes place over IPv4	no communication	client-server communication takes place over IPv4
IPv6-unaware client (IPv6-enabled node)	client-server communication takes place over IPv4	client-server communication takes place over IPv4	no communication	client-server communication takes place over IPv4
IPv6-aware client (IPv6-only node)	no communication	no communication	client-server communication takes place over IPv6	client-server communication takes place over IPv6
IPv6-aware client (IPv6-enabled node)	client-server communication takes place over IPv4	client-server communication takes place over IPv4	client-server communication takes place over IPv6	client-server communication takes place over IPv6

See [Enabling IPv6 for a Fabric](#) on page 1151 to enable network communication over the IPv6 protocol for a cluster/fabric.

Moving Objects Across Fabrics and from AWS S3 to Fabric

Describes how objects are moved or transferred across buckets from one fabric to another or from Amazon S3 to Data Fabric.

The Object Copier Hub (OCH) is a service that facilitates the data movement across buckets between fabrics in a global namespace, and from Amazon S3 to Data Fabric.

The OCH service supports the copy, delete, and remote delete operations across fabrics and between Amazon S3 and Data Fabric.

The OCH service listens to bucket events and consumes notifications from AWS SQS for cloud S3 buckets or Data FabricStreams/Kafka for Data Fabric buckets.

The following sections explain the OCH in detail.

Object Copier Hub

Event-based object copier supporting data transfer and deletion between any S3-compatible sources and destinations.

Key capabilities

Following are the key capabilities of the object copier hub service:

- Consumes notifications from AWS SQS for cloud S3 buckets or MapR Streams/Kafka for Data Fabric buckets.

Supports standard queues to move objects from AWS S3 to Data Fabric.

- Copies objects between Data Fabric buckets that reside on the same fabric or between buckets across fabrics.

- Supports delete operations on destination buckets.
- Large object multipart copy is supported.
- Allows multiple independent copiers to run concurrently. Each copier has its own source and destination bucket mapping, listener, and worker pool.
- Operates over HTTPS with mutual TLS (mTLS). Both server and client authenticate using PKCS12 certificates. All data stored is encrypted with AES-256-GCM
- Uses REST APIs and OCH CLI to carry out the operations related to data movement across buckets

Things to note

- Set `EnableMultipart: true` in the create-copier request to enable large object multipart copy.
- Each copier runs a single event listener consumer and a single copier worker pool. To consume from multiple queues, create a separate copier configuration for each queue.
- Each event queue must be configured with exactly one copier such that there is one consumer per producer. One copier can manage multiple source-destination bucket pairs.
- Once you create a copier, edits to the copier configuration is not possible apart from the source and destination bucket mappings. If you wish any other changes, you must delete the copier and create a new copier.

Installing the mapr-och package

Describes how to install the mapr-och package.

About this task

 **ATTENTION:** The mapr - och package is not supported on RHEL 9 and Ubuntu 22.

To install the mapr - och package on RHEL, run the following command:

```
apt install mapr-och
```

To install the mapr - och package on Ubuntu, run the following command:

```
yum -y install mapr-och
```

After installation , the mapr - och package can be started to run as the the mapr - och service. This service is the backbone of the object copier hub, and is used to create and manage copiers that move data from one fabric to another fabric.

If you wish to use the object copier hub to move objects across fabrics, you must complete the steps mentioned in

[Prerequisites to use Object Copier Hub to move data from Fabric to Fabric](#) on page 3534 before you start the mapr-och service.

To start the mapr-och service, see [Starting the mapr-och service](#) on page 3536.

Prerequisites to use Object Copier Hub to move data from Fabric to Fabric

Lists the prerequisite settings to use the Object Copier Hub service to move data from a bucket in one fabric to a bucket in another fabric.

Overview

The following steps must be performed on the respective fabric node, to be able to use the Object Copier Hub, after installing the `mapr-och` package on the edge node. See [Installing the mapr-och package](#) on page 3534 to install the package.

NOTE: Copy the `clusters.conf` from the Data Fabric cluster to the node where OCH is running.

```
scp /opt/mapr/conf/mapr-clusters.conf root@<och-node-ip>:/opt/mapr/conf/
mapr-clusters.conf
```

1. Copy source cluster `mapr-clusters.conf` to the node on which the `mapr-och` service is installed.
2. Copy source cluster ticket `maprticket_0` to the `/tmp/` folder on the object copier hub node where the OCH is installed. Alternatively, export the ticket as `MAPR_TICKETFILE_LOCATION` variable. This is to enable listening on Data Fabric (Kafka) Streams.

```
export MAPR_TICKETFILE_LOCATION=</path/to/ticketfile>
```

3. [Configure environment and proxy settings](#) for Data Fabric.
4. [Enable streams events](#) for Data Fabric.
5. [Change the consumer ACEs](#) for default Data Fabric streams.

Configure environment and proxy settings

Run the following commands to configure the proxy settings for the `mapr-och` service.

```
vi /etc/systemd/system/mapr-och.service
[Service]
Environment="https_proxy=<enter https proxy host FQDN>:80"
Environment="http_proxy=<enter http proxy host FQDN>:80"
Environment="no_proxy=localhost,127.0.0.1"
```

Reload the systemd manager configuration and restart the `mapr-och` service.

```
systemctl daemon-reload
service mapr-och restart
```

Configure the port and log level settings in the OCH configuration file `opt/mapr/conf/och.conf`

```
//log level settings
och.log.level=info
och.port=8080

//port level settings
etcd.peer.port=2380
etcd.client.port=2379
```

Enable Streams events

To enable Streams events on Data Fabric, run the following commands:

```
maprcli config save -values {"s3.events.disable":"0"} -json

/opt/mapr/bin/mc event add <account alias>/<bucket name>
arn:aws:sqs:us-west-2:444455556666:event-topic --event put
```

```
/opt/mapr/bin/mc event add <account alias>/<bucket name>
arn:aws:sqs:us-west-2:444455556666:event-topic --event delete
```

Change the Consumer ACEs

To change the consumer ACEs for Data Fabric streams, run the following command as the mapr user:

```
maprcli stream edit -path /var/objstore/event-stream -consumeperm
u:root -json
```

NOTE: You can start the mapr-och service after you have performed all the prerequisite steps. See [Starting the mapr-och service](#) on page 3536 for details.

Prerequisites to use Object Copier Hub to move data from AWS S3 to Fabric

Lists the prerequisite settings to use the Object Copier Hub service to move objects from a bucket on AWS S3 to a bucket on another fabric.

Steps to perform on AWS S3

The following steps must be performed on AWS S3 to be able to copy data from AWS S3 source bucket to Data Fabric.

1. Create Amazon SQS standard queue. See <https://docs.aws.amazon.com/AWSSimpleQueueService/latest/SQSDeveloperGuide/creating-sqs-standard-queues.html>
2. Enable notifications on your source bucket. See <https://docs.aws.amazon.com/AmazonS3/latest/userguide/ways-to-add-notification-config-to-bucket.html>
3. Create Role ARN and giving it permissions to consume messages from SQS. See https://docs.aws.amazon.com/IAM/latest/UserGuide/access_policies-cross-account-resource-access.html

Starting the mapr-och service

Describes how to start the mapr-och service.

About this task

When you are working on moving data between buckets from one fabric to another fabric, you must complete the environment and proxy settings.

Once the installation is complete, run the following command to start the mapr-och service:

```
service mapr-och start
```

To check the status and ensure that the mapr-och service has started successfully, run the following command:

```
service mapr-och status
```

Sample JSON to Move Objects from Fabric to Fabric

Sample JSON to use for the OCH CLI copier command to move objects from a bucket on one fabric to a bucket on another fabric.

In case of movement of objects across buckets from one fabric to another fabric, the object copier hub uses HPE Data Fabric Streams for storing events.

Following is a demo JSON file that copies objects from a bucket in one fabric to a bucket in another fabric:

```
cat och-df-df-config.json

{
  "name": "kr2",
  "isSQLListener": false,
  "kafkaConfig": {
    "topics": [
      "/var/objstore/event-stream:event-topic"
    ]
  },
  "sourceClient": {
    "isAWS": false,
    "dfConfig": {
      "accessKey": "<enter the access key here>",
      "secretKey": "<enter the secret key here>",
      "endpoint": "https://<hostname for source bucket>:9000",
      "chainCA": "/tmp/chain-ca-src.pem"
    }
  },
  "destClient": {
    "dfConfig": {
      "accessKey": "<enter access key here>",
      "secretKey": "<enter secret key here>",
      "endpoint": "<host name for destination bucket>:9000",
      "chainCA": "/tmp/chain-ca-dest.pem"
    }
  },
  "bucketMap": [
    {
      "sourceBucket": "bucket2",
      "destBucket": "bucketnew2"
    }
  ]
}
```

Fields in the Data Fabric to Data Fabric copier configuration

REMEMBER:

- Values of `isSQLListener` and `sourceClient.isAWS` must always match at the source and the destination (false for Data Fabric to Data Fabric)
- All four `dfConfig` fields are mandatory for both source and destination
- `chainCA` files must exist on the Object Copier Hub node before starting — copy them from each fabric's CA
- Only events from buckets listed in `bucketMap` are processed; all other bucket events are ignored

The following table describes the fields in the copier configuration JSON file.

Field	Mandatory?	Description
name	Yes	Unique identifier for the copier instance. Used for logging, etcd storage keys, and API operations. Must be a non-empty string (e.g., "copier1").

isSQLListener	Yes	This flag toggles between AWS SQS Queue config and Kafka Queue config. Set to false for Data Fabric-to-Data Fabric (Kafka/Data Fabric Streams).  NOTE: <code>sourceClient.isAWS</code> at both source and destination must be set to true for data movement from AWS S3 to Data Fabric. <code>sourceClient.isAWS</code> at both source and destination must be set to false (Data Fabric to Data Fabric).
maxWorkers	No	Number of parallel copy worker goroutines. Each worker processes copy requests from its own queue independently. Default: 10 if omitted or ≤ 0 .
queueSize	No	Buffered channel size per worker Default: 100 if omitted or ≤ 0 .
destinationPrefix	No	String prepended to all destination object keys. Leave empty to preserve original key paths. Example: "backup/" would copy file.txt & backup/file.txt.
enableMultipart	No	Set to true to enable multipart upload for large objects. When enabled, objects exceeding <code>multipartThreshold</code> are split into parts and uploaded in parallel.
multipartThreshold	No	Size in bytes above which objects use multipart upload. Only applies when <code>enableMultipart=true</code> . Default value: 524288000 (500 MB).
multipartSize	No	Size in bytes of each individual part in a multipart upload. Default value: 104857600 (100 MB).
multipartConcurrency	No	Max number of parts uploaded in parallel during multipart upload. Default value: 10.

The following table describes the `kafkaConfig` fields from the JSON configuration file. Use `kafkaConfig` when `isSQLListener=false`

Field	Mandatory?	Description
topics	Yes	Topic name to consume event notifications from. For Streams, use the full stream path format. Hardcoded to default stream <code>"/var/objstore/event-stream:event-topic"</code> .

The following table describes the `sourceClient` fields from the JSON configuration file that represent the source credentials.

Field	Mandatory?	Description
isAWS	Yes	Set to false for Data Fabric source. Must match <code>isSQLListener</code> . When <code>isSQLListener</code> is false, <code>dfConfig</code> fields are required.

The following table describes the `sourceClient.dfConfig` fields from the JSON configuration file. The details are required when `isAWS=false`.

Field	Mandatory?	Description
accessKey	Yes	S3 access key for the source fabric. Obtain from the MOSS/MinIO admin console or <code>maprccli s3keys generate</code> on the source fabric.
secretKey	Yes	S3 secret key paired with the access key above. Generated alongside the access key on the source fabric.

endpoint	Yes	Full URL of the source S3 gateway including protocol and port. Format: https://<hostname-or-ip>:9000. The HTTPS protocol and port 9000 (default MOSS port) are required.
chainCA	Yes	Absolute file path to the PEM-encoded CA certificate chain file. Used to verify the source fabric's TLS certificate. Copy from the source fabric's /opt/mapr/conf/ca/chain-ca.pem to OCH node and provide its path

The following table describes the `destClient.dfConfig` fields from the JSON configuration file that represent the source & destination bucket routing. Destination is always Data Fabric.

Field	Mandatory?	Description
accessKey	Yes	S3 access key for the destination fabric. Obtain from the MOSS/MinIO admin console or <code>maprccli s3keys generate</code> on the destination fabric.
secretKey	Yes	S3 secret key paired with the access key above. Generated alongside the access key on the destination fabric.
endpoint	Yes	Full URL of the destination S3 gateway including protocol and port. Format: https://<hostname-or-ip>:9000. Must be reachable from the OCH node over the network.
chainCA	Yes	Absolute file path to the PEM-encoded CA certificate chain file on the OCH node for the destination fabric. Copy from the source fabric's /opt/mapr/conf/ca/chain-ca.pem to OCH node and provide the .pem file path.

The following table describes the `bucketMap` fields from the JSON configuration file that represent the source & destination bucket routing.

Field	Mandatory?	Description
sourceBucket	Yes	Name of the bucket on the source fabric to watch for events. Only S3 events from buckets listed here are processed; all others are ignored.
destBucket	Yes	Name of the destination bucket where objects will be copied to. This bucket must already exist on the destination fabric before starting the copier. Otherwise copy/delete operation fails.

Sample JSON to Move Objects from AWS S3 to Data Fabric

Sample JSON to use for the OCH CLI copier command to move objects from AWS bucket to Data Fabric bucket.

While moving data from AWS S3 bucket to a Data Fabric bucket, the object copier hub uses standard SQS queues for storing events.

Following is a demo JSON file that copies data from an Amazon bucket to a Data Fabric bucket:

```
cat och-sqs-aws-df-demo-new.json
{
  "name": "copy-traffic-bucket-hub-demo",
  "isSQSListener": true,
  "sqsConfig": {
    "queueUrl": "https://sqs.us-west-1.amazonaws.com/746013851261/s3-events-och",
    "maxMessages": 10,
    "visibilityTimeout": 30,
    "waitTimeSeconds": 20,
    "pollInterval": 5000000000,
    "awsConfig": {
      "awsRegion": "us-west-1",
      "awsAccessKey": "xxxxxxxxxxxxxxxxxxxx",
      "awsSecretKey": "xxxxxxxxxxxxxxxxxxxx",
    }
  }
}
```

```

    "roleArn": "arn:aws:iam::746013851261:role/sqs-consumer-role-j"
  },
  "sourceClient": {
    "isAWS": true,
    "awsConfig": {
      "awsRegion": "us-west-1",
      "awsAccessKey": "xxxxxxxxxxxxxxxxxxxx",
      "awsSecretKey": "xxxxxxxxxxxxxxxxxxxx"
    }
  },
  "destClient": {
    "dfConfig": {
      "accessKey": "xxxxxxxxxxxxxxxxxxxx",
      "secretKey": "xxxxxxxxxxxxxxxxxxxx",
      "endpoint": "https://m2-hux6k-01-n2.mip.storage.hpccorp.net:9000",
      "chainCA": "/tmp/chain-ca-142cluster.pem"
    }
  },
  "bucketMap": [
    {
      "sourceBucket": "traffic-signal-sensors",
      "destBucket": "traffic-governance"
    }
  ]
}

```

Fields in the AWS-to-Data Fabric copier configuration

REMEMBER:

- `isSQLListener` and `sourceClient.isAWS` must be `true` for AWS S3 to
- SQS queue must be configured to receive S3 event notifications from the source bucket (set up via AWS S3 `Properties` `Event notifications`)
- `sqsConfig.awsConfig` credentials are for SQS access; `sourceClient.awsConfig` credentials are for S3 object reads — they can be the same IAM user or separate users with scoped permissions
- `roleArn` is optional but suggested — use it for cross-account access or when assuming a role with narrower permissions
- The `chainCA` file must exist on the OCH node before starting — copy it from the destination cluster's CA certificate store.

The following table describes the fields in the copier configuration JSON file.

Field	Mandatory?	Description
<code>name</code>	Yes	Unique identifier for this copier instance. Used for logging, etcd storage keys, and API operations. Must be a non-empty string (e.g., "copier2").
<code>isSQLListener</code>	Yes	Set to <code>true</code> for AWS-to-DF (SQS listener). Must match <code>sourceClient.isAWS</code> — both must be <code>true</code> for AWS source.
<code>maxWorkers</code>	No	Number of parallel copy worker goroutines. Default: 10 if omitted or ≤ 0 .
<code>queueSize</code>	No	Buffered channel size per worker. Default: 100 if omitted or ≤ 0 .
<code>destinationPrefix</code>	No	String prepended to all destination object keys. Leave empty to preserve original key paths.

enableMultipart	No	Set to true to enable multipart upload for large objects. Objects exceeding multipartThreshold are split and uploaded in parallel.
multipartThreshold	No	Size in bytes above which multipart upload is used. Default: 524288000 (500 MB). Only applies when enableMultipart=true.
multipartSize	No	Size in bytes of each part in multipart upload. Default: 104857600 (100 MB).
multipartConcurrency	No	Max parallel part uploads during multipart. Default: 10.

The following table describes the `sqsConfig` fields from the JSON configuration file. Use `sqsConfig` when `isSQLListener=true`.

Field	Mandatory?	Description
queueUrl	Yes	Full SQS queue URL from the AWS console. Format: <code>https://sqs.<region>.amazonaws.com/<account-id>/<queue-name></code> . This queue must be configured to receive S3 event notifications from your source bucket.
maxMessages	No	Maximum number of messages to receive per SQS poll (1–10). Default: 10.
visibilityTimeout	No	The time in seconds for which an SQS message stays invisible after being received. This prevents other consumers from processing it. Default: 30.
waitTimeSeconds	No	Seconds the SQS <code>ReceiveMessage</code> call waits for messages (long polling). Default: 20. Range: 0–20. Set to 20 for cost-efficient long polling.
pollInterval	No	Duration in nanoseconds between SQS poll cycles. Default: 5000000000 (5 seconds). Controls how frequently the listener checks for new messages.

The following table describes the `sqsConfig.awsConfig` fields from the JSON configuration file that represent the AWS credentials for SQS queue access.

Field	Mandatory?	Description
awsRegion	Yes	AWS region where the SQS queue lives (e.g., "us-west-1"). Must match the region in the queue URL. Obtain from the AWS console under the SQS queue details.
awsAccessKey	Yes	IAM access key ID with <code>sqs:ReceiveMessage</code> , <code>sqs:DeleteMessage</code> , and <code>sqs:GetQueueAttributes</code> permissions on the target queue. Create via AWS IAM <code>Users</code> <code>Security</code> credentials.
awsSecretKey	Yes	IAM secret access key paired with the access key above. Generated once when creating the IAM access key.
roleArn	No	ARN of an IAM role to assume for SQS access (e.g., "arn:aws:iam::746013851261:role/sqs-consumer-role"). Use when cross-account access or scoped permissions are needed. The IAM user above must have <code>sts:AssumeRole</code> permission on this role. Either this role or the above IAM USER must have consumer permissions on SQS queue. Suggested to use role instead of IAM user directly for reading from queue.

The following table describes the `sourceClient` fields from the JSON configuration file that represent the AWS source credentials for reading S3 objects.

Field	Mandatory?	Description
isAWS	Yes	Set to true for AWS S3 source. Must match the value set for <code>isSQLListener</code> . When true, <code>awsConfig</code> fields are required.

The following table describes the `sourceClient.awsConfig` fields from the JSON configuration file that are required when `isAWS=true`

Field	Mandatory?	Description
<code>awsRegion</code>	Yes	AWS region of the source S3 bucket (e.g., "us-west-1"). Must match where your source bucket resides.
<code>awsAccessKey</code>	Yes	IAM access key ID with <code>s3:GetObject</code> and <code>s3:ListBucket</code> permissions on the source bucket. Can be the same IAM user as the SQS credentials or a separate one with S3-scoped permissions.
<code>awsSecretKey</code>	Yes	IAM secret access key paired with the access key above.
<code>roleArn</code>	No	ARN of an IAM role to assume for bucket access (for example, "arn:aws:iam::746013851261:role/sqs-consumer-role"). Use when cross-account access or scoped permissions are needed. The IAM user above must have <code>sts:AssumeRole</code> permission on this role. Either this role or the above IAM USER must have <code>s3:GetObject</code> and <code>s3:ListBucket</code> permissions on the source bucket

The following table describes the `destClient.dfConfig` fields from the JSON configuration file that represent the source & destination bucket routing. Destination is always Data Fabric.

Field	Mandatory?	Description
<code>accessKey</code>	Yes	S3 access key for the destination Data Fabric cluster. Obtain from MOSS/MinIO admin console or <code>maprcli s3keys generate</code> on the destination cluster.
<code>secretKey</code>	Yes	S3 secret key paired with the access key above. Generated alongside the access key on the destination cluster.
<code>endpoint</code>	Yes	Full URL of the destination S3 gateway including protocol and port. Format: <code>https://<hostname-or-ip>:9000</code> . Must be reachable from the OCH node.
<code>chainCA</code>	Yes	Absolute file path to the PEM-encoded CA certificate chain file on the OCH node for the destination cluster. Copy from the source cluster's <code>/opt/mapr/conf/ca/chain-ca.pem</code> to OCH node and provide its path

The following table describes the `bucketMap` fields from the JSON configuration file that represent the source & destination bucket routing.

Field	Mandatory?	Description
<code>sourceBucket</code>	Yes	Name of the AWS S3 bucket to watch for events. Only events from buckets listed here are processed; all others are ignored. Must match the bucket configured to send notifications to your SQS queue.
<code>destBucket</code>	Yes	Name of the destination bucket on the Data Fabric cluster

Object Copier Lifecycle

Describes the object copier lifecycle and the commands associated with the lifecycle.

The following steps comprise the object copier lifecycle.

- Create an object copier using the given configuration
- Start the copier to start the listener. When the copier starts successfully, it listener starts and the copier begins to consume AWS SQS events and copy objects.

- Stop the copier. When the copier stops, the copier stops consuming events. The queue offset is preserved for smooth resumption of service when the copier restarts.
- Delete the copier. When you delete a copier, the copier stops and removes all the configuration related information from Data Fabric. You must create another copier to start using a copier on the node again.

Copier lifecycle methods

The following methods comprise the object copier lifecycle:

- create-copier
- start-copier
- stop-copier
- delete-copier

OCH CLI

CLI commands to manage the Object Copier Hub.

ochcli is a command-line tool for managing OCH copiers. It communicates with the OCH server over HTTPS with mTLS authentication.

CLI Path: /opt/mapr/bin/ochcli

Syntax

Following is the OCH CLI syntax:

```
ochcli --help
Usage: ochcli <command> [options]

Commands:
  create-copier    Create a new copier from a JSON config file
  info-copier      Get info about a copier
  list-copier      List all copiers
  start-copier     Start a copier
  stop-copier      Stop a copier
  delete-copier    Delete a copier
  add-buckets      Add source/destination bucket pairs to a copier
  delete-buckets   Delete bucket pairs from a copier

Common Options:
  --cert-path <path>      Path to client PKCS12 certificate (env:
MAPR_OCH_CLIENT_CERT_PATH)
  --password-path <path>  Path to wallet password file (env:
MAPR_OCH_CLIENT_PASSWORD_PATH)
  --ca-path <path>        Path to CA certificate PEM file (env:
MAPR_OCH_CA_PATH)
  --host <hostname:port>  OCH server hostname:port (env:
MAPR_OCH_HOSTNAME_PORT)
  -json                  Output response in JSON format

Run 'ochcli <command> --help' for command-specific options.
```

Troubleshooting Object Copier Hub (OCH)

Copy operation times out or fails

If `/opt/mapr/logs/och.log` contains a time-out entry for the copy operation using the Object Copier Hub, check the time on both the source and destination nodes (whether AWS or Data Fabric). If the time is not in sync, the source and destination nodes must be time-synced.

Run the following command to set the time on the source and destination nodes to the time of other machine.

```
sudo date -s "$$(ssh user@<other-machine-ip> 'date-Ins')"
```

Note: In case copy is failing with timeout issues, run this command to sync the time on both machines.

TLS handshake issues

During the copy operation if you encounter TLS handshake error, verify the proxy settings in `mapr-och.service` file. Check if these variables have been correctly set.

```
Environment="https_proxy=<enter https proxy host FQDN>:80"
Environment="http_proxy=<enter http proxy host FQDN>:80"
Environment="no_proxy=localhost,127.0.0.1"
```

Sample OCH configuration in JSON format

contains a sample OCH JSON format configuration.

The following is a sample OCH configuration in JSON format.

```
{
  "name": "<copier-name>",
  "isSQSListener": "<true if using SQS listener, false if using Kafka>",
  "enableMultipart": "<optional: true to enable multipart copy for large objects, default: false>",
  "multipartThreshold": "<optional: minimum object size in bytes to trigger multipart copy, default: 524288000 (500MB)>",
  "multipartSize": "<optional: size of each part in bytes during multipart copy, default: 104857600 (100MB)>",
  "multipartConcurrency": "<optional: number of concurrent part uploads, default: 10>",
  "sqsConfig": {
    "queueUrl": "<SQS queue URL, for example, https://sqs.us-east-1.amazonaws.com/123456789/queue-name>",
    "awsConfig": {
      "awsRegion": "<AWS region for SQS, e.g. us-east-1>",
      "awsAccessKey": "<AWS access key ID for SQS access>",
      "awsSecretKey": "<AWS secret access key for SQS access>",
      "roleArn": "<optional: IAM role ARN to assume for SQS access>"
    }
  },
  "kafkaConfig": {
    "topics": [
      "/var/objstore/event-stream:event-topic"
    ]
  },
  "sourceClient": {
    "isAWS": "<true if source is AWS S3, false if source is DataFabric>",
    "awsConfig": {
      "awsRegion": "<AWS region for source S3 bucket>",
      "awsAccessKey": "<AWS access key ID for source S3 access>",
      "awsSecretKey": "<AWS secret access key for source S3 access>",
      "roleArn": "<optional: IAM role ARN to assume for source S3 access>"
    }
  },
  "dfConfig": {
```

```

    "accessKey": "<DataFabric access key for source>",
    "secretKey": "<DataFabric secret key for source>",
    "endpoint": "<https://hostname:9000>",
    "chainCA": "<path to CA certificate chain file for source endpoint>"
  },
  "destClient": {
    "dfConfig": {
      "accessKey": "<DataFabric access key for destination>",
      "secretKey": "<DataFabric secret key for destination>",
      "endpoint": "<https://hostname:9000>",
      "chainCA": "<path to CA certificate chain file for destination endpoint>"
    }
  },
  "bucketMap": [
    {
      "sourceBucket": "<source bucket name to listen for events>",
      "destBucket": "<destination bucket name to copy objects to>"
    }
  ]
}

```

Creating a Copier

Describes how to create a copier with OCH CLI and REST.

Create copier by using OCH CLI

You can create a copier from a JSON file that contains the copier configuration.

NOTE: Before you create a copier, you can export the following variables that would be valid for the session during which you have exported the paths:

```

--cert-path <path>      Path to client PKCS12 certificate (env:
MAPR_OCH_CLIENT_CERT_PATH)
--password-path <path>  Path to wallet password file (env:
MAPR_OCH_CLIENT_PASSWORD_PATH)
--ca-path <path>        Path to CA certificate PEM file (env:
MAPR_OCH_CA_PATH)

```

If you export the paths, you do not need to specify the paths while running the OCH CLI commands to manage the copiers.

Run the following command to create a copier by using the OCH CLI. For a sample `och-copier-config.json` to copy object from one fabric to another fabric, see

[Sample JSON to Move Objects from Fabric to Fabric](#) on page 3536

For a sample `och-copier-config.json` to move objects from an AWS S3 bucket to Data Fabric bucket, see [Sample JSON to Move Objects from AWS S3 to Data Fabric](#) on page 3539.

```

ochcli create-copier /path/to/och-copier-config.json --cert-path
<path> --password-path <path> --ca-path <path> --host <hostname:port> -json

```

Following is a sample success output:

```

{
  "code": 201,
  "msg": "copier created successfully"
}

```

Create copier by using REST

Run the following curl command to create a copier with REST API:

```
curl -s -X POST --cert-type P12 \
  --cert /path/to/och-client.p12:$(cat /path/to/och-wallet-password) \
  --cacert /path/to/ca.pem \
  -H "Content-Type: application/json" \
  -d @/path/to/och-copier-config.json \
  https://<OCH_SERVER_HOSTNAME>:8080/create-copier
```

When the copier is created successfully, you should see the following output:

```
< HTTP/1.1 201 Created
```

Starting a Copier

Describes how to start a copier with OCH CLI and REST.

Start copier by using OCH CLI

You can start a copier from a JSON file that contains the copier configuration.

Run the following command to start a copier by reading the och-copier-config.json and by using the OCH CLI.

```
ochcli start-copier my-copier -json --cert-path <path> --password-path
<path> --ca-path <path> --host <hostname:port>
```

Following is a sample success output:

```
{
  "code": 200,
  "msg": "copier my-copier started successfully"
}
```

Start copier by using REST

Run the following curl command to start a copier with REST API:

```
curl -s -X POST --cert-type P12
  --cert /path/to/och-client.p12:$(cat /path/to/och-wallet-password)
  --cacert /path/to/ca.pem
  -H "Content-Type: application/json"
  -d '{"name": "<COPIER_NAME>"}'
  https://<OCH_SERVER_HOSTNAME>:8080/start-copier
```

When the copier starts successfully, you should see the following output:

```
< HTTP/1.1 201 OK
```

Viewing Copier Information

Describes how to view copier information and status with OCH CLI and REST.

View copier information by using OCH CLI

You can view copier information on the CLI .

Run the following command to start a copier by reading the `och-copier-config.json` and by using the OCH CLI.

```
ochcli info-copier my-copier -json --cert-path <path> --password-path
<path> --ca-path <path> --host <hostname:port>
```

Following is a sample success output:

```
{
  "code": 200,
  "msg": {
    "name": "my-copier",
    "status": "Running",
    "activeWorkers": 10,
    "multipartSupport": false,
    "startTime": "2026-04-12T22:40:16.298205739-06:00",
    "lastProcessedTime": "2026-04-12T22:43:51.422149598-06:00",
    "eventStore": "<queueURL>",
    "bucketMap": [
      {
        "sourceBucket": "bucket1",
        "destBucket": "bucket2"
      }
    ],
    "stats": {
      "objectStats": {
        "copied": 20,
        "failed": 0,
        "skipped": 0
      },
      "eventStats": {
        "processed": 20,
        "remaining": 0
      }
    },
    "objectMetrics": {
      "latencyMs": 930,
      "throughputBytesPerSec": 281875.2688172043
    }
  }
}
```

View copier information by using REST

Run the following curl command to view copier information with REST API:

```
curl -s -X POST --cert-type P12 \
  --cert /path/to/och-client.p12:$(cat /path/to/och-wallet-password) \
  --cacert /path/to/ca.pem \
  -H "Content-Type: application/json" \
  -d '{"name":"<COPIER_NAME>"}' \
  https://<OCH_SERVER_HOSTNAMR>:8080/info-copier
```

Following is a sample success output:

```
{
  "name": "my-copier",
  "status": "Running",
  "activeWorkers": 10,
  "multipartSupport": false,
  "startTime": "2026-04-12T22:40:16.298205739-06:00",
```

```

"lastProcessedTime": "2026-04-12T22:43:51.422149598-06:00",
"eventStore": "<queueURL>",
"bucketMap": [
  {
    "sourceBucket": "bucket1",
    "destBucket": "bucket2"
  }
],
"stats": {
  "objectStats": {
    "copied": 20,
    "failed": 0,
    "skipped": 0
  },
  "eventStats": {
    "processed": 20,
    "remaining": 0
  }
},
"objectMetrics": {
  "latencyMs": 930,
  "throughputBytesPerSec": 281875.2688172043
}
}

```

Listing copiers

Describes how to list the currently running copiers by using the OCH CLI and REST.

List copiers by using OCH CLI

You can list the currently running copiers by using the OCH CLI.

Run the following command to start a copier by reading the `och-copier-config.json` and by using the OCH CLI.

```

ochcli list-copier -json --cert-path <path> --password-path
<path> --ca-path <path> --host <hostname:port>

```

Following is a sample success output:

```

{
  "code": 200,
  "msg": {
    "CopyHub": {
      "port": 8080,
      "logLevel": "info",
      "etcdClientPort": 2379,
      "etcdPeerPort": 2380
    },
    "copiers": [
      {
        "name": "copier1",
        "status": "Running",
        "activeWorkers": 10,
        "multipartSupport": false,
        "startTime": "2026-04-09T12:34:29.530137804Z",
        "lastProcessedTime": "2026-04-09T14:06:52.993098464Z",
        "eventStore": "/var/objstore/event-stream:event-topic",
        "bucketMap": [
          {
            "sourceBucket": "bucket1",
            "destBucket": "bucket2"
          }
        ]
      }
    ]
  }
}

```

```

    },
    {
      "sourceBucket": "bucket3",
      "destBucket": "bucket4"
    }
  ],
  "stats": {
    "objectStats": {
      "copied": 60,
      "failed": 0,
      "skipped": 0
    },
    "eventStats": {
      "processed": 60,
      "remaining": 0
    }
  },
  "objectMetrics": {
    "latency (ms)": 283,
    "throughput (bytes copied/sec)": 180668.6858587938
  }
},
{
  "name": "copier2",
  "status": "Running",
  "activeWorkers": 10,
  "multipartSupport": false,
  "startTime": "2026-04-09T12:35:00.034257023Z",
  "lastProcessedTime": "2026-04-09T14:06:50.548037012Z",
  "eventStore": "<QueueURL>",
  "bucketMap": [

      "processed": 60,
      "remaining": 0
    }
  },
  "objectMetrics": {
    "latency (ms)": 513,
    "throughput (bytes copied/sec)": 199370.47733393905
  }
}
]
}
}
}

```

List copier by using REST

Run the following curl command to view copier information with REST API:

```

curl -s -X POST --cert-type P12 \
  --cert /path/to/och-client.p12:$(cat /path/to/och-wallet-password) \
  --cacert /path/to/ca.pem \

```

```
-H "Content-Type: application/json" \
https://<OCH_SERVER_HOSTNAME>:8080/list-copier
```

Following is a sample success output:

```
{
  "CopyHub": {
    "port": 8080,
    "logLevel": "info",
    "etcdClientPort": 2379,
    "etcdPeerPort": 2380
  },
  "copiers": [
    {
      "name": "copier1",
      "status": "Running",
      "activeWorkers": 10,

    "objectMetrics": {
      "latency (ms)": 513,
      "throughput (bytes copied/sec)": 199370.47733393905
    }
  }
]
}

```

Deleting copiers

Describes how to delete copiers by using the OCH CLI and REST.

Delete copiers by using OCH CLI

You can delete a copier by using the OCH CLI.

Run the following command to delete a copier by reading the `och-copier-config.json` and by using the OCH CLI.

```

ochcli delete-copier my-copier -json --cert-path <path> --password-path
<path> --ca-path <path> --host <hostname:port>

```

Following is a sample success output:

```

{
  "code": 200,
  "msg": "copier my-copier deleted successfully"
}

```

Delete copier by using REST

Run the following curl command to delete a copier with REST API:

```

curl -s -X POST --cert-type P12 \
  --cert /path/to/och-client.p12:$(cat /path/to/och-wallet-password) \
  --cacert /path/to/ca.pem \
  -H "Content-Type: application/json" \
  -d '{"name": "<COPIER_NAME>"}' \
  https://<OCH_SERVER_HOSTNAME>:8080/delete-copier

```

Following is a sample success output:

```

< HTTP/1.1 200 OK

```

Stopping Copier

Describes how to stop a copier by using the OCH CLI and REST.

Stop copier by using OCH CLI

You can stop a copier from a JSON file that contains the copier configuration.

Run the following command to stop a copier by reading the `och-copier-config.json` and by using the OCH CLI.

```
ochcli info-copier my-copier -json --cert-path <path> --password-path
<path> --ca-path <path> --host <hostname:port>
```

Following is a sample success output:

```
{
  "code": 200,
  "msg": {
    "name": "my-copier",
    "status": "Running",
    "activeWorkers": 10,
    "multipartSupport": false,
    "startTime": "2026-04-12T22:40:16.298205739-06:00",
    "lastProcessedTime": "2026-04-12T22:43:51.422149598-06:00",
    "eventStore": "<queueURL>",
    "bucketMap": [
      {
        "sourceBucket": "bucket1",
        "destBucket": "bucket2"
      }
    ],
    "stats": {
      "objectStats": {
        "copied": 20,
        "failed": 0,
        "skipped": 0
      },
      "eventStats": {
        "processed": 20,
        "remaining": 0
      }
    },
    "objectMetrics": {
      "latencyMs": 930,
      "throughputBytesPerSec": 281875.2688172043
    }
  }
}
```

Stop copier by using REST

Run the following curl command to stop a copier by using a REST API call:

```
curl -s -X POST --cert-type P12 \
  --cert /path/to/och-client.p12:$(cat /path/to/och-wallet-password) \
  --cacert /path/to/ca.pem \
  -H "Content-Type: application/json" \
  -d '{"name":"<COPIER_NAME>"}' \
  https://<OCH_SERVER_HOSTNAMR>:8080/info-copier
```

Following is a sample success output:

```
{
  "name": "my-copier",
  "status": "Running",
  "activeWorkers": 10,
  "multipartSupport": false,
  "startTime": "2026-04-12T22:40:16.298205739-06:00",
```

```

"lastProcessedTime": "2026-04-12T22:43:51.422149598-06:00",
"eventStore": "<queueURL>",
"bucketMap": [
  {
    "sourceBucket": "bucket1",
    "destBucket": "bucket2"
  }
],
"stats": {
  "objectStats": {
    "copied": 20,
    "failed": 0,
    "skipped": 0
  },
  "eventStats": {
    "processed": 20,
    "remaining": 0
  }
},
"objectMetrics": {
  "latencyMs": 930,
  "throughputBytesPerSec": 281875.2688172043
}
}

```

Adding Source and Destination Buckets to Copier

Describes how to add source and destination buckets to copier by using the OCH CLI and REST.

Add source and destination buckets to copier by using OCH CLI

You must add source and destination buckets a copier for the OCH to know the source and destination for the data movement.

Run the following command to add source and destination buckets to a copier by using the OCH CLI.

```

ochcli add-buckets my-copier
src-bucket1:dst-bucket1,src-bucket2:dst-bucket2 -json --cert-path
<path> --password-path <path> --ca-path <path> --host <hostname:port>

```

Following is a sample success output:

```

{
  "code": 200,
  "msg": "buckets added successfully"
}

```

Add source and destination buckets to copier by using REST

Run the following curl command to add source and destination buckets a copier by using a REST API call:

```

curl -s -X POST --cert-type P12 \
  --cert /path/to/och-client.p12:$(cat /path/to/och-wallet-password) \
  --cacert /path/to/ca.pem \
  -H "Content-Type: application/json" \
  -d '{"name":"<COPIER_NAME>","bucketMap":
[{"sourceBucket":"src-bucket","destBucket":"dst-bucket"}]}' \
  https://<OCH_SERVER_HOSTNAME>:8080/add-buckets

```

Following is a sample success output:

```
< HTTP/1.1 200 OK
```

Removing Source and Destination Buckets for Copier

Describes how to remove source and destination buckets to copier by using the OCH CLI and REST.

Remove source and destination buckets to copier by using OCH CLI

You can remove source and destination buckets a copier for the OCH to know the source and destination for the data movement.

Run the following command to remove source and destination buckets for a copier by using the OCH CLI.

```
ochcli delete-buckets my-copier src-bucket1,src-bucket2 -json --cert-path
<path> --password-path <path> --ca-path <path> --host <hostname:port>
```

Following is a sample success output:

```
{
  "code": 200,
  "msg": "buckets deleted successfully"
}
```

Remove source and destination buckets to copier by using REST

Run the following curl command to remove source and destination bucket pairs for a copier by using a REST API call:

```
curl -s -X POST --cert-type P12 \
  --cert /path/to/och-client.p12:$(cat /path/to/och-wallet-password) \
  --cacert /path/to/ca.pem \
  -H "Content-Type: application/json" \
  -d '{"name":"<COPIER_NAME>","bucketMap":
[{"sourceBucket":"src-bucket","destBucket":"dst-bucket"}]}' \
  https://<OCH_SERVER_HOSTNAME>:8080/add-buckets
```

Following is a sample success output:

```
< HTTP/1.1 200 OK
```

8.1.0 Development

This section contains information related to application development for Ezmeral ecosystem components and HPE Data Fabric products, including the file system, Database (Key-Value and JSON), and Event Streams.

Application Development Process

Before you start developing applications on the HPE Data Fabric platform, consider how you will get the data into the platform, the storage format of the data, the type of processing or modeling that is required, and how the data will be accessed.

At a high-level, building an application comes down to the following steps:

1. [Step 1: Select a Data Storage Format](#) on page 3555
2. [Step 2: Write Data to HPE Data Fabric](#) on page 3558
3. [Step 3: Explore Ways to Work With the Data](#) on page 3558
4. [Step 4: Set Up the Development Environment](#) on page 3561
5. [Step 5: Build the Application](#) on page 3569

Step 1: Select a Data Storage Format

Consider the data format options and determine how you want to use to store your data.

Keep in mind that a single application can access data from a variety of data formats. The following data formats are available.

HPE Data Fabric File Store

HPE Data Fabric File Store is a random read-write distributed file system that allows applications to concurrently read and write directly to files. This data store is great for storing and scanning large data sets of historical data, and for sharing files between various services and applications. Any node with access to the file system can access files on it.

Consider the following examples:

- Write large amounts of user click-stream data for a web site in a simple directory structure based on the date, and then process that data using tools like Spark, Drill, Hive or another MapReduce application.
- Store various types of images, audio files, and video files in one shared directory so that web or mobile applications can render the content as required.
- Share configuration files or internationalized resources among various applications by storing these files in a shared directory.
- Simplify the deployment of new applications by adding java libraries (.jar files) to a shared directory and then including the directory in the classpath of one or more applications.
- Store the Docker files and images in a shared location which can be accessed by various servers. This provides a single, shared location from which users can launch containers.

When you store large data sets, use a file format in which the data can be consumed efficiently. For example, Parquet, ORC, sequence files are good for storing and scanning. Parquet is great for storing data on the file system because it stores data in columnar format, which can be partitioned. Parquet also works

well for use cases where you query the data with Drill or process the data with Spark applications. Note that you can use CSV or JSON formats, but they scanning these formats is less efficient.

For more information about the file system, see [File System](#) on page 558.

HPE Data Fabric Database

HPE Data Fabric Database is an enterprise-grade, high performance, NoSQL database management system that supports both binary and JSON tables. Consider using HPE Data Fabric Database tables when you want to query and organize large amounts data. It also integrates with Drill, Apache Spark, Hive and other MapReduce tools to provide applications the ability to scan or query large data sets in an efficient, distributed way.

HPE Data Fabric Database provides the following features:

- **A flexible schema.** Each row or document can have its own set of attributes.
- **Efficient random access.** Applications can quickly access one or more records using a row key, document ID, or a conditional queries.
- **Easy and efficient data mutation.** Applications can insert, update, and delete rows or documents.

HPE Data Fabric Database Binary Tables

HPE Data Fabric Database binary tables consist of rows that are identified by primary keys and row data is identified by key/value pairs. HPE Data Fabric Database tables are similar to HBase tables in that HPE Data Fabric Database does not determine or store the datatype of each value in the table. But, HPE Data Fabric Database tables perform operations more efficiently than HBase table. You might want to use binary tables when you want to create or use an existing HBase application. However, on the Converged Data Platform, JSON tables are usually preferred due to their flexibility.

HPE Data Fabric Database JSON Tables

A HPE Data Fabric Database JSON tables provide a flexible, powerful schema that you can customize based on the data that you want to represent. Each row in a JSON table corresponds to an JSON document with an unique `_id` and each JSON document can have a different set of columns. HPE Data Fabric Database JSON tables determine the datatype of each value based on the type of data written to the document.

The following example lists three JSON documents from a single JSON table. Note that the attributes associated with each document varies.

JSON Document

```
{
  "_id" : "rp-prod132546",
  "name" : "Marvel T2 Athena",
  "brand" : "Pinarello",
  "category" : "bike",
  "type" : "Road Bike",
  "price" : 2949.99,

  "size" : "55cm",
  "wheel_size" : "700c",
  "frameset" : {
    "frame" : "Carbon Torayaca",
    "fork" : "Onda 2V C"
  },
  "groupset" : {
    "chainset" : "Camp. Athena",
    "brake" : "Camp."
  },
  "wheelset" : {
    "wheels" : "Camp. Zonda",
    "tyres" : "Vittoria Pro"
  }
}
```

JSON Document

```
{
  "_id" : "rp-prod106702",
  "name" : "Ultegra SPD-SL 6800",
  "brand" : "Shimano",
  "category" : "pedals",
  "type" : "Components",
  "price" : 112.99,

  "features" : [
    "Low profile design increases power transfer",
    "Supplied with floating SP-9 pedals",
    "Weight: 260g (pair)"
  ]
}
```

JSON Document

```
{
  "_id" : "rp-prod113104",
  "name" : "Bianchi Pride Jersey",
  "brand" : "Nalini",
  "category" : "Jersey",
  "type" : "Clothing",
  "price" : 76.99,

  "features" : [
    "100% Polyester",
    "3/4 hidden zip",
    "3 rear pocket"
  ],
  "color" : "black"
}
```

For more information, see [HPE Data Fabric Database](#) on page 702.

HPE Data Fabric Streams

HPE Data Fabric Streams is a publish/subscribe messaging solution that uses the Apache Kafka API. HPE Data Fabric Streams writes events as messages in a topic and topics are part of a stream. Producer applications can publish events to a stream and consumer applications can read all or a subset of the messages in a stream. By default, messages are stored in a topic for 7 days and then automatically purged. However, you can shorten or extend the time-to-live (ttl) for messages in a stream based on your use case.

For more information, see [HPE Data Fabric Streams](#) on page 837.

Step 2: Write Data to HPE Data Fabric

Depending on your use case, move existing data onto the HPE Data Fabric platform or write data directly to the platform.

You can write batch data or streaming data to HPE Data Fabric. Batch data refers to data that is already in a data-store while streaming data refers to the continuous flow of real-time messages that have yet to be written to a data-store. Streaming data is generally processed as it is received while batch data is processed after a set of data is written to the datastore. There are many ways to write batch and streaming data to the platform, the following sections provide a few examples.

Write Batch Data to the Platform

You can use an NFS client, hadoop command, or ecosystem components to write batch data to file system. Basic POSIX file system operations can be used to move data to file system. For example, you can use NFS clients, POSIX clients, or applications that utilize libraries such as java.io to access the file system. Hadoop commands and hdfs APIs can be used to add or update files on the file system. For example, you can use the `hadoop distcp` command to [copy data from HDFS to file system](#). Hadoop Ecosystem components, such as Apache Flume, can also be used to push log files to file system.

You can also write, update, or delete batch data to HPE Data Fabric Database tables. Applications can use the OJAI API to write to JSON tables or the HBase API to write to binary tables.

Write Streaming Data to the Platform

Write streaming event data as messages in HPE Data Fabric Event Data Streams topics using Kafka APIs or a REST client application. [C](#), [Java](#), or [Python](#) applications can produce messages to one or more topics in event streams. Additionally, applications written in any language can use the [REST Proxy](#) to produce messages to one or more topics in an event stream. For example, a financial service application, written in Java, could produce messages about stock market activity to an event stream topic.

Step 3: Explore Ways to Work With the Data

Once the data is in the HPE Data Fabric platform, explore the various features and components available on the platform and determine your path. You may want to access data in its initial format or perform some data modeling or processing prior to accessing the data.

The following sections provide some examples to help you determine which approach will work for your particular use case.

Process Data

When developing applications that ingest data, consider if the data requires some processing before the data can be consumed or stored.

Consider the following scenarios:

- **Process the Data Before Querying the Data**

To efficiently query data, you may want to convert the data into a different format. For example, if you want to use Drill to query event data, you can convert streaming data from topics to a JSON table to enable more efficient querying. To do this, ingest event data using HPE Data Fabric Streams, use the HPE Data Fabric Streams API to read the data from topics and the JSON API to store the data in a JSON table, then use Drill to query the JSON tables.

- **Process Data before Storing the Data**

You may also want to process the data based on business needs to perform some pre-processing before long term storage. For example, you can consume streaming data from a HPE Data Fabric Streams topic with a Spark Streaming application which performs calculations or adds additional data before storing the data in a different data-store such as a HPE Data Fabric Database JSON table.

- **Perform Calculations as the Data is Stored**

You may want to modify a single row in a table and then incrementally aggregate data. For example, you can use HPE Data Fabric Database tables to store large amounts of customer information or product catalog data and then read and write to a subset of that data. Then, modify a single row in a table to incrementally aggregate data. For example, to aggregate the number of clicks on a page, you can have a row key for each date and page. Internally, you can design the table to increment based on timestamp. The following example shows a row of data for the info page on 2017-02-22:

```

2017-01-22-info.html => key
Total : 1230 +1
H00 : 100
M1:1
M2: 5
...
M30 : 10
...
H20 : 50 +1
M1:1
...
M25: 1

```

- **Process Large Sets of Data**

There are also many methods to process files in their initial state. To process large sets of data on the HPE Data Fabric File Store, it is common to use Spark or MapReduce applications. MapReduce applications perform parallel, distributed processing of data in batches and are therefore a great way to process large datasets. Spark applications can be used to iteratively process large sets of data with machine learning algorithms. For an example of using a machine learning algorithm with a Spark application, see [Building a Recommendation Engine with Spark](#).

Access Data

There are many use cases for why you might want to access data and many methods to access the data. Operational applications or E-commerce services may want to access data on the HPE Data Fabric platform to provide customers a view of transactional data. Business users may want to view user profile data or submit queries through a BI tool to visually analyze the data.

The following sections will provide some examples for how to access the data so that you can envision that will work for your use case.

- **Access Data in HPE Data Fabric File Store**

The most common way to access data in the HPE Data Fabric File Store is via a NFS mount point that is remote or local to the cluster. You can use HDFS commands as well but they are generally only used for migrating hadoop applications to the HPE Data Fabric platform. If you require high throughput, security, and scalability, consider installing the [POSIX client](#) as this provides a more efficient way to access data in the HPE Data Fabric File Store. You can also query the data directly using Drill.

- **Access Data in HPE Data Fabric Database**

The methods that you can use to access HPE Data Fabric Database table data differs based on the table type. You can access HPE Data Fabric Database binary table data with the HBase shell and applications that use the HBase API. You can access HPE Data Fabric Database JSON table data with the dbshell, and java applications that use the OJAI API. You can also use Drill or Spark to query HPE Data Fabric Database binary and JSON table data directly.

- **Access Data in HPE Data Fabric Streams**

Data in HPE Data Fabric Streams can be accessed by one or more stream consumers and the number of consumers can change over time depending on business needs.

Similar to the various ways you can write data to topics a stream, data in stream topics can be accessed by applications that utilize the Kafka API or a REST interface. You can also use Spark to query streams for new messages at a given interval and access any new messages that are available.

HPE Data Fabric Streams provides flexibility to add new consumers without making changes to the producer application. For example, you have a HPE Data Fabric Streams producer that writes all twitter feeds to a stream. Today, this stream is accessed by a single consumer application that provides access to twitter feeds with content related to IOT. The next week, there may be a request check for how many tweets originate from a specific account. Providing access to different data in an existing stream can be achieved by creating a new consumer which reads from the same stream.

Step 4: Set Up the Development Environment

Before you start building the application, figure out how your the application will connect to the cluster and what the library dependencies and installation requirements are.

Applications are often run on edge nodes which are nodes that are not part of the cluster. Setting up an edge node so that it can be used to develop and run applications consists of the following steps:

- Selecting a client that you will use to connect to the cluster.
- Installing additional clients required for your use case.
- Determining the application dependencies.

NOTE: The dependencies to build and run applications differ based on your use case and the various types of data or tools that are part of an application.

The following sub-topics include the various methods to connect to the cluster, and minimal requirements to build and run applications.

Connect to the Cluster

Applications are often run on nodes that are not part of the Data Fabric cluster. There are many methods to connect to a Data Fabric cluster; this section briefly describes each option.

Data Fabric Client

The Data Fabric client includes the libraries and utilities required on an edge node to perform the following: connect to the cluster, submit MapReduce applications, submit YARN applications, run `hadoop fs` commands, and run `hadoop mfs` commands. However, to run applications that access data from HPE Data Fabric Database or HPE Data Fabric Streams, you must configure additional dependencies. For more information about the Data Fabric client, see [HPE Data Fabric Client](#) on page 360 and [How Data Fabric Clients Connect to the Cluster](#) on page 1094.

NOTE: Although it is not recommended, you can include the file system JAR file in the application instead of installing the Data Fabric client. However, there are caveats and specific requirements to make this work. For information, see [Using the File System JAR to Connect to the Cluster](#) on page 3562.

Data Fabric POSIX Clients

Data Fabric POSIX clients enable app servers, web servers, and other client nodes and applications to read and write directly and securely to the file system. For more information about the POSIX clients, see [POSIX Clients](#) on page 605 and [POSIX Clients](#) on page 387.

Data Fabric NFS Clients

You can mount the cluster itself via NFS so that your applications can read and write data directly. For more information, see [Managing the HPE Data Fabric NFS Service](#) on page 1810.

Using the File System JAR to Connect to the Cluster

The file system JAR file includes the Data Fabric client libraries required to connect to the cluster. While this is strongly discouraged, application developers can bundle the file system JAR file in Data Fabric file system, HPE Data Fabric Database, and HPE Data Fabric Streams applications instead of installing the Data Fabric client on the edge node (node that runs the application). Applications should not bundle the file system JAR file unless the application meets certain requirements.

IMPORTANT: When bundling the file system JAR file, if there is a binary mismatch between the bundled JAR file and the version that the cluster expects, this can result in failures. In release 5.2.2 and later, the system detects the mismatch and prevents the application from starting. In releases earlier than 5.2.2, nodes running applications may run out of memory or shut down unexpectedly.

Requirements

You can bundle the file system JAR (maprfs-<version>-mapr.jar) with applications that meet all of the following requirements:

- The application communicates directly with the file system, HPE Data Fabric Database, or HPE Data Fabric Streams
- The application does not run as a MapReduce or YARN job/application on the cluster.
- The application does not include file system JARs on the local machine in its classpath.
- The application accesses a cluster that is not secure.

Configuring the Cluster Connection

When you include the file system JAR in an application instead of installing the Data Fabric client on the edge node, you must create and configure a `mapr-clusters.conf` file on node that runs the application.

1. Set a `MAPR_HOME` environment variable to a location such as `/opt/mapr`.
2. Create the `mapr-clusters.conf` file in the `$MAPR_HOME/conf` directory.
3. Configure the `mapr-clusters.conf` file with the cluster name and the list of CLDB nodes.

For example, the `mapr-clusters.conf` on an edge node would contain the following content if it was connecting to a cluster named `my.cluster` with CLDB nodes on `centos765`, `centos234`, and `centos123`:

```
my.cluster secure=false centos765 centos234 centos123
```

For more information about how to configure `mapr-clusters.conf`, see [mapr-clusters.conf](#) on page 3370.

For more information about how the Data Fabric client connects to the cluster, see [How Data Fabric Clients Connect to the Cluster](#) on page 1094.

Using Maven to Include file system JAR as a Dependency

If you use Maven to bundle the file system JAR file with an application and you plan to run the application on a Data Fabric cluster where a patch has been applied, ensure that you specify both a system scope and a local system path to the file.

For example, to bundle the file system JAR file, the `pom.xml` file may include the following:

```
...
<groupId>com.mapr.hadoop</groupId>
  <artifactId>maprfs</artifactId>
  <version>${mapr.core.version}</version>
  <scope>system</scope>
  <systemPath>/opt/mapr/lib/maprfs-5.2.0-mapr.jar</systemPath>
...
```

By default, the Data Fabric Maven repository includes JAR files from <https://repository.mapr.com/maven/>. This default Maven repository includes JAR files associated with the GA packages for each Data Fabric release. Therefore, when a patch has been applied to the cluster, failure to specify a system scope may result in errors due to a binary mismatch between the file system JAR files used by the application and the cluster.

Known Issues

Nodes running applications with a bundled file system JAR file may run out of memory or shut down unexpectedly in the following scenarios:

The version of the file system JAR included in the application differs from the version that is available on the cluster.

This may occur when a patch was applied to some, but not all the nodes in the cluster. It can also occur when Maven is bundling the GA version of the JAR file when the cluster expects a newer, patched version.

Two versions of the JAR are available on the node.

For YARN applications, the NodeManager nodes that run the tasks or containers store local versions of the dependencies included with the application. In this scenario, since both the cluster's file system JAR and the version included in the application are available on the node, it is unknown which JAR will be used when processing the application.

HPE Data Fabric Database JSON Application Requirements

The following tables include the minimal node requirements for building and running HPE Data Fabric Database JSON table applications.

Java Applications

Node Requirements	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	<p>Select one of the following options:</p> <ul style="list-style-type: none"> • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. <p>For more information, see Connect to the Cluster on page 3562.</p>
The OJAI Query Service is installed	<p>To use secondary indexes, you may need to enable this service. See Preparing Clusters for Querying using Secondary Indexes on JSON Tables on page 1719 for more information.</p>
HPE Data Fabric Database libraries are configured as a dependency.	<p>When you build an application, use the Maven Repository to determine the dependencies. The POM file should include the Data Fabric Repository and the OJAI Driver project.</p> <p>When you run the application, provide the dependencies in the application's classpath.</p> <p>For more information, see Compiling and Running Java OJAI Applications on page 3855</p>
Other items to consider.	<p>If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file.</p> <p>For example, to use the HPE Data Fabric Database OJAI Connector for Apache Spark, see Configuring the HPE Data Fabric Database OJAI Connector for Apache Spark on page 5442</p>

HPE Data Fabric Database Binary Application Requirements

The following tables include the minimal node requirements for building and running HPE Data Fabric Database binary table applications.

Java Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	<p>Select one of the following options:</p> <ul style="list-style-type: none"> • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. <p>For more information, see Connect to the Cluster on page 3562.</p>
The HBase client is installed.	<p>Install the HBase client. The HBase client is as part of the EEP installation. For more information, see 8.1.0 Installation on page 77.</p> <p> NOTE: The HBase client is include when you install PACC.</p>
HBase client library files are configured as an application dependency.	<p>When you build the application, use the Maven Repository to determine the dependencies. The POM file should include the Data Fabric Repository and the HBase client dependency.</p> <p>When you run an application, include the hbase classpath script and additional dependencies in the application's classpath.</p> <p>For more information, see Compiling and Running HPE Data Fabric Database Binary Applications on page 3673</p>
Other Items	<p>If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file.</p>

C Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	<p>Select one of the following options:</p> <ul style="list-style-type: none"> • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. <p>For more information, see Connect to the Cluster on page 3562.</p>
The HBase Client is installed.	<p>Install the HBase client. The HBase client is as part of the EEP installation. For more information, see 8.1.0 Installation on page 77.</p> <p> NOTE: The HBase client is include when you install PACC.</p>
The libMapRClient library and libjvm shared libraries are in the application's library search path and the libMapRClient header files are in this directory:/opt/mapr/include/hbase	<p>For more information, see Building and Launching C Applications on page 3667.</p>

HPE Data Fabric Streams Application Requirements

The following tables include the minimal node requirements for building and running HPE Data Fabric Streams consumer and producer applications.

Java Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	<p>Select one of the following options:</p> <ul style="list-style-type: none"> • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. <p>For more information, see Connect to the Cluster on page 3562.</p>
The Streams Java Client is installed.	<p>Install the HPE Data Fabric Streams Java Client. The HPE Data Fabric Streams Java client (mapr - kafka) is available as part of the EEP installation. For more information, see 8.1.0 Installation on page 77.</p> <p> NOTE: The Streams Java Client is included when you install PACC.</p>
Streams Java client and the Data Fabric Streams project library files are configured as an application dependency.	<p>When you build the application, use the Maven Repository to determine the dependencies. The POM file should include the Data Fabric Repository, the HPE Data Fabric Streams Java Client dependency, and the HPE Data Fabric Streams project dependency.</p> <p>When you run an application, include the dependencies in the application's classpath.</p> <p>For more information, see Compiling and Running HPE Data Fabric Streams Java Apps on page 3988</p>
Other Items	<p>If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file.</p>

File System Application Requirements

The following tables include the minimal node requirements for building and running file system applications.

Java Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	<p>Select one of the following options:</p> <ul style="list-style-type: none"> • Install and configure the Data Fabric client. • Install the PACC and run an application container. • Use the file system JAR to connect to the cluster. <p>For more information, see Connect to the Cluster on page 3562.</p>

Node Requirement	Method(s) to Meet Requirement
Include hadoop-common libraries as a dependency.	<p>When you compile the application, use the Maven Repository to determine the dependencies. The POM file should include the Data Fabric Repository and the hadoop-common dependency:</p> <pre> <repositories> <repository> <id>mapr-releases</id> <url>https://repository.mapr.com/maven/</url> <snapshots><enabled>false</enabled></snapshots> <releases><enabled>true</enabled></releases> </repository> </repositories> <dependencies> <dependency> <groupId>org.apache.hadoop</groupId> <artifactId>hadoop-common</artifactId> <version>\${hadoop.version}</version> </dependency> </dependencies> </pre> <p>When you run the application, include the following in the application's classpath: `hadoop classpath`</p> <p>For more information, see Compiling and Running a Java Application on page 3632.</p>

**NOTE:**

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see [Using the File System JAR to Connect to the Cluster](#) on page 3562.

C Applications

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	<p>Select one of the following options:</p> <ul style="list-style-type: none"> • Install and configure the Data Fabric client. • Install the PACC and run an application container. <p>For more information, see Connect to the Cluster on page 3562.</p>

Node Requirement	Method(s) to Meet Requirement
Include the libhdfs libraries and Data Fabric libraries when you compile the application.	<p>The Data Fabric libraries are available in the following location: <code>/opt/mapr/lib</code></p> <p>Link to the libhdfs libraries in the following location: <code>MAPR_HOME/hadoop/hadoop-2.x/</code></p> <p>For more information, see Compiling and Running C Applications on File System Clients on page 3574</p>

YARN Application Requirements

The following tables include the minimal node requirements for building and running YARN applications.

Node Requirement	Method(s) to Meet Requirement
A connection to the Data Fabric cluster.	<p>Select one of the following options:</p> <ul style="list-style-type: none"> • Install and configure the Data Fabric client. • Install the PACC and run an application container. <p>For more information, see Connect to the Cluster on page 3562.</p>
Hadoop libraries are configured as an application dependency.	<p>When you compile the application, use the Maven Repository to determine the dependencies. The POM file should include the Data Fabric Repository and the hadoop-common dependency:</p> <pre><repositories> <repository> <id>mapr-releases</id> <url>https:// repository.mapr.com/maven/</url> <snapshots><enabled>false</enabled></ snapshots> <releases><enabled>true</enabled></ releases> </repository> </repositories> <dependencies> <dependency> <groupId>org.apache.hadoop</groupId> <artifactId>hadoop-common</ artifactId> <version>\${hadoop.version}</version> </dependency> </dependencies></pre> <p>When you run the application, include the following in the application's classpath: <code>`hadoop classpath`</code></p> <p>Note: Based on how you submit the application, the classpath locations and requirements differ. See External Applications and Classpath on page 4573 and Classpath Construction on page 4573.</p>

Node Requirement	Method(s) to Meet Requirement
Other Items	<ul style="list-style-type: none"> If an ecosystem component, such as Spark, runs or integrates with the application, you may need to include additional dependencies in the POM file. Any third-party library that is required by a MapReduce program must be accessible to this node and the data node that processes the job or application. For more information, see Managing Third-Party Libraries on page 4574.

Step 5: Build the Application

Start building an application! This section lists a few of the sample applications available in HPE Data Fabric.

NOTE: When building and running your application, you may want to use a classpath for printing to standard output. The following classpaths are available:

mapr classpath

Prints CLASSPATH to standard output. This classpath could be used to build your application classpath to run HPE Data Fabric applications for YARN and other components.

mapr clientclasspath

Prints CLASSPATH for HPE Data Fabric Database clients to standard output. The clientclasspath could be used to build the classpath to run your HPE Data Fabric Database (binary and JSON) and HPE Data Fabric Streams applications.

HPE Data Fabric Database JSON

[Managing JSON Tables](#) on page 3711

This section describes how to create, list, and delete JSON tables as well as set permissions and manage column families using either the Data Fabric Java API library or the HPE Data Fabric Database Shell commands.

[Creating JSON Documents in Java OJAI](#) on page 3734

This section provides several Java examples of creating a document.

[Examples: Inserting JSON Documents](#) on page 3743

This section shows how to insert a document or data into a document store (HPE Data Fabric Database JSON table) with Java and dbshell.

[Examples: Querying JSON Documents](#) on page 3814

This section provides several examples of querying documents.

[HPE Data Fabric Database JSON MapReduce: Sample App](#) on page 3906

This sample Java application extends the Apache Hadoop MapReduce framework to read records (JSON documents) from a JSON table and inserts new documents into another JSON table. This API library allows you to write your own MapReduce applications to write data from one JSON table to another.

HPE Data Fabric Database Binary

[C API Examples](#) on page 3651

This section provides examples using the HPE Data Fabric Database libMapRClient C API to operate on HPE Data Fabric Database binary tables.

[HPE Data Fabric Database Sample C Application on page 3655](#)

This section provides additional sample C applications that accesses and performs operations on HPE Data Fabric Database binary tables.

HPE Data Fabric Streams Streams

[Sample Java Consumer on page 3931](#)

This sample Java consumer application iterates through the returned records, extracts the value of each message, and prints the value to standard output.

[Sample Java Producer on page 3932](#)

This sample Java producer application publishes messages to a stream topic.

[Developing a HPE Data Fabric Streams C Application on page 4009](#)

These sample C applications publish messages to a stream topic and consumes the messages.

[Developing HPE Data Fabric Streams Python Applications on page 4542](#)

These sample Python applications publish messages to a stream topic and consumes the messages.

file system

[Sample Applications on page 3636](#)

This sample Java application demonstrates how to set, get, modify, and delete ACEs on files using the Java APIs.

[hdfs_write_revised.c on page 3579](#)

This C application demonstrates how to write to files by using the hdfsWrite() and hdfsPwrite() APIs.

[hdfs_read_revised.c on page 3586](#)

This C application demonstrates how to read from files by using the hdfsRead() and hdfsPread() APIs.

[hdfs_connect_as_user.c on page 3593](#)

This C application demonstrates how to create and write to files impersonating another user by using the hdfsConnectAsUser() API.

Github Repo

You can find additional sample code on the [MapR Demos Github repository](#).

File Store and Apps

The following sections provide information about accessing the File Store with C and Java applications.

Copying Data from Apache Hadoop to a Data Fabric Cluster

Describes the procedure to copy data from an Apache Hadoop to a Data Fabric cluster.

You can use the hdfs protocol, webhdfs protocol, or NFS for the HPE Data Fabric to copy data from Apache Hadoop to a Data Fabric cluster.

The following table describes these methods:

Method	Description
hdfs:// protocol	Use the <code>hadoop distcp</code> command with the <code>hdfs://</code> protocol to copy data from an HDFS cluster into a Data Fabric cluster if the HDFS cluster and the Data Fabric cluster use the same RPC protocol version. For all other scenarios, use the <code>webhdfs://</code> protocol or NFS for the HPE Data Fabric gateway to copy data to a Data Fabric cluster.

Method	Description
webhdfs:// protocol	Use the <code>hadoop distcp</code> command with the <code>webhdfs://</code> protocol to copy data from an HDFS cluster into a Data Fabric cluster.
NFS	Mount a Data Fabric cluster to an HDFS cluster using NFS for the HPE Data Fabric mount. Then use the <code>hadoop distcp</code> command to copy data between the two clusters.

Copy Data Using the `hdfs://` Protocol

Describes the procedure to copy data from a HDFS cluster to a HPE Data Fabric cluster using the `hdfs://` protocol.

Before you can copy data from an HDFS cluster to a HPE Data Fabric cluster using the `hdfs://` protocol, you must configure the HPE Data Fabric cluster to access the HDFS cluster. To do this, complete the steps listed in [Configuring a HPE Data Fabric Cluster to Access an HDFS Cluster](#) for the security scenario that best describes your HDFS and HPE Data Fabric clusters, and then complete the steps listed under [Verifying Access to an HDFS Cluster](#).

You also need the following information:

- `<NameNode>` - the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>` - the port for connecting to the NameNode in the HDFS cluster
- `<HDFS path>` - the path to the HDFS directory from which you plan to copy data
- `<Data Fabric File system path>` - the path in the HPE Data Fabric cluster to which you plan to copy HDFS data
- `<file>` - a file in the HDFS path

To copy data from HDFS to HPE Data Fabric file system using the `hdfs://` protocol, complete the following steps:

1. Run the following Hadoop command to determine if the HPE Data Fabric cluster can read the contents of a file in a specified directory on the HDFS cluster:

```
hadoop fs -cat <NameNode>:<NameNode port>/<HDFS path>/<file>
```

Example

```
hadoop fs -cat hdfs://nn1:8020/user/sara/contents.xml
```

2. If the HPE Data Fabric cluster can read the contents of the file, run the `distcp` command to copy the data from the HDFS cluster to the HPE Data Fabric cluster:

```
hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> maprfs:///<Data Fabric File system path>
```

Example

```
hadoop distcp hdfs://nn1:8020/user/sara maprfs:///user/sara
```

Copying Data Using the `webhdfs://` Protocol

Describes how to copy data from a HDFS cluster to a HPE Data Fabric cluster using the `webhdfs://` protocol.

Before you can copy data from an HDFS cluster to a HPE Data Fabric cluster using the `webhdfs://` protocol, you must configure the HPE Data Fabric cluster to access the HDFS cluster. To do this, complete the steps listed in [Configuring a HPE Data Fabric Cluster to Access an HDFS Cluster](#) for the security scenario that best describes your HDFS and HPE Data Fabric clusters, and then complete the steps listed under [Verifying Access to an HDFS Cluster](#).

The HDFS cluster must have WebHDFS enabled. Verify that the following parameter exists in the `hdfs-site.xml` file and that the value is set to `true`.

```
<property>
<name>dfs.webhdfs.enabled</name>
<value>true</value>
</property>
```

You also need the following information:

- `<NameNode>` - the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode HTTP Port>` - the HTTP port on the NameNode in the HDFS cluster
- `<HDFS path>` - the path to the HDFS directory from which you plan to copy data
- `<Data Fabric filesystem path>` - the path in the HPE Data Fabric cluster to which you plan to copy HDFS data

To copy data from the HDFS to the HPE Data Fabric file system using the `webhdfs://` protocol, complete the following step:

Run the following command from a node in the HPE Data Fabric cluster:

```
hadoop distcp webhdfs://<NameNode>:<NameNode HTTP Port>/<HDFS path>
maprfs:///<Data Fabric filesystem path>
```

Example

```
hadoop distcp webhdfs://nn2:50070/user/sara maprfs:///user/sara
```

NOTE: The triple slashes in `maprfs:///...` are required.

Copying Data Using NFS for the HPE Data Fabric

Describes how to copy files from one Data Fabric cluster to another using NFS for the HPE Data Fabric.

If NFS for the HPE Data Fabric is installed on the Data Fabric cluster, you can mount the Data Fabric cluster to the HDFS cluster and then copy files from one cluster to the other using `hadoop distcp`. If you do not have NFS for the HPE Data Fabric installed and a mount point configured, see [Accessing Data with NFS v3](#) on page 1818 and [Managing the HPE Data Fabric NFS Service](#) on page 1810.

To perform a copy using `distcp` via NFS for the HPE Data Fabric, you need the following information:

- `<Data Fabric NFS Server>` - the IP address or hostname of the NFS server in the Data Fabric cluster
- `<maprfs_nfs_mount>` - the NFS export mount point configured on the Data Fabric cluster; default is `/mapr`
- `<hdfs_nfs_mount>` - the NFS for the HPE Data Fabric mount point configured on the HDFS cluster
- `<NameNode>` - the IP address or hostname of the NameNode in the HDFS cluster
- `<NameNode Port>` - the port on the NameNode in the HDFS cluster

- `<HDFS path>` - the path to the HDFS directory from which you plan to copy data
- `<Data Fabric file system path>` - the path in the Data Fabric cluster to which you plan to copy HDFS data

To copy data from HDFS to the Data Fabric file system using NFS for the HPE Data Fabric, complete the following steps:

1. Mount HDFS.

Issue the following command to mount the Data Fabric cluster to the HDFS NFS for the HPE Data Fabric mount point:

```
mount <Data Fabric NFS Server>:/<maprfs_nfs_mount> /<hdfs_nfs_mount>
```

Example

```
mount 10.10.100.175:/mapr /hdfsmount
```

2. Copy data.

- Issue the following command to copy data from the HDFS cluster to the Data Fabric cluster:

```
hadoop distcp hdfs://<NameNode>:<NameNode Port>/<HDFS path> file:///<hdfs_nfs_mount>/<MapR file system path>
```

Example

```
hadoop distcp hdfs://nn1:8020/user/sara/file.txt file:///hdfsmount/user/sara
```

- Issue the following command from the Data Fabric cluster to verify that the file was copied to the Data Fabric cluster:

```
hadoop fs -ls /<MapR file system path>
```

Example

```
hadoop fs -ls /user/sara
```

Accessing the File System with C Applications

HPE Data Fabric provides a modified version of `libhdfs` that supports access to the Data Fabric file system. You can develop applications with C that read files, write to files, change file permissions and file ownership, create and delete files and directories, rename files, and change the access and modification times of files and directories.

`libMapRClient` supports and makes modifications to the `hadoop-<version>` version of `libhdfs`. The API reference notes which APIs are supported by `hadoop-<version>`.

`libMapRClient`'s version of `libhdfs` contains the following changes and additions:

- There are no calls to a JVM, so applications run faster and more efficiently.
- Changes to APIs
 - *hadoop-<version>*: Support for `hdfsBuilder` structures for connections to HDFS is limited. Some of the parameters are ignored.

- *hadoop-<version>*: `hdfsGetDefaultBlockSize()`: If the file system that the client is connected to is an instance of file system, the returned value is 256 MB, regardless of the actual setting.
- *hadoop-<version>*: `hdfsCreateDirectory()`: The parameters for buffer size, replication, and block size are ignored for connections to the Data Fabric file system.
- *hadoop-<version>*: `hdfsGetDefaultBlockSizeAtPath()`: If the file system that the client is connected to is an instance of file system, the returned value is 256 MB, regardless of the actual setting.
- *hadoop-<version>*: `hdfsOpenFile()`: The parameters for buffer size and replication are ignored for connections to the Data Fabric file system.
- APIs that are unique to `libMapRClient` for *hadoop-<version>*
 - `hdfsCreateDirectory2()`
 - `hdfsGetNameContainerSizeBytes()`
 - `hdfsOpenFile2()`
 - `hdfsSetRpcTimeout()`
 - `hdfsSetThreads()`

Installing and Configuring File System C Clients

Install the `mapr-client` package on the nodes on which you plan to build and run client applications. This package installs the `libMapRClient` library. See [Setting Up the Client](#).

NOTE: The `mapr-core` package contains the files that are in the `mapr-client` package. If you have installed the `mapr-core` package, you do not need to install the `mapr-client` package.

The modified versions of `libhdfs` are installed in this directory:

`MAPR_HOME/hadoop/hadoop-<version>/`

Compiling and Running C Applications on File System Clients

The HPE Data Fabric file system exposes the HDFS API. If you already have a client program built to use `libhdfs`, you do not have to relink your program just to access the file system. However, re-linking to the Data Fabric-specific shared library `libMapRClient`.so will give you better performance on the file system. Unlike `libhdfs`.so, `libMapRClient`.so does not make Java calls to access the file system.

The following script sets environment variables to necessary values and compiles one of the sample applications. Use this script as an example for building and launching your own applications.

When you set `HADOOP_HOME` for your own client applications, set it to the path for the version of `libhdfs` that your application uses. The path is:

`MAPR_HOME/hadoop/hadoop-<version>/`

Also, set the path to your application in the `gcc` command, of course.

This script assumes that `MAPR_HOME` is set to the default value of `/opt/mapr`.

```
#!/bin/bash
#Setup environment
export HADOOP_HOME=${MAPR_HOME}/hadoop/hadoop-<version>/
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:${MAPR_HOME}/lib/
export LD_RUN_PATH=${LD_RUN_PATH}:${MAPR_HOME}/lib
GCC_OPTS="-Wl,--allow-shlib-undefined -I. -I${HADOOP_HOME}/include/"
```

```
#Compile and Link
gcc ${GCC_OPTS} ${HADOOP_HOME}src/c++/libhdfs/hdfs_read.c -o hdfs_read -L$
{MAPR_HOME}/lib -lMapRClient

#Launch the application
./hdfs_read
```

**NOTE:**

- The compiled libMapRClient is statically linked to the following third-party libraries:
 - Crypto++: libcryptoapp.a (v5.6.2)
 - Protobuf: libprotobuf-lite.a (v2.5.0)
- If a client application connects to the local fileserver, before launching the application you can set the MAPR_CLIENT_SHMEM environment variable to control how much of the local system memory should be devoted to the resources and buffers used for communication between the client application and the local fileserver. By default, the size of the shared memory is 20 MB. If you want to change this value, specify it as a number of pages. For example, to set the shared memory at 128 MB, multiply 128 by 1024 bytes and then divide the product by 8192 bytes. In this case, the value would be 16384 pages.

Overview of the File System C APIs in libMapRClient

Although you can use the file system C APIs to perform other tasks, the most common use of the file system C APIs is to write to and read from files.

Review the following information for an overview of the steps required to use file system C APIs in libMapRClient:

1. Create a connection to the MapR file system running on a MapR cluster. For information about connections, see [Establishing Connections to Filesystems](#).
2. Create or open a file. You can create explicitly or by calling one of the hdfsOpen() APIs and specifying a file that doesn't exist. Opening a file sets the current offset to 0, the first byte in the file. You can move file offset explicitly with the hdfsSeek() API. Writes done by hdfsWrite() and reads done by hdfsRead() increment the offset by the number of bytes written or read.

Use hdfsTell() to find out what the current offset is.

For information about how to specify the location of a file to create or open, see [Specifying Paths to Files and Directories](#).

3. Write to or read from the file. When you write to a file, you pass a buffer that contains the data that you want to write. Writes can be done from the default offset, which is 0 when the file is opened, appended to the end of the file, or done from an offset that you specify. Write buffers are flushed to the server periodically. For more information about writes, see [Writing to Files](#).

When you read from a file, you pass a pointer to a buffer for storing the data that is read. Reads can be done from the default offset or from an offset that you specify. For more information about reads, see [Reading from Files](#).

4. Close the file.

Closing a file implicitly flushes any remaining write buffers to the server. It also frees resources that are associated with the file.

5. Disconnect from the file system.

For more detailed information about these steps, see:

Establishing Connections to the File System

The APIs for establishing connections to the file system and returning file-system handles are:

- `hadoop-<version>: hdfsConnect()`
- `hadoop-<version>: hdfsConnectAsUser()`

NOTE: This API ignores the impersonation request and is therefore equivalent to `hdfsConnect()`.

- `hadoop-<version>: hdfsConnectNewInstance()`

The `hdfsConnectAsNewUserInstance()` API is not supported for connections to file system file servers.

These APIs behave in the same way:

- If `default` is specified for the `host` parameter, the APIs connect to the first cluster listed in the file `MAPR_HOME/conf/mapr-clusters.conf`. (`MAPR_HOME` defaults to `/opt/mapr.`)
- If a hostname or IP address is specified for the `host` parameter:
 1. Look in `MAPR_HOME/conf/mapr-clusters.conf` on the client node to match the specified hostname or IP address to a CLDB host and port.
 2. If they find a match, they try to connect to the cluster, and all standard features for connections to Data Fabric clusters are available. These features include high availability across CLDBs and secure connections.
 3. If they do not find a match or if they cannot locate a `mapr-clusters.conf` file, they try to connect to the CLDB host specified in the call to create the connection. However, the standard features for connections to Data Fabric clusters are not available. For example, if the cluster is secured, the connection will fail.

It is possible to have more than one open connection at a time. For each connection, simply return the file-system handle to a different instance of `hdfsFS`, as in this example:

```
//Connect to Cluster 1 (picked up from /opt/mapr/conf/
mapr-clusters.conf)
    hdfsFS fs1 = hdfsConnectNewInstance("default", 7222);
//Connect to Cluster 2
    hdfsFS fs2 = hdfsConnectNewInstance("n1c", 7222);
//Connect to Cluster 3
    hdfsFS fs3 = hdfsConnectNewInstance("n1d", 7222);
```

You can then obtain file handles for files in each connected cluster, as in this example. For each cluster, this example code calls `hdfsOpenFile()`, passing in the handle to the file system, the absolute path to a file (and the file is created before being opened, if it doesn't already exist) and a file-access flag that specifies to open the file in write-only mode. This mode truncates existing files to offset 0, deleting their content.

Ignore the last three parameters for this example. `hdfsOpenFile()` returns a handle to the file or an error message, if the open operation fails.

```
//Create files for write operations on all clusters
const char* writePath = "/tmp/write-file1.txt";
hdfsFile writeFile1 = hdfsOpenFile(fs1, writePath, O_WRONLY, 0, 0,
0);
```

```

        if (!writeFile1) {
            fprintf(stderr, "Failed to open %s for writing on Cluster 1!\n",
writePath);
            exit(-2);
        }
        hdfsFile writeFile2 = hdfsOpenFile(fs2, writePath, O_WRONLY, 0, 0,
0);
        if (!writeFile2) {
            fprintf(stderr, "Failed to open %s for writing on Cluster 2!\n",
writePath);
            exit(-2);
        }
        hdfsFile writeFile3 = hdfsOpenFile(fs3, writePath, O_WRONLY, 0, 0,
0);
        if (!writeFile3) {
            fprintf(stderr, "Failed to open %s for writing on Cluster 3!\n",
writePath);
            exit(-2);
        }
        fprintf(stderr, "Opened %s for writing successfully on all 3
clusters...\n", writePath);

```

After working with the files, close them and disconnect from the file system, as in this example:

```

// Close all files
if (writeFile1)
    hdfsCloseFile(fs1, writeFile1);
if (writeFile2)
    hdfsCloseFile(fs2, writeFile2);
if (writeFile3)
    hdfsCloseFile(fs3, writeFile3);

// Disconnect from all clusters
hdfsDisconnect(fs1);
hdfsDisconnect(fs2);
hdfsDisconnect(fs3);

```

Specifying Paths to Files and Directories

Many of the APIs require clients to pass a path to a file or directory. You can specify absolute paths or relative paths. Absolute paths must begin with a forward slash. Relative paths are relative to the working directory, which you can set by calling `hdfsSetWorkingDirectory()` and find out by calling `hdfsGetWorkingDirectory()`. Any path that does not begin with a forward slash is considered to be relative to the working directory.

The maximum length of paths is 4096 bytes.

You cannot specify paths to a cluster other than the cluster for the current connection. All paths are local to the cluster connected to. You can, however, explicitly connect to multiple clusters, as described in [Establishing Connections to the File System](#) on page 3576.

Writing to Files

There are two APIs for writing to files: `hdfsWrite()` and `hdfsPwrite()`. With both APIs, you pass a buffer that contains the data to write. You also pass the length of the buffer in bytes. The maximum length of the buffer is the maximum size of the datatype that is used to specify the buffer length. The datatype is a custom datatype: `tSize`, a signed 32-bit integer.

Both APIs return the number of bytes that were written. Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

For an example of both APIs in action, see [hdfs_write_revised.c](#).

NOTE: The `core-site.xml` flags:

- `fs.mapr.flush.unaligned` default setting (`false`) enables flushes to the server in 8K boundaries. Unaligned flushes can happen only if idle flusher (`fs.mapr.write.idleflush.timeout`) is triggered. If this behavior is not desired, set the value for `fs.mapr.flush.unaligned` to `true`, which will enable flushing of unaligned write buffers (so that even small writes can be flushed on every subsequent write call).
- `fs.mapr.write.idleflush.timeout` automatically flushes the buffer, by default, after 3 seconds for all the open files. This can be disabled by setting the value to 0. If value is specified, buffer is flushed automatically between n to $n+1$ seconds. For example, if value is 3 seconds, the write buffer is not cached after 4 seconds.

See also: [Default core Parameters](#).

Using `hdfsWrite()`

When a file is opened in write-only mode or read-write mode, the file is truncated from offset 0, effectively deleting the content of the file. Therefore, the initial write to the file begins at offset 0. You can start subsequent writes anywhere in the file after first calling `hdfsSeek()` to move to the desired offset. After a write operation, the offset is located at the last written byte.

If the file is opened in append mode, data is appended to the end of the file only.

If a call to `hdfsSeek()` moves the offset past the end of the file before a call to `hdfsWrite()`, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

On error, pending write buffers are flushed to the server.

Using `hdfsPwrite()`

Whereas `hdfsWrite()` increments the current offset by the amount of bytes returned by the API (except in case of error), `hdfsPwrite()` does not change the value of current offset. If the current offset before the call to `hdfsPwrite()` is 0 and you specify the offset 10 for the write operation, after the write the current offset remains 0.

If a call to `hdfsPwrite()` specifies an offset that is past the end of the file, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

On error, pending write buffers are flushed to the server.

Reading from Files

There are two APIs for reading from files: `hdfsRead()` and `hdfsPread()`. With both `hdfsRead()` and `hdfsPread()`, you pass a pointer to a buffer for the runtime to read bytes into and the length of the buffer. The maximum length of the buffer is the maximum size of the datatype that is used to specify the buffer length. The datatype is a custom datatype: `tSize`, a signed 32-bit integer.

Both functions return the number of bytes that are actually read.

For an example of both APIs in action, see [hdfs_read_revised.c](#).

Using `hdfsRead()`

Whenever you open a file, the file pointer is placed at offset 0. If you want to start reading at an offset other than 0, call `hdfsSeek()` to move the file pointer forward to that offset before you call `hdfsRead()`.

When you call `hdfsSeek()`, you specify the offset as a value of type `tOffset`, which is a fixed-width, signed 64-byte integer type for storing offsets. `tOffset` is defined in `hdfs.h`.

If a file is already open and you are not sure what the current offset is, you can find out by calling `hdfsTell()`.

After `hdfsRead()` finishes a read operation, the current offset is set to the last byte read plus one.

Using `hdfsPread()`

With `hdfsPread()`, you specify the offset at which you want to start reading, so you don't first have to call `hdfsSeek()` to move to that offset.

However, the offset that you specify does not change the current offset in the file. After `hdfsPread()` finishes the read operation, the current offset is not set to the last byte read plus one. Instead, the current offset remains as it was before the read operation.

Sample Applications

The following applications demonstrate how to write to and read from files using the APIs:

`hdfs_write_revised.c`

Sample Application

This application demonstrates how to write to files by using the APIs `hdfsWrite()` and `hdfsPwrite()`: `hdfs_write_revised.c`

Before running this application:

- Ensure that you have access either to a cluster running file system.
- Ensure that a text-based file that you have access to exists on the cluster. Note the path to the file and the size of the file in bytes.
- The content of the file will be deleted before the first write is performed by the application.
- Decide on the length in bytes of a string to write to the file.

To build and run it, download it from this page to a Data Fabric client or to a system with the `mapr-core` package installed. Then, modify the `run.sh` script in [Building and Running C Applications on file system Clients](#) to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `errno.h`
- `fcntl.h`

The APIs are defined in `hdfs.h`. The file `fcntl.h` defines the file-access flags.

The application performs the actions that are described in the following sections.

Takes a filename, file size, and buffer size as input

When you launch the application, provide the path and name of the file, the size of the file, and the number of bytes to write.

```
hdfs_write <filename> <filesize>
<buffer size>
```

Sets an RPC timeout

`hdfsSetRpcTimeout()` is specific to the `libMapRClient` version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.

```
int err = hdfsSetRpcTimeout(30);
if (err) {
    fprintf(stderr, "Failed to set rpc
timeout!\n");
    exit(-1);
}
```

Connects to a file system, using an API that is supported in the hadoop-2.x version of libhdfs

The application tries to connect to the first file system cluster that is specified in the `mapr-clusters.conf` file in the `MAPR_HOME/conf` directory on the client. After connecting to the file system, the application returns a handle to the file system.

```
hdfsFS fs = hdfsConnect("default", 0);
if (!fs) {
    fprintf(stderr, "Oops! Failed to
connect to hdfs!\n");
    exit(-1);
}
```

Stores the values of the arguments

The application stores the values of the arguments in a character array and in two variables of type `tSize`. This datatype is defined in `hdfs.h` and is a fixed-width, signed 32-byte integer type for storing the size of data for read or write operations.

```
const char* rfile = argv[1];
tSize fileSize = strtoul(argv[2],
NULL, 10);
tSize bufferSize = strtoul(argv[3],
NULL, 10);
```

Opens the file that you specified

The application opens the specified file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the file system
- The name of the file, which you supplied when you launched the application.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_WRONLY`. This flag creates the file if the file does not exist and truncates the file if the file does exist. If the file existed and you wanted to preserve the content of the file, you would specify `O_WRONLY | O_APPEND` for flag. These flags are defined in the header file `fcntl.h`.
- The default chunk size for the directory in which the file is either located or will be created. This value is specified by the 0 in the last parameter.

Although there are two other parameters in the `hdfsOpenFile()` function – the fourth and fifth, the `libMapRClient` version of `libhdfs` ignores them.

```
hdfsFile writeFile = hdfsOpenFile(fs,
rfile, O_WRONLY, 0, 0, 0);
if (!writeFile) {
    fprintf(stderr, "Failed to open %s
for writing!\n", rfile);
    exit(-2);
}
```

Creates a buffer of the size that you specified and populates the buffer

At this point that the application, creates a string to populate the buffer. This is the data that the application will write.

```
char* buffer = malloc(sizeof(char) *
bufferSize);
if(buffer == NULL) {
    fprintf(stderr, "Failed to allocate
memory!\n");
    return -2;
}
int i;
for (i=0; i<bufferSize; i++) {
    buffer[i] = 'a' + i%26;
}
```

Writes an entire file with `hdfsWrite()`

The application calls the function `writeLength()`:

```
int ret = writeLength(fs, writeFile,
buffer, bufferSize, fileSize);
if (ret < 0) {
    goto done;
}
```

This function writes the content of the buffer to the file, starting at offset 0.

```
int
writeLength(hdfsFS fs, hdfsFile
writeFile, char *buffer, tSize
bufferSize, tSize writeSize)
{
    tSize writeBytes = 0;
    tSize ret = 0;
    uint64_t totalWrite = 0;
    if (fs == NULL || writeFile == NULL
|| buffer == NULL) {
        return -1;
    }
    if (writeSize == 0) {
        return 0;
    }
    for
(writeBytes=0; writeBytes<writeSize;
writeBytes+=bufferSize) {
        ret = hdfsWrite(fs, writeFile,
(void*)buffer, bufferSize);
        if (ret > 0) {
```

Seeks an offset and writes from that offset with hdfsWrite()

```

        totalWrite += ret;
    } else {
        fprintf(stderr, "hdfsWrite
failed with error %d \n", errno);
        hdfsCloseFile(fs, writeFile);
        return -1;
    }
}
return 0;
}

```

The application next calls the function `writeAtOffset()`:

```

tSize writeBytes =
writeAtOffset(fs, writeFile, 0,
buffer, bufferSize);
if (writeBytes < 0) {
    goto done;
}

```

This function writes the content of the buffer to the file, starting at the specified offset. If the file already exists, the file is first truncated to this offset before the write operation begins. In this case, the specified offset is 0.

The difference between this function and the previous function is that, before writing, it calls `hdfsSeek()` to move to the specified offset in the file.

```

tSize
writeAtOffset(hdfsFS fs, hdfsFile
writeFile, tOffset offset,
               char *buffer, tSize
bufferSize)
{
    tSize ret = 0;
    if (fs == NULL || writeFile == NULL
|| buffer == NULL) {
        return -1;
    }
    ret = hdfsSeek(fs, writeFile,
offset);
    if (!ret) {
        //hdfsWrite will return -1 if
ret != number of bytes asked to
//be written.
        ret = hdfsWrite(fs, writeFile,
buffer, bufferSize);
        if (ret < 0) {
            fprintf(stderr, "hdfsWrite
failed with error %d \n", errno);
        }
    } else {
        fprintf(stderr, "hdfsSeek failed
with error %d \n", errno);
    }
    if (ret < 0) {
        //hdfsWrite does a flush in case
of an error, explicit flush
//is not required.
        hdfsCloseFile(fs, writeFile);
    }
}

```

```

    }
    //Current offset within the file
    will be positioned at (offset +
    writeBytes)th byte.
    return ret;
}

```

Performs a positional write with `hdfsPwrite()`

The application next calls the function `positionalWrite()`:

```

writeBytes = positionalWrite(fs,
writeFile, 20, buffer, bufferSize);
if (writeBytes < 0) {
    goto done;
}

```

This function writes the content of the buffer to the file, starting at the offset that you specify.

```

tSize
positionalWrite(hdfsFS fs, hdfsFile
writeFile, tOffset offset,
                char *buffer, tSize
bufferSize)
{
    tSize writeBytes = 0;
    if (fs == NULL || writeFile == NULL
|| buffer == NULL) {
        return -1;
    }
    writeBytes = hdfsPwrite(fs,
writeFile, offset, buffer,
bufferSize);
    if (writeBytes < 0) {
        fprintf(stderr, "hdfsPwrite
failed with error %d \n", errno);
        hdfsCloseFile(fs, writeFile);
    }
    //Current offset within the file
    will not be advanced if hdfsPwrite is
    used
    return writeBytes;
}

```

Closes the file

```
hdfsCloseFile(fs, writeFile);
```

Frees the buffer

```
free(buffer);
```

Disconnects from the file system

```
hdfsDisconnect(fs);
```

hdfs_read_revised.c

Sample Application

This application demonstrates how to read from files by using the APIs `hdfsRead()` and `hdfsPread()`: `hdfs_read_revised.c`

Before running this application:

- Ensure that you have access to a cluster running file system.

- Ensure that a text-based file that you have access to exists on the cluster. Note the path to the file.
- Decide on the number of bytes to read from the file.

To build and run it, download it from this page and copy it to a Data Fabric client. Then, modify the `run.sh` script in [Building and Running C Applications on file system Clients](#) to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `errno.h`
- `fcntl.h`

The APIs are defined in `hdfs.h`. The file `fcntl.h` defines the file-access flags.

The application performs the actions that are described in the following sections.

Takes a filename and buffer size as input

After compiling the application, type the following command to launch the application and pass in the path and name of the file, as well as the size of the buffer to read data into:

```
hdfs_read <filename> <buffer size>
```

Sets an RPC timeout

`hdfsSetRpcTimeout()` is specific to the `libMapRClient` version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.

```
int err = hdfsSetRpcTimeout(30);
if (err) {
    fprintf(stderr, "Failed to set rpc
timeout!\n");
    exit(-1);
}
```

Connects to a file system, using an API that is supported in the hadoop-2.x version of libhdfs

The application tries to connect to the first file system cluster that is specified in the `mapr-clusters.conf` file in the `MAPR_HOME/conf` directory on the client. After connecting to the file system, the application returns a handle to the file system.

```
hdfsFS fs = hdfsConnect("default", 0);
if (!fs) {
    fprintf(stderr, "Oops! Failed to
connect to hdfs!\n");
    exit(-1);
}
```

Stores the values of the arguments

The application stores them in a character array and in a variable of type `tSize`. This datatype is defined in `hdfs.h` and is a fixed-width, signed 32-byte integer

type for storing the size of data for read or write operations.

```
const char* rfile = argv[1];
tSize bufferSize = strtoul(argv[2],
NULL, 10);
```

Opens the file that you specified

The application opens the specified file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the file system
- The name of the file, which you supplied when you launched the application.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_RDONLY`, which specifies read-only mode.
- The default chunk size for the directory in which the file is either located or will be created. This value is specified by the 0 in the last parameter.

Although there are two other parameters in the `hdfsOpenFile()` function – the fourth and fifth, the `libMapRClient` version of `libhdfs` ignores them.

```
hdfsFile readFile = hdfsOpenFile(fs,
rfile, O_RDONLY, 0, 0, 0);
if (!readFile) {
    fprintf(stderr, "Failed to open %s
for reading!\n", rfile);
    exit(-2);
}
```

Creates a buffer of the size that you specified

This is the buffer that the application will read data into.

```
char* buffer = malloc(sizeof(char)
* bufferSize);
if(buffer == NULL) {
    fprintf(stderr, "Failed to allocate
memory!\n");
    return -2;
}
```

Reads an entire file with `hdfsRead`

The application calls the function `readEntireFile()`:

```
//Read entire file from the beginning
int ret = readEntireFile(fs,
readFile, buffer, bufferSize);
if (ret < 0) {
    goto done;
}
```

This function uses a `WHILE` loop. In each loop iteration, the function reads an amount of data that is equal to the size of the buffer. When the amount of bytes read is less than the size of the buffer, the end of the file has been reached and the function breaks the

loop. The number of bytes read is added to a total in each iteration.

```
int
readEntireFile(hdfsFS fs, hdfsFile
readFile, char *buffer, tSize
bufferSize)
{
    tSize readBytes = bufferSize;
    uint64_t totalRead = 0;
    if (fs == NULL || readFile == NULL
|| buffer == NULL) {
        return -1;
    }
    while (readBytes == bufferSize) {
        readBytes = hdfsRead(fs,
readFile, (void*)buffer, bufferSize);
        if (readBytes > 0) {
            totalRead += readBytes;
        } else {
            if (readBytes < 0) {
                fprintf(stderr, "hdfsRead
failed with error %d \n", errno);
                hdfsCloseFile(fs, readFile);
                return -1;
            }
            break;
        }
    }
    return 0;
}
```

Seeks an offset and reads from that offset with hdfsRead()

The application next calls the function `readAtOffset()`, passing in 0 as the offset from which to start reading the file.

```
//Read file at a particular offset
//In this case, we are reading from
offset 0
tSize readBytes = readAtOffset(fs,
readFile, 0, buffer, bufferSize);
if (readBytes < 0) {
    goto done;
}
```

This function calls `hdfsSeek()` to move to the specified offset in the file.

If the seek is successful, the function reads from that offset until the buffer is full. The function then returns the number of bytes that were read.

If the seek or the read is not successful (meaning `hdfsSeek()` or `hdfsRead()` returned -1), the function closes the file and returns -1.

The offset in the file is the next byte after the end of the data that was read.

```
tSize
readFromOffset(hdfsFS fs, hdfsFile
readFile, tOffset offset,
               char *buffer, tSize
```

```

bufferSize)
{
    tSize ret = 0;
    if (fs == NULL || readFile == NULL
    || buffer == NULL) {
        return -1;
    }
    ret = hdfsSeek(fs, readFile,
offset);
    if (!ret) {
        ret = hdfsRead(fs, readFile,
buffer, bufferSize);
        if (ret < 0) {
            fprintf(stderr, "hdfsRead
failed with error %d \n", errno);
        }
    } else {
        fprintf(stderr, "hdfsSeek failed
with error %d \n", errno);
    }
    if (ret < 0) {
        hdfsCloseFile(fs, readFile);
    }
    //Current offset within the file
will be positioned at (offset +
readBytes)th byte.
    return ret;
}

```

Performs a positional read with `hdfsPread()`

The application calls `positionalRead()`, passing 100 as the offset from which to start the read.

```

readBytes = positionalRead(fs,
readFile, 100, buffer, bufferSize);
if (readBytes < 0) {
    goto done;
}

```

The function reads data into the buffer, starting at offset 100, without first calling `hdfsSeek()` to move the offset to that position. The offset is not moved to 100 before the read begins. The offset stays where it is, the read begins at offset 100, and (after the read) the offset remains where it was before the read. The offset in the file is ignored by the positional read.

```

tSize
positionalRead(hdfsFS fs, hdfsFile
readFile, tOffset offset,
               char *buffer, tSize
bufferSize)
{
    tSize readBytes = 0;
    if (fs == NULL || readFile == NULL
    || buffer == NULL) {
        return -1;
    }
    readBytes = hdfsPread(fs, readFile,
offset, buffer, bufferSize);
    if (readBytes < 0) {
        fprintf(stderr, "hdfsPread failed

```

```

with error %d \n", errno);
    hdfsCloseFile(fs, readFile);
}
//Current offset within the file
will not be advanced if hdfsPread is
used
return readBytes;
}

```

Closes the file

```
hdfsCloseFile(fs, readFile);
```

Frees the buffer

```
free(buffer);
```

Disconnects from the file system

```
hdfsDisconnect(fs);
```

hdfs_connect_as_user.c

Sample Application

This application demonstrates how to create and write to files impersonating another user by using the API `hdfsConnectAsUser()`.

Before running this application, ensure that you have access to a cluster running Data Fabric file system.

To build and run it, download it from this page and copy it to a Data Fabric client or to a system with the `mapr-core` package installed. Then, modify the `run.sh` script in [Building and Running C Applications on file system Clients](#) to point to this sample application. Run the script and then run the application.

The application includes these header files:

- `stdio.h`
- `hdfs.h`
- `stdlib.h`
- `string.h`

NOTE: The impersonation APIs are defined in `hdfs.h`.

The application performs the actions that are described in the following sections.

Takes two usernames and a hostname as input

After compiling the application, type the following command to launch the application and pass in the two usernames (to impersonate) and host name:

```
hdfs_connect_as_user <username1>
<username2> <hostname>if (argc < 4) {
    fprintf(stderr, "Provide two
usernames to impersonate and the host
name\n");
    printf("USAGE: ./
hdfs_connect_as_user mapruser1
mapruser2 10.10.xx.xxx\n");
    exit(EXIT_FAILURE);
}
```

Stores the values of the arguments

The application stores the values of the arguments in character arrays. The application uses the port, 7222, to connect to the given host, and uses character arrays for user directory and file path.

```
char *impersonate_user1 = argv[1];
char *impersonate_user2 = argv[2];
char *host_addr = argv[3];
int port_num = 7222;
char user1_dir[100];
char writePath[100];
int ret_val;
```

Populates the directory path and file path

The application creates a default path for the user directory and file.

```
sprintf(user1_dir, "/tmp/%s_dir",
impersonate_user1);
sprintf(writePath, "%s/test_file",
user1_dir);
```

Sets an RPC timeout

The `hdfsSetRpcTimeout()` is specific to the `libMapRClient` version of `libhdfs` and takes a value that is specified in seconds. The default is 99 seconds. If you change this value, set it either to 0 (which eliminates timeouts) or to a value greater than 30.

```
int err = hdfsSetRpcTimeout(30);
if (err) {
    fprintf(stderr, "Failed to set rpc
timeout!\n");
    exit(-1);
}
```

Connects to the file system as the impersonated user

The application connects to the file system as the impersonated user (<username1>) using `hdfsConnectAsUser()`. If successful, this operation returns a handle to the file system.

```
printf("Impersonate user: %s\n",
impersonate_user1);
printf("Connecting using
hdfsConnectAsUser() as user %s\n",
impersonate_user1);
hdfsFS fs_handle =
hdfsConnectAsUser(host_addr,
port_num, impersonate_user1);
if (fs_handle == NULL) {
    printf("hdfsConnectAsUser()
failed.\n");
    exit(EXIT_FAILURE);
}
```

Creates a directory as the impersonated user

The application creates a directory under `/tmp` as the impersonated user (<username1>).

```
printf("User1: Create a directory :
%s\n", user1_dir);
ret_val =
hdfsCreateDirectory(fs_handle,
user1_dir);
if (ret_val != EXIT_SUCCESS) {
    printf("hdfsCreateDirectory()
failed.\n");
    exit(EXIT_FAILURE);
}
```

Creates and opens a file

The application creates a file and opens the file, passing the following values to the `hdfsOpenFile()` function:

- The handle to the file system.
- A flag to indicate the mode in which to open the file. In this case, the flag is `O_WRONLY|O_CREAT`. This flag creates the file and opens it for writing.

For more details, see `hdfsOpenFile()` documentation.

```
printf("User1: Create and write to
the file as user1 : %s\n", writePath);
```

Writes to the open file

```
hdfsFile writeFile =
hdfsOpenFile(fs_handle, writePath,
O_WRONLY|O_CREAT, 0, 0, 0);
if(!writeFile) {
    printf("hdfsOpenFile() failed.\n");
    exit(EXIT_FAILURE);
}
```

The application writes to the open file as the impersonated user (<username1>).

```
char* buffer = "Hello, from user 1!";
tSize num_written_bytes =
hdfsWrite(fs_handle, writeFile,
(void*)buffer, strlen(buffer)+1);
if (hdfsFlush(fs_handle, writeFile)) {
    printf("failed to flush %s\n",
writePath);
    exit(EXIT_FAILURE);
}
```

Closes the file

The application closes the file after successfully writing to the file as the impersonated user (<username1>).

```
printf("User1: Close file %s.\n",
writePath);
hdfsCloseFile(fs_handle, writeFile);
```

Connects to the file system as the impersonating user

The application connects to the file system as the second user (<username2>) using hdfsConnectAsUser() and returns a handle to the file system.

```
printf("Impersonate user: %s\n",
impersonate_user2);
printf("Connecting using
hdfsConnectAsUser() as user %s\n",
impersonate_user2);
hdfsFS fs_handle2 =
hdfsConnectAsUser(host_addr,
port_num, impersonate_user2);
if (fs_handle2 == NULL) {
    printf("hdfsConnectAsUser()
failed.\n");
    exit(EXIT_FAILURE);
}
```

Tries to write to the file as the impersonating user

The application tries to open the file created by the impersonated user (<username1>) and write to the file as the impersonating user (<username2>). This operation fails as the impersonating user (<username2>) is denied access to the file created by the impersonated user (<username1>) and the application returns error EACCES.

```
printf("User2: Try opening file
created by user1 for writing : %s\n",
writePath);
hdfsFile writeFile2 =
hdfsOpenFile(fs_handle2, writePath,
```

```

O_WRONLY, 0, 0, 0);
int errNum = errno;
if(writeFile2) {
    printf("User2: hdfsOpenFile()
should have failed for %s.\n",
impersonate_user2);
    exit(EXIT_FAILURE);
} else {
    if (errNum == EACCES) {
        printf("User2: As expected
hdfsOpenFile() with EACCES.\n");
    } else {
        printf("User2: hdfsOpenFile()
failed with errno:%d expected %d.\n",
errNum, EACCES);
        exit(EXIT_FAILURE);
    }
}
}

```

Deletes a directory

The application deletes a directory as the impersonated user (<username1>) using the file system handle created for this user.

```

printf("Delete directory : %s\n",
user1_dir);
ret_val = hdfsDelete(fs_handle,
user1_dir, 1);
if (ret_val != EXIT_SUCCESS) {
    printf("hdfsDelete() failed.\n");
    exit(EXIT_FAILURE);
}

```

Disconnects the impersonating user

The application disconnect the impersonating user (<username2>) from the file system.

```

printf("Disconnect the impersonation
user2.\n");
ret_val = hdfsDisconnect(fs_handle2);
if (ret_val != EXIT_SUCCESS) {
    printf("hdfsDisconnect()
failed.\n");
    exit(EXIT_FAILURE);
}

```

Disconnects the impersonated user

The application disconnect the impersonated user (<username1>) from the file system.

```

printf("Disconnect the impersonation
user1.\n");
ret_val = hdfsDisconnect(fs_handle);
if (ret_val != EXIT_SUCCESS) {
    printf("hdfsDisconnect()
failed.\n");
    exit(EXIT_FAILURE);
}

```

```

Reference for the file system C APIs

The following sections describe the custom datatypes, structures, and APIs in the `libMapRClient` version of `libhdfs`:

Type Definitions

`libhdfs` defines the following custom data types, which are supported by `libMapRClient`:

tObjectKind

An enumeration, the values of which are 'F' for file and 'D' for directory. Used to specify whether an object is a file or directory.

tOffset

A signed 64-bit integer that is used to specify an offset within a file and the size of a file.

tPort

An unsigned 16-bit integer that is used to specify a port to use in connections to filesystems.

tSize

A signed 32-bit integer that is used to specify the size of data in bytes to read or write.

tTime

A data type of `time_t` that is used to specify a time in seconds.

Structures

`libhdfs` defines these structures, which are supported by `libMapRClient`.

hdfsBuilder

Supported by libhdfs for hadoop-2.x

This structure can be passed to `hdfsBuilderConnect()` for creating connections to file system clusters. In the `libMapRClient`, four of the parameters are ignored. `forceNewInstance` is ignored, though the header file does not indicate this.

```
struct hdfsBuilder {
    int forceNewInstance;
    const char *nn;
    tPort port;
    const char *kerbTicketCachePath; // Ignored
    const char *userName;           // Ignored
    struct hdfsBuilderConfOpt *opts; // Ignored
};
```

Parameters

`nn`

Specifies the CLDB node to connect to when `hdfsBuilderConnect()` is called. This value is set by `hdfsBuilderSetNameNode()`.

- If `default` is specified for the `host` parameter, `hdfsBuilderConnect()` will connect to the first cluster listed in the file `MAPR_HOME/conf/mapr-clusters.conf`. (`MAPR_HOME` defaults to `/opt/mapr`.)
- If a hostname or IP address is specified for the `host` parameter, `hdfsBuilderConnect()`, look in `MAPR_HOME/conf/mapr-clusters.conf` on the client node to match the specified hostname or IP address to a CLDB host and port.
 - If they find a match, they try to connect to the cluster and all standard features for connections to Data Fabric clusters are available. These features include high availability across CLDBs and secure connections.
 - If they do not find a match or if they cannot locate a `mapr-clusters.conf` file, they try to connect to the CLDB host specified in the call to create the connection. However, the standard features for connections to Data Fabric clusters are not available. For example, if the cluster is secured, the connection will fail.

`port`

Specifies the port to connect to on the CLDB node. This value is set by `hdfsBuilderSetNameNodePort()`.

hdfsFileInfo

Supported by `libhdfs` for `hadoop-2.x`

This structure is returned by `hdfsGetPathInfo()` and deleted by `hdfsFreeFileInfo()`. It contains information about the file or directory that is specified in the call to `hdfsGetPathInfo()`.

`ParameterstObjectKind mKind`

Specifies whether the object is a file or directory.

`char *mName`

Specifies the name of the object.

`tTime mLastMod`

Specifies the epoch time in milliseconds of the last modification to the object.

`tOffset mSize`

Specifies the size of the object in bytes.

short mReplication

Specifies the count of replicas of the object.

tOffset mBlockSize

Specifies the block size for the object.

char *mOwner

Specifies the owner of the object.

char *mGroup

Specifies the group that is associated with the object.

short mPermissions

Specifies the permissions on the object.

tTime mLastAccess

Specifies the epoch time in milliseconds at which the object was created.

APIs

The following sections provide information about the hdfs APIs:

hdfsAvailable()

Supported by libMapRClient for hadoop-2.x

Returns the number of bytes that can be read from an input stream without blocking. This number is simply the size of the file in bytes.

Signature

```
int hdfsAvailable(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the hdfsConnect() APIs.
file	The file handle. Obtain this handle with one of the hdfsOpenFile() APIs.

Return Value

Returns the size of the file in bytes, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the arguments provided are invalid.

hdfsBuilderConnect()

Supported by libMapRClient for hadoop-2.x

Connects to a Data Fabric file system using the parameters that are specified in an hdfsBuilder structure.

Signature

```
hdfsFS hdfsBuilderConnect(struct hdfsBuilder *bld)
```

Parameters

Parameter	Description
bld	The builder to use for the connection. This value cannot be NULL.

Return Value

Returns the handle to the file system or NULL on error.

hdfsBuilderSetForceNewInstance()

Not supported for file system

This API is ignored.

hdfsBuilderSetKerbTicketCachePath()

Not supported for file system

This API is ignored.

hdfsBuilderSetNameNode()

Supported by libMapRClient for hadoop-2.x

Specifies a CLDB node for an hdfsBuilder structure.

Signature

```
void hdfsBuilderSetNameNode(struct hdfsBuilder *bld, const char *nn)
```

Parameters

Parameter	Description
bld	An hdfsBuilder structure. This value cannot be NULL.
nn	The hostname or IP address of a name node. Use NULL to connect to the local file system. Use default to connect to the first file system cluster that is listed in the MAPR_HOME/conf/mapr-clusters.conf file on the client.

hdfsBuilderSetNameNodePort()

Supported by libMapRClient for hadoop-2.x

Sets the port in an hdfsBuilder structure.

Signature

```
void hdfsBuilderSetNameNodePort(struct hdfsBuilder *bld, tPort port)
```

Parameters

Parameter	Description
bld	An <code>hdfsBuilder</code> structure. This value cannot be NULL.
port	The port to use for connections. If the CLDB node is set to NULL or default, use 0.

hdfsBuilderSetUserName()

Not supported for file system

This API is ignored.

hdfsChmod()

Supported by libMapRClient for hadoop-2.x

Changes permissions on a file or directory in the manner of the `chmod` command.

Signature

```
int hdfsChmod(hdfsFS fs, const char* path, short mode)
```

Parameters

Parameter	Description
fs	The handle to the file system. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The path to the file or directory.
mode	The bitmask for the new permissions.

Return Value

Returns 0 on success, -1 on error.

Check `errno` for error codes and meanings.

`errno` is set to `EINVAL` if the input arguments are invalid.

`errno` is set to `EPERM` if the process does not have enough privileges to perform the operation.

hdfsChown()

Supported by libMapRClient for hadoop-2.x

Changes ownership of a file or directory in the manner of the `chown` command.

**ATTENTION:**

- To permit a client to resolve user or group from a server, set the `fs.mapr.server.resolve.user` parameter to `true` in `core-site.xml`, for both secure and non secure clusters. Setting this is essential when the client does not belong to the same domain as the mapr cluster nodes, and does not have any knowledge of users present in that domain.
- To permit CLDB to resolve user or group, set the `cldb.security.resolve.user` configuration parameter to `1` on a non-secure cluster as follows:

```
maprcli config save -values {"cldb.security.resolve.user":1}
```

You do not have to set this parameter for a secure cluster, as it is already set to `1`.

Signature

```
int hdfsChown(hdfsFS fs, const char* path, const char *owner, const char *group)
```

Parameters

Parameter	Description
fs	The handle to the file system. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The path to the file or directory
owner	The user to own the file or directory. Set to <code>NULL</code> to keep the owner as is.
group	The group to own the file or directory. Set to <code>NULL</code> to keep the owner as is.

Return Value

Returns `0` on success, `-1` on error.

Check `errno` for error codes and meanings.

`errno` is set to `EINVAL` if the input arguments are invalid.

`errno` is set to `EPERM` if the process does not have enough privileges to perform the operation.

hdfsCloseFile()

Supported by `libMapRClient` for `hadoop-2.x`

Closes an open file. Flushes all pending write buffers for the file and releases resources that are associated with the file.

Signature

```
int hdfsCloseFile(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
file	The file handle. Obtain this handle with one of the <code>hdfsOpenFile()</code> APIs.

Return Value

Returns 0 on success, -1 on error.

Check `errno` for error codes and meanings.

hdfsConnect()

Supported by libMapRClient for hadoop-2.x

Connects to a file system cluster.

If a connection to the cluster in which the remote host is located already exists, the functions return a handle to this existing connection.

If a connection to the cluster does not already exist, the functions return a handle to a new connection instance.

Note that if `default` is used for the `host` parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see [Establishing Connections to file system](#).

Signature

```
hdfsFS hdfsConnect(const char* host, tPort port)
```

Parameters

Parameter	Description
host	<p>A string containing either a hostname or an IP address of a CLDB node of a file system cluster.</p> <p>To connect to the first file system cluster that is specified in <code>MAPR_HOME/conf/mapr-clusters.conf</code> on the client, pass the value <code>default</code> and use the port number 0.</p> <p>This parameter does not accept NULL as a value.</p>
port	The port on which the host is listening.

Return Value

Returns a handle to the connected file system, or NULL on error.

Check `errno` for error codes and meanings.

hdfsConnectAsUser()

Supported by libMapRClient for hadoop-2.x

Connects to a file system cluster as specified user.

If a connection to the cluster in which the remote host is located already exists, the functions return a handle to this existing connection.

If a connection to the cluster does not already exist, the functions return a unique handle to a connection instance for each user.

NOTE: If `default` is used for the `host` parameter, this means connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client.

For more information about connections, see [Establishing Connections to file system](#).

Signature

```
hdfsFS hdfsConnectAsUser(const char* host, tPort port, const char* user)
```

Parameters

Parameter	Description
host	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in <code>MAPR_HOME/conf/mapr-clusters.conf</code> on the client, pass the value <code>default</code> and use the port number 0. This parameter does not accept NULL as a value.
port	The port on which the host is listening.
user	The user connected to the cluster.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsConnectAsUid()

Connects to a file system cluster as specified user ID.

Supported by libMapRClient for hadoop-2.x

If a connection to the cluster in which the remote host is located already exists, the function returns a handle to this existing connection.

If a connection to the cluster does not already exist, the function returns a unique handle to a connection instance for the specified user ID.

NOTE: To connect to the first cluster listed in the `MAPR_HOME/conf/mapr-clusters.conf` file on the client, use `default` as the value for the `host` parameter.

For more information about connections, see [Establishing Connections to the File System](#) on page 3576.

Signature

```
hdfsFS hdfsConnectAsUid(const char* host, tPort port, uid_t uid)
```

Parameters

Parameter	Description
host	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in MAPR_HOME/conf/mapr-clusters.conf on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
port	The port on which the host is listening.
user ID	The ID of the user connected to the cluster.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsConnectAsUserNewInstance()

Supported by libMapRClient for hadoop-2.x

Connects to a file system cluster as specified user.

The function returns a handle to a new connection instance.

NOTE: If default is used for the host parameter, this means connect to the first cluster listed in the MAPR_HOME/conf/mapr-clusters.conf file on the client.

For more information about connections, see [Establishing Connections to file system](#).

Signature

```
hdfsFS hdfsConnectAsUserNewInstance(const char* host, tPort port, const char* user)
```

Parameters

Parameter	Description
host	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in MAPR_HOME/conf/mapr-clusters.conf on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
port	The port on which the host is listening.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsConnectNewInstance()

Supported by libMapRClient for hadoop-2.x

Connects to a file system cluster.

The function returns a handle to a new connection instance.

NOTE: If default is used for the host parameter, this means connect to the first cluster listed in the MAPR_HOME/conf/mapr-clusters.conf file on the client.

For more information about connections, see [Establishing Connections to file system](#).

Signature

```
hdfsFS hdfsConnectNewInstance(const char* host, tPort port)
```

Parameters

Parameter	Description
host	A string containing either a hostname or an IP address of a CLDB node of a file system cluster. To connect to the first file system cluster that is specified in MAPR_HOME/conf/mapr-clusters.conf on the client, pass the value default and use the port number 0. This parameter does not accept NULL as a value.
port	The port on which the host is listening.
user	The user connected to the cluster.

Return Value

Returns a handle to the connected file system, or NULL on error.

hdfsCopy()

This API is not supported.

hdfsCreateDirectory()

Supported by libMapRClient for hadoop-2.x

Creates a file or directory at the specified path. Intermediate directories in the path that do not exist are created.

Signature

```
int hdfsCreateDirectory(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The handle of the file system in which to create the file or directory. Obtain this handle with one of the hdfsConnect() APIs.
path	The path of the directory.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are not valid, EEXIST if the directory already exists, or EACCES if the parent directory does not allow the user write permission.

*hdfsCreateDirectory2()**Supported by libMapRClient for hadoop-2.x*

Makes the given file and all non-existent parents into directories. Stores the size of the name container in a location that you pass a pointer into, so that you can keep track of this size. The size is in bytes.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Signature

```
int hdfsCreateDirectory2(hdfsFS fs, const char* path, tSize
    *nameSizeInBytes)
```

Parameters

Parameter	Description
fs	The handle of the file system in which to create the file or directory. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The path of the directory.
nameSizeInBytes	A pointer to a memory buffer that can store the size in bytes of the name container.

Return Value

Returns 0 on success, -1 on error.

Check `errno` for error codes and meanings.

*hdfsDelete()**Supported by libMapRClient for hadoop-2.x*

Deletes the specified directory or file.

Signature

```
int hdfsDelete(hdfsFS fs, const char* path, int recursive)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file or directory to delete is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The path of the file.

Parameter	Description
recursive	<p>A value of 0 deletes the specified directory, if the directory is empty. If the directory is not empty, an error is returned.</p> <p>A non-zero value deletes the specified directory and all of its subdirectories.</p> <p>If the specified object is a file, not a directory, this parameter is ignored.</p>

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings. Some of the key errors are ESTALE, EACCES, and EPERM.

hdfsDisconnect()

Supported by libMapRClient for hadoop-2.x

Disconnects from the specified file system.

Even if there is an error, the resources that are associated with the file system handle are freed.

Signature

```
int hdfsDisconnect(hdfsFS fs)
```

Parameter

Parameter	Description
fs	The handle of the file system to disconnect from. Obtain this handle with one of the hdfsConnect () APIs.

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsExists()

Supported by libMapRClient for hadoop-2.x

Checks whether a given directory or file exists on the file system.

Signature

```
int hdfsExists(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle with one of the hdfsConnect () APIs.
path	The directory or file to check the existence of.

Return Value

Returns 0 if the directory or file exists, -1 on error.

Check errno for error codes and meanings.

hdfsExists2()

Supported by libMapRClient for hadoop-2.x

Checks the file system directly (avoiding a client cache) to determine whether a given file or directory exists.

Signature

```
int hdfsExists2(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The directory or file to check the existence of.

Return Value

Returns 0 if the directory or file exists, -1 on error.

Check errno for error codes and meanings.

hdfsFileFreeReadStatistics()

This API is not supported.

hdfsFileGetReadStatistics()

This API is not supported.

hdfsFileIsOpenForRead()

This API is not supported.

hdfsFileIsOpenForWrite()

This API is not supported.

hdfsFlush()

Supported by libMapRClient for hadoop-2.x

Flushes the write buffer for the specified file to the server

Signature

```
int hdfsFlush(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.

Parameter	Description
file	The file handle. Obtain this handle with one of the <code>hdfsOpenFile()</code> APIs.

Return Value

Returns 0 on success, -1 on error.

Check `errno` for error codes and meanings.

`errno` is set to `EINVAL` if the input arguments are invalid.

hdfsFreeBuilder()

Supported by libMapRClient for hadoop-2.x

Frees the memory that was used by an `hdfsBuilder` structure and its parameter values.

Signature

```
void hdfsFreeBuilder(struct hdfsBuilder *bld)
```

Parameters

Parameter	Description
bld	An <code>hdfsBuilder</code> structure. The value cannot be NULL.

hdfsFreeFileInfo()

Supported by libMapRClient for hadoop-2.x

Frees up the array of `hdfsFileInfo` structures that is returned by `hdfsListDirectory()`, including allocated fields.

Signature

```
void hdfsFreeFileInfo(hdfsFileInfo *hdfsInfo, int numEntries)
```

Parameters

Parameter	Description
hdfsInfo	The array of dynamically-allocated <code>hdfsFileInfo</code> structures.
numEntries	The size of the array.

hdfsFreeHosts()

Supported by libMapRClient for hadoop-2.x

Frees an array that was returned by `hdfsGetHosts()`.

Signature

```
void hdfsFreeHosts(char ***blockHosts)
```

Parameters

Parameter	Description
blockHosts	The two-dimensional array that was returned by <code>hdfsGetHosts()</code> .

hdfsGetCapacity()

Supported by libMapRClient for hadoop-2.x

Returns the capacity in bytes of the connected file system.

Signature

```
tOffset hdfsGetCapacity(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this handle by calling one of the <code>hdfsConnect()</code> APIs.

Return Value

Returns the capacity in bytes of the connected file system, -1 on error.

Check `errno` for error codes and meanings.

`errno` can be set to `EINVAL` in case of error.

hdfsGetDefaultBlockSize()

Supported by libMapRClient for hadoop-2.x

Gets the default size of blocks for the connected file system.

Signature

```
tOffset hdfsGetDefaultBlockSize(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The handle of file system. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.

Return Value

Returns 256 MB.

Returns -1 on error.

Check `errno` for error codes and meanings.

hdfsGetDefaultBlockSizeAtPath()

Supported by libMapRClient for hadoop-2.x

Gets the block size of a file at the specified path.

Signature

```
tOffset hdfsGetDefaultBlockSizeAtPath(hdfsFS fs, const char *path)
```

Parameters

Parameter	Description
fs	The handle of the file system. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The location and name of the file.

Return Value

Returns 256 MB.

Check `errno` for error codes and meanings.

hdfsGetHosts()

Supported by libMapRClient for hadoop-2.x

Gets hostnames where a particular block, as determined by the offset and block size, is stored. Due to replication, a single block could be present on multiple hosts.

This function can be useful for understanding the performance implications of file access, and to validate or verify changes to the replication factor.

Signature

```
char*** hdfsGetHosts(hdfsFS fs, const char* path, tOffset start, tOffset length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The path of the file.
start	The start of the block.
length	The length of the block.

Return Value

If successful, returns a dynamically-allocated two-dimensional array of hostnames. The last element in the array is NULL.

Returns NULL on error.

Check `errno` for error codes and meanings.

hdfsGetNameContainerSizeBytes()

Unique to libMapRClient

Get the size of the container hosting the path.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Signature

```
int tSize hdfsGetNameContainerSizeBytes(hdfsFS fs, const char *path)
```

Parameters

Parameter	Description
path	Path of the file or directory residing on the container.

Return Value

Returns size of the container on success; -1 on error.

Check errno for error codes and meanings.

errno is set to EINVAL if the input arguments are invalid.

hdfsGetPathInfo()

Supported by libMapRClient for hadoop-2.x

Returns a dynamically-allocated `hdfsFileInfo` structure that contains information about the given path.

Call `hdfsFreeFileInfo()` when the structure is no longer needed.

See `hdfsFileInfo()` for information about the information that this object contains.

Signature

```
hdfsFileInfo * hdfsGetPathInfo(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The file system handle. Obtain this by calling one of the <code>hdfsConnect()</code> APIs.
path	The path of the file.

Return Value

Returns a dynamically-allocated `hdfsFileInfo` structure on success, and NULL on error.

errno is set to EINVAL for invalid arguments and to EACCES for invalid access.

hdfsGetUsed()

Supported by libMapRClient for hadoop-2.x

Returns the total number of bytes that are being used by all of the files in the file system.

Signature

```
tOffset hdfsGetUsed(hdfsFS fs)
```

Parameters

Parameter	Description
fs	The file system handle.

Return Value

Returns the total size in bytes or -1 on error.

Check errno for error codes and meanings.

hdfsGetWorkingDirectory()

Supported by libMapRClient for hadoop-2.x

Gets the current working directory for the file system. Before calling this method, the application must have called `hdfsSetWorkingDirectory()`.

Signature

```
char* hdfsGetWorkingDirectory(hdfsFS fs, char *buffer, size_t bufferSize)
```

Parameters

Parameter	Description
fs	The file system handle.
buffer	The buffer in which to copy path of current working directory.
bufferSize	The length of user-buffer.

Return Value

Returns the buffer on success, NULL on error.

errno is set to EINVAL for invalid arguments.

hdfsGetXattr()

Supported by libMapRClient for hadoop-2.x

Gets extended attribute values from a file.

Signature

```
int hdfsGetXattr(hdfsFS fs, const char* path, const char *name, char
*value, size_t size);
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
name	The name of the extended attribute.
path	The path to the file.
size	The size of the buffer.

Parameter	Description
value	The value for the extended attribute that is read from the system and written to the buffer.

Return Value

Returns:

- Current size of the value of the extended attribute on success
- -1 on error

Check `errno` for error codes and meanings.

hdfsListDirectory()

Supported by libMapRClient for hadoop-2.x

Gets list of files and directories for a given path. Returns the information in a dynamically allocated array of `hdfsFileInfo` structures.

`hdfsFreeFileInfo()` should be called to deallocate memory when this structure is no longer needed.

This method is the equivalent of the `ls -l` command.

Signature

```
hdfsFileInfo *hdfsListDirectory(hdfsFS fs, const char* path, int
*numEntries)
```

Parameters

Parameter	Description
fs	The handle of the file system. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The path of the directory.
numEntries	Set to the number of files/directories in path. Cannot be 0 or NULL.

Return Value

Returns a dynamically-allocated array of `hdfsFileInfo` structures on success and NULL on error.

Check `errno` for error codes and meanings.

hdfsMove()

This API is not supported.

hdfsNewBuilder()

Supported by libMapRClient for hadoop-2.x

Returns an `hdfsBuilder` structure. You can set values for its parameters and then pass it to `hdfsBuilderConnect()`.

Signature

```
struct hdfsBuilder *hdfsNewBuilder(void)
```

Return Value

Returns a new `hdfsBuilder` structure.

Returns `ENOMEM` if unable to allocate memory for a new `hdfsBuilder` structure.

hdfsOpenFile()

Supported by `libMapRClient` for `hadoop-2.x`

Opens a file in the specified mode. Creates the file and intermediate directories if they do not exist.

Requires a valid file system handle, which one of the `hdfsConnect()` APIs can provide.

Before the call to `hdfsOpenFile()`, `hdfsExists()` can check that the file exists, if a check is needed.

After finishing work on a file, call `hdfsCloseFile()` to free the memory that is associated with the file.

Signature

```
hdfsFile hdfsOpenFile(hdfsFS fs, const char* path, int flags, int
bufferSize, short replication, tSize blockSize)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The full path to the file.

Parameter	Description
flags	<p>One of the following values. These flags are included in the <code>fcntl.h</code> header file.</p> <p>O_RDONLY Opens the file in read-only mode with the current offset at 0.</p> <p>O_RDWR Opens the file in read-write mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file to offset 0.</p> <p>O_RDWR O_APPEND Opens the file in read-write mode with the current offset at 0. Writing to the file with <code>hdfsWrite()</code> appends the written data to the end of the file. Data written with <code>hdfsPwrite()</code> is not appended, but written starting at the offset specified in the call to that API.</p> <p>O_WRONLY Opens the file in write-only mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file.</p> <p>O_WRONLY O_APPEND Opens the file in write-only mode with the current offset at 0. Writing to the file with <code>hdfsWrite()</code> appends the written data to the end of the file. Data written with <code>hdfsPwrite()</code> is not appended, but written starting at the offset specified in the call to that API.</p>
bufferSize	<i>Ignored for files on Data Fabric file system</i>
replication	<i>Ignored for files on Data Fabric file system</i>
blocksize	The size of chunks for the file in bytes. Specify 0 if you want to use the value that is specified for the <code>fs.mapr.block.size</code> parameter in the <code>/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml</code> file on the client (if the client is using the libMapRClient version of hadoop-2.x). If this parameter is not set in <code>core-site.xml</code> , the default value is taken from the directory's <code>.dfs_attributes</code> file.

Return Value

Returns the handle to the open file or NULL on error.

Check `errno` for error codes and meanings.

*hdfsOpenFile2()**Supported by libMapRClient for hadoop-2.x*

Opens a file in a given mode. Creates the file if the file does not exist.

If `hdfsOpenFile2()` creates a file, it stores the size of the name container in a location that you pass a pointer into, so that you can keep track of this size. The size is in bytes.

Keeping track of the size of the name container is useful when you are creating files that are less than or equal to 64 KB. When the size of all of the such files together for one name container exceeds 64 GB, operations on the name container can become inefficient. If the size of a name container reaches 64 GB, you can switch to a new or different volume.

Before the call to `hdfsOpenFile2()`, `hdfsExists()` can check that the file exists, if a check is needed.

After finishing work on a file, call `hdfsCloseFile()` to free the resources that are associated with the file.

Signature

```
hdfsFile hdfsOpenFile2(hdfsFS fs, const char* path, int flags, int
bufferSize, short replication, tSize blockSize, tSize *nameSizeInBytes)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The full path to the file.

Parameter	Description
flags	<p>One of the following values. These flags are included in the <code>fcntl.h</code> header file.</p> <p>O_RDONLY Opens the file in read-only mode with the current offset at 0.</p> <p>O_RDWR Opens the file in read-write mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file.</p> <p>O_RDWR O_APPEND Opens the file in read-write mode with the current offset at 0. Writing to the file with <code>hdfsWrite()</code> appends the written data to the end of the file. Data written with <code>hdfsPwrite()</code> is not appended, but written starting at the offset specified in the call to that API.</p> <p>O_WRONLY Opens the file in write-only mode. If the file already exists, it is truncated to offset 0, effectively deleting the content of the file.</p> <p>O_WRONLY O_APPEND Opens the file in write-only mode with the current offset at 0. Writing to the file with <code>hdfsWrite()</code> appends the written data to the end of the file. Data written with <code>hdfsPwrite()</code> is not appended, but written starting at the offset specified in the call to that API.</p>
bufferSize	<i>Ignored for files on Data Fabric file system</i>
replication	<i>Ignored for files on Data Fabric file system</i>
blocksize	The size of chunks for the file in bytes. Use 0 if you want to use the value that is specified for the <code>fs.mapr.block.size</code> parameter in the <code>/opt/mapr/hadoop/hadoop-2.x/etc/hadoop/core-site.xml</code> file on the client (if the client is using the <code>libMapRClient</code> version of <code>hadoop-2.x</code>). If this parameter is not set in <code>core-site.xml</code> , the default value is taken from the directory's <code>.dfs_attributes</code> file.
nameSizeInBytes	A pointer to a memory buffer that can store the size in bytes of the name container. The value is returned only if <code>hdfsOpenFile2()</code> creates the specified file because the file does not already exist.

Return Value

Returns the handle to the open file or NULL on error.

Check `errno` for error codes and meanings.

hdfsPread()

Supported by libMapRClient for hadoop-2.x

Reads an open file from a specified offset.

Whereas `hdfsRead()` increments the current offset in the file by the number of bytes that are read, `hdfsPread()` does not change the current offset. For example, if the current offset is 0 and `hdfsPread()` starts reading from offset 100, after the read the current offset is still 0.

Signature

```
tSize hdfsPread(hdfsFS fs, hdfsFile file, tOffset position, void* buffer,
tSize length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
file	The file handle. Obtain this handle with one of the <code>hdfsOpenFile()</code> APIs.
position	Offset from which to read.
buffer	The buffer to copy read bytes into.
length	The length of the buffer. The maximum size of <code>tSize</code> is the maximum buffer length.

Return Value

Returns the number of bytes actually read, which can be less than the length of the buffer if the end of the file is reached during the read. Returns -1 on error.

On error, `errno` is set to one of the following values:

- `EACCES` if the access permissions are violated.
- `ESTALE` if the file doesn't exist on the server.
- `EINVAL` if the arguments are invalid or if the file type doesn't support read operations.

To recover from errors, close the file by calling `hdfsCloseFile()`.

hdfsPwrite()

Supported by libMapRClient for hadoop-2.x

Writes starting at a specified position in an open file.

Whereas `hdfsWrite()` increments the current offset by the amount of bytes returned by the API (except in case of error), `hdfsPwrite()` does not change the value of current offset. If the current offset before the call to `hdfsPwrite()` is 0 and you specify the offset 10 for the write operation, after the write the current offset remains 0.

If a call to `hdfsPwrite()` specifies an offset that is past the end of the file, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

On error, pending write buffers are flushed to the server.

Signature

```
tSize hdfsPwrite(hdfsFS fs, hdfsFile file, tOffset position, const void*
buffer, tSize length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
file	The handle of the file. Obtain this handle with one of the <code>hdfsOpenFile()</code> APIs.
position	The offset at which to start writing.
buffer	The data to write.
length	The number of bytes to write. The maximum length is the maximum size of <code>tSize</code> .

Return Value

Returns the number of bytes written, -1 on error.

Check `errno` for error codes and meanings.

hdfsRead()

Supported by libMapRClient for hadoop-2.x

Reads data from the current offset in an open file. After the read, the current offset is incremented by the number of bytes read.

To read from a specific offset, first call `hdfsSeek()` to move to that offset in the file. Then, call `hdfsRead()`.

Alternatively, call `hdfsPread()`, specifying an offset in the call. `hdfsPread()` does not increment the current offset in the file. The offset that you specify in the call is used only for the read.

Signature

```
tSize hdfsRead(hdfsFS fs, hdfsFile file, void* buffer, tSize length)
```

Parameters

Parameter	Description
fs	The file system handle. File system handle can be obtained using one of the <code>hdfsConnect()</code> APIs.

Parameter	Description
file	The file handle. Obtain this handle with one of the <code>hdfsOpenFile()</code> APIs.
buffer	The buffer to copy bytes into during the read.
length	The length of the buffer. The maximum length of the buffer is the maximum size of <code>tSize</code> .

Returned Value

Returns the number of bytes actually read, which can be less than the length of the buffer if the end of the file is reached during the read. Returns -1 on error.

Check `errno` for error codes and meanings.

`hdfsReadStatisticsGetRemoteBytesRead()`

This API is not supported.

`hdfsRename()`

Supported by `libMapRCient` for `hadoop-2.x`

Renames the specified file. For information about the format to use for paths, see [Specifying Paths to Files and Directories](#).

Signature

```
int hdfsRename(hdfsFS fs, const char* oldPath, const char* newPath)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
oldPath	The path of the source file.
newPath	The path of the destination file.

Return Value

Returns 0 on success, -1 on error.

Check `errno` for error codes and meanings.

`hdfsSeek()`

Supported by `libMapRClient` for `hadoop-2.x`

Moves the current offset to another offset in the specified file.

Signature

```
int hdfsSeek(hdfsFS fs, hdfsFile file, tOffset desiredPos)
```

Parameters

Parameter	Description
fs	The handle for the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
file	The handle to the file. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
desiredPos	The offset to move forward to.

Return Value

Returns 0 on success, -1 on error.

Check `errno` for error codes and meanings.

hdfsSetTicketAndKeyFile()

Dynamically loads a ticket file

Supported by libMapRClient for hadoop-2.x

Use this API to dynamically load a ticket file to connect to newly added clusters and nodes, without restarting your application.

Signature

```
int hdfsSetTicketAndKeyFile(const char *fname)
```

Parameters

Parameter	Description
fname	The name of the ticket file to reload.

Return Value

Returns 0 on success, -1 on error.

Check `errno` for error codes and meanings.

hdfsSetReplication()

This API is not supported.

hdfsSetRpcTimeout()

Unique to libMapRClient

Sets the RPC timeout in seconds. Before creating a connection to a file system cluster, you can set an RPC timeout for your connections to CLDB nodes and file servers, passing the number of seconds for the timeout as an integer.

Signature

```
int hdfsSetRpcTimeout(int seconds)
```

Parameters

Parameter	Description
seconds	<p>The time in seconds to wait before timing out.</p> <p>The default is 99 seconds. If you change the value, set it either to 0 or to greater than 30 seconds.</p> <p>If RPC timeout is set to 0, remote procedure calls will continue to be retried until they are successful.</p>

Return Value

Returns 0 on success, -1 on error.

Check errno for error codes and meanings.

hdfsSetThreads()

Unique to libMapRClient

Configures the number of threads for flushing write buffers. This number is specific to individual clients. The default number is 8.

The number of threads must be positive. If it isn't, EINVAL is returned.

Signature

```
int hdfsSetThreads(int threads)
```

Parameters

Parameter	Description
threads	The number of threads for flushing write buffers.

Return Value

Returns the current number of flush threads for the client, -1 on error. Check errno for error codes and meanings.

hdfsSetWorkingDirectory()

Supported by libMapRClient for hadoop-2.x

Set the working directory. All relative paths will be resolved relative to it.

For example, if you call this API to set the working directory to `/mycluster/myvolume` and subsequently call `hdfsOpenFile()` with the path `/temp/tmp.txt`, the full path to the file to open is assumed to be `/mycluster/myvolume/temp/tmp.txt`.

Signature

```
int hdfsSetWorkingDirectory(hdfsFS fs, const char* path)
```

Parameters

Parameter	Description
fs	The handle of the file system where the directory is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The path of the new working directory.

Return Value

Returns 0 on success, -1 on error.

Check `errno` for error codes and meanings.

`errno` is set to `EINVAL` for invalid arguments.

`hdfsSetXattr()`

Supported by `libMapRClient` for `hadoop-2.x`

Sets extended attribute on a file.

Signature

```
int hdfsSetXattr(hdfsFS fs, const char* path, const char *name, int
nameLen, char *value, int valueLen);
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
name	The name of the extended attribute.
nameLen	The length of the name of the extended attribute.
path	The path to the file.
value	The value for the extended attribute.
valueLen	The length of the value of the extended attribute.

Return Value

Returns 0 on success, -1 on error.

Check `errno` for error codes and meanings.

`hdfsTell()`

Supported by `libMapRClient` for `hadoop-2.x`

Gets the current offset in the file in bytes.

Signature

```
tOffset hdfsTell(hdfsFS fs, hdfsFile file)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
file	The file handle. Obtain this handle with one of the <code>hdfsOpenFile()</code> APIs.

Return Value

Returns the current offset in bytes, or -1 on error.

Check `errno` for error codes and meanings.

hdfsUtime()

Changes the access and modification times of a file or directory.

Supported by libMapRClient for hadoop-2.x

Signature

```
int hdfsUtime(hdfsFS fs, const char* path, tTime mtime, tTime atime)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file or directory is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
path	The path to the file or directory.
mtime	The new modification time or 0 (if you want to set only the access time) in seconds.
atime	The new access time or 0 (if you want to set only the modification time) in seconds. For more information, see the <code>atimeUpdateTimeInterval</code> entry in volume create on page 2929.

Return Value

Returns 0 on success, -1 on error.

`errno` is set to `EINVAL` if the input arguments are invalid.

`errno` is set to `EPERM` if the process does not have enough privileges to perform the operation.

hdfsWrite()

Supported by libMapRClient for hadoop-2.x

Writes to the specified open file.

If the file is opened in write-only mode, writes start at offset 0 because write-only mode causes the content of the file to be truncated when the file is opened.

If the file is opened in append mode, data is appended to the end of the file.

If there are concurrent writes that start at the same offset, only the last write to finish persists.

If a call to `hdfsSeek()` moves the offset past the end of the file before a call to `hdfsWrite()`, the result is a hole in the file between the previous end of the file and the offset at which the write begins.

You can obtain the size of a file in bytes by calling `hdfsGetPathInfo()`.

Flushes to the server happen automatically at intervals during a write operation. After a write operation is finished, either call `hdfsFlush()` explicitly or call `hdfsFlush()` implicitly by calling `hdfsCloseFile()` to be sure that any data remaining in the write buffer is flushed.

On error, pending write buffers are flushed to the server.

Signature

```
tsize hdfsWrite(hdfsFS fs, hdfsFile file, const void* buffer, tSize length)
```

Parameters

Parameter	Description
fs	The handle of the file system where the file is located. Obtain this handle with one of the <code>hdfsConnect()</code> APIs.
file	The handle of the file. Obtain this handle with one of the <code>hdfsOpenFile()</code> APIs.
buffer	The buffer containing the data to be written.
length	The number of bytes to write. This value cannot be zero. The maximum length of the buffer is the maximum size of the <code>tSize</code> data type.

Return Value

Returns the number of bytes written, -1 on error.

Check `errno` for error codes and meanings.

Accessing HPE Data Fabric File Store in Java Applications

As a high-performance file system, portions of the HPE Data Fabric File Store file client are based on a native `maprfs` library. When developing an application, specifying dependence on the JAR file that includes the `maprfs` library enables you to build applications without having to manage platform-specific dependencies.

The following sections describe how to access the HPE Data Fabric File Store in a Java program.

Writing a Java Application

In your Java application, you will use a Configuration object to interface with the file system. When you instantiate a Configuration object, it is created with values from Hadoop configuration files.

If the program is built with JAR files from the Data Fabric installation, the Hadoop 1 configuration files are in the `$MAPR_HOME/hadoop/hadoop-<version>/conf` directory, and the Hadoop 2 configuration files are in the `$HADOOP_HOME/etc/hadoop` directory. This Hadoop configuration directory is in the `hadoop` classpath that you include when you compile and run the Java program.

If the program is built through maven using `mapr` maven artifacts, the default Hadoop configuration files are included in the maven artifacts. The user needs to programmatically update the Hadoop configuration to match the Hadoop configuration files on the Data Fabric cluster.

Sample Code

The following sample code shows how to interface with Data Fabric file system using Java. The example creates a directory, writes a file, then reads the contents of the file.

```
/* Copyright (c) 2009 & onwards. MapR
Tech, Inc., All rights reserved */

//package com.mapr.fs;

import java.net.*;
import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;

/**
 * Assumes mapr installed in /opt/mapr
 *
 * Compilation:
 * javac -cp $(hadoop classpath)
 * MapRTest.java
 *
 * Run:
 * java -cp .:$(hadoop classpath)
 * MapRTest /test
 */
public class MapRTest
{
    public static void main(String
args[]) throws Exception {
        byte buf[] = new
byte[ 65*1024];
        int ac = 0;
        if (args.length != 1) {

System.out.println("usage: MapRTest
pathname");
            return;
        }

        // maprfs:/// -> uses
the first entry in /opt/mapr/conf/
mapr-clusters.conf
        // maprfs:///mapr/
my.cluster.com/
        // /mapr/my.cluster.com/

        // String uri = "maprfs:///";
String dirname = args[ac++];

        Configuration conf = new
Configuration();

        //FileSystem fs =
FileSystem.get(URI.create(uri),
conf); // if wanting to use a
different cluster
        FileSystem fs =
FileSystem.get(conf);

        Path dirpath = new
Path( dirname + "/dir");
        Path wfilepath = new
```

```

Path( dirname + "/file.w");
    //Path rfilepath = new
Path( dirname + "/file.r");
    Path rfilepath = wfilepath;

    // try mkdir
    boolean res =
fs.mkdirs( dirpath);
    if (!res) {

System.out.println("mkdir failed,
path: " + dirpath);
    return;
    }

    System.out.println( "mkdir( "
+ dirpath + ") went ok, now writing
file");

    // create wfile
    FSDataOutputStream ostr =
fs.create( wfilepath,
            true, // overwrite
            512, // buffersize
            (short) 1, //
replication
            (long)
(64*1024*1024) // chunksize
            );
    ostr.write(buf);
    ostr.close();

    System.out.println( "write( "
+ wfilepath + ") went ok");

    // read rfile
    System.out.println( "reading
file: " + rfilepath);
    FSDataInputStream istr =
fs.open( rfilepath);
    int bb = istr.readInt();
    istr.close();
    System.out.println( "Read
ok");
    }
}

```

Compiling and Running a Java Application

You can compile and run the Java application using JAR files from the mapr maven repository or from the Data Fabric installation.

Using JARs from the Maven Repository

Maven artifacts from version 2.1.2 onward are published to <https://repository.mapr.com/maven/>. When compiling for Data Fabric core version 6.1, add the following dependency to the pom.xml file for your project:

```

<dependency>
  <groupId>org.apache.hadoop</

```

```
groupId>
  <artifactId>hadoop-common</
artifactId>
  <version>2.7.0-mapr-1808</version>
</dependency>
```

This dependency adds the dependencies from the mapr maven repository the next time you do a `mvn clean install`. The JAR that includes the `maprfs` library is a dependency for the `hadoop-common` artifact.

For a complete list of artifacts and further details, see [Maven Artifacts for the HPE Data Fabric](#) on page 5559.

Using JARs from the Data Fabric Installation

The `maprfs` library is included in the `hadoop` classpath. Add the `hadoop` classpath to the `JAVA` classpath when you compile and run the Java application.

- To compile the sample code, use the following command:

```
javac -cp $(hadoop classpath)
MapRTest.java
```

- To run the sample code, use the following command:

```
java -cp .:$(hadoop classpath)
MapRTest /test
```

Loading the Data Fabric Native Library

By default, the root class loader will load the native library to allow all children to see and access it. If the native library is loaded by a child class, other classes will not be able to access the library. To allow applications and associated child classes to access the symbols and variables in the native library, we recommend loading the native library via the root loader.

The loading of the native library via the root class loader is accomplished by injecting code into the root loader. If Data Fabric runs on top of applications (such as Tomcat) where it does not have access to the root class loader, the native library will not be loaded. Child classes that try to access the symbols under the assumption that the root class loader successfully loaded the native library will fail.

The parameter `-Dmapr.library.flatclass`, when specified with Java, disables the injection of code via the root class loader, thus disabling the loading of the native library using the root class loader. Instead, the application trying to access the symbols can load the native library themselves. However, since the native library can be loaded only once and can only be seen by the application loading it, ensure that only one application within the JVM attempts to load and access the native library.

Garbage Collection in Data Fabric

The garbage collection (GC) algorithms in Java provide opportunities for performance optimizations for your application. Java provides the following GC algorithms:

- *Serial GC*. This algorithm is typically used in client-style applications that don't require low pause times. Specify `-XX:+UseSerialGC` to use this algorithm.

- *Parallel* GC, which is optimized to maximize throughput. Specify `-XX:+UseParNewGC` to use this algorithm.
- *Mostly-Concurrent* or *Concurrent Mark-Sweep* GC, which is optimized to minimize latency. Specify `-XX:+UseConcMarkSweepGC` to use this algorithm.
- *Garbage First* GC, a new GC algorithm intended to replace Concurrent Mark-Sweep GC. Specify `-XX:+UseG1GC` to use this algorithm.

Consider testing your application with different GC algorithms to determine their effects on performance.

Flags for GC Debugging

Set the following flags in Java to log the GC algorithm's behavior for later analysis:

```
-verbose:gc
-Xloggc:<filename>
-XX:+PrintGCDetails
-XX:+PrintGCDateStamps
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
```

For more information, see the Java [Garbage Collection Tuning](#) document or the Java [Garbage Collection](#) links.

Converting fid and volid

The following file system APIs are available in `com.mapr.fs.MapRFileSystem` for converting fid to file path and volid to volume name:

- `public String getMountPathFidCached(String fidStr)` throws `IOException`
- `public String getVolumeNameCached(int volId)` throws `IOException`
- `public String getVolumeName(int volId)` throws `IOException`
- `public String getMountPathFid(String fidStr)` throws `IOException`

Converting fid to File Path

The `getMountPathFid(string)` and `getMountPathFidCached(string)` APIs can be used for converting file ID to the full path to the file. The `getMountPathFid()` API makes a call to CLDB and file system to get the file path from the fid. Because this API does not cache or store this information locally, it might make repeated requests to CLDB and file system for the same fid and this might result in many RPCs to both CLDB and file system. The `getMountPathFidCached()` API makes a call the CLDB and file system one time and stores the information locally in the shared library of the client. For subsequent calls, it uses the locally stored information to retrieve the file path from the fid. However, if there are many files in the volume, there might still be a large number of calls to CLDB and file system to determine the file path for each fid in the volume. The caching is useful if the API attempts to determine the file path for the same fid repeatedly. The cache is purged after 15 seconds. If the file name changes before the cache is purged, you will see the old name for the file until the cache expires. You can use these APIs to convert the fid to the file path.

For example, the [sample consumer application](#) and the sample [uncached consumer application](#) for consuming audit logs as stream messages use these methods as shown below.

- **Sample Cached Consumer**

```
{
    String token =
    st1.nextToken();
    /* If the field has fid,
    expand it using Cached API */
    if (token.endsWith("Fid")) {
        String lfidStr =
        st1.nextToken();
        String path= null;
        try {
            path =
            fs.getMountPathFidCached(lfidStr);
            // Expand FID to path
        } catch (IOException e){
        }
        lfidPath =
        "\"FidPath\\\": \""+path+"\", \"";
        // System.out.println("\nPath
        for fid " + lfidStr + "is " +
        path);
    }
}
```

- **Sample Uncached Consumer**

```
{
    String token =
    st1.nextToken();
    if (token.endsWith("Fid")) {
        String lfidStr =
        st1.nextToken();
        String path= null;
        try {
            path =
            fs.getMountPathFid(lfidStr); //
            Expand FID to path
        } catch (IOException e){
        }
        lfidPath =
        "\"FidPath\\\": \""+path+"\", \"";
        // System.out.println("\nPath
        for fid " + lfidStr + "is " +
        path);
    }
}
```

Converting valid to Volume Name

The `getVolumeName()` and `getVolumeNameCached()` APIs can be used for converting volume IDs to volume name. The `getVolumeName()` API makes a call to the CLDB every time to get the volume name from the valid and this may result in too many RPCs to CLDB. The `getVolumeNameCached()` API makes a call to the CLDB one time and stores the information locally in the shared library of the client. For subsequent calls, it uses the locally stored information to retrieve the

volume name from the valid. The cache is purged after 15 seconds. You can use these APIs to convert the valid to volume name.

For example, the [sample consumer application](#) and the sample [uncached consumer application](#) for consuming audit logs as stream messages uses these methods as shown below.

- **Sample Cached Consumer**

```
if (token.endsWith("volumeId")) {
    String valid =
    st1.nextToken();
    String name= null;
    try {
        int volumeId =
        Integer.parseInt(valid);
        // Cached API to
        convert volume Id to volume Name
        name =
        fs.getVolumeNameCached(volumeId);
    }
    catch (IOException e){
    }
    lvolName =
    "\"VolumeName\": \""+name+"\", ";
    //
    System.out.println("\nVolume Name
    for valid " + valid + " is " +
    name);
}
```

- **Sample Uncached Consumer**

```
if (token.endsWith("volumeId")) {
    String valid =
    st1.nextToken();
    String name= null;
    try {
        int volumeId =
        Integer.parseInt(valid);
        // API to convert
        volume Id to volume Name
        name =
        fs.getVolumeName(volumeId);
    }
    catch (IOException e){
    }
    lvolName =
    "\"VolumeName\": \""+name+"\", ";
    //
    System.out.println("\nVolume Name
    for valid " + valid + " is " +
    name);
}
```

Sample Applications

Demonstrates how to set ACEs using the Java APIs.

Sample Application

The sample application demonstrates how to set, get, modify, and delete ACES on files using the Java APIs.

Before running this application, verify that you have access to a cluster running file system. To build and run this application:

1. Set the classpath:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the java file:

```
javac FileAceTest.java
```

3. Run the final FileAceTest.class file.

The application imports the following libraries:

- java.io.*
- java.net.*
- java.util.*

The application performs the actions described in the following sections.

Connects to a file system

The application tries to connect to the first file system cluster that is specified in the `mapr-clusters.conf` file in the `$MAPR_HOME/conf` directory on the client. After connecting to the file system, the application returns a handle to the file system.

```
Configuration conf = new
Configuration();
FileSystem fs = FileSystem.get(conf);
//MapRFileSystem fs =
getMapRFileSystem();
```

Creates a new directory and a new file in the directory

The application creates a new directory and a file in the directory.

```
Path testDir = new Path(rootDir +
"FileAceTest");
mkdir(fs, testDir);

Path testFile = new Path(testDir + "/"
testFile");
createFile(fs, testFile);
```

Sets ACEs on the new directory and the file

The application then sets ACEs to grant m7user1 user or the root user permissions to list the contents of the directory, which is required for the user to write and/or execute files in the directory. In addition, the

application sets ACEs on the file in the directory to grant the m7user1 user read access on the file.

```
MapRFileAce ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DFILE);
ace.setBooleanExpression("u:m7user1");
aces.add(ace);
ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DDIR);
ace.setBooleanExpression("u:m7user1|
u:root");
aces.add(ace);
((MapRFileSystem)fs).setAces(testDir,
aces);
((MapRFileSystem)fs).setAces(testFile,
aces);
```

Verifies the ACEs set on the directory and file

The application then prints the ACEs set on the directory and file.

```
List<MapRFileAce> newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
for (int i = 0; i <
newDirAces.size(); ++i) {

System.out.println(newDirAces.get(i).g
etAccessType() + ": " +

newDirAces.get(i).getBooleanExpressio
n());
}

List<MapRFileAce> newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
for (int i = 0; i <
newFileAces.size(); ++i) {

System.out.println(newFileAces.get(i).
getAccessType() + ": " +

newFileAces.get(i).getBooleanExpressio
n());
}
```

Modifies the ACEs on the directory and file

The application modifies the ACEs on the directory to grant m7user2 user also permissions to list the contents of the directory, which is required for the users to write and/or execute files in the directory. It also modifies the ACEs on the file to grant write access on the file to m7user2 user. Please note that when modifying ACEs on the file to grant write access

to m7user2 user, the application does not change read access, which was granted to m7user1 user.

```
aces = new ArrayList<MapRFileAce>();
ace = new
MapRFileAce(MapRFileAce.AccessType.REA
DDIR);
ace.setBooleanExpression("u:m7user1|
u:root|u:m7user2");
aces.add(ace);
ace = new
MapRFileAce(MapRFileAce.AccessType.WRI
TEFILE);
ace.setBooleanExpression("u:m7user2");
aces.add(ace);
((MapRFileSystem)fs).modifyAces(testDi
r, aces);
((MapRFileSystem)fs).modifyAces(testFi
le, aces);
```

Verifies the changes to ACEs on the directory and file

The application prints the changes in ACEs on the directory and the file.

```
newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
for (int i = 0; i <
newDirAces.size(); ++i) {

System.out.println(newDirAces.get(i).g
etAccessType() + ": " +

newDirAces.get(i).getBooleanExpressio
n());
}

newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
for (int i = 0; i <
newFileAces.size(); ++i) {

System.out.println(newFileAces.get(i).
getAccessType() + ": " +

newFileAces.get(i).getBooleanExpressio
n());
}
```

Deletes ACEs on directory and file

The application deletes all ACEs on the directory and the file.

```
((MapRFileSystem)fs).deleteAces(testDi
r);
((MapRFileSystem)fs).deleteAces(testFi
le);
```

Verifies the ACEs on the directory and the file

The application prints the ACEs on the directory and the file after they are deleted.

```
newDirAces =
((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " +
testDir);
if (newDirAces == null ||
newDirAces.size() == 0)
    System.out.println("AceCount: 0");
else
    System.out.println("AceCount: " +
newDirAces.size());
System.out.println("");
newFileAces =
((MapRFileSystem)fs).getAces(testFile)
;
System.out.println("Path: " +
testFile);
if (newFileAces == null ||
newFileAces.size() == 0)
    System.out.println("AceCount: 0");
else
    System.out.println("AceCount: " +
newFileAces.size());
```

Example FileAceTest.java File

```
import java.io.*;
import java.net.*;
import java.util.*;

import org.apache.hadoop.fs.*;
import org.apache.hadoop.conf.*;

import com.mapr.fs.MapRFileAce;
import com.mapr.fs.MapRFileSystem;

public class FileAceTest {
    public FileSystem fs = null;

    public static void mkdir(FileSystem fs, Path path) throws IOException {
        boolean res = fs.mkdirs(path);
        if (!res) {
            throw new IOException("mkdir failed, path: " + path);
        }
    }

    public static void createFile(FileSystem fs, Path path) throws Exception {

    System.out.println("AceCount: 0");
else
    System.out.println("AceCount: " + newFileAces.size());

// Get
System.out.println("GETTING ACES");
newDirAces = ((MapRFileSystem)fs).getAces(testDir);
System.out.println("Path: " + testDir);
for (int i = 0; i < newDirAces.size(); ++i) {
    System.out.println(newDirAces.get(i).getAccessType() + ": " +
        newDirAces.get(i).getBooleanExpression());
}
System.out.println("");
newFileAces = ((MapRFileSystem)fs).getAces(testFile);
System.out.println("Path: " + testFile);
for (int i = 0; i < newFileAces.size(); ++i) {
    System.out.println(newFileAces.get(i).getAccessType() + ": " +
        newFileAces.get(i).getBooleanExpression());
}

// Remove path
rmR(fs, testDir);
}
}

```

Troubleshooting

My application that includes maprfs-0.1.jar is now missing dependencies and fails to link.

As of version 2.1.2, the contents of maprfs-0.1.jar are now in two JAR files:

- maprfs-<version>.jar

- `maprfs-jni-<version>.jar`

The `<version>` refers to the version of the distribution. For example, if you have an existing application written for `maprfs-0.1.jar` and you update it to load `maprfs-2.1.2.jar`, you must also include `maprfs-jni-2.1.2.jar`. This change was made to enable loading on distributed class-loader environments that use the `maprfs` libraries to access the filesystem from multiple contexts.

These JAR files are installed in the `/opt/mapr/hadoop/hadoop<version>/lib/` directory, or can be accessed via the Maven Central Repository.

HPE Data Fabric Database and Apps

This section contains information about developing client applications for JSON and key-value tables.

Why use HPE Data Fabric Database?

From a developer's point-of-view, HPE Data Fabric Database provides the following capabilities:

- **Extreme scale for CRUD operations:** Enabled by the integration of HPE Data Fabric Database with the HPE Data Fabric Filesystem, CRUD operations are extremely fast and efficient.
- **Flexible data model:** HPE Data Fabric Database can be used as both a [document database](#) and a [column-oriented database](#). So if the content structure changes, the applications do not need to be re-written.
- **Rich query:** Integration with [Apache Drill](#) on page 4676 for HPE Data Fabric Database provides a low-latency distributed query engine for large-scale datasets, including structured and semi-structured/nested data.
- **Integration with Apache Spark:** HPE Data Fabric Database provides [HPE Data Fabric Database Connectors for Apache Spark](#) on page 5440 that allow you to access HPE Data Fabric Database tables through Spark applications.
- **Strong data consistency:** Consistently fast response with strong data consistency with row/document level ACID transactions and in-memory database options for faster speeds.

HPE Data Fabric Database JSON provides additional benefits:

- **High performance via [Secondary Indexes on page 754](#):** No memory copying. No need to retrieve the full document to make updates due the log-based database architecture. No application changes needed to leverage secondary indexes for efficient query execution.
- **Easy application development:** JSON constructs such as maps, arrays, and data types are supported natively.
- **Language-specific client APIs:** Java, Python, and Node.js client APIs

NOTE: HPE Data Fabric has a universal namespace which means that the same namespace is used for files, tables, and streams. A universal namespace streamlines application development for different operations.

How Do I Get Started with HPE Data Fabric Database JSON?

The following diagram illustrates an end-to-end flow associated with getting started with HPE Data Fabric Database JSON.

NOTE: *This flow is not the only way to get started!*

You can also run through end-to-end examples using preconfigured, single node HPE Data Fabric clusters. The following table describes an option:

Container for Developers

[Development Environment for HPE Data Fabric](#) on page 68 is a Docker container that runs a single node cluster. Using [HPE Data Fabric Database JSON: Getting Started](#), you can do the following:

- Set up the Docker container
- Import data into HPE Data Fabric Database JSON tables
- Use HPE Data Fabric Database Shell to query, insert, and update JSON documents in HPE Data Fabric Database JSON tables
- Use Drill to query HPE Data Fabric Database JSON tables
- Run sample Java OJAI applications
- Run a sample Spark application using the HPE Data Fabric Database OJAI Connector for Apache Spark

Installing the mapr-client Package

The `mapr-client` package must be installed on each node where you will be building and running your applications. This package installs all of the MapR Libraries needed for application development regardless of programming language or type of HPE Data Fabric Database table (binary or JSON).

About this task

NOTE: The `mapr-core` package contains the files that are in the `mapr-client` package. If you have installed the `mapr-core` package, you do not need to install the `mapr-client` package.

Complete the following steps to install the `mapr-client` package from a repository:

Procedure

1. Configure the repository to point to <https://package.ezmeral.hpe.com/releases/<release version>/<operating system>>

For example, if your VM has a CentOS operating system, edit the `/etc/yum.repos.d/mapr_core.repo` file to add the location.

2. Based on your operating system, run one of the following commands to install the package:
 - On RHEL/Centos: `yum install mapr-client`
 - On Ubuntu: `apt-get install mapr-client`
 - On SLES: `zypper install mapr-client`

Passing the HPE Data Fabric Database Table Path

This topic describes the methods for passing a HPE Data Fabric Database table name. Binary table names can be passed by either specifying the table path in the API or by setting the table path in the `core-site.xml` file. JSON table names are passed by specifying the table path in the API.

Specifying the Table Path in the API

With this method, you provide the complete path to the table using the following format: `/mapr/<cluster>/<volume>/<table>`

NOTE: This format is independent of the programming language. This method is used for both HPE Data Fabric Database binary and JSON tables.

For example, if you were adding a new column family to a table and you had the following information:

- Cluster name: `newyork`
- Volume name: `vol1`
- Table name: `table1`

The table path would be `/mapr/newyork/vol1/table1`

Specifying the Table Path in the `core-site.xml` File

With this method, you specify the table path with `hbase.table.namespace.mappings` property in the `/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop/core-site.xml` file.

NOTE: This method is specific to HPE Data Fabric Database binary tables only. This method is independent of the programming language.

In the following example, all tables that you create and access via the API, will be in the `/tables_dir1` directory. If you specified the table name `table1` in the API, the full path to the table would be `/tables_dir1/table1`.

```
<property>
  <name>hbase.table.namespace.mappings</name>
  <value>*:/tables_dir1</value>
</property>
```

Tuning Parameters for Client Apps

Though tuning client applications is generally not necessary, Data Fabric does offer tuning parameters to change the behavior of client-side caching.

Client application cache pending puts in buffers that are unique to each tablet (*region*, in HBase terminology). Individual put buffers are flushed when they are full or idle. As a result of this architecture and behavior, client applications tend to send RPCs of 128KB when flushing puts to disk, which results in better performance than flushing a single global buffer would, as that could result in a large number of small RPCs.

You can change the values of parameters that affect how put buffers are flushed. Set values for them in the `hbase-site.xml` file or `core-site.xml` file in your Data Fabric installation. If a non-default value for a parameter is set in both files, the value in the `hbase-site.xml` file is used.

`db.mapr.putbuffer.threshold.mb`

Specifies the size of the cumulative put buffer for all tablets in the client application. When this threshold is reached, the put buffer that is most full is flushed to its tablet.

The default value is 32MB.

Increasing this value can improve performance when an application performs operations on very large tables or on a very large number of tables.

`db.mapr.putbuffer.threshold.sec`

Specifies the number of seconds that HPE Data Fabric Database should wait before flushing an idle put buffer.

The default value is 3.

This parameter has no effect if automatic flushing is enabled.

fs.mapr.tabletru.size.kb

Specifies the size of the metadata cache for all tables in a client application..

The metadata for each tablet is 128 bytes.

The default value of this parameter is 512KB, which allows for the caching of the metadata of 4,096 tablets.

When this metadata cache is full, any operation on a tablet for which the metadata is not cached requires an RPC to fetch that tablet's metadata. Moreover, caching the newly retrieved metadata removes from the cache the metadata of a different tablet.

Increasing this value can improve performance when an application performs operations on very large tables or on a very large number of tables.

fs.mapr.threads

Specifies the number of threads to use when flushing put buffers. Each thread makes synchronous RPCs when flushing.

The default value is 64.

Developing Applications for Binary Tables

HPE Data Fabric Database provides a C API, `libMapRCliant` and partially supports the Apache HBase 1.1 Java APIs for performing operation on HPE Data Fabric Database binary tables.

The HPE Data Fabric Database C API, `libMapRCliant`, runs more efficiently on HPE Data Fabric Database and performs faster against HPE Data Fabric Database tables than the open source library of C APIs, `libhbase`, that is used to create and access Apache HBase tables. The `libMapRCliant` header files are in this directory: `/opt/mapr/include/hbase`

HPE Data Fabric Database also supports all of the Apache HBase 1.1 Java APIs, except where noted in this documentation. For a number of critical Java APIs, for filters, and for comparators, this documentation explicitly lists what is supported, rather than what is not supported.

You can easily port existing applications that use the open-source version of `libhbase` or the HBase Java APIs to use HPE Data Fabric Database binary tables.

Current Limitations

- Custom HBase filters are not supported.
- HBase co-processors are not supported.

NOTE: Filters used with Scan operations support regular expressions. When you filter scans on HPE Data Fabric Database tables, you can use regular expressions that comprise the Perl Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See [HBase Java Regular Expressions Support](#) on page 3701 for a list of supported regular expressions.

Creating C Apps - Binary Tables

Data Fabric provides a library of C APIs – `libMapRCliant` – for performing operations on HPE Data Fabric Database binary tables.

The HPE Data Fabric Database `libMapRCliant` C API library is Data Fabric's extension of the `libhbase` C API library. The `libMapRCliant` header files are in this directory: `/opt/mapr/include/hbase`

`libMapRCliant` uses the following conventions:

- All data types are prefixed with 'hb_'.

- All exported functions are annotated with `HBASE_API`, prefixed with 'hb_' and named using the following convention: 'hb_<subject>_<operation>_[<object>|<property>]'
- All asynchronous APIs take a callback which is triggered when a request completes. This callback can be triggered in the caller's thread or in another thread. To avoid any potential deadlock or starvation, applications should not block in the callback routine.
- All callbacks take a void pointer for application developers to supply their own data. This void pointer is passed when callback is triggered.

NOTE: No explicit batching is supported for asynchronous APIs.

WARNING: It is the responsibility of applications to free up all backing data buffers. However, for asynchronous APIs, applications must wait before freeing buffers until after receiving callbacks or manipulating results. For better performance of asynchronous APIs, `libMapRClient` does not copy data buffers that are allocated for mutations, gets, and scans. These buffers hold table names, name space identifiers, row keys, column-family names, and column names or qualifiers. Instead, `libMapRClient` temporarily takes ownership of the buffers and references them with pointers until the callback is triggered. Therefore, applications should not free memory buffers before receiving callbacks for mutations. Applications also should not free memory buffers before receiving results for gets and scans. If applications must read results, the applications should not free memory buffers until the results are destroyed.

NOTE: When one of these asynchronous APIs is invoked, a work item is created and queued for processing on the client:

- `hb_client_destroy()`
- `hb_get_send()`
- `hb_mutation_send()`
- `hb_scanner_destroy()`
- `hb_scanner_next()`

The work item is picked up as soon as possible by a thread in a thread pool.

Client applications can often call these asynchronous APIs faster than the work items are processed. To ensure that the queue of work items does not grow without bound, the configuration parameter `fs.mapr.pool.queue.max_size` is set by default to 10,000. You can modify this parameter in the `/opt/mapr/conf/dbclient.conf` file for a client.

Whenever the number of work items in the queue reaches this limit, `libMapRClient` returns the `ENOBUFFS` error for each asynchronous call. Client applications are expected to handle this error, and can try the call again later.

libMapRClient C APIs

This section provides the HPE Data Fabric Database `libMapRClient` C API library. This library is MapR's extension of the `libhbase` C API library. The `libMapRClient` header files are in the directory: **`/opt/mapr/include/hbase`**.

The `libMapRClient` API implements functions in addition to the functions in the `libhbase` API.

NOTE: Your applications need include only the `hbase.h` header file. The header files are provided for display purposes.

admin.h

Describes the APIs for Apache HBase table administration operations such as creating and

	enabling tables, checking if tables exist, and deleting tables, to name a few .
client.h	Describes the APIs for Apache HBase client side operations such as creating and terminating client connections, and flushing buffered client-side writes to Apache HBase.
coldesc.h	Describes the APIs for performing operations such as creation, deletion, and setting the maximum and minimum number of cell versions to be retained for each Apache HBase column family.
connection.h	<p>LibMapRClient includes a function in the <code>connection.h</code> header file: <code>hb_connection_create_as_user()</code>. This function provides support for impersonation, so that you can connect to a HPE Data Fabric cluster and access HPE Data Fabric Database tables by using a specific username.</p> <p>The user that is passed with the <code>hb_connection_create_as_user()</code> API must have permissions on the tables that the application accesses. For example, to read from a table, the user must have the <code>readperm</code> permission. To write to a table, the user must have the <code>writeperm</code> permission. See Enabling Table and Stream Authorizations with ACEs on page 1625.</p> <p>For <code>hb_connection_create()</code> and <code>hb_connection_create_as_user()</code>, the standard C APIs for Apache HBase require a list of ZooKeeper nodes. For HPE Data Fabric Database, this list is interpreted as a list of CLDB nodes. The <code>zk_root</code> parameter is ignored. If <code>zk_quorum</code> is NULL, then the connection is created to the default cluster that is listed in the <code>mapr-clusters.conf</code> file.</p>
get.h	Describes the APIs to query and fetch data from Apache HBase tables.
hbase.h	Describes the APIs and data structures of a C client for Apache HBase.
log.h	Describes the APIs to manage Apache HBase logs.
macros.h	Defines internal macros that Apache HBase uses for its operations.
multiget.h	Describes the APIs to queue and manage multiple GET requests to fetch data from Apache HBase tables.
mutations.h	Describes the APIs for row and column mutations on Apache HBase tables.
result.h	Describes the buffers for internal temporary storage of results.
scanner.h	Describes the APIs for the client side scanner to scan and request rows from the Apache HBase server.

types.h

Defines the data types and error codes that Apache HBase uses.

C API Examples

This section provides examples using the HPE Data Fabric Database libMapRClient C API to operate on HPE Data Fabric Database binary tables.

The HPE Data Fabric Database libMapRClient C API library is Data Fabric's extension of the libhbase C API library. The libMapRClient header files are in this directory: /opt/mapr/include/hbase

Filtering SCAN Operation Results Example

This example shows filtering on the results of a SCAN operation.

```
for (uint32_t i = 0; i < num_filters; ++i) {
    hb_scanner_t scanner = NULL;
    hb_scanner_create(client, &scanner);
    hb_scanner_set_table(scanner, table_name, table_name_len);
    hb_scanner_set_num_max_rows(scanner, 3); // maximum 3 rows at a time
    hb_scanner_set_num_versions(scanner, 10); // up to 10 versions of the
cell
    hb_scanner_set_filter(scanner, (byte_t *)filters[i],
strlen(filters[i]));
    hb_scanner_next(scanner, scan_callback, NULL); // dispatch the call
    wait_for_scan();
}
```

This example uses the following array of filters:

```
static char filters[][200] = {"RandomRowFilter(0.5)",
    "ColumnCountGetFilter(2)",
    "ColumnPaginationFilter(1)",
    "ColumnPrefixFilter('column-a')",
    "FamilyFilter(=, 'binaryprefix:f')",
    "PrefixFilter('row_') AND QualifierFilter(<, 'binaryprefix:g')",
    "SKIP TimestampsFilter(1392222222222)",
    "WHILE ValueFilter(=, 'binaryprefix:cell2_value_v1')",
    "FuzzyRowFilter('row00', '00001')",
    "TimestampsFilter(1430937732000, 1431024132000)"};
```

NOTE: For more information about support for HBase Java Filters by the HPE Data Fabric Database C API, see [HBase Java Filters Support](#) on page 3668

Filtering GET Operation Results Example

This example shows filtering on the results of a GET operation.

```
{
    bytebuffer rowKey = bytebuffer_strcpy("row_with_two_cells");
    hb_get_t get = NULL;
    hb_get_create(rowKey->buffer, rowKey->length, &get);
    hb_get_add_column(get, FAMILIES[0], 1, NULL, 0);
    hb_get_add_column(get, FAMILIES[1], 1, NULL, 0);
    hb_get_set_table(get, table_name, table_name_len);
    hb_get_set_num_versions(get, 10); // up to ten versions of each column
    hb_get_set_filter(get, (byte_t *)filters[9], strlen(filters[9]));
    get_done = false;
    hb_get_send(client, get, get_callback, rowKey);
    wait_for_get();
}
```

This example uses the following array of filters:

```
static char filters[][200] = {"RandomRowFilter(0.5)",
    "ColumnCountGetFilter(2)",
    "ColumnPaginationFilter(1)",
    "ColumnPrefixFilter('column-a')",
    "FamilyFilter(=, 'binaryprefix:f')",
    "PrefixFilter('row_') AND QualifierFilter(<, 'binaryprefix:g')",
    "SKIP TimestampsFilter(1392222222222)",
    "WHILE ValueFilter(=, 'binaryprefix:cell2_value_v1')",
    "FuzzyRowFilter('row00', '00001')",
    "TimestampsFilter(1430937732000, 1431024132000)"};
}
```

NOTE: For more information about support for HBase Java Filters by the HPE Data Fabric Database C API, see [HBase Java Filters Support](#) on page 3668

Impersonation Example

This sample application demonstrates the capabilities of the new C API for impersonation.

The sample also shows how to use the API in your own programs. The application is located in the /opt/mapr/examples/interactive directory.

Prerequisite for compiling and running this sample application

Install the mapr-client package on the node where you will build the application. See [Installing the Data Fabric Client \(Non-FIPS\)](#) on page 361. If the mapr-core package is already installed, you do not need to install the mapr-client package.

Compiling this sample application

To compile and run this sample application, set the MAPR_IMPERSONATION_ENABLED environment variable to true and then read the instructions in the README file in the /opt/mapr/examples/interactive directory.

Though the application links against libjvm, a Java virtual machine (JVM) is not spawned. However, the libMapRClient does have Java dependencies.

Set Time Range Example

This example scans HPE Data Fabric Database binary tables and sets the time range.

```
int32_t scanWithTimeranges( std::string table_name, int32_t num_versions,
    uint64_t max_num_rows, std::string start_row_key,
    std::string end_row_key, int64_t min_ts, int64_t max_ts,
    std::string name_space, std::string column_name) {
    hb_scanner_t scanner = NULL;
    int32_t retCode;

    scan_num_rows = 0;
    scan_cell_count = 0;
    scan_done = false;
    // scanner object create
    hb_scanner_create(client, &scanner);

    scan_data_t *scan_data = (scan_data_t *) calloc(1,
    sizeof(scan_data_t));

    // set the table to scan
    scan_data->table_name_ = bytebuffer_printf("%s",
    table_name.c_str());
    hb_scanner_set_table(scanner, (char *)
```

```

scan_data->table_name_>buffer, scan_data->table_name_>length));

    // start and end row - optional
    scan_data->start_row_key_ = bytebuffer_printf("%s",
start_row_key.c_str());
    hb_scanner_set_start_row(scanner, scan_data->start_row_key_>buffer,
        scan_data->start_row_key_>length);

    scan_data->end_row_key_ = bytebuffer_printf("%s",
end_row_key.c_str());
    hb_scanner_set_end_row(scanner, scan_data->end_row_key_>buffer,
        scan_data->end_row_key_>length);

    // add columns
    bytebuffer cfName = bytebuffer_printf("%s",
data_qualifier[0].c_str());
    bytebuffer columnName = bytebuffer_printf("%s",
data_qualifier[1].c_str());
    retCode=hb_scanner_add_column(scanner, (byte_t
*)cfName->buffer, cfName->length, columnName->buffer, columnName->length);

    // set versions
    hb_scanner_set_num_versions(scanner, num_versions);

    // set timerange
    hb_scanner_set_timerange(scanner, min_ts, max_ts);

    // scan data
    retCode = hb_scanner_next(scanner, scan_callback, scan_data);
    return retCode;
}

```

Set Time Stamp Example

This example scans HPE Data Fabric Database binary tables and sets the time stamp.

```

int32_t scanWithTimestamp( std::string table_name, int32_t num_versions,
uint64_t max_num_rows, std::string start_row_key,
                        std::string end_row_key, int64_t ts, std::string
name_space, std::string column_name) {
    hb_scanner_t scanner = NULL;
    int32_t retCode;

    scan_num_rows = 0;
    scan_cell_count = 0;
    scan_done = false;

    // scanner object create
    hb_scanner_create(client, &scanner);

    scan_data_t *scan_data = (scan_data_t *) calloc(1,
sizeof(scan_data_t));

    // set the table to scan
    scan_data->table_name_ = bytebuffer_printf("%s",
table_name.c_str());
    hb_scanner_set_table(scanner, (char *)
scan_data->table_name_>buffer, scan_data->table_name_>length));

    // start and end row - optional
    scan_data->start_row_key_ = bytebuffer_printf("%s",
start_row_key.c_str());
    hb_scanner_set_start_row(scanner, scan_data->start_row_key_>buffer,
        scan_data->start_row_key_>length);
}

```

```

        scan_data->end_row_key_ = bytebuffer_printf("%s",
end_row_key.c_str());
        hb_scanner_set_end_row(scanner, scan_data->end_row_key_->buffer,
                                scan_data->end_row_key_->length);

        // add columns
        bytebuffer cfName = bytebuffer_printf("%s",
data_qualifier[0].c_str());
        bytebuffer columnName = bytebuffer_printf("%s",
data_qualifier[1].c_str());
        retCode=hb_scanner_add_column(scanner, (byte_t
*)cfName->buffer, cfName->length, columnName->buffer, columnName->length);

        // set versions
        hb_scanner_set_num_versions(scanner, num_versions);

        // set timestamp
        hb_scanner_set_timestamp(scanner, ts);

        // scan data
        retCode = hb_scanner_next(scanner, scan_callback, scan_data);
        return retCode;
}

```

Delete Specific Cells Example

This example deletes specific cells that correspond to a specific timestamp.

```

nt32_t deleteRowExactTS(std::string table_name, std::string row_key,
                        std::vector<std::string> data, int64_t ts) {

    int32_t retCode = 0;
    // initialize delete object
    hb_delete_t del = NULL;

    row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
    row_data->key = bytebuffer_printf("%s", row_key.c_str());
    row_data->tablename = bytebuffer_printf("%s", table_name.c_str());

    // create delete object
    hb_delete_create(row_data->key->buffer, row_data->key->length,
&del);

    cell_data_t *prevCell=NULL;
    // add cells that needs to be deleted
    for(int t=0; t < (int)data.size(); t++) {
        vector<string> data_qualifier = split(data.at(t), ':');
        cell_data_t *cell_data= new_cell_data();
        if(t==0)
            row_data->first_cell = cell_data;
        else
            prevCell->next_cell = cell_data;

        cell_data->columnFamily =
bytebuffer_printf("%s", data_qualifier[0].c_str());
        cell_data->columnName =
bytebuffer_printf("%s", data_qualifier[1].c_str());

        //add column, fam/column/ts to delete the exact version
        retCode=hb_delete_add_column_exact(del,
cell_data->columnFamily->buffer, cell_data->columnFamily->length,
cell_data->columnName->buffer, cell_data->columnName->length, ts);
    }
}

```

```

        prevCell = cell_data;
    }

    // set the table name in delete mutation object
    hb_mutation_set_table(del, (const char
*)row_data->tablename->buffer, row_data->tablename->length);

    //send the delete request
    retCode = hb_mutation_send(client, del, delete_callback, row_data);
    return retCode;
}

```

HPE Data Fabric Database Sample C Application

Data Fabric provides a sample C application that accesses and performs operations on HPE Data Fabric Database binary tables. This section describes the various operation performed by the application.

The sample C application is located in the `/opt/mapr/examples/sample` directory.

Prerequisites

In order to compile and run the sample application, install the `mapr-client` package on the node where you will build the application. See [Impersonation Example](#) on page 3652. If the `mapr-core` package is already installed, you do not need to install the `mapr-client` package.

Compiling

To compile and run the sample application, read the instructions in the README file in the `/opt/mapr/examples/sample` directory.

Set the log level and specify the log stream

APIs used

These two APIs are defined in the header file `log.h`:

- `hb_log_set_level()`: Sets the log output level. The levels are defined in the header file `types.h`.
- `hb_log_set_stream()`: Sets the location of the log output. By default, log messages are sent to `stderr`.

Code

```

hb_log_set_level(HBASE_LOG_LEVEL_DEBUG); // defaults to INFO
const char *logFilePath = getenv("HBASE_LOG_FILE");
if (logFilePath != NULL) {
    FILE* logFile = fopen(logFilePath, "a");
    if (!logFile) {
        retCode = errno;
        fprintf(stderr, "Unable to open log file \"%s\"", logFilePath);
        perror(NULL);
        goto cleanup;
    }
    hb_log_set_stream(logFile); // defaults to stderr
}

```

Log levels are specified in the header file `types.h`.

```

/**
 * Log levels
 */

```

```
typedef enum {
    HBASE_LOG_LEVEL_INVALID = 0,
    HBASE_LOG_LEVEL_FATAL   = 1,
    HBASE_LOG_LEVEL_ERROR   = 2,
    HBASE_LOG_LEVEL_WARN    = 3,
    HBASE_LOG_LEVEL_INFO    = 4,
    HBASE_LOG_LEVEL_DEBUG   = 5,
    HBASE_LOG_LEVEL_TRACE   = 6
} HBaseLogLevel;
```

Create a connection

API used: `hb_connection_create()`

Use this function to connect to the Data Fabric cluster.

This API takes three parameters:

```
const char *zk_ensemble,      /* [in] NULL terminated, comma separated
                               * string of CLDB servers. e.g.
                               * "<server1[:port]>,...". */
const char *zk_root,          /* [in] Ignored for MapR-DB. */
hb_connection_t *connection_ptr); /* [out] pointer to hb_connection_t */
```

There are two methods by which you can use the `zk_ensemble` parameter to determine how the Data Fabric client connection locates the Data Fabric cluster to connect to:

Set `zk_ensemble` to NULL to connect to the default cluster that is defined in the `mapr-clusters.conf` file.

HPE recommends this method, which uses the configuration information that is listed for the cluster in the `mapr-clusters.conf` file.

Set `zk_ensemble` to a string that includes hostnames or IP addresses.

With this method, the client application can connect to a non-default cluster explicitly. The client application searches through the `mapr-clusters.conf` file to find a cluster entry with a matching hostname/IP address. The first entry that is found to contain a matching `hostname[:port]/IP address[:port]` is used for the connection, as is the configuration information for that entry.

If none of the hostnames or IP addresses specified for `zk_ensemble` are located in entries in `mapr-clusters.conf`, or if `mapr-clusters.conf` does not exist, the client application tries to connect to the first specified `hostname[:port]/IP address[:port]`. If the client application cannot make a connection, it moves to the next specified `hostname[:port]/IP address[:port]`.

WARNING: Because no `mapr-clusters.conf` file is involved, no additional configuration information is used for connections. For example, connections made in this way cannot be secure because no security parameters are provided.

Examples

```
//connect to default cluster specified in mapr-clusters.conf (preferred)
if ((err = hb_connection_create(NULL,
                                NULL,
                                &connection)) != 0) {
    HBASE_LOG_ERROR("Could not create MapR-DB connection : errorCode = %d.",
```

```
err);
    goto cleanup;
}

//Connect directly to cluster with these specified IP addresses.
//Typically this means there is no mapr-clusters.conf and security not used.
if ((err = hb_connection_create("192.168.1.1:7222,192.168.1.2:7222",
                                NULL /* ignored */,
                                &connection)) != 0) {
    HBASE_LOG_ERROR("Could not create MapR-DB connection : errorCode = %d.",
err);
    goto cleanup;
}
```

Code in the sample application

```
if ((retCode = hb_connection_create(zk_ensemble,
                                    zk_root_znode,
                                    &connection)) != 0) {
    HBASE_LOG_ERROR("Could not create HBase connection : errorCode = %d.",
retCode);
    goto cleanup;
}
```

This API is defined in the header file `connection.h`:

Create a table

The sample application creates a table by calling a function named `ensureTable`.

APIs used

The definition of this function uses these APIs:

APIs defined in the header file `admin.h`.

- `hb_admin_table_create()`: Creates a table. Returns 0 on success or an error code.
- `hb_admin_table_delete()`: Deletes a table. Returns 0 on success or an error code.
- `hb_admin_destroy()`: Disconnects the `hb_admin` object, releasing any internal objects or connections that were created in the background.
- `hb_admin_table_disable()`: Disables an HBase table. Returns 0 on success or an error code. Only sets a flag in memory to say that the table is disabled.

NOTE: Tables never need to be disabled or enabled in HPE Data Fabric Database, which has no notion of disabling or enabling tables. However, applications ported from HBase to HPE Data Fabric Database will attempt to disable and enable tables. By placing a flag in memory, HPE Data Fabric Database allows those applications to proceed without error when performing admin functions on tables.

- `hb_admin_table_enable()`: Enables an HBase table. Returns 0 on success or an error code. As with `hb_admin_table_disable`, this function sets a flag in memory and performs no other operation.
- `hb_admin_table_enabled()`: Checks whether an HBase table is enabled. Returns 0 if the table is enabled. If the table is disabled, returns either the error message `HBASE_TABLE_DISABLED` or an error code, if an error occurs. In HPE Data Fabric Database, this API only checks for the existence of an in-memory flag that indicates whether to consider a table as disabled or enabled.

- `hb_admin_table_exists()`: Checks whether a table exists. Returns 0 on success or an error code.

APIs defined in the header file `coldesc.h`.

- `hb_coldesc_create()`: Creates a column-family descriptor. Returns a handle to an `hb_columndesc` object or NULL, if unsuccessful.
- `hb_coldesc_set_maxversions()`: Sets the maximum number of cell versions to be retained for the column family. The default is 3.
- `hb_coldesc_set_minversions()`: Sets the minimum number of cell versions to be retained for the column family. The default is 0.
- `hb_coldesc_set_ttl()`: Sets the time-to-live value in seconds for data in column cells. The default is forever.
- `hb_coldesc_set_inmemory()`: Boolean. Determines whether preference is given to values of this column family for storage with row keys. Because row keys are cached in memory in preference to row data, column-family data that is stored inline with the row keys is also cached in memory.

For all column families in a table together, up to 200 bytes of row data will be stored inline with each row key. Storing data inline with a row key might speed retrieval of the data from a column family because disk access can often be avoided. For each column family, up to 32 bytes can be stored inline with each row key even if its `inmemory` parameter is set to `false`, but preference will be given to column families where this parameter is set to `true`. A column family can have more than 32 bytes stored inline if its `inmemory` parameter is set to `true`.

If the total number of bytes for all column families together exceeds 200 for a row, then preference for inclusion within the inline storage for that row is given to column families that have the `inmemory` parameter set to `true`. All of the data for a column family will be stored in-line with the row key, or none will be. If the contents in a column family for a particular row are larger than the maximum number of bytes that are allowed to be stored for that column family, no data at all will be stored in-line for that column family.

The default value for the `inmemory` parameter is `false`.

- `hb_coldesc_destroy()`: Releases resources that are held by a column-family descriptor.

Sequence of steps in the `ensureTable` function

1. Create an admin handle from the connection.
2. Using the admin handle, check whether the specified table exists.
3. If the table exists, delete it.
4. Specify columns and column families for the table.
5. Create the table.
6. Check whether the table is enabled. If it isn't enabled, enable it.
7. Disable the table and then enable it again.
8. Destroy the column descriptors.
9. Destroy the `hb_admin` structure.

Code for the ensureTable function at line 325

```

static int
ensureTable(hb_connection_t connection, const char *table_name) {
    int32_t retCode = 0;
    hb_admin_t admin = NULL;

    if ((retCode = hb_admin_create(connection, &admin)) != 0) {
        HBASE_LOG_ERROR("Could not create HBase admin : errorCode = %d.",
retCode);
        goto cleanup;
    }

    if ((retCode = hb_admin_table_exists(admin, NULL, table_name)) == 0) {
        HBASE_LOG_INFO("Table '%s' exists, deleting...", table_name);
        if ((retCode = hb_admin_table_delete(admin, NULL, table_name)) != 0) {
            HBASE_LOG_ERROR("Could not delete table %s[%d].", table_name,
retCode);
            goto cleanup;
        }
    } else if (retCode != ENOENT) {
        HBASE_LOG_ERROR("Error while checking if the table exists: errorCode =
%d.", retCode);
        goto cleanup;
    }

    hb_coldesc_create(FAMILIES[0], 1, &HCD[0]);
    hb_coldesc_set_maxversions(HCD[0], 2);
    hb_coldesc_set_minversions(HCD[0], 1);
    hb_coldesc_set_ttl(HCD[0], 2147480000);
    hb_coldesc_set_inmemory(HCD[0], 1);

    hb_coldesc_create(FAMILIES[1], 1, &HCD[1]);

    HBASE_LOG_INFO("Creating table '%s'...", table_name);
    if ((retCode = hb_admin_table_create(admin, NULL, table_name, HCD, 2)) ==
0) {
        HBASE_LOG_INFO("Table '%s' created, verifying if enabled.", table_name);
        retCode = hb_admin_table_enabled(admin, NULL, table_name);
        CHECK_API_ERROR(retCode,
            "Table '%s' is %senabled, result %d.", table_name, retCode?"not
":"");
        retCode = hb_admin_table_disable(admin, NULL, table_name);
        CHECK_API_ERROR(retCode,
            "Attempted to disable table '%s', result %d.", table_name);
        retCode = hb_admin_table_disable(admin, NULL, table_name);
        CHECK_API_ERROR(retCode,
            "Attempted to disable table '%s' again, result %d.", table_name);
        retCode = hb_admin_table_enable(admin, NULL, table_name);
        CHECK_API_ERROR(retCode,
            "Attempted to enable table '%s', result %d.", table_name);
        retCode = hb_admin_table_enable(admin, NULL, table_name);
        CHECK_API_ERROR(retCode,
            "Attempted to enable table '%s' again, result %d.", table_name);
    }
    hb_coldesc_destroy(HCD[0]);
    hb_coldesc_destroy(HCD[1]);

cleanup:
    if (admin) {
        hb_admin_destroy(admin, NULL, NULL);
    }
}

```

```
    return retCode;
}
```

Code to call the ensureTable function

```
if ((retCode = ensureTable(connection, table_name)) != 0) {
    HBASE_LOG_ERROR("Failed to ensure table %s : errorCode = %d", table_name,
retCode);
    goto cleanup;
}
```

Create a client

API used

`hb_client_create()`: Initializes a handle to `hb_client_t` object that can be passed to other APIs. You need to use this method only once per cluster. The returned handle is thread-safe. This API is defined in the `client.h` header file.

Code

```
if ((retCode = hb_client_create(connection, &client)) != 0) {
    HBASE_LOG_ERROR("Could not connect to HBase cluster : errorCode = %d.",
retCode);
    goto cleanup;
}
```

Asynchronously put ten rows of one cell each

APIs used in this operation

The first 6 APIs are defined in the header file `mutations.h`:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the name of the table for the put operation.
- `hb_mutation_set_bufferable()`: Sets whether or not the RPC call for the put operation can be buffered on the client side.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

The last API is defined in the header file `client.h`:

- `hb_client_flush()`: Flushes any buffered client-side write operations to the server. The callback is invoked after everything that was buffered at the time of the call is flushed. Invocation of the callback is a guarantee that all outstanding RPC calls are complete.

Sequence of steps in this code extract

1. Create a row object named `row_data`.
2. Create a put object.

3. Specify the name of the table.
4. Set whether or not the RPC call for the put operation can be buffered on the client side.
5. Create cell data.
6. Create a cell.
7. Add the cell to the row.
8. Queue the put.
9. After following the steps above 10 times, flush the puts to the server.
10. Wait for the RPC calls to complete.

Code

```
// let's send a batch of 10 puts with single cell asynchronously
outstanding_puts_count += num_puts;
for (int i = 0; i < num_puts; ++i) {
    row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
    row_data->key = bytebuffer_printf("%s%02d", rowkey_prefix, i);
    hb_put_create(row_data->key->buffer, row_data->key->length, &put);
    hb_mutation_set_table(put, table_name, table_name_len);
    hb_mutation_set_durability(put, DURABILITY_SKIP_WAL);
    hb_mutation_set_bufferable(put, false);

    cell_data_t *cell_data = new_cell_data();
    row_data->first_cell = cell_data;
    cell_data->value = bytebuffer_printf("%s%02d", value_prefix, i);

    hb_cell_t *cell = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
    cell_data->hb_cell = cell;

    cell->row = row_data->key->buffer;
    cell->row_len = row_data->key->length;
    cell->family = FAMILIES[rand() % 2];
    cell->family_len = 1;
    cell->qualifier = column_a->buffer;
    cell->qualifier_len = column_a->length;
    cell->value = cell_data->value->buffer;
    cell->value_len = cell_data->value->length;
    cell->ts = HBASE_LATEST_TIMESTAMP;

    hb_put_add_cell(put, cell);
    HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                  cell->row_len, cell->row);
    hb_mutation_send(client, put, put_callback, row_data);
}
hb_client_flush(client, client_flush_callback, NULL);
wait_for_flush();

wait_for_puts(); // outside the loop, wait for 10 puts to complete
```

Asynchronously put two cells in a single row

APIs used

These APIs are defined in the header file `mutations.h`:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.

- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a row object named `row_data`.
2. Create a put object.
3. Specify the name of the table.
4. Create cell data for the first cell.
5. Create the first cell.
6. Add the data to the first cell.
7. Add the first cell to the row.
8. Create cell data for the second cell.
9. Create the second cell.
10. Add the data to the second cell.
11. Add the second cell to the row.
12. Queue the put.
13. Wait 3 seconds, flush the queue, and wait for the RPC calls to complete.

`wait_for_puts()` without `hb_client_flush()`: Waits for all outstanding put requests to be flushed. If `hb_client_flush()` is not called before `wait_for_puts()`, it can take up to three seconds for outstanding put requests to be flushed.

Code

```
// now, let's put two cells in a single row
outstanding_puts_count++;
{
    row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
    row_data->key = bytebuffer_printf("row_with_two_cells");
    hb_put_create(row_data->key->buffer, row_data->key->length, &put);
    hb_mutation_set_table(put, table_name, table_name_len);
    hb_mutation_set_durability(put, DURABILITY_SYNC_WAL);

    // first cell
    cell_data_t *cell1_data = new_cell_data();
    row_data->first_cell = cell1_data;
    cell1_data->value = bytebuffer_printf("cell1_value_v1");

    hb_cell_t *cell1 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
    cell1_data->hb_cell = cell1;
```

```

cell1->row = row_data->key->buffer;
cell1->row_len = row_data->key->length;
cell1->family = FAMILIES[0];
cell1->family_len = 1;
cell1->qualifier = column_a->buffer;
cell1->qualifier_len = column_a->length;
cell1->value = cell1_data->value->buffer;
cell1->value_len = cell1_data->value->length;
cell1->ts = 1391111111111L;
hb_put_add_cell(put, cell1);

// second cell
cell_data_t *cell2_data = new_cell_data();
cell1_data->next_cell = cell2_data;
cell2_data->value = bytebuffer_printf("cell2_value_v1");

hb_cell_t *cell2 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
cell2_data->hb_cell = cell2;

cell2->row = row_data->key->buffer;
cell2->row_len = row_data->key->length;
cell2->family = FAMILIES[1];
cell2->family_len = 1;
cell2->qualifier = column_b->buffer;
cell2->qualifier_len = column_b->length;
cell2->value = cell2_data->value->buffer;
cell2->value_len = cell2_data->value->length;
cell2->ts = 1391111111111L;
hb_put_add_cell(put, cell2);

HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                cell1->row_len, cell1->row);
hb_mutation_send(client, put, put_callback, row_data);
wait_for_puts();
}

```

Asynchronously put a second version in one column of one row

APIs used

These APIs are defined in the header file mutations.h:

- `hb_put_create()`: Creates a structure for the put operation and returns its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_put_add_cell()`: Adds a cell to the put structure. The row key of the cell must be the same as the row key of the put structure.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a row object named `row_data`.
2. Create a put object.
3. Specify the name of the table.

4. Create cell data for the first cell.
5. Create the first cell.
6. Add the data to the cell, using a later timestamp than in the previous operation.
7. Add the first cell to the row.
8. Queue the put.
9. Wait 3 seconds, flush the queue, and wait for the RPC calls to complete.

Code

```
// now, let's put second version in one column
outstanding_puts_count++;
{
    row_data_t *row_data = (row_data_t *) calloc(1, sizeof(row_data_t));
    row_data->key = bytebuffer_printf("row_with_two_cells");
    hb_put_create(row_data->key->buffer, row_data->key->length, &put);
    hb_mutation_set_table(put, table_name, table_name_len);
    hb_mutation_set_durability(put, DURABILITY_SYNC_WAL);

    // first cell
    cell_data_t *cell1_data = new_cell_data();
    row_data->first_cell = cell1_data;
    cell1_data->value = bytebuffer_printf("cell1_value_v2");

    hb_cell_t *cell1 = (hb_cell_t*) calloc(1, sizeof(hb_cell_t));
    cell1_data->hb_cell = cell1;

    cell1->row = row_data->key->buffer;
    cell1->row_len = row_data->key->length;
    cell1->family = FAMILIES[0];
    cell1->family_len = 1;
    cell1->qualifier = column_a->buffer;
    cell1->qualifier_len = column_a->length;
    cell1->value = cell1_data->value->buffer;
    cell1->value_len = cell1_data->value->length;
    cell1->ts = 1392222222222L;
    hb_put_add_cell(put, cell1);

    HBASE_LOG_INFO("Sending row with row key : '%.*s'.",
                   cell1->row_len, cell1->row);
    hb_mutation_send(client, put, put_callback, row_data);
    wait_for_puts();
}
```

Scan the entire table

APIs used

These APIs and more are defined in the header file `scanner.h`:

- `hb_scanner_create()`: Creates a client side row scanner. The returned scanner is not thread safe. No RPC will be invoked until the call to fetch the next set of rows is made. You can set the various attributes of this scanner until that point. @returns 0 on success, non-zero error code in case of failure.
- `hb_scanner_next()`: Request the next set of results from the server. You can set the maximum number of rows returned by this call using `hb_scanner_set_num_max_rows()`.

- `hb_scanner_num_max_rows()`: Sets the maximum number of rows to scan per call to `hb_scanner_next()`.
- `hb_scanner_num_versions()`: Sets the maximum versions of a column to fetch.
- `hb_scanner_set_table()`: Sets the name of the table to scan.

Sequence of steps

1. Create the scanner object.
2. Set the name of the table to scan.
3. Set the number of rows to scan at a time.
4. Set the number of versions to scan.
5. Request the next set of results from the server.
6. `wait_for_scan()`: wait for the rpc call to complete.

Code

```
// now, scan the entire table
{
    hb_scanner_t scanner = NULL;
    hb_scanner_create(client, &scanner);
    hb_scanner_set_table(scanner, table_name, table_name_len);
    hb_scanner_set_num_max_rows(scanner, 3); // maximum 3 rows at a time
    hb_scanner_set_num_versions(scanner, 10); // up to 10 versions of the
cell
    hb_scanner_next(scanner, scan_callback, NULL); // dispatch the call
    wait_for_scan();
}
```

Fetch a row that has two cells

APIs used

- `hb_get_add_column()`: Adds a column family and optionally a column qualifier to an `hb_get_t` object.
- `hb_get_create()`: Creates an `hb_get_t` object and populates the handle `get_ptr`.
- `hb_get_send()`: Queues the get request. The callback specified by `cb` is called on completion. Any buffers attached to the get object can be reclaimed only after the callback is received.
- `hb_get_set_num_versions()`: Sets maximum number of latest values of each column to be fetched. This API is optional.
- `hb_get_set_table()`: Sets the name of the table to get data from.

Sequence of steps

1. Create a row object named `rowKey`.
2. Create a get object.
3. Specify the column families and optional column qualifiers to get values from.

4. Specify the name of the table.
5. Specify the number of versions of the column values to get.
6. Queue the get request.
7. Wait for the get to complete.

Code

```
// fetch a row with row-key="row_with_two_cells"
{
    bytearray rowKey = bytearray_strcpy("row_with_two_cells");
    hb_get_t get = NULL;
    hb_get_create(rowKey->buffer, rowKey->length, &get);
    hb_get_add_column(get, FAMILIES[0], 1, NULL, 0);
    hb_get_add_column(get, FAMILIES[1], 1, NULL, 0);
    hb_get_set_table(get, table_name, table_name_len);
    hb_get_set_num_versions(get, 10); // up to ten versions of each column
    get_done = false;
    hb_get_send(client, get, get_callback, rowKey);
    wait_for_get();
}
```

Delete a specific version of a column in the row that was fetched

APIs used

The APIs that are used are defined in the header file `mutations.h`.

- `hb_delete_add_column()`: Set the column criteria for `hb_delete_t` object. Set the qualifier to `NULL` to delete all columns of a family. Only the cells with timestamp less than or equal to the specified timestamp are deleted. Set the timestamp to `INT64_MAX` to delete all versions of the column. This API is optional for deletes.
- `hb_delete_create()`: Creates a structure for delete operation and return its handle.
- `hb_mutation_set_table()`: Sets the table name for the mutation.
- `hb_mutation_send()`: Queues the put operation for sending to the server. Mutations are not performed atomically and can be batched in a non-deterministic way on either the client side or the server side. Any buffer attached to a mutation object (put or delete) must not be altered until the callback has been received.

Sequence of steps

1. Create a delete object for a row with a particular row key.
2. Add a column to the delete object.
3. Specify the name of the table from which to delete the cell version.
4. Queue the delete.
5. Wait three seconds for the delete to be flushed, then wait for the RPC call to complete.

Code

```
// delete a specific version of a column
{
    bytebuffer rowKey = bytearray_strcpy("row_with_two_cells");
    hb_delete_t del = NULL;
    hb_delete_create(rowKey->buffer, rowKey->length, &del);
    hb_delete_add_column(del, FAMILIES[0], 1,
        column_a->buffer, column_a->length, 139111111112L);
    hb_mutation_set_table(del, table_name, table_name_len);
    delete_done = false;
    hb_mutation_send(client, del, delete_callback, rowKey);
    wait_for_delete();
}
```

Destroy the client and the connection

APIs used

- `hb_client_destroy()`: Cleans up `hb_client_t` handle and releases any held resources. The callback is called after the connections are closed, but just before the client is freed. This API is defined in the header file `client.h`.
- `hb_connection_destroy()`: Destroys the connection and frees all resources allocated at creation time. This API is defined in the header file `connection.h`.

Sequence of steps

1. Destroy the client.
2. Destroy the connection.

Code

```
if (client) {
    HBASE_LOG_INFO("Disconnecting client.");
    hb_client_destroy(client, client_disconnection_callback, NULL);
    wait_client_disconnection();
}
if (connection) {
    hb_connection_destroy(connection);
}
```

Building and Launching C Applications

This topic describes basic setup for building and launching C application using the `libMapRClient` C API library

Prerequisites

The HPE Data Fabric Database `libMapRClient` C API library is Data Fabric's extension of the `libhbase` C API library). The `libMapRClient` header files are in this directory: **`/opt/mapr/include/hbase`**

- Verify that the `mapr-client` package is installed on the node. The `mapr-client` package must be installed on each node that builds an application. The `libMapRClient` header files are in this directory: `/opt/mapr/include/hbase`.
- Verify that both the `libMapRClient` library and `libjvm` shared libraries are in the application's library search path.

Building Applications

When building applications that use `libMapRClient`, run this command:

```
gcc -o <application_name> <source_file> -I/opt/mapr/include/hbase -L/opt/mapr/lib/ -lMapRClient -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

For example, the following command builds the `hello_hbase` application with the `hello_hbase.c` source code:

```
gcc -o hello_hbase hello_hbase.c -I/opt/mapr/include/hbase -L/opt/mapr/lib/ -lMapRClient -L/usr/lib/jvm/java-7-sun/jre/lib/amd64/server -ljvm
```

NOTE:

- The compiled `libMapRClient` is statically linked to the following third-party libraries: Crypto++: `libcryptoapp.a` (v5.6.2) Protobuf: `libprotobuf-lite.a` (v2.5.0)
- The `libMapRClient` library has dependencies on `libjvm`, though a JVM is not instantiated. In general, the `libjvm` library is located within the JDK/JRE installation directory.

Launching Applications

Before launching an application, set this value for the environment variable `LD_LIBRARY_PATH`:

```
/opt/mapr/lib:/usr/lib/jvm/java-6-openjdk-amd64/jre/lib/amd64/server
```

If the client is on Windows, append the following directories to the `PATH` environment variable:

- `$MAPR_HOME/lib`
- `$JAVA_HOME/bin/server`

If the application uses the `hb_connection_create_as_user` API for impersonation, set the `MAPR_IMPERSONATION_ENABLED` environment variable to `true`.

What To Do Next

Launch the application!

HBase Java Filters Support

The `hb_get_set_filter()` and `hb_scanner_set_filter()` C APIs are used to filter the results of GET and SCAN operations. These APIs are in the `get.h` and `scanner.h` header files.

They both take filters that are passed as strings, as well as the length of these strings. HPE Data Fabric Database parses the strings to construct filters.

Their signatures are:

```
int32_t hb_get_set_filter(hb_get_t get, const byte_t *filter, const int32_t filterLen);
int32_t hb_scanner_set_filter(hb_scanner_t scanner, const byte_t *filter, const int32_t filterLen);
```

For examples, see [Filtering GET Operation Results Example](#) on page 3651 and [Filtering SCAN Operation Results Example](#) on page 3651.

Filter Format and Arguments

Filters are specified in the Thrift Filter Language and are in this format: `FilterName (argument, argument, ... , argument)`. Arguments that represent strings are enclosed in single quotation marks

('). Arguments that represent booleans, integers, or comparison operators (<, <=, =, !=, >, >=) are not enclosed in single quotation marks.

Binary Operators

You can combine filters by using the binary operators AND and OR. For example, `PrefixFilter ('Row') AND PageFilter (1) AND FirstKeyOnlyFilter ()` returns all key-value pairs that match the following conditions:

- The row containing the key-value must start with the prefix "Row".
- The key-value must be located in the first row of the table.
- The key-value must be the first key-value pair in the row.

For another example, `(RowFilter (=, 'binary:Row 1') AND TimeStampsFilter (74689, 89734)) OR ColumnRangeFilter ('abc', true, 'xyz', false))` returns all key-value pairs that

Match both of the following conditions:

- The key-value is in a row for which the row key is "Row 1".
- The key-value has a timestamp of either 74689 or 89734.

Or match this condition:

- The key-value is located in a column that is lexicographically greater than or equal to "abc" and less than "xyz".

Unary Operators

You can also use the following unary operators with filters:

- SKIP

For a particular row, if any of the key-values don't pass the filter condition, the entire row is skipped. For example, `SKIP ValueFilter (0)` omits rows in which any values are not 0.

- WHILE

Rows are tested in order against the filter condition. Rows that meet the condition are included in the result set. When a row fails to meet the condition, filter processing stops and no more rows are tested.

Evaluation of Filters

When filters are combined with the binary operators, unary operators, or both, they are evaluated according to these rules:

1. First, evaluate the contents of parentheses.
2. Next, evaluate filters that use unary operators. Both SKIP and WHILE operators have the same precedence.
3. Finally, evaluate filters that use the binary operators. AND has higher precedence than OR.

For example, in a filter of the form `Filter1 AND Filter2 OR Filter3`, `Filter1 AND Filter2` is evaluated and the result is X. Then, `X OR Filter3` is evaluated.

For another example, a filter of the form `Filter1 AND SKIP Filter2 OR Filter3` is evaluated in these steps:

1. Evaluate `SKIP Filter2` with the result being X.

2. Evaluate `Filter1 AND X` with the result being `Y`.

3. Evaluate `Y OR Filter3`.

Compare Operators and Comparators

This topic describes the compare operators and comparators for comparison filters.

The comparison filters `DependentColumnFilter`, `FamilyFilter`, `QualifierFilter`, `RowFilter`, and `ValueFilter` use the following syntax:

```
filter(<compareOperator>, <comparatorType:Value>)
```

Compare Operators

The following compare operators are supported: `<`, `<=`, `=`, `!=`, `>`, `>=`

Comparators

There are four comparators:

Comparator	Description
BinaryComparator	<p>This comparator lexicographically compares against the specified byte array.</p> <p>Values are byte arrays.</p> <p>For example, <code>binary:abc</code> matches values that are lexicographically greater than "abc".</p>
BinaryPrefixComparator	<p>This comparator lexicographically compares against a specified byte array. It only compares up to the length of this byte array.</p> <p>Values are byte arrays.</p> <p>For example, <code>binaryprefix:abc</code> matches values in which the first 3 characters are lexicographically equal to "abc".</p>
RegexStringComparator	<p>This comparator compares against the specified byte array using the given regular expression.</p> <p>You can use only the <code>=</code> and <code>!=</code> compare operators with this comparator.</p> <p>Values are regular expressions.</p> <p>For example, <code>regexstring:ab*yz</code> matches values that begin with "ab" and end with "yz".</p>
SubStringComparator	<p>This comparator tests whether the given substring appears in a specified byte array. The comparison is case insensitive.</p> <p>You can use only the <code>=</code> and <code>!=</code> compare operators with this comparator.</p> <p>Values are strings.</p> <p>For example, <code>substring:abc123</code> matches values that contain the substring "abc123".</p>

Supported Filters

Filter	Format	Description
ColumnCountGetFilter	ColumnCountGetFilter(<i>x</i>)	Returns the first <i>x</i> columns in a row. Used for GET operations.
ColumnPaginationFilter	ColumnPaginationFilter(<i>x</i> , <i>y</i>)	Returns the first <i>x</i> columns after the number <i>y</i> of columns that is specified for the offset.
ColumnPrefixFilter	ColumnPrefixFilter('prefix')	Returns only those key-values in columns that have names that start with the specified prefix. The column prefix must be of the form "qualifier".
ColumnRangeFilter	ColumnRangFilter('minColumn', 'maxColumn', <i>boolean</i> , <i>boolean</i>)	<p>Returns only those key-values that are in columns that have names between minColumn and maxColumn.</p> <p>For example, if minColumn is 'an', and maxColumn is 'be', the filter returns key-values from columns named 'ana', 'bad', but not from columns named 'bed' or 'eye'. If minColumn is null, there is no lower bound. If maxColumn is null, there is no upper bound.</p> <p>This filter also takes two boolean variables to indicate whether to include the minColumn and maxColumn.</p>
DependentColumnFilter	DependentColumnFilter('family', 'qualifier')	Tries to locate the specified column in each row and returns all key-values that have the same timestamp in that column. If a row does not contain the specified column, none of the key-values in that row are returned.
FamilyFilter	FamilyFilter(<i>compareOperator</i> , 'comparator:value')	Filters by column family. If the comparison returns true, the filter returns all of the key-values in the matching column family.
FirstKeyOnlyFilter	FirstKeyOnlyFilter()	Returns the first key-value from each row.
FirstKeyValueMatchingQualifiersFilter	FirstKeyValueMatchingQualifier('qualifier_1', 'qualifier_2', ... 'qualifier_n')	Serially compares each qualifier in a row with the given qualifiers. If the current qualifier matches any of the given qualifiers, the filter stops and includes the current row (up to the current qualifier) in the result set.

Filter	Format	Description
FuzzyRowFilter	<code>FuzzyRowFilter('rowkey', 'fuzzy_info')</code>	<p>Filters data based on fuzzy row key. Performs fast-forwards during scanning. It takes pairs (row key, fuzzy info) to match row keys. Where fuzzy info is a byte array with 0 or 1 as its values:</p> <p>0 - means that this byte in provided row key is fixed, i.e. row key's byte at same position must match</p> <p>1 - means that this byte in provided row key is NOT fixed, i.e. row key's byte at this position can be different from the one in provided row key</p> <p>Example: Let's assume row key format is <code>userId_actionId_year_month</code>. Length of <code>userId</code> is fixed and is 4, length of <code>actionId</code> is 2 and year and month are 4 and 2 bytes long respectively. Let's assume that we need to fetch all users that performed certain action (encoded as "99") in Jan of any year. Then the pair (row key, fuzzy info) would be the following: row key = <code>"????_99_????_01"</code> (one can use any value instead of "?") fuzzy info = <code>"\x01\x01\x01\x01\x00\x00\x00\x00\x01\x01\x01\x01\x00\x00\x00"</code> i.e. fuzzy info tells the matching mask is <code>"????_99_????_01"</code>, where at ? can be any value.</p>
InclusiveStopFilter	<code>InclusiveStopFilter('rowKey')</code>	Returns all key-values that are in the rows up to and including the specified row that has the specified row key.
KeyOnlyFilter	<code>KeyOnlyFilter()</code>	Returns the key component of each key-value.
MultipleColumnPrefixFilter	<code>MultipleColumnPrefixFilter('prefix_1', 'prefix_2', ..., 'prefix_n')</code>	Returns the key-values from columns that have names that begin with any of the specified prefixes.
PageFilter	<code>PageFilter(pageSize)</code>	Returns the number of rows that is equivalent to the specified page size..
PrefixFilter	<code>PrefixFilter('rowKey_prefix')</code>	Returns the key-values from a row that has a key which starts with the specified row-key prefix.
QualifierFilter	<code>QualifierFilter(compareOperator, 'comparator:value')</code>	Filters by column. If the comparison returns true, the filter returns all of the key-values in the matching column.
RandomRowFilter	<code>RandomRowFilter(probability)</code>	Filters by probability. For example, <code>RandomRowFilter(0.25)</code> means that there is a 1 in 4 chance that the filter will pick the first row, a 1 in 4 chance that the filter will pick the next row, and so on until all rows in the table have been processed in this way.

Filter	Format	Description
RowFilter	<code>RowFilter(compareOperator, 'comparator:value')</code>	Filters by row key. If the comparison returns true, the filter returns all of the key-values in the matching row.
SingleColumnValueExcludeFilter	<code>SingleColumnValueExcludeFilter('columnFamily', 'qualifier', compareOperator, 'comparator:value')</code>	This filter takes the same arguments and behaves the same as <code>SingleColumnValueFilter</code> : however, if the column is found and the condition passes, all of the columns of the row will be returned except for the tested column value.
SingleColumnValueFilter	<code>SingleColumnValueFilter('columnFamily', 'qualifier', compareOperator, 'comparator:value')</code>	This filter takes a column family, a qualifier, a compare operator and a comparator. If the specified column is not found: all of the columns of that row will be emitted. If the column is found and the comparison with the comparator returns true, all of the columns of the row will be emitted. If the condition fails, the row will not be returned.
SkipFilter	<code>SKIP filter</code>	See the description of the SKIP unary operator above .
TimeStampsFilter	<code>TimeStampsFilter('timestamp_1', 'timestamp_2', ..., 'timestamp_n')</code>	Returns the key-values that have timestamps that match any of the specified timestamps.
ValueFilter	<code>ValueFilter(compareOperator, 'comparator:value')</code>	Filters by key-value. If the comparison returns true, the filter returns the matching key-value.
WhileMatchFilter	<code>WHILE filter</code>	See the description of the WHILE unary operator above .

Creating Java Apps - Binary Tables

This topics describes the supported Apache HBase Java APIs used for CRUD operations on HPE Data Fabric Database [binary tables](#).

HPE Data Fabric Database supports all of the Apache HBase 1.0 Java APIs, except where noted in this documentation. For a number of critical Java APIs, for filters, and for comparators, this documentation explicitly lists what is supported, rather than what is not supported.

Code written for Apache HBase can be easily ported to use HPE Data Fabric Database binary tables.

HPE Data Fabric Database binary tables do not support low-level HBase API calls that are used to manipulate the state of an Apache HBase cluster. HBase API calls that are not supported by HPE Data Fabric Database tables report successful completion to allow legacy code written for Apache HBase to continue executing, but do not perform any actual operations.

NOTE: For the list of supported HBase v0.98 APIs, refer to the [HBase Java API Support](#) on page 3675.

Compiling and Running HPE Data Fabric Database Binary Applications

For applications that use the HPE Data Fabric Database Java API for binary tables, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

Compile and Determine Dependencies

1. Add the Data Fabric maven repository to the list of repositories in your application's `pom.xml`, if it is not there already:

```
<repository>
  <id>mapr-releases</id>
  <url>https://repository.mapr.com/maven/</url>
  <snapshots><enabled>true</enabled></snapshots>
  <releases><enabled>true</enabled></releases>
</repository>
```

For more information, see [Maven Artifacts for the HPE Data Fabric](#) on page 5559.

2. Add a dependency to the HBase client project:

```
<dependencies>
<dependency>
  <groupId>org.apache.hbase</groupId>
  <artifactId>hbase-client</artifactId>
  <version><version selected from the repository></version>
</dependency>
</dependencies>
```

NOTE:

- The hbase-client version mentioned above is an example. The actual version that your application requires is based on the current EEP and Data Fabric core version that you are running. The file versions are listed in the following location: <https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/hbase/hbase-client/> Ensure that the version tags include reference to m7-<maprversion>. Otherwise, your applications will not be able to access HPE Data Fabric Database binary tables.
- If your application uses both the HPE Data Fabric Database JSON and HPE Data Fabric Database Binary APIs, you may encounter a conflict in the netty library used by each API. To avoid this, exclude the netty library from your hbase-client dependency as follows:

```
<dependency>
  <groupId>org.apache.hbase</groupId>
  <artifactId>hbase-client</artifactId>
  <version><version selected from the repository></version>
  <exclusions>
    <exclusion>
      <artifactId>netty-all</artifactId>
      <groupId>io.netty</groupId>
    </exclusion>
  </exclusions>
</dependency>
```

3. Use Maven to compile the application and resolve dependencies. For example, you can run `mvn clean package`.

Running Applications

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see [Using the File System JAR to Connect to the Cluster](#) on page 3562.

If the cluster is secure, the node must also have a Data Fabric ticket configured for the user that runs the application. See [Managing Tickets](#) on page 2100.

You can use the following command to launch HPE Data Fabric Database binary applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

NOTE: The classpath should include items that are part of the 'hbase classpath' script plus any other required dependencies.

HBase Java API Support

This topic describes the methods in the Apache HBase Java API library that are supported for HPE Data Fabric Database tables.

Admin Method Support

This topic lists the methods that the HPE Data Fabric Database supports in the HBase interface Admin.

The HPE Data Fabric Database tables support the following HBase methods, except where noted.

abort(String why, Throwable e)

Modifier and Type: void

Purpose: Aborts the server or client

Supported: No

addColumn(TableName tableName, HColumnDescriptor column)

Modifier and Type: void

Purpose: Adds a column to an existing table

Supported: Yes

assign(byte[] regionName)

Modifier and Type: void

Purpose: Assigns a region

Supported: No

balancer()

Modifier and Type: boolean

Purpose: Invokes the balancer

NOTE: The HPE Data Fabric Database does not require balancing. Therefore, the method is ignored.

Supported: No

cloneSnapshot(byte[] snapshotName, TableName tableName)

Modifier and Type: void

Purpose: Creates a new table by cloning the snapshot content

Supported: No

cloneSnapshot(String snapshotName, TableName tableName)

Modifier and Type: void

Purpose: Creates a new table by cloning the snapshot content

Supported: No

close()

Modifier and Type: void

	<i>Purpose:</i> Releases any resources held
	<i>Supported:</i> Yes
closeRegion(byte[] regionname, String serverName)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Closes a region
	<i>Supported:</i> No
closeRegion(ServerName sn, HRegionInfo hri)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Closes a region
	<i>Supported:</i> No
closeRegion(String regionname, String serverName)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Closes a region
	<i>Supported:</i> No
closeRegionWithEncodedRegionName(String encodedRegionName, String serverName)	<i>Modifier and Type:</i> boolean
	<i>Purpose:</i> For expert administrators.
	<i>Supported:</i> No
compact(TableName tableName, byte[] columnFamily)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Compacts a column family within a table
	<i>Supported:</i> No
compact(TableName tableName)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Compacts a table
	<i>Supported:</i> No
compactRegion(byte[] regionName, byte[] columnFamily)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Compacts a column family within a region
	<i>Supported:</i> No
compactRegion(byte[] regionName)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Compacts an individual region
	<i>Supported:</i> No
compactRegionServer(ServerName sn, boolean major)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Compacts all regions on the region server
	<i>Supported:</i> No
coprocessorService()	<i>Modifier and Type:</i> CoprocessorRpcChannel
	<i>Purpose:</i> Creates and returns a RpcChannel instance connected to the active master
	<i>Supported:</i> No
coprocessorService(ServerName sn)	<i>Modifier and Type:</i> CoprocessorRpcChannel
	<i>Purpose:</i> Creates and returns a RpcChannel instance connected to the active master
	<i>Supported:</i> No
createNamespace(NamespaceDescriptor descriptor)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Creates a new namespace
	<i>Supported:</i> No
createTable(HTableDescriptor desc, byte[] startKey, byte[] endKey, int numRegions)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Creates a new table with the specified number of regions

createTable(HTableDescriptor desc, byte[][] splitKeys)	<p><i>Supported:</i> Yes</p> <p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Creates a new table with an initial set of empty regions defined by the specified split keys</p> <p><i>Supported:</i> Yes</p>
createTable(HTableDescriptor desc)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Creates a new table</p> <p><i>Supported:</i> Yes</p>
createTableAsync(HTableDescriptor desc, byte[][] splitKeys)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Creates a new table but does not block and wait for it to come online</p> <p> NOTE: The HPE Data Fabric Database treats this method as synchronous and returns null when the table is created.</p>
deleteColumn(String tableName, String columnName)	<p><i>Supported:</i> Yes</p> <p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes a column from a table</p> <p><i>Supported:</i> Yes</p>
deleteColumn(TableName tableName, byte[] columnName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes a column from a table</p> <p><i>Supported:</i> Yes</p>
deleteNamespace(String name)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes an existing namespace.</p> <p><i>Supported:</i> No</p>
deleteSnapshot(byte[] snapshotName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes an existing snapshot</p> <p><i>Supported:</i> No</p>
deleteSnapshot(String snapshotName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes an existing snapshot</p> <p><i>Supported:</i> No</p>
deleteSnapshots(Pattern pattern)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes existing snapshots whose names match the specified pattern</p> <p><i>Supported:</i> No</p>
deleteSnapshots(String regex)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes existing snapshots whose names match the specified pattern</p> <p><i>Supported:</i> No</p>
deleteTable(String tableName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes a table</p> <p><i>Supported:</i> Yes</p>
deleteTable(byte[] tableName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes a table</p> <p><i>Supported:</i> Yes</p>

deleteTable(TableName tableName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Deletes a table</p> <p><i>Supported:</i> Yes</p>
deleteTables(Pattern pattern)	<p><i>Modifier and Type:</i> HTableDescriptor[]</p> <p><i>Purpose:</i> Delete tables that match the passed-in pattern, and waits on completion</p> <p><i>Supported:</i> Yes</p>
deleteTables(String regex)	<p><i>Modifier and Type:</i> HTableDescriptor[]</p> <p><i>Purpose:</i> Delete tables that match the passed-in regular expression, and waits on completion</p> <p><i>Supported:</i> Yes</p>
disableTable (String tableName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Disables table, and waits for completion</p> <p> NOTE: The HPE Data Fabric Database does not require disabling of tables. Therefore, although it supports these methods, it only flags the table as disabled, and does not perform any other operation.</p> <p><i>Supported:</i> Yes</p>
disableTable(TableName tableName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Disables table, and waits for completion</p> <p> NOTE: The HPE Data Fabric Database does not require disabling of tables. Therefore, although it supports these methods, it only flags the table as disabled, and does not perform any other operation.</p> <p><i>Supported:</i> Yes</p>
disableTableAsync (String tableName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Disables the table, but does not block and wait for it be completely disabled</p> <p><i>Supported:</i> Yes</p>
disableTableAsync(TableName tableName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Disables the table, but does not block and wait for it be completely disabled</p> <p><i>Supported:</i> Yes</p>
disableTables(Pattern pattern)	<p><i>Modifier and Type:</i> HTableDescriptor[]</p> <p><i>Purpose:</i> Disables tables that match the passed-in pattern, and waits on completion</p> <p><i>Supported:</i> Yes</p>
disableTables(String regex)	<p><i>Modifier and Type:</i> HTableDescriptor[]</p> <p><i>Purpose:</i> Disable tables that match the passed-in regular expression, and waits on completion</p> <p><i>Supported:</i> Yes</p>
enableCatalogJanitor(boolean enable)	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Enables/Disables the catalog janitor</p> <p><i>Supported:</i> No</p>

enableTable(String tableName)*Modifier and Type:* void*Purpose:* Enables a table

NOTE: The HPE Data Fabric Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation.

Supported: Yes**enableTable(byte[] tableName)***Modifier and Type:* void*Purpose:* Enables a table

NOTE: The HPE Data Fabric Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation.

Supported: Yes**enableTable(TableName tableName)***Modifier and Type:* void*Purpose:* Enables a table

NOTE: The HPE Data Fabric Database does not require enabling of tables. Therefore, although it supports this method, it only flags the table as enabled, and does not perform any other operation.

Supported: Yes**enableTableAsync (String tableName)***Modifier and Type:* void*Purpose:* Enables the table, but does not block and wait for it be completely enabled*Supported:* Yes**enableTableAsync(TableName tableName)***Modifier and Type:* void*Purpose:* Enables the table, but does not block and wait for it be completely enabled*Supported:* Yes**enableTables(Pattern pattern)***Modifier and Type:* HTableDescriptor[]*Purpose:* Enable tables that match the passed-in pattern, and waits on completion*Supported:* Yes**enableTables(String regex)***Modifier and Type:* HTableDescriptor[]*Purpose:* Enable tables that match the passed-in regular expression. and waits on completion*Supported:* Yes**execProcedure(String signature, String instance, Map<String,String> props)***Modifier and Type:* void*Purpose:* Executes a distributed procedure on a cluster*Supported:* No**execProcedureWithRet(String signature, String instance, Map<String,String> props)***Modifier and Type:* >byte[]*Purpose:* Executes a distributed procedure on a cluster.*Supported:* No

flush(TableNames tableName)	<p><i>Modifier and Type:</i> >void</p> <p><i>Purpose:</i> Flushes a table</p> <p><i>Supported:</i> Yes</p>
flush(byte[] tableNameOrRegionName)	<p><i>Modifier and Type:</i> >void</p> <p><i>Purpose:</i> Flushes a table</p> <p><i>Supported:</i> Yes</p>
flush(String tableNameOrRegionName)	<p><i>Modifier and Type:</i> >void</p> <p><i>Purpose:</i> Flushes a table</p> <p><i>Supported:</i> Yes</p>
flushRegion(byte[] regionName)	<p><i>Modifier and Type:</i> >void</p> <p><i>Purpose:</i> Flushes an individual region</p> <p><i>Supported:</i> Yes</p>
getAlterStatus(byte[] tableName)	<p><i>Modifier and Type:</i> Pair<Integer, Integer></p> <p><i>Purpose:</i> Gets the status of the alter command - indicates the number of regions that have received the updated schema Asynchronous operation</p> <p> NOTE: The HPE Data Fabric Database always returns (0,0).</p> <p><i>Supported:</i> No</p>
getAlterStatus(TableNames tableName)	<p><i>Modifier and Type:</i> Pair<Integer, Integer></p> <p><i>Purpose:</i> Gets the status of the alter command - indicates the number of regions that have received the updated schema Asynchronous operation</p> <p> NOTE: The HPE Data Fabric Database always returns (0,0).</p> <p><i>Supported:</i> No</p>
getClusterStatus()	<p><i>Modifier and Type:</i> ClusterStatus</p> <p><i>Purpose:</i> Gets the status of the cluster</p> <p><i>Supported:</i> No</p>
getCompactionState(String tableNameOrRegionName)	<p><i>Modifier and Type:</i> CompactionState</p> <p><i>Purpose:</i> Get the current compaction state of a table</p> <p><i>Supported:</i> No</p>
getCompactionState(TableNames tableName)	<p><i>Modifier and Type:</i> org.apache.hadoop.hbase.protobuf.generated.AdminProtos.GetRegionInfoResponse.CompactionState</p> <p><i>Purpose:</i> Gets the current compaction state of a table</p> <p><i>Supported:</i> No</p>
getCompactionStateForRegion(byte[] regionName)	<p><i>Modifier and Type:</i> org.apache.hadoop.hbase.protobuf.generated.AdminProtos.GetRegionInfoResponse.CompactionState</p> <p><i>Purpose:</i> Gets the current compaction state of a region</p> <p><i>Supported:</i> No</p>
getConfiguration()	<p><i>Modifier and Type:</i> org.apache.hadoop.conf.Configuration</p>

	<i>Purpose:</i> Gets the configuration used by the instance <i>Supported:</i> Yes
getConnection()	<i>Modifier and Type:</i> Connection <i>Purpose:</i> Gets the connection used by this object <i>Supported:</i> Yes
getMasterCoproprocessors()	<i>Modifier and Type:</i> String[] <i>Purpose:</i> Helper delegate to getClusterStatus().getMasterCoproprocessors() <i>Supported:</i> No
getMasterInfoPort()	<i>Modifier and Type:</i> int <i>Purpose:</i> Gets the information port of the current master, if one is available <i>Supported:</i> No
getNamespaceDescriptor(String name)	<i>Modifier and Type:</i> NamespaceDescriptor <i>Purpose:</i> Gets a namespace descriptor by name <i>Supported:</i> No
getOnlineRegions(ServerName sn)	<i>Modifier and Type:</i> List<HRegionInfo> <i>Purpose:</i> Gets all the online regions on a region server <i>Supported:</i> No
getOperationTimeout()	<i>Modifier and Type:</i> int <i>Purpose:</i> The HPE Data Fabric Database never uses the timeout value  NOTE: If you use the v1.1 API with the HPE Data Fabric Database, the method is ignored. <i>Supported:</i> No
getQuotaRetriever(QuotaFilter filter)	<i>Modifier and Type:</i> QuotaRetriever <i>Purpose:</i> Returns a QuotaRetriever to list the quotas based on the filter <i>Supported:</i> No
getTableDescriptor (byte[] tableName)	<i>Modifier and Type:</i> HTableDescriptor <i>Purpose:</i> Gets the table descriptor <i>Supported:</i> Yes
getTableDescriptor(TableName tableName)	<i>Modifier and Type:</i> HTableDescriptor <i>Purpose:</i> Gets the table descriptor <i>Supported:</i> Yes
getTableDescriptors(List<String> names)	<i>Modifier and Type:</i> HTableDescriptor[] <i>Purpose:</i> Gets table descriptors <i>Supported:</i> Yes
getTableDescriptorsByTableName(List<TableName> tableNames)	<i>Modifier and Type:</i> HTableDescriptor[] <i>Purpose:</i> Gets table descriptors <i>Supported:</i> Yes
getTableRegions (byte[] tableName)	<i>Modifier and Type:</i> List<HRegionInfo> <i>Purpose:</i> Gets the regions of a given table <i>Supported:</i> Yes

getTableRegions(TableNames tableName)	<p><i>Modifier and Type:</i> List<HRegionInfo></p> <p><i>Purpose:</i> Gets the regions of a given table</p> <p><i>Supported:</i> Yes</p>
isAborted()	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Queries on the catalog janitor state. The HPE Data Fabric Database always returns false.</p> <p><i>Supported:</i> No</p>
isCatalogJanitorEnabled()	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Queries on the catalog janitor state. The HPE Data Fabric Database always returns false.</p> <p><i>Supported:</i> No</p>
isProcedureFinished(String signature, String instance, Map<String,String> props)	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Checks the current state of the specified procedure</p> <p><i>Supported:</i> No</p>
isSnapshotFinished(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Checks the current state of the passed snapshot</p> <p><i>Supported:</i> No</p>
isTableAvailable(String tableName)	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Checks if all regions of the table are available</p> <p><i>Supported:</i> Yes</p>
isTableAvailable(TableNames tableName, byte[][] splitKeys)	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Checks if the table has been created with the specified number of splitkeys that was used while creating the given table</p> <p><i>Supported:</i> No</p>
isTableAvailable(TableNames tableName)>	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Returns true if all regions of the table are available</p> <p><i>Supported:</i> Yes</p>
isTableDisabled(String tableName)	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Checks if the table is offline</p> <p> NOTE: Although the HPE Data Fabric Database supports this method, it only checks the flag.</p> <p><i>Supported:</i> Yes</p>
isTableDisabled(TableNames tableName)	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Checks if the table is offline</p> <p> NOTE: Although the HPE Data Fabric Database supports this method, it only checks the flag.</p> <p><i>Supported:</i> Yes</p>
isTableEnabled(String tableName)	<p><i>Modifier and Type:</i> boolean</p> <p><i>Purpose:</i> Checks if the table is online</p>

isTableEnabled(TableNames tableName)

NOTE: Although the HPE Data Fabric Database supports this method, it only checks the flag, and does not change the flag.

Supported: Yes

Modifier and Type: boolean

Purpose: Checks if the table is online

listNamespaceDescriptors()

NOTE: Although the HPE Data Fabric Database supports this method, it only checks the flag, and does not change the flag.

Supported: Yes

Modifier and Type: NamespaceDescriptor[]

Purpose: Lists available namespace descriptors

listSnapshots()

Supported: No

Modifier and Type:

List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>

Purpose: Lists completed snapshots

Supported: No

listSnapshots(Pattern pattern)

Modifier and Type:

List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>

Purpose: Lists all the completed snapshots that match the given pattern

Supported: No

listSnapshots(String regex)

Modifier and Type:

List<org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription>

Purpose: Lists all the completed snapshots that match the given regular expression

Supported: No

listTableDescriptorsByNamespace(String name)

Modifier and Type: HTableDescriptor[]

Purpose: Gets the list of table descriptors by namespace

Supported: No

listTableNames()

Modifier and Type: TableName[]

Purpose: Lists all the names of userspace tables

Supported: Yes

listTableNames(Pattern pattern, boolean includeSysTables)

Modifier and Type: TableName[]

Purpose: Lists all the names of userspace tables that match the specified pattern

Supported: Yes

listTableNames(Pattern pattern)

Modifier and Type: TableName[]

Purpose: Lists all the names of userspace tables that match the specified pattern

Supported: Yes

listTableNames(String regex, boolean includeSysTables)

Modifier and Type: TableName[]

listTableNames(String regex)	<p><i>Purpose:</i> Lists all the names of userspace tables that match the specified regular expression</p> <p><i>Supported:</i> Yes</p> <p><i>Modifier and Type:</i> TableName[]</p> <p><i>Purpose:</i> Lists all the names of userspace tables that match the specified regular expression</p> <p><i>Supported:</i> Yes</p>
listTableNamesByNamespace(String name)	<p><i>Modifier and Type:</i> TableName[]</p> <p><i>Purpose:</i> Gets the list of table names by namespace</p> <p><i>Supported:</i> Yes</p>
listTables()	<p><i>Modifier and Type:</i> HTableDescriptor[]</p> <p><i>Purpose:</i> Lists all the userspace tables</p> <p><i>Supported:</i> Yes</p>
listTables(Pattern pattern, boolean includeSysTables)	<p><i>Modifier and Type:</i> HTableDescriptor[]</p> <p><i>Purpose:</i> Lists all the tables that match the given pattern.</p> <p> NOTE: The HPE Data Fabric Database does not have system tables and therefore, the boolean value is ignored.</p> <p><i>Supported:</i> Yes</p>
listTables(Pattern pattern)	<p><i>Modifier and Type:</i> HTableDescriptor[]</p> <p><i>Purpose:</i> Lists all the userspace tables matching the given pattern.</p> <p><i>Supported:</i> Yes</p>
listTables(String regex, boolean includeSysTables)	<p><i>Modifier and Type:</i> HTableDescriptor[]</p> <p><i>Purpose:</i> Lists all the tables matching the given pattern.</p> <p> NOTE: The HPE Data Fabric Database does not have system tables and therefore, the boolean value is ignored.</p> <p><i>Supported:</i> Yes</p>
listTables(String regex)	<p><i>Modifier and Type:</i> HTableDescriptor[]</p> <p><i>Purpose:</i> Lists all the userspace tables that match the given regular expression.</p> <p><i>Supported:</i> Yes</p>
majorCompact(byte[] tableNameOrRegionName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Compacts a table, or an individual region.</p> <p><i>Supported:</i> Deprecated</p>
majorCompact(String tableNameOrRegionName)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Compacts a table, or an individual region.</p> <p><i>Supported:</i> Deprecated</p>
majorCompact(byte[] tableNameOrRegionName, byte[] columnFamily)	<p><i>Modifier and Type:</i> void</p> <p><i>Purpose:</i> Compacts a column family within a table, or a region</p> <p><i>Supported:</i> Deprecated</p>

majorCompact(String tableNameOrRegionName, String columnFamily)	<i>Modifier and Type:</i> void <i>Purpose:</i> Compact a column family within a table, or a region <i>Supported:</i> Deprecated
majorCompactRegion(byte[] regionName, byte[] columnFamily)	<i>Modifier and Type:</i> void <i>Purpose:</i> Compacts a column family within a region <i>Supported:</i> No
majorCompactRegion(byte[] regionName)	<i>Modifier and Type:</i> void <i>Purpose:</i> Compacts a table, or an individual region <i>Supported:</i> No
mergeRegions(byte[] nameOfRegionA, byte[] nameOfRegionB, boolean forcible)	<i>Modifier and Type:</i> void <i>Purpose:</i> Merges two regions <i>Supported:</i> No
modifyColumn(TableName tableName, HColumnDescriptor columnFamily)	<i>Modifier and Type:</i> void <i>Purpose:</i> Modifies an existing column family on a table <i>Supported:</i> Yes
modifyColumn(TableName tableName, HColumnDescriptor columnFamily)	<i>Modifier and Type:</i> void <i>Purpose:</i> Modifies an existing column family on a table <i>Supported:</i> Yes
modifyNamespace(NamespaceDescriptor descriptor)	<i>Modifier and Type:</i> void <i>Purpose:</i> Modifies an existing namespace <i>Supported:</i> No
modifyTable (byte[] tableName, HTableDescriptor htd)	<i>Modifier and Type:</i> void <i>Purpose:</i> Modifies an existing table <i>Supported:</i> Yes
modifyTable(final String tableName, final HTableDescriptor htd)	<i>Modifier and Type:</i> void <i>Purpose:</i> Modifies an existing table <i>Supported:</i> Yes
modifyTable(TableName tableName, HTableDescriptor htd)	<i>Modifier and Type:</i> void <i>Purpose:</i> Modifies an existing table. This method is the more IRB friendly version. <i>Supported:</i> Yes
move(byte[] encodedRegionName, byte[] destServerName)	<i>Modifier and Type:</i> void <i>Purpose:</i> Moves the region to the destination <i>Supported:</i> No
offline(byte[] regionName)	<i>Modifier and Type:</i> void <i>Purpose:</i> Offlines specified region from master's in-memory state <i>Supported:</i> No
restoreSnapshot(byte[] snapshotName, boolean takeFailSafeSnapshot)	<i>Modifier and Type:</i> void <i>Purpose:</i> Restores the specified snapshot on the original table <i>Supported:</i> No
restoreSnapshot(byte[] snapshotName)	<i>Modifier and Type:</i> void

	<i>Purpose:</i> Restores the specified snapshot on the original table
	<i>Supported:</i> No
restoreSnapshot(String snapshotName, boolean takeFailSafeSnapshot)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Restores the specified snapshot on the original table
	<i>Supported:</i> No
restoreSnapshot(String snapshotName)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Restores the specified snapshot on the original table
	<i>Supported:</i> No
rollWALWriter(ServerName serverName)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Rolls the log writer.
	<i>Supported:</i> No
runCatalogScan()	<i>Modifier and Type:</i> int
	<i>Purpose:</i> Requests a scan of the catalog table
	<i>Supported:</i> No
setBalancerRunning(boolean on, boolean synchronous)	<i>Modifier and Type:</i> boolean
	<i>Purpose:</i> Turns the load balancer on or off
	 NOTE: The HPE Data Fabric Database does not require balancing. Therefore, the method just sets a flag. There is no impact on the Data Fabric table.
	<i>Supported:</i> No
setQuota(QuotaSettings quota)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Applies the new quota settings
	<i>Supported:</i> No
shutdown()	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Shuts down the HBase cluster
	<i>Supported:</i> No
snapshot(byte[] snapshotName, TableName tableName)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Creates a timestamp consistent snapshot for the given table
	<i>Supported:</i> No
snapshot(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Takes a snapshot, and waits for the server to complete that snapshot (blocking).
	<i>Supported:</i> No
snapshot(String snapshotName, TableName tableName, org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription.Type type)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Creates a typed snapshot of the table
	<i>Supported:</i> No
snapshot(String snapshotName, TableName tableName)	<i>Modifier and Type:</i> void
	<i>Purpose:</i> Takes a snapshot for the given table
	<i>Supported:</i> No

split(byte[] tableNameOrRegionName)*Modifier and Type:* void*Purpose:* Splits a table

NOTE: The `tableNameOrRegionName` parameter has a different format when used with Data Fabric tables than with Apache HBase tables. With Data Fabric tables, specify both the table path and the FID as a comma-separated list.

Supported: Yes**split(TableNames tableName, byte[] splitPoint)***Modifier and Type:* void*Purpose:* Splits a table.

NOTE: The `tableNameOrRegionName` parameter has a different format when used with Data Fabric tables than with Apache HBase tables. With Data Fabric tables, specify both the table path and the FID as a comma-separated list.

Supported: No**split(TableNames tableName)***Modifier and Type:* void*Purpose:* Splits a table.

NOTE: The `tableNameOrRegionName` parameter has a different format when used with Data Fabric tables than with Apache HBase tables. With Data Fabric tables, specify both the table path and the FID as a comma-separated list.

Supported: Yes**splitRegion(byte[] regionName, byte[] splitPoint)***Modifier and Type:* void*Purpose:* Splits an individual region.*Supported:* No**splitRegion(byte[] regionName)***Modifier and Type:* void*Purpose:* Splits an individual region*Supported:* Yes**stopMaster()***Modifier and Type:* void*Purpose:* Shuts down the current HBase master only*Supported:* No**stopRegionServer(String hostnamePort)***Modifier and Type:* void*Purpose:* Stops the designated region server*Supported:* No**tableExists(TableNames tableName)***Modifier and Type:* boolean*Purpose:* Returns whether a table with the specified name exists*Supported:* Yes**tableExists(byte[] tableName)***Modifier and Type:* boolean*Purpose:* Returns whether a table with the specified name exists*Supported:* Yes

tableExists(String tableName)*Modifier and Type:* boolean*Purpose:* Returns whether a table with the specified name exists*Supported:* Yes**takeSnapshotAsync(org.apache.hadoop.hbase.protobuf.generated.HBaseProtos.SnapshotDescription snapshot)***Modifier and Type:* org.apache.hadoop.hbase.protobuf.generated.MasterProtos.SnapshotResponse*Purpose:* Takes a snapshot without waiting for the server to complete that snapshot (asynchronous). Ensure that you take only a single snapshot at a time, or the results may be undefined.*Supported:* No**truncateTable(TableName tableName, boolean preserveSplits)***Modifier and Type:* void*Purpose:* Truncates a table*Supported:* Yes**unassign(byte[] regionName, boolean force)***Modifier and Type:* void*Purpose:* Unassigns a region from the current hosting region server*Supported:* No**updateConfiguration()***Modifier and Type:* void*Purpose:* Updates the configuration, and triggers an online configuration change on all the region servers*Supported:* No**updateConfiguration(ServerName server)***Modifier and Type:* void*Purpose:* Updates the configuration, and triggers an online configuration change on all the region servers*Supported:* No*BufferedMutator Method Support*

This table indicates which methods HPE Data Fabric Database supports in the HBase interface BufferedMutator.

The following HBase methods are supported with HPE Data Fabric Database tables, except where noted.

Method Name	Modifier and Type	Description	Supported?
close()	void	Performs a flush() and releases any resources held.	Yes
flush()	void	Executes all the buffered, asynchronous Mutation operations and waits until they are done.	Yes
getConfiguration()	org.apache.hadoop.conf.Configuration	Returns the Configuration object used by this instance.	Yes
getName()	TableName	Gets the fully qualified table name instance of the table that this BufferedMutator writes to.	Yes
getWriteBuffer()	long	Get the internal write buffer.	No

Method Name	Modifier and Type	Description	Supported?
getWriteBufferSize()	long	Returns the maximum size in bytes of the write buffer for this HTable.	No
mutate(List<? extends Mutation> mutations)	void	Send some Mutation objects to the table.	Yes
mutate(Mutation mutation)	void	Sends a Mutation to the table.	Yes
setWriteBufferSize()	long	Sets the maximum size (in bytes) of the write buffer for this HTable	No

Connection Method Support

This table indicates which methods HPE Data Fabric Database supports in the HBase interface Connection.

The following HBase methods are supported with HPE Data Fabric Database tables, except where noted. For full details about this interface, see [Interface Connection](#).

Method Name	Modifier and Type	Description	Supported?
close()	void	Close this connection.	Yes
getAdmin()	Admin	Retrieve an Admin implementation to administer an HBase cluster.	Yes
getBufferedMutator(BufferedMutatorParams params)	BufferedMutator	Retrieve a BufferedMutator for performing client-side buffering of writes.	Yes
getBufferedMutator(TableName tableName)	BufferedMutator		Yes
getConfiguration()	org.apache.hadoop.conf.Configuration	Retrieve the Configuration object used by this connection.	Yes
getRegionLocator(TableName tableName)	RegionLocator	Retrieve a RegionLocator implementation to inspect region information on a table.	Yes
getTable(TableName tableName)	Table	Retrieve a Table implementation for accessing a table.	Yes
getTable(TableName tableName, ExecutorService pool)	Table		Yes
isClosed()	boolean	Returns whether the connection is closed or not.	Yes

ConnectionFactory Method Support

This table indicates which methods HPE Data Fabric Database supports in the HBase class ConnectionFactory.

The following HBase methods are supported with HPE Data Fabric Database tables, except where noted. For full details about this class, see the [ConnectionFactory class in the Client package](#).

Method Name	Modifier and Type	Description	Supported?
createConnection()	static Connection	Create a new Connection instance using default HBaseConfiguration.	Yes
createConnection(org.apache.hadoop.conf.Configuration conf)	static Connection	Create a new Connection instance using the passed conf instance.	Yes
createConnection(org.apache.hadoop.conf.Configuration conf, ExecutorService pool)	static Connection	Create a new Connection instance using the passed conf instance.	Yes
createConnection(org.apache.hadoop.conf.Configuration conf, ExecutorService pool, User user)	static Connection	Create a new Connection instance using the passed conf instance.	Yes
createConnection(org.apache.hadoop.conf.Configuration conf, User user)	static Connection	Create a new Connection instance using the passed conf instance.	Yes

RegionLocator Method Support

This table indicates which methods HPE Data Fabric Database supports in the HBase interface RegionLocator.

The following HBase methods are supported with HPE Data Fabric Database tables, except where noted. For full details about this interface, see [Interface RegionLocator](#) interface in the Client package.

Method Name	Modifier and Type	Description	Supported?
close()	void	Close this connection.	Yes
getAllRegionLocations()	List<HRegionLocation>	Retrieves all of the regions associated with this table.	Yes
getConfiguration()	Configuration	Retrieve the Configuration Object used by this RegionLocator.	Yes
getEndKeys()	byte[][]	Gets the ending row key for every region in the currently open table.	Yes
getName()	TableName	Gets the fully qualified table name instance of this table.	Yes
getRegionLocation(byte[] row)	HRegionLocation	Finds the region on which the given row is being served.	Yes
getRegionLocation(byte[] row, boolean reload)	HRegionLocation		Yes
getStartEndKeys()	Pair<byte[],byte[]>	Gets the starting and ending row keys for every region in the currently open table.	Yes
getStartKeys()	byte[][]	Gets the starting row key for every region in the currently open table.	Yes

Table Method Support

This table indicates which methods HPE Data Fabric Database supports in the HBase interface Table.

The following HBase methods are supported with HPE Data Fabric Database tables, except where noted. For full details about this interface, see [Interface Table](#) in the Client package.

Method Name	Modifier and Type	Description	Supported?
<code>append(Append append)</code>	Result	Appends values to one or more columns within a single row.	Yes
<code>batch(List<? extends Row> actions)</code>	Object[]	A batch call on Deletes, Gets, Puts, Increments, Appends and RowMutations.	Deprecated
<code>batch(List<? extends Row> actions, Object[] results)</code>	void	Method that does a batch call on Deletes, Gets, Puts, Increments and Appends.	Yes
<code>batchCallback(List<? extends Row> actions, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)</code>	Object[]	Method that does a batch call on Deletes, Gets, Puts, Increments and Appends with a callback.	Yes ^{Footnote.}
<code>batchCallback(List<? extends Row> actions, Object[] results, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)</code>	<R> void	Same as <code>batch(List, Object[])</code> , but with a callback. HPE Data Fabric Database ignores the callback.	Yes ^{Footnote.}
<code>batchCoprocessorService(com.google.protobuf.Descriptors.MethodDescriptor, com.google.protobuf.Message request, byte[] startKey, byte[] endKey, R responsePrototype, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)</code>	<R extends com.google.protobuf.Message> void	Creates an instance of the given Service subclass for each table region spanning the range from the startKey row to endKey row (inclusive), all the invocations to the same region server will be batched into one call.	No
<code>batchCoprocessorService(com.google.protobuf.Descriptors.MethodDescriptor, com.google.protobuf.Message request, byte[] startKey, byte[] endKey, R responsePrototype)</code>	<R extends com.google.protobuf.Message> Map<byte[], R>		No

¹ Not fully supported. When used with HPE Data Fabric Database, the callback is ignored.

² Not fully supported. When used with HPE Data Fabric Database, the durability is ignored.

Method Name	Modifier and Type	Description	Supported?
checkAndDelete(byte[] row, byte[] family, byte[] qualifier, byte[] value, Delete delete)	boolean	Atomically checks if a row/family/qualifier value matches the expected value.	Yes
checkAndDelete(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, Delete delete)	boolean		Yes
checkAndMutate(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, RowMutations mutation)	boolean		Yes
checkAndPut(byte[] row, byte[] family, byte[] qualifier, byte[] value, Put put)	boolean		Yes
checkAndPut(byte[] row, byte[] family, byte[] qualifier, CompareFilter.CompareOp compareOp, byte[] value, Put put)	boolean		Yes
close()	void	Releases any resources held or pending changes in internal buffers.	Yes
coprocessorService(byte[] row)	CoprocessorRpcChannel	Creates and returns a RpcChannel instance connected to the table region containing the specified row.	No

Method Name	Modifier and Type	Description	Supported?
<code>coprocessorService(Class<T> service, byte[] startKey, byte[] endKey, org.apache.hadoop.hbase.client.coprocessor.Batch.Call<T,R> callable, org.apache.hadoop.hbase.client.coprocessor.Batch.Callback<R> callback)</code>	<code><T extends com.google.protobuf.Service, R> void</code>	Creates an instance of the given Service subclass for each table region spanning the range from the startKey row to endKey row (inclusive), and invokes the passed Batch.Call.call(T) method with each Service instance.	No
<code>coprocessorService(Class<T> service, byte[] startKey, byte[] endKey, org.apache.hadoop.hbase.client.coprocessor.Batch.Call<T,R> callable)</code>	<code><T extends com.google.protobuf.Service, R> Map<byte[],R></code>		No
<code>delete(Delete delete)</code>	<code>void</code>	Deletes the specified cells/row.	Yes
<code>delete(List<Delete> deletes)</code>	<code>void</code>	Deletes the specified cells/rows in bulk.	Yes
<code>exists(Get get)</code>	<code>boolean</code>	Test for the existence of columns in the table, as specified by the Get.	Yes
<code>existsAll(List<Get> gets)</code>	<code>boolean[]</code>	Test for the existence of columns in the table, as specified by the Gets, in batch.	Yes
<code>get(Get get)</code>	<code>Result</code>	Extracts certain cells from a given row.	Yes
<code>get(List<Get> gets)</code>	<code>Result[]</code>	Extracts certain cells from the given rows, in batch.	Yes
<code>getConfiguration()</code>	<code>org.apache.hadoop.conf.Configuration</code>	Returns the Configuration object used by this instance.	Yes
<code>getName()</code>	<code>TableName</code>	Gets the fully qualified table name instance of this table.	Yes
<code>getScanner(byte[] family, byte[] qualifier)</code>	<code>ResultScanner</code>	Gets a scanner on the current table for the given family and qualifier.	Yes
<code>getScanner(byte[] family)</code>	<code>ResultScanner</code>	Gets a scanner on the current table for the given family.	Yes
<code>getScanner(Scan scan)</code>	<code>ResultScanner</code>	Returns a scanner on the current table as specified by the Scan object.	Yes
<code>getTableDescriptor()</code>	<code>HTableDescriptor</code>	Gets the table descriptor for this table.	Yes
<code>getWriteBufferSize()</code>	<code>long</code>	Returns the maximum size in bytes of the write buffer for this HTable.	No

Method Name	Modifier and Type	Description	Supported?
increment(Increment increment)	Result	Increments one or more columns within a single row.	Yes
incrementColumnValue(byte[] row, byte[] family, byte[] qualifier, long amount, Durability durability)	long	Atomically increments a column value.	Yes Footnote .
incrementColumnValue(byte[] row, byte[] family, byte[] qualifier, long amount)	long	See incrementColumnValue(byte[], byte[], byte[], long, Durability).	Yes
mutateRow(RowMutations rm)	void	Performs multiple mutations atomically on a single row.	Yes
put(List<Put> puts)	void	Puts some data in the table, in batch.	Yes
put(Put put)	void	Puts some data in the table.	Yes
setWriteBufferSize(long writeBufferSize)	void	Sets the size of the buffer in bytes.	No

HColumnDescriptor and HTableDescriptor Support

This section describes the supported fields in the HColumnDescriptor and the HTableDescriptor classes.

HPE Data Fabric Database supports all of the methods that are in these classes. However, it supports only a subset of their fields.

HColumnDescriptor Class

Field	Description
BLOCKSIZE	Size of blocks in files stored to the filesystem (hfiles).
BLOOMFILTER	Whether or not to use bloomfilters.
COMPRESSION	Compression type.
IN_MEMORY	Whether to serve from memory or not.
MIN_VERSIONS	Minimum number of versions to keep.
NAME	Name of the column family.
TTL	Time to live of cell contents.
VERSIONS	Number of versions to keep.

HTableDescriptor Class

Field	Description
AUTOSPLIT	Specifies whether to split the table into regions automatically as the table grows. The average size of each region is determined by the <code>regionsize</code> parameter. The default value is <code>true</code> .

Field	Description
BULKLOAD	Boolean. Specifies whether to perform a full bulk load of the table. The default is false. For more information, see Bulk Loading and Data Fabric Tables .

Field	Description
DELETE_TTL	<p>Used for multi-master replication.</p> <p>Normally, delete operations are purged after the affected table cells are updated. Whereas the result of an update is saved in a table until another change overwrites or deletes it, the result of a delete is not saved. In multi-master replication, this difference can lead to tables being unsynchronized.</p> <p>Example</p> <p>Suppose that you have set up multi-master replication between table customers in the cluster sanfrancisco and table customers in the cluster newyork. Client applications then make these two changes:</p> <ol style="list-style-type: none"> 1. On /mapr/sanfrancisco/customers, put row A at 10:00:00 AM. 2. On /mapr/newyork/customers, delete row A at 10:00:01 AM. <p>On /mapr/sanfrancisco/customers, the order of operations is:</p> <ol style="list-style-type: none"> 1. Put row A with a timestamp of 10:00:00 AM 2. Delete row A with a timestamp of 10:00:01 AM (This operation is replicated from /mapr/newyork/customers.) <p>On /mapr/newyork/customers, the order of operations is:</p> <ol style="list-style-type: none"> 1. Delete row A with a timestamp of 10:00:01 AM 2. Put row A with a timestamp of 10:00:00 AM (This operation is replicated from /mapr/sanfrancisco/customers.) <p>Now, though the put happened on /mapr/sanfrancisco/customers at 10:00:00 AM, the put reaches /mapr/newyork/customers several seconds after that. Suppose that the actual time that the put arrives at /mapr/newyork/customers is 10:00:03 AM.</p> <p>To ensure that both tables stay synchronized, /mapr/newyork/customers should preserve the delete until after the put is replicated. Then, the delete can be applied after the put. Therefore, the time-to-live for the delete should be at least long enough for the put to arrive at /mapr/newyork/customers. In this case, the time-to-live should be at least 3 seconds.</p> <p>In general, the time-to-live for deletes should be greater than the amount of time that it takes replicated operations to reach replicas. By default, the value is 24 hours.</p> <p>For example, suppose (to extend the scenario above) that you pause replication during weekdays and resume it on weekends. The put takes place on Monday morning /mapr/sanfrancisco/customers at 10:00:00 AM and the delete takes place at /mapr/newyork/customers at 10:00:01 AM. Replication does not resume until 12:00:00 AM Saturday morning. Given the volume of operations to be replicated and the potential for network problems, it is possible that these operations will not be replicated until Sunday. In this scenario, a value of 7 days for DELETE_TTL (7 multiplied by 24 hours) should provide sufficient margin.</p>

Field	Description
NAME	Name of the table.

Support for HBase Java Filters Support

HPE Data Fabric Database supports the following Java filters, which work identically to their Apache HBase versions. See the [Apache HBase API](#) for more information, specifically, the [Apache HBase Filter](#) package.

Filter	Description
ColumnCountGetFilter	Simple filter that returns first N columns on row only. This filter was written to test filters in Get and as soon as it gets its quota of columns, <code>filterAllRemaining()</code> returns true. This makes this filter unsuitable as a Scan filter.
ColumnPaginationFilter	A filter, based on the <code>ColumnCountGetFilter</code> , takes two arguments: limit and offset. This filter can be used for row-based indexing, where references to other tables are stored across many columns, in order to efficient lookups and paginated results for end users. Only most recent versions are considered for pagination.
ColumnPrefixFilter	This filter is used for selecting only those keys with columns that matches a particular prefix. For example, if prefix is 'an', it will pass keys with columns like 'and', 'anti' but not keys with columns like 'ball', 'act'.
ColumnRangeFilter	This filter is used for selecting only those keys with columns that are between minColumn to maxColumn. For example, if minColumn is 'an', and maxColumn is 'be', it will pass keys with columns like 'ana', 'bad', but not keys with columns like 'bed', 'eye' If minColumn is null, there is no lower bound. If maxColumn is null, there is no upper bound. minColumnInclusive and maxColumnInclusive specify if the ranges are inclusive or not.
DependentColumnFilter	A filter for adding inter-column timestamp matching Only cells with a correspondingly timestamped entry in the target column will be retained Not compatible with <code>Scan.setBatch</code> as operations need full rows for correct filtering
FamilyFilter	This filter is used to filter based on the column family. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the column family portion of a key. This filter can be wrapped with <code>WhileMatchFilter</code> and <code>SkipFilter</code> to add more control. Multiple filters can be combined using <code>FilterList</code> . If an already known column family is looked for, use <code>Get.addFamily(byte[])</code> directly rather than a filter.

Filter	Description
FilterList	<p>Implementation of Filter that represents an ordered List of Filters which will be evaluated with a specified boolean operator</p> <p>FilterList.Operator.MUST_PASS_ALL (AND) or FilterList.Operator.MUST_PASS_ONE (OR). Since you can use Filter Lists as children of Filter Lists, you can create a hierarchy of filters to be evaluated.</p> <p>FilterList.Operator.MUST_PASS_ALL evaluates lazily: evaluation stops as soon as one filter does not include the KeyValue.</p> <p>FilterList.Operator.MUST_PASS_ONE evaluates non-lazily: all filters are always evaluated. Defaults to FilterList.Operator.MUST_PASS_ALL .</p>
FirstKeyOnlyFilter	<p>A filter that will only return the first KV from each row.</p> <p>This filter can be used to more efficiently perform row count operations.</p>
FirstKeyValueMatchingQualifiersFilter	<p>The filter looks for the given columns in KeyValue. Once there is a match for any one of the columns, it returns ReturnCode.NEXT_ROW for remaining KeyValues in the row.</p> <p>Note: It may emit KVs which do not have the given columns in them, if these KVs happen to occur before a KV which does have a match. Given this caveat, this filter is only useful for special cases like RowCounter .</p>
FuzzyRowFilter	<p>Filters data based on fuzzy row key. Performs fast-forwards during scanning. It takes pairs (row key, fuzzy info) to match row keys. Where fuzzy info is a byte array with 0 or 1 as its values:</p> <ul style="list-style-type: none"> 0 - means that this byte in provided row key is fixed, i.e. row key's byte at same position must match 1 - means that this byte in provided row key is NOT fixed, i.e. row key's byte at this position can be different from the one in provided row key <p>Example: Let's assume row key format is <code>userId_actionId_year_month</code>. Length of <code>userId</code> is fixed and is 4, length of <code>actionId</code> is 2 and year and month are 4 and 2 bytes long respectively. Let's assume that we need to fetch all users that performed certain action (encoded as "99") in Jan of any year. Then the pair (row key, fuzzy info) would be the following: row key = "????_99_????_01" (one can use any value instead of "?") fuzzy info = "\x01\x01\x01\x01\x00\x00\x00\x00\x01\x01\x01\x01\x00\x00\x00" i.e. fuzzy info tells the matching mask is "????_99_????_01", where at ? can be any value.</p>
InclusiveStopFilter	<p>A Filter that stops after the given row. There is no "RowStopFilter" because the Scan spec allows you to specify a stop row. Use this filter to include the stop row, eg: [A,Z].</p>
KeyOnlyFilter	<p>A filter that will only return the key component of each KV (the value will be rewritten as empty).</p> <p>This filter can be used to grab all of the keys without having to also grab the values.</p>

Filter	Description
MultipleColumnPrefixFilter	This filter is used for selecting only those keys with columns that matches a particular prefix. For example, if prefix is 'an', it will pass keys with columns like 'and', 'anti' but not keys with columns like 'ball', 'act'.
PageFilter	<p>Implementation of Filter interface that limits results to a specific page size. It terminates scanning once the number of filter-passed rows is > the given page size.</p> <p>Note that this filter cannot guarantee that the number of results returned to a client are <= page size. This is because the filter is applied separately on different region servers. It does however optimize the scan of individual HRegions by making sure that the page size is never exceeded locally.</p>
PrefixFilter	Pass results that have same row prefix.
QualifierFilter	<p>This filter is used to filter based on the column qualifier. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the column qualifier portion of a key.</p> <p>This filter can be wrapped with WhileMatchFilter and SkipFilter to add more control. Multiple filters can be combined using FilterList . If an already known column qualifier is looked for, use <code>Get.addColumn(byte[], byte[])</code> directly rather than a filter.</p>
RandomRowFilter	A filter that includes rows based on a chance.
RowFilter	<p>This filter is used to filter based on the key. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the row, and column qualifier portions of a key.</p> <p>This filter can be wrapped with WhileMatchFilter to add more control. Multiple filters can be combined using FilterList. If an already known row range needs to be scanned, use CellScanner start and stop rows directly rather than a filter.</p>
SingleColumnValueExcludeFilter	A Filter that checks a single column value, but does not emit the tested column. This will enable a performance boost over SingleColumnValueFilter , if the tested column value is not actually needed as input (besides for the filtering itself).

Filter	Description
SingleColumnValueFilter	<p>This filter is used to filter cells based on value. It takes a <code>CompareFilter</code>. <code>CompareOp</code> operator (equal, greater, not equal, etc), and either a byte [] value or a <code>ByteArrayComparable</code>.</p> <p>If we have a byte [] value then we just do a lexicographic compare. For example, if passed value is 'b' and cell has 'a' and the compare operator is LESS, then we will filter out this cell (return true). If this is not sufficient (eg you want to deserialize a long and then compare it to a fixed long value), then you can pass in your own comparator instead.</p> <p>You must also specify a family and qualifier. Only the value of this column will be tested. When using this filter on a <code>CellScanner</code> with specified inputs, the column to be tested should also be added as input (otherwise the filter will regard the column as missing).</p> <p>To prevent the entire row from being emitted if the column is not found on a row, use <code>setFilterIfMissing(boolean)</code>. Otherwise, if the column is found, the entire row will be emitted only if the value passes. If the value fails, the row will be filtered out.</p> <p>In order to test values of previous versions (timestamps), set <code>setLatestVersionOnly(boolean)</code> to false. The default is true, meaning that only the latest version's value is tested and all previous versions are ignored.</p> <p>To filter based on the value of all scanned columns, use <code>ValueFilter</code>.</p>
SkipFilter	<p>A wrapper filter that filters an entire row if any of the Cell checks do not pass.</p> <p>For example, if all columns in a row represent weights of different things, with the values being the actual weights, and we want to filter out the entire row if any of its weights are zero. In this case, we want to prevent rows from being emitted if a single key is filtered. Combine this filter with a <code>ValueFilter</code>:</p> <pre>scan.setFilter(new SkipFilter(new ValueFilter(CompareOp.NOT_EQUAL, new BinaryComparator(Bytes.toBytes(0)))));</pre> <p>Any row which contained a column whose value was 0 will be filtered out (since <code>ValueFilter</code> will not pass that Cell). Without this filter, the other non-zero valued columns in the row would still be emitted.</p>
TimestampsFilter	<p>Filter that returns only cells whose timestamp (version) is in the specified list of timestamps (versions).</p> <p>Note: Use of this filter overrides any time range/time stamp options specified using <code>Get.setTimeRange(long, long)</code>, <code>Scan.setTimeRange(long, long)</code>, or <code>Scan.setTimeStamp(long)</code>. See the Apache HBase API, Client package for detailed information.</p>

Filter	Description
ValueFilter	<p>This filter is used to filter based on column value. It takes an operator (equal, greater, not equal, etc) and a byte [] comparator for the cell value.</p> <p>This filter can be wrapped with WhileMatchFilter and SkipFilter to add more control. Multiple filters can be combined using FilterList. To test the value of a single qualifier when scanning multiple qualifiers, use SingleColumnValueFilter.</p>
WhileMatchFilter	<p>A wrapper filter that returns true from filterAllRemaining() as soon as the wrapped filters Filter.filterRowKey(byte[], int, int), Filter.filterKeyValue(org.apache.hadoop.hbase.Cell), Filter.filterRow() or Filter.filterAllRemaining() methods returns true.</p>

HBase Java Regular Expressions Support

This topics defines the subset of Java regular expressions that are supported for HPE Data Fabric Database tables.

Filters used with Scan operations support regular expressions. When you filter scans on HPE Data Fabric Database tables, you can use regular expressions that comprise the [Perl-Compatible Regular Expressions library](#), as well as a subset of the regular expressions that are supported in java.util.regex.pattern.

Characters

Pattern	Description
x	The character x
\\	The backslash character
\\On	The character with octal value On (0 <= n <= 7)
\\Onn	The character with octal value Onn (0 <= n <= 7)
\\xhh	The character with hexadecimal value 0xhh
\\t	The tab character ("\\u0009")
\\n	The newline (line feed) character ("\\u000A")
\\r	The carriage-return character ("\\u000D")
\\f	The form-feed character ("\\u000C")
\\a	The alert (bell) character ("\\u0007")
\\e	The escape character ("\\u001B")
\\cx	The control character corresponding to x

Character Classes

Pattern	Description
[abc]	a, b, or c (simple class)
[Supported Regular Expressions in HPE Data Fabric Database Tables^abc]	Any character except a, b, or c (negation)
[a-zA-Z]	a through z or A through Z, inclusive (range)

Predefined Character Classes

Pattern	Description
.	Any character (may or may not match line terminators)
\d	A digit: [0-9]
\D	A non-digit: [Supported Regular Expressions in HPE Data Fabric Database Tables^0-9]
\s	A whitespace character: [\t\n\r\b\f]
\S	A non-whitespace character: [Supported Regular Expressions in HPE Data Fabric Database Tables^\s]
\w	A word character: [a-zA-Z_0-9]
\W	A non-word character: [Supported Regular Expressions in HPE Data Fabric Database Tables^\w]

Classes for Unicode Blocks and Categories

Pattern	Description
\p{Lu}	An uppercase letter (simple category)
\p{Sc}	A currency symbol

Boundaries

Pattern	Description
^	The beginning of a line
\$	The end of a line
\b	A word boundary
\B	A non-word boundary
\A	The beginning of the input
\G	The end of the previous match

Pattern	Description
\Z	The end of the input but for the final terminator, if any
\z	The end of the input

Greedy Quantifiers

Pattern	Description
X?	X, once or not at all
X*	X, zero or more times
X+	X, one or more times
X{n}	X, exactly n times
X{n,}	X, at least n times
X{n,m}	X, at least n but not more than m times

Reluctant Quantifiers

Pattern	Description
X??	X, once or not at all
X*?	X, zero or more times
X+?	X, one or more times
X{n}?	X, exactly n times
X{n,}?	X, at least n times
X{n,m}?	X, at least n but not more than m times

Possessive Quantifiers

Pattern	Description
X?+	X, once or not at all
X*+	X, zero or more times
X++	X, one or more times
X{n}+	X, exactly n times
X{n,}+	X, at least n times
X{n,m}+	X, at least n but not more than m times

Logical Operators

Pattern	Description
XY	X followed by Y
X Y	Either X or Y
(X)	X, as a capturing group

Back References

Pattern	Description
\n	Whatever the nth capturing group matches

Quotation

Pattern	Description
\	Nothing, but quotes the following character
\Q	Nothing, but quotes all characters until \E
\E	Nothing, but ends quoting started by \Q

Special Constructs

Pattern	Description
(?:X)	X, as a non-capturing group
(?=X)	X, via zero-width positive lookahead
(?!X)	X, via zero-width negative lookahead
(?<=X)	X, via zero-width positive lookbehind
(?<!X)	X, via zero-width negative lookbehind
(?>X)	X, as an independent, non-capturing group

HBase Java Comparators Support

HPE Data Fabric Database supports the following Java filters, which work identically to their Apache HBase versions. See the [Apache HBase API](#) for more information, specifically, the [Apache HBase Filter](#) package.

Comparator	Description
>BinaryComparator	A binary comparator which lexicographically compares against the specified byte array using <code>Bytes.compareTo(byte[], byte[])</code> .
BinaryPrefixComparator	A comparator which compares against a specified byte array, but only compares up to the length of this byte array. For the rest it is similar to BinaryComparator.

Comparator	Description
BitComparator	A bit comparator which performs the specified bitwise operation on each of the bytes with the specified byte array. Then returns whether the result is non-zero.
NullComparator	A binary comparator which lexicographically compares against the specified byte array using <code>Bytes.compareTo(byte[], byte[])</code> .
RegexStringComparator	<p>This comparator is for use with <code>CompareFilter</code> implementations, such as <code>RowFilter</code>, <code>QualifierFilter</code>, and <code>ValueFilter</code>, for filtering based on the value of a given column. Use it to test if a given regular expression matches a cell value in the column.</p> <p>Only <code>EQUAL</code> or <code>NOT_EQUAL</code> comparisons are valid with this comparator.</p> <p>For example:</p> <pre>ValueFilter vf = new ValueFilter(CompareOp.EQUAL, new RegexStringComparator(// v4 IP address "(((25[0-5] 2[0-4][0-9] [01]? [0-9][0-9]?)\\.){3,3}" + "(25[0-5] 2[0-4][0-9] [01]? [0-9][0-9]?)\\.([0-9]{1,3})?)" + " " + // v6 IP address "(((\\dA-Fa-f){1,4}:){7}[\\ \\dA-Fa-f]{1,4})?(:([\\d]{1,3}.)*" + "{3}[\\d]{1,3})?)(\\d{1,3} [0-9]{1,3})?)"</pre>
SubstringComparator	<p>This comparator is for use with <code>SingleColumnValueFilter</code>, for filtering based on the value of a given column. Use it to test if a given substring appears in a cell value in the column. The comparison is case insensitive.</p> <p>Only <code>EQUAL</code> or <code>NOT_EQUAL</code> tests are valid with this comparator.</p> <p>For example:</p> <pre>SingleColumnValueFilter scvf = new SingleColumnValueFilter("col", CompareOp.EQUAL, new SubstringComparator("substr"));</pre>

Unsupported HBase Java Methods

This topic identifies the HBase Java methods that are not supported for HPE Data Fabric Database tables. Attempts to call any of these methods results in an `UnsupportedOperationException` exception.

Methods for ACLs for cells:

- `Put.setACL(String user, org.apache.hadoop.hbase.security.access.Permission perms)`
- `Append.setACL(Map<String, org.apache.hadoop.hbase.security.access.Permission> perms)`

- `Delete.setACL(Map<String, org.apache.hadoop.hbase.security.access.Permission> perms)`
- `Increment.setACL(Map<String, org.apache.hadoop.hbase.security.access.Permission> perms)`

Methods for cell visibility:

- `Put.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Append.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Delete.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`
- `Increment.setCellVisibility(org.apache.hadoop.hbase.security.visibility.CellVisibility expression)`

Methods for time-to-live for cell values:

- `Put.setTTL(long ttl)`
- `Append.setTTL(long ttl)`
- `Delete.setTTL(long ttl)`
- `Increment.setTTL(long ttl)`

Other methods

- `Delete.deleteFamilyVersion(byte[] family, long timestamp)`
- `Scan.setReversed(boolean reversed)`
- `Scan.setBatch()`
- `Scan.setCaching()`
- `Scanner.next(int nbRows)`

Impersonation through the HBase REST Gateway

Impersonation enables access to tables via user IDs other than the user that runs the Gateway.

You can enable user impersonation to access HPE Data Fabric Database tables via the HBase REST Gateway. This feature is not supported in earlier combinations of Data Fabric and HBase packages.

Impersonation is only supported if the REST Gateway is running as the `mapr` user (`MAPR_USER`).

You can enable impersonation via the Gateway on both non-secure and secure Data Fabric clusters (secured using either MapR SASL or Kerberos). HPE Data Fabric Database does not support gateway impersonation using a Thrift interface.

NOTE: Impersonation for HBase REST Gateway is enabled by default on secure clusters.

Enabling Impersonation on a Non-Secure Cluster

About this task

To enable impersonation on a non-secure cluster, follow these steps:

Procedure

1. Install the `mapr-hbase` package on a cluster that is running version 4.0.2 or later. This package contains all of the HBase binaries. For installation details, see [HBase Client and HPE Data Fabric Database](#).
2. Enable simple authentication via the REST Gateway by appending the following property to the `hbase-site.xml` file (`/opt/mapr/hbase/hbase<hbase_version>/conf/hbase-site.xml`): The simple authentication protocol is a Hadoop pseudo authenticator that serves as an example and is part of the `hadoop-common` package.

```
<property>
<name>hbase.rest.authentication.type</name>
<value>simple</value>
</property>
```

3. Set the following environment variable to enable impersonation:

```
export MAPR_IMPERSONATION_ENABLED=1
```

4. Start the REST Gateway server as the `MAPR_USER`.

```
/opt/mapr/hbase/hbase<hbase_version>/bin/hbase-daemon.sh start rest -p
port
```

Using Custom Authentication

This section describes how to use Hadoop pseudo authentication for custom authentication.

About this task

Editing the `hbase-site.xml` file is the procedure to follow if you want to use Hadoop pseudo authentication. Alternatively, you can write and use your own authenticator to substitute for the "simple" configuration by implementing the Hadoop AuthenticationHandler interface. If you are using custom authentication, place your authenticator jar in the following directory:

```
/opt/mapr/hbase/hbase-<hbase_version>/lib/
```

Then start the REST Gateway.

Mapping to HBase Table Namespaces

This section describes mapping table namespaces between Apache HBase tables and HPE Data Fabric Database [binary tables](#).

The HPE Data Fabric implementations of the HBase Java API and `libhbase` differentiate between Apache HBase tables and HPE Data Fabric Database tables according to table names. In certain cases, such as migrating code from Apache HBase tables to HPE Data Fabric Database tables, users need to force the API they are using to access a HPE Data Fabric Database table, even though the table name could map to an Apache HBase table. The `hbase.table.namespace.mappings` property allows you to map Apache HBase table names to HPE Data Fabric Database tables. This property is typically set in the configuration file `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/core-site.xml`.

In general, if a table name includes a slash (/), the name is assumed to be a path to a HPE Data Fabric Database table, because slash is not a valid character for Apache HBase table names. In the case of "flat" table names without a slash, namespace conflict is possible, and you might need to use table mappings.

Table Mapping Naming Conventions

A table mapping takes the form *name:map*, where *name* is the table name to redirect and *map* is the modification made to the name. The value in *name* can be a literal string or contain the *** wildcard. When mapping a name with a wild card, the mapping is treated as a directory. Requests to tables with names that match the wild card are sent to the directory in the mapping.

When mapping a name that is a literal string, you can choose from two different behaviors:

- End the mapping with a slash to indicate that this mapping is to a directory. For example, the mapping `mytable1:/user/aaa/` sends requests for table `mytable1` to the full path `/user/aaa/mytable1`.
- End the mapping without a slash, which creates an alias and treats the mapping as a full path. For example, the mapping `mytable1:/user/aaa` sends requests for table `mytable1` to the full path `/user/aaa`.

Mappings and Table Listing Behaviors

When you use the `list` command without specifying a directory, the command's behavior depends on two factors:

- Whether a table mapping exists
- Whether Apache HBase is installed and running

Here are three different scenarios and the resulting `list` command behavior for each.

- There is a table mapping for `*`, as in `*/tables`. In this case, the `list` command lists the tables in the mapped directory.
- There is no mapping for `*`, and Apache HBase is installed and running. In this case, the `list` command lists the HBase tables.
- There is no mapping for `*`, and Apache HBase is not installed or is not running.
 - For HBase 0.98.12, the shell will try to connect to an HBase cluster but it will return an error instead.
 - For HBase 1.1 or above, if the `mapr.hbase.default.db` property in the `hbase-site.xml` is set to `hbase`, the `list` command will return an error stating that HBase is not available. If the `mapr.hbase.default.db` property is set to `maprdb`, `list` command will list the HPE Data Fabric Database tables under the user's home directory.

Example 1: Map all HBase tables to HPE Data Fabric Database tables in a directory

In this example, any flat table name `foo` is treated as a HPE Data Fabric Database table in the directory `/tables_dir/foo`.

```
<property>
  <name>hbase.table.namespace.mappings</name>
  <value>*/tables_dir</value>
</property>
```

Example 2: Map specific Apache HBase tables to specific HPE Data Fabric Database tables

In this example, the Apache HBase table name `mytable1` is treated as a HPE Data Fabric Database table at `/user/aaa/mytable1`. The Apache Hbase table name `mytable2` is treated as a HPE Data Fabric

Database table at `/user/bbb/mytable2`. All other Apache HBase table names are treated as stock Apache HBase tables.

```
<property>
  <name>hbase.table.namespace.mappings</name>
  <value>mytable1:/user/aaa/, mytable2:/user/bbb/</value>
</property>
```

Example 3: Combination of specific table names and wildcards

Mappings are evaluated in order. In this example, the flat table name `mytable1` is treated as a HPE Data Fabric Database table at `/user/aaa/mytable1`. The flat table name `mytable2` is treated as a HPE Data Fabric Database table at `/user/bbb/mytable2`. Any other flat table name `foo` is treated as a HPE Data Fabric Database table at `/tables_dir/foo`.

```
<property>
  <name>hbase.table.namespace.mappings</name>
  <value>mytable1:/user/aaa/, mytable2:/user/bbb/, */tables_dir</value>
</property>
```

Thread-pool Settings for Performance

The HPE Data Fabric Database C APIs internally have one thread pool per client. Threads work on the async tasks enqueued by a client application. There are two thread-pool parameters that you can modify in the `/opt/mapr/conf/dbclient.conf` file for better application performance.

fs.mapr.pool.threads

This parameter controls the number of connections that a client application makes with HPE Data Fabric Database for append, increment, read, and scan requests. For a higher rate of throughput to HPE Data Fabric Database, you can increase this value. The default value is 10.

fs.mapr.highpri.pool.threads

This parameter controls the number of threads that invoke application-provided callbacks. If an application's callbacks are not lightweight but instead perform complex calculations that require significant processing, increase this value to avoid delays in invoking callbacks. The default value is 2.

Building MapReduce Applications

This section provides information about building and running custom MapReduce application that access HPE Data Fabric Database binary tables.

The steps for building and running custom MapReduce applications that run against HPE Data Fabric Database are the same as the steps for building and running custom MapReduce applications that run against Apache HBase. The steps are documented in the Apache HBase Reference Guide at <http://hbase.apache.org/book.html#mapreduce>.

However, you must use an HBase JAR file from MapR's Maven repository at <https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/hbase/hbase-server/>. The name of the JAR file that you use must contain the version of HBase and the version of MapR that you are using.

For example, if you are using HBase 1.1 and MapR version 5.1, you would use the file `hbase-server-1.1.1-mapr-1602.jar`.

Performing Bulkloads with MapReduce

This section describes custom MapReduce applications used to perform bulkloads for HPE Data Fabric Database binary tables.

You can use the `HFileOutputFormat configureIncrementalLoad()` method for writing custom MapReduce applications to perform bulk loads. Although the name of the method implies that you can use

it only for incremental bulk loads, the method also works for full bulk loads, provided that the `-bulkload`, `BULKLOAD`, or `BulkLoad` parameter for a table is set to true, as described in [Bulk Loading and HPE Data Fabric Database Tables](#).

If you have a custom MapReduce applications that does not use `HFileOutputFormat.configureIncrementalLoad()`, simply use the path to the HPE Data Fabric Database table that you want to load. Using `HFileOutputFormat.configureIncrementalLoad()` provides at least two advantages:

This method performs a number of tasks that your application would otherwise need to do explicitly:

1. Inspects the table to configure a total order partitioner
2. Uploads the partitions file to the cluster and adds it to the DistributedCache
3. Sets the number of reduce tasks to match the current number of regions
4. Sets the output key/value class to match `HFileOutputFormat`'s requirements
5. Sets the reducer up to perform the appropriate sorting (either `KeyValueSortReducer` or `PutSortReducer`)

This method turns off Speculative Execution automatically. For details, see the note below.

WARNING: Turning off Speculative Execution

Speculative Execution of MapReduce tasks is on by default. For custom applications that load HPE Data Fabric Database binary tables, it is recommended to turn Speculative Execution off. When it is on, the tasks that import data might run multiple times. Multiple tasks for an incremental bulkload could insert one or more versions of a record into a table. Multiple tasks for a full bulkload could cause loss of data if the source data continues to be updated during the load.

If your custom MapReduce application uses `HFileOutputFormat.configureIncrementalLoad()`, you do not have to turn off Speculative Execution manually.

`HFileOutputFormat.configureIncrementalLoad()` turns it off automatically. Speculative Execution is automatically turned off for MapReduce utilities such as `CopyTable` and `ImportTsv`.

If you are writing a custom MapReduce application that does not use the `HFileOutputFormat.configureIncrementalLoad()` method for bulk loading, you must turn off Speculative Execution manually.

Turn off Speculative Execution by setting the following MapReduce version 2 parameter to false:
`mapreduce.map.speculative`

If the job is programmatically written, you can turn off Speculative Execution at the code level:
`job.setSpeculativeExecution(false);`

Setting for OJAI Applications to Use Data Fabric Client Features

Describes how to set the classpath for OJAI applications to use Data Fabric client features.

When you launch an OJAI application that needs to submit MapReduce or YARN applications, or to run `hadoop fs` or `hadoop mfs` commands, ensure that you prefix the classpath with `/opt/mapr/conf:/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop`. Alternatively, copy the `core-site.xml` file to the `/src/main/resources/` folder.

Developing Applications for JSON Tables

As part of its support for JSON tables, HPE Data Fabric Database implements the OJAI API. The OJAI API provides methods for creating, reading, updating, and deleting JSON documents in HPE Data Fabric Database JSON tables. It is available in Java, and starting in EEP 6.0, also available in Node.js, Python,

C#, and Go. HPE Data Fabric Database also provides a HPE Data Fabric Database JSON Client API for managing JSON tables and a HPE Data Fabric Database JSON REST API for performing basic operations using HTTP calls.

The following shows the general flow for developing an OJAI client application that accesses HPE Data Fabric Database JSON tables:

1. Make a connection to HPE Data Fabric Database using the OJAI Connection and Driver interfaces.
2. Request a HPE Data Fabric Database JSON table using the JSON DocumentStore.
3. Specify the table, document, or column family operation.
4. Perform the operation on the table.
5. Return the results.

For additional information about OJAI, refer to the following:

- [OJAI wiki page](#)
- [OJAI github repository](#) - The README file provides an introduction to OJAI

The HPE Data Fabric Database JSON Client API, implemented in Java, enables you to create, drop, and alter HPE Data Fabric Database JSON tables and column families.

You can also use HTTP calls to create, delete, and query HPE Data Fabric Database JSON tables [Using the HPE Data Fabric Database JSON REST API](#) on page 3887.

API Documentation

The following are links to the detailed API pages:

- [Java OJAI Client API](#)
- [Node.js OJAI Client API](#)
- [Python OJAI Client API](#)
- [C# OJAI Client API](#)
- [Go OJAI Client API](#)
- [HPE Data Fabric Database JSON Client API](#)

NOTE: Beginning with MapR version 6.0, the HPE Data Fabric Database Table interface in the HPE Data Fabric Database JSON Client API is deprecated and replaced by the DocumentStore interface in the OJAI API.

Managing JSON Tables

This section describes how to create, list, and delete JSON tables, alter JSON table attributes, set permissions, and manage column families. You can perform these operations using either the HPE Data Fabric Database JSON Client API library or HPE Data Fabric Database Shell commands.

HPE Data Fabric Database JSON Client API

The HPE Data Fabric Database JSON Client API is a Java library. There is not a Python implementation of the library, but you can create and drop HPE Data Fabric Database JSON tables in the Python OJAI client.

Admin API

Use the methods in this interface to perform these tasks:

- Create JSON tables
- Alter JSON tables
- Delete JSON tables
- List JSON tables in a folder
- See if a JSON table exists

For a full list of methods, see the [Admin interface](#)

TableDescriptor API

Use the methods in this interface to perform these tasks:

- Create tables with non-default values for one or more of their parameters
- Alter tables

For a full list of interfaces and methods, see the [TableDescriptor interface](#).

HPE Data Fabric Database Shell

The `mapr dbshell` is a tool for the creation and lightweight manipulation of JSON tables and documents. To run `dbshell`, enter `mapr dbshell` on the command line after logging into a node in a cluster. See [HPE Data Fabric Database Shell \(JSON Tables\)](#) on page 7401 for more information.

Creating JSON Tables

This topic describes how to create HPE Data Fabric Database JSON tables using either programmatic APIs or `dbshell`.

NOTE: Before creating a table, you typically create a directory and Data Fabric volume. This is not required; however, it is a good practice. For example, assuming both the directory and volume names are `sample`, the command would be:

```
// Create directories with hadoop
hadoop fs -mkdir /sample

// Create a Data Fabric volume using maprccli create volume
maprccli volume create -name sample -path /sample -type rw
```

Java

The following Java code examples show you how to create a table in the following ways:

- By using the default values for the table attributes,
- By setting specific values for the table attributes.

See the [Admin](#) and [TableDescriptor](#) APIs for more information.

The following example shows how to create a table by calling an `Admin` object's `createTable()` method and passing, as an argument, the path that you want to use for the new table:

```
public void createJSONTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tablePath);
        }
    }
}
```

```
    }
}
```

Tables created with this version of the `createTable()` method use the default values for their attributes.

Alternatively, the following example shows how to create a table by passing a `TableDescriptor` object as an argument to the `createTable()` method:

```
/* Create a TableDescriptor for the table to create,
 * passing in the path of the table.
 */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Pass the TableDescriptor object and the path to the table
 * to the Admin.createTable() method.
 */
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tableDescriptor);
        }
    }
}
```

This alternative allows you to set values for some of the table's attributes.

Node.js

To create a table in the Node.js OJAI client, call the `Connection.createStore()` method:

```
connection.createStore(table_path)
    .then((store) => {
        // Process result
        ...
    });
```

The method returns a `DocumentStore` object.

Python

To create a table in the Python OJAI client, call the `Connection.create_store()` method:

```
store = connection.create_store(store_path=table_path)
```

The method returns a `DocumentStore` object.

dbshell

The following **dbshell** command shows code syntax for creating a table:

```
# mapr dbshell
maprdb root:> create /<tablePath>/<tableName>
```

C#

To create a table in the C# OJAI client, call the `connection.CreateStore(string storePath)` method:

```
var store = connection.CreateStore(string storePath);
```

The method returns a `DocumentStore` object.

Go

To create a table in the Go OJAI client, call the `connection.CreateStore()` function:

```
store, error := connection.CreateStore("/store_path")
```

The function returns a new `DocumentStore` and an error.

Listing JSON Tables

This topic describes how to list the JSON tables by using either the HPE Data Fabric Database JSON Client API or HPE Data Fabric Database Shell.

Permission Required

The `readAce` permission on the volumes where the JSON tables are located. [Setting Whole Volume ACEs](#) on page 1627

Java

The table is listed by calling HPE Data Fabric Database JSON Client API Admin object's `listTables()` method and passing, as an argument, the path of the folder.

Use a conditional loop to iterate through the returned list and retrieve the names of the tables.

```
public void listTables(String parentFolder) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        for(Path tablePath : admin.listTables(parentFolder)) {
            System.out.println(tablePath);
        }
    }
}
```

NOTE: The parameter `parentFolder` provides a path to a folder that is in the filesystem. See **"Table Paths"** in [HPE Data Fabric Database JSON Tables](#) for examples.

dbshell

```
# mapr dbshell
maprdb root:> list /demo
/demo/user
/demo/checkin
/demo/review
/demo/business
/demo/tip
5 table(s) found.
```

See [dbshell list](#) on page 7419 for further details.

Altering JSON Table Attributes

This topic describes how to change the values of table attributes by using the HPE Data Fabric Database JSON Client API.

In this example, the code turns off the bulk load flag on the table. Applications will typically need to turn off this flag after a bulk load of the table with the `import`, `importJSON`, or `copytable` utility.

Create a `TableDescriptor` object for an existing table by passing the path of the table to the `Admin` interface's `getTableDescriptor()` method.

Permissions Required

The `readAce` and `writeAce` permissions on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1627.

Example

Tables are altered a by using the `TableDescriptor` object and then passing that object to the `Admin` interface's `alterTable()` method.

```
public void alterTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        TableDescriptor tableDesc = admin.getTableDescriptor(tablePath);
        // set bulk load to false
        tableDesc.setBulkLoad(false);
        admin.alterTable(tableDesc);
    }
}
```

Deleting JSON Tables

This topic describes how to delete HPE Data Fabric Database JSON tables using either programmatic APIs or `dbshell`.

Java

To delete a table in the Java OJAI client, call an `Admin` object's `deleteTable()` method and pass, as an argument, the path of the table to delete:

```
public void deleteTable(String tablePath) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (admin.tableExists(tablePath)) {
            admin.deleteTable(tablePath);
        }
    }
}
```

Node.js

To delete a table in the Node.js OJAI client, call the `Connection.deleteStore()` method:

```
connection.deleteStore(table_path)
  then((deleteResponse) => {
    // Process deleteReponse
  });
```

Python

To delete a table in the Python OJAI client, call the `Connection.delete_store()` method:

```
rc = connection.delete_store(store_path=table_path)
```

dbshell

```
# mapr dbshell
maprdb root:> drop <table path>
```

See [dbshell drop](#) on page 7405 for additional details.

C#

To delete a table in the C# OJAI client, call the `connection.DeleteStore(string storePath)` method:

```
connection.DeleteStore(string storePath);
```

Go

To delete a table in the Go OJAI client, call the `connection.DeleteStore()` function:

```
err := connection.DeleteStore("/store_path")
```

Permissions Required

You must have both the `readAce` and `writeAce` permissions on the volumes where the JSON tables are located to delete it. For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1627.

Permission Types for Fields and Column Families in JSON Tables

By using ACEs, you can grant or deny access to fields and column families that are in JSON tables.

There are three types of permission:

- Traverse (`traverseperm`)
- Read (`readperm`)
- Write (`writeperm`)

Traverse (traverseperm)

This permission allows the grantee to descend a hierarchy of fields to access fields on which the grantee has write or read permission.

For example, suppose that a user has read and write access to only field `b` below.

To access field b, the user would need to be able to traverse (pass through) field a. In this case, because the entire document is in the default column family, the user could be granted traverse permission on the default column family. Field a would inherit the traverse permission.

If a user was denied traverse permission on the default column family, the user would not be able to access field b. Granting traverse permission on field a in this case would have no effect.

In the example below, field a is part of the cf1 column family.

To be able to read and write at field b, the user could be granted the traverse permission on the column family.

Read (readperm)

The read permission allows the grantee to read from a field.

This permission extends to fields that are nested below the field on which the permission was granted. However, grantees can be explicitly denied the permission on any of the nested fields.

Write (writeperm)

This permission allows the grantee to delete a field, insert a value into a field, or overwrite field value.

As illustrated in the two diagrams below, deleting a field also deletes all fields that are nested within that field, even those fields on which the write permission is explicitly denied.

*Obtaining readperm and writeperm on Fields*

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm and writeperm permissions on that field. How you obtain these permissions depends on whether the field is in the default column family or a non-default column family.

If the field is in the default column family

In the document below, you want to perform an operation on field c, which is in the default column family. The operation requires you to have `readperm` and `writeperm` on field c.

Figure 28: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have `readperm` and `writeperm` on the default column family

In this case, field c inherits these permissions, assuming that the permissions were not denied on field a or b.

If you do not have `readperm` and `writeperm` on field a or b, you need `traverseperm` on the field that denied you those permissions. You also need `readperm` and `writeperm` explicitly granted to you on field c. You could be granted these permissions with the `maprcli table cf colperm set` command, as in these examples:

```
maprcli table cf colperm set -path
<path to JSON table>
-cfname default -name
a.b -traverseperm u:<user ID> |
<existing ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname default
```

```
-name a.b.c -readperm u:<user ID>
| <existing ACE for this
field> -writeperm
u:<user ID> | <existing ACE for this
field>
```

Case 2: You do not have readperm and writeperm on the default column family

In this case, you need the traverseperm permission on the default column family. Fields a and b inherit this permission. You also need readperm and writeperm on field c.

You could be granted these permissions with commands similar to these:

```
maprccli table cf edit -path
<path to JSON table> -cfname
default -traverseperm
u:<user ID> | <existing ACE for this
field>
maprccli table cf colperm set -path
<path to JSON table> -cfname
default -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Data Fabric Database's native JSON support. For information about them, see [Column Families in JSON table](#).

In the following document, you want to perform an operation on field c, which is in the column family cf1 that is defined at field b with the path a . b.

Figure 29: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path a.b

Case 1: You do not have readperm and writeperm on field b

You need traverseperm on field b and both readperm and writeperm on field c. You can be granted these permissions with commands similar to these:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname
cf1 -name a.b.c
-readperm u:<user ID> | <existing ACE
for this field> -writeperm u:<user
ID> |
<existing ACE for this field>
```

Case 2: You do have readperm and writeperm on field b

You do not need any further permissions. Field c inherits your readperm and writeperm permissions from field b.

Obtaining readperm or writeperm on Fields

In this scenario, you want to perform an operation on a field, and the operation requires that you have readperm or writeperm permissions on that field. How you obtain either permission depends on whether the field is in the default column family or a non-default column family.

If the field is in the default column family

In the following document, you want to perform an operation on field *c*, which is in the default column family. The operation requires you to have readperm or writeperm on field *c*.

Figure 30: Schematic diagram of an JSON document in which all fields are in the default column family

Case 1: You have the same permission (readperm or writeperm) on the default column family

In this case, field *c* inherits the permission, assuming that the permission was not denied on field *a* or *b*.

If you do not have readperm or writeperm on field *a* or *b*, you need traverseperm on the field that denied you the permission that you need. You also need readperm or writeperm explicitly granted to you on field *c*.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
```

```
default -name a.b -traverseperm
u:<user ID> | <existing ACE for this
field>
```

The next example command grants readperm:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname
default -name a.b.c -readperm u:<user
ID> | <existing ACE for this field>
```

Case 2: You do not have the same permission (readperm or writeperm) on the default column family

In this case, you need the traverseperm permission on the default column family. You also need readperm or writeperm explicitly granted to you on field c.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
```

This next example command grants readperm:

```
/opt/mapr/bin/maprcli table cf
colperm set -path <path to JSON
table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

If the field is in a non-default column family

NOTE: Non-default column families are an advanced feature of HPE Data Fabric Database's native JSON support. For information about them, see [Column Families in JSON Tables](#).

In the following document, you want to perform an operation on field c, which is in the column family that is defined at field b with the path a.b. The operation requires you to have readperm or writeperm on field c.

Figure 31: Schematic diagram of an JSON document in which fields b and c are in a column family that has the path a.b

Case 1: You do not have the permission you need (readperm or writeperm) on field b

You need traverseperm on field b, and you need readperm or writeperm granted to you explicitly on field c.

Example commands to grant these permissions:

```
/opt/mapr/bin/maprcli table cf
edit -path <path to JSON
table> -cfname cf1
-traverseperm u:<user ID> | <existing
ACE for this field>
maprcli table cf colperm set -path
<path to JSON table> -cfname cf1
-name a.b.c -readperm u:<user ID> |
<existing ACE for this field>
```

Case 2: You do have the permission you need (readperm or writeperm) on field b

You do not need any further permissions. Field c inherits your readperm and writeperm permissions from field b.

Setting Permissions on Arrays

If you are granting permissions on a field and the field contains array data, you must grant the permission on the array field. This grants access not only to array data in the field, but also nested documents and

scalar data. It is also possible to set permissions on subfields within nested documents that are stored in an array.

NOTE: This topic describes the behavior of permissions in HPE Data Fabric Database version 6.1 and later, regardless of the Data Fabric version you used to grant the permissions.

Granting Permissions on Array Elements

Suppose you have the following documents where person is:

- An array of nested documents in document id001
- A single nested document in document id002
- A scalar value in document id003

```
{
  "_id" : "id001",
  "person" : [
    {"name" : {"last" : "Smith", "first" : "John"}},
    {"name" : {"last" : "Subramaniam", "first" : "Ananya"}}
  ]
}
{
  "_id" : "id002",
  "person" : {"name" : {"last" : "Doe", "first" : "Jane"}}
}
{
  "_id" : "id003",
  "person" : "Unknown"
}
```

If you grant a user read permission on the array `person[]`, that user can read every field in every nested document within the array in document id001. The permission also enables the user to read the `person` field in documents id002 and id003.

If you receive an error when trying to grant permission on `person[]` because you previously granted permission on `person`, then you (or an administrator with the appropriate permissions) must first remove the existing permission on `person`. If you expect the schema of the `person` field to evolve to include non-array and array data, then you should grant the permission on `person[]` rather than `person` to avoid having to remove the conflicting `person` permission.

You cannot grant permissions on individual elements in an array; for example: `person[1]`. Granting permission on an array enables access to the entire array.

Granting Permissions on Nested Document Fields in an Array

If you want to restrict read access to only specific fields in `person`, whether the field is an array of nested documents or a single nested document, perform the following steps:

1. Deny the user read permission on the array `person[]`.
2. Grant the user traverse permission on the array `person[]`.
3. Grant the user read permission on the specific fields.

For example, to grant the user read permission on only the first names in the nested documents for the third step, grant read permission on `person[].name.first`. The permission enables the user to read the field in all nested documents in documents id001 and id002.

If permissions already exist on `person.name.first`, then all attempts to define permissions on `person[].name.first` fails. You (or an administrator with the appropriate permissions) must first remove the existing permission on `person.name.first`. Similar to the scenario described in the previous section, if you expect the schema of the `person` field to evolve to include individual nested documents as well as arrays of nested documents, then you should grant the permission on `person[].name.first` to avoid having to remove the conflicting permission.

If you already have permissions on `person[].name.first`, then attempting to define permissions on `person.name.first` fails. There is no need to add this permission.

Granting Permissions on JSON Tables

Summarizes the default ACEs for the supported ways of setting read, traverse, and write permissions.

The default permissions for column families are determined when tables are created. The default permissions for fields are inherited from the column family where the fields are located.

Action	Method	Permissions	Default Access-Control Expressions
Set default permissions on new column families when creating a JSON table.	Java API	-defaultreadperm -defaulttraverseperm -defaultwriteperm	u:<ID of the process>
	maprcli table create		u:<user ID of table creator>
	mapr dbshell		
	Control System		
Set default permissions on new column families when editing a JSON table.	maprcli table edit		Current ACEs
	Control System		
Set permissions on a column family when creating the column family.	maprcli table cf create	-readperm -traverseperm -writeperm -indexperm	ACEs for -defaultreadperm, -defaulttraverseperm, and -defaultwriteperm
	Control System		
Set permissions on a column family when editing the column family.	maprcli table cf edit		Current ACEs
	Control System		
Set permissions on individual fields.	maprcli table cf colperm set		Inherited from column family or parent field
	Control System		
Set the dynamic mask	maprcli table cf column datamask set	-defaultunmaskedreadperm -unmaskedreadperm	Set to the table creator
	maprcli table cf colperm set		
	maprcli table create		
	maprcli table edit		
	maprcli table cf create		
	maprcli table cf edit		
	maprcli table cf colperm set		
	Control System		

Managing Column Families

JSON tables store data in column families, which are collections of fields that are stored together on disk.

Each table has a default column family, which is default storage for all fields in the documents of a table. You can create additional column families to store data for a collection of fields in a separate location on disk. Queries that operate only on data that is stored in a column family are more efficient and better performing than queries on the same data when that data is stored with other data in a table. You can also cache values from a column family in memory.

Applications do not need to be aware of the existence of column families. They perform CRUD operations by using the paths of fields in a document. For example, to update any of the fields below a . c, an application does not need to be aware that the field is in the column family at the path a . c. The application simply moves through the document along the path to the field.

For more information, see [Column Families in JSON Tables](#) on page 734.

Creating Column Families

You can create column families with the HPE Data Fabric Database JSON Java API library by using the `Admin.createTable(TableDescriptor tableDescriptor)` method.

Add a column family to the `TableDescriptor` object before passing that object to the `createTable()` method.

Restriction

If any existing column family in a JSON table, including the default column family, uses a time-to-live that is greater than 0, you cannot create any additional column families in that table. See [Setting TTL for Data](#).

Permissions Required

- [readAce](#) and [writeAce](#) on the volume
- [lookupdir](#) on directories in the path
- `createrenamefamilyperm` on the table

Example

Here is an example of using the API to create two column families -- the default column family and a custom column family -- during the creation of a table:

```
/* Create a TableDescriptor for the table to create,
   passing in the path of the table. */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Create a FamilyDescriptor for the default column family.
   When you create a table with the API, you must also create
   the default column family.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor defaultfamilyDesc = MapRDB.newDefaultFamilyDescriptor();
tableDescriptor.addFamily(defaultfamilyDesc);

/* Create a FamilyDescriptor for the custom column family
   to create. The setJsonFieldPath() method specifies the field
   at which to create the column family.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor familyDescriptor = MapRDB.newFamilyDescriptor()
    .setName("CF1")
    .setJsonFieldPath("a.b");
tableDescriptor.addFamily(familyDescriptor);
```

```
// Pass the TableDescriptor to the Admin.createTable() method.
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tableDescriptor);
        }
    }
}
```

Alternative Method

You can also create column families in JSON tables by running the command `table cf create`.

Altering Column Families

You can alter column families, including the default column family for a table, by using the `Admin.alterFamily()` method in the HPE Data Fabric Database JSON Java API library.

Permissions Required

- `readAce` and `writeAce` on the volume
- `lookupdir` on directories in the path
- `createrenamefamilyperm` on the table

Example

Here is an example of using the API to change the name of a column family:

```
public void alterColumnFamily(String tablePath, String familyName,
String newFamilyName) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {

        /* Get a TableDescriptor object for the table. This object
           gives access to the column families that are in the table. */
        TableDescriptor tableDesc = admin.getTableDescriptor(tablePath);

        /* Get a FamilyDescriptor object for the column family to
           change the name of. */
        FamilyDescriptor familyDesc = tableDesc.getFamily(familyName);

        // Rename the column family.
        familyDesc.setName(newFamilyName);

        /* Call alterFamily(), passing in the path of the table,
           the original name of the column family, and the
           FamilyDescriptor in which the new name was set. */
        admin.alterFamily(tablePath, familyName, familyDesc);
    }
}
```

Alternative Method

You can also edit column families in JSON tables by running the command `table cf edit`.

Deleting Column Families

You can delete a column family (except for the default column family) in a JSON table with the `Admin.deleteFamily()` Java method.

IMPORTANT: Starting in the 6.0 release, you cannot delete a column family from a JSON table.

Permissions Required

The readAce and writeAce permissions on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1627.

Behavior

The data that is in the specified column family is deleted. If the column family is followed by one or more column families in a hierarchy, the other column families in the hierarchy are unaffected and still accessible. For example, if column family CF1 at path a.c is followed by column family CF2 at path a.c.f, CF2 remains accessible and only the data in CF1 is deleted.

Before deleting the column family CF1 at a.c	After deleting the column family CF1 at a.c
<pre>{ "a" : { "b" : "value_b", "c" : { "d" : "value_d", "e" : "value_e", "f" : { "g" : "value_g", "h" : "value_h" } } } }</pre>	<pre>{ "a" : { "b" : "value_b", "c" : { "d" : "", "e" : "", "f" : { "g" : "value_g", "h" : "value_h" } } } }</pre>

Example of using the Admin.deleteFamily() method

```
public void deleteColumnFamily(String tablePath, String familyName) throws
DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (admin.tableExists(tablePath)) {
            admin.deleteFamily(tablePath, familyName);
        }
    }
}
```

Parameter	Description
tablePath	The path of the table in the filesystem. See the "Table Paths" section in HPE Data Fabric Database JSON Tables on page 731.
familyName	The name of the column family to delete. You cannot delete the default column family. If familyName is equal to "default", the API returns an exception.

Setting TTL for Data

You can delete stale JSON documents in JSON tables automatically by setting a time-to-live (TTL) value on the column family.

TTL is set only on the default column family in a JSON table. The duration that you set applies to each entire JSON document in the JSON table.

NOTE: Only the default column family can exist in order to set TTL; no other column families can exist in the JSON table. You also cannot set the TTL for a JSON table if it has secondary indexes.

Data can become stale. If the data in an JSON document has not been updated within a certain period of time, you might want to delete the document. In the case of a large amount of JSON documents, applications should not have to track the time between updates and then delete the expired documents.

Because the time-to-live that is set on a column family affects an entire JSON table, only the default column family is allowed to have a non-default time-to-live value. In addition, to prevent multiple column families from having non-default time-to-live values, additional column families can not be created in a table if the default column family has a non-default value. This is because if more than one column family had a non-default TTL value, fragments of documents would expire at different times, leading to inconsistent views of data.

Permission Required

The writeAce permission on the volumes where the JSON tables are located. For information about how to set permissions on volumes, see [Setting Whole Volume ACEs](#) on page 1627.

Example: Setting the default column family to a non-default time-to-live value

If you set the time-to-live parameter for the default column family to 864,000 seconds, JSON documents in that table are considered to be stale if the document's data has not been updated within 10 days and are automatically deleted.

The following code example creates a JSON table, the default column family and sets the TTL to a non-default value of 10 days (864,000 seconds).

```
/* Create a TableDescriptor for the table to create,
   passing in the path of the table. */
TableDescriptor tableDescriptor = MapRDB.newTableDescriptor(tablePath);

/* Create a FamilyDescriptor for the default column family.
   When you create a table with the API, you must also create
   the default column family.
   Set the TTL to 10 days.
   After creating the FamilyDescriptor, add it to
   the TableDescriptor. */
FamilyDescriptor defaultfamilyDesc = MapRDB.newDefaultFamilyDescriptor()
    .setTTL(864000);
tableDescriptor.addFamily(defaultfamilyDesc);

// Pass the TableDescriptor to the Admin.createTable() method.
public void createJSONTable(String tablePath, TableDescriptor
tableDescriptor) throws DBException {
    try (Admin admin = MapRDB.newAdmin()) {
        if (!admin.tableExists(tablePath)) {
            admin.createTable(tableDescriptor);
        }
    }
}
```

Managing JSON Documents

To perform CRUD operations (create, read, update, and delete) on JSON documents in HPE Data Fabric Database JSON tables using the OJAI API, you use Document, DocumentStore, and DocumentMutation objects.

You can also perform these operations using [HPE Data Fabric Database Shell \(JSON Tables\)](#) on page 7401.

Document

To create a JSON document, you must create a `Document` object. See the following for information specific to each language:

Java

To create a JSON document in Java OJAI, use the [Document](#) interface.

See [Creating JSON Documents in Java OJAI](#) on page 3734 to learn about the different ways to create `Document` objects in Java.

Node.js

To create a `Document` object in Node.js OJAI, simply create a JSON object.

See [Sample OJAI Code for Creating JSON Documents](#) on page 3739 for an example of how to do this.

Python

The preferred approach is to create a `Document` object in Python is to create a Python dictionary. You can also use the [Document](#) interface.

See [Creating JSON Documents in Python OJAI](#) on page 3738 to learn about these two ways to create JSON documents in Python.

C#

To create a `Document` object in C# OJAI, create a C# object.

See [Sample OJAI Code for Creating JSON Documents](#) on page 3739 for an example of how to do this.

For C# OJAI examples, see this [Github page](#).

Go

To create a `Document` object in Go OJAI, create a Go structure.

See [Sample OJAI Code for Creating JSON Documents](#) on page 3739 for an example of how to do this.

DocumentStore

After you create a `Document` object, you can pass it to the `DocumentStore` interface. The interface has methods to perform the following tasks:

- Delete documents from tables
- Insert documents into tables
- Replace documents in tables

See the following for API links to the `DocumentStore` interface in each language:

Java

[DocumentStore](#)

NOTE: By default, OJAI implements non-buffered writes. If you want buffered writes instead, use the `ojai.mapr.documentstore.buffer-writes` option and with the Document object. This option is available only in the Java OJAI API. See [Enabling Buffered Writes in Java OJAI](#) on page 3859 for more information.

Node.js

[DocumentStore](#)

Python

[DocumentStore](#)

C#

[DocumentStore](#)

For C# OJAI examples, see this [Github page](#).

Go

[DocumentStore](#)

DocumentMutation

To make changes to JSON documents, create a DocumentMutation object. A DocumentMutation enables you to perform OJAI mutations, which includes replacing, updating, combining, and deleting fields in a JSON document. For a list of available mutations, see [Using OJAI Mutation Syntax](#) on page 3751.

Java

To create a DocumentMutation object, call the methods in the DocumentMutation class corresponding to the mutation operations you want to perform. See [DocumentMutation](#) for a list of available methods.

Pass the DocumentMutation object to either the [DocumentStore.checkAndUpdate](#) or [DocumentStore.update](#) method to apply the changes to the document. The first method accepts a [QueryCondition](#) parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.

Node.js

To create a DocumentMutation object, create a JSON object [Using OJAI Mutation Syntax](#) on page 3751.

Pass the DocumentMutation object to either the [DocumentStore.checkAndUpdate](#) or [DocumentStore.update](#) method to apply the changes to the document. The `DocumentStore.checkAndUpdate()` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.

Python

To create a DocumentMutation object, create a Python dictionary object [Using OJAI Mutation Syntax](#) on page 3751.

Pass the DocumentMutation object to either the [DocumentStore.check_and_update](#) or [DocumentStore.update](#) method to apply the changes to the document. The `DocumentStore.check_and_update()` method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both

C#

methods have an `_id` parameter corresponding to the document to be updated.

To create a `DocumentMutation` object, create a C# object [Using OJAI Mutation Syntax](#) on page 3751.

Pass the `DocumentMutation` object to either the [DocumentStore.CheckAndUpdate](#) or [DocumentStore.Update](#) method to apply the changes to the document. The [DocumentStore.CheckAndUpdate](#) method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.

For C# OJAI examples, see this [Github page](#).

Go

To create a `DocumentMutation` object, create a Go structure [Using OJAI Mutation Syntax](#) on page 3751.

Pass the `DocumentMutation` structure to either the [DocumentStore.CheckAndUpdate](#) or [DocumentStore.Update](#) method to apply the changes to the document. The [DocumentStore.CheckAndUpdate](#) method accepts an OJAI query condition parameter that must evaluate to true for the mutation to be applied. Both methods have an `_id` parameter corresponding to the document to be updated.

By default, the default maximum size of a JSON document is 32 MB. A `DocumentMutation` does not enforce this limit. HPE Data Fabric Database enforces the limit when you pass your `DocumentMutation` object to the `DocumentStore` method. See [JSON Document Size](#) on page 717 for information about how to increase this limit.

See [Examples: Updating JSON Documents](#) on page 3759 for examples that use mutations.

Creating JSON Documents in OJAI

The way you create a JSON document in your OJAI application depends on the language you use.

Creating JSON Documents in Java OJAI

There are several ways to create JSON documents in your Java OJAI application. They all require you to call the `Connection.newDocument` method to create a `Document` object.

More information

[Connection](#)

[Document](#)

Create a Document Using a Document Object in Java OJAI

You can create a new JSON document in your Java OJAI client by first calling the `Connection.newDocument()` method to create a `Document` object, and then calling methods on the object to specify document fields and values.

The following shows the detailed sequence of steps:

1. Create a new JSON document by calling the `newDocument()` method in the `Connection` class.
2. Specify the ID of the document with the `setId()` method.
3. Specify field names and their values with the `set()` or `setArray()` method.
4. Return the results in a `Document` object.

For example, suppose you want to create the following JSON document:

```
{
  "_id" : "movie00000001",
  "title" : "OJAI -- The Documentary",
  "studio" : "MapR Technologies, Inc.",
  "release_date" : "2015-09-29",
  "trailers" : {
    "teaser" : "https://10.10.21.90/trailers/teaser",
    "theatrical" : "https://10.10.21.90/trailers/theatrical"
  },
  "characters" : [
    "Heroic Developer",
    "Evil Release Manager",
    "Mad Development Manager"
  ],
  "box_office_gross" : 1000000000L
}
```

The following method creates the document:

```
public Document buildDocument() {
    return connection.newDocument()
        .setId("movie00000001")
        .set("title", "OJAI -- The Documentary")
        .set("studio", "MapR Technologies, Inc.")
        .set("release_date", Values.parseDate("2015-09-29"))
        .set("trailers.teaser", "https://10.10.21.90/trailers/teaser")
        .set("trailers.theatrical", "https://10.10.21.90/trailers/
theatrical")
        .setArray("characters",
            ImmutableList.of(
                "Heroic Developer", "Evil Release Manager", "Mad
Development Manager"))
        .set("box_office_gross", 1000000000L);
}
```

Create a Document from a JSON String in Java OJAI

You can create a new JSON document in your Java OJAI client by passing a JSON string to the `Connection.newDocument()` method.

To create the following JSON document:

```
{
  "_id":"id001",
  "a":1,
  "b":"aString",
  "array":[
    1,
    2,
    "arrStr",
    {
      "c":"arrMapStr"
    }
  ]
}
```

Call `Connection.newDocument()`, passing in a JSON string with escaped quotes:

```
Document pojoDoc = connection.newDocument(
    "{\"_id\":\"id001\",\"a\":1,\"b\":\"aString\",\"array\":[1,2,\"arrStr\"],\"c\":{\"arrMapStr\"}}");
```

Create a Document from a JavaBean

You can create a new JSON document in your Java OJAI client by passing a JavaBean to the `Connection.newDocument(Object bean)` method. Through an example, the content shows you a sample JavaBean class, how to create a bean for that class, how to create a JSON document from the bean, and how to convert a JSON document back to a bean.

Sample JavaBean Class

Suppose that you are using a JavaBean class named `ExampleJson`:

```
package com.example;

import java.util.ArrayList;
import java.util.HashMap;
import java.util.List;
import java.util.Map;
import javax.annotation.Generated;
import com.fasterxml.jackson.annotation.JsonAnyGetter;
import com.fasterxml.jackson.annotation.JsonAnySetter;
import com.fasterxml.jackson.annotation.JsonIgnore;
import com.fasterxml.jackson.annotation.JsonInclude;
import com.fasterxml.jackson.annotation.JsonProperty;
import com.fasterxml.jackson.annotation.JsonPropertyOrder;

@JsonInclude(JsonInclude.Include.NON_NULL)
@Generated("org.jsonschema2pojo")
@JsonPropertyOrder({
    "a",
    "b",
    "array"
})

public class ExampleJson {

    @JsonProperty("a")
    private Double a;
    @JsonProperty("b")
    private String b;
    @JsonProperty("array")
    private List<Object> array = new ArrayList<Double>();
    @JsonIgnore
    private Map<String, Object> additionalProperties = new HashMap<String, Object>();

    /**
     *
     * @return
     * The a
     */
    @JsonProperty("a")
    public Double getA() {
        return a;
    }

    /**
     *
     */
```

```

    * @param a
    * The a
    */
    @JsonProperty("a")
    public void setA(Double a) {
        this.a = a;
    }

    /**
     *
     * @return
     * The b
     */
    @JsonProperty("b")
    public String getB() {
        return b;
    }

    /**
     *
     * @param b
     * The b
     */
    @JsonProperty("b")
    public void setB(String b) {
        this.b = b;
    }

    /**
     *
     * @return
     * The array
     */
    @JsonProperty("array")
    public List<Object> getArray() {
        return array;
    }

    /**
     *
     * @param array
     * The array
     */
    @JsonProperty("array")
    public void setArray(List<Object> array) {
        this.array = array;
    }

    @JsonAnyGetter
    public Map<String, Object> getAdditionalProperties() {
        return this.additionalProperties;
    }

    @JsonAnySetter
    public void setAdditionalProperty(String name, Object value) {
        this.additionalProperties.put(name, value);
    }
}

```

Create a Bean

You can create a bean for the `ExampleJson` class with the following code:

```
ExampleJson bean = new ExampleJson();

bean.setA(1);
bean.setB("aString");

List arrList = new ArrayList();
arrList.add(1);
arrList.add(2);
arrList.add("arrStr");

Map arrMap = new HashMap();
arrMap.put("c", "arrMapStr");
arrList.add(arrMap);
bean.setArray(arrList);
```

Create a New Document from a Bean

After creating the `ExampleJson` bean, you can create a JSON document using the bean with the following call:

```
Document pojoDoc = connection.newDocument(bean);
```

The document will have the following structure:

```
{
  "a":1,
  "b":"aString",
  "array":[
    1,
    2,
    "arrStr",
    {
      "c":"arrMapStr"
    }
  ]
}
```

Create a JavaBean from a JSON Document

You can also create a JavaBean from a JSON document. For example, suppose you modify the document that you created earlier:

```
pojoDoc.set("d", "10");
```

The following converts the modified document back into an `ExampleJson` bean:

```
ExampleJson bean = pojoDoc.toJavaBean(ExampleJson.class);
```

Creating JSON Documents in Python OJAI

There are two ways to create JSON documents in your Python OJAI application, one of which is the preferred approach.

The preferred way to create a Python dictionary object and then pass it to the `Connection.new_document()` method:

```
json_dict = {
    "_id" : "movie00000001",
    "title" : "OJAI -- The Documentary",
    "studio" : "MapR Technologies, Inc.",
    "release_date" : "2015-09-29",
    "trailers" : {
        "teaser" : "https://10.10.21.90/trailers/teaser",
        "theatrical" : "https://10.10.21.90/trailers/theatrical"
    },
    "characters" : [
        "Heroic Developer",
        "Evil Release Manager",
        "Mad Development Manager"
    ],
    "box_office_gross" : 1000000000L
}
new_document = connection.new_document(dictionary=json_dict)
```

Alternatively, you can call Document interface methods to set fields and values:

```
doc = connection.new_document()
    .set_id("movie00000001")
    .set('title', 'OJAI - The Documentary')
    .set('studio', 'MapR Technologies, Inc.')
    .set('release_date', ODate.parse(date_str='2015-09-29'))
    .set('trailers.teaser', 'https://10.10.21.90/trailers/teaser')
    .set('trailers.theatrical', 'https://10.10.21.90/trailers/
theatrical')
    .set('characters', ['Heroic Developer', 'Evil Release Manager',
'Mad Development Manager'])
    .set('box_office_gross', 10000000000)
```

See the following for more details about the APIs:

- [Connection](#)
- [Document](#)

Sample OJAI Code for Creating JSON Documents

The sample code in this section shows you how to create a JSON document.

Java

The code is available at [OJAI_001_GetConnectionCreateDocument.java](#).

                @"age":{"$numberInt":"50"}, " +
                @"address": " +
                    @"{" +
                        @"street":"555 Moon Way", " +
                        @"city":"Gotham" +
                    @"}" +
            @"}";

        // Create a document from jsonStr
        var documentJson = connection.NewDocument(jsonStr);

        // Print the OJAI Document
        Console.WriteLine(documentJson.ToJsonString());

        // Create new document with the same fields using constructor
        var documentConstructed = connection.NewDocument()
            .SetID("id001")
            .Set("name", "Joe")
            .Set("age", 50)
            .Set("address.street", "555 Moon Way")
            .Set("address.city", "Gotham");

        // Print the OJAI Document
        Console.WriteLine(documentConstructed.ToJsonString());

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The code is available at [001_get_connection_create_document.go](#).

```
package main

import (
    "fmt"
```

```

    client "github.com/mapr/private-maprdb-go-client"
)
func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    // Create a connection to data access server
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Json string or map from which the Document will be created
    newMap := map[string]interface{}{
        "_id": "id001",
        "name": "Joe",
        "age": 50,
        "address": map[string]interface{}{
            "street": "555 Moon Way",
            "city": "Gotham",
        },
    }

    // Create new document from json_document
    newDocument := connection.CreateDocumentFromMap(newMap)

    // Print the new OJAI Document
    fmt.Println(newDocument.AsJsonString())

    // Close connection
    connection.Close()
}

```

Examples: Inserting JSON Documents

This section contains sample code that inserts a JSON document into a HPE Data Fabric Database JSON table. It also shows the HPE Data Fabric Database Shell syntax for inserting documents.

Java

The following code is available at [OJAI_002_GetStoreAndInsertDocuments.java](#).

After you create the JSON document, call the [DocumentStore.insertOrReplace](#) method to insert the document into HPE Data Fabric Database.

```

*/
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

import com.mapr.ojai.examples.data.Dataset;
import com.mapr.ojai.examples.data.User;

public class OJAI_002_GetStoreAndInsertDocuments {

    public static void main(String[] args) {

        System.out.println("==== Start Application ===");

        // Create an OJAI connection to MapR cluster
        final Connection connection = DriverManager.getConnection("ojai:mapr:");

        // Get an instance of OJAI
        final DocumentStore store = connection.getStore("/demo_table");

        for (final User someUser : Dataset.users) {
            // Create an OJAI Document form the Java bean (there are other ways
too)
            final Document userDocument = connection.newDocument(someUser);

            System.out.println("\t inserting "+ userDocument.getId());

            // insert the OJAI Document into the DocumentStore
            store.insertOrReplace(userDocument);
        }

        // Close this instance of OJAI DocumentStore
        store.close();

        // close the OJAI connection and release any resources held by the
connection
        connection.close();

        System.out.println("==== End Application ===");
    }
}

```

Node.js

The following code is available at [OJAI_002_GetStoreAndInsertDocuments.js](#).

The following code creates a list of JSON objects and then calls the [DocumentStore.insertOrReplace](#) method to insert the document into HPE Data Fabric Database.

```

Go

The following code is available at [002_get_store_and_insert_documents.go](https://github.com/mapr/private-maprdb-go-client).

The following code creates a list of JSON dictionary objects, creates [Document](#) objects, and calls the [DocumentStore.InsertOrReplaceDocument](#) function to insert the documents into HPE Data Fabric Database.

```

package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    isExists, err := connection.IsStoreExists(storeName)
    if err != nil {
        panic(err)
    }
    var store *client.DocumentStore
    if isExists {
        store, err = connection.GetStore(storeName)
    }
}

```

```

        if err != nil {
            panic(err)
        }
    } else {
        store, err = connection.CreateStore(storeName)
        if err != nil {
            panic(err)
        }
    }
}

// Slice of maps from which the Document will be created
documentArray := []map[string]interface{}{
    {
        "_id":      "user0000",

"542-5656"},
        },
    },
}

```

```

for _, docMap := range documentArray {
    // Create new document from json_document
    newDocument := connection.CreateDocumentFromMap(docMap)
    // Print the new OJAI Document
    fmt.Println(newDocument.AsJsonString())
    //Insert the OJAI Document into the DocumentStore
    store.InsertOrReplaceDocument(newDocument)
}

// Close connection
connection.Close()
}

```

Using OJAI Mutation Syntax

To perform updates using OJAI, you specify the document you want to update using its `_id` field, create *mutations* for that document, and then update it in your document store. OJAI defines a syntax for specifying mutations. Mutations allow you to append, decrement, delete, increment, combine, replace, and update fields in a document. This topic describes the syntax for the supported mutation operations and provides examples.

The following table lists the mutations OJAI supports. Each entry in the table contains a brief description of the mutation and a link to a section in this topic that describes the mutation in more detail.

Mutation Operation	Description
Append	Appends values to binary, string, and array fields
Decrement	Decrements field values
Delete	Deletes fields
Increment	Increments field values
Merge	Combines a nested document with an existing document
Put	Replaces field values or adds new fields
Set	Updates field values or adds new fields

The examples in this topic use the following sample JSON document:

```

{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
      "d" : 10,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}

```

OJAI Append Mutations

Syntax

```
{"$append":{"fieldpath":value}}
```

```
{"$append":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The `$append` mutation is a read-modify-write operation. Use it to append specified values to existing binary, string, or array type fields. If there is type mismatch in any intermediate field specified in a *fieldpath* for the document, the mutation fails with an error. For example, an append mutation on field path `a.b.c` fails if the field `a` is a scalar.

To append multiple field paths, use an array notation to list the field paths.

Example

The following mutation appends an element to the array `a.b` and appends the string " MapR" to the end of the string already in the field path `a.c.e`:

```
{ "$append": [ { "a.b": { "appd": 1 } },
  { "a.c.e": " MapR" } ] }
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
1  { "decimal" : 123.456 }, { "appd" :
1  } ],
    "c" : {
      "d" : 10,
      "e" : "Hello MapR"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Decrement Mutations**Syntax**

```
{ "$decrement": "fieldpath" }
```

```
{ "$decrement":
  { "fieldpath": decrementValue } }
```

```
{ "$decrement":
  [ { "fieldpath1": decrementValue1 },
    { "fieldpath2": decrementValue2, ... } ] }
```

Description

The `$decrement` mutation decrements the value in the *fieldpath*. To decrement multiple field paths, use an array notation to list the field paths.

If the *fieldpath* does not exist, the mutation adds a new field to the document with the value *decrementValue*.

The *decrementValue* is optional and defaults to -1.

The mutation fails if there is a type mismatch in the field.

Example

The following updates the value 10 in a.c.d to 5 by using the decrement mutation:

```
{"$decrement":{"a.c.d":5}}
```

The mutation results in the following document, with the field update highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
    { "decimal" : 123.456 } ],
    "c" : {
      "d" : 5,
      "e" : "Hello"
    }
  },
  "m" : "MapR wins"
}
```

OJAI Delete Mutations**Syntax**

```
{"$delete":"fieldpath"}
```

```
{"$delete":
["fieldpath1","fieldpath2",...]}
```

Description

The \$delete mutation removes either a single field or a list of fields from a document. If the field does not exist, the delete ignores that field.

Example

The following mutation removes two fields from the document:

```
{"$delete":["a.b[1]","a.c.e"]}
```

The mutation results in the following document:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false } ],
    "c" : {
      "d" : 10
    }
  },
  "m" : "MapR wins"
}
```

OJAI Increment Mutations

Syntax

```
{"$increment": "fieldpath"}
```

```
{"$increment":  
{"fieldpath": incrementValue}}
```

```
{"$increment":  
[{"fieldpath1": incrementValue1},  
{"fieldpath2": decrementValue2, ...}]}
```

Description

The `$increment` mutation increments the value in the *fieldpath*. To increment multiple field paths, use an array notation to list the field paths.

If the *fieldpath* does not exist, the mutation adds a new field to the document with the value *incrementValue*.

The *incrementValue* is optional and defaults to 1.

The mutation fails if there is a type mismatch in the field.

Example

The following updates the value 10 in `a.c.d` to 15 by using the increment mutation:

```
{"$increment": {"a.c.d": 5}}
```

The mutation results in the following document, with the field update highlighted in bold:

```
{  
  "_id" : "id1",  
  "a" : {  
    "b" : [ { "boolean" : false },  
    { "decimal" : 123.456 } ],  
    "c" : {  
      "d" : 15,  
      "e" : "Hello"  
    }  
  },  
  "m" : "MapR wins"  
}
```

OJAI Merge Mutations

Syntax

```
{"$merge":  
{"fieldpath": nestedDocument}}
```

Description

The `$merge` mutation combines a *nestedDocument* with an existing document at a specified *fieldpath*. If the original document already contains subfields specified in the *nestedDocument*, then the mutation replaces the values for those subfields. Otherwise, it adds new subfields to the document.

NOTE: The `$merge` mutation does not support the array notation that other mutation operations provide.

Examples

To specify more than one merge operation in a single mutation, use the syntax described at either [Specifying Multiple Mutation Operations](#) on page 3757 or [OJAI Mutations Without Explicit Mutation Operation Names](#) on page 3758. When using these syntax variations, avoid specifying overlapping field paths. HPE Data Fabric Database treats these as [conflicting mutations](#) and discards conflicts.

The following mutation replaces the pre-existing field path `a.c.d` with the value `11`. It adds a new subfield `y` to the nested document `a.c`.

```
{"$merge":{"a.c":{"d":11,"y":"yo"}}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false },
    { "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello",
      "y" : "yo"
    }
  },
  "m" : "MapR wins"
}
```

The following mutation replaces the value in the field path `a.b` and adds a new subfield `a.d`:

```
{"$merge":{"a":{"b":1,"d":"MapR"}}
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : 1,
    "c" : {
      "d" : 10,
      "e" : "Hello"
    },
    "d" : "MapR"
  },
  "m" : "MapR wins"
}
```

OJAI Put Mutations

Syntax

```
{"$put":{"fieldpath":value}}
```

```
{"$put":[{"fieldpath1":value1},
{"fieldpath2":value2},...]}
```

Description

The \$put mutation is a replace operation. It is not a read-modify-write operation; it does no validation on the data. If the specified *fieldpath* exists, the mutation replaces the *fieldpath*'s value with the new *value*, regardless of the type of the original value. For example, you can update a field *a.b* from an array to a nested document. If the *fieldpath* does not exist, the mutation creates a new field with the given *value*. Because the operation does no data validation, it is significantly faster than the [set](#) operation.

To replace multiple field paths, use an array notation to list the field paths.

Example

The following example replaces the pre-existing fields *a.b* and *a.c.d* with values whose types differ from the original types. It also adds a new field *a.x*.

```
{ "$put": [ { "a.b": { "boolean": true } },
  { "a.c.d": "eureka" }, { "a.x": 1 } ] }
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : { "boolean" : true },
    "c" : {
      "d" : "eureka",
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

The mutation behaves as follows for the pre-existing fields:

- For *a.b*, the mutation replaces the original array of nested documents with a single nested document.
- For *a.c.d*, the mutation changes the field from an integer to a string.

OJAI Set Mutations**Syntax**

```
{ "$set": { "fieldpath": value } }
```

```
{ "$set": [ { "fieldpath1": value1 },
  { "fieldpath2": value2 }, ... ] }
```

Description

The \$set mutation updates one or more fields in a document. It is a read-modify-write operation. It validates the type of the existing value before applying the mutation. If the specified *fieldpath* does not exist in a document, the mutation creates a new field. If the *fieldpath* exists but is not of the same type as the type of new *value*, then the entire mutation fails.

Example

To update multiple field paths, use an array notation to list the field paths.

The following example updates the pre-existing fields `a.b[0]` and `a.c.d`. It also adds a new field `a.x`.

```
{ "$set": [ { "a.b[0].boolean": true },
  { "a.c.d": 11 }, { "a.x": 1 } ] }
```

The mutation results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : true },
    { "decimal" : 123.456 } ],
    "c" : {
      "d" : 11,
      "e" : "Hello"
    },
    "x" : 1
  },
  "m" : "MapR wins"
}
```

Specifying Multiple Mutation Operations

You can specify more than one operation in a single mutation by specifying each operation separated by a comma.

The following is a mutation with six operations:

```
{
  "$set": { "x": [1, 2, 3] },
  "$put": { "a.c.e": { "$binary": "AAAADg==" } },
  "$increment": "a.b[1].decimal",
  "$delete": "a.b[0]",
  "$merge": { "newDoc": { "k": "MapR DBShell rocks!!" } },
  "$append": { "m": "!!!" }
}
```

It results in the following document, with the field updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "decimal" : 124.456 } ],
    "c" : {
      "d" : 10,
      "e" : { "$binary" : "AAAADg==" }
    }
  },
  "m" : "MapR wins!!!",
  "newDoc" : { "k" : "MapR DBShell rocks!!" },
  "x" : [ 1, 2, 3 ]
}
```

The mutation applies the updates in the following manner:

- The `$set` mutation adds a new array field `x` with the value `[1, 2, 3]`.

- The `$put` mutation replaces the string `"Hello"` with the nested document `{"$binary": "AAAADg=="}`.
- The `$increment` mutation increments the value `123.456` in the second element of the array `a.b`.
- The `$delete` mutation deletes the field path `a.b[0]`, resulting in a single element array `a.b`.
- The `$merge` mutation adds a new field `newDoc` with the nested document `{"k": "MapR DBShell rocks!!"}` as its value.
- The `$append` mutation appends the string `"!!!"` to the end of the string `"MapR wins"`.

Conflicting Mutations

When you specify a mutation with field paths that are overlapping, HPE Data Fabric Database detects the conflict, discards the previous conflicting operation, and proceeds with the next operation.

For example, suppose you have the following document:

```
{"_id": "id1", "a": {"b": {"c": 5}}}
```

The following mutation has two operations with overlapping fields `a.b`:

```
{"$delete": "a.b", "$set": {"a.b.d": 10}}
```

You may have intended for the mutation to first delete `a.b` and then to replace it with `a.b.d` as follows:

```
{"_id": "id1", "a": {"b": {"d": "10"}}}
```

But the *actual* result is the following:

```
{"_id": "id1", "a": {"b": {"c": 5, "d": "10"}}}
```

In this case, the set operation on `a.b.d` causes the delete operation on `a.b` to be discarded.

NOTE: In the earlier example in this section, the `$increment` and `$delete` operations are not conflicting because one operates on `a.b[1]`, while the other operates on `a.b[0]`. On the other hand, the following are conflicting operations:

```
{"$increment": "a.b[1].decimal", "$delete": "a.b"}
```

OJAI Mutations Without Explicit Mutation Operation Names

You can specify a mutation without using an explicit mutation name. These mutations run as merge operations.

For example, the following mutation merges the fields `k` and `a.c.d` to the document by adding a new field `k` and updating `a.c.d`:

```
{"k": "eureka", "a": {"c": {"d": 1234}}}
```

The mutation results in the following document, with updates highlighted in bold:

```
{
  "_id" : "id1",
  "a" : {
    "b" : [ { "boolean" : false }, { "decimal" : 123.456 } ],
    "c" : {
```

```

        "d" : 1234,
        "e" : "Hello"
    }
},
"k" : "eureka",
"m" : "MapR wins"
}

```

Examples: Updating JSON Documents

This section contains sample code that updates a JSON document in a HPE Data Fabric Database JSON table using an OJAI mutation. It also shows the HPE Data Fabric Database Shell syntax for updating documents.

See [Using OJAI Mutation Syntax](#) on page 3751 for more details about OJAI mutations.

Java

The following code is available at [OJAI_012_UpdateDocument.java](#). It does the following:

- Finds a document using the [DocumentStore.findById](#) method
- Creates a [DocumentMutation](#) that updates a field
- Updates the document by calling the [DocumentStore.update](#) method

```

        // Create an OJAI connection to MapR cluster
        final Connection connection = DriverManager.getConnection("ojai:mapr:");

        // Get an instance of OJAI DocumentStore
        final DocumentStore store = connection.getStore("/demo_table");

        String docId = "user0002";

        // Print the document before update

```

```

    System.out.println( "\t"+
store.findById(docId).getMap("address").toString() );

    // Create a DocumentMutation to update the zipCode field
    DocumentMutation mutation = connection.newMutation()
        .set("address.zipCode", 95196L);

    System.out.println("\tUpdating document "+ docId);

    // Update the Document with '_id' = "user0002"
    store.update(docId, mutation);

    // Print the document after update
    System.out.println( "\t"+
store.findById(docId).getMap("address").toString() );

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
    connection
    connection.close();

    System.out.println("==== End Application ===");
}
}

```

Node.js - Update

The following code is available at [OJAI_011_UpdateDocument.js](#). It does the following:

- Finds a document using the [DocumentStore.findById](#) method
- Creates an OJAI mutation that updates a field
- Updates the document by calling the [DocumentStore.update](#) method

```

/*

    console.log(`Document with id ${docId} before update`)
    console.log(docAfterUpdate);
  });

```

Python - Update

The following code is available at [012_update_document.py](#). It does the following:

- Finds a document using the `DocumentStore.find_by_id` method
- Creates an OJAI mutation that updates a field

- Updates the document by calling the [DocumentStore.update](#) method

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
    "ssl=true;" \
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
    "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

doc_id = 'user0002'

# Print the document before update
document_before_update = store.find_by_id(doc_id)
print("Document with id {0} before update".format(doc_id))
print(document_before_update)

# Create mutation to update the zipCode field
mutation = {'$set': {'address.zipCode': 95196}}

# Execute update
store.update(_id=doc_id, mutation=mutation)

document_after_update = store.find_by_id(doc_id)
print('Document with id {0} after update'.format(doc_id))
print(document_after_update)
```

Python - Check and Update

The following code is available at [013_check_and_update_document.py](#). It does the following:

- Finds a document using the [DocumentStore.find_by_id](#) method
- Creates an OJAI mutation that updates a field
- Creates an OJAI condition to apply in the check and update
- Performs the check and update on the document by calling the [DocumentStore.check_and_update](#) method

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
    "ssl=true;" \
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
    "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

doc_id = 'user0001'

# Print the document before update
document_before_update = store.find_by_id(doc_id)
print("Document with id {0} before update".format(doc_id))
print(document_before_update)
```

```
# Create mutation to update the zipCode field
mutation = {'$put': {'address.zipCode': 99999}}

# Create condition
condition = {'$eq': {'address.street': '320 Blossom Hill Road'}}

# Execute check_and_update.
# Returns True if condition True and document was updated.
update_result = store.check_and_update(_id=doc_id,
                                       mutation=mutation,
                                       query_condition=condition)

print(update_result)

document_after_update = store.find_by_id(doc_id)
print('Document with id {0} after update'.format(doc_id))
print(document_after_update)
```

dbshell

The following dbshell command is equivalent to the code examples. See [dbshell update](#) on page 7420 for more information and examples.

```
# mapr dbshell
maprdb root:> update /demo_table --id user002 --m {"$set":
{"address.zipCode":95196}}
```

C# - Update

The following code is available at [012_UpdateDocument.cs](#). It does the following:

- Finds a document using the [DocumentStore.FindById](#) method to print the document before update.
- Creates an OJAI mutation that updates a field.
- Updates the document by calling the [DocumentStore.Update](#) method.

```
using System;
using MapRDB.Driver;

public class UpdateDocument
{
    public void UpdateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        var docId = "user0002";

        // Print the document before update
        var documentBeforeUpdate = store.FindById(docId);
```

```

        Console.WriteLine($"Document with id {docId} before update:");
        Console.WriteLine(documentBeforeUpdate);

        // Create mutation to update the zipCode field
        var mutation =
connection.NewDocumentMutation().Set("address.zipCode", (long)95196);

        // Execute update
        store.Update(docId, mutation);

        // Print the document after update
        var documentAfterUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} after update:");
        Console.WriteLine(documentAfterUpdate);

        // Close the OJAI connection
        connection.Close();
    }
}

```

C# - Check and Update

The following code is available at [013_CheckAndUpdateDocument.cs](#). It does the following:

- Finds a document using the `DocumentStore.FindById` method to print the document before update.
- Creates an OJAI mutation that updates a field.
- Creates an OJAI condition to apply in the check and update.
- Performs the check and update on the document by calling the `DocumentStore.CheckAndUpdate` method.

```

using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class CheckAndUpdateDocument
{
    public void CheckAndUpdateDocument()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        var docId = "user0001";

        // Print the document before update
        var documentBeforeUpdate = store.FindById(docId);
        Console.WriteLine($"Document with id {docId} before update:");
        Console.WriteLine(documentBeforeUpdate);

        // Create mutation to update the zipCode field
        var mutation =

```

```

connection.NewDocumentMutation().SetOrReplace("address.zipCode", 99999);

    // Create condition
    var condition = connection
        .NewQueryCondition()
        .Is("address.street", QueryOp.EQUAL, "320 Blossom Hill
Road")
        .Close()
        .Build();

    // Execute CheckAndUpdate.
    // Returns True if condition True and document was updated
    var updateResult = store.CheckAndUpdate(docId, condition, mutation);

    Console.WriteLine(updateResult);

    // Print the document after update
    var documentAfterUpdate = store.FindById(docId);
    Console.WriteLine($"Document with id {docId} after update:");
    Console.WriteLine(documentAfterUpdate);

    // Close the OJAI connection
    connection.Close();
}
}

```

Go - Update

The following code is available at [012_update_document.go](https://github.com/mapr/private-maprdb-go-client). It does the following:

- Finds a document using the `DocumentStore.FindByIdString` function to print the document before update
- Creates an OJAI mutation that updates a field
- Updates the document by calling the `DocumentStore.Update` function

```

package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"
    documentId := "user0002"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }
}

```

```

// Get a store and assign it as a DocumentStore struct
store, err := connection.GetStore(storeName)
if err != nil {
    panic(err)
}

// Print the document before update
documentBeforeUpdate, err := store.FindByIdString(documentId)
if err != nil {
    panic(err)
}
fmt.Printf("Document with id %v before update.\n %v", documentId,
documentBeforeUpdate.AsJsonString())

// Create mutation to update the zipCode field
mutation := map[string]interface{}{"$set": map[string]interface{}{
"address.zipCode": 95196}}

// Execute update
err = store.Update(client.BosiFromString(documentId),
client.MosmFromMap(mutation))
if err != nil {
    panic(err)
}

// Print the document after update
documentAfterUpdate, err := store.FindByIdString(documentId)
if err != nil {
    panic(err)
}
fmt.Printf("Document with id %v after update.\n %v", documentId,
documentAfterUpdate.AsJsonString())

// Close connection
connection.Close()
}

```

Go - Check and Update

The following code is available at [013_check_and_update_document.go](#). It does the following:

- Finds a document using the [DocumentStore.FindByIdString](#) function to print the document before update
- Creates an OJAI mutation that updates a field
- Creates an OJAI condition to apply in the check and update
- Performs the check and update on the document by calling the [DocumentStore.CheckAndUpdate](#) function

```

package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +

```

```

    "auth=basic;" +
    "user=mapr;" +
    "password=mapr;" +
    "ssl=true;" +
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
    "sslTargetNameOverride=node1.cluster.com"

storeName := "/demo_table"
documentId := "user0001"

// Create a connection to DAG
connection, err := client.MakeConnection(connectionString)
if err != nil {
    panic(err)
}

// Get a store and assign it as a DocumentStore struct
store, err := connection.GetStore(storeName)
if err != nil {
    panic(err)
}

// Print the document before update
documentBeforeUpdate, err := store.FindByIdString(documentId)
if err != nil {
    panic(err)
}
fmt.Printf("Document with id %v before update.\n %v\n", documentId,
documentBeforeUpdate.AsJsonString())

// Create mutation to update the zipCode field
mutation := map[string]interface{}{"$put": map[string]interface{}
{"address.zipCode": 99999}}

// Create condition
condition := map[string]interface{}{"$eq": map[string]interface{}
{"address.street": "320 Blossom Hill Road"}}

// Execute update
// Returns True if condition True and document was updated.
res, err := store.CheckAndUpdate(
    client.BosiFromString(documentId),
    client.MoscFromMap(condition),
    client.MosmFromMap(mutation))
if err != nil {
    panic(err)
}

// Print the document after update
documentAfterUpdate, err := store.FindByIdString(documentId)
if err != nil {
    panic(err)
}
fmt.Printf("Update result: %v.\nDocument with id %v after update.\n
%v\n",
    res,
    documentId,
    documentAfterUpdate.AsJsonString())

// Close connection
connection.Close()
}

```

Querying JSON Documents

This section describes how to query JSON documents in HPE Data Fabric Database JSON tables using the OJAI API library and HPE Data Fabric Database Shell. It includes sample programs using the OJAI API library and shows how to run the same queries in HPE Data Fabric Database Shell.

Querying in OJAI Applications

To query HPE Data Fabric Database JSON tables in your OJAI applications, you use the OJAI Query interface. The typical flow of your application involves creating a connection, obtaining a handle to the HPE Data Fabric Database JSON table you want to query, constructing the query, performing the query, and then processing the results.

NOTE: The Node.js, Python, C#, and Go OJAI clients are supported starting in EEP 6.0.

Description

The DocumentStore interface includes a Query interface. The Query interface allows you to build a query programmatically.

Java

To construct an OJAI query, call the following methods in the Query interface:

- [Query.select](#)
- [Query.where](#)
- [Query.orderBy](#)
- [Query.offset](#)
- [Query.limit](#)

To run the query, pass the Query object to the [DocumentStore.find](#) method.

Node.js

To construct an OJAI query, create a Node.js JSON object using [OJAI Query Syntax](#) on page 3793.

To run the query, pass the Query object to the [DocumentStore.find](#) method.

Python

To construct an OJAI query, create a Python dictionary object using [OJAI Query Syntax](#) on page 3793.

To run the query, pass the Query object to the [DocumentStore.find](#) method.

NOTE: The following Query methods are available in the Python OJAI API, but creating a Python dictionary is the preferred approach:

- [Query.select](#)
- [Query.where](#)
- [Query.order_by](#)
- [Query.offset](#)
- [Query.limit](#)

C#

To construct an OJAI query, create a C# object.

To run the query, pass the Query object to the [DocumentStore.Find](#) method.

NOTE: The following Query methods are available in the C# OJAI API:

- [Query.Select](#)
- [Query.Where](#)
- [Query.OrderBy](#)
- [Query.Offset](#)
- [Query.Limit](#)

Go

To construct an OJAI query, create a Go object.

To run the query, pass the Query object to the [DocumentStore.FindQuery](#) function.

NOTE: The following Query functions are available in the Go OJAI API:

- [Query.Select](#)
- [Query.WhereCondition](#)
- [Query.OrderBy](#)
- [Query.Offset](#)
- [Query.Limit](#)

Basic Application Flow

The following steps describe the basics in developing client applications that query HPE Data Fabric Database JSON tables using the OJAI API.

Java

1. Create a [Connection](#) instance to your Data Fabric cluster using the [DriverManager](#) class:

```
Connection connection =
    DriverManager.getConnection("ojai:m
    apr:");
```

NOTE: Do not omit the ending colon in the connection string.

2. Obtain a [DocumentStore](#) handle to a HPE Data Fabric Database JSON table using the connection object:

```
DocumentStore store =
    connection.getStore(tablePath);
```

3. Create a [Query](#) object using the connection object:

```
Query query =
connection.newQuery();
```

4. Perform the query operation on the table:

```
QueryResult result =
store.find(query);
```

5. Process the results.

The following code snippet iterates through the [QueryResult](#) and prints each document as a JSON string:

```
for (final Document userDocument :
result) {
    // Print the OJAI Document

    System.out.println(userDocument.asJ
sonString());
}
```

To process individual fields within a document, use the [DocumentReader](#) interface. The following code snippet iterates through the fields in a document and prints the fields that are strings:

```
Iterable it =
result.documentReaders();
for (DocumentReader reader : it) {
    EventType et = null;
    while ((et = reader.next()) !=
null) {
        if (et ==
EventType.STRING) {

            System.out.println("Value of field
" + reader.getFieldName() + ": " +
reader.getString());
        }
    }
}
```

6. Close the result stream, the connection to the document store, and the connection to Data Fabric:

```
result.close();
store.close;
connection.close();
```

Node.js

1. Create a connection:

```

ConnectionManager.getConnection('localhost:5678?;user=mapr;password=mapr;ssl=false')
    .then((connection) => {
        // Process connection
        ...
    });

```

2. Obtain a handle to a HPE Data Fabric Database JSON table using the connection object:

```

connection.getStore(tablePath)
    .then((store) => {
        // Process store
        ...
    });

```

3. Create a query object:

```
const query = {};
```

4. Perform the query operation on the table:

```
const stream = store.find(query)
```

5. Process the results:

```
stream.on('data', (document) => console.log(document));
```

6. Close the connection to Data Fabric:

```

stream.on('end', () => {
    console.log('end');
    connection.close();
});

```

Python

1. Create a [Connection](#) instance to your Data Fabric cluster using the [ConnectionFactory](#) class:

```

connection_str =
'localhost:5678?;user=mapr;password=mapr;ssl=false'
connection =
ConnectionFactory.get_connection(connection_str=connection_str)

```

2. Obtain a [DocumentStore](#) handle to a HPE Data Fabric Database JSON table using the connection object:

```
store =
connection.get_store(table_path)
```

3. Create a [Query](#) object using the connection object:

```
query =
connection.new_query().build()
```

4. Perform the query operation on the table:

```
query_result = store.find(query)
```

5. Process the results.

The following code snippet iterates through the [QueryResult](#) and prints each document as a Python dictionary:

```
for doc in query_result:
    print(doc)
```

6. Close the connection to Data Fabric:

```
connection.close()
```

C#

1. Create a [Connection](#) instance to your Data Fabric cluster using the ConnectionFactory class:

```
var connectionStr =
    $"localhost:5678?auth=basic;" +
        $"user=mapr;" +
        $"password=mapr;" +
        $"ssl=true;" +
        $"sslCA=/opt/mapr/conf/
ssl_truststore.pem;" +

    $"sslTargetNameOverride=node1.mapr.
com";
var connection =
    ConnectionFactory.CreateConnection(
        connectionStr);
```

2. Obtain a [DocumentStore](#) handle to a HPE Data Fabric Database JSON table using the connection object:

```
var store =
    connection.GetStore(storePath);
```

3. Create a [Query](#) object using the connection object:

```
var query =
connection.NewQuery().Build();
```

4. Perform the query operation on the table:

```
var queryResult =
store.Find(query);
```

5. Process the results.

The following code snippet iterates through the [QueryResult](#) and prints each document as a JSON:

```
var documentStream = await
queryResult.GetDocumentAsyncStream(
).GetAllDocuments();
foreach (var document in
documentStream)
{
    Console.WriteLine(document.ToJsonSt
ring());
}
```

6. Close the connection to Data Fabric:

```
connection.Close();
```

Go

1. Create a [Connection](#) instance to your Data Fabric cluster:

```
connectionString :=
"localhost:5678?
auth=basic;user=mapr;password=mapr;
ssl=false"
connection, error :=
client.MakeConnection(connectionString)
```

2. Obtain a [DocumentStore](#) handle to a HPE Data Fabric Database JSON table using the connection object:

```
store, error :=
connection.CreateStore("/
store_path")
```

3. Create a [Query](#) object:

```
query, err := client.MakeQuery()
query.Build()
```

4. Perform the query operation on the table:

```
queryResult, err :=
store.FindQuery(query,
&client.FindOptions{})
```

5. Process the results.

The following code snippet iterates through the [QueryResult](#) and prints each document as a JSON:

```
for _, doc := range
queryResult.DocumentList() {
    fmt.Println(doc)
}
```

6. Close the connection to Data Fabric:

```
connection.Close()
```

See [Examples: Querying JSON Documents](#) on page 3814 for complete code examples.

Related concepts

[OJAI Distributed Query Service](#) on page 711

OJAI queries either directly access HPE Data Fabric Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for HPE Data Fabric Database JSON, powered by Apache Drill. The Data Fabric client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of Drill.

[OJAI wiki page](#)

Comparisons and Sorts in OJAI Queries

When running OJAI queries with comparisons and sorts, you need to be aware of how different data types behave. You also need to understand how sorting works in Data Fabric DB queries. Depending on the component that runs the sort, you may encounter unexpected behavior.

OJAI supports comparisons using the `QueryCondition` interface. For information about how to use this interface, see [Query Conditions in OJAI Applications](#) on page 3779.

When using the OJAI Query where and orderby, and comparing and sorting across different data types, there are subtleties you should take into consideration. See [Using Comparable JSON Document Data Types in Comparisons and Sorts](#) on page 720 and [Using Non-comparable JSON Document Data Types in Comparisons and Sorts](#) on page 721 for more information.

If you do not have a secondary index defined that can generate your query's specified orderby, then your query requires an explicit sort. If you have installed the [OJAI Distributed Query Service](#) on page 711, the service performs the sort. If you have not, the Data Fabric client performs the sort, but restricts the amount of data it can sort. The default sort limit is 5000 documents. For example, if your query returns 10,000 documents, and you specify a query result limit of 5000 documents, the Data Fabric client can perform the sort.

IMPORTANT: The Data Fabric client returns an error if your query result size exceeds the client's sort limit.

You can avoid errors due to the client sort limitation by adhering to the following guidelines:

- If you know the largest possible query result size when your queries specify an order by, you can increase the sort limit of your client to that maximum size by setting the `ojai.mapr.query.max-client-sort-limit` parameter.

The following code snippets increase the limit to 6000:

Java

```
query.setOption("ojai.mapr.query.max-client-sort-limit", 6000);
```

NOTE: This option is not applicable to the Java OJAI Thin Client.

Node.js

```
const query
= {"$select":"col","$options":
{"ojai":{"mapr":{"query":
{"max-client-sort:6000}}}}
const stream = store.find(query)
```

Python

```
query = {"$select":"col","$options":
{"ojai":{"mapr":{"query":
{"max-client-sort:6000}}}}
query_result = store.find(query)
```

C#

```
var query =
connection.NewQuery()
    .Select("col")
    .SetMaxClientSortLimit(6000)
    .Build();

var queryResult =
store.Find(query);
```

Go

```
query := map[string]interface{}{
    "$select":"col",
    "$options":map[string]interface{}{
        "ojai":map[string]interface{}{
```

```
"mapr":map[string]interface{}{
  "query":map[string]interface{}{
    "max-client-sort":6000}}}}
queryResult, err :=
store.FindQueryMap(query,
&client.FindOptions{})
```

You can also set this option across all your OJAI clients by modifying a data access gateway property. See [Administering the Data Access Gateway - Application Properties](#) for details.

- If you do not know the largest possible query result size, specify a `limit` in your queries. If your query result size exceeds that `limit`, the client sorts the entire result set but returns only a subset of the rows up to the specified limit. This avoids the error, but may result in unintended behavior if your application is not expecting a truncated result. You should take corrective action if necessary.

See [Querying with Order By](#) on page 3844 for an example of how to set a query `limit`.

Permissions and OJAI Queries

You need to understand permission requirements because they affect filter conditions in your OJAI queries.

HPE Data Fabric Database enforces permissions when your application processes the query result. In the basic application flow shown in the previous section, this corresponds to step 5. In an application, if user1 performs the query while user2 processes the result, then the result corresponds to user2's permissions.

You should create a separate OJAI connection for each unique user. Sharing a connection across users can result in non-optimal queries or invalid permission errors.

The following permissions are required to query documents:

- The `readAce` permission on the volumes where the JSON tables that contain the documents are located. See [Setting Whole Volume ACEs](#) on page 1627.
- The `readperm` permission on the JSON table's column families containing fields being queried. See [Enabling Table and Stream Authorizations with ACEs](#) on page 1625.

If the user does not have the `readperm` permission on a field, HPE Data Fabric Database treats the field as non-existent for that user. When a query selects a non-existent field, HPE Data Fabric Database ignores the field. If a query filters on a non-existent field, the query behaves as follows:

Filter Condition on Non-existent Field	Behavior
Filter for specific values in the field	No documents qualify the filter because a non-existent field does not match any value.
Filter for non-matches in the field	All documents qualify the filter because a non-match on a non-existent field is a no-op.

The exception is the `rowkey` field. Access control on the `rowkey` is not available. Users can always select and filter on `rowkey`.

For information about setting permissions, see [Permission Types for Fields and Column Families in JSON Tables](#) on page 1662.

OJAI Query Options

OJAI supports query options that enable you to modify the behavior of your queries. This includes an option to force secondary index usage and options to influence the behavior of sorts.

Available Query Options

The following table lists available query options. Some options may or may not apply, depending on whether your query uses the OJAI Distributed Query Service. The detailed descriptions make a note of this.

Option Name	Description	Details
<code>ojai.mapr.query.hint-using-index</code>	Forces the Data Fabric client to use a particular index, regardless of cost considerations	Forcing Secondary Index Usage in OJAI on page 3778
<code>ojai.mapr.query.force-noncovering-sort</code>	Enables sort behavior to avoid partial sorts due to secondary index lags	Avoiding Partial Sorts with Secondary Indexes in OJAI on page 3778
<code>ojai.mapr.query.max-client-sort-limit</code>	Sets the Data Fabric client sort limit	Comparisons and Sorts in OJAI Queries on page 3775
<code>ojai.mapr.query.force-drill</code>	When set to true, forces the Data Fabric client to use the OJAI Distributed Query Service	Forcing Usage of the OJAI Distributed Query Service on page 3779
<code>ojai.mapr.drill.<OJAI Distributed Query Service Property Name></code>	Sets options for the OJAI Distributed Query Service	Setting OJAI Distributed Query Service Properties on page 3779

Setting Query Options

To set these options in your OJAI application, see the following topics:

Java	Setting Query Options in Java OJAI on page 3859
Node.js	Setting Query Options in Node.js Using OJAI Query Syntax on page 3867
Python	Setting Query Options in Python Using OJAI Query Syntax on page 3877
C#	Setting Query Options in C# OJAI on page 3881
Go	Setting Query Options in Go OJAI on page 3885

Forcing Secondary Index Usage in OJAI

To force the Data Fabric client to use an index, specify the name of the index with the `ojai.mapr.query.hint-using-index` option.

Regardless of cost considerations, the Data Fabric client attempts to use the specified index. To use the index, the index must benefit filter conditions, the order by, or projections in the query as described at [Queries that Benefit from Secondary Indexes](#) on page 780. Otherwise, the Data Fabric client ignores the option.

To force the Data Fabric client to *not* use any indexes, specify the table name without the full path as the second parameter in the calls shown earlier. For example, if the full path of your table is `/mapr/sanfrancisco/volume1/customer`, pass the name `customer` as the second parameter.

NOTE: Setting this option in your OJAI application has no effect if you are using the OJAI Distributed Query Service.

Avoiding Partial Sorts with Secondary Indexes in OJAI

Partial sorts can occur due to secondary index lags. To avoid these lags, set the `ojai.mapr.query.force-noncovering-sort` option to TRUE.

This option forces the OJAI Distributed Query Service to explicitly sort the data. Do not set this option if you do not expect to encounter index lags. Otherwise, you lose the ordering advantage that secondary indexes provide.

For more information about why partial sorts occur, see [Partial Sorts with Non-Covering Indexes](#) on page 789.

Forcing Usage of the OJAI Distributed Query Service

When set to `true`, the Data Fabric client uses the OJAI Distributed Query Service execution path, rather than selecting an execution path that it determines to be most optimal. See [OJAI Distributed Query Service](#) on page 711 for more information about the different query execution paths.

Setting OJAI Distributed Query Service Properties

OJAI queries may leverage the OJAI Distributed Query Service. To modify OJAI Distributed Query Service property settings in your OJAI application, prefix the OJAI Distributed Query Service property name with `ojai.mapr.drill`.

For example, the option `ojai.mapr.drill.planner.enable_index_planning` disables using secondary indexes when queries use the Query Service.

See [Index Planning and Execution Configuration Options](#) on page 4867 for the list of available OJAI Distributed Query Service properties.

Related concepts

[OJAI Distributed Query Service](#) on page 711

OJAI queries either directly access HPE Data Fabric Database JSON or leverage the OJAI Distributed Query Service. The OJAI Distributed Query Service provides distributed query support for HPE Data Fabric Database JSON, powered by Apache Drill. The Data Fabric client automatically determines whether OJAI queries benefit from using the OJAI Distributed Query Service, when the service is available. This section describes the architecture, including the code paths and components involved. It also discusses queries that originate from Drill SQL, which leverage the full functionality of Drill.

Query Conditions in OJAI Applications

You can create a query condition in an OJAI application in either of two ways. One way is to create an OJAI `QueryCondition` object and call methods in the class to construct your query condition. Another way is to create an OJAI query condition in a JSON format.

Creating an OJAI QueryCondition Object

The Java and Python OJAI clients support a `QueryCondition` interface. After you create a `QueryCondition` object, call methods in the class to construct your query condition.

Creating a QueryCondition Object

Java

Java OJAI provides a `QueryCondition.is()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryCondition.Op`
- The value to compare the field path against

The field path is either a field in a JSON document, a subfield within a nested document, or an array element.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data

You can specify the value using either a Java typed value (for example, `int`, `float`, or `String`) or a Java OJAI object. The API supports the following OJAI types:

- `ODate`
- `OInterval`
- `OTime`
- `OTimestamp`

Nested Documents

You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Java Map object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.

Arrays

You can specify only equality and non-equality conditions on arrays. You specify an array using a Java List object. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.is()`, `QueryCondition` also supports the following methods:

QueryCondition Method	Description
<code>equals()</code> <code>notequals()</code>	Match for equality or non-equality on nested documents and arrays
<code>in()</code>	Search for individual elements in an array
<code>like()</code>	Search for string values using SQL LIKE expressions

QueryCondition Method	Description
<code>matches()</code>	Search for string values using regular expressions. You can use regular expressions that compose the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in <code>java.util.regex.pattern</code> . See HBase Java Regular Expressions Support on page 3701 for a list of supported regular expressions.
<code>and()</code>	Begins a new AND condition block
<code>or()</code>	Begins a new OR condition block
<code>elementAnd()</code>	Begins a new <code>elementAnd</code> block. See OJAI Query Condition Operators on page 3796 for a detailed description of this operator.
<code>close()</code>	Closes a compound condition block
<code>build()</code>	Builds the condition

NOTE: The material described in this section is a subset of the QueryCondition API. It introduces you to the basics of the API. For the complete API, see the [QueryCondition](#) interface.

Python

Python OJAI provides a `QueryCondition.is_()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryConditionOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. See [OJAI Query Conditions Using Container Field Paths](#) on page 3805 for details.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data

You can specify the value using either a Python scalar value (for example, `int`, `float`, or `str`) or a Python OJAI object.

The API supports the following OJAI types:

- ODate
- OInterval
- OTime
- OTimestamp

Nested Documents

You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Python dictionary object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.

Arrays

You can specify only equality and non-equality conditions on arrays. You specify an array using a Python list object. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.is_()`, `QueryCondition` also supports the following methods:

QueryCondition Method	Description
<code>equals_()</code> <code>not_equals_()</code>	Match for equality or non-equality on nested documents and arrays
<code>in_()</code>	Search for individual elements in an array
<code>like_()</code>	Search for string values using SQL LIKE expressions
<code>matches_()</code>	<p>Search for string values using regular expressions.</p> <p>You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in <code>java.util.regex.pattern</code>. See HBase Java Regular Expressions Support on page 3701 for a list of supported regular expressions.</p>

QueryCondition Method	Description
<code>and_()</code>	Begins a new AND condition block
<code>or_()</code>	Begins a new OR condition block
<code>element_and()</code>	Begins a new elementAnd block. See OJAI Query Condition Operators on page 3796 for a detailed description of this operator.
<code>close()</code>	Closes a compound condition block
<code>build()</code>	Builds the condition

**NOTE:**

- The material described in this section is a subset of the QueryCondition API. It introduces you to the basics of the API. For the complete API, see the [QueryCondition](#) interface.
- The preferred approach for creating query conditions in Python is to create the condition in a JSON format. See [Creating an OJAI Query Condition Using a JSON String](#) on page 3791

C#

C# OJAI provides a `QueryCondition.ls()` method for specifying query conditions. The method takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. For details, see [OJAI Query Conditions Using Container Field Paths](#) on page 3805.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data

You can specify the value using either a C# scalar value (for example, `int`, `float`, or `string`) or a C# OJAI object. The API supports the following OJAI types:

- `OjaiDate`
- `OjaiInterval`

- OjaiTime
- OjaiTimestamp

Nested Documents You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a C# object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.

Arrays You can specify only equality and non-equality conditions on arrays. You specify an array using a C# list of values of the specified type. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.ls()`, `QueryCondition` also supports the following methods:

QueryCondition Method	Description
Condition()	Search for values using a specific condition.
Equals() NotEquals()	Match for equality or non-equality on nested documents and arrays.
Exists() NotExists()	Search for a field if the given field path exists, or verify that a field path does not exist.
In() NotIn()	Search for individual elements in an array or verify their absence.
Like() NotLike()	Search for string values using SQL LIKE expressions or verify they do not match the specified SQL LIKE expression.

QueryCondition Method	Description
Matches() NotMatches()	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library, as well as a subset of the regular expressions that are supported in <code>java.util.regex.pattern</code> . For a list of supported regular expressions, see HBase Java Regular Expressions Support on page 3701.
SizeOf()	Search for a value of the specified size. The value must be one of the following types: <ul style="list-style-type: none"> • string • binary • iDictionary • iList
TypeOf() NotTypeOf()	Search for value of the specified Type or verify its absence.
And()	Begins a new AND condition block.
Or()	Begins a new OR condition block.
ElementAnd()	Begins a new ElementAnd block. For a detailed description of this operator, see OJAI Query Condition Operators on page 3796.
Close()	Closes a compound condition block.
Build()	Builds the condition.

**NOTE:**

- The material described in this section is a subset of the [QueryCondition](#) API. It introduces you to the basics of the API. For the complete API, see the [QueryCondition](#) interface.
- The preferred approach for creating query conditions in C# is to create the condition in a JSON format. See [009_FindQueryWithSelectAndCondition.cs](#) or [Example: Creating a QueryCondition Object](#) on page 3788.

Go

Go OJAI provides a `QueryCondition.ls()` function for specifying query conditions. The function takes three arguments:

- The field path to apply the condition to
- The condition operator, represented as a `QueryOp`
- The value to compare the field path against

The field path is either a field in a JSON document, a sub-field within a nested document, or an array element. Starting in MapR 6.1, you can also specify a container field path. For details, see [OJAI Query Conditions Using Container Field Paths](#) on page 3805.

Depending on the type of the field path, you specify the comparison value as follows:

Scalar Data

You can specify the value using either a Go scalar value (for example, `int`, `float64`, or `string`) or a Go OJAI object. The API supports the following OJAI types:

- `OjaiDate`
- `OjaiTime`
- `OjaiTimestamp`

Nested Documents

You can specify only equality and non-equality conditions on nested documents. You specify the nested document using a Go object. In the case of equality, all of the fields in the nested document must match. The order of the fields is not relevant.

Arrays

You can specify only equality and non-equality conditions on arrays. You specify an array using a Go `list` of values of the specified type. In the case of equality, the order of the elements and the element values must match.

In addition to `QueryCondition.ls()`, `QueryCondition` also supports the following functions:

QueryCondition Function	Description
<code>AddCondition()</code>	Search for values using a specific condition.

QueryCondition Function	Description
Equals() NotEquals()	Match for equality or non-equality on nested documents and arrays.
Exists() NotExists()	Search for a field if the given field path exists, or verify that it does not exist.
In() NotIn()	Search for individual elements in an array or verify their absence.
Like() NotLike()	Search for string values using SQL LIKE expressions or verify they do not match the specified SQL LIKE expression.
Matches() NotMatches()	Search for string values using regular expressions. You can use regular expressions that comprise the Perl-Compatible Regular Expressions (PCRE) library, as well as a subset of the regular expressions that are supported in <code>java.util.regex.pattern</code> . For a list of supported regular expressions, see HBase Java Regular Expressions Support on page 3701.
TypeOf() NotTypeOf()	Search for value of the specified Type or verify its absence.
And()	Begins a new AND condition block.
Or()	Begins a new OR condition block.
ElementAnd()	Begins a new ElementAnd block. For a detailed description of this operator, see OJAI Query Condition Operators on page 3796.
Close()	Closes a compound condition block.
Build()	Builds the condition.

**NOTE:**

- The material described in this section is a subset of the Query API. It introduces you to the basics of the API. For the complete API, see the [Query](#) interface.
- The preferred approach for creating query conditions in Go is to create the condition in a JSON format. See [009_find_query_with_select_and_condition.go](#) or [Example: Creating a QueryCondition Object](#) on page 3788.

Example: Creating a QueryCondition Object

The following example shows how to define a QueryCondition object for this query condition:

```
(a.b[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

Java

```
QueryCondition qc =
connection.newCondition()
    .and()
        .is("a.b[0].boolean",
Op.EQUAL, false)
    .or()
        .is("a.c.d",
Op.NOT_EQUAL, 5)
        .is("a.b[1].decimal",
Op.GREATER, 1)
        .is("a.b[1].decimal",
Op.LESS, 10)
    .close()
    .close()
    .build();
```

Pass the QueryCondition object to the [Query.where](#) method. For a complete Java code example, see the *Java - OJAI QueryCondition Object* example at [Querying with Conditions](#) on page 3831.

Python

```
qc = connection.new_condition()
    .and_()
        .is_('a.b[0].boolean',
QueryConditionOp.EQUAL, False)
    .or_()
        .is_('a.c.d',
QueryConditionOp.NOT_EQUAL, 5)
        .is_('a.b[1].decimal',
QueryConditionOp.GREATER, 1)
        .is_('a.b[1].decimal',
QueryConditionOp.LESS, 10)
    .close()
    .close()
    .build()
```

Pass the QueryCondition object to the [Query.where](#) method. For a complete Python code example, see

the *Python - OJAI QueryCondition Object* example at [Querying with Conditions](#) on page 3831.

C#

```
var condition =
connection.NewQueryCondition()
    .And()
        .Is("a.b[0].boolean",
QueryOp.EQUAL, false)
    .Or()
        .Is("a.c.d",
QueryOp.NOT_EQUAL, 5)
        .Is("a.b[1].decimal",
QueryOp.GREATER, 1)
        .Is("a.b[1].decimal",
QueryOp.LESS, 10)
    .Close()
    .Build();
```

Pass the Condition object to the `Query.Where` method. For a complete C# code example, see the *C# - OJAI QueryCondition Object* example at [Querying with Conditions](#) on page 3831.

Go

```
condition, err :=
client.MakeCondition(
    client.And(),

    client.Is("a.b[0].boolean",
client.EQUAL, false),
    client.Or(),
        client.Is("a.c.d",
client.NOT_EQUAL, 5),

    client.Is("a.b[1].decimal",
client.GREATER, 1),

    client.Is("a.b[1].decimal",
client.LESS, 10),
    client.Close(),
    client.Close())
condition.Build()
```

Pass the [Condition](#) object to the [Query.WhereCondition](#) function. For a complete Go code example, see the *Go - OJAI QueryCondition Object* example at [Querying with Conditions](#) on page 3831.

Examples: Using the QueryCondition.elementAnd Method

The following example shows how to write the `elementAnd` condition described at [Using elementAnd with Nested Documents](#) on page 3808, using a `QueryCondition` object:

Java

```
QueryCondition qc =
connection.newCondition()
    .elementAnd("grades[]")
        .is("course",
QueryConditionOp.EQUALS, "history")
```

```

        .is("score",
QueryConditionOp.EQUALS, 12)
        .close()
        .build();

```

Python

```

qc = connection.new_condition()
    .element_and("grades[]")
    .is_("course",
QueryConditionOp.EQUALS, "history")
    .is_("score",
QueryConditionOp.EQUALS, 12)
    .close()
    .build()

```

C#

```

var condition =
connection.NewQueryCondition()
    .ElementAnd("grades[]")
    .Is("course", QueryOp.EQUALS,
"history")
    .Is("score", QueryOp.EQUALS,
12)
    .Close()
    .Build();

```

Go

```

        condition, err :=
client.MakeCondition(
            client.ElementAnd("grades[]"),
            client.Is("course",
client.EQUAL, "history"),
            client.Is("score",
client.EQUAL, 12),
            client.Close())
        condition.Build()

```

The following code corresponds to the example described at [Using elementAnd with Scalar Values](#) on page 3810 using a QueryCondition object:

Java

```

QueryCondition qc =
connection.newCondition()
    .elementAnd("values[]")
    .is("$",
QueryConditionOp.GREATER, 7)
    .is("$",
QueryConditionOp.LESS, 14)
    .close()
    .build();

```

Python

```

qc = connection.new_condition()
    .element_and("values[]")
    .is_("$",
QueryConditionOp.GREATER, 7)
    .is_("$",
QueryConditionOp.LESS, 14)
    .close()
    .build()

```

C#

```
var condition =
connection.NewQueryCondition()
    .ElementAnd("values[]")
        .Is("$", QueryOp.GREATER, 7)
        .Is("$", QueryOp.LESS, 14)
    .Close()
    .Build();
```

Go

```
condition, err :=
client.MakeCondition(
    client.ElementAnd("values[]"),
    client.Is("$",
client.EQUAL, 7),
    client.Is("$",
client.EQUAL, 14),
    client.Close())
condition.Build()
```

Creating an OJAI Query Condition Using a JSON String

You can create a query condition using OJAI syntax to specify the condition in JSON format. This is the preferred approach for the Node.js, Python, C#, and Go OJAI clients.

The following example shows you how to create the following query condition using the syntax:

```
(a.b[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 ||
a.b[1].decimal < 10))
```

Java

This is a Java string for the condition:

```
String jc = new String(
    '{ \
        "$and": [ \
            {"$eq": \
{"a.b[0].boolean":false}}, \
            {"$or": [ \
                {"$ne":{"a.c.d":5}}, \
                {"$gt": \
{"a.b[1].decimal":1}}, \
                {"$lt": \
{"a.b[1].decimal":10}} \
            ]} \
        ]} \
    ');
```

Pass the string to the [Query.where](#) method. See the [Java - OJAI Query Condition in JSON Format](#) example at [Querying with Conditions](#) on page 3831 for a complete Java code example.

Node.js

This is a Node.js JSON object for the condition:

```
query =
{ "$where":
  { "$and": [
    { "$eq":
      {"a.b[0].boolean":false}},
    { "$or": [
      { "$ne": {"a.c.d":5}},
      { "$gt":
```

```
{
  "a.b[1].decimal": 1,
  {
    "$lt": {
      "a.b[1].decimal": 10
    }
  }
};
```

See the *Node.js - OJAI Query Condition in JSON Format* example at [Querying with Conditions](#) on page 3831 for a complete Node.js code example.

Python

This is a Python dictionary for the condition:

```
query = {
  "$where": {
    "$and": [
      {
        "$seq": {
          "a.b[0].boolean": false
        }
      },
      {
        "$or": [
          {
            "$ne": {
              "a.c.d": 5
            }
          },
          {
            "$gt": {
              "a.b[1].decimal": 1
            }
          },
          {
            "$lt": {
              "a.b[1].decimal": 10
            }
          }
        ]
      }
    ]
  }
}
```

See the *Python - OJAI Query Condition in JSON Format* example at [Querying with Conditions](#) on page 3831 for a complete Python code example.

C#

This is a JSON string for the condition:

```
var query =
  @"{"$where": " +
    @"{"$and": [ " +
      @"{"$seq":
{"a.b[0].boolean": false}}, " +
      @"{"$or": [ " +
        +
          @"{"$ne": {"a.c.d":
{"$numberInt": "5"}}}, " +
        +
          @"{"$gt": {"a.b[1].decimal":
{"$decimal": "1"}}}, " +
        +
          @"{"$lt": {"a.b[1].decimal":
{"$decimal": "10"}}} " +
        +
        @"] " +
      @"] " +
    @"]";
```

Go

This is a JSON string for the condition:

```
query := "{ \"$where\": " +
  "{ \"$and\": [ " +
    "{ \"$seq\": " +
    "{ \"a.b[0].boolean\": false}}, " +
    "{ \"$or\": [ " +
      "{ \"$ne\": " +
        "{ \"a.c.d\": " +
          "{ \"$numberInt\": \"5\"}}}, " +
          "{ \"$gt\": { \"a.b[1].decimal\": " +
            "{ \"$decimal\": \"1\"}}}, " +
            "{ \"$lt\": { \"a.b[1].decimal\": " +
              "{ \"$decimal\": \"10\"}}}" +
        @"] " +
      @"] " +
    @"]";
```

```
{\"a.c.d\":5}}, \" +
    \"{\\\"$gt\\\":
    {\\\"a.b[1].decimal\\\":1}}, \" +
    \"{\\\"$lt\\\":
    {\\\"a.b[1].decimal\\\":10}}\" +
    \"}\" +
    \"}\" +
    \"}\"
```

To learn about the complete OJAI syntax for query conditions, see [OJAI Query Condition Syntax](#) on page 3796.

 **NOTE:** The OJAI clients are supported starting in EEP 6.0.0.

OJAI Query Syntax

OJAI defines a syntax for specifying queries on JSON documents. You can use this syntax in Node.js and Python OJAI client applications and HPE Data Fabric Database shell.

See [Query with --query](#) on page 7408 to learn about how to use this syntax in HPE Data Fabric Database shell.

An OJAI query can include the following components:

- [Projection](#)
- [Condition](#)
- [Order by](#)
- [Limit](#)
- [Offset](#)
- [Options](#)

You can specify some or all these components in a query, separating each component with a comma.

OJAI Query Projection

Syntax

```
"$select": "fieldpath"

"$select":
["fieldpath1", "fieldpath2", ...]
```

Description

The projection is the list of field paths to select in your query. You can specify a single field path or multiple. When specifying multiple, use an array notation to list the field paths.

See [JSON Document Field Paths](#) on page 722 for more information about the syntax of different JSON document field paths.

Examples

Single field path:

```
"$select": "a.c.d"
```

Multiple field paths:

```
"$select":["a.c.d", "a.c.e", "m[0]"]
```

OJAI Query Condition

Syntax

```
"$where":OJAIQueryCondition
```

Description

The condition filters your query result. See [OJAI Query Condition Syntax](#) on page 3796 for more information about the syntax of an *OJAIQueryCondition*.

Example

If you have the following condition:

```
(a.b[0].boolean == false && (a.c.d != 5 || a.b[1].decimal > 1 || a.b[1].decimal < 10))
```

This is the OJAI JSON syntax for the condition:

```
"$where":{
  "$and":[
    {"$eq":{
      "a.b[0].boolean":false}},
    {"$or":[
      {"$ne":{"a.c.d":5}},
      {"$gt":{
        "a.b[1].decimal":1}},
      {"$lt":{
        "a.b[1].decimal":10}}
    ]
  ]
}
```

OJAI Query Order By

Syntax

```
"$orderby":fieldpath
```

```
"$orderby":{"fieldpath":"order"}
```

```
"$orderby":[fieldpath1,fieldpath2,...]
```

```
"$orderby":[{"fieldpath1":"order"},
{"fieldpath2":"order"},...]
```

Description

The order by specifies the field paths on which to sort your query result. You can specify a single field path or multiple. When specifying multiple, use an array notation to list the field paths. For each field path, you can optionally specify an *order* of either asc or desc. Both *order* keywords are case insensitive. The default is asc. When specifying an *order*, enclose the *fieldpath* and *order* with curly braces.

Examples

Order on a single field path in the default asc order:

```
"$orderby": "a.c.e"
```

Order on a single field path in the desc order:

```
"$orderby": {"a.c.e": "desc"}
```

Order on two field paths, where the second specifies a desc order:

```
"$orderby": ["a.c.d", {"a.c.e": "desc"}]
```

OJAI Query Limit**Syntax**

```
"$limit": positive-integer
```

Description

The number of documents to return from the query.

Example

Return only ten documents:

```
"$limit": 10
```

OJAI Query Offset**Syntax**

```
"$offset": positive-integer
```

Description

The number of documents to skip before returning results to the client. The offset value has a direct effect on query time; as the offset value increases, query time also increases.

Example

Process the query and skip the first five documents in the result set before returning the results to the client.

```
"$offset": 5
```

OJAI Query Options**Syntax**

```
"$options": {optionName: optionValue}
```

```
"$options":  
[{optionName1: optionValue1},  
{optionName2: optionValue2}, ...]
```

Description

Settings that influence a query's execution path. See [OJAI Query Options](#) on page 3777 for a list of available options.

When specifying the *optionName*, you must separate the components of the option name, replacing the dots with curly braces and colons and enclosing each component in quotes.

Example

Force the query to use the OJAI Distributed Query Service by setting the `ojai.mapr.query.force-drill` option:

```
"$options":{"ojai":{"mapr":{"query":{"force-drill":true}}}}
```

OJAI Query Condition Syntax

OJAI defines a syntax for specifying query conditions that allows you to express query conditions in a JSON format. This topic describes the supported operators and provides examples of these query conditions.

When writing an OJAI application, you can also apply query conditions by calling OJAI API methods, corresponding to specific operators. This section does not discuss this alternative. For details on that alternative, see [Query Conditions in OJAI Applications](#) on page 3779.

 **NOTE:** Using the JSON format is the preferred approach for Python and Node.js OJAI clients.

OJAI Query Condition Operators

OJAI supports comparison, existence, between, match, like, type of, size of, in, and logical operators.

Click the name in the following box to navigate to the section that provides details on each operator.

- | | | |
|---|--|---|
| <ul style="list-style-type: none">EqualsGreater ThanGreater Than or EqualsLess ThanLess Than or EqualsNot Equals | <ul style="list-style-type: none">ExistsNot ExistsBetween on page 3797MatchesNot MatchesLikeNot Like | <ul style="list-style-type: none">Type OfNot Type OfSize Of on page 3800InNot InAndOrElement And |
|---|--|---|

Comparison Operators

Operators

Operator	Syntax
Equals	<pre>{"\$eq": {"fieldpath": value}}</pre>
Greater Than	<pre>{"\$gt": {"fieldpath": value}}</pre>
Greater Than or Equals	<pre>{"\$ge": {"fieldpath": value}}</pre>
Less Than	<pre>{"\$lt": {"fieldpath": value}}</pre>

Operator	Syntax
Less Than or Equals	<pre>{"\$le": {"fieldpath": value}}</pre>
Not Equals	<pre>{"\$ne": {"fieldpath": value}}</pre>

Description

Compares the data in *fieldpath* against *value* for the specified operator.

Float and double data are approximate representations of decimal values. They may not return true in equality comparisons against their equivalent decimal values.

You can specify only equality and non-equality conditions on nested documents and arrays.

In the case of equality on nested documents, all of the fields in the nested document must match. The order of the fields is not relevant.

In the case of equality on arrays, both the order of the elements and the element values must match.

Existence Operators**Exists****Syntax**

```
{"$exists": "fieldpath"}
```

Description

Checks for existence of *fieldpath*.

Not Exists**Syntax**

```
{"$notexists": "fieldpath"}
```

Description

Checks for non-existence of *fieldpath*.

See [Existence Conditions with Container Field Paths](#) on page 3806 for details about how these operators behave when you use them with container field paths.

Between**Syntax**

```
{"$between": {"fieldpath": [startValue, endValue]}}
```

Description

Checks if the value in *fieldpath* is in the range specified by *startValue* and *endValue*, where the values are inclusive.

Matches Operators

Operators

Operator	Syntax
Matches	<pre>{"\$matches": {"fieldpath":matchValue}}</pre>
Not Matches	<pre>{"\$notmatches": {"fieldpath":matchValue}}</pre>

Description

Performs a regular expression match on *fieldPath* using *matchValue*.

You can use regular expressions that compose the Perl-Compatible Regular Expressions (PCRE) library as well as a subset of the regular expressions that are supported in `java.util.regex.pattern`. See [HBase Java Regular Expressions Support](#) for a list of supported regular expressions.

Like Operators

Operators

Operator	Syntax
Like	<pre>{"\$like": {"fieldpath":likeValue}}</pre>
Not Like	<pre>{"\$notlike": {"fieldpath":likeValue}}</pre>

Description

Performs a SQL LIKE comparison on *fieldPath* where *likeValue* is a string with wildcard characters '%' and '_'.

Special-Purpose Characters for the Like Operators

The OJAI API allows you to use four special-purpose characters or patterns with \$like operator expressions:

Special-Purpose Character	Description	Example
%	Matches any string of zero or more characters.	"abc%" matches "abc", "abcd", "abcde232136", etc. "%abc" matches "abc", "pqrabc", etc.
_	Matches a single character.	"_am" matches "ram", "sam", "Sam", "cam".

Special-Purpose Character	Description	Example
[]	Matches a single character in the specified set or range.	"[r-t]am" matches "ram", "sam", and "tam" but not "Sam" or "cam".
[^]	Matches a single character not in the specified set or range.	"[^r-t]am" matches "Sam", "pam", "jam", or "cam" but not "ram", "sam" and "tam".

When any of these special characters is used as a literal, the character can be enclosed within []:

Literal	Corresponding Like Expression
"[a]"	"[[]a]"
"a%"	"a[%]"
"a_c"	"a[_]c"

Note that "^" and "]" need not be escaped.

Type of Operators

Type Of

Syntax

```
{"$typeof":  
{"fieldpath":"typeValue"}}
```

Description

Checks whether *fieldpath* is of type *typeValue*.

Not Type Of

Syntax

```
{"$nottypeof":  
{"fieldpath":"typeValue"}}
```

Description

Checks whether *fieldpath* is not of type *typeValue*.

typeValue can be any of map, array, binary, date, time,

timestamp, interval,
double, float, long,
int, short, byte,
string, boolean, or
null.

Size Of

Syntax

```
{"$sizeof":{"fieldpath":  
{"comparisonOp":intValue}}}
```

Description

Compares the size of the data in *fieldpath* against *intValue*, using *comparisonOp*. The size varies depending on the type of *fieldPath*:

String	Length of string
Array	Number of elements in the array
Nested document	Number of subfields in the nested document

comparisonOp can be any of \$eq, \$lt, \$le, \$gt, \$ge, or \$ne.

In Operators

In

Syntax

```
{"$in":  
{"fieldpath":inOp  
Values}}
```

Description

Checks whether the data in *fieldpath* is in the list specified by *inOpValues*.

Not In

Syntax

```
{"$notin":  
{"fieldpath":inOp  
Values}}
```

Description

Checks whether the data in *fieldpath* is not in the list specified by *inOpValues*

Logical Operators

And

Syntax

```
{"$and":  
[OJAIQueryCondi  
tions]}
```

Or	Description	Applies logical AND on a list of conditions. <i>OJAIQueryConditions</i> is a comma-separated list of OJAI query conditions.
	Syntax	<pre>{"\$or": [<i>OJAIQueryConditions</i>]}</pre>
Element And	Description	Applies logical OR on a list of conditions. <i>OJAIQueryConditions</i> is a comma-separated list of OJAI query conditions.
	Syntax	<pre>{ "\$elementAnd": { "<i>containerFieldPath</i>": [<i>OJAIQueryConditions</i>] } }</pre>
		 NOTE: Supported starting in MapR 6.1.
		Description
		Applies multiple conditions as part of a group. All conditions must be true for a common array element. <i>OJAIQueryConditions</i> is the comma-separated list of the OJAI query conditions. <i>containerFieldPath</i> exhibits the following behaviors: <ul style="list-style-type: none"><i>containerFieldPath</i> specifies the container path prefix of the common container element.

- If *containerFieldPath* refers to a container of nested documents, then you must use field paths relative to the common prefix in your *OJAIQueryConditions*.
- If the *containerFieldPath* refers to a container of scalar values, then you use the \$ symbol to refer to individual elements in your *OJAIQueryConditions*.

NOTE: There is no `elementOr` operator because it is semantically equivalent to an OR operator.

This section contains examples that show you how to use different OJAI query condition operators in combination with different field references and data types.

[OJAI Query Conditions Using Container Field Paths](#) on page 3805

Starting in MapR 6.1, HPE Data Fabric Database supports the notion of a *container field path*. A container field path enables you to perform comparisons on a field path that is either a single value or an arbitrary array element. You can use container field paths with arrays and nested documents, including nested documents with multiple levels of nesting and multidimensional arrays.

[OJAI Query Conditions Using elementAnd](#) on page 3808

The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

OJAI Query Condition Examples

This section contains examples that show you how to use different OJAI query condition operators in combination with different field references and data types.

The examples in this section use the following JSON documents:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "003", "name" : "Ipod 003", "tags" : 10 }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
```

```
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" : 10 }, { "t" : "apple", "v" : 9 } ] }, { "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

Example	Documents Returned
<pre>{"\$exists":"tags.v"}</pre> <p>Matches documents where tags is a nested document that has a v subfield.</p>	008
<pre>{"\$eq":{"tags":10}}</pre> <p>Matches documents where tags equals the scalar value 10.</p>	003
<pre>{"\$eq":{"tags.t":"ipod"}}</pre> <p>Matches documents where tags is a nested document with a subfield t equal to "ipod".</p>	005, 008
<pre>{"\$eq":{"tags":{"t":"ipod"}}</pre> <p>Matches documents where tags is a nested document with a single subfield t equal to "ipod".</p>	005
<pre>{"\$eq":{"tags":{"v":10,"t":"ipod"}}</pre> <p>Matches documents where tags is a nested document with two subfields, v and t. v is equal to 10, and t is equal to "ipod". The order of subfields in the condition does not matter.</p>	008
<pre>{"\$eq":{"tags":["electronics","ipod","apple"]}}</pre> <p>Matches documents where tags is an array with the three elements listed.</p>	001
<pre>{"\$eq":{"tags":["ipod","electronics","apple"]}}</pre> <p>This example does not match any document, whereas the previous does, because the order of the elements in this example does not match the order in document 001.</p>	None
<pre>{"\$between":{"tags":[5,15]}}</pre> <p>Matches documents where tags is a scalar value between 5 and 15.</p>	003
<pre>{"\$like":{"tags[1]":"ip%"}}</pre> <p>Matches documents where the first array element in tags qualifies the wildcard string "ip%"</p>	001, 004
<pre>{"\$typeof":{"tags":"map"}}</pre> <p>Matches documents where tags is a nested document.</p>	005, 008
<pre>{"\$typeof":{"tags":"array"}}</pre> <p>Matches documents where tags is an array.</p>	001, 004, 006, 007

Example	Documents Returned
<pre>{"\$sizeof":{"tags":{"\$ge":3}}</pre> <p>Matches documents where the size of the data in tags is greater than or equal to three.</p> <ul style="list-style-type: none"> 001 matches because the array has three elements 002 matches because the string is of length four 004 matches because the nested document has three subfields 	001, 002, 004
<pre>{"\$in":{"tags":["ipod", 10, {"t":"ipod"}]}}</pre> <p>Matches documents where tags equals any of the values listed. Note that the values can be of different types.</p>	002, 003, 005
<pre>{ "\$and":[{"\$lt":{"tags[1].v":10}}, {"\$matches":{"tags[1].t":"ap{2}"}}] }</pre> <p>Matches documents where the first array element in tags has a nested document with a subfield v less than one, and the same nested document also matches the regular expression "ap{2}".</p>	007
<pre>{ "\$or":[{"\$exists":"tags.v"}, {"\$typeof":{"tags":"string"}}] }</pre> <p>Matches documents where either tags is a nested document with a subfield v, or tags is a scalar string.</p>	002, 008

NOTE: You can improve the performance of queries with conditions by using secondary indexes. See [Queries that Benefit from Secondary Indexes](#) on page 780 for more details.

OJAI Query Conditions Using Container Field Paths

Starting in MapR 6.1, HPE Data Fabric Database supports the notion of a *container field path*. A container field path enables you to perform comparisons on a field path that is either a single value or an arbitrary array element. You can use container field paths with arrays and nested documents, including nested documents with multiple levels of nesting and multidimensional arrays.

Conditions with Container Field Paths on Arrays

If you have a field that has a single value rather than an array of values, when using the container notation, HPE Data Fabric Database treats the single value as an array with one element. This enables you to use a container field path to access a field that has both array elements and scalar values. The array elements and scalar values can be of any type.

Suppose you have the following set of documents:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "003", "name" : "Ipod 003", "tags" : 10 }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :
"apple" } ] }
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :
10 }, { "t" : "apple", "v" : 9 } ] }
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

To find all documents that contain the tag named "ipod", you can use the following OJAI query condition, where you reference tags using a container field path:

```
{"$eq":{"tags[]":"ipod"}}
```

The expression matches the following documents, with the matching condition highlighted in bold:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",
"apple" ] }
{ "_id" : "002", "name" : "Ipod 002", "tags" : "ipod" }
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" :
"ipod" } ] }
```

Note that the matching documents have the following characteristics:

- In 001 and 004, tags are array fields.
- In 002, tags is a scalar value.
- In 001 and 004, the tags arrays have elements in addition to "ipod".

You can also use the AND operator to match multiple container field path conditions.

For example, the following condition finds all documents that have both "ipod" and "apple" tags:

```
{
  "$and": [
    {"$eq":{"tags[]":"ipod"}},
    {"$eq":{"tags[]":"apple"}}
  ]
}
```

The expression matches the following document, with the matching conditions highlighted in bold:

```
{ "_id" : "001", "name" : "Ipod 001", "tags" : [ "electronics", "ipod",  
"apple" ] }
```

Conditions with Container Field Paths on Nested Documents

You can also use the container field path in combination with a nested document subfield reference.

For example, using the same set of documents shown earlier, the following OJAI query condition finds all documents in which "ipod" is specified in the subfield named `t` within the `tags` nested document:

```
{"$eq":{"tags[].t":"ipod"}}
```

This expression returns the following documents, with the matching condition highlighted in bold:

```
{ "_id" : "004", "name" : "Ipod 004", "tags" : [ 10, "ipod", { "t" : "ipod"  
} ] }  
{ "_id" : "005", "name" : "Ipod 005", "tags" : { "t" : "ipod" } }  
{ "_id" : "006", "name" : "Ipod 006", "tags" : [ { "t" : "ipod" }, { "t" :  
"apple" } ] }  
{ "_id" : "007", "name" : "Ipod 007", "tags" : [ { "t" : "ipod", "v" :  
10 }, { "t" : "apple", "v" : 9 } ] }  
{ "_id" : "008", "name" : "Ipod 008", "tags" : { "t" : "ipod", "v" : 10 } }
```

Note that the matching documents have the following characteristics:

- In 005 and 008, `tags` is a single nested document.
- In 006 and 007, `tags` is an array of nested documents.
- In 004, the `tags` array has both scalar data and a nested document.
- In 004 and 006, the `tags` array have other array elements that do not match the nested document subfield `t`.

Existence Conditions with Container Field Paths

[Existence Operators](#) on page 3797 check for the existence and non-existence of a specified field path. When you use `$exists` with a container field path, the specified field path can be any element in an array.

Using the same set of documents shown earlier, the following OJAI query condition finds all documents where the `tags` array has a nested document with a subfield `t`:

```
{"$exists":"tags[].t"}
```

The expression matches the following documents with the matching condition highlighted in bold:

```
{ "_id":"004", "name":"Ipod 004", "tags":[10, "ipod", { "t":"ipod" } ] }  
{ "_id":"005", "name":"Ipod 005", "tags":{"t":"ipod" } }  
{ "_id":"006", "name":"Ipod 006", "tags":[{"t":"ipod"}, {"t":"apple" } ] }  
{ "_id":"007", "name":"Ipod 007", "tags":[{"t":"ipod", "v":10},  
{"t":"apple", "v":9} ] }
```

When you use `$notexists` with a container field path, it matches *any* element in the array that does not meet the existence condition:

```
{"$notexists":"tags[].t"}
```

The expression returns the following documents with the matching condition highlighted in bold:

```
{ "_id": "001", "name": "Ipod 001", "tags": [ "electronics", "ipod", "apple" ] }
{ "_id": "002", "name": "Ipod 002", "tags": "ipod" }
{ "_id": "003", "name": "Ipod 003", "tags": "10" }
{ "_id": "004", "name": "Ipod 004", "tags": [ "10", "ipod", { "t": "ipod" } ] }
```

Even document 004 has a tags[] . t element, the other elements in that document's tags array do not; therefore, the document qualifies the condition.

Conditions with Container Field Paths Across Multiple Levels of Nested Documents

The following are examples of query conditions that match the sample document shown at [Container Field Paths Across Multiple Levels of Nested Documents](#):

```
{"$eq":{"projects[].customer.contacts[].emails[].value":"jdoe@gmail.com"}}
```

```
{"$eq":{"projects[].customer.contacts[].role":"CEO"}}
```

Conditions with Container Field Paths on Multidimensional Arrays

The following examples reference documents that store the high and low temperatures for each day in a week. They use a two-dimensional array to store this data. The first element of each nested array element is the high temperature for a day, and the second element is the low. Typically, the two-dimensional array has seven array pairs, one for each day of the week. But in cases where data is unavailable, the document has only the days available.

For example, document 002 has a single dimensional array because it has data for only one day that week.

```
{
  "_id" : "001",
  "temps" : [[61,49],[74,51],[75,51],[74,52],[78,54],[75,53],[75,54]],
  "weekOf" : "4/29/2018"
}
{
  "_id" : "002",
  "temps" : [81,60],
  "weekOf" : "5/12/2018"
}
{
  "_id" : "003",
  "temps" : [[80,55],[78,54],[79,54],[77,53],[79,54],[77,54],[78,54]],
  "weekOf" : "5/13/2018"
}
```

As described at [Container Field Paths with Multidimensional Arrays](#), you can specify a container field path in a dimension only if it does not precede a dimension that specifies an explicit element. For example, the following condition is not allowed because the first dimension specifies a container field path and precedes element 1 in the second dimension:

```
// Invalid condition
{"$ge":{"temps[][1]":60}}
```

The following table shows examples of conditions on multidimensional arrays that HPE Data Fabric Database supports:

Example	Documents Returned
<pre>{"\$ge":{"temps[][]":60}}</pre> <p>Matches documents that have any temperature greater than 60.</p> <ul style="list-style-type: none"> Documents 001 and 003 match because all days have high temperatures above 60. Document 002 matches because day 1 has a low temperature of 60. <p>Although temps in this document is a one-dimensional array, the container notation treats it as a two-dimensional array.</p>	001, 002, 003
<pre>{"\$ge":{"temps[1][]":75}}</pre> <p>Matches documents that have any temperature greater than 75 on the second day of the week</p>	003
<pre>{"\$eq":{"temps[]":[78,54]}}</pre> <p>Matches documents that have a high and low temperature of 78 and 54 on the same day.</p> <ul style="list-style-type: none"> Day 5 from document 001 matches this condition. Days 2 and 7 from document 003 match this condition. 	001, 003

[Indexes on Container Field Paths in Range Conditions](#) on page 786

OJAI Query Conditions Using elementAnd

The `elementAnd` operator allows you to specify multiple conditions on the same array element using a container field path. This is in contrast to the `and` operator where conditions can refer to any array element. You can use `elementAnd` with both nested documents and scalar values. You can also use it in combination with other operators, including `between`, `and`, and `or`.

Using elementAnd with Nested Documents

Assume that you have the following set of documents that reflect student scores on courses. Each document has an array of grades. Grades is a nested document that reflects how the students scored on each course they took.

```
{ "_id": "001", "grades": [ { "course": "math", "score": 15.5 },
  { "score": 12, "course": "history" }, { "course": "english", "score": 8 } ] }
{ "_id": "002", "grades": [ { "course": "math", "score": 4 },
  { "course": "history", "score": 12, "cmts": "..."},
  { "course": "english", "score": 18 } ] }
{ "_id": "003", "grades": [ { "course": "math", "score": 11 },
  { "course": "history", "score": 15 }, { "course": "english", "score": 12 },
  { "course": "sports", "score": 4 } ] }
```

```
{ "_id": "004", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12, "details": { "info": "..."} } ] }
{ "_id": "005", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 10 }, { "course": "physics", "score": 11 } ] }
```

If you want to find the students who scored 12 in history, you use the following `elementAnd` condition:

```
{
  "$elementAnd": {
    "grades[]": [
      { "$eq": { "course": "history" } },
      { "$eq": { "score": 12 } }
    ]
  }
}
```

The condition matches the following documents, with the matching conditions highlighted in bold:

```
{ "_id": "001", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12 }, { "course": "english", "score": 8 } ] }
{ "_id": "002", "grades": [{ "course": "math", "score": 4 },
{ "course": "history", "score": 12, "cmts": "..."} ],
{ "course": "english", "score": 18 } ] }
{ "_id": "004", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12, "details": { "info": "..."} } ] }
```

The example illustrates the following behavior:

- The positions of the subfields in the nested document are not significant.
- In document 002, there are other subfields in the nested document that do not match the specified conditions.

In contrast, the following example expresses a different condition, using `and` instead of `elementAnd`:

```
{
  "$and": [
    { "$eq": { "grades[].course": "history" } },
    { "$eq": { "grades[].score": 12 } }
  ]
}
```

This condition returns documents corresponding to students who have taken history and scored 12 on *any* course. The following are the matching documents, with the matching conditions highlighted in bold:

```
{ "_id": "001", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12 }, { "course": "english", "score": 8 } ] }
{ "_id": "002", "grades": [{ "course": "math", "score": 4 },
{ "course": "history", "score": 12, "cmts": "..."} ],
{ "course": "english", "score": 18 } ] }
{ "_id": "003", "grades": [{ "course": "math", "score": 11 },
{ "course": "history", "score": 15 }, { "course": "english", "score": 12 },
{ "course": "sports", "score": 4 } ] }
{ "_id": "004", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12, "details": { "info": "..."} } ] }
```

The example illustrates the following behavior:

- Besides returning the same documents as the previous `elementAnd` example, this condition also returns document 003.

- Document 003 matches because that student took history and scored 12 on english, rather than history.
- Document 005 does not match because although the student took history, the student did not score 12 on any courses.

Using `elementAnd` with Scalar Values

If you apply `elementAnd` to a container of scalar values, you use the `$` symbol to denote an unspecified container element.

Suppose you have the following documents:

```
{ "_id" : "001", "name" : "a", "values" : [1, 2, 3, 6, 15] }
{ "_id" : "002", "name" : "b", "values" : [3, 6, 9, 10, 15] }
{ "_id" : "003", "name" : "c", "values" : [14] }
{ "_id" : "004", "name" : "c", "values" : 11 }
```

To find all documents where `values[]` contains a number between 7 and 11 (inclusive), you can use the following condition:

```
{
  "$elementAnd": {
    "values[]": [
      {"$ge": {"$": 7}},
      {"$le": {"$": 11}}
    ]
  }
}
```

The condition returns the following documents, with the matching numbers highlighted in bold:

```
{ "_id": "002", "name": "b", "values": [3, 6, 9, 10, 15] }
{ "_id": "004", "name": "c", "values": 11 }
```

The example illustrates the following behavior:

- In document 002, multiple elements in the array match the condition.
- In document 004, `values` is a scalar value.

Suppose you apply the following condition that uses `and` instead of `elementAnd`:

```
{
  "$and": [
    {"$ge": {"values[]": 7}},
    {"$le": {"values[]": 11}}
  ]
}
```

All documents except 003 match this and condition because in the matching documents, `values[]` contains *some* number greater than or equal to 7 and *some* number less than or equal to 11. The difference is that the same number does not need to match both conditions, which is the case for document 001.

Using `between` with `elementAnd`

You cannot use a container field path in a `between` condition. To use the `between` operator to match against an arbitrary array element, you must include the `between` condition in an `elementAnd` condition.

The following table shows the proper way to specify a between condition that is equivalent to the `elementAnd` example from the previous section:

Correct Condition	Incorrect Condition
<pre>{ "\$elementAnd": { "values[]": [{"\$between": {"\$": [7, 11]}}] } }</pre>	<pre>{"\$between": {"values[]": [7, 11]}}</pre>

This example uses `between` to match against an arbitrary scalar array element. You can also use `between` to match against a subfield in a nested document, in which the nested document is an arbitrary array element.

For example, using the sample documents shown earlier, the following table shows the correct way to apply the `between` operator on the subfield `score` in the nested documents that are elements in the `grades` array:

Correct Condition	Incorrect Condition
<pre>{ "\$elementAnd": { "grades[]": [{"\$between": {"score": [15.5, 20]}}] } }</pre>	<pre>{"\$between": {"grades[] .score": [15.5, 20]}}</pre>

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{ "_id": "001", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12 }, { "course": "english", "score": 8 } ] }
{ "_id": "002", "grades": [{ "course": "math", "score": 4 },
{ "cmts": "...", "course": "history", "score": 12 },
{ "course": "english", "score": 18 } ] }
{ "_id": "004", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "details": { "info": "...", "score": 12 } } ] }
{ "_id": "005", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 10 }, { "course": "physics", "score": 11 } ] }
```

Using Other Operators in `elementAnd` Conditions

You can also use operators like `or` in `elementAnd`'s query condition list.

For example, the following condition finds all students who scored 12 in either history or english:

```
{
  "$elementAnd": {
    "grades[]": [
      {"$or": [
        {"$eq": {"course": "history"}},
        {"$eq": {"course": "english"}}
      ]},
      {"$eq": {"score": 12}}
    ]
  }
}
```

```
    }
  }
}
```

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{ "_id": "001", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12 }, { "course": "english", "score": 8 } ] }
{ "_id": "002", "grades": [{ "course": "math", "score": 4 },
{ "cmts": "...", "course": "history", "score": 12 },
{ "course": "english", "score": 18 } ] }
{ "_id": "003", "grades": [{ "course": "math", "score": 11 },
{ "course": "history", "score": 15 }, { "course": "english", "score": 12 },
{ "course": "sports", "score": 4 } ] }
{ "_id": "004", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12, "details": { "info": "..." } } ] }
```

Combining elementAnd with Other Operators

You can combine `elementAnd` with other operators like `and`.

For example, using the sample documents shown earlier, suppose you want to find all students who scored 12 in history as well scored 15.5 in math. The following condition expresses this criteria:

```
{
  "$and": [
    {
      "$elementAnd": {
        "grades[]": [
          { "$eq": { "course": "history" } },
          { "$eq": { "score": 12 } }
        ]
      }
    },
    {
      "$elementAnd": {
        "grades[]": [
          { "$eq": { "course": "math" } },
          { "$eq": { "score": 15.5 } }
        ]
      }
    }
  ]
}
```

The condition returns the following documents, with the matching conditions highlighted in bold:

```
{ "_id": "001", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12 }, { "course": "english", "score": 8 } ] }
{ "_id": "004", "grades": [{ "course": "math", "score": 15.5 },
{ "course": "history", "score": 12, "details": { "info": "..." } } ] }
```

[Composite Indexes and Container Field Paths](#) on page 764

Querying with HPE Data Fabric Database Shell

This section describes how to query JSON documents using either the `find` or `findbyid` command in HPE Data Fabric Database Shell (dbshell). It introduces the functionality the `find` command supports and describes the two ways to specify your queries. It also provides links to reference pages and examples.

The `findbyid` command allows you to retrieve a single document with a specified id from a HPE Data Fabric Database JSON table.

The `find` command allows you to specify projections and filter conditions (using JSON strings) to retrieve specific documents. It also allows you to specify the following options:

- Range of document IDs to retrieve
- Offset from which to start retrieval
- Order by to sort fields in the document
- Limit on the number of documents to retrieve

To invoke HPE Data Fabric Database shell, run the following command on a Data Fabric cluster node:

```
% mapr dbshell
```

For a complete list and description of options available, see [dbshell find or findbyid](#) on page 7405.

Alternatives for Writing Dbshell Query Commands

You can construct your dbshell queries in one of two ways:

- Use individual options in the `find` command
- Use the `--query` option in the `find` command and specify keywords as arguments to `--query`

The following example illustrates the differences between the two alternatives.

Suppose you want to query the table `/apps/tab` with the following criteria:

- Select fields `f1` and `f2`
- Limit the result to ten documents
- Skip the first two documents
- Filter documents where the field `f3` equals 15
- Sorts on field `f1`

Click on each of the following tabs to see the syntax for each alternative:

Use Individual Options in `find`

```
find /apps/tab --fields f1,f2 --limit
10 --offset 2 --where {"$eq":
{"f3":15}} --orderby f1
```

Use the `--query` Option in `find`

```
find /apps/tab --query {"$select":
["f1","f2"],"$limit":10,"$offset":2,"$
where":{"$eq":
{"f3":15}},"$orderby":"f1"}
```

For more examples on how to use the two query alternatives, see the following links:

Use Individual Options in find	Use the --query Option in find
Query Examples with Other Options on page 7413	<ul style="list-style-type: none"> • Query with --query on page 7408 • Query with --orderby on page 7412

NOTE: With both options, you need to specify the query condition using [OJAI Query Condition Syntax](#) on page 3796.

Examples: Querying JSON Documents

This section provides query examples using the OJAI API. The examples include querying by document ID, retrieving all documents in a store, selecting individual fields, specifying query conditions, and ordering your query result. For reference, the examples also include the equivalent HPE Data Fabric Database Shell (dbshell) commands.

If you hover over the right hand side of all code examples, you can use the  icon to copy and paste the code.

You can also download the code examples from github at <https://github.com/mapr-demos/ojai-examples.git>.

Querying By ID

The examples in this section show you how to query for a single document ID.

Java

This example retrieves a single document identified by the ID user001.

NOTE: To query for a range of document IDs, you must specify an OJAI [QueryCondition](#). See [Querying with Conditions](#) on page 3831 for examples of the syntax.

  // fetch the OJAI Document by its '_id' field
  return store.findById('user0001');
})
.then((doc) => {
  // Print the OJAI Document
  console.log(doc);
  connection.close();
});
```

Python

This example retrieves a single document identified by the ID user0001.

NOTE: To query for a range of document IDs, you must specify an OJAI [QueryCondition](#). See [Querying with Conditions](#) on page 3831 for examples of the syntax.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
                 "ssl=true;" \
                 "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
                 "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# fetch the OJAI Document by its '_id' field
doc = store.find_by_id("user0001")

# Print the OJAI Document
print(doc)

# close the OJAI connection
connection.close()
```

dbshell

The following is the equivalent of the code examples using dbshell. See [dbshell find or findbyid](#) on page 7405 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> findbyid /demo_table --id user0001
```

C#

This example retrieves a single document identified by the ID user0001.

NOTE: To query for a range of document IDs, you must specify an OJAI [QueryCondition](#). See [Querying with Conditions](#) on page 3831 for examples of the syntax.

```
using System;
using MapRDB.Driver;

public class FindById
```

```

{
    public void FindById()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Fetch the OJAI Document by its '_id' field
        var document = store.FindById("user0001");

        // Print the OJAI Document
        Console.WriteLine(document);

        // Close the OJAI connection
        connection.Close();
    }
}

```

Go

This example retrieves a single document identified by the ID user0001.

NOTE: To query for a range of document IDs, you must specify an OJAI [Condition](#). See [Querying with Conditions](#) on page 3831 for examples of the syntax.

```

package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }
}

```

```

    }

    // Fetch the OJAI Document by its '_id' field
    doc, err := store.FindByIdString("id0001")
    if err != nil {
        panic(err)
    }

    // Print the OJAI Document
    fmt.Println(doc.AsJsonString())

    // Close connection
    connection.Close()
}

```

Querying and Returning All Documents

The examples in this section show you two ways of retrieving all documents from a document store.

Java - Example 1

The following example queries a document store and returns all documents by using the [DocumentStore.find](#) method.

```

/**
 * Copyright (c) 2017 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License");
 * you may not use this file except in compliance with the License.
 * You may obtain a copy of the License at
 *
 * http://www.apache.org/licenses/LICENSE-2.0
 *
 * Unless required by applicable law or agreed to in writing, software
 * distributed under the License is distributed on an "AS IS" BASIS,
 * WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
 * See the License for the specific language governing permissions and
 * limitations under the License.
 */
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.DocumentStream;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;

public class OJAI_004_FindAll {

    public static void main(String[] args) {

        System.out.println("==== Start Application ===");

        // Create an OJAI connection to MapR cluster
        final Connection connection = DriverManager.getConnection("ojai:mapr:");

        // Get an instance of OJAI DocumentStore
        final DocumentStore store = connection.getStore("/demo_table");

        // fetch all OJAI Documents from this store
        final DocumentStream stream = store.find();

        for (final Document userDocument : stream) {

```

```

        // Print the OJAI Document
        System.out.println(userDocument.asJsonString());
    }

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
connection
    connection.close();

    System.out.println("==== End Application ===");
}
}

```

Java - Example 2

The following example queries a document store and returns all documents. It creates a [Query](#) object and passes that to the [DocumentStore.findQuery](#) method.

```

/**
 * Copyright (c) 2017 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License"); you may
not use this file except in compliance with
 * the License. You may obtain a copy of the License at

 * http://www.apache.org/licenses/LICENSE-2.0
 *
 * Unless required by applicable law or agreed to in writing, software
distributed under the License is distributed on
 * an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either
express or implied. See the License for the
 * specific language governing permissions and limitations under the
License.
 */
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.DocumentStream;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;
import org.ojai.store.Query;

public class OJAI_005_FindAllQuery {

    public static void main(final String[] args) {

        System.out.println("==== Start Application ===");

        // Create an OJAI connection to MapR cluster
        final Connection connection = DriverManager.getConnection("ojai:mapr:");

        // Get an instance of OJAI DocumentStore
        final DocumentStore store = connection.getStore("/demo_table");

        // Build an OJAI query
        final Query query = connection.newQuery().build();

        // fetch all OJAI Documents from this store
    }
}

```

```

    final DocumentStream stream = store.find(query);

    for (final Document userDocument : stream) {
        // Print the OJAI Document
        System.out.println(userDocument.asJsonString());
    }

    // Close this instance of OJAI DocumentStore
    store.close();

    // close the OJAI connection and release any resources held by the
    connection
    connection.close();

    System.out.println("==== End Application ===");
}
}

```

Node.js - Example 1

The following example queries a document store and returns all documents by using the [DocumentStore.find](#) method.

```

/*
 * Copyright (c) 2018 MapR, Inc.

 * WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
 * See the License for the specific language governing permissions and
 * limitations under the License.
 */

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
    'auth=basic;' +
    'user=mapr;' +
    'password=mapr;' +
    'ssl=true;' +
    'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
    'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
    .then((conn) => {
        connection = conn;
        // Get a store
        return connection.getStore('/demo_table');
    })
    .then((store) => {
        // fetch all OJAI Documents from table
        return store.find({});
    });

```

```

})
.then((queryResult) => {
  queryResult.on('data', (document) => console.log(document));
  queryResult.on('end', () => {
    // close the OJAI connection
    connection.close();
  });
});
});

```

Node.js - Example 2

The following example queries a document store and returns all documents. It creates an empty query and passes that to the [DocumentStore.find](#) method.

```

/*
 * Copyright (c) 2018 MapR, Inc.
 *
 * Licensed under the Apache License, Version 2.0 (the "License");
 * you may not use this file except in compliance with the License.

 */

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // options for find request
    const options = {
      'ojai.mapr.query.include-query-plan': true,
      'ojai.mapr.query.timeout-milliseconds': 10000
    }
    // fetch all OJAI Documents from table
    return store.find({}, options)
  })
  .then((queryResult) => {
    // get query plan
    console.log(queryResult.queryPlan);
  })

```

```

    queryResult.on('data', (document) => {
        // Print OJAI Documents from document stream
        console.log(document);
    });
    queryResult.on('end', () => {
        // close the OJAI connection
        connection.close();
    });
});

```

Python - Example 1

The following example queries a document store and returns all documents by using the [DocumentStore.find](#) method.

```

from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
    "ssl=true;" \
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
    "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# fetch all OJAI Documents from table
query_result = store.find()

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc)

# close the OJAI connection
connection.close()

```

Python - Example 2

The following example queries a document store and returns all documents. It creates a [Query](#) object and passes that to the [DocumentStore.find](#) method.

```

from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
    "ssl=true;" \
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
    "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Build an OJAI query
query = connection.new_query().build()

# options for find request
options = {
    'ojai.mapr.query.include-query-plan': True,
    'ojai.mapr.query.result-as-document': True,

```

```

    'ojai.mapr.query.timeout-milliseconds': 10000
}

# fetch all OJAI Documents from table
query_result = store.find(query, options=options)

# get query plan
print(query_result.get_query_plan())

doc_stream = query_result
# Print OJAI Documents from document stream
for doc in doc_stream:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()

```

dbshell

The following is the equivalent of the code examples using dbshell. See [dbshell find or findbyid](#) on page 7405 for more details about the syntax dbshell provides.

```

# mapr dbshell
maprdb root:> find /demo_table

```

C# - Example 1

The following example queries a document store and returns all documents by using the [GetAllDocuments](#) method.

```

using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindAllDocuments
{
    public async void FindAllDocuments()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Fetch all OJAI Documents from table
        var queryResult = store.Find();
        var documentStream = await queryResult.GetAllDocuments();

        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }

        // Close the OJAI connection
    }
}

```

```

        connection.Close();
    }
}

```

C# - Example 2

The following example queries a document store and returns all documents. It creates a [Query](#) object and passes that to the [DocumentStore.Find](#) method.

```

using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindAllQuery
{
    public async void FindAllQuery()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Build an OJAI query
        var query = connection.NewQuery().Build();

        // Options for find request
        var options = new QueryOptions()
        {
            IncludeQueryPlan = true,
            Timeout = 1000
        };

        // Fetch all OJAI Documents from table
        var queryResult = store.Find(query, options);

        // Get query plan
        Console.WriteLine(queryResult.GetQueryPlan());

        var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}

```

Go - Example 1

The following example queries a document store and returns all documents by using the [DocumentStore.FindAll](#) function.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Fetch all OJAI Documents from table
    findResult, err := store.FindAll(&client.FindOptions{IncludeQueryPlan:
false, ResultAsDocument: true})

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Go - Example 2

The following example queries a document store and returns all documents. It creates a [Query](#) object and passes that to the [DocumentStore.FindQuery](#) function.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
```

```

// Create connection string
connectionString := "192.168.33.11:5678?" +
    "auth=basic;" +
    "user=mapr;" +
    "password=mapr;" +
    "ssl=true;" +
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
    "sslTargetNameOverride=node1.cluster.com"

storeName := "/demo_table"

// Create a connection to DAG
connection, err := client.MakeConnection(connectionString)
if err != nil {
    panic(err)
}

// Get a store and assign it as a DocumentStore struct
store, err := connection.GetStore(storeName)
if err != nil {
    panic(err)
}

// Options for find request
options := &client.FindOptions{IncludeQueryPlan: true,
ResultAsDocument: true}

// Build an OJAI query
query, err := client.MakeQuery()
if err != nil {
    panic(err)
}

// Fetch all OJAI Documents from table
findResult, err := store.FindQuery(query, options)

// Get query plan
fmt.Println(findResult.QueryPlan())

// Print OJAI Documents from document stream
for _, doc := range findResult.DocumentList() {
    fmt.Println(doc)
}

// Close connection
connection.Close()
}

```

Paginating Your Result

An alternative to returning all documents from a store is to specify a limit in the query. Another alternative is to paginate the result using offset and limit. [Querying with Order By](#) on page 3844 contains an example that shows you how to use offset and limit. Although the example also uses order by, you can use offset and limit independent of order by.

Querying with Select

The examples in this section query a document store and retrieve specific fields from the documents.

NOTE: Selecting a specific field is also known as a *projection*. You can improve the performance of projection queries by using secondary indexes. See [Using Indexes to Optimize Projections in Queries](#) on page 790 for more details.

Java

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using the [Query.select](#) method.

```

var store = connection.GetStore("/demo_table");

//Create an OJAI query
var query = connection.NewQuery().Select("_id",
"address.zipCode").Build();

// Options for find request
var options = new QueryOptions(1000, true);

// Fetch OJAI Documents by query
var queryResult = store.Find(query, options);

var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
// Print OJAI Documents from document stream
foreach (var document in documentStream)
{
    Console.WriteLine(document.ToDictionary());
}

// Close the OJAI connection
connection.Close();
    }
}

```

Go

The following example shows how to retrieve the `_id` and `address.zipCode` fields from all documents in a store using an OJAI query.

```

package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }
}

```

```

// Get a store and assign it as a DocumentStore struct
store, err := connection.GetStore(storeName)
if err != nil {
    panic(err)
}

// Options for find request
options := &client.FindOptions{ResultAsDocument: true}

// Create an OJAI query
query := map[string]interface{}{"$select": []interface{}{"_id",
"address.zipCode"}}

// Fetch all OJAI Documents from table
findResult, err := store.FindQueryMap(query, options)

// Print OJAI Documents from document stream
for _, doc := range findResult.DocumentList() {
    fmt.Println(doc)
}

// Close connection
connection.Close()
}

```

Querying with Conditions

The examples in this section query a document store and return documents that have specific conditions.

For more information about how to specify query conditions in OJAI, see [Query Conditions in OJAI Applications](#) on page 3779.

NOTE: You can improve the performance of queries with conditions by using secondary indexes. See [Queries that Benefit from Secondary Indexes](#) on page 780 for more details.

Java - OJAI QueryCondition Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the [Query.where](#) method. It uses an OJAI [QueryCondition](#) to specify the condition.

```

/**

      console.log(document);
    });
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });
});

```

Python - OJAI QueryCondition Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the [Query.where](#) method. It uses an OJAI [QueryCondition](#) to specify the condition.

```

from mapr.ojai.ojai_query.QueryOp import QueryOp
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
  "ssl=true;" \
  "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
  "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

```

```
# Create an OJAI query
query = connection.new_query()\
    .where(connection.new_condition()\
        .is_('address.zipCode', QueryOp.EQUAL, 95196)\
        .close()\
        .build())\
    .build()

# fetch the OJAI Documents by query
query_result = store.find(query)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc)

# close the OJAI connection
connection.close()
```

Python - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
    "ssl=true;" \
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
    "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$where": {"$eq": {"address.zipCode": 95196}}}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
}

# fetch OJAI Documents by query
query_result = store.find(query, options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()
```

dbshell

The following two dbshell commands are equivalent to the code examples. See [dbshell find or findbyid](#) on page 7405 for more details about the syntax dbshell provides.

```
# mapr dbshell
maprdb root:> find /demo_table --q {"$where":{"$eq":
{"address.zipCode":95196}}}
```

```
maprdb root:> find /demo_table --where {"$eq":
{"address.zipCode":95196}}
```

C# - OJAI QueryCondition Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the [Query.Where](#) method. It uses an OJAI [QueryCondition](#) to specify the condition.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithCondition
{
    public async void FindQueryWithCondition()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI query
        var query = connection
            .NewQuery()
            .Where(connection
                .NewQueryCondition()
                .Is("address.zipCode", QueryOp.EQUAL, 95196)
                .Close()
                .Build())
            .Build();

        // Fetch the OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
        queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document);
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

C# - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithConditionJson
{
    public async void FindQueryWithConditionJson()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI query
        var query =
            @"{" +
                @"{" +
                    @"$where":" +
                        @"{" +
                            @"$eq":{"address.zipCode":
{""$numberLong"":""95196""}}}" +
                            @"}" +
                        @"}" +
                    @"}" +
                @"}";

        // Fetch OJAI Documents by query
        var queryResult = store.FindQuery(query);

        var documentStream = await queryResult.GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToDictionary());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go - OJAI QueryCondition Object

The following example shows how to return all documents from a store where `address.zipCode` equals 95196, using the [Query.WhereCondition](#) function. It uses an OJAI [Condition](#) to specify the condition.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)
```

```

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create a condition
    condition, err := client.MakeCondition(client.Is("address.zipCode",
client.EQUAL, 95196), client.Close())
    if err != nil {
        panic(err)
    }
    condition.Build()

    // Create an OJAI query
    query, err := client.MakeQuery(client.WhereCondition(condition))
    if err != nil {
        panic(err)
    }
    query.Build()

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQuery(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}

```

Go - OJAI Query Condition in JSON Format

The following example uses an OJAI query condition specified in JSON format to return all documents from a store where `address.zipCode` equals 95196.

```

package main

import (

```

```

    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{
        "$where": map[string]interface{}{
            "$eq": map[string]interface{}{
                "address.zipCode": 95196
            }
        }
    }

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}

```

Querying with Select and Conditions

The examples in this section query a document store and return specific fields from documents that have specific conditions.

For more information about how to specify query conditions in OJAI, see [Query Conditions in OJAI Applications](#) on page 3779.

NOTE: You can improve the performance of queries with conditions by using secondary indexes. See [Queries that Benefit from Secondary Indexes](#) on page 780 for more details.

Java

The following example shows how to return the name, address.zipCode, age, and phoneNumber fields from documents that have address.zipCode equal to 95196. It uses the [Query.select](#) and [Query.where](#) methods, specifying the query condition as a JSON string.

```

 */

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
    'auth=basic;' +
    'user=mapr;' +
    'password=mapr;' +
    'ssl=true;' +
    'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
    'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
    .then((conn) => {
        connection = conn;
        // Get a store
        return connection.getStore('/demo_table');
    })
    .then((store) => {
        // Create an OJAI query
        const query = {"$select": ["name",
            "adress.zipCode",
            "age",
            "phoneNumbers[0]"],
            "$where": {"$eq": {"address.zipCode": 95196}}};
        // fetch OJAI Documents by query
        return store.find(query);
    })
    .then((queryResult) => {
        queryResult.on('data', (document) => {
            // Print OJAI Documents from document stream
            console.log(document);
        });
    });

```

```

    queryResult.on('end', () => {
        // close the OJAI connection
        connection.close();
    });
});

```

Python

The following example shows how to return the name, address.zipCode, age, and phoneNumber fields from documents that have address.zipCode equal to 95196. It uses an OJAI query and condition.

```

from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
    "ssl=true;" \
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
    "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$select": ["name",
                    "address.zipCode",
                    "age",
                    "phoneNumbers[0]"],
        "$where": {"$eq": {"address.zipCode": 95196}}}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
}

# fetch OJAI Documents by query
query_result = store.find(query,
                          options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())

# close the OJAI connection
connection.close()

```

dbshell

The following two dbshell commands are equivalent to the code examples. See [dbshell find or findbyid](#) on page 7405 for more details about the syntax dbshell provides.

```

find /demo_table --query {
    "$select":["name","address.zipCode","age","phoneNumber[0]"],
    "$where":{"$eq":{"address.zipCode":95196}}
}

find /demo_table
--fields name,address.zipCode,age,phoneNumber[0]
--where {"$eq":{"address.zipCode":95196}}

```

NOTE: The commands are shown split across multiple lines for readability. When using dbshell, you must enter them in a single line.

C#

The following example shows how to return the name, address.zipCode, age, and phoneNumber fields from documents that have address.zipCode equal to 95196. It uses an OJAI query and condition.

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithSelectAndCondition
{
    public async void FindQueryWithSelectAndCondition()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI condition
        var condition = connection
            .NewQueryCondition()
            .Is("address.zipCode", QueryOp.EQUAL, 95196)
            .Close()
            .Build();

        // Create an OJAI query
        var query = connection
            .NewQuery()
            .Select("name", "adress.zipCode", "age", "phoneNumbers[0]")
            .Where(condition)
            .Build();

        // Fetch OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
        queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document.ToJsonString());
        }

        // Close the OJAI connection
        connection.Close();
    }
}
```

Go

The following example shows how to return the name, address.zipCode, age, and phoneNumber fields from documents that have address.zipCode equal to 95196. It uses an OJAI query and condition.

```
package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }

    // Options for find request
    options := &client.FindOptions{ResultAsDocument: true}

    // Create an OJAI query
    query := map[string]interface{}{"$select": []interface{}{"firstName",
        "address.zipCode", "age", "phoneNumbers[0]"},
        "$where": map[string]interface{}{
            "$eq": map[string]interface{}{"address.zipCode": 95196}}}

    // Fetch all OJAI Documents from table
    findResult, err := store.FindQueryMap(query, options)

    // Print OJAI Documents from document stream
    for _, doc := range findResult.DocumentList() {
        fmt.Println(doc)
    }

    // Close connection
    connection.Close()
}
```

Querying with Order By

The examples in this section query a document store and return specific fields from the documents, sorted in a specific order. One of the examples also uses offset and limit.

NOTE: You can improve the performance of order by queries by using secondary indexes. See [Using Indexes to Optimize ORDER BY Queries](#) on page 787 for more information.

Java - Order By

The following example shows how to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sorting the documents by `_id`. It uses the [Query.select](#) and [Query.orderBy](#) methods.

NOTE: The example sorts in the default ascending order. To sort in descending order, modify the `orderBy` method call as follows:

```
orderBy("_id", SortOrder.DESC)
```

```

 */
package com.mapr.ojai.examples;

import org.ojai.Document;
import org.ojai.DocumentStream;
import org.ojai.store.Connection;
import org.ojai.store.DocumentStore;
import org.ojai.store.DriverManager;
import org.ojai.store.Query;

public class OJAI_011_FindQueryWithOrderByLimitOffset {

    public static void main(final String[] args) {

        System.out.println("==== Start Application ===");
    }
}

```

```
// Create an OJAI connection to MapR cluster
final Connection connection = DriverManager.getConnection("ojai:mapr:");

// Get an instance of OJAI DocumentStore
final DocumentStore store = connection.getStore("/demo_table");

// Build an OJAI query with an order by, offset, and limit
final Query query = connection.newQuery()
    .select("_id", "firstName", "lastName", "address.zipCode")
    .orderBy("_id")
    .offset(2)
    .limit(1)
    .build();

// fetch all OJAI Documents from this store
final DocumentStream stream = store.find(query);

for (final Document userDocument : stream) {
    // Print the OJAI Document
    System.out.println(userDocument.asJsonString());
}

// Close this instance of OJAI DocumentStore
store.close();

// close the OJAI connection and release any resources held by the
connection
connection.close();

System.out.println("==== End Application ===");
}
}
```

Node.js - Order By

The following example uses an OJAI query to return the `_id` and name fields from documents in a store and to sort the documents by `_id`.

NOTE: The example sorts in the default ascending order. To sort in descending order, modify the `orderby` specification as follows:

```
order_by('_id', desc)
```

```

 */

const { ConnectionManager } = require('node-maprdb');
```

```

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // Create an OJAI query
    const query = {"$select": ["_id", "name"], "$orderby": {"_id": "asc"}};
    // fetch OJAI Documents by query
    return store.find(query);
  })
  .then((queryResult) => {
    queryResult.on('data', (document) => {
      // Print OJAI Documents from document stream
      console.log(document);
    });
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });
});

```

Node.js - Order By with Offset and Limit

The following example uses an OJAI query to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sort the documents by `_id`, offset the result by two documents, and limit the result to a single document.

NOTE: The example sorts in the default ascending order. To sort in descending order, modify the `orderby` specification as follows:

```
"$orderby": {"_id": "desc"}
```

```

```

```

const { ConnectionManager } = require('node-maprdb');

const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';

let connection;

// Create a connection to data access server
ConnectionManager.getConnection(connectionString)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
  .then((store) => {
    // Create an OJAI query
    const query = { "$offset": 2,
      "$select": [ "_id",
        "firstName",
        "lastName",
        "address.zipCode"],
      "$limit": 1,
      "$orderby": { "_id": "asc" } };
    // fetch OJAI Documents by query
    return store.find(query);
  })
  .then((queryResult) => {
    queryResult.on('data', (document) => {
      // Print OJAI Documents from document stream
      console.log(document);
    });
    queryResult.on('end', () => {
      // close the OJAI connection
      connection.close();
    });
  });

```

Python - Order By

The following example uses an OJAI query to return the `_id` and name fields from documents in a store and to sort the documents by `_id`.

NOTE: The example sorts in the default ascending order. To sort in descending order, modify the `orderby` specification as follows:

```
"$orderby": { "_id": "desc" }
```

```

from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
  "ssl=true;" \
  "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
  "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

```

```
# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$select": ["_id", "name"], "$orderby": {"_id": "asc"}}

# fetch OJAI Documents by query
query_result = store.find(query)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc)

# close the OJAI connection
connection.close()
```

Python - Order By with Offset and Limit

The following example uses an OJAI query to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sort the documents by `_id`, offset the result by two documents, and limit the result to a single document.

NOTE: The example sorts in the default ascending order. To sort in descending order, modify the `orderby` method call as follows:

```
order_by('_id', desc)
```

```
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

# Create a connection to data access server
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \
    "ssl=true;" \
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
    "sslTargetNameOverride=node1.mapr.com"
connection = ConnectionFactory.get_connection(connection_str=connection_str)

# Get a store and assign it as a DocumentStore object
store = connection.get_store('/demo_table')

# Create an OJAI query
query = {"$offset": 2,
        "$select": ["_id",
                    "firstName",
                    "lastName",
                    "address.zipCode"],
        "$limit": 1,
        "$orderby": {"_id": "asc"}}

# options for find request
options = {
    'ojai.mapr.query.result-as-document': True
}

# fetch OJAI Documents by query
query_result = store.find(query, options=options)

# Print OJAI Documents from document stream
for doc in query_result:
    print(doc.as_dictionary())
```

```
# close the OJAI connection
connection.close()
```

dbshell

The following dbshell commands are equivalent to the code examples. See [dbshell find](#) or [findbyid](#) on page 7405 for more details about the syntax dbshell provides.

```
find /demo_table --query {
  "$select":["_id","firstName","lastName","address.zipCode"],
  "$orderby":"_id"
}

find /demo_table
  --fields _id,firstName,lastName,address.zipCode
  --orderby _id

find /demo_table --query {
  "$select":["_id","firstName","lastName","address.zipCode"],
  "$orderby":"_id",
  "$offset":2,
  "$limit":1
}

find /demo_table
  --fields _id,firstName,lastName,address.zipCode
  --orderby _id
  --offset 2
  --limit 1
```

NOTE: The commands are shown split across multiple lines for readability. When using dbshell, you must enter them in a single line.

C# - Order By

The following example uses an OJAI query to return the `_id` and name fields from documents in a store and to sort the documents by `_id`.

NOTE: The example sorts in the default ascending order. To sort in descending order, modify the `OrderBy` specification as follows:

```
.OrderBy("_id", SortOrder.DESC)
```

```
using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithOrderBy
{
    public async void FindQueryWithOrderBy()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);
```

```

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI query
        var query = connection
            .NewQuery()
            .Select("_id", "name")
            .OrderBy("_id", SortOrder.ASC)
            .Build();

        // Fetch OJAI Documents by query
        var queryResult = store.Find(query);

        var documentStream = await
        queryResult.GetDocumentAsyncStream().GetAllDocuments();
        // Print OJAI Documents from document stream
        foreach (var document in documentStream)
        {
            Console.WriteLine(document);
        }

        // Close the OJAI connection
        connection.Close();
    }
}

```

C# - Order By with Offset and Limit

The following example uses an OJAI query to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sort the documents by `_id`, offset the result by two documents, and limit the result to a single document.

NOTE: The example sorts in the default ascending order. To sort in descending order, modify the `OrderBy` method call as follows:

```
.OrderBy("_id", SortOrder.DESC)
```

```

using System;
using MapRDB.Driver;
using MapRDB.Driver.Ojai;

public class FindQueryWithOrderByLimitOffset
{
    public async void FindQueryWithOrderByLimitOffset()
    {
        // Create a connection to data access server
        var connectionStr = $"localhost:5678?auth=basic;" +
            $"user=mapr;" +
            $"password=mapr;" +
            $"ssl=true;" +
            $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
            $"sslTargetNameOverride=node1.mapr.com";
        var connection = ConnectionFactory.CreateConnection(connectionStr);

        // Get a store and assign it as a DocumentStore object
        var store = connection.GetStore("/demo_table");

        // Create an OJAI query
        var query = connection
            .NewQuery()

```

```

        .Select("_id", "firstName", "lastName", "address.zipCode")
        .Offset(2)
        .Limit(1)
        .OrderBy("_id", SortOrder.ASC)
        .Build();

    // Fetch OJAI Documents by query
    var queryResult = store.Find(query);

    var documentStream = await
queryResult.GetDocumentAsyncStream().GetAllDocuments();
    // Print OJAI Documents from document stream
    foreach (var document in documentStream)
    {
        Console.WriteLine(document.ToString());
    }

    // Close the OJAI connection
    connection.Close();
}
}

```

Go - Order By

The following example uses an OJAI query to return the `_id` and `firstName` fields from documents in a store and to sort the documents by `_id`.

The example sorts in the default ascending order. To sort in descending order, modify the `orderby` specification as follows:

```
"$orderby": map[string]interface{}{"_id": "desc"}}
```

```

package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }
}

```

```

// Options for find request
options := &client.FindOptions{ResultAsDocument: true}

// Create an OJAI query
query := map[string]interface{}{"$select": []interface{}{"_id",
"firstName"},
"$orderby": map[string]interface{}{"_id": "asc"}}

// Fetch all OJAI Documents from table
findResult, err := store.FindQueryMap(query, options)

// Print OJAI Documents from document stream
for _, doc := range findResult.DocumentList() {
    fmt.Println(doc)
}

// Close connection
connection.Close()
}

```

Go - Order By with Offset and Limit

The following example uses an OJAI query to return the `_id`, `firstName`, `lastName`, and `address.zipCode` fields from documents in a store, sort the documents by `_id`, offset the result by two documents, and limit the result to a single document.

The example sorts in the default ascending order. To sort in descending order, modify the `orderby` function call as follows:

```
"$orderby": map[string]interface{}{"_id": "desc"}}
```

```

package main

import (
    "fmt"
    client "github.com/mapr/private-maprdb-go-client"
)

func main() {
    // Create connection string
    connectionString := "192.168.33.11:5678?" +
        "auth=basic;" +
        "user=mapr;" +
        "password=mapr;" +
        "ssl=true;" +
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
        "sslTargetNameOverride=node1.cluster.com"

    storeName := "/demo_table"

    // Create a connection to DAG
    connection, err := client.MakeConnection(connectionString)
    if err != nil {
        panic(err)
    }

    // Get a store and assign it as a DocumentStore struct
    store, err := connection.GetStore(storeName)
    if err != nil {
        panic(err)
    }
}

```

```

// Options for find request
options := &client.FindOptions{ResultAsDocument: true}

// Create an OJAI query
query := map[string]interface{}{"$select": []interface{}{"_id",
"firstName", "lastName", "address.zipCode"},
"$offset": 2,
"$limit": 1,
"$orderby": map[string]interface{}{"_id": "asc"}}

// Fetch all OJAI Documents from table
findResult, err := store.FindQueryMap(query, options)

// Print OJAI Documents from document stream
for _, doc := range findResult.DocumentList() {
    fmt.Println(doc)
}

// Close connection
connection.Close()
}

```

Using the Java OJAI Client

This topic describes HPE Data Fabric Database functionality that is applicable to only the Java OJAI client. This includes instructions on how to compile your Java OJAI application, enable buffered writes, use the read your own writes feature, and enable available query options.

Additional Resources

Examples: <https://github.com/mapr-demos/ojai-examples/tree/master/java/src/main/java/com/mapr/ojai/examples>

Compiling and Running Java OJAI Applications

For applications that use the Java OJAI API, use Maven to compile and determine the application's dependencies. Then, when you run the application, specify those dependencies in the application's classpath.

Compile and Determine Dependencies

Use Maven to compile and determine the application dependencies.

1. Add MapR's Maven repository to your `pom.xml` file, if it is not already added:

```

<repositories>
  <repository>
    <id>mapr-releases</id>
    <url>https://repository.mapr.com/nexus/content/repositories/
releases</url>
    <snapshots><enabled>true</enabled></snapshots>
    <releases><enabled>true</enabled></releases>
  </repository>
</repositories>

```

2. Add a dependency to the MapR OJAI driver project:

```
<dependencies>
  <dependency>
    <groupId>com.mapr.ojai</groupId>
    <artifactId>mapr-ojai-driver</artifactId>
    <version>6.0.0-mapr</version>
  </dependency>
</dependencies>
```

NOTE: Replace the <version> property with the HPE Data Fabric Database version that you are using.

3. Use Maven to compile the application and resolve dependencies.

Run the Application

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see [Using the File System JAR to Connect to the Cluster](#) on page 3562.

When the cluster is secure, the node must also have a MapR ticket configured for the user that runs the application.

You can use the following command to launch HPE Data Fabric Database JSON applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

Enable OJAI Tracing

To help debug your Java OJAI application, you can enable OJAI tracing. MapR uses the log4j API to log tracing messages. To enable writing these messages to standard output, follow these steps:

1. Set the following property in your /opt/mapr/conf/log4j.properties file:

```
log4j.logger.com.mapr.ojai.store.impl=TRACE, stdout
```

2. Add the following to your java launch command:

- In your java classpath, add the library that includes custom MapR log4j classes:

```
-cp /opt/mapr/lib/central-logging-8.1.0-mapr.jar:<other classpaths>:.
```

- Define the location of the log4j.properties file:

```
-Dlog4j.configuration=file:/opt/mapr/conf/log4j.properties
```

Reading Your Own Writes in Java OJAI

The Java OJAI DocumentStore and Query APIs provide the ability to track writes to JSON tables. Use these APIs to ensure your application reads recent writes on JSON tables with secondary indexes.

Description

You should use this feature if it is important for your query results to reflect synchronized data between a JSON table and its secondary indexes. Because HPE Data Fabric Database updates secondary indexes asynchronously, it is possible for a JSON table and its secondary indexes to become out-of-sync while the index update is in progress.

For example, consider the following scenario:

- Your application updates a JSON table.
- The JSON table includes an address field that is a nested document with a zipCode subfield.
- You have a secondary index on zipCode.
- Later in your application, you query the JSON table filtering on zipCode.

You want your query result to reflect the updates from earlier in your application. To achieve this, use the DocumentStore and Query APIs that enable you to retrieve up-to-date information from the index. The APIs synchronize write operations on the JSON table with read operations on a secondary index.

See [Asynchronous Secondary Index Updates](#) on page 797 for more information about index updates.

NOTE: The Python and Node.js OJAI APIs do not support this feature.

API Details

The OJAI DocumentStore and Query interfaces provide the following methods to support this functionality.

DocumentStore.beginTrackingWrites

Begins tracking the write operations performed through this instance of DocumentStore. The method takes an optional previousWritesContext parameter. If you specify this parameter, the tracking uses that context as the base state.

DocumentStore.endTrackingWrites

Flushes any buffered writes operations for this DocumentStore and returns a writesContext. Use this context to ensure that writes are visible to later queries. You can use the context across DocumentStore objects in the same, as well as different, client processes, when the stores refer to the same JSON table. For example, you can pass the writesContext returned by one DocumentStore to a second DocumentStore, to begin write tracking on the second store.

DocumentStore.clearTrackedWrites

Stops the write tracking and clears any state on this DocumentStore instance.

Query.waitForTrackedWrites

Sets the writesContext parameter for this query. A writesContext allows this query to "see" all the writes that happened inside the writesContext of a DocumentStore.

For the complete API, see [Java OJAI Client API](#).

Read Your Own Writes Example

A complete code example is available on github at [OJAI_013_ReadYourOwnWrite.java](#). The following are code snippets from that example. Each step contains links to corresponding lines of code in the github example:

1. Call [beginWriteTracking](#) to set the starting point for the commit context on the JSON table /demo_table:

```
// Create an OJAI connection to MapR cluster
final Connection connectionNode1 =
    DriverManager.getConnection("ojai:mapr:");

// Get an instance of OJAI DocumentStore
final DocumentStore storeNode1 = connectionNode1.getStore("/demo_table");

// initiate tracking of commit-context
storeNode1.beginTrackingWrites();
```

2. [Update](#) the zipCode of an existing user and [insert](#) a new user in /demo_table:

```
// issue a set of mutations/insert/delete/etc
storeNode1.update("user0000",
    connectionNode1.newMutation().set("address.zipCode", 95110L));
storeNode1.insertOrReplace(connectionNode1.newDocument(
    "{ \"_id\": \"user0004\", \"firstName\": \"Joel\", \"lastName\": \"Smith\", \"age\": 56, \"address\": { \"zipCode\": { \"$numberLong\": 95110 } } }"));
```

3. Call [endWriteTracking](#) to flush the write operations after step 1, including updates to the secondary index:

```
final String commitContext = storeNode1.endTrackingWrites();
```

The call also returns a commitContext.

4. Issue a query that calls [waitForTrackedWrites](#) with the `commitContext` from step 3:

```
/*
 * Next section of the code can run on the same or on a different node,
 * the `commitContext` obtained earlier needs to be propagated to that
 * node.
 */

// Create an OJAI connection to MapR cluster
final Connection connectionNode2 =
    DriverManager.getConnection("ojai:mapr:");

// Get an instance of OJAI DocumentStore
final DocumentStore storeNode2 = connectionNode2.getStore("/demo_table");

// Build an OJAI query and set its commit context with timeout of 2
seconds
final Query query = connectionNode2.newQuery()
    .select("_id", "firstName", "lastName", "address.zipCode")
    .where("{\"_id$gt\": {\"address.zipCode\": 95110}}")
    .waitForTrackedWrites(commitContext)
    .build();
```

The query filters on the indexed subfield `address.zipCode`. The `commitContext` ensures that the query result includes the changes made in step 2.

Setting Query Options in Java OJAI

This topic describes how to set query options in your Java OJAI application.

See [OJAI Query Options](#) on page 3777 for a list of available query options.

To set an option, pass the option name as the first parameter to the [Query.setOption](#) method:

```
query.setOption("ojai.mapr.query.hint-using-index", indexName);
```

Enabling Buffered Writes in Java OJAI

By default, HPE Data Fabric Database JSON does not buffer writes. You can improve performance by enabling buffered writes in your Java OJAI application.

Description

The buffered writes option can be set in the [Connection.getStore](#) method. You pass the option setting through a `Document` object in the second parameter to the method. The `Document` object sets `ojai.mapr.documentstore.buffer-writes` to either `true` or `false`. The default value is `false`, which means that writes are not buffered.

Example Code Snippet

The following code sample enables buffered writes:

```
final DocumentStore store =
    connection.getStore(
        "/demo_table",
        connection.newDocument().set("ojai.mapr.documentstore.buffer-writes",
            true));
```

Using the Java OJAI Thin Client

Starting with EEP 6.3.0, you can use the Java OJAI Thin Client to write HPE Data Fabric Database JSON applications. The Java OJAI Thin Client provides a lightweight library that supports the OJAI API. You

can connect to HPE Data Fabric Database JSON, and add, update, and query documents in a HPE Data Fabric Database JSON table.

Java OJAI Thin Client Benefits

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Data Fabric Database JSON through the OJAI interface
- An OJAI interface that is tailored to Java developers
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

Comparing the Java OJAI Client and the Java OJAI Thin Client

Note these considerations when deciding whether to use the Java OJAI Client or the Java OJAI Thin Client:

- Both the Java OJAI client and Java OJAI Thin Client use the same API ([Java OJAI Client API](#)).
- The Java OJAI client is more scalable, more performant, and more fault tolerant, but also more complicated to deploy. See [Using the Java OJAI Client](#) on page 3855.
- The Java OJAI Thin Client requires you to specify the service ([Data Fabric Data Access Gateway](#)) to which you will connect.
- The Java OJAI Thin Client is a pure Java client, while the Java OJAI client requires a JNI library.

Installing the Data Fabric Data Access Gateway

To use the Java OJAI Thin Client, you must install the [Data Fabric Data Access Gateway](#) on your HPE Data Fabric cluster. The gateway serves as a proxy for translating requests between the Java OJAI Thin Client and the HPE Data Fabric cluster. To administer the gateway and configure load balancing, see [Administering the Data Access Gateway](#) on page 2235.

Java OJAI Thin Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Java OJAI Thin Client Connection String

The string you use to connect your OJAI client to a HPE Data Fabric cluster must have the following format:

```
"ojai:mapr:thin:@<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

<hostname>

Name of the HPE Data Fabric Data Access Gateway host

<port>

Port number (see [Ports Used by HPE Data Fabric Software](#) on page 3469) that gRPC clients use to connect to the HPE Data Fabric Data Access Gateway
Default: 5678

auth=<scheme_name>	The authentication scheme for the current connection; currently, only basic
user=<username>	The user name for basic authentication
password=<password>	The password for basic authentication
ssl=true false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and cluster security settings. The default for this option is <code>true</code> , which is the required setting if connecting to a secure HPE Data Fabric cluster. If connecting to a nonsecure HPE Data Fabric cluster, set it to <code>false</code> . If set to <code>false</code> , the other SSL parameters are ignored.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3886. Must be set if the <code>ssl</code> option is <code>true</code> .

Here is an example of a connection string:

```
"ojai:mapr:thin:@localhost:5678?
auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
```

Advanced Parameters

Advanced parameters such as `maxmsgsize` are optional for the Java OJAI Thin Client connection string:

maxmsgsize	If you use thin-client version 1.0.2-mapr and later, <code>maxmsgsize</code> sets the maximum message size that the gRPC client accepts. The default is set to 32 MB, as this is the default maximum document size for HPE Data Fabric Database JSON tables. The value specified in the connection string should be less than or equal to the value set in the Data Access Gateway configuration on the server side (see Administering the Data Access Gateway on page 2235).
-------------------	--

Maven Coordinates

The Maven coordinates are:

```
<dependency>
  <groupId>com.mapr.ojai</groupId>
  <artifactId>mapr-ojai-driver-thin</artifactId>
  <version>1.0.3-mapr</version>
</dependency>
```

Additional Resources

The Java OJAI Client examples at the following location also apply to the Java OJAI Thin Client. Only the connection string and the Maven artifact name will be different for the thin client: <https://github.com/mapr-demos/ojai-examples/tree/master/java/src/main/java/com/mapr/ojai/examples>

Using the Node.js OJAI Client

Starting with EEP 6.0, you can use the Node.js OJAI client to write HPE Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Data Fabric Database JSON from middleware components, and add, update, and query documents in a HPE Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Data Fabric Database JSON through the OJAI interface in Node.js
- An OJAI interface that is tailored to Node.js developers
- Support for Callback and Promise/Async Node.js asynchronous programming models
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing
- Use of JavaScript to manipulate HPE Data Fabric Database JSON documents

To use the Node.js OJAI client, you must install the [Data Fabric Data Access Gateway](#) on your HPE Data Fabric cluster. The gateway serves as a proxy for translating requests between the Node.js client and the HPE Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. See [Administering the Data Access Gateway](#) on page 2235 for information about how to administer the gateway and configure load balancing.

 **IMPORTANT:** HPE Data Fabric does not support running the Node.js OJAI client in a web browser.

Additional Resources

Examples: <https://github.com/mapr-demos/ojai-examples/tree/master/nodejs>

Source Code: <https://github.com/mapr/maprdb-node-client>

Getting Started with the Node.js OJAI Client

This section describes the software required to run the Node.js OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Node.js OJAI applications.

The Node.js OJAI client is available starting in the EEP 6.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Node.js	Supported versions: <ul style="list-style-type: none"> • 6.x • 8.x • 9.x • 10.x
Node.js OJAI client	Install the client by using the following command: <pre>npm install node-maprdb</pre>

You also must have access to the following software:

- MapR/Data Fabric cluster 6.1 or later
- [Data Access Gateway](#) 2.0 or later

To run a Node.js OJAI application, you simply need to install and configure the Data Access Gateway:

- [Installing the Data Access Gateway Service](#) on page 2236
- [Modifying Configuration Settings for the Data Access Gateway Service](#) on page 2236

Node.js OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Node.js OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

<hostname>	Name of the Data Access Gateway host. For information about the host name, see Configuring SSL for OJAI Clients on page 3886.
<port>	Port number (see Ports Used by HPE Data Fabric Software on page 3469) that gRPC clients use to connect to the Data Access Gateway Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only <code>basic</code>
user=<username>	The user name for basic authentication
password=<password>	The password for basic authentication
ssl=true false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is <code>true</code> , which is the required setting if connecting to a secure Data Access Gateway. If connecting to a non-secure Data Access Gateway, set it to <code>false</code> . If set to <code>false</code> , the other SSL parameters are ignored. Note that the <code>grpc.service.ssl.enabled</code> property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 2235.

sslCA=<path to PEM file containing CA certificate>

Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see [Configuring SSL for OJAI Clients](#) on page 3886.

Required when the `ssl` option is set to `true`.

sslTargetNameOverride=<CA certificate common name>

Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string.

For example, imagine that you are using the following:

- Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`.
- Internal DNS is `node1.mydomain.com`.
- CA signed certificate is issued to `node1.mydomain.com`.

Using these names, you must specify the following connection string:

```
"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;sslTargetNameOverride=node1.mydomain.com"
```

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
"localhost:5678?ssl=false;auth=basic;user=fred;password=george"
```

Node.js OJAI Connection Retry Options

If your OJAI client cannot connect to your cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
<code>ojai.mapr.rpc.wait-multiplier</code>	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
<code>ojai.mapr.rpc.wait-max-attempt</code>	Maximum wait time between attempts regardless of the multiplier parameter	18000 ms
<code>ojai.mapr.rpc.max-retries</code>	Maximum number of retry attempts	7

The following examples demonstrate how these parameters work, including the default case:

Attempt #	Wait Time (in ms) for each Retry Attempt	
	Default Parameters:	
	<pre>{ 'ojai.mapr.rpc.wait-multiplier': 1000, 'ojai.mapr.rpc.wait-max-attempt': 18000, 'ojai.mapr.rpc.max-retries': 7 }</pre>	<pre>{ 'ojai.mapr.rpc.wait-multiplier': 2, 'ojai.mapr.rpc.wait-max-attempt': 90, 'ojai.mapr.rpc.max-retries': 5 }</pre>
1	10	10
2	10*1000 = 10000	10*2 = 20
3	18000 10000*1000 = 10,000,000, which exceeds 18000	20*2 = 40
4	18000	40*2 = 80
5	18000	90 80*2 = 160, which exceeds 90
6	18000	Error
7	18000	N/A
8	Error	N/A

To set these retry options, you must pass them in the `ConnectionManager.getConnection` call:

```
const connectionString = 'localhost:5678?' +
  'auth=basic;' +
  'user=mapr;' +
  'password=mapr;' +
  'ssl=true;' +
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' +
  'sslTargetNameOverride=node1.mapr.com';
const options = {
  'ojai.mapr.rpc.wait-multiplier': 5,
  'ojai.mapr.rpc.wait-max-attempt': 50,
  'ojai.mapr.rpc.max-retries': 3
}

let connection;

ConnectionManager.getConnection(connectionString, options)
  .then((conn) => {
    connection = conn;
    // Get a store
    return connection.getStore('/demo_table');
  })
```

Writing Node.js OJAI Applications

For information about writing a Node.js OJAI application, see the Node.js sections in the following topics:

Querying in OJAI Applications on page 3769	Provides an introduction to the basic flow of an OJAI application that queries a HPE Data Fabric Database JSON table
Examples: Querying JSON Documents on page 3814	Contains code samples of OJAI applications that query HPE Data Fabric Database JSON tables
Managing JSON Documents on page 3731	Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Data Fabric Database JSON tables

Node.js OJAI Client Classes and Methods

This topic lists and describes the classes supported by the Node.js OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
ConnectionManager	Manages connections to HPE Data Fabric Database JSON.
Connection	Provides a logical connection to an OJAI data source: for example, HPE Data Fabric Database JSON.
DocumentStore	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Data Fabric Database JSON tables.
QueryResult	Encapsulates the stream of result sets for an OJAI query.
OTime	Encapsulates the OJAI TIME type.
OTimestamp	Encapsulates the OJAI TIMESTAMP type.
ODate	Encapsulates the OJAI DATE type.

See [Node.js OJAI Client API](#) for details about each class, including the methods available in each class.

Setting Query Options in Node.js OJAI

There are two categories of options you can set in your Node.js OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a Node.js OJAI Method Call

Option Name	Description
<code>ojai.mapr.query.include-query-plan</code>	Enables or disables availability of the query plan for retrieval Value: <code>true false</code> Default: <code>false</code>
<code>ojai.mapr.query.timeout-milliseconds</code>	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.find` method.

The following code snippet sets the query timeout to 3000 milliseconds:

```
const docStream = store.find(
  query,
  { 'ojai.mapr.query.timeout-milliseconds': 3000 }
);
```

Setting Query Options in Node.js Using OJAI Query Syntax

[OJAI Query Options](#) on page 3777 describes query options that are available in all OJAI clients. To use these options in Node.js OJAI, you must construct your query in JSON format and use the `$options` keyword. See [OJAI Query Syntax](#) for details about the syntax, including an example.

Using the Python OJAI Client

Starting with EEP 6.0, you can use the Python OJAI client to write HPE Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Data Fabric Database JSON, and add, update, and query documents in a HPE Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Data Fabric Database JSON through the OJAI interface in Python
- An OJAI interface that is tailored to Python developers
- Use of Python types to manipulate HPE Data Fabric Database JSON documents
- Support for Python multiprocessing and multithreading modules
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the Python OJAI client, you must install the [Data FabricData Access Gateway](#) on your HPE Data Fabric cluster. The gateway serves as a proxy for translating requests between the Python client and the HPE Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. See [Administering the Data Access Gateway](#) on page 2235 for information about how to administer the gateway and configure load balancing.

Getting Started with the Python OJAI Client

This section describes the software required to run the Python OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Python OJAI applications.

The Python OJAI client is available starting with the EEP 6.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Python	Use Python 2.7 or later
pip	See https://pip.pypa.io/en/stable/installing/ for instructions specific to your environment.
Python OJAI client	Install the client by using the following command: <pre>pip install maprdb-python-client</pre>

You also must have access to the following software:

- MapR/Data Fabric cluster 6.1 or later

- [MapR Data Access Gateway 2.0 or later](#)

To run a Python OJAI application, you simply need to install and configure the Data Access Gateway:

- [Installing the Data Access Gateway Service](#) on page 2236
- [Modifying Configuration Settings for the Data Access Gateway Service](#) on page 2236

Python OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Python OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

<hostname>

Name of the Data Access Gateway host. For information about the host name, see [Configuring SSL for OJAI Clients](#) on page 3886.

<port>

Port number (see [Ports Used by HPE Data Fabric Software](#) on page 3469) that gRPC clients use to connect to the Data Access Gateway

Default: 5678

auth=<scheme_name>

The authentication scheme for the current connection; currently, only `basic`

user=<username>

The user name for basic authentication

password=<password>

The password for basic authentication

ssl=true|false

Whether to establish a secure connection using SSL/TLS

An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is `true`, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a non-secure Data Access Gateway, set it to `false`.

If set to `false`, the other SSL parameters are ignored.

Note that the `grpc.service.ssl.enabled` property controls the SSL setting for the Data Access Gateway. For more information, see [Administering the Data Access Gateway](#) on page 2235.

sslCA=<path to PEM file containing CA certificate>

Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see [Configuring SSL for OJAI Clients](#) on page 3886.

**sslTargetNameOverride=<CA certificate
common name>**

Required when the `ssl` option is set to `true`.

Fully qualified domain name specified in the SSL server certificate, which is different from the `<hostname>` in the connection string.

For example, imagine that you are using the following:

- Public network host name is `ec2-203-0-113-25.compute-1.amazonaws.com`.
- Internal DNS is `node1.mydomain.com`.
- CA signed certificate is issued to `node1.mydomain.com`.

Using these names, you must specify the following connection string:

```
"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;sslTargetNameOverride=node1.mydomain.com"
```

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
"localhost:5678?ssl=false;auth=basic;user=fred;password=george"
```

Python OJAI Connection Retry Options

If your OJAI client cannot connect to your cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
<code>ojai.mapr.rpc.wait-multiplier</code>	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
<code>ojai.mapr.rpc.wait-max-attempt</code>	Maximum wait time between attempts regardless of the multiplier parameter	18000 ms
<code>ojai.mapr.rpc.max-retries</code>	Maximum number of retry attempts	7

The following examples demonstrate how these parameters work, including the default case:

Attempt #	Wait Time (in ms) for each Retry Attempt	
	Default Parameters:	
	<pre>{ 'ojai.mapr.rpc.wait-multiplier': 1000, 'ojai.mapr.rpc.wait-max-attempt': 18000, 'ojai.mapr.rpc.max-retries': 7 }</pre>	<pre>{ 'ojai.mapr.rpc.wait-multiplier': 2, 'ojai.mapr.rpc.wait-max-attempt': 90, 'ojai.mapr.rpc.max-retries': 5 }</pre>
1	10	10
2	$10 \times 1000 = 10000$	$10 \times 2 = 20$
3	18000 $10000 \times 1000 = 10,000,000$, which exceeds 18000	$20 \times 2 = 40$
4	18000	$40 \times 2 = 80$
5	18000	90 $80 \times 2 = 160$, which exceeds 90
6	18000	Error
7	18000	N/A
8	Error	N/A

To set these retry options, you must pass them in the `ConnectionFactory.get_connection` call:

```
connection_str = 'localhost:5678?auth=basic;user=mapr;password=mapr;' \
  'ssl=true;' \
  'sslCA=/opt/mapr/conf/ssl_truststore.pem;' \
  'sslTargetNameOverride=node1.mapr.com'
options = {
  'ojai.mapr.rpc.wait-multiplier': 5,
  'ojai.mapr.rpc.wait-max-attempt': 50,
  'ojai.mapr.rpc.max-retries': 3
}
connection =
ConnectionFactory.get_connection(connection_str=connection_str,options=options)
```

Writing a Python OJAI Application

For information about writing a Python OJAI application, see the Python sections in the following topics:

[Querying in OJAI Applications](#) on page 3769

Provides an introduction to the basic flow of an OJAI application that queries a HPE Data Fabric Database JSON table

[Examples: Querying JSON Documents](#) on page 3814

Contains code samples of OJAI applications that query HPE Data Fabric Database JSON tables

[Managing JSON Documents](#) on page 3731

Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Data Fabric Database JSON tables

Python OJAI Client Classes and Methods

This topic lists and describes the classes supported by the Python OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
Connection	Provides a logical connection to an OJAI data source: for example, HPE Data Fabric Database JSON.
ConnectionDriver	Provides a connection handler, which enables you to get and check connections
ConnectionManager	Manages connections to HPE Data Fabric Database JSON.
Document	Provides the primary, DOM-based interface for inspecting OJAI documents.
DocumentMutation	Encapsulates a mutation to an existing OJAI document in a store.
DocumentStore	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Data Fabric Database JSON tables.
DocumentStream	Encapsulates the result set of an OJAI query.
QueryResult	Encapsulates the result set of an OJAI query.
Query	Encapsulates an OJAI query.
QueryCondition	Encapsulates a query condition; similar to a SQL where clause.
Value	Encapsulates the value of a field, scalar, or complex type in an OJAI document.
OTime	Encapsulates the OJAI TIME type.
OTimestamp	Encapsulates the OJAI TIMESTAMP type.
ODate	Encapsulates the OJAI DATE type.
OInterval	Encapsulates the OJAI INTERVAL type.

See [Python OJAI Client API](#) for details about each class, including the methods available in each class.

Multiprocessing and Multithreading in Python OJAI Applications

Python supports multiprocessing and multithreading modules that enable you to spawn either multiple processes or multiple threads in a Python program. This section contains examples that show you how to use these modules in your Python OJAI application.

Multiprocessing in Python OJAI Applications

The following code example spawns multiple processes using the Python multiprocessing module. When you use the module, you must create a separate OJAI connection for each process.

The code example is available at [014_multiprocessing_example.py](#).

```

"""Following example works with Python Client"""

import multiprocessing
from mapr.ojai.storage.ConnectionFactory import ConnectionFactory

"""Create a connection, get store, insert_or_replace/update document in
store via multiprocessing"""

# Create a connection string using path:user@password
connection_str = "localhost:5678?auth=basic;user=mapr;password=mapr;" \

```

```

        "ssl=true;" \
        "sslCA=/opt/mapr/conf/ssl_truststore.pem;" \
        "sslTargetNameOverride=node1.mapr.com"

# Create method which will be used for multiprocessing
def sample():
    # Create connection from connection_url
    # Cannot share connection for processes,
    # so need to create connection for each process.
    connection =
    ConnectionFactory().get_connection(connection_str=connection_str)

    # Get a store and assign it as a DocumentStore object
    store = connection.get_or_create_store('/tmp/store_name')

    # Insert 15 documents, represented as Python dictionaries,
    # into DocumentStore
    for i in range(15):
        store.insert_or_replace(doc={'_id': str(i), 'name': 'Greg'})

    # Create DocumentMutation object using the OJAIConnection object
    mutation = connection.new_mutation()

    # Set mutation value
    mutation.set_or_replace(field_path='name', value='T')

    # Update 15 Document in store
    for i in range(15):
        store.update(_id=str(i), mutation=mutation)

# Create simple method for run process from Pool
def run(unused_var):
    pass

# Create data for multiprocessing
proces_count = 7
map_iterable = [1] # simple iterator

# Create Pool object using the function and process_count value
p = multiprocessing.Pool(proces_count, initializer=sample)

# Run processes from the Pool
p.map(run, map_iterable)

```

Multithreading in Python OJAI Applications

You can use either the Python thread or threading module to spawn multiple threads in your Python application. When you use these modules, you can share an OJAI connection across threads.

Thread Module

The following code example uses the thread module. It is available at [015_thread_example.py](#).

```

"""Following example works with
Python Client"""
import thread
import time
from
mapr.ojai.storage.ConnectionFactory
import ConnectionFactory

```

```

"""Create a connection, get store,
insert_or_replace/update document in
store via thread using same
connection"""

# Create method which will be used
for threads
def run_thread(name, conn):
    # Print that thread started with
    threadName
    print('\n Start thread ', name)

    # Get a store and assign it as a
    DocumentStore object
    store =
    conn.get_or_create_store('/tmp/
    store_name')

    # Insert 15 documents,
    represented as Python dictionaries,
    # into DocumentStore
    for index in range(15):

    store.insert_or_replace(doc={'_id':
    str(index), 'name': 'Greg'})

    # Create DocumentMutation object
    using the OJAIConnection object
    mutation = conn.new_mutation()

    # Set mutation value

    mutation.set_or_replace(field_path='na
    me', value='T')

    # Update 15 Document in store
    for index in range(15):
        store.update(_id=str(index),
        mutation=mutation)

    # Print that thread done with
    threadName
    print('\n Done thread ', name)

# Create a connection string using
path:user@password
connection_str = "localhost:5678?
auth=basic;user=mapr;password=mapr;" \
    "ssl=true;" \
    "sslCA=/opt/mapr/conf/
ssl_truststore.pem;" \

"sslTargetNameOverride=node1.mapr.com"

# Create connection from
connection_url
# Can share connection for processes,
# so need to only one connection
instance for all threads

```

```

connection =
ConnectionFactory.get_connection(connection_str)

# Create 10 threads using the same
connection instance
for i in range(10):
    thread_name =
    'Thread-{}'.format(str(i))

thread.start_new_thread(run_thread,
(thread_name, connection,))

# This thread implementation doesn't
return thread object
# so thread status cannot be checked
# Wait 10 seconds
time.sleep(10)

# Close connection
connection.close()

```

Threading Module

The following code example uses the threading module. It is available at [016_threading_example.py](#).

```

"""Following example works with
Python Client"""
import threading
import time

from
mapr.ojai.storage.ConnectionFactory
import ConnectionFactory

"""Create a connection, get store,
insert_or_replace/update document in
store via thread using same
connection"""

# Create a connection string using
path:user@password
connection_str = "localhost:5678?
auth=basic;user=mapr;password=mapr;" \
                "ssl=true;" \
                "sslCA=/opt/mapr/conf/
ssl_truststore.pem;" \

"sslTargetNameOverride=node1.mapr.com"

# Create connection from
connection_url
# Can share connection for processes,
# so need to only one connection
instance for all threads
connection =
ConnectionFactory.get_connection(connection_str)

# Create child for sample threading
implementation

```

```

class MyThread(threading.Thread):
    # Implement __init__() method,
    # which takes thread name and
    # connection object
    def __init__(self, name,
connection):

threading.Thread.__init__(self)
    self.name = name
    self.connection = connection

    # Implement run() method
    def run(self):
        # Print that thread started
        # with threadName
        print('\n Start thread ',
self.name)

        # Get a store and assign it
        # as a DocumentStore object
        store =
connection.get_or_create_store('/tmp/
store_name')

        # Insert 15 documents,
        # represented as Python dictionaries,
        # into DocumentStore
        for index in range(15):

store.insert_or_replace(doc={'_id':
str(index), 'name': 'Greg'})

        # Create DocumentMutation
        # object using the OJAIConnection object
        mutation =
connection.new_mutation()

        # Set mutation value

mutation.set_or_replace(field_path='na
me', value='T')

        # Update 15 Document in store
        # for index in range(15):

store.update(_id=str(index),
mutation=mutation)

        # Print that thread done with
        # threadName
        print('\n Done thread ',
self.name)

# This thread implementation return
# thread object
# so thread status can be checked via
# native methods
# Simple thread waiter for thread
# list:
def waiter(threads):
    for my_thread in threads:

```

```

        # Check that current thread
        is alive
        if my_thread.is_alive():
            time.sleep(1)
            # Wait until current
            thread finished
            waiter(thread)
        # Move to the next thread if
        this is not alive
        elif not my_thread.is_alive():
            pass

# Create list instance for storing
created threads objects
thread_list = []

# Create and run 10 threads
for i in range(10):
    # Create thread instance using
    MyThread and OJAIconnection object
    thread =
    MyThread(name='Thread-{0}'.format(str(
    i)),

    connection=connection)

    # Start current thread
    thread.start()

    # Append thread object into
    thread_list
    thread_list.append(thread)

# Wait until all threads will finished
waiter(thread_list)

# Close connection
connection.close()

```

Setting Query Options in Python OJAI

There are two categories of options you can set in your Python OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a Python OJAI Method Call

Option Name	Description
<code>ojai.mapr.query.include-query-plan</code>	Enables or disables availability of the query plan for retrieval Value: True False Default: False
<code>ojai.mapr.query.result-as-document</code>	Enables or disables returning the query result as an OJAI Document class object versus a Python dictionary Value: True False Default: False; returns query result as a Python dictionary

Option Name	Description
ojai.mapr.query.timeout-milliseconds	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the [DocumentStore.find](#) method.

The following code snippet sets the option to return the query result as a [Document](#) object:

```
options = {'ojai.mapr.query.result-as-document': True}
query_result = store.find(query, options=options)
```

Setting Query Options in Python Using OJAI Query Syntax

[OJAI Query Options](#) on page 3777 describes query options that are available in all OJAI clients. To use these options in Python OJAI, you must construct your query in JSON format and use the `$options` keyword. See [OJAI Query Syntax](#) for details about the syntax, including an example.

Using the C# OJAI Client

Starting with EEP 6.1.0, you can use the C# OJAI client to write HPE Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Data Fabric Database JSON, and add, update, and query documents in a HPE Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Data Fabric Database JSON through the OJAI interface in C#
- An OJAI interface that is tailored to C# developers
- Use of C# types to manipulate HPE Data Fabric Database JSON documents
- Support for C# asynchronous programming and threading mechanism
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the C# OJAI client, you must install the [Data Fabric Data Access Gateway](#) on your HPE Data Fabric cluster. The gateway serves as a proxy for translating requests between the C# client and the HPE Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. See [Administering the Data Access Gateway](#) on page 2235 for information about how to administer the gateway and configure load balancing.

Additional Resources

Examples: <https://github.com/mapr-demos/ojai-examples/tree/master/csharp>

Getting Started with the C# OJAI Client

This section describes the software required to run the C# OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write C# OJAI applications.

The C# OJAI client is available starting in the EEP 6.0.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Visual Studio 2017	https://visualstudio.microsoft.com/vs/
C# OJAI client	<ul style="list-style-type: none">Install the client by using the NuGet Command Line Interface (CLI).Install the MapRDB.Driver using the NuGet Package Manager Console:<div>Install-Package MapRDB.Driver -Version 1.0.0</div>Use the dotnet command line interface:<div>dotnet add package MapRDB.Driver</div>Use the NuGet Package Manager UI. For instructions, follow this link.

You also must have access to the following software:

- MapR cluster 6.1 or later
- [MapR Data Access Gateway](#) 2.0 or later

To run a C# OJAI application, you simply need to install and configure the MapR Data Access Gateway:

- [Installing the Data Access Gateway Service](#) on page 2236
- [Modifying Configuration Settings for the Data Access Gateway Service](#) on page 2236

C# OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway
- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

C# OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix ojai:mapr:thin:v1@ is optional.

<hostname>	Name of the Data Access Gateway host. For information about the host name, see Configuring SSL for OJAI Clients on page 3886.
<port>	Port number (see Ports Used by HPE Data Fabric Software on page 3469) that gRPC clients use to connect to the Data Access Gateway Default: 5678

auth=<scheme_name>	The authentication scheme for the current connection; currently, only basic
user=<username>	The user name for basic authentication
password=<password>	The password for basic authentication
ssl=true false	<p>Whether to establish a secure connection using SSL/TLS</p> <p>An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is <code>true</code>, which is the required setting if connecting to a secure Data Access Gateway. If connecting to a non-secure Data Access Gateway, set it to <code>false</code>.</p> <p>If set to <code>false</code>, the other SSL parameters are ignored.</p> <p>Note that the <code>grpc.service.ssl.enabled</code> property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 2235.</p>
sslCA=<path to PEM file containing CA certificate>	<p>Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3886.</p> <p>Required when the <code>ssl</code> option is set to <code>true</code>.</p>
sslTargetNameOverride=<CA certificate common name>	<p>Fully qualified domain name specified in the SSL server certificate, which is different from the <code><hostname></code> in the connection string.</p> <p>For example, imagine that you are using the following:</p> <ul style="list-style-type: none"> Public network host name is <code>ec2-203-0-113-25.compute-1.amazonaws.com</code>. Internal DNS is <code>node1.mydomain.com</code>. CA signed certificate is issued to <code>node1.mydomain.com</code>. <p>Using these names, you must specify the following connection string:</p> <pre>"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;sslTargetNameOverride=node1.mydomain.com"</pre> <p>Other examples of connection strings are the following:</p> <pre>"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem" "localhost:5678?ssl=false;auth=basic;user=fred;password=george"</pre>

C# OJAI Connection Retry Options

If your OJAI client cannot connect to your MapR cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
retryExponentialMultiplier	Multiplier that determines the wait time for subsequent attempts after the initial 10 ms wait. The previous wait time is multiplied by this parameter.	1000
retryCount	Maximum number of retry attempts	7

To set these retry options, you must pass them in the `ConnectionFactory.CreateConnection` call:

```
var connectionStr = $"localhost:5678?auth=basic;" +
    $"user=mapr;" +
    $"password=mapr;" +
    $"ssl=true;" +
    $"sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
    $"sslTargetNameOverride=node1.mapr.com";
var connection = ConnectionFactory.CreateConnection(connectionStr, 3, 5);
```

Writing a C# OJAI Application

For information about writing a C# OJAI application, see the C# sections in the following topics:

[Querying in OJAI Applications](#) on page 3769

Provides an introduction to the basic flow of an OJAI application that queries a HPE Data Fabric Database JSON table

[Examples: Querying JSON Documents](#) on page 3814

Contains code samples of OJAI applications that query HPE Data Fabric Database JSON tables

[Managing JSON Documents](#) on page 3731

Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Data Fabric Database JSON tables

C# OJAI Client Classes and Methods

This topic lists and describes the classes supported by the C# OJAI client and provides a link to document pages that describe the methods in each class.

Class Name	Description
Value	Encapsulates the value of a field, scalar, or complex in an OJAI document.
OjaiDocument	Provides the primary, DOM-based interface for inspecting OJAI documents
OjaiDocumentStream/QueryResult	Encapsulates the result set of an OJAI query.
OjaiDocumentMutation	Encapsulates a mutation to an existing OJAI document in a store.
Query	Encapsulates an OJAI query.
QueryCondition	Encapsulates a query condition; similar to a SQL where clause.
ConnectionFactory	Provides a logical connection to an OJAI data source: for example, HPE Data Fabric Database JSON.
MapRDBConnection	Provides a connection handler, which enables you to get and check connections.

Class Name	Description
OjaiDocumentStore	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Data Fabric Database JSON tables.
OTime	Encapsulates the OJAI TIME type.
OTimestamp	Encapsulates the OJAI TIMESTAMP type.
ODate	Encapsulates the OJAI DATE type.
OInterval	Encapsulates the OJAI INTERVAL type.

See the [C# OJAI Client API](#) for details about each class, including the methods available in each class.

Setting Query Options in C# OJAI

There are two categories of options you can set in your C# OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a C# OJAI Method Call

Option Name	Description
IncludeQueryPlan	Enables or disables availability of the query plan for retrieval Value: true false Default: false
Timeout	Query timeout in milliseconds Maximum allowed value is 2147483647. Default: None; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.Find` method.

The following code snippet sets the query timeout to 3000 milliseconds:

```
var queryResult = store.Find(query, new QueryOptions() { Timeout = 3000 });
var queryResult = store.Find(query, new QueryOptions(3000));
```

Setting Query Options in C# Using OJAI Query Syntax

[OJAI Query Options](#) on page 3777 describes query options that are available in all OJAI clients. To use these options in C# OJAI, you must construct your query in JSON format and use the `$options` keyword. See [OJAI Query Syntax](#) for details about the syntax, including an example.

Using the Go OJAI Client

Starting with EEP 6.0.0, you can use the Go OJAI client to write HPE Data Fabric Database JSON applications. The client provides you with a lightweight library that supports the OJAI API. You can connect to HPE Data Fabric Database JSON, and add, update, and query documents in a HPE Data Fabric Database JSON table.

The client provides you with the following benefits:

- Easy installation and use
- Access to HPE Data Fabric Database JSON through the OJAI interface in Go

- An OJAI interface that is tailored to Go developers
- Use of Go types to manipulate HPE Data Fabric Database JSON documents
- Support for Go multithreading using Goroutines
- Support for L3/L4 (transport level) and L7 (application level) proxy load balancing

To use the Go OJAI client, you must install the [Data Fabric Data Access Gateway](#) on your HPE Data Fabric cluster. The gateway serves as a proxy for translating requests between the Go client and the HPE Data Fabric cluster. The gateway also performs data processing to keep the client lightweight. To administer the gateway and configure load balancing, see [Administering the Data Access Gateway](#) on page 2235.

Additional Resources

Examples: <https://github.com/mapr-demos/ojai-examples/tree/master/golang>

Source Code: <https://github.com/mapr/maprdb-go-client>

Getting Started with the Go OJAI Client

This section describes the software required to run the Go OJAI client, client/server security, and how to specify your connection string. It also provides links to documentation that shows you how to write Go OJAI applications.

The Go OJAI client is available starting in the EEP 6.0.0 release.

Software Requirements

You must have the following software installed to run the client:

Client Software	Installation Notes
Golang 1.10 (or later)	
Go OJAI client	Install the client using the following command: <pre>go get github.com/mapr/maprdb-go-client</pre>

You also must have access to the following software:

- MapR cluster 6.1 or cluster from later versions of Data Fabric
- [Data Access Gateway](#) 2.0 or later

To run a Go OJAI application, you must install and configure the Data Access Gateway:

- [Installing the Data Access Gateway Service](#) on page 2236
- [Modifying Configuration Settings for the Data Access Gateway Service](#) on page 2236

For some sample code, see https://github.com/magpierre/mapr_go_client_mqtt. `main.go` shows a simple Go client that reads from an MQTT messaging protocol and writes to a Data Fabric JSON database.

Go OJAI Client Security

The client supports username/password authentication. The initial connection (and token renewal) use these credentials. Subsequent communication uses JWT.

When connecting to a secure cluster, the client uses:

- X.509 certificates to authenticate with the Data Access Gateway

- TLS v1.2 to encrypt communication between the client and the Data Access Gateway

Go OJAI Client Connection String

The string you use to connect your OJAI client to the cluster must have the following format:

```
"[ojai:mapr:thin:v1@]<hostname>[:<port>][?<option_name>=<option_value>;...]"
```

The prefix `ojai:mapr:thin:v1@` is optional.

<hostname>	Name of the Data Access Gateway host
<port>	Port number (see Ports Used by HPE Data Fabric Software on page 3469) that gRPC clients use to connect to the Data Access Gateway Default: 5678
auth=<scheme_name>	The authentication scheme for the current connection; currently, only <code>basic</code>
user=<username>	The user name for basic authentication
password=<password>	The password for basic authentication
ssl=true false	Whether to establish a secure connection using SSL/TLS An error is returned if there is a mismatch between your client and Data Access Gateway security settings. The default for this option is <code>true</code> , which is the required setting if connecting to a secure Data Access Gateway. If connecting to a nonsecure Data Access Gateway, set it to <code>false</code> . If set to <code>false</code> , the other SSL parameters are ignored. Note that the <code>grpc.service.ssl.enabled</code> property controls the SSL setting for the Data Access Gateway. For more information, see Administering the Data Access Gateway on page 2235.
sslCA=<path to PEM file containing CA certificate>	Path to a local file containing Certificate Authority (CA) signed certificates in PEM format. For information about the PEM format, see Configuring SSL for OJAI Clients on page 3886. Must be set if the <code>ssl</code> option is <code>true</code> .
sslTargetNameOverride=<CA certificate common name>	Fully qualified domain name specified in the SSL server certificate, which is different from the <code><hostname></code> in the connection string. For example, imagine that you are using the following: <ul style="list-style-type: none"> • Public network host name is <code>ec2-203-0-113-25.compute-1.amazonaws.com</code>. • Internal DNS is <code>node1.mydomain.com</code>. • CA signed certificate is issued to <code>node1.mydomain.com</code>.

Using these names, you must specify the following connection string:

```
"ec2-203-0-113-25.compute-1.amazonaws.com:5678?ssl=true;sslCA=/opt/app/conf/rootca.pem;sslTargetNameOverride=node1.mydomain.com"
```

Other examples of connection strings are the following:

```
"ojai:mapr:thin:v1@localhost:5678?auth=basic;user=fred;password=george;sslCA=/opt/app/conf/rootca.pem"
"localhost:5678?ssl=false;auth=basic;user=fred;password=george"
```

sslValidate=true|false

When `ssl=true`, indicates whether or not the client should validate the server certificate against a list of CA certificates. The default is `true`.

Go OJAI Connection Retry Options

If your OJAI client cannot connect to your Data Fabric cluster, it waits 10 ms. After 10 ms, it makes a second connection attempt. If that fails, it continues the attempts up to a configurable number of retries. The following parameters control the number of retries and the wait time between attempts:

Connection Option Parameter	Description	Default Value
MaxAttempt	Maximum number of retry attempts	9
WaitBetweenSeconds	Maximum wait time between attempts	12 s
CallTimeoutSeconds	Maximum call timeout	60 s

To set these retry options, you must pass them in the `client.MakeConnectionWithRetryOptions` call:

```
connectionString := "localhost:5678?" +
    "auth=basic;" +
    "user=mapr;" +
    "password=mapr;" +
    "ssl=true;" +
    "sslCA=/opt/mapr/conf/ssl_truststore.pem;" +
    "sslTargetNameOverride=node1.cluster.com"
options := &client.ConnectionOptions{MaxAttempt:3,
    WaitBetweenSeconds:10, CallTimeoutSeconds:60}
connection, _ :=
    client.MakeConnectionWithRetryOptions(connectionString, options)
```

Writing a Go OJAI Application

For information about writing a Go OJAI application, see the Go sections in the following topics:

[Querying in OJAI Applications](#) on page 3769

Provides an introduction to the basic flow of an OJAI application that queries a HPE Data Fabric Database JSON table

[Examples: Querying JSON Documents on page 3814](#)

Contains code samples of OJAI applications that query HPE Data Fabric Database JSON tables

[Managing JSON Documents on page 3731](#)

Describes how to perform CRUD (create, query, update, and delete) operations on JSON documents in HPE Data Fabric Database JSON tables

Go OJAI Client Structures and Functions

This topic lists and describes the structures supported by the Go OJAI client and provides a link to document pages that describe the functions in each structure.

Structure Name	Description
Document	Provides the primary, DOM-based interface for inspecting OJAI documents.
QueryResult	Encapsulates the result set of an OJAI query.
DocumentMutation	Encapsulates a mutation to an existing OJAI document in a store.
Query	Encapsulates an OJAI query.
Condition	Encapsulates a query condition; similar to a SQL where clause.
Connection	Provides a logical connection to an OJAI data source: for example, HPE Data Fabric Database JSON.
DocumentStore	Encapsulates a store, typically persistent, of OJAI documents: for example, HPE Data Fabric Database JSON tables.
OTime	Encapsulates the OJAI TIME type.
OTimestamp	Encapsulates the OJAI TIMESTAMP type.
ODate	Encapsulates the OJAI DATE type.

For details about each structure, including the functions available in each structure, see the [Go OJAI Client API](#).

Setting Query Options in Go OJAI

There are two categories of options you can set in your Go OJAI application. This topic describes both and shows you how to set each.

Setting Query Options Using a Go OJAI Function Call

Option Name	Description
<code>IncludeQueryPlan</code>	Enables or disables availability of the query plan for retrieval. Value: <code>true false</code> Default: <code>false</code>
<code>ResultAsDocument</code>	Enables or disables returning the query result as an OJAI Document object list versus a Go map list. Value: <code>True False</code> Default: <code>False</code> : returns query result as a Go map list
<code>Timeout</code>	Query timeout in milliseconds. Maximum allowed value is 2147483647 Default: <code>None</code> ; no timeout

To set any of these query options, you must pass the option as the second parameter in the `DocumentStore.FindQueryWithContext` function.

The following code snippet sets the query timeout to 3000 milliseconds:

```
timeoutCtx, cancel := context.WithTimeout(context.Background(),
time.Duration(3*time.Second))
result, err := suite.store.FindQueryWithContext(query, findOptions,
timeoutCtx)
cancel()
```

Setting Query Options in Go Using OJAI Query Syntax

[OJAI Query Options](#) on page 3777 describes query options that are available in all OJAI clients. To use these options in Go OJAI, you must construct your query in JSON format and use the `$options` keyword. See [OJAI Query Syntax](#) for details about the syntax, including an example.

Configuring SSL for OJAI Clients

Describes certificates and how to configure SSL for OJAI clients, including which PEM file to point to and how to determine which DAG host name to use.

The process of installing Data Fabric with security enabled automatically generates default `ssl_keystore` and `ssl_truststore` files on the first CLDB server used by all clients and servers. Data Access Gateway (DAG) and other cluster services use these certificates to perform authentication and encryption for websites that use the HTTPS protocol.

The certificates are generated in the `/opt/mapr/conf` directory under `ssl_truststore.*` and `ssl_keystore.*`. The `ssl_truststore.*` files contain the client side certificates (signer for the certificate in the `ssl_keystore`). The `ssl_keystore.*` files contain the server side certificates (a single self-signed certificate with a wildcard SubjectDN).

When you configure a client to connect to a cluster, you create a connection string. If the connection is SSL enabled, you must include the path to the certificate of trust. You can either configure the client to use the default certificates or you can point to custom certificates. However, if the certificate on the server side is signed using a real certificate signing authority, you do not need to include an `ssl_truststore` in the connection string because the default `ssl_truststore` will recognize the signed certificate.

For additional information, see [SSL Certificates](#) on page 909.

Using the Default Certificates Generated by Data Fabric

For an application running on a cluster node, provide the path to the PEM file, as shown in the following example:

```
sslCA=/opt/mapr/conf/ssl_truststore.pem
```

For an application that is not running on a cluster node, copy the `ssl_truststore.pem` file from `/opt/mapr/conf/` to a location on the non-cluster node and then specify the path to the `ssl_truststore.pem` file:

```
sslCA=/path/to/certificate/ssl_truststore.pem
```

Using Custom Certificates

If an administrator created custom certificates for the cluster (as described in [SSL Certificates](#) on page 909), the certificates must have an equivalent truststore in PEM format. Create a PEM version of the truststore file and use that PEM file with the clients. For example, `sslCA=/path/to/custom/certificates/ssl_truststore.pem`.

For additional information, see [Importing a Certificate Authority Signed \(CA Signed\) SSL Certificate Into a Cluster](#).

Determining which DAG Host Name to Use

Open the `ssl_truststore.pem` file and locate the certificate with `Subject = C`. The certificate with `Subject = C` also has a CN host name. Use this CN host name.

If you see a wildcard character (*) instead of a file name, you can use any host that is running DAG and suffix it with `.ec2.internal`, as shown:

```
*.ec2.internal
```

Using the HPE Data Fabric Database JSON REST API

Starting in the EEP 5.0 release, you can use a REST API to access HPE Data Fabric Database JSON tables. The REST API allows you to use HTTP calls to perform basic operations on HPE Data Fabric Database JSON tables.

The API supports the following operations:

- Create and delete HPE Data Fabric Database JSON tables
- Insert, update, and delete documents from a table
- Retrieve documents while specifying filter conditions and projections

The REST API has the following characteristics:

- Operations are stateless
- Operations are synchronous
- Request responses are not buffered
- Web connections are secure when connecting to secure MapR clusters
- Supports the following methods of authentication:
 - Basic authentication
 - Token-based authentication using [JSON Web Tokens \(JWT\)](#)
- [Supports user impersonation](#) - All data access calls are run on behalf of the authenticated user
- Returns HTTP error codes and detailed error responses in the response message body

When connecting to a MapR cluster, you must use HTTPS in your requests.

With basic authentication, you pass a username and password in your Web client. With token based authentication, you generate a token and then pass the token in the header of subsequent API requests.

The [MapR Data Access Gateway](#) is the service that supports this web API. You should configure multiple instances of this service across your MapR cluster to distribute request processing. To achieve load balancing, you must install an external load balancer. Using token based authentication and an external load balancer, you can achieve high availability and failover. Because the REST API is stateless, you do not have to regenerate your authentication token when different service instances process your API request. This applies even in the event of failovers and service restart. You must regenerate your token when it expires.

The API does not support the following features:

- HPE Data Fabric Database JSON administrative commands, except the commands noted earlier
- [Read Your Own Writes](#)

To modify properties that the HPE Data Fabric Database JSON REST API uses, see [Application Properties](#).

Related concepts

[Understanding the HPE Data Fabric Data Access Gateway](#) on page 1098

The HPE Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Data Fabric cluster.

[Administering the Data Access Gateway](#) on page 2235

The HPE Data Fabric Data Access Gateway is a service that acts as a proxy and gateway for translating requests between lightweight client applications and the HPE Data Fabric cluster. This section describes considerations when upgrading the service, how to modify configuration settings, and how to administer and manage the service.

Getting Started with the HPE Data Fabric Database JSON REST API

A simple way to invoke the HPE Data Fabric Database JSON REST API is to use cURL commands. This section contains a sequence cURL commands that demonstrate the basic functionality of the API.

NOTE: The HPE Data Fabric Database JSON REST API is available starting in the EEP 5.0 release.

The operations shown are the following:

- Create a HPE Data Fabric Database JSON table
- Insert documents into the table
- Retrieve documents from the table, including retrievals that contain field projections and conditions
- Update individual documents and fields within a document

To learn about the complete API, see the reference material at [Understanding the HPE Data Fabric Database JSON REST API](#) on page 3893.

The examples in this section assume that you installed the Data Fabric Data Access Gateway on the host 10.10.100.42. The examples use HTTPS with the default HTTPS port of 8243. For information about installing the Data Access Gateway, see [Installing the Data Access Gateway Service](#) on page 2236.

NOTE: The examples URL encode the slashes in the table path (%2F) to differentiate them from the slashes in the command API.

Using Basic Authentication

The commands in this section use basic authentication. To use this form of authentication, you must pass the username and password in all commands, using the `-u` option.

1. Create a HPE Data Fabric Database JSON table in the path `/apps/employees`:

```
curl -X PUT \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

2. Insert 3 documents into the table:

```
curl -X POST \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr \
  -H 'Content-Type: application/json' \
  -d '[{"_id": "user001", "first_name": "John", "last_name": "Doe"},
      {"_id": "user002", "first_name": "Jane", "last_name": "Doe"},
      {"_id": "user003", "first_name": "Simon", "last_name": "Davis"}]'
```

3. Retrieve all of the documents:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F' \
  -u root:mapr
```

The command returns the following:

```
{
  "DocumentStream": [
    {
      "_id": "user001",
      "first_name": "John",
      "last_name": "Doe"
    },
    {
      "_id": "user002",
      "first_name": "Jane",
      "last_name": "Doe"
    },
    {
      "_id": "user003",
      "first_name": "Simon",
      "last_name": "Davis"
    }
  ]
}
```

4. Limit the GET request to 2 documents starting at offset 1:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F?
  offset=1&limit=2' \
  -u root:mapr
```

The command returns the following:

```
{
  "DocumentStream": [
    {
      "_id": "user002",
      "first_name": "Jane",
      "last_name": "Doe"
    },
    {
      "_id": "user003",
      "first_name": "Simon",
      "last_name": "Davis"
    }
  ]
}
```

5. Retrieve only the first names in the documents:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
fields=first_name' \
-u root:mapr
```

The command returns the following:

```
{
  "DocumentStream": [
    {
      "first_name": "John"
    },
    {
      "first_name": "Jane"
    },
    {
      "first_name": "Simon"
    }
  ]
}
```

6. Retrieve all documents with a last name of 'Doe':

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}' \
-u root:mapr
```

NOTE: You must pass '-g' in the cURL command due to the nested braces in the condition.

The command returns 2 documents:

```
{
  "DocumentStream": [
    {
      "_id": "user001",
      "first_name": "John",
      "last_name": "Doe"
    },
    {
      "_id": "user002",
      "first_name": "Jane",
      "last_name": "Doe"
    }
  ]
}
```

7. Retrieve the id and first name of documents with a last name of 'Doe':

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}&fields=_id,first_name' \
-u root:mapr
```

NOTE: You must pass '-g' in the cURL command due to the nested braces in the condition.

The command returns the following:

```
{
  "DocumentStream": [
    {
      "_id": "user001",
      "first_name": "John"
    },
    {
      "_id": "user002",
      "first_name": "Jane"
    }
  ]
}
```

8. Run the same command, also retrieving the query plan:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":
{"last_name":"Doe"}}&fields=_id,first_name&getPlan=true' \
-u root:mapr
```

The output includes the query plan:

```
{
  "DocumentStream": [
    {
      "_id": "user001",
      "first_name": "John"
    },
    {
      "_id": "user002",
      "first_name": "Jane"
    }
  ],
  "QueryPlan": [
    [
      {
        "streamName": "DBDocumentStream",
        "parameters": {
          "queryConditionPath": true,
          "projectionPath": [
            "_id",
            "first_name"
          ],
          "primaryTable": "/apps/employees"
        }
      ]
    ]
  ]
}
```

9. Update the first name in one of the documents, specifying the `id` in the command:

```
curl -X POST \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
-H 'Content-Type: application/json' \
-u root:mapr \
-d '{"$set":{"first_name":"Jay"}}'
```

10. Retrieve the updated document, specifying the `id` in the command:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
-u root:mapr
```

The document contains an updated first name:

```
{
  "_id": "user001",
  "first_name": "Jay",
  "last_name": "Doe"
}
```

11. Replace the same document, but this time with a user who has only a first name:

```
curl -X PUT \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
-H 'Content-Type: application/json' \
-u root:mapr \
-d '{"_id":"user001","first_name":"Jonathan"}'
```

12. Retrieve the new document by passing the `id` in the request:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
-u root:mapr
```

The document contains only a first name:

```
{
  "_id": "user001",
  "first_name": "Jonathan"
}
```

Using Token-Based Authentication

To use token-based authentication, you first create a token, authenticating with a username and password. You then pass the generated token in all subsequent commands.

1. Generate a token using the following command:

```
curl -X POST \
  'https://10.10.100.42:8243/auth/v2/token' \
  -u root:mapr
```

The command returns the following token:

```
{
  "token":
  "eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJyb290IiwiaXVkJjoid2ViIiwiaXhwIjoxNTIwMjY5MTQwLCJpYXQiOiJlMjAyNjc5NDNB9.NT8L2deiA6v55bfbU_opiG1XXGPP0IwfSex3jW5A1ZsoI1ar09it7-XwNtRqfL_I29IHlyfmuHcT5eSIpwq6ng"
}
```

2. Pass the token in your cURL command, as shown in the following GET:

```
curl -X GET \
  https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees \
  -H 'Authorization:
  Bearer
  eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJyb290IiwiaXVkJjoid2ViIiwiaXhwIjoxNTIwMjY5MTQwLCJpYXQiOiJlMjAyNjc5NDNB9.NT8L2deiA6v55bfbU_opiG1XXGPP0IwfSex3jW5A1ZsoI1ar09it7-XwNtRqfL_I29IHlyfmuHcT5eSIpwq6ng'
```

Understanding the HPE Data Fabric Database JSON REST API

The section describes the details of the HPE Data Fabric Database JSON REST API.

The following table summarizes the commands the API supports. Click on the command for details about the command parameters and examples.

Category	REST API Command	Description
Authentication	POST /auth/v2/token on page 3894	Creates an authentication token
Table Operations	PUT /api/v2/table/{path} on page 3894	Creates a HPE Data Fabric Database JSON table
	DELETE /api/v2/table/{path} on page 3894	Drops a HPE Data Fabric Database JSON table
Table Document Operations	POST /api/v2/table/{path} on page 3895	Adds one or more documents to a HPE Data Fabric Database JSON table
	PUT /api/v2/table/{path}/document/{id} on page 3896	Updates a document by id in a HPE Data Fabric Database JSON table
	POST /api/v2/table/{path}/document/{id} on page 3897	Updates a partial document by id in a HPE Data Fabric Database JSON table using mutations
	DELETE /api/v2/table/{path}/document/{id} on page 3898	Deletes a single document by id in a HPE Data Fabric Database JSON table
	GET /api/v2/table/{path} on page 3898	Retrieves one or more documents from a HPE Data Fabric Database JSON table
	GET /api/v2/table/{path}/document/{id} on page 3901	Retrieves a single document by id from a HPE Data Fabric Database JSON table

POST /auth/v2/token

Authenticates a user. If successful, creates an authentication token that you use in subsequent API requests. By default, the token expires in 30 minutes. After a token expires, you must rerun this command to generate a new token.

Request Example

The following creates an authentication token for user root:

```
curl -X POST \
'https://10.10.100.42:8243/auth/v2/token' \
-u root:mapr
```

Response Example

```
200 OK

{
  "token":
  "eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJtYXByIiwiaXVkiJoid2ViIiwiaXhwIjoxNTE2NzQ2MDc4Lk4pYXQ1OjE1MTY3NDQyNzh9.6YXWX72UP9_U9DPmT8c-_DQRDwY_TL0DEdsBaBqoaLf8iK0qHNctyBTbF05ktUJMTubV0j6D7pF0EyEuV8lhjA"
```

For an example that shows how to use the token returned by this API call in a subsequent GET command, see [Using Token-Based Authentication](#) on page 3892.

PUT /api/v2/table/{path}

Creates a HPE Data Fabric Database JSON table

Parameters

Name	Description
path string (path)	Required: Path to the new HPE Data Fabric Database JSON table

Request Example

The following creates a table with the path /apps/employees:

```
curl -X PUT \
'https://10.10.100.42:8243/api/v2/table/%2Fapps/employees' \
-u root:mapr
```

Response Example

```
201 Created
```

DELETE /api/v2/table/{path}

Drops a HPE Data Fabric Database JSON table

Parameters

Name	Description
path string (path)	Required: Path to the HPE Data Fabric Database JSON table

Request Example

The following drops a table with the path /apps/employees:

```
curl -X DELETE \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u <username>:<password>
```

Response Example

```
200 OK
```

POST /api/v2/table/{path}

Adds or replaces one or more documents in a HPE Data Fabric Database JSON table

Parameters

Name	Description
path string (path)	Required: Path to the HPE Data Fabric Database JSON table
fieldAsKey string (query)	The name of the field that serves as the key in the JSON document
mode string (query)	<p>Defines the behavior of the operation.</p> <p>The following are the possible values:</p> <ul style="list-style-type: none"> <code>insertOrReplace</code> - Inserts new document if specified document ID does not exist; otherwise, replaces existing document specified by the ID. <code>insert</code> - Inserts new document; if the specified document ID already exists, returns an error. <code>replace</code> - Replaces document with specified ID; returns an error if document does not exist. <p>Default: <code>insertOrReplace</code></p>
body (body)	The body of the documents to add or replace

Request Example

The following inserts 3 documents into /apps/employees:

```
curl -X POST \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr \
  -H 'Content-Type: application/json' \
  -d '[{"_id":"user001","first_name":"John","last_name":"Doe"},
{"_id":"user002","first_name":"Jane","last_name":"Doe"},
{"_id":"user003","first_name":"Simon","last_name":"Davis"}]'
```

Response Example

```
200 OK
```

PUT /api/v2/table/{path}/document/{id}
Updates a single document by id in a HPE Data Fabric Database JSON table

Parameters

Name	Description
path string (path)	Required: Path to the HPE Data Fabric Database JSON table
id string (path)	Required: Id of the document to update. If the document with the specified id does not exist, the mode parameter determines the behavior.
condition string (query)	Query condition (in JSON format) used to perform OJAI DocumentStore.checkAndReplace evaluation. See OJAI Query Condition Syntax on page 3796 for a description of the syntax.
mode string (query)	Defines the behavior of the operation. The following are the possible values: <ul style="list-style-type: none">insertOrReplace - Inserts new document if specified document ID does not exist; otherwise, replaces existing document specified by the ID.insert - Inserts new document; if the specified document ID already exists, returns an error.replace - Replaces document with specified ID if it exists Default: insertOrReplace
body (body)	Required: The body of the new document

Request Example

The following replaces the document with id user001 in /apps/employees with an employee who has only a first name:

```
curl -X PUT \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
-H 'Content-Type: application/json' \
-u root:mapr \
-d '{"_id":"user001","first_name":"Jonathan"}'
```

Response Example

```
200 OK
```

POST /api/v2/table/{path}/document/{id}

Updates a partial document by id in a HPE Data Fabric Database JSON table using mutations

Parameters

Name	Description
path string (path)	Required: Path to the HPE Data Fabric Database JSON table
id string (path)	Required: Id of the document to update. If the document does not exist, inserts a new document.
condition string (query)	Query condition (in JSON format) used to perform OJAI DocumentStore.checkAndUpdate evaluation. See OJAI Query Condition Syntax on page 3796 for a description of the syntax.
body (body)	Required: The mutation specifying updates to the document. See Using OJAI Mutation Syntax on page 3751 for a description of the syntax.

Request Example

The following updates the first_name field the document in /apps/employees with id user001, replacing the field with the value Jay:

```
curl -X POST \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
user001' \
-H 'Content-Type: application/json' \
-u root:mapr \
-d '{"$set":{"first_name":"Jay"}}'
```

Response Example

```
200 OK
```

DELETE /api/v2/table/{path}/document/{id}

Deletes a single document by id in a HPE Data Fabric Database JSON table

Parameters

Name	Description
path string (path)	Required: Path to the HPE Data Fabric Database JSON table
id string (path)	Required: Id of the document to delete
condition string (query)	Query condition (in JSON format) used to perform OJAI DocumentStore.checkAndDelete evaluation. See OJAI Query Condition Syntax on page 3796 for a description of the syntax.

Request Example

The following deletes the document with id user003 in /apps/employees:

```
curl -X DELETE \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/
  user003' \
  -u <username>:<password>
```

Response Example

```
200 OK
```

GET /api/v2/table/{path}

Retrieves one or more documents from a HPE Data Fabric Database JSON table

Parameters

Name	Description
path string (path)	Required: Path to the HPE Data Fabric Database JSON table
condition string (query)	Query condition (in JSON format) to evaluate on documents retrieved. See OJAI Query Condition Syntax on page 3796 for a description of the syntax.
fields string (query)	The fields from the document to retrieve. See JSON Document Field Paths on page 722 for details about how to specify field paths.

Name	Description
fromId string (query)	Starting id of the range of documents to retrieve (inclusive)
told string (query)	Ending id of the range of documents to retrieve (exclusive)
getPlan string (query)	If set to true, returns the query plan used to retrieve the documents Value: True False Default: False
limit integer (query)	The maximum number of documents to retrieve
offset integer (query)	The number of documents to skip past before returning results
orderBy string (query)	The fields on which to sort the result. Specify the fields in a comma separated list, in the format <field name>:<sort order> where <sort order> is either asc or desc. <sort order> is optional and defaults to asc.
query string (query)	Query string with predefined keywords that define the behavior of the query. See Query with --query on page 7408 for syntax details.
withTags string (query)	Enables or disables output with extended type tags Value: True False Default: True

Request Examples

1. The following retrieves all documents from /apps/employees:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees' \
  -u root:mapr
```

2. The following specifies an offset and limit in the GET request:

```
curl -X GET \
  'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees%2F?offset=1&limit=2' \
  -u root:mapr
```

3. The following retrieves only the first names in the documents:

```
curl -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
fields=first_name' \
-u root:mapr
```

4. The following retrieves all documents with a last name of 'Doe':

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}' \
-u root:mapr
```

NOTE: You must pass '-g' in the cURL command due to the nested braces in the condition.

5. The following retrieves the id and first name of documents with a last name of 'Doe':

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}&fields=_id,first_name' \
-u root:mapr
```

6. The following runs the same command and includes a request for the query plan:

```
curl -g -X GET \
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees?
condition={"$eq":{"last_name":"Doe"}}&fields=_id,first_name&getPlan=true' \
-u root:mapr
```

Response Examples

200 OK

```
{
  "DocumentStream": [
    {
      "_id": "user001",
      "first_name": "John",
      "last_name": "Doe"
    },
    {
      "_id": "user002",
      "first_name": "Jane",
      "last_name": "Doe"
    },
    {
      "_id": "user003",
      "first_name": "Simon",
      "last_name": "Davis"
    }
  ]
}
```

If you have configured the MapR Data Access Gateway to limit the number of documents in retrieval requests, and your result set exceeds the limit, the API response includes a warning. In the following example, the limit is set to 2:

```
{
  "DocumentStream": [
    {
      "_id": "user001",
      "first_name": "John",
      "last_name": "Doe"
    },
    {
      "_id": "user002",
      "first_name": "Jane",
      "last_name": "Doe"
    }
  ],
  "WARNING": "result truncated due to limit set to 2."
}
```

The following shows an example of output that includes a query plan. It corresponds to the output from example #6 in the previous section:

```
{
  "DocumentStream": [
    {
      "_id": "user001",
      "first_name": "John"
    },
    {
      "_id": "user002",
      "first_name": "Jane"
    }
  ],
  "QueryPlan": [
    [
      {
        "streamName": "DBDocumentStream",
        "parameters": {
          "queryConditionPath": true,
          "projectionPath": [
            "_id",
            "first_name"
          ],
          "primaryTable": "/apps/employees"
        }
      ]
    ]
  ]
}
```

GET /api/v2/table/{path}/document/{id}

Retrieves a single document by id from a HPE Data Fabric Database JSON table

Parameters

Name	Description
path string (path)	Required: Path to the HPE Data Fabric Database JSON table
id string (path)	Required: Id of the document to retrieve
condition string (query)	Query condition (in JSON format) to evaluate on document retrieved. See OJAI Query Condition Syntax on page 3796 for a description of the syntax.
fields string (query)	The fields from the document to retrieve. See JSON Document Field Paths on page 722 for details about how to specify field paths.
withTags string (query)	Enables or disables output with extended type tags Value: True False Default: True

Request Example

The following retrieves the document with id user003 from /apps/employees:

```
curl -X GET \  
'https://10.10.100.42:8243/api/v2/table/%2Fapps%2Femployees/document/  
user003' \  
-u <username>:<password>
```

Response Example

```
200 OK  
  
{  
  "_id": "user003",  
  "first_name": "Simon",  
  "last_name": "Davis"  
}
```

HPE Data Fabric Database JSON MapReduce API

This API library extends the Apache Hadoop MapReduce framework, so that you can write your own MapReduce applications to write data from one JSON table to another.

Prerequisites to using this API Library

- Ensure that you have a firm grasp of MapReduce concepts and experience writing MapReduce applications.
- Before running a MapReduce application that uses this API, ensure that the destination JSON table or tables already exist and that any column families other than the default are already created on the destination tables.

Classes

The following table summarizes the information that is in the [HPE Data Fabric Database JSON MapReduce API](#), which you can refer to for complete details of the classes.

Category	Class	Description
Utility	MapRDBMapReduceUtil	Simplifies the use of the API for most use cases.
Input formatters	TableInputFormat	Describes how to read documents from HPE Data Fabric Database JSON tables.
Record reader	TableRecordReader	Reads documents (records) from HPE Data Fabric Database JSON tables.
	TableRecordReaderImpl	Iterates over HPE Data Fabric Database JSON table data. Returns key-value pair as ByteBufWritableComparable and Document respectively.
Record writers	BulkLoadRecordWriter	Bulk loads documents into HPE Data Fabric Database JSON tables.
	TableMutationRecordWriter	Modifies documents that are in HPE Data Fabric Database JSON tables.
	TableRecordWriter	Writes documents to HPE Data Fabric Database JSON tables.
Output formatters	BulkLoadOutputFormat	Describes how to bulk load documents into HPE Data Fabric Database JSON tables.
	TableOutputFormat	Describes how to write documents to HPE Data Fabric Database JSON tables.
	TableMutationOutputFormat	Writes DocumentMutation from the MapReduce phase to JSON tables . The key is of type Value and the value is a DocumentMutation.
Serializers	DocumentSerialization	Defines the serializer and deserializer for passing data from Document objects between map and reduce phases.
	DBDocumentSerialization	Converts a JSON document from HPE Data Fabric Database format to binary SequenceFile format.
	ValueSerialization	Serializes a JSON key and passes it between MapReduce phases.
Partitioner	TablePartitioner	Specifies how to partition data from the source JSON table.
	TotalOrderPartitioner<K,V>	Globally sorts data according to row key and then partitions the sorted data. This class is useful when the destination table has been pre-split into two or more tablets.

Using MapRDBMapReduceUtil to Set Default Values in Configurations and Jobs

The centerpiece of this API is the `MapRDBMapReduceUtil` class, which you can use in the `createSubmittableJob()` method of your applications to perform these actions:

- Set default values in the configuration for a MapReduce application and set the input and output format classes.
- Set default types for output keys and values.
- Configure a `TotalOrderPartitioner` and return the number of reduce tasks to use for a job.

To set default values in the configuration for a MapReduce application and set the input and output format classes, use the following methods:

```
configureTableInputFormat(org.apache.hadoop.mapreduce.Job job, String
srcTable)
```

The `configureTableInputFormat` method performs the following actions:

- Set the serialization class for `Document` and `Value` objects. These interfaces are part of the OJAI (Open JSON Application Interface) API.
- Set the field `INPUT_TABLE` in `TableInputFormat` to the path and name of the source table, and pass this value to the configuration for the MapReduce application.
- Set the input format class for the job to `TableInputFormat`.

```
configureTableOutputFormat(org.apache.hadoop.mapreduce.Job job, String
destTable)
```

The `configureTableOutputFormat` method performs the following actions:

- Set the field `OUTPUT_TABLE` in `TableOutputFormat` to the path and name of the destination table, and pass this value to the configuration for the MapReduce applications.
- Set the output format class for the job to `TableOutputFormat`.

If you want to set values for other fields in `TableInputFormat` or `TableOutputFormat`, or write your own logic for them, you can pass field values to configurations and specify these classes for jobs as you would in common MapReduce applications.

To set default types for output keys and values, use the following methods:

```
setMapOutputKeyValueClass(org.apache.hadoop.mapreduce.Job job)
setOutputKeyValueClass(org.apache.hadoop.mapreduce.Job job)
```

NOTE: You can also set types for output keys and values from the map phase, if those types will differ from the final output types.

To configure `TotalOrderPartitioner` and return the number of reduce tasks to use for a job, you can use a code line similar to the following in your application's method for creating a job:

```
int numReduceTasks =
MapRDBMapReduceUtil.setPartitioner(org.apache.hadoop.mapreduce.Job job,
String destPath);
```

The `setPartitioner()` method finds out whether a table has been pre-split into two or more tablets, counts the number of tablets, writes the number to a partitioner file, and sends that file to an instance of

TotalOrderPartitioner. This line also returns the number of tablets to numReduceTasks. Your code can then use that variable to set the number of reducers, like the following:

```
job.setNumReduceTasks(numReduceTasks);
```

NOTE: The sample application gives an example of how to use MapRDBMapReduceUtil.

Mutating Rows in Destination Tables

Use the TableMutationRecordWriter class when you need to mutate rows.

For example, suppose that you are tracking the number of users who are performing various actions on your retail website. To do this, at intervals you run your MapReduce application and save the results in JSON documents in HPE Data Fabric Database. Suppose that you count the number of users who went through the order process but abandoned their orders. After every run of the application, you want to update an JSON document by adding the current count to the total count and by updating a field that tracks the date and time that the MapReduce application was last run.

You could do that by setting values in a DocumentMutation object (see the [OJAI \(Open JSON Application Interface\) Javadoc](#)). You would then serialize that and write it to the table with TableMutationRecordWriter.

Compiling and Running Applications

You can compile applications that use the HPE Data Fabric Database Java API by using the required JAR file from the MapR installation. Run applications with the mapr command.

To compile an application, use the following command:

```
javac -cp 'mapr classpath' <Application jars>
```

To launch an application, use the following command

```
mapr <Main class jar> <commandline arguments>
```

NOTE: If you want to add JAR files to the classpath that the mapr command uses, add them with the environment variable MAPR_CLASSPATH. For example:

```
export MAPR_CLASSPATH=/home/apps/awesome-1.0.jar
mapr com.company.MyAwesomeApp
```

**IMPORTANT:** Turn off speculative execution

Speculative execution of MapReduce tasks is on by default. For custom applications that load HPE Data Fabric Database tables, it is recommended to turn speculative execution off. When it is on, the tasks that import data might run multiple times. Multiple tasks for an incremental bulkload could insert one or more versions of a record into a table. Multiple tasks for a full bulkload could cause loss of data if the source data continues to be updated during the load.

If your custom MapReduce application uses `MapRDBMapReduceUtil.configureTableOutputFormat()`, you do not have to turn off speculative execution manually. This method turns it off automatically.

Turn off speculative execution by using either of these methods:

- Set the following MapReduce version 2 parameter to false: `mapreduce.map.speculative`
- Include the following line in the method in your application that sets parameters for jobs:

```
job.setSpeculativeExecution(false);
```

HPE Data Fabric Database JSON MapReduce: Sample App

This sample application reads records (JSON documents) from a JSON table and inserts new documents into another JSON table.

After reading records from a JSON table, the application aggregates data within those records, creates new JSON documents that contain the aggregated records, and then inserts the new documents into another JSON table. Each record contains the name of an author and the name of a book that the author has written.

The JSON documents have this structure:

```
{
  "_id" : <string or binary>,
  "authorid": "<string>",
  "name": "<string>",
  "book": {
    "id": <int>,
    "title": "<string>"
  }
}
```

The structure of each aggregate record will look like this:

```
{
  "_id" : <string or binary>,
  "authorid": "<string>",
  "book": {
    [
      "title": "<string>",
      "title": "<string>",
      ...
    ]
  }
}
```

Prerequisites

- Ensure that your user ID has the `-readAce` and `-writeAce` privileges on the volumes where you plan to create the source and destination tables.

- Create the source JSON table. You can create the source table and populate it with sample records by running [sample_dataset.txt](#) from the `mapr dbshell` utility.

```
$ mapr dbshell < sample_dataset.txt
```

- Create the destination JSON table. A simple way to create this table is to use the `create` command in the [HPE Data Fabric Database Shell \(JSON Tables\)](#) on page 7401 utility.

Compiling and Running

To compile an application, use the following command:

```
javac -cp <classpath> <java source file(s)>
```

To launch an application, use the following command:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class>  
<command line arguments>
```

To run the application, supply the paths and names of the source and destination tables as arguments:

```
CombineBookList <source_table> <destination_table>
```

Code Walkthrough

```
private static Job createSubmittableJob(Configuration conf, String[]  
otherArgs)  
    throws IOException {  
  
    srcTable = otherArgs[0];  
    destTable = otherArgs[1];  
  
    Job job = new Job(conf, NAME + "_" + destTable);  
    job.setJarByClass(CombineBookList.class);  
    MapRDBMapReduceUtil.configureTableInputFormat(job, srcTable);  
    job.setMapperClass(CombineBookListMapper.class);  
    MapRDBMapReduceUtil.setMapOutputKeyValueClass(job);  
    MapRDBMapReduceUtil.configureTableOutputFormat(job, destTable);  
    job.setReducerClass(CombineBookListReducer.class);  
    MapRDBMapReduceUtil.setOutputKeyValueClass(job);  
    job.setNumReduceTasks(1);  
    return job;  
}
```

The `createSubmittableJob()` method uses methods that are in the [MapRDBMapReduceUtil](#) class to perform the following tasks:

Set the input format to the default table input format

You can call the `configureTableInputFormat()` method, passing in the job and also passing in the path and name of the source table:

```
MapRDBMapReduceUtil.configureTableInputFormat(job, srcTable);
```

The default behavior is to do the following:

- Set the serialization class for [Document](#) and [Value](#) objects. These interfaces are part of the OJAI (Open JSON Application Interface) API.
- Set the field INPUT_TABLE in [TableInputFormat](#) to the path and name of the source table, and pass this value to the configuration for the MapReduce application.
- Set the input format class for the job to [TableInputFormat](#).

If you want to customize [TableInputFormat](#), you can call it as you would normally set the input format for a job:

```
job.setInputFormatClass(TableInputFormat.class);
```

Set the type for keys and values that are output from the mapper

You can call the `setMapOutputKeyValueClass()` method to use the default type for keys and values:

```
MapRDBMapReduceUtil.setMapOutputKeyValueClass(job);
```

If you want to customize the output keys and values, you can call `Job.setMapOutputKeyClass()` and `Job.setMapOutputValueClass()` as you would normally for MapReduce applications.

Set the output format to the default table output format

You can call the `configureTableOutputFormat()` method, passing in the job and also passing in the path and name of the destination table, which must already exist at runtime:

```
MapRDBMapReduceUtil.configureTableOutputFormat(job, destTable);
```

The default behavior is to do the following:

- Set the field OUTPUT_TABLE in [TableOutputFormat](#) to the path and name of the destination table, and pass this value to the configuration for the MapReduce applications.
- Set the output format class for the job to [TableOutputFormat](#).

If you want to customize [TableOutputFormat](#), you can call it as you would normally set the output format for a job:

```
job.setOutputFormatClass(TableOutputFormat.class);
```

You also have the option of using the [BulkLoadOutputFormat](#) class for bulk loading.

Set the type of the keys and values that are output from the reducer

You can call the `setOutputKeyValueClass()` method to use the default type for keys and values:

```
MapRDBMapReduceUtil.setOutputKeyValueClass(job);
```

If you want to customize the output keys and values, you can call `Job.setOutputKeyClass()` and `Job.setOutputValueClass()` as you would normally for MapReduce applications.

The `map()` method in the mapper class `CombineBookListMapper` takes the value of the `_id` field in a document as a key and the JSON document with that `_id` field value as a `Document`. The mapper does nothing with the `Value` object. For each record, the mapper writes the value of the `authorid` field and the full JSON document itself to the context.

```
public static class CombineBookListMapper extends Mapper<Value, Document,
Value, Document> {
    @Override
    public void map(Value key, Document record, Context context) throws
IOException, InterruptedException {
        context.write(record.getValue("authorid"), record);
    }
}
```

Both the `Value` and `Document` interfaces are part of the OJAI (Open JSON Application Interface) API. The javadoc for the OJAI API is [here](#).

The `reduce()` method in the reducer class `CombineBookListReducer` takes the map output key, which is the value of the `authorid` field, and the map output value, which is an iterator of `Document` objects that each contain a full record. For each author ID, the reducer creates a document. For each document in the iterator, the reducer extracts the value of the `book` field and adds that value to the list books within a new JSON document.

```
public static class CombineBookListReducer extends Reducer<Value,
Document, Value, Document> {

    @Override
    public void reduce(Value key, Iterable<Document> values,
        Context context) throws IOException, InterruptedException {
        Document d = MapRDB.newDocument();
        List<Document> books = new ArrayList<Document>();

        for (Document b : values) {
            books.add((Document)b.getValue("book"));
        }

        d.setId(key);
        d.set("books", books);
        context.write(key, d);
    }
}
```

The [MapRDB](#) class is part of the HPE Data Fabric Database JSON API, not the HPE Data Fabric Database JSON MapReduce API.

Apache Kafka Wire Protocol Service

HPE Data Fabric Streams supports Apache Kafka Wire Protocol Service. Apache Kafka Wire Protocol Service is a TCP/IP service that emulates a Kafka cluster backed by HPE Data Fabric Streams. The service makes it possible for Apache Kafka clients written in any programming language to access topics in HPE Data Fabric Streams.

Before Apache Kafka Wire Protocol Service was introduced, you had to use a modified version of the open-source libraries (`kafka-clients.jar` and `librdkafka.so`) for user applications to connect and publish/subscribe messages to topics in HPE Data Fabric Streams. With Apache Kafka Wire Protocol Service, you can simply use the Apache Kafka client libraries.

Apache Kafka Wire Protocol Service provides the following benefits:

- User applications can connect, publish, and subscribe to HPE Data Fabric Streams topics using standard Apache Kafka client libraries. Starting with data access gateway 6.0, only topics created through Apache Kafka Wire Protocol Service are supported.
- User applications developed using Apache Kafka clients do not require any modification to work with this new system, including recompilation, reconfiguration, or dependency management.
- Supports available Apache Kafka clients in multiple programming languages, both from the Apache Software Foundation and the community.

For more information, see [Getting Started with Apache Kafka Wire Protocol Service](#) on page 3912.

Architecture

The Apache Kafka Wire Protocol Service works within DAG (data access gateway) to act as a Kafka Broker (server in an Apache Kafka cluster). For all application purposes, the HPE Data Fabric cluster (with DAG and Apache Kafka Wire Protocol Service) runs like an Apache Kafka cluster.

The following image shows the communication paths between Apache Kafka clients and HPE Data Fabric with DAG and Apache Kafka Wire Protocol Service acting as brokers:

Monitoring

DAG is not a Kafka Broker; therefore, Broker metrics are not available. However, you can monitor Data Fabric core services, as described in [Using HPE Data Fabric Monitoring \(Spyglass Initiative\)](#) on page 1959.

Limitations

The following list describes unsupported functionality in the initial release of Apache Kafka Wire Protocol Service:

- Quotas
- Transactions
- Idempotent Producer
- Kafka ACL-based security
- Topic-level security using ACEs.
- Group ACEs for Consumer Groups
- Delegation tokens
- Log directories

Getting Started with Apache Kafka Wire Protocol Service

Describes the steps required to install, configure, and use Apache Kafka Wire Protocol Service.

The following sections describe the prerequisites and steps required to use Apache Kafka Wire Protocol Service.

Prerequisites

Apache Kafka Wire Protocol Service has the following component version requirements:

- HPE Data Fabric 7.3.0 or later

WARNING:

Although, Apache Kafka Wire Protocol Service is available in Data Fabric versions 7.1 and 7.2, it is not forward compatible. To ensure continued support and compatibility for this service on these versions, upgrade to Data Fabric version 7.3 or later.

- Data Access Gateway (DAG)

To determine the DAG versions for supported combinations of core and EEPs, see [Data Access Gateway Support Matrix](#) on page 7762. For information about EEP and core version support, see [Ecosystem Pack Support and Lifecycle Status](#) on page 7664.

- Apache Kafka clients 2.6.x

1 - Install Data Access Gateway

Apache Kafka Wire Protocol Service is included with the Data Access Gateway (DAG) package (mapr-data-access-gateway) and is installed when you install DAG.

You can install DAG on multiple Data Fabric [data nodes](#) alongside the mfs (file server) service through the Data Fabric Installer or manually using package managers. For more information about installing DAG, see [Installing Data Access Gateway](#) on page 316 and [Data Access Gateway Support Matrix](#) on page 7762.

High Availability

Apache Kafka Wire Protocol Service runs on all Data Fabric nodes that run DAG.

Port

The default DAG port for Apache Kafka Wire Protocol Service is 9092; however, you can change the port as described in [Configuring Apache Kafka Wire Protocol Service](#) on page 3916.

2 - Configure Apache Kafka Wire Protocol Service

Set cluster and node-specific settings, as described in [Configuring Apache Kafka Wire Protocol Service](#) on page 3916.

3 - Administer Kafka Topic

Use maprccli commands to administer Kafka topics as described in [kafkatopic](#) on page 2738.

4 - Secure Apache Kafka Wire Protocol Service

See [Securing Apache Kafka Wire Protocol Service](#) on page 3917.

5 - Use Apache Kafka Client Libraries to Connect to HPE Data Fabric Streams

For a list of available clients, see <https://wiki.apache.org/confluence/display/KAFKA/Clients>.

6 - (Optional) - View Sample Applications

See [Sample Kafka Python Producer and Consumer](#) on page 3913.

Sample Kafka Python Producer and Consumer

This topic provides kafka-python examples with SASL and SSL client configurations for Apache Kafka Wire Protocol Service.

NOTE: The Apache Kafka Wire Protocol Service provided by Data Fabric works with kafka-python versions 2.0.x, 2.1.0, 2.1.1, 2.1.2.

1. If you have not done so already, install kafka-python:

```
pip3 install kafka-python
$pip3 install kafka-python
$pip3 list | grep kafka-python
```

2. Save the [Sample Kafka Python Producer and Consumer](#) on page 3913 code in a file with the following name:

- SASL: saslPlaintextKafkaPythonClient.py
- SSL: sslPlaintextKafkaPythonClient.py

3. Run the sample code with the following command:

NOTE: When running the SASL sample code, you must fill in the username and password. When running the SSL sample code, you must fill the ssl_password from the file /opt/mapr/conf/store-passwords.txt.

SASL

```
python3
saslPlaintextKafkaPythonClient.py
<broker> <topicName>
```

For example:

```
python3
saslPlaintextKafkaPythonClient.py
localhost:9092
topicTestKafkaPythonClient_SASL
```

SSL

```
python3
sslPlaintextKafkaPythonClient.py
<broker> <topicName>
```

For example:

```
python3
sslPlaintextKafkaPythonClient.py
localhost:9092
topicTestKafkaPythonClient_SSL
```

Sample Kafka Python Producer and Consumer

SASL

```
from kafka import KafkaProducer
from kafka import KafkaConsumer
```

```

import sys
import time

#Specify 'broker' and 'topic'
arguments. Example: 'python3
saslPlaintestKafkaPythonClient.py
localhost:9092
topicTestKafkaPythonClient_SASL'
server = sys.argv[1]
print("BROKER: " + server)
topic = sys.argv[2]
print("TOPIC: " + topic)

#PRODUCER
print("\n**Starting Producer**")
producer=KafkaProducer(bootstrap_servers=[server],

security_protocol='SASL_PLAINTEXT',

sasl_mechanism='PLAIN',

sasl_plain_username='<username>',

sasl_plain_password='<user-password>')

numMsgProduced = 0
for _ in range(100):
    producer.send(topic, b'msg')
    numMsgProduced += 1
producer.flush()
print("Messages produced: " +
str(numMsgProduced))
time.sleep(2)

# CONSUMER
print("\n**Starting Consumer**")
consumer =
KafkaConsumer(bootstrap_servers=[server],

auto_offset_reset='earliest',

security_protocol='SASL_PLAINTEXT',

sasl_mechanism='PLAIN',

sasl_plain_username='<username>',

sasl_plain_password='<user-password>')

consumer.subscribe(topics=[topic])
numMsgConsumed = 0
for _ in range(10):
    records =
consumer.poll(timeout_ms=500)
    for topic_data, consumer_records
in records.items():
        for consumer_record in
consumer_records:
            # print("Received message:
" +

```

SSL

```

str(consumer_record.value.decode('utf-8')))
        numMsgConsumed += 1
print("Messages consumed: " +
      str(numMsgConsumed))

```

```

from kafka import KafkaProducer
from kafka import KafkaConsumer
import sys
import time

#Specify 'broker' and 'topic'
arguments. Example 'python3
sslPlaintestKafkaPythonClientJSK.py
localhost:9092
topicTestKafkaPythonClient_SSL'
server = sys.argv[1]
print("BROKER: " + server)
topic = sys.argv[2]
print("TOPIC: " + topic)

#PRODUCER
print("\n**Starting Producer**")
producer=KafkaProducer(bootstrap_servers=[server],

security_protocol='SSL',

ssl_check_hostname=False,

ssl_password='<>', #from /opt/mapr/
conf/store-passwords.txt
ssl.server.keystore.password

ssl_cafile='/opt/mapr/conf/
ssl_truststore.pem',

ssl_certfile='/opt/mapr/conf/
ssl_keystore-signed.pem',

ssl_keyfile='/opt/mapr/conf/
ssl_keystore.pem')

numMsgProduced = 0
for _ in range(100):
    producer.send(topic, b'msg')
    numMsgProduced += 1
producer.flush()
print("Messages produced: " +
      str(numMsgProduced))
time.sleep(2)

# CONSUMER
print("\n**Starting Consumer**")
consumer =
KafkaConsumer(bootstrap_servers=[server],

auto_offset_reset='earliest',

security_protocol='SSL',

```

```

ssl_check_hostname=False,

ssl_password='<>', #from /opt/mapr/
conf/store-passwords.txt
ssl.server.keystore.password

ssl_cafile='/opt/mapr/conf/
ssl_truststore.pem',

ssl_certfile='/opt/mapr/conf/
ssl_keystore-signed.pem',

ssl_keyfile='/opt/mapr/conf/
ssl_keystore.pem')

consumer.subscribe(topics=[topic])
numMsgConsumed = 0
for _ in range(10):
    records =
    consumer.poll(timeout_ms=500)
    for topic_data, consumer_records
    in records.items():
        for consumer_record in
        consumer_records:
            # print("Received message:
            " +
            str(consumer_record.value.decode('utf-8')))
            numMsgConsumed += 1
    print("Messages consumed: " +
    str(numMsgConsumed))

```

Configuring Apache Kafka Wire Protocol Service

Describes the Apache Kafka Wire Protocol Service configuration files and instructions.

The following sections provide configuration information for DAG (Data Access Gateway) and Apache Kafka clients and applications:

Configuring Apache Kafka Wire Protocol Service

DAG packages include the following configuration files for Apache Kafka Wire Protocol Service:

kafka-server.conf

- This file is stored in /opt/mapr/data-access-gateway/conf and loaded from the local file system.
- This file contains node-specific options, such as the port number and security protocol. Set the options in this file on a per-node basis.
- By default, the Apache Kafka Wire Protocol Service listens on port 9092.
- If the DAG service instances are behind a firewall, the firewall rules must be configured to allow this traffic.

For a list of configurable parameters, see [Apache Kafka Wire Protocol Service Settings](#) on page 3917.

Configuring Apache Kafka Clients and Applications

Standard Apache Kafka client configurations are supported. For additional information on configuration, see [the official Apache Kafka documentation](#).

Apache Kafka Wire Protocol Service Settings

Lists and describes parameters that you can configure in `kafka-server.conf`.

You can configure the following parameters in `/opt/mapr/data-access-gateway/conf/kafka-server.conf`:

Parameter	Description
<code>kafka.server.rpc.port</code>	TCP port that Apache Kafka Wire Protocol Service listens to for incoming client requests. Default is 9092.
<code>kafka.server.rpc.security-protocol</code>	Configures authentication and encryption schemes. Supports PLAINTEXT or SASL_PLAINTEXT as the value. To enable authentication, set to SASL_PLAINTEXT. Note that DAG 5.0 does not support encryption.
<code>kafka.server.rpc.sasl-mechanism</code>	Configures the list of SASL authentication mechanisms. This parameter is only effective when <code>kafka.server.rpc.security-protocol</code> is set to SASL_PLAINTEXT. In DAG 5.0, only PLAIN is supported.

Securing Apache Kafka Wire Protocol Service

Describes the security mechanisms that Apache Kafka Wire Protocol Service does and does not support.

Authentication

Starting from Data Access Gateway 5.1, Apache Kafka Wire Protocol Service supports SASL/PLAIN and SSL authentication between clients and file servers.

Authorization

Kafka Wire Protocol Service does not support [ACLs](#). The topic owner has all permissions.

On-Wire Encryption

Starting from Data Access Gateway 5.1, on-wire encryption for Apache Kafka Wire Protocol Service is supported using SSL. See [Enabling SSL for Apache Kafka Wire Protocol Service](#) on page 3917.

Enabling SSL for Apache Kafka Wire Protocol Service

Describes the security protocol values that are needed to enable SSL for Apache Kafka Wire Protocol Service.

Data Access Gateway 5.1 and later added SSL support for the Apache Kafka Wire Protocol Service. This section provides examples for configuring `/opt/mapr/data-access-gateway/conf/kafka-server.conf` to enable SASL_SSL and SSL security in server-side and client-side configurations.

New Security Protocol Values

Release 7.2.0 and later support two new values for the `security-protocol` parameter of `kafka-server.conf`:

- SASL_SSL
- SSL

When you specify the SASL_SSL value, you must also specify the corresponding `sasl-mechanism` value as indicated in the following table:

Specifying security-protocol as ...	With sasl-mechanism as ...	Enables
SASL_SSL	PLAIN ¹	Username/password-based (PAM) client authentication with SSL encryption and one-way SSL server authentication.
SSL	(Unspecified)	SSL authentication (two-way mutual SSL authentication) and SSL encryption.

¹PLAIN is the only mechanism currently supported.

SASL_SSL Server-Side Configuration Example

Here is a typical SASL_SSL server-side configuration example:

```
kafka.server = {
  rpc = {
    # TCP port for the Kafka Wire protocol service. Default is 9092
    port = 9092

    # Configures authentication and encryption schemes
    # Supported values are PLAINTEXT|SASL_PLAINTEXT|SASL_SSL|SSL
    # To enable authentication, set to SASL_PLAINTEXT, SASL_SSL or SSL
    # Encryption is supported for SASL_SSL and SSL
    security-protocol = SASL_SSL

    # Configures list of SASL authentication mechanisms
    # The only supported mechanism in this release is PLAIN
    # Effective only if "security-protocol" is set to SASL_PLAINTEXT or
    SASL_SSL
    sasl-mechanism = PLAIN
  }
}
```

SASL_SSL Client-Side Configuration

You can configure the SASL_SSL client-side configuration the same way it is configured in Apache Kafka. In this configuration, /opt/mapr/conf/ssl_truststore performs the one-way SSL server authentication. For example:

```
security.protocol=SASL_SSL
ssl.truststore.location=/opt/mapr/conf/ssl_truststore
ssl.truststore.password=<some_password>
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
sasl.mechanism=PLAIN
sasl.jaas.config=org.apache.kafka.common.security.plain.PlainLoginModule
required.username="user1" password="user1";
```

SSL Server-Side Configuration

To make the SSL protocol work correctly in a server-side configuration, the cluster administrator MUST specify the rpc.ssl.principal-mapping-rules in the server config file. For example:

```
kafka.server = {
  rpc = {
    # TCP port for the Kafka Wire protocol service. Default is 9092
    port = 9092

    # Configures authentication and encryption schemes
```

```
# Supported values are PLAINTEXT|SASL_PLAINTEXT|SASL_SSL|SSL
# To enable authentication, set to SASL_PLAINTEXT, SASL_SSL or SSL
# Encryption is supported for SASL_SSL and SSL
security-protocol = SSL

ssl.principal-mapping-rules = [
  "RULE: ^CN=.*O=(. *?),.*$/$1/L," ,
  "DEFAULT"
]
}
}
```

The `ssl.principal-mapping-rules` parameter specifies a list of mapping rules. For information about how to configure the mapping rules, see [Customizing the SSL User Name](#) in the Kafka documentation.

SSL Client-Side Configuration

You can configure the client-side configuration the same way it is configured in Apache Kafka. In this configuration, the `/opt/mapr/conf/ssl_truststore` performs the SSL server authentication. To perform client authentication by the server, you must add the CA of the client certificate to the `/opt/mapr/conf/ssl_truststore`. Both the server and the client use this trust store file.

```
security.protocol=SSL
ssl.truststore.location=/opt/mapr/conf/ssl_truststore
ssl.truststore.password=<some_password>
ssl.keystore.location=/<client_cert_path>/example_ssl_client_keystore
ssl.keystore.password=<some_password>
ssl.key.password=<some_password>
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
```

Supported Apache Kafka RPCs

Lists the Apache Kafka RPCs that Apache Kafka Wire Protocol Service supports and provides links to the correlating API request documentation in the Kafka Protocol Guide.

Model Context Protocol (MCP)

Overview

MCP (Model Context Protocol) is an open-source standard for connecting AI applications or LLMs to external data sources. MCP provides AI agents a consistent way to connect with various tools, services, and data. It is a Universal connector – like a USB-C port - for AI apps.

MCP follows a client/server architecture. AI agents such as Claude or Cursor use the MCP client to communicate with the MCP servers. The MCP server exposes three standard external capabilities such as **tools**, **resources** (data), and **prompts** (templates).

Starting with version Data Fabric 8.0.0, HPE Data Fabric includes an MCP server with the following capabilities:

- **Data Fabric Native MCP server:** Embedded MCP server helps in simplifying operations, improving security, and aligning with platform-native support.
- **Uniform data coverage:** Support for Files, Objects, and Iceberg tables as queryable tools/resources via MCP protocol.
 - *Files / Objects:* Instant access to metadata, summaries, and lightweight lookups.
 - *Iceberg:* Facilitates advanced analytics through Spark, as MCP submits SQL jobs, Spark processes, results are returned
- **Governed by design:** MCP access is **read-only**, ensuring minimal risk while enforcing policy compliance across access paths.

Architecture

The MCP service runs within data access gateway (DAG).

The following image shows the communication paths between MCP Hosts, MCP Service in DAG, and various data sources in HPE Data

Getting Started with Data Fabric MCP

The following sections describe the prerequisites and steps required to use the MCP server.

Prerequisites

MCP server requires the following components:

- MCP server runs within Data Access Gateway (DAG).
- To use MCP Object store endpoints, you must have Data Fabric Object store installed and configured in the cluster. See [Installing the HPE Data Fabric Object Store](#) on page 330 for more information.
- To use MCP Apache Iceberg endpoints, you need Apache Spark, Apache Livy, Apache Hive meta store installed and configured in the cluster. See the following documentation for more information:
 - For Apache Livy, see [Livy](#) on page 5222.
 - For Apache Spark, see [Apache Spark](#) on page 5408.
 - For Apache Hive, see [Hive](#) on page 4934.

Security Encryption

Data Fabric MCP server listens on an HTTPS port. The communication between LLM agent and Fabric MCP server is encrypted using SSL.

Authentication

The OAuth is recommended for Authentication. See [Understanding Authorization in MCP](#).

NOTE: Data Fabric MCP server supports both OAuth and HTTP Basic schemes for authentication. However, OAuth is recommended for the production environment.

Access Control

Data Fabric MCP server provides Role-based access control for the data stored in the Data Fabric cluster. Refer to the respective MCP endpoint pages (See [Data Fabric MCP Endpoints](#) on page 3924 for details).

Configure MCP

To configure MCP servers, see [Configuring Data Fabric MCP Server](#) on page 3922.

Configuring Data Fabric MCP Server

This topics describes various configuration settings required for MCP.

Configuring Data Fabric MCP Service

DAG packages include the following configuration files for Data Fabric MCP Service:

`mcp-server.conf`

- This file is stored in `/opt/mapr/data-access-gateway/conf` and loaded from the local file system.
- This file contains node-specific options, such as the port number and security protocol. Set the options in this file on a per-node basis.
- By default, the Data Fabric MCP service listens on port 5679.
- If the DAG service instances are behind a firewall, the firewall rules must be configured to allow this traffic.

See [Data Fabric MCP Server Settings](#) on page 3922 for list of MCP server settings.

Configuring SSL for MCP Server

MCP Server uses the default SSL configuration of the Data Fabric cluster. See [SSL Certificates](#) on page 909 for more information.

Configuring OAuth for MCP Server

You must configure SSO to use OAuth in the MCP server. See [Configuring SSO](#) on page 1289 for more information.

Data Fabric MCP Server Settings

This topics describes various configuration settings required for MCP.

Data Fabric MCP Server Settings

The Spark MCP endpoints can operate in two modes, either with impersonation enabled or impersonation disabled.

Impersonation-enabled mode:

Impersonation enabled is the default mode, and is the recommended mode.

In this mode, all Spark sessions are impersonated according to the credentials of the specific user. A separate session gets created for each user, with a default idle time of 30 minutes. As each session reserves cluster resources, the number of concurrent active sessions is limited. You can configure this limit.

Before accessing Spark for the first time, you must call the `create_sql_session` tool. This tool must also be used to recreate expired sessions.

Impersonation-disabled mode

The impersonation-disabled mode is not a recommended mode, as it carries security risks. In this mode, all users have access to data that is available to the session-user.

In Impersonation-disabled mode, sessions are pre-created (by default, three) under the user specified as session-user in the configuration. However, there is no latency in creating sessions, and all sessions in this mode will be re-created automatically if they crash or expire.

To add the required spark parameters, you need to first create a Spark section in `/opt/mapr/data-access-gateway/conf/mcp-server.conf` file.

Following are the list of various Spark parameters:

NOTE: To use any Spark endpoint you must have installed `mapr-livy`, `mapr-spark`, `mapr-hive`, `mapr-hivemetastore` packages.

Table

Parameters	Description
<code>mcp.spark.enabled</code>	To enable Spark endpoint.
<code>mcp.spark.session-use</code>	The user that will create sessions in impersonation-disabled mode
<code>mcp.spark.pool.size</code>	Number of sessions pre-created for impersonation-disabled mode. Default value: 3
<code>mcp.spark.userpool.size</code>	Number of available concurrent sessions/users for impersonation mode. Default value: 3
<code>mcp.spark.session.ttl</code>	ttl for Spark sessions for impersonation-disabled mode. Default value: 10
<code>mcp.spark.session.userttl</code>	ttl for Spark sessions for impersonation-enabled mode. Default value: 30 minutes
<code>mcp.spark.impersonation-enabled</code>	To enable or disable impersonation mode. Default value: true

Table

Parameters	Description
<code>mcp.spark.driver.memory</code>	Driver memory for Spark session. Default value: 1 GB

Table (Continued)

Parameters	Description
mcp.spark.driver.cores	Number of driver cores per Spark session. Default value: 1
mcp.spark.executor.memory	Executor memory per Spark session. Default value: 1 GB
mcp.spark.executor.cores	Number of executor cores per Spark session. Default value: 1
mcp.spark.executor.instances	Number of executors per Spark session. Default value: 1

Table

Parameters	Description
mcp.spark.iceberg.extensions	Extension to use for Iceberg integration. Default value: org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
mcp.spark.iceberg.catalog	iceberg catalog to use (org.apache.iceberg.spark.SparkCatalog by default) Default value: org.apache.iceberg.spark.SparkCatalog
mcp.spark.iceberg.catalog.type	Catalog type. Default value: hive
mcp.spark.iceberg.catalog.uri	Catalog URI. Default value: thrift://localhost:9083
mcp.spark.iceberg.useBuiltIn	Use built in Iceberg library. Default value: true

**NOTE:**

For information about configuring the MCP server to use Apache Polaris as an Iceberg catalog backend for Spark SQL queries, including Keycloak SSO authentication and Polaris role-based access control, see [Configuring Polaris as a metastore for Spark](#).

Data Fabric MCP Endpoints

Data Fabric 8.0.0 includes MCP endpoints for the following services:

- Data Fabric Files System.
- Data Fabric Object Store.
- Apache Iceberg tables.
- Apache Spark

MCP Endpoints for Filesystem

Endpoints are used to query the Data Fabric Files related information from MCP server.

Configuration

To enable MCP File service, set enable to true, for example:

```
file {
## Enables the MCP interface for Data Fabric File-system
enabled = true
}
```

Endpoint URL

For File interface:

```
https://<FQDN>:5679/file
```

For S3:

```
https://FQDN:5679/s3
```

Access Control

MCP server allows read-only access to DF files.

MCP Endpoints for Object Store

Endpoints are used to query the S3 Object store related information from MCP server.

Access Control

Super users (such as mapr, and root) are considered as prohibited session users.

A session user must be any user other than root and mapr user with least privileges (to view/list buckets or objects).

Authenticated users will have access to Objects and Buckets, based on the session user settings configured in the conf file. MCP server allows read-only access to files and objects.

Configuration

Set enabled to true for S3 service to enable in MCP Service. For Access control, add user with least privilege access using which only can view buckets and objects:

```
s3 {
## Enables the MCP interface for Data Fabric Object-store
## Refer to Data Fabric documentation for additional configuration steps
enabled = true

## S3 user with the least privileges to access buckets using MCP protocol
##
session-user = "<user with least privilege>"

## MCP server will regenerate temporary s3keys for this duration
key-expiry-mins = 60
}
```

Endpoint URL**For S3:**

```
https://<FQDN>:5679/s3
```

MCP Endpoints for Apache Iceberg Tables

Endpoints are used to query the Iceberg table from MCP server.

Starting with Data Fabric 8.1.0, the MCP server supports Apache Polaris as an Iceberg catalog backend, enabling centralized catalog management with Keycloak SSO authentication and Polaris role-based access control for Spark SQL queries. For setup details, see [Configuring Polaris as a metastore for Spark](#).

Prerequisites

To use MCP Apache Iceberg endpoints, you must have Apache Spark, Apache Livy, Apache Hive meta store installed and configured in the cluster. See the following documentation for more information:

- For Apache Livy, see [Livy](#) on page 5222.
- For Apache Spark, see [Apache Spark](#) on page 5408.
- For Apache Hive, see [Hive](#) on page 4934.

Configuration

To enable MCP Iceberg endpoint, set `enable` to `true` in MCP configuration file:

```
spark {
  enabled = true
}
```

Endpoint URL

```
https://<FQDN>:5679/spark
```

Access Control

Allows read-only access to Iceberg tables, and to the creation of temporary views.

MCP Endpoints for Apache Spark

The Apache Spark MCP endpoint can operate in two modes: with impersonation enabled and disabled. Impersonation enabled is the default mode. Impersonation enabled is the default mode.

In impersonation enabled mode, all Spark sessions will be impersonated according to the user's credentials. A separate session will be created for each user, with a default idle time of 30 minutes. Since each session reserves cluster resources, their simultaneous number is limited and can be controlled by an option.

Impersonation enabled mode is recommended because it is secure and each user only has access to data they have permission to access. In this mode, before accessing Spark for the first time, you must call the "create_sql_session" tool. This tool should also be used to recreate expired sessions.

You can also use impersonation disabled mode. In this mode, sessions are pre-created (by default, there are three) under the user specified as the session-user in the configuration. This mode carries security risks, as all users will have access to data visible to the session-user. However, no time is spent creating sessions, and all sessions in this mode will be re-created automatically if they crash or expire.

To configure a Spark endpoint, you need a Spark section in the configuration file. This is the list of possible parameters:

MCP Spark endpoint options:

- mcp.spark.enabled - enable Spark endpoint
- mcp.spark.session-user - user which will create sessions in non-impersonation mode
- mcp.spark.pool.size - amount of sessions precreated for non-impersonation mode (3 by default)
- mcp.spark.userpool.size - amount of available concurrent sessions/users for impersonation mode (3 by default)
- mcp.spark.session.ttl - ttl for Spark sessions for non-impersonation mode (10h by default)
- mcp.spark.session.userttl - ttl for Spark sessions for impersonation mode (30m by default)
- mcp.spark.impersonation-enabled - enable or disable impersonation mode (true by default)

Spark options - these options are passed to the Spark engine:

- mcp.spark.driver.memory - driver memory for Spark session (1g by default)
- mcp.spark.driver.cores - amount of driver cores per Spark session (1 by default)
- mcp.spark.executor.memory - executor memory per Spark session (1g by default)
- mcp.spark.executor.cores - amount of executor cores per Spark session (1 by default)
- mcp.spark.executor.instances - amount of executors per Spark session (1 by default)

Iceberg options:

- mcp.spark.iceberg.extensions - extension to use for Iceberg integration (org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions by default)
- mcp.spark.iceberg.catalog - iceberg catalog to use (org.apache.iceberg.spark.SparkCatalog by default)
- mcp.spark.iceberg.catalog.type - catalog type (hive by default)
- mcp.spark.iceberg.catalog.uri - catalog uri (by default Hive Metastore uri which is set to thrift://localhost:9083)
- mcp.spark.iceberg.useBuiltIn - use built in Iceberg library (true by default)

NOTE:

To use Spark endpoints you need to install mapr-livy, mapr-spark, mapr-hive, mapr-hivemetastore packages.

Registering MCP Server with AI Applications

This topic describes various configuration settings required for MCP.

Registering MCP server with AI applications includes the following steps:

- Obtain Authentication Headers
- Configure TLS/SSL verification
- Register MCP Server

Obtain Authentication Headers

Data Fabric MCP server supports both OAuth and Basic Authentication schemes. However, HPE recommends using only the OAuth scheme for production deployments. OAuth requires a JWT token for authentication.

To obtain JWT token from Keycloak configured in Data Fabric cluster, see [About Access and Refresh Tokens](#) on page 1312. Use the generated JWT token for MCP Registration.

Obtain CA Certificates

By default, the MCP server uses self-signed certificates. To avoid connection failure, you must provide SSL CA certificates of the Data Fabric cluster to the AI application.

Copy `/opt/mapr/conf/ssl_truststore.pem` from a Data Fabric cluster node to the machine running the AI Application.

Register MCP Server

To register a Data Fabric MCP server with AI applications (such as Claude, Cusror and so on), do the steps that follow:

1. Edit the MCP servers settings in your AI application.
2. Add Data Fabric MCP server configuration, for example:

```
{
  "mcpServers": {
    "<MCP_SEVER_NAME>": {
      "command": "npx",
      "args": [
        "-y",
        "mcp-remote",
        "https://<MCP_HOST>:5679/<MCP_ENDPOINT>",
        "--header",
        "Authorization: Bearer <JWT_token>"
      ],
      "env": {
        "NODE_EXTRA_CA_CERTS": "</path/to/ssl_truststore.pem>"
      }
    }
  }
}
```

3. Restart the AI application.

HPE Data Fabric Streams and Apps

HPE Data Fabric Streams brings integrated publish and subscribe messaging to HPE Data Fabric.

HPE Data Fabric Streams is built into the HPE Data Fabric. It requires no additional process to manage, leverages the same architecture as the rest of the platform, and requires minimal additional management.

1. [The Getting Started with HPE Data Fabric Streams section](#) provides overall instructions for setting up, producing, and consuming streams.
2. [The HPE Data Fabric Streams section](#) provides conceptual information.
3. [The Administering Streams section](#) provides information about creating and managing streams, topics, and stream replication.

⚠ ATTENTION: As of core version 6.1, the HPE Data Fabric Streams API enforces a maximum of 4096 partitions for a topic. If you create an application with the HPE Data Fabric Streams 6.1 API, the maximum number of partitions is 4096. If you previously created an application with HPE Data Fabric Streams 6.0.1 API (or older) and you have upgraded, the original number of partitions can be used. For example, if you were using more than 4096 partitions in core version 6.0.1 or earlier, you can continue with the same number of partitions after upgrading.

Getting Started with HPE Data Fabric Streams

If you have a basic understanding of HPE Data Fabric Streams components and the typical flow of messages from producers to consumers, you can get started.

Prerequisites

- Ensure that your Linux, Windows, or OS X system has Java SDK 7 or later installed.
- Install the latest version of HPE Data Fabric on a cluster.
- Install the core client (mapr-client) package, if you want to run the producer and consumer from a machine outside the cluster. See [Installing the Data Fabric Client \(Non-FIPS\)](#) on page 361 for more information.

Procedure

1. On a node in the HPE Data Fabric cluster, follow these steps:

a) Create a stream.

- Run this command if you plan to run the producer and consumer with the same user ID that you are using to create the stream:

```
maprcli stream create -path /<path to and name of the stream>
```

- Run this command if you plan to run the producer and consumer with user IDs that are different from the user ID that you are using to create the stream:

```
maprcli stream create -path /<path to and name of the stream> -consumeperm u:<user ID> -produceperm u:<user ID>
```

The two additional parameters grant security permissions. By default, these permissions are granted to the user ID that ran the `maprcli stream create` command.

-consumeperm

Grants permission to read messages from topics that are in the stream.

-produceperm

Grants permission to publish messages to topics that are in the stream.

b) Create a topic.

Run this command to create the topic:

```
maprcli stream topic create -path <path and name of the stream> -topic <name of the topic>
```

2. On the system where the mapr-client is installed, compile and launch the Java consumer first and then launch the Java producer.

In both the consumer and producer, change this text to the path and name of your stream and to the name of the first of the topics:

```
/<path to and name of the stream>:<name of topic>
```

For the steps of compiling and launching, see [Compiling and Running HPE Data Fabric Streams Java Apps](#) on page 3988.

Launch the consumer first, and then launch the producer. If you launch the producer first and then the consumer, the producer publishes 50 messages, but the consumer (as consumers do by default) starts reading from the head of the partition, which is after the 50 messages.

NOTE: As of MapR 6.0, the message offset in a partition starts from zero (0). If you are upgrading and do not enable the HPE Data Fabric Database/HPE Data Fabric Streams feature, **mfs.feature.db.streams.v6.support**, the message offset in a partition starts from one (1).

Figure 32: Result of starting the producer before starting the consumer for this step

If you launch the consumer first, the partition is empty and the consumer continuously polls for new messages.

Figure 33: The position of a consumer on an empty partition

After you launch the producer, the fifty messages are published to the partition, and the consumer can move forward in the partition, reading the messages.

Figure 34: Result of starting the consumer first and then starting the producer for this step

Sample Java Consumer

You need to first add the following dependency to the POM file:

```
<dependency>
  <groupId>commons-logging</groupId>
  <artifactId>commons-logging</artifactId>
  <version>1.1.1</version>
</dependency>
```

```
/* This code is successfully tested for common-logging version 1.11 and
1.2. */

import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;

public class SampleConsumer {
    // Set the stream and topic to read from
    public static String topic = "<path to and name of the stream>:<name
of topic>";

    // Declare a new consumer.
```

```

public static KafkaConsumer<Integer, String> consumer;

public static void main(String[] args) {
    configureConsumer();

    // Subscribe to the topic.
    consumer.subscribe(Collections.singletonList(topic));

    // Set the timeout interval for requests for unread messages.
    Duration pollTimeout = Duration.ofMillis(1000);

    try {
        while (true) {
            ConsumerRecords<Integer, String> records =
consumer.poll(pollTimeout);
            records.forEach(record -> {
                System.out.printf("%s %d %d %s %s \n", record.topic(),
                    record.partition(), record.offset(),
record.key(), record.value());

            });
        } finally {
            consumer.close();
        }
    }

    /* Set the value for a configuration parameter.
    This configuration parameter specifies which
    class to use to deserialize the value of each message. */
    public static void configureConsumer() {
        Properties props = new Properties();
        props.put(ConsumerConfig.GROUP_ID_CONFIG, "consumer-group");
        props.put(ConsumerConfig.AUTO_OFFSET_RESET_CONFIG, "earliest");
        props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
"org.apache.kafka.common.serialization.IntegerDeserializer");
        props.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
            "org.apache.kafka.common.serialization.StringDeserializer");
        consumer = new KafkaConsumer(props);
    }
}

```

Sample Java Producer

```

import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;

import java.util.Properties;

public class SampleProducer {
    // Set the stream and topic to publish to.
    public static String topic = "/<path to and name of the stream>:<name
of topic>";
    // Set the number of messages to send.
    public static int numMessages = 50;

    // Declare a new producer.
    public static KafkaProducer<Integer, String> producer;

    public static void main(String[] args) {
        configureProducer();
    }
}

```

```

        for(int i = 0; i < numMessages; i++) {
            // Set content of each message.
            String messageText = "Msg " + i;

            /* Add each message to a record. A ProducerRecord object
               identifies the topic or specific partition to publish
               a message to. */
            ProducerRecord<Integer, String> rec = new ProducerRecord(topic,
i, messageText);

            // Send the record to the producer client library.
            producer.send(rec);
            System.out.println("Sent message number " + i);
        }
        producer.close();
        System.out.println("All done.");
    }

    /* Set the value for a configuration parameter.
       This configuration parameter specifies which class
       to use to serialize the value of each message. */
    public static void configureProducer() {
        Properties props = new Properties();
        props.put(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
            "org.apache.kafka.common.serialization.IntegerSerializer");
        props.put(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
            "org.apache.kafka.common.serialization.StringSerializer");
        producer = new KafkaProducer(props);
    }
}

```

For additional information, see <https://github.com/mapr-demos/mapr-streams-sample-programs>.

Consuming CDC Records

The OJAI changelog interfaces are used to consume changed data records (propagated by the Change Data Capture feature).

The general CDC flow of understanding architectural concepts, performing administrative tasks to set up and use CDC, performing CRUD operations on a database table, and developing applications for consuming CDC changed data records. This diagram provides hotspot links to help you navigate to the applicable documentation.

1. [Learning about CDC](#)
2. [Administering Change Data Capture](#)
3. [Building a consumer app for CDC](#)
4. [Using dbshell to perform CRUD operations on HPE Data Fabric Database JSON tables](#)
5. [Developing client applications for HPE Data Fabric Database JSON tables.](#)
6. [Using hbshell to perform CRUD operations on HPE Data Fabric Database binary tables.](#)
7. [Developing client applications for HPE Data Fabric Database binary tables.](#)

Javadoc

See the following Java documentation for detailed information about CDC APIs.

[QueryResult](#)

Deserializer for consuming CDC records

The deserializer converts stream messages into individual change data records. When your application creates a CDC consumer, you must also register the ChangeData deserializer by setting the value `.deserializer` configuration parameter to `com.mapr.db.cdc.ChangeDataRecordDeserializer`.

NOTE: When applications consume from a CDC change topic, the record key retrieved from `poll()` is not deserialized. The record key is not equal to the `_id` field of the document. If you want to retrieve the exact `_id` of the document, you must call the `ChangeDataRecord.getId()` method.

Interfaces for working with CDC records

The following OJAI interfaces and enumerations create consumers for CDC changed data.

ChangeNode

Contains the change to a single field in a document.

ChangeEvent

Identifies the change event associated with the current change node. The value of `ChangeEvent` can be one of the following:

- NULL (no event)
- NODE (a change with real value)
- START_MAP (a node representing the beginning of a map)
- END_MAP (a node representing the end of a map)
- START_ARRAY (a node representing the beginning of an array)
- END_ARRAY (a node representing the end of an array)

ChangeOp

Identifies the type of the operation performed on the current field. The values of `ChangeOp` can be one of the following:

- NULL (no operation)
- SET (replace the current field with the given value)
- PUT (add an extra version of the value)
- MERGE (combine the given value with the existing values in the table)
- DELETE (delete all values older than or equal to the delete operation timestamp)
- DELETE_EXACT (delete the version of the value with the given timestamp)

ChangeDataRecord

Contains all the changes made on a single document/row in the source table.

ChangeDataRecordType

Specifies the mode of change for the change data record. The following values are specified:

- RECORD_INSERT
- RECORD_UPDATE
- RECORD_DELETE

ChangeDataReader

Is a parser that traverses over the individual change tree nodes on a change data record. It provides cursor-like semantics that can be moved, one tree node at a time, by invoking the `next` method. The APIs retrieve the properties of individual change nodes

(for example: data type, field name, field value, and so on).

Open Data Format

The CDC Open Format feature allows you to create applications in languages other than Java that consume CDC (Change Data Capture) changed data records. For example, C/C++, Python, and C#.NET) are supported.

This functionality is provided with an open format decoder/serializer in the HPE Data Fabric Streams C library. The decoder translates the internal format to the open data format, decodes/deserializes the data, and returns the value of the changed data record as a human readable JSON string.

All languages that are binding through the HPE Data Fabric Streams C library can retrieve the open data format and, with a simple JSON parser, consume changed data records.

Building Consumers for CDC

HPE Data Fabric Streams consumers read and process CDC changed data records. The consumer is built with the OJAI API library.

Description

When building a consumer, the general steps are to:

- Set the consumer properties using Apache Kafka and HPE Data Fabric configuration parameters.
- Subscribe to the stream topic.
- Consume the events and determine record type.
- Process the change data records.

The following examples refer to the [MapR CDC Sample](#). See the [QueryResult](#) for specific API information.

Set Configuration

This code snippet configures the consumer properties using the Apache Kafka configuration parameters. See [HPE Data Fabric Streams Configuration Parameters](#) for Consumers. This could be externalized in a file or hard coded in the application code. The following code examples show both methods.

NOTE: CDC uses a optimized serialization format for all the events, so `value.deserializer` must be set to **`com.mapr.db.cdc.ChangeDataRecordDeserializer`**.

```
// Consumer configuration parameters specified in application
```

```
Properties consumerProperties = new Properties();
consumerProperties.setProperty("group.id",
"cdc.consumer.demo_table.fts_geo");
consumerProperties.setProperty("enable.auto.commit", "true");
consumerProperties.setProperty("auto.offset.reset", "latest");
consumerProperties.setProperty("key.deserializer",
"org.apache.kafka.common.serialization.ByteArrayDeserializer");
consumerProperties.setProperty("value.deserializer",
"com.mapr.db.cdc.ChangeDataRecordDeserializer");
```

```
// Consumer configuration parameters specified in an external file
```

```
key.deserializer=org.apache.kafka.common.serialization.ByteArrayDeserializer
value.deserializer=com.mapr.db.cdc.ChangeDataRecordDeserializer
```

```
enable.auto.commit=true
auto.offset.reset=latest
group.id=cdc.consumer.demo_table.fts_geo
```

Subscribe to topic

This code snippet creates the consumer and subscribes to the HPE Data Fabric Streams topic that contains the change data records. The consumer is created using a key (bytes[]) and a `ChangeDataRecord` object for the value.

```
// Consumer used to consume MapR-DB CDC events

KafkaConsumer<byte[], ChangeDataRecord> consumer = new
KafkaConsumer<byte[], ChangeDataRecord>(consumerProperties);
consumer.subscribe(Arrays.asList("/demo_changelog:demo_table"));
```

Consume the events and determine record type

This code snippet polls the topic to determine whether there are any changes and, if so, iterates through the change data records to retrieve the change data record IDs based on the change data record type. The `ChangeDataRecordType` interface is used to determine the type of record and the `ChangeDataRecord` interface is used to retrieve the record type and record ID.

```
while (true) {
    ConsumerRecords<byte[], ChangeDataRecord> changeRecords =
consumer.poll(500);
    Iterator<ConsumerRecord<byte[], ChangeDataRecord>> iter =
changeRecords.iterator();

    while (iter.hasNext()) {
        ConsumerRecord<byte[], ChangeDataRecord> crec = iter.next();
        // The ChangeDataRecord contains all the changes made to a document
        ChangeDataRecord changeDataRecord = crec.value();
        String documentId = changeDataRecord.getId().getString();

        if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_INSERT) {
            System.out.println("\n\t Document Inserted " + documentId);
            insertAndUpdateDocument(changeDataRecord, producer);
        } else if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_UPDATE) {
            System.out.println("\n\t Document Updated " + documentId);
            insertAndUpdateDocument(changeDataRecord, producer);
        } else if (changeDataRecord.getType() ==
ChangeDataRecordType.RECORD_DELETE) {
            System.out.println("\n\t Document Deleted " + documentId);
            deleteDocument(changeDataRecord, producer);
        }
    }
}
}
```

Process the records

This code snippet processes the change data records and based on the type of event (insert, update, delete), using the `ChangeDataRecordType` class and the `changeDataRecord.getType()` method, checks and retrieves the record type.

```
// Use the ChangeNode Iterator to capture all the individual changes

    Iterator<KeyValue<FieldPath, ChangeNode>> cdrItr =
changeDataRecord.iterator();

    while (cdrItr.hasNext()) {
        Map.Entry<FieldPath, ChangeNode> changeNodeEntry = cdrItr.next();
        String fieldPathAsString = changeNodeEntry.getKey().asPathString();
        ChangeNode changeNode = changeNodeEntry.getValue();
        ...
        ...
    }
```

To process and retrieve an inserted new document, you can check to see if the field path is NULL or empty. When a *new document is inserted*, all the changes are made in a single object represented as a Map. You then retrieve the map value by using the `changeNode.getMap()` or `changeNode.getString()` methods depending on the field value.

```
if (fieldPathAsString == null || fieldPathAsString.equals("")) { // Insert
    Map<String, Object> documentInserted = changeNode.getMap();

    if (documentInserted.containsKey("firstName")) {
        fieldToIndex.put("firstName", (String)
documentInserted.get("firstName"));
        sendIndexingMessage = true;
    }

    if (documentInserted.containsKey("lastName")) {
        fieldToIndex.put("lastName", (String)
documentInserted.get("lastName"));
        sendIndexingMessage = true;
    }

    if (documentInserted.containsKey("address")) {
        addressMessage.set("address",
jsonMapper.convertValue((Map)documentInserted.get("address"),
JsonNode.class));
        sendAddressMessage = true;
    }
}
```

To process and retrieve updated documents, you can check the field path and retrieve the value depending on the expected value type. When a *document is updated*, the iterator contains one `ChangeNode` by updated field. You can then access the field path and value directly. You then retrieve the map value by using the `changeNode.getMap()` or `changeNode.getString()` methods depending on the field value.

```
if (fieldPathAsString.equalsIgnoreCase("firstName")) {
    fieldToIndex.put("firstName", changeNode.getString());
    sendIndexingMessage = true;
}
else if (fieldPathAsString.equalsIgnoreCase("lastName")) {
    fieldToIndex.put("lastName", changeNode.getString());
    sendIndexingMessage = true;
}
```

```

        else if (fieldPathAsString.equalsIgnoreCase("address")) {
            addressMessage.set("address",
                jsonMapper.convertValue( changeNode.getMap(), JsonNode.class) );
            sendAddressMessage = true;
        }

```

To process delete operations, you can directly retrieve the document ID using the `changeDataRecord.getId()` method and process the document deletion with the `deleteDocument` method. The delete operation is a single change data record.

Consumer Application for CDC JSON Data

This example consumes changed data records from HPE Data Fabric Database JSON tables.

Example of Consuming JSON Changed Data Records

In this example, the following occurs:

- Initialize the consumer properties using Apache Kafka and Data Fabric configuration parameters.
- Display the change data record properties.
- Iterate through the change nodes, determine the type of operation, and retrieve the operation value.
- Retrieve the properties of individual change node (for example: data type, field name, field value, and so on) by using various methods of the `ChangeDataReader` interface.
- Display the change data record values by using the `ChangeNode` interface.
- Subscribe to the stream topic, consume the events, and determine record type.

For changed data records from HPE Data Fabric Database JSON table data, the following are unique:

- There are multiple property values that can be retrieved through the `ChangeDataReader` interface. For example, `getDouble` or `getFloat`.
- There are multiple values for single fields in documents that can be retrieved through `ChangeNode` interface. See the code line: `Value value = changeNode.getValue();`

```

Consumer Application for CDC Binary Data

This example consumes changed data records from HPE Data Fabric Database Binary tables.

Example of Consuming Binary Changed Data Records

In this example, the following occurs:

- Initialize the consumer properties using Apache Kafka and HPE Data Fabric configuration parameters.
- Display the change data record properties.
- Iterate through the change nodes, determine the type of operation, and retrieve the operation value.
- Display the change data record values by using the ChangeNode interface.
- Subscribe to the stream topic, consume the events, and determine record type.

For changed data records from HPE Data Fabric Database Binary table data, the following are unique:

- An additional package must be imported: `java.nio.ByteBuffer`
- There is single value for single fields in documents that can be retrieved through ChangeNode interface. See the code line: `ByteBuffer value = changeNode.getBinary();`

```

package com.mapr.qa.cdc.tests.binary;

import org.apache.kafka.clients.consumer.ConsumerRecord;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;

```

```

import org.ojai.*;
import org.ojai.store.Connection;
import org.ojai.store.Driver;
import org.ojai.store.DriverManager;
import org.ojai.store.cdc.*;

import java.nio.ByteBuffer;

    CDCBinaryExample cdcBinaryExample = new CDCBinaryExample();
    cdcBinaryExample.consume(pollTimeout, topic, method);
}
}

```

Open Format

Describes the CDC open format.

Open Format Mapping

The following shows the mapping between the HPE Data Fabric CDC data types and the JSON open format data types.

```
{
  "map": {
    "null": null,
    "boolean" : true,
    "string": "eureka",
    "byte" : {"$numberByte": 127},
    "short": {"$numberShort": 32767},
    "int": {"$numberInt": 2147483647},
    "long": {"$numberLong": 9223372036854775807},
    "float" : {"$numberFloat": 3.4028235E38},
    "double" : 1.7976931348623157e308,
    "decimal": {"$decimal":
"12345678901234567890189012345678901.23456789"},
    "date": {"$dateDay": "yyyy-mm-dd"},
    "time" : {"$time" : "HH:mm:ss[.sss]"},
    "timestamp" : {"$date" : "yyyy-MM-ddTHH:mm:ss.SSSXXX"},
    "interval" : {"$interval" : number_of_milliseconds},
    "binary" : {"$binary" : "base64_encoded_binary_value"},
    "array" : [42, "open sesame", 3.14, {"$dateDay": "2015-01-21"}]
  }
}
```

JSON Record Format

When the consumer retrieves the changed data record (by the key-value pair), the record is returned as a string in JSON format (a readable open format). The information about the mutation is returned as an array where each array element is one (1) change.

NOTE: If you use the default print, the string returns float values of up to six (6) digits of precision and double values of up to fifteen (15) digits. If the data exceeds this default and you want the exact number returned, use the CDC API that returns a float or double value.

The following example changed data record shows two (2) mutations.

```
{
  "_id": "row1"
  "$opType": "$RECORD_UPDATE",
  "$opTime": 1518654391801,

  "$mutations": [
    {
      "$fieldPath": "arrayB",
      "$fieldOp": "$SET",
      "$fieldValue": [{"$numberInt": 100}, false, "set a map"]
    },
    {
      "$fieldPath": "arrayC",
      "$fieldOp": "$SET",
      "$fieldValue": [{"$numberInt": 200}, false, "set a map"]
    }
  ]
}
```

Example

The following sample code initialized consumer properties for open format and consumes the changelog data from the topic.

```

/*
 * Initialize Basic Consumer Properties for Open Format
 * @return
 */

private Properties getOpenFormatListenerProperties() {
    Properties props = new Properties();
    props.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
"org.apache.kafka.common.serialization.StringDeserializer");
    props.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
"org.apache.kafka.common.serialization.StringDeserializer");
    return props; }

/*
 * Consume from changelog topic
 */
public void startConsume(String topic) {
    KafkaConsumer<String, String> consumer = new KafkaConsumer<String,
String> (getOpenFormatListnerProperties());
    List<String> topicList = new ArrayList<>();
    topicList.add(topic);
    consumer.subscribe(topicList);

    ConsumerRecords<String, String> consumerRecords =
consumer.poll(pollTimeout);
    Iterator<ConsumerRecord<String, String>> iterator =
consumerRecords.iterator();
    while (iterator.hasNext())

        { ConsumerRecord<String, String> record = iterator.next(); String
cdcResult = record.value(); }
}

```

Consuming Audit Logs

Audit Streaming (available from v6.0.1) provides a way to process the audit data in real-time.

When audit streaming is enabled, the HPE Data Fabric generates audit logs that are sent as an audit stream, opening the possibility of real-time processing of the audit data. See [Streaming Audit Logs](#) on page 923 for more information.

Use the sample consumer application, or build your custom consumer application, to consume the audit logs that are available as a stream topic, when audit streaming is enabled.

The sample application uses file system APIs to get the file path and name from the FID, and the volume name from the volume ID.

Determine When to use Cached or Uncached Version of the File System API

Caching the file path and file name, along with the volume name at the initial API call, reduces the load on CLDB for subsequent API calls.

However, there could be cases when the uncached version of the application is more suitable for use. Consider the following example:

For the initial API call, File1 is returned as the file name for FID 1. The result is cached.

The file is then renamed to File2. For subsequent API calls, to get the file name for FID 1, the result from the cache is used. The cache, unaware of the rename operation, returns the name as File1, which is incorrect, as the file is already renamed to File2. For such a case, use the uncached version.

Evaluate your use case, and then use the cached, or the uncached version, as appropriate.

Sample Cached Consumer Application for Audit Stream

The Consumer.java application demonstrates how to connect to the file system, and consume the messages in a stream topic.

Sample Application

Before running this application, ensure that you have access to a cluster running file system. To build and run this application:

1. Set the classpath as shown below:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the Java file as shown below:

```
javac -cp `mapr classpath` Consumer.java
```

3. Run the final Consumer.class file. For example:

```
java -cp `mapr classpath` Consumer
```

This application requires the following imports:

- org.apache.kafka.clients.consumer.ConsumerRecord
- org.apache.kafka.clients.consumer.ConsumerRecords
- org.apache.kafka.clients.consumer.KafkaConsumer
- org.apache.hadoop.conf.Configuration
- com.mapr.fs.MapRFileSystem
- com.google.common.io.Resources
- java.net.URI
- java.io.IOException
- java.io.InputStream
- java.util.Iterator
- java.util.Properties
- java.util.Random
- java.util.StringTokenizer
- java.util.regex.Pattern

The application performs the actions described in the following sections.

Initializes the consumer properties

The [configuration parameters](#) for the consumer are stored in consumer .props file. This file should be present in the current directory or mapr classpath. For example, your consumer .props file could look similar to the following:

```
#bootstrap.servers=localhost:9092
group.id=test
enable.auto.commit=true
key.deserializer=org.apache.kafka.common.serialization.StringDeserializer
value.deserializer=org.apache.kafka.common.serialization.StringDeserializer
# fast session timeout makes it more fun to play with failover
## apps specific ?
session.timeout.ms=10000

# These buffer sizes are needed to avoid consumer switching to
# a mode where it processes one bufferful every 5 seconds with
multiple
# timeouts along the way.
fetch.min.bytes=50000
# receive.buffer.bytes=262144 //
fixed size buffer
max.partition.fetch.bytes=2097152

auto.offset.reset=earliest
```

The application initializes the consumer properties stored in the consumer .props file.

```
public static void main(String[]
args) throws
IOException, InterruptedException {
    KafkaConsumer<String, String>
consumer;
    try (InputStream props =
Resources.getResource("consumer.props"
).openStream()) {
        Properties properties = new
Properties();
        properties.load(props);
        if
(properties.getProperty("group.id")
== null) {

properties.setProperty("group.id",
"group-" + new
Random().nextInt(100000));
        }
        consumer = new
KafkaConsumer<>(properties);
    }
}
```

Subscribes to the topic to read from

The application initializes the file system object, with the last parameter as true so that the audit logs generated by the operations for converting fid to file path and volid to volume name are sent

to the `ExpandAudit.json.log` file used by the `expandaudit` on page 3234 utility and not to the stream. It then selects the stream and subscribes to the topic to read at path `/var/mapr/auditstream/auditlogstream:<clustername>`.

```
Configuration conf = new
Configuration();
String uri = MAPRFS_URI;
uri = uri + "mapr/";
conf.set("fs.default.name", uri);
MapRFileSystem fs = new
MapRFileSystem();
fs.initialize(URI.create(uri), conf,
true);
Pattern pattern
= Pattern.compile("/var/
mapr/auditstream/
auditlogstream:<clustername>.+");
consumer.subscribe(pattern);
```

Requests unread messages from the topic

The application requests to read unread messages in the subscribed topic. It then iterates through the returned records, extracts the value of each message, and prints the value to the standard output.

```
boolean stop = false;
int pollTimeout = 1000;
while (!stop) {
    ConsumerRecords<String,
String> consumerRecords =
consumer.poll(pollTimeout);
    Iterator<ConsumerRecord<String,
String>> iterator =
consumerRecords.iterator();
    if (iterator.hasNext()) {
        while (iterator.hasNext()) {
            ConsumerRecord<String,
String> record = iterator.next();
            String value = record.value();
            String rvalue =
value.replace("\\", "");
            String recordValue
= processRecord(fs, rvalue,
value);
            System.out.println(("
Consumed Record: " + recordValue));
        }
    } else {
        Thread.sleep(1000);
        //stop = true;
    }
}
```

Gets the record and expands individual fields

The application then takes the record and expands `fid` in the message to path to file using the `getMountPathFidCached()` API and

valid in the message to volume name using the `getVolumeNameCached()` API.

```
while (st.hasMoreTokens()) {
    String field = st.nextToken();
    StringTokenizer st1 = new
StringTokenizer(field, ":");
    while (st1.hasMoreTokens()) {
        String token =
st1.nextToken();
        if (token.endsWith("Fid")) {
            String lfidStr =
st1.nextToken();
            String path= null;
            try {
                path =
fs.getMountPathFidCached(lfidStr); //
Expand FID to path
            } catch (IOException e){
            }
            lfidPath =
"\FidPath\":" + path + "\", ";
            // System.out.println("\nPATH
for fid " + lfidStr + " is " + path);
        }
        if (token.endsWith("volumeId")) {
            String valid =
st1.nextToken();
            String name= null;
            try {
                int volumeId =
Integer.parseInt(valid);
                name =
fs.getVolumeNameCached(volumeId); //
Cached API to convert volume Id to
volume Name
            } catch (IOException e){
            }
            lvolName =
"\VolumeName\":" + name + "\", ";
            //
System.out.println("\nVolume Name for
valid " + valid + " is " + name);
        }
    }
}
```

Returns the record

The application finally returns the record after expanding the fid and valid to file path and volume name respectively.

```
String result = "";
StringTokenizer st2 = new
StringTokenizer(value, ",");
while (st2.hasMoreTokens()) {
    String tokens = st2.nextToken();
    result = result + tokens + ", ";
    if (tokens.contains("Fid")) {
        result = result + lfidPath;
    }
    if (tokens.contains("volumeId"))
    {
        result = result + lvolName;
    }
}
```

```

    }
}
return result.substring(0,
result.length() - 1);

```

Sample Uncached Consumer Application for Audit Stream

The ConsumerUncached.java application demonstrates how to connect to the HPE Data Fabric file system, and consume the messages in a stream topic.

Sample Application

Before running this application, ensure that you have access to a cluster running file system. To build and run this application:

1. Set the classpath as shown below:

```
export CLASSPATH=`hadoop classpath`
```

2. Compile the Java file as shown below:

```
javac -cp `mapr classpath` ConsumerUncached.java
```

3. Run the final `ConsumerUncached.class` file. For example:

```
java -cp .:`mapr classpath` ConsumerUncached
```

This application requires the following:

- `org.apache.kafka.clients.consumer.ConsumerRecord`
- `org.apache.kafka.clients.consumer.ConsumerRecords`
- `org.apache.kafka.clients.consumer.KafkaConsumer`
- `org.apache.hadoop.conf.Configuration`
- `com.mapr.fs.MapRFileSystem`
- `com.google.common.io.Resources`
- `java.net.URI`
- `java.io.IOException`
- `java.io.InputStream`
- `java.util.Iterator`
- `java.util.Properties`
- `java.util.Random`
- `java.util.StringTokenizer`
- `java.util.regex.Pattern`

The application performs the actions described in the following sections.

Initializes the consumer properties

The [configuration parameters](#) for the consumer are stored in `consumer.props` file. This file should be present in the current directory or `mapr classpath`. For example, your `consumer.props` file could look similar to the following:

```
#bootstrap.servers=localhost:9092
group.id=test
enable.auto.commit=true
key.deserializer=org.apache.kafka.common.serialization.StringDeserializer
value.deserializer=org.apache.kafka.common.serialization.StringDeserializer

# fast session timeout makes it more
# fun to play with failover
## apps specific ?
session.timeout.ms=10000

# These buffer sizes are needed to
# avoid consumer switching to
# a mode where it processes one
# bufferful every 5 seconds with
# multiple
```

```
# timeouts along the way.
fetch.min.bytes=50000
# receive.buffer.bytes=262144 //
fixed size buffer
max.partition.fetch.bytes=2097152

auto.offset.reset=earliest
```

The application initializes the consumer properties stored in the `consumer.props` file.

```
public static void main(String[]
args) throws
IOException, InterruptedException {
    KafkaConsumer<String, String>
consumer;
    try (InputStream props =
Resources.getResource("consumer.props"
).openStream()) {
        Properties properties = new
Properties();
        properties.load(props);
        if
(properties.getProperty("group.id")
== null) {

properties.setProperty("group.id",
"group-" + new
Random().nextInt(100000));
        }
        consumer = new
KafkaConsumer<>(properties);
    }
}
```

Subscribes to the topic to read from

The application initializes the filesystem object, with the last parameter as `true` so that the audit logs generated by the operations for converting fid to file path and valid to volume name are sent to the `ExpandAudit.json.log` file used by the [expandaudit](#) on page 3234 utility and not to the stream. It then selects the stream and subscribes to the topic to read at path `/var/mapr/auditstream/auditlogstream:<clustername>`.

```
Configuration conf = new
Configuration();
String uri = MAPRFS_URI;
uri = uri + "mapr/";
conf.set("fs.default.name", uri);
MapRFileSystem fs = new
MapRFileSystem();
fs.initialize(URI.create(uri), conf,
true);

Pattern pattern =
Pattern.compile("/var/mapr/
auditstream/
auditlogstream:<clustername>.+");
consumer.subscribe(pattern);
```

Requests unread messages from the topic

The application requests to read unread messages in the subscribed topic. It then iterates through the returned records, extracts the value of each message, and prints the value to the standard output.

```
boolean stop = false;
int pollTimeout = 1000;
while (!stop) {
    ConsumerRecords<String,
String> consumerRecords =
consumer.poll(pollTimeout);
    Iterator<ConsumerRecord<String,
String>> iterator =
consumerRecords.iterator();
    if (iterator.hasNext()) {
        while (iterator.hasNext()) {
            ConsumerRecord<String,
String> record = iterator.next();
            String value =
record.value();
            String rvalue =
value.replace("\\", "");
            String recordValue =
processRecord(fs, rvalue, value);
            System.out.println(("
Consumed Record: " + recordValue));
        }
    } else {
        //stop = true;
    }
}
```

Gets the record and expands individual fields

The application then takes the record and expands fid in the message to path to file using the getMountPathFid() API and valid in the message to volume name using the getVolumeName() API.

```
public static String
processRecord(MapRFileSystem fs,
String rvalue, String value)
{
    StringTokenizer st = new
StringTokenizer(rvalue, ",");
    String lfidPath = "";
    String lvolName = "";

    while (st.hasMoreTokens()) {
        String field =
st.nextToken();
        StringTokenizer st1 = new
StringTokenizer(field, ":");
        while (st1.hasMoreTokens())
        {
            String token =
st1.nextToken();
            if
(token.endsWith("Fid")) {
                String lfidStr =
st1.nextToken();
                String path= null;
                try {
                    path =
```

```

fs.getMountPathFid(lfidStr);
        } catch (IOException e)
    { }
        lfidPath =
        "\"FidPath\\\":\\\""+path+"\\\", \"";
        if
        (token.endsWith("volumeId")) {
            String volid =
            st1.nextToken();
            String name= null;
            try {
                int volumeId =
                Integer.parseInt(volid);
                name =
                fs.getVolumeName(volumeId);
            }
            catch (IOException e){ }
            lvolName =
            "\"VolumeName\\\":\\\""+name+"\\\", \"";
        }
    }
}

```

Returns the record

The application finally returns the record after expanding the fid and volid to file path and volume name respectively.

```

String result = "";
StringTokenizer st2 = new
StringTokenizer(value, ",");
while (st2.hasMoreTokens()) {
    String tokens = st2.nextToken();
    result = result + tokens + ",";
    if (tokens.contains("Fid")) {
        result = result + lfidPath;
    }
    if (tokens.contains("volumeId")) {
        result = result + lvolName;
    }
    return result.substring(0,
result.length() - 1);
}

```

HPE Data Fabric Streams Java Applications

This section contains information about developing client applications with Java, including information about the HPE Data Fabric Streams and Apache Kafka Java APIs, configuration parameters, and compiling and running producers and consumers.

Apache Kafka Support

HPE Data Fabric supports the following Apache Kafka Java API versions:

Table

Core version	Apache Kafka API
7.8 and later	3.6.1
7.0 through 7.7	2.6.1
6.2 and later	2.1
6.1 and later	1.1
6.0.1 and later	1.0
6.0.0 and earlier	0.9.0

Partition Assignment in Release 7.8.0 and Later

Release 7.8.0 added a significant change to the Consumer behavior related to partition assignment flow. In release 7.8.0 and later, partition assignment happens synchronously, according to the Apache Kafka contract defined in [ConsumerRebalanceListener](#).

The process of updating the consumer assignment from the client side and invoking all related callbacks (in [ConsumerRebalanceListener](#)) happens within the `consumer.poll()` call in the user thread. This means that even after you call `consumer.assign()` / `consumer.subscribe()`, the new assignment will not come up to your consumer (the result of the `consumer.assignment()` call will not update) until you invoke `consumer.poll()`. You might need to do this multiple times or configure a longer timeout to complete the assignment in time. Also, the callback methods of the [ConsumerRebalanceListener](#) class are now guaranteed to be called synchronously from within the poll call by the user thread.

By comparison, with the old behavior, the partition assignment happened asynchronously in a background thread after you called `consumer.assign()` / `consumer.subscribe()`. It was enough to sleep for a couple of seconds to update your `consumer.assignment()` result and invoke the callback methods of the [ConsumerRebalanceListener](#) class in a background thread.

The new (synchronous) behavior is toggleable and can be disabled (switched to asynchronous behavior) by setting `streams.async.subscription.callback.enabled=true` in `core-site.xml`. In release 7.8.0 and later, the default value is `false`, meaning that by default the new behavior is enabled.

So, if you're planning to upgrade to release 7.8.0 or later and your application relies on the old behavior in a way that it sleeps right after `consumer.assign()` / `consumer.subscribe()` until partition assignment happens (that is, [ConsumerRebalanceListener](#) callbacks are invoked and the `consumer.assignment()` result is updated), do one of the following:

- Disable the new behavior.

- Redesign your application so that it starts polling without the new assignment and uses [ConsumerRebalanceListener#onPartitionsAssigned\(\)](#) as a way to notify about successful assignment.

Synchronous Consumer Partition Assignment

As of HPE Data Fabric 7.8, synchronous consumer partition assignment is supported. For streams created with HPE Data Fabric 7.8 and later, this feature is enabled by default. To disable this feature, set `streams.async.subscription.callback.enabled=true` in `core-site.xml`. By default, this value is set to `false`.

With this feature enabled, consumer assignment updates and the invocation of related callbacks (in [ConsumerRebalanceListener](#)) occur synchronously within the `consumer.poll()` call in the user thread.

When setting a new consumer partition assignment, `consumer.assignment()` does not update until you invoke `consumer.poll()`.

NOTE: For the call to update, you might have to invoke `consumer.poll()` multiple times, or with a long enough timeout for assignment to be completed.

IMPORTANT: If you have an application that is set to sleep until consumer partition assignment is updated, you must perform one of the following actions to ensure the application continues to work as intended:

- Disable synchronous consumer partition assignment with `streams.async.subscription.callback.enabled=true` in `core-site.xml`.
- Enable the application to begin polling without the new user assignment. You can use [ConsumerRebalanceListener#onPartitionsAssigned\(\)](#) to notify of successful consumer partition assignment.

Log Compaction

As of HPE Data Fabric 6.1, log compaction is supported. Log compaction can be enabled for streams created with HPE Data Fabric core 6.1 and later. In addition, clients older than HPE Data Fabric 6.1 are prevented from consuming from streams that have had log compaction enabled on them at least once in their lifetime.

When a stream on a source cluster has both log compaction and replication enabled, the replica cluster does not automatically have log compaction enabled. You must explicitly enable log compaction on the replica cluster.

- If a replica cluster has been upgraded and the stream data for a source cluster is compacted (that is, one or more messages have been deleted), then the source cluster replicates the compacted data to the replica cluster.
- If a replica cluster has **not** been upgraded, then the source cluster fails the replication and an error is generated that requests a replica cluster upgrade.

In the context of a scan by a client that is **not** upgraded, the (upgraded) server inspects the row header to check if it is serving a compacted row. If it is serving a compacted row, then the server fails the consumer request. This behavior applies both to a stream that is explicitly configured for compaction and a replica that has received a compacted row.

IMPORTANT: To perform log compaction on older streams, the `-force` option can be used. The `-force` option should only be used when ALL clients have been upgraded to HPE Data Fabric 6.1.

Idempotent Producer

As of HPE Data Fabric 6.1, the idempotent producer (exactly once) feature is supported. You can implement the idempotent producer with HPE Data Fabric core 6.1 and later.

NOTE: For HPE Data Fabric 7.8 and later, the idempotent producer feature is enabled by default.

When creating a producer instance, use the following configuration:

```
props.put(ProducerConfig.ENABLE_IDEMPOTENCE_CONFIG, true)
```

The idempotent producer feature is supported by EEP HPE Data Fabric 6.0 clients and HPE Data Fabric 6.1.0 servers.

- You must upgrade all servers to v6.1.0 and enable all the v6.1.0 features, before you enable the idempotent producer.
- If you use a pre-HPE Data Fabric 6.1 client and a HPE Data Fabric 6.1 server, and if a group of messages are atomically persisted without a valid producer ID, the server treats the request as a non-idempotent producer.
- If you use a HPE Data Fabric 6.1 client and a pre-HPE Data Fabric 6.1 server, the idempotent producer is not supported. In this case, the idempotent producer fails to produce to the stream and the following exception is thrown:

```
Exception in thread "main" java.util.concurrent.ExecutionException:
org.apache.kafka.common.errors.UnknownTopicOrPartitionException:

```

TimestampType Permissions

The following discussion describes the [ACE](#) permissions that you need when using the timestamp type parameter. See [Stream Security](#) on page 874 for general information about HPE Data Fabric Streams streams security.

A HPE Data Fabric Streams stream topic inherits the default timestamp type value from its stream. To override the stream's default value, set the timestamp type for the topic to a different value.

- Setting the value at the stream-level requires `adminperm` permissions. The stream-level timestamp type parameter is `defaulttimestamptype`. See [stream create](#) on page 2708 and [stream edit](#) on page 2715 for more information on setting this parameter using the `maprc li` command.
- Setting the `timestamptype` at the topic-level requires `topicperm` permissions. The topic-level timestamp type parameter is `timestamptype`. See [stream topic create](#) on page 2731 and [stream topic edit](#) on page 2734 for more information on setting this parameter using the `maprc li` command.

User Impersonation

As of HPE Data Fabric 6.0, user impersonation is supported for HPE Data Fabric Streams.

You can set up user impersonation programmatically. To do so, use the `UserGroupInformation.doAs()` method in the Hadoop documentation. See [Class UserGroupInformation](#) for more information.

If you are setting up user impersonation in a secure cluster, you need to generate an impersonation ticket. See the Generating and Printing Service with Impersonation Ticket section in the [maprlogin Command Examples](#) on page 3287 topic.

After generating the ticket:

1. Ensure that user `mapruser1` has read permissions on the ticket.
2. If you moved the ticket file to a different location, set the `$MAPR_TICKETFILE_LOCATION` environment variable with the appropriate path.

For more information about impersonation, see:

- [How Impersonation Works](#) on page 2215
- [Generating a Service with Impersonation Ticket](#) on page 2104
- [Managing Impersonation](#) on page 2214

Backward Compatibility

As of HPE Data Fabric 6.0.1, along with the support of Apache Kafka, the `java.util.Collection` interface is being used. This impacts applications using certain APIs. See [HPE Data Fabric Streams Java API Library](#) on page 3967 for detailed information.

References

- [HPE Data Fabric Streams Sample Programs](#) on GitHub.

HPE Data Fabric Streams Java API Library

Use the HPE Data Fabric Streams Admin Java API library as an alternative to `maprc li` commands and the REST APIs for performing administrative tasks on streams and topics. This library can also be used for analysis of the contents of streams.

Javadoc

The following Apache Kafka Java API versions are supported:

Table

Core version	Apache Kafka API
7.8 and later	3.6.1
7.0 through 7.7	2.6.1
6.2 and later	2.1.1
6.1 and later	1.1
6.0.1 and later	1.0
6.0.0 and earlier	0.90

See the following APIs for detailed information:

HPE Data Fabric Streams Java APIs (as of 7.8)

The following HPE Data Fabric Streams Java APIs are available as of HPE Data Fabric 7.8:

Table

Interface	Method	Description
StreamDescriptor	void setCompact(boolean compact)	Sets log compaction on a stream.
StreamDescriptor	boolean getCompact()	Gets the log compaction on a stream. Returns true if the stream has log compaction on the stream.
StreamDescriptor	void setMinCompactionLagMS(long ts)	Sets the time in (milliseconds) that a message should remain uncompacted in the topic-partition. Applies only if log compaction is enabled on the stream.
StreamDescriptor	long getMinCompactionLagMS()	Returns the minimum time (in milliseconds) a message will remain uncompacted in the topic-partition. Applies only if log compaction is enabled on the stream.
StreamDescriptor	void setDeleteRetentionMS(long ts)	Sets the time (in milliseconds) for which deleted records are retained. Applies only if log compaction is enabled on the stream.
StreamDescriptor	long getDeleteRetentionMS()	Returns the time (in milliseconds) for which deleted records are retained. Applies only if log compaction is enabled on the stream.
Producer	ProducerConfig class	The idempotence producer option is set by setting the enable.idempotence value of true passed through the ProducerConfig class.

NOTE: For Apache Kafka 3.6.1, some methods are not supported.

Admin methods:

- Using Topic IDs:
 - `DescribeTopicsResult describeTopics(TopicCollection topics, DescribeTopicsOptions options)`

- `DeleteTopicsResult deleteTopics(TopicCollection topics, DeleteTopicsOptions options)`

- With more than one group:

```
ListConsumerGroupOffsetsResult
listConsumerGroupOffsets(Map<String, ListConsumerGroupOffsetsSpec>
groupSpecs, ListConsumerGroupOffsetsOptions options)
```

- And the following additional methods:

```
public DescribeUserScramCredentialsResult
describeUserScramCredentials(List<String> users,
DescribeUserScramCredentialsOptions options) {
public AlterUserScramCredentialsResult
alterUserScramCredentials(List<UserScramCredentialAlteration>
alterations, AlterUserScramCredentialsOptions options) {
public DescribeFeaturesResult
describeFeatures(DescribeFeaturesOptions options) {
public UpdateFeaturesResult updateFeatures(Map<String, FeatureUpdate>
featureUpdates, UpdateFeaturesOptions options) {
public DescribeMetadataQuorumResult
describeMetadataQuorum(DescribeMetadataQuorumOptions options) {
public UnregisterBrokerResult unregisterBroker(int brokerId,
UnregisterBrokerOptions options) {
public DescribeProducersResult
describeProducers(Collection<TopicPartition> partitions,
DescribeProducersOptions options) {
public DescribeTransactionsResult
describeTransactions(Collection<String> transactionalIds,
DescribeTransactionsOptions options) {
public AbortTransactionResult abortTransaction(AbortTransactionSpec
spec, AbortTransactionOptions options) {
```

Consumer methods:

- `OptionalLong currentLag(TopicPartition topicPartition)`
- `void enforceRebalance(String reason)`

HPE Data Fabric Streams Java APIs (as of 6.0.1)

The following table lists the new Interfaces and APIs for HPE Data Fabric 6.0.1. They are the delta between HPE Data Fabric 6.0.1 and 6.0.0, meaning, they are applicable to HPE Data Fabric 6.0.1 but not HPE Data Fabric 6.0.0.

Table

Interface and Methods	Description
Admin.close	Long duration for TimeUnit.
Admin.createTopic	TopicDescriptor array for topic attributes.
Admin.editTopic	TopicDescriptor array for topic attributes.
Admin.getTopicDescriptor	Method for retrieving topic attributes.

Table (Continued)

Interface and Methods	Description
Admin.listTopic	Method for listing all the topics in a stream.
Admin.streamExists	Method for determining whether a stream exists.
StreamDescriptor.getDefaultTimestampType	Method for retrieving the timestamp type.
StreamDescriptor.setDefaultTimestampType	Method for setting the timestamp type.
TopicDescriptor	New HPE Data Fabric interface.
TopicDescriptor.getPartitions	Method associated with the new interface.
TopicDescriptor.setPartitions	Method associated with the new interface.
TopicDescriptor.getTimestampType	Method associated with the new interface.
TopicDescriptor.setTimestampType	Method associated with the new interface.
Enum TimestampType	New Enum class and associated methods.

Backward Compatibility

As of HPE Data Fabric 6.0.1, Apache Kafka 1.0 is supported. The following pause, resume, seekToBeginning, and seekToEnd APIs support the Collection Interface. The deprecated APIs will continue to run unchanged, however, they may be removed in a future release.

Table

Replacement Collection APIs	Deprecated APIs
void pause(Collection<TopicPartition> partitions);	void pause(TopicPartition... partitions);
void resume(Collection<TopicPartition> partitions);	void resume(TopicPartition... partitions);
void seekToBeginning(Collection<TopicPartition>);	void seekToBeginning(TopicPartition... partitions);
void seekToEnd(Collection<TopicPartition>);	void seekToEnd(TopicPartition... partitions);

The following subscribe and assign APIs support the Collection Interface (which is more generalized) as well as the List Interface. Support for the List Interface has been retained for backward binary compatibility.

Table

Replacement Collection APIs	Retained APIs
void subscribe(Collection<String> topics);	void subscribe(java.util.List<java.lang.String> topics);
void subscribe(Collection<String> topics, ConsumerRebalanceListener);	void subscribe(java.util.List<java.lang.String> topics, ConsumerRebalanceListener listener);
void assign(Collection<TopicPartition> partitions);	void assign(java.util.List<TopicPartition> partitions);

Stream and Topic Operations Summary

Provides a summary of stream topic operations and the interface, class, or method used for the operation.

The following stream and topic operations is not an inclusive list, but a sampling. For detailed information, see the following libraries:

Table

Operation	Interface/Method Used
Creating streams	StreamDescriptor is used to set the attributes for streams that you plan to create. Admin.createStream(String streamPathAndName, StreamDescriptor desc) - create the stream.
Editing stream attributes	StreamDescriptor is used to edit the stream's attribute values. Admin.editStream(String streamPathAndName, StreamDescriptor desc) - set or modify the stream's attribute values.
Retrieving the default timestamp type on a stream	StreamDescriptor.getDefaultTimestampType() - retrieves the default timestamp type on the stream.  NOTE: This method is new as of 6.0.1
Sets the default timestamp type on a stream	StreamDescriptor.setDefaultTimestampType(TimestampType logAppendTime) - sets the default timestamp type on the stream.  NOTE: TimestampType Enum is new as of 6.0.1
Deleting streams	Admin.deleteStream(String streamPathAndName)
Determining stream existence	Admin.streamExists(String streamPathAndName) - determines whether a stream exists or not. Returns: true false  NOTE: This method is new as of 6.0.1
Creating topics	Admin.createTopic(String streamPathAndName, String topicName, TopicDescriptor desc) is used when creating a topic with the defaults for partitions and timestamp type.  NOTE: TopicDescriptor is new as of 6.0.1 Admin.createTopic(String streamPathAndName, String topicName) is used when accepting the default number of partitions. Admin.createTopic(String streamPathAndName, String topicName, int npartitions) - creates a topic with a specific number of partitions.  NOTE: If you do not specify the number of partitions for a stream topic, the default number of partitions is inherited from the stream.
Editing topics	Admin.editTopic(String streamPathAndName, String topicName, TopicDescriptor desc) - sets the partitions and timestamp type attributes of a topic.  NOTE: TopicDescriptor is new as of 6.0.1 Admin.editTopic(String streamPathAndName, String topicName, int npartitions)
Retrieving topic attributes	Admin.getTopicDescriptor(String streamPathAndName, String topicName) - retrieves topic attributes.  NOTE: This method is new as of 6.0.1
Deleting topics	Admin.deleteTopic(String streamPathAndName, String topicName) - deletes topics.

Table (Continued)

Operation	Interface/Method Used
Listing topics	<p><code>Admin.listTopics(String streamPathAndName)</code> - lists all topics in a stream.</p> <p> NOTE: This method is new as of 6.0.1</p>
Counting topics	<p><code>Admin.countTopics(String streamPathAndName)</code> - counts the number of topics in a stream.</p>
Gets/Sets topic timestamp type	<p>TopicDescriptor is used to retrieve the timestamp type attribute value of a topic.</p> <p> NOTE: TopicDescriptor is new as of 6.0.1</p> <p><code>TopicDescriptor.getTimestampType()</code> - retrieves the default timestamp type of a topic.</p> <p><code>TopicDescriptor.setTimestampType(TimestampType timestampType)</code> - sets the default timestamp type of a topic.</p>
Gets/Sets topic partitions	<p>TopicDescriptor is used to retrieve the partition attribute value of a topic.</p> <p> NOTE: TopicDescriptor is new as of 6.0.1</p> <p><code>TopicDescriptor.getPartitions()</code> - retrieves the partitions of a topic.</p> <p><code>TopicDescriptor.setPartitions(int numPartitions)</code> - sets the partitions of a topic.</p>
Enabling and tuning log compaction	<p>TopicDescriptor is used to enable and tune log compaction at the stream-level.</p> <ul style="list-style-type: none"> <code>setCompact(boolean compact)</code> - sets log compaction. <code>getCompact()</code> - returns true if log compaction is set on the stream. <code>setMinCompactionLagMS(long ts)</code> - set the lag time (in milliseconds) that a message should remain uncompactd. <code>getMinCompactionLagMS()</code> - retrieves the value of the lag time. <code>setDeleteRetentionMS(long ts)</code> - sets the time (in milliseconds) for which deleted records are retained. <code>getDeleteRetentionMS()</code> - returns the time value of which deleted records are retained. <p>In addition, the Admin interface is used with the following method to set compaction at the topic-level:</p> <ul style="list-style-type: none"> <code>compactTopic(java.lang.String streamPath, java.lang.String topicName)</code>
Enabling an Idempotent Producer	<p>The Producer interface along with the ProducerConfig class is used to enable idempotence (exact-once message delivery semantics) publishing.</p>

Managing Streams with Java

Provides Java code snippets for performing CRUD operations on HPE Data Fabric Streams streams.

Creating Streams

StreamDescriptor is used to set attributes for streams that you want to create.

```
public StreamDescriptor createStreamDescriptor(int numPartitions, String
adminUsers, String producerUsers, String consumerUsers, String copyUsers,
```

```
String topicUsers) {
    StreamDescriptor desc = Streams.newStreamDescriptor();
    desc.setDefaultPartitions(numPartitions);
    desc.setCompressionAlgo("zlib");
    desc.setAutoCreateTopics(false);
    desc.setAdminPerms(adminUsers);
    desc.setConsumePerms(consumerUsers);
    desc.setCopyPerms(copyUsers);
    desc.setTopicPerms(topicUsers);

    return desc;
}
```

Admin is used with the createStream method to create the stream with the pre-established attribute values.

```
public void createStreamUtilFunction(String streamPathAndName,
StreamDescriptor desc) throws IllegalArgumentException, IOException{
    Configuration conf = new Configuration();
    Admin streamAdmin = Streams.newAdmin(conf);
    streamAdmin.createStream(streamPathAndName, desc);
    streamAdmin.close();
}
```

Editing Stream Attributes

StreamDescriptor is used to retrieve the stream's attribute values. Admin with the editStream method is used to set or modify the stream's attribute values.

```
Admin.editStream(String streamPathAndName, StreamDescriptor desc)
```

```
Configuration conf = new Configuration();
Admin streamAdmin = Streams.newAdmin(conf);
    StreamDescriptor desc =
streamAdmin.getStreamDescriptor(streamPathAndName);
```

```
public void editStreamUtilFunction(String streamPathAndName,
StreamDescriptor desc) throws IllegalArgumentException, IOException{
    Configuration conf = new Configuration();
    Admin streamAdmin = Streams.newAdmin(conf);
    streamAdmin.editStream(streamPathAndName, desc);
    streamAdmin.close();
}
```

Deleting Streams

```
public void deleteStreamUtilFunction(String streamPathAndName) throws
IllegalArgumentException, IOException{
    Configuration conf = new Configuration();
    Admin streamAdmin = Streams.newAdmin(conf);
    streamAdmin.deleteStream(streamPathAndName);
    streamAdmin.close();
}
```

Managing Topics with Java

Provides Java code snippets for performing CRUD operations on HPE Data Fabric Streams stream topics.

Creating Topics

The createTopic API is used to create a topic with the default number of partitions.

```
Admin.createTopic(String streamPathAndName, String topicName)
```

NOTE: If you do not specify the number of partitions for a stream topic, the default number of partitions is inherited from the stream.

```
public void createTopicUtilFunction(String streamPathAndName, String
topicName) throws IOException{
    Configuration conf = new Configuration();
    Admin streamAdmin = Streams.newAdmin(conf);
    streamAdmin.createTopic(streamPathAndName, topicName);
    streamAdmin.close();
}
```

The createTopic API is used to create a topic with a specific number of partitions.

```
Admin.createTopic(String streamPathAndName, String topicName, int
npartitions)
```

```
public void createTopicWithPartitionsUtilFunction(String streamPathAndName,
String topicName, int npartitions) throws IOException{
    Configuration conf = new Configuration();
    Admin streamAdmin = Streams.newAdmin(conf);
    streamAdmin.createTopic(streamPathAndName, topicName, npartitions);
    streamAdmin.close();
}
```

Editing Topics

The editTopic API is used to change timestamp type and the number of partitions for a topic.

```
Admin.editTopic(String streamPathAndName, String topicName, int npartitions)
```

```
public void editTopicUtilFunction(String streamPathAndName, String
topicName, int npartitions) throws IOException{
    Configuration conf = new Configuration();
    Admin streamAdmin = Streams.newAdmin(conf);
    streamAdmin.editTopic(streamPathAndName, topicName, npartitions);
    streamAdmin.close();
}
```

Retrieving Topic Attributes

The getTopicDescriptor API is used to get or set the topic's attribute values. TopicDescriptor is passed into methods to set and retrieve topic partitions and timestamp type. The Enum TimestampType values are CREATE_TIME and LOG_APPEND_TIME.

NOTE: TopicDescriptor is available as of MapR 6.0.1.

Deleting Topics

The `deleteTopic` API is used to delete a topic from a stream.

```
Admin.deleteTopic(String streamPathAndName, String topicName)
```

```
public void deleteTopicUtilFunction(String streamPathAndName, String
topicName) throws IOException{
    Configuration conf = new Configuration();
    Admin streamAdmin = Streams.newAdmin(conf);
    streamAdmin.deleteTopic(streamPathAndName, topicName);
    streamAdmin.close();
}
```

Counting Topics

The `countTopics` API is used to count the number of topics in a stream. See the [mapr streamanalyzer](#) on page 7464 utility for a sample application that counts and queries topic messages.

```
Admin.countTopics(String streamPathAndName)
```

```
public int countTopicsUtilFunction(String streamPathAndName){
    Configuration conf = new Configuration();
    Admin streamAdmin = Streams.newAdmin(conf);
    int count = streamAdmin.countTopics(streamPathAndName);
    streamAdmin.close();

    return count;
}
```

Using Timestamps on Streams and Topics

Provides a code example for using timestamps on HPE Data Fabric Streams streams and topics.

Passing Timestamp Value

The timestamp value can be passed as part of the `ProducerRecord`, for example:

```
ProducerRecord<String, String> producerRecord =
    new ProducerRecord<String, String>(topicName, partition, timestamp,
key, value);
```

NOTE: The timestamp value is retained if the timestamp type is `createtime`. If the timestamp type is `logappendtime`, then the timestamp value is ignored and instead the server timestamp is used.

Retrieving Timestamp Type

This example sets and retrieves the timestamp type. The following code example performs the following:

- Creates a stream with a default timestamp type of `LogAppendTime`.
- Creates a topic with a specific timestamp type of `CreateTime`.
- Retrieves the topics's timestamp type.

```
// Create stream with default timestamp type as "LogAppendTime"
// Create a topic with timestamp type as "CreateTime"
Configuration conf = new Configuration();
Admin streamAdmin = Streams.newAdmin(conf);
```

```
// Create a stream
    StreamDescriptor sDesc = Streams.newStreamDescriptor();
    sDesc.setDefaultTimestampType(TimestampType.LOG_APPEND_TIME);
    streamAdmin.createStream(streamName, sDesc);

// Create a topic
    TopicDescriptor tDesc = Streams.newTopicDescriptor();
    tDesc.setTimestampType(TimestampType.CREATE_TIME);
    streamAdmin.createTopic(streamName, topicName, tDesc);

// Get topic timestamp type
    TopicDescriptor rDesc = streamAdmin.getTopicDescriptor(streamName,
topicName);
    System.out.println(rDesc.getTimestampType().name);
```

Enabling Log Compaction

Provides a code example for using timestamps on HPE Data Fabric Streams streams and topics.

Log compaction is enabled through the HPE Data Fabric Streams StreamDescriptor interface with the setCompact method where the compact value is set to **true**. Additionally, use the setDeleteRetentionMS and setMinCompactionLagMS methods to set the time delay before compacting records and the time that deleted records are retained.

Configuration values include:

- compact - used to set log compaction at the stream-level.
- min.compaction.lag.ms - used to set a **minimum** time delay (milliseconds) before starting to compact records after they are written. Records won't get compacted until after this period. The setting gives consumers time to retrieve every record.
- delete.retention.ms - used to set the **minimum** time (milliseconds) that deleted records are retained.

NOTE: You can set not set log compaction when creating the stream; only when editing the stream configuration. The configuration parameters, min.compaction.lag.ms and delete.retention.ms can be set when both creating and editing streams.

Enabling Log Compaction

The following code example performs the following:

- Enables log compaction at the stream-level.
- Sets the mininum time delay before log compaction starts
- Set the minimum time that deleted record are retained.

```
// Creates a stream
// Sets log compaction on the stream
// Sets the minimum time for a message to stay uncompactd
// Sets the time that deleted records are retained.

(Admin streamAdmin = Streams.newAdmin(conf))
    StreamDescriptor streamDescriptor = Streams.newStreamDescriptor();
    streamDescriptor.setCompact(true);
    streamDescriptor.setDeleteRetentionMS(deleteRetentionMs);
    streamDescriptor.setMinCompactionLagMS(minCompactionLagMs);
    streamAdmin.editStream(streamName, streamDesc);
}
```

For More Information

See the following topics for more information:

- [Log Compaction](#) on page 851
- maprccli [stream create](#) on page 2708 and [stream edit](#) on page 2715
- [Preparing Clusters for Log Compaction](#) on page 1775

Enabling an Idempotent Producer

Describes how to enable an idempotent producer. Idempotence refers to exactly-once message delivery semantics.

To enable idempotence, the `enable.idempotence` configuration must be set to **true**. When set, the `retries` configuration defaults to `Integer.MAX_VALUE` and the `Acks` configuration defaults to `all`.

The idempotence producer option is set by setting the `enable.idempotence` value of `true` passed through the `ProducerConfig` class.

Constant Field Values		
org.apache.kafka.clients.producer.ProducerConfig		
Modifier and Type	Constant Field	Value
public static final java.lang.String	ENABLE_IDEMPOTENCE_CONFIG	enable.idempotence

Example Code Snippet:

```
props.put(ProducerConfig.ENABLE_IDEMPOTENCE_CONFIG, true);
```

NOTE: The default is false, which retains at-least-once message delivery semantics.

TIP: There are no API changes for the Idempotent Producer functionality, so existing applications do not need to be modified except to enable the producer configuration property.

Example: Subscribing and Querying with Timestamps

This sample Java consumer application uses the `subscribe` API to subscribe to the input topics and queries offsets upon partition-assignment.

In the query, the `offsetsForTimes` API returns the earliest offset in a topic-partition with a timestamp greater than or equal to the input timestamp. The consumer then seeks to that offset if it is greater than the consumer's current position. Following this, the consumer polls for messages. If there are messages following that offset with timestamps earlier than the input timestamp, then those messages are skipped by the consumer.

```
import java.util.Arrays;
import java.util.Collection;
import java.util.HashMap;
import java.util.Map;
import java.util.Properties;

import org.apache.kafka.clients.consumer.Consumer;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRebalanceListener;
import org.apache.kafka.clients.consumer.ConsumerRecord;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.clients.consumer.OffsetAndTimestamp;
import org.apache.kafka.common.TopicPartition;
```

```

public class TimeBasedConsumer {
    private static long kPollTimeout = 100;
    private static int kNumRecordsToProcess = 10;

    public static void main(String[] args) {
        if (args.length < 2) {
            String usage = "Usage: Program <topicName> <startTimestamp>";
            System.err.println(usage);
            throw new IllegalArgumentException(usage);
        }
        String topic = args[0];
        Long startTimestamp = Long.parseLong(args[1]);
        Properties properties = new Properties();
        properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
"org.apache.kafka.common.serialization.StringDeserializer");
        properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
"org.apache.kafka.common.serialization.StringDeserializer");
        properties.put(ConsumerConfig.GROUP_ID_CONFIG, "testgroup");
        properties.put(ConsumerConfig.AUTO_OFFSET_RESET_CONFIG, "earliest");
        KafkaConsumer<String, String> consumer = new KafkaConsumer<String,
String>(properties);
        SeekToTimeOnRebalance seekToTimeOnRebalance = new
SeekToTimeOnRebalance(consumer, startTimestamp);

        // subscribe to the input topic and listen for assignments.
        consumer.subscribe(Arrays.asList(topic), seekToTimeOnRebalance);

        int numRecords = 0;
        // poll and process the records.
        while (numRecords < kNumRecordsToProcess) {
            ConsumerRecords<String, String> records =
consumer.poll(kPollTimeout);
            for (ConsumerRecord<String, String> record : records) {
                // The offsetsForTimes API returns the earliest offset in a
topic-partition with a timestamp
                // greater than or equal to the input timestamp. There could be
messages following that offset
                // with timestamps lesser than the input timestamp. Let's skip such
messages.
                if (record.timestamp() < startTimestamp) {
                    System.out.println("Skipping out of order record with key " +
record.key() +
                                " timestamp " + record.timestamp());
                    continue;
                }
                numRecords++;
                System.out.println("record key " + record.key() +
                                "record timestamp " + record.timestamp() +
                                "record offset " + record.offset());
            }
        }
        consumer.close();
    }

    public static class SeekToTimeOnRebalance implements
ConsumerRebalanceListener {
        private Consumer<?, ?> consumer;
        private final Long startTimestamp;

        public SeekToTimeOnRebalance(Consumer<?, ?> consumer, Long
startTimestamp) {
            this.consumer = consumer;
            this.startTimestamp = startTimestamp;
        }
    }
}

```

```

    }

    @Override
    public void onPartitionsAssigned(Collection<TopicPartition> partitions)
    {
        Map<TopicPartition, Long> timestampsToSearch = new HashMap<>();
        for (TopicPartition partition : partitions) {
            timestampsToSearch.put(partition, startTimestamp);
        }
        // for each assigned partition, find the earliest offset in that
        partition with a timestamp
        // greater than or equal to the input timestamp
        Map<TopicPartition, OffsetAndTimestamp> outOffsets =
        consumer.offsetsForTimes(timestampsToSearch);
        for (TopicPartition partition : partitions) {
            Long seekOffset = outOffsets.get(partition).offset();
            Long currentPosition = consumer.position(partition);
            // seek to the offset returned by the offsetsForTimes API
            // if it is beyond the current position
            if (seekOffset.compareTo(currentPosition) > 0) {
                consumer.seek(partition, seekOffset);
            }
        }
    }

    @Override
    public void onPartitionsRevoked(Collection<TopicPartition> partitions) {
    }

}
}

```

Querying Topic Messages

Describes how HPE Data Fabric Streams topic messages can be queried.

Time-based Querying

The **consumer.offsetsForTimes** API is used to get offsets in a topic-partition. This API takes in a Map of TopicPartition and timestamp. The offset is returned in an OffsetAndTimestamp object when offsetsForTime is called.

The following shows how the Map is constructed:

```

Long timestamp = 1522195205L;
TopicPartition topicPartition = new TopicPartition(topic,partition);

HashMap<TopicPartition, Long> offsetsForTimesMap = new
HashMap<TopicPartition, Long>();
offsetsForTimesMap.put(topicPartition, timestamp);

// Invocation to offsetsForTimes
Map<TopicPartition, OffsetAndTimestamp> offsetForTimesResultMap =
consumer.offsetsForTimes(offsetsForTimesMap);

```

Direct Querying

The Streams class is used to directly query topic messages. See the [mapr streamanalyzer](#) on page 7464 utility for a sample application that counts and queries topic messages.

- The getMessageStore() APIs are used to get the DocumentStore object which represents the underlying topic messages for a specified stream.

- The `DocumentStore.find()` APIs are used to query the messages that are in the `DocumentStore` object. While running `find()` on the returned `DocumentStore` object, message fields can be projected based on the specified field name.

NOTE: `DocumentStore` is a part of the open-source OJAI API.

The logical schema of each message is the same, where analytics applications can run queries on these fields. See [Logical Schema of Messages](#) on page 845 for more information.

```
{
  "_id":<STRING>,
  "topic":<STRING>,
  "partition":<SHORT>,
  "offset":<LONG>,
  "timestamp":<LONG>,
  "producer":<VARCHAR>,
  "key":<BINARY>,
  "value":<VARBINARY>
}
```

Apache Kafka Java APIs

HPE Data Fabric Streams supports these Apache Kafka Java APIs.

Javadoc

For information about EEP and core version support, see [Ecosystem Pack Support and Lifecycle Status](#) on page 7664.

See the following APIs for detailed information:

- [HPE Data Fabric Streams Java API Library](#)
- For core 7.8 and above: [Apache Kafka 3.6.1 APIs used with HPE Data Fabric Streams](#)
- For core 7.7 and below: [Apache Kafka 2.6.1 APIs used with HPE Data Fabric Streams](#)

Admin APIs

The following Admin APIs, `org.apache.kafka.clients.admin` package, are applicable to HPE Data Fabric support of Apache Kafka.

NOTE: The AdminClient API options (`CreateTopicsOptions`, `DeleteTopicsOptions`, `DescribeTopicsOptions`, `ListTopicsOptions`, `CreatePartitionsOptions`, and `DescribeTopicsOptions`), are ignored. All of the methods assume that a topic belongs to the default stream unless a stream path is specified in the topic name.

If a default stream name is not specified and the topic path does not contain a stream name, the an exception is reported via the Result object. For example:

- If the topic name is specified as `topic1`, then the API assumes the full topic path as `/defaultStream:topic1`.
- If the topic name is specified as `/defaultStream:topic1`, then that will be the full topic path.

NOTE: The AdminClient default stream configuration parameter is `streams.admin.default.stream`. See [Configuration Parameters](#) on page 3983 for more information.

NOTE: For a complete list of supported APIs, see:

- For core 7.8 and above: [Apache Kafka 3.6.1 APIs used with HPE Data Fabric Streams](#)
- For core 7.7 and below: [Apache Kafka 2.6.1 APIs used with HPE Data Fabric Streams](#)

Consumer APIs

The following Consumer APIs, `org.apache.kafka.clients.consumer` package, are applicable to HPE Data Fabric support of Apache Kafka.

Table

Modifier and Type	Method
long	timestamp()
long	timestamptype()

Table

Modifier and Type	Method
void	pause(Collection<TopicPartition> partitions)
void	resume(Collection<TopicPartition> partitions)
void	seekToBeginning(Collection<TopicPartition>)
void	seekToEnd(Collection<TopicPartition>)
void	subscribe(Collection<String> topics);
void	subscribe(Collection<String> topics, ConsumerRebalanceListener)
void	assign(Collection<TopicPartition> partitions)
java.util.Map<TopicPartition, OffsetAndTimestamp>	offsetsForTimes(java.util.Map<TopicPartition, java.lang.Long> timestampsToSearch)
java.util.Map<TopicPartition, java.lang.Long>	beginningOffsets(Collection<TopicPartition>)
java.util.Map<TopicPartition, java.lang.Long>	endOffsets(Collection<TopicPartition> partitions)
ConsumerRecords<K,V>	poll(long timeout)
void	commitSync()
void	commitAsync()

The following consumer interface and classes are applicable to HPE Data Fabric support of Apache Kafka.

- `org.apache.kafka.clients.consumer.ConsumerConfig`
- `org.apache.kafka.clients.consumer.ConsumerRebalanceCallback` (interface)
- `org.apache.kafka.clients.consumer.ConsumerRecord<K,V>`
- `org.apache.kafka.clients.consumer.ConsumerRecords<K,V>`
- `org.apache.kafka.clients.consumer.KafkaConsumer<K, V>` implements `Consumer<K, V>`

NOTE: For a complete list of supported APIs, see:

- For core 7.8 and above: [Apache Kafka 3.6.1 APIs used with HPE Data Fabric Streams](#)
- For core 7.7 and below: [Apache Kafka 2.6.1 APIs used with HPE Data Fabric Streams](#)

Producer APIs

The following producer interface and classes, `org.apache.kafka.clients.producer` package, are applicable to HPE Data Fabric support of Apache Kafka.

Table

Modifier and Type	Method
<code>java.util.concurrent.Future<RecordMetadata></code>	<code>send(ProducerRecord<K,V> record)</code>
<code>void</code>	<code>flush()</code>
<code>void</code>	<code>close()</code>

The following producer interface and classes are applicable to HPE Data Fabric support of Apache Kafka.

- `org.apache.kafka.clients.producer.Callback` (Interface)
- `org.apache.kafka.clients.producer.KafkaProducer<K,V>`
- `org.apache.kafka.clients.producer.ProducerConfig`
- `org.apache.kafka.clients.producer.ProducerRecord<K,V>`
- `org.apache.kafka.clients.producer.RecordMetadata`

NOTE: For a complete list of supported APIs, see:

- For core 7.8 and above: [Apache Kafka 3.6.1 APIs used with HPE Data Fabric Streams](#)
- For core 7.7 and below: [Apache Kafka 2.6.1 APIs used with HPE Data Fabric Streams](#)

Common APIs

The following common APIs, `org.apache.kafka.clients.common` packages, are applicable to HPE Data Fabric support of Apache Kafka.

Table

Modifier and Type	Method
<code>java.lang.String</code>	<code>key()</code>
<code>byte[]</code>	<code>value()</code>

The following APIs are applicable to HPE Data Fabric support for Apache Kafka.

- `org.apache.kafka.common.PartitionInfo`

Supported methods in `PartitionInfo`:

- `int partition()`
- `java.lang.String topic()`
- `java.lang.String toString()`

- `org.apache.kafka.common.serialization.Serializer<T>` (Interface)
- `org.apache.kafka.common.serialization.Deserializer<T>` (interface)
- `org.apache.kafka.common.TopicPartition`

NOTE: For a complete list of supported APIs, see:

- For core 7.8 and above: [Apache Kafka 3.6.1 APIs used with HPE Data Fabric Streams](#)
- For core 7.7 and below: [Apache Kafka 2.6.1 APIs used with HPE Data Fabric Streams](#)

Configuration Parameters

This topic describes configuration parameters that are either specific to HPE Data Fabric Streams or supported from Apache Kafka.

AdminClient

Table

Parameter	Description
<code>streams.admin.default.stream</code>	<p>This parameter, when set during creation of the AdminClient instance, ensures that the specified stream is using the AdminClient instance for all administrative operations.</p> <p>Syntax:</p> <pre>/mapr/<cluster name>/<volume name>/<stream name></pre>
<code>streams.rpc.timeout.ms</code>	<p>Specifies the length of time in milliseconds to wait for a response from the HPE Data Fabric Streams server if soft mount is configured (<code>fs.mapr.hardmount</code> is set to false). Default: 120000 Minimum: 30000</p> <p> NOTE: Applicable as of MapR 6.0.1, is used instead of <code>fs.mapr.rpc.timeout</code></p> <p>For producer and consumer applications, make sure the <code>streams.rpc.timeout.ms</code> configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.</p>

Table (Continued)

Parameter	Description
<code>use.brokers</code>	<p>A boolean flag that specifies whether or not the Apache Kafka clients (Producer, Consumer, Admin) should connect to Apache Kafka brokers or HPE Data Fabric Streams services. Default: <code>false</code></p> <p>false To connect the Apache Kafka clients to HPE Data Fabric Streams services, set this flag as <code>false</code>. The <code>bootstrap.servers</code> property is optional and is ignored.</p> <p>true To connect the Apache Kafka clients to Apache Kafka brokers, set this flag as <code>true</code>. The <code>bootstrap.servers</code> property is required, and must be filled in the client configuration and console scripts.</p>

Consumer

Table

Parameter	Description
<code>streams.consumer.buffer.memory</code>	Specifies how much memory to use for caching pre-fetched messages. Messages that are in subscribed topics and partitions are pre-fetched and cached to improve performance. Default 64MB
<code>streams.consumer.default.stream</code>	Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream.
<code>streams.rpc.timeout.ms</code>	<p>Specifies the length of time in milliseconds to wait for a response from the HPE Data Fabric Streams server if a soft mount is configured (<code>fs.mapr.hardmount</code> is set to <code>false</code>). Default: 305000 Minimum: 300000</p> <p>For producer and consumer applications, make sure the <code>streams.rpc.timeout.ms</code> configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.</p>

Table (Continued)

Parameter	Description
<code>use.brokers</code>	<p>A boolean flag that specifies whether or not the Apache Kafka clients (Producer, Consumer, Admin) should connect to Apache Kafka brokers or HPE Data Fabric Streams services. Default: <code>false</code></p> <p>false To connect the Apache Kafka clients to HPE Data Fabric Streams services, set this flag as <code>false</code>. The <code>bootstrap.servers</code> property is optional and is ignored.</p> <p>true To connect the Apache Kafka clients to Apache Kafka brokers, set this flag as <code>true</code>. The <code>bootstrap.servers</code> property is required, and must be filled in the client configuration and console scripts.</p>

Table

Parameter	Description
<code>auto.commit.interval.ms</code>	The frequency in milliseconds that the offsets are committed. Default: 1000ms
<code>auto.offset.reset</code>	<p>Specifies what HPE Data Fabric Streams should do when there is no initial offset, such as when a consumer starts reading from a partition. Default: <code>latest</code></p> <p>earliest Reset the offset to the offset of the earliest message in the partition.</p> <p>latest Reset the offset to the offset of the latest message in the partition.</p>
<code>enable.auto.commit</code>	If true, periodically commits the highest offsets of the messages fetched by the consumer in all of the partitions for the topics that the consumer is subscribed to. Default: <code>true</code>

Table (Continued)

Parameter	Description
<code>fetch.min.bytes</code>	<p>The minimum amount of data the server should return for a fetch request. If insufficient data is available, the server will wait for this minimum amount of data to accumulate before answering the request.</p> <p>This minimum applies to the totality of what a consumer has subscribed to.</p> <p>Works in conjunction with the timeout interval that is specified in the poll function. If the minimum number of bytes is not reached by the time that the interval expires, the poll returns with nothing.</p> <p>For example, suppose the value is set to 6 bytes and the timeout on a poll is set to 100ms. If there are 5 bytes available and no further bytes come in before the 100ms expire, the poll returns with nothing. Default: 1 byte</p>
<code>fetch.max.bytes</code>	<p>The maximum amount of data the server should return for a fetch request. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress.</p> <p> NOTE: This parameter is new as of MapR 6.0.1.</p>
<code>fetch.max.wait.ms</code>	<p>The maximum amount of time the HPE Data Fabric Streams server will block before answering the fetch request if there isn't sufficient data to satisfy the requirement given by <code>fetch.min.bytes</code>.</p>
<code>group.id</code>	<p>A string 2457 up to bytes long that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group ID, multiple consumer processes indicate that they are all part of the same consumer group. Putting consumers into groups provides benefits that are described in Consumer Groups.</p> <p>It is possible for a single consumer to be in a group.</p>
<code>max.poll.records</code>	<p>Places an upper bound on the number of records returned from each call.</p> <p> NOTE: This parameter is new as of MapR 6.0.1.</p>
<code>max.partition.fetch.bytes</code>	<p>The number of bytes of message data to attempt to fetch for each partition in each poll request. These bytes will be read into memory for each partition, so this parameter helps control the memory that the consumer uses. Default: 64KB</p> <p>The size of the poll request must be at least as large as the maximum message size that the server allows or else it is possible for producers to send messages that are larger than the consumer can fetch.</p> <p>If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress.</p> <p> NOTE: This is a behavior change as of MapR 6.0.1.</p>

Producer**Table**

Parameter	Description
<code>streams.buffer.max.time.ms</code>	Messages are buffered in the producer for at most the specified time. A thread will flush all the messages that have been buffered for more than the time specified. Default: 3 * 1000 msec create default stream
<code>streams.parallel.flushers.per.partition</code>	If enabled, producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order. Default: true create default stream
<code>streams.producer.default.stream</code>	Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. Syntax: <div style="background-color: #f0f0f0; padding: 5px; margin: 5px 0;"> <code>/mapr/<cluster name>/<volume name>/<stream name></code> </div> create default stream
<code>fs.mapr.hardmount</code>	Specifies whether to use a hard mount or a soft mount for connections to the MapR Streams server. The default is to use a hard mount and the value is true. If a value for this parameter is set in the <code>core-site.xml</code> file, the value in that file is ignored. create default stream
<code>fs.mapr.rpc.timeout</code>	Specifies the length of time in seconds to wait for a response from the HPE Data Fabric Streams server if the configuration parameter <code>fs.mapr.hardmount</code> is set to false. Default: 300. Minimum value: 30. <div style="background-color: #fff9c4; padding: 5px; margin: 5px 0;">  NOTE: Applicable to MapR 6.0.0 and earlier. As of MapR 6.0.1, use <code>streams.mapr.timeout.ms</code>. </div> If a soft mount is used, the time expires while a producer waits for a response from the HPE Data Fabric Streams server, and the producer used the <code>KafkaProducer.send(ProducerRecord<K,V> record, Callback callback)</code> method, the callback is invoked with the error EAGAIN, which means "Resource temporarily unavailable." create default stream
<code>streams.rpc.timeout.ms</code>	Specifies the length of time in milliseconds to wait for a response from the HPE Data Fabric Streams server if soft mount is configured (<code>fs.mapr.hardmount</code> is set to false). Default: 30000 Minimum: 30000 For producer and consumer applications, make sure the <code>streams.rpc.timeout.ms</code> configuration value for both producers and consumers is set to greater than 50000 to avoid Message Fetch RPC overload.

Table (Continued)

Parameter	Description
<code>use.brokers</code>	<p>A boolean flag that specifies whether or not the Apache Kafka clients (Producer, Consumer, Admin) should connect to Apache Kafka brokers or HPE Data Fabric Streams services. Default: false</p> <p>false To connect the Apache Kafka clients to HPE Data Fabric Streams services, set this flag as false.</p> <p>The <code>bootstrap.servers</code> property is optional and is ignored.</p> <p>true To connect the Apache Kafka clients to Apache Kafka brokers, set this flag as true.</p> <p>The <code>bootstrap.servers</code> property is required, and must be filled in the client configuration and console scripts.</p>

Table

Parameter	Description
<code>buffer.memory</code>	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are generated faster than they can be delivered to the server the producer will block. Default: 33554432
<code>client.id</code>	Producers can tag records with a client ID that identifies the producer. Consumers can then be aware of which producer sent a message or set of messages. Apache Drill or other analytic tools querying messages can include this ID in the filters for their queries. Default: No client ID.
<code>metadata.max.age.ms</code>	The producer generally refreshes the topic metadata from the server when there is a failure. It will also poll for this data regularly. Default: 300 * 1000 msec

Compiling and Running HPE Data Fabric Streams Java Apps

For producer and consumer applications that use the HPE Data Fabric Streams Java API, use Maven to compile and determine the application dependencies. Then, when you run the application, specify those dependencies in the application classpath.

Compile and Determine Dependencies

For an example `pom.xml` file, see [HPE Data Fabric Streams Streams Sample Programs](#) on GitHub.

1. Add the HPE Maven repository to your `pom.xml` file, if it is not already added:

```
<repositories>
  <repository>
    <id>mapr-releases</id>
    <url>https://repository.mapr.com/nexus/content/repositories/
releases</url>
    <snapshots><enabled>true</enabled></snapshots>
    <releases><enabled>true</enabled></releases>
  </repository>
</repositories>
```

2. Add a dependency to the Data Fabric Streams Java client (kafka-clients) project:

```
<dependency>
  <groupId>org.apache.kafka</groupId>
  <artifactId>kafka-clients</artifactId>
  <version><version selected from the repository></version>
</dependency>
```

NOTE: The kafka-clients version mentioned above is an example. The actual version that your application requires is based on the current EEP and Data Fabric core version that you are running. The versions are listed in the following locations: <https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/kafka/kafka-clients/>

3. Add a dependency to the Data Fabric Streams project:

If you are using EEP version 9.1.2 and later:

```
<dependency>
  <groupId>org.apache.kafka</groupId>
  <artifactId>kafka-eventstreams</artifactId>
  <version><version selected from the repository></version>
</dependency>
```

If you are using EEP version 8.1.0 through 9.1.1:

```
<dependency>
  <groupId>com.mapr.kafka</groupId>
  <artifactId>mapr-streams</artifactId>
  <version><version selected from the repository></version>
</dependency>
```

NOTE: The Data Fabric Streams project version mentioned above is an example. The actual version that your application requires is based on the current EEP and Data Fabric version that you are running. The versions are listed in the following locations:

- For EEP version 9.1.2 and later: <https://repository.mapr.com/nexus/content/groups/mapr-public/org/apache/kafka/kafka-eventstreams/>
- For EEP version 8.1.0 through 9.1.1: <https://repository.mapr.com/nexus/content/groups/mapr-public/com/mapr/kafka/kafka-eventstreams/>
- Starting with EEP 8.1.0, this library is deprecated: <https://repository.mapr.com/nexus/content/groups/mapr-public/com/mapr/streams/mapr-streams/>

4. Use Maven to compile the application and resolve dependencies. For example, you can run `mvn clean package`.

Run the Application

When you develop a Java application, you can use a dependency management tool such as Maven to compile your application. However, it is recommended that you do the following instead:

1. Compile the Java application without including dependencies
2. Specify the required classpath when you submit the application to the cluster

If you choose to bundle the JAR file, and there is a mismatch between the bundled JAR file and the version that your Data Fabric cluster expects, this can result in failures. The failures differ depending on the version of Data Fabric you are using. For more information, see [Using the File System JAR to Connect to the Cluster](#) on page 3562.

When the cluster is secure, the node must also have a Data Fabric ticket configured for the user that runs the application.

Use the following command to launch HPE Data Fabric Streams applications:

```
java -cp <classpath>:. -Djava.library.path=/opt/mapr/lib <main class JAR>
<command line arguments>
```

Migrating Apache Kafka Java Applications to HPE Data Fabric Streams

There are only two steps that you need to follow to migrate applications written with the Apache Kafka Java API to HPE Data Fabric Streams.

About this task

The following steps assume that migration is from either:

- Apache Kafka 2.6.1 to HPE Data Fabric Streams 6.2 or higher
- Apache Kafka 2.1.1 to HPE Data Fabric Streams 6.2 or higher
- Apache Kafka 1.1 to HPE Data Fabric Streams 6.1 or higher
- Apache Kafka 1.0 to HPE Data Fabric Streams 6.0.1 or higher
- Apache Kafka 0.9.0 to HPE Data Fabric Streams 6.0.0 or earlier

IMPORTANT: For information on backward compatibility, see [HPE Data Fabric Streams Java API Library](#) on page 3967

Procedure

1. Change the names of topics to include the path and name of the MapR Stream stream in which the topic is located.

Here is the syntax to use:

```
/<path and name of stream>:<name of topic>
```

For example, you might have a stream in a MapR cluster that is named `stream_A`, and the stream might be in a volume named `IoT` and in a directory named `automobile_sensors`. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this:

```
/mapr/IoT/automobile_sensors/stream_A:<name of topic>
```

2. If a producer application uses the Kafka interface `Partitioner` to compute which partitions to publish messages to, revise the application so that it uses the `Kafka StreamsPartitioner` interface instead.

Differences between HPE Data Fabric Streams and Apache Kafka Configuration

Describes the HPE Data Fabric Streams supportability of Apache Kafka configuration parameters for producers and consumers.

Kafka Producer

Name	Description	Supported for producers in HPE Data Fabric Streams?
<code>bootstrap.servers</code>	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form <code>host1:port1,host2:port2,...</code> Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).	No. Cluster details are discovered from the file <code>mapr-clusters.conf</code> .
<code>key.serializer</code>	Serializer class for key that implements the <code>Serializer</code> interface.	Yes
<code>value.serializer</code>	Serializer class for value that implements the <code>Serializer</code> interface.	Yes

Name	Description	Supported for producers in HPE Data Fabric Streams?
acks	The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common:	Ignored, all writes in HPE Data Fabric Streams are synchronous, and number of replicas is determined at the volume level, with a default of 3.
	acks=0 If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won't generally know of any failures). The offset given back for each record will always be set to -1.	
	acks=1 This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost.	
	acks=all This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee.	
buffer.memory	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server the producer will either block or throw an exception based on the preference specified by <code>block.on.buffer.full</code> .	Yes
	This setting should correspond roughly to the total memory the producer will use, but is not a hard bound since not all memory the producer uses is used for buffering. Some additional memory will be used for compression (if compression is enabled) as well as for maintaining in-flight requests.	

Name	Description	Supported for producers in HPE Data Fabric Streams?
<code>compression.type</code>	The compression type for all data generated by the producer. The default is none (i.e. no compression). Valid values are none, gzip, snappy, or lz4. Compression is of full batches of data, so the efficacy of batching will also impact the compression ratio (more batching means better compression).	Ignored. Compression is configured per stream.
<code>retries</code>	Setting a value greater than zero will cause the client to resend any record whose send fails with a potentially transient error. Note that this retry is no different than if the client resent the record upon receiving the error. Allowing retries will potentially change the ordering of records because if two records are sent to a single partition, and the first fails and is retried but the second succeeds, then the second record may appear first.	Ignored. HPE Data Fabric Streams always does automatic retries on transient errors.
<code>ssl.key.password</code>	The password of the private key in the key store file. This is optional for client.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.keystore.location</code>	The location of the key store file. This is optional for client and can be used for two-way authentication for client.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.keystore.password</code>	The store password for the key store file. This is optional for client and only needed if <code>ssl.keystore.location</code> is configured.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.truststore.location</code>	The location of the trust store file.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.truststore.password</code>	The password for the trust store file.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.

Name	Description	Supported for producers in HPE Data Fabric Streams?
batch.size	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. This configuration controls the default batch size in bytes.	Ignored. HPE Data Fabric always batches records for optimal performance.
	No attempt will be made to batch records larger than this size.	
	Requests sent to brokers will contain multiple batches, one for each partition with data available to be sent.	
	A small batch size will make batching less common and may reduce throughput (a batch size of zero will disable batching entirely). A very large batch size may use memory a bit more wastefully as we will always allocate a buffer of the specified batch size in anticipation of additional records.	
client.id	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just ip/port by allowing a logical application name to be included in server-side request logging.	Yes
connections.max.idle.ms	Close idle connections after the number of milliseconds specified by this config.	Ignored.

Name	Description	Supported for producers in HPE Data Fabric Streams?
<code>linger.ms</code>	The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay—that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle's algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get <code>batch.size</code> worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will 'linger' for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting <code>linger.ms=5</code> , for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absence of load.	Ignored.
<code>max.block.ms</code>	The configuration controls how long <code>{@link KafkaProducer#send()}</code> and <code>{@link KafkaProducer#partitionsFor}</code> will block. These methods can be blocked for multiple reasons. For e.g: buffer full, metadata unavailable. This configuration imposes maximum limit on the total time spent in fetching metadata, serialization of key and value, partitioning and allocation of buffer memory when doing a <code>send()</code> . In case of <code>partitionsFor()</code> , this configuration imposes a maximum time threshold on waiting for metadata	Ignored. HPE Data Fabric Streams has a similar parameter: <code>streams.rpc.timeout.ms</code>
<code>max.request.size</code>	The maximum size of a request. This is also effectively a cap on the maximum record size. Note that the server has its own cap on record size which may be different from this. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.	Ignored.

Name	Description	Supported for producers in HPE Data Fabric Streams?
<code>partitioner.class</code>	Partitioner class that implements the Partitioner interface.	Use the Kafka StreamsPartitioner interface.
<code>receive.buffer.bytes</code>	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	Ignored.
<code>request.timeout.ms</code>	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	Ignored. HPE Data Fabric Streams has a similar parameter: <code>streams.rpc.timeout.ms</code>
<code>sasl.kerberos.service.name</code>	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>security.protocol</code>	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>send.buffer.bytes</code>	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	Ignored.
<code>ssl.enabled.protocols</code>	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.	Ignored.
<code>ssl.keystore.type</code>	The file format of the key store file. This is optional for client. Default value is JKS	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.protocol</code>	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.provider</code>	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.truststore.type</code>	The file format of the trust store file. Default value is JKS.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.

Name	Description	Supported for producers in HPE Data Fabric Streams?
<code>timeout.ms</code>	The configuration controls the maximum amount of time the server will wait for acknowledgments from followers to meet the acknowledgment requirements the producer has specified with the <code>acks</code> configuration. If the requested number of acknowledgments are not met when the timeout elapses an error will be returned. This timeout is measured on the server side and does not include the network latency of the request.	Ignored. HPE Data Fabric Streams has a similar parameter: <code>streams.rpc.timeout.ms</code>
<code>block.on.buffer.full</code>	When our memory buffer is exhausted we must either stop accepting new records (block) or throw errors. By default this setting is true and we block, however in some scenarios blocking is not desirable and it is better to immediately give an error. Setting this to false will accomplish that: the producer will throw a <code>BufferExhaustedException</code> if a record is sent and the buffer space is full.	Ignored.
<code>max.in.flight.requests.per.connection</code>	The maximum number of unacknowledged requests the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries (i.e., if retries are enabled).	Ignored. HPE Data Fabric Streams has a similar parameter: <code>streams.parallel.flushers.per.partition</code>
<code>metadata.fetch.timeout.ms</code>	The first time data is sent to a topic we must fetch metadata about that topic to know which servers host the topic's partitions. This fetch to succeed before throwing an exception back to the client.	Ignored.
<code>metadata.max.age.ms</code>	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	Yes
<code>metric.reporters</code>	A list of classes to use as metrics reporters. Implementing the <code>MetricReporter</code> interface allows plugging in classes that will be notified of new metric creation. The <code>JmxReporter</code> is always included to register JMX statistics.	No
<code>metrics.num.samples</code>	The number of samples maintained to compute metrics.	No.
<code>metrics.sample.window.ms</code>	The number of samples maintained to compute metrics.	No.

Name	Description	Supported for producers in HPE Data Fabric Streams?
<code>reconnect.backoff.ms</code>	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	Ignored. HPE Data Fabric Streams has a similar parameter: <code>streams.rpc.timeout.ms</code>
<code>retry.backoff.ms</code>	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	Ignored. HPE Data Fabric Streams has a similar parameter: <code>streams.rpc.timeout.ms</code>
<code>sasl.kerberos.kinit.cmd</code>	Kerberos kinit command path. Default is <code>/usr/bin/kinit</code>	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>sasl.kerberos.min.time.before.relogin</code>	Login thread sleep time between refresh attempts.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>sasl.kerberos.ticket.renew.jitter</code>	Percentage of random jitter added to the renewal time.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>sasl.kerberos.ticket.renew.window.factor</code>	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.cipher.suites</code>	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol. By default all the available cipher suites are supported.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.endpoint.identification.algorithm</code>	The endpoint identification algorithm to validate server hostname using server certificate.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.keymanager.algorithm</code>	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
<code>ssl.trustmanager.algorithm</code>	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.

Kafka Consumer

Name	Description	Supported for consumers in HPE Data Fabric Streams?
bootstrap.servers	A list of host/port pairs to use for establishing the initial connection to the Kafka cluster. The client will make use of all servers irrespective of which servers are specified here for bootstrapping—this list only impacts the initial hosts used to discover the full set of servers. This list should be in the form host1:port1,host2:port2,.... Since these servers are just used for the initial connection to discover the full cluster membership (which may change dynamically), this list need not contain the full set of servers (you may want more than one, though, in case a server is down).	No. Cluster details are discovered from the file <code>mapr-clusters.conf</code> .
key.deserializer	Deserializer class for key that implements the Deserializer interface.	Yes
value.deserializer	Deserializer class for value that implements the Deserializer interface.	Yes
fetch.min.bytes	The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request. The default setting of 1 byte means that fetch requests are answered as soon as a single byte of data is available or the fetch request times out waiting for data to arrive. Setting this to something greater than 1 will cause the server to wait for larger amounts of data to accumulate which can improve server throughput a bit at the cost of some additional latency.	Yes
fetch.max.bytes	The maximum amount of data the server should return for a fetch request. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress.  NOTE: This is new as of MapR 6.0.1.	Yes, as of MapR 6.0.1.
group.id	A unique string that identifies the consumer group this consumer belongs to. This property is required if the consumer uses either the group management functionality by using <code>subscribe(topic)</code> or the Kafka-based offset management strategy.	Yes

Name	Description	Supported for consumers in HPE Data Fabric Streams?
heartbeat.interval.ms	The expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than session.timeout.ms, but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	No
max.poll.records	Places an upper bound on the number of records returned from each call.  NOTE: This parameter is new as of MapR 6.0.1.	Yes, as of MapR 6.0.1.
max.partition.fetch.bytes	The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be #partitions * max.partition.fetch.bytes. This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition. If the first record batch in the first non-empty partition of the fetch is larger than this configuration, the record batch is still returned to ensure that the consumer can make progress.  NOTE: This is a behavior change as of MapR 6.0.1.	Yes
session.timeout.ms	The timeout used to detect failures when using Kafka's group management facilities.	Ignored
ssl.key.password	The password of the private key in the key store file. This is optional for client.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.keystore.location	The location of the key store file. This is optional for client and can be used for two-way authentication for client.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.

Name	Description	Supported for consumers in HPE Data Fabric Streams?
ssl.keystore.password	The store password for the key store file. This is optional for client and only needed if ssl.keystore.location is configured.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.truststore.location	The location of the trust store file.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.truststore.password	The password for the trust store file.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
auto.offset.reset	<p>What to do when there is no initial offset in Kafka or if the current offset does not exist any more on the server (e.g. because that data has been deleted):</p> <p>earliest automatically reset the offset to the earliest offset</p> <p>latest automatically reset the offset to the latest offset</p> <p>none throw exception to the consumer if no previous offset is found for the consumer's group</p> <p>anything else throw exception to the consumer.</p>	Yes
connections.max.idle.ms	Close idle connections after the number of milliseconds specified by this config.	Ignored
enable.auto.commit	If true the consumer's offset will be periodically committed in the background.	Yes
partition.assignment.strategy	The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used	Ignored. HPE Data Fabric Streams distributes partitions equally among the consumers in a group.
receive.buffer.bytes	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	Ignored.

Name	Description	Supported for consumers in HPE Data Fabric Streams?
request.timeout.ms	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	Ignored. HPE Data Fabric Streams has a similar parameter: <code>streams.rpc.timeout.ms</code>
sasl.kerberos.service.name	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
security.protocol	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
send.buffer.bytes	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	Ignored.
ssl.enabled.protocols	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.keystore.type	The file format of the key store file. This is optional for client. Default value is JKS	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.protocol	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.provider	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.truststore.type	The file format of the trust store file. Default value is JKS.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
auto.commit.interval.ms	The frequency in milliseconds that the consumer offsets are auto-committed to Kafka if <code>enable.auto.commit</code> is set to true.	Yes

Name	Description	Supported for consumers in HPE Data Fabric Streams?
check.crcs	Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.	Ignored. HPE Data Fabric Streams always does end-to-end crc computation and verification.
client.id	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just ip/port by allowing a logical application name to be included in server-side request logging.	Yes
fetch.max.wait.ms	The maximum amount of time the server will block before answering the fetch request if there isn't sufficient data to immediately satisfy the requirement given by fetch.min.bytes.	No
metadata.max.age.ms	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	Yes
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	No
metrics.num.samples	The number of samples maintained to compute metrics.	No
metrics.sample.window.ms	The number of samples maintained to compute metrics.	No
reconnect.backoff.ms	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	Ignored. HPE Data Fabric Streams has a similar parameter: <code>streams.rpc.timeout.ms</code>
retry.backoff.ms	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	Ignored. HPE Data Fabric Streams has a similar parameter: <code>streams.rpc.timeout.ms</code>
sasl.kerberos.kinit.cmd	Kerberos kinit command path. Default is <code>/usr/bin/kinit</code>	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.

Name	Description	Supported for consumers in HPE Data Fabric Streams?
sasl.kerberos.min.time.before.relogin	Login thread sleep time between refresh attempts.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
sasl.kerberos.ticket.renew.jitter	Percentage of random jitter added to the renewal time.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
sasl.kerberos.ticket.renew.window.factor	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.cipher.suites	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol. By default all the available cipher suites are supported.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate server hostname using server certificate.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.keymanager.algorithm	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.
ssl.trustmanager.algorithm	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	Ignored. Authentication and authorization are handled through HPE Data Fabric security. See Security on page 901 for more information.

HPE Data Fabric Streams Parameters

The following HPE Data Fabric Streams parameters are for the Admin API.

Table

HPE Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
streams.rpc.timeout.ms	<p>Specifies the length of time in milliseconds to wait for a response from the HPE Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 120000 Minimum: 30000</p> <p> NOTE: Applicable as of MapR 6.0.1, is used instead of fs.mapr.rpc.timeout</p>	<p>request.timeout.ms</p> <p>reconnect.backoff.ms</p> <p>retry.backoff.ms</p>

The following HPE Data Fabric Streams parameter are for the Producer API:

Table

HPE Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
<code>streams.buffer.max.time.ms</code>	<p>Messages are buffered in the producer for at most the specified time. A thread will flush all the messages that have been buffered for more than the time specified.</p> <p>Default: 3 * 1000 msec</p>	<code>linger.ms</code>
<code>streams.parallel.flushers.per.partition</code>	<p>If enabled, producer may have multiple parallel send requests to the server for each topic partition. If this setting is set to true, it is possible for messages to be sent out of order.</p> <p>Default: true</p>	<code>max.in.flight.requests.per.connection</code>
<code>streams.partitioner.class</code>	<p>The class that implements the <code>StreamsPartitioner</code> interface. This interface lets you write custom algorithms for determining which topic and partition to use for messages that match specific criteria. Use this configuration parameter only for producers that are written in Java.</p>	Not applicable.
<code>streams.producer.default.stream</code>	<p>Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to.</p> <p>For example, the producer can specify the name of a stream together with the name of a topic to write to, like this:</p> <pre>/<stream>/<topic></pre> <p>However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located.</p> <p>If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.</p>	Not applicable.

Table (Continued)

HPE Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
streams.rpc.timeout.ms	<p>Specifies the length of time in milliseconds to wait for a response from the HPE Data Fabric Streams server if soft mount is configured (fs.mapr.hardmount is set to false). Default: 30000 Minimum: 30000</p> <p>If the time expires while a producer waits for a response from the HPE Data Fabric Streams server, and the producer used the <code>KafkaProducer.send(ProducerRecord<K,V> record, Callback callback)</code> method, the callback is invoked with the error <code>EAGAIN</code>, which means "Resource temporarily unavailable."</p> <p> NOTE: Applicable as of MapR 6.0.1, is used instead of <code>fs.mapr.rpc.timeout</code></p>	<p>max.block.ms</p> <p>request.timeout.ms</p> <p>timeout.ms</p> <p>reconnect.backoff.ms</p> <p>retry.backoff.ms</p>

The following HPE Data Fabric Streams parameters are for the Consumer API:

Table

HPE Data Fabric Streams Parameter	Description	Kafka Parameter Replaced
streams.consumer.default.stream	<p>Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream.</p> <p>This default value is also used for the <code>KafkaConsumer.listTopics()</code> method.</p>	Not applicable.
streams.rpc.timeout.ms	<p>Specifies the length of time in milliseconds to wait for a response from the HPE Data Fabric Streams server if a soft mount is configured (fs.mapr.hardmount is set to false). Default: 305000 Minimum: 300000</p> <p> NOTE: Applicable as of MapR 6.0.1, is used instead of <code>fs.mapr.rpc.timeout</code></p>	<p>request.timeout.ms</p> <p>reconnect.backoff.ms</p> <p>retry.backoff.ms</p>

HPE Data Fabric Streams C Applications

You can develop C applications for HPE Data Fabric Streams. The HPE Data Fabric Streams C Client is a distribution of `librdkafka` that works with HPE Data Fabric Streams. The HPE Data Fabric Streams C Client is available in Ecosystem Pack (EEP) 3.0 and later.

The following Apache Kafka `librdkafka` versions are supported:

Table

Core release	EEP Release	Kafka <code>librdkafka</code> version
As of 7.10.0	As of 9.4.0	2.6.0**
As of 7.9.0	As of 9.3.1	2.0.2*

Table (Continued)

Core release	EEP Release	Kafka librdkafka version
As of 6.0.1	As of 5.0	0.11.3
As of 5.2.1 through 6.0.0	As of 3.0	0.9.0

*Librdkafka 2.0.2 in core 7.9 is **not** compatible with HPE Data Fabric Stream clients for Python¹ or C#² applications. Nodes running Python or C# applications should not be upgraded to HPE Data Fabric 7.9.

Librdkafka 2.6.0 in core 7.10 is **not compatible with HPE Data Fabric Stream clients for C#² applications. Nodes running C# applications should not be upgraded to HPE Data Fabric 7.10.

¹[HPE Data Fabric Streams Python Applications](#) on page 4542

²[HPE Data Fabric Streams C#/.NET Applications](#) on page 4553

The HPE Data Fabric Streams C Client supports a majority of the librdkafka C APIs plus additional [configuration properties](#) that are available only with HPE Data Fabric Streams. When developing applications for HPE Data Fabric Streams or migrating Kafka applications to HPE Data Fabric Streams, see the list of [librdkafka APIs Supported by HPE Data Fabric Streams C Client](#) on page 4023 which also describes API behavior. Reference [rdkafka.h](#) for API signatures.

When developing and running HPE Data Fabric Streams C applications, note the following:

- You can create producers and high-level consumers. Low-level consumers are not supported.
- Consuming or producing topics in a Kafka cluster is not supported.
- As of HPE Data Fabric 6.0, the HPE Data Fabric Streams offset values start at 0.
- HPE Data Fabric Security is supported. Kafka application-level security is not supported. See [Security](#) on page 901.
- User impersonation is not supported.

CAUTION: As of HPE Data Fabric 6.1, the mapr-core package has a dependency on mapr-librdkafka. If the mapr-librdkafka package is installed, do not remove it manually. Doing so could result in the removal of HPE Data Fabric core packages, rendering the node unusable.

Synchronous Consumer Partition Assignment

See [Synchronous Consumer Partition Assignment for Streams](#) on page 4572

Configuring the HPE Data Fabric Streams C Client

After installing the HPE Data Fabric Client and before developing applications, you must configure your client C library by setting the library path.

Linux

For Linux installations, add /opt/mapr/lib to the end of LD_LIBRARY_PATH.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib
```

IMPORTANT: For HPE Data Fabric 6.0.1, the libjvm.so configuration is *not* required.

For HPE Data Fabric 6.0.0 and earlier, add the `/opt/mapr/lib` and the path to the directory that contains `libjvm.so` to the end of `LD_LIBRARY_PATH`.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib:
lib:<path_to_libjvm.so_directory>
```

The location of the `libjvm.so` differs based on where you installed Java. You can use `find / -name libjvm*` to determine the file location. For example, if the `libjvm.so` file is in the following location:

```
/usr/lib/jvm/java-7-openjdk-amd64/jre/lib/amd64/server/libjvm.so
```

Then, you set the library path like this:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib:/usr/lib/jvm/
java-7-openjdk-amd64/jre/lib/amd64/server/
```

Mac

For Mac installations, add `/opt/mapr/lib` to the end of the `DYLD_LIBRARY_PATH` and the `LD_LIBRARY_PATH`.

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/mapr/lib
```

IMPORTANT: For HPE Data Fabric 6.0.1, the libjvm.so configuration is *not* required.

For HPE Data Fabric 6.0.0 and earlier, add `/opt/mapr/lib` and the path to the directory that contains `libjvm.dylib` to the end of `DYLD_LIBRARY_PATH`.

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib:
lib:<path_to_libjvm.dylib_directory>
```

The location of the `libjvm.dylib` differs based on where you installed Java. You can use `find / -name libjvm*` to determine the file location. For example, if the `libjvm.dylib` file is in the following location:

```
/Library/Java/JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/
Home/jre/lib/server/libjvm.dylib
```

Then, you set the library path like this:

```
export DYLD_LIBRARY_PATH=$DYLD_LIBRARY_PATH:/opt/mapr/lib:/Library/Java/
JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/Home/jre/lib/server
```

Windows

NOTE: As of HPE Data Fabric 6.0.1, the HPE Data Fabric C client is available on Windows.

For Windows installations, no additional configuration is required. Link your application and run your programs against the HPE Data Fabric Client dynamic link libraries (dll) located at: `C:\opt\mapr\lib`. The corresponding `librdkafka` header is `C:\opt\mapr\include\librdkafka`.

Developing a HPE Data Fabric Streams C Application

This topic includes basic information about how to develop a HPE Data Fabric Streams C application. Sample applications are provided.

Before you Begin

Confirm that your environment meets the following requirements:

- The HPE Data Fabric cluster version is 5.2.1 or greater.
- HPE Data Fabric core client (mapr-client) package is installed on the node and it is configured to access the cluster. Or, it is a HPE Data Fabric cluster node. See [Installing the Data Fabric Client \(Non-FIPS\)](#) on page 361 for more information.
- The HPE Data Fabric Streams C Client is installed and configured on the node. See [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.
- GNU Compiler Collection (GCC) is installed on the node.

Creating, Compiling and Running C Apps

The following sections describes how to create a producer and consumer in C, compile the source code, generate executables, and run the applications.

Create Producer

This topic describes how to create a HPE Data Fabric Streams streams producer in C. While the code to generate a HPE Data Fabric Streams stream producer varies depending on the use case, in general, the producer code should contain the following:

1. Include the rdkafka.h header file (/opt/mapr/include/librdkafka/rdkafka.h)
2. Use rd_kafka_conf_new() to create the producer configuration.
3. Use rd_kafka_new () to create the producer handle.
4. Use rd_kafka_topic_conf_new() to create the topic configuration.
5. Use rd_kafka_topic_new () to create a topic handle for the producer.
6. Use rd_kafka_produce() to produce messages.
7. Optionally, use rd_kafka_poll() to poll for callbacks. This is useful to see if there are messages that have yet to be sent to the server.
8. Use rd_kafka_topic_destroy () to destroy the topic handle destroy
9. Use rd_kafka_destroy () to destroy the producer handle.

NOTE: For more details on the APIs, see [Supported APIs for HPE Data Fabric Streams C Client](#) and [rdkafka.h](#) on page 4105

For example, the following source code produces 5 messages to topic /MapR_Streams:MapR-Topic1:

```
/*
 * This file contains the producer function.
 */
#include <stdio.h>
```

```

#include <stdlib.h>
#include <string.h>
#include <rdkafka.h>
#include <errno.h>

/* msgDeliveryCB: Is the delivery callback.
 * The delivery report callback will be called once for each message
 * accepted by rd_kafka_produce() with err set to indicate
 * the result of the produce request. An application must call
rd_kafka_poll()
 * at regular intervals to serve queued delivery report callbacks.
 */
static void msgDeliveryCB (rd_kafka_t *rk,
                           const rd_kafka_message_t *rkmessage, void
*opaque) {
    if (rkmessage->err != RD_KAFKA_RESP_ERR_NO_ERROR) {
        printf("FAILURE: Message not delivered to partition.\n");
        printf("ERROR: %s", rd_kafka_err2str(rkmessage->err));
    } else {
        printf("Produced: %.*s\n", (int)rkmessage->len, (const
char*)rkmessage->payload);
    }
}

/*
 * Method      : int producer(int nummsgs_p, const char *fullTopicName)
 * Description : This is a simple producer method. In this method the
producer
 *              produces messages to a topic.
 */

int producer(int nummsgs_p, const char *fullTopicName) {
    printf("***** PRODUCER *****\n");
    rd_kafka_t *prodHndle;
    rd_kafka_conf_t *prodCfg;
    char errstr[1000];
    int totalMsgs = nummsgs_p;

    printf("Create producer configuration object\n");
    /*
     * rd_kafka_conf_new(): This API creates default rd_kafka_conf_t object
to
     * be passed at the time of producer object creation using rd_kafka_new
call.
     */
    prodCfg = rd_kafka_conf_new();
    if (prodCfg == NULL) {
        printf("Failed to create conf\n");
        return (EXIT_FAILURE);
    }
    /* rd_kafka_conf_set_dr_msg_cb(): This API sets the producer callback
     * 'msgDeliveryCB' in producer config 'prodCfg'
     * The delivery report callback will be called once for each message
     * accepted by rd_kafka_produce() with err set to indicate
     * the result of the produce request. An application must call
rd_kafka_poll()
     * at regular intervals to serve queued delivery report callbacks.
     */
    rd_kafka_conf_set_dr_msg_cb(prodCfg, msgDeliveryCB);

    printf("Create Producer Kafka handle\n");
    /*
     * rd_kafka_new(): Creates a new Kafka handle and starts its operation
     * according to the specified type (RD_KAFKA_CONSUMER or

```

```

RD_KAFKA_PRODUCER).
    * prodCfg object passed here is freed by this function and must not be
    used
    * or destroyed by the application subsequently. errstr must be a
    pointer to
    * memory of at least size errstr_size where
    * `rd_kafka_new()` may write a human readable error message in case the
    * creation of a new handle fails. In which case the function returns
    NULL.
    */
    prodHndle = rd_kafka_new(RD_KAFKA_PRODUCER, prodCfg, errstr,
sizeof(errstr));
    if (prodHndle == NULL) {
        printf("Failed to create producer: %s\n", errstr);
        return (EXIT_FAILURE);
    }

    /*
    * Following code does following:
    * 1. Create a topic handle for each producer-topic combination
    * 2. Produce 'totalMsgs' # of messages using topic handle created in
step 1
    * 3. Wait for all messages to be produced and callback to be delivered.
    * 4. Move on to next topic and repeat.
    */

    int totalTopics = 1;
    for (int nTopics = 0; nTopics < totalTopics ; nTopics++) {
        printf("Create topic handle\n");
        rd_kafka_topic_conf_t *prodTopicCfg;
        /*
        * rd_kafka_topic_conf_new(): This API Creates topic conf object
        * required to create topic handle which then will be used for each
        * producer-topic combination
        */

        prodTopicCfg = rd_kafka_topic_conf_new();
        if (prodTopicCfg == NULL) {
            printf("Failed to create new topic conf\n");
            return (EXIT_FAILURE);
        }

        rd_kafka_topic_t *prodTopicHndl;
        /*
        * rd_kafka_topic_new(): This API Creates topic handle for a
given
        * producer, topic name and topic config. Topic handles are
refcounted
        * internally and calling rd_kafka_topic_new()
        * again with the same topic name will return the previous
topic handle
        * without updating the original handle's configuration.
        * Applications must eventually call rd_kafka_topic_destroy()
for each
        * succesfull call to rd_kafka_topic_new() to clear up
resources.
        */
        prodTopicHndl = rd_kafka_topic_new(prodHndle, fullTopicName,
prodTopicCfg);
        if (prodTopicHndl == NULL) {
            printf("Failed to create new topic handle\n");
            return (EXIT_FAILURE);
        }
        prodTopicCfg = NULL; /* Now owned by topic */
    }

```

```

const char* key ="Key";
printf("Send/Produce message to topic: %s\n", fullTopicName);
for (int i = 0; i < totalMsgs; i++) {
    char payload[1000];
    if (i == 0)
        sprintf(payload, "%s", "Welcome to MapR Streams
CAPI");
    else
        sprintf(payload, "MapR Streams CAPI Message
Payload %d", i);
    /*
    * rd_kafka_produce(): This API produces a single message
    * to the cluster. prodTopicHandle must be created using
    * rd_kafka_topic_new() api. This is an asynch
non-blocking API.
    * RD_KAFKA_PARTITION_UA is used to indicate automatic
partition
    * partitioning, using topics partitioner or fixed
that
    * can be provided. RD_KAFKA_MSG_F_COPY flag indicates
its own
    * library copies the payload and application manages
set
    * payload memory. If API fails to send, errno will be
specific
    * accordingly and will be able to access librdkafka
    * error using rd_kafka_last_error() api.
    */
    if (rd_kafka_produce(prodTopicHndl,
                        RD_KAFKA_PARTITION_UA,

Create Consumer

This topic describes how to create a HPE Data Fabric Streams streams consumer in C. While the code to generate a HPE Data Fabric Streams stream consumer varies depends on the use case, in general, the consumer code should contain the following:

1. Include the rdkafka.h header file (/opt/mapr/include/librdkafka/rdkafka.h).
2. Use rd_kafka_conf_new() to create the consumer configuration.
3. Use rd_kafka_conf_set() to set the configuration parameters. For this API, you must set the "group.id."
4. Use rd_kafka_new () to create the consumer handle.
5. Use rd_kafka_subscribe() or rd_kafka_assign() to specify which topics to consume.
6. Use rd_kafka_consumer_poll() to poll for messages that are ready to be consumed.

7. Use `rd_kafka_consumer_close()` to perform auto commits and prepare to destroy the consumer handle.
8. Use `rd_kafka_destroy()` to destroy the consumer handle.

For example, the following source code consumes 5 messages from topic `/MapR_Streams:MapR-Topic1`:

```
/*
 * This file contains the consumer function.
 */

#include <stdio.h>
#include <stdlib.h>
#include <rdkafka.h>
#include <string.h>

/*
 * Method      : int consumer(int expected_nummsgs, const char
 *fullTopicName)
 * Description : This is a simple consumer method. In this method the
consumer
 *              consumes messages from a topic.
 */

int consumer(int expected_nummsgs, const char *fullTopicName) {
    printf("***** CONSUMER START *****\n");
    rd_kafka_t *consHndle;
    rd_kafka_conf_t *consCfg;
    rd_kafka_topic_conf_t *consTopicCfg;
    char errstr[1000];
    rd_kafka_resp_err_t errCode;

    printf("Create new consumer configuration object\n");
    /*
     * rd_kafka_conf_new(): This API creates default rd_kafka_conf_t object
to
     * be passed at the time of consumer object creation using rd_kafka_new
call.
     */
    consCfg = rd_kafka_conf_new();
    if(consCfg == NULL) {
        printf("Failed to create consumer conf\n");
        return(EXIT_FAILURE);
    }
    /*
     * rd_kafka_conf_set(): This API is used to set config parameters in the
     * rd_kafka_conf_t object. group.id Must be set for all the consumers.
     * All changes to the consCfg must be done before creating consumer
object.
     */
    if(RD_KAFKA_CONF_OK != rd_kafka_conf_set(consCfg,
        "group.id", "consumerGroup",
        errstr, sizeof(errstr))) {
        printf("rd_kafka_conf_set() failed with error: %s\n", errstr);
        return (EXIT_FAILURE);
    }
    /*
     * rd_kafka_topic_conf_new(): This API Creates topic conf object
     * required to set the default topic configuration.
     */
    printf("Set topic configurations\n");
    consTopicCfg = rd_kafka_topic_conf_new();
```

```

    /* rd_kafka_topic_conf_set(): This API sets the config property by name.
    * consTopicCfg should have been previously set up with
`rd_kafka_topic_conf_new()`
    * property set in this call is 'auto.offset.reset', when set to
    * earliest will return messages on rd_kafka_consumer_poll from
beginning of
    * time (for the very first time consumption) or from last committed
offset
    * for online consumer. If property is set to 'latest' it will return the
    * messages produced after consumer has started(for first time consumer)
or
    * from the last committed offset for online consumer
    */
    if (RD_KAFKA_CONF_OK != rd_kafka_topic_conf_set(consTopicCfg,
"auto.offset.reset",
                                "earliest", errstr, sizeof(errstr))) {

    * rd_kafka_conf_set_default_topic_conf(): This API sets the default
topic
    * configuration to use for automatically subscribed topics
    * The topic config object is not usable after this call.
    */
    rd_kafka_conf_set_default_topic_conf(consCfg, consTopicCfg);

    printf("Create consumer Kafka handle\n");
    /*
    * rd_kafka_new():Creates a new Kafka handle and starts its operation
    * according to the specified type (RD_KAFKA_CONSUMER or
RD_KAFKA_PRODUCER).
    * consCfg object passed here is freed by this function and must not be
used
    * or destroyed by the application subsequently. errstr must be a
pointer to
    * memory of at least size errstr_size where
    * `rd_kafka_new()` may write a human readable error message in case the
    * creation of a new handle fails. In which case the function returns
NULL.
    */

    consHndle = rd_kafka_new(RD_KAFKA_CONSUMER, consCfg, errstr,
sizeof(errstr));
    if(consHndle == NULL) {
        printf("Failed to create consumer:%s", errstr);
        return (EXIT_FAILURE);
    }

    /* rd_kafka_poll_set_consumer() is used to redirect the main queue
which is
    * serviced using rd_kafka_poll() to the rd_kafka_consumer_poll(). With
one api
    * 'rd_kafka_consumer_poll()' both callbacks and message are serviced.
    * Once queue is forwarded using this API, it is not permitted to call
    * rd_kafka_poll to service non message delivery callbacks.
    */
    rd_kafka_poll_set_consumer(consHndle);

    /* Topic partition list (tp_list) is supplied as an input to the
consumer
    * subscribe(using rd_kafka_subscribe()). The api rd_kafka_subscribe()

```

```

expects
    * that the partition argument to be set to RD_KAFKA_PARTITION_UA and
internally
    * all partitions are assigned to the consumer.
    * Note: partition balancing/assignment is done if more consumers are
part
    * of the same consumer group.
    */

    printf("Create topic partition list for topic: %s\n", fullTopicName);

expected_nummsgs, fullTopicName);
    }
}

```

NOTE: For more details on the APIs, see [Supported APIs for HPE Data Fabric Streams C Client](#) and [rdkafka.h](#) on page 4105

Compile the Apps

This topic describes how to compile HPE Data Fabric Streams streams producers and consumers in C. When you compile a HPE Data Fabric Streams C application, you must link it with the librdkafka library in the /opt/mapr/lib/ library path and include the header file directory to ensure that your application references the header file included with HPE Data Fabric Streams C Client.

IMPORTANT: For MapR 6.0.0 and earlier, When you compile a HPE Data Fabric Streams C application, you must link it with the librdkafka library in the /opt/mapr/lib/ library path, *the libjvm library*, and include the header file directory to ensure that your application references the header file included with HPE Data Fabric Streams C Client.

The following steps compile the source code and generate executables in the same directory as the Makefile. For example, in the **librdkafka_example** directory, the consumer and producer executables are generated from the producer.c and consumer.c source files.

1. On your node, create a directory. For example: **librdkafka_example**.
2. In your directory (**librdkafka_example**), create a producer application. For example, if you are using the provided sample producer application:
 - a. Create a file named producer.c.
 - b. Copy the contents of the sample producer application into that file.
3. In your directory (**librdkafka_example**), create a consumer application. For example, if you are using the provided sample consumer application:
 - a. Create a file named consumer.c.
 - b. Copy the contents of the sample consumer application into that file.

4. In your directory (**librdkafka_example**), create a file named Makefile with the following content:

```
CC= g++
HEADERDIR=/opt/mapr/include/librdkafka/
CCFLAGS= -Wall -I$(HEADERDIR) -g -std=c99

export LD_LIBRARY_PATH=/opt/mapr/lib

LIBDIR= /opt/mapr/lib/
%.o: %.c
    gcc $(CCFLAGS) -c $<

consumer: consumer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

producer: producer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

all: consumer producer

clean:
    /bin/rm -f *.o consumer producer
```

IMPORTANT: For MapR 6.0.0 and earlier, use the following Makefile:

```
CC= g++
HEADERDIR=/opt/mapr/include/librdkafka/
CCFLAGS= -Wall -I$(HEADERDIR) -g -std=c99

#Edit JAVA_HOME to be appropriate for your environment
JAVA_HOME=/usr/lib/jvm/java-7-openjdk-amd64/
export LD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/amd64/
server

LIBDIR= /opt/mapr/lib/
%.o: %.c
    gcc $(CCFLAGS) -c $<

consumer: consumer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

producer: producer.o
    gcc -o $@ $@.o -lrdkafka -L$(LIBDIR) $(CCFLAGS)

all: consumer producer

clean:
    /bin/rm -f *.o consumer producer
```

5. Complete the following edits to the Makefile:

For Mac users, locate the following line of code:

```
export LD_LIBRARY_PATH=/opt/mapr/lib
```

Then, replace this line with the following line of code:

```
export DYLD_LIBRARY_PATH=/opt/mapr/lib
```

IMPORTANT: For MapR 6.0.0 and earlier, the following steps apply:

- a. For Mac users, locate the following line of code:

```
export LD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/amd64/
server
```

Then, replace this line with the following line of code:

```
export DYLD_LIBRARY_PATH=/opt/mapr/lib:$(JAVA_HOME)/jre/lib/server
```

- b. Based on your environment, edit `JAVA_HOME`. This ensures that `LD_LIBRARY_PATH` or `DYLD_LIBRARY_PATH` will include the full path to the directory containing the `libjvm` library.

NOTE: You can use `find / -name libjvm*` to determine the `JAVA_HOME` directory on your machine. However, note that the results of this command include the full path to the `libjvm` file not just the `JAVA_HOME` directory.

For example, `JAVA_HOME` may be set to `Library/Java/JavaVirtualMachines/jdk1.8.0_121.jdk/Contents/Home/` on a Mac and `JAVA_HOME` may be set to `/usr/lib/jvm/java-1.7.0-openjdk-1.7.0.79.x86_64/` on Linux.

6. From your directory (**librdkafka_example**), run the following commands to compile the source code:

```
make clean
```

```
make all
```

Run the Apps

Once you have the application executables, complete the following steps to run the application:

1. On a cluster node, use the `maprcli` to create a stream. For example, **MapR_Streams**.

```
maprcli stream create -path /MapR_Streams
```

NOTE: As long as `autocreate` is enabled for the stream when you run `stream create`, the producer will create the topic. By default, `autocreate` is enabled. For more information, see [stream create](#) on page 2708.

2. At the command line, set the library path to include **/opt/mapr/lib** and the path to the directory that contains the **libjvm** library. For more information, see [Configuring the HPE Data Fabric Streams C Client](#) on page 4007.

NOTE: You must complete this step at the command line even though you already set the library path in the Makefile. If you do not complete the step, an error similar to the following displays when you run the application in the next step: `error while loading shared libraries: librdkafka.so.1: cannot open shared object file: No such file or directory`

- From your directory (**librdkafka_example**), run the producer application from the command line. For example, if the application is called producer:

```
./producer
```

The following appears on the console assuming that the stream name is MapR_Streams:

```
***** PRODUCER *****
Create producer configuration object
Create Producer Kafka handle
Create topic handle
Send/Produce message to topic: /MapR_Streams:MapR-Topic1
Wait for messages to be delivered
Produced: Welcome to MapR Streams CAPI
Produced: MapR Streams CAPI Message Payload 1
Produced: MapR Streams CAPI Message Payload 2
Produced: MapR Streams CAPI Message Payload 3
Produced: MapR Streams CAPI Message Payload 4

Destroy topic handle
Destroy producer handle

PASS: 5 messages produced and sent to topic partition /
MapR_Streams:MapR-Topic1
```

- From your directory (**librdkafka_example**), run the consumer application from the command line. For example, if the application is called consumer:

```
./consumer
```

The following appears on the console assuming that the stream name is MapR_Streams:

```
***** CONSUMER START *****
Create new consumer configuration object
Set topic configurations
Create consumer Kafka handle
Create topic partition list for topic: /MapR_Streams:MapR-Topic1
Subscribe consumer to the topic:
Destroy topic partition list:

Start message consumption:
1 Consumed: Welcome to MapR-ES CAPI
2 Consumed: MapR Streams CAPI Message Payload 1
3 Consumed: MapR Streams CAPI Message Payload 2
4 Consumed: MapR Streams CAPI Message Payload 3
5 Consumed: MapR Streams CAPI Message Payload 4

Commit the offsets before closing the consumer

Close and destroy consumer handle

PASS: 5 messages consumed from topic /MapR_Streams:MapR-Topic1
```

Migrating Kafka C Applications to HPE Data Fabric Streams

With some modification, you can use existing Kafka C applications to consume and produce topics in HPE Data Fabric Streams. The HPE Data Fabric Streams C Client is a distribution of librdkafka that is compatible with HPE Data Fabric Streams.

- Install and [configure the MapR Streams C Client](#).

- When you refer to a topic in the application code, include the path and name of the stream in which the topic is located:

```
/<path and name of stream>:<name of topic>
```

For example, you might have a stream in a HPE Data Fabric cluster that is named `stream_A`, and the stream might be in a volume named `IoT` and in a directory named `automobile_sensors`. You want to redirect a producer application to a topic in that stream. The syntax of the path to the topic might look like this: `/mapr/IoT/automobile_sensors/stream_A:<name of topic>`.

NOTE: Optionally, use the `streams.consumer.default.stream` and `streams.producer.default.stream` configuration parameters. When you configure these parameters, applications can specify just the topic name to write or read from the default stream. To use these HPE Data Fabric-specific parameters in your application, compile your application with the `rdkafka.h` file (`/opt/mapr/include/librdkafka/rdkafka.h`) that was installed with the HPE Data Fabric Streams C Client. See the [Compile the Apps](#) on page 4018 section of [Developing a HPE Data Fabric Streams C Application](#) on page 4009.

- See [Configuration Properties for HPE Data Fabric Streams C Client](#) on page 4095 for the list of supported configuration parameters, including a few parameters that are HPE Data Fabric-specific. Make changes to your application, as needed.

NOTE: SSL-related configuration parameters are ignored. When you set these parameters, the HPE Data Fabric Streams Client issues a warning indicating that the parameters are not supported.

- Review the list of `librdkafka` APIs that are **not** supported by the HPE Data Fabric Streams C Client and make changes to your application, as needed.

Simple/low level consumer APIs that are not supported

- `rd_kafka_queue_new`
- `rd_kafka_queue_destroy`
- `rd_kafka_consume_start`
- `rd_kafka_consume_start_queue`
- `rd_kafka_consume_stop`
- `rd_kafka_consume`
- `rd_kafka_consume_batch`
- `rd_kafka_consume_callback`
- `rd_kafka_consume_queue`
- `rd_kafka_consume_batch_queue`
- `rd_kafka_consume_callback_queue`
- `rd_kafka_offset_store`
- `rd_kafka_pause_partitions`
- `rd_kafka_resume_partitions`

Producer/Consumer common APIs that are not supported

- `rd_kafka_conf_set_dr_cb`

- rd_kafka_conf_set_throttle_cb
- rd_kafka_conf_set_stats_cb
- rd_kafka_conf_set_socket_cb
- rd_kafka_conf_set_open_cb
- rd_kafka_conf_dump
- rd_kafka_conf_dump_free
- rd_kafka_name
- rd_kafka_set_log_level
- rd_kafka_mem_free
- rd_kafka_set_log_level
- rd_kafka_mem_free

Topic APIs that are not supported

- rd_kafka_query_watermark_offsets

NOTE: As of HPE Data Fabric 6.0.1, this API is supported.

- rd_kafka_get_watermark_offsets

NOTE: As of HPE Data Fabric 6.0.1, this API is supported.

Cluster APIs that are not supported

- rd_kafka_memberid
- rd_kafka_metadata
- rd_kafka_metadata_destroy

Miscellaneous APIs that are not supported

- rd_kafka_version
- rd_kafka_version_str
- rd_kafka_get_debug_contexts
- rd_kafka_dump
- rd_kafka_thread_cnt
- rd_kafka_message_timestamp

librdkafka APIs Supported by HPE Data Fabric Streams C Client

This topic lists the librdkafka APIs supported by the HPE Data Fabric Streams C Client. It also describes behavior differences between librdkafka and the HPE Data Fabric Streams C Client.

Table

Core release	EEP Release	Kafka librdkafka version
As of HPE Data Fabric 7.10.0	As of 9.4.0	2.6.0**
As of HPE Data Fabric 7.9.0	As of 9.3.1	2.0.2*
As of HPE Data Fabric 6.0.1	As of 5.0	0.11.3

Table (Continued)

Core release	EEP Release	Kafka librdkafka version
As of HPE Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

*Librdkafka 2.0.2 in core 7.9 is **not** compatible with HPE Data Fabric Stream clients for Python¹ or C#² applications. Nodes running Python or C# applications should not be upgraded to HPE Data Fabric 7.9.

Librdkafka 2.6.0 in core 7.10 is **not compatible with HPE Data Fabric Stream clients for C#² applications. Nodes running C# applications should not be upgraded to HPE Data Fabric 7.10.

- [Miscellaneous API](#) on page 4086

Producer APIs

API Behavior
Same as librdkafka.

A P I Behavior
Same as librdkafka.
When this API is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.
Same as librdkafka. This API should be used with either RD_KAFKA_V_TOPIC or RD_KAFKA_V_RKT.

<div><div>A</div><div>P</div><div>Behavior</div></div>	<p>When this API is called with NULL payload, an invalid argument error is sent to the callback. librdkafka creates a message with NULL payload and key value instead.</p>
<div><div>k</div><div>a</div><div>r</div><div>k</div><div>a</div><div>-</div><div>b</div><div>r</div><div>o</div><div>d</div><div>u</div><div>c</div><div>e</div><div>-</div><div>b</div><div>a</div><div>s</div><div>i</div><div>c</div><div>h</div></div>	<p>This API returns a positive number to indicate that messages are waiting to be produced to a streams topic but the value does not indicate the actual number of messages. librdkafka returns the actual number of messages that are waiting to be sent to or acknowledged by the broker.</p>

Consumer APIs

<div><div>A</div><div>P</div><div>Behavior</div></div>	<p>If this API is called for a consumer that is already subscribed to topics, no operation is performed.</p>
--	--

A P I B e h a v i o r	Behavior
r d k a f k a t o p i c p a r t i t i o n l i s t _ t	<p>This API returns the number of topic partitions the consumer is assigned to. However, it returns 0 when topic partitions have yet to be created by the producer. librdkafka returns the number of partitions assigned to a consumer even when the partitions have not been created.</p> <p> NOTE: For this API to work, the argument partitions must be explicitly allocated or initialized with either <code>rd_kafka_topic_partition_list_t *parts = NULL</code> or <code>rd_kafka_topic_partition_list_new(0);</code>. For example:</p> <pre>RD_EXPORT rd_kafka_resp_err_t rd_kafka_assignment (rd_kafka_t *rk, rd_kafka_topic_partition_list_t **partitions);</pre>

librdkafka	Same as librdkafka.

API Behavior
Same as librdkafka.
<p>When you are querying or retrieving a topic that is non-existent topic/partition (using <code>rd_kafka_query_watermark_offsets()</code> and <code>rd_kafka_get_watermark_offsets()</code> APIs), the timeout is honored even though you still receive the correct error message.</p>

A P I B e h a v i o r	Behavior
When you are querying or retrieving a topic that is non-existent topic/partition (using <code>rd_kafka_query_watermark_offsets()</code> and <code>rd_kafka_get_watermark_offsets()</code> APIs), the timeout is honored even though you still receive the correct error message.	

Additional Information

For more information and API signatures, see [rdkafka.h](#) on page 4105.

librdkafka APIs NOT Supported by HPE Data Fabric Streams C Client

This topic lists the librdkafka APIs that are *not* supported by the HPE Data Fabric Streams C Client.

These APIs are also documented in the [rdkafka.h](#) on page 4105 as not supported by HPE Data Fabric Streams. If you want to see the list of supported librdkafka APIs, see [librdkafka APIs Supported by HPE Data Fabric Streams C Client](#) on page 4023.

Data Fabric does not support any librdkafka API that is not listed in the [librdkafka APIs Supported by HPE Data Fabric Streams C Client](#) on page 4023.

 **NOTE:** Data Fabric does not support admin and transactional APIs for librdkafka 2.0.2 in core 7.9.

Table

Core release	EEP Release	Kafka librdkafka version
HPE Data Fabric 7.10.0	As of 9.4.0	2.6.0**
As of HPE Data Fabric 7.9.0	As of 9.3.1	2.0.2*
As of HPE Data Fabric 6.0.1	As of 5.0	0.11.3
As of HPE Data Fabric 5.2.1 through 6.0.0	As of 3.0	0.9.0

*Librdkafka 2.0.2 in core 7.9 is **not** compatible with HPE Data Fabric Stream clients for Python¹ or C#² applications. Nodes running Python or C# applications should not be upgraded to HPE Data Fabric 7.9.

Librdkafka 2.6.0 in core 7.10 is **not compatible with HPE Data Fabric Stream clients for C#² applications. Nodes running C# applications should not be upgraded to HPE Data Fabric 7.10.

Data Fabric does not support the following admin APIs and transactional APIs for librdkafka 2.6.0.

Table

Admin API grouping	unsupported APIs
Configuration management methods	rd_kafka_ConfigSource_name rd_kafka_ConfigEntry_name rd_kafka_ConfigEntry_value rd_kafka_ConfigEntry_source rd_kafka_ConfigEntry_is_read_only rd_kafka_ConfigEntry_is_default rd_kafka_ConfigEntry_is_sensitive rd_kafka_ConfigEntry_is_synonym rd_kafka_ConfigEntry_synonyms

Configuration Properties for HPE Data Fabric Streams C Client

This topic describes the configuration properties supported by the HPE Data Fabric Streams C Client. This includes librdkafka configuration properties that HPE Data Fabric Streams supports and additional properties that are specific to HPE Data Fabric Streams.

Global Configuration Properties

Property Name	
	Same as librdkafka.
	See Configuring Properties for Message Size on page 4571.

<div>Property Name</div>	
<div>Behavior</div>	<div>See Configuring Properties for Message Size on page 4571.</div>
<div></div>	<div>Same as librdkafka.</div>
<div></div>	<div>Same as librdkafka.</div>

Property Name	
Behavior	Same as librdkafka.
Usage	Same as librdkafka.
Notes	Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Data Fabric 6.0.1.

<div>Properties</div>	
<div>Name</div>	
<div>Behavior</div>	
<div>Same as librdkafka. Available as of librdkafka 0.11.3. Supported as of HPE Data Fabric 6.0.1.</div>	

Consumer Configuration Properties

Property Name	
Behavior	Same as librdkafka.
Default	Same as librdkafka.
Default	Same as librdkafka.

<div>Property Name</div>	
<div>Behavior</div>	<div>Same as librdkafka.</div>
<div>Configuration</div>	<div>Same as librdkafka.</div>
<div>Default</div>	<div>Same as librdkafka.</div>

Property Name	
Behavior	Same as librdkafka.
Same as librdkafka.	

Topic Configuration

Property Name	
Behavior	Same as librdkafka.
	Supports the following values: beginning, end, earliest, latest, none, smallest, and largest. As of HPE Data Fabric 6.0.1, beginning and end are supported.
	 NOTE: librdkafka additionally supports error.

HPE Data Fabric-Specific Configurations

<p>Property Name</p>	
<p>Behavior</p>	<p>Specifies the path and name of the stream that the consumer subscribes to if, when subscribing to a topic, the consumer does not specify a stream. For example, the consumer can specify the name of a stream together with the name of a topic to write to, like this: /<stream>:<topic>.</p> <p> NOTE: rd_kafka_list groups API uses this consumer configuration to obtain the consumer groups.</p>

Property Name	
Behavior	<p>Enables the producer to have multiple parallel send requests to the server for each topic partition. When this property is set to true, the default value, it is possible for messages to be sent out of order.</p>

Property Name	Behavior
Streams	<p>Specifies the stream that the producer will use by default if the producer does not provide the name of a stream when specifying a topic to write to. For example, the producer can specify the name of a stream together with the name of a topic to write to, like this: <code>/<stream>:<topic></code>. However, if the stream is not specified, the value of this configuration parameter is assumed to be the stream in which the topic is located. If the producer specifies the name of a topic without also providing the path and name of the stream, and there is no value for this configuration parameter, HPE Data Fabric Streams assumes that the topic specified is in Apache Kafka and does nothing.</p>

Additional Information

For more information, see [rdkafka.h](#) on page 4105.

rdkafka.h

This rdkafka header file has been updated to be compatible with HPE Data Fabric Streams. After you install the HPE Data Fabric Streams C Client, this file is available in the following directory: `/opt/mapr/include/librdkafka/`

librdkafka 2.6.0

Apache librdkafka 2.6.0 is supported as of HPE Data Fabric 7.10.0/EEP 9.4.0.

IMPORTANT: As of release 6.0.1, the `RD_KAFKA_MSG_F_BLOCK` call provides *blocking* behavior, whereas, the `RD_KAFKA_MSG_F_COPY` and `RD_KAFKA_MSG_F_FREE` calls are *non-blocking*.

/**
 * @brief Generic event callback to be used with the event API to trigger
 *        callbacks for \c rd_kafka_event_t objects from a background
 *        thread serving the background queue.
 *
 * How to use:
 * 1. First set the event callback on the configuration object with this
 *    function, followed by creating an rd_kafka_t instance
 *    with rd_kafka_new().
 * 2. Get the instance's background queue with
rd_kafka_queue_get_background()
 *    and pass it as the reply/response queue to an API that takes an
 *    event queue, such as rd_kafka_CreateTopics().
 * 3. As the response event is ready and enqueued on the background queue
the
 *    event callback will be triggered from the background thread.
 * 4. Prior to destroying the client instance, loose your reference to the
 *    background queue by calling rd_kafka_queue_destroy().
 *
 * The application must destroy the \c rkev passed to \p event cb using
 * rd_kafka_event_destroy().
 *
 * The \p event_cb \c opaque argument is the opaque set with
 * rd_kafka_conf_set_opaque().
 *
 * @remark This callback is a specialized alternative to the poll-based
 *        event API described in the Event interface section.
 *
 * @remark The \p event_cb will be called spontaneously from a background
 *        thread completely managed by librdkafka.
 *        Take care to perform proper locking of application objects.
 *
 * @warning The application MUST NOT call rd_kafka_destroy() from the
 *        event callback.
 *
 * @sa rd_kafka_queue_get_background

/**
* @brief \b Consumer: Set rebalance callback for use with
*         coordinated consumer group balancing.
*
* The \p err field is set to either RD_KAFKA_RESP_ERR_ASSIGN_PARTITIONS
* or RD_KAFKA_RESP_ERR_REVOKE_PARTITIONS and 'partitions'
* contains the full partition set that was either assigned or revoked.
*
* Registering a \p rebalance_cb turns off librdkafka's automatic
* partition assignment/revocation and instead delegates that responsibility
* to the application's \p rebalance_cb.
*
* The rebalance callback is responsible for updating librdkafka's
* assignment set based on the two events:
RD_KAFKA_RESP_ERR_ASSIGN_PARTITIONS
* and RD_KAFKA_RESP_ERR_REVOKE_PARTITIONS but should also be able to
handle
* arbitrary rebalancing failures where \p err is neither of those.
* @remark In this latter case (arbitrary error), the application must
*         call rd_kafka_assign(rk, NULL) to synchronize state.
*
* For eager/non-cooperative `partition.assignment.strategy` assignors,

```

```

* such as `range` and `roundrobin`, the application must use
* rd_kafka_assign() to set or clear the entire assignment.
* For the cooperative assignors, such as `cooperative-sticky`, the
application
* must use rd_kafka_incremental_assign() for
* RD_KAFKA_RESP_ERR_ASSIGN_PARTITIONS and rd_kafka_incremental_unassign()
* for RD_KAFKA_RESP_ERR_REVOKE_PARTITIONS.
*
* Without a rebalance callback this is done automatically by librdkafka
* but registering a rebalance callback gives the application flexibility
* in performing other operations along with the assigning/revocation,
* such as fetching offsets from an alternate location (on assign)
* or manually committing offsets (on revoke).
*
* rebalance_cb is always triggered exactly once when a rebalance completes
* with a new assignment, even if that assignment is empty. If an
* eager/non-cooperative assignor is configured, there will eventually be
* exactly one corresponding call to rebalance_cb to revoke these partitions
* (even if empty), whether this is due to a group rebalance or lost
* partitions. In the cooperative case, rebalance_cb will never be called if
* the set of partitions being revoked is empty (whether or not lost).
*
* The callback's \p opaque argument is the opaque set with
* rd_kafka_conf_set_opaque().
*
* @remark The \p partitions list is destroyed by librdkafka on return
* return from the rebalance_cb and must not be freed or
* saved by the application.
*
* @remark Be careful when modifying the \p partitions list.
* Changing this list should only be done to change the initial
* offsets for each partition.
* But a function like `rd_kafka_position()` might have unexpected
* effects for instance when a consumer gets assigned a partition
* it used to consume at an earlier rebalance. In this case, the
* list of partitions will be updated with the old offset for that
* partition. In this case, it is generally better to pass a copy
* of the list (see `rd_kafka_topic_partition_list_copy()`).
* The result of `rd_kafka_position()` is typically outdated in
* RD_KAFKA_RESP_ERR_ASSIGN_PARTITIONS.
*
* @sa rd_kafka_assign()
* @sa rd_kafka_incremental_assign()
* @sa rd_kafka_incremental_unassign()
* @sa rd_kafka_assignment_lost()
* @sa rd_kafka_rebalance_protocol()
*
* The following example shows the application's responsibilities:
* @code
* static void rebalance_cb (rd_kafka_t *rk, rd_kafka_resp_err_t err,
* rd_kafka_topic_partition_list_t *partitions,
* void *opaque) {
*
* switch (err)
* {
* case RD_KAFKA_RESP_ERR_ASSIGN_PARTITIONS:
* // application may load offsets from arbitrary external
* // storage here and update \p partitions
* if (!strcmp(rd_kafka_rebalance_protocol(rk), "COOPERATIVE"))
* rd_kafka_incremental_assign(rk, partitions);
* else // EAGER
* rd_kafka_assign(rk, partitions);
* break;
*
* }
* }

```

```

*         case RD_KAFKA_RESP_ERR__REVOKE_PARTITIONS:
*             if (manual_commits) // Optional explicit manual commit
*                 rd_kafka_commit(rk, partitions, 0); // sync commit
*
*             if (!strcmp(rd_kafka_rebalance_protocol(rk), "COOPERATIVE"))
*                 rd_kafka_incremental_unassign(rk, partitions);
*             else // EAGER
*                 rd_kafka_assign(rk, NULL);
*
*             break;
*
*         default:
*             handle_unlikely_error(err);
*             rd_kafka_assign(rk, NULL); // sync state
*             break;
*     }
* }
* @endcode
*
* @remark The above example lacks error handling for assign calls, see
* the examples/ directory.

/**
* @brief Set SASL/OAUTHBEARER token refresh callback in provided conf
object.
*
* @param conf the configuration to mutate.
* @param oauthbearer_token_refresh_cb the callback to set; callback
function
* arguments:<br>
*   \p rk - Kafka handle<br>
*   \p oauthbearer_config - Value of configuration property
*                           sasl.oauthbearer.config.
*   \p opaque - Application-provided opaque set via
*               rd_kafka_conf_set_opaque()
*
* The SASL/OAUTHBEARER token refresh callback is triggered via
rd_kafka_poll()
* whenever OAUTHBEARER is the SASL mechanism and a token needs to be
retrieved,
* typically based on the configuration defined in \c

```

```

sasl.oauthbearer.config.
*
* The callback should invoke rd_kafka_oauthbearer_set_token()
* or rd_kafka_oauthbearer_set_token_failure() to indicate success
* or failure, respectively.
*
* The refresh operation is eventable and may be received via
* rd_kafka_queue_poll() with an event type of
* \c RD_KAFKA_EVENT_OAUTHBEARER_TOKEN_REFRESH.
*
* Note that before any SASL/OAUTHBEARER broker connection can succeed the
* application must call rd_kafka_oauthbearer_set_token() once -- either
* directly or, more typically, by invoking either rd_kafka_poll(),
* rd_kafka_consumer_poll(), rd_kafka_queue_poll(), etc, in order to cause
* retrieval of an initial token to occur.
*
* Alternatively, the application can enable the SASL queue by calling
* rd_kafka_conf_enable_sasl_queue() on the configuration object prior to
* creating the client instance, get the SASL queue with
* rd_kafka_queue_get_sasl(), and either serve the queue manually by calling
* rd_kafka_queue_poll(), or redirecting the queue to the background thread
to
* have the queue served automatically. For the latter case the SASL queue
* must be forwarded to the background queue with rd_kafka_queue_forward().
* A convenience function is available to automatically forward the SASL
queue
* to librdkafka's background thread, see
* rd_kafka_sasl_background_callbacks_enable().
*
* An unsecured JWT refresh handler is provided by librdkafka for
development
* and testing purposes, it is enabled by setting
* the \c enable.sasl.oauthbearer.unsecure.jwt property to true and is
* mutually exclusive to using a refresh callback.
*
* @sa rd_kafka_sasl_background_callbacks_enable()
* @sa rd_kafka_queue_get_sasl()

RD_KAFKA_MSG_F_PARTITION                                \
    0x8 /**< produce_batch() will
honor         * per-message partition. */

/**
 * @brief Produce and send a single message to broker.
 *
 * \p rkt is the target topic which must have been previously created with
 * `rd_kafka_topic_new()`.
 *
 * `rd_kafka_produce()` is an asynchronous non-blocking API.
 * See `rd_kafka_conf_set_dr_msg_cb` on how to setup a callback to be called
 * once the delivery status (success or failure) is known. The delivery
report
 * is triggered by the application calling `rd_kafka_poll()` (at regular
 * intervals) or `rd_kafka_flush()` (at termination).
 *
 * Since producing is asynchronous, you should call `rd_kafka_flush()`
before
 * you destroy the producer. Otherwise, any outstanding messages will be
 * silently discarded.
 *
 * When temporary errors occur, librdkafka automatically retries to produce
the
 * messages. Retries are triggered after retry.backoff.ms and when the
 * leader broker for the given partition is available. Otherwise, librdkafka
 * falls back to polling the topic metadata to monitor when a new leader is
 * elected (see the topic.metadata.refresh.fast.interval.ms and
 * topic.metadata.refresh.interval.ms configurations) and then performs a
 * retry. A delivery error will occur if the message could not be produced
 * within message.timeout.ms.
 *
 * See the "Message reliability" chapter in INTRODUCTION.md for more
 * information.
 *
 * \p partition is the target partition, either:
 *   - RD_KAFKA_PARTITION_UA (unassigned) for
 *     automatic partitioning using the topic's partitioner function, or
 *   - a fixed partition (0..N)
 *
 * \p msgflags is zero or more of the following flags OR:ed together:
 *   RD_KAFKA_MSG_F_BLOCK - block \p produce*() call if
 *
 *                       \p queue.buffering.max.messages or
 *                       \p queue.buffering.max.kbytes are exceeded.
 *                       Messages are considered in-queue from the point
 * they are accepted by produce() until their corresponding delivery report
 * callback/event returns. It is thus a requirement to call rd_kafka_poll()

```

```

(or
* equiv.) from a separate thread when F_BLOCK is used. See WARNING on \c
* RD_KAFKA_MSG_F_BLOCK above.
*
* RD_KAFKA_MSG_F_FREE - rdkafka will free(3) \p payload when it is done
* with it.
* RD_KAFKA_MSG_F_COPY - the \p payload data will be copied and the
* \p payload pointer will not be used by rdkafka
* after the call returns.
* RD_KAFKA_MSG_F_PARTITION - produce_batch() will honour per-message
* partition, either set manually or by the
* configured partitioner.
*
* .._F_FREE and .._F_COPY are mutually exclusive. If neither of these
are
* set, the caller must ensure that the memory backing \p payload remains
* valid and is not modified or reused until the delivery callback is
* invoked. Other buffers passed to `rd_kafka_produce()` don't have this
* restriction on reuse, i.e. the memory backing the key or the topic
name
* may be reused as soon as `rd_kafka_produce()` returns.
*
* If the function returns -1 and RD_KAFKA_MSG_F_FREE was specified, then
* the memory associated with the payload is still the caller's
* responsibility.
*
* \p payload is the message payload of size \p len bytes.
*
* \p key is an optional message key of size \p keylen bytes, if non-NULL it
* will be passed to the topic partitioner as well as be sent with the
* message to the broker and passed on to the consumer.
*
* \p msg_opaque is an optional application-provided per-message opaque
* pointer that will be provided in the message's delivery report callback
* (\c dr_msg_cb or \c dr_cb) and the \c rd_kafka_message_t \c _private
field.
*
* @remark on_send() and on_acknowledgement() interceptors may be called
* from this function. on_acknowledgement() will only be called if
the
* message fails partitioning.
*
* @remark If the producer is transactional (\c transactional.id is
configured)
* producing is only allowed during an on-going transaction, namely
* after rd_kafka_begin_transaction() has been called.
*
* @returns 0 on success or -1 on error in which case errno is set
accordingly:
* - ENOBUFS - maximum number of outstanding messages has been reached:
* "queue.buffering.max.messages"
* (RD_KAFKA_RESP_ERR_QUEUE_FULL)
* - EMSGSIZE - message is larger than configured max size:
* "messages.max.bytes".
* (RD_KAFKA_RESP_ERR_MSG_SIZE_TOO_LARGE)
* - ESRCH - requested \p partition is unknown in the Kafka cluster.
* (RD_KAFKA_RESP_ERR_UNKNOWN_PARTITION)
* - ENOENT - topic is unknown in the Kafka cluster.
* (RD_KAFKA_RESP_ERR_UNKNOWN_TOPIC)
* - ECANCELED - fatal error has been raised on producer, see
* rd_kafka_fatal_error(),
* (RD_KAFKA_RESP_ERR_FATAL).
* - ENOEXEC - transactional state forbids producing
* (RD_KAFKA_RESP_ERR_STATE)

```

* @brief Wait until all outstanding produce requests, et.al, are completed.
*        This should typically be done prior to destroying a producer
instance
*        to make sure all queued and in-flight produce requests are
completed
*        before terminating.
*
* @remark This function will call rd_kafka_poll() and thus trigger
callbacks.
*
* @remark The \c linger.ms time will be ignored for the duration of the
call,
*        queued messages will be sent to the broker as soon as possible.
*
* @remark If RD_KAFKA_EVENT_DR has been enabled
*        (through rd_kafka_conf_set_events()) this function will not call
*        rd_kafka_poll() but instead wait for the librdkafka-handled
*        message count to reach zero. This requires the application to
*        serve the event queue in a separate thread.
*        In this mode only messages are counted, not other types of
*        queued events.
*
* @returns RD_KAFKA_RESP_ERR__TIMED_OUT if \p timeout_ms was reached
before all
*        outstanding requests were completed, else
RD_KAFKA_RESP_ERR_NO_ERROR
*
* @sa rd_kafka_outq_len()
*/

/**
* @brief Purge messages currently handled by the producer instance.
*
* @param rk          Client instance.
* @param purge_flags Tells which messages to purge and how.
*
* The application will need to call rd_kafka_poll() or rd_kafka_flush()

```

```

* afterwards to serve the delivery report callbacks of the purged messages.
*
* Messages purged from internal queues fail with the delivery report
* error code set to RD_KAFKA_RESP_ERR__PURGE_QUEUE, while purged messages
that
* are in-flight to or from the broker will fail with the error code set to
* RD_KAFKA_RESP_ERR__PURGE_INFLIGHT.
*
* @warning Purging messages that are in-flight to or from the broker
*           will ignore any subsequent acknowledgement for these messages
*           received from the broker, effectively making it impossible
*           for the application to know if the messages were successfully
*           produced or not. This may result in duplicate messages if the
*           application retries these messages at a later time.
*
* @remark This call may block for a short time while background thread
*           queues are purged.
*
* @returns RD_KAFKA_RESP_ERR_NO_ERROR on success,
*           RD_KAFKA_RESP_ERR__INVALID_ARG if the \p purge flags are invalid
*           or unknown,
*           RD_KAFKA_RESP_ERR__NOT_IMPLEMENTED if called on a non-producer
*           client instance.

/**
 * @name Miscellaneous APIs
 * @{
 *
 */

/**
 * @brief Adds one or more brokers to the kafka handle's list of initial
 *        bootstrap brokers.
 *
 * Additional brokers will be discovered automatically as soon as rdkafka
 * connects to a broker by querying the broker metadata.
 *
 * If a broker name resolves to multiple addresses (and possibly
 * address families) all will be used for connection attempts in
 * round-robin fashion.
 *
 * \p brokerlist is a , -separated list of brokers in the format:
 *   \c \<broker1>,\<broker2>,...
 * Where each broker is in either the host or URL based format:
 *   \c \<host>[:\<port>]
 *   \c \<proto>://\<host>[:port]
 * \c \<proto> is either \c PLAINTEXT, \c SSL, \c SASL, \c SASL_PLAINTEXT
 * The two formats can be mixed but ultimately the value of the
 * `security.protocol` config property decides what brokers are allowed.
 *
 * Example:
 *   brokerlist = "broker1:10000,broker2"
 *   brokerlist = "SSL://broker3:9000,ssl://broker2"
 *
 * @returns the number of brokers successfully added.
 *
 * @remark Brokers may also be defined with the \c metadata.broker.list or
 *         \c bootstrap.servers configuration property (preferred method).
 *
 * @deprecated Set bootstrap servers with the \c bootstrap.servers
 *              configuration property.

```

```

/**
 * @name Interceptors
 *
 * @{
 *
 * @brief A callback interface that allows message interception for both
 *        producer and consumer data pipelines.
 *
 * Except for the on_new(), on_conf_set(), on_conf_dup() and
on_conf_destroy()
 * interceptors, interceptors are added to the
 * newly created rd_kafka_t client instance. These interceptors MUST only
 * be added from on_new() and MUST NOT be added after rd_kafka_new()
returns.
 *
 * The on_new(), on_conf_set(), on_conf_dup() and on_conf_destroy()
interceptors
 * are added to the configuration object which is later passed to
 * rd_kafka_new() where on_new() is called to allow addition of
 * other interceptors.
 *
 * Each interceptor reference consists of a display name (ic_name),
 * a callback function, and an application-specified opaque value that is
 * passed as-is to the callback.
 * The ic_name must be unique for the interceptor implementation and is used
 * to reject duplicate interceptor methods.
 *
 * Any number of interceptors can be added and they are called in the order
 * they were added, unless otherwise noted.
 * The list of registered interceptor methods are referred to as
 * interceptor chains.
 *
 * @remark Contrary to the Java client the librdkafka interceptor interface
 *        does not support message key and value modification.
 *        Message mutability is discouraged in the Java client and the
 *        combination of serializers and headers cover most use-cases.
 *
 * @remark Interceptors are NOT copied to the new configuration on
 *        rd_kafka_conf_dup() since it would be hard for interceptors to
 *        track usage of the interceptor's opaque value.
 *        An interceptor should rely on the plugin, which will be copied
 *        in rd_kafka_conf_dup(), to set up the initial interceptors.
 *        An interceptor should implement the on_conf_dup() method
 *        to manually set up its internal configuration on the newly
created
 *        configuration object that is being copied-to based on the
 *        interceptor-specific configuration properties.
 *        conf_dup() should thus be treated the same as conf_init().
 *
 * @remark Interceptors are keyed by the interceptor type (on_..()), the
 *        interceptor name (ic_name) and the interceptor method function.
 *        Duplicates are not allowed and the .._add_on_..() method will
 *        return RD_KAFKA_RESP_ERR_CONFLICT if attempting to add a
duplicate
 *        method.
 *        The only exception is on_conf_destroy() which may be added
multiple
 *        times by the same interceptor to allow proper cleanup of
 *        interceptor configuration state.
 */

/**
 * @brief on_conf_set() is called from rd_kafka_*_conf_set() in the order

```

```

*         the interceptors were added.
*
* @param conf Configuration object.
* @param ic_opaque The interceptor's opaque pointer specified in ..add..().

/**
 * @name Admin API
 * @{
 */

```

```

* @brief The Admin API enables applications to perform administrative
*        Apache Kafka tasks, such as creating and deleting topics,
*        altering and reading broker configuration, etc.
*
* The Admin API is asynchronous and makes use of librdkafka's standard
* \c rd_kafka_queue_t queues to propagate the result of an admin operation
* back to the application.
* The supplied queue may be any queue, such as a temporary single-call
queue,
* a shared queue used for multiple requests, or even the main queue or
* consumer queues.
*
* Use \c rd_kafka_queue_poll() to collect the result of an admin operation
* from the queue of your choice, then extract the admin API-specific result
* type by using the corresponding \c rd_kafka_event_CreateTopics_result,
* \c rd_kafka_event_DescribeConfigs_result, etc, methods.
* Use the getter methods on the \c .._result_t type to extract response
* information and finally destroy the result and event by calling
* \c rd_kafka_event_destroy().
*
* Use rd_kafka_event_error() and rd_kafka_event_error_string() to acquire
* the request-level error/success for an Admin API request.
* Even if the returned value is \c RD_KAFKA_RESP_ERR_NO_ERROR there
* may be individual objects (topics, resources, etc) that have failed.
* Extract per-object error information with the corresponding
* \c rd_kafka_..._result_topics|resources|..() to check per-object errors.
*
* Locally triggered errors:
* - \c RD_KAFKA_RESP_ERR__TIMED_OUT - (Controller) broker connection did
not
*   become available in the time allowed by
AdminOption_set_request_timeout.
