### Kafka Streams Security

Discusses Kafka Streams security topics.

### Internal Topics

All Kafka Streams application's internal topics are grouped in the Kafka Streams application directory: **/apps/kafka-streams**.

- The **/apps** directory has only write access to **mapr user**. The **/apps/kafka-streams** directory is not modifiable/deletable by any user other than **mapr user**.
- All users can create sub-directories inside the **/apps/kafka-streams** directory. Only the following users have read/write/delete permission for sub-directories or files created in this directory.
  - **mapr user**
  - Current user of the sub-directory:
    - If security is enabled, the current user is the Data Fabric ticket identity. See [Managing Tickets](#) on page 2100 for more information.
    - If security is **not** enabled, the current Data Fabric identity.

### Kafka Streams Application Specific Folders

Some Kafka Streams applications need to create internal topics. These topics are created in the **/apps/kafka-streams/<application.id>** directory.

 **IMPORTANT:** This directory is created at runtime by the Kafka Streams application and can only be modified by the current user or super users. This directory can only be deleted by the [Application Reset Tool](#) on page 5248 (ART) and, again, by only the current user or super users.

### Application Reset Tool and Cleanup APIs

The application reset tool allows to reset a Kafka Streams application's internal state, such that it can re-process its input data from scratch. Kafka Streams internal topics can be cleaned using application reset tool.

Only the current user of the Kafka Streams application or **mapr user** has permissions to clean up a Kafka Streams application using Application Reset Tool. The Application Reset Tool is integrated with the cleanup APIs so that the application's internal topics are prefixed with the same directory.

The application reset tool takes `application.id` as the input for cleaning up Kafka Streams application. As part of this process, all internal-topics are deleted for the application user under the **/apps/kafka-streams/<application.id>** directory, including the **/apps/kafka-streams/<application.id>** directory. See [Application Reset Tool](#) on page 5248 for more information.

### Changes in Kafka 2.6.1

Describes several differences to note when upgrading from Kafka 2.1.1 to 2.6.1.

**Classpath change**

- Kafka 2.6.1 uses classes from `kafka-eventstreams.jar` instead of `mapr-streams.jar` to access the cluster.
- If an application fails with a `ClassNotFoundException` or `NoClassDefFoundError` for classes in packages under `com.mapr.kafka.eventstreams.*`, verify that `kafka-eventstreams.jar` is in the Java classpath. You can find `kafka-eventstreams.jar` in the `/opt/mapr/lib/` directory, or you can download it from the Maven repository.

**Scala changes**

- Scala version 2.11 is no longer supported. Scala versions 2.12 and 2.13 are supported.
- Scala code leveraging the `NewTopic(String, int, short)` constructor with literal values must explicitly call `toShort` on the second literal.

**RocksDBs change**

- Kafka Streams version 2.6.1 requires RocksDB version 5.18.4.

**Default consumer group id**

- The default consumer group id has been changed from the empty string (`"`) to `null`. Consumers that use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of the consumer configuration. For more information, see [KIP-289](#).

**client.dns.lookup**

The default value for the `client.dns.lookup` configuration has been changed from default to `use_all_dns_ips`. If a hostname resolves to multiple IP addresses, clients and brokers will now attempt to connect to each IP in sequence until the connection is successfully established. For more information, see [KIP-602](#).

**DSL**

- Use the DSL operator, `cogroup()`, to aggregate multiple streams together at once.
- Kafka Streams DSL switches its used store types. While this change is mainly transparent to users, there are some corner cases that may require code changes.

**KStream.toTable() API**

Use the `KStream.toTable()` API to translate an input event stream into a `KTable`.

**Serde type Void**

Use the Serde type, `Void`, to represent null keys or null values from an input topic.

**Sticky partitioning**

The `DefaultPartitioner` now uses a sticky partitioning strategy. This means that records for a specific topic with null keys and no assigned partition will be sent to the same partition until the batch is ready to be sent. When a new batch is created, a new partition is chosen. This decreases latency to produce, but it

may result in uneven distribution of records across partitions in edge cases. Generally, users will not be impacted, but this difference may be noticeable in tests and other situations producing records for a very short amount of time.

## Rebalancing

- We are introducing incremental cooperative rebalancing to the clients' group protocol, which allows consumers to keep all of their assigned partitions during a rebalance and in the end revoke only those which must be migrated to another consumer for the overall cluster balance. The ConsumerCoordinator will choose the latest RebalanceProtocol that is commonly supported by all of the consumer's supported assignors.
- We are introducing a new rebalancing protocol for Kafka Connect based on incremental cooperative rebalancing. The new protocol does not require stopping all the tasks during a rebalancing phase between Connect workers. Instead, only the tasks that need to be exchanged between workers are stopped and they are started in a follow-up rebalance. The new Connect protocol is enabled by default. For more details on how it works and how to enable the old behavior of eager rebalancing, checkout incremental cooperative rebalancing design.

## Deprecated APIs

- Deprecated `UsePreviousTimeOnInvalidTimestamp` and replaced with `UsePartitionTimeOnInvalidTimeStamp`.
- Provided support to query stale stores (for high availability) and the stores belonging to a specific partition by deprecating `KafkaStreams.store(String, QueryableStoreType)` and replacing it with `KafkaStreams.store(StoreQueryParameters)`.
- The internal `PartitionAssignor` interface has been deprecated and replaced with a new `ConsumerPartitionAssignor` in the public API. Some methods/signatures are slightly different between the two interfaces. Users implementing a custom `PartitionAssignor` should migrate to the new interface as soon as possible.
- The blocking `KafkaConsumer#committed` methods have been extended to allow a list of partitions as input parameters rather than a single partition. It enables fewer request/response iterations between clients and brokers fetching for the committed offsets for the consumer group. The old overloaded functions are deprecated and we would recommend users making their code changes to leverage the new methods

- The default consumer group id has been changed from the empty string ("") to null. Consumers who use the new default group id will not be able to subscribe to topics and fetch or commit offsets. The empty string as consumer group id is deprecated but will be supported until a future major release. Old clients that rely on the empty string group id will now have to explicitly provide it as part of their consumer configuration.

### Kafka REST Proxy

The Kafka REST Proxy provides a RESTful interface to HPE Data Fabric Streams clusters to consume and produce messages and to perform administrative operations.

It allows you to:

- Consume messages from topics or concrete topic partitions.
- Produce messages to topics or partitions.
- View the state of the cluster.

Use cases include ingesting messages into a stream-processing framework and scripting administrative operations.

### Configuration

This section describes how to configure the Kafka REST Proxy for HPE Data Fabric Streams.

You can set these configuration parameters in the `kafka-rest.properties` file. The Control System displays information about the Kafka REST Proxy for the HPE Data Fabric Streams service. By default, the service runs on port **8082**.

To install the Kafka REST Proxy, see [Installing HPE Data Fabric Streams Tools](#) on page 314.

To configure the Kafka REST Proxy for HPE Data Fabric Streams, edit the following file:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

To view the Kafka REST Proxy for HPE Data Fabric Streams log files, see the following location:

```
/opt/mapr/kafka-rest/kafka-rest-<version>/logs/kafka-rest.log
```

**NOTE:** After installation, Warden automatically detects the configuration and starts the service. To configure the Kafka REST Proxy for HPE Data Fabric Streams, stop the service, configure the parameters, and restart the service. To stop and restart services, see [maprccli node services](#). For example:

```
maprccli node services -name kafka-rest -action stop
```

```
https://<host>:8443/rest/node/services?
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

### Configuration Parameters

This section provides the Kafka REST Proxy for HPE Data Fabric Streams parameters.

These parameters are configurable in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

**NOTE:** Starting in EEP 8.0.0, Schema Registry (version 6.0.0.0) supports Avro, JSON Schema, and Protobuf formats.

**Table**

Parameter	Description
<code>api.v2.enable</code>	Enables the REST Proxy v2 API when set to <code>true</code> . Default is <code>true</code> . This parameter is available starting in Kafka REST 6.0.0.0.
<code>api.v3.enable</code>	Enables the REST Proxy v3 API when set to <code>true</code> . Default is <code>false</code> . This parameter is available starting in Kafka REST 6.0.0.0.
<code>advertised.listeners</code>	List of advertised listeners used when generating absolute URLs in responses. Supports <code>http</code> and <code>https</code> protocols. Each listener must include the protocol, hostname, and port. For example: <code>http://myhost:8080</code> , <code>https://0.0.0.0:8081</code> . This parameter is available starting in Kafka REST 6.0.0.0.
<code>schema.registry.enable</code>	Enables Avro serialization and deserialization support with Schema Registry. Starting in Schema Registry 6.0.0.0, enables JSON Schema, and Protobuf serialization and deserialization as well as Avro.
<code>schema.registry.url</code>	The base URL for the schema registry for use by the Avro serializer. Starting in Schema Registry 6.0.0.0, also for use by the JSON Schema and Protobuf serializers, as well as Avro. This setting is ignored if <code>schema.registry.enable</code> is set to <code>false</code> . The default value is resolved from Zookeeper.
<code>schema.registry.service.id</code>	Indicates the ID of the schema registry service. Default: <code>default_</code>
<code>schema.registry.discovery.timeout</code>	The timeout in milliseconds for request to Schema Registry URL storage. Default: 60000
<code>schema.registry.discovery.retries</code>	The number of retries for Schema Registry URL discovery. Default: 6
<code>schema.registry.discovery.interval</code>	The interval in milliseconds between retries for Schema Registry URL discovery. Default: 15000
<code>streams.default.stream</code>	The default stream the consumer should poll messages from and the producer should send messages to. If the topic name does not specify the stream path, and the property has a valid value, then this topic name is found in the default stream.
<code>id</code>	Unique ID for this REST server instance. This is used in generating unique IDs for consumers that do not specify their ID. The ID is empty by default, which makes a single server setup easier to get up and running, but is not safe for multi-server deployments where automatic consumer IDs are used. Type: <code>string</code> . Default: <code>empty</code>
<code>consumer.threads</code>	The number of threads to run consumer requests on. Type: <code>int</code> . Default: 1
<code>simpleconsumer.cache.max.records</code>	Maximum number of records that can be stored in a single cache. Records with higher offsets replace records with lower ones. The value must be greater than 0. Type: <code>int</code> . Default: 1000.

Table (Continued)

Parameter	Description
simpleconsumer.max.caches.num	Maximum number topic-partition combinations for which records are cached. If this parameter is set to 0, then caching is disabled and extra records are thrown away. Cache improves performance if records are fetched sequentially thus increasing offsets.  A pool of caches are available to store extra fetch records by a KafkaConsumer for a particular TopicPartition. The cache increases performance when records are fetched from a particular topic partition in a sequential manner. For example, every next request will start with the following offset after the offset of the latest fetched record in the previous request. Type: int. Default: 0
simpleconsumer.max.poll.time	Specifies the maximum number of milliseconds that are spent for polling records by a simpleconsumer. The greater the value means greater latency but higher throughput. Type: int. Default: 1000
simpleconsumer.pool.size.max	Maximum number of SimpleConsumers that can be instantiated. If 0, then the pool size is not limited. Type: int. Default: 25
simpleconsumer.pool.timeout.ms	Amount of time to wait for an available SimpleConsumer from the pool before failing. Use 0 for no timeout. Type: int. Default: 1000
consumer.instance.timeout.ms	Amount of idle time (in milliseconds) before a consumer instance is automatically destroyed. Type: int. Default: 300000 (5 minutes)
consumer.iterator.backoff.ms	Amount of time (in milliseconds) to backoff when an iterator runs out of data. If a consumer has a dedicated worker thread, this is effectively the maximum error for the entire request timeout. This parameter should be small enough to closely target the timeout, but large enough to avoid busy waiting. Type: int. Default: 50
consumer.request.max.bytes	Maximum number of bytes in unencoded message keys and values returned by a single request. This can be used by administrators to limit the memory used by a single consumer and to control the memory usage required to decode responses on clients that cannot perform a streaming decode. Note that the actual payload will be larger due to overhead from base64 encoding the response data and from JSON encoding the entire response. Type: long. Default: 6710884
consumer.request.timeout.ms	The maximum total time (in milliseconds) to wait for messages for a request if the maximum number of messages has not yet been reached. Type: int. Default: 1
producer.threads	Number of threads to run producer requests on. Type: int. Default: 5
producer.streams.buffer.max.time.ms	Buffers messages in the producer for the maximum time specified time. A thread flushes all the messages that have been buffered beyond the time specified. Default: 1
producers.max.caches.num	Maximum number user names for which producers are cached. If 0, then caching is disabled and producer will be created for each request. Default: 20
request.logger.name	Name of the SLF4J logger to write the NCSA Common Log Format request log. Type: string. Default: io.confluent.rest-utils.requests.
response.mediatype.default	The default response media type that should be used if no specify types are requested in an Accept header. Type: string. Default: application/vnd.kafka.v1+json

**Table (Continued)**

Parameter	Description
response.mediatype.preferred	An ordered list of the server's preferred media types used for responses, from most preferred to least. Type: list. Default: application/vnd.kafka.v1+json, application/vnd.kafka+json, application/json
access.control.allow.methods	Sets the value to the Jetty Access-Control-Allow-Origin header for specified methods. Type: string. Default: empty
access.control.allow.origin	Sets the value for the Jetty Access-Control-Allow-Origin header. Type: string. Default: empty
host.name	The host name used to generate absolute URLs in responses. If empty, the default canonical hostname is used. Type: string. Default: empty
debug	Boolean indicating whether extra debugging information is generated in some error response entities. Type: Boolean. Default: false
shutdown.graceful.ms	Amount of time to wait after a shutdown request for outstanding requests to complete. Type: int. Default: 1000
metric.reporters	A list of classes to use as metrics reporters. Implementing the MetricReporterInterface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics. Type: list. Default: empty
metrics.jmx.prefix	Prefix to apply to metric names for the default JMX reporter. Type: string. Default: kafka.rest
metrics.num.samples	The number of samples maintained to compute metrics. Type: int. Default: 2
metrics.sample.window.ms	The metrics system maintains a configurable number of samples over a fixed window size. This configuration controls the size of the window. For example, used to maintain two samples each measured over a 30 second period. When a window expires, the oldest window is erased and overwritten. Type: long. Default: 30000

#### Security Parameters

Describes Kafka REST security parameters.

By default, Kafka REST is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (MapR-SASL) enabled. Default security provides authentication, encryption, and impersonation for Kafka REST.

Configure security for Kafka REST through the security parameters in the `kafka-rest.properties` file.

```
/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties
```

**NOTE:** Ensure that both a `ssl_keystore` and a `ssl_truststore` file have been created.

**Table**

Parameter	Description	Type	Default
authentication.cookie.expiration	Authentication cookie expiration time in seconds.	long	7200 (2 hours)
authentication.enable	Whether or not to enable authentication.	boolean	false

**Table (Continued)**

Parameter	Description	Type	Default
impersonation.enable	Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user.	boolean	false
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: http://localhost:8082	list	none
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none
ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	<ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .DES.</li> <li>• .MD5.</li> <li>• .RC4.</li> </ul>
ssl.client.auth	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store.	boolean	false
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if ssl_endpoint_identification_algorithm=https. Leave blank to use Jetty's default.	string	none

Table (Continued)

Parameter	Description	Type	Default
ssl.key.password	<p>The password of the private key in the keystore file.</p> <p>This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.</p> <p> <b>NOTE:</b> If the ssl-client.xml file is changed, Kafka REST must be restarted.</p>	string	empty
ssl.keymanager.algorithm	<p>The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.</p>	string	empty
ssl.keystore.location	<p>Location of the keystore file.</p> <p>This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.</p> <p> <b>NOTE:</b> If the ssl-client.xml file is changed, Kafka REST must be restarted.</p>	string	empty
ssl.keystore.password	<p>The store password for the keystore file.</p> <p>This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.</p> <p> <b>NOTE:</b> If the ssl-client.xml file is changed, Kafka REST must be restarted.</p>	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLS-v1.2-
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty

Table (Continued)

Parameter	Description	Type	Default
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false
headers.file	The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.	string	empty

### SSL Security Configuration

Describes how to configure Kafka REST security.

### Secure by Default

As of release 6.0, the Data Fabric Installer performs the Kafka REST configuration for new installations. This means that:

- If Data Fabric core is installed as *secure*, then Kafka REST is also installed as *secure*.
- If Data Fabric core is installed as *insecure*, then Kafka REST is also installed as *insecure*.

### Manually Securing Kafka REST Only

 **CAUTION:** This configuration is *not* a typical configuration.

If you have an *insecure* Data Fabric cluster, and you want to *secure* Kafka REST, do the following:

1. Generate the server and client certificates.
2. Add any necessary property configurations to the `kafka-rest.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8082,https://0.0.0.0:8085
ssl.keystore.location=<ssl-keystore-path>
ssl.keystore.password=<ssl-keystore-password>
ssl.key.password=<ssl-keystore-password>
```

3. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

4. Run a curl command to ensure that HTTPS is enabled.

```
curl -X GET https://node1:8085/streams/%2Ftesting/topics --cacert
<certificate-path>
```

### Manually Unsecuring Kafka REST

 **WARNING:** This scenario is *NOT* recommended or supported.

If you have an *secure* Data Fabric cluster, and you want to *insecure* Kafka REST, do the following:

1. In the `kafka-rest.properties` configuration file, change **https://** to **http://** for the listeners and remove the **ssl.\*** properties. For example:

```
listeners=http://0.0.0.0:8082
```

2. Restart Kafka REST.

```
maprcli node services -name kafka-rest -action restart -nodes <space
delimited list of nodes>
```

### *User Impersonation*

Describes how to disable, enable, and use impersonation with Kafka REST.

User impersonation enables Kafka REST jobs to be submitted as a particular user. Without impersonation, Kafka REST submits jobs as the user that started Kafka REST server.

On an HPE Data Fabric cluster, the impersonated user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable. By default, impersonation is disabled for unsecured clusters and enabled for secure clusters.

### **Enabling User Impersonation**

To enable user impersonation, set the following properties in `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties`:

- `authentication.enable=true`
- `impersonation.enable=true`

### **Disabling User Impersonation**

In the `/opt/mapr/kafka-rest/kafka-rest-<version>/config/kafka-rest.properties` file, disable PAM authentication and the `impersonation.enable` property.

1. To disable PAM authentication, set `authentication.enable=false`.
2. To disable user impersonation, set `impersonation.enable=false`.

### **Example: Verify that a list of topics is owned by an impersonated user**

This example demonstrates how to get a list of topics from a particular stream and then verifies that the list of topics is owned by a particular user. Depending on whether or not impersonation is enabled (the default), you may need to use a different `curl` command.

```
$ sudo maprcli stream info -json -path /stream
{
 "timestamp":1598950735841,
 "timeofday":"2020-09-01 08:58:55.841 GMT+0000 AM",
 "status":"OK",
 "total":1,
 "data":[
 {
 "path":"/stream",
 "physicalsize":57344,
 "logicalsize":32768,
 "numtopics":1,
 "defaultpartitions":1,
 "ttl":604800,
 "compression":"lz4",
```

```

 "autocreate":true,
 "produceperm":"u:root",
 "consumeperm":"u:root",
 "topicperm":"u:root",
 "copyperm":"u:root",
 "adminperm":"u:root",
 "kafkatopic":false,
 "ischangealog":false,
 "defaulttimestamptype":"CreateTime",
 "compact":false,
 "mincompactionlag":0,
 "deleteretention":86400000,
 "throttlefactor":0,
 "pidexpirysecs":604800
 }
}
]
}

```

If impersonation is enabled (the default), use the following query, where the query is submitted as the root user.

```

curl -u root -X GET https://`hostname`:8082/topics/
%2Fstream%3Atopic1 --cacert /opt/mapr/conf/ssl_truststore.pem
Enter host password for user 'root':
{"name":"/stream:topic1","configs":null,"partitions":
 [{"partition":0,"leader":0,"replicas":
 [{"broker":0,"leader":true,"in_sync":true},
 {"broker":0,"leader":false,"in_sync":true}]}]}

```

If impersonation is disabled, use the following query, where the query is submitted as the mapr user.

```

curl -X GET https://`hostname`:8082/topics/%2Fstream%3Atopic1 --cacert /opt/
mapr/conf/ssl_truststore.pem
{"error_code":40401,"message":"Topic not found."}

```

### *Saving Kafka REST Configurations*

Describes how Kafka REST configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka REST is stored in a folder with a timestamp.

- The configuration files are saved *and* overwritten by new configuration files when upgrading from:
  - 4.1.0 to 5.1.2
  - 5.1.2 to 6.0.0.0
- The configuration files are saved only (not overwritten) when upgrading from:
  - 5.1.2 to 5.1.2

### **Example**

The following example shows the list of configuration files that are saved when upgrading from mapr-kafka-rest 5.1.2 (EEP 7.0.0) to mapr-kafka-rest 5.1.2 (EEP 7.0.1):

```

ls /opt/mapr/kafka-rest/
kafka-rest-5.1.2 kafka-rest-5.1.2.0.202009100923 kafka-restversion

ls /opt/mapr/kafka-rest/kafka-rest-5.1.2.0.202009100923/config/
headers.xml kafka-rest.properties log4j.properties warden.kafka-rest.conf

```

## Services Management

The Kafka REST Proxy for HPE Data Fabric Streams service can be started, restarted, and stopped via the `maprcli nodes services` command or using the REST API equivalent.

The following `maprcli nodes services` commands summarize the commands. For more information, see [node services](#) on page 2598.

### CLI commands

```
maprcli node services -name kafka-rest -action start -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action stop -nodes <node_list>
```

```
maprcli node services -name kafka-rest -action restart -nodes <node_list>
```

### REST

```
https://<host>:8443/rest/node/services?
name=kafka-rest&action=stop&nodes=<node_names>
```

where `node_names` is the node on which to perform the action; either a list of nodes, or a filter that matches a set of nodes .

## HTTP Methods and URI Summary

This section provides HTTP method and URI summaries for multiple Kafka REST Proxy API versions for HPE Data Fabric Streams.

### API v3: Kafka REST Proxy Summary

Availability of Kafka REST Proxy API v3 started in Kafka REST 6.0.0.0 on Core 6.2.0.

API v3 is disabled by default. To enable API v3, set the `api.v3.enable` parameter in the `kafka-rest.properties` file to `true`. See [Configuration Parameters](#) on page 5254.

**NOTE:** Kafka REST 6.0.0.0 supports [API v3](#) and [API v2](#) only. Kafka REST 6.0.0.0 does not support API v1.

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

HTTP Method	URI	Description
GET	<a href="#">GET /v3/clusters</a> on page 5281	Retrieves a list of metadata about clusters. Only retrieves the current HPE Data Fabric cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}</a> on page 5283	Retrieves metadata about a specific cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics</a> on page 5284	Retrieves a list of topic names on the specific cluster.
POST	<a href="#">POST /v3/clusters/{string: cluster_id}/topics</a> on page 5292	Creates a new topic on the specific cluster.
DELETE	<a href="#">DELETE /v3/clusters/{string: cluster_id}/topics/{string: topic_name}</a> on page 5294	Deletes a topic from the specific cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}</a> on page 5285	Retrieves metadata about a specific topic within a cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions</a> on page 5287	Retrieves a list of partitions for the topic within a cluster.

HTTP Method	URI	Description
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id} on page 5289</a>	Retrieves metadata about a specific partition within a topic and a cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas on page 5290</a>	Retrieves a list of replicas within a partition, a topic and a cluster.
GET	<a href="#">GET /v3/clusters/{string: cluster_id}/topics/{string: topic_name}/partitions/{string: partition_id}/replicas/{string: broker_id} on page 5291</a>	Retrieves metadata about a specific replica within a partition, a topic and a cluster.

### API v2: Kafka REST Proxy Summary

Availability of Kafka REST Proxy API v2 started in Kafka REST 4.0.0 on Core 6.0.x.

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

HTTP Method	URI	Description
GET	<a href="#">/topics</a>	Retrieves a list of topic names.
GET	<a href="#">/topics/{string: topic_name}</a>	Retrieves metadata about a specific topic.
POST	<a href="#">/topics/{string: topic_name}</a>	Produces messages to a topic.
GET	<a href="#">/topics/{string: topic_name}/partitions</a>	Retrieves a list of partitions for the topic.
GET	<a href="#">/topics/{string: topic_name}/partitions/{string: partition_id}</a>	Retrieves metadata about a specific partition within a topic.
GET	<a href="#">GET /topics/{string: topic_name}/partitions/{string: partition_id}/offsets on page 5270</a>	Returns a summary with beginning and end offsets for the given topic and specific partition. Supported as of Kafka Rest 6.0.0.0.
POST	<a href="#">/topics/{string: topic_name}/partitions/{string: partition_id}</a>	Produces messages into a partition of a topic.
POST	<a href="#">/consumers/{string: group_name}</a>	Creates a new consumer instance in the consumer group.
DELETE	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}</a>	Destroys the consumer instance.
POST	<a href="#">/consumers/{string: group_name}/instances/{string: consumer_instance_id}/offsets</a>	Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.
GET	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/offsets</a>	Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/subscription</a>	Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription.
GET	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/subscription</a>	Gets the current subscribed list of topics.
DELETE	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/subscription</a>	Unsubscribes from topics currently subscribed to.

HTTP Method	URI	Description
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/assignments</a>	Manually assigns a list of partitions to a consumer.
GET	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/assignments</a>	Retrieves the list of partitions manually assigned to this consumer.
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/positions</a>	Overrides the fetch offsets that the consumer will use for the next set of records to fetch.
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/positions/beginning</a>	Seek to the first offset for each of the given partitions.
POST	<a href="#">/consumers/{string: group_name}/instances/{string: instance_id}/positions/end</a>	Seek to the last offset for each of the given partitions.
GET	<a href="#">GET /consumers/{string: group_name}/instances/{string: instance_id}/records</a>	Fetches data for the topics or partitions specified using one of the subscribe/assign APIs.
GET	<a href="#">/streams/{string: stream_name}/topics</a>	Retrieves a list of topics in a given stream.

### API v1: Kafka REST Proxy Summary

The following table lists the HTTP methods, URIs (with links to examples), and descriptions:

**NOTE:** Kafka REST 6.0.0.0 does not support API v1. Kafka REST 6.0.0.0 supports API v1 and v2 only.

HTTP Method	URI	Description
GET	<a href="#">/topics</a>	Retrieves a list of topic names.
GET	<a href="#">/topics/{topic: string}</a>	Retrieves metadata about a specific topic.
POST	<a href="#">/topics/{topic: string}</a>	Produces a message into a topic.
GET	<a href="#">/topics/{topic: string}/partitions</a>	Retrieves a list of partitions for the topic.
GET	<a href="#">/topics/{topic: string}/partitions/{partition_id: string}</a>	Retrieves metadata about specific partition in a topic.
POST	<a href="#">/topics/{topic: string}/partitions/{partition_id: string}</a>	Produces messages to one partition of the topic.
GET	<a href="#">/topics/{topic: string}/partition/{partition_id: string}/messages?offset={int}&amp;count={int}</a>	Consumes messages from one partition of the topic.
GET	<a href="#">/stream/{stream: string}/topics</a>	Retrieves a list of topics in a given stream.
POST	<a href="#">/consumers/{group: string}</a>	Creates a new consumer instance in the consumer group.
POST	<a href="#">/consumers/{group: string}/instances/{instance: string}/offsets</a>	Commits offsets for the consumer. Returns a list of the partitions with the committed offsets.
DELETE	<a href="#">/consumers/{group: string}/instances/{instance: string}</a>	Destroys the consumer instance.
GET	<a href="#">/consumers/{group: string}/instances/{instance: string}/topics/{topic: string}</a>	Consumes messages from a topic.

*API v2 HTTP Methods and URIs*

Availability of Kafka REST Proxy API v2 started in Kafka REST 4.0.0 on Core 6.0.x.

**GET /topics**

Retrieves a list of topic names.

**Description**

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 5254

**Table**

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Returns a list of topic names in the default stream. Returns topic names that contain a stream path.
<b>streams.default.stream</b> is not defined	Returns {"error_code":80001,"message":"HPE Data Fabric Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}

**Syntax**

```
http://<host>:8082/topics
```

**Request Example**

```
$ curl "Content-Type: application/vnd.kafka.v2+json" "http://localhost:8082/topics"
```

**Response Example**

```
[
 "streaming_data/stream:testtopic1",
 "streaming_data/stream:testtopic2"
]
```

**GET /topics/{string: topic\_name}**

Retrieves metadata about a specific topic.

**Description**

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 5254

**Table**

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets metadata about a specific HPE Data Fabric Streams topic. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, topic1 is equivalent to default_stream:topic1
<b>streams.default.stream</b> is not defined	Gets metadata about a specific HPE Data Fabric Streams topic. A fully qualified topic name is passed that contains the stream path.

**NOTE:** The full name for the HPE Data Fabric Streams topic contains characters such as a forward slash (/) and a colon (:), therefore, it should be encoded. For example, /streaming\_data/stream:topic-1 is equivalent to %2Fstreaming\_data%2Fstream%3Atopic-1.

#### Table

Parameters	Description
topic_name (string)	Name of the topic to get metadata about.

#### Syntax

Syntax for a topic in a default stream where the default stream is configured:

```
http://<host>:8082/topics/<topic_string>
```

Syntax for a topic where the fully qualified topic name is specified:

```
http://<host>:8082/topics/%2F<streaming_data>%2F<stream>%3A<topic1>
```

#### Request Example

```
curl "http://localhost:8082/topics/test"
```

#### Response Example

```
{
 "name": "test",
 "configs": null,
 "partitions":
 [
 {
 "partition": 0,
 "leader": 0,
 "replicas":
 [
 {"broker": 0, "leader": true, "in_sync": true},
 {"broker": 0, "leader": false, "in_sync": true}
]
 }
]
}
```

POST /topics/{string: topic\_name}  
Produces messages to a topic.

#### Description

Depending on the configuration, the type of information retrieved has different behavior. See the streams.default.stream in [Configuration Parameters](#) on page 5254

#### Table

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Produces messages into specific HPE Data Fabric Streams topics. If the topic name does not contain a stream path, then the default stream path is used.

Table (Continued)

Parameters Defined	Response
<b>streams.default.stream</b> is not defined	Produces messages into a HPE Data Fabric Streams topic. The topic name should contain a stream path and be encoded.

**NOTE:** If the topic does not exist, the following error results: [{"error\_code":40401, "message": "Topic not found."}]. New topics are not created by the POST operation.

Table

Parameters	Description
<b>topic_name</b> ( <i>string</i> )	Name of the topic to produce the messages to.

### Syntax

```
http://<host>:8082/topics/<topic_string>
```

### Request Example

This example produces a message using binary embedded data with the value, Kafka, to the topic, test.

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2" --data '{"records":[{"value":"S2Fma2E="}]}' "http://localhost:8082/topics/test"
```

### Response Example

```
{
 "offsets":
 [{
 "partition":0,
 "offset": 1,
 "error_code":null,
 "error":null
 }],
 "key_schema_id":null,
 "value_schema_id":null
}
```

GET /topics/{string: topic\_name}/partitions  
Retrieves a list of partitions for the topic.

### Description

Depending on the configuration, the type of information retrieved has different behavior. See the **streams.default.stream** in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets metadata about specific HPE Data Fabric Streams partitions within a topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<b>streams.default.stream</b> is not defined	Gets metadata about specific HPE Data Fabric Streams partitions within topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
<b>topic_name</b> ( <i>string</i> )	Name of the topic.

**Syntax**

```
http://<host>:8082/topics/<topic_name>/partitions
```

**Request Example**

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
"http://localhost:8082/topics/testtopic1/partitions"
```

**Response Example**

```
[
 {
 "partition":0,
 "leader":0,
 "replicas":
 [{
 "broker":0,
 "leader":true,
 "in_sync":true
 }]
 },
 {
 "partition":1,
 "leader":0,
 "replicas":
 [{
 "broker":0,
 "leader":true,
 "in_sync":true
 }]
 }
]
```

GET /topics/{string: topic\_name}/partitions/{string: partition\_id}  
Retrieves metadata about a specific partition within a topic.

**Description**

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets metadata about a specific partition within a HPE Data Fabric Streams topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<b>streams.default.stream</b> is not defined	Gets metadata about specific HPE Data Fabric Streams partitions within a topic. The user could only pass fully qualified topic names that contains stream path.

Table

Parameters	Description
<b>topic_name</b> ( <i>string</i> )	Name of the topic.
<b>partition_id</b> ( <i>int</i> )	ID of the partition to inspect.

**Syntax**

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

**Request Example**

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2"
http://localhost:8082/topics/%2Fstreaming_data%2Fstream%3Atesttopic1/
partitions/0
```

**Response Example**

```
{
 "partition":0,
 "leader":0,
 "replicas":
 [{
 "broker":0,
 "leader":true,
 "in_sync":true
 }]
}
```

GET /topics/{string: topic\_name}/partitions/{string: partition\_id}/offsets

Returns a summary with beginning and end offsets for the given topic and specific partition.

**Description**

Information retrieved varies depending on the configuration. See the `streams.default.stream` in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets summary with beginning and end offsets for the specific partition of the HPE Data Fabric Streams topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<b>streams.default.stream</b> is not defined	Gets summary with beginning and end offsets for the specific HPE Data Fabric Streams partition within a topic. You can only pass the fully qualified topic names that contain the stream path.

Table

Parameter	Description
<b>topic_name</b> ( <i>string</i> )	Name of the topic.
<b>partition_id</b> ( <i>int</i> )	ID of the partition to inspect.

## Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>/offsets
```

## Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2" http://localhost:8082/topics/%2Fstreaming_data%2Fstream%3Atesttopic1/partitions/0/offsets
```

## Response Example

```
{
 "beginning_offset":0,
 "end_offset":0
}
```

POST /topics/{string: topic\_name}/partitions/{string: partition\_id}  
Produces messages into a partition of a topic.

## Description

Depending on the configuration, the type of information retrieved has different behavior. See the `streams.default.stream` in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Produces messages into a partition of HPE Data Fabric Streams topic. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, messages are produced into topics in the default stream path.
<b>streams.default.stream</b> is not defined	Produces messages into a partition within HPE Data Fabric Streams topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
<b>topic_name</b> ( <i>string</i> )	Topic to produce the messages to.
<b>partition_id</b> ( <i>int</i> )	Partition to produce the messages to.

## Syntax

```
http://<host>:8082/topics/<topic_name>/partitions/<partition_id>
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.binary.v2+json" --data '{"records":[{"key":"a2v5","value":"Y29uZmx1ZW50"}]}' "http://localhost:8082/topics/testtopic1/partitions/0"
```

### Response Example

```
{
 "offsets":
 [{
 "partition":0,
 "offset":1,
 "error_code":null,"error":null}
],
 "key_schema_id":null,
 "value_schema_id":null
}
```

POST /consumers/{string: group\_name}  
Creates a new consumer instance in the consumer group.

### Description

Table

Parameters	Description
<b>group_name</b> ( <i>string</i> )	The name of the consumer group to join.
<b>name</b> ( <i>string</i> )	Name for the consumer instance, which will be used in URLs for the consumer. This must be unique, at least within the proxy process handling the request. If omitted, falls back on the automatically generated ID. Using automatically generated names is recommended for most use cases.
<b>format</b> ( <i>string</i> )	The format of consumed messages, which is used to convert messages into a JSON-compatible form. Valid values: "binary", "avro", "json". If unspecified, defaults to "binary".
<b>auto.offset.reset</b> ( <i>string</i> )	Sets the <b>auto.offset.reset</b> setting for the consumer. Values: latest, earliest, none
<b>auto.commit.enable</b> ( <i>string</i> )	Sets the <b>auto.commit.enable</b> setting for the consumer.

**NOTE:** You cannot set the time-to-live (TTL) for consumer instances or consumer groups. However, consumers can be configured to be deleted after some idle time. The amount of idle time before a consumer instance is automatically destroyed is set by the `consumer.instance.timeout.ms` property in the **kafka-rest.properties** file. See [Configuration Parameters](#) on page 5254.

### Syntax

```
http://<host>:8082/consumers/<group_name>
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json"
--data '{"name":"user","format": "binary", "auto.offset.reset":
"earliest"}'
http://localhost:8082/consumers/grouptest
```

### Response Example

The response JSON object is in the following form:

- **instance\_id** (*string*) – Unique ID for the consumer instance in this group. The `instance_id` is automatically generated if the `name` parameter is not specified.

- **base\_uri** (*string*) – Base URI used to construct URIs for subsequent requests against this consumer instance. This will be of the form `http://hostname:port/consumers/consumer_group/instances/instance_id`.

```
{
 "instance_id": "user",
 "base_uri": "http://localhost:8082/consumers/groupptest/instances/
user"
}
```

**DELETE** /consumers/{string: group\_name}/instances/{string: instance\_id}  
Destroys the consumer instance.

### Description

The request must be made to the specific REST proxy instance holding the consumer instance.

Table

Parameters	Description
<b>group_name</b> ( <i>string</i> )	The name of the consumer group.
<b>instance</b> ( <i>string</i> )	The ID of the consumer instance

### Syntax

```
http://<host>:8082/topics/<group_name>/instances/<instance_string>
```

### Request Example

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/consumers/my_binary_consumer/instances/
rest-consumer-11561681-
8ba5-4b46-bed0-905ae1769bc6
```

### Response Example

```
HTTP/1.1 204 No Content
```

**POST** /consumers/{string: group\_name}/instances/{string: consumer\_instance\_id}/offsets  
Commits a list of offsets for the consumer. When the post body is empty, it commits all the records that have been fetched by the consumer instance.

### Parameters

Table

Parameters	Description
<b>group_name</b> ( <i>string</i> )	The name of the consumer group.
<b>instance_id</b> ( <i>string</i> )	The ID of the consumer instance.
<b>offsets</b>	A list of offsets to commit for partitions.
<b>offsets[i].topic</b> ( <i>string</i> )	Name of the topic
<b>offsets[i].partition</b> ( <i>int</i> )	Partition ID
<b>offset</b>	The offset to commit.

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_instance_id>/offsets
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"offsets": [{"topic":
"/mystream:first", "partition": 0, "offset": 5}]}'
https://node2:8082/consumers/grouptest/instances/user/offsets
```

### Response Example

```
HTTP/1.1 200 OK
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/offsets

Gets the last committed offsets for the given partitions (whether the commit happened by this process or another).

### Parameters

Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.
<b>partitions</b>	A list of partitions to find the last committed offsets.
<b>partitions[i].topic</b> ( <i>string</i> )	Name of the topic.
<b>partitions[i].partition</b> ( <i>int</i> )	Partition ID

### Syntax

```
http://localhost:8082/consumers/<group_name>/instances/<consumer_name>/offsets
```

### Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.binary.v2+json" --data
'{"partitions": [{"topic": "/stream:topic", "partition": 0}]}'
https://node2:8082/consumers/grouptest/instances/user/offsets
```

### Response Example

The response JSON object is in the following form:

- offsets - A list of committed offsets.
- offsets[i].topic (string) – Name of the topic for which an offset was committed
- offsets[i].partition (int) – Partition ID for which an offset was committed
- offsets[i].offset (int) – Committed offset

- `offsets[i].metadata (string)` – Metadata for the committed offset

```
{
 "offsets": [
 {
 "topic": "/stream:topic",
 "partition": 0,
 "offset": 21,
 "metadata": ""
 }
]
}
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/subscription

Subscribes to the given list of topics or a topic pattern to get dynamically assigned partitions. If a prior subscription exists, it would be replaced by the latest subscription.

### Parameters

Table

Parameter	Description
<code>group_name (string)</code>	Name of the consumer group.
<code>instance (string)</code>	ID of the consumer instance.

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"topics":["/stream:first","/stream:second"]}'
https://localhost:8082/consumers/groupptest/instances/user/subscription
```

### Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/subscription

Gets the current subscribed list of topics.

### Parameters

Table

Parameter	Description
<code>group_name (string)</code>	Name of the consumer group.
<code>instance (string)</code>	ID of the consumer instance.

**Syntax**

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

**Request Example**

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/grouptest/instances/user/subscription
```

**Response Example**

The response JSON object is in the following form:

- topics – A list of subscribed topics
- topics[i] (string) – Name of the topic

```
{
 "topics": [
 "/stream:first",
 "/stream:second"
]
}
```

**DELETE** /consumers/{string: group\_name}/instances/{string: instance\_id}/subscription  
Unsubscribes from topics currently subscribed to.

**Parameters**

Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.

**Syntax**

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
subscription
```

**Request Example**

```
curl -X DELETE -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/grouptest/instances/user/subscription
```

**Response Example**

```
HTTP/1.1 204 No Content
```

**POST** /consumers/{string: group\_name}/instances/{string: instance\_id}/assignments  
Manually assigns a list of partitions to a consumer.

## Parameters

Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.

## Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
assignments
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions":[{"topic":"first","partition":0}]}'
https://localhost:8082/consumers/grouptest/instances/user/assignments
```

## Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/assignments  
Retrieves the list of partitions currently assigned to this consumer.

## Parameters

Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.

## Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
assignments
```

## Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/grouptest/instances/user/assignments
```

## Response Example

The response JSON object is in the following form:

- partitions – A list of partitions assigned to this consumer.
- partitions[i].topic (*string*) – Name of the topic.

- partitions[i].partition (*int*) – Partition ID

```
{
 "partitions": [
 {
 "topic": "test",
 "partition": 0
 },
 {
 "topic": "test",
 "partition": 1
 }
]
}
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/positions  
Overrides the fetch offsets that the consumer will use for the next set of records to fetch.

**Parameters**

Table

Parameter	Description
group_name ( <i>string</i> )	Name of the consumer group.
instance ( <i>string</i> )	ID of the consumer instance.
offsets	A list of offsets
offsets[i].topic ( <i>string</i> )	Name of the topic
offsets[i].partition ( <i>int</i> )	Partition ID
offsets[i].offset ( <i>int</i> )	Seek to offset for the next set of records to fetch.

**Syntax**

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/positions
```

**Request Example**

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data '{"offsets": [{"topic": "/stream:first", "partition": 0, "offset": 3}]}' https://localhost:8082/consumers/grouptest/instances/user/positions
```

**Response Example**

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/positions/beginning  
Seek to the first offset for each of the given partitions.

## Parameters

Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.
<b>partitions</b>	A list of partitions.
<b>partitions[i].topic</b> ( <i>string</i> )	Name of the topic
<b>partitions[i].partition</b> ( <i>int</i> )	Partition ID

## Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions/beginning
```

## Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions": [{"topic": "/stream:first", "partition": 0}]}'
https://localhost:8082/consumers/grouptest/instances/user/positions/
beginning
```

## Response Example

```
HTTP/1.1 204 No Content
```

POST /consumers/{string: group\_name}/instances/{string: instance\_id}/positions/end  
Seek to the last offset for each of the given partitions.

## Parameters

Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.
<b>partitions</b>	A list of partitions.
<b>partitions[i].topic</b> ( <i>string</i> )	Name of the topic
<b>partitions[i].partition</b> ( <i>int</i> )	Partition ID

## Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/
positions/end
```

### Request Example

```
curl -X POST -H "Content-Type: application/vnd.kafka.v2+json" --data
'{"partitions": [{"topic": "/stream:first", "partition": 0}]}'
https://localhost:8082/consumers/grouptest/instances/user/positions/end
```

### Response Example

```
HTTP/1.1 204 No Content
```

GET /consumers/{string: group\_name}/instances/{string: instance\_id}/records

Fetches data for the topics or partitions specified using one of the subscribe/assign APIs.

### Parameters

The format of the embedded data returned by this request is determined by the format specified in the initial consumer instance creation request and must match the format of the Accept header.

**NOTE:** This request *must* be made to the specific REST proxy instance holding the consumer instance.

Table

Parameter	Description
<b>group_name</b> ( <i>string</i> )	Name of the consumer group.
<b>instance</b> ( <i>string</i> )	ID of the consumer instance.
<b>timeout</b>	The number of milliseconds for the underlying client library poll(timeout) request to fetch the records. Default: 5000ms.
<b>max_bytes</b>	The maximum number of bytes of unencoded keys and values that should be included in the response. This provides approximate control over the size of responses and the amount of memory required to store the decoded response. The actual limit is the minimum of this setting and the server-side configuration consumer.request.max.bytes. Default: unlimited

### Syntax

```
http://<host>:8082/consumers/<group_name>/instances/<consumer_name>/records
```

### Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
https://localhost:8082/consumers/grouptest/instances/user/records
```

### Response Example

```
[
 {
 "topic": "test",
 "key": "a2V5",
 "value": "Y29uZmx1ZW50",
 "partition": 1,
 "offset": 100,
 },
 {
```

```
[
 {
 "topic": "test",
 "key": "a2V5",
 "value": "a2Fma2E=",
 "partition": 2,
 "offset": 101,
 }
]
```

GET /streams/{string: stream\_name}/topics

Retrieves a list of topics in a given stream.

### Description

Stream names contain characters such as backslashes (/) and colons (:) and, therefore, should be encoded.

Table

Parameters	Description
<b>stream_name</b> ( <i>string</i> )	The name of the stream.

### Syntax

```
http://<host>:8082/streams/<stream_name>/topics
```

### Request Example

```
curl -X GET -H "Content-Type: application/vnd.kafka.v2+json"
http://localhost:8082/streams/%2Fstreaming_data%2Fstream/topics
```

### Response Example

```
[
 "/streaming_data/stream:testtopic1",
 "/streaming_data/stream:testtopic2"
]
```

### API v3 HTTP Methods and URIs

Availability of Kafka REST Proxy API v3 started in Kafka REST 6.0.0.0 on Core 6.2.0. API v3 is disabled by default. To enable API v3, set the `api.v3.enable` parameter in the `kafka-rest.properties` file to `true`. See [Configuration Parameters](#).

**NOTE:** Kafka REST 6.0.0.0 supports [API v3](#) and [API v2](#) only. Kafka REST 6.0.0.0 does not support API v1.

GET /v3/clusters

Retrieves a list of metadata about the cluster.

### Description

Retrieves one cluster only. Always retrieves the current HPE Data Fabric cluster.

### Syntax

```
http://<host>:8082/v3/clusters
```

**Request Example**

```
curl -X GET -H "Content-Type: application/json" http://localhost:8082/v3/clusters
```

**Response Example**

```
{

```

```
]
 }
```

GET /v3/clusters/{string: cluster\_id}  
Retrieves metadata about a specific cluster.

Parameters

Parameters	Description
cluster_id (string)	Cluster's id.

Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>
```

Request Example

```
curl -X GET -H "Content-Type: application/json" http://localhost:8082/v3/clusters/682798077049224619
```

Response Example

```
{

 }
}
```

GET /v3/clusters/{string: cluster\_id}/topics  
Retrieves a list of topic names on the specific cluster.

**Description**

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Returns a list of topic names and metadata in the default stream. Returns topic names and metadata that contains a stream path.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.

**Syntax**

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

**Request Example**

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics"
```

**Response Example**

]
}

```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}  
Retrieves metadata about a specific topic within a cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets metadata about a specific HPE Data Fabric Streams topic on this cluster. A fully qualified topic name can be passed or not. If the topic name is not fully qualified, the metadata is retrieved and appended to the default stream path. For example, topic1 is equivalent to default_stream:topic1.
<b>streams.default.stream</b> is not defined	Gets metadata about a specific HPE Data Fabric Streams topic on this cluster. A fully qualified topic name is passed that contains the stream path.

**NOTE:** The full name for the HPE Data Fabric Streams topic contains characters such as a forward slash (/) and a colon (:). Therefore, the topic should be encoded. For example, /streaming\_data/stream:topic-1 is equivalent to %2Fstreaming\_data%2Fstream%3Atopic-1.

Table

Parameters	Description
<b>cluster_id</b> ( <i>string</i> )	Cluster's id.
<b>topic_name</b> ( <i>string</i> )	Name of the topic.

### Syntax

```
http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>
```

### Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2"
```

### Response Example

```
{
 "kind": "KafkaTopic",
 "metadata": {
 "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/
topics/str:tp-2",
 "resource_name": "crn:///kafka=682798077049224619/topic=str:tp-2"
 },
 "cluster_id": "682798077049224619",
 "topic_name": "/str:tp-2",

682798077049224619/topics/str:tp-2/partitions"
 },
 "configs": {
 "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/str:tp-2/configs"
 },
}
```

```

 "partition_reassignments":
 {
 "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/str:tp-2/partitions/-/reassignment"
 }
 }

```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}/partitions

Retrieves a list of partitions for the topic within a cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about specific HPE Data Fabric Streams partitions within a topic on this cluster. The user could pass fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific HPE Data Fabric Streams partitions within topic on this cluster. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.
<code>topic_name</code> ( <i>string</i> )	Name of the topic.

### Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions
```

### Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/clusters/682798077049224619/topics/tp-2/partitions"
```

```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}/partitions/{string: partition\_id}  
Retrieves metadata about a specific partition within a topic and a cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about a specific partition within a HPE Data Fabric Streams topic on this cluster. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific HPE Data Fabric Streams partitions within a topic. The user could only pass fully qualified topic names that contains stream path.

Table

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.
<code>topic_name</code> ( <i>string</i> )	Name of the topic.
<code>partition_id</code> ( <i>int</i> )	ID of the partition to inspect.

### Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>
```

### Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1"
```

**Response Example**

```
{
 "kind": "KafkaPartition",
 "metadata": {
 "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1",

 "reassignment": {
 "related": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/topics/str:tp-2/partitions/1/reassignment"
 }
}
```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}/partitions/{string: partition\_id}/replicas  
Retrieves a list of replicas within a partition, a topic, and a cluster.

**Description**

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 5254.

**Table**

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Gets metadata about specific replicas of the HPE Data Fabric Streams partition within a topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<code>streams.default.stream</code> is not defined	Gets metadata about specific replicas of the HPE Data Fabric Streams partition within a topic. The user could only pass fully qualified topic name that contains stream path.

**Table**

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.
<code>topic_name</code> ( <i>string</i> )	Name of the topic.
<code>partition_id</code> ( <i>int</i> )	ID of the partition to inspect.

## Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>/replicas
```

## Request Example

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1/replicas"
```

## Response Example

```
{
 "kind": "KafkaReplicaList",
 "metadata": {
 "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/

 "topic_name": "/str:tp-2",
 "partition_id": 1,
 "broker_id": 0,
 "is_leader": true,
 "is_in_sync": true,
 "broker": {
 "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/brokers/0"
 }
 }
]
}
```

GET /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}/partitions/{string: partition\_id}/replicas/{string: broker\_id}

Retrieves metadata about a specific replica within a partition, a topic, and a cluster.

## Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<b>streams.default.stream</b> is defined	Gets metadata about specific broker of the HPE Data Fabric Streams partition within a topic. You can pass a fully qualified topic name or not. If a fully qualified topic name is not used, metadata is retrieved and appended to the default stream path.
<b>streams.default.stream</b> is not defined	Gets metadata about specific broker of the HPE Data Fabric Streams partition within a topic. The user could only pass fully qualified topic name that contains stream path.

Table

Parameters	Description
<b>cluster_id</b> ( <i>string</i> )	Cluster's id.
<b>topic_name</b> ( <i>string</i> )	Name of the topic.
<b>partition_id</b> ( <i>int</i> )	ID of the partition to inspect.
<b>broker_id</b> ( <i>int</i> )	ID of the broker to inspect.

**Syntax**

```
http://<host>:8082/v3/clusters/<cluster_id>/topics/<topic_name>/partitions/
<partition_id>/replicas/<broker_id>
```

**Request Example**

```
$ curl -X GET -H "Content-Type: application/json" "http://localhost:8082/v3/
clusters/682798077049224619/topics/tp-2/partitions/1/replicas/0"
```

**Response Example**

```
{
 "kind": "KafkaReplica",
 "metadata": {

POST /v3/clusters/{string: cluster\_Id}/topics

Creates a new topic on the specific cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 5254

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Creates a topic in the default stream and returns its metadata.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
<code>cluster_id</code> ( <i>string</i> )	Cluster's id.

### Syntax

```
http://<host>:8082/v3/clusters/<cluster_id>/topics
```

### Request Example

```
$ curl -X POST -H "Content-Type: application/json" --data '{"topic_name":
"new-topic", "partitions_count": 4}' "http://localhost:8082/v3/clusters/
682798077049224619/topics"
```

### Request Response

```
{
 "kind": "KafkaTopic",
 "metadata": {
 {
 "self": "http://node1.cluster.com:8082/v3/clusters/682798077049224619/
topics/new-topic",
 "resource_name": "crn:///kafka=682798077049224619/topic=new-topic"
 },
 "cluster_id": "682798077049224619",
 "topic_name": "new-topic",
 "is_internal": false,
 "replication_factor": 0,
 "partitions": {
 "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/new-topic/partitions"
 },
 "configs": {
 "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/new-topic/configs"
 },
 "partition_reassignments": {

```

```

 "related": "http://node1.cluster.com:8082/v3/clusters/
682798077049224619/topics/new-topic/partitions/-/reassignment"
 }
}

```

**DELETE** /v3/clusters/{string: cluster\_id}/topics/{string: topic\_name}

Deletes a topic from the specific cluster.

### Description

The behavior of the information retrieved depends on the configuration. See `streams.default.stream` in [Configuration Parameters](#) on page 5254.

Table

Parameters Defined	Response
<code>streams.default.stream</code> is defined	Deletes topic from the default stream.
<code>streams.default.stream</code> is not defined	Returns {"error_code":80001,"message":"HPE Ezmeral Data Fabric Event Data Streams does not currently support this API. Set the streams.default.stream parameter to return topics for the default stream"}.

Table

Parameters	Description
<code>cluster_id</code> (string)	Cluster's id.
<code>topic_name</code> (string)	Name of the topic.

### Syntax

```
http://<host>:8082/v3/clusters/<string: cluster_id>/topics/<string:
topic_name>
```

### Request Example

```
$ curl -X DELETE -H "Content-Type: application/json" "http://
localhost:8082/v3/clusters/682798077049224619/topics/new-topic"
```

### Response Example

```
HTTP/1.1 204 No Content
```

### Kafka Connect

Kafka Connect is a utility for streaming data between HPE Data Fabric Streams and other storage systems.

Examples of other systems include:

- Relational databases
- Logs and metrics
- Hadoop and data warehouses
- NoSQL data stores

Kafka Connect makes it easy to integrate all your data via Kafka, making it available as realtime streams. For example, you can use Kafka Connect to:

- Stream changes from a relational database to make events available with low latency for stream processing applications.
- Import realtime logs and metrics into HPE Data Fabric Streams and process them to detect anomalies.
- Implement a process of loading data into HPE Data Fabric Streams from your primary data storage systems, performing filtering, transformations, and enrichment with a stream processing framework, and publish the data to the HPE Data Fabric File Store.

**NOTE:** Built-in security is not available.

### Architecture of Kafka Connect

Kafka Connect for HPE Data Fabric Streams has the following major models in its design: connector, worker, and data.

#### Connector Model

A connector is defined by specifying a Connector class and configuration options to control what data is copied and how to format it.

- Each Connector instance is responsible for defining and updating a set of Tasks that actually copy the data.
- Kafka Connect manages the Tasks; the Connector is only responsible for generating the set of Tasks and indicating to the framework when they need to be updated.
- Source and Sink Connectors/Tasks are distinguished in the API to ensure the simplest possible API for both.

There are two types of tasks:

- **Source** - Source tasks ingest data from data storage systems and stream the data to HPE Data Fabric Streams.
- **Sink** - Sink tasks stream data from HPE Data Fabric Streams to other storage systems.

HPE Data Fabric supports the following connectors:

- JDBC Source Connector

The Kafka JDBC source connector is a type connector used to stream data from relational databases into HPE Data Fabric Streams topics. JDBC Source Connector for HPE Data Fabric Streams supports integration with Hive 2.1.

- JDBC Sink Connector

The Kafka JDBC sink connector is a type connector used to stream data from HPE Data Fabric Streams topics to relational databases that have a JDBC driver.

- HDFS Sink Connector

The Kafka HDFS sink connector is a type connector used to stream data from HPE Data Fabric Streams to file system. By default, the resulting data is produced to file system in Avro format. In addition, Parquet files can be written to file system.

#### Worker Model

A Kafka Connect for HPE Data Fabric Streams cluster consists of a set of Worker processes that are containers that execute Connectors and Tasks. A worker is a JVM process with a REST API that is able to execute streaming tasks.

- Workers automatically coordinate with each other to distribute work and provide scalability and fault tolerance.
- The Workers distribute work among any available processes, but are not responsible for management of the processes;
- Any process management strategy can be used for Workers. For example, cluster management tools like YARN or Mesos, configuration management tools like Chef or Puppet, or direct management of process lifecycles.

## Data Model

Connectors copy streams of messages from a partitioned input stream to a partitioned output stream, where at least one of the input or output is *always* Kafka.

- Each of these streams is an ordered set messages where each message has an associated offset.
- The format and semantics of these offsets are defined by the Connector to support integration with a wide variety of systems; however, to achieve certain delivery semantics in the face of faults requires that offsets are unique within a stream and streams can seek to arbitrary offsets.
- Message contents are represented by Connectors in a serialization-agnostic format.
- Pluggable Converters are available for storing this data in a variety of serialization formats.
- Schemas are built-in, allowing important metadata about the format of messages to be propagated through complex data pipelines. However, schema-free data can also be use when a schema is simply unavailable.

## Connectors, Tasks, and Workers

Describes how Kafka Connect for HPE Data Fabric Streams works and how connectors, tasks, offsets, and workers are associated.

## Connectors

Connectors (or a **connector instance**) are logical jobs that are responsible for managing the copying of data between HPE Data Fabric Streams and another systems. Each connector instantiates a set of **tasks** that copies the data. By allowing the connector to break a single job into many tasks, support is built-in for parallelism and scalable data copying with very little configuration. **Connector plugins** are jars that add the classes that implement a connector.

## Offsets

As connectors run, Kafka Connect tracks **offsets** for each one so that connectors can resume from their previous position in the event of failures or graceful restarts for maintenance. They track the current position in the stream of data being copied and because each connector may need to track many offsets for different **partitions** of the stream. For example, when loading data from a database, the offset might be a transaction ID that identifies a position in the database change log.

Users generally do not need to worry about the format of offsets, especially since they differ from connector to connector. However, Kafka Connect does require persistent storage for offset data to ensure it can recover from faults. This storage for offset data is configurable. See [Standalone Worker Configuration Options](#) on page 5301 and [Distributed Worker Configuration Options](#) on page 5302.

## Workers

Connectors and tasks are logical units of work and must be scheduled to execute in a process. Kafka Connect calls these processes **workers**. With Kafka Connect for Data Fabric streams, the worker processors run as a service. This service can be run in either standalone mode or distributed mode.

- In standalone mode, the cluster consists of a single worker that is supplied with tasks that are useful for testing and debugging purposes.
- In distributed mode, the cluster consisting from multiple workers with the same group.id, offset.storage.topic, and config.storage.topic. Connector tasks are submitted via the Kafka Connect REST API.

The following list the location of the standalone and distributed worker configuration files:

```
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

**NOTE:** Distributed mode is supported on release 5.2.1 and above

**NOTE:** Port 8083 is the default port.

**NOTE:** If you running multiple workers on the same node, the rest.port parameter must be different for each worker.

### *Configuring in Standalone Mode*

The section describes how to configure and execute workers in Kafka connect standalone mode.

Standalone mode is the simplest mode, where a single process is responsible for executing all connectors and tasks. Since it is a single process, it requires minimal configuration.

Configuring and running in standalone mode, involves configuring the standalone properties and connector parameters before executing the standalone shell command along with the properties files on the command line.

The following parameters must be provided in the **connect-standalone.properties** file.

- offset.storage.file.filename - Storage for connector offsets which are stored on the local filesystem in standalone mode. Using the same file leads to offset data being deleted or overwritten with different values.
- rest.port - Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this parameter must have different values for each instance.

**NOTE:** If you are running multiple standalone instances on the same host, these parameters must be different for each instances. Therefore, an additional properties file is created for the instance with different parameter values.

To run a worker in standalone mode:

1. Edit the **./config/connect-standalone.properties** file and add the name of the local file that will store the connector offsets.
2. Edit the **quickstart-sqlite.properties** file (JDBC connector configuration file).
3. Run the **./bin/connect-standalone.sh** command along with the properties files on the command line.

For example:

```
cd /opt/mapr/kafka/kafka-<version>
./bin/connect-standalone.sh
./config/connect-standalone.properties
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-sqlite.properties
```

The first parameter is always a configuration file for the worker. This configuration gives you control over settings such as which cluster to use and the serialization format. See [JDBC Connector](#) on page 5306 for more information. All additional parameters should be connector configuration files. Each file contains a single connector configuration.

#### Configuring in Distributed Mode

This section describes how to configure and run workers in Kafka Connect distributed mode.

Distributed mode provides scalability and automatic fault tolerance for Kafka Connect. In distributed mode, multiple worker processes are started using the same group.id. These processes automatically coordinate to schedule execution of connectors and tasks across all available workers. If a worker is added, shuts down, or fails unexpectedly, the rest of the workers detect this and automatically coordinate to redistribute connectors and tasks across the updated set of available workers.

**NOTE:** Distributed mode is available as of EEP 2.0.1.

The following diagrams illustrates a three-node Kafka Connect distributed mode cluster where:

- Connectors are monitoring the source or sink system for changes that require reconfiguring tasks.
- Tasks are automatically balanced across the active workers by copying a subset of a connector's data.
- The division of work between tasks is shown by the partitions that each task is assigned.

Interaction with a distributed-mode cluster is via the REST API (rather than on the command line). To create a connector, the workers are started and then REST request is made to create a connector. See [REST API](#) on page 5322.

**NOTE:** Kafka Connect workers do not have a special “leader” process that you have to interact with to use the REST API. All nodes can respond to REST requests, including creating, listing, modifying, and destroying connectors.

To run the worker in distributed mode:

1. In the `connect-distributed.properties` file, define the topics that will store the connector state, task configuration state, and connector offset state.

In distributed mode, the workers need to be able to discover each other and have shared storage for connector configuration and offset data. In addition to the usual worker settings, ensure you have configured the following for the cluster:

- **group.id** - ID that uniquely identifies the cluster these workers belong to. Ensure this is unique for all groups that work with a cluster.

- **config.storage.topic** - Topic to store the connector and task configuration state in. Although this topic can be auto-created if your cluster has auto topic creation enabled, it is highly recommended that you create it before starting the cluster. This topic should **always** have a single partition and be highly replicated (3x or more).
  - **offset.storage.topic** - Topic to store the connector offset state in. To support large HPE Data Fabric Streams clusters, this topic should have a large number of partitions (for example, 25 or 50 partitions and highly replicated (3x or more).
  - **rest.port** - Port where the REST interface listens for HTTP requests. If you run more than one worker per host (for example, if you are testing distributed mode locally during development), this setting must have different values for each instance.
2. Set the group.id value for all of the workers in the cluster.

**NOTE:** All workers that belong to the same cluster must have the same group.id value.

3. Start the Kafka Connect service in distributed mode:

```
maprcli node services -name kafka-connect -action start -nodes
<node_list>
```

For more information, see [Managing Kafka Connect Services](#) on page 5316.

**NOTE:** >Distributed mode does not have any additional command line parameters. If other instances are already running, new workers either start a new group or join an existing one, and then wait for work to do. For information on managing the connectors running in the cluster, see [REST API](#) on page 5322.

## Connector Configuration

This section describes how and where connectors are configured.

Connector configurations are key-value mappings. For standalone mode, these parameters are defined in a properties file and passed to the Connect process on the command line. In distributed mode, they will be included in the JSON payload for the request that creates (or modifies) the connector. Most configurations are connector dependent, but there are a few settings common to all connectors:

- name - Unique name for the connector. Attempting to register again with the same name will fail.
- connector.class - The Java class for the connector
- tasks.max - The maximum number of tasks that should be created for this connector. The connector may create fewer tasks if it cannot achieve this level of parallelism.

Sink connectors also have one additional option to control their input:

- topics - A list of topics to use as input for this connector

For other options, consult the documentation for the JDBC and HDFS connectors. See [JDBC Connector](#) on page 5306 and [HDFS Connector](#) on page 5316.

## Worker Configuration

This section describes how and where to configure workers.

Whether you're running standalone or distributed mode, Kafka Connect workers are configured by passing a properties file containing any required or overridden options as the first parameter to the worker process.

*Common Worker Configuration Options*

You can set common worker configuration options for standalone or distributed mode in the `connect-<standalone/distributed>.properties` file. The options control basic functionality, including which cluster to communicate with and data format.

**Setting the Schema Registry URL for the Avro Converter**

Set the Schema Registry URL for the converter through the following properties:

- `key.converter.schema.registry.url=<URL:PORT>`
- `value.converter.schema.registry.url=<URL:PORT>`
- For Avro, use `io.confluent.connect.avro.AvroConverter`.
- For Protobuf, use `io.confluent.connect.protobuf.ProtobufConverter`.
- For JSON Schema, use `io.confluent.connect.json.JsonSchemaConverter`.

If you do not set these properties, the Schema Registry URL is taken from ZooKeeper.

The following table describes the common worker configuration parameters:

Parameter	Description
<b>plugin.path</b>	The comma-separated list of paths to directories that contain Kafka Connect plugins. <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: empty</li> </ul>
<b>key.converter</b>	Converter class for key Connect data. This controls the format of the data that will be written to HPE Data Fabric Streams for source connectors or read from Data Fabric Streams for sink connectors. <ul style="list-style-type: none"> <li>• Type: class</li> <li>• Default: empty</li> </ul>
<b>value.converter</b>	Converter class for value Connect data. This controls the format of the data that will be written to HPE Data Fabric Streams for source connectors or read from Data Fabric Streams for sink connectors. <ul style="list-style-type: none"> <li>• Type: class</li> <li>• Default: empty</li> </ul>
<b>internal.key.converter</b>	Converter class for internal key Connect data that implements the Converter interface. Used for converting data like offsets and configs. <ul style="list-style-type: none"> <li>• Type: class</li> <li>• Default:</li> </ul>
<b>internal.value.converter</b>	Converter class for offset value Connect data that implements the Converter interface. Used for converting data like offsets and configs. <ul style="list-style-type: none"> <li>• Type: class</li> <li>• Default:</li> </ul>

Parameter	Description
<b>offset.flush.interval.ms</b>	Interval (milliseconds) at which to try committing offsets for tasks. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 60000</li> </ul>
<b>offset.flush.timeout.ms</b>	Maximum number of milliseconds to wait for records to flush and partition offset data to be committed to offset storage before cancelling the process and restoring the offset data to be committed in a future attempt. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 5000</li> </ul>
<b>rest.advertised.host.name</b>	If set, this is the hostname that will be given out to other workers to connect to. <ul style="list-style-type: none"> <li>Type: string</li> </ul>
<b>rest.advertised.port</b>	If set, this is the port that will be given out to other workers to connect to. <ul style="list-style-type: none"> <li>Type: int</li> </ul>
<b>rest.host.name</b>	Hostname for the REST API. If this is set, it will only bind to this interface. <ul style="list-style-type: none"> <li>Type: string</li> </ul>
<b>rest.port</b>	Port for the REST API to listen on. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 8083</li> </ul>
<b>task.shutdown.graceful.timeout.ms</b>	Amount of time to wait (milliseconds) for tasks to shutdown gracefully. This is the total amount of time, not per task. All task have shutdown triggered, then they are waited on sequentially. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 5000</li> </ul>
<b>streams.consumer.streams.default.stream</b>	If set, topic names can be used in the Sink task configuration without the stream name. The defined default stream is used.
<b>streams.producer.producer.default.stream</b>	If set, topic names can be used in the Source task configuration without the stream name. The defined default stream is used.

#### *Standalone Worker Configuration Options*

This section describes worker parameters that are specific to standalone configurations.

The `offset.storage.file.filename` and `rest.port` parameter are specific to the standalone worker configuration. These parameters are sent in the `connect-standalone.properties` file.

**Table**

Parameter	Description
<b>rest.port</b>	Port the REST interface listens on for HTTP requests. If you run multiple standalone instances on the same host, this setting must have different values for each instance. Type: int. Default: 8083

Table (Continued)

Parameter	Description
<b>offset.storage.file.filename</b>	The file to store connector offsets in. By storing offsets on disk, a standalone process can be stopped and started on a single node and resume where it previously left off. Type: string. Default: empty

*Distributed Worker Configuration Options*

This topic describes the worker parameters that are specific to distributed configurations.

In addition to the common worker configuration options, the following are available in distributed mode.

These parameters are set in the `connect-distributed.properties` file.

Table

Parameter	Description	Type	Default
<b>group.id</b>	A unique string that identifies the Connect cluster group that the worker belongs to.	string	""
<b>config.storage.topic</b>	The name of the HPE Data Fabric Streams topic to store connector and task configuration data in. This <i>must</i> be the same for all workers with the same group.id. For example: <code>/path/to/stream:topic-prefix-</code>	string	""
<b>status.storage.topic</b>	The name of the HPE Data Fabric Streams topic where connector and task configuration updates are stored. This <i>must</i> be the same for all workers with the same group.id.	string	""
<b>offset.storage.topic</b>	The HPE Data Fabric Streams topic to store offset data for connectors in. This <i>must</i> be the same for all workers with the same group.id. For example: <code>/path/to/stream:topic-prefix-</code>	string	""
<b>heartbeat.interval.ms</b>	The expected time between heartbeats to the group coordinator when using Kafka's group management facilities.  Heartbeats are used to ensure that the worker's session stays active and to facilitate rebalancing when new members join or leave the group. The value must be set lower than <code>session.timeout.ms</code> , but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	int	3000
<b>session.timeout.ms</b>	The timeout used to detect failures when using Kafka's group management facilities.	int	30000
<b>connections.max.idle.ms</b>	Close idle connections after the number of milliseconds specified by this config.	long	540000
<b>receive.buffer.bytes</b>	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	int	32768
<b>request.timeout.ms</b>	The configuration controls the maximum amount of time the client will wait for the response of a request.  If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	int	40000

Table (Continued)

Parameter	Description	Type	Default
<b>send.buffer.bytes</b>	The size of the TCP send buffer (SO_SNDBUF) to use when sending data.	int	131072
<b>worker.sync.timeout.ms</b>	When the worker is out of sync with other workers and needs to resynchronize configurations, wait up to this amount of time before giving up, leaving the group, and waiting a backoff period before rejoining.	int	3000
<b>worker.unsync.backoff.ms</b>	When the worker is out of sync with other workers and fails to catch up within worker.sync.timeout.ms, leave the Connect cluster for this long before rejoining.	int	300000
<b>client.id</b>	An id string to pass to the server when making requests. The purpose of this is to be able to track the source of requests beyond just IP/port by allowing a logical application name to be included in server-side request logging.	string	""
<b>metadata.max.age.ms</b>	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	long	300000
<b>metric.reporters</b>	A list of classes to use as metrics reporters. Implementing the MetricReporterinterface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.	list	[]
<b>metrics.num.samples</b>	The number of samples maintained to compute metrics.	int	2
<b>metrics.sample.window.ms</b>	The number of samples maintained to compute metrics.	long	30000
<b>reconnect.backoff.ms</b>	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	long	50
<b>retry.backoff.ms</b>	The amount of time to wait before attempting to retry a failed fetch request to a given topic partition. This avoids repeated fetching-and-failing in a tight loop.	long	100

*Security Configuration Options*

Describes Kafka Connect security parameters.

Security mechanisms provide an authentication, encryption, and impersonation layer between the Kafka Connect REST API clients and the Kafka Connect REST Gateway. By default, Kafka Connect is secure when installed on a secure cluster. A secure cluster is a cluster installed with the default security (MapR-SASL) enabled. Default security provides authentication, encryption, and impersonation for Kafka Connect.

Configure security for Kafka Connect through the security parameters in the connect-distributed.properties file.

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

**NOTE:** Ensure that both a ssl\_keystore and a ssl\_truststore file have been created.

Table

Parameter	Description	Type	Default
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. If a listener uses HTTPS, the appropriate SSL configuration parameters need to be set as well. Each listener must include the protocol, hostname, and port. For example: http://localhost:8082	list	none
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none
authentication.enable	Enable authentication. Data Fabric supports multiple authentication methods at same time: Basic and MapR-SASL.	boolean	false
authentication.cookie.expiration	The option is used to specify expiration time (in seconds) for authentication cookie.	long	7200 (2 hours)
impersonation.enable	Whether or not to enable impersonation, if disabled - all manipulation will be performed from the admin of cluster user.	boolean	false
headers.file	The option is used to specify XML file that contains security and custom headers. The headers will be added to a response by Jetty server.	string	none
hadoop.http.authentication.types	A list of hadoop authentication types for MultiMechsAuthenticationHandler	list	maprauth, basic
ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .*DES.*</li> <li>• .*MD5.*</li> <li>• .*RC4.*</li> </ul>
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if ssl_endpoint_identification_algorithm=http s. Leave blank to use Jetty's default.	string	none
ssl.key.password	The password of the private key in the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty

**Table (Continued)**

Parameter	Description	Type	Default
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.keystore.location	Location of the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keystore.password	The store password for the keystore file. If this parameter is not set, the property value is obtained from the ssl-client.xml file.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLSv1.2
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS

### SSL Security Configuration

Describes how to configure Kafka Connect security on a HPE Data Fabric cluster.

### Secure by Default

As of Core 6.0, the Installer performs the Kafka Connect configuration for new installations. This means that:

- If core is installed as *secure*, then Kafka Connect is also installed as *secure*.
- If core is installed as *unsecure*, then Kafka Connect is also installed as *unsecure*.

### Manually Securing Kafka Connect Only

**CAUTION:** This configuration is *not* a typical configuration.

If you have an *unsecure* HPE Data Fabric cluster, and you want to *secure* Kafka Connect, do the following:

1. Generate the server and client certificates.
2. Add any necessary property configurations to the `connect-distributed.properties` configuration file. For example:

```
listeners=http://0.0.0.0:8083
ssl.keystore.location=<ssl-keystore-path>
ssl.keystore.password=<ssl-keystore-password>
ssl.key.password=<ssl-keystore-password>
```

**3. Restart Kafka Connect.**

```
maprcli node services -name kafka-connect -action restart -nodes <space
delimited list of nodes>
```

**4. Run a curl command to ensure that HTTPS is enabled.**

```
curl -X GET https://node1:8083/connectors --cacert <certificate-path>
```

*User Impersonation*

Describes how to disable, enable, and use impersonation with Kafka Connect.

User impersonation enables Kafka Connect jobs to be submitted as a particular user. Without impersonation, Kafka Connect submits jobs as the user that started the worker

On a HPE Data Fabric cluster, the impersonated user is typically the `mapr` user or the user specified in the `MAPR_USER` environment variable. By default, impersonation and PAM authentication in Kafka Connect are enabled on all types of security.

**Disabling User Impersonation**

To disable user impersonation, disable the PAM authentication and impersonation properties in the `opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties` file.

1. To disable PAM authentication, set `authentication.enable=false`.
2. To disable impersonation, set `impersonation.enable=false`.

**JDBC Connector**

The topics describes the JDBC connector, drivers, and configuration parameters.

The JDBC connector allows you to import data from any relational database into HPE Data Fabric Streams and export data from HPE Data Fabric Streams to any relational database with a JDBC driver. By using JDBC, this connector can support a wide variety of databases without requiring custom code for each one.

The JDBC connector provides flexibility regarding which databases you can import data from and how that data is imported. JDBC connector implements the data copying functionality on the generic JDBC APIs, and relies on JDBC drivers to handle the database-specific implementation of those APIs.

The supported relational databases include:

- MySQL
- Oracle
- PostgreSQL
- SQLite
- SQL Server
- Hive is supported for the JDBC Source Connector

*JDBC Driver*

Kafka Connect for HPE Data Fabric Streams provides a JDBC driver jar along with the connector configuration.

**IMPORTANT:**

**NOTE:**

Using Hive-JDBC driver with Connect-JDBC requires different jars in the `share/java/kafka-connect-jdbc/` directory depending on whether Connect HDFS is installed on the same node:

- If only Connect-JDBC is installed, you must keep the `hive-jdbc-<version>-standalone` jar.
- If both Connect-JDBC and Connect-HDFS are installed on the same node, you must keep `hive-jdbc` (not *standalone*) and `curator-client` jars.

The JDBC driver (`kafka-connect-jdbc`) is set up by specifying the CLASSPATH variable. See [Installing HPE Data Fabric Streams Tools](#) on page 314.

The packaged connector is installed in the **`share/java/kafka-connect-jdbc`** directory, relative to the installation directory.

Alternatively, to add a new driver to the CLASSPATH,

1. Put the classpath of the connectors in the **`kafka-connect-jdbc`** directory:

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<connector version>/
share/java/kafka-connect-jdbc/
```

2. Create a symlink into the **`share/java/kafka-connect-jdbc/`** directory.

*JDBC Configuration Options*

Use the following parameters to configure the Kafka Connect for HPE Data Fabric Streams JDBC connector; they are modified in the `quickstart-sqlite.properties` file.

**Configuration Modes**

In *standalone* mode, JDBC connector configuration is specified in the **`quickstart-sqlite.properties`** file. Additional configurations such as the offset storage location and the port for the REST interface are specified in the **`connect-standalone.properties`** file. See [Configuring in Standalone Mode](#) on page 5297.

```
/opt/mapr/kafka-connect-jdbc/kafka-connect-jdbc-<version>/etc/
kafka-connect-jdbc/quickstart-sqlite.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See [POST /connectors](#) on page 5323 and [PUT /connectors/\(string:name\)/config](#) on page 5326 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state, and connector offset state are specified in the **`connect-distributed.properties`** file. See [Configuring in Distributed Mode](#) on page 5298 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

## JDBC Source Configuration Options

Table

Parameters	Description
<b>connection.url</b>	JDBC connection URL for the database to load. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>connection.user</b>	JDBC connection user. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: NULL</li> </ul>
<b>connection.password</b>	JDBC connection password. <ul style="list-style-type: none"> <li>Type: password</li> <li>Default: NULL</li> </ul>
<b>connection.attempts</b>	Maximum number of attempts to retrieve a valid JDBC connection. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 3</li> </ul>
<b>connection.backoff.ms</b>	Backoff time in milliseconds between connection attempts. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 10000</li> </ul>
<b>table.whitelist</b>	List of tables to include in copying. If specified, table.blacklist may not be set. <ul style="list-style-type: none"> <li>Type: list</li> <li>Default: []</li> </ul>
<b>table.blacklist</b>	List of tables to exclude from copying. If specified, table.whitelist may not be set. <ul style="list-style-type: none"> <li>Type: list</li> <li>Default: []</li> </ul>
<b>numeric.precision.mapping</b>	Whether or not to attempt mapping <i>numeric</i> values by precision to integral types. <ul style="list-style-type: none"> <li>Type: boolean</li> <li>Default: false</li> </ul>
<b>schema.pattern</b>	Schema pattern to fetch table metadata from the database. <p>"" - Retrieves those without a schema.</p> <p>* - NULL (default) means that the schema name should not be used to narrow the search, all tables metadata would be fetched, regardless their schema.</p>

Table (Continued)

Parameters	Description
<b>mode</b>	<p>The mode for updating a table each time it is polled. Options include:</p> <ul style="list-style-type: none"> <li>• bulk - perform a bulk load of the entire table each time it is polled.</li> <li>• incrementing - use a strictly incrementing column on each table to detect only new rows. Note that this will not detect modifications or deletions of existing rows.</li> <li>• timestamp - use a timestamp (or timestamp-like) column to detect new and modified rows. This assumes the column is updated with each write, and that values are monotonically incrementing, but not necessarily unique.</li> <li>• timestamp+incrementing - use two columns, a timestamp column that detects new and modified rows and a strictly incrementing column which provides a globally unique ID for updates so each row can be assigned a unique stream offset.</li> <li>• Type: string</li> <li>• Default: ""</li> </ul> <p>Valid Values: [, bulk, timestamp, incrementing, timestamp+incrementing]  The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an autoincrementing column. This column may not be nullable.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul> <p> <b>NOTE:</b> If you are using Hive JDBC with incrementing or timestamp mode, you should set the <code>validate.non.null</code> property to false because there are no "not null" columns in Hive.</p>
<b>timestamp.column.name</b>	<p>The name of the timestamp column to use to detect new or modified rows. This column may not be nullable.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul>
<b>validate.non.null</b>	<p>By default, the JDBC connector will validate that all incrementing and timestamp tables have NOT NULL set for the columns being used as their ID/timestamp. If the tables don't, JDBC connector will fail to start. Setting this to false will disable these checks.</p> <ul style="list-style-type: none"> <li>• Type: boolean</li> <li>• Default: true</li> </ul> <p> <b>NOTE:</b> If this parameter is false, specify exactly all columns that need to be imported to HPE Data Fabric Streams in the query parameter. For example instead of "query" : "select * from table", use "query" : "select col1, col2 from table"</p>

Table (Continued)

Parameters	Description
<b>incrementing.column.name</b>	<p>The name of the strictly incrementing column to use to detect new rows. Any empty value indicates the column should be autodetected by looking for an auto-incrementing column. This column may not be nullable.</p> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>query</b>	<p>If specified, the query to perform to select new or updated rows. Use this setting to join tables, select subsets of columns in a table, or filter data. If used, this connector will only copy data using this query – whole-table copying will be disabled. Different query modes may still be used for incremental updates, but in order to properly construct the incremental query, it must be possible to append a WHERE clause to this query (i.e. no WHERE clauses may be used). If you use a WHERE clause, it must handle incremental queries itself.</p> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b>poll.interval.ms</b>	<p>Frequency (milliseconds) to poll for new data in each table.</p> <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 5000</li> </ul>
<b>batch.max.rows</b>	<p>Maximum number of rows to include in a single batch when polling for new data. This setting can be used to limit the amount of data buffered internally in the connector.</p> <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 100</li> </ul>
<b>table.poll.interval.ms</b>	<p>Frequency (milliseconds) to poll for new or removed tables, which may result in updated task configurations to start polling for data in added tables or stop polling for data in removed tables.</p> <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 60000</li> </ul>
<b>topic.prefix</b>	<p>Prefix to prepend to table names to generate the name of the Kafka topic to publish data to, or in the case of a custom query, the full name of the topic to publish to. For example: /path/to/stream:topic-prefix-.</p> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>

Table (Continued)

Parameters	Description
<b>table.types</b>	<p>By default, the JDBC connector will only detect tables with type TABLE from the source Database. This config allows a command separated list of table types to extract. Options include:</p> <ul style="list-style-type: none"> <li>• TABLE</li> <li>• VIEW</li> <li>• SYSTEM TABLE</li> <li>• GLOBAL TEMPORARY</li> <li>• LOCAL TEMPORARY</li> <li>• ALIAS</li> <li>• SYNONYM</li> </ul> <p>Typically, TABLE or VIEW are used.</p> <ul style="list-style-type: none"> <li>• Type: list</li> <li>• Default: TABLE</li> </ul>
<b>timestamp.delay.interval.ms</b>	<p>How long to wait after a row with certain timestamp appears before it is included in the result. You may choose to add some delay to allow transactions with earlier timestamp to complete. The first execution fetches all available records (for example, starting at timestamp 0) until the current time minus the delay. Every following execution retrieves data from the last time data was fetched until the current time minus the delay.</p> <ul style="list-style-type: none"> <li>• Type: long</li> <li>• Default: 0</li> </ul>

### JDBC Sink Configuration Options

Table

Parameters	Description
<b>connection.url</b>	<p>JDBC connection URL.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: ""</li> </ul>
<b>connection.user</b>	<p>JDBC connection user.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: NULL</li> </ul>
<b>connection.password</b>	<p>JDBC connection password.</p> <ul style="list-style-type: none"> <li>• Type: password</li> <li>• Default: NULL</li> </ul>

Table (Continued)

Parameters	Description
<b>insert.mode</b>	<p>The insertion mode to use.</p> <ul style="list-style-type: none"> <li>• INSERT - Use standard SQL INSERT statements.</li> <li>• UPSERT - Use the appropriate upsert semantics for the target database if it is supported by the connector. For example: INSERT or IGNORE</li> <li>• UPDATE - Use the appropriate update semantics for the target database if it is supported by the connector. For example: UPDATE</li> <li>• Type: string</li> <li>• Default: INSERT</li> <li>• Valid Values: insert, upsert, update</li> </ul>
<b>batch.size</b>	<p>Specifies how many records to attempt to batch together for insertion into the destination table, when possible.</p> <ul style="list-style-type: none"> <li>• Type: int</li> <li>• Default: 3000</li> <li>• Valid Values: 0,...</li> </ul>
<b>table.name.format</b>	<p>A format string for the destination table name, which may contain <code>\${topic}</code> as a placeholder for the originating topic name. For example, <code>table_\${topic}</code> for the topic <code>orders</code> maps to the table name <code>table_orders</code>.</p> <ul style="list-style-type: none"> <li>• Type: string</li> <li>• Default: <code>\${topic}</code></li> </ul>
<b>pk.mode</b>	<p>The primary key mode, also refer to <code>pk.fields</code> documentation for interplay. Supported modes are:</p> <ul style="list-style-type: none"> <li>• none - No keys utilized.</li> <li>• kafka - Kafka coordinates are used as the PK.</li> <li>• record_key - Field(s) from the record key are used, which may be a primitive or a struct.</li> <li>• record_value - Field(s) from the record value are used, which must be a struct.</li> <li>• Type: string</li> <li>• Default: none</li> <li>• Valid Values: none, kafka, record_key, record_value</li> </ul>

Table (Continued)

Parameters	Description
<b>pk.fields</b>	<p>List of comma-separated primary key field names. The runtime interpretation of this config depends on the pk.mode:</p> <ul style="list-style-type: none"> <li>• none - Ignored as no fields are used as primary key in this mode.</li> <li>• kafka - Must be a trio representing the Kafka coordinates. Defaults to __connect_topic,__connect_partition,__connect_offset if empty.</li> <li>• record_key - If empty, all fields from the key struct will be used, otherwise used to extract the desired fields - for primitive key only a single field name must be configured.</li> <li>• record_value - If empty, all fields from the value struct will be used, otherwise used to extract the desired fields.</li> <li>• Type: list</li> <li>• Default: ""</li> </ul>
<b>fields.whitelist</b>	<p>List of comma-separated record value field names. If empty, all fields from the record value are utilized, otherwise used to filter to the desired fields. Note: pk.fields is applied independently in the context of which field(s) form the primary key columns in the destination database, while this configuration is applicable for the other columns.</p> <ul style="list-style-type: none"> <li>• Type: list</li> <li>• Default: ""</li> </ul>
<b>auto.create</b>	<p>Whether to automatically create the destination table based on record schema if it is found to be missing by issuing CREATE.</p> <ul style="list-style-type: none"> <li>• Type: boolean</li> <li>• Default: false</li> </ul>
<b>auto.evolve</b>	<p>Whether to automatically add columns in the table schema when found to be missing relative to the record schema by issuing ALTER.</p> <ul style="list-style-type: none"> <li>• Type: boolean</li> <li>• Default: false</li> </ul>
<b>max.retries</b>	<p>The maximum number of times to retry on errors before failing the task.</p> <ul style="list-style-type: none"> <li>• Type: int</li> <li>• Default: 10</li> <li>• Valid Values: 0,..</li> </ul>
<b>retry.backoff.ms</b>	<p>The time in milliseconds to wait following an error before a retry attempt is made.</p> <ul style="list-style-type: none"> <li>• Type: int</li> <li>• Default: 3000</li> <li>• Valid Values: 0,..</li> </ul>

### Whitelists and Custom Query JDBC Examples

This section provides common usage scenarios using whitelists and custom queries.

#### Using Whitelists

Use a whitelist to limit changes to a subset of tables in a MySQL database, using id and modified columns that are standard on all whitelisted tables to detect rows that have been modified. This mode is the most robust because it can combine the unique, immutable row IDs with modification timestamps to guarantee modifications are not missed even if the process dies in the middle of an incremental update query.

The following is an example of a whitelist.

**NOTE:** Before running this example, you need to create the stream /kafka-connect

```

name=mysql-whitelist-timestamp-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector tasks.max=10
connection.url=jdbc:mysql://mysql.example.com:3306/my_database?
user=alice&password=secret
table.whitelist=users,products,transactions
mode=timestamp+incrementing
timestamp.column.name=modified
incrementing.column.name=id
topic.prefix=/kafka-connect:mysql-

```

#### Using Custom Queries

Use a custom query instead of loading tables to join data from multiple tables. As long as the query does not include its own filtering, you can still use the built-in modes for incremental queries (in this case, using a timestamp column).

**NOTE:** This limits you to a single output per connector and because there is no table name, the topic “prefix” is actually the full topic name in this case.

The following is an example of a custom query.

**NOTE:** Before running this example, you need to create the stream /kafka-connect

```

name=mysql-whitelist-timestamp-source
connector.class=io.confluent.connect.jdbc.JdbcSourceConnector
tasks.max=10
connection.url=jdbc:postgresql://postgres.example.com/test_db?
user=bob&password=secret&ssl=true
query=SELECT users.id,
users.name,
transactions.timestamp,
transactions.user_id,
transactions.payment FROM users JOIN transactions ON (users.id =
transactions.user_id)
mode=timestamp
timestamp.column.name=timestamp
topic.prefix=/kafka-connect:mysql-joined-data

```

### Streaming Data JDBC Examples

This section provides common usage scenarios of streaming data between different databases to or from HPE Data Fabric Streams.

## Streaming Data from HPE Data Fabric Streams to a MySQL Database

The following is example code for streaming data from HPE Data Fabric Streams stream topics to a MySQL database.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "mysql-sink-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSinkConnector",
"connection.url": "jdbc:mysql://hostname:3306/mysql_db?
user=<user>&password=<password>",
"auto.create": "true",
"topics": "/kafka-connect:topic1",
"tasks.max": "2",
"insert.mode": "insert"
}}
```

## Streaming Data from a MySQL Database to HPE Data Fabric Streams

The following is example code for streaming data from a MySQL database to HPE Data Fabric Streams stream topics.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
{"name": "mysql-source-connector",
"config": {
"connector.class": "io.confluent.connect.jdbc.JdbcSourceConnector",
"connection.url": "jdbc:mysql://hostname:3306/newdb?
user=<user>&password=<password>"
"mode": "incrementing",
"incrementing.column.name": "id",
"topic.prefix": "/kafka-connect:mysql-",
"tasks.max": "1"
}}
```

## Streaming Data from a Hive Database to HPE Data Fabric Streams

### IMPORTANT:

Using Hive-JDBC driver with Connect-JDBC requires different jars in the share/java/kafka-connect-jdbc/ directory depending on whether Connect HDFS is installed on the same node:

- If only Connect-JDBC is installed, you must keep the hive-jdbc-<version>-standalone jar.
- If both Connect-JDBC and Connect-HDFS are installed on the same node, you must keep hive-jdbc (not *standalone*) and curator-client jars.

The following is example code for streaming data from a Hive database to HPE Data Fabric Streams stream topics.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json
```

```
{
 "name": "hive-source-connector",
 "config": {
 "connector.class": "io.confluent.connect.jdbc.JdbcSourceConnector",
 "connection.url": "jdbc:hive2://hostname:10000/
 database_name;user=<user>;password=<password>",
 "mode": "bulk",
 "topic.prefix": "/kafka-connect:hive-",
 "tasks.max": "1"
 }
}
```

**NOTE:** For a secure HPE Data Fabric cluster, use next connection.url jdbc:hive2://hostname:10000/database\_name;auth=maprsasl

## Managing Kafka Connect Services

Lists the commands you use to start, stop, or restart Kafka Connect Services

Use the `maprccli node services` command with the `-action` parameter as follows:

```
maprccli node services -name kafka-connect -action start -nodes <node_list>
```

```
maprccli node services -name kafka-connect -action stop -nodes <node_list>
```

```
maprccli node services -name kafka-connect -action restart -nodes
<node_list>
```

For more information see [node services](#) on page 2598

## HDFS Connector

These topics describe the Kafka Connect for HPE Data Fabric Streams HDFS connector, driver, and configuration parameters.

The HDFS connector allows you to export data from HPE Data Fabric Streams topics to file system or HDFS files in a variety of formats. In addition, Hive integration is available, which can be use to make data immediately available for querying with HiveQL.

### HDFS Configuration Options

Use the following parameters to configure the Kafka Connect for HPE Data Fabric Streams HDFS connector.

**NOTE:** For the HDFS connector, both Avro and Parquet files can be written.

In *standalone* mode, specify the HDFS connector configuration in the **quickstart-hdfs.properties** file. You can also configure the offset storage location and the port for the REST interface, which are specified in the **connect-standalone.properties** file. See [Configuring in Standalone Mode](#) on page 5297.

```
/opt/mapr/kafka-connect-hdfs/kafka-connect-hdfs-<version>/etc/
kafka-connect-hdfs/quickstart-hdfs.properties
/opt/mapr/kafka/kafka-<version>/config/connect-standalone.properties
```

In *distributed* mode, HDFS connector configuration is provided in the POST and PUT requests when creating or modifying the connector. See [POST /connectors](#) on page 5323 and [PUT /connectors/\(string:name\)/config](#) on page 5326 for more information about using the REST API. Additional configurations such as defining the topics that will store the connector state, task configuration state, and connector offset state are specified in the **connect-distributed.properties** file. See [Configuring in Distributed Mode](#) on page 5298 .

```
/opt/mapr/kafka/kafka-<version>/config/connect-distributed.properties
```

Table

Parameter	Description
<b><i>flush.size</i></b>	Number of records written to the file system before invoking file commits. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: ""</li> </ul>
<b><i>hdfs.url</i></b>	The file system connection URL. This configuration has the format of <code>maprfs://hostname:port</code> and specifies the data fabric file system to export data to. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>connect.hdfs.keytab</i></b>	The path to the keytab file for the HDFS connector principal. This keytab file should only be readable by the connector user. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>connect.hdfs.principal</i></b>	The principal used when the file system is using Kerberos for authentication. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>format.class</i></b>	The format class used when writing data to the file system. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "io.confluent.connect.hdfs.avro.AvroFormat"</li> </ul> <div>  <b>NOTE:</b> If you want to write to a Parquet set, use "io.confluent.connect.hdfs.parquet.ParquetFormat" </div>
<b><i>hadoop.conf.dir</i></b>	The Hadoop configuration directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>hadoop.home</i></b>	The Hadoop home directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>hdfs.authentication.kerberos</i></b>	Specifies whether the file system uses Kerberos for authentication. <ul style="list-style-type: none"> <li>Type: boolean</li> <li>Default: false</li> </ul>
<b><i>hdfs.namenode.principal</i></b>	The Kerberos principal for CLDB. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>

Table (Continued)

Parameter	Description
<b><i>hive.conf.dir</i></b>	The Hive configuration directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>hive.database</i></b>	The database used when the connector creates tables in Hive. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "default"</li> </ul>
<b><i>hive.home</i></b>	The Hive home directory. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>hive.integration</i></b>	Specifies whether Hive is integrated when running the connector. <ul style="list-style-type: none"> <li>Type: boolean</li> <li>Default: false</li> </ul>
<b><i>hive.metastore.uris</i></b>	The Hive metastore URIs. Can be an IP address or fully-qualified domain name and port of the metastore host. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>logs.dir</i></b>	Top-level file system directory to store the write ahead logs. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "logs"</li> </ul>
<b><i>partitioner.class</i></b>	The partitioner used when writing data to the file system. You can use DefaultPartitioner, which preserves the Kafka partitions; FieldPartitioner, which partitions the data to different directories according to the value of the partitioning field specified in partition.field.name; TimeBasedPartitioner, which partitions data according to the time ingested to the file system. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "io.confluent.connect.hdfs.partitionner.DefaultPartitioner"</li> </ul>
<b><i>rotate.interval.ms</i></b>	The time interval (milliseconds) before invoking file commits. This configuration ensures that file commits are invoked every configured interval. This configuration is useful when data ingestion rate is low and the connector didn't write enough messages to commit files. The default value -1 means that this feature is disabled. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: -1</li> </ul>

Table (Continued)

Parameter	Description
<b><i>schema.compatibility</i></b>	The schema compatibility rule used when the connector is observing schema changes. The supported configurations are NONE, BACKWARD, FORWARD and FULL. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "NONE"</li> </ul>
<b><i>topics</i></b>	A list of topics to use as input for the HDFS connector. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>topics.dir</i></b>	Top-level file system directory to store the data ingested from Kafka. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "topics"</li> </ul>
<b><i>locale</i></b>	The locale used when partitioning with TimeBasedPartitioner. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>partition.duration.ms</i></b>	The duration of a partition (milliseconds) used by TimeBasedPartitioner. The default value -1 means that TimeBasedPartitioner is not being used. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: -1</li> </ul>
<b><i>partition.field.name</i></b>	The name of the partitioning field when FieldPartitioner is used. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>path.format</i></b>	This configuration is used to set the format of the data directories when partitioning with TimeBasedPartitioner. The format set in this configuration converts the Unix timestamp to proper directories strings. For example, if you set <code>path.format='year'=YYYY/'month'=MM/'day'=dd/'hour'=HH/</code> , the data directories will have the format <code>/year=2015/month=12/day=07/hour=15</code> <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>
<b><i>shutdown.timeout.ms</i></b>	Clean shutdown timeout. This makes sure that asynchronous Hive metastore updates are completed during connector shutdown. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 3000</li> </ul>
<b><i>timezone</i></b>	The timezone to use when partitioning with TimeBasedPartitioner. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: ""</li> </ul>

Table (Continued)

Parameter	Description
<b><i>filename.offset.zero.pad.width</i></b>	Sets the width to the zero-pad offsets in the file system file names. If the offsets are too short it provides fixed width filenames that can be ordered by simple lexicographic sorting. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 10</li> </ul>
<b><i>kerberos.ticket.renew.period.ms</i></b>	The period in milliseconds to renew the Kerberos ticket. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 3600000 (milliseconds)</li> </ul>
<b><i>retry.backoff.ms</i></b>	Used to notify Kafka Connect to retry delivering a message batch or performing recovery in case of transient exceptions. The retry backoff is in milliseconds. <ul style="list-style-type: none"> <li>Type: long</li> <li>Default: 5000 (milliseconds)</li> </ul>
<b><i>schema.cache.size</i></b>	The sized of the schema cache used in the Avro converter. <ul style="list-style-type: none"> <li>Type: int</li> <li>Default: 1000</li> </ul>
<b><i>storage.class</i></b>	The underlying storage layer. The default is MapR-FS. <ul style="list-style-type: none"> <li>Type: string</li> <li>Default: "io.confluent.connect.hdfs.storage.HdfsStorage"</li> </ul>

### HDFS Examples

These examples provides sample code for streaming data to and from the file system.

### Streaming Data from HPE Data Fabric Streams to the File System

This example provides sample code for streaming data from HPE Data Fabric Streams to the file system.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json

{
 "name": "maprfs-sink-connector",
 "config": {
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "1",
 "topics": "/kafka-connect:topic1",
 "hdfs.url": "maprfs:///",
 "flush.size": "5",
 "rotate.interval.ms": "1000"
 }
}
```

## Streaming Data from HPE Data Fabric Streams to the File System in Parquet

This example provides sample code for streaming data from HPE Data Fabric Streams to the file system in Parquet.

```
POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json

{
 "name": "hdfs-connector-parquet",
 "config": {
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "/kafka-connect:topic2",
 "hdfs.url": "maprfs:///",
 "format.class": "io.confluent.connect.hdfs.parquet.ParquetFormat",
 "flush.size": "3"
 }
}
```

### Hive Integration

This topic describes how to integrate a Hive database with Kafka Connect for HPE Data Fabric Streams.

Kafka Connect for HPE Data Fabric Streams supports Hive integration. If a Hive database is enabled, an external Hive table is created and that can be queried via Hive shell.

**NOTE:** As of Kafka Connect 4.0.0 for HPE Data Fabric Streams Hive 2.1 is supported.

The Hive table name is constructed using a topic name in the following manner:

- In the HPE Data Fabric Streams topic, /stream\_path:topic-name, the first forward slash (/) is removed, all other slashes are translated to underscores ( \_ ), and the colon (:) is translated to an underscore ( \_ ).
- All non-alphanumeric and non-underscore characters are removed from the string representing the Hive table name.

### Renaming Topics for Hive usage

The following example shows a topic named /test-12:test1 is renamed for Hive usage.

```
$ hadoop fs -ls -R /topics
drwxr-xr-x - mapr mapr 1 2016-10-05 19:46 /topics/+tmp
drwxr-xr-x - mapr mapr 1 2016-10-05 19:46 /topics/+tmp/
test12_test1
drwxr-xr-x - mapr mapr 0 2016-10-05 19:50 /topics/+tmp/
test12_test1/partition=1
drwxr-xr-x - mapr mapr 1 2016-10-05 19:46 /topics/
test12_test1
drwxr-xr-x - mapr mapr 2 2016-10-05 19:50 /topics/
test12_test1/partition=1
-rwxr-xr-x 3 mapr mapr 241 2016-10-05 19:47 /topics/
test12_test1/partition=1/test12_test1+1+00000000078+00000000080.avro
-rwxr-xr-x 3 mapr mapr 241 2016-10-05 19:50 /topics/
test12_test1/partition=1/test12_test1+1+00000000081+00000000083.avro
```

The following query and results shows the topic data in the Hive table.

```
> select * from test12_test1;
OK
```

```

16/10/05 20:06:59 INFO mapred.FileInputFormat: Total input paths to
process : 2

### Streaming Data from HPE Data Fabric Streams to the Hive database

This example provides sample code for streaming data from HPE Data Fabric Streams to the Hive database.

```

POST /connectors HTTP/1.1
Host: connect.example.com
Content-Type: application/json
Accept: application/json

{
 "name": "hdfs-connector-hive",
 "config": {
 "hive.integration": "true",
 "hive.database": "db3",
 "hive.conf.dir": "/opt/mapr/hive/hive-1.2/conf",
 "hive.metastore.uris": "thrift://localhost:9083",
 "schema.compatibility": "BACKWARD",
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "1",
 "topics": "/kafka-connect:topic3",
 "hdfs.url": "maprfs:///",
 "flush.size": "1"
 }
}

```

### REST API

The Kafka Connect REST API for HPE Data Fabric Streams manages connectors.

In standalone mode, a connector request is submitted on the command line. This mode is useful for getting status information, adding and removing connectors without stopping the process, and testing and debugging.

In distributed mode, the REST API is the primary interface to the cluster. Requests can be made to any cluster member where the REST API automatically forwards requests.

### Content Types

The REST API supports application/json as both the request and response entity content type. For example:

```

Accept: application/json
Content-Type: application/json

```

### Status & Errors

The REST API returns standards-compliant HTTP statuses.

**NOTE:** By default, the Kafka Connect REST API for HPE Data Fabric Streams service is run on port 8083.

Table

HTTP	URI	Description
GET	/connectors	Gets a list of active connectors.
POST	/connectors	Creates a new connector, returning the current connector information is successful.
GET	/connectors/(string:name)	Gets information about the connector.
GET	/connectors/(string:name)/config	Gets the configuration for the connector.
PUT	/connectors/(string:name)/config	Creates a new connector using the given configuration or updates the configuration for an existing connector.
GET	/connectors/(string:name)/tasks	Gets a list of tasks current running for the connector.
DELETE	/connectors/(string:name)/	Deletes a connector, halting all tasks and deleting its configuration.
GET	/connector-plugins	Lists the connector plugins available on this worker,
POST	/connectors/(string:name)/restart	Restarts a connector and its tasks.
GET	/connectors/(string:name)/tasks/(int:taskId)/status	Gets the status for a task.
POST	/connectors/(string:name)/tasks/(int:number of tasks)/restart	Restarts an individual task.
PUT	/connectors/(string:name)/pause	Pauses the connector and its tasks, which stops message processing until the connector is resumed.
PUT	/connectors/(string:name)/resume	Resumes a paused connector or do nothing if the connector is not paused.
GET	/connectors/(string:name)/status	Get current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks.

*GET /connectors*

Gets a list of active connectors.

### Syntax

```
http://<host>:8083/connectors
```

### Request Example

```
GET /connectors HTTP/1.1 Host: connect.example.com Accept: application/json
```

### Response Example

The response JSON object is in the following form:

- **connectors** (array) – List of connector names.

```
HTTP/1.1 200 OK Content-Type: application/json ["my-jdbc-source",
"my-hdfs-sink"]
```

*POST /connectors*

Creates a new connector, returning the current connector information if successful.

## Description

The POST request along with the parameters is used to create connectors in distributed mode.

The following table provides the parameters needed to create a new connector.

Table

Parameters	Description
<b>name</b> ( <i>string</i> )	Name of the created connector
<b>config</b> ( <i>map</i> )	Configuration parameters for the connector. See <a href="#">HDFS Connector</a> on page 5316 and <a href="#">JDBC Connector</a> on page 5306 for configuration options.
<b>tasks</b> ( <i>array</i> )	List of active tasks generated by the connector.
<b>tasks[i].connector</b> ( <i>string</i> )	Name of the connector that the task belongs to.
<b>tasks[i].task</b> ( <i>int</i> )	Task ID within the connector.

## Syntax

```
http://<host>:8083/connectors/?
name=<connector_name>&config=<config_parameters>
```

## Request Example

```
POST /connectors HTTP/1.1 Host: connect.example.com Content-Type:
application/json Accept: application/json
{
 "name": "hdfs-sink-connector",
 "config": {
 "connector.class":
"io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "1",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
 }
}
```

## Response Example

The response JSON object is in the following form:

- **name** (*string*) – Name of the connector to create.
- **config** (*map*) – Configuration parameters for the connector. All values should be strings.
- **tasks** (*array*) – List of active tasks generated by the connector.

```
HTTP/1.1 201 Created Content-Type: application/json
{
 "name": "hdfs-sink-connector",
 "config":
 {
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "test-topic",
```

```

 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
 },
 "tasks": [
 { "connector": "hdfs-sink-connector", "task": 1 },
 { "connector": "hdfs-sink-connector", "task": 2 },
 { "connector": "hdfs-sink-connector", "task": 3 }
]
}

```

*GET /connector/(string:name)*

Gets information about a specific connector.

### Description

Table

Parameters	Description
<b>name</b> ( <i>string</i> )	Name of the created connector.
<b>config</b> ( <i>map</i> )	Configuration parameters for the connector.
<b>tasks</b> ( <i>array</i> )	List of active tasks generated by the connector.
<b>tasks[i].connector</b> ( <i>string</i> )	Name of the connector the task belongs to.
<b>tasks[i].task</b> ( <i>int</i> )	Task ID within the connector.

### Syntax

```
http://<host>:8083/connectors/<name>
```

### Request Example

```
GET /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
Accept: application/json
```

### Response Example

```

HTTP/1.1 200 OK Content-Type: application/json
{
 "name": "hdfs-sink-connector",
 "config": {
 "connector.class":
"io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000" },
 "tasks": [
 { "connector": "hdfs-sink-connector", "task": 1 },
 { "connector": "hdfs-sink-connector", "task": 2 },
 { "connector": "hdfs-sink-connector", "task": 3 }
]
}

```

*GET /connectors/(string:name)/config*  
Gets the configuration for the connector.

### Description

Table

Parameters	Description
<b>config</b> ( <i>map</i> )	Configuration parameters for the connector.

### Syntax

```
http://<host>:8083/connectors/<string_name>/config
```

### Request Example

```
GET /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
```

### Response Example

```
HTTP/1.1 200 OK Content-Type: application/json
{
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
}
```

*PUT /connectors/(string:name)/config*

Creates a new connector using the given configuration or updates the configuration for an existing connector. Returns information about the connector after the change has been made.

### Description

The PUT request along with the parameters is used to create connectors in distributed mode.

Table

Parameters	Description
<b>name</b> ( <i>string</i> )	Name of the created connector.
<b>config</b> ( <i>map</i> )	Configuration parameters for the connector. See <a href="#">HDFS Connector</a> on page 5316 and <a href="#">JDBC Connector</a> on page 5306 for configuration options.
<b>tasks</b> ( <i>array</i> )	List of active tasks generated by the connector.
<b>tasks[i].connector</b> ( <i>string</i> )	Name of the connector that the task belongs to.
<b>tasks[i].task</b> ( <i>int</i> )	Task ID within the connector.

### Syntax

```
http://<host>:8083/connectors/<string_name>/config
```

## Request Example

```
PUT /connectors/hdfs-sink-connector/config HTTP/1.1 Host:
connect.example.com Accept: application/json
{
 "connector.class": "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
}
```

## Response Example

The response JSON object is in the following form:

- config (map) – Configuration parameters for the connector. All values should be strings.

**NOTE:** In this example, the return status indicates that the connector was created. In the case of a configuration update, the status would be 200 OK.

```
HTTP/1.1 201 Created Content-Type: application/json
{
 "name": "hdfs-sink-connector",
 "config":
 {
 "connector.class":
 "io.confluent.connect.hdfs.HdfsSinkConnector",
 "tasks.max": "10",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000"
 },
 "tasks": [
 { "connector": "hdfs-sink-connector", "task": 1 },
 { "connector": "hdfs-sink-connector", "task": 2 },
 { "connector": "hdfs-sink-connector", "task": 3 }
]
}
```

**GET /connectors/(string:name)/tasks**

Gets a list of tasks currently running for the connector.

## Description

Table

Parameters	Description
<b>tasks</b> (array)	List of active task configurations created by the connector.
<b>tasks[i].id</b> (string)	ID of the task.
<b>tasks[i].id.connector</b> (string)	Name of the connector that the task belongs to.
<b>tasks[i].id.task</b> (int)	Task ID within the connector.
<b>tasks[i].config</b> (map)	Configuration parameters for the task.

**Syntax**

```
http://<host>:8083/connectors/<connector_name>/tasks
```

**Request Example**

```
GET /connectors/hdfs-sink-connector/tasks HTTP/1.1 Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 200 OK
[
 {
 "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000" },
 {
 "task.class": "io.confluent.connect.hdfs.HdfsSinkTask",
 "topics": "test-topic",
 "hdfs.url": "hdfs://fakehost:9000",
 "hadoop.conf.dir": "/opt/hadoop/conf",
 "hadoop.home": "/opt/hadoop",
 "flush.size": "100",
 "rotate.interval.ms": "1000" }
]
```

*DELETE /connectors/(string:name)/*

Deletes a connector by halting all tasks and deleting its configuration.

**Syntax**

```
http://<host>:8083/connectors/<connector_name>/
```

**Request Example**

```
DELETE /connectors/hdfs-sink-connector HTTP/1.1 Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 204 No Content
```

*GET /connector-plugins*

Lists the connector plugins available on this worker.

**Syntax**

```
http://<host>:8083/connector-plugins>
```

**Request Example**

```
GET /connector-plugins/ HTTP/1.1
Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 200 OK

[
 {
 "class": "io.confluent.connect.hdfs.HdfsSinkConnector"
 },
 {
 "class": "io.confluent.connect.jdbc.JdbcSourceConnector"
 }
]
```

*POST /connectors/(string:name)/restart*  
 Restarts a connector and its tasks.

**Syntax**

```
http://<host>:8083/connectors/<string_name>/restart
```

**Request Example**

```
POST /connectors/hdfs-sink-connector/restart HTTP/1.1
Host: connect.example.com
```

**Response Example**

Return 409 (Conflict) if rebalance is in process.

```
HTTP/1.1 200 OK
```

*GET /connectors/(string:name)/tasks/(int:taskId)/status*  
 Gets the status for a task.

**Syntax**

```
http://<host>:8083/connectors/<string_name>/tasks/<task ID>/status
```

**Request Example**

```
GET /connectors/hdfs-sink-connector/tasks/1/status HTTP/1.1
Host: connect.example.com
```

**Response Example**

```
HTTP/1.1 200 OK

{"state":"RUNNING","id":1,"worker_id":"192.168.86.101:8083"}
```

*POST /connectors/(string:name)/tasks/(int:number of tasks)/restart*

Restarts an individual task.

### Syntax

```
http://<host>:8083/connectors/<string_name>/tasks/<number of tasks>/restart
```

### Request Example

```
GET /connectors/hdfs-sink-connector/tasks/1/restart HTTP/1.1
Host: connect.example.com
```

### Response Example

```
HTTP/1.1 200 OK
```

*PUT /connectors/(string:name)/pause*

Pauses the connector and its tasks, which stops message processing until the connector is resumed.

### Syntax

```
http://<host>:8083/connectors/<string_name>/pause
```

**NOTE:** This call is asynchronous and the tasks will not transition to PAUSED state at the same time.

### Request Example

```
PUT /connectors/hdfs-sink-connector/pause HTTP/1.1
Host: connect.example.com
```

### Response Example

```
HTTP/1.1 202 Accepted
```

*PUT /connectors/(string:name)/resume*

Resumes a paused connector or do nothing if the connector is not paused.

### Syntax

```
http://<host>:8083/connectors/<string_name>/resume
```

**NOTE:** This call is asynchronous and the tasks will not transition to RUNNING state at the same time.

### Request Example

```
PUT /connectors/hdfs-sink-connector/resume HTTP/1.1
Host: connect.example.com
```

### Response Example

```
HTTP/1.1 202 Accepted
```

**GET /connectors/{string:name}/status**

Gets current status of the connector, including whether it is running, failed or paused, which worker it is assigned to, error information if it has failed, and the state of all its tasks.

**Syntax**

```
http://<host>:8083/connectors/<string_name>/status
```

**Request Example**

```
GET /connectors/hdfs-sink-connector/status HTTP/1.1
Host: connect.example.com
```

**Response Example**

The response JSON object includes the following:

- name (string) – Name of the connector
- connector (map) – Map containing connector status
- tasks[i] (map) – Map containing the task status

```
HTTP/1.1 200 OK
```

```
{
 "name": "hdfs-sink-connector",
 "connector": {
 "state": "RUNNING",
 "worker_id": "localhost:8083"
 },
 "tasks": [
 {
 "id": 0,
 "state": "RUNNING",
 "worker_id": "localhost:8083"
 },
 {
 "id": 1,
 "state": "FAILED",
 "worker_id": "localhost:8083",
 "trace": "org.apache.kafka.common.errors.RecordTooLargeException\n"
 }
]
}
```

**Saving Kafka Connect Configurations**

Describes how Kafka Connect configurations are saved during an upgrade.

Starting in EEP 6.0.0, the configuration for a previously installed version of Kafka Connect is stored in a folder with a timestamp.

- Files are saved *and* overwritten by new configuration files:
  - when upgrading from 4.1.0 to 5.1.2.
  - when upgrading from 5.1.2 to 10.0.0.

- Files are saved only (*not* overwritten):
  - when upgrading from 5.1.2 to 5.1.2.

### Example

The following example shows the list of configuration files that are saved when upgrading from `mapr-kafka-connect 5.1.2 (EEP 7.0.0)` to `mapr-kafka-connect 5.1.2 (EEP 7.0.1)`:

```
ls /opt/mapr/kafka/
kafka-2.1.1 kafka-2.1.1.0.202009090438 kafkaversion

ls /opt/mapr/kafka/kafka-2.1.1.0.202009090438/config/
connect-console-sink.properties connect-distributed.properties
connect-file-source.properties connect-standalone.properties
connect-console-source.properties connect-file-sink.properties
connect-log4j.properties
```

### Kafka Schema Registry

Kafka Schema Registry provides a RESTful interface for storing and retrieving schemas.

Schema Registry can store and retrieve Avro schemas.

Starting in version 6.0.0, Schema Registry can store and retrieve Avro, JSON Schema, and Protobuf schemas.

When you implement Kafka Schema Registry for your data schemas, they can self-evolve for compatibility with downstream consumers.

Kafka Schema Registry acts as a standalone serving layer for metadata, interacting with both the producer and consumer. It stores schemas for keys and values of records.

Kafka Schema Registry enables you to perform the following tasks:

- Store a versioned history of all schemas.
- Provide multiple compatibility settings.
- Support schema evolution according to the configured compatibility settings and the expanded support for the schema format.
- Provide serializers that interface with Kafka clients and manage schema storage and retrieval for Kafka messages that are sent in one of the supported schema formats.

- Develop your own custom formats to use with this interface.

You can also perform these tasks:

- List schemas by subject and also list all versions of a subject (schema).
- Retrieve a schema by version or ID.
- Retrieve the latest version of a schema.
- Verify that a schema is compatible with a certain version.

## Architecture

Kafka Schema Registry is designed to be distributed with a single master architecture. ZooKeeper coordinates the master election, based on the configuration. Kafka-coordinated master election is not currently supported.

HPE Data Fabric Streams is designed to be the durable backend for schema registry, providing a write-ahead change log for the state of schema registry and the schemas it contains.

## Interoperability

Kafka Schema Registry can interface with the following components:

- Kafka Client (producer, consumer APIs)
- KStreams
- KSQL
- Kafka Connect
- Kafka REST

## Performance and Scalability Impact

You can improve performance by decreasing the size of the message payload. Without Kafka Schema Registry, the message payload contains the user data and the schema metadata. With the Kafka Schema Registry, the message payload contains the user data and only the schema ID that is unique for each schema.

For scalability, you can launch Kafka Schema Registry on several nodes.

## For More Information

- [Installing Kafka Schema Registry](#)
- [Confluent Schema Registry documentation](#)

## Building and Deploying Kafka Schema Registry

To build and deploy Kafka Schema Registry with Maven, you must first install development versions of Kafka common and rest-utils utilities.

You can run Kafka Schema Registry instances on several cluster nodes. One node is the primary node and the other ones are secondary nodes.

Kafka Schema Registry requires ZooKeeper and HPE Data Fabric Streams.

The REST interface to schema registry includes a built-in Jetty server. The wrapper scripts bin/schema-registry-start and bin/schema-registry-stop are the recommended methods for starting and stopping the service.

In Apache Kafka, a schema is produced when:

- A message is produced and there is no equivalent schema in the schema registry
- A schema is created for key or value portion of the message

The associated schema subject is a “topic-key”:

- Each schema is associated with a version
- Every schema gets a globally unique ID

The consumer gets the messages' schema using the schema ID:

```
$ curl -X GET http://localhost:8087/schemas/ids/1
{"schema":"\"string\""}

```

You can also query a schema for a given topic using the associated schema subject. For example, for topic1 (for either key or value), schema, all, latest, or specific schema versions can be queried using the following REST commands:

```
$ curl -X GET http://localhost:8087/subjects/topic1-value/versions
[1]
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
{"subject":"Kafka-value", "version":1, "id":1, "schema":"\"string\""}
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
{"subject":"Kafka-value", "version":1, "id":1, "schema":"\"string\""}

```

For a complete list of supported APIs, see [Confluent Schema Registry API Reference](#).

### Kafka Schema Registry Limitations

Describes the limitations related to the Kafka Schema Registry.

- **No Replication Support**

Replication for Kafka Schema Registry is not supported.

- **Manually Configure Kafka REST, KSQL, and Kafka Connect to work with Schema Registry**

You must manually modify the Kafka REST, KSQL, and Kafka Connect configuration files if you want them to work with the Schema Registry.

### Kafka Schema Registry Security

Describes security mechanisms for Kafka Schema Registry.

### Schema Registry Communication Paths

The following image depicts the Schema Registry communication paths:

The following table lists the supported security mechanisms for the Schema Registry communication paths:

**NOTE:** Path B does not have a network connection and therefore does not need to be secured. However, impersonation works seamlessly for this path through Schema Registry Server.

Security Features	Supported Mechanisms	Communication Paths Secured
<b>Authentication</b>	MapR-SASL (ticket-based security)	D – Schema Registry Server and ZooKeeper
		A - Schema Registry Client and Schema Registry Server
		C – Schema Registry Server and Schema Registry Server
	Basic (PAM)	A - Schema Registry Client and Schema Registry Server
		C – Schema Registry Server and Schema Registry Server
	Cookie	A - Schema Registry Client and Schema Registry Server
<b>Encryption</b>	MapR-SASL (ticket-based security)	C – Schema Registry Server and Schema Registry Server
		D - Schema Registry Server and ZooKeeper
		A - Schema Registry Client and Schema Registry Server
	SSL/TLS	C -Schema Registry Server and Schema Registry Server
		A - Schema Registry Client and Schema Registry Server
		C - Schema Registry Server and Schema Registry Server
<b>Authorization</b>	Based on filesystem permissions.	A - Schema Registry Client and Schema Registry Server
<b>Impersonation</b>	User impersonation	A - Schema Registry Client and Schema Registry Server
		B – Schema Registry Server to Streams for Apache Kafka
		C - Schema Registry Server and Schema Registry Server
<b>Auditing</b>	Not supported	--

### Kafka Schema Registry Configuration

Describes how to configure the Kafka Schema Registry for HPE Data Fabric Event Store.

Set the Schema Registry configuration parameters in the `/opt/mapr/schema-registry/schema-registry-<version>/etc/schema-registry/schema-registry.properties` file.

**schema.registry.service.id**

This parameter indicates the ID of the schema registry service. The default setting for this parameter is `default_`.

See [Schema Registry Configuration Options](#) for additional Schema Registry parameters.

By default, the Schema Registry service runs on port 8087.

*Security Parameters*

Describes Schema Registry security parameters.

Security mechanisms provide an authentication, encryption, and impersonation layer between the Schema Registry REST API clients and the Schema Registry Server. In secure clusters, Schema Registry is secured by default.

**Requirement:** Before you configure Schema Registry security parameters, verify that an `ssl_keystore` and an `ssl_truststore` file have been created.

The following table lists the Schema Registry security parameters:

Parameter	Description	Type	Default
authorization.enable	Set 'true' or 'false' to enable or disable authorization for Schema Registry service. See <a href="#">Schema Registry Authorization</a> on page 5338.	boolean	false
authentication.cookie.expiration	Authentication cookie expiration time in seconds.	long	7200 (2 hours)
authentication.enable	Whether or not to enable authentication.	boolean	false
impersonation.enable	Whether or not to enable impersonation. If disabled, all manipulation will be performed from the admin of cluster user. See <a href="#">Schema Registry Impersonation</a> on page 5339.	boolean	false
listeners	Comma-separated list of listeners that listen for API requests over either HTTP or HTTPS. Each listener must include the protocol, hostname, and port. For example: <code>http://localhost:8087</code>	list	none
ssl.cipher.suites	A list of SSL cipher suites. This list is a comma-separated list. Leave blank to use Jetty's default.	list	none

ssl.cipher.suites.exclude	A list of disabled SSL cipher suites. This is a comma-separated list. Leave blank to use Jetty's default.	list	<ul style="list-style-type: none"> <li>• TLS_DHE.*</li> <li>• TLS_EDH.*</li> <li>• .DES.</li> <li>• .MD5.</li> <li>• .RC4.</li> </ul>
ssl.client.auth	Specifies whether or not to acquire the HTTPS client to authenticate via the server's trust store.	boolean	false
ssl.disabled.protocols	The list of SSL protocols that will not be accepted by clients. This is a comma-separated list.	list	<ul style="list-style-type: none"> <li>• SSLv3</li> <li>• TLSv1.0</li> </ul>
ssl.enabled.protocols	The list of SSL protocols that can be accepted from clients. The list is a comma-separated list. Leave blank to use Jetty's defaults.	list	empty
ssl.endpoint.identification.algorithm	The endpoint identification algorithm to validate the server hostname using the server certificate. IMPORTANT: Jetty requires that the key's CN, stored in the keystore, must match the FQDN if ssl_endpoint_identification_algorithm=https. Leave blank to use Jetty's default.	string	none
ssl.key.password	The password of the private key in the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. <b>Note:</b> If the ssl-client.xml file is changed, Schema Registry must be restarted.	string	empty
ssl.keymanager.algorithm	The algorithm used by the key manager factory for SSL connections. Leave blank to use Jetty's default.	string	empty

ssl.keystore.location	Location of the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. <b>Note:</b> If the ssl-client.xml file is changed, Schema Registry must be restarted.	string	empty
ssl.keystore.password	The store password for the keystore file. This parameter should be taken from the /opt/mapr/conf/ssl-client.xml file. If this parameter is not set, the property value is obtained from the ssl-client.xml file. <b>Note:</b> If the ssl-client.xml file is changed, Schema Registry must be restarted.	string	empty
ssl.keystore.type	The type of keystore file.	string	JKS
ssl.protocol	The SSL protocol used to generate the SslContextFactory.	string	TLS
ssl.provider	The SSL security provider name. Leave blank to use Jetty's default.	string	none
ssl.trustmanager.algorithm	The algorithm used by the trust manager factory for SSL connections. Leave blank to use Jetty's default.	string	none
ssl.truststore.location	Location of the trust store. Required only to authenticate HTTPS clients.	string	empty
ssl.truststore.password	The store password for the trust store file.	string	empty
ssl.truststore.type	The type of trust store file.	string	JKS
ssl.trustallcerts.enable	Set to true if you want to disable certificates verification.	boolean	false
headers.file	The option is used to specify the XML file that contains security and custom headers. The headers will be added to a response by the Jetty server.	string	empty

*Schema Registry Authorization*

Describes authorization for Kafka Schema Registry.

In secure clusters, authorization is enabled by default.

You can enable or disable authorization for the Schema Registry in the `<schema-registry-dir>/etc/schema-registry/schema-registry.properties` file through the following option:

```
authorization.enable=[true|false]
```

## Permissions

Permissions grant access to internal data in the Schema Registry, such as schemas, subjects, and server configurations. *Read* permission grants access to view data. *Modify* permission grants access to add, update, and remove data.

The following sections describe operations that require *read* and *modify* access.

**NOTE:** To avoid any unexpected behaviours when using Schema Registry with KSQL, Kafka Rest, Kafka Connect, or custom Java applications, both *read* and *modify* permissions are required.

## REST API Operations that Require Read Access

<b>GET</b> /schemas/ids/{int: id}	Get the schema string identified by the input ID.
<b>GET</b> /subjects/	Get a list of versions registered under the specified subject.
<b>GET</b> /subjects/(string: subject)/versions/(versionId: version)	Get a specific version of the schema registered under this subject.
<b>GET</b> /subjects/(string: subject)/versions/(versionId: version)/schema	Get the avro schema for the specified version of this subject.
<b>GET</b> /config	Get global compatibility level.
<b>GET</b> /config/(string: subject)	Get compatibility level for a subject.
<b>POST</b> /subjects/(string: subject)	Check if a schema has already been registered under the specified subject. If so, this returns the schema string along with its globally unique identifier, its version under this subject and the subject name.
<b>POST</b> /compatibility/subjects/(string: subject)/versions/(versionId: version)	Test input schema against a particular version of a subject's schema for compatibility.

## REST API Operations that Require Modify Access

<b>DELETE</b> /subjects/(string: subject)	Deletes the specified subject and its associated compatibility level if registered.
<b>POST</b> /subjects/(string: subject)/versions	Register a new schema under the specified subject.
<b>DELETE</b> /subjects/(string: subject)/versions/(versionId: version)	Deletes a specific version of the schema registered under this subject.
<b>PUT</b> /config	Update global compatibility level.
<b>PUT</b> /config/(string: subject)	Update compatibility level for the specified subject.

### Schema Registry Impersonation

Describes impersonation for Kafka Schema Registry.

Impersonation authorizes the impersonated user to perform permission-sensitive operations on the Schema Registry. In secure clusters, impersonation is enabled by default.

**Requirement:** For impersonation to work, Schema Registry authentication must be enabled; otherwise, the server will not start and the system will return an error. When authentication is enabled, all commands run as the authenticated user instead of the Schema Registry principal. The Schema Registry principal is the user that started the Schema Registry server.

You can enable or disable impersonation for the Schema Registry in the <schema-registry-client>/etc/schema-registry/schema-registry.properties file through the following option:

```
impersonation.enable=[true|false]
```

### Related concepts

[Schema Registry Authorization](#) on page 5338

Describes authorization for Kafka Schema Registry.

### Kafka Schema Registry Use Cases

Describes typical use cases to register and query a schema and serialize and deserialize data.

#### Use Case 1: Registering and Querying a Schema for a Kafka Topic

While Kafka topics do not have a schema, having an external store that tracks this metadata for a given Kafka topic helps answer the following questions:

- What are the different events in any given Kafka topic?
- What can I put into a given Kafka topic?
- Do all Kafka events have a similar type of schema?
- How do I parse and use the data in a given Kafka topic?

#### Sample workflow code:

The following sample commands register and query a schema in a Kafka topic:

```
Register a new version of a schema under the subject "Kafka-key"
$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
 --data '{"schema": "{\"type\": \"string\"}'}' \
 http://localhost:8087/subjects/Kafka-key/versions
{"id":1}

Register a new version of a schema under the subject "Kafka-value"
$ curl -X POST -H "Content-Type: application/vnd.schemaregistry.v1+json" \
 --data '{"schema": "{\"type\": \"string\"}'}' \
 http://localhost:8087/subjects/Kafka-value/versions
{"id":1}

List all subjects
$ curl -X GET http://localhost:8087/subjects
["Kafka-value", "Kafka-key"]

List all schema versions registered under the subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions
[1]

Fetch a schema by globally unique id 1
$ curl -X GET http://localhost:8087/schemas/ids/1
{"schema":"string"}

Fetch version 1 of the schema registered under subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/1
```

```

{"subject":"Kafka-value","version":1,"id":1,"schema":"\"string\""}
Fetch the most recently registered schema under subject "Kafka-value"
$ curl -X GET http://localhost:8087/subjects/Kafka-value/versions/latest
{"subject":"Kafka-value","version":1,"id":1,"schema":"\"string\""}

```

### Use Case 2: Serializing and Deserializing Data in a Kafka Topic

Schema Registry 5.1.2 works with the Avro format only. Schema Registry 6.0.0 works with the Avro format and also JSON Schema and Protobuf formats.

In addition to storing the schema metadata for a topic, Kafka Schema Registry also provides mechanisms for reading and writing data to a Kafka topic in supported formats.

You can plug the appropriate Serializer into the KafkaProducer to send messages to Kafka. A Serializer is available for each of the supported formats.

For Avro, use the `KafkaAvroSerializer`.

For JSON Schema, use the `KafkaJsonSchemaSerializer`.

For Protobuf, use the `KafkaProtobufSerializer`.

Currently, primitive types of `null`, `Boolean`, `Integer`, `Long`, `Float`, `Double`, `String`, `byte[]`, and the complex `IndexedRecord` type are supported.

Sending data of other types to `KafkaAvroSerializer` causes a `SerializationException` to occur. Typically, `IndexedRecord` is used for the value of the Kafka message. If used, the key of the Kafka message is often of one of the primitive types.

For example, when sending a message to a topic `t`, the schema for the key and the value is automatically registered in the Kafka Schema Registry under the subject `t-key` and `t-value`, respectively, if the compatibility test passes. The only exception is when the `null` type is never registered in the Kafka Schema Registry.

For consuming messages from a Kafka topic, the deserializer can be plugged analogically to the serializer.

### Use Case 3: Supporting KSQL Streams or Tables in Supported formats

KSQL requires that you use the Kafka Schema Registry to create KSQL Streams or Tables in supported formats.

Schema Registry supports Avro format. Specify `VALUE_FORMAT='AVRO'` to work with topics that contain messages in Avro format.

Starting in version 6.0.0, Schema Registry supports JSON Schema and Protobuf in addition to Avro. For JSON Schema and Protobuf, specify either `VALUE_FORMAT='JSON_SR'` or `VALUE_FORMAT='PROTOBUF'` to work with topics that contain messages in JSON Schema or Protobuf format.

#### Sample workflow code:

The following commands create and register a schema using an Avro console producer:

```

Create a stream

$ maprcli stream create -path /sample-stream -produceperm p -consumeperm
p -topicperm p

Use Avro console producer to create and register a schema

/sample-stream:pageviews-avro-topic

```

```
CREATE STREAM pageviews WITH (KAFKA_TOPIC='pageviews-avro-topic',
VALUE_FORMAT='AVRO');

CREATE TABLE users WITH (KAFKA_TOPIC='users-avro-topic',
VALUE_FORMAT='AVRO',
KEY='userid');
```

## Managing Kafka Schema Registry

Describes how to manage the internal stream for Kafka Schema Registry.

### Schema Registry Internal Stream

By default, the `schema-registry-internal-stream` topic stores the schemas.

The `schema-registry-internal-stream` topic is located in `/apps/schema-registry/schema-registry-internal-stream`. The `kafkastore.stream` property in the `SR_CONF_DIR/schema-registry.properties` file sets the internal stream topic. By default, the `kafkastore.stream` property is set to `/apps/schema-registry/schema-registry-internal-stream`.

The internal stream is automatically created if it does not already exist. If the internal stream already exists and has the same permissions as the default, the system returns a warning. If `kafkastore.stream` is set to a value other than the default, the system returns an error if the stream does not exist. You must explicitly set permissions on the stream you designate as the Schema Registry internal stream.

You can use Warden and `/opt/mapr/server/configure.sh` to manage and configure Kafka Schema Registry. Any time you change Schema Registry configurations, run `configure.sh` for changes to take effect.

### Secure Cluster Default Permissions on the Internal Stream

By default, the internal stream is readable by all the users and writable only by the cluster administrator. For secure clusters, the default permissions are:

- `-produceperm u:$CLUSTER_ADMIN`
- `-consumeperm p`
- `-topicperm u:$CLUSTER_ADMIN`

The cluster admin is typically `mapr` or the value set for `MAPR_USER`.

### Log Compaction for the Schema Registry Internal Stream

Log compaction is the process of purging messages previously published to a topic partition while retaining the latest version. Log compaction for the Schema Registry internal stream is enabled by default.

**IMPORTANT:** Log compaction requires a gateway on the same cluster as the Schema Registry internal stream. Also, TTL should be disabled because it can interfere with log compaction.

### Installing a Gateway

Run the command appropriate for your system:

- RedHat/CentOS

```
yum install mapr-gateway
```

- Ubuntu

```
apt-get install mapr-gateway
```

- SLES

```
zypper install mapr-gateway
```

### Related concepts

[Log Compaction](#) on page 851

Log compaction purges previous, older messages that were published to a topic-partition and retains the latest version of the record.

### More information

[Preparing Clusters for Log Compaction](#) on page 1775

Describes how to prepare your environment so you can use log compaction.

### Enabling High Availability for Kafka Schema Registry

You can enable high availability by installing multiple instances of schema registry on the same cluster.

### About this task

One node in the cluster acts as the primary instance. Only the primary instance can publish writes to the underlying Kafka log. The primary node can also manage read requests.

All other secondary nodes manage only read requests. These nodes serve registration requests indirectly by forwarding them to the current primary node and returning any response supplied by the primary node.

### Procedure

1. Install schema registry on several nodes. For installation instructions, see [Installing Kafka Schema Registry](#).
2. Configure high availability for the ensemble of ZooKeeper nodes. You can find the steps for this in the [open source documentation](#), section Clustered (Multi-Server) Setup.
3. Modify the schema registry configuration file on each node to specify the `kafkastore.connection.url` property with the ZooKeeper nodes that form the HA ensemble.
4. Run the `configure.sh -R` command on each schema registry node.

### Schema Registry Demos

Provides demonstrations for using Kafka Schema Registry to store and retrieve schemas.

The following topics demonstrate how to use Kafka Schema Registry to store and retrieve schemas in the supported formats:

*Kafka Schema Registry Demo for Avro*

Implements a Kafka Schema Registry demo example that stores and retrieves Avro schemas.

### Maven Dependencies

Add the following repositories to the POM file to resolve Confluent and Data Fabric dependencies:

```
<repositories>
 <repository>
 <id>confluent</id>
 <url>http://packages.confluent.io/maven/</url>
 </repository>
```

```

<repository>
 <id>mapr-maven</id>
 <url>https://repository.mapr.com/maven/</url>
 <releases><enabled>true</enabled></releases>
 <snapshots><enabled>true</enabled></snapshots>
</repository>
</repositories>

```

The following dependencies are needed for Avro and Kafka:

```

<dependency>
 <groupId>org.apache.avro</groupId>
 <artifactId>avro</artifactId>
 <version>1.9.2</version>
</dependency>
<dependency>
 <groupId>io.confluent</groupId>
 <artifactId>kafka-avro-serializer</artifactId>
 <version>5.1.2.0-mapr-700</version>
</dependency>

```

### Creating a Java class that corresponds to the Avro schema

Add the following plugins to the pom.xml file:

- Plugin to build code:

```

<plugin>
 <groupId>org.apache.avro</groupId>
 <artifactId>avro-maven-plugin</artifactId>
 <version>1.8.2</version>
 <executions>
 <execution>
 <phase>generate-sources</phase>
 <goals>
 <goal>schema</goal>
 <goal>protocol</goal>
 <goal>idl-protocol</goal>
 </goals>
 <configuration>
 <sourceDirectory>${project.basedir}/src/main/resources/avro</sourceDirectory>
 <stringType>String</stringType>
 <createSetters>false</createSetters>
 <enableDecimalLogicalType>true</enableDecimalLogicalType>
 <fieldVisibility>private</fieldVisibility>
 </configuration>
 </execution>
 </executions>
</plugin>

```

- Plugin to force the discovery of the generated classes:

```
<plugin>
 <groupId>org.codehaus.mojo</groupId>
 <artifactId>build-helper-maven-plugin</artifactId>
 <version>3.0.0</version>
 <executions>
 <execution>
 <id>add-source</id>
 <phase>generate-sources</phase>
 <goals>
 <goal>add-source</goal>
 </goals>
 <configuration>
 <sources>
 <source>target/generated-sources/avro</source>
 </sources>
 </configuration>
 </execution>
 </executions>
</plugin>
```

- Create a file with filename extension .avsc in the src/main/resources directory.

An example of an Avro schema is as follows:

```
{
 "namespace": "com.example",
 "type": "record",
 "name": "Employee",
 "doc": "Represents an Employee at a company",
 "fields": [
 {
 "name": "firstName",
 "type": "string",
 "doc": "The persons given name"
 },
 ...
]
}
```

```

 {"name": "lastName", "type": "string"},
 {"name": "age", "type": "int", "default": -1},
 {"name": "emails", "default": [], "type": {"type": "array", "items":
"string"}},
 {"name": "phoneNumber", "type": "string"}
]
}

```

The `Employee.class` Java class is auto-generated in the `target/classes/com/example` directory after executing the following commands:

```

$ mvn clean
$ mvn package

```

You can use this class in your program after performing these steps.

### Creating an Avro Producer

1. Import the following properties for the Kafka Producer:

```

import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroSerializer;
import io.confluent.kafka.serializers.KafkaAvroSerializerConfig;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.ArrayList;
import java.util.List;
import java.util.Properties;

```

2. Configure the following properties for Event Data Streams:

```

Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
 IntegerSerializer.class.getName());

// Configure the KafkaAvroSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
 KafkaAvroSerializer.class.getName());

//Schema registry location.
properties.setProperty(KafkaAvroSerializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
 "http://localhost:8087");

KafkaProducer<Integer, Employee> producer =
 new KafkaProducer<>(properties);

```

3. The following code sends  $n$  different objects of class `Employee.java` to the topic `avro_example` in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
Employee employee;

for (int i = 0; i < n; i++) {

 List<String> emails = new ArrayList<>();
 for (int j = 0; j < i; j++) {
 emails.add("john" + j + ".doe" + i + "@mail.com");
 }

 employee = Employee.newBuilder()
 .setFirstName("John" + i)
 .setLastName("Doe")
 .setAge(i + 5)
 .setEmails(emails)
 .setPhoneNumber("+1-202-555-" + i + i + i + i)
 .build();

 ProducerRecord<Integer, Employee> record =
 new ProducerRecord(topic, i, employee);

 producer.send(record, (recordMetadata, e) -> {
 if (e == null) {
 System.out.println("Success! ");
 System.out.println(recordMetadata.toString());
 } else {
 e.printStackTrace();
 }
 });
}

producer.flush();
producer.close();
```

### Creating an Avro Consumer

1. Import the following properties for the Kafka Consumer:

```
import com.example.Employee;
import io.confluent.kafka.serializers.KafkaAvroDeserializer;
import io.confluent.kafka.serializers.KafkaAvroDeserializerConfig;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.util.Collections;
import java.util.Properties;
```

- The properties to configure are similar to the Kafka producer, only Deserializers must be used instead of Serializers. Add one more property called `KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG`:

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
 IntegerDeserializer.class.getName());

//Use Kafka Avro Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
 KafkaAvroDeserializer.class.getName());

//Use Specific Record or else you get Avro GenericRecord.
properties.put(KafkaAvroDeserializerConfig.SPECIFIC_AVRO_READER_CONFIG,
 "true");

//Schema registry location.
properties.put(KafkaAvroDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
 "http://localhost:8087");

KafkaConsumer<Integer, Employee> consumer =
 new KafkaConsumer<>(properties);
```

- The following code reads objects of the `Employee.java` class from the `avro_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:avro_example";
consumer.subscribe(Collections.singletonList(topic));

try {
 while (true) {
 ConsumerRecords<Integer, Employee> records =
 consumer.poll(Duration.ofMillis(100));
 records.forEach(record -> {

 Employee employeeRecord = record.value();

 System.out.printf("%s %d %d %s \n", record.topic(),
 record.partition(), record.offset(), employeeRecord);
 });
 }
} finally {
 consumer.close();
}
```

#### *Kafka Schema Registry Demo for JSON Schema*

Implements a Kafka Schema Registry demo example that stores and retrieves schemas in JSON Schema format.

#### **Maven Dependencies**

Add the following repositories to the POM file to resolve Confluent and Data Fabric dependencies:

```
<repositories>
 <repository>
 <id>confluent</id>
 <url>http://packages.confluent.io/maven/</url>
 </repository>
 <repository>
 <id>mapr-maven</id>
```

```

 <url>https://repository.mapr.com/maven/</url>
 <releases><enabled>true</enabled></releases>
 <snapshots><enabled>true</enabled></snapshots>
 </repository>
</repositories>

```

The following dependencies are needed for JSON Schema and Kafka:

```

<dependency>
 <groupId>com.fasterxml.jackson.core</groupId>
 <artifactId>jackson-annotations</artifactId>
 <version>2.10.5</version>
</dependency>

<dependency>
 <groupId>io.confluent</groupId>
 <artifactId>kafka-json-schema-serializer</artifactId>
 <version>6.0.0.0-eep-800</version>
</dependency>

```

### Create a Java class that corresponds to JSON Schema

Create a Java class that includes Jackson annotations, for example:

```

import com.fasterxml.jackson.annotation.JsonProperty;

public class User {
 @JsonProperty
 public String firstName;
 @JsonProperty
 public String lastName;
 @JsonProperty
 public short age;
 public User() {}
 public User(String firstName, String lastName, short age) {
 this.firstName = firstName;
 this.lastName = lastName;
 this.age = age;
 }
 public String toString() {
 return String.format("first name: " + firstName
 + "; last name: " + lastName + "; age: " + age);
 }
}

```

### Create a JSON Schema Producer

1. Import the following properties for the Kafka Producer:

```

import io.confluent.kafka.serializers.json.KafkaJsonSchemaSerializer;
import
io.confluent.kafka.serializers.json.KafkaJsonSchemaSerializerConfig;
import io.demo.example.User;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.Properties;

```

2. Configure the following properties for the Event Data Streams:

```
Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
 IntegerSerializer.class.getName());

// Configure the KafkaJsonSchemaSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
 KafkaJsonSchemaSerializer.class.getName());

// Schema registry location.
properties.setProperty(KafkaJsonSchemaSerializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
 "http://localhost:8087");

KafkaProducer<Integer, User> producer =
 new KafkaProducer<>(properties);
```

3. Use the following code to send n different objects of class User.java to the topic json-schema\_example in the /sample-stream stream:

```
String topic = "/sample-stream:json-schema_example";

for (int i = 0; i < n; i++) {
 User user = new User("John" + i, "Doe", (short) (i + 30));

 ProducerRecord<Integer, User> record =
 new ProducerRecord(topic, i, user);

 producer.send(record, (recordMetadata, e) -> {
 if (e == null) {
 System.out.println("Success!");
 System.out.println(recordMetadata.toString());
 } else {
 e.printStackTrace();
 }
 });
}

producer.flush();
producer.close();
```

### Create a JSON Schema Consumer

1. Import the following properties for the Kafka Consumer:

```
import io.confluent.kafka.serializers.json.KafkaJsonSchemaDeserializer;
import
io.confluent.kafka.serializers.json.KafkaJsonSchemaDeserializerConfig;
import io.demo.example.User;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;
```

2. Add the `KafkaJsonSchemaDeserializerConfig.JSON_VALUE_TYPE` property to the properties of the Kafka Consumer to deserialize the output to the needed class.

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
 IntegerDeserializer.class.getName());

//Use Kafka JSON Schema Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
 KafkaJsonSchemaDeserializer.class.getName());

//A class that the message value should be deserialized to.
properties.put(KafkaJsonSchemaDeserializerConfig.JSON_VALUE_TYPE,
 User.class.getName());

//Schema registry location.
properties.put(KafkaJsonSchemaDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG,
 "http://localhost:8087");

KafkaConsumer<Integer, User> consumer =
 new KafkaConsumer<>(properties);
```

3. Use the following code to read objects of the `User.java` class from the `json-schema_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:json-schema_example";
consumer.subscribe(Collections.singletonList(topic));

try {
 while (true) {
 ConsumerRecords<Integer, User> records =
 consumer.poll(Duration.ofMillis(100));

 records.forEach(record -> {

 User userRecord = record.value();

 System.out.printf("%s %d %d %s \n", record.topic(),
 record.partition(), record.offset(),
userRecord);
 });
 }
} finally {
 consumer.close();
}
```

#### *Kafka Schema Registry Demo for Protobuf*

Implements a Kafka Schema Registry demo example that stores and retrieves Protobuf schemas.

#### **Maven Dependencies**

Add the following repositories to the POM file to resolve Confluent and Data Fabric dependencies:

```
<repositories>
 <repository>
 <id>confluent</id>
 <url>http://packages.confluent.io/maven/</url>
 </repository>
```

```

<repository>
 <id>mapr-maven</id>
 <url>https://repository.mapr.com/maven/</url>
 <releases><enabled>true</enabled></releases>
 <snapshots><enabled>true</enabled></snapshots>
</repository>
</repositories>

```

The following dependencies are needed for Protobuf and Kafka:

```

<dependency>
 <groupId>com.google.protobuf</groupId>
 <artifactId>protobuf-java</artifactId>
 <version>3.17.3</version>
</dependency>

<dependency>
 <groupId>io.confluent</groupId>
 <artifactId>kafka-protobuf-serializer</artifactId>
 <version>6.0.0.0-ee-800</version>
</dependency>

```

### Create a Java class that corresponds to the Protobuf schema

Add the following plugin to the pom.xml file:

```

<plugin>
 <groupId>com.github.os72</groupId>
 <artifactId>protoc-jar-maven-plugin</artifactId>
 <version>3.11.4</version>
 <executions>
 <execution>
 <phase>generate-sources</phase>
 <goals>
 <goal>run</goal>
 </goals>
 <configuration>
 <inputDirectories>
 <include>src/main/resources/</include>
 </inputDirectories>
 <outputTargets>
 <outputTarget>
 <type>java</type>
 <addSources>none</addSources>
 <outputDirectory>src/main/java/</outputDirectory>
 </outputTarget>
 </outputTargets>
 </configuration>
 </execution>
 </executions>
</plugin>

```

Create a file with the .proto extension in the src/main/resources/proto directory. For example, person.proto. An example of a Protobuf schema is as follows:

```

syntax = "proto3";
package io.demo.example;
option java_outer_classname = "PersonImpl";

message Person {
 int32 id = 1;

```

```

 string firstName = 2;
 string lastName = 3;
 string email = 4;
}

```

The `PersonImpl.class` Java class is auto-generated in the `src/main/java/io/demo/example` directory after running the following commands:

```

$ mvn clean
$ mvn package

```

You can use this class in your program to manage the class `Person.class`.

### Create a Protobuf Producer

To create a Protobuf producer:

1. Import the following properties for the Kafka Producer:

```

import io.confluent.kafka.serializers.protobuf.KafkaProtobufSerializer;
import
io.confluent.kafka.serializers.protobuf.KafkaProtobufSerializerConfig;
import io.demo.example.PersonImpl.Person;
import org.apache.kafka.clients.producer.KafkaProducer;
import org.apache.kafka.clients.producer.ProducerConfig;
import org.apache.kafka.clients.producer.ProducerRecord;
import org.apache.kafka.common.serialization.IntegerSerializer;

import java.util.Properties;

```

2. Configure the following properties for the Event Data Streams:

```

Properties properties = new Properties();
properties.setProperty(ProducerConfig.KEY_SERIALIZER_CLASS_CONFIG,
 IntegerSerializer.class.getName());

// Configure the KafkaProtobufSerializer.
properties.setProperty(ProducerConfig.VALUE_SERIALIZER_CLASS_CONFIG,
 KafkaProtobufSerializer.class.getName());

// Schema registry location.
properties.setProperty(KafkaProtobufSerializerConfig.SCHEMA_REGISTRY_URL_
CONFIG,
 "http://localhost:8087");

KafkaProducer<Integer, Person> producer =
 new KafkaProducer<>(properties);

```

3. Use the following code to send n different objects of class `Person.java` to the topic `proto_example` in the `/sample-stream` stream:

```
String topic = "/sample-stream:proto_example";
Person person;

for (int i = 0; i < n; i++) {
 Person person = Person.newBuilder()
 .setId(i)
 .setFirstName("John")
 .setLastName("Doe")
 .setEmail("john" + i + ".doe@mail.com")
 .build();

 ProducerRecord<Integer, Person> record =
 new ProducerRecord(topic, i, person);

 producer.send(record, (recordMetadata, e) -> {
 if (e == null) {
 System.out.println("Success!");
 System.out.println(recordMetadata.toString());
 } else {
 e.printStackTrace();
 }
 });
}

producer.flush();
producer.close();
```

### Create a Protobuf Consumer

To create a Protobuf consumer:

1. Import the following properties for the Kafka Consumer:

```
import io.confluent.kafka.serializers.protobuf.KafkaProtobufDeserializer;
import
io.confluent.kafka.serializers.protobuf.KafkaProtobufDeserializerConfig;
import io.demo.example.PersonImpl.Person;
import org.apache.kafka.clients.consumer.ConsumerConfig;
import org.apache.kafka.clients.consumer.ConsumerRecords;
import org.apache.kafka.clients.consumer.KafkaConsumer;
import org.apache.kafka.common.serialization.IntegerDeserializer;

import java.time.Duration;
import java.util.Collections;
import java.util.Properties;
```

2. Add the `KafkaProtobufDeserializerConfig.SPECIFIC_PROTOBUF_VALUE_TYPE` property to the properties of the Kafka Consumer to deserialize the output to the needed class.

```
Properties properties = new Properties();
properties.put(ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG,
 IntegerDeserializer.class.getName());

//Use Kafka Protobuf Deserializer.
properties.put(ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG,
 KafkaProtobufDeserializer.class.getName());

//A class generated by Protocol buffers that the message value should be
deserialized to.
properties.put(KafkaProtobufDeserializerConfig.SPECIFIC_PROTOBUF_VALUE_TY
PE,
 Person.class.getName());

//Schema registry location.
properties.put(KafkaProtobufDeserializerConfig.SCHEMA_REGISTRY_URL_CONFIG
,
 "http://localhost:8087");

KafkaConsumer<Integer, Person> consumer =
 new KafkaConsumer<>(properties);
```

3. Use the following code to read objects of the `Person.java` class from the `proto_example` topic in the `/sample-stream` stream:

```
String topic = "/sample-stream:proto_example";
consumer.subscribe(Collections.singletonList(topic));

try {
 while (true) {
 ConsumerRecords<Integer, Person> records =
 consumer.poll(Duration.ofMillis(100));

 records.forEach(record -> {

 Person personRecord = record.value();

 System.out.printf("%s %d %d %s \n", record.topic(),
 record.partition(), record.offset(),
personRecord);
 });
 } finally {
 consumer.close();
 }
}
```

### Structured Streaming in Spark

Starting in EEP 5.0.0, structured streaming is supported in Spark.

### Related Links

Spark streaming is integrated with HPE Data Fabric Streams for Apache Kafka.

- [Data Fabric Event Store For Apache Kafka Clients and Tools](#)

**Prerequisites for Using Structured Streaming in Spark**

To deploy a structured streaming application in Spark, you must create a Data Fabric Streams topic and install a Kafka client on all nodes in your cluster.

*Creating a Data Fabric Streams Topic***Procedure**

- Create a Data Fabric Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

*Installing a Kafka Client***Procedure**

- Install a kafka-client on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

**Using Structured Streaming to Create a Word Count Application**

The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.

*Using Apache Kafka***Example****Scala**

```
val spark = SparkSession
 .builder
 .appName("StructuredKafkaWordCount")
 .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
 .readStream
 .format("kafka")
 .option("kafka.bootstrap.servers", bootstrapServers)
 .option(subscribeType, topics)
 .load()
 .selectExpr("CAST(value AS STRING)")
 .as[String]
//Generate a running word count
val wordCounts =
 lines.flatMap(_.split(" "))
 .groupByKey("value").count()
//Run the query that prints the
running counts to the console
val query = wordCounts.writeStream
 .outputMode("complete")
 .format("console")
 .option("checkpointLocation",
checkpointLocation)
 .start()

query.awaitTermination()
```

**Java**

```

SparkSession spark = SparkSession
 .builder()
 .appName("JavaStructured
KafkaWordCount")
 .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
 .readStream()
 .format("kafka")
 .option("kafka.bootstrap
.servers", bootstrapServers)
 .option(subscribeType,
topics)
 .load()
 .selectExpr("CAST(value
AS STRING)")
 .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
unt();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
 .outputMode("complete")
 .format("console")
 .start();

query.awaitTermination();

```

**Python**

```

spark = SparkSession\
 .builder\
 .appName("StructuredKafkaWor
dCount")\
 .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
 .readStream\
 .format("kafka")\
 .option("kafka.bootstrap.ser
vers", bootstrapServers)\
 .option(subscribeType,
topics)\
 .load()\
 .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row

```

```
explode(
 split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that prints the
running counts to the console
query = wordCounts\
 .writeStream\
 .outputMode('complete')\
 .format('console')\
 .start()

query.awaitTermination()
```

### Using Data Fabric Event Store for Apache Kafka

#### Example

For Data Fabric Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```
var topic: String = "/user/mapr/stream:reviews"
val df1 = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
 "maprdemo:9092").option("subscribe", topic).option("group.id",
 "testgroup").option("startingOffsets",
 "earliest").option("failOnDataLoss",
 false).option("maxOffsetsPerTrigger", 1000).load()
```

### Writing a Structured Spark Stream to HPE Data Fabric Database JSON Table

The example in this section writes a structured stream in Spark to HPE Data Fabric Database JSON table.

#### Example

To write a structured Spark stream to HPE Data Fabric Database JSON table, use MapRDBSourceConfig.Format for Java and Scala and com.mapr.db.spark.streaming for Python to format the tablePath, idFieldPath, createTable, bulkMode, and sampleSize parameters.

#### Scala

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig
import org.apache.spark.sql.streaming.
{StreamReader, StreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._

df.select($"value" as "_id")
 .writeStream
 .format(MapRDBSourceConfig.Format)
 .option(MapRDBSourceConfig.TablePath
Option, "/table/path")
 .option(MapRDBSourceConfig.IdFieldPa
```

**Java**

```
thOption, "value")
 .option(MapRDBSourceConfig.CreateTableOption, true)
 .option(MapRDBSourceConfig.BulkModeOption, true)
 .option(MapRDBSourceConfig.SampleSizeOption, 1000)
 .outputMode("append")
}
```

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig;
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.Session;
import
org.apache.spark.sql.streaming.DataStreamReader;
import
org.apache.spark.sql.streaming.DataStreamWriter;
import
org.apache.spark.sql.streaming.StreamingQueryException;
```

```
DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
 return df.selectExpr("CAST(value AS STRING) as _id")
 .writeStream()
 .format(MapRDBSourceConfig.Format())
 .option(MapRDBSourceConfig.TablePathOption(), "/table/path")
 .option(MapRDBSourceConfig.IdFieldPathOption(), "value")
 .option(MapRDBSourceConfig.CreateTableOption(), true)
 .option(MapRDBSourceConfig.BulkModeOption(), true)
 .option(MapRDBSourceConfig.SampleSizeOption(), 1000)
 .outputMode("append");
}
```

**Python**

```
from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
 return df.selectExpr("CAST(value AS STRING) as _id") \
 .writeStream \
 .format("com.mapr.db.spark.streaming") \
 .option("checkpointLocation", checkpoint_dir) \
 .option("tablePath", table_path) \
```

```

 .option("idFieldPath",
"value") \
 .option("createTable",
True) \
 .option("bulkMode", True) \
 .option("sampleSize", 1000)

```

### Writing a Spark Stream Word Count Application to HPE Data Fabric Database

The example in this section writes a Spark stream word count application to HPE Data Fabric Database.

#### Example

##### Scala

```

val spark = SparkSession
 .builder
 .appName("StructuredKafkaWordCou
nt")
 .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
 .readStream
 .format("kafka")
 .option("kafka.bootstrap.servers
", bootstrapServers)
 .option(subscribeType, topics)
 .load()
 .selectExpr("CAST(value AS
STRING)")
 .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
 .format(MapRDBSourceConfig.Forma
t)
 .option(MapRDBSourceConfig.Table
PathOption, resultTable)
 .option(MapRDBSourceConfig.Creat
eTableOption, true)
 .option(MapRDBSourceConfig.IdFie
ldPathOption, "value")
 .outputMode("complete")
 .start()

query.awaitTermination()

```

##### Java

```

SparkSession spark = SparkSession
 .builder()
 .appName("JavaStructuredKaf
kaWordCount")
 .getOrCreate();

//Create a DataSet representing the

```

```

stream of input lines from Kafka
Dataset<String> lines = spark
 .readStream()
 .format("kafka")
 .option("kafka.bootstrap.servers", bootstrapServers)
 .option(subscribeType,
topics)
 .load()
 .selectExpr("CAST(value
AS STRING)")
 .as(Encoders.STRING());

//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").count();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
 .format(MapRDBSourceConfig
.Format())
 .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
 .option(MapRDBSourceConfig
.CreateTableOption(), true)
 .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
 .outputMode("complete");
 .start();

query.awaitTermination();

```

## Python

```

spark = SparkSession\
 .builder\
 .appName("StructuredKafkaWordCount")\
 .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
 .readStream\
 .format("kafka")\
 .option("kafka.bootstrap.servers", bootstrapServers)\
 .option(subscribeType,
topics)\
 .load()\
 .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#Explode turns each item in an array

```

```

into a separate row
explode(
 split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB
query = wordCounts\
 .writeStream\
 .format("com.mapr.db.spa
rk.streaming") \
table_path) \
 .option("tablePath",
True) \
 .option("createTable",
"value") \
 .outputMode('complete')\
 .start()

query.awaitTermination()

```

## NiFi

This topic provides an overview of Apache NiFi on HPE Data Fabric.

Starting from EEP 9.0.0, HPE Data Fabric supports Apache NiFi.

Apache NiFi is a dataflow system based on the concepts of flow-based programming which supports powerful and scalable directed graphs of data routing, transformation, and system mediation logic. NiFi has a web-based user interface for the design, control, feedback, and monitoring of dataflows.

The following diagram shows the NiFi architecture:

To transfer data in and out of HPE Data Fabric, NiFi supports the following sources and sinks.

- SQL Databases (MySQL, Postgres, etc.)
- NoSQL Databases (MongoDB, Redis, etc.)
- File storage (S3 compatible, SMB, FTP)
- Cloud services (GCP, Azure, AWS)
- HTTP requests
- Other

To install NiFi, see [Installing NiFi](#) on page 317 and to view the NiFi release notes, see [NiFi Release Notes](#) on page 8166.

To learn more about NiFi, see [Apache NiFi documentation](#).

### Accessing NiFi UI

This topic describes how to access NiFi the UI.

NiFi automatically starts after successful configuration.

Cluster Type	NiFi UI Endpoints
Secured	https://HOST_FQDN:12443/nifi
Unsecured	http://HOST_FQDN:12080/nifi

To log in to the NiFi UI on a secured cluster, you must have a username and password. By default, credentials are randomly generated and are located in the [NiFi Logs](#) on page 5363. For example:

```
cat /opt/mapr/nifi/nifi-<version>/logs/nifi-app.log | grep Generated
```

By default, a single-user login strategy is used on secured clusters. To change credentials, run:

```
/opt/mapr/nifi/nifi-<version>/bin/nifi.sh set-single-user-credentials
"USERNAME" "PASSWORD"
```

After changing credentials, you must restart the NiFi services:

```
maprcli node services -name nifi -action restart -nodes <nodes list>
```

If you change ports, you must launch the reconfiguration script to update the Warden configurations with the proper values. To learn more, see [Sensitive Values Encryption](#).

### NiFi Logs

This topic describes how to view the logs for NiFi on HPE Data Fabric.

You can locate the logs for NiFi at /opt/mapr/nifi/nifi-<version>/logs/ folder.

### Configuring NiFi

This topic describes where to locate configuration files for NiFi and how to configure NiFi for cluster mode.

The configuration files for NiFi are located at /opt/mapr/nifi/nifi-<version>/conf directory. Configuration is not necessary to start using NiFi.

Configuration Files	Description
nifi.properties	NiFi server side configuration
bootstrap.conf	NiFi launcher configuration
logback.xml	Logging settings

Configuration Files	Description
authorizers.xml	Authorization configuration
login-identity-providers.xml	Authentication configuration
state-management.xml	NiFi cluster-storing state configuration

NiFi automatically starts after successful configuration.

To learn more about NiFi configurations, see [Administration Guide](#).

### Configuring NiFi for Cluster Mode

To ensure that NiFi works on cluster mode, specify Connect String for zk-provider in state-management.xml file.

For example:

```
node4.cluster.com:5181
```

For example: On secured cluster, make the following changes in nifi.properties file.

- nifi.web.https.host=node5.cluster.com (set to FQDN on each node)
- nifi.sensitive.props.key=abcd123456789 (set same on each node)
- nifi.cluster.protocol.is.secure=true (is necessary if clusters work with https)
- nifi.cluster.is.node=true
- nifi.cluster.skip.hostname.verify=true (is necessary if certificate is wildcard without subjectAltNames)
- nifi.cluster.node.address=node5.cluster.com (set to FQDN on each node)
- nifi.zookeeper.connect.string=node4.cluster.com:5181 (set similar to state-management.xml)

### Starting, Stopping, and Restarting NiFi Services

This topic describes how to start, stop, and restart NiFi services on HPE Data Fabric.

#### About this task

The Warden daemon starts the NiFi server automatically at installation time.

You can start and stop NiFi from the command line or from the Control System. You can use the `maprc li node services` command to start NiFi on multiple nodes at one time.

### Starting, Stopping, and Restarting NiFi Services Using Command Line

#### About this task

Perform the following steps to start or stop or restart NiFi from the command line:

#### Procedure

1. Make a list of nodes on which NiFi is configured.

2. Run the `maprccli node services` command with either `start`, `restart`, or `stop`, and specify the nodes on which NiFi is configured, separated by spaces.

```
maprccli node services -name nifi -action start|stop|restart -nodes
<nodes list>
```

## Starting, Stopping, and Restarting NiFi Services Using Scripts

### About this task

You can manually start or stop or restart or check the status by using the script located at `opt/mapr/nifi/nifi-<version>/bin/nifi.sh`.

For example:

```
/opt/mapr/nifi/nifi-1.16.3/bin/nifi.sh start|stop|restart|status
```

## Manually configuring SSO (OIDC) for NiFi

This topic describes how to manually configure SSO (OIDC) for NiFi.

### About this task

You must manually configure SSO (OIDC) for NiFi when a non-administrative user starts NiFi. In order to configure SSO (OIDC), a cluster admin user must first retrieve the cluster SSO configuration and then update the NiFi configuration file `nifi.properties`.

### Procedure

1. As a cluster admin user, run the `maprccli cluster getsssoconf` command to retrieve the SSO configuration values. For example:

```
maprccli cluster getsssoconf
clientid clientsecret providername
issuerendpoint
edf-client FWIx44ym9kBmeR3XkSPPfLsCPQQ3sNMo keycloak https://
<IP_address>:6443/realms/master
```

2. Update the NiFi configuration file `nifi.properties` with the SSO configuration values retrieved from running the `maprccli cluster getsssoconf` command.

- Set the property `nifi.security.user.oidc.client.id` to `clientid`.
- Set the property `nifi.security.user.oidc.client.secret` to `clientsecret`.
- Set the property `nifi.security.user.oidc.discovery.url` to `issuerendpoint` and append `/.well-known/openid-configuration`.

For example:

```
nifi.security.user.oidc.client.id=edf-client
nifi.security.user.oidc.client.secret=FWIx44ym9kBmeR3XkSPPfLsCPQQ3sNMo
nifi.security.user.oidc.discovery.url=https://<IP_address>:6443/realms/
master/.well-known/openid-configuration
```

You can now start NiFi as a non-administrative user with SSO (OIDC).

## NiFi Security

This topic describes how the Login Identity Provider provides authentication options for username and password for NiFi.

NiFi supports different authorization providers. The user authentication through username and password is performed by Login Identity Provider. Login Identity Provider provides three options to authenticate username and password:

1. Single User
2. Lightweight Directory Access Protocol/ Active Directory (LDAP/ AD)
3. Kerberos

To learn more, see [User Authentication](#).

By default, you can log in using Single User option on secured clusters.

MapR-SASL does not support UI login and impersonation.

## Kerberos

To authenticate username and password by using Kerberos on cluster, perform the following:

1. Add the following properties in `opt/mapr/nifi/nifi-<version>/conf/nifi.properties` file.

```
nifi.security.user.authorizer=managed-authorizer
nifi.security.user.login.identity.provider=kerberos-provider
nifi.kerberos.krb5.file=/etc/krb5.conf
```

2. Add the following providers in `/opt/mapr/nifi/nifi-<version>/conf/login-identity-providers.xml` file.

```
<provider>
 <identifier>kerberos-provider</identifier>
 <class>org.apache.nifi.kerberos.KerberosProvider</class>
 <property name="Default Realm">YOUR_REALM</property>
 <property name="Authentication Expiration">12 hours</property>
</provider>
```

3. Add the following authorizers in /opt/mapr/nifi/nifi-<version>/conf/authorizers.xml file.

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<authorizers>
 <userGroupProvider>
 <identifier>file-user-group-provider</identifier>
 <class>org.apache.nifi.authorization.FileUserGroupProvider</
class>
 <property name="Users File">./conf/users.xml</property>
 <property name="Legacy Authorized Users File"></property>
 <property name="Initial User Identity 1">YOUR_USER@REALM
(example: root/admin@NODE1)</property>
 </userGroupProvider>
 <accessPolicyProvider>
 <identifier>file-access-policy-provider</identifier>
 <class>org.apache.nifi.authorization.FileAccessPolicyProvider</
class>
 <property name="User Group Provider">file-user-group-provider</
property>
 <property name="Authorizations File">./conf/authorizations.xml</
property>
 <property name="Initial Admin Identity"> YOUR_USER@REALM
(example: root/admin@NODE1) </property>
 <property name="Legacy Authorized Users File"></property>
 <property name="Node Identity 1"></property>
 </accessPolicyProvider>
 <authorizer>
 <identifier>managed-authorizer</identifier>
 <class>org.apache.nifi.authorization.StandardManagedAuthorizer</
class>
 <property name="Access Policy
Provider">file-access-policy-provider</property>
 </authorizer>
</authorizers>
```

You can now log in with YOUR\_USER and set proper policies for other users .

## LDAP/AD

To authenticate username and password by using LDAP/AD on cluster, perform the following:

1. Add the following properties in opt/mapr/nifi/nifi-<version>/conf/nifi.properties file.

```
nifi.security.user.login.identity.provider=ldap-provider
nifi.security.user.authorizer=managed-authorizer
```

2. Add the following providers in /opt/mapr/nifi/nifi-<version>/conf/login-identity-providers.xml file.

```
<provider>
 <identifier>ldap-provider</identifier>
 <class>org.apache.nifi.ldap.LdapProvider</class>
 <property name="Authentication Strategy">SIMPLE</property>
 <property name="Manager DN">MANAGER_DN (example:
cn=admin,dc=mapr,dc=local)</property>
 <property name="Manager Password">PASSWORD</property>
 <property name="TLS - Keystore"></property>
 <property name="TLS - Keystore Password"></property>
 <property name="TLS - Keystore Type"></property>
 <property name="TLS - Truststore"></property>
 <property name="TLS - Truststore Password"></property>
 <property name="TLS - Truststore Type"></property>
 <property name="TLS - Client Auth"></property>
 <property name="TLS - Protocol"></property>
 <property name="TLS - Shutdown Gracefully"></property>
 <property name="Referral Strategy">FOLLOW</property>
 <property name="Connect Timeout">10 secs</property>
 <property name="Read Timeout">10 secs</property>
 <property name="Url">LDAP_URL (example: ldap://127.0.0.1:389)</
property>
 <property name="User Search Base">dc=mapr,dc=local</property>
 <property name="User Search Filter">(cn={0})</property>
 <property name="Identity Strategy">USE_DN</property>
 <property name="Authentication Expiration">12 hours</property>
</provider>
```

3. Add the following authorizers in /opt/mapr/nifi/nifi-`<version>`/conf/authorizers.xml file.

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<authorizers>
 <userGroupProvider>
 <identifier>file-user-group-provider</identifier>
 <class>org.apache.nifi.authorization.FileUserGroupProvider</
class>
 <property name="Users File">./conf/users.xml</property>
 <property name="Legacy Authorized Users File"></property>
 <property name="Initial User Identity 1">ADMIN_USER (example:
cn=admin,dc=mapr,dc=local)</property>
 </userGroupProvider>
 <accessPolicyProvider>
 <identifier>file-access-policy-provider</identifier>
 <class>org.apache.nifi.authorization.FileAccessPolicyProvider</
class>
 <property name="User Group Provider">file-user-group-provider</
property>
 <property name="Authorizations File">./conf/authorizations.xml</
property>
 <property name="Initial Admin Identity">ADMIN_USER (example:
cn=admin,dc=mapr,dc=local) </property>
 <property name="Legacy Authorized Users File"></property>
 <property name="Node Identity 1"></property>
 </accessPolicyProvider>
 <authorizer>
 <identifier>managed-authorizer</identifier>
 <class>org.apache.nifi.authorization.StandardManagedAuthorizer</
class>
 <property name="Access Policy
Provider">file-access-policy-provider</property>
 </authorizer>
</authorizers>
```

You can now log in with ADMIN\_USER and add new users, groups and policies to NiFi. .

### Configuring SSO with OpenID in NiFi

This topic describes about Configuring SSO with OpenID in NiFi.

Starting from EEP 9.4.0, NiFi supports the automatic configuration of OpenID Connect using HPE cluster-level SSO parameters. And, NiFi allows both login/password authentication, and SSO login methods.

#### Automatic configuration SSO with OpenID

Starting from 9.4.0, NiFi automatically maps the cluster-level SSO parameters and the corresponding OpenID configuration properties. Following OpenID properties are automatically mapped with values from the [cluster-level SSO parameters](#):

- nifi.security.user.oidc.discovery.url
- nifi.security.user.oidc.client.id
- nifi.security.user.oidc.client.secret
- nifi.security.user.oidc.claim.identifying.user

\$HadoopProvider is the default value for the above-mentioned properties that comes with NiFi out-of-box. And \$HadoopProvider value causes the automatic mapping of OpenID and Cluster-level SSO properties.

Automatic configuration only works if NiFi is started by the `cluster admin`.

If cluster-level SSO is disabled (SSO parameters are set or reset), OpenID will be disabled in NiFi.

If you do any changes to the cluster-level SSO parameters, restart the NiFi, for the changes to take effect.

### Manual configuration

To manually configure SSO with OpenID, see [Apache NiFi documentation for OpenID Connect](#). Ensure that you provide literal values for all OIDC properties instead of using \$HadoopProvider values.

### Disabling NiFi SSO with OpenID

To disable SSO with OpenID in NiFi, comment out the `nifi.security.user.oidc.discovery.url` property, or leave its value blank.

### Login Page

- If both OpenID, and user name and password authentication methods are enabled, then user will get the options to choose an authentication method on the login page:

The screenshot shows the NiFi login interface. On the left is the NiFi logo (a blue drop with a grid). To the right of the logo is the text "Log In" in a large, bold, blue font. Further right is a link labeled "home" in a smaller blue font. Below "Log In" are two input fields: "User" with the placeholder text "user" and "Password" with the placeholder text "password". To the right of the password field is a blue button labeled "LOG IN". Below these fields is a wide, dark blue button labeled "LOG IN WITH SSO".

- If SSO with OpenID is enabled, but user name and password authentication is not, then SSO login page appears.
- If SSO with OpenID is disabled, the SSO button will be inactive.

### Troubleshooting

#### SSO button is inactive with auto-configuration

Ensure that the cluster-level SSO parameters are set with [cluster setsssoconf](#) , and can be retrieved with [cluster getsssoconf](#) command.

Ensure NiFi is configured to launch with the cluster admin user (that is default).

To verify, check the `run.as` value in `bootstrap.conf`.

### Integrating NiFi with EEP Components

This topic describes how to configure NiFi to work with other EEP components in HPE Data Fabric. The information in this topic relates specifically to the EEP components and HPE distribution for Apache NiFi.

### HDFS

NiFi works with HDFS by using default HDFS processors.

If Hadoop configuration resources property is not set, Nifi automatically detects them in runtime.

### HBase and HPE Data Fabric Database Binary

Install and configure HBase on your cluster. See [Installing HBase](#) on page 297.

NiFi works with HBase by using default HBase processors. However, you must create `EEP_HbaseMaprDbClientService` service which automatically detects the configuration.

**NOTE:** Both HBase and HPE Data Fabric Database Binary uses the same implementation of NiFi.

### Hive

Install and configure Hive on your cluster. See [Installing Hive](#) on page 302.

To work with `SelectHive3_EEP_QL` and `UpdateHive3_EEP_Table` processors, configure `Hive3_EEP_ConnectionPool` with the following configuration details:

- Database Connection URL
  - 
  - On secured cluster:

```
jdbc:hive2:// <host>:10000/default;auth=maprsasl;ssl=true;
```

- See [Using JDBC or Beeline to Connect to HiveServer2](#) on page 5056.
- Database User
- Password

`PutHive3_EEP_Streaming` automatically detects Hive configuration.

**NOTE:** When you change the Hive version, you must manually configure Hive on pre-configured processors.

### Kafka

Kafka processors on the cluster node does not require any additional component installations.

**NOTE:** HPE Data Fabric does not support Kafka Transactions.

### HPE Data Fabric Object Store

Install, configure and generate `AccessKey` and `SecretKey` for HPE Data Fabric Object Store.

To work with S3 processors, you must specify the following:

- Access Key ID
- Secret Access Key
- Endpoint Override URL ([https://FQDN\\_HOST:9000](https://FQDN_HOST:9000))

### Installing Custom Processors for NiFi

This topic describes how to install custom processors for NiFi.

You can extend the capability of NiFi by installing custom processors, or processors that were not bundled with the NiFi package.

You can use one of the following methods to install custom processors:

- [Autoloading Custom Processors](#) on page 5372. This method does not require a restart to NiFi.
- [Installing Custom Processors](#) on page 5373. This method requires a restart to NiFi.

### Autoloading Custom Processors

Autoloading allows you to install custom processors without restarting NiFi.

See the instructions for [Autoloading Custom Processors](#) in the official Apache NiFi documentation.

To check the autoloading process of your custom processors, view `/opt/mapr/nifi/nifi-*/logs/nifi-app.log` and check the NAR Auto-Loader messages.

For example:

```
$ cat /opt/mapr/nifi/nifi-*/logs/nifi-app* | grep "NAR Auto-Loader"
2023-05-08 13:03:51,724 INFO [main] org.apache.nifi.nar.NarAutoLoader

```

### Installing Custom Processors

This is the original method for installing custom processors, which requires a restart to NiFi.

See the instructions for [Installing Custom Processors](#) in the official Apache NiFi documentation.

## OTel

This topic provides an overview of OpenTelemetry on HPE Data Fabric.

Starting from EEP 9.2.0, HPE Data Fabric supports OpenTelemetry (OTel).

OTel is an observability framework that allows you to instrument, generate, collect, and export telemetry data.

To install OTel, see [Installing OTel](#) on page 318 and to view the OTel release notes, see [OTel Release Notes](#) on page 8180.

To learn more about OTel, see [the official OpenTelemetry documentation](#).

### Adding an OTel Endpoint

This topic describes how to add an OTel endpoint using either the HPE Data Fabric UI or the command line.

#### Adding an OTel Endpoint with the HPE Data Fabric UI

To add an OTel endpoint with the HPE Data Fabric UI:

1. Log on to the Data Fabric UI.
2. Click the **Fabric administration** tab.
3. On the **OTEL endpoints** card, click **Add endpoint**. The **Add OTEL endpoint** side drawer opens.
4. Enter the **Name**.
5. Enter the **URL** of your OTel endpoint.

6. If your OTel endpoint contains a port, enter the port number.
7. To enable your OTel endpoint to return logs and/or metrics data, select **Logs** and/or **Metrics**.
8. Click **Select file** to select a key file to upload. Alternatively, drag and drop the key file to the **Upload files** area.
9. Click **Select file** to select a client certificate file to upload. Alternatively, drag and drop the client certificate file to the **Upload files** area.
10. Click **Add**.

### Adding an OTel Endpoint with the Command Line

Use the following command to add an OTel endpoint:

```
maprcli otelendpoint add -name secureendpoint -url <endpoint-url> -port
<endpoint-port> -certfile <cert-path> -keyfile <key-path> -customopts
'{"exportlogs":"<true-or-false>","exportmetrics":"<true-or-false>"}
```

To generate logs and/or metrics for your cluster, set `exportlogs` and/or `exportmetrics` as `true`. To disable generation of logs and/or metrics, set `exportlogs` and/or `exportmetrics` as `false`.

### OTel Logs and Metrics

This topic describes how to view the logs for OpenTelemetry (OTel) on HPE Data Fabric.

#### Viewing Logs and Metrics in the HPE Data Fabric UI

To view the logs and metrics generated by OTel:

1. Log on to the Data Fabric UI.
2. Click the **Fabric administration** tab.
3. On the **Clusters** screen, locate the cluster for which you want to view logs and metrics.
4. Open the **Actions** menu, and select **Logs and metrics**.
5. You can now view logs and metrics for the cluster on the **Logs** and **Metrics** tabs.

### Starting, Stopping, and Restarting OTel Services

This topic describes how to start, stop, and restart OTel services on HPE Data Fabric.

#### Starting and Stopping OTel Services Using the HPE Data Fabric UI

To start or stop the generation of logs and/or metrics by OTel:

1. Log on to the Data Fabric UI.
2. Click the **Fabric administration** tab.
3. On the **OTEL endpoints** card, click the ellipsis under **Actions** for the OTel endpoint.
4. Click **Edit**. The **Edit OTel endpoint** side drawer opens.
5. To enable logs and/or metrics, select the **Logs** and/or **Metrics** check boxes. To disable logs and/or metrics, deselect the **Logs** and/or **Metrics** check boxes.
6. Click **Save**.

## Restarting OTel Services Using the Command Line

To restart OTel services, run the following command:

```
maprccli node services -name ezotelcol -nodes <hostname> -action restart
```

## Apache Polaris

Apache Polaris is an open-source, fully featured catalog for Apache Iceberg. It implements Iceberg's REST API, enabling seamless multi-engine interoperability across a wide range of platforms, including Apache Flink, and Apache Spark.

This section contains the information about the Polaris implementation from Data Fabric Ecosystem Pack.

### Installing Polaris

You can download and install, Polaris from the DEP repository.

See [Installing Polaris](#) on page 318 for more information.

### Polaris Logs and Credentials

Describes about Polaris logs and Administrator credentials.

#### Logs

All logs are written to <polaris\_home>/server/logs/polaris.log file.

#### Administrator credentials

Administrator credentials for internal authentication are stored in <polaris\_home>/server/config/credentials.txt

### Configuring Polaris

This section contains information about configuring polaris with various components.

#### Mapping Keycloak Roles to Polaris

**IMPORTANT:** Keycloak user names are mapped to Polaris principal. And, Keycloak roles are mapped to principal-roles.

Configure the following Polaris properties for Keycloak:

```
quarkus.oidc.tenant-enabled to true
quarkus.oidc.auth-server-url to OIDC provider with realm
quarkus.oidc.client-id set cliend_id, by default on DF cluster is edf-client
quarkus.oidc.roles.role-claim-path to userRoles
polaris.authentication.type to external
polaris.oidc.principal-mapper.name-claim-path set to preferred_username
```

#### Example Configuration:

```
quarkus.oidc.tenant-enabled=true
quarkus.oidc.auth-server-url=https://<HOSTNAME>:6443/realms/master
quarkus.oidc.client-id=edf-client
quarkus.oidc.roles.role-claim-path=userRoles
polaris.authentication.type=external
polaris.oidc.principal-mapper.name-claim-path=preferred_username
polaris.oidc.principal-roles-mapper.filter=^.*$
polaris.oidc.principal-roles-mapper.mappings[0].regex=^.*$
```

```
polaris.oidc.principal-roles-mapper.mappings[0].replacement=PRINCIPAL_ROLE:
$0
```

Polaris has an `admin` user that can create principals and catalogs. In Keycloak, Admin configuration properties must match to the admin user. Ensure that matching is done as follows:

Polaris properties	Description	Default value
<code>polaris.admin.name</code>	Admin user name.	<code>root</code>
<code>polaris.admin.service.role</code>	Role for the service admin.	<code>service_admin</code>
<code>polaris.admin.catalog.role</code>	Role for the catalog admin.	<code>catalog_admin</code>

`configure.sh` configures the SSO by default, if SSO properties are already available in the cluster. After you configure Polaris, the settings of admin user configuration changes to default settings of Data Fabric Keycloak as follows:

- `polaris.admin.name` to `admin`
- `polaris.admin.service.role` to `fabric-manager`
- `polaris.admin.catalog.role` to `fabric-manager`.

### Configuring Polaris admin Tool to PostgreSQL

Describes how to configure PostgreSQL metastore to Polaris.

#### Configuring Polaris Server to PostgreSQL

1. Change `polaris.persistence.type` to `relational-jdbc` in `<polaris_home>/server/config/application.properties`:

```
polaris.persistence.type=relational-jdbc
```

2. Add `quarkus.datasource.jdbc.url` to `quarkus.datasource.jdbc.url=jdbc:postgresql://:5432/<polaris_db>`:

```
quarkus.datasource.jdbc.url=jdbc:postgresql://<HOSTNAME>:5432/
<polaris_db>
```

where `<polaris_db>` is name of the database in PostgreSQL.

3. Configure credentials for metastore access using one of the following ways:

- a. Update `application.properties`:

Add `quarkus.datasource.username` and `quarkus.datasource.password` variables to `<polaris_home>/server/config/application.properties`:

```
quarkus.datasource.username=postgres
quarkus.datasource.password=password
```

OR

**b. Update env variables:**

Add QUARKUS\_DATASOURCE\_USERNAME and QUARKUS\_DATASOURCE\_PASSWORD variables to <polaris\_home>/server/config/polaris-env.sh:

```
export QUARKUS_DATASOURCE_USERNAME=postgres
export QUARKUS_DATASOURCE_PASSWORD=password
```

**OR****c. Use Hadoop credentials provider:**

1. Add quarkus.datasource.username and quarkus.datasource.password to the Keystore:

```
hadoop credential create quarkus.datasource.username -value
postgres -provider localjceks://file/opt/mapr/polaris/
polaris-1.0.1/server/config/polariscreds.jceks
hadoop credential create quarkus.datasource.password -value
password -provider localjceks://file/opt/mapr/polaris/
polaris-1.0.1/server/config/polariscreds.jceks
```

2. Add POLARIS\_CREDS\_STORE variable to polaris-env.sh

```
export POLARIS_CREDS_STORE=localjceks://file/opt/mapr/polaris/
polaris-1.0.1/server/config/polariscreds.jceks
```

**Configuring PostgreSQL metastore for Polaris Admin Tool**

1. Add quarkus.datasource.jdbc.url to polaris\_home>/admin/config/application.properties:

```
quarkus.datasource.jdbc.url=jdbc:postgresql://<HOSTNAME>:5432/
<polaris_db>
```

where <polaris\_db> is name of the database in PostgreSQL.

2. Configure credentials for metastore access using one of the following ways:

- a. Use Hadoop credentials provider. If the server is configured to use the Hadoop credentials provider, the admin tool automatically uses the Hadoop configuration. If Hadoop server is already configured, proceed to [Step 3](#).

**OR**

- b. Add quarkus.datasource.username and quarkus.datasource.password to <polaris\_home>/admin/config/application.properties:

```
quarkus.datasource.username=postgres
quarkus.datasource.password=password
```

3. To use PostgreSQL as metastore, perform bootstrap initialization using admin tool. Realm must be the same as in `<polaris_home>/admin/config/application.properties`:

```
<polaris_home>/bin/admin
bootstrap --realm=<realm> -c=<realm,admin_name,secret>
```

**For example:**

```
<polaris_home>/bin/admin
bootstrap --realm=POLARIS -c=POLARIS,admin,secret
```

### Configuring SSL Security for Polaris

Describes how to configure SSL security for Polaris.

1. To use an SSL endpoint for Polaris, add the following configuration to `<polaris_home>/server/config/application.properties`:

```
quarkus.http.ssl.certificate.key-store-file=/opt/mapr/conf/ssl_keystore
quarkus.http.ssl.certificate.key-store-file-type=JKS
quarkus.http.ssl.certificate.key-store-password=
quarkus.http.ssl-port=8181
quarkus.http.insecure-requests=disabled

quarkus.management.ssl.certificate.key-store-file=/opt/mapr/conf/
ssl_keystore
quarkus.management.ssl.certificate.key-store-file-type=JKS
quarkus.management.ssl.certificate.key-store-password=
quarkus.management.ssl-port=8182
quarkus.management.insecure-requests=disabled
```

Comment out the following line:

```
quarkus.http.port=8181
quarkus.management.port=8182
```

2. Add Hadoop Keystore with SSL password to `polaris-env.sh`:

```
export POLARIS_SSL_CREDS_STORE=localjceks://file/opt/mapr/conf/
maprkeycreds.jceks,localjceks://file/opt/mapr/conf/maprtrustcreds.jceks
```

3. Restart Polaris.

**NOTE:** `configure.sh` automatically sets the default configuration for SSL.

### Configuring MapR File System to Polaris

Describes how to configure MapR File system to Polaris.

You can use `catalog-users` property to restrict the access to catalog data in the MapR Filesystem. The `catalog-users` property enables the public access to a directory with Iceberg tables in the MapR filesystem, or sets the correct users.

`catalog-users` property does not have any influence on the Polaris RBAC model; it only relates to permissions for files that are stored on MapR-FS.

If `catalog-users` is not set to `catalog`, the directory will be available for all users in MapR-FS.

The `catalog-users` can be used in the `catalog create` and `catalog update` commands.

**Example 1:**

To create a catalog and provide access to data in MapR-FS, only for the devuser and adminuser, run the following command:

```
polaris --access-token ${TOKEN} catalogs create --type
internal --storage-type
MFS --property catalog-users=devuser,adminuser --default-base-location
"maprfs:///tmp/testcatalog" test_catalog
```

**Example 2:**

To change POSIX permissions for the catalog that is already created:

```
polaris --access-token ${TOKEN} catalogs update --set-property
catalog-users=newuser test_catalog
```

**Configuring Object Store to Polaris**

Describes how to configure Object Store to Polaris.

Configure Polaris to use the Object Store, using one of the following ways:

1. Add `polaris.storage.aws.access-key` and `polaris.storage.aws.secret-key` to `<polaris_home>/server/config/application.properties`:

```
polaris.storage.aws.access-key=object_store_access_key
polaris.storage.aws.secret-key=object_store_secret_key
```

**OR**

Use Hadoop credentials provider as follows:

- a. Use Hadoop credentials provider and add `polaris.storage.aws.access-key` and `polaris.storage.aws.secret-key` to keystore:

```
hadoop credential create polaris.storage.aws.access-key -value
<access_key> -provider localjceks://file/opt/mapr/polaris/
polaris-1.0.0/server/config/polariscreds.jceks
hadoop credential create polaris.storage.aws.secret-key -value
<secret_key> -provider localjceks://file/opt/mapr/polaris/
polaris-1.0.0/server/config/polariscreds.jceks
```

- b. Add `POLARIS_CREDS_STORE` variable to `polaris-env.sh`:

```
export POLARIS_CREDS_STORE=localjceks://file/opt/mapr/polaris/
polaris-1.0.1/server/config/polariscreds.jceks
```

2. Restart Polaris.

**Configuring Polaris as a metastore for Spark**

This topic describes the full integration of the MCP server with Apache Polaris, Apache Spark, and Keycloak SSO.

## Data Flow

- User dMCP Server** — HTTPS request with Authorization: Bearer <JWT> (or Basic auth). Contains the MCP tool call (create\_sql\_session or execute\_query).
- MCP Server dLivy** — Creates a Spark session. Injects the user's JWT into the session config as the Polaris catalog token. Spark starts on YARN.
- Spark execution** — Spark executes the SQL. Before reading any table, it calls Polaris to resolve table metadata and file locations.
- Spark dPolaris** — Iceberg REST API call with the user's JWT in Authorization: Bearer. Polaris validates the token against Keycloak, resolves the Polaris principal, and checks catalog role privileges.
- Spark dMapR FS** — Reads Parquet files at the locations returned by Polaris. Returns rows to Livy, which returns them to MCP Server, which returns them to the user.

## Authentication Flow (SSO)

On first connection, the client (for example, mcp-remote) triggers an OAuth PKCE flow — a browser window opens to Keycloak. After the user logs in, Keycloak issues an access token + refresh token. The access token is sent with every subsequent MCP request. The MCP server validates the JWT signature using Keycloak's JWKS endpoint, then forwards the same token to Polaris.

## Key design points

- Single credential end-to-end.** The user's Keycloak JWT is used by MCP Server, Spark, and Polaris. No service account impersonation.
- Polaris principal = Keycloak username.** Polaris extracts the preferred\_username claim from the JWT to identify the principal. The names must match exactly.
- The Spark catalog configuration is injected dynamically.** The MCP server injects the Polaris catalog URL, warehouse, and user JWT into the Livy session config at creation time. No static Spark catalog config is needed in spark-defaults.conf.

## Keycloak Setup

Keycloak runs on port 6443, realm master. The `edf-client` OAuth client is pre-configured by the platform installation. It must be of type **confidential** with `client_credentials` and `authorization_code` grant types enabled.

### Get admin token

```
ADMIN_TOKEN=$(curl -sk -X POST \
 https://<keycloak-host>:6443/realms/master/protocol/openid-connect/token \
 -H "Content-Type: application/x-www-form-urlencoded" \
 -d
 "client_id=admin-cli&username=admin&password=<admin-password>&grant_type=password" \
 | jq -r .access_token)
```

### Create a user

The Keycloak username **must exactly match** the Polaris principal name created in the **Polaris Setup** section.

```
curl -sk -X POST https://<keycloak-host>:6443/admin/realms/master/users \
 -H "Authorization: Bearer $ADMIN_TOKEN" \
 -H "Content-Type: application/json" \
 -d '{
 "username": "mapruser1",
 "enabled": true,
 "credentials": [{"type": "password", "value": "mapruser1", "temporary":
false}]
 }'
```

### Obtain the edf-client secret

The `edf-client` secret is needed when configuring the MCP client (Claude Code, Claude Desktop, etc.). It rotates when the cluster is reinstalled.

```
CLIENT_UUID=$(curl -sk \
 "https://<keycloak-host>:6443/admin/realms/master/clients?
clientId=edf-client" \
 -H "Authorization: Bearer $ADMIN_TOKEN" | jq -r '.[0].id')

CLIENT_SECRET=$(curl -sk \
 "https://<keycloak-host>:6443/admin/realms/master/clients/$CLIENT_UUID/
client-secret" \
 -H "Authorization: Bearer $ADMIN_TOKEN" | jq -r .value)

echo $CLIENT_SECRET
```

## Polaris Setup

Polaris runs on port 8181. Administration is supported by the Polaris CLI or REST API. Authenticate using service account credentials (`edf-client`), not the user's credentials.

### Obtain the Polaris admin token

```
POLARIS_TOKEN=$(curl -sk -X POST \
 https://<keycloak-host>:6443/realms/master/protocol/openid-connect/token \
 -d
 "client_id=edf-client&client_secret=$CLIENT_SECRET&grant_type=client_credentials" \
 | jq -r .access_token)
```

## Create the catalog

```
POLARIS=/opt/mapr/polaris/current/client/bin/polaris

$POLARIS --access-token $POLARIS_TOKEN \
 catalogs create \
 --storage-type MFS \
 --default-base-location maprfs:///polaris/mcp-warehouse \
 mcp-catalog
```

## Create the Polaris principal name

The Polaris principal name must match the Keycloak username created earlier in the **Keycloak Setup > Create a user** section.

```
$POLARIS --access-token $POLARIS_TOKEN principals create mapruser1
```

## Create roles

There are two types of roles:

- **Principal role** - assigned to a principal; groups catalog roles
- **Catalog role** - scoped to a specific catalog; holds catalog privileges

```
Principal role
$POLARIS --access-token $POLARIS_TOKEN principal-roles create
mcp-principal-role

Catalog role
$POLARIS --access-token $POLARIS_TOKEN catalog-roles create \
 --catalog mcp-catalog mcp-catalog-role
```

## Grant privileges

```
Grant full catalog access to the catalog role
$POLARIS --access-token $POLARIS_TOKEN privileges catalog grant \
 --catalog mcp-catalog \
 --catalog-role mcp-catalog-role \
 CATALOG_MANAGE_CONTENT
```

Available privileges: CATALOG\_MANAGE\_CONTENT (full DDL+DML), TABLE\_READ\_DATA (SELECT only), TABLE\_WRITE\_DATA, NAMESPACE\_CREATE

## Assign roles

```
Attach catalog role to principal role
$POLARIS --access-token $POLARIS_TOKEN catalog-roles grant \
 --catalog mcp-catalog \
 --principal-role mcp-principal-role \
 mcp-catalog-role

Attach principal role to principal
$POLARIS --access-token $POLARIS_TOKEN principal-roles grant \
 --principal mapruser1 \
 mcp-principal-role
```

**MCP server configuration**

Config file: /opt/mapr/data-access-gateway/conf/mcp-server.conf

```
mcp = {
 http = {
 port = 5679
 secure = true
 auth.enabled = true
 }
 file.enabled = true
 spark {
 enabled = true
 impersonation-enabled = true # Run Spark jobs as the authenticated
user
 disable-sql-policy = true # Allow DDL/DML (CREATE, INSERT, DROP)

 iceberg {
 catalog {
 backend = "polaris"
 name = "mcp-catalog"
 uri = "https://<polaris-host>:8181/api/catalog"
 warehouse = "mcp-catalog"
 use-bearer-token = true # Forward user JWT to Polaris
 scope = "PRINCIPAL_ROLE:ALL"
 token-refresh-enabled = true
 access-delegation = "vended-credentials"
 client.region = "us-east-1"
 }
 }
 }
}
```

**Key options:**

Option	Description
impersonation-enabled	Livy starts the Spark job under the user's Linux account (MapR ticket required)
disable-sql-policy	Without this, only SELECT is allowed
use-bearer-token	When true: user JWT is passed as spark.sql.catalog.<name>.token. When false: client.id/client.secret are used instead (service account mode)
scope	Polaris OAuth scope. PRINCIPAL_ROLE:ALL grants access based on all assigned principal roles

Restart after changes:

```
maprcli node services -name data-access-gateway -action restart -nodes $
(hostname -f)
```

**Spark configuration**

Config file: /opt/mapr/spark/spark-3.5.5/conf/spark-defaults.conf

```
spark.jars.ext.libs.use true
spark.sql.extensions
org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions
```

**Do not add** `spark.sql.catalog.*` entries here for the Polaris catalog. The MCP server injects the full catalog configuration dynamically at session creation time:

```
spark.sql.catalog.mcp-catalog
org.apache.iceberg.spark.SparkCatalog
spark.sql.catalog.mcp-catalog.type rest
spark.sql.catalog.mcp-catalog.uri https://
<polaris-host>:8181/api/catalog
spark.sql.catalog.mcp-catalog.warehouse mcp-catalog
spark.sql.catalog.mcp-catalog.rest.auth.type oauth2
spark.sql.catalog.mcp-catalog.token <user JWT>
spark.sql.catalog.mcp-catalog.scope PRINCIPAL_ROLE:ALL
```

If you also need a static Hive catalog (for non-Polaris use):

```
spark.sql.catalog.hive org.apache.iceberg.spark.SparkCatalog
spark.sql.catalog.hive.type hive
spark.sql.catalog.hive.uri thrift://<hive-host>:9083
```

### Claude Code Configuration

Claude Code reads MCP Server configuration from:

- **Global:** `~/.claude.json` - applies to all projects
- **Project-level:** `.claude/settings.json` (committed) or `.claude/settings.local.json` (ignored by Git, for secrets)

### Add via CLI

```
claude mcp add spark-mcp \
 --env NODE_TLS_REJECT_UNAUTHORIZED=0 \
 -- npx -y mcp-remote https://<mcp-host>:5679/spark \
 --static-oauth-client-info
"{\"client_id\": \"edf-client\", \"client_secret\": \"$CLIENT_SECRET\"}" \
 --debug
```

`--scope user` adds it globally; without the flag it's scoped to the current project.

**Alternatively, edit `.claude/settings.local.json` directly:**

```
{
 "mcpServers": {
 "spark-mcp": {
 "command": "npx",
 "args": [
 "-y",
 "mcp-remote",
 "https://<mcp-host>:5679/spark",
 "--static-oauth-client-info",
 "{\"client_id\": \"edf-client\", \"client_secret\": \"<edf-client-secret>\"}",
 "--debug"
],
 "env": {
 "NODE_TLS_REJECT_UNAUTHORIZED": "0"
 }
 }
 }
}
```

NODE\_TLS\_REJECT\_UNAUTHORIZED=0 disables TLS certificate verification - this is required when the cluster uses a self-signed MapR CA certificate.

### First launch - SSO login

On the first `claude` session after adding the server, `mcp-remote` prints a URL to the terminal. Open it in a browser and log in with your cluster credentials. After login, the token is cached at `~/.mcp-auth/mcp-remote-*/` and reused on subsequent runs.

To force re-authentication:

```
rm -rf ~/.mcp-auth/mcp-remote-*/
```

### Verify the connection

```
claude mcp list # Should show spark-mcp
claude mcp get spark-mcp # Shows connection status and available tools
```

### Example Prompt

Start a Claude Code session in a project connected to the MCP server:

```
claude
```

Use a natural prompt. For example:

I need to analyze user activity data. First, set up a Spark session, then show me what tables are available in the `mcp-catalog`. After that, count the number of events per user for the last 7 days and show me the top 10 most active users.

Claude will:

1. Call `create_sql_session` - waits ~2 min for Spark to start on YARN
2. Call `execute_query` with `SHOW NAMESPACES IN \mcp-catalog``
3. Call `execute_query` with `SHOW TABLES IN \mcp-catalog`.db``
4. Construct and execute the aggregation query:

```
SELECT user_id, COUNT(*) AS event_count
FROM `mcp-catalog`.db.events
WHERE event_date >= DATE_SUB(CURRENT_DATE(), 7)
GROUP BY user_id
ORDER BY event_count DESC
LIMIT 10
```

5. Return formatted results and optionally suggest follow-up analyses.

### Follow-up example prompts:

- *"Now join this with the users table to get the actual usernames"*
- *"Export the top 10 results to a new table called `mcp-catalog.analytics.top_users`"*
- *"Show me the event trend by day for these top 10 users"*
- *"Describe the schema of the events table in detail"*

## Troubleshooting

Symptom	Cause	Resolution
401 Unauthorized from MCP	Invalid or expired JWT; wrong basic credentials	Re-authenticate; get fresh token from Keycloak
invalid_client_credentials in mcp-remote log	edf-client secret rotated (cluster reinstall)	Re-fetch secret (section 2.3), update config, clear ~/.mcp-auth/
No active idle user session	execute_query called before create_sql_session	Always call create_sql_session first
create_sql_session times out	YARN is slow to allocate containers	Wait; first session takes 2-3 minutes
Failed to execute query on Polaris table	Missing catalog name prefix or access denied	Use `mcp-catalog`.db.table format; verify principal has privileges
policy denied: Statement 1 blocked	SQL policy blocks DDL/DML	Set disable-sql-policy = true in mcp-server.conf
No code verifier saved for session	mcp-remote lost state mid-auth flow	Fix the secret, clear ~/.mcp-auth/, retry

## Polaris and Global Namespace Integration Support

Polaris and Global Namespace (GNS) integration provides support for multi-cluster analytics. This integration provides centralized governance, shared catalogs, and cross-cluster access without copying data.

The Polaris catalog service can store its catalog (that is, the catalog metadata) in a GNS path. This capability applies to GNS locations backed by MFS as well as to GNS locations backed by an Object Store, and in both cases Polaris supports these GNS-backed locations without requiring any additional configuration changes.

To use external NFS, the Polaris Administrator must follow these steps:

1. Add `polaris.features."ENABLE_GNS_NFS_SUPPORT"` to the application properties.
2. Add `"FILE"` to `polaris.features."SUPPORTED_CATALOG_STORAGE_TYPES"`.

```
polaris.features."ENABLE_GNS_NFS_SUPPORT"=true
polaris.features."SUPPORTED_CATALOG_STORAGE_TYPES"=["FILE", "MFS",
"S3", "GCS", "AZURE"]
```

3. Restart Polaris.

To control where an external GNS is mounted, Polaris uses the `polaris.features."CATALOG_NFS_GNS_PREFIX"` property. This property defines a list of NFS mount locations where the catalog can be created when using FILE storage. Each entry must be specified as an absolute file:/// URI (for example, `file:///mnt/gns_cluster1`), not as a plain filesystem path.

For example:

```
polaris.features."CATALOG_NFS_GNS_PREFIX"=["file:///mnt/gns_cluster1",
"file:///mnt/gns_cluster2"]
```

## Polaris Federation

Polaris supports federation with external Iceberg REST catalogs (for example, catalogs served by other Polaris deployments). Federation enables clients to access tables that are managed by remote Iceberg REST catalog services through the local Polaris instance. In this model, Polaris exposes the remote catalog through its own REST endpoint, so engines connect only to the local Polaris service while transparently accessing remote tables. Authorization is enforced on both the local and remote catalogs, so effective privileges are determined by the intersection of permissions in each system.

To use Polaris federation:

1. Enable the federation feature on the local Polaris instance where external catalogs will be created:

```
add to <polaris_home>/server/conf/application.properties
polaris.features."ENABLE_CATALOG_FEDERATION"=true
```

2. Create an external catalog that points to the remote Iceberg REST catalog:

```
polaris --client-id ${POLARIS_CLIENT} \
--client-secret ${POLARIS_SECRET} \
catalogs create \
--type EXTERNAL \
--storage-type <storage_type> \
--default-base-location "<path_to_catalog>" \
--allowed-location "<path_to_catalog>" \
--catalog-connection-type iceberg-rest \
--iceberg-remote-catalog-name <remote_polaris_catalog_name> \
--catalog-uri "https://<remote_polaris_url>:8181/api/catalog" \
--catalog-authentication-type OAUTH \
--catalog-token-uri "https://<remote_polaris_url>:8181/api/catalog/v1/
oauth/tokens" \
--catalog-client-id "<remote_polaris_client_id>" \
--catalog-client-secret "<remote_polaris_secret>" \
--catalog-client-scope "PRINCIPAL_ROLE:ALL" \
<catalog_local_name>
```

3. Create (or reuse) Polaris **principals**, **roles**, and **catalog roles**, then assign the appropriate catalog roles to the **external catalog** you created in Step 2.

This step must ensure permissions are correct in **both** the local and remote Polaris instances. See the **Note** below.

4. Use an Iceberg engine/catalog implementation that supports REST catalogs. Example using spark-shell:

```
spark-shell \
--conf
spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions \
--conf spark.sql.catalog.spark_demo.warehouse=<catalog_local_name> \
--conf spark.sql.catalog.spark_demo.type=rest \
--conf
spark.sql.catalog.spark_demo.header.X-Iceberg-Access-Delegation=vended-credentials \
--conf
spark.sql.catalog.spark_demo=org.apache.iceberg.spark.SparkCatalog \
--conf spark.sql.catalog.spark_demo.uri=https://
<local_polaris_url>:8181/api/catalog \
--conf spark.sql.catalog.spark_demo.oauth2-server-uri=https://
<local_polaris_url>:8181/api/catalog/v1/oauth/tokens \
--conf spark.sql.catalog.spark_demo.rest.auth.type=oauth2 \
--conf
spark.sql.catalog.spark_demo.credential='<credentials_for_local_principal>' \
--conf spark.sql.catalog.spark_demo.scope='PRINCIPAL_ROLE:ALL'
```

#### NOTE:

- **Iceberg-only requirement:** For federation, you must use Iceberg's `org.apache.iceberg.spark.SparkCatalog` (or an equivalent Iceberg REST implementation). Federation does **not** support Polaris “generic tables”.
- **Authorization is enforced in both places:** Local and remote principals must have appropriate permissions. Effective access is constrained by what is allowed on **both** instances.  
For example, if the local principal has *admin*, and the remote principal has *read-only*, the user can **read only**. If both are *admin*, the user can perform **all** operations allowed by the remote service.
- **Connectivity is validated at catalog creation time:** Polaris does not perform lazy probing of the remote service; catalog creation fails if the remote REST endpoint is unreachable or authentication is rejected.

## Ranger

This section describes the HPE Data Fabric implementation of Apache Ranger™ and provides all relevant details needed to use Ranger. The documentation in this section does not duplicate the documentation on the [Apache Ranger](#) site.

Apache Ranger is a framework to enable, monitor and manage data security across the Hadoop platform in the HPE Data Fabric. Apache Ranger provides centralized security administration and fine-grain access control for user access within Apache Hadoop, Apache Hive, Apache HBase, and other Apache components.

In the Data Fabric, Ranger enables:

- Centralized security administration to manage security-related tasks for HiveServer2 and Hive Metastore from a central user interface or using REST APIs.

- Fine-grained authorization for specific operations that are managed through a central administration tool.
- A standardized authorization method that is currently supported for HiveServer2 and Hive Metastore.

The following diagram shows the Ranger architecture as implemented within Data Fabric.

To install Ranger, see [Installing Ranger](#) on page 319 and [Installing Ranger Using the Installer](#) on page 7549. To view the Ranger release notes, see [Ranger Release Notes](#) on page 8197.

### Getting Started with Ranger

Describes how to start using Apache Ranger with the HPE Data Fabric.

Using the following steps to install, configure, and integrate Ranger with HiveServer2 and create a policy that you can test:

1. Install Ranger as described in [Installing Ranger](#) on page 319 or [Installing Ranger Using the Installer](#) on page 7549.
2. Configure the Ranger Admin and Usersync services as described in [Configuring Ranger](#) on page 5391.
3. Configure and enable the Hive plug-in, and create the Hive service in Ranger, as described in [Integrating HiveServer2 with Ranger](#) on page 5401.
4. Open the Ranger Admin UI using the secure address:
  - Secure address: `https://<FQDN>:6182`
5. In the Admin UI, navigate to the Hive service, remove all policies, and create a new policy such as the following. This policy provides `mapruser1` with `SELECT` and `CREATE` permissions on any database,

any table, and any column:

The screenshot shows the Ranger Policy configuration interface. The form includes the following fields and controls:

- Policy Name:** A text input field with a dropdown arrow.
- Policy Label:** A text input field with a dropdown arrow.
- Database:** A dropdown menu with a search icon and an 'Include' button.
- Table:** A dropdown menu with a search icon and an 'Include' button.
- Column:** A dropdown menu with a search icon and an 'Include' button.
- Description:** A text input field.
- Audit Logging:** A toggle switch set to 'Yes'.
- Buttons:** 'Enabled' and 'Normal' radio buttons.
- Bottom Section:** Tabs for 'Select Role', 'Select Group', 'Select User', 'Permissions', and 'Delegate Admin'. The 'Select User' tab is active, showing 'mapruser1'.

6. Click **Save** to save the new policy.
7. Check the logs to ensure that the policy refreshed successfully. After you create or update a policy, the Ranger-enabled HiveServer2 or Hive Metastore download the policy changes from the Admin service. To check the HiveServer2 log, navigate to `/opt/mapr/hive/hive-3.1.3/logs/mapr/mapr-hiveserver2-node1.cluster.com.log`. You should see something like this:

```
2022-09-26T10:59:33,936 INFO [main] util.RangerRolesProvider:
RangerRolesProvider(serviceName=hivedev): found updated version.
lastKnownRoleVersion=-1; newVersion=1
2022-09-26T10:59:34,229 INFO [main] util.PolicyRefresher:
PolicyRefresher(serviceName=hivedev): found updated version.
lastKnownVersion=-1; newVersion=18
2022-09-26T10:59:34,244 INFO [main] policyengine.PolicyEngine: Policy
engine will not perform in place update while processing policy-deltas.
2022-09-26T10:59:34,271 INFO [main]
policyengine.RangerPolicyRepository: This policy engine contains 1
policy evaluators
```

8. As the `mapruser1`, go to Beeline, and connect to HiveServer2:

```
$ hive --service beeline
Beeline version 3.1.3.0-eeep-900-SNAPSHOT by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:10000/
default;auth=maprsasl;ssl=false
Connecting to jdbc:hive2://node1.cluster.com:10000/
default;auth=maprsasl;ssl=false
22/09/26 11:18:24 [main]: WARN maprsasl.MaprSaslClient: SASL Server
qopProperty: auth-confis different from Client:
auth-conf,auth-int,auth.Using Server one
Connected to: Apache Hive (version 3.1.3.0-eeep-900-SNAPSHOT)
Driver: Hive JDBC (version 3.1.3.0-eeep-900-SNAPSHOT)
Transaction isolation: TRANSACTION_REPEATABLE_READ
```

9. Try to run SELECT, CREATE, and DROP commands. SELECT and CREATE should succeed, but DROP should fail:

```
0: jdbc:hive2://node1.cluster.com:10000/default> SELECT * FROM web_log;
...
INFO : OK
0: jdbc:hive2://node1.cluster.com:10000/default> CREATE TABLE test(t int);
...
INFO : OK
0: jdbc:hive2://node1.cluster.com:10000/default> DROP TABLE test;
Error: Error while compiling statement: FAILED:
HiveAccessControlException Permission denied: user [mapruser1] does not
have [DROP] privilege on [default/test] (state=42000,code=40000)
```

### For More Information

To learn about Ranger policies, users, groups, reports, and auditing, see the [Ranger User Guide](#).

For a list of Ranger features, see [Apache Ranger Features](#).

For information about REST API commands, see the Ranger REST API [Resources](#) page.

### Configuring Ranger

Describes how to set up Ranger services and run the configuration script.

Use these steps:

1. Set up Ranger services:
  - a. In the `install.properties` file in the Ranger Admin home directory (`/opt/mapr/ranger/ranger-<version>/ranger-admin/install.properties`), modify the properties using one of the following options:
    - If you have skipped [Step 1.](#) and [2.](#) in [Installing Ranger](#) on page 319 procedure, modify the following properties:

```
db_root_user=root
db_root_password=<root_db_password>

db_name=<created_db_name>
db_user=<created_db_user>
db_password=<created_db>

rangerAdmin_password=<min_8_char_with_numeric_and_min_one_capital>
rangerTagsync_password=<min_8_char_with_numeric_and_min_one_capital>

rangerUsersync_password=<min_8_char_with_numeric_and_min_one_capital>
keyadmin_password=<min_8_char_with_numeric_and_min_one_capital>
```

- If you have performed [Step 1.](#) and [2.](#) in [Installing Ranger](#) on page 319 procedure, modify the following properties:

```
db_name=<created_db_name>
db_user=<created_db_user>
db_password=<created_db>

rangerAdmin_password=<min_8_char_with_numeric_and_min_one_capital>
rangerTagsync_password=<min_8_char_with_numeric_and_min_one_capital>

rangerUsersync_password=<min_8_char_with_numeric_and_min_one_capital>
keyadmin_password=<min_8_char_with_numeric_and_min_one_capital>
```

Later you will use the keyadmin\_password to log on to the Ranger web UI.

- b.** Run the setup script:

```
sudo /opt/mapr/ranger/ranger-<version>/ranger-admin/setup.sh
```

The /ranger-admin/setup.sh script copies some basic ugsync-related properties to the ugsync install.properties and then runs the ugsync script. However, to custom configure ugsync, you must edit /opt/mapr/ranger/ranger-2.3.0/ranger-usersync/install.properties and then run `sudo /opt/mapr/ranger/ranger-2.3.0/ranger-usersync/setup.sh`.

2. Run the configuration script as root. Running `configure.sh` restarts the Ranger Admin and Ranger UserSync services:

```
/opt/mapr/server/configure.sh -R
```

### Starting, Stopping, and Restarting Ranger Services

Describes how to start, stop, and restart Ranger services on the HPE Data Fabric.

The Warden daemon starts the Ranger daemon automatically at installation time. You can start, stop, or restart Ranger services from the Control System or from the command line (CLI).

The mapr-ranger package provides two services:

Service	Function
ranger-admin	Creates and synchronizes Ranger policies and applies them to the plug-in.
ranger-usersync	Gathers user information from Linux or Active Directory/Lightweight Directory Access Protocol (AD/LDAP) servers.

### Starting, Stopping, and Restarting Ranger Using the Control System

See:

- [Starting the Services on the Cluster Using the Control System](#) on page 1401
- [Stopping a Service on the Cluster Using the Control System](#) on page 1402
- [Restarting the Services on the Cluster Using the Control System](#) on page 1403

## Starting, Stopping, and Restarting Ranger Using the CLI

Using the `maprccli node services` command, you can start Ranger services on multiple nodes at the same time.

Use the following steps to start or stop or restart Ranger services from the `maprccli` command line:

1. Make a list of the nodes on which Ranger is configured.
2. Run the `maprccli node services` command with either `start`, `restart`, or `stop`, and specify the nodes on which Ranger is configured separated by spaces:

```
maprccli node services -name <ranger_service_name> -action start|stop|
restart -nodes <node_list>
```

## Configuring Security for Ranger

Describes how to configure security for Ranger.

### Configuring Encryption

Optionally, you can configure parameters that are used to encrypt passwords for Ranger internal use cases:

```
#Encryption
password_encryption_key=
password_salt=f77aLYLo
password_iteration_count=1000
password_encryption_algorithm=PBEWithHmacSHA512AndAES_128
```

Note that the `password_encryption_key` is empty by default. If you do not explicitly set the `password_encryption_key`, Ranger generates a key automatically. If reconfiguration using `setup.sh` is needed later, Ranger uses the generated key, and no user interaction is needed.

### Configuring SSL over DB

The following settings are SSL over DB related:

```
#SSL config
db_ssl_enabled=false
db_ssl_required=false
db_ssl_verifyServerCertificate=false
#db_ssl_auth_type=1-way|2-way, where 1-way represents standard one way ssl
authentication and 2-way represents mutual ssl authentication
db_ssl_auth_type=2-way
javax_net_ssl_keyStore=
javax_net_ssl_keyStorePassword=
javax_net_ssl_trustStore=
javax_net_ssl_trustStorePassword=
javax_net_ssl_trustStore_type=jks
javax_net_ssl_keyStore_type=jks

mysql_enabled_tls_protocols=TLSv1.2
```

### Configuring SSL Security

In a secure cluster, Ranger configures SSL security by using the EEP-specific key store by default. In a secure cluster, the Ranger Admin UI runs on `https://<hostname>:6182`.

To override the default SSL configuration, you can use either of the following options:

- Public CA Certificates

- Self-Signed Certificate

Only one step is different in these configuration options. If you use a self-signed certificate, you need to create the certificate, as directed in step 2.

### SSL Configuration for Services

1. If Ranger is configured and running, stop the Ranger service on each node:

```
maprccli node services -name ranger-admin -action stop -nodes `hostname`
maprccli node services -name ranger-usersync -action stop -nodes
`hostname`
```

2. If using the self-signed option, create the self-signed certificates. For example, to create the Admin keystore:

```
keytool -genkey -keyalg RSA -alias rangeradmin -keystore
ranger-admin-keystore.jks -storepass xasecure -validity 360 -keysize 2048
chmod 400 ranger-admin-keystore.jks
```

To create the Usersync trust store:

```
keytool -export -keystore ranger-admin-keystore.jks -alias
rangeradmin -file ranger-admin-trust.cer
chown mapr:mapr ranger-admin-trust.cer
keytool -import -file ranger-admin-trust.cer -alias
rangeradmintrust -keystore mytruststore.jks -storepass changeit
chown mapr:mapr mytruststore.jks
```

3. Modify the Ranger Admin `install.properties` file as follows:

```
polycmgr_external_url=https://FQDN:6182
polycmgr_http_enabled=false
polycmgr_https_keystore_file=/path/to/ranger-admin-keystore.jks
polycmgr_https_keystore_keyalias=rangeradmin
polycmgr_https_keystore_password=xasecure
```

4. Modify the Ranger Usersync `install.properties` file as follows:

```
SSL Authentication
AUTH_SSL_ENABLED=true
AUTH_SSL_KEYSTORE_FILE=/etc/ranger/usersync/conf/cert/unixauthservice.jks
AUTH_SSL_KEYSTORE_PASSWORD=UnIx529p
AUTH_SSL_TRUSTSTORE_FILE=/path/to/mytruststore.jks
AUTH_SSL_TRUSTSTORE_PASSWORD=changeit
```

5. Run the Ranger Admin `setup.sh` script to configure the new options:

```
sudo /opt/mapr/ranger/ranger-<version>/ranger-admin/setup.sh
```

6. Restart the services if Ranger is already configured; otherwise, you must run `configure.sh` once the full configuration is completed:

```
maprccli node services -name ranger-admin -action start -nodes `hostname`
maprccli node services -name ranger-usersync -action start -nodes
`hostname`
```

## SSL Configuration for Plug-ins

1. Add the certificates that you specified for the services into the `install.properties` file of the corresponding plug-in as follows:

```
SSL_KEYSTORE_FILE_PATH=/path/to/ranger-admin-keystore.jks
SSL_KEYSTORE_PASSWORD=xasecure
SSL_TRUSTSTORE_FILE_PATH=/path/to/mytruststore.jks
SSL_TRUSTSTORE_PASSWORD=changeit
```

2. Run the script for the plug-in:

```
enable-<component>-plugin.sh
```

## Configuring the Security Type

In releases 7.2.0 and later, you can use a *security type* property to specify the authentication between Ranger and the HPE Data Fabric. This property determines the authentication protocol used by the Ranger Admin service. You can set the security type in the `install.properties` file or in the `ranger-admin-site.xml` file.

If you set the security type in this file . . .	Use this property name
<code>install.properties</code>	<code>security_type</code>
<code>site.xml</code>	<code>ranger.security.type</code>

Possible values for the property are:

Value	Description
<code>none</code>	The Ranger Admin runs in non-secure mode, and no authentication is required for API calls.
<code>maprsasl</code>	The Ranger Admin uses MapR-SASL authentication.
<code>kerberos</code>	The Ranger Admin uses Kerberos authentication.

If a value is not specified, Ranger uses the value found in `mapr-clusters.conf`.

## Configuring LDAP for Ranger

Describes how to configure Ranger security so that the Ranger Admin service authenticates users through LDAP authentication, and the Ranger UserSync service sources users and groups from LDAP storage.

LDAP configuration consists of:

- Preparing the LDAP server
- Configuring the UserSync service
- Configuring the Admin service to enable LDAP

## Preparing the LDAP Server

The following information about preparing the LDAP server is provided as an example. Your installation could require different procedures and steps. The following example was created with OpenLDAP running on a dedicated node installed with Ubuntu 18.04. To prepare the LDAP server, you must install the server, configure it, and provide some test data:

1. Install the OpenLDAP server:

```
sudo apt update && sudo apt install -y slapd ldap-utils
sudo dpkg-reconfigure slapd
```

2. The terminal UI asks for some configuration information. Press **Enter** in all cases except when prompted for the admin password. When you are prompted to confirm the admin password, type `mapr`.
3. Verify that the service is running and responding:

```
$ ldapsearch -x -D 'cn=admin,dc=cluster,dc=com' -w mapr -b
'dc=cluster,dc=com' -LLL -H ldap://node2:389
dn: dc=cluster,dc=com
objectClass: top
objectClass: dcObject
objectClass: organization
o: cluster.com
dc: cluster

dn: cn=admin,dc=cluster,dc=com
objectClass: simpleSecurityObject
objectClass: organizationalRole
cn: admin
description: LDAP administrator
userPassword:: e1NTSEF9bXVTRkNncXFEM1hIY0M1QkFiZjc2TXV1d0VYK2FjcXk=
```

#### 4. Provide some test data. For example:

```
$ cat test_data.ldif
dn: ou=People,dc=cluster,dc=com
objectClass: organizationalUnit
ou: People

dn: ou=Groups,dc=cluster,dc=com
objectClass: organizationalUnit
ou: Groups

dn: cn=ldapuser1,ou=People,dc=cluster,dc=com
cn: ldapuser1
objectClass: person
sn: ldapuser1

dn: cn=ldapuser2,ou=People,dc=cluster,dc=com
cn: ldapuser2
objectClass: person
sn: ldapuser2

dn: cn=ldapuser3,ou=People,dc=cluster,dc=com
cn: ldapuser3
objectClass: person
sn: ldapuser3

dn: cn=ldapuser4,ou=People,dc=cluster,dc=com
cn: ldapuser4
objectClass: person
sn: ldapuser4

dn: cn=ldapgroupA,ou=Groups,dc=cluster,dc=com
objectClass: groupOfNames
member: cn=ldapuser1,ou=People,dc=cluster,dc=com
member: cn=ldapuser2,ou=People,dc=cluster,dc=com
cn: ldapgroupA

dn: cn=ldapgroupB,ou=Groups,dc=cluster,dc=com
objectClass: groupOfNames
member: cn=ldapuser3,ou=People,dc=cluster,dc=com
member: cn=ldapuser4,ou=People,dc=cluster,dc=com
cn: ldapgroupB

$ ldapadd -x -D 'cn=admin,dc=cluster,dc=com' -w mapr -H ldap://
node2:389 -f test_data.ldif
adding new entry "ou=People,dc=cluster,dc=com"

adding new entry "ou=Groups,dc=cluster,dc=com"

adding new entry "cn=ldapuser1,ou=People,dc=cluster,dc=com"
adding new entry "cn=ldapuser2,ou=People,dc=cluster,dc=com"
adding new entry "cn=ldapuser3,ou=People,dc=cluster,dc=com"
adding new entry "cn=ldapuser4,ou=People,dc=cluster,dc=com"
adding new entry "cn=ldapgroupA,ou=Groups,dc=cluster,dc=com"
adding new entry "cn=ldapgroupB,ou=Groups,dc=cluster,dc=com"
```

**5.** Specify user passwords, and verify LDAP authentication:

```
$ for i in $(seq 4) ; do ldappasswd -D 'cn=admin,dc=cluster,dc=com' -w
mapr -x "cn=ldapuser${i},ou=People,dc=cluster,dc=com" -s "pass${i}" -H
ldap://node2:389 ; done
$ for i in $(seq 4) ; do ldapwhoami -x -D "cn=ldapuser${
{i},ou=People,dc=cluster,dc=com" -w "pass${i}" -H ldap://node2:389 ; done
dn:cn=ldapuser1,ou=People,dc=cluster,dc=com
dn:cn=ldapuser2,ou=People,dc=cluster,dc=com
dn:cn=ldapuser3,ou=People,dc=cluster,dc=com
dn:cn=ldapuser4,ou=People,dc=cluster,dc=com
```

6. Run `ldapsearch` again to check if everything is okay. The result should look like this:

```
$ ldapsearch -x -D 'cn=admin,dc=cluster,dc=com' -w mapr -b
'dc=cluster,dc=com' -LLL -H ldap://node2:389
dn: dc=cluster,dc=com
objectClass: top
objectClass: dcObject
objectClass: organization
o: cluster.com
dc: cluster

dn: cn=admin,dc=cluster,dc=com
objectClass: simpleSecurityObject
objectClass: organizationalRole
cn: admin
description: LDAP administrator
userPassword:: e1NTSEF9bXVTRkNncXFEM1hIY0M1QkFiZjc2TXV1d0VYK2FjcXk=

dn: ou=People,dc=cluster,dc=com
objectClass: organizationalUnit
ou: People

dn: ou=Groups,dc=cluster,dc=com
objectClass: organizationalUnit
ou: Groups

dn: cn=ldapuser1,ou=People,dc=cluster,dc=com
cn:: bGRhcHVzZXIyIA==
objectClass: person
sn: ldapuser1
userPassword:: e1NTSEF9eUVKaU1SYU5ub3AxewXjVXk5aDVuNGJuYldmMVdHSDk=

dn: cn=ldapuser2,ou=People,dc=cluster,dc=com
cn:: bGRhcHVzZXIyIA==
objectClass: person
sn: ldapuser2
userPassword:: e1NTSEF9NmtLSHFxeUVwTTBtNHVBQjU3TGZueGduN3VaSXovWlc=

dn: cn=ldapuser3,ou=People,dc=cluster,dc=com
cn:: bGRhcHVzZXIzIA==
objectClass: person
sn: ldapuser3
userPassword:: e1NTSEF9UWVyeVZFVW9EMWpGdUpBZng4NVBQNmVKTzVsbjhwWEM=

dn: cn=ldapuser4,ou=People,dc=cluster,dc=com
cn:: bGRhcHVzZXI0IA==
objectClass: person
sn: ldapuser4
userPassword:: e1NTSEF9cy9xdm82RGh3Z2RjamZRbGZSZmdMTW03QjRCajJtdmM=

dn: cn=ldapgroupA,ou=Groups,dc=cluster,dc=com
objectClass: groupOfNames
member: cn=ldapuser1,ou=People,dc=cluster,dc=com
member: cn=ldapuser2,ou=People,dc=cluster,dc=com
cn: ldapgroupA

dn: cn=ldapgroupB,ou=Groups,dc=cluster,dc=com
objectClass: groupOfNames
member: cn=ldapuser3,ou=People,dc=cluster,dc=com
member: cn=ldapuser4,ou=People,dc=cluster,dc=com
cn: ldapgroupB
```

## Configuring the UserSync Service

The UserSync service can source users and groups from the LDAP server and push them to the Ranger Admin service. To configure this functionality:

1. Specify the following properties in the UserSync `install.properties` file:

```
SYNC_SOURCE = ldap
SYNC_LDAP_URL = ldap://node2:389
SYNC_LDAP_BIND_DN = cn=admin,dc=cluster,dc=com
SYNC_LDAP_BIND_PASSWORD = mapr
SYNC_LDAP_SEARCH_BASE = dc=cluster,dc=com
SYNC_GROUP_SEARCH_ENABLED=true
SYNC_GROUP_USER_MAP_SYNC_ENABLED=true
```

2. Run the UserSync `setup.sh` script, and restart `ranger-usersync`. You should see the following users in the admin users tab:

<input type="checkbox"/> ldapuser1	User	External	LDAPAD	ldapgroup1	Visible	✖
<input type="checkbox"/> ldapuser2	User	External	LDAPAD	ldapgroup1	Visible	✖
<input type="checkbox"/> ldapuser3	User	External	LDAPAD	ldapgroup1	Visible	✖
<input type="checkbox"/> ldapuser4	User	External	LDAPAD	ldapgroup1	Visible	✖

You should see the following groups in the groups tab:

<input type="checkbox"/> ldapgroup1	External	LDAPAD	Visible	👤	✖
<input type="checkbox"/> ldapgroup2	External	LDAPAD	Visible	👤	✖

## Configuring the Admin Service

The Admin service authenticates users when logging into the web UI through LDAP authentication. To configure this functionality:

1. Specify the following properties in the Admin `install.properties` file:

```
authentication_method=LDAP
xa_ldap_url=ldap://node2:389
xa_ldap_userDNpattern=cn={0},ou=People,dc=cluster,dc=com
xa_ldap_groupSearchBase=dc=cluster,dc=com
xa_ldap_base_dn=dc=cluster,dc=com
xa_ldap_bind_dn=cn=admin,dc=cluster,dc=com
xa_ldap_bind_password=mapr
```

2. Run the Admin service `setup.sh` script, and restart the service. After restarting the service, you should be able to log in to the web UI by using `ldapuser1` and password `pass1`:

### Integrating HiveServer2 with Ranger

Describes how to integrate HiveServer2 with Ranger.

Use these steps:

1. Ensure that the `mapr-ranger-hive-plugin` is installed, as described in [Installing Ranger](#) on page 319. If HiveServer2 is installed in HA mode, you must ensure that the `mapr-ranger-hive-plugin` is installed on both nodes for which HA is enabled.
2. Open the Ranger Admin UI using the secure address:
  - Secure address: `https://<FQDN>:6182`
3. In the **Service Manager** screen, create a Hive (Hadoop SQL) service by providing the following properties:

Properties Type	Property	Specify ...
Main Properties	Service Name	Any name for the service
	Username	<code>&lt;cluster-admin&gt;</code>
	Password	<code>&lt;cluster-admin-password&gt;</code>
	Jdbc.driverClass Name	<code>org.apache.hive.jdbc.HiveDriver</code>
	Jdbc.url	<code>jdbc:hive2://FQDN:10000/;ssl=true</code>
	policy.download.auth.users	Cluster admin or component's main user

4. Test the connection between Ranger and Hive:

5. Modify the following properties in the `install.properties` in the Ranger Hive plug-in home directory (`/opt/mapr/ranger/ranger-<version>/ranger-hive-plugin/install.properties`):

**IMPORTANT:** The `REPOSITORY_NAME` must be the same as the Service Name you specified in step 3, or the plug-in will not work.

```
POLICY_MGR_URL=http(s)://FQDN:<ranger-admin-port>
REPOSITORY_NAME=hivedev
COMPONENT_INSTALL_DIR_NAME=/opt/mapr/hive/hive-3.1.3
```

6. Enable the plug-in:

```
sudo /opt/mapr/ranger/ranger-<version>/ranger-hive-plugin/
enable-hive-plugin.sh
```

7. Restart Hive services:

```
maprcli node services -name hs2 -action restart -nodes `hostname`
maprcli node services -name hivemeta -action restart -nodes `hostname`
maprcli node services -name hcat -action restart -nodes `hostname`
```

8. To verify that the plug-in is active, navigate to **Audit > Plugin Status**:

## Integrating Hive Metastore with Ranger

Describes how to integrate Hive Metastore with Ranger.

Hive Metastore interacts directly with external clients such as Spark and Drill. Therefore, filtering and masking functionalities are not applicable for external clients.

Hive Metastore stores and manages metadata about Hive resources such as databases, tables, and columns. It is responsible for queries such as the following (not a complete list):

- CREATE
- SHOW
- DESCRIBE
- ALTER
- DROP
- SELECT

Integrating Ranger with Hive Metastore protects the preceding queries but does not protect queries that work with real, physical data, such as the following (not a complete list):

- UPDATE
- INSERT
- DELETE
- TRUNCATE

After you have successfully enabled the Ranger Hive plug-in and configured policies, use the following steps to enable Ranger authorization in the Hive Metastore:

1. In the `hive-site.xml` file, set the `hive.security.authorization.manager` property to `org.apache.ranger.authorization.hive.authorizer.RangerHiveAuthorizerFactory`:

```
<property>

<name>hive.security.authorization.manager</name>
<value>org.apache.ranger.authorization.hive.authorizer.RangerHiveAuthoriz
erFactory</value>

</property>
```

2. In the `hive-site.xml` file, add the `HiveMetaStoreAuthorizer` class to `hive.metastore.pre.event.listeners`:

```
<property>

<name>hive.metastore.pre.event.listeners</name>
<value>org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEventListener,org.apache.hadoop.hive.ql.security.authorization.plugin.metastore.HiveMetaStoreAuthorizer</value>

</property>
```

3. Restart the Hive Metastore. Restarting causes Ranger privilege checks to be performed on each request to the Hive Metastore:

```
maprcli node services -nodes <nodes> -name hivemeta -action restart
```

4. To disable Hive Metastore authentication with Ranger, return the following properties to their default values:

```
<property>

<name>hive.security.authorization.manager</name>
<value>org.apache.hadoop.hive.ql.security.authorization.plugin.fallback.FallbackHiveAuthorizerFactory</value>

</property>
<property>

<name>hive.metastore.pre.event.listeners</name>
<value>org.apache.hadoop.hive.ql.security.authorization.AuthorizationPreEventListener</value>

</property>
```

### Integrating Yarn with Ranger

Describes how to integrate Yarn with Ranger.

Use these steps:

1. Ensure that the Ranger Admin is configured, as described in [Installing Ranger](#) on page 319 and [Configuring Ranger](#) on page 5391.
2. Open the Ranger Admin UI using either the secure or non-secure address:
  - Secure address: `https://<FQDN>:6182`
  - Non-secure address: `http://<FQDN>:6080`
3. In the **Service Manager** screen, create a Yarn service by providing the following properties:

Properties Type	Property	Specify . . .
Main Properties	Service Name	Any name for the service
	Username	<cluster-admin>
	Password	<cluster-admin-password>
	YARN REST URL	<yarn-url-address>
	In <b>Add New Configurations</b> , add the property: policy.download.auth.users	Cluster admin or component's main user

Service Name \*

Display Name

Description

Active Status ☒ Enabled ☐ Disabled

Select Tag Service

Username \*

Password \*

YARN REST URL \*

Authentication Type

Common Name for Certificate

Add New Configurations

Name	Value	
policy.download.auth.users	mapr	<input type="button" value="X"/>

- To test the connection between Ranger and Yarn, click **Test Connection**.

5. Modify the following properties in the `install.properties` in the Ranger Yarn plug-in home directory (`RANGER_HOME/ranger-yarn-plugin/install.properties`):

```
POLICY_MGR_URL=http(s)://policymanager.xasecure.net:6182 (or 6080)
POLICY_MGR_URL=http://FQDN:6182

This is the repository name created within policy manager in item #1
REPOSITORY_NAME=yarndev

Hadoop installation directory
COMPONENT_INSTALL_DIR_NAME=/opt/mapr/hadoop/hadoop-<version>
```

6. Enable the plug-in:

```
sudo RANGER_HOME/ranger-yarn-plugin/enable-yarn-plugin.sh
```

7. Restart Yarn services:

```
/opt/mapr/bin/maprccli node services -name resourcemanager -action
restart -nodes `hostname`
/opt/mapr/bin/maprccli node services -name nodemanager -action
restart -nodes `hostname`
```

Ranger adds the following property to `yarn-site.xml`:

```
<property>
 <name>yarn.authorization-provider</name>

 <value>org.apache.ranger.authorization.yarn.authorizer.RangerYarnAuthoriz
er</value>
</property>
```

8. To verify that the plug-in is active, navigate to **Audit > Plugin Status**:

The screenshot shows the Ranger web interface with the 'Audit' tab selected and 'Plugin Status' sub-tab. A search bar is at the top. Below it, a table lists the installed plugins. The table has columns for Service Name, Service Type, Application, Host Name, Plugin IP, Cluster Name, Last Update, Policy (Time), Active, Tag (Time), and Download. One plugin, 'yarndev', is listed with details for its installation and status.

Service Name	Service Type	Application	Host Name	Plugin IP	Cluster Name	Last Update	Policy (Time)	Active	Tag (Time)	Download
yarndev	yarn	yarn	node1.cluster.com	192.168.33.11	cyber-mapr cluster	10/19/2022 11:42:46 AM 12 seconds ago	10/19/2022 11:42:52 AM 12 seconds ago	10/19/2022 11:42:53 AM 12 seconds ago	---	---

9. To verify that the policies are synced and applied, navigate to **Audit > Plugins**:

Export Date ( Eastern Daylight Time )	Service Name	Plugin ID	Plugin IP	Cluster Name	Http Response Code	Status
10/19/2022 11:42:52 AM	yamdev	yam@node1.cluster.com-yamdev	192.168.33.11	cyber.mapr.cluster	200	Policies synced to plugin
10/19/2022 12:24:22 PM	yamdev	yam@node1.cluster.com-yamdev	192.168.33.11	cyber.mapr.cluster	200	Policies synced to plugin
10/19/2022 12:12:22 PM	yamdev	yam@node1.cluster.com-yamdev	192.168.33.11	cyber.mapr.cluster	200	Policies synced to plugin
10/19/2022 12:09:34 PM	yamdev	yam@node1.cluster.com-yamdev	192.168.33.11	cyber.mapr.cluster	200	Policies synced to plugin
10/19/2022 11:54:22 AM	yamdev	yam@node1.cluster.com-yamdev	192.168.33.11	cyber.mapr.cluster	200	Policies synced to plugin
10/19/2022 11:46:29 AM	yamdev	yam@node1.cluster.com-yamdev	192.168.33.11	cyber.mapr.cluster	200	Policies synced to plugin

## Ranger Security and Data Fabric Security

Describes how Ranger security supplements the security features provided by the HPE Data Fabric.

### Ranger Manages Security for Ecosystem Components

Security for the HPE Data Fabric ensures that platform services can communicate securely and that users can successfully leverage those services. The HPE Data Fabric supports all four pillars of security (authentication, authorization, auditing, and encryption) without external security tools. The pillars are supported through a combination of technologies, including MapR-SASL, PAM, and tickets.

Ranger security provides an easy-to-use, optional security framework that is implemented on top of the existing platform security. Ranger allows you to manage security for HPE Ezmeral ecosystem components. Ranger is available for users who are migrating from other platforms and who want a familiar security interface on the HPE Data Fabric.

### Ranger Limitations

Ranger does not integrate with Data Fabric platform security. You must manage Ranger security separately from Data Fabric security. To manage Ranger security, see [Getting Started with Ranger](#) on page 5389. To manage Data Fabric security, see [Security](#) on page 901.

You can use Ranger to manage security for ecosystem components if a Ranger plug-in is available to support the component. In EEP 9.0.0, Ranger provides security for Hive operations, as only the Hive plug-in is currently available. Other plug-ins are being developed to expand Ranger's capabilities on the Data Fabric platform.

While Data Fabric security can be extended to support a [secure trust relationship](#) between two or more clusters, using Ranger across multiple Data Fabric clusters is currently not supported.

### Data Fabric Security Invoked Before Ranger Security

Ranger is another component in the HPE Data Fabric ecosystem. Like the other ecosystem components, Ranger leverages platform security. Ranger services use Data Fabric security to communicate with each other. For example, Ranger clients (plug-ins) authenticate themselves to the Ranger Admin service using MapR-SASL tickets.

Using the Hive plug-in, Ranger can manage which users execute certain types of Hive Metastore queries. Both Hive and Ranger use MapR-SASL for service communications. Hive uses MapR-SASL for authentication, and also uses Ranger for authorization.

Data Fabric security is invoked before Ranger security. If a Ranger-authorized user attempts to perform an operation that the user is not authorized to perform on the platform, platform security disallows the operation. And the Ranger plug-in cannot enforce any rule governing the operation. For example, Ranger is invoked only after Hive is started properly and accessed by a user who performs a query. Data Fabric security manages all of those operations.

**More information**

[Security](#) on page 901

Provides an overview of the Data Fabric security features.

**Syncing Keycloak Users, Groups and Roles with Ranger**

Describes how to sync the Keycloak Users, Groups, and Roles so that the Ranger admin authorizes the users and groups to manage the policies and users.

Configuring SSO authentication for Ranger Admin happens by default similar to the way it happens for other EEP components. However, this is only *authentication*, and not *authorization*. Users logged in via SSO by default won't be able to manage policies and users.

You can solve this problem by syncing Users, Groups, and Roles from Keycloak to Ranger Admin.

To Sync Users, Groups, and Roles from Keycloak to Ranger, do the following:

1. Create a dedicated user (for example, `usersync`) in your Keycloak realm with `view-users` role, from built-in `realm-management` client. See [Keycloak Documentation](#) for details.
2. To sync the users, groups, and roles from Keycloak to the Ranger admin, set the following properties in `/opt/mapr/ranger/ranger-<version>/ranger-usersync/install.properties`:

```
SYNC_SOURCE=keycloak
SYNC_KEYCLOAK_USERNAME=<username>
SYNC_KEYCLOAK_PASSWORD=<password>
```

Here username and password are credentials of the dedicated user created earlier in Keycloak.

**NOTE:** Keycloak users with `fabric-manager` role will get the administrator privileges in Ranger Admin.

3. Run the Ranger Admin `setup.sh` script to configure the new options:

```
sudo /opt/mapr/ranger/ranger-<version>/ranger-usersync/setup.sh
```

4. Run the configuration script:

```
sudo /opt/mapr/server/configure.sh -R
```

**Apache Spark**

Apache Spark is an open-source processing engine that you can use to process Hadoop data. The following diagram shows the components involved in running Spark jobs. See [Spark Cluster Mode Overview](#) for additional component details.

HPE Data Fabric supports the following types of cluster managers:

- Spark's standalone cluster manager
- YARN

The configuration and operational steps for Spark differ based on the Spark mode you choose to install. The steps to integrate Spark with other components are the same when using either Standalone or YARN cluster mode, except where otherwise noted.

This section provides documentation about configuring and using Spark with HPE Data Fabric, but it does not duplicate the [Apache Spark](#) documentation.

You can also refer to additional documentation available on the [Apache Spark Product Page](#).

### Getting Started with Spark Interactive Shell

After you have a basic understanding of Apache Spark and have it installed and running on your cluster, you can use it to load datasets, apply schemas, and query data from the Spark interactive shell.

### Reading Data from file system

#### 1. Copy sample data into file system:

- For this example, the dataset constitutes a CSV file of a list of auctions.
- Download the file from GitHub: <https://github.com/mapr-demos/getting-started-spark-on-mapr/tree/master/data>.
- Copy the file into your cluster, in the /apps/ directory, using the cp/scp or hadoop put command:

```
scp ./data/auctiondata.csv mapr@[mapr-cluster-node]:/mapr/[cluster-name]/
apps/
or
$ hadoop fs -put ./data/auctiondata.csv /apps
```

- This dataset is from eBay online auctions. The dataset contains the following fields:

```
auctionid - Unique identifier of an auction.
bid - Proxy bid placed by a bidder.
bidtime - Time (in days) that the bid was placed from the start of the
auction.
bidder - eBay username of the bidder.
```

```

bidderrate - eBay feedback rating of the bidder.
openbid - Opening bid set by the seller.
price - Closing price that the item sold for (equivalent to the second
highest bid + an increment).
item - Type of item.

```

The table below shows the fields with some sample data:

auctionid	bid	bidtime	bidder	bidderrate	openbid	price	item	daystolive
821303470 5	95	2.927373	jake7870	0	95	117.5	xbox	3

2. Start the Spark interactive shell:

- \$SPARK\_HOME represents the home of your Spark installation in MapR, for example: /opt/mapr/spark/spark-2.2.1/.

```
$ $SPARK_HOME/bin/spark-shell --master local[2]
```

3. Once the Spark shell is ready, load the dataset:

```
val auctionData = spark.read.textFile("/apps/auctiondata.csv")
```

4. Display the first entry:

```
auctionData.first()
```

5. Count the number of entries:

```
auctionData.count()
```

6. Use other Spark actions:

```
// Displays first 20 lines
auctionData.show()

// Displays first 3 lines - change value to see more/less
auctionData.take(3)
```

7. Transform the dataset into a new one that contains only xbox lines, and count them:

```
val auctionWithXbox = auctionData.filter(line => line.contains("xbox"))
auctionWithXbox.count()
```

- This could also be done in a single line by chaining transformations and actions:

```
auctionData.filter(line => line.contains("xbox")).count()
```

## 8. Use Spark Dataframes:

```
val auctionDataFrame = spark.read.format("csv").option("inferSchema",
true).load("/apps/
auctiondata.csv").toDF("auctionid","bid","bidtime","bidder","bidderrate",
"openbid","price","item","daystolive")
```

## 9. Use a filter transformation on the Dataframe:

```
auctionDataFrame.filter($"price" < 30).show()
```

**Figure 35: Schematic representation of performing transformations and actions on a dataset**

### Writing Data from file system

Using the same dataset, save all xbox items as a file in file system:

- You can use the `filter($"item" === "xbox")` filter and `write.json` or other options to save the result of the action to file system.

```
auctionDataFrame.filter($"item" === "xbox").write.json("/apps/results/json/
xbox")
```

This command creates the `/apps/results/json/xbox` directory in which you will see the JSON file(s) created. You can use the same command to create Parquet or any other file format:

```
auctionDataFrame.filter($"item" === "xbox").write.parquet("/apps/results/
parquet/xbox")
```

## Writing Data to HPE Data Fabric Database JSON

The first step when you are working with HPE Data Fabric Database JSON is to define a document `_id` that uniquely identifies the document.

Add a new `_id` field in the csv file and generate UUIDs to add to this field.

To load the Dataframe into the MapR-DB JSON:

```
dataframe.saveToMapRDB("tableName", createTable = true, bulkInsert =
false, idFieldPath = "_id")
```

The following commands will create a table and insert the data into: `/apps/auction_json_table`.

```
import spark.implicits._
import java.util.UUID
import org.apache.spark.sql.SparkSession
import org.apache.spark.sql.types._
import org.apache.spark.sql.SaveMode
import com.mapr.db.spark.sql._ // import the MapR-DB OJAI Connector
val generateUUID = udf(() => UUID.randomUUID().toString) // create UDF to
generate UUID
// showing that you can create your own schema
val customSchema =
 StructType(
 Array(
 StructField("actionid", StringType, true),
 StructField("bid", DoubleType, true),
 StructField("bidtime", DoubleType, true),
 StructField("bidder", StringType, true),
 StructField("bidderrate", IntegerType, true),
 StructField("openbid", DoubleType, true),
 StructField("price", DoubleType, true),
 StructField("item", StringType, true),
 StructField("daystolive", IntegerType, true)
)
)
```

You can now query the table using the HPE Data Fabric Database shell. Open a terminal on your cluster and run the following command:

```
$ mapr dbshell
maprdb mapr:> find /apps/auction_json_table --limit 10
```

## Reading Data from HPE Data Fabric Database JSON

Now that you have the data in HPE Data Fabric Database JSON, you can create and query a Spark Dataframe using the following commands:

```
import com.mapr.db.spark.sql._
import org.apache.spark.sql.SparkSession
val dataFromMapR = spark.loadFromMapRDB("/apps/auction_json_table")
dataFromMapR.printSchema
dataFromMapR.count

dataFromMapR.filter($"price" < 30).show() // use a filter
```

## Related Links

- [Spark configure.sh](#) on page 5429

- [HPE blog](#)

## Apache Spark Feature Support

HPE Data Fabric supports most Apache Spark features. However, there are some exceptions.

### GPU Aware Scheduling Support on Spark

Starting from EEP 9.0.0, you can use RAPIDS Accelerator for Apache Spark by Nvidia to accelerate the processing for Spark by using the GPUs.

To use RAPIDS Accelerator on HPE Data Fabric:

1. Follow the setup instructions in the official RAPIDS documentation: [Getting Started](#) (link opens an external site in a new browser tab or window).
2. Set the Apache Spark version with the following option:

```
spark.rapids.shims-provider.override
```

The value for this option must be the name of a corresponding shim. You can find a list of available shims [here](#).

For example, to use the RAPIDS plugin with Spark version 3.3.2.100-ee-912, you can set the version to 332 as follows:

```
spark.rapids.shims-provider.override=com.nvidia.spark.rapids.shims.spark332.SparkShimServiceProvider
```

For examples, limitations, and a full list of configuration details for RAPIDS, see [RAPIDS](#).

### Delta Lake Support on Spark

Starting from EEP 8.x.x, Apache Spark 3 provides Delta Lake support on HPE Data Fabric.

Delta Lake is an open-source storage layer that supports ACID (Atomicity, Consistency, Isolation, and Durability) transactions to provide reliability, consistency, and scalability to Apache Spark applications. Delta Lake runs on the top of the existing storage and is compatible with Apache Spark APIs. For more details, see [Delta Lake documentation](#).

You can use any Apache Spark APIs to read and write data with Delta Lake. Delta Lake stores the data in Parquet format as versioned Parquet files. Delta Lake has a well-defined open protocol called [Delta Transaction Protocol](#) that provides ACID transactions to Apache Spark applications.

To enable the Delta Lake:

1. Download the Delta Lake library from [Maven repository](#).

2. Add the Delta Lake library and set the following configuration options. For example:

```
/opt/mapr/spark/spark-3.1.2/bin/
spark-shell --jars ~/
delta-core_2.1.2-1.0.0.jar
--conf "spark.sql.extensions="
io.delta.sql.DeltaSparkSessionExtension
--conf
"spark.sql.catalog.spark_catalog="
org.apache.spark.sql.delta.catalog.
DeltaCatalog
```

Delta Lake stores the commits of every successful transaction (Spark job) as a DeltaLog or a Delta Lake transaction log.

For example: You can view these commit logs on MinIO Browser by navigating to `/<table_name>/_delta_Log/`.

Commits in the transaction log:

```
/<table_name>/_delta_log/
00000000000000000000000000000000.json
/<table_name>/_delta_log/
00000000000000000000000000000001.json
/<table_name>/_delta_log/
00000000000000000000000000000003.json
```

Delta lake uses optimistic concurrency control to provide ACID transactions between writes operation. See [Concurrency Control](#).

To accelerate the data lake operations, use optimizations provided by Delta Lake. Z-Ordering method is used to combine related information in the same files. Delta Lake automatically maintains minimum and maximum values for each column in delta table and stores these values as part of the metadata. The co-location of related information is used by Delta Lake in data skipping algorithm which optimizes performance by reducing the amount of data to be read by Apache Spark. To learn more, see [Optimizations](#).

See [Setup Apache Spark with Delta Lake](#) and [Advanced Dependency Management](#) to start using Delta Lake.

## Spark SQL and Apache Derby Support on Spark

If you are using Spark SQL with Derby database without Hive or Hive Metastore installation, you will see the following exception:

```
java.lang.RuntimeException: Unable to
instantiate
org.apache.hadoop.hive.ql.metadata.SessionHiveMetaStoreClient
```

Add the `hive-service-2.3.*.jar` and `log4j2` jars to `/opt/mapr/spark/spark-3.x.x/jars` location to use Spark SQL with Derby Database without Hive or Hive Metastore installation.

The log4j2 jars are located at /opt/mapr/lib/log4j2/log4j-\*.jar location.

Spark 3.1.2 and Spark 3.2.0 does not support log4j1.2 logging on HPE Data Fabric.

### Spark Thrift JDBC/ODBC Server Support

Running the Spark Thrift JDBC/ODBC Server on a secure cluster is supported only on Spark 2.1.0 or later.

You can run the Spark Thrift JDBC/ODBC Server to enable connections to Hive 1.2.1 using Beeline; however, you can connect only to Hive versions supported by your Spark version.

### Spark SQL and Hive Support for Spark 2.1.0

Spark 2.1.0 is able to connect to Hive 2.1 Metastore; however, only features of Hive 1.2 are supported.

### Spark SQL and Hive Support for Spark 2.0.1

Spark SQL is supported, but it is not fully compatible with Hive. For details, see the [Apache Spark documentation](#).

The following Hive functions are not supported in Spark SQL:

- Tables with buckets
- UNION type
- Unique join
- Column statistics collecting
- Output formats: File format (for CLI), Hadoop Archive
- Block-level bitmap indexes and virtual columns
- Automatic determination of the number of reducers for JOIN and GROUP BY
- Metadata-only query
- Skew data flag
- STREAMTABLE hint in JOIN
- Merging of multiple small files for query results

### Spark SQL and Hive Support for Spark 1.6.1

Spark SQL is supported, but it is not fully compatible with Hive. For details, see the [Apache Spark documentation](#). The following Spark SQL operations support the following Hive table formats:

	Hive 1.2 Table Format				
Spark SQL Operations	AVRO	ORC	Parquet	RC	default
create	Yes	Yes	Yes	Yes	Yes
drop	Yes	Yes	Yes	Yes	Yes
insert into	Yes	Yes	Yes	Yes	Yes

insert overwri te	Yes	Yes	Yes	Yes	Yes
select	Yes	Yes	Yes	Yes	Yes
load data	Yes	Yes	Yes	Yes	Yes

### Iceberg Support

Describes support for Iceberg in HPE Data Fabric 7.6.x and later.

#### Apache Iceberg

Apache Iceberg is an open-source table format that helps to simplify the data processing of huge data sets on a file system or object store. Iceberg brings the simplicity of SQL tables to huge data sets.

Iceberg has the following capabilities:

- Iceberg tables are fast, safe, scalable, and can easily integrate with analytics engines like Spark, PrestoDB, Hive, and so on.
- Iceberg supports Atomicity, Consistency, Isolation, and Durability (ACID) transactions.
- You can use analytics engines like Spark, PrestoDB, Hive, and Impala to safely perform ACID transactions on the same table at the same time.
- Iceberg supports schema evolution, hidden partitioning, partition layout evolution, and time travel, which minimize unpleasant surprises.

For details, see the [Apache Iceberg](#) documentation.

#### Data Fabric and Iceberg

Starting from Data Fabric 7.6.x, you can perform the following operations in the HPE Data Fabric Object Store:

- Create a schema for Avro, ORC, or Parquet data types, and modify the schema if needed.
- Create Iceberg tables using a specific schema and perform ACID transactions.
- Create a snapshot of a table to check time travel.
- Grant access permissions for an Iceberg table to different users.
- Perform data migration of data files into an Iceberg table, as well as migrate the metadata.
- Query an Iceberg table through Apache Spark.
- Create an Iceberg table in an external S3 bucket and query it through the HPE Data Fabric Object Store.

With these features, you can build a reliable and scalable Data-Lakehouse architecture.

**IMPORTANT:** DEP Spark Iceberg support is fully consistent with Apache Spark Iceberg integration. For more information, see <https://iceberg.apache.org/multi-engine-support/#apache-spark>.

#### Getting Started with Iceberg

Summarizes what you need to know to begin using Iceberg with HPE Data Fabric release 7.6.x.

## Version Support

HPE Data Fabric 7.6.x has been tested with:

- [Iceberg 1.4.2](#)
- [mapr-spark-3.3.3.0](#)
- [iceberg-spark-runtime-3.3\\_2.12-1.4.2.jar](#)

Other data-processing engines, such as open-source Spark, PrestoDB, Flink, and data-processing technologies, such as Snowflake, have not been tested.

## Catalog Support

Catalogs manage the metadata for datasets and tables in Iceberg. You must specify the catalog when interacting with Iceberg tables through Spark. The following built-in catalogs have been tested for use with Data Fabric 7.6.x:

- HiveCatalog
- HadoopCatalog

## Spark Setup for Iceberg

Setting up Spark to use Iceberg is a two-step process:

1. Add the `org.apache.iceberg:iceberg-spark-runtime-<spark.version>_<scala.version>:<iceberg.version>` jar file to your application classpath. Add the runtime to the `jars` folder in your spark directory. Add it directly to the application classpath by using the `--package` or `--jars` option.
2. Configure a catalog. For information about using catalogs with Iceberg, see [Catalogs](#).

For examples, see the [Spark and Iceberg Quickstart](#).

## Configuring Your Spark Application

Consider adding the following parameters to your Spark application:

```
spark.sql.catalog.<catalog_name>.type=hive
spark.sql.catalog.<catalog_name>.warehouse=<path_to_your_warehouse>
spark.sql.catalog.<catalog_name>=org.apache.iceberg.spark.SparkSessionCatalog
spark.sql.legacy.pathOptionBehavior.enabled=true
```

## Configuring Polaris Spark Client

Describes how to configure Apache Polaris Spark Client for Spark.

### Polaris Spark Client

Apache Polaris version 1.0.1 has released a Spark client, which helps to provide an end-to-end solution for Apache Spark to manage Iceberg tables using Polaris.

Polaris Spark client includes Iceberg libraries and all other dependencies for working with Polaris and Iceberg tables.

## Configuring Polaris Spark Client

1. Download `org.apache.polaris:polaris-spark-3.5_2.12:1.0.1.0-dep-1000` jar file from Maven repository, and add to `<spark_home>/jars`.
2. After that you can use `spark.sql.extensions=org.apache.iceberg.spark.extensions.IcebergSparkSessionExtensions` and `spark.sql.catalog.<catalog_name>=org.apache.iceberg.spark.SparkCatalog` to start a session with Iceberg support.

For Spark session examples on how to connect to Polaris and Iceberg tables, see <https://polaris.apache.org/releases/1.0.1/polaris-spark-client/>.

## Spark Standalone

This section includes topics about configuring and using Spark in Standalone mode.

To integrate Spark with other ecosystem components, see [Integrating Spark](#).

For additional documentation, see the [Apache Spark](#) website.

## Installing Spark Standalone

This topic describes how to use package managers to download and install Spark Standalone from the EEP repository.

## Prerequisites

To set up the EEP repository, see [Step 11: Install Ecosystem Components Manually](#) on page 284.

## About this task

Spark is distributed as four separate packages:

Package	Description
<code>mapr-spark</code>	Install this package on any node where you want to install Spark. This package is dependent on the <code>mapr-client</code> , <code>mapr-hadoop-client</code> , <code>mapr-hadoop-util</code> , and <code>mapr-librdkafka</code> packages.
<code>mapr-spark-master</code>	Install this package on Spark master nodes. Spark master nodes must be able to communicate with Spark worker nodes over SSH without using passwords. This package is dependent on the <code>mapr-spark</code> and the <code>mapr-core</code> packages.
<code>mapr-spark-historyserver</code>	Install this optional package on Spark History Server nodes. This package is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.
<code>mapr-spark-thriftserver</code>	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. It is dependent on the <code>mapr-spark</code> and <code>mapr-core</code> packages.

Run the following commands as root or using `sudo`.

## Procedure

1. Create the `/apps/spark` directory on the cluster filesystem, and set the correct permissions on the directory.

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

**NOTE:** Beginning with EEP 6.2.0, the `configure.sh` script creates the `/apps/spark` directory automatically.

2. Install Spark using the appropriate commands for your operating system:

### On CentOS 8.x / Red Hat 8.x

```
dnf install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

### On Ubuntu

```
apt-get install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

### On SLES

```
zypper install
mapr-spark mapr-spark-master
mapr-spark-historyserver
mapr-spark-thriftserver
```

**NOTE:** The `mapr-spark-historyserver`, `mapr-spark-master`, and `mapr-spark-thriftserver` packages are optional.

Spark is installed into the `/opt/mapr/spark` directory.

3. For Spark 2.x:

Copy the `/opt/mapr/spark/spark-<version>/conf/slaves.template` into `/opt/mapr/spark/spark-<version>/conf/slaves`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

For Spark 3.x:

Copy the `/opt/mapr/spark/spark-<version>/conf/workers.template` into `/opt/mapr/spark/spark-<version>/conf/workers`, and add the hostnames of the Spark worker nodes. Put one worker node hostname on each line.

For example:

```
localhost
worker-node-1
worker-node-2
```

4. Set up [passwordless ssh](#) for the `mapr` user such that the Spark master node has access to all secondary nodes defined in the `conf/slaves` file for Spark 2.x and `conf/workers` file for Spark 3.x.

5. As the `mapr` user, start the worker nodes by running the following command in the master node. Since the Master daemon is managed by the Warden daemon, do not use the `start-all.sh` or `stop-all.sh` command.

For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
```

For Spark 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/start-workers.sh
```

6. If you want to integrate Spark with HPE Data Fabric Streams, install the Streams Client on each Spark node:

- On Ubuntu:

```
apt-get install mapr-kafka
```

- On RedHat/CentOS:

```
yum install mapr-kafka
```

7. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the HPE Data Fabric Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).
8. After installing Spark Standalone but before running your Spark jobs, follow the steps outlined at [Configuring Spark Standalone](#) on page 5420.

### Configuring Spark Standalone

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run [configure.sh -R](#) as the final step in the configuration process.

#### *Configure High Availability for SparkMaster*

You configure high availability for the Spark Primary instance so that the instance does not become the single point of failure.

By using ZooKeeper to provide leader election and some state storage, you can launch multiple primary nodes in your cluster that are connected to the same ZooKeeper instance. Zookeeper elects one primary node to be the “leader,” and the others remain in standby mode. If the leader goes down, Zookeeper elects another primary node, recovers the old primary node's state, and resumes scheduling.

1. Set `SPARK_DAEMON_JAVA_OPTS` in `spark-env.sh` with the appropriate ZooKeeper information for the cluster.

```
export SPARK_DAEMON_JAVA_OPTS="-Dspark.deploy.recoveryMode=ZOOKEEPER
-Dspark.deploy.zookeeper.url=<zookeeper1:5181,zookeeper2:5181, ...>
-Djava.security.auth.login.config=/opt/mapr/conf/
mapr.login.conf -Dzookeeper.sasl.client=false
```

2. Restart the Spark Primary instance and Spark History Server services:

- For Spark 2.0.1 and later:

```
maprccli node services -nodes <node-ip> -name spark-master -action
restart
```

- For Spark 1.6.1:

```
maprccli node services -nodes <node-ip> -name spark-master -action
restart
maprccli node services -nodes <node-ip> -name
spark-historyserver -action restart
```

### 3. On the primary node, restart the Spark Secondary instances as the mapr user.

For Spark 2.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-slaves.sh
/opt/mapr/spark/spark-<version>/sbin/start-slaves.sh
```

For Spark 3.x:

```
/opt/mapr/spark/spark-<version>/sbin/stop-workers.sh
/opt/mapr/spark/spark-<version>/sbin/start-workers.sh
```

#### *Configure Scratch Directory for Spark Standalone*

By default, Spark uses the /tmp directory as scratch space. Map output files and RDDs are stored in the scratch directory. To use a different directory, or a comma-separated list of multiple directories, set SPARK\_LOCAL\_DIRS to the path to the new directory by adding the following line to the \$SPARK\_HOME/conf/spark-env.sh file:

```
export SPARK_LOCAL_DIRS=$SPARK_HOME/<path to scratch directory>
```

Make this change before starting the Spark services.

#### **Community Edition (Without NFS Support)**

Reserve space on your local disk to use as the scratch directory for Spark.

#### **Enterprise Edition and Enterprise Database Edition (With NFS Support)**

Create a local volume on each node with the maprccli volume create command, or from the Control System. Mount that local volume with NFS to a directory. Set that directory as the scratch directory for Spark.

**NOTE:** Due to <https://issues.apache.org/jira/browse/SPARK-6313>, make sure to set spark.files.useFetchCache=false in your spark-defaults.conf file.

#### **Using Spark Standalone**

For a simple test of your Spark installation, run the following command:

- On Spark 2.0.1 or later:

```
/opt/mapr/spark/spark-<version>/bin/run-example --master spark://<Spark
Master node hostname>:7077 SparkPi 10
```

- On Spark 1.6.1:

```
MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/
spark-<version>/bin/run-example org.apache.spark.examples.SparkPi 10
```

For more information about running Spark applications, see the [Apache Spark Documentation](#).

*Run the Spark Shell in Standalone Mode*

### Procedure

- To run the Spark shell, use the following command:

- On Spark 2.0.1 and later:

```
/opt/mapr/spark/spark-<version>/bin/spark-shell --master spark://<Spark
Master node hostname>:7077
```

- On Spark 1.6.1:

```
MASTER=spark://<Spark Master node hostname>:7077 /opt/mapr/spark/
spark-<version>/bin/spark-shell
```

### Security with Spark Standalone

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the Data Fabric installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure clusters. See [Spark configure.sh](#) on page 5429 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

### Spark on YARN

This section contains topics about installing, configuring and using Spark on YARN.

**IMPORTANT:** Spark 2.0.1 (and later) YARN mode is supported only on clusters in MRv2 (YARN) mode. It is not supported on clusters in MRv1 (classic) mode.

To integrate Spark with other ecosystem components, see [Integrating Spark](#) on page 5503

For additional documentation, see the [Apache Spark](#) documentation.

### Installing Spark on YARN

Describes how to use package managers to download and install Spark on YARN from the EEP repository.

### Prerequisites

To set up the EEP repository, see [Step 11: Install Ecosystem Components Manually](#) on page 284.

### About this task

Spark is distributed as three separate packages:

Package	Description
mapr-spark	Install this package on any node where you want to install Spark. This package is dependent on the following packages: <ul style="list-style-type: none"> <li>mapr-client</li> <li>mapr-hadoop-client</li> <li>mapr-hadoop-util</li> <li>mapr-librdkafka</li> </ul>
mapr-spark-historyserver	Install this optional package on Spark History Server nodes. This package is dependent on the following packages: <ul style="list-style-type: none"> <li>mapr-spark</li> <li>mapr-core</li> </ul>
mapr-spark-thriftserver	Install this optional package on Spark Thrift Server nodes. This package is available starting in the EEP 4.0 release. This package is dependent on the following packages: <ul style="list-style-type: none"> <li>mapr-spark</li> <li>mapr-core</li> </ul>

To install Spark on YARN (Hadoop 2), execute the following commands as root or using sudo:

### Procedure

1. Verify that JDK 11 or later is installed on the node where you want to install Spark.
2. Create the /apps/spark directory on the cluster file system, and set the correct permissions on the directory:

```
hadoop fs -mkdir /apps/spark
hadoop fs -chmod 777 /apps/spark
```

**NOTE:** Beginning with EEP 6.2.0, the `configure.sh` script creates the /apps/spark directory automatically when using the Installer. However, you must manually create this directory when performing a manual installation.

3. Install the packages:

#### On Ubuntu

```
apt-get install
mapr-spark mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On Red Hat / Rocky

```
dnf install mapr-spark
mapr-spark-historyserver
mapr-spark-thriftserver
```

#### On SLES

```
zypper install
mapr-spark mapr-spark-historyserver
mapr-spark-thriftserver
```

**NOTE:** The `mapr-spark-historyserver` and `mapr-spark-thriftserver` packages are optional.

4. If you want to integrate Spark with HPE Data Fabric Streams, install the Streams Client on each Spark node:

- **On Ubuntu:**

```
apt-get install mapr-kafka
```

- **On Red Hat / Rocky:**

```
yum install mapr-kafka
```

5. If you want to use a Streaming Producer, add the `spark-streaming-kafka-producer_2.12.jar` from the Data Fabric Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<versions>/jars/`).

For repository-specific information, see [Maven Artifacts for the HPE Data Fabric](#) on page 5559

6. Run `configure.sh -R`:

```
/opt/mapr/server/configure.sh -R
```

7. After installing Spark on YARN but before running your Spark jobs, follow the steps outlined in [Configuring Spark on YARN](#) on page 5424.

### Configuring Spark on YARN

Starting in EEP 4.0, after following the steps outlined in the sub-topics in this section, you must run [configure.sh -R](#) as the final step in the configuration process.

#### *Configure Data Fabric Client Node to Run Spark Applications*

When Spark runs on YARN, Data Fabric client nodes require the `hadoop-yarn-server-web-proxy` JAR file to run Spark applications. On Windows, the client node also requires an update to the `SPARK_DIST_CLASSPATH`. A Data Fabric client node (a node with the `mapr-client` package, but without `mapr-core` packages) is also known as an edge node.

The `mapr-client` package does not include the JAR file required to run Spark applications. Therefore, you must copy the following JAR file from a Data Fabric cluster node to the same location on the Data Fabric client node where you want to run the Spark application:

```
/opt/mapr/hadoop/hadoop-<version>/share/hadoop/yarn/
hadoop-yarn-server-web-proxy-<version>.jar
```

For example, here is a JAR file path for Hadoop 3.3.5:

```
/opt/mapr/hadoop/hadoop-3.3.5/share/hadoop/yarn/
hadoop-yarn-server-web-proxy-3.3.5.100-ee-920.jar
```

#### *Configure Spark JAR Location*

#### **About this task**

By default, Spark on YARN uses Spark JAR files that are installed locally. The Spark JAR files can also be added to a world-readable location on file system. When you add the JAR files to a world-readable

location, YARN can cache them on nodes to avoid distributing them each time an application runs. Complete the following steps to add the Spark JAR files to a world-readable location on file system:

### Procedure

1. Create a zip archive containing all the JARs from the SPARK\_HOME/jars directory. For example:

```
cd /opt/mapr/spark/spark-<version>/jars/
zip /opt/mapr/spark/spark-<version>/spark-jars.zip ./*
```

2. Copy the zip file from the local filesystem to a world-readable location on file system. You can upload it to the home of the current user:

```
hadoop fs -put /opt/mapr/spark/spark-<version>/spark-jars.zip
```

For example:

```
hadoop fs -put /opt/mapr/spark/spark-3.2.0/spark-jars.zip /user/mapr/
```

3. Set the spark.yarn.archive property in the spark-defaults.conf file located in /opt/mapr/spark/spark-<version>/conf/spark-defaults.conf to point to the world-readable location where you added the zip file. Apply this setting on the node where you will be submitting your Spark jobs.

```
spark.yarn.archive maprfs:///<path to zip>
```

For example:

```
spark.yarn.archive maprfs:///user/mapr/spark-jars.zip
```

*Configure Spark with the NodeManager Local Directory Set to file system*

### About this task

This procedure configures Spark to use the mounted NFS directory instead of the /tmp directory on the local file system. Note that spill to disk should be configured to spill to the file system node local storage only if local disks are unavailable or space is limited on those disks.

### Procedure

1. Install the mapr-loopbacknfs and nfs-utils packages if they are not already installed. For reference, see [Installing the mapr-loopbacknfs Package](#) on page 388 and [Setting Up Data Fabric NFS](#).
2. Start the mapr-loopbacknfs service by following the steps at [Managing the mapr-loopbacknfs Service](#) on page 1872.
3. To configure Spark Shuffle on NFS, complete these steps **on all nodes**:
  - a) Create a local volume for Spark Shuffle:

```
sudo -u mapr maprcli volume create -name mapr.$
(hostname -f).local.spark -path /var/mapr/local/$(hostname -f)/
spark -replication 1 -localvolumehost $(hostname -f)
```

- b) Point the NodeManager local directory to the Spark Shuffle volume mounted through NFS by setting the following property in the `/opt/mapr/hadoop/hadoop-<version>/etc/hadoop/yarn-site.xml` file on the NodeManager nodes:

```
<property>
 <name>yarn.nodemanager.local-dirs</name>
 <value>/mapr/my.cluster.com/var/mapr/local/${mapr.host}/spark</value>
</property>
```

- c) (Optional) Configure how many times the NodeManager can attempt to delete application-related directories from a volume when Spark is configured to use the mounted NFS directory instead of the `/tmp` directory on the local file system. Increasing the value (default is 2) of this property can prevent application cache data from accumulating in the volume. This functionality is available by default starting in EEP 7.1.0. For previous EEP versions, request the patch. See [Applying a Patch](#).

```
<property>
 <name>yarn.nodemanager.max-retry-file-delete</name>
 <value>2</value>
</property>
```

- d) Restart the NodeManager service and the Resource Manager service on the main node to pick up the `yarn-site.xml` changes:

```
maprccli node services -name nodemanager -action restart -nodes <node 1> <node 2> <node 3>
maprccli node services -name resourcemanager -action restart -nodes <node 1> <node 2> <node 3>
```

## Using Spark on YARN

This section includes information about using Spark on YARN in a Data Fabric cluster.

For a simple test of your Spark installation, run the following command as the `mapr` user:

- On Spark 2.0.1 or later:

```
/opt/mapr/spark/spark-<version>/bin/run-example --master
yarn --deploy-mode client SparkPi 10
```

- On Spark 1.6.1:

```
MASTER=yarn-client /opt/mapr/spark/spark-<version>/bin/run-example
org.apache.spark.examples.SparkPi 10
```

**NOTE:** These commands will fail if it is run as the root user.

For more information about running Spark applications, see the [Apache Spark documentation](#).

### Deployment Modes

Spark is preconfigured for YARN and does not require any additional configuration to run.

Two deployment modes can be used to launch Spark applications on YARN:

- In `cluster` mode, jobs are managed by the YARN cluster. The Spark driver runs inside an Application Master (AM) process that is managed by YARN. This means that the client can go away after initiating the application.

- In `client` mode, the Spark driver runs in the client process, and the Application Master is used only to request resources from YARN.

Data Fabric recommends using `cluster` deployment mode instead of `client` mode. If the Spark client that runs the job exits after submitting the job, there is no impact on job completion.

**Note:** In `cluster` deployment mode, the local directories used by the Spark executors and the Spark driver are the local directories that are configured for YARN (`yarn.nodemanager.local-dirs`).

**NOTE:** `SPARK_LOCAL_DIRS` is ignored when you run Spark on YARN.

*Run Spark from the Spark Shell*

### About this task

In `yarn-client` mode, complete the following steps to run Spark from the Spark shell:

### Procedure

1. Navigate to the Spark-on-YARN installation directory, and insert your Spark version into the command.

```
cd /opt/mapr/spark/spark-<version>/
```

2. Issue the following command to run Spark from the Spark shell:

- On Spark 2.0.1 and later:

```
./bin/spark-shell --master yarn --deploy-mode client
```

- On Spark 1.6.1:

```
MASTER=yarn-client ./bin/spark-shell
```

**NOTE:** You must use `yarn-client` mode to run Spark from the Spark shell. The `yarn-cluster` mode is not supported.

### Security with Spark on YARN

Starting in the EEP 4.0 release, for secure clusters, you no longer need to manually configure your cluster to enable Spark security features. Using the Data Fabric installer for new installations or running `configure.sh -R` for manual installs and upgrades automatically enables security features on secure clusters. See [Spark configure.sh](#) on page 5429 for details, including instructions on how to avoid enabling security features on secure clusters.

When running Spark applications on a secure cluster, you must pass the `-Dmapr_sec_enabled` flag to Spark. For secure clusters, this flag is set in `spark-env.sh`. For situations where your Spark application does not invoke this script, e.g., a Spark web service, you must manually pass the flag.

*Configure SSL Encryption for Spark on YARN*

### Prerequisites

Starting in EEP 8.0.0, if you are Non-Admin user starting a Spark Application, you must generate the KeyStore and KeyStore password and set it in Spark configuration files. For details, see [Security - Spark Documentation](#). Otherwise, KeyStore and default KeyStore password generates automatically.

Starting in EEP 6.0.0, you can remove `spark.ssl.keyStorePassword`, `spark.ssl.trustStorePassword`, and `spark.ssl.keyPassword` from the

spark-defaults.conf file for additional security. These passwords are stored in the /opt/mapr/conf/ssl-client.xml file and Spark can access passwords from this file itself.

**NOTE:** If passwords are present in both /opt/mapr/conf/ssl-client.xml and /opt/mapr/spark/spark-<version>/conf/spark-defaults.conf files, then the password from the spark-defaults.conf file is used.

### About this task

Complete the following step to manually configure encryption for the Spark HTTP file and broadcast servers:

### Procedure

In the spark-defaults.conf file on each spark node, configure the following properties. Starting in EEP 6.0.0, the configured algorithms mentioned in the following code are no longer available for your web service to pick up. You must remove the spark.ssl.enabledAlgorithms TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA, TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA line to let parties negotiate the matching ciphers.

- For Spark 2.0.1 and later:

```
spark.ssl.fs.enabled true
spark.ssl.keyPassword <ssl-keystore-password>
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.keyStorePassword <ssl-keystore-password>
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.protocol TLSv1.2
spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA, TLS_RSA_WITH_AES_256_CBC_SHA
```

**NOTE:** Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running configure.sh -R](#), as the final step in the configuration process, enables these settings.

- For Spark 1.6.1:

```
spark.ssl.akka.enabled true
spark.ssl.fs.enabled true
spark.ssl.keyPassword <ssl-keystore-password>
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.keyStorePassword <ssl-keystore-password>
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.trustStorePassword <ssl-keystore-password>
spark.ssl.protocol TLSv1.2
spark.ssl.enabledAlgorithms
TLS_RSA_WITH_AES_128_CBC_SHA, TLS_RSA_WITH_AES_256_CBC_SHA
```

Spark UI SSL is not needed when running Spark on YARN because encryption is provided by the YARN protocol. **For versions prior to EEP 4.1.0**, to enable users logged in with a normal user account (not mapr or root) to run spark jobs on the cluster, disable Spark SSL for Spark-on-YARN jobs. To disable Spark SSL, add spark.ssl.ui.enabled false to the spark-defaults.conf file on each spark node. The spark-defaults.conf file is in the following location: /opt/mapr/spark/spark-<version>/conf/. Make sure SSL is enabled for the Spark history server.

When you manually configure encryption for Spark, set the same protocol and algorithms for each node. Otherwise, the connection between those components might fail.

### Spark configure.sh

Starting in the EEP 4.0 release, run `configure.sh -R` to complete your Spark configuration when manually installing Spark or upgrading to a new version.

The command is the following:

```
/opt/mapr/server/configure.sh -R
```

**NOTE:** You do not need to run this script for new installs, if you are using the Installer in EEP 4.0 or later.

In the case of [Spark Standalone](#) on page 5418 and [Spark on YARN](#) on page 5422, this is the last step in the configuration process.

All security configuration properties are specified within the following comment block in the `SPARK_HOME/conf/spark-defaults.conf` file:

```
#SECURITY BLOCK
...
#END OF THE SECURITY CONFIGURATION BLOCK
```

Do not remove these comments from the file, as well as any other comments within the block inserted by `configure.sh`. The script uses these comments to locate security properties.

To set ports to special values, use the `spark.driver.port` and `spark.blockManager.port` properties.

Starting in EEP 6.0.0, Spark services such as the History Server, Thrift Server, or Primary are restarted by `configure.sh` only for changes to the following Spark configuration files: `spark-defaults.conf`, `spark-env.sh`, `hive-site.xml`, or `log4j.properties`. If these files are unchanged, `configure.sh` does not restart any of the Spark services.

An update to Spark causes the `conf` directory from the previous the Spark version to be saved to the `spark-<old-version>.<old-timestamp>` directory. If your Spark version did not change during the update, then configurations from the `spark-<old-version>.<old-timestamp>` directory is automatically copied to the `spark-<version>` directory by the `configure.sh` script.

If you use `.customSecure`, at the first run, the `configure.sh` script copies the `hive-site.xml` file from Hive. For subsequent times, the `hive-site.xml` file is not copied from Hive and you would need to manually modify the `$SPARK_HOME/conf/hive-site.xml` file.

### Related concepts

[Customizing Security in HPE Data Fabric](#) on page 2211

Describes the `.customSecure` file and how HPE Data Fabric 6.x handles custom security settings.

### Spark SQL Thrift Server

Spark SQL Thrift (Spark Thrift) was developed from Apache Hive HiveServer2 and operates like HiveServer2 Thrift server.

Spark Thrift is supported on secure clusters. You can run the Spark Thrift server and connect to Hive versions supported by Spark 2.1.0 and later with Business Intelligence (BI) tools or the Beeline command-line tool.

Starting in the EEP 4.0 release, the Spark Thrift server is available as a separate package. To install this package, see [Installing Spark Standalone](#) on page 321 or [Installing Spark on YARN](#) on page 323, depending on the type of cluster manager you are installing.

In EEP 3.0, MapR introduces additional security mechanisms for Spark with the Spark Thrift server. MapR-SASL and Kerberos are supported:

- For JDBC connections into Spark Thrift server
- Between Spark and Hive metastore

To enable these security mechanisms for the Spark Thrift server, starting in the EEP 4.0 release, for secure clusters, running `configure.sh -R` configures MapR-SASL security. The script modifies or creates a `SPARK_HOME/conf/hive-site.xml` file as follows:

- If Hive is installed in your cluster, the script copies `HIVE_HOME/conf/hive-site.xml` to `SPARK_HOME/conf` and modifies the file.
- If Hive is not installed and you are using MapR-SASL security, the script creates a new `SPARK_HOME/conf/hive-site.xml` file.
- Each time the script runs, if there is a pre-existing `SPARK_HOME/conf/hive-site.xml` file, the script saves a copy of the file in `SPARK_HOME/conf/hive-site.xml.old` before modifying it.

You can configure security manually by following the steps outlined in sub-topics listed on this page.

To launch the Spark Thrift server, perform the procedures required to configure [Apache Spark](#) on page 5408 to use [Hive](#) on page 4934.

#### IMPORTANT:

- Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 10000.
- Starting in the EEP 5.0.4 and EEP 6.3.0 releases, if you start and stop the Spark Thrift server by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number remains 2304.

#### Default Behavior

The default behavior of the Spark Thrift server is as follows:

1. After installation, the Spark Thrift server is started in the local master mode.
2. If the Spark master package is installed, then Spark Thrift server is started in the standalone master mode.
3. If the `spark.master` property is set in the `spark-defaults.conf` file, then Spark Thrift server uses the master set by this property.

## Known Limitations

- MapR-SASL support is implemented for Spark 2.1.0 and later versions of Spark. For Spark version information, see [Component Versions for Released Ecosystem Packs](#) on page 7704.
- The ODBC drivers do not support MAPR-SASL.
- Username and password authentication through PAM is not supported in EEP 3.0.
- Spark Thrift server supports only features and commands in Hive 1.2.
- Although Spark 2.1.0 can connect to Hive 2.1 Metastore, only Hive 1.2 features and commands are supported by Spark 2.1.0.

For information related to Spark Thrift server, see:

MapR	Apache
<ul style="list-style-type: none"> <li>• <a href="#">Hive Release Notes</a> on page 7962</li> <li>• <a href="#">Hive and Tez</a></li> <li>• <a href="#">Integrate Spark SQL with Hive</a></li> <li>• <a href="#">Hive</a></li> <li>• <a href="#">Authentication for HiveServer2</a></li> <li>• <a href="#">Spark Feature Support</a></li> </ul>	<ul style="list-style-type: none"> <li>• <a href="#">Apache Spark 2.1.0 Security</a></li> <li>• <a href="#">Apache Thrift</a></li> <li>• <a href="#">Setting Up HiveServer2</a></li> </ul>

## Spark Thrift Server Clients

With Spark Thrift server, you can use JDBC and ODBC connection interfaces that enable a variety of external tools to access Spark and run SQL queries.

- The ODBC interface is used by BI tools (often produced by HPE Data Fabric partners such as [Tableau](#) or [Microstrategy](#)).
- The JDBC interface is used by clients such as Squirrel SQL or the Beeline simple SQL shell.

Data Fabric Hive JDBC clients that connect to HiveServer2 can also connect to Spark Thrift server without additional configuration. For details about clients, see [HiveServer2 Clients](#) and [Connecting to HiveServer2](#).

**IMPORTANT:** Starting in the EEP 4.0 release, if you start and stop the Spark Thrift server using Warden, the connection port number is 2304. If you start and stop by running the `/opt/mapr/spark/<spark-version>/sbin/{start,stop}-thriftserver.sh` scripts, the port number is 10000. Beginning with EEP 6.3.0, the connection port number is 2304 for both start/stop methods (using Warden and using `thriftserver.sh` scripts).

## MapR-SASL JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for MapR-SASL environments is:

```
jdbc:hive2://<hostname>:2304/default;auth=maprsasl;ssl=true
```

Otherwise, the port you use depends on the EEP version:

<b>EEP 4.0 through 6.2.x</b>	<code>jdbc:hive2://&lt;hostname&gt;:10000/default;auth=maprsasl;ssl=true</code>
<b>EEP 6.3.0 and later</b>	<code>jdbc:hive2://&lt;hostname&gt;:2304/default;auth=maprsasl;ssl=true</code>

### Kerberos JDBC Connection String Format

If you start and stop the Spark Thrift server through Warden, starting in EEP 4.0, then the JDBC connection string format for clusters secured with Kerberos is:

```
jdbc:hive2://<hostname>:2304/default;principal=mapr/<FQDN@REALM>;ssl=true
```

Otherwise, the port you use depends on the EEP version:

<b>EEP 4.0 through 6.2.x</b>	<code>jdbc:hive2://&lt;hostname&gt;:10000/default;principal=mapr/&lt;FQDN@REALM&gt;;ssl=true</code>
<b>EEP 6.3.0 and later</b>	<code>jdbc:hive2://&lt;hostname&gt;:2304/default;principal=mapr/&lt;FQDN@REALM&gt;;ssl=true</code>

### Starting the Thrift Server on a Custom Port

To start the Spark Thrift Server on a custom port, use the `hive.server2.thrift.port` option. For example, you can specify the following in the `/opt/mapr/spark/spark-2.4.4/conf/hive-site.xml` file:

```
<property>
<name>hive.server2.thrift.port</name>
<value>34512</value>
</property>
```

For more information, see the [Apache HiveServer2](#) documentation.

### Using Authentication with Spark Thrift Server

Spark Thrift server supports both MapR-SASL and Kerberos authentication. The authentication method that you configure for the Spark Thrift server determines how the connection is secured. Clients might require additional configuration and specific connection strings based on the authentication type.

To enable authentication, see:

- [Configuring Spark Thrift Server with MapR-SASL](#) on page 5433
- [Configuring Spark Thrift Server with Kerberos](#) on page 5433

To configure PAM for Spark Thriftserver, run `configure.sh` on the secure cluster.

For information about Hive integration, see:

- [Integrate Spark SQL with Hive](#)
- [Setting Up HiveServer2](#)
- [Hive](#)
- [Spark Feature Support](#)

## Configuring Spark Thrift Server with MapR-SASL

Describes how to enable and start the Spark Thrift server on all nodes.

You can configure Spark Thrift server to use MapR-SASL for its communications with various components on a secure Data Fabric cluster. Minimal configuration is required.

**NOTE:** Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done through the 6.0 Installer, the installer enables this configuration. For manual installs and upgrades, [running `configure.sh -R`](#) enables these settings.

To manually enable MapR-SASL authentication on a non-secure cluster or in versions earlier than EEP 4.0:

1. Verify that the `hive.server2.authentication` property in `hive-site.xml` is set to the value, `MAPRSASL`.

```
<property>
 <name>hive.server2.authentication</name>
 <value>MAPRSASL</value>
</property>
```

2. Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/`.

**IMPORTANT:** The Data Fabric administrative user (generally, the account named `mapr`) should start the Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

## Bringing up the Spark Thrift server on every node

When you start and stop Warden after enabling Spark or after running [configure.sh](#) on page 3186 or after installing a patch, Spark starts only on one (1) node and not on all nodes. This happens because by default, the Warden configuration file for Spark has the value `1` instead of `all`. For example:

```
grep services /opt/mapr/conf/conf.d/warden.spark-thriftserver.conf
services=spark-thriftserver:1:cldb
```

To fix this issue permanently:

1. Modify `/opt/mapr/spark/spark-2.4.0/warden/warden.spark-thriftserver.conf` and change `1` to `all`:

```
grep services /opt/mapr/spark/spark-2.4.0/warden/
warden.spark-thriftserver.conf
 services=spark-thriftserver:all:cldb
```

2. Run `/opt/mapr/server/configure.sh -R`.

The change is then propagated to the `/opt/mapr/conf/conf.d/warden.spark-thriftserver.conf` file.

## Configuring Spark Thrift Server with Kerberos

You can configure Spark Thrift server to use Kerberos for its communications with various components on a secure Data Fabric cluster if necessary.

**NOTE:** Data Fabric clusters do not provide Kerberos infrastructure. The information in this section assume a Linux-based Kerberos environment, and the specific commands for your environment may vary. Consult with your Kerberos administrator for assistance.

To enable Kerberos authentication:

1. Create a Kerberos identity and keytab. You can use the following commands in a Linux-based Kerberos environment to set up the identity and update the keytab file.
  - The `hive.keytab` file must be owned and readable only by the `mapr` user.
  - `FQDN@REALM` is case-sensitive.

```
kadmin
: addprinc -randkey mapr/<FQDN@REALM>
: ktadd -k /opt/mapr/conf/hive.keytab mapr/<FQDN@REALM>
```

2. Configure the following properties in `hive-site.xml` on each node where HiveServer2 is installed:

Property	Value
<code>hive.server2.authentication</code>	KERBEROS
<code>hive.server2.authentication.kerberos.principal</code>	<code>mapr/FQDN@REALM</code> (where <code>mapr/FQDN@REALM</code> is the principal that you want to use for the Spark Thrift server)
<code>hive.server2.authentication.kerberos.keytab</code>	<code>/opt/mapr/conf/mapr.keytab</code> (where <code>/opt/mapr/conf/mapr.keytab</code> is path to the keytab that must be used)

```
<property>
 <name>hive.server2.authentication</name>
 <value>KERBEROS</value>
 <description>authenticationtype</description>
</property>
<property>
 <name>hive.server2.authentication.kerberos.principal</name>
 <value>mapr/FQDN@REALM</value>
 <description>Spark Thrift server principal. If _HOST is used as
the FQDN portion,
 it will be replaced with the actual hostname of the running
instance.
 </description>
</property>
<property>
 <name>hive.server2.authentication.kerberos.keytab</name>
 <value>/opt/mapr/conf/mapr.keytab</value>
 <description>Keytab file for Spark Thrift server principal</
description>
</property>
```

3. Reconfigure the following options in `env.sh` (`/opt/mapr/conf/env.sh`) on each node where HiveServer2 is installed:

**NOTE:** These configurations are listed in the portion of the file that begins with `if [ "$MAPR_SECURITY_STATUS" = "true" ];`. However, you should make the changes in the `/opt/mapr/conf/env_override.sh` file. For more information, see [About env\\_override.sh](#) on page 3467.

Existing Configuration	Required Configuration
MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=maprsasl_keytab"	MAPR_HIVE_SERVER_LOGIN_OPTS="-Dhadoop.login=hybrid"
MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=maprsasl"	MAPR_HIVE_LOGIN_OPTS="-Dhadoop.login=hybrid"

- Restart Spark Thrift server to apply this change. `sbin` is in your Spark directory at `/opt/mapr/spark/spark-<spark_version>/`.

**IMPORTANT:** The MapR administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files will be owned by this user, and impersonation support (where applicable) will function correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

- [Setting Up HiveServer2](#)
- [Hive](#)

## Configuring Spark Thrift Server Encryption

**ATTENTION:** This section can be skipped if you are running a secure cluster. If you are using Data Fabric 7.x, EEP supports Spark Thrift Server encryption, by default. If you are using Data Fabric 6.1 or 6.2, you can ignore this section, as EEP versions supported by these Data Fabric versions support Spark Thrift Server encryption. See [Ecosystem Pack Support and Lifecycle Status](#) on page 7664 for details of EEP versions supported for various Data Fabric versions.

Spark Thrift server encryption is supported when authentication is enabled. You can configure encryption with MapR-SASL or with SSL/TLS.

### Configuring Encryption with MapR-SASL or Kerberos

Starting in EEP 4.0, for secure clusters, you can skip the steps outlined in this section. For new installs done using Data Fabric Installer, the Installer enables this configuration. For manual installs and upgrades, [running configure.sh -R](#) enables these settings.

To manually configure encryption with MapR-SASL or Kerberos authentication on a non-secure cluster or in versions earlier than EEP 4.0, complete the following steps:

1. Set the `hive.server2.thrift.sasl.qop` property in `hive-site.xml` to the value `auth-conf`. The SASL Quality of Protection (QOP), or `sasl.qop`, setting and the authentication with confidentiality (`auth-conf`) value support authentication:

```
<property>
 <name>hive.server2.thrift.sasl.qop</name>
 <value>auth-conf</value>
</property>
```

2. Restart Spark Thrift server to apply the change:

**IMPORTANT:** The cluster administrative user (generally, the account named `mapr`) should start Spark Thrift server. Then, process identifier (PID) files are owned by this user, and impersonation support (where applicable) functions correctly.

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

## Configuring Encryption with SSL/TLS

To enable encryption with SSL/TLS:

1. Add the following properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

```
spark.ssl.enabled true
spark.ssl.fs.enabled true
spark.ssl.trustStore /opt/mapr/conf/ssl_truststore
spark.ssl.keyStore /opt/mapr/conf/ssl_keystore
spark.ssl.protocol TLSv1.2
spark.ssl.keyStorePassword mapr123
spark.ssl.trustStorePassword mapr123
```

After the properties are added, event logs will indicate that the job is encrypted.

2. To connect using Beeline with encryption, add the following properties to the `/opt/mapr/spark/spark-<version>/conf/hive-site.xml` file:

```
<property>
 <name>hive.server2.use.SSL</name>
 <value>true</value>
 <description>enable/disable SSL </description>
</property>

<property>
 <name>hive.server2.keystore.path</name>
 <value>/opt/mapr/conf/ssl_keystore</value>
 <description>path to keystore file</description>
</property>

<property>
 <name>hive.server2.keystore.password</name>
 <value>mapr123</value>
 <description>keystore password</description>
</property>
```

3. To start the Spark Thriftserver, use the following command:

```
/opt/mapr/spark/spark-<version>/sbin/start-thriftserver.sh --hiveconf
hive.server2.thrift.port=2304 --master yarn --deploy-mode client
```

The following example shows a connection string using Beeline (PAM+SSL):

```
./bin/beeline
Beeline version 1.2.0-mapr-1808-spark by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connecting to jdbc:hive2://node1.cluster.com:2304/
default;ssl=true;user=mapr;password=mapr;sslTrustStorePassword=mapr123;ss
lTrustStore=/opt/mapr/conf/ssl_truststore
Connected to: Spark SQL (version 2.1.0-mapr-mep-3.x-1808)
Driver: Hive JDBC (version 1.2.0-mapr-1808-spark)
Transaction isolation: TRANSACTION_REPEATABLE_READ
1: jdbc:hive2://node1.cluster.com:2304/default>
```

### Enabling High Availability for Spark Thrift Server

With EEPs 5.0.4 or 6.3.0 and later, you can enable high availability for the Spark Thrift Server. Note the following characteristics of high availability for the Spark Thrift Server:

- Unlike a HiveServer2 high-availability (HA) configuration, all Spark Thrift Servers are in an active state. ZooKeeper keeps track of the Thrift Servers. ZooKeeper chooses one of them to work and makes a record of the choice. If one of the Thrift Servers goes down, ZooKeeper looks for another Thrift Server, makes a record, and works with it.
- After configuration, you can use Beeline to connect to the Spark Thrift Server on each node. The Control System displays one thrift server as active with the others on standby, but you can connect to any of them.
- If a Spark Thrift Server stops or fails, ZooKeeper removes the record for the failed Spark Thrift Server, and the client connects to the next one in the ZooKeeper list.
- At its core, the running Spark Thrift Server is a job that you can start in YARN mode. This makes it possible to configure queues for the Spark Thrift Server in a multi-tenant cluster if high availability is enabled. You can do this by using the `./sbin/start-thriftserver` script and applying the special properties that YARN provides for managing queues.
- You don't need to configure load balancing. Spark handles load-balancing automatically through the use of parallelized requests and efficient resource management.

To enable high availability, use the following steps:

1. Install Spark Thrift Server on all the cluster nodes where it is needed:

#### On Ubuntu

```
apt-get install
mapr-spark-thriftserver
```

#### On Red Hat / CentOS

```
yum install mapr-spark-thriftserver
```

#### On SLES

```
zypper install
mapr-spark-thriftserver
```

2. Add the following properties to the `/opt/mapr/spark/spark-<spark_version>/conf/hive-site.xml` file on all the nodes where the Spark Thrift Server is installed

```
<property>
<name>hive.zookeeper.quorum</name>
<value><zk_host1_>, <zk_host_2>, ..., <zk_host_n></value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value><zk_port></value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value><zk_namespace></value>
</property>
```

For example:

```
<property>
<name>hive.zookeeper.quorum</name>
<value>node1.cluster.com, node2.cluster.com, node3.cluster.com</value>
</property>

<property>
<name>hive.zookeeper.client.port</name>
<value>5181</value>
</property>

<property>
<name>hive.server2.support.dynamic.service.discovery</name>
<value>true</value>
</property>

<property>
<name>hive.server2.zookeeper.namespace</name>
<value>ts2-ts2</value>
</property>
```

**NOTE:** The values that you provide for the `hive.server2.zookeeper.namespace` property should be different for the `hive-site.xml` in the Spark and Hive directories.

- Restart the Spark Thrift Server to apply the changes following the script in the `.sbin` directory at `/opt/mapr/spark/spark-<spark_version>/` or by running a `maprcli` command on all configured nodes:

```
./sbin/stop-thriftserver.sh
./sbin/start-thriftserver.sh
```

or

```
maprcli node services -nodes <host_1>,<host_2>,<host_n> -name
spark-thriftserver -action restart
```

- Launch the Zookeeper command line interface, and check the Spark Thriftserver znode by running the following commands:

```
/opt/mapr/zookeeper/zookeeper-<version>/bin/zkCli.sh -server <ip:port of
zookeeper instance>
ls /<hive.server2.zookeeper.namespace>
```

For example:

```
/opt/mapr/zookeeper/zookeeper-3.4.11/bin/zkCli.sh -server
node1.cluster.com:5181
ls /ts2-ts2
[serverUri=node1.cluster.com:2304;version=;sequence=0000000000]
```

- Using Beeline, you can connect to the Spark Thrift Server by using the following string:

```
beeline> !connect jdbc:hive2://<hostname -f>:5181/
default;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=<hive.server2.z
ookeeper.namespace>;
```

For example:

```
./bin/beeline
Warning: Unable to determine $DRILL_HOME
Beeline version 1.2.0-mapr-spark-MEP-6.0.0-1912 by Apache Hive
beeline> !connect jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts
2;auth=maprsasl;
Connecting to jdbc:hive2://node1.cluster.com:5181/
default;ssl=true;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=ts2-ts

**NOTE:** High availability for the Spark Thrift Server can be used in conjunction with HiveServer2 high availability. For more information about HiveServer2 high availability, see [Enabling High Availability for Hive](#) on page 5079.

### Spark History Server SSL

Describes how to enable SSL for Spark History Server.

**NOTE:** For secure clusters, Spark History Server UI authentication is enabled by default. If passwords are present in both `/opt/mapr/conf/ssl-client.xml` and `/opt/mapr/spark/spark-<spark_version>/conf/spark-defaults.conf` files, the password from the `spark-defaults.conf` file is used

Starting in EEP 4.0, for secure clusters, you can skip this step. For new installs done through the 6.0 MapR Installer, the installer enables this configuration. For manual installs and upgrades, [running configure.sh -R](#) enables these settings.

### HPE Data Fabric Database Connectors for Apache Spark

This section describes the HPE Data Fabric Database connectors that you can use with Apache Spark.

[Apache Spark](#) is a software framework that is used to process data in memory in a distributed manner. Spark is replacing MapReduce in many use cases. The HPE Data Fabric Database Connectors for Spark enable users to write applications that access HPE Data Fabric Database JSON and Binary tables.

#### Understanding the HPE Data Fabric Database OJAI Connector for Spark

Using the HPE Data Fabric Database OJAI connector for Spark enables you build real-time and batch pipelines between your data and HPE Data Fabric Database JSON. Before getting started, it is important that you understand Spark terminology and workflow, system requirements and support, and OJAI connector and API features.

The HPE Data Fabric Database OJAI connector includes a set of APIs that enable you to write applications that consume HPE Data Fabric Database JSON tables and use them in Spark. The HPE Data Fabric Database OJAI Connector for Apache Spark is a companion to the [HPE Data Fabric Database Binary Connector for Apache Spark](#) on page 5491, which provides the equivalent functionality for HPE Data Fabric Database Binary tables.

### HPE Data Fabric Database OJAI Connector with Spark Workflow

You can use the HPE Data Fabric Database OJAI Connector to extract data from HPE Data Fabric Database or file system and transform that data using either Spark or Spark SQL, and then load it into HPE Data Fabric Database JSON:

## HPE Data Fabric Database OJAI Connector for Apache Spark Features

Principal features of the HPE Data Fabric Database OJAI Connector for Apache Spark include the following:

- Support for Scala and, beginning with EEP 4.1, Java and Python APIs

This matrix shows the programming languages and features supported:

	Scala	Java	Python
RDD	Yes	Yes	No
DataFrame	Yes	Yes	Yes
Dataset	Yes	Yes	No
DStream	Yes	No	No

- APIs that enable you to load data from a HPE Data Fabric Database JSON table to an Apache Spark RDD, DataFrame, or Dataset
- Projection and filter pushdown for better performance
- Custom partitioner for RDDs that enables you to partition data for better performance
- APIs that save an Apache Spark RDD, DataFrame, or DStream to a HPE Data Fabric Database JSON table using either normal or bulk insert
- Support for Scala and Java bean classes
- Support for data locality
- Support for secondary indexes starting from EEP 7.0.0 and EEP 6.3.1.

The following features are not supported:

- HPE Data Fabric Database Binary tables  
Only HPE Data Fabric Database JSON tables are supported; access to HPE Data Fabric Database binary tables is provided through the HPE Data Fabric Database Binary Connector.
- Secondary indexes are not supported for previous EEP 7.0.0 and EEP 6.3.1 versions.

## Supported Product Versions and System Requirements

To use the HPE Data Fabric Database OJAI Connector for Apache Spark, you must have the following minimum software versions:

- MapR: 5.2.1 or later
- EEP 3.0 or later
- Spark 2.1.0 or later
- Scala 2.11 or later
- Java 8 or later

Support for DataFrames and Datasets is available starting in the EEP 4.0 release.

## OJAI API

The HPE Data Fabric Database OJAI Connector for Apache Spark uses the [OJAI API](#) internally to access HPE Data Fabric Database JSON tables.

### More information

[Spark SQL, DataFrames and Datasets Guide](#)

[Spark Streaming Programming Guide](#)

*Configuring the HPE Data Fabric Database OJAI Connector for Apache Spark*

Before using the HPE Data Fabric Database OJAI Connector for Apache Spark, you must edit the `pom.xml` file for your project.

Add the Spark core dependency into the `pom.xml` file:

**NOTE:** If all dependent JAR files are already present on the node, consider setting the scope parameter to `provided`. For example:

```
<scope>provided</scope>
```

Setting the scope this way reduces the size of the JAR file.

```
<dependency>
 <groupId>org.apache.spark</groupId>
 <artifactId>spark-core_<scala_version></artifactId>
 <version><spark_artifact_version></version>
</dependency>
```

Add the Spark Maven dependency to the `pom.xml` file:

```
<dependency>
 <groupId>com.mapr.db</groupId>
 <artifactId>maprdb-spark</artifactId>
 <version><spark_artifact_version></version>
</dependency>
```

For example, see the dependencies for Spark 2.4.4.0 (EEP 6.3.0 release):

```
<dependency>
 <groupId>org.apache.spark</groupId>
 <artifactId>spark-core_2.11</artifactId>
 <version>2.4.4.0-mapr-630</version>
</dependency>
<dependency>
 <groupId>com.mapr.db</groupId>
 <artifactId>maprdb-spark</artifactId>
 <version>2.4.4.0-mapr-630</version>
</dependency>
```

To enable Maven to download dependencies, add the following repository information to the `pom.xml` file:

```
<repository>
 <id>mapr-releases</id>
 <url>https://repository.mapr.com/maven/</url>
 <snapshots>
 <enabled>false</enabled>
 </snapshots>
 <releases>
 <enabled>true</enabled>
```

```
</releases>
</repository>
```

[Maven Artifacts for the HPE Data Fabric](#) on page 5559

Maven artifacts can be used for dependency management when developing applications based on the the HPE Data Fabric.

### *Loading Data from HPE Data Fabric Database Using the HPE Data Fabric Database OJAI Connector for Apache Spark*

The HPE Data Fabric Database OJAI Connector for Apache Spark supports loading data as an Apache Spark RDD. Starting in the EEP 4.0 release, the connector introduces support for Apache Spark DataFrames and Datasets. DataFrames and Datasets perform better than RDDs. Whether you load your HPE Data Fabric Database data as a DataFrame or Dataset depends on the APIs you prefer to use. It is also possible to convert an RDD to a DataFrame.

#### Loading Data from HPE Data Fabric Database as an Apache Spark RDD

You can use the following API to load JSON-format data from a HPE Data Fabric Database table into an Apache Spark RDD of a JSON document:

##### Scala

For loading as an RDD, apply the following method on a SparkContext object:

```
def loadFromMapRDB[T](table: String):
 RDD[T]
```

##### Java

For loading as an RDD, apply the following method on a MapRDBJavaSparkContext object:

```
mapRDBSparkContext.loadFromMapRDB(tabl
eName: String, clazz: Class)
```

**NOTE:** The only required parameter to the methods is tableName. All the others are optional.

The following example creates a userprofilesRDD by calling loadFromMapRDB from SparkContext (Scala) or MapRDBSparkContext (Java) and supplying the table ("/tmp/user\_profiles"):

##### Scala

```
import com.mapr.db.spark._

val userprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles")
```

##### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
```

The following example creates a `userInfo` RDD by calling `loadFromMapRDB` from `SparkContext` (Scala) or `MapRDBSparkContext` (Java) and supplying the table ("`/tmp/UserInfo`"):

**Scala**

```
import com.mapr.db.spark._

val userInfo =
 sc.loadFromMapRDB("/tmp/UserInfo")
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAIObject> userInfo
=
mapRDBSparkContext.loadFromMapRDB("/tm
p/UserInfo")
```

In the previous example, the `userInfo` data contains the following information:

- Address (map type)
- Date of birth (date type)
- First name (string type)
- Interests (string type)
- Last name (string type)

The following prints the fields and shows the output for a sample user:

**Scala**

```
userInfo.foreach(println(_))
```

**Java**

```
userInfo.foreach(System.out::println)
;
```

```
{
 "address":
 {"Pin":95035,"city":"milpitas","street":"350 holger way"},
 "dob":"1947-11-29",
 "first_name":"David",
 "interests":["football","books","movies"],
 "last_name":"Jones"
}
```

The following example shows a join operation performed on two different JSON documents using `address.city` as the join key:

**Scala**

```
import com.mapr.db.spark._

val maprd1 = sc.loadFromMapRDB("/tmp/
user_profiles")

val maprd2 = sc.loadFromMapRDB("/tmp/
user_income")
```

```
val collection = maprd1.map(a =>
(a.`address.city`[String],a))
.cogroup(maprd2.map(a=>(a.`address.city`[String],a)))
.map(a =>
(a._1,a._2._1.size,a._2._2.size)).collect
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaSparkContext;
import scala.Tuple2;
import scala.Tuple3;
import java.util.Collection;

MapRDBJavaRDD<OJAIDocument> maprd1 =
mapRDBSparkContext.loadFromMapRDB("/tmp/user_profiles");
MapRDBJavaRDD<OJAIDocument> maprd2 =
mapRDBSparkContext.loadFromMapRDB("/tmp/user_income");

List collection =
maprd1.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a))
.cogroup(maprd2.mapToPair(a -> new
Tuple2<>(a.getString("address.city"),
a)))
.map(a -> new Tuple3<>(a._1,
((Collection<?>)a._2._1).size(),
((Collection<?>)a._2._2).size()))
.collect();
```

The resulting RDD, collection, contains the count of the users in the user\_profiles and user\_income HPE Data Fabric Database tables.

The following example adds a new field into all the JSON documents:

**Scala**

```
import com.mapr.db.spark._

val maprd = sc.loadFromMapRDB("/tmp/user_profiles")
val documents = maprd.map(a =>
{ a.`address.country` = "USA";
a}).collect
documents.saveToMapRDB("/tmp/cleaned_user_profiles")
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaSparkContext;

MapRDBJavaRDD<OJAIDocument> maprd =
mapRDBSparkContext.loadFromMapRDB("/tmp/user_profiles");
List<OJAIDocument> documents =
```

```
maprd.map(a ->
{a.set("address.country", "USA");
return a;})

.collect();
mapRDBSparkContext.saveToMapRDB(docume
nts, "/tmp/cleaned_user_profiles");
```

### Improving Performance by Using Projection Pushdown and Filter Pushdown

To improve performance, you can supply a WHERE clause and projection fields to the `loadFromMapRDB` API. In the following example, a condition is supplied to the `loadFromMapRDB` function and only certain fields are specified in the SELECT clause:

#### Scala

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")

 .where([condit
ion])
 .select("addre
ss",
"first_name",
 "_id",
"last_name")
```

#### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")

 .where([condition])
 .select("address",
"first_name",
 "_id",
"last_name");
```

The data is loaded based on the condition. The condition is pushed down to the server, and the server returns data based on the filtering. Only the fields specified in the SELECT clause are projected.

In the following example, the WHERE clause is used as a filter condition:

**Scala**

```
import com.mapr.db.spark._

val userprofilesRDD =
 sc.loadFromMapRDB("/tmp/
 user_profiles")
 .where(field("sa
 lary") >= 100)
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
.where(MapRDB.newCondition().is("salar
y",
QueryCondition.Op.GREATER_OR_EQUAL,
100));
```

The `userprofilesRDD` includes only those documents with a salary field greater than 100.

By specifying an `_id` field, you can find and retrieve a row for a given key:

**Scala**

```
import com.mapr.db.spark._

val userprofilesRDD =
 sc.loadFromMapRDB("/tmp/
 user_profiles")
 .where(field("_i
 d") === "k2")
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import org.ojai.store.QueryCondition;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
 .where(MapRDB.newCon
 dition().is("_id",
 QueryCondition.Op.EQUAL, "k2"));
```

**WHERE Clause Semantics**

The `loadFromMapRDB` API supports a `WHERE` clause to push down the filter to the JSON document API, ensuring that only relevant documents are propagated to the RDD.

You can use two options to provide the filter condition:

- Scala domain-specific language (DSL)
- `QueryCondition` (from OJAI API)

Following is an example of using `loadFromMapRDB` and supplying a condition by using Scala DSL:

#### Scala

```
Condition isDoe = field("last_name")
=== "Doe"
val userprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles").where(isDoe)
```

For more information about using Scala DSL, see [Scala DSL for Specifying Filter Conditions](#) on page 5450.

Following is an example of passing the condition using the `QueryCondition` API:

#### Scala

```
val maprd =
sc.loadFromMapRDB(tableName)
 .where(MapRDB.newConditio
n()
 .is("_id",
QueryCondition.Op.EQUAL, "k2")
 .build())
```

#### Java

```
MapRDBJavaRDD rdd =
mapRDBJavaSparkContext.loadFromMapRDB(
tableName)
 .where(MapRDB.newConditio
n().is("_id",
QueryCondition.Op.EQUAL,
"k2").build());
```

For more information about `QueryCondition`, see [Querying with Conditions](#) on page 3831.

**NOTE:** For additional information, see [Java Examples](#) in the source code.

### Creating an Apache Spark RDD of a Class

When loading data as an Apache Spark RDD, if you have a custom class in your application, you can present the data as objects of your class.

#### Scala

You must define the custom class using Jackson semantics for Scala modules. The following example defines a custom `User` class:

```
case class User (@JsonProperty("_id")
id:String,

@JsonProperty("first_name")
firstName:String,

@JsonProperty("last_name") lastName:
String,
@JsonProperty("dob") dob:
ODate,
```

```
@JsonProperty("interests") interests:
List[String])
```

In the following example, by supplying User as a type parameter to the function while loading the HPE Data Fabric Database table, you can create an RDD of the User class:

```
val userprofilesRDD =
sc.loadFromMapRDB[User]("/tmp/
user_profiles")
 .where("conditio
n")
```

When specifying a bean class, the SELECT clause is unnecessary and is ignored.

You must define a custom bean class as follows:

```
public static class Person implements
Serializable {
 private String _id;
 private String firstName;
 private String lastName;
 private Date dob;
 private Seq<String>
interests;
 public String get_id()
{ return _id; }
 public void set_id(String
_id) { this._id = _id; }
 public String
getFirstName() { return firstName; }
 public void
setFirstName(String firstName)
{ this.firstName = firstName; }
 public String
getLastName() { return lastName; }
 public void
setLastName(String lastName)
{ this.lastName = lastName; }
 public Date getDob()
{ return dob; }
 public void setDob(Date
dob) { this.dob = dob; }
 public Seq<String>
getInterests() { return interests; }
 public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
}
```

In the following example, by supplying the User bean class as a type parameter while loading the HPE Data Fabric Database table, you can create a MapRDBJavaRDD of the User class:

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
```

## Java

```
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkContext());
MapRDBJavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tmp/user_profiles",
User.class).where(<condition>);
```

### Scala DSL for Specifying Filter Conditions

When loading data from HPE Data Fabric Database as an Apache Spark RDD, you can use Scala DSL to specify filter conditions. This section shows examples of these filter conditions.

In the following examples, a class named `field` is introduced to represent a field in a condition. The `field` condition takes an argument as a String. The following table shows conditions written using Scala DSL:

Condition	Example
equality	<pre>val idOnlyPredicate = field("_id") === "k2"</pre>
greaterThan	<pre>val simplePredicateWithComparisonOperator = field("a.c.d") &gt; 10</pre>
notexists	<pre>val simpleNotExistsPredicate = field("a.c.e") notexists</pre>
IN	<pre>val inPredicate = field("a.c.d") in Seq(0Date.parse("2011-05-21"), 0Date.parse("2013-02-22"))</pre>
typeof	<pre>val simpleTypeOfPredicate = field("a.c.d") typeof "INT"</pre>
complex condition with and	<pre>val inPredicateWithMapAndArray = (field("a.c.d") in Seq(5,10)) and (field("a.c.e") notin Seq("aaa","bbb"))</pre>
another complex condition	<pre>val compositePredicateWithAndOnly = ((field("a.b") notexists ) and (field("p.q") typeof "DATE")) and (field("a.c.d") &gt; 20L)</pre>
between	<pre>val predicateWithBetweenOp = field("a.c.d") between (0Date.parse("2015-01-15"), 0Date.parse("2015-05-15"))</pre>
predicate with equality check on Sequence of elements (representing array)	<pre>val eqPredicateWithList = field("a.b") === Seq(12345L, "xyz")</pre>

Condition	Example
predicate with equality check on a map	<pre>val eqWithMapPredicate = field("a") === Map("k" -&gt; "kite",                                              "m" -&gt; "map")</pre>

The HPE Data Fabric Database OJAI Connector for Apache Spark supports these predicates:

- >
- >=
- <
- <=
- ===
- !=
- between
- exists
- notin
- in
- notexists
- typeof
- nottypeof
- like
- notlike
- matches
- notmatches
- sizeof

Here are examples for these operators:

- `field("a") > 10`
- `field("a") >= 10`
- `field("a") < 10`
- `field("a") <= 10`
- `field("a") === 10`
- `field("a") === Seq("aa", 10)`
- `field("a") === Map("aa" -> 10)`

- `field("a") != 10`
- `field("a") != Seq("aa", 10)`
- `field("a") != Map("aa" -> 10)`
- `field("a") between (10,20)`
- `field("a") exists`
- `field("a") notin Seq(10,20)`
- `field("a") in Seq(10, 20)`
- `field("a") notexists`
- `field("a") typeof "INT"`
- `field("a") nottypeof "INT"`
- `field("a") like "%s"`
- `field("a") notlike "%s"`
- `field("a") matches "*s"`
- `field("a") notmatches "*s"`

For `typeof`, these are the right-hand side values:

- `"INT"`
- `"INTEGER"`
- `"LONG"`
- `"BOOLEAN"`
- `"STRING"`
- `"SHORT"`
- `"BYTE"`
- `"NULL "`
- `"FLOAT"`
- `"DOUBLE"`
- `"DECIMAL "`
- `"DATE"`
- `"TIME"`
- `"TIMESTAMP"`
- `"INTERVAL "`

- "BINARY"
- "MAP"
- "ARRAY"

The `sizeof` operator can have the following operations:

- `sizeof(field("a")) === 10`
- `sizeof(field("a")) < 10`
- `sizeof(field("a")) > 10`
- `sizeof(field("a")) >= 10`
- `sizeof(field("a")) <= 10`
- `sizeof(field("a")) != 10`

#### Java DSL for Specifying Filter Conditions

When loading data from HPE Data Fabric Database as an Apache Spark RDD, you can use Java DSL to specify filter conditions. This section shows examples of these filter conditions.

Condition	Example
equality	<pre>QueryCondition equality = MapRDB.newCondition().is("_id", QueryCondition.Op.EQUAL, "k2").build();</pre>
greatherThan	<pre>QueryCondition greatherThan = QueryCondition simpleWithComparisonOperator = MapRDB.newCondition().is("a.b.c", QueryCondition.Op.GREATER, 10).build();</pre>
notexists	<pre>QueryCondition notexists = MapRDB.newCondition().notExists("a.c.e").build();</pre>
IN	<pre>List&lt;ODate&gt; odateList = new ArrayList&lt;&gt;(); odateList.add(ODate.parse("2011-05-21")); odateList.add(ODate.parse("2013-02-22")); QueryCondition in = MapRDB.newCondition().in("a", odateList).build();</pre>
typeof	<pre>QueryCondition typeOf = MapRDB.newCondition().typeOf("a.c.d", Value.Type.INT).build();</pre>
complex condition with and	<pre>QueryCondition complexConditionWithAnd = MapRDB.newCondition() .and() .condition(MapRDB.newCondition().in("a", Arrays.asList(5, 10))) .condition(MapRDB.newCondition().notIn("b", Arrays.asList("aaa", "bbb"))) .close().build();</pre>

Condition	Example
another complex condition	<pre>QueryCondition anotherComplexCondition = MapRDB.newCondition()     .and()     .condition(MapRDB.newCondition().notExists("a.b"))     .condition(MapRDB.newCondition().typeOf("p.q", Value.Type.DATE))     .condition(MapRDB.newCondition().is("a.c.d",     QueryCondition.Op.GREATER, 20L))     .close().build();</pre>

The HPE Data Fabric Database OJAI Connector for Apache Spark supports these predicates:

- is (LESS, LESS\_OR\_EQUAL, EQUAL, NOT\_EQUAL, GREATER\_OR\_EQUAL, GREATER)
- equals
- and
- exists
- in
- like
- matches
- notEquals
- notExists
- notIn
- notLike
- notMatches
- notTypeOf
- or
- sizeOf
- typeOf

Here are examples for these operators:

- MapRDB.newCondition().is("a", QueryCondition.Op.GREATER, 10);
- MapRDB.newCondition().is("a",QueryCondition.Op.GREATER\_OR\_EQUAL, 10);
- MapRDB.newCondition().is("a", QueryCondition.Op.LESS, 10);
- MapRDB.newCondition().is("a", QueryCondition.Op.LESS\_OR\_EQUAL, 10);
- MapRDB.newCondition().is("a", QueryCondition.Op.EQUAL, 10);
- MapRDB.newCondition().is("a", QueryCondition.Op.NOT\_EQUAL, 10);
- MapRDB.newCondition().exists("a");

- `MapRDB.newCondition().notIn("a", Arrays.asList(10, 20));`
- `MapRDB.newCondition().in("a", Arrays.asList(10, 20));`
- `MapRDB.newCondition().notExists("a");`
- `MapRDB.newCondition().typeOf("a", Value.Type.INT);`
- `MapRDB.newCondition().notTypeOf("a", Value.Type.INT);`
- `MapRDB.newCondition().like("a", "%s");`
- `MapRDB.newCondition().notLike("a", "%s");`
- `MapRDB.newCondition().matches("a", "*s");`
- `MapRDB.newCondition().notMatches("a", "*s");`

For `typeOf`, these are the right-hand side values:

- `"INT"`
- `"INTEGER"`
- `"LONG"`
- `"BOOLEAN"`
- `"STRING"`
- `"SHORT"`
- `"BYTE"`
- `"NULL"`
- `"FLOAT"`
- `"DOUBLE"`
- `"DECIMAL"`
- `"DATE"`
- `"TIME"`
- `"TIMESTAMP"`
- `"INTERVAL"`
- `"BINARY"`
- `"MAP"`
- `"ARRAY"`

The `sizeOf` operator can have the following operations:

- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.EQUAL, 10);`

- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.LESS, 10);`
- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.GREATER, 10);`
- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.LESS_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.GREATER_OR_EQUAL, 10);`
- `MapRDB.newCondition().sizeOf("a", QueryCondition.Op.NOT_EQUAL, 10);`

#### Using the Custom Partitioner with the HPE Data Fabric Database OJAI Connector for Apache Spark

In any distributed computing system, partitioning data is crucial to achieve the best performance. Apache Spark provides a mechanism to register a custom partitioner for partitioning the pipeline. The HPE Data Fabric Database OJAI Connector for Apache Spark includes a custom partitioner you can use to optimally partition data in an RDD.

The HPE Data Fabric Database OJAI Connector for Apache Spark's custom partitioner takes the following classes as keys:

- `String`
- `ByteBuffer` (as serializable `ByteBuffer`)

You can register this custom partitioner with either the `partitionBy` function or the `repartitionAndSortWithinPartitions` function.

The connector supports two versions of the custom partitioner. One version takes a HPE Data Fabric Database JSON table as an input. The partition information of the table is used to partition the data, so the `saveToMapRDB` call can use a `bulkInsert` to store the data. The `bulkInsert` option requires that you have the data already sorted on the `_id` key.

The other version of the custom partitioner takes an array of splits as an input.

#### Specifying tablename for the Partitioner

If you already have a table that has been created and partitioned based on a set of keys, you can specify that the RDD be partitioned in the same way (using the same set of keys). In the following example, `/srctable` is provided as a reference partitioner for `/dsttable`:

**Scala**

```
sc.loadFromMapRDB("/srctable")
 .keyBy(doc =>
doc._id[String])
 .repartitionAndSortWithinP
artitions(MapRDBSpark.newPartitioner[S
tring]("/dsttable"))
 .saveToMapRDB("/
dsttable", createTable = false,
bulkInsert = true)
```

#### Specifying a String Seq as an Array of Splits

In the following example, the first line creates an array of splits as `id1, id2 ... id9`. The rest of the example splits the RDD based on the array of splits:

**Scala**

```
val dstSplits: Array[String] = (1 to
9 by 3).map("id" + _).toArray
val partitionRDD =
sc.loadFromMapRDB("/srctable")
```

```

 .keyBy(doc =>
doc._id[String])
 .repartitionAndSortWithinPartitions(MapRDBSpark.newPartitioner[String](dstSplits))
 .saveToMapRDB("/dsttable", createTable = true, bulkInsert = true)

```

### Specifying a ByteBuffer Seq as an Array of Splits

Suppose you have an array of byte buffers to use as the array of splits for the partitioner. You must convert the byte buffers to serializable byte buffers first:

Scala

```

// Converting bytebuffer to serializable bytebuffer
val dstSplits =
 arrayOfByteBuffer.map(x => MapRDBSpark.serializableBinaryValue(x))
sc.loadFromMapRDB("/srctable")
 //KeyBy serializable bytebuffer
 .keyBy(doc => doc.getBinarySerializable(binaryField))
 .repartitionAndSortWithinPartitions(
 MapRDBSpark.newPartitioner(dstSplits))
 .saveToMapRDB("/dsttable", createTable = true, bulkInsert = true)

```

### Specifying tablename for the Partitioner with ByteBuffer as Id Fields

Suppose you have a table with keys that are binary or ByteBuffer, and you have an RDD with some rows and some values. You can repartition the RDD based on the partitions of the table. The following example reads the document from /srctable, but you could provide any table. In the second line, the example specifies a keyBy call on an ID that is binary serializable. In the last line, /dsttable is the RDD that has a key of serializable ByteBuffer s:

Scala

```

sc.loadFromMapRDB("/srctable")
 .keyBy(doc => doc.getIdBinarySerializable())
 .repartitionAndSortWithinPartitions(
 MapRDBSpark.newPartitioner[ByteBuffer]("/dsttable"))

```

**NOTE:** You must provide the key type of the PairedRDD on which the partitioning is specified. If the IDs are serializable bytebuffers, specify ByteBuffer. Otherwise, specify String.

After the data is partitioned with the custom partitioner, all the downstream transformations should be non-partition-changing transformations. Here is the code for passing on partitioner for an RDD:

Scala

```

user_profiles.repartitionAndSortWithinPartitions(
 (MapRDBSpark.newPartitioner[String](<table-name>))

```

Or you can use the `partitionBy` function on the RDD:

#### Scala

```
user_profiles.partitionBy(MapRDBSpark.
newPartitioner[String](<table-name>))
```

The key of the data for this partitioner should be of the same type as that of the key of the table name. This partitioner yields a single partition if the table supplied to it is not pre-split. The number of partitions is calculated based on the table's existing tablet information.

For a table created with the `bulkInsert` option set to `true`, one of the following applies:

- If the table is pre-split, then the resulting partitions can be  $> 1$ .
- If the table is no-split, then the resulting partitions will be 1 if no partition information is available from the RDD lineage.

### Loading Data from HPE Data Fabric Database as an Apache Spark DataFrame

To load data from a HPE Data Fabric Database JSON table into an Apache Spark DataFrame, invoke the following API:

#### Scala

For loading as a DataFrame, apply the following method on a `SparkSession` object:

```
def loadFromMapRDB[T](tableName:
String,
 schema: StructType):
DataFrame

import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB[T]
("/tmp/user_profiles"): DataFrame
```

#### Java

For loading as a DataFrame (Datasets of Row), apply the following method on a `MapRDBJavaSession` object:

```
def loadFromMapRDB(tableName: String,
schema: StructType, sampleSize:
Double): DataFrame

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
maprSession.loadFromMapRDB("/tmp/
user_profiles");
```

**NOTE:** Java supports only DataSets of Row (`Dataset<Row>`).

**Python**

For loading as a DataFrame, apply the following method on a SparkSession object:

```
loadFromMapRDB(table_name, schema,
sample_size)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")
```

**NOTE:** PySpark supports only DataFrames (Dataset<Row>).

**NOTE:** The only required parameter to the methods is tableName. All the others are optional.

This creates a DataFrame object corresponding to the HPE Data Fabric Database table specified by the tableName parameter.

Both DataFrames and HPE Data Fabric Database tables work with structured data. DataFrames need a fixed schema, whereas HPE Data Fabric Database allows for a flexible schema. When loading data into a DataFrame, you can map your data to a schema by specifying the schema parameter in the loadFromMapRDB call. You can also provide an application class as the type [T] parameter in the call. These two approaches are the preferred methods for loading data into DataFrames.

For data exploration use cases, you might not know the schema of your HPE Data Fabric Database table. For those situations, the HPE Data Fabric Database OJAI connector for Apache Spark can infer the schema by sampling data from the table.

Whenever possible, the HPE Data Fabric Database OJAI Connector for Apache Spark [pushes projections and filters](#) for better performance. This allows HPE Data Fabric Database to project and filter data before returning it to your client application.

The following subtopics describe these techniques.

#### Optimizing HPE Data Fabric Database Lookups in Spark Jobs

The lookupFromMapRDB( ) API utilizes the primary and secondary indexes on a HPE Data Fabric Database table to optimize table lookups and outputs the results to an Apache Spark DataFrame.

**IMPORTANT:** The lookupFromMapRDB( ) API functionality requires a patch. The patch works with EEP 6.2.0 (Core 6.1.0, Spark 2.4.0.0) and EEP 6.3.0 (Core 6.1.0, Spark 2.4.4.0). To install patches, see [Applying a Patch](#)

The loadFromMapRDB( ) API in [MapR Database Connectors for Apache Spark](#) is optimized to load massive amounts of data from HPE Data Fabric Database tables with high throughput. In cases where a Spark job needs to lookup a small number of documents based on the equality (or short range) condition on a primary or secondary key, the lookupFromMapRDB( ) API should be used.

Invoke the lookupFromMapRDB( ) API when the filter conditions in short range and equality queries reference primary and secondary keys. If the filter condition references any non-primary keys (fields other than the \_id field), a secondary index must exist on the secondary keys. Indexes on the filtering keys is essential to achieving reasonable performance of lookup queries in HPE Data Fabric Database tables.

The lookupFromMapRDB( ) API uses the secondary keys in indexes to lookup values in the primary table. For example, if a query contains the filter conditions mydate = '2012-03-26' and myid = '120026015', a [secondary index](#) (of type composite) created on the mydate and myid fields must exist for the query to quickly output results.

Examples on the following tabs demonstrate how to invoke the lookupFromMapRDB( ) API to perform a lookup in a HPE Data Fabric Database table and output the results to an Apache Spark DataFrame:

**Scala**

```
import com.mapr.db.spark.sql._
import spark.implicits._
val df = spark.lookupFromMapRDB("/tbl")
df.filter("mydate" === "2012-03-26"
 && $"myid" === 120026015).show
```

**Java**

```
SparkSession sparkSession =
SparkSession.builder().getOrCreate();
MapRDBJavaSession mapRDBJavaSession =
new MapRDBJavaSession(sparkSession);
Dataset<Row> df2 =
mapRDBJavaSession.lookupFromMapRDB("/tbl");
df2.filter("mydate = '2012-03-26' and
myid = '120026015']").show();
```

**Python**

```
from pyspark.sql import SparkSession
df = spark.lookupFromMapRDB("/tbl")
df.filter("mydate = '2012-03-26' and
myid = '120026015']").show()
```

**Loading Data into a DataFrame Using an Explicit Schema**

If you know the schema of your data, you can specify an explicit schema when loading a DataFrame.

The following example loads data into a user profile table using an explicit schema:

**Scala**

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val addressSchema =
StructType(StructField("Pin",
IntegerType) ::

StructField("city", StringType) ::

StructField("street", StringType) ::
Nil)

val personSchema =
StructType(StructField("_id",
StringType) ::

StructField("first_name",
StringType) ::

StructField("last_name",
StringType) ::

StructField("address",
addressSchema) ::

StructField("interests",
ArrayType(StringType)) :: Nil)

val df
```

**Java**

```
= sparkSession.loadFromMapRDB("/tmp/
user_profiles", personSchema)
```

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.Session;

StructField[] addressSchema = {
 new
 StructField("Pin", IntegerType, true,
 Metadata.empty()),
 new
 StructField("city", StringType, true,
 Metadata.empty()),
 new
 StructField("street", StringType,
 true, Metadata.empty())
};
StructField[] schemaFields = {
 new StructField("_id", StringType,
 true, Metadata.empty()),
 new StructField("first_name",
 StringType, true, Metadata.empty()),
 new StructField("address", new
 StructType(addressSchema), true,
 Metadata.empty()),
 new StructField("interests", new
 ArrayType(StringType, true), true,
 Metadata.empty())
};
StructType personSchema = new
StructType(schemaFields);
MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles", personSchema);
```

**Python**

```
from pyspark.sql import SparkSession

addressSchema = [StructField("Pin",
IntegerType(), True),
 StructField("city",
StringType(), True),

StructField("street", StringType(),
True)]
schemaFields = [StructField("_id",
StringType(), True),

StructField("first_name",
StringType(), True),

StructField("last_name",
StringType(), True),

StructField("address",
StructType(addressSchema), True),
```

```
StructField("interests",
ArrayType(StringType()), True)]
personSchema =
StructType(schemaFields)

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles", personSchema)
```

To create the DataFrame object named `df`, pass the schema as a parameter to the load call. Invoke the `loadFromMapRDB` method on a `SparkSession` object.

The resulting schema of the object is the following:

```
df.printSchema()

root
|-- _id: String (nullable = true)
|-- first_name: String (nullable = true)
|-- last_name: String (nullable = true)
|-- address: Struct (nullable = true)
| |-- Pin: integer (nullable = true)
| |-- city: string (nullable = true)
| |-- street: string (nullable = true)
|-- interests: array (nullable = true)
| |-- element: string (containsNull = true)
```

When specifying `StructField` in a schema, optionally specify whether the field is nullable. In the example above, all fields are nullable.

Depending on the nullability of the field in the schema and the existence of fields in the HPE Data Fabric Database table, the load returns an `InvalidSchema` exception in the following cases:

- The schema contains a non-nullable field and the load attempts to put a NULL value into the field.
- The schema contains a non-nullable field and the field does not exist in the HPE Data Fabric Database table.
- The HPE Data Fabric Database table has fields that do not exist in the specified schema.

#### Loading Data into a DataFrame Using a Type Parameter

If the structure of your data maps to a class in your application, you can specify a type parameter when loading into a DataFrame.

Specify the application class as the type parameter in the load call. The load infers the schema from the class.

The following example creates a DataFrame with a `Person` schema by passing the `Person` class as the type parameter in the load call:

#### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)

case class Person(_id:
String,
```

**Java**

```

 First_name: String,
 last_name: String,
 Address: Address,
 Interests: Seq[String])

val df
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles")

```

```

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;
import
org.apache.spark.sql.SparkSession;

public static class Address
implements Serializable {
 private Integer pin;
 private String street;
 private String city;

 public Integer getPin() { return
pin; }
 public void setPin(Integer pin)
{ this.pin = pin; }
 public String getStreet()
{ return street; }
 public void setStreet(String
street) { this.street = street; }
 public String getCity() { return
city; }
 public void setCity(String city)
{ this.city = city; }
}
public static class Person implements
Serializable {
 private String _id;
 private String firstName;
 private String lastName;
 private Date dob;
 private Seq<String> interests;

 public String get_id() { return
_id; }
 public void set_id(String _id)
{ this._id = _id; }
 public String getFirstName()
{ return firstName; }
 public void setFirstName(String
firstName) { this.firstName =
firstName; }
 public String getLastName()
{ return lastName; }
 public void setLastName(String
lastName) { this.lastName =
lastName; }
 public Date getDob() { return
dob; }
 public void setDob(Date dob)
{ this.dob = dob; }
 public Seq<String>

```

```
getInterests() { return interests; }
 public void
setInterests(Seq<String> interests)
{ this.interests = interests; }
}
MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB(tableName,
Person.class);
```

You must invoke the `loadFromMapRDB` method on a `SparkSession` or `MapRDBJavaSession` object.

All fields in an application bean class are nullable by default. The only circumstance in which the load returns an `InvalidSchema` exception is if the HPE Data Fabric Database table contains fields not included in the bean class.

The resulting schema of the object is as follows:

```
df.printSchema()

root
|-- _id: String (nullable = true)
|-- first_name: String (nullable = true)
|-- last_name: String (nullable = true)
|-- address: Struct (nullable = true)
| |-- Pin: integer (nullable = true)
| |-- street: string (nullable = true)
| |-- city: string (nullable = true)
|-- interests: array (nullable = true)
| |-- element: string (containsNull = true)
```

### Loading Data into a DataFrame Using Schema Inference

If you do not know the schema of the data, you can use schema inference to load data into a `DataFrame`. This section describes how to use schema inference and restrictions that apply

When you do not specify a schema or a type when loading data, schema inference triggers automatically. The HPE Data Fabric Database OJAI Connector for Apache Spark internally samples documents from the HPE Data Fabric Database JSON table and determines a schema based on that data sample. By default, the sample size is 1000 documents. Alternatively, you can specify a sample size parameter. The parameter is optional in the `loadFromMapRDB` call and is named `sampleSize`. The following example specifies using a sample size of 100 documents:

#### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df =
sparkSession.loadFromMapRDB(tableName,
sampleSize : 100)
```

#### Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJavaSession;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
```

```
Dataset<Row> df =
maprSession.loadFromMapRDB(tableName,
100);
```

### Python

```
from pyspark.sql import SparkSession

df = spark.loadFromMapRDB(table_name,
100)
```

**IMPORTANT:** Because schema inference relies on data sampling, it is non-deterministic. It is not well suited for production use where you need predictable results. Inferring schema results in reading sample rows from the table, hence execution time varies with number of rows in the source table.

## Sampling Using Reader Functions

An alternative to sampling data using the `loadFromMapRDB` call is to use reader functions.

To use the `DataFrame` reader function (for Scala only), call the following methods:

```
val df = sparkSession.read.maprdb(tableName)
```

To use the reader function with basic Spark, call the `read` function on a `SQLContext` object as follows:

### Scala

```
import org.apache.spark.sql.SQLContext

val df =
sqlContext.read.format("com.mapr.db.spark.sql")
 .option("tableName",
<table-name>)
 .option("sampleSize",
100).load()
```

### Java

```
import
org.apache.spark.sql.SQLContext;

Dataset<Row> df = sqlContext.read()
 .format("com.mapr.db
 .spark.sql")
 .option("tableName",
<table-name>).load();
```

### Python

```
from pyspark.sql import SQLContext

df = sql_context.read\
 .format("com.mapr.db.spark.sql.De
 faultSource")\
 .option("tableName",
<table-name>).load()
```

## Type Conflict Resolution When Sampling

When sampling data during schema inference, you might encounter conflicting value types within a field. The connector uses the following rules to resolve type conflicts:

- If the two conflicting types are each one of the following, the resolved type is the wider of the two types:
  - `ByteType`
  - `ShortType`
  - `IntegerType`
  - `LongType`
  - `FloatType`
  - `DoubleType`

The type list above is arranged in increasing order of width. For example, if one document contains a field of type `ByteType` and the other contains a field of type `FloatType`, the resultant type is `FloatType`.

- If one of the types is `DecimalType`, then the resultant type is `DecimalType`, if and only if `DecimalType` is the wider of the two types.
- If the two types are `StructType`, each with different fields, then the resultant type is a new `StructType` that contains all the fields in each `StructType`.
- If the two types are `ArrayType`, each with different element types, then the resultant type is a new `ArrayType` where the type of the elements in the array is resolved using the aforementioned rules.
- If none of the above rules can be used for resolving type conflicts, then during data conversion, the load reports a `ConflictType` exception.

Suppose `Name` contains `String` values in some rows and a map with `first_name` and `last_name` as nested fields in other rows. During schema inference, the conflict resolution logic encounters two different types for the same field, `StringType` and `MapType`. It will note the conflict and return a `ConflictType` exception later when converting the data during the load.

By default, conflict exceptions occur during data conversion. To change this so that the exception is returned during the conflict resolution stage, set the `FailOnConflict` option to `true` :

**Scala**

```
val df =
 spark.read.maprdb(<tableName>,
 Map("sampleSize" -> 100,
 "FailOnConflict" -> true))
```

## Invalid Schemas

When using schema inference, missing and extra fields are resolved in the following ways:

- If a field in the inferred schema is missing in the HPE Data Fabric Database JSON document, the field is set to null.
- If there are fields in a HPE Data Fabric Database JSON document that are not in the inferred schema, the load returns an `InvalidSchema` exception.

## Type Mapping Between HPE Data Fabric Database JSON and DataFrames

This table maps data types between HPE Data Fabric Database JSON OJAI and Apache Spark `DataFrame`.

**NOTE:** Not all DataFrame data types are supported by HPE Data Fabric Database, for a list of supported data types, see [JSON Documents](#) on page 715.

OJAI Data Type	DataFrame Data Type
Boolean	BooleanType
String	StringType
Byte	ByteType
Short	ShortType
Int	IntegerType
Long	LongType
Float	FloatType
Double	DoubleType
Decimal	DecimalType
Date	DateType
Time	TimestampType
TimeStamp	TimeStampType
Interval	CalendarIntervalType
Binary	BinaryType
Map	StructType
Array	ArrayType

**NOTE:** The OJAI Time data type is converted to a Spark TimestampType with the date set to the epoch date. Spark SQL does not support a TIME type.

## Loading Data from HPE Data Fabric Database as an Apache Spark Dataset

You can use one of three ways to load data from HPE Data Fabric Database into an Apache Spark Dataset:

- Load the data into a Dataset.
- Load the data into a DataFrame, and then convert it to a Dataset.
- Load the data into a Dataset using a custom encoder.

### Load into a Dataset

#### Scala

For loading as a Dataset, apply the following method on a SparkSession object:

```
def loadFromMapRDB[T](table: String,
 schema : StructType).as [T]: Dataset

import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[T]
("/tmp/user_profiles").as [T]: Dataset
```

**Java**

For loading as a Dataset, apply the following method on a MapRDBJavaSession object:

```
def loadFromMapRDB[T <:
java.lang.Object](tableName: String,
schema: StructType, sampleSize:
Double, clazz: Class[T]): Dataset[T]

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);

Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
```

**NOTE:** The only required parameter to the methods is tableName. All the others are optional.

**Load into DataFrame and Convert to Dataset**

To load the data as a DataFrame, see [Loading Data from HPE Data Fabric Database as an Apache Spark DataFrame](#) on page 5458. To convert the DataFrame to a Dataset, use the as[<type>] method. The <type> can be any of the basic types in Scala.

The following code example creates a Dataset[Person] using the as[<type>] method:

**Scala**

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

case class Address(Pin: Integer,
street: String, city: String)

case class Person (_id:String,
first_name:String,
last_name: String, dob:
java.sql.Date,
Interests: Seq[String,
address: Address)

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

public static class Address
implements Serializable {
private Integer pin;
private String street;
private String city;

public Integer getPin() { return
```

```

pin; }
 public void setPin(Integer pin)
 { this.pin = pin; }
 public String getStreet()
 { return street; }
 public void setStreet(String
street) { this.street = street; }
 public String getCity() { return
city; }
 public void setCity(String city)
 { this.city = city; }
}

public static class Person implements
Serializable {
 private String _id;
 private String firstName;
 private String lastName;
 private Date dob;
 private Seq<String> interests;
 public String get_id()
 { return _id; }
 public void
set_id(String _id) { this._id = _id; }
 public String
getFirstName() { return firstName; }
 public void
setFirstName(String firstName)
 { this.firstName = firstName; }
 public String
getLastName() { return lastName; }
 public void
setLastName(String lastName)
 { this.lastName = lastName; }
 public Date getDob()
 { return dob; }
 public void setDob(Date
dob) { this.dob = dob; }
 public Seq<String>
getInterests() { return interests; }
 public void
setInterests(Seq<String> interests)
 { this.interests = interests; }
}
Dataset<Person> ds =
maprSession.loadFromMapRDB(tableName,
Person.class);

```

### Load into Dataset Using Custom Encoder

You can create a custom encoder for Java bean classes by calling the `Encoders.bean` method. `Encoders.bean` only support Java classes. To create a Dataset of the Scala class, the previous code can be used. The following example shows how to load into a Dataset by creating a custom encoder for a Java class named `beanClass`:

#### Scala

```

import
org.apache.spark.sql.Session

import com.mapr.db.spark.sql._

```

```
val ds =
 sparkSession.loadFromMapRDB("/tmp/
 user_profiles")
 .as(Encoders.bean(beanClass))
```

**Java**

```
import
 com.mapr.db.spark.sql.api.java.MapRDBJ
 avaSession;

maprSession.loadFromMapRDB("/tmp/
 user_profiles").as(Encoders.bean(beanC
 lass));
```

**Filter Pushdown**

After you have loaded data into a Dataset, you can apply filter pushdowns. The following example filters on `first_name`:

**Scala**

```
ds.filter($"first_name" === "David")
```

**Java**

```
ds.filter(col("first_name").equalTo("D
 avid")).show();
```

See [Projection and Filter Pushdown with Apache Spark DataFrames and Datasets](#) on page 5470 for other examples.

**Projection and Filter Pushdown with Apache Spark DataFrames and Datasets**

Projection and filter pushdown improve query performance. When you apply the `select` and `filter` methods on DataFrames and Datasets, the HPE Data Fabric Database OJAI Connector for Apache Spark pushes these elements to HPE Data Fabric Database where possible.

**Projection Pushdown**

Projection pushdown minimizes data transfer between HPE Data Fabric Database and the Apache Spark engine by omitting unnecessary fields from table scans. It is especially beneficial when a table contains many columns.

When you invoke the following `select` method on a DataFrame, the connector pushes the projection:

**Scala**

```
import
 org.apache.spark.sql.SparkSession
 import com.mapr.db.spark.sql._

val df
 = sparkSession.loadFromMapRDB("/tmp/
 user_profiles")
 df.select("_id", "first_name",
 "last_name")
```

**Java**

```
import
 com.mapr.db.spark.sql.api.java.MapRDBJ
 avaSession;

MapRDBJavaSession maprSession = new
```

```
MapRDBJavaSession(sparkSession);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.select("_id", "first_name",
"last_name");
```

### Python

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.select("_id", "first_name",
"last_name")
```

The equivalent example using Datasets is as follows:

### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
ds.select("_id", "first_name",
"last_name")
```

### Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles", Person.class);
ds.select("_id", "first_name",
"last_name");
```

## Filter Pushdown

Filter pushdown improves performance by reducing the amount of data passed between HPE Data Fabric Database and the Apache Spark engine when filtering data.

Consider the following example:

### Scala

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df
= sparkSession.loadFromMapRDB("/tmp/
user_profiles")
df.filter("first_name = 'Bill'")
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> df =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
df.filter("first_name = 'Bill'")
```

**Python**

```
from pyspark.sql import SparkSession

df
= spark_session.loadFromMapRDB("/tmp/
user_profiles")
df.filter("first_name = 'Bill'")
```

The HPE Data Fabric Database OJAI Connector for Apache Spark pushes the filter `firstName = 'Bill'` down to HPE Data Fabric Database.

The equivalent example using Datasets is as follows:

**Scala**

```
import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val ds
= sparkSession.loadFromMapRDB[Person]
("/tmp/user_profiles").as[Person]
ds.filter($"first_name" === "Bill")
```

**Java**

```
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

Dataset ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles").as(Encoders.bean(Perso
n.getClass()));
ds.filter(col("first_name").equalTo("B
ill"));
```

The following DataFrame filters those rows in which `first_name` is either "David" or "Peter":

**Scala**

```
df.filter($"first_name" === "David"
|| $"first_name" === "Peter")
```

**Java**

```
df.filter(col("first_name").equalTo("D
avid").or(col("first_name").equalTo("P
eter")))
```

**Python**

```
df.filter((col("first_name") ==
"David") | (col("first_name") ==
"Peter"))
```

The following DataFrame retrieves only the rows in which the first\_name is "David" and the last\_name is "Jones":

**Scala**

```
df.filter($"first_name" === "David"
&& $"last_name" === "Jones")
```

**Java**

```
df.filter(col("first_name").equalTo("D
avid").and(col("last_name").equalTo("J
ones")))
```

**Python**

```
df.filter((col("first_name") ==
"David") & (col("last_name") ==
"Jones"))
```

The following uses a not condition to return rows where the first\_name is not "David" and the last\_name is not "Peter":

**Scala**

```
df.filter(not($"first_name" ===
"David" || $"last_name" === "Peter"))
```

**Java**

```
df.filter(not(col("first_name").equalT
o("David").or(col("last_name").equalT
o("Peter"))))
```

**Python**

```
df.filter(~((col("first_name") ==
"David") | (col("last_name") ==
"Peter")))
```

The HPE Data Fabric Database OJAI Connector pushes down all of the filters shown in the earlier examples. It can push down the following types of filters, provided that the field is not an Array or Map:

- Equal To (=)
- Not Equal To (!=)
- Less Than (<)
- Less Than or Equal To (<=)
- Greater Than (>)
- Greater Than or Equal To (>=)
- In Predicate (IN)
- Like predicate (LIKE)
- AND, OR

- NOT

## Restrictions

Pushdowns with DataFrames and Datasets are not supported in the following scenarios:

- Filters on complex types, including arrays, maps, and structs

For example, a filter on a field in a map, as shown in the following example, is not pushed down:

### Scala

```
df.filter($"address.city" === "Milpitas")
```

### Java

```
df.filter(col("address.city").equalTo("Milpitas"));
```

### Python

```
df.filter(col("address.city") == "Milpitas")
```

- Filters with functions `sizeof`, `typeof`, and `matches`

Spark SQL does not support these functions.

- Projections on complex types, including arrays, maps, and structs

For example, if you select an element of an array, as shown in the following example, it is not pushed down:

### Scala

```
ds.select($"hobbies" (0))
```

### Java

```
df.select(col("hobbies").getItem(0));
```

### Python

```
df.select(col("hobbies").getItem(0))
```

These limitations do not apply to pushdowns on RDDs. An alternative is to apply the [pushdown using an RDD](#), and then [convert the RDD to a DataFrame](#).

**NOTE:** HPE Data Fabric Database 6.0 introduces support for [Secondary Indexes](#) on page 754, but the HPE Data Fabric Database OJAI Connector for Spark does not currently leverage them.

## Converting an Apache Spark RDD to an Apache Spark DataFrame

When APIs are only available on an Apache Spark RDD but not an Apache Spark DataFrame, you can operate on the RDD and then convert it to a DataFrame.

You can convert an RDD to a DataFrame in one of two ways:

- Use the helper function, `toDF`.
- Convert the RDD to a DataFrame using the `createDataFrame` call on a `SparkSession` object.

## Using the `toDF` Helper Function

The `toDF` method is available through `MapRDBTableScanRDD`. The following example loads an RDD that filters on `first_name` equal to "Peter" and projects the `_id` and `first_name` fields, and then converts the RDD to a DataFrame:

**Scala**

```
import com.mapr.db.spark.sql._

val df =
 sc.loadFromMapRDB(<table-name>)
 .where(field("first_name")
 === "Peter")
 .select("_id",
 "first_name").toDF()
```

**Using SparkSession.createDataFrame**

With this approach, you can convert an RDD[Row] to a DataFrame by calling createDataFrame on a SparkSession object. The API for the call is as follows:

**Scala**

```
def createDataFrame(RDD, schema:
 StructType)
```

You might need to first convert an RDD[OJAIDocument] to an RDD[Row]. The following example shows how to do this:

**Scala**

```
val df = sparkSession.createDataFrame(
 rdd.map(doc
 =>MapRDBSpark.docToRow(doc, schema)),
 schema)
```

rdd is of type RDD[OJAIDocument]. The docToRow call converts rdd to an RDD[Row] that is then passed to createDataFrame.

*Working with Complex JSON Document Types*

The HPE Data Fabric Database OJAI Connector for Apache Spark provides APIs to process JSON documents loaded from HPE Data Fabric Database.

Suppose you want to calculate the number of users located in each city:

**Scala**

```
import com.mapr.db.spark.sql._

val customerprofilesRDD =
 sc.loadFromMapRDB("/tmp/
 user_profiles")
val numberOfCustaccCities =
 customerprofilesRDD.map(a =>
 (a.`address.city`[String],a))
 .groupByKey
 y()
 .map(a =>
 (a._1, a._2.size))
```

**Java**

```
import
 com.mapr.db.spark.api.java.MapRDBJavaS
 parkContext;
import scala.Tuple2;
import java.util.Collection;

MapRDBJavaRDD<OJAIDocument>
 customerprofilesRDD =
```

```
mapRDBSparkContext.loadFromMapRDB("/tmp/user_profiles");
JavaRDD numberOfCustaccCities =
customerprofilesRDD.mapToPair
(a -> new
Tuple2<>(a.getString("address.city"),
a)).groupByKey()
.map(a -> new Tuple2<>(a._1,
((Collection<?>)a._2).size()));
```

If you have not provided an explicit cast, then the object is returned as `AnyRef`. To access methods specific to a class, such as `String` or `Integer`, you can cast it to a specific type later in the process.

Now suppose you want to collect all the addresses (address is of type `Map`) of all customers:

#### Scala

```
import com.mapr.db.spark.sql._

val customerprofilesRDD
= sc.loadFromMapRDB("/tmp/
user_profiles")
val customersAddress =
customerprofilesRDD.map(a =>
a.address).collect
```

#### Java

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaRDD<OJAI Document>
customerprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
List<String> customersAddress =
customerprofilesRDD.map(a ->
a.getString("address")).collect();
```

`customersAddress` contains all of the addresses, but is returned as an `AnyRef` object.

The HPE Data Fabric Database OJAI Connector for Apache Spark introduces three new classes to wrap complex JSON types:

Class	Type
<code>DBMapValue</code>	<code>Map[String, AnyRef]</code>
<code>DBArrayValue</code>	<code>Array[AnyRef]</code>
<code>DBBinaryValue</code>	<code>ByteBuffer</code>

These classes are not exposed; however, you can access the underlying elements of `DBArrayValue` and `DBMapValue` by using the same functions as in `Seq` and `Map`. `DBArrayValue` works like a sequence, while `DBMapValue` works like a map.

`DBBinaryValue` is a class wrapper around `ByteBuffer`. `ByteBuffer` is not serializable, so you will get serialization errors if you use the `ByteBuffer` in Spark code. You must ensure that byte buffers are converted to `DBBinaryValue` or serialized byte buffers. The HPE Data Fabric Database OJAI Connector for Apache Spark provides an API to convert `ByteBuffer`s to serializable byte buffers.

## Accessing Values in a Map

`DBMapValue` is a type of `Map[String, AnyRef]`. Any functions that you can use to access values in the Map, you can also use to access values in `DBMapValue`. In the following example, `customeraddress` contains the address of the customers who reside in San Jose. `customeraddress` is an `Array[DBMapValue]`:

Scala

```
val customerAddress = maprd.map(a =>
 a.address[Map[String, AnyRef]])
 .filter(a => a != null &&
 a.get("city").contains("San Jose"))
 .collect
```

This example can also be written in Scala using a functional approach as follows:

Scala

```
val customerAddress = maprd.map(a
=> (a.address[Map[String, AnyRef]],
a).join(my_documents)
 .filter(a =>
Option(a).map(a =>
a.get("city").contains("San
Jose")).getOrElse(false)))
 .collect
```

**NOTE:** You can push the condition specified in the filter condition to the HPE Data Fabric Database table scan by using the `where` clause.

## Accessing the Array JSON Object

This example uses a sequence to access the Array JSON object:

Scala

```
val custInterests = maprd.map(a =>
 a.interests[Seq[AnyRef]])
 .filter(a => a !=
null && a(0) == "sports")
 .collect
```

## ByteBuffer Serialization

The HPE Data Fabric Database OJAI Connector for Apache Spark provides the following API to enable serialization of the `ByteBuffer`:

Scala

```
MapRDBSpark.serializableBinaryValue(
byteBuffer)
```

The following example shows an array of byte buffers or binary values that are converted to serialized byte buffers by using `MapRDBSpark.serializableBinaryValue`:

Scala

```
val dstSplits =
arrayOfByteBuffer.map(x =>
```

```
MapRDBSpark.serializableBinaryValue(x)
)
```

#### *Saving Data to a HPE Data Fabric Database JSON Table*

The HPE Data Fabric Database OJAI Connector for Apache Spark provides an API to save an Apache Spark RDD to a HPE Data Fabric Database JSON table. Starting in the EEP 4.0 release, the connector introduces support for saving Apache Spark DataFrames and DStreams to HPE Data Fabric Database JSON tables.

Saving an Apache Spark RDD to a HPE Data Fabric Database JSON Table

#### **Saving an RDD[OJAIDocument] to HPE Data Fabric Database**

The HPE Data Fabric Database OJAI Connector for Apache Spark provides the following API to save an RDD[OJAIDocument] to a HPE Data Fabric Database table:

##### **Scala**

For saving an RDD, apply the following method on the RDD:

```
def saveToMapRDB(tablename: String,
createTable: Boolean =
false, bulkInsert: Boolean =
false, idFieldPath: String =
DocumentConstants.ID_KEY) : Unit
```

##### **Java**

For saving an RDD, apply one of the following methods on a MapRDBJavaSparkContext object:

```
def saveToMapRDB[D](javaRDD:
JavaRDD[D], tableName: String,
createTable: Boolean, bulkInsert:
Boolean, idField: String): Unit

def saveRowRDDToMapRDB(javaRDD:
JavaRDD[Row], tableName: String,
createTable: Boolean, bulkInsert:
Boolean, idField: String): Unit

def saveToMapRDB[K, V <: AnyRef]
(javaPairRDD: JavaPairRDD[K, V],
keyClazz: Class[K], valueClazz:
Class[V], tableName: String,
createTable: Boolean, bulkInsert:
Boolean): Unit
```

**NOTE:** The only required parameter to the methods is tableName. All the others are optional.

In the following example, address and first\_name data is loaded from the "/tmp/user\_profiles" table, stored as an RDD (userprofilesRDD), and then saved to the "/tmp/user\_firstname\_and\_address" table:

##### **Scala**

```
import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
 .where("condition
")
```

```

 .select("address"
, "first_name")

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address")

```

**Java**

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(sc);
JavaRDD userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles")
 .where("condition")
 .select("address",
"first_name");
mapRDBSparkContext.saveToMapRDB(userpr
ofilesRDD, "/tmp/
user_firstname_and_address", true,
false, "_id");

```

The HPE Data Fabric Database OJAI Connector for Apache Spark also provides the following API to insert an RDD[OJAIDocument] to a HPE Data Fabric Database table:

**NOTE:** The insertToMapRDB API is available starting in the EEP 4.1.0 release.

**Scala**

```

import com.mapr.db.spark._

val userprofilesRDD =
sc.loadFromMapRDB("/tmp/
user_profiles")
userprofilesRDD.insertToMapRDB(tablena
me, createTable = true, bulkInsert =
false, idFieldPath = "_id")

```

**Java**

```

import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
org.apache.spark.sql.SparkSession;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
MapRDBJavaRDD<OJAIDocument>
userprofilesRDD =
mapRDBSparkContext.loadFromMapRDB("/tm
p/user_profiles");
mapRDBSparkContext.insertRowRDDToMapRD
B(userprofilesRDD, tablename);

```

**NOTE:** The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

This API supports the following parameters:

### Scala

Parameter	Default	Description
<code>tableName</code>	Not applicable	The name of the HPE Data Fabric Database table in which you are saving the document.
<code>createTable</code>	false	Creates the table before saving the documents. Note that if the table already exists and <code>createTable</code> is set to true, the API throws an exception.
<code>idFieldPath</code>	<code>_id</code>	Specifies the key to be used for the document.
<code>bulkInsert</code>	false	Loads a group of rows simultaneously. <code>bulkInsert</code> is similar to a bulk load in MapReduce.

### Java

Parameter	Default	Description
RDD (JavaRDD or JavaPairRDD)	Not applicable	Specifies the RDD which you are saving to the HPE Data Fabric Database table.
<code>tableName</code>	Not applicable	Specifies the name of the HPE Data Fabric Database table in which you are saving the document.
<code>createTable</code>	false	Creates the table before saving the document. Note that if the table already exists and <code>createTable</code> is set to true, the API throws an exception.
<code>idFieldPath</code>	<code>_id</code>	Specifies the key to be used for the document.
<code>bulkInsert</code>	false	Loads a group of rows simultaneously. <code>bulkInsert</code> is similar to a bulk load in MapReduce.
<code>keyClazz</code> (Only for JavaPairRDD)	Not applicable	Specifies the class type which is the key in the JavaPairRDD which you are saving into the HPE Data Fabric Database table.
<code>valueClazz</code> (Only for JavaPairRDD)	Not applicable	Specifies the class type which is the value in the JavaPairRDD which you are saving into the HPE Data Fabric Database table.

In Java, `saveToMapRDB` method works with JavaRDD and JavaPairRDD. For saving JavaRDD[Row], use the `saveRowRDDToMapRDB` method.

The following example specifies a key by using the `idFieldPath` parameter and the `bulkInsert` value to save the RDD:

**Scala**

```
import com.mapr.db.spark._

userprofilesRDD.saveToMapRDB("/tmp/
user_firstname_and_address",

idFieldPath = "user_id",

bulkInsert = false)
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

MapRDBJavaSparkContext
mapRDBSparkContext = new
MapRDBJavaSparkContext(spark.sparkCont
ext());
mapRDBSparkContext.saveToMapRDB(userpr
ofilesRDD, "/tmp/
user_firstname_and_address", false,
false, "user_id");
```

The following example saves an RDD of Person objects into the newly created /tmp/Userinfo table:

**Scala**

```
import com.mapr.db.spark._

val sparkConf =
new SparkConf().setAppName("json
app").setMaster("local[*]")
val sc = new SparkContext(sparkConf)
val people =
sc.parallelize(getUsers())
people.saveToMapRDB("/tmp/UserInfo",
createTable= true)
```

**Java**

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;

SparkConf sparkConf = new
SparkConf().setAppName("json
app").setMaster("local[*]");
SparkContext sc = new
SparkContext(sparkConf);
JavaRDD rdd =
sc.parallelize(getUsers());
mapRDBSparkContext.saveToMapRDB(rdd,
"/tmp/UserInfo", true);
```

The following example shows the getUsers function that allocates the Person objects:

**Scala**

```
def getUsers(): Array[Person] = {
 val users: Array[Person] =

 Array(
 Person("DavUSCalif", "David",
```

```

"Jones",
 ODate.parse("1947-11-29"),
 Seq("football", "books",
"movies"),
 Map("city" -> "milpitas",
"street" -> "350 holger way",
"Pin" -> 95035)),

 Person("PetUSUtah", "Peter",
"pan",
 ODate.parse("1974-1-29"),
 Seq("boxing", "music",
"movies"),
 Map("city" -> "salt lake",
"street" -> "351 lake way", "Pin" ->
89898)),

 Person("JamUSAriz", "James",
"junior",
 ODate.parse("1968-10-2"),
 Seq("tennis", "painting",
"music"),
 Map("city" -> "phoenix",
"street" -> "358 pond way", "Pin" ->
67765)),

 Person("JimUSCalif", "Jimmy",
"gill",
 ODate.parse("1976-1-9"),
 Seq("cricket",
"sketching"),
 Map("city" -> "san jose",
"street" -> "305 city way", "Pin" ->
95652)),

 Person("IndUSCalif",
"Indiana", "Jones",
 ODate.parse("1987-5-4"),
 Seq("squash", "comics",
"movies"),
 Map("city" -> "sunnyvale",
"street" -> "35 town way", "Pin" ->
95985)))

 users
}

```

### Saving a JSON Document to HPE Data Fabric Database

To save a JSON document using the HPE Data Fabric Database OJAI Connector for Apache Spark, you must first convert the JSON document into an OJAI document and then save the RDD, as shown in the following example:

#### Scala

```

import com.mapr.db.spark._

val documents = sc.parallelize((1 to
10)
 .map(i => s""""_id":
"$i", "test": "$i"}"""))
val maprd = documents.map(a =>

```

**Java**

```
MapRDBSpark.newDocument(a))
maprd.saveToMapRDB("/tmp/testData")
```

```
import
com.mapr.db.spark.api.java.MapRDBJavaS
parkContext;
import
org.apache.spark.api.java.JavaSparkCon
text;

JavaRDD<String> documents =
JavaSparkContext.fromSparkContext(sc)
 .parallelize(Arrays.asList(
1, 2, 3, 4, 5, 6, 7, 8, 9, 10))
 .map(i -> { return
"\id\": \"\" + i + "\", \"test\":
\"\" + i + "\""; });
JavaRDD<OJAIIDocument> maprd =
documents.map(MapRDBSpark::newDocument
);
mapRDBSparkContext.saveToMapRDB(maprd,
"/tmp/testData");
```

An `_id` field is required to save JSON data into a table, so an `_id` field must be present. If you need only to convert the JSON data to an OJAI document (without saving to HPE Data Fabric Database), the `_id` field is not required. If the HPE Data Fabric Database table already contains a record with the same `_id` value, HPE Data Fabric Database replaces the record. Otherwise, it inserts a new record.

Just as you can load a JSON document into a Scala bean class (see [Creating an RDD of a Class](#)), you can save the RDD of Scala class objects in a HPE Data Fabric Database JSON table. `saveToMapRDB` can save any bean object as a JSON document by converting it to a JSON document.

**Table Splits and saveToMapRDB**

If the `createTable` parameter is set to `true`, `saveToMapRDB` can use the partition information from the RDD's lineage to create the splits for a new table:

**Scala**

```
sc.loadFromMapRDB("/tmp/
user_profiles").saveToMapRDB("/
userProfiles",

createTable = true)
```

Suppose `/tmp/user_profiles` has a table with five splits. `saveToMapRDB` uses this information to create the `/userProfiles` table with the same number and range of splits. You can also supply this information by using `MapRDBSpark.newPartitioner`:

**Scala**

```
sc.loadFromMapRDB("/tmp/
user_profiles").keyBy(doc =>
doc.get("_id"))
 .repartitionAndSortWithinPartitions(
MapRDBSpark.newPartitioner[String]
("/profiles"))
 .saveToMapRDB("/userProfiles",
createTable = true)
```

For more information about partitioning, see [Using the Custom Partitioner with the HPE Data Fabric Database OJAI Connector for Apache Spark](#) on page 5456.

### Saving an Apache Spark DataFrame to a HPE Data Fabric Database JSON Table

To save an Apache Spark DataFrame to a HPE Data Fabric Database, invoke the `saveToMapRDB` method on the DataFrame object (Scala). This returns a `DataFrameWriter` object, from which you can invoke the `saveToMapRDB` method. For Java and Python, invoke the `saveToMapRDB` method on the `MapRDBJavaSession` object or `SparkSession` object, respectively.

If a row with the same ID already exists, the `saveToMapRDB` method updates or overwrites that row. If you want an exception to be thrown in this case, you can use the [insertToMapRDB](#) method.

#### Scala

```
import com.mapr.db.spark.sql._

df.write.saveToMapRDB("/tmp/userInfo")
```

For EEP 4.1.0 and later, you can directly invoke the `saveToMapRDB` method on the DataFrame object:

```
def saveToMapRDB(tableName: String,
 idFieldPath : String = "_id",
 createTable: Boolean = false,
 bulkInsert:Boolean = false): Unit

import
org.apache.spark.sql.SparkSession
import com.mapr.db.spark.sql._

val df = spark.loadFromMapRDB("/tmp/
user_profiles")
df.saveToMapRDB(tableName,
createTable = true)
```

#### Java

For saving a DataFrame (`Dataset<Row>`), apply the following method on a `MapRDBJavaSession` object:

```
def saveToMapRDB[T](df: DataFrame[T],
 tableName: String, idFieldPath:
String, createTable: Boolean,
bulkInsert: Boolean): Unit

import
com.mapr.db.spark.sql.api.java.MapRDBJ
avaSession;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(sparkSession);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");

maprSession.saveToMapRDB(ds, "/tmp/
userInfo");
```

#### Python

For saving a DataFrame, apply the following method on a DataFrame:

```
def saveToMapRDB(dataframe,
 table_name, id_field_path =
```

```
default_id_field, create_table =
False, bulk_insert = False)

from pyspark.sql import SparkSession

df = spark.loadFromMapRDB("/tmp/
user_profiles")

sparkSession.saveToMapRDB(df,
table_name, create_table=True)
```

### Inserting an Apache Spark DataFrame into a HPE Data Fabric Database JSON Table

Starting in the EEP 4.1.0 release, you can use the `insertToMapRDB` API to insert an Apache Spark DataFrame into a Data Fabric Database JSON table in Python. The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

PySpark supports only `DataFrame(Dataset<Row>)`:

#### Python

```
sparkSession.insertToMapRDB(df,
tableName, idFieldPath, bulkInsert)
```

### Using Alternate Write Modes for HPE Data Fabric Database OJAI Connector

You can use alternate write modes supported by Data Fabric Database OJAI Connector for Apache Spark to save an Apache Spark DataFrame to a Data Fabric Database JSON table.

Normally, the Apache Spark `DataFrameWriter` class supports the following write modes:

- Append
- Overwrite
- ErrorIfExists
- Ignore

The HPE Data Fabric Database OJAI Connector for Apache Spark returns an `OperationNotSupported` exception if you attempt to use one of these modes. The following example returns the error:

#### Scala

```
import org.apache.spark.sql.SaveMode
import com.mapr.db.spark.sql._

df.write.mode(SaveMode.Append).saveToM
apRDB("/tmp/userInfo")
```

The HPE Data Fabric Database OJAI Connector for Apache Spark provides the following alternative modes:

#### Insert

Inserts the data into the HPE Data Fabric Database table. Throws a `DBException` if a row with same `_id` value already exists in the table.

#### Overwrite

Overwrites the data in the table with the current DataFrame data. This operation drops the table and creates a new table with the data.

#### ErrorIfExists

Returns an exception (`TableExistsException`) if the table already exists. Otherwise, creates the table and inserts the data.

**Ignore**

Ignores the data in the table if the table already exists. Otherwise, creates the table and inserts the data.

**InsertOrReplace**

Replaces the row with the row in the DataFrame, if a row with the same `_id` already exists in the table. Otherwise, inserts the new row.

You cannot specify these modes using the Apache Spark `SaveMode` method. Doing so results in the same `OperationNotSupported` exception noted earlier. To use these modes, you must call the `option` method on a `DataFrameWriter` object. The following example sets the `Insert` mode:

**Scala**

```
df.write.option("Operation",
 "Insert").saveToMapRDB("/tmp/
 usersInfo")
```

**NOTE:** The `UPDATE` mode for HPE Data Fabric Database OJAI Connector is not supported and it results in an `OperationNotSupported` exception.

### Saving an Apache Spark DStream to a HPE Data Fabric Database JSON Table

The HPE Data Fabric Database OJAI Connector for Apache Spark enables you to use HPE Data Fabric Database as a sink for Apache Spark DStreams.

**NOTE:** Saving of Apache Spark DStream to HPE Data Fabric Database JSON table is currently only supported in Scala.

The following API saves a `DStream[OJAIDocument]` object to a HPE Data Fabric Database table:

**Scala**

```
def saveToMapRDB(tablename: String,
 createTable: Boolean,
 bulkInsert: Boolean,
 idFieldPath: String): Unit
```

The parameters are as follows:

Parameter	Default	Description
<code>tableName</code>	Not applicable	The name of the HPE Data Fabric Database table to which you are saving the DStream.
<code>createTable</code>	<code>false</code>	Creates the table before saving the DStream. Note that if the table already exists and <code>createTable</code> is set to <code>true</code> , the API throws an exception.
<code>idFieldPath</code>	<code>_id</code>	Specifies the key to be used for the DStream.
<code>bulkInsert</code>	<code>false</code>	Loads a group of streams simultaneously. <code>bulkInsert</code> is similar to a bulk load in MapReduce.

 **NOTE:** The only required parameter for this function is `tableName`. All the others are optional.

The following example creates a `DStream` object, converts it to a `DStream[OJAI Document]` object, and then stores it in HPE Data Fabric Database:

Scala

```
val clicksStream: DStream[String] =
 createKafkaStream(...)
clicksStream.map(MapRDBSpark.newDocument()).saveToMapRDB("/clicks",
 createTable=true)
```

 **NOTE:** You must use the `map(MapRDBSpark.newDocument())` API to convert the `DStream` object to a `DStream[OJAI Document]` object.

If `clicksStream` is a `DStream` of Strings, it can be saved to HPE Data Fabric Database using the `saveToMapRDB` API:

Scala

```
clicksStream.map(MapRDBSpark.newDocument(_)).saveToMapRDB("/clicks",
 createTable = true);
```

 **NOTE:** To use the `saveToMapRDB` API, you need to transform the `DStream` object to a `DStream[OJAI Document]` by using the Apache Spark Map API.

### Saving an Apache Spark Dataset to a HPE Data Fabric Database JSON Table

Starting in the EEP 4.1.0 release, the HPE Data Fabric Database OJAI Connector for Apache Spark provides the following API to save a Dataset to a HPE Data Fabric Database table:

Scala

For saving a Dataset, apply the following method on a Spark object:

```
def saveToMapRDB(tableName: String,
 idFieldPath : String = "_id",
 createTable: Boolean =
 false, bulkInsert:Boolean = false):
 Unit

import
org.apache.spark.sql.Session
import com.mapr.db.spark.sql._

val ds = spark.loadFromMapRDB("/tmp/
 user_profiles")
ds.saveToMapRDB(tableName,
 createTable = true)
```

Java

For saving a Dataset, apply the following method on a `MapRDBJavaSession` object:

```
def saveToMapRDB[T](ds: Dataset[T],
 tableName: String, idFieldPath:
 String,
 createTable: Boolean,
 bulkInsert: Boolean): Unit

import
```

```
com.mapr.db.spark.sql.api.java.MapRDBJavaSession;
import
org.apache.spark.sql.Session;

MapRDBJavaSession maprSession = new
MapRDBJavaSession(spark);
Dataset<Row> ds =
maprSession.loadFromMapRDB("/tmp/
user_profiles");
maprSession.saveToMapRDB(ds, true);
```

The HPE Data Fabric Database OJAI Connector for Apache Spark also provides the following API to insert a Dataset into a HPE Data Fabric Database table:

#### Scala

```
import com.mapr.db.spark._

ds.insertToMapRDB(tableName,
idFieldPath, bulkInsert)
```

#### Java

```
import
com.mapr.db.spark.sql.api.java.MapRDBJavaSession;

maprSession.insertToMapRDB(ds,
tableName, idFieldPath, bulkInsert)
```

**NOTE:** The `insertToMapRDB` API throws an exception if a row with the same ID already exists.

### Word Count Example Using HPE Data Fabric Database OJAI Connector

wordWithId.drop(1).mkString(" "))
 }).toSeq
 }

 private case class Word(_id:
String, words: String)
 }

```

### *Using Serialization with the HPE Data Fabric Database OJAI Connector for Apache Spark*

In the context of the HPE Data Fabric Database OJAI Connector for Apache Spark, serialization refers to the methods that read and write objects into bytes. This section describes how to configure your application to use a more efficient serializer.

The Apache Spark cluster framework requires serialization to exchange objects between driver and cluster executors. This type of serialization has nothing to do with the way HPE Data Fabric Database serializes the objects onto the disk.

Because classes used in Spark transformations or actions must be serializable, classes created for the HPE Data Fabric Database OJAI Connector for Apache Spark are serializable.

Spark uses Java serialization by default, but it can alternatively use Kyro Serialization. A new Kyro registrator is introduced so you can avoid using the default Java serialization. Kyro serialization provides better performance than Java serialization.

The following example shows how to set the new Kyro registrator in sparkconf:

**Scala**

```
new sparkconf()
 .set("spark.serializer",
 "org.apache.spark.serializer.KryoSerializer")
 .set("spark.kryo.registrator",
 "com.mapr.db.spark.OJAIKryoRegistrator")
```

A JSON document can use both complex and primitive value types. Java can serialize the primitive types, but for complex types (such as Map, Array, and Binary), you must use wrappers to achieve serialization. See [Working with Complex JSON Document Types](#) on page 5475 for details about these wrappers.

Time-related data types, such as `ODate`, `OInterval`, `OTime`, and `OTimeStamp`, use Java serialization by default. For efficiency, new serializers and comparators have been created for these data types.

Here are the new serializers and the type which each serializer applies:

Serializer	Type
<code>ODateSerializer</code>	<code>ODate</code> type
<code>OTimeSerializer</code>	<code>OTime</code>
<code>OTimeStampSerializer</code>	<code>OTimeStamp</code>
<code>OIntervalSerializer</code>	<code>OInterval</code>
<code>DBBinaryValueSerializer</code>	<code>ByteBuffer</code>

**HPE Data Fabric Database Binary Connector for Apache Spark**

This section describes the three main interaction points between Spark and HBase APIs and provides examples for each interaction point.

The interaction points are:

Basic Spark	You can have an HBase Connection at any point in your Spark DAG.
Spark Streaming	You can have an HBase Connection at any point in your Spark Streaming application.
Spark Structured Streaming	Using Spark structured streaming to write data to a HPE Data Fabric Database binary table is currently not supported.
Spark Bulk Load	This option is currently not supported for HPE Data Fabric Database.
SparkSQL/DataFrames	You can write SparkSQL that draws on tables that are represented in HBase.

The following pages provide examples of each of these interaction points.

*Configuring the HPE Data Fabric Database Binary Connector for Apache Spark*

**About this task**

Use these steps to configure the HPE Data Fabric Database Binary Connector for Apache Spark:

**Procedure**

1. Verify that the `mapr-hbase` package is installed. For more information, refer to the [HBase release notes](#).
2. Copy the `HBASE_HOME/conf/hbase-site.xml` file to `SPARK_HOME/conf/`.

### 3. Specify the hbase-site.xml file in the SPARK\_HOME/conf/spark-defaults.conf:

```
spark.yarn.dist.files SPARK_HOME/conf/hbase-site.xml
```

#### *HPE Data Fabric Database Binary Connector for Apache Spark Integration with Basic Spark*

This page describes integration between Apache Spark and HBase APIs.

This section describes Spark integration with HBase APIs at the lowest and simplest levels. All other interaction points are built upon the concepts described here.

At the root of all integration with Spark and HBase APIs is the HBaseContext. The HBaseContext takes in HBase configurations and pushes them to the Spark executors. This allows you to have an HBase Connection per Spark executor in a static location.

#### **HBaseContext Usage Example**

This example shows how HBaseContext can be used to do a foreachPartition on an RDD in Scala:

```
val sc = new SparkContext("local", "test")
val config = new HbaseConfiguration()
...
val hbaseContext = new HBaseContext(sc, config)

rdd.hbaseForeachPartition(hbaseContext, (it, conn) => {
 val bufferedMutator = conn.getBufferedMutator(TableName.valueOf("/apps/
my_table"))
 it.foreach((putRecord) => {
 val put = new Put(putRecord._1)
 putRecord._2.foreach((putValue) =>
 put.addColumn(putValue._1,
 putValue._2, putValue._3))
 bufferedMutator.mutate(put)
 })
 bufferedMutator.flush()
 bufferedMutator.close()
})
```

Here is the same example implemented in Java:

```
JavaSparkContext jsc = new JavaSparkContext(sparkConf);

try {
 List<byte[]> list = new ArrayList<>();
 list.add(Bytes.toBytes("1"));
 ...
 list.add(Bytes.toBytes("5"));

 JavaRDD<byte[]> rdd = jsc.parallelize(list);
 Configuration conf = HBaseConfiguration.create();
 JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);

 hbaseContext.foreachPartition(
 rdd,
 new VoidFunction<Tuple2<Iterator<byte[]>, Connection>>() {
 public void call(Tuple2<Iterator<byte[]>, Connection> t) throws
Exception {
 Table table = t._2().getTable(TableName.valueOf(tableName));
 BufferedMutator mutator =
t._2().getBufferedMutator(TableName.valueOf(tableName));
 while (t._1().hasNext()) {
 byte[] b = t._1().next();
 Result r = table.get(new Get(b));
 if (r.getExists()) {
 mutator.mutate(new Put(b));
 }
 }
 }
 })
```

```

 }
 }
 mutator.flush();
 mutator.close();
 table.close();
}
});
} finally {
 jsc.stop();
}

```

All functionality between Spark and HBase Client is supported both in Scala and in Java, with the exception of SparkSQL, which supports any language that is supported by Spark. This section focuses on Scala examples.

The example here shows how to do a `foreachPartition` with a connection. A number of other Spark base functions are supported out of the box:

bulkPut	Enables massively parallel sending of puts to HBase.
bulkDelete	Enables massively parallel sending of deletes to HBase.
bulkGet	Enables massively parallel sending of gets to HBase to create a new RDD.
mapPartition	Enables the Spark Map function with a Connection object to allow full access to HBase.
hBaseRDD	Simplifies a distributed scan to create an RDD.

You can see examples of these commands in the [source code of the HBase-Spark Module](#).

#### *HPE Data Fabric Database Binary Connector for Apache Spark Integration with Spark Streaming*

**Spark Streaming** is a micro-batching, stream-processing framework built on top of Spark. HBase APIs and Spark Streaming make great companions. When used alongside Spark Streaming, HBase APIs can serve as:

- A place to grab reference data or profile data on the fly.
- A place to store counts or aggregates in a way that supports the Spark Streaming promise of only once processing.

The HPE Data Fabric Database Binary Connector for Apache Spark integration points with Spark Streaming are similar to its normal Spark integration points. You can use the following commands straight off a Spark Streaming DStream:

bulkPut	Enables massively parallel sending of puts to HBase APIs.
bulkDelete	Enables massively parallel sending of deletes to HBase APIs.
bulkGet	Enables massively parallel sending of gets to HBase APIs to create a new RDD.
mapPartition	Enables the Spark Map function with a Connection object to allow full access to HBase APIs.
hBaseRDD	Simplifies a distributed scan to create an RDD.

#### **bulkPut Example with DStreams**

The following example shows a `bulkPut` with DStreams. It is similar to the RDD bulk put.

**NOTE:** To invoke the `hbaseBulkPut` method, make sure you import the `HBaseDStreamFunctions` class.

```
import org.apache.hadoop.hbase.spark.HBaseDStreamFunctions._

val sc = new SparkContext("local", "test")
val config = new HBaseConfiguration()

val hbaseContext = new HBaseContext(sc, config)
val ssc = new StreamingContext(sc, Milliseconds(200))

val rdd1 = ...
val rdd2 = ...
val queue = mutable.Queue[
 RDD[(Array[Byte],
 Array[(Array[Byte],
 Array[Byte],
 Array[Byte])])]]]()

queue += rdd1
queue += rdd2

val dStream = ssc.queueStream(queue)

dStream.hbaseBulkPut(
 hbaseContext,
 TableName.valueOf(tableName),
 (putRecord) => {
 val put = new Put(putRecord._1)
 putRecord._2.foreach((putValue) =>
 put.addColumn(putValue._1, putValue._2, putValue._3))
 put
 })
```

The `hbaseBulkPut` function has three inputs:

- The `hbaseContext` that carries the configuration broadcast information link to the HBase Connections in the executors.
- The table name of the table you are putting data into.
- A function that will convert a record in the DStream into an HBase Put object.

The code snippet above has been extracted from <https://github.com/mapr/hbase/blob/1.1.8-mapr-1703/hbase-spark/src/test/scala/org/apache/hadoop/hbase/spark/HBaseDStreamFunctionsSuite.scala>.

#### *Bulk Loading Data into HBase with Spark*

There are two options for bulk loading data into HBase with Spark:

**NOTE:** The bulk load operation is currently not supported for HPE Data Fabric Database.

#### **Basic bulk load functionality**

The basic bulk load functionality works for cases where your rows have millions of columns and cases where your columns are not consolidated.

#### **Thin-record bulk load option**

The thin-record bulk load option with Spark is designed for tables that have fewer than 10,000 columns per row. The advantage of this option is higher throughput and less overall load on the Spark shuffle operation.

Both implementations work more or less like the MapReduce bulk load process. A partitioner partitions the RowKeys based on region splits, and the RowKeys are sent to the reducers in order, so that HFiles can be written directly from the reduce phase.

In Spark terms, the bulk load is implemented around a `SparkrepartitionAndSortWithinPartitions` followed by a `Spark foreachPartition`. Here is an example of using the basic bulk load functionality:

### Bulk Loading Example

**NOTE:** Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in :paste mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark._
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.util.Bytes._
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.SparkSession
import org.apache.hadoop.hbase.client.{HBaseAdmin, HConnectionManager}

val tableName = "table1"
val stagingFolder = "/home/mapr"
val columnFamily1 = "cf1"
@transient val conf = HBaseConfiguration.create()
val hbaseContext = new HBaseContext(sc, conf)
conf.set(TableInputFormat.INPUT_TABLE, tableName)
conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
conf.setInt("hbase.zookeeper.property.clientPort", 5181)
val rdd = sc.parallelize(Array(
 (toBytes("1"), (toBytes(columnFamily1), toBytes("a"),
toBytes("foo1"))),
 (toBytes("3"), (toBytes(columnFamily1), toBytes("b"),
toBytes("foo2.b"))))
))
rdd.hbaseBulkLoad(hbaseContext,
 TableName.valueOf(tableName),
 t => {
 val rowKey = t._1
 val family: Array[Byte] = t._2._1
 val qualifier = t._2._2
 val value: Array[Byte] = t._2._3
 val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
 Seq((keyFamilyQualifier, value)).iterator
 },
 stagingFolder)
val connection = HConnectionManager.createConnection(conf)
val table = connection.getTable(TableName.valueOf(tableName))
val load = new LoadIncrementalHFiles(conf)
load.doBulkLoad(
 new Path(stagingFolder),
 connection.getAdmin,
 table,
 connection.getRegionLocator(TableName.valueOf(tableName)))
```

### Required Parameters for Bulk Loading with Spark

The `hbaseBulkLoad` function takes three required parameters:

- The name of the table you intend to bulk load to.
- A function that converts a record in the RDD to a tuple key-value pair, with the tuple key being a `KeyFamilyQualifier` object and the value being the cell value. The `KeyFamilyQualifier` object holds the `RowKey`, `Column Family`, and `Column Qualifier`. The shuffle partitions on the `RowKey` but sorts by all three values.
- The temporary path for the HFile to be written out to. Following the Spark bulk load command, use the `HBase LoadIncrementalHFiles` object to load the newly created HFiles into HBase.

### Additional Parameters for Bulk Loading with Spark

You can set the following attributes with additional parameter options on `hbaseBulkLoad`:

- Max file size of the HFiles
- A flag to exclude HFiles from compactions
- Column Family settings for compression, bloomType, blockSize, and dataBlockEncoding

The following example shows the use of additional parameters:

**NOTE:** Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in `:paste` mode.

```
import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{FamilyHFileWriteOptions,
HBaseContext, KeyFamilyQualifier}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, HConstants, TableName}
import org.apache.spark.sql.Session
val tableName = "table2"
val stagingFolder = "/home/mapr"
val columnFamily1 = "cf1"
val sc = spark.sparkContext
@transient val conf = HBaseConfiguration.create()
conf.set(TableInputFormat.INPUT_TABLE, tableName)
conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
conf.setInt("hbase.zookeeper.property.clientPort", 5181)
val hbaseContext = new HBaseContext(sc, conf)
val rdd = sc.parallelize(Array(
 (Bytes.toBytes("1"),
 (Bytes.toBytes(columnFamily1),
 Bytes.toBytes("a"), Bytes.toBytes("foo1"))),
 (Bytes.toBytes("3"),
 (Bytes.toBytes(columnFamily1),
 Bytes.toBytes("b"),
 Bytes.toBytes("foo2.b")))))
val familyHBaseWriterOptions =
 new java.util.HashMap[Array[Byte], FamilyHFileWriteOptions]
val f1Options = new FamilyHFileWriteOptions("GZ", "ROW", 128, "PREFIX")
familyHBaseWriterOptions.put(Bytes.toBytes(columnFamily1), f1Options)
rdd.hbaseBulkLoad(hbaseContext,
 TableName.valueOf(tableName),
 t => {
 val rowKey = t._1
 val family:Array[Byte] = t._2._1
 val qualifier = t._2._2
```

```

 val value = t._2._3
 val keyFamilyQualifier= new KeyFamilyQualifier(rowKey, family,
qualifier)
 Seq((keyFamilyQualifier, value)).iterator
 },
 stagingFolder,
 familyHBaseWriterOptions,
 compactionExclude = false,
 HConstants.DEFAULT_MAX_FILE_SIZE)
val connection = HConnectionManager.createConnection(conf)
val table = connection.getTable(TableName.valueOf(tableName))
val load = new LoadIncrementalHFiles(conf)
load.doBulkLoad(new Path(stagingFolder),
 connection.getAdmin, table,
connection.getRegionLocator(TableName.valueOf(tableName)))

```

### Thin-Record Bulk Load Example

The following example shows how to call the thin-record bulk load implementation:

**NOTE:** Before executing the following example by using Spark Shell, you must create a table in HBase Shell. Run the code in :paste mode.

```

import org.apache.hadoop.fs.Path
import org.apache.hadoop.hbase.client.HConnectionManager
import org.apache.hadoop.hbase.mapreduce.{LoadIncrementalHFiles,
TableInputFormat}
import org.apache.hadoop.hbase.spark.HBaseRDDFunctions._
import org.apache.hadoop.hbase.spark.{HBaseContext, _}
import org.apache.hadoop.hbase.util.Bytes
import org.apache.hadoop.hbase.{HBaseConfiguration, TableName}
import org.apache.spark.sql.Session
val tableName = "table3"
val stagingFolder = "/home/mapr"
val columnFamily1 = "cf1"
@transient val conf = HBaseConfiguration.create()
val hbaseContext = new HBaseContext(sc, conf)
conf.set(TableInputFormat.INPUT_TABLE, tableName)
conf.set("hbase.zookeeper.quorum", "node1.cluster.com")
conf.setInt("hbase.zookeeper.property.clientPort", 5181)
val rdd = sc.parallelize(Array(
 ("1", List(Bytes.toBytes(columnFamily1), Bytes.toBytes("a"),
Bytes.toBytes("foo1"))),
 ("3", List(Bytes.toBytes(columnFamily1), Bytes.toBytes("b"),
Bytes.toBytes("foo2.b")))))
rdd.hbaseBulkLoadThinRows(hbaseContext,
 TableName.valueOf(tableName),
 t => {
 val rowKey = t._1
 val familyQualifiersValues = new FamiliesQualifiersValues
 val q = t._2
 val family:Array[Byte] = q.head
 val qualifier = q(1)
 val value:Array[Byte] = q(2)
 println(s"family: $family")
 println(s"qualifier: $qualifier")
 println(s"value: $value")
 familyQualifiersValues +=(family, qualifier, value)
 (new ByteArrayWrapper(Bytes.toBytes(rowKey)),
familyQualifiersValues)}, stagingFolder, new java.util.HashMap[Array[Byte],
FamilyHFileWriteOptions], compactionExclude = false, 20)
val connection = HConnectionManager.createConnection(conf)

```

```
val table = connection.getTable(TableName.valueOf(tableName))
val load = new LoadIncrementalHFiles(conf)
load.doBulkLoad(
 new Path(stagingFolder),
 connection.getAdmin,
 table,
 connection.getRegionLocator(TableName.valueOf(tableName)))
```

The big difference in using bulk load for thin rows is that the function returns a tuple with the first value being the RowKey and the second value being an object of FamiliesQualifiersValues. FamiliesQualifiersValues contains all the values for this row for all column families.

### SparkSQL and DataFrames

The HPE Data Fabric Database Binary Connector for Apache Spark leverages [DataSource API \(SPARK-3247\)](#) introduced in Spark-1.2.0. The connector bridges the gap between simple HBase KV store and complex relational SQL queries and enables users to perform complex data analytical work on top of HPE Data Fabric Database binary tables using Spark. HBase Dataframe is a standard Spark Dataframe, and is able to interact with any other data sources, such as Hive, Orc, Parquet, JSON, and others. The HPE Data Fabric Database Binary Connector for Apache Spark applies critical techniques such as partition pruning, column pruning, predicate pushdown and data locality.

To use the HPE Data Fabric Database Binary Connector for Apache Spark, you need to define the Catalog for the schema mapping between HPE Data Fabric Database binary tables and Spark tables, prepare the data and populate the HPE Data Fabric Database binary table, then load the HBase DataFrame. After that, users can do integrated query and access records in a HPE Data Fabric Database binary table with SQL query. The following examples illustrate the basic procedure.

### Define Catalog Example

The catalog defines a mapping between HPE Data Fabric Database binary tables and Spark tables. There are two critical parts of this catalog. One is the rowkey definition. The other is the mapping between the table column in Spark and the column family and column qualifier in HPE Data Fabric Database binary table. The following example defines a schema for a HPE Data Fabric Database binary table with name as my\_table, row key as key and a number of columns (col1 - col8). Note that the rowkey also has to be defined in details as a column (col0), which has a specific cf (rowkey).

```
def catalog = s"""{
 "table":{"namespace":"default", "name":"/path_to/my_table"},
 "rowkey":"key",
 "columns":{
 "col0":{"cf":"rowkey", "col":"key", "type":"string"},
 "col1":{"cf":"cf1", "col":"col1", "type":"boolean"},
 "col2":{"cf":"cf2", "col":"col2", "type":"double"},
 "col3":{"cf":"cf3", "col":"col3", "type":"float"},
 "col4":{"cf":"cf4", "col":"col4", "type":"int"},
 "col5":{"cf":"cf5", "col":"col5", "type":"bigint"},
 "col6":{"cf":"cf6", "col":"col6", "type":"smallint"},
 "col7":{"cf":"cf7", "col":"col7", "type":"string"},
 "col8":{"cf":"cf8", "col":"col8", "type":"tinyint"}
 }
}""".stripMargin
```

### Save the DataFrame Example

Data prepared by the user is a local Scala collection that has 256 HBaseRecord objects. The sc.parallelize(data) function distributes data to form an RDD. toDF returns a DataFrame. writefunction returns a DataFrameWriter used to write the DataFrame to external storage systems (e.g. HPE Data Fabric Database here). Given a DataFrame with a specified schema catalog, the save

function creates a HPE Data Fabric Database binary table with five (5) regions and saves the DataFrame inside.

```
case class HBaseRecord(
 col0: String,
 col1: Boolean,
 col2: Double,
 col3: Float,
 col4: Int,
 col5: Long,
 col6: Short,
 col7: String,
 col8: Byte)

object HBaseRecord
{
 def apply(i: Int, t: String): HBaseRecord = {
 val s = s""""row${"%03d".format(i)}""""
 HBaseRecord(s,
 i % 2 == 0,
 i.toDouble,
 i.toFloat,
 i,
 i.toLong,
 i.toShort,
 s"String$i: $t",
 i.toByte)
 }
}

val data = (0 to 255).map { i => HBaseRecord(i, "extra")}

sc.parallelize(data).toDF.write.options(Map(
 HBaseTableCatalog.tableCatalog -> catalog,
 HBaseTableCatalog.newTable -> "5")
).format("org.apache.hadoop.hbase.spark")
.save()
```

### Load the DataFrame Example

In the `withCatalog` function, `sqlContext` is a variable of `SQLContext`, which is the entry point for working with structured data (rows and columns) in Spark. `read` returns a `DataFrameReader` that can be used to read data in a `DataFrame`. The `option` function adds input options for the underlying data source to the `DataFrameReader`. The `format` function specifies the input data source format for the `DataFrameReader`. The `load()` function loads input as a `DataFrame`. The data frame `df` returned by the `withCatalog` function can be used to access the HPE Data Fabric Database binary table, as shown in the Language Integrated Query and SQL Query examples.

```
def withCatalog(cat: String): DataFrame = {
 sqlContext
 .read
 .options(Map(HBaseTableCatalog.tableCatalog->cat))
 .format("org.apache.hadoop.hbase.spark")
 .load()
}
val df = withCatalog(catalog)
```

### Language Integrated Query Example

DataFrame can do various operations, such as join, sort, select, filter, orderBy, and so on. In the following example, `df.filter` filters rows using the given SQL expression. `select` selects a set of columns: `col0`, `col1` and `col4`.

```
val s = df.filter(("col0" <= "row050" && "col0" > "row040") ||
 "col0" === "row005" ||
 "col0" <= "row005")
 .select("col0", "col1", "col4")
s.show
```

### SQL Query Example

`registerTempTable` registers `df` DataFrame as a temporary table using the table name `table1`. The lifetime of this temporary table is tied to the `SQLContext` that was used to create `df`. `sqlContext.sqlfunction` allows the user to execute SQL queries.

```
df.registerTempTable("table1")
sqlContext.sql("select count(col1) from table1").show
```

### Query with Different Timestamps

In `HBaseSparkConf`, you can set four parameters related to timestamp:

- `TIMESTAMP`
- `MIN_TIMESTAMP`
- `MAX_TIMESTAMP`
- `MAX_VERSIONS`

With `MIN_TIMESTAMP` and `MAX_TIMESTAMP`, you can query records with different timestamps or time ranges. In the meantime, use a concrete value instead of `tsSpecified` and `oldMs` in the following examples. The first example shows how to load `df` DataFrame with different timestamps. `tsSpecified` is specified by the user. `HBaseTableCatalog` defines the HBase and Relation relation schema. `writeCatalog` defines the catalog for the schema mapping.

```
val df = sqlContext.read
 .options(Map(
 HBaseTableCatalog.tableCatalog -> writeCatalog,
 HBaseSparkConf.TIMESTAMP -> tsSpecified.toString)
).format("org.apache.hadoop.hbase.spark")
 .load()
```

The following example shows how to load `df` DataFrame with different time ranges. `oldMs` is specified by the user.

```
val df = sqlContext.read
 .options(Map(
 HBaseTableCatalog.tableCatalog -> writeCatalog,
 HBaseSparkConf.MIN_TIMESTAMP -> "0",
 HBaseSparkConf.MAX_TIMESTAMP -> oldMs.toString)
).format("org.apache.hadoop.hbase.spark")
 .load()
After loading df DataFrame, users can query data.
```

```
df.registerTempTable("table")
sqlContext.sql("select count(col1) from table").show
```

### *Native Avro Support*

The HPE Data Fabric Database Binary Connector for Apache Spark supports different data formats such as Avro, JSON, and others. The following use case shows how Spark supports Avro. You can persist the Avro record into HPE Data Fabric Database binary tables directly. Internally, the Avro schema is converted to a native Spark Catalyst data type automatically. Note that both key-value parts in a HPE Data Fabric Database binary table can be defined in Avro format.

1. Define the catalog for schema mapping. catalog is a schema for a HPE Data Fabric Database binary table named Avro table, a row key as key, and one column col1. The rowkey also has to be defined in details as a column (col0), which has a specific cf (rowkey).

```
def catalog = s"""{
 "table":{"namespace":"default", "name":"/path_to/
 avro_table"},
 "rowkey":"key",
 "columns":{"
 "col0":{"cf":"rowkey", "col":"key",
 "type":"string"},
 "col1":{"cf":"cf1", "col":"col1", "type":"binary"}
 }
}""".stripMargin
```

2. Prepare the data. `schemaString` is defined first. Then it is parsed to get `avroSchema`. `avroSchema` is used to generate `AvroHBaseRecord`. data prepared by users is a local Scala collection that has 256 `AvroHBaseRecord` objects.

```
object AvroHBaseRecord {
 val schemaString =
 s"""{"namespace": "example.avro",
 "type": "record", "name": "User",
 "fields": [
 {"name": "name", "type": "string"},
 {"name": "favorite_number", "type": ["int", "null"]},
 {"name": "favorite_color", "type": ["string", "null"]},
 {"name": "favorite_array", "type": {"type": "array",
"items": "string"}},
 {"name": "favorite_map", "type": {"type": "map",
"values": "int"}}
]}""".stripMargin

 val avroSchema: Schema = {
 val p = new Schema.Parser
 p.parse(schemaString)
 }

 def apply(i: Int): AvroHBaseRecord = {
 val user = new GenericData.Record(avroSchema);
 user.put("name", s"name${"%03d".format(i)}")
 user.put("favorite_number", i)
 user.put("favorite_color", s"color${"%03d".format(i)}")
 val favoriteArray = new GenericData.Array[String](
 2,
 avroSchema.getField("favorite_array").schema())
 favoriteArray.add(s"number${i}")
 favoriteArray.add(s"number${i+1}")
 user.put("favorite_array", favoriteArray)
 import collection.JavaConverters._
 val favoriteMap = Map[String, Int] (("key1" -> i), ("key2" ->
(i+1))).asJava
 user.put("favorite_map", favoriteMap)
 val avroByte = AvroSedes.serialize(user, avroSchema)
 AvroHBaseRecord(s"name${"%03d".format(i)}", avroByte)
 }
}

val data = (0 to 255).map { i =>
 AvroHBaseRecord(i)
}
```

3. Save the DataFrame. Given a data frame with the specified schema catalog, the following example creates a HPE Data Fabric Database binary table with five (5) regions and saves the data frame inside.

```
sc.parallelize(data).toDF.write.options(
 Map(
 HBaseTableCatalog.tableCatalog -> catalog,
 HBaseTableCatalog.newTable -> "5")
).format("org.apache.spark.sql.execution.datasources.hbase")
.save()
```

4. Load the DataFrame. In the `withCatalog` function, `read` returns a `DataFrameReader` that can be used to read data in as a `DataFrame`. The option function adds input options for the underlying data source to the `DataFrameReader`. There are two options: one is to set `avroSchema` as `AvroHBaseRecord.schemaString`. The other option is to set `HBaseTableCatalog.tableCatalog` as `avroCatalog`. The `load()` function loads input in as a `DataFrame`. The data frame `df` returned by the `withCatalog` function can be used to access the HPE Data Fabric Database binary table.

```
def avroCatalog = s"""{
 |"table":{"namespace":"default", "name":"avrotable"},
 |"rowkey":"key",
 |"columns":{"
 | |"col0":{"cf":"rowkey", "col":"key", "type":"string"},
 | |"col1":{"cf":"cf1", "col":"col1", "avro":"avroSchema"}
 |}
 |}""".stripMargin

def withCatalog(cat: String): DataFrame = {
 sqlContext
 .read
 .options(Map(
 "avroSchema" -> AvroHBaseRecord.schemaString,
 HBaseTableCatalog.tableCatalog -> avroCatalog
).format("org.apache.spark.sql.execution.datasources.hbase"))
 .load()
}
val df = withCatalog(catalog)
```

5. Query data using SQL. After loading `df` `DataFrame`, you can query data. `registerTempTable` registers `df` `DataFrame` as a temporary table using the table name `avrotable`. The `sqlContext.sql` function allows you to execute SQL queries.

```
df.registerTempTable("avrotable")
val c = sqlContext.sql("select count(1) from avrotable")
```

## Integrating Spark

This section includes the following topics about configuring Spark to work with other ecosystem components.

### Integrate Spark-SQL (Spark 2.3.1 and later) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 2.3.0 or later users.

## Prerequisites

**NOTE:** For Spark 2.2.1 and 2.3.1 versions, use the 4.0.0 avro version of `com.databricks:spark-avro_2.11`.

## About this task

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

## Procedure

1. Download the Avro 1.7.7 JAR file to the Spark jars (`opt/mapr/spark/spark-<version>/jars`) directory.

You can download the file from the maven repository: <http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7>

2. Add the following properties in `spark-defaults.conf`:

```
spark.driver.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
spark.executor.extraClassPath /opt/mapr/spark/spark-<spark_version>/jars/
avro-1.7.7.jar
```

### Integrate Spark-SQL (Spark 1.6.1) with Avro

You integrate Spark-SQL with Avro when you want to read and write Avro data. This information is for Spark 1.6.1 or earlier users.

#### About this task

Use the following steps to perform the integration. Previous versions of Spark do not require these steps.

#### Procedure

1. Download the Avro 1.7.7 JAR file to the Spark lib (`opt/mapr/spark/spark-<version>/lib`) directory.  
You can download the file from the maven repository: <http://mvnrepository.com/artifact/org.apache.avro/avro/1.7.7>
2. Use one of the following methods to add the Avro 1.7.7 JAR to the classpath:
  - Prepend the Avro 1.7.7 JAR file to the `spark.executor.extraClassPath` and `spark.driver.extraClassPath` in the `spark-defaults.conf` (`/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf`) file:

```
spark.executor.extraClassPath /opt/mapr/spark/
spark-<spark_version>/lib/avro-1.7.7.jar:<rest_of_path>
spark.driver.extraClassPath /opt/mapr/spark/spark-<spark_version>/lib/
avro-1.7.7.jar:<rest_of_path>
```

- Specify the Avro 1.7.7 JAR files with command line arguments on the spark shell:

```
/opt/mapr/spark/spark-<version>/bin/spark-shell \
--packages com.databricks:spark-avro_2.10:2.0.1 \
--driver-class-path /opt/mapr/spark/spark-<version>/lib/avro-1.7.7.jar \
--conf spark.executor.extraClassPath=/opt/mapr/spark/
spark-<version>/lib/avro-1.7.7.jar --master <master-url>
```

### Integrate Spark with HBase

Integrate Spark with HBase or HPE Data Fabric Database when you want to run Spark jobs on HBase or HPE Data Fabric Database tables.

#### About this task

If you installed Spark with the MapR Installer, these steps are not required.

## Procedure

1. Configure the HBase version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

```
hbase_versions=<version>
```

The HBase version depends on the current EEP and MapR version that you are running.

2. If you want to create HBase tables with Spark, add the following property to `hbase-site.xml`:

```
<property>
hbase.table.sanity.checks</name>
<value>>false</value>
</property>
```

3. On each Spark node, copy the `hbase-site.xml` to the `{SPARK_HOME}/conf/` directory.

**TIP:** Starting in the EEP 7.0.0 release, you do not have to complete step 3. Running `configure.sh` copies the `hbase-site.xml` file to the Spark directory automatically.

4. Specify the `hbase-site.xml` file in the `SPARK_HOME/conf/spark-defaults.conf` file:

```
spark.yarn.dist.files SPARK_HOME/conf/hbase-site.xml
```

5. To verify the integration, complete the following steps:

- a) Create an HBase or HPE Data Fabric Database table:

```
create '<table_name>' , '<column_family>'
```

- b) Run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
/opt/mapr/spark/spark-<spark_version>/bin/spark-submit --master
<master> [--deploy-mode <deploy-mode>] --class
org.apache.hadoop.hbase.spark.example.rdd.HBaseBulkPutExample /opt/
mapr/hbase/hbase-<hbase_version>/lib/
hbase-spark-<hbase_version>-mapr.jar <table_name> <column_family>
```

The master URL for the cluster is either `spark://<host>:7077`, `yarn`, or `local` (without `deploy-mode`). The `deploy-mode` is either `client` or `cluster`.

- c) Check the data in the HBase or MapR-DB table:

```
hbase(main):001:0> scan '<table_name>'
```

## Integrate Spark-SQL (Spark 2.0.1 and later) with Hive

You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 2.0.1 or later users.

## About this task

For information about Spark-SQL and Hive support, see [Spark Feature Support](#).

**NOTE:** If you installed Spark with the MapR Installer, the following steps are not required.

## Procedure

1. Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration. Do not create a symbolic link instead of copying the file. You may need to edit the file with settings that are specific to the Spark Thrift server.
2. Add 644 permission to the `hive-site.xml` using the following command:

```
sudo chmod 644 /opt/mapr/spark/spark-<sparkVersion>/conf/hive-site.xml
```

3. If Hive is configured on Tez (not on MR), you must remove the Tez property from the Spark conf directory `hive-site.xml`. Delete this entry:

```
<property>
 <name>hive.execution.engine</name>
 <value>tez</value>
</property>
```

4. If Hive is configured on PAM, set "`hive.metastore.sasl.enabled = true`" in the `hive-site.xml` located in the Spark conf directory.
5. Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

Property	Configuration Requirements
<code>spark.yarn.dist.files</code>	For Spark on YARN, specify the location of the <code>hive-site.xml</code> file:  <pre>/opt/mapr/spark/spark-&lt;spark-version&gt;/conf/hive-site.xml</pre>
<code>spark.sql.hive.metastore.version</code>	Specify the Hive version that you are using.   <b>NOTE:</b> If you are using Hive Metastore 2.1, set the version to 1.2.1.

6. Depending on whether you plan to run with impersonation, perform one of the following:
  - Configure user impersonation. See [Hive User Impersonation](#) for the steps to configure impersonation in the Spark Thrift server.
  - Set `hive.server2.enable.doAs` to `false` in the `hive-site.xml` file.
7. To verify the integration, run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
<spark-home>/bin/run-example --master <master> [--deploy-mode
<deploy-mode>] sql.hive.SparkHiveExample
```

The master URL for the cluster is either `spark://<host>:7077` or `yarn`. The `deploy-mode` is either `client` or `cluster`.

## What to do next

**NOTE:** The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

**NOTE:** If you plan to access Hive tables that store data in HPE Data Fabric Database, you need to copy the Hive HBase handler jar into the Spark jars directory. For example:

```
cp /opt/mapr/hive/hive-2.1/lib/hive-hbase-handler-2.1.1-mapr-1707.jar /opt/
mapr/spark/spark-2.1.0/jars/
```

## Integrate Spark-SQL (Spark 1.6.1) with Hive

You integrate Spark-SQL with Hive when you want to run Spark-SQL queries on Hive tables. This information is for Spark 1.6.1 or earlier users.

## About this task

For information about Spark-SQL and Hive support, see [Spark Feature Support](#).

**NOTE:** If you installed Spark with the MapR Installer, the following steps are not required.

## Procedure

1. Copy the `hive-site.xml` file into the `SPARK_HOME/conf` directory so that Spark and Spark-SQL recognize the Hive Metastore configuration.
2. Configure the Hive version in the `/opt/mapr/spark/spark-<version>/mapr-util/compatibility.version` file:

```
hive_versions=<version>
```

3. Add the following additional properties to the `/opt/mapr/spark/spark-<version>/conf/spark-defaults.conf` file:

Property	Configuration Requirements
<code>spark.yarn.dist.files</code>	<p>Option 1: For Spark on YARN, specify the location of the <code>hive-site.xml</code> and the datanucleus JARs:</p> <pre>/opt/mapr/hive/hive-<code>&lt;hive-version&gt;</code>/conf/hive-site.xml,/opt/mapr/hive/<code>&lt;version&gt;</code>/lib/datanucleus-api-jdo-<code>&lt;version&gt;</code>.jar,/opt/mapr/hive/<code>&lt;version&gt;</code>/lib/datanucleus-core-<code>&lt;version&gt;</code>.jar,/opt/mapr/hive/hive-1.2/lib/datanucleus-rdbms-<code>&lt;version&gt;</code>.jar</pre> <p>Option 2: For Spark on YARN, store <code>hive-site.xml</code> and datanucleus JARs on file system, and use the following syntax:</p> <pre>maprfs:///&lt;path to hive-site.xml&gt;,maprfs:///&lt;path to datanucleus jar files&gt;</pre>
<code>spark.sql.hive.metastore.version</code>	Specify the Hive version that you are using. For example, for Hive 1.2.x, set the value to 1.2.0.
<code>spark.sql.hive.metastore.jars</code>	<p>Specify the classpath to JARs for Hive, Hive dependencies, and Hadoop. These files must be available on the node from which you submit Spark jobs:</p> <pre>/opt/mapr/hadoop/hadoop-<code>&lt;hadoop-version&gt;</code>/etc/hadoop:/opt/mapr/hadoop/hadoop-<code>&lt;hadoop-version&gt;</code>/share/hadoop/common/lib/*:&lt;rest of hadoop classpath&gt;:/opt/mapr/hive/hive-<code>&lt;version&gt;</code>/lib/accumulo-core-<code>&lt;version&gt;</code>.jar:/opt/mapr/hive/hive-<code>&lt;version&gt;</code>/lib/hive-contrib-<code>&lt;version&gt;</code>.jar:&lt;rest of hive classpath&gt;</pre> <p>For example, when you run with Hive 1.2, you can set the following classpath:</p> <pre>/opt/mapr/hadoop/hadoop-2.7.0/etc/hadoop:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/lib/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/common/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/*:/opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/yarn/*:/opt/mapr/hive/hive-1.2/lib/accumulo-core-1.6.0.jar:/opt/mapr/hive/hive-1.2/lib/hive-contrib-1.2.0-mapr-1607.jar:/opt/mapr/hive/hive-1.2/lib/*</pre> <p>For more information, see the <a href="#">Apache Spark documentation</a>.</p>

4. To verify the integration, run the following command as the `mapr` user or as a user that `mapr` impersonates:

```
MASTER=<master-url> <spark-home>/bin/run-example sql.hive.HiveFromSpark
```

The master URL for the cluster is either `spark://<host>:7077`, `yarn-client`, or `yarn-cluster`.

## What to do next

**NOTE:** The default port for both HiveServer 2 and the Spark Thrift server is 10000. Therefore, before you start the Spark Thrift server on a node where HiveServer 2 is running, verify that there is no port conflict.

### Integrate Spark with HPE Data Fabric Streams

Integrate Spark with MapR Streams to enable Spark to query HPE Data Fabric Streams for new messages at a given interval, process any new messages that are available, and also publish messages into HPE Data Fabric Streams.

You can use Spark to access HPE Data Fabric Streams through Spark's receiver-less, direct approach.

For more information, see the [Apache Spark documentation](#).

**NOTE:** Before you integrate Spark with HPE Data Fabric Streams, verify that the Streams Client is install on all Spark nodes. For more information, see the [Installing Manually](#) on page 152.

### *Configure Spark 2.2.1 and later to Consume HPE Data Fabric Streams Messages*

Using the Kafka 0.10 API, you can configure a Spark application to query HPE Data Fabric Streams for new messages at a given interval. This information is for Spark 2.2.1 and later users.

## About this task

### Procedure

1. Install the [Data Fabric core Kafka package](#), if you have not already done so.
2. Copy the Kafka client jar into the Spark jars directory as shown below:

```
cp /opt/mapr/lib/kafka-clients-<version>.jar SPARK_HOME/jars
```

3. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-0-9_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

**NOTE:** If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the MapR Maven repository to the Spark classpath (/opt/mapr/spark/spark-<spark\_version>/jars/).

4. Consider the following when you write the Spark application:
  - a) Verify that it meets the following requirements:
    - Imports and use classes from `org.apache.spark.streaming.kafka010`. The following code snippet imports three classes.

```
import org.apache.spark.streaming.kafka010.{ConsumerStrategies,
KafkaUtils, LocationStrategies}
```

- Defines key and value deserializers in the kafkaParams map.

```
val kafkaParams = Map[String, String](
 ConsumerConfig.GROUP_ID_CONFIG -> groupId,
 ConsumerConfig.KEY_DESERIALIZER_CLASS_CONFIG ->
 "org.apache.kafka.common.serialization.StringDeserializer",
 ConsumerConfig.VALUE_DESERIALIZER_CLASS_CONFIG ->
 "org.apache.kafka.common.serialization.StringDeserializer",
 ConsumerConfig.AUTO_OFFSET_RESET_CONFIG -> offsetReset)
```

- Does not configure a broker address or Zookeeper as these are not required for HPE Data Fabric Streams.
- b) Optionally, define a value for `spark.streaming.kafka.consumer.poll.ms` in the Spark configuration.

**NOTE:** You can configure the poll timeout using Spark option `spark.streaming.kafka.consumer.poll.ms`. If you do not configure `spark.streaming.kafka.consumer.poll.ms`, the `spark.network.timeout` property is used. If `spark.network.timeout` is empty, the default is 120 seconds.

```
val sparkConf = new SparkConf()
 .setAppName("v09DirectKafkaWordCount")
 .set("spark.streaming.kafka.consumer.poll.ms", pollTimeout)
```

Example:

<https://github.com/mapr/spark/blob/3.5.1.0-ee930/examples/src/main/scala/org/apache/spark/examples/streaming/V010DirectKafkaWordCount.scala> is a sample consumer program.

The `KafkaUtils.createDirectStream` method creates an input stream to read HPE Data Fabric Streams messages. The `ConsumerStrategies.Subscribe` method creates the consumer strategy that will limit the set of topics the stream subscribes to. This is derived from the topics parameter passed into the program. Using `LocationStrategies.PreferConsistent` will distribute partitions evenly across available executors.

```
val consumerStrategy = ConsumerStrategies.Subscribe[String, String](
 topicsSet, kafkaParams)
val messages = KafkaUtils.createDirectStream[String, String](
 ssc, LocationStrategies.PreferConsistent, consumerStrategy)
```

#### Configure Spark to Produce HPE Data Fabric Streams Messages

Using the Kafka 0.9 API, you can configure a Spark application to produce Data Fabric Streams messages.

#### Procedure

1. Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_2.11
version = <spark_version>-mapr-<mapr_eco_version>
```

**NOTE:** If you would like to use Streaming Producer Examples, you must add the appropriate Spark streaming Kafka producer jar from the HPE Maven repository to the Spark classpath (`/opt/mapr/spark/spark-<spark_version>/jars/`).

- When you write the Spark program, import and use classes from `org.apache.spark.streaming.kafka.producer._` and `org.apache.spark.streaming.dstream`.

The import of `org.apache.spark.streaming.stream.DStream` adds the following method from `DStream`:

```
sendToKafka(topic: String, conf: ProducerConf)
```

In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the `topics` parameter.

```
val producerConf = new ProducerConf(bootstrapServers =
 kafkaBrokers.split(",").toList)
 .withKeySerializer("org.apache.kafka.common.serialization.ByteArraySerializer")
 .withValueSerializer("org.apache.kafka.common.serialization.StringSerializer")

val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
 defaultRDD)

dStream.foreachRDD(_.sendToKafka(topics, producerConf))
dStream.count().print()
```

The `org.apache.kafka.common.serialization.ByteArraySerializer` and `org.apache.kafka.common.serialization.StringSerializer` properties are used by default, and in case you do not want to use another serializer, `withKeySerializer` and `withValueSerializer` methods are not necessary.

### Example

Source code for a sample producer program can be found at <https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala>

### Integrate Spark with R

You integrate Spark with R when you want to run R programs as Spark jobs.

### About this task

#### Procedure

- On each node that will submit Spark jobs, install R 3.2.2 or greater:

- On Ubuntu:

```
apt-get install r-base-dev
```

- On CentOS/RedHat:

```
yum install R
```

For more information about installing R, see the [R documentation](#).

- To verify the integration, run the following commands as the `mapr` user or as a user that `mapr` impersonates:

## a) Start Spark R:

- On Spark 2.0.1, 2.1.0, and later:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master>
[--deploy-mode <deploy-mode>]
```

- On Spark 1.6.1:

```
/opt/mapr/spark/spark-<version>/bin/sparkR --master <master-url>
```

## b) Run the following command to create a DataFrame using sample data:

On Spark 1.6.1:

```
people <- read.df(sqlContext, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

On Spark 2.0.1, 2.1.0, and later:

```
people <- read.df(spark, "file:///opt/mapr/spark/spark-<version>/
examples/src/main/resources/people.json", "json")
```

## c) Run the following command to display the data from the DataFrame that you just created:

```
head(people)
```

**Integrate Spark with Kafka**

From EEP-5.0.0, Spark can be integrated with Kafka-1.0. You can configure a Spark application to produce Kafka messages.

**About this task**

**NOTE:** Starting from EEP-8.0.0, HPE Data Fabric does not support spark-streaming-kafka-producer. To learn about Kafka integration on Apache Spark 3.1.2 and later in HPE Data Fabric, see [Structured Streaming + Kafka Integration Guide \(Kafka broker version 0.10.0 or higher\)](#).

**NOTE:** Starting from HPE Data Fabric 7.8.0, the configuration option `use.brokers` is available. This option is a boolean flag that specifies the type of server you are using to load the Apache Kafka client. By default, this value is set to `false`. Set this value to `true` if you are using Apache Kafka brokers as a server to load the Apache Kafka client.

For more information, see [Configuration Parameters](#) on page 3983.

**Procedure****1.** Add the following dependency:

```
groupId = org.apache.spark
artifactId = spark-streaming-kafka-producer_<scala_version>
version = <spark_version>-mapr-<mapr_eco_version>
```

2. When you write the Spark program, import and use classes from:

```
org.apache.spark.streaming.kafka.producer._
org.apache.spark.streaming.dstream.
```

The import of `org.apache.spark.streaming.stream.DStream` adds the following method from `DStream`:

```
sendToKafka(topic: String, conf: ProducerConf)
```

3. In the code below, calling `sendToKafka` will send `numMessages` messages to the set of topics specified by the `topics` parameter:

```
val producerConf = new ProducerConf(
 bootstrapServers = kafkaBrokers.split(",").toList)

val items = (0 until numMessages.toInt).map(i => Item(i, i).toString)
val defaultRDD: RDD[String] = ssc.sparkContext.parallelize(items)
val dStream: DStream[String] = new ConstantInputDStream[String](ssc,
 defaultRDD)

dStream.foreachRDD(_.sendToKafka(topics, producerConf))
dStream.count().print()
```

### Example

Source code for a sample producer program can be found at <https://github.com/mapr/spark/blob/2.2.1-mapr-1803/examples/src/main/scala/org/apache/spark/examples/streaming/KafkaProducerExample.scala>

### Spark JDBC and ODBC Drivers

Data Fabric provides JDBC and ODBC drivers so you can write SQL queries that access the Apache Spark data-processing engine. This section describes how to download the drivers, and install and configure them.

You can download the Spark JDBC driver from [https://package.ezmeral.hpe.com/tools/MapR-JDBC/MapR\\_Spark/](https://package.ezmeral.hpe.com/tools/MapR-JDBC/MapR_Spark/) and the Spark ODBC driver from [https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR\\_Spark/](https://package.ezmeral.hpe.com/tools/MapR-ODBC/MapR_Spark/).

**IMPORTANT:** To access the Data Fabric internet repository, you must specify the email and token of an HPE Passport account. For more information, see [Using the HPE Data Fabric Token-Authenticated Internet Repository](#) on page 153.

After downloading the driver, refer to the documentation at [Spark JDBC Driver](#) to install and configure the JDBC driver and [Spark ODBC Driver](#) for the ODBC driver. A copy of the documentation also is available in each download package. The following table describes the driver versions available for various EEP releases:

	EEP version	Driver version	Driver link	Documentation link
JDBC version	EEP 6.0.0+	2.6.3	<a href="#">Spark JDBC Driver for version 2.6.3</a>	<a href="#">Spark JDBC Documentation for version 2.6.3</a>
	EEP 3.0.1+	1.1.8	<a href="#">Spark JDBC Driver for version 1.1.8</a>	<a href="#">Spark JDBC Documentation for version 1.1.8</a>

	EEP version	Driver version	Driver link	Documentation link
ODBC version	EEP 6.0.0+	2.6.1	<a href="#">Spark ODBC Driver for version 2.6.1</a>	<a href="#">Spark ODBC Documentation for version 2.6.1</a>
	EEP 2.0.2+	1.2.5	<a href="#">Spark ODBC Driver for version 1.2.5</a>	<a href="#">Spark ODBC Documentation for version 1.2.5</a>

**NOTE:** When connecting to the Spark Thrift Server using beeline and the JDBC driver, you might encounter the following error:

```
"Unsupported transaction isolation level: 4"
```

To avoid this error, pass the `isolation` parameter to beeline as follows:

```
bin/beeline --isolation=default
```

## Spark API Changes

This topic describes the public API changes that occurred for specific Spark versions.

### Spark 2.3.1 API Changes

EEP 6.0.0 supports Spark version 2.3.1.

For more information about Spark 2.3.1, see the [Spark Release Notes](#) on page 8212.

For a complete list of all new and changed APIs, refer to the [open source documentation](#).

### Spark 2.1.0 API Changes

This topic describes the public API changes that occurred between Apache Spark 2.0.1 and Spark 2.1.0.

For more information about Spark 2.1.0, see the [Spark Release Notes](#) and the [Spark 2.1.0 API Documentation](#).

## New API

- The `DataType` API is now mostly stable. Please see `InterfaceStability` annotations for the classes you need.
- Add the `from_json` and `to_json` functions to SQL.
- `StructType` now accepts Python Dictionaries.
- New ML algorithms have been added for Spark R.
- `SparkContext.addFile` is now supported for SparkR.
- SparkR now supports multinomial logistics regression.
- MLlib supports MLR in DataFrames, LSH.
- MLlib model loading is now backward-compatible with Spark 1.6.

## Changed API

- Parquet-MR is bumped to 1.8.1.
- `spark.sql.warehouse.dir` now needs to be set before `SparkSession` creation and is shared between multiple `SparkSessions`.

- Values generated by non-deterministic functions will not change after coalesce or union.
- The default `Locale` for `DateFormat/NumberFormat` is now `Locale.US`.
- Function `SIZE` returns -1 when its input parameter is null.

### Spark 2.0.1-1703 API Changes

This release does not introduce any changes to public Spark API apart from Structured Streaming, which is not supported by the MapR platform.

### Spark 2.0.1-1611 API Changes

This topic describes the public API changes that occurred between Apache Spark 1.6.1 and Spark 2.0.1.

### Removed Methods

The following items have been removed from [Apache Spark 2.0.1](#):

- Bagel (the Spark implementation of Google Pregel)
- Most of the deprecated methods from Spark 1.x, including:

Category	Subcategory	Instead of this removed API...	Use...
GraphX		<code>mapReduceTriplets</code>	<code>aggregateMessages</code>
		<code>runSVDPlusPlus</code>	<code>run</code>
		<code>GraphKryoRegistrator</code>	
SQL	<code>DataType</code>	<code>DataType.fromCaseClassString</code>	<code>DataType.fromJson</code>
	<code>DecimalType</code>	<code>DecimalType()</code>	<code>DecimalType(precision, scale)</code> precision explicitly
		<code>DecimalType(Option[PrecisionInfo])</code>	<code>DecimalType(precision, scale)</code>
		<code>PrecisionInfo</code>	<code>DecimalType(precision, scale)</code>
		<code>precisionInfo</code>	precision and scale
		<code>Unlimited</code>	(No longer supported)
	<code>Column</code>	<code>Column.in()</code>	<code>isin()</code>
	<code>DataFrame</code>	<code>toSchemaRDD</code>	<code>toDF</code>
		<code>createJDBCTable</code>	<code>write.jdbc()</code>
		<code>saveAsParquetFile</code>	<code>write.parquet()</code>
		<code>saveAsTable</code>	<code>write.saveAsTable()</code>
		<code>save</code>	<code>write.save()</code>
		<code>insertInto</code>	<code>write.mode(SaveMode.Append).saveAsTable()</code>
	<code>DataframeReader</code>	<code>DataFrameReader.load(path)</code>	<code>option("path", path).load()</code>
	<code>Functions</code>	<code>cumeDist</code>	<code>cume_dist</code>
		<code>denseRank</code>	<code>dense_rank</code>
		<code>percentRank</code>	<code>percent_rank</code>
		<code>rowNumber</code>	<code>row_number</code>
		<code>inputFileName</code>	<code>input_file_name</code>
		<code>isNaN</code>	<code>isnan</code>

Category	Subcategory	Instead of this removed API...	Use...
		sparkPartitionId	spark_partition_id
		callUDF	udf
Core	SparkContext	Constructors no longer take preferredNodeLocationData param	
		tachyonFolderName	externalBlockStoreFolderName
		initLocalProperties, clearFiles, clearJars	(No longer needed)
		runJob method no longer takes allowLocal param	
		defaultMinSplits	defaultMinPartitions
		[Double, Int, Long, Float]AccumulatorParam	implicit objects from AccumulatorParam
		rddTo[Pair, Async, Sequence, Ordered]RDDFunctions	implicit functions from RDD
		[double, numeric]RDDToDoubleRDDFunctions	implicit functions from RDD
		intToIntWritable, longToLongWritable, floatToFloatWritable, doubleToDoubleWritable, boolToBoolWritable, bytesToBytesWritable, stringToText	implicit functions from WritableConverter
		[int, long, double, float, boolean, bytes, string, writable]WritableConverter	implicit functions from WritableConverter
	TaskContext	runningLocally	isRunningLocally
		addOnCompleteCallback	addTaskCompletionListener
		attemptId	attemptNumber
	JavaRDDLike	splits	partitions
		toArray	collect
	JavaSparkContext	defaultMinSplits	defaultMinPartitions
		clearJars, clearFiles	(No longer needed)
	PairRDDFunctions	PairRDDFunctions.reduceByKeyToDriver	reduceByKeyLocally
	RDD	mapPartitionsWithContext	TaskContext.get
		mapPartitionsWithSplit	mapPartitionsWithIndex
		mapWith	mapPartitionsWithIndex
		flatMapWith	mapPartitionsWithIndex and flatMap
		foreachWith	mapPartitionsWithIndex and foreach
		filterWith	mapPartitionsWithIndex and filter
		toArray	collect
	TaskInfo	TaskInfo.attempt	TaskInfo.attemptNumber
	Guava Optional	Guava Optional	org.apache.spark.api.java.Optional

Category	Subcategory	Instead of this removed API...	Use...
	Vector	Vector, VectorSuite	
Configuration options and params		--name	
		--driver-memory	spark.driver.memory
		--driver-cores	spark.driver.cores
		--executor-memory	spark.executor.memory
		--executor-cores	spark.executor.cores
		--queue	spark.yarn.queue
		--files	spark.yarn.dist.files
		--archives	spark.yarn.dist.archives
		--addJars	spark.yarn.dist.jars
		--py-files	spark.submit.pyFiles

Note also the following deprecated configuration options and parameters:

- Methods from Python DataFrame that returned RDD have been moved to `dataframe.rdd`. For example, `df.map` is now `df.rdd.map`.
- Some streaming connectors (Twitter, Akka, MQTT, and ZeroMQ) have been removed.
- `org.apache.spark.shuffle.hash.HashShuffleManager` no longer exists. `SortShuffleManager` is the default since Spark 1.2.
- DataFrame is no longer a class. It is a subtype of DataSet.

## Behavior Changes

Spark 2.0.1 implements the following behavior changes:

- Spark 2.0.1 uses Scala 2.11 instead of 2.10.
- Floating literals in SQL are now parsed as decimal type instead of double type.
- The Kryo version is now 3.0.
- Jersey version is now 2.
- Java RDD `flatMap` and `mapPartitions` functions now require functions that return Java iterator instead of Iterable.
- Java RDD `countByKey` and `countApproxDistinctByKey` now return `Map[K => Long]` instead of `Map[K => Object]`.
- When writing Parquet files, the summary files are no longer written (set `parquet.enable.summary-metadata` to true to re-enable).
- Lots were changed in MLLib. Follow the [Apache Spark Migration Guide](#).
- `SparkContext.emptyRDD` now returns RDD instead of EmptyRDD.
- Spark Standalone Master no longer serves the jobs history.

- [org.apache.spark.api.java.JavaPairRDD](#) methods were changed:
  - `countByKey` and `countApproxDistinctByKey` now return `java.lang.Long` instead of `scala.Long`.
  - `sampleByKey` and `sampleByKeyExact` now return `java.lang.Double` instead of `scala.Double`.
- The Old Application History format that created folders for each application has been removed.
- `org.apache.spark.Logging` is now private. You can use `slf4j` directly instead.

### Other Deprecated Items

- Java 7 is now deprecated.
- Python 2.6 is now deprecated.
- [TaskContext.isRunningLocally](#) now is always false, as there is no more local execution of `yarn-client` and `yarn-cluster` as masters. Use `--master yarn` and `--deploy-mode client/cluster`.
- Instead of `HiveContext`, use `SparkSession.builder.enableHiveSupport`.
- Instead of `SQLContext`, use `SparkSession.builder`.
- Some methods related to `Accumulators`, `ShuffleWriteMetrics`, `SparkLLoop`, `DataSet`, and `SQLContext` are now deprecated. You will see warnings in your application logs if you use them.

### Structured Streaming in Spark

Starting in EEP 5.0.0, structured streaming is supported in Spark.

### Related Links

Spark streaming is integrated with HPE Data Fabric Streams for Apache Kafka.

- [Data Fabric Event Store For Apache Kafka Clients and Tools](#)

### Prerequisites for Using Structured Streaming in Spark

To deploy a structured streaming application in Spark, you must create a Data Fabric Streams topic and install a Kafka client on all nodes in your cluster.

*Creating a Data Fabric Streams Topic*

### Procedure

- Create a Data Fabric Streams topic consisting of the stream path and topic name separated by a colon (:); for example, `/test_stream:topic1`.

*Installing a Kafka Client*

### Procedure

- Install a `kafka-client` on all nodes of your cluster or copy the `kafka-clients.jar` file from `/opt/mapr/lib/kafka-clients-<version>mapr<release>.jar` to `/opt/mapr/spark/spark-<version>/jars/`.

### Using Structured Streaming to Create a Word Count Application

The example in this section creates a dataset representing a stream of input lines from Kafka and prints out a running word count of the input lines to the console.

*Using Apache Kafka***Example****Scala**

```

val spark = SparkSession
 .builder
 .appName("StructuredKafkaWordCo
unt")
 .getOrCreate()

import spark.implicits._
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
 .readStream
 .format("kafka")
 .option("kafka.bootstrap.server
s", bootstrapServers)
 .option(subscribeType, topics)
 .load()
 .selectExpr("CAST(value AS
STRING)")
 .as[String]
//Generate a running word count
val wordCounts =
 lines.flatMap(_.split("
")).groupBy("value").count()
//Run the query that prints the
running counts to the console
val query = wordCounts.writeStream
 .outputMode("complete")
 .format("console")
 .option("checkpointLocation",
checkpointLocation)
 .start()

query.awaitTermination()

```

**Java**

```

SparkSession spark = SparkSession
 .builder()
 .appName("JavaStructured
KafkaWordCount")
 .getOrCreate();
//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
 .readStream()
 .format("kafka")
 .option("kafka.bootstrap
.servers", bootstrapServers)
 .option(subscribeType,
topics)
 .load()
 .selectExpr("CAST(value
AS STRING)")
 .as(Encoders.STRING());
//Generate a running word count
Dataset<Row> wordCounts =
 lines.flatMap(
 (FlatMapFunction<String, String>)
 x -> Arrays.asList(x.split("

```

**Python**

```

 ")).iterator(),
 Encoders.STRING()).groupBy("value").count();

//Run the query that prints the
running counts to the console
StreamingQuery query =
wordCounts.writeStream()
 .outputMode("complete")
 .format("console")
 .start();

query.awaitTermination();

```

```

spark = SparkSession\
 .builder\
 .appName("StructuredKafkaWordCount")\
 .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
 .readStream\
 .format("kafka")\
 .option("kafka.bootstrap.servers", bootstrapServers)\
 .option(subscribeType,
topics)\
 .load()\
 .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#explode turns each item in an array
into a separate row
explode(
 split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that prints the
running counts to the console
query = wordCounts\
 .writeStream\
 .outputMode('complete')\
 .format('console')\
 .start()

query.awaitTermination()

```

*Using Data Fabric Event Store for Apache Kafka***Example**

For Data Fabric Event Store, the topic name consists of the stream name and topic, and the bootstrap servers are not used. For example:

```
var topic: String = "/user/mapr/stream:reviews"
val df1 = spark.readStream.format("kafka").option("kafka.bootstrap.servers",
 "maprdemo:9092").option("subscribe", topic).option("group.id",
 "testgroup").option("startingOffsets",
 "earliest").option("failOnDataLoss",
 false).option("maxOffsetsPerTrigger", 1000).load()
```

**Writing a Structured Spark Stream to HPE Data Fabric Database JSON Table**

The example in this section writes a structured stream in Spark to HPE Data Fabric Database JSON table.

**Example**

To write a structured Spark stream to HPE Data Fabric Database JSON table, use MapRDBSourceConfig.Format for Java and Scala and com.mapr.db.spark.streaming for Python to format the tablePath, idFieldPath, createTable, bulkMode, and sampleSize parameters.

**Scala**

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig
import org.apache.spark.sql.streaming.
{StreamReader, StreamWriter}
import org.apache.spark.sql.
{DataFrame, Row, SparkSession}

def dataStreamWriter(spark:
SparkSession, df: DataFrame):
DataStreamWriter[Row] = {
import spark.implicits._

df.select($"value" as "_id")
.writeStream
.format(MapRDBSourceConfig.Format)
.option(MapRDBSourceConfig.TablePath
Option, "/table/path")
.option(MapRDBSourceConfig.IdFieldPa
thOption, "value")
.option(MapRDBSourceConfig.CreateTab
leOption, true)
.option(MapRDBSourceConfig.BulkModeO
ption, true)
.option(MapRDBSourceConfig.SampleSiz
eOption, 1000)
.outputMode("append")
}
```

**Java**

```
import
com.mapr.db.spark.streaming.MapRDBSourceConfig;
import org.apache.spark.sql.Dataset;
import org.apache.spark.sql.Row;
import
org.apache.spark.sql.SparkSession;
import
org.apache.spark.sql.streaming.DataStr
```

```

eamReader;
import
org.apache.spark.sql.streaming.DataStreamWriter;
import
org.apache.spark.sql.streaming.StreamingQueryException;

DataStreamWriter<Row>
dataStreamWriter(Dataset<Row> df) {
 return df.selectExpr("CAST(value
AS STRING) as _id")
 .writeStream()
 .format(MapRDBSourceConfig
.Format())
 .option(MapRDBSourceConfig
.TablePathOption(), "/table/path")
 .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
 .option(MapRDBSourceConfig
.CreateTableOption(), true)
 .option(MapRDBSourceConfig
.BulkModeOption(), true)
 .option(MapRDBSourceConfig
.SampleSizeOption(), 1000)
 .outputMode("append");
}

```

### Python

```

from pyspark.sql import *

def data_stream_writer_func(df,
checkpoint_dir, table_path):
 return df.selectExpr("CAST(value AS
STRING) as _id") \
 .writeStream \
 .format("com.mapr.db.spark.
streaming") \
 .option("checkpointLocation
", checkpoint_dir) \
 .option("tablePath",
table_path) \
 .option("idFieldPath",
"value") \
 .option("createTable",
True) \
 .option("bulkMode", True) \
 .option("sampleSize", 1000)

```

### Writing a Spark Stream Word Count Application to HPE Data Fabric Database

The example in this section writes a Spark stream word count application to HPE Data Fabric Database.

#### Example

##### Scala

```

val spark = SparkSession
 .builder
 .appName("StructuredKafkaWordCou
nt")
 .getOrCreate()

import spark.implicits._

```

```
//Create a DataSet representing the
stream of input lines from Kafka
val lines = spark
 .readStream
 .format("kafka")
 .option("kafka.bootstrap.servers", bootstrapServers)
 .option(subscribeType, topics)
 .load()
 .selectExpr("CAST(value AS
STRING)")
 .as[String]

//Generate a running word count
val wordCounts =
lines.flatMap(_.split("
")).groupBy("value").count()

//Run the query that saves the result
to MapR-DB
val query = wordCounts.writeStream
 .format(MapRDBSourceConfig.Format)
 .option(MapRDBSourceConfig.Table
PathOption, resultTable)
 .option(MapRDBSourceConfig.Creat
eTableOption, true)
 .option(MapRDBSourceConfig.IdFie
ldPathOption, "value")
 .outputMode("complete")
 .start()

query.awaitTermination()
```

## Java

```
SparkSession spark = SparkSession
 .builder()
 .appName("JavaStructuredKaf
kaWordCount")
 .getOrCreate();

//Create a DataSet representing the
stream of input lines from Kafka
Dataset<String> lines = spark
 .readStream()
 .format("kafka")
 .option("kafka.bootstrap.s
ervers", bootstrapServers)
 .option(subscribeType,
topics)
 .load()
 .selectExpr("CAST(value
AS STRING)")
 .as(Encoders.STRING());

//Generate a running word count
Dataset<Row> wordCounts =
lines.flatMap(
(FlatMapFunction<String, String>)
x -> Arrays.asList(x.split("
")).iterator(),
Encoders.STRING()).groupBy("value").co
```

**Python**

```

unt();

//Run the query that saves the result
to MapR-DB
StreamingQuery query =
wordCounts.writeStream()
 .format(MapRDBSourceConfig
.Format())
 .option(MapRDBSourceConfig
.TablePathOption(), resultTable)
 .option(MapRDBSourceConfig
.CreateTableOption(), true)
 .option(MapRDBSourceConfig
.IdFieldPathOption(), "value")
 .outputMode("complete");
 .start();

query.awaitTermination();

```

```

spark = SparkSession\
 .builder\
 .appName("StructuredKafkaWo
rdCount")\
 .getOrCreate()

#Create a DataSet representing the
stream of input lines from Kafka
lines = spark\
 .readStream\
 .format("kafka")\
 .option("kafka.bootstrap.ser
vers", bootstrapServers)\
 .option(subscribeType,
topics)\
 .load()\
 .selectExpr("CAST(value AS
STRING)")

#Split the lines into words
words = lines.select(
#Explode turns each item in an array
into a separate row
explode(
 split(lines.value, ' ')
).alias('word')
)

#Generate a running word count
wordCounts =
words.groupBy('word').count()

#Run the query that saves the result
to MapR-DB
query = wordCounts\
 .writeStream\
 .format("com.mapr.db.spa
rk.streaming") \
 .option("tablePath",
table_path) \
 .option("createTable",
True) \

```

```

 .option("idFieldPath",
"value") \
 .outputMode('complete')\
 .start()

query.awaitTermination()

```

### PAM Authentication for Spark

Spark supports PAM authentication on secure Data Fabric clusters.

In EEP-5.0.0, PAM authentication and encryption is enabled by default for all Spark Web UIs. After running `configure.sh`, if the cluster is secure and Spark is installed, Spark will be configured using PAM.

**NOTE:** Spark PAM is available in Spark-2.2.1 from EEP-5.0 and in Spark-2.1.0 from EEP-4.1.1.

See [Configuring PAM](#) on page 2121 for information on how PAM works with Data Fabric.

### Read or Write LZO Compressed Data for Spark

This topic provides details for reading or writing LZO compressed data for Spark.

#### Procedure

1. Install the LZO library:

```
sudo yum install lzo-devel lzo
```

2. Clone `hadoop-lzo` and build it:

```
[mapr@node1 ~]$ git clone https://github.com/twitter/hadoop-lzo
[mapr@node1 ~]$ cd hadoop-lzo
[mapr@node1 hadoop-lzo]$ mvn package
```

3. Copy the jar file to hadoop classpath:

```
[mapr@node1 hadoop-lzo]$ sudo cp target/
hadoop-lzo-0.4.21-SNAPSHOT.jar /opt/mapr/hadoop/hadoop-2.7.0/share/
hadoop/yarn/lib/
```

4. Add two LZO compression codes to `core-site.xml`:

```
property: io.compression.codecs
codecs:
com.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec/
```

It will look like this:

```
<property>
 <name>io.compression.codecs</name>

 <value>org.apache.hadoop.io.compress.DefaultCodec,org.apache.hadoop.io.co
mpress.GzipCodec,org.apache.hadoop.io.compress.BZip2Codec,org.apache.hado
op.io.compress.DeflateCodec,org.apache.hadoop.io.compress.SnappyCodec,com
.hadoop.compression.lzo.LzoCodec,com.hadoop.compression.lzo.LzopCodec</
value>
</property>

<property>
 <name>io.compression.codec.lzo.class</name>
 <value>com.hadoop.compression.lzo.LzoCodec</value>
</property>
```

## 5. Run Spark and read LZO compressed data:

```
[mapr@node1 spark]$./bin/spark-shell --master yarn
spark.read.csv("/user/mapr/LzoCompressedCsv").show
```

## 6. Write LZO compressed data with Spark:

```
scala>
df.write.option("codec", "com.hadoop.compression.lzo.LzopCodec").csv("csv1")

[mapr@node1 spark]$ hadoop fs -ls /user/mapr/csv1
Found 2 items
-rwxr-xr-x 3 mapr mapr 0 2017-12-15 12:42 /user/mapr/csv1/_SUCCESS
-rwxr-xr-x 3 mapr mapr 493366 2017-12-15 12:42 /user/mapr/csv1/part-00000-256a95a9-eb9c-4048-b7ce-c95dfbef54d7.csv.lzo
```

**Ports Used by Spark**

To run a Spark job from a client node, ephemeral ports should be opened in the cluster for the client from which you are running the Spark job.

If you do not want to open all the ephemeral ports, you can use the configuration parameter to specify the range of ports.

To set ports to special values, use the `spark.driver.port`, `spark.blockManager.port`, and `spark.port.maxRetries` properties. The `spark.port.maxRetries` property is 16 by default.

For example, if you need to open port 200 for `spark.blockManager.port` from 40000, set `spark.blockManager.port = 40000` and `spark.port.maxRetries = 200`.

For a list of Web UIs ports dynamically used when starting spark contexts, see the [open source documentation](#).

The default port numbers that need to be opened on the firewall behind the client and MapR cluster nodes for Spark jobs to operate in YARN client, YARN cluster, and standalone modes are as follows:

Service	Port Number
Spark Connect Server	15002
Spark Standalone Master (RPC)	7077
Spark Standalone Master (Web UI)	8580, 8980*
Spark Standalone Worker	8581, 8981*
Spark Thrift Server	2304
Spark History Server	18080,18480*
Spark External Shuffle Service (if yarn shuffle service is enabled)	7337
CLDB	7222
ZooKeeper	5181
Nodes running ResourceManager	8032
MapR Filesystem Server	5660, 5692

\* refers to ports for secure clusters

### ACL Configuration for Spark

Starting in the EEP 6.0 release, the ACL configuration for Spark is disabled by default.

If you are authorized by PAM, you will have access to all Spark UIs. For the Spark History Server, you can only see the logs of your own Spark jobs if PAM is enabled (regardless of ACL being enabled).

Starting in Spark-2.4.4.0, MapR Spark ACLs behave like Apache Spark ACLs. With this change, all users can log in to the Spark History Server UI and see the full list of applications. Only an application owner or the users specified in `spark.ui.view.acls` or `history.ui.admin.acls` can see application details. Users specified in `history.ui.admin.acls` can see the details for all applications.

By default on a secure cluster:

```
spark.acls.enable false
spark.admin.acls mapr
spark.admin.acls.groups mapr
spark.ui.view.acls mapruser1
```

Other Example:

```
spark.acls.enable true - ACL is enabled and restricted access to Spark
master and thriftserver UIs for other users.
spark.admin.acls mapr - Administrator or "sudoer" of ACL access.
spark.admin.acls.groups mapr - Group of administrators.
spark.ui.view.acls mapruser1 - user who can be logged in to Spark master
and thriftserver UIs.
```

### Helm Charts for Spark

Starting with the EEP 9.4.0 release, Helm chart integration for Spark is supported. This topic provides detailed information about Data Fabric's Helm and Spark integration, including installation steps.

**Helm charts** are packages of pre-configured Kubernetes resources that simplify the deployment, versioning, and management of applications on Kubernetes clusters. They bundle all the necessary YAML configuration files, templates, and dependencies into a single, reusable package that can be installed with a single command using the Helm CLI.

Starting with EEP 9.4.0, Helm chart integration for Spark on Data Fabric is supported. The Spark Helm chart enables containerized deployment of Spark applications to Kubernetes clusters (such as OpenShift

Container Platform) by packaging the Tenant Operator, required RBAC configurations, secrets, and Spark runtime settings. This allows users to run Spark shells and submit Spark applications using Kubernetes as the cluster manager, with Data Fabric providing the underlying data layer.

This topic outlines the steps to set up and deploy a Data Fabric tenant on a Kubernetes cluster, including installing prerequisites, configuring the Tenant Operator, generating secrets, and running Spark applications.

For the latest Helm chart files and instructions, refer to the [Commits · mapr/data-fabric-helm-charts](#) branch of the data-fabric-helm-charts repository. See the [Release release/fy26-q2 · mapr/data-fabric-helm-charts](#) tag for the current release.

### Prerequisites

- **kubectl:** Ensure that you have `kubectl` installed and configured to interact with your Kubernetes cluster.
- **Helm:** Ensure you have Helm installed.
- **Kubernetes Cluster Access:** Verify you have the necessary permissions to deploy resources to your Kubernetes cluster.
- **Placeholder Values:** Be prepared to replace placeholder values (such as registry URLs or secrets) with your actual environment-specific data.

You can find all necessary images in the <https://hub.docker.com/u/maprtech> repository.

### 1. Install Cert-Manager

Cert-Manager is required for managing certificates within the cluster.

- Apply Cert-Manager CRDS:

```
kubectl apply -f https://github.com/jetstack/cert-manager/releases/download/v1.8.0/cert-manager.crd.yaml
```

- Add the Jetstack Helm Repository and Update:

```
helm repo add jetstack https://charts.jetstack.io
helm repo update
```

- Install Cert-Manager in the 'cert-manager' Namespace:

```
helm install cert-manager jetstack/cert-manager --namespace cert-manager --create-namespace --version v1.8.0
```

### 2. Create a PriorityClass

A PriorityClass can be used to ensure critical pods are scheduled with higher priority.

- Save the following YAML as `hpe-critical-priorityclass.yaml`:

```
apiVersion: scheduling.k8s.io/v1
kind: PriorityClass
metadata:
 name: hpe-critical
value: 1000000
globalDefault: false
description: "Priority class for critical HPE pods"
```

- Apply the PriorityClass:

```
kubectl apply -f hpe-critical-priorityclass.yaml
```

### 3. Add Registry Certificate on Nodes

Install the registry certificate on all cluster nodes according to your internal security procedures.

**NOTE:** The exact steps for this will vary depending on your specific environment. Refer to your internal documentation for guidance.

### 4. Install Tenant Operator

Install the Tenant Operator using Helm:

```
helm install tenant-operator tenant-operator-chart/ -n
test-tenant --create-namespace -f tenant-operator-chart/values.yaml
```

### 5. Generate External Secrets

Run the external secret generation script (`gen-external-secrets.sh`) on a cluster node. This script is assumed to be located in your environment.

### 6. Apply External Secrets and Additional Configurations

#### a. Apply External Secrets

- Create the `hpe-externalclusterinfo` Namespace:

```
kubectl create namespace hpe-externalclusterinfo
```

- Apply the External Secrets YAML:

```
kubectl apply -f /tmp/mapr-external-secrets.yaml
```

#### b. Create the `hpe-secure` Namespace and LDAP ConfigMap

- Create the `hpe-secure` namespace if it does not already exist:

```
kubectl create namespace hpe-secure
```

- Save the following as `ldapclient-cm.yaml` (replace with your actual LDAP configuration):

```
apiVersion: v1
kind: ConfigMap
metadata:
 name: ldapclient-cm
 namespace: hpe-secure
 annotations:
 kubectl.kubernetes.io/last-applied-configuration: "{}"
data:
 ldap.conf: |
 BASE http://example.com
 URI test
 TLS_CACERTDIR /etc/openssl/certs
 TLS_REQCERT allow
 SASL_NOCANON on
```

- Apply the ConfigMap:

```
kubectl apply -f ldapclient-cm.yaml
```

### c. Create an ImagePull Secret (in the tenant namespace)

- Save the following as `imagepull-secret.yaml` (replace `.....` with your base64-encoded `.dockerconfigjson`):

```
apiVersion: v1
kind: Secret
metadata:
 name: imagepull
 namespace: sampletenant
 labels:
 hpe.com/cluster: none
 hpe.com/component: imagepull
 hpe.com/namespace: Tenant
 hpe.com/tenant: sampletenant
 hpe.com/version: 7.0.0
data:
 .dockerconfigjson: "....."
type: kubernetes.io/dockerconfigjson
```

- Apply the secret:

```
kubectl apply -f imagepull-secret.yaml
```

### d. Create a Cluster Role for Persistent Volume Operations

- Save the following as `hpe-pvcreate-clusterrole.yaml`:

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
 name: hpe-pvcreate
rules:
- apiGroups: [""]
 resources: ["persistentvolumes"]
 verbs: ["create", "delete", "get", "list", "watch"]
```

- Apply the ClusterRole:

```
kubectl apply -f hpe-pvcreate-clusterrole.yaml
```

## 7. Deploy the Tenant

Deploy the tenant using the correct container images, DEP or EEP cluster name, and repository references.

- Refer to the example configuration:

```
kubectl apply -f tenant-crs/external-full.yaml
```

## 8. Update Role Bindings

Modify the roles (`hpe-sampletenant-role` and `hpe-sampletenant-terminalrole`) to include the necessary permissions for managing persistent volumes, secrets, pods, and ConfigMaps as required by your tenant workloads.

## 9. Run Ticket Creator and Launch Spark Shell

### a. Run the Ticket Creator Script

- Navigate to the tenant CLI and execute the bundled to the pod script:

```
./ticketcreator.sh
```

### b. Launch Spark Shell (or any other executable)

- Execute the Spark Shell command, replacing placeholder values as needed:

```
/opt/mapr/spark/spark-3.5.1/bin/spark-shell \
--master k8s://https://<kubernetes controller host>:6443 \
--conf spark.executor.instances=2 \
--conf spark.mapr.user.secret=<generated secret name> \
--conf spark.kubernetes.container.image=<spark image> \
--conf spark.kubernetes.namespace=<tenant namespace> \
--conf spark.kubernetes.container.image.pullPolicy=Always \
--conf spark.mapr.cluster.configMap=cluster-cm \
--conf spark.authenticate=false \
--conf spark.authenticate.enableSaslEncryption=false \
--conf
spark.kubernetes.authenticate.driver.serviceAccountName=hpe-<tenant
namespace>
```

**IMPORTANT:** Replace the following placeholders:

- `<kubernetes controller host>`: The hostname or IP address of your Kubernetes controller.
- `<generated secret name>`: The name of the secret generated by the `ticketcreator.sh` script.
- `<spark image>`: The full name of the Spark container image you intend to use.
- `<tenant namespace>`: The namespace where your tenant is deployed (for example, `sampletenant`).

For the github readme instructions to integrating Helm Charts for Spark, see [Tenant Operator Installation Guide](#).

## YARN

YARN is a resource-management and scheduling framework that distributes resource-management and job-management duties. YARN assigns the resource-management and job-management duties as follows:

- **ResourceManager:** manages cluster resources and tracks resource usage and node health.
- **ApplicationMaster:** a framework-specific process that negotiates resources for a single application (a single job or a directed acyclic graph of jobs), which runs in the first *container* allocated for the application.
- A YARN component called the HistoryServer archives job metrics and metadata. Status on completed applications is available via REST APIs.

The ResourceManager allocates resources among all the applications running the cluster. The ResourceManager includes a pluggable scheduler, which is responsible for allocating resources according to the resource requirements of the running applications. Current MapReduce schedulers, including the Capacity Scheduler and the Fair Scheduler, can be plugged into the YARN scheduler directly.

Label-based scheduling provides job placement control on a multi-tenant Hadoop cluster. Administrators can control exactly which nodes are chosen to run jobs submitted by different users and groups. An administrator assigns node labels in a text file, then composes queue labels or job labels based on the node labels. When users run jobs, they can place them on specified nodes on a per-job basis (using a job label) or on a per-queue level (using a queue label).

The ResourceManager caches the mapping file, and checks every two minutes (the default monitoring period) for updates. If the file has been modified, the ResourceManager updates the labels for all active ApplicationMasters immediately.

Each application runs an ApplicationMaster to negotiate resources from the ResourceManager. The ApplicationMaster works with the NodeManagers to execute and monitor tasks. The duties of the ApplicationMaster are divided as follows:

- **NodeManager:** One instance runs on each node, to manage that node's resources.
- **Container:** An abstraction representing a unit of resources on a node.

The NodeManager provides containers to an application. The ResourceManager and the NodeManager provide the system for distributed management of applications and resources.

### ResourceManager

Describes the role of the ResourceManager.

The ResourceManager is mainly concerned with arbitrating available resources in the cluster among competing applications, with the goal of maximum cluster utilization. The ResourceManager includes a pluggable scheduler called the YarnScheduler, which allows different policies for managing constraints such as capacity, fairness, and service level agreements.

The ResourceManager manages resources as follows:

- Each NodeManager takes instructions from the ResourceManager, reporting and handling containers on a single node
- Each ApplicationMaster requests resources from the ResourceManager, then works with containers provided by NodeManagers

The ResourceManager communicates with application clients via an interface called the ClientService. A client can submit or terminate an application and gain information about the scheduling queue or cluster statistics through the ClientService.

Administrative requests are served by a separate interface called the AdminService, through which operators can get updated information about cluster operation.

Behind the scenes, the ResourceTrackerService receives node heartbeats from the NodeManager to track new or decommissioned nodes. The NMLivelinessMonitor and NodesListManager keep an updated status of which nodes are healthy so that the scheduler and the ResourceTrackerService can allocate work appropriately.

A component called the ApplicationMasterService manages ApplicationMasters on all nodes, keeping the scheduler informed. A component called the AMLivelinessMonitor keeps a list of ApplicationMasters and their last heartbeat times, in order to let the ResourceManager know what applications are healthy on the cluster. Any ApplicationMaster that does not heartbeat within a certain interval is marked as dead and re-scheduled to run on a new container.

At the core of the ResourceManager is an interface called the ApplicationsManager, which maintains a list of applications that have been submitted, are running, or are completed. The ApplicationsManager accepts job submissions, negotiates the first container for an application (in which the ApplicationMaster will run) and restarts the ApplicationMaster if it fails.

The ResourceManager and NodeManagers communicate via heartbeats.

Configure the ResourceManager for high availability so that the failure of the ResourceManager service is a not single point of failure for the cluster. High availability of the ResourceManager is configured by default when you run `configure.sh` without specifying the `-RM` parameter.

### **ApplicationMaster**

Describes the role of the ApplicationMaster.

The ApplicationMaster is an instance of a framework-specific library that negotiates resources from the ResourceManager and works with the NodeManager to execute and monitor the granted resources (bundled as containers) for a given application. An application can be a process or set of processes, a service, or a description of work.

The ApplicationMaster is run in a container like any other application. The ApplicationsManager, part of the ResourceManager, negotiates for the container in which an application's ApplicationMaster runs when the application is scheduled by the YarnScheduler.

While an application is running, the ApplicationMaster manages the following:

- Application life cycle
- Dynamic adjustments to resource consumption
- Execution flow
- Faults
- Providing status and metrics

The ApplicationMaster is designed to support a specific framework, and can be written in any language since its communication with the NodeManagers and the ResourceManager is accomplished using extensible communication protocols. The ApplicationMaster can be customized to extend the framework or run any other code. For this reason, the ApplicationMaster is not considered trustworthy, and is not run as a trusted service.

An ApplicationMaster typically requests resources on multiple nodes to complete a job by sending the ResourceManager requests that include locality preferences and attributes of the containers. When the ResourceManager is able to allocate a resource to the ApplicationMaster, it generates a lease that the ApplicationMaster pulls on a subsequent heartbeat. A security token associated with the lease guarantees its authenticity when the ApplicationManager presents the lease to the NodeManager to gain access to the container.

The Application Master heartbeats to the ResourceManager to communicate its changing resource needs, and to let the ResourceManager know it is still alive. In response, the ResourceManager can return a lease on additional containers on other nodes, or cancel the lease on some containers. The ApplicationMaster can then adjust its execution strategy to fit the increase or decrease in available resources. When cluster resources become scarce, the ResourceManager can also request that the ApplicationMaster relinquish some resources. The ApplicationMaster can move work to other running containers in order to give up resources gracefully.

## Containers

A YARN container is a result of a successful resource allocation, meaning that the ResourceManager has granted an application a lease to use a specific set of resources in certain amounts on a specific node. The ApplicationMaster presents the lease to the NodeManager on the node where the container has been allocated, thereby gaining access to the resources.

To launch the container, the ApplicationMaster must provide a container launch context (CLC) that includes the following information:

- Environment variables
- Dependencies (local resources such as data files or shared objects needed prior to launch)
- Security tokens
- The command necessary to create the process the application plans to launch

The CLC makes it possible for the ApplicationMaster to use containers to run a variety of different kinds of work, from simple shell scripts to applications to virtual machines.

## MapReduce Version 2

Provides an overview of how MapReduce works.

YARN dynamically allocates resources for applications as they execute. The MapReduce version 1 (MRv1) has been rewritten to run as an application on top of YARN; this new version is called MapReduce version 2.0 (MRv2).

Figure 2. A comparison between MapReduce 1.0 and MapReduce 2.0

The main advancement in YARN architecture is the separation of resource management and job management, which were both handled by the same process (the JobTracker) in Hadoop 1.x. Cluster resources and job scheduling are managed by the ResourceManager, while resource negotiation and job monitoring are managed by an ApplicationMaster for each application running on the cluster. In MapReduce, each node advertises a relatively fixed number of map slots and reduce slots. This can lead

to resource under-utilization, for example, when there is a heavy reduce load and map slots are available, because the map slots cannot accept reduce tasks (and vice versa).

YARN generalizes resource management for use by new engines and frameworks, allowing resources to be allocated and reallocated for different concurrent applications sharing a cluster. Existing MapReduce applications can run on YARN without any changes. At the same time, because MapReduce is now merely another application on YARN, MapReduce is free to evolve independently of the resource management infrastructure.

### How Applications Work in YARN

Describes the data flow during application execution in YARN.

The following diagram and steps describe how data flows during application execution in YARN.

The following steps summarize execution of the application:

1. A client submits an application to the YARN Resource Manager, including the information required for the Container Life Cycle (CLC).
2. The Applications Manager (in the Resource Manager) negotiates a container and bootstraps the Application Master instance for the application.
3. The Application Master registers with the Resource Manager and requests containers.
4. The Application Master communicates with Node Managers to launch the containers it has been granted, specifying the CLC for each container.
5. The Application Master manages application execution. During execution, the application provides progress and status information to the Application Master. The client can monitor the application's status by querying the Resource Manager or by communicating directly with the Application Master.
6. The Application Master reports completion of the application to the Resource Manager.

- The ApplicationMaster deregisters with the ResourceManager, which then cleans up the ApplicationMaster container.

### Direct Shuffle on YARN

Explains the shuffle phase of a MapReduce application.

### Overview of Direct Shuffle

During the shuffle phase of a MapReduce application, HPE Data Fabric writes to a file system volume limited by its topology to the local node instead of writing intermediate data to local disks controlled by the operating system. This improves performance and reduces demand on local disk space while making the output available cluster-wide.

Direct Shuffle is the default shuffle mechanism for HPE Data Fabric. However, you can modify the `yarn-site.xml` and `mapred-site.xml` configuration files to enable Apache Shuffle for MapReduce applications. See [Apache Shuffle on YARN](#).

The LocalVolumeAuxiliaryService runs in the NodeManager process. The LocalVolumeAuxiliaryService manages the local volume on each node and cleans up shuffle data after a MapReduce application has finished executing.

- The MRAppMaster service initializes the application by calling `initializeApplication()` on the LocalVolumeAuxiliaryService.

2. The MRAppMaster service requests task containers from the ResourceManager. The ResourceManager sends the MRAppMaster information that MRAppMaster uses to request containers from the NodeManager.
3. The NodeManager on each node launches containers using information about the node's local volume from the LocalVolumeAuxiliaryService.
4. Data from map tasks is saved in MRAppMaster for later use in TaskCompletion events, which are requested by reduce tasks.
5. As map tasks complete, map outputs and map-side spills are written to the local volumes on the map task nodes, generating Task Completion events.
6. ReduceTasks fetch Task Completion events from the Application Manager. The task Completion events include information on the location of map output data, enabling reduce tasks to copy data from MapOutput locations.
7. Reduce tasks read the map output information.
8. Spills and interim merges are written to local volumes on the reduce task nodes.
9. MRAppMaster calls `stopApplication()` on the LocalVolumeAuxiliaryService to clean up data on the local volume.

### Configuration for Direct Shuffle

The default YARN parameters for Direct Shuffle are as follows:

```
<property>
 <name>yarn.nodemanager.aux-services</name>
 <value>mapreduce_shuffle,mapr_direct_shuffle</value>
 <description>shuffle service that needs to be set for Map Reduce to
run</description>
</property>
<property>
 <name>yarn.nodemanager.aux-services.mapr_direct_shuffle.class</name>
 <value>org.apache.hadoop.mapred.LocalVolumeAuxService</value>
</property>
```

The default mapred parameters for Direct Shuffle are as follows:

```
<property>
 <name>mapreduce.job.shuffle.provider.services</name>
 <value>mapr_direct_shuffle</value>
</property>
<property>
 <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
 <value>org.apache.hadoop.mapreduce.task.reduce.DirectShuffle</value>
</property>
<property>
 <name>mapreduce.job.map.output.collector.class</name>
 <value>org.apache.hadoop.mapred.MapRFsOutputBuffer</value>
</property>
<property>
 <name>mapred.ifile.outputstream</name>
 <value>org.apache.hadoop.mapred.MapRIFileOutputStream</value>
</property>
<property>
 <name>mapred.ifile.inputstream</name>
 <value>org.apache.hadoop.mapred.MapRIFileInputStream</value>
</property>
```

```
<property>
 <name>mapred.local.mapoutput</name>
 <value>>false</value>
</property>
<property>
 <name>mapreduce.task.local.output.class</name>
 <value>org.apache.hadoop.mapred.MapRFsOutputFile</value>
</property>
```

### Apache Shuffle on YARN

You can disable Direct Shuffle and enable Apache Shuffle by modifying the configuration options in the `yarn-site.xml` and `mapred-site.xml` files. This page describes how to configure Apache Shuffle for MapReduce applications.

The shuffling phase in Hadoop is the process of transferring mappers intermediate output to the reducers. Direct shuffle increases the load on file system disks. You can enable the Apache Shuffle to reduce the load on file system disks.

### Configuration for Apache Shuffle

Add the following property to `yarn-site.xml` file:

```
<property>
 <name>yarn.nodemanager.aux-services</name>
 <value>mapreduce_shuffle</value>
</property>
```

Add the following properties to `mapred-site.xml` file:

```
<property>
 <name>mapreduce.job.shuffle.provider.services</name>
 <value>mapreduce_shuffle</value>
</property>
<property>
 <name>mapreduce.job.reduce.shuffle.consumer.plugin.class</name>
 <value>org.apache.hadoop.mapreduce.task.reduce.Shuffle</value>
</property>
<property>
 <name>mapreduce.job.map.output.collector.class</name>
 <value>org.apache.hadoop.mapred.MapTask$MapOutputBuffer</value>
</property>
<property>
 <name>mapred.ifile.outputstream</name>
 <value>org.apache.hadoop.mapred.HFileOutputStream</value>
</property>
<property>
 <name>mapred.ifile.inputstream</name>
 <value>org.apache.hadoop.mapred.HFileInputStream</value>
</property>
<property>
 <name>mapred.local.mapoutput</name>
 <value>true</value>
</property>
<property>
 <name>mapreduce.task.local.output.class</name>
 <value>org.apache.hadoop.mapred.YarnOutputFiles</value>
</property>
```

### Logging Options on YARN

Describes the logging options that are available on YARN.

For YARN applications, there are various logging options to choose from based on the Data Fabric version and the types of applications that you run. In 4.0.2 and later versions, you have the following logging options:

- For MapReduce version 2 (MRv2) applications, the default logging option is to log files on the local file system. However, central logging and YARN log aggregation are also available.
- For non-MapReduce applications, the default logging option is to log files on the local file system. However, YARN log aggregation is also available.

### Centralized Logging for MRv2

Centralized logging provides an application-centric view of all the log files generated by NodeManager nodes throughout the cluster. It enables users to gain a complete picture of application execution by having all the logs available in a single directory, without having to navigate from node to node.

The MapReduce program generates three types of log output:

- Standard output stream: captured in the `stdout` file
- Standard error stream: captured in the `stderr` file
- Log4j logs: captured in the `syslog` file

Centralized logs are available cluster-wide as they are written to the following local volume on the Data Fabric file system:

```
var/mapr/local/<NodeManager node>/
logs/yarn/user logs
```

Since the log files are stored in a local volume directory that is associated with each NodeManager node, you run the `maprc li job link logs` command to create symbolic links for all the logs in a single directory. You can then use tools such as `grep` and `awk` to analyze them from an NFS mount point. You can also view the entire set of logs for a particular application using the HistoryServer UI.

### YARN Log Aggregation

The YARN log aggregation option aggregates logs from the local file system and moves log files for completed applications from the local file system to the Data Fabric file system. This allows users to view the entire set of logs for a particular application using the HistoryServer UI or by running the `yarn logs` command.

### Support for ADLS

Starting with MapR 6.1, you can use Azure Data Lake Store (ADLS) as a data source or destination for all applications.

#### Prerequisites for Using ADLS

Setting up Azure Data Lake Store (ADLS) on the Azure portal enables you to access ADLS from any application.

- Create an account on the [Azure portal](#).
- Create an Azure Data Lake Store ([get started with Azure Data Lake Storage](#)).

**Authenticating ADLS Account**

To access data stored in Azure Data Lake Store (ADLS), you must first authenticate your ADLS account using your ADLS credentials.

**Procedure**

1. Obtain the following properties from your Azure application:

- `dfs.adls.oauth2.access.token.provider.type`  
ClientCredential, Refresh Tokens, or Client Keys to obtain the authentication type.
- `dfs.adls.oauth2.client.id`  
Create an Azure Active Directory application and get your application ID and authentication key.
- `dfs.adls.oauth2.refresh.url`  
Navigate to Azure Active Directory and click on Endpoints. Use the OAUTH 2.0 TOKEN ENDPOINT value.
- `dfs.adls.oauth2.credential`  
Obtain the access token key value from App Registrations in your Azure account.

2. Add the properties obtained in step 1 to the `core-site.xml` file:

```
<!--ADL-->
<property>
 <name>dfs.adls.oauth2.access.token.provider.type</name>
 <value>ClientCredential</value>
</property>

<property>
 <name>dfs.adls.oauth2.client.id</name>
 <value>f377fab9-c0a3-4531-a1c9-77345105</value>
</property>

<property>
 <name>dfs.adls.oauth2.refresh.url</name>
 <value>https://login.microsoftonline.com/25735fb/oauth2/token</value>
</property>

<property>
 <name>dfs.adls.oauth2.credential</name>
 <value>WTkn4xS0ISSqzyo4R6bu/OW2oPyGNMzWRw/d2z2CGiw=</value>
</property>
```

**NOTE:** The `core-site.xml` file can be overwritten using the command line. You can also specify these properties at runtime. The syntax for overwriting ADLS properties at runtime using the command line is as follows:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount
-Ddfs.adls.oauth2.access.token.provider.type=ClientCredential
-Ddfs.adls.oauth2.client.id=f377fab9-c0a3-4531-a1c9-77345105
-Ddfs.adls.oauth2.refresh.url=https://login.microsoftonline.com/
25735fb/oauth2/token
-Ddfs.adls.oauth2.credential=WTkn4xS0ISSqzyo4R6bu/OW2oPyGNMzWRw/
d2z2CGiw= adl://testhue.azuredatalakestore.net/some_folder/testfile
adl://testhue.azuredatalakestore.net/some_folder/wordcountout
```

To provide your ADLS credentials securely, see [Securely Providing ADLS Credentials](#) on page 5541.

3. Provide your application with file access.
4. For secure clusters, MapR-SASL (Simple Authentication and Security Layer), and Kerberos, import the required CA certificate.
  - [Open source documentation](#)
  - [Azure documentation](#)
  - [Azure documentation on authorization and access control](#)

#### *Securely Providing ADLS Credentials*

You can provide your ADLS credentials securely by hiding the open, readable configuration on the command line using the Hadoop credential provider.

**Procedure**

1. Generate a jceks file for ADLS authorization:

```
hadoop credential create dfs.adls.oauth2.client.id -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client ID
hadoop credential create dfs.adls.oauth2.credential -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value client secret
hadoop credential create dfs.adls.oauth2.refresh.url -provider jceks://
hdfs/user/USER_NAME/adlskeyfile.jceks -value refresh URL
```

2. Run the DistCp example using the jceks file:

```
hadoop distcp
[-D hadoop.security.credential.provider.path=localjceks://hdfs/user/
USER_NAME/adlskeyfile.jceks]
hdfs://<NameNode Hostname>:9001/user/foo/007020615
adl://<Account Name>.azuredatalakestore.net/testDir/
```

3. Configure the core-site.xml file to use the jceks file:

```
<property>
 <name>hadoop.security.credential.provider.path</name>
 <value>localjceks://hdfs/user/USER_NAME/adlskeyfile.jceks</value>
 <description>Path to interrogate for protected credentials.</
description>
</property>
```

*Using ADLS for Data Input or Output*

You can use Azure Data Lake Store (ADLS) as a source or destination for your application data.

**Prerequisites**

For general information about the features of ADLS, refer to the [Azure Data Lake Store documentation](#).

For information about configuring ADLS as storage for a Hadoop cluster, refer to the official [Apache documentation](#).

The Azure Data Lake Storage access path syntax is:

```
adl://<Account Name>.azuredatalakestore.net/
```

You can use ADLS the same way as you use file system, substituting an adl scheme instead of maprfs, hdfs, webhdfs, and so on.

**Procedure**

1. Create a directory and read data:

```
[mapr@node4 ~]$ hadoop fs -mkdir adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/

Found 1 items
drwxr-xr-x - 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:09
adl://<username>.azuredatalakestore.net/testdir
```

## 2. Put data into ADLS from your local file system:

```
[mapr@node4 ~]$ hadoop fs -put testfile adl://
<username>.azuredatalakestore.net/testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
testdir

Found 1 itemsrw-r--r- 1 9d3f4f74-8337-4dae-ad77-f63459438553
331c9f66-6875-4e13-a74f-458dd23e4bde 0 2018-04-16 09:10
adl://<username>.azuredatalakestore.net/testdir/testfile
```

## 3. Delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

## 4. Run YARN jobs with your input and output stored in ADLS:

```
yarn jar /opt/mapr/hadoop/hadoop-2.7.0/share/hadoop/mapreduce/
hadoop-mapreduce-examples-2.7.0-mapr-1710-SNAPSHOT.jar wordcount

### Deleting Data from ADLS

You can delete your data from Azure Data Lake Store (ADLS).

#### Procedure

- To delete data from ADLS:

```
[mapr@node4 ~]$ hadoop fs -rm -r adl://<username>.azuredatalakestore.net/
testdir

[mapr@node4 ~]$ hadoop fs -ls adl://<username>.azuredatalakestore.net/
```

### Configuring ATS 1.0 or 1.5 for Hadoop 3.3 (Required for Tez UI)

Describes how to configure the YARN Application Timeline Server (ATS) 1.0 and 1.5 for Hadoop 3.3.x. You must complete this process in order to use the Tez UI.

EEP 9.0.0 introduced Hadoop 3.3, which uses ATsv2 by default. Hive 3 and the Tez UI currently do not support ATsv2, but you can configure ATsv1 for use with Hadoop 3, and doing so enables the Tez UI.

**NOTE:** ATsv2 is incompatible with the Tez UI. ATsv2 should not be installed across the cluster nodes if you are enabling the Tez UI by configuring ATS v1.5.

**IMPORTANT:** Check that the `mapr-timelineserver` package, which corresponds to ATSV2, is not installed. If the package is installed, remove it before proceeding.

After removing the `mapr-timelineserver` package, remove the following properties from `yarn-site.xml`:

```
<!--TIMELINE SERVER SECTION-->
<property>
 <description>Indicate to clients whether Timeline service is
 enabled or not. If enabled, the TimelineClient library used by
 end-users will post entities and events to the Timeline server.</
 description>
 <name>yarn.timeline-service.enabled</name>
 <value>true</value>
</property>
<property>
 <name>yarn.timeline-service.hostname</name>
 <value><HOSTNAME></value>
</property>
<property>
 <name>yarn.timeline-service.version</name>
 <value>2.0f</value>
</property>
<property>
 <name>yarn.timeline-service.http-cross-origin.enabled</name>
 <value>true</value>
</property>
<property>
 <name>yarn.system-metrics-publisher.enabled</name>
 <value>true</value>
</property>
<property>
 <name>yarn.rm.system-metrics-publisher.emit-container-events</name>
 <value>true</value>
</property>
<property>
 <name>yarn.nodemanager.aux-services.timeline_collector.class</name>

 <value>org.apache.hadoop.yarn.server.timelineservice.collector.PerNodeTi
 melineCollectorsAuxService</value>
</property>
<!--TIMELINE SERVER SECTION END-->
<!--TIMELINE SECURITY SECTION-->
<property>
 <name>yarn.timeline-service.http-authentication.type</name>

 <value>org.apache.hadoop.security.token.delegation.web.MaprDelegationTok
 enAuthenticationHandler</value>
</property>
<!--TIMELINE SECURITY SECTION END-->
```

Use the following steps:

1. Install ATS manually using the appropriate command for your distribution:

**NOTE:** ATS 1.5 is the recommended version. ATS 1.5 is faster and more stable, with better scalability and fewer lost events.

To manage ATS 1.5 with Warden, you must install and configure `mapr-timelineserv1`.

- RHEL, Rocky, or Oracle Linux:

```
yum install mapr-timelineservv1
```

- Ubuntu:

```
apt install mapr-timelineservv1
```

- SLES:

```
zypper install mapr-timelineservv1
```

2. Run `configure.sh` to configure and automatically start ATS 1.0:

```
configure.sh -R -TL <hostname>
```

3. On all nodes where you are installing the ATS, ensure the following properties are present in the `yarn-site.xml` file.

**IMPORTANT:** For ATS 1.5, update the value of `yarn.timeline-service.version` to 1.5f and proceed with the configuration of ATS 1.5 on all nodes.

```
<property>
 <name>yarn.timeline-service.enabled</name>
 <value>true</value>
</property>
<property>
 <name>yarn.timeline-service.hostname</name>
 <value><hostname></value>
</property>
<property>
 <name>yarn.resourcemanager.system-metrics-publisher.enabled</name>
 <value>true</value>
</property>
<property>
 <name>yarn.timeline-service.http-cross-origin.enabled</name>
 <value>true</value>
</property>
<property>
 <name>yarn.timeline-service.version</name>
 <value>1.0f</value>
 <description>Timeline server version. Should be 1.0f or 1.5f</
description>
</property>
```

4. For ATS 1.5, add these additional properties:

```
<property>
 <name>yarn.timeline-service.entity-group-fs-store.summary-store</
name>

<value>org.apache.hadoop.yarn.server.timeline.RollingLevelDBTimelineStore
</value>
</property>
<property>
 <name>yarn.timeline-service.store-class</name>

<value>org.apache.hadoop.yarn.server.timeline.EntityGroupFSTimelineStore<
/value>
</property>
<property>
 <name>yarn.timeline-service.entity-group-fs-store.active-dir</name>
 <value>/apps/ats/active/</value>
</property>
<property>
 <name>yarn.timeline-service.entity-group-fs-store.done-dir</name>
 <value>/apps/ats/done/</value>
</property>
<property>
 <name>yarn.timeline-service.levelldb-timeline-store.path</name>
 <value>/opt/mapr/hadoop/hadoop-<version>/ats/levelldb/</value>
</property>
<property>

<name>yarn.timeline-service.entity-group-fs-store.group-id-plugin-classes
</name>

<value>org.apache.tez.dag.history.logging.ats.TimelineCachePluginImpl</
value>
</property>
```

5. For ATS 1.5, create the following directories in the Hadoop file system:

Directory	Permission	uid and gid Owner
yarn.timeline-service.entity-group-fs-store.active-dir	1777	Cluster admin
yarn.timeline-service.entity-group-fs-store.done-dir	0700	Cluster admin

Use these commands:

```
hadoop fs -mkdir -p /apps/ats/active/
hadoop fs -mkdir -p /apps/ats/done/
hadoop fs -chmod 1777 /apps/ats/active/
hadoop fs -chmod 0700 /apps/ats/done/
```

6. For ATS 1.5, create the following directory in the local file system:

```
sudo mkdir -p /opt/mapr/hadoop/hadoop-<version>/ats/levelldb/
```

7. Change the owner manually:

```
sudo chown -R mapr:root /opt/mapr/hadoop/hadoop-<version>/ats
```

8. For ATS 1.5, copy the following libraries from Tez:

```
sudo cp /opt/mapr/tez/tez-<version>/
tez-yarn-timeline-cache-plugin-<artifact_name>.jar /opt/mapr/hadoop/
hadoop-<hadoop_version>/share/hadoop/yarn/lib/
sudo cp /opt/mapr/tez/tez-<version>/tez-api-<artifact_name>.jar /opt/
mapr/hadoop/hadoop-<hadoop_version>/share/hadoop/yarn/lib/
sudo cp /opt/mapr/tez/tez-<version>/tez-common-<artifact_name>.jar /opt/
mapr/hadoop/hadoop-<hadoop_version>/share/hadoop/yarn/lib/
```

9. If the cluster is secure, add the security property to yarn-site.xml:

```
<property>
 <name>yarn.timeline-service.http-authentication.type</name>

 <value>org.apache.hadoop.security.token.delegation.web.MaprDelegationTokenAuthenticationHandler</value>
</property>
```

10. On all nodes, restart all YARN services (RM, NM, and JHS):

```
maprcli node services -nodes `hostname -f` -name resourcemanager -action
restart
maprcli node services -nodes `hostname -f` -name nodemanager -action
restart
maprcli node services -nodes `hostname -f` -name historyserver -action
restart
```

11. To manually configure the Tez UI server so that it can be managed by Warden and the Control System, copy and rename the warden.tezui.conf.template file in the Tez conf dir:

```
mv /opt/mapr/tez/tez-<version>/conf/warden.tezui.conf.template /opt/mapr/
conf/conf.d/warden.tezui.conf
```

12. To start, stop, or restart ATS manually, use the following commands as needed:

**To start ATS:**

```
maprcli node
services -nodes `hostname -f` -name
timelineservv1 -action start
```

**To stop ATS:**

```
maprcli node
services -nodes `hostname -f` -name
timelineservv1 -action stop
```

**To restart ATS:**

```
maprcli node
services -nodes `hostname -f` -name
timelineservv1 -action restart
```

**Configuring ATS 2.0 for Hadoop 3.3**

Describes how to install and configure the YARN Application Timeline Server (ATS) 2.0 for Hadoop 3.3.

Use these steps:

1. Install the following packages:

Package	See for more information
mapr-timelineserver	<a href="#">Installing Hadoop and YARN</a> on page 295
mapr-hbase	<a href="#">Install HBase on a Cluster Node</a> on page 297
mapr-hbase-master	
mapr-hbase-regionserver	

2. Run the `configure.sh` script:

```
/opt/mapr/server/configure.sh -R -TL <FQDN>
```

3. Add the property for `hbase-site.xml` to the `yarn-site.xml`:

- Example for local path:

```
<property>
 <name>yarn.timeline-service.hbase.configuration.file</name>
 <value>file:/opt/mapr/hbase/hbase-1.4.14/conf/hbase-site.xml</value>
</property>
```

- Example for Data Fabric file system path:

```
<property>
 <name>yarn.timeline-service.hbase.configuration.file</name>
 <value>maprfs:/tmp/hbase-site.xml</value>
</property>
```

4. Create the timeline service schema:

```
echo "export HBASE_CLASSPATH="/opt/mapr/hadoop/hadoop-3.3.4/share/hadoop/
yarn/timelineservice/*"" >> /opt/mapr/hbase/hbase-1.4.14/conf/
hbase-env.sh
/opt/mapr/hbase/hbase-1.4.14/bin/hbase
org.apache.hadoop.yarn.server.timelineservice.storage.TimelineSchemaCreat
or -create
```

5. Restart all YARN services: RM, NM, JHS, and ATS:

```
maprcli node services -nodes 'hostname -f' -name resourcemanager -action
restart
maprcli node services -nodes 'hostname -f' -name timelineserver -action
restart
maprcli node services -nodes 'hostname -f' -name historyserver -action
restart
maprcli node services -nodes 'hostname -f' -name nodemanager -action
restart
```

6. To access the Timeline Server 2.0 web UI, navigate to the following URL:

```
https://<TIMELINEHOSTNAME>:8090/ui2/#/cluster-overview
```

## Zeppelin

Apache Zeppelin is an open source, Web-based data-science notebook. You can use it with Data Fabric components to conduct data discovery, ETL, machine learning, and data visualization.

You can run the package-based Zeppelin product only on a Data Fabric node (and not on an edge node). Out of the box, Zeppelin is integrated with open-source data-processing engines such as Apache Spark, Apache Drill, and Apache Hive, as well as with native Data Fabric engines (file system, HPE Data Fabric Database, and HPE Data Fabric Streams). Using the notebook simply requires connecting to Zeppelin through your browser.

Zeppelin provides the following benefits for your data-engineering and data-science use cases:

- An interactive development environment for writing, testing, and sharing data processing code snippets
- Support for a variety of interpreters for integrating with different backend components
- Support for extensible visualization libraries

For release-specific information, see [Zeppelin Release Notes \(Package-Based\)](#) on page 8271.

For installation information, see [Installing Zeppelin](#) on page 326.

For additional information about Zeppelin, refer to the [open source documentation](#).

### Configuring Zeppelin Interpreters

Out-of-box, the interpreters in Apache Zeppelin on the HPE Data Fabric are preconfigured to run against different backend engines. You may need to perform manual steps to configure the Livy, Spark, and JDBC interpreters. You can configure the idle timeout threshold for interpreters.

To configure an interpreter:

1. Log in as the cluster administrator (typically mapr).

2. In the top right-hand menu, click **Interpreter**:

3. Search for the required interpreter.
4. Edit the required fields. For example, to configure the %livy interpreter, you need to edit the `zeppelin.livy.url` property. For a secure cluster, change `http` to `https`, and set the hostname instead of using the default `localhost`. Note that nonsecure clusters are not supported by releases 7.0.0 and later.
5. Click **Save**.

### Cloning the Zeppelin Interpreter

Describes how to change interpreter settings for different notebooks.

You can create a new notebook with custom settings by cloning the existing default interpreter. Use these steps:

1. Log in as the cluster administrator (typically `mapr`).
2. In the top right-hand menu, click **Interpreter**:

3. Click **Create**.
4. Enter the interpreter name, and select the interpreter group for which you want to clone the interpreter.
5. Set permissions for this new interpreter if required.  
Enter comma-separated users and groups in the fields. An empty field (\*) implies that anyone can run this interpreter.
6. Click **Save** to save your changes. The interpreter is relaunched automatically.

### Zeppelin Multiuser and Multi-Instance Support

Describes support for multiple users and multiple instances of the Zeppelin package-based product.

To work with different users in Zeppelin you must log in to the Zeppelin user interface (UI) as a required user. The user that you use for login purposes must already be created on the cluster and have a folder within the Data Fabric file system with the correct permissions (for example: /user/<user\_name>).

To work in different Zeppelin instances with a separate user, you need to install the Zeppelin package on a separate cluster node (one Zeppelin instance per node) and log in as a required user.

### Configuring Impersonation in Zeppelin

Impersonation for Apache Zeppelin is enabled and configured through the user interface for each interpreter. The following provides details for performing these configuration functions.

Set the interpreter for which impersonation is to be enabled to be instantiated by selecting or checking the following from the user interface:

- **Per User**
- **Isolated**
- **User Impersonate**

Excluding Spark and JDBC-based interpreters such as Hive and Drill, impersonation operates in the background using one of the following methods:

- Passwordless sudo (default one)
- SSH-keys

### Passwordless sudo

For passwordless sudo use cases, interpreter processes for each user are started using sudo from the user that runs the notebook.

**NOTE:** This operation excludes Spark and JDBC-based interpreters, such as JDBC, Hive, and Drill.

The settings for the user that runs Zeppelin Server (the cluster admin) are configured to use sudo without a password. Typically, this configuration is done by adding the following line to the sudo configuration:

```
mapr ALL=(ALL) NOPASSWD: ALL
```

**WARNING:** Use caution when performing sudo configurations. Passwordless sudo configurations can weaken security on your cluster.

Note that on a secure cluster, the interpreter process is launched from the user that runs the notebook. As such, that user needs to specify a user ticket.

### SSH-key-based Impersonation

With SSH-key-based impersonation, the Zeppelin server user logs into the user shell with SSH (as opposed to executing commands with sudo). This method is more secure than using passwordless sudo configurations and can involve more configuration steps.

To enable SSH-key based impersonation:

1. Create a directory for the Zeppelin SSH key:

```
mkdir -p /opt/mapr/zeppelin/zeppelin-0.9.0/conf/sshkeys
```

2. Generate the keys (without passphrase):

```
ssh-keygen -f /opt/mapr/zeppelin/zeppelin-0.9.0/conf/sshkeys/zeppelin_key
```

3. Copy the keys to target users with the ssh-copy-id (using localhost as the host):

```
ssh-copy-id -i /opt/mapr/zeppelin/zeppelin-0.9.0/conf/sshkeys/zeppelin_key.pub <user>@localhost
```

For example:

```
ssh-copy-id -i /opt/mapr/zeppelin/zeppelin-0.9.0/conf/sshkeys/zeppelin_key.pub mapruser1@localhost
```

4. Configure Zeppelin to use those keys for impersonation by setting ZEPPELIN\_IMPERSONATE\_CMD to the following value in conf/zeppelin-env.sh:

```
export ZEPPELIN_IMPERSONATE_CMD='ssh -i ${ZEPPELIN_HOME}/conf/sshkeys/zeppelin_key ${ZEPPELIN_IMPERSONATE_USER}@localhost '
```

- Restart the Zeppelin server for these configurations to take effect:

```
maprccli node services -action restart -nodes $(hostname) -name zeppelin
```

- Optionally, enable impersonation for interpreters of your choice in the Zeppelin user interface by setting the interpreter to be instantiated. To do so, select **Per User** and **Isolated** process, and then check **User Impersonate** as shown below:

The screenshot shows the Zeppelin user interface for configuring an interpreter. At the top, there's a search bar with 'spark' entered and a list of interpreters: %spark, %sql, %pyspark, %ipyspark, %r, %ir, %shiny, %kotlin. Below this, under the 'Option' section, there are three settings: 'The interpreter will be instantiated' set to 'Per User' in a dropdown, 'in' set to 'isolated' in a dropdown, and 'process' with an information icon and a plus sign. Below these are three checkboxes: 'User Impersonate' (checked), 'Connect to existing process' (unchecked), and 'Set permission' (unchecked).

### Configuring Impersonation for the Spark Interpreter

Describes how to configure impersonation for the Spark Interpreter

The Spark interpreter uses the `--proxy-user` argument of the `spark-submit` utility to perform impersonation operations, as opposed to launching interpreter processes with `sudo`. As such, the Spark interpreter does not require the `NOPASSWD` permission or an existing `maprticket` for the target user.

To enable impersonation with the Spark interpreter you must configure the interpreter in the user interface to be instantiated **Per User** in **Isolated** process and check **User Impersonate**.

### Configuring Impersonation for JDBC Interpreters

For databases that use the JDBC interface and support inbound impersonation, you can configure impersonation to work without using `sudo`.

To do so, configure interpreter in the user interface to be instantiated **Per User** in **Isolated** process, check **User Impersonate**, and then configure the `default.proxy.user.property` property in the interpreter settings to contain the corresponding property name to be used to set the user to impersonate in the JDBC connection string.

See this table for a guide to the property you must set:

For	Set this property
Hive	<code>default.proxy.user.property=hive.server2.proxy.user</code>
Drill	<code>default.proxy.user.property=impersonation_target</code>

### Enabling Kerberos Security for Zeppelin

Describes how to set the principal and keytab properties for the Zeppelin server and configure interpreters to enable Kerberos for your Zeppelin installation.

### Setting the Principal and Keytab Properties

Use these steps:

- Set the principal and keytab of the Zeppelin server. To do this, you must edit the following properties in the `zeppelin-site.xml`:
  - `zeppelin.server.kerberos.principal`
  - `zeppelin.server.kerberos.keytab`

For example:

```
<property>
 <name>zeppelin.server.kerberos.principal</name>
 <value>mapr/node1.cluster.com@NODE1</value>
 <description>principal for accessing kerberized hdfs</description>
</property>

<property>
 <name>zeppelin.server.kerberos.keytab</name>
 <value>/opt/mapr/conf/mapr.keytab</value>
 <description>keytab for accessing kerberized hdfs</description>
</property>
```

2. Restart the Zeppelin server:

```
maprcli node services -action restart -nodes $(hostname) -name zeppelin
```

3. Configure your interpreters to work in the Kerberized environment, as described in the following sections. Note that the Spark, HBase, and HPE Data Fabric Database Shell interpreters do not require additional configuration to work properly in a Kerberized environment.

### Configure the Livy Interpreter

To make the Livy interpreter work with the Livy server that is configured to use Kerberos-based authentication, add the `zeppelin.livy.principal` and `zeppelin.livy.keytab` options with corresponding values to the Livy interpreter configuration:

**livy** %livy, %sql, %pyspark, %sparkr, %shared

**Option**

The interpreter will be instantiated Per User in isolated process ⓘ +

☐ User Impersonate

☐ Connect to existing process

☐ Set permission

**Properties**

Name	Value
zeppelin.livy.url	https://node1.cluster.com:8998
zeppelin.livy.isMaprSecured	<input type="checkbox"/>
zeppelin.livy.principal	mapr/node1.cluster.com@NODE1
zeppelin.livy.keytab	/opt/mapr/conf/mapr.keytab

## Configure the Hive Interpreter

To configure the Hive interpreter to work with the Kerberos-enabled HiveServer2, set the value of the `principal` option in the JDBC connection URL, and set `zeppelin.jdbc.auth.type`, `zeppelin.jdbc.principal` and `zeppelin.jdbc.keytab.location` properties in the Hive interpreter configuration:

The screenshot shows the configuration for the Hive interpreter. Under the 'Option' section, 'The interpreter will be instantiated' is set to 'Per User', 'in' is set to 'isolated', and 'process' is set to 'process'. There are three checkboxes: 'User impersonate', 'Connect to existing process', and 'Set permission', all of which are unchecked. Under the 'Properties' section, there is a table with two columns: 'Name' and 'Value'.

Name	Value
default.url	jdbc:hive2://node1.cluster.com:10000/default;ssl=true;principal=mapr/node1.cluster.com@NODE1
zeppelin.jdbc.auth.type	KERBEROS
zeppelin.jdbc.keytab.location	/opt/mapr/conf/mapr.keytab
zeppelin.jdbc.principal	mapr/node1.cluster.com@NODE1

## Configure the Drill Interpreter

To configure the Drill interpreter to work with Kerberos-enabled Drillbits, set the value of the `auth`, `user` and `keytab` options in the JDBC connection URL:

The screenshot shows the configuration for the Drill interpreter. Under the 'Option' section, 'The interpreter will be instantiated' is set to 'Per User', 'in' is set to 'isolated', and 'process' is set to 'process'. There are three checkboxes: 'User impersonate', 'Connect to existing process', and 'Set permission', all of which are unchecked. Under the 'Properties' section, there is a table with two columns: 'Name' and 'Value'.

Name	Value
default.url	jdbc:drill:drillbit=node1.cluster.com:31010;auth=kerberos;user=mapr/node1.cluster.com@NODE1;keytab=/opt/mapr/conf/mapr.keytab

## Using Zeppelin to Access Different Backend Engines

Contains links to examples for how to use Apache Zeppelin interpreters to access different backend engines. This includes running Apache Drill queries, Apache Hive queries, and Apache Spark jobs, as well as accessing database and streaming solutions.

## Links to Docker-Container-Based Zeppelin Information

The following pages were created for the Docker-container-based Zeppelin product but are also relevant for the package-based Zeppelin product:

- [Running Shell Commands in Zeppelin \(Docker Container\)](#)
- [Running Drill Queries in Zeppelin \(Docker Container\)](#)
- [Running Hive Queries in Zeppelin \(Docker Container\)](#)
- [Running Spark Jobs in Zeppelin \(Docker Container\)](#)
- [Running Database Shell Commands in Zeppelin \(Docker Container\)](#)
- [Accessing the Database in Zeppelin \(Docker Container\) Using the Database Binary Connector](#)
- [Accessing the Database in Zeppelin \(Docker Container\) Using the the Database OJAI Connector](#)
- [Accessing the Event Store For Apache Kafka in Zeppelin \(Docker Container\) Using the Livy Interpreter](#)
- [Accessing the Event Store For Apache Kafka in Zeppelin \(Docker Container\) Using the Spark Interpreter](#)

## Configuring Conda Python for Zeppelin

Describes how to configure Conda Python for Zeppelin.

The following steps assume that the miniconda distribution of Conda Python is already installed. For more information see the [Conda documentation](#).

Use these steps:

1. Create a Conda zip archive containing Python and all the libraries that you need.

### Python 2

The following example creates a custom Conda environment with Python 2 and three packages (matplotlib, numpy, and pandas):

```
mkdir custom_pyspark_env
conda create -p ./
custom_pyspark_env python=2 numpy
pandas matplotlib
cd custom_pyspark_env
zip -r custom_pyspark_env.zip ./
```

### Python 3

The following example creates a custom Conda environment with Python 3 and three packages (matplotlib, numpy, and pandas):

```
mkdir custom_pyspark3_env
conda create -p ./
custom_pyspark3_env python=3 numpy
pandas matplotlib
cd custom_pyspark3_env
zip -r custom_pyspark3_env.zip ./
```

**IMPORTANT:** Do not create an archive named `pyspark.zip`. This name is reserved for PySpark internals.

2. Upload the archive to the Data Fabric file system. For example, if the archive name is `custom_pyspark_env.zip`, and you want to put the archive in a directory that all users can read:

```
hadoop fs -mkdir /apps/zeppelin
hadoop fs -put custom_pyspark_env.zip /apps/zeppelin
```

3. Add the full path (including `maprfs://` schema) to the archive into `spark.yarn.dist.archive`, and configure the Spark / Livy interpreter to use Python from this distribution.

Note that all archives listed in the property will be extracted into a working directory of YARN application.

4. For the Spark interpreter, set the `PYSPARK_PYTHON` and `PYSPARK_DRIVER_PYTHON` environment variables (it can be done by configuring Spark interpreter):

The screenshot shows the 'spark' configuration page. Under the 'Option' section, 'The interpreter will be instantiated' is set to 'Globally' in a 'shared' 'process'. Two checkboxes, 'Connect to existing process' and 'Set permission', are unchecked. The 'Properties' section contains a table with three rows:

Name	Value	Description
spark.yarn.dist.archives	maprfs:///apps/zeppelin/custom_pyspark_env.zip	Sets additional archives for spark
PYSPARK_PYTHON	./custom_pyspark_env.zip/bin/python	Python binary executable to use for PySpark in both driver and workers (default is python2.7 if available, otherwise python). Property 'spark.pyspark.python' take precedence if it is set
PYSPARK_DRIVER_PYTHON	./custom_pyspark_env.zip/bin/python	Python binary executable to use for PySpark in driver only (default is 'PYSPARK_PYTHON'). Property 'spark.pyspark.driver.python' take precedence if it is set

5. For the Livy interpreter, set the `livy.spark.yarn.appMasterEnv.PYSPARK_PYTHON` property:

The screenshot shows the 'livy' configuration page. Under the 'Option' section, 'The interpreter will be instantiated' is set to 'Globally' in a 'shared' 'process'. Two checkboxes, 'Connect to existing process' and 'Set permission', are unchecked. The 'Properties' section contains a table with two rows:

Name	Value	Description
livy.spark.yarn.dist.archives	maprfs:///apps/zeppelin/custom_pyspark_env.zip	Sets additional archives for spark
livy.spark.yarn.appMasterEnv.PYSPARK_PYTHON	./custom_pyspark_env.zip/bin/python	Sets default python interpreter for PySpark

## SSO Roles Mapping in Zeppelin

Describes how Zeppelin roles are derived from a JWT.

When SSO is enabled on cluster, Zeppelin supports JWT-based authentication just as most of the other components. In terms of JWT-based authorization, Zeppelin extends the Core approach of deriving user roles from a `userRoles` JWT claim:

```
"userRoles":
[

 "default-roles-user46",

 "offline_access",

 "admin",

 "developer",

 "uma_authorization",

 "cluster-admin"

]
```

In addition to `userRoles` claim, Zeppelin checks `groups` claim as well:

```
"groups":
[

 "engineering",

 "design-team",

 "marketing",

 "sales"

]
```

**IMPORTANT:** If you are using Keycloak, you must create a mapper in Keycloak, to put user groups into JWT.

For details, see [Keycloak Client Scopes](#), and [Roles and Permissions When SSO Is Configured](#) on page 1311.

### Zeppelin front page load time delayed

Provides troubleshooting steps when the Zeppelin front page takes a long time to load.

### About this task

The Zeppelin front page may have significantly delayed load times when running in an environment with restricted internet access.

The root cause is that upon opening the Zeppelin UI, Zeppelin attempts to initialize its Helium Plugin System by downloading the plugin repository metadata (repdata) from the Internet. In environments where Internet access is restricted, the Zeppelin UI will remain inaccessible until the request to fetch the repodata times out.

To mitigate this issue, create a local snapshot of the repodata.

Download the repodata file using this command:

```
wget https://zeppelin.apache.org/helium.json -O /opt/mapr/zeppelin/zeppelin-0.10.1/conf/helium-repo-snapshot.json
```

To configure Zeppelin to use the local repodata snapshot, add the following property to `zeppelin-env.sh`:

```
export ZEPPELIN_HELIUM_REGISTRY="helium, file://${ZEPPELIN_HOME}/conf/helium-repo-snapshot.json"
```

**NOTE:** The local repodata snapshot file must not be named `helium.json` because that file name is reserved for another purpose.

## Maven and the HPE Data Fabric

This section discusses topics associated with Maven and the HPE Data Fabric.

### Maven Artifacts for the HPE Data Fabric

Maven artifacts can be used for dependency management when developing applications based on the the HPE Data Fabric.

You can access the Data Fabric Maven repository by browsing [Nexus](#) or as follows:

```
